UNIVERSAL CYCLOPÆDIA AND ATLAS

A NEW EDITION UNDER DIRECTION OF

CHARLES KENDALL ADAMS, LL.D.

PRESIDENT OF THE UNIVERSITY OF WISCONSIN

EDITOR-IN-CHIEF

ASSISTED BY A CORPS OF ASSOCIATE EDITORS
COMPOSED OF THE ABLEST AND MOST DISTINGUISHED SCHOLARS
IN THE UNITED STATES AND CANADA, AND OF EMINENT
SPECIALISTS IN BOTH EUROPE AND AMERICA

A NEWLY REVISED AND ENLARGED EDITION

ROSSITER JOHNSON, PH.D., LL.D.

EDITOR OF REVISION

ILLUSTRATED WITH COLORED PLANS, PLATES, AND ENGRAVINGS

COMPLETE IN TWELVE ROYAL OCTAVO VOLUMES

VOLUME VIII

PECULIAR PHONETIC SYMBOLS

USED IN THE WRITING OR TRANSLITERATION OF THE DIFFERENT LANGUAGES.

ā, ē, etc.: long vowels; in the Scandinavian languages the accent (*á*, *é*, etc.) is used to denote length.

ą: a nasalized *a*; so used in the transliteration of the Iranian languages.

å: labialized guttural *a* in Swedish.

æ: open *a* of Eng. *hat*, used chiefly in O. Eng.

aí: used in Gothic to denote *e* (open), in distinction from *ái*, the true diphthong.

aú: used in Gothic to denote *o* (open), in distinction from *áu*, the true diphthong.

bh: in Sanskrit a voiced labial aspirate (cf. *ch*).

ƀ: voiced bilabial (or labio-dental?) spirant, used in discussions of Teutonic dialects.

ç: voiceless palatal sibilant, similar to Eng. *sh*, used especially in transliteration of Sanskrit.

č: frequently used, e. g. in Slavonic languages, to denote the sound of Eng. *ch* in *cheek*.

c: voiceless palatal explosive, commonly used in transliteration of Sanskrit and the Iranian languages.

ch: as used in the transliteration of Sanskrit, a voiceless palatal aspirate, an aspirate being an explosive with excess of breath; as used in German grammar, the symbol for a voiceless palatal or guttural spirant.

dh: voiced dental aspirate (cf. *ch*) in Sanskrit.

ḍ: voiced cerebral explosive, so used in transliteration of Sanskrit.

ḍh: voiced cerebral aspirate (cf. *ch*) in Sanskrit.

đ: voiced dental (interdental) spirant, equivalent to Eng. *th* in *then*; so used in the Teutonic and Iranian languages and in phonetic writing.

ë: a short open *e*, used in Teutonic grammar, partieularly in writing O. H. G.

ə: the short indefinite or "obscure" vowel of Eng. *gardener*; used in the reconstruction of Indo-Eur. forms, and in transliterating the Iranian languages.

gh: in Sanskrit a voiced guttural aspirate (ef. *ch*).

ǥ: voiced velar (back-guttural) explosive, used most frequently in Indo-Eur. reconstructions.

ɜ: voiced guttural (or palatal) spirant, equivalent to Mod. Greek *γ*, and used in transliteration of Iranian languages and O. Eng.

ḥ: a voiceless breathing, the Sanskrit *visarga*.

ḥᵛ: a labialized *h*, similar to *wh* in Eng. *what*; used in transliteration of Gothie and the Iranian languages.

ḥ: voiceless guttural (or palatal) spirant, equivalent to German *ch*, and used in transliteration of the Iranian languages.

i̯: the semi-vowel *y*, or consonant form of *i*; used in phonetic writing and reconstructions of Indo-Eur. forms.

j: in the transliteration of Sanskrit and the Iranian languages a voiced palatal explosive; in the Teutonic languages a semi-vowel (= *y*), for wlhich in Indo-Eur. reconstructions *i* is generally used.

jh: in Sanskrit a voiced palatal aspirate (cf. *ch*).

kh: in Sanskrit a voiceless guttural aspirate (cf. *ch*).

ɬ: the guttural ("thiek" or "deep") of the Slavonic and some of the Scandinavian languages.

l̥: vowel *l*; used in transliterating Sanskrit, in reconstructing Indo-Eur. forms, and in other phonetic writing.

n̥: nasal vowel; used in reconstruction of Indo-Eur. forms and in phonetic writing.

ṇ: in Sanskrit the cerebral nasal.

ñ: in Sanskrit the guttural nasal (see following).

ŋ: the guttural nasal, equivalent to Eng. *n* in *longer*; used in transliteration of Iranian languages.

ñ: palatal nasal, similar to *gn* in Fr. *regner*; used in transliterating Sanskrit and in phonetic writing.

ö: palatalized *o*; used in German and in phonetic writing.

ǫ: short open *o* in Scandinavian.

ø: short palatalized *o* (ö) in Scandinavian.

ph: in Sanskrit, voiceless labial aspirate (cf. *ch*).

ɋ: voiceless velar (back-guttural) explosive; used in reconstructions of Indo-Eur. forms and in other phonetic writing.

r̥: vowel *r*; used in transliterating Sanskrit, in reconstructions of Indo-Eur. forms, and in other phonetic writing.

š: voiceless cerebral sibilant, equivalent to Eng. *sh*; used in transliterating the Iranian languages and in phonetic writing.

ṣ: voiceless cerebral spirant; used in transliterating Sanskrit.

th: in Sanskrit a voiceless dental aspirate (cf. *ch*).

ṭh: in Sanskrit a voiceless cerebral aspirate (cf. *ch*).

ṭ: in Sanskrit a voiceless cerebral explosive.

ţ: a form of dental spirant used in transliterating the Iranian languages (represented in Justi's transliteration by ṭ).

þ: voiceless dental (interdental) spirant, equivalent to Eng. *th* in *thin*; used in Teutonic dialects and in phonetic writing.

u̯: consonant form of *u*; used in phonetic writing.

ž: voieed cerebral sibilant, equivalent to *s* in Eng. *pleasure*, and to *j* in Fr. *jardin*; used in Iranian, Slavonic, and in phonetic writing.

ʒ: a symbol frequently used in the writing of O. H. G. to indicate a voiced dental sibilant (Eng. *z*), in distinction from *z* as sign of the affricata (*ts*).

EXPLANATION OF THE SIGNS AND ABBREVIATIONS USED IN THE ETYMOLOGIES.

>, yielding by descent, i. e. under the operation of phonetic law.
<, descended from.
=, borrowed without change from.
: , cognate with.
+, a sign joining the constituent elements of a compound.
*, a sign appended to a word the existence of which is *inferred*.

ablat.	ablative
accus.	accusative
adjec.	adjective
adv.	adverb
cf.	compare
conjunc.	conjunction
deriv. of	derivative of
dimin.	diminutive
fem.	feminine
genit.	genitive
imper.	imperative
impf.	imperfect
indic.	indicative
infin.	infinitive
masc.	masculine
nomin.	nominative
partic.	participle
perf.	perfect
plur.	plural
prep.	preposition
pres.	present

KEY TO THE PRONUNCIATION.

aa..... as *a* in *father*, and in the second syllable of *armada*.

ăă..... same, but less prolonged, as in the initial syllable of *armada*, *Arditi*, etc.

a..... as final *a* in *armada*, *peninsula*, etc.

ă..... as *a* in *fat*, and *i* in French *fin*.

ay or ā.. as *ay* in *nay*, or as *a* in *fate*.

ăy or *ā*.. same, but less prolonged.

ã..... as *a* in *welfare*.

aw..... as *a* in *fall*, *all*.

ee..... as in *meet*, or as *i* in *machine*.

ĕe..... same, but less prolonged, as final *i* in *Arditi*.

e..... as in *men*, *pet*.

e..... obscure *e*, as in *Bigelow*, and final *e* in *Heine*.

ė..... as in *her*, and *eu* in French *-eur*.

i..... as in *it*, *sin*.

ī..... as in *fire*, *swine*.

ī..... same, but less prolonged.

ō..... as in *mole*, *sober*.

ō..... same, but less prolonged, as in *sobriety*.

o..... as in *on*, *not*, *pot*.

oo..... as in *fool*, or as *u* in *rule*.

o͝o..... as in *book*, or as *u* in *put*, *pull*.

oi..... as in *noise*, and *oy* in *boy*, or as *eu* in German *Beust*.

ow..... as in *now*, and as *au* in German *haus*.

ö..... as in *Göthe*, and as *eu* in French *neuf*, *Chintreuil*

ŭ..... as in *but*, *hub*.

ŭ..... obscure *o*, as final *o* in *Compton*.

ü..... as in German *sũd*, and as *u* in French *Buzançais*, *vu*.

y or *l*.... see *l* or y.

yu..... as *u* in *mule*.

yŭ..... same, but less prolonged, as in *singular*.

ch..... as in German *ich*.

g..... as in *get*, *give* (never as in gist, eongest).

hw..... as *wh* in *which*.

kh..... as *ch* in German *nacht*, *g* in German *tag*, *ch* in Scotch *loch*, and *j* in Spanish *Badajos*, etc.

ṅ..... nasal *n*, as in French *fin*, *Bourbon*, and nasal *m*, as in French *nom*, Portuguese *Sam*.

ñ or n-y.. Spanish *ñ*, as in *cañon*, *piñon*, French and Italian *gn*, etc., as in *Boulogne*.

l or y.... French *l*, liquid or mouillé, as (-i)ll- in French *Baudrillart*, and (-*i*)*l* in *Chintreuil*.

th..... as in *thin*.

th..... as in *though*, *them*, *mother*.

v..... as *w* in German *zwei*, and *b* in Spanish *Cordoba*.

sh..... as in *shine*.

zh..... as *s* in pleasure, and *j* in French *jour*.

All other letters are used with their ordinary English values.

NOTE.

The values of most of the signs used in the above Key are plainly shown by the examples given. But those of ö, ü, *ch*, *kh*, ñ, and *v*, which have no equivalents in English, can not be sufficiently indicated without a brief explanation, which is here given.

ö. The sound represented by this symbol is approximately that of -u- in *hurt* or -e- in *her*, but is materially different from either. It is properly pronounced with the tongue in the position it has when ā is uttered and with the lips in the position assumed in uttering ō.

ü. This vowel is produced with the lips rounded as in uttering oo and with the tongue in the position required in uttering ee, into which sound it is most naturally corrupted.

ch and *kh*. These are both rough breathings or spirants made with considerable force, *ch* being made between the flat of the tongue and the hard palate, and *kh* between the tongue and the soft palate. *ch* approaches in sound to English sh, but is less sibilant and is made further back in the mouth; *kh* is a guttural and has a hawking sound.

l or y. These are both used to represent the sound of French l mouillé, in (-i)ll- and (-i)l, which resembles English -y- in *lawyer*. Final *l*, that is, (-i)l, may be approximated by starting to pronounce lawyer and stopping abruptly with the -y-.

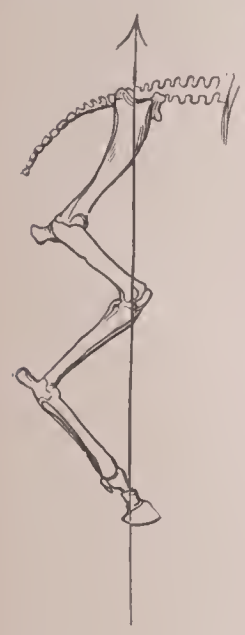
ñ or n-y. The consonants represented by ñ (Spanish ñ, French and Italian gn, etc.) are practically equivalent to English -ni- or -ny- in bunion, bunyon, onion, etc., and, except when final, are represented by n-y. Final ñ, as French -gn(e), may be produced by omitting the sound of -on in the pronunciation of *onion*.

v. This may be pronounced by attempting to utter English v with the use of the lips alone.

See PREFACE (vol. i., p. xli.) and the article PRONUNCIATION OF FOREIGN NAMES.

THE
UNIVERSAL CYCLOPÆDIA.

Mechanics, Animal: that branch of mechanics which treats of the muscular force of animals as exerted in locomotion. The muscular force is utilized either through one of the elementary machines or mechanical powers (see MECHANICAL POWERS), or through a simple combination of two or more of them. In walking or leaping on the ground the "jointed links" or "knee-joint" is the simple machine employed when the body is raised from the ground, and the lever when a limb only is raised or moved, the earth furnishing the resistance in the first case, and the body in the second. The application of the principle of the lever involves the consequence that the bones of the limbs in these efforts sustain great cross-strains, which from their structure they are not calculated to bear. The bones of the hind leg of the horse, for instance, are arranged as in the engraving, and whether in leaping or in hauling a load the action of the muscles of the hinder parts is to straighten out the links which form the hind legs. The ground gives a point of support, but not a fulcrum in the sense of the lever; and instead of the greatest effort being a cross-breaking effort, it is transmitted through the axes of the bones, in which direction, as short columns, they are capable of withstanding great pressure. When the limbs are raised from the ground the body acts as the point of resistance, and the bones act generally as levers; but when the ground forms the point of resistance, the principle of the lever does not furnish the means of calculating the effort necessary to elevate the weight of the body. The jointed construction shown in the sketch corresponds to the device known as "lazy tongs" in mechanics, and acts in the same manner, except that muscular force is applied at each joint. When this system of jointed links is extended to nearly a straight line, a very slight muscular effort at each joint transmits a powerful force through the axis of the extended system in the direction of motion. Swimming animals usually make use of the "inclined plane," combined with the lever or the jointed links, although some animals, like the cuttlefish, make use of an apparatus which involves the principle of the hydrostatic press; a quantity of water being drawn into the body by a large opening, and then ejected by a smaller opening with a greater velocity.



The kinematics of animal movements have been made the subject of extended experiments, and have been fully treated by various authors. (See GAITS.) The dynamics of animal movements have received less attention. The latter study is the more important, as the structure of nearly all animals is based, to some extent, on their mode of progression, and the conditions under which they are obliged to move from place to place, or the mode in which they procure food, defend themselves, or escape from their enemies.

The general law that in animal locomotion the same mechanical principles are applied as in artificial constructions furnishes the basis of the study of animal movements.

Mechanicsburg: borough. See the Appendix.

Mechanicsville: village. See the Appendix.

Mechanicville: village. See the Appendix.

Mechlin: See the Appendix.

Mecklenburg Declaration of Independence: a series of resolutions published in *The Register* at Raleigh, N. C., Apr. 30, 1819, purporting to have been adopted by the citizens of Mecklenburg in that State on May 20, 1775. The resolutions contained several phrases almost or quite identical with portions of the famous Declaration of July 4, 1776. Before the publication of 1819 the general public had never heard of the Mecklenburg resolutions, but now they were widely copied throughout the country, and everybody began to ask questions. Was it possible that such a series of resolutions had actually been passed thirteen months before the Declaration of July 4, 1776, and that the fact had been concealed from the patriots of the Revolution? John Adams, who first learned of the resolutions in 1819, declared in a letter to Jefferson that if he had known of them in 1776 he would have made the halls of Congress ring with them, and that they would have been published in every Whig newspaper in the colonies; and Jefferson in reply expressed his surprise that Adams should not have seen at a glance that the publication was fraudulent. From that day to this the question as to whether the resolutions were actually passed by the citizens of Mecklenburg has been in dispute. In 1831 a committee of the Legislature was instructed to investigate all the questions involved, and the results of these investigations convinced a large majority of the people of the State that the claim was established. In accordance with that popular belief, May 20 was made a State holiday in North Carolina. On the other hand, several historical scholars have investigated the subject with care, and have arrived at an opposite conclusion. President J. C. Welling, of the Columbian University of Washington, looked into the evidence with characteristic thoroughness, and published the results of his researches in *The North American Review* in 1874. The conclusion which he reached was that no such resolutions were passed in 1775. A similar conclusion was reached by an independent study of the most comprehensive nature carried on by Lyman C. Draper, long the secretary of the State Historical Society of Wisconsin. The results of his study have never been published, but they are embodied in a MS. of 474 pp. This monograph, with the accompanying documents mostly in MS., constitutes twelve folio volumes. It is the object of this article to set forth as judicially as possible the evidence for and against the genuineness of the resolutions. The resolutions are as follows:

"*Resolved*, 1. That whoever directly or indirectly abetted, or in any way, form, or manner, countenanced the unchartered and dangerous invasion of our rights, as claimed by Great Britain, is an enemy to this country—to America—and to the inherent and inalienable rights of man.

"*Resolved*, 2. That we, the citizens of Mecklenburg County, do hereby dissolve the political bands which have connected us to the mother-country, and hereby absolve ourselves from all allegiance to the British crown, and abjure

all political connection, contract, or association with that nation, who have wantonly trampled on our rights and liberties, and inhumanly shed the blood of American patriots at Lexington.

"*Resolved*, 3. That we do hereby declare ourselves a free and independent people; are, and of right ought to be, a sovereign and self-governing association, under the control of no power other than that of our God and the general government of the Congress; to the maintenance of which independence we solemnly pledge to each other our mutual co-operation, our lives, our fortunes, and our most sacred honor.

"*Resolved*, 4. That as we acknowledge the existence and control of no law or legal officer, civil or military, within this county, we do hereby ordain and adopt as a rule of life, all, each, and every of our former laws; wherein, nevertheless, the crown of Great Britain can never be considered as holding rights, privileges, immunities, or authority therein.

"*Resolved*, 5. That it is also further decreed that all, each, and every military officer in this county is hereby retained in his former command and authority, he acting conformably to these regulations. And that every member present of this delegation shall henceforth be a civil officer —viz., a justice of the peace in the character of a '*committeeman*,' to issue process, hear and determine all matters of controversy, according to said adopted laws, and to preserve peace and union and harmony in said county; and to use every exertion to spread the love of country and fire of freedom throughout America until a more general organized government be established in this province.

"Abraham Alexander, *Chairman*.

John McKnitt Alexander, *Secretary*."

Accompanying the publication of these resolutions in 1819 was a certificate, of which the following is a copy:

"The foregoing is a true copy of the papers on the above subject left in my hands by John McKnitt Alexander, deceased. I find it mentioned on file that the original book was burned April 1st, 1800; that a copy of the proceedings was sent to Hugh Williamson, in New York, then writing a history of North Carolina, and that a copy was sent to General W. R. Davie. J. McKnitt."

The signer of this certificate, J. McKnitt, is conceded to have been Joseph McKnitt Alexander, the son of John McKnitt Alexander referred to in the certificate. The Alexander family was very numerous in North Carolina, and it is known that J. McKnitt had acquired the habit of omitting his surname. Thus it appears that forty-four years after it purported to have been adopted this interesting series of resolutions first appeared in print, vouched for by a son of one of the secretaries of the meeting. On the appearance of the resolutions in 1819 they were at once republished in all parts of the country. The challenge of Jefferson made it necessary that proofs of their authenticity should be forthcoming, or that the claim in their behalf should be abandoned. The result of efforts extending over seventy years has been the collection of evidence sufficient to convince any unprejudiced mind of the following points—(1) that a meeting of citizens took place in Mecklenburg County; (2) that a series of resolutions was passed; and (3) that a special messenger, Capt. Jack, was sent with the resolutions to Congress; but none of this evidence establishes the identity of the resolutions in question. For several years it seems not to have been doubted that the testimony of the witnesses applied to the Declaration embodied in the five resolutions quoted, but on Dec. 18, 1838, Peter Force, the antiquary, announced the discovery of another set of resolutions, indorsed as adopted by the people of Mecklenburg County, not on May 20, but on May 31, 1775. These resolutions, twenty in number, contained no declaration of independence, but, after reciting in the preamble that the British Parliament had declared the American colonies in actual rebellion, made such provisions for the government of the colony as seemed necessary in view of the suspension of the regular authority. Among the many considerations which bear out the theory that this series of resolutions, and not the so-called Declaration, was what the witnesses really had in mind, may be mentioned the following: (1) The difference in date (May 20–31) is the exact difference between old style and new style, and both calendars were then in use in many localities. (2) The resolutions published on the 31st contained no reference to a previous Declaration of Independence; but, on the other hand, no other reason is given for the action taken at the meeting than the fact that Parliament had declared the colonies in rebellion. (3) The testimony of witnesses with regard to the Declaration applies far more pertinently to the twenty resolutions. (4) Contemporary evidence establishes the fact that these resolutions, and not those containing the Declaration, were taken to Congress by Capt. Jack. (5) The twenty resolutions were immediately published both in the North and in the South, while the Declaration, though of a more important and startling nature, did not appear till after the lapse of forty-four years. (6) The subsequent conduct of the men mentioned as prominent in passing the earlier resolutions was grossly inconsistent with such action, since they took the oath of loyalty to the king, and in the Provincial Congress expressly disclaimed the intention of shaking off connection with the parent state. (7) It was discovered in 1853 that the five resolutions containing the Declaration had been reproduced from memory five months after the burning of the records in 1800, nor is there anything to prove that J. McKnitt Alexander had ever refreshed his memory by consulting the original documents during the twenty-five years that had elapsed since their passage.

These facts represent but a small portion of the evidence against the genuineness of the alleged Declaration, and the conclusion is inevitable that, unless some new evidence of overwhelming importance is discovered, the opinion of impartial investigators must be adverse to the authenticity of that document. For a more complete discussion of the matter, see the following authorities: In addition to *The North American Review*, vol. cxviii., pp. 256–293, and *Magazine of American History*, vol. xxi., pp. 31–43 and 221–233, the subject is very fully presented in the following works: Frothingham's *Rise of the Republic*, p. 422; Randall's *Life of Jefferson*, iii., p. 570; Wheeler's *North Carolina*, ii., 255; Hawks, Swain, and Graham, *Revolutionary History of North Carolina*, pp. 47–98. The most exhaustive treatment of the subject is to be found in Draper's *Mecklenburg Declaration: its Origin, History, and Actors, with a Bibliography of its Literature and Explanatory Documents*; MSS., 3 vols. folio, Wisconsin Historical Society Collections (1876): of vol. iii., pp. 328–474 are devoted to a critical examination of the literature of the subject. The *Illustrative Documents*, printed and in MS., constitute nine volumes. C. K. Adams.

Mecklenburg-Schwerin, mek'len-boorch-shvā-reen': grand duchy of Northern Germany; bounded N. by the Baltic, and E., S., and W. by Prussia. Area, 5,135 sq. miles. Pop. (1900) 607,835, chiefly of Slavonian origin, of which they still retain marks in their features. The ground is low and level, dotted with small lakes, and covered with forests. Along the shore of the Baltic the soil is sandy or marshy, but farther inland it is fertile and well suited to agriculture and pasturage. The principal crops are rye, wheat, barley, oats, potatoes, and hay. Cattle and horses are reared, and, especially the latter, are much valued. Capital, Schwerin.

Mecklenburg-Strelitz, -strā'lits: grand duchy of Northern Germany, consisting of two separate parts—Stargard, between Mecklenburg-Schwerin and Pomerania, and Ratzeburg, between Mecklenburg-Schwerin and Lauenburg. The total area is 1,131 sq. miles. Pop. (1900) 102,628. Capital, Neu-Strelitz.

Mecoptera: See Entomology.

Medal [from Fr. *médaille*: Ital. *medaglie* < Vulg. Lat. **metal'lea*, deriv. of *metal'lum*, metal. See Metallurgy]: in the usual sense, a flat metal disk, stamped on each side with one or more inscriptions, and often a figure or group, the whole in low-relief like that of a coin. Although such medals are *coinage*, in the sense of being struck in the coining-press, they are distinguished from coins in not being intended for use as money. A medal is struck in commemoration of a victory, as has long been a custom among the nations of Europe; or in honor of a great soldier, as in the case of the gold medal voted by Congress to Gen. Grant; or in recognition of any important event, as a treaty of peace, the disappearance of a pestilence, the visit of a foreign potentate, the completion of a public building; or even the appearance of a brilliant comet, or a misfortune such as the great fire of London in 1666. In the Paris mint (*la Monnaie* or *l'Hôtel des Monnaies*, on the Quai Conti) a very large collection may be seen of the medals struck in that institution, as well as others. There are about 600 of the single reign of Louis XIV., and nearly as many were devoted to the triumphs of Napoleon I. during the brief period of his power, 1796 to 1815. The size of such medals rarely exceeds 3 inches in diameter; one of about 4½ inches, struck at the Paris mint in 1842, is often cited as the largest piece of coinage existing. This Paris mint is the center of artistic

work in die-sinking and medal-coining. Many artists are kept busy there, and orders are sent thither from all parts of the world. The term *medal* is used also for the great cast medallions of the fifteenth and sixteenth centuries (see MEDALLION), also for any ancient or unfamiliar coin, especially if large and striking in design, and also to many small tokens of success or favor, prizes at an exhibition, school rewards, etc., even when not ornamented in relief, or even when not of metal. RUSSELL STURGIS.

Medallion: originally a large medal; hence, and very commonly, a flat, circular work of art of any sort, even if several feet in diameter and carved in marble; and, thirdly, any piece of ornament consisting of an independent design isolated by its own frame, within the bounds of a larger composition (see below). In the first sense the term is applied to unusually large coins, even to some silver coins of the Greek cities, and especially to the remarkable bronze pieces of the Roman emperors, those without the S. C. (for *Senatus Consultum*), and thus shown to be not a part of the regular bronze coinage. (See NUMISMATICS.) In the second sense the bas-reliefs in question may be considered as imitations of medals, as if medals had been copied larger for general popular inspection. Thus the arch of Constantine, at Rome, is decorated with ten bas-reliefs within circular molded frames about 8 feet in diameter; eight of these, which are generally thought to have been taken from an arch of Trajan no longer existing, represent scenes of the imperial life and ceremonial, very much as the same scenes would be represented on a coined medal of unusual finish and elaboration, except that they are in higher relief. At the time of the Renaissance a similar decoration was used in building; thus in the courtyard of the Palazzo Riccardi at Florence, in a band over the arches of the ground floor, are eight disks sculptured by Donatello, alternating with others inclosing armorial shields; but in the third sense a medallion may be of any shape, square or oblong, or even irregular. Thus, on a Sèvres vase, a painting with figures and an elaborate landscape background will often be inclosed within a frame of the general shape of a trapezoid, the rest of the vase being decorated with simple gilding and scroll-work; but this painting is spoken of as a medallion, or as being in a medallion. In carpets which are woven in one piece and rugs, table-cloths, etc., there is very often a central pattern, between which and the border there is left a space somewhat less richly ornamented; this central division is spoken of as the medallion, and a carpet of this kind is often called a medallion carpet. RUSSELL STURGIS.

Mede'a [= Lat. = Gr. Μήδεια]: in Greek mythology, the beautiful daughter of Æëtes, King of Colchis, and Hecate, the sister of Circe. Both mother and aunt educated her in sorcery, in which she attained great proficiency, but being kindly disposed, she used her knowledge to bring to naught the plans of her teachers, and exerted herself especially to prevent the sacrifice of foreigners. Æëtes, being fearful that she might dethrone him, imprisoned her, but thanks to her magic powers, she easily escaped, and fled to the temple of the Sun, on neutral ground. At this juncture Jason and the Argonauts came to Colchis in search of the GOLDEN FLEECE (*q. v.*) Medea fell in love with JASON (*q. v.*), and made it possible for him to get and carry off the Golden Fleece. At the close of her career in Corinth she fled to Athens, where she married the aged king Ægeus, and bore to him a son, Medus, according to one myth. When Theseus had come to Athens from Trœzen, she plotted his death, but was finally forced to flee from Athens. She returned to Colchis, found her father deposed by his brother Perses, and restored him to the throne. Her son Medus became the eponymous hero of the Medes. According to another myth she fled from Athens to Phœnicia, married the king, and begat Medus by him. She at last became immortal, and like Helen, married Achilles in Elysium. Her story is variously told, and has furnished much material for the artist and the tragedian. See the tragedy of Euripides, entitled *Medea*. J. R. S. STERRETT.

Medellin, mā-dāl-yeen': capital of the department of Antioquia, Colombia, and, with the exception of Bogotá, the largest and most important city of the republic. It is in a beautiful valley (incorrectly called the "Cañon"), watered by a small river which flows to the Cauca; 147 miles N. W. of Bogotá, and 4,852 feet above the sea (see map of South America, ref. 2–B). It is well built, with wide and straight streets, and has a delightful climate and an abundant water-supply. The inhabitants are noted for their intelligence and progressive spirit, and the city is an educational center, containing a university, a school of arts and technology, library, museum, theological seminary, several charitable institutions, a park, etc.; it is the episcopal city of a large diocese, and has a mint and other Government institutions. Many of the wealthier residents are engaged in mining enterprises, this being the metropolis of the Antioquia gold belt; a large proportion of the metal is exported to England. Medellin was founded in 1674, but during the colonial period was an unimportant village. Since 1825 it has grown steadily, supplanting the older town of Antioquia. Pop. (including the suburb of Buenos Ayres) about 30,000. H. H. SMITH.

Medford: city (founded in 1630, incorporated as a city in 1892); Middlesex co., Mass. (for location of county, see map of Massachusetts, ref. 2–H); on the Mystic river, and the Boston and Maine Railroad; 5 miles N. by W. of Boston. It is the seat of Tufts College (Universalist, chartered in 1852), and contains a house erected in 1634, which still retains its original walls and shape. The city is noted for its manufactures of rum, crackers, and felt boots, and has a public library, print and dye works, pressed and face brick-works, brass-foundry, carriage-factories, and paper-mills. Pop., township (1880) 7,573; (1890) 11,079; (1900) 18,244. EDITOR OF "MERCURY."

Medford: city; capital of Taylor co., Wis. (for location of county, see map of Wisconsin, ref. 4–C); on Black river, and Wis. Cent. Railroad; 67 miles N. W. of Stevens Point, in an agricultural and lumbering region, and has two weekly newspapers. Pop. (1880) 504; (1890) 1,193; (1900) 1,758.

Med'hurst, WALTER HENRY: missionary and linguist; b. in London, England, in 1796; went to the East in 1816 as a missionary; resided at Batavia (Java) eight years (1822–30), laboring also in Borneo; settled at Canton, China, about 1830, and at Shanghai in 1843; spent six years in the interior of China; died in London, Jan. 24, 1857. He acquired a remarkable knowledge of the Chinese, Japanese, and Javanese languages, translated the Bible into Chinese, edited the *Chinese Repository* (20 vols., Canton, 1838–51); published a *Chinese and English Dictionary* (2 vols., Batavia, 1842–43), and many other linguistic works; wrote an *Account of the Malayan Archipelago*; a valuable work on *China, its State and Prospects, with especial reference to the Diffusion of the Gospel* (1838), followed by *A Glance at the Interior of China* (1850); and translated the Chinese classic called *Shu-King* (1848), besides numerous minor works from the Chinese and other Oriental languages.

Me'dia (in Gr. Μηδία): a territory of Asia; bordering N. on the Caspian Sea, and bounded on the other sides by Parthia and Hyrcania, Assyria and Armenia, and Persia and Susiana, corresponded nearly to the present Persian provinces Irak-Adjem, Azerbaidjan, Ghilan, and Mazandaran. The Medes were closely allied to the Persians in language and religion, and they distinguished themselves by their horsemanship and their skill with the bow. The original inhabitants of Media were called Aryans, though the name *Madai* is given them even in Gen. x. 2. They came first into notice when attacked by the Assyrians about 830 B. C. The great monarchy established by them dates from 650 B. C., with Ecbatana for its capital. In 625 B. C. their king, Cyaxares, in league with Nabopolassar of Babylon, took Nineveh and overthrew the Assyrian empire. The revolt of the Persians under Cyrus brought the Median kingdom to an end, 558 B. C. The Medes, who originally were a warlike race, are later spoken of as a very effeminate people. The country produced abundance of fruit and horses. The grapes of Ecbatana (Hamadan) are celebrated to this day. The inhabitants of Media were worshipers of the sun, and their priests were called Magi. Revised by J. R. S. STERRETT.

Media: borough; capital of Delaware co., Pa. (for location of county, see map of Pennsylvania, ref. 6–J); on the Phila., Wil. and Balt. Railroad; 5 miles N. of Chester, 12 miles W. of Philadelphia. It is in an agricultural region; contains the Delaware County Institute of Science and an academy, each with a library of over 3,000 volumes; and has 2 national banks with combined capital of $200,000, 3 weekly newspapers, and, in its vicinity, the State Training-school for Feeble-minded Children. Pop. (1880) 1,919; (1890) 2,736; (1900) 3,075. EDITOR OF "AMERICAN."

Mediæ, or **Medials**: in phonetics, the voiced non-aspirated explosives *g*, *d*, *b*, which are distinguished from the *tenues k*, *t*, *p* on the one hand, and the *aspiratæ* k^h, t^h, p^h,

g^h, d^h, b^h on the other. The term is merely a translation of the Greek μέσα, intermediate, which the early Greek grammarians applied to the group because they regarded the sounds as intermediate between the *tenues* (ψιλά) and the *aspiratæ* (δασέα); as in Dionysios Thrax (*Techne*, p. 631 b) "they have been named μέσα because they are more shaggy than the bare sounds and barer than the shaggy sounds" (ὅτι τῶν μὲν ψιλῶν ἐστι δασύτερα, τῶν δὲ δασέων ψιλότερα). The terms δασέα and ψιλά were originally chosen as involving the contrast, hairy, shaggy *versus* bald, bare. See PHONETICS and LANGUAGE. BENJ. IDE WHEELER.

Medical Electricity: the use of electricity as a therapeutic means in the treatment of disease. In the year 1804, and further back, the static form, obtained from the large glass friction apparatus, was used somewhat empirically, the spark being thrown from the brass balls of the machine. Later investigations have shown what real value this powerful agent has in many forms of nervous disease, notably in paralysis and neuralgia. Duchesne, of Boulogne, was among the first to treat patients with the localized induced current, and Remak in Germany employed the galvanic current with equally successful results. Three forms of electricity are employed, viz., the induced or faradic current, the galvanic current, and the static current. The two first are examples of dynamical electricity, and the other of frictional electricity. Galvanic electricity, or galvanism, and induced electricity, or faradism, as it has been called out of compliment to its discoverer, Faraday, are the two modes generally made use of, while frictional electricity is rarely resorted to. Electro-magnetism, a species of induced current produced by the rotary apparatus, has been the favorite form of treatment among quacks and empirics. Faradism is furnished by an instrument containing a coil of wire surrounded by another, the inner one, containing in its center a bundle of wires or a rod of soft iron. Through the inner coil a galvanic current is passed and an induced current thereby generated in the outer. The former is known as the direct or *primary* current, the latter as the induced or *secondary*. At the end of the wires in every instrument is a small hammer of soft iron fastened to a spring, and a pole containing a platinum-pointed screw is placed at a short distance from it, opposite the end of the bundle of wires. This hammer breaks the current in the coil of wire, and rapidly vibrates, producing shocks. The galvanic current used in medicine is obtained from a series of cells sufficient in number to give a current of *tension*. Tension is the resistance offered to the passage of a current. One cell supplies a current, the poles of other cells being alternately joined, and there are finally but two terminal poles. We find that as the current from the original cell passes through the cells which follow, its *tension* or power is increased, and the effect is appreciable to a greater or less degree in proportion to the number of cells included in the circuit. *Quantity* is another attribute of the galvanic current, but is not as a rule desired in medical electricity. A current of *quantity* is furnished by a large surface of metal in the battery-cell, while *tension* is the product of a number of small metal plates.

The best *galvanic cell* for medical purposes is the Bunsen, which has been adopted by Stöhrer, of Dresden, and the Grenêt, a modification of the latter, is that most commonly used. The Siemens and Halske cell is now employed to a great extent. It consists of an outer cell of glass with elements of zinc and copper, a diaphragm of porous earthenware, and a diaphragm of papier-maché between the solutions. The *static current* may be furnished by the Holtz electric machine, which is undoubtedly the best. The Ruhmkorff coil has been used, one wire only being brought in contact with the patient, the air forming the other conductor. A spark having all the peculiarities of the ordinary friction spark will be produced.

For the application of electricity to the body we make use of various appliances called *electrodes*. These are either sponge-covered or present a polished metallic surface to the skin. Some have sponges of different sizes for the face or smaller parts of the body, and large ones for the trunk and limbs. The points of Duchesne consist of two cones of metal attached to handles. The sensation upon the skin is like that associated with the entrance of many small needles. The electric brush is often used to restore diminished cutaneous sensibility. It consists of a number of fine wires bound together in a handle. This electrode, as well as the other metallic ones, are used upon the dry skin. Various double electrodes and electrodes for special parts, such as the eye, uterus, and bladder, are employed in different cases.

Rational electro-therapeutics should be based upon electro-physiology. Remak, Dubois-Reymond, Ziemssen, Onimus and Le Gros, Brenner, Benedikt, and Erb stand in the front rank as authorities. Morgan gave to the world a work of very great value which remains as a monument to his greatness.

Certain facts have been evolved from the labors of the workers in this field. We have been taught that a motor nerve, when stimulated by an electric current, is followed by a contraction of the muscles it supplies. The theory of *electrotonus* is based upon the following facts: If a portion of a motor nerve is included between the poles of a galvanic battery it is said to be *polarized* and in a state of "electrotonus." At the positive pole the irritability of the nerve is diminished, while at the negative it is excited and more susceptible to stimulation. The condition at the positive pole is called *anelectrotonous*, and that at the negative *catelectrotonous*. The positive pole is known as the *anode*, the negative the *cathode*, and these give the names to the states described. A nerve is said to be *tetanized* when the muscle supplied is thrown into a state of permanent tetanic contraction by a rapidly intermitting current. The passage of a number of these shocks for some time will diminish the irritability of the nerve to such an extent that finally there will be no further response. This is a valuable fact to consider in connection with electro-therapeutics. An ascending current, i. e. a current running toward the spinal cord or brain, causes a greater irritability in a nerve than a descending one. The stimulus is felt at the negative pole when the current commences, and when it is broken it is felt at the positive pole. Greater sensation is felt at the negative pole, and with very weak currents no sensation may be felt except at the negative electrode when the current is started or *opened*. With stronger currents sensation may be felt at discontinuing the current and at both poles. With very strong currents sensation is diffuse, not limited to the region to which the electrode is applied.

The action of the faradic current upon the surface of the body is probably the same as that of a galvanic, except that it is a momentary shock instead of a constant current. It does not affect the deeper muscles nor nerves as much as the skin. When an electrode is applied to the moistened skin it is followed by prickling sensations, attended by redness and tingling. The faculty of perceiving sensation by the cutaneous nerves and muscles has been called the *electro-muscular sensibility*. The sensation produced by the galvanic current is one of warmth, like that which always follows the application of local stimulants, such as liniments or a mustard plaster. When the faradic current is applied to the skin previously dried, or when the electrodes are lightly brought in contact with it, there is appreciable pain produced. Cutaneous sensibility is more exaggerated by rapidly succeeding shocks from a faradic instrument than by slow ones. The galvanic current produces deeper impressions than the faradic. It likewise produces electrolytic changes which do not follow the use of the faradic. The effects of the galvanic current upon various parts of the body may be briefly enumerated as follows: The application of the electrodes of a battery of moderate strength to any part of the head or face will be attended by the occurrence of flashes of light appreciated by the individual, a metallic taste, giddiness, dizziness, and a peculiar sensation at the root of the nose. The possibility of the passage of a galvanic current through the bones of the cranium has been doubted by Cyon and other writers, though other physiologists, Ziemssen and Erb among them, agree as to its feasibility. The passage of such a galvanic current, according to certain neuro-therapeutists, is followed by beneficial results in many diseases of the brain, but there is at the present day no proof of this at all.

Electricity for the Purpose of Diagnosis.—By it we may detect local tenderness, exalted sensibility, or their opposite conditions, anæsthesia and paralysis. We may sometimes ascertain whether there is disease of the nerve-centers, the brain, or spinal cord—whether a paralysis is of recent date or long standing. We may settle the question of doubtful death; we may also detect malingering. There are several important physiological facts to be taken into consideration—the function of muscles or nerves, their loss of contraction and senation, or the reverse; and as various nervous diseases are associated with these conditions, we are enabled by electricity to determine the extent of such changes. A

reference to a few morbid conditions will make these facts more clear. The existence of some recent disease of the brain will be characterized by increased muscular contractility oftentimes when there is paralysis of the muscles. Certain local paralyses, or central diseases attended with atrophy of the muscles or disease of some part of the nerve destroying its conductivity, are associated with loss of reaction.

Galvanism and faradism are used for the relief of pain and spasm and to procure sleep, for the improvement of the nutritive processes, to restore lost muscular power, for stimulation of secretion, to influence circulation by means of the vaso-motor system, to produce absorption of fluids, morbid tissues, and deposits, and in the form of the galvano-cautery for surgery. Both forms of current are used in the treatment of paralysis, the galvanic perhaps being the most important for paralysis from central diseases. One of the most decided and unquestionable uses of electricity is in cases of headache and sleeplessness of brain-fag. The gentle application of galvanic currents in these cases or of the faradic currents sometimes acts marvelously. There are many cases of paralysis in which faradic currents will produce no muscular contraction, while the galvanic current will be followed by vigorous contractions of the muscles. In cases of this kind treatment is begun with the galvanic current, and afterward the faradic is used. It should always be the rule to use that current which produces the maximum of muscular contraction with the minimum of pain. In cases of spinal or brain disease, such as apoplexy, it is injudicious to use any electrical treatment for the muscles in the early stages, because there is active irritation at the seat of lesion. The forms of paralysis from all causes, whether they be from pressure, from injury, or from rheumatism, may be treated successfully. Paralyses of special parts are treated by differently shaped instruments. There are electrodes for applying it to the vocal cords, to the muscles of the orbit, to the ear, to the stomach, larynx, bladder, etc.

Galvanism asserts itself most favorably in neuralgia of all kinds. It is indicated particularly in sciatica, tic douloureux, spinal irritation, and a number of other conditions attended by pain. Forms of hysteria are particularly under the control of galvanism. Writers' cramp and chorea are benefited to some degree by both currents. Little can be said of the value of electricity in the treatment of skin diseases. Electricity has produced very few authenticated cures, and those reported are undoubtedly due for the most part to other remedies (or galvanism only so far as it proved of use as a general tonic) and disappearance of the causes. Electricity has been used by Simpson, Thomas, Dubois, Murray, and Allen in obstetrics for the production of uterine contractions. A most important use of electricity is its application for the production of absorption of morbid products in different parts of the body.

When the two poles of a galvanic battery are connected with needles, and these needles thrust into the tissues of the body, a process goes on which has been called *electrolysis*. At the *negative* pole bubbles of hydrogen gas are disengaged, which separate mechanically the surrounding tissues and break them down, so that the disintegrated particles may be taken up in the circulation. At the *positive*, oxygen is disengaged, which forms an acid with certain elements of the tissue, and the albumen is coagulated, forming a clot if this happens in a cavity filled with blood. With this mode of treatment the physician is enabled to disperse certain tumors of small size. The same treatment has been used in the removal of small hairs from the lips of women.

A platinum wire placed between the poles of a powerful battery possessing the requirement of sufficient electromotive force will become in a very few minutes white hot. Such wires properly adjusted in handles may be used in place of the knife or *écraseur* in many surgical operations, especially in deep cavity operations, where the use of the knife is impossible. The galvanic cautery is unattended by pain or hæmorrhage. Its cuts are covered by perfect cicatrices, and it is very valuable in certain uterine operations. Care must be exercised by all persons who use electricity to avoid applying strong currents to the head. It is unadvisable to use it for over ten or fifteen minutes at a time, and then very carefully. Revised by WILLIAM PEPPER.

Medical Schools: See SCHOOLS.

Medici, mā′dĕe-chĕe: a famous Florentine family who in the fourteenth century became prominent in public affairs, and later attained the sovereign power. They acquired great wealth as merchants, and spent it in a manner that won them popularity. COSIMO DE' MEDICI, "Pater Patriæ," b. 1389, was the son of Giovanni, *gonfaloniere*, and by his liberality, urbanity, and prudence won great influence with the people, but avoided the appearance of power, being content with the substance. He adorned Florence with splendid public buildings, patronized art, and died Aug. 1, 1461.—His grandson, LORENZO THE MAGNIFICENT, b. Jan. 1, 1448, was the splendid patron of Greek learning and of all the liberal arts, being himself no mean poet. He brought Florence to a great pitch of opulence and power, and, notwithstanding the hostility of Pope Sixtus IV., exercised a great influence throughout Italy. D. Apr. 8, 1492. —His son, Pope LEO X., did much to advance the fortunes of his family. (See LEO X.)—COSIMO, b. June 11, 1519, the first Grand Duke of Florence, was a successor of Alessandro (1510–37), the subverter of Florentine liberty. Cosimo was declared grand duke by Pius V. 1569, and died Apr. 21, 1574. The grand ducal line of the Medici family ended in 1743 with Jean Gaston de' Medici (1671–1737), but the princely line of Ottajano, the ducal house of Sarto, etc., have perpetuated the name till our times. The popes Leo X. and XI. and Clement VII., Queens Catharine and Marie de Médicis of France, some eminent cardinals and Dukes of Urbino, were also of this family. See CATHARINE DE' MEDICI and MARIE DE MÉDICIS.

Medicine [from Lat. *medici′na* (sc. *ars*, art), the art of a physician, or of healing, deriv. of *me′dicus*, medical, a physician, deriv. of *mede′ri*, heal]: the art and science of curing disease. Its origin is obscure, but dates back to the early existence of the human race, coincident with the liability to injuries, sickness, and processes of decay. Medicine in its primitive state comprised a recognition of the relative virtues of different articles of food, an empirical use of medicinal herbs and roots, and superstitious rites. For ages it was merely traditional usage in families or communities. Hence it was practiced, as it is to-day in barbarous tribes, by the local chiefs. Superstition ascribed disease to evil spirits or to the displeasure of divinities, and reverenced the gifted physicians as superhuman. Temples were erected to their worship, whose priests were guided in their treatment by invocation of the oracle. The profession thus became a sacerdotal order, within which acquired knowledge of medicine was preserved and secretly transmitted. The Chinese have practiced and written of medicine from the remotest ages, but without intelligence or method, being possessed only of a vast collection of extravagant empiric formulas. The Hindu practice has always been simple, restricted to a knowledge of dietetics, hygiene, and mild antiphlogistic measures. The methodical study of medicine began in the fabulous age of Egypt. At first the method pursued was to expose the sick by the wayside, that passers-by who had suffered from similar maladies might recognize them and declare the means of cure. Herodotus tells us that the Babylonians, Chaldæans, and other nations had no physicians, but followed this custom. Afterward, in Egypt, the sick were required, upon recovery, to go to the temple and record on tablets their symptoms and remedies. The temples of Canopus and Vulcan were the repositories, and a skilled priesthood arose which framed a code controlling public hygiene, individual regimen, and the treatment of disease. Thus far back in a period of mythology Egypt possessed a store of medical knowledge, had able surgeons, many devoted to the study and pursuit of a single specialty, as lithotomy, and remedies bearing the name of Isis and Osiris came down through subsequent Grecian, Roman, and early Christian centuries. The reports concerning the practice of medicine in Greece in early times are legendary. Æsculapius, instructed in the healing art by Chiron the Centaur, became so skilled that he incurred the displeasure of Pluto, and was stricken by a thunderbolt from Jove. He became the god of medicine, temples were erected bearing his name, and the officiating priesthood were designated the Asclepiadæ. The sons of Æsculapius, Machaon, and Podalirius, accompanied the Greeks in the Trojan war, and their skill was immortalized in the songs of Homer. Hygieia, the goddess of health, and Hercules, reputed to cure epilepsy—the "sacred disease" or "disease of Hercules"—were also worshiped. The practice of the Asclepiadæ was simple. Temples were located in salubrious places, and their interiors were purified by burning fragrant incense and secret remedies. Thither the sick were brought

for treatment. Recourse was had to baths, gymnastics, mineral and thermal springs, and the use of unctions. Remedies were prescribed by the oracle and skill of the priesthood. Votive tablets inscribed with records of the disease and cure were deposited within or placed upon the columns and gates. Pythagoras and the sect which took his name supplanted the Asclepiadæ. They promulgated the knowledge which had before been kept a secret, and sought the philosophy of disease, but confined their treatment to dietetics and hygiene. The Pythagoreans declined about 500 B. C. Hippocrates was born in the year 460 B. C., and is known as the "father of physic." He was descended remotely from the Asclepiadæ through a long line of physicians. He developed a system of theories on disease and medicine which has given to his school and period of practice the title "dogmatic." He acquired anatomy by dissection of animals, and was skilled in surgery. His study of symptoms and diseases was careful and accurate; he recognized stages and crises in diseases; he relied upon the power of nature, which he termed "first of physicians"; stimulating when nature failed, moderating when her forces were excited. His remedies were mainly vegetable and dietetic. His works were numerous, chief of which are *The Prognostics*, *Aphorisms*, *On Epidemics*, *Regimen in Acute Disease*. With the founding of the Alexandrian Library (320 B. C.) the Alexandrian school began. Most celebrated were Erasistratus and Herophilus. The latter was an anatomist, studied the nerves, the brain, and to this day his name is retained connected with its circulation, the confluence of venous sinuses being termed the "torcular Herophili." Two Alexandrian schools of medicine flourished successively—the "Empirical" of Philenus and Serapion, who renounced "dogmatism" and relied only on experience, and the "Methodists," whose influence extended over Greece, thence to Rome, and lasted for at least two Christian centuries. Methodism asserted that the body was permeated in health by atoms which entered from without and moved freely in every part and direction of the organism. Disturbances of this perfect relation by constriction or relaxation were states of disease, and all medication was therefore by astringents or relaxants.

Medicine was introduced into Rome from Greece 200 B. C. Asclepiades, who practiced in Rome 100 B. C., was a Methodist. Chief among Roman physicians was Celsus, "the Cicero of medicine," great as a surgeon and scholar, whose work, *De Medicina*, in eight books, is a record of medical knowledge down to his time. Claudius Galen, known as Galen, by his teachings and writings so influenced medicine that he was esteemed infallible authority for fully twelve centuries. He was born at Pergamos A. D. 130, but lived and practiced in Rome. He is reputed to have written 200 distinct treatises upon every subject then known in medicine. He was educated at Alexandria, and his knowledge of anatomy was matured by dissection of animals. He was a "Humoralist," regarding disease as due to putridity of the "four humors"—blood, phlegm, bile, and black bile. The Methodists, on the other hand, found disease only in the tissues, and were known as "Solidists." As long as medicine was swayed by theories, the conflict of Humoralism and Solidism was constantly revived. Chief among Galen's works are treatises *On the Use of the Different Parts of the Body*, *On Temperaments*, *On the Seat of Disease*, *Methods of Cure*. During the Dark Ages medicine declined in Europe, but was preserved and advanced by the Arabian school, which dominated from the ninth to the end of the fourteenth century. Symptoms were studied, new diseases described, Galen's works were translated and commentated, rendering famous the names of Rhazes, Avicenna, Albucasis, Avenzoar, Averroës, etc., and drawing the students of the whole Continent to the renowned Spanish schools of Cordova, Seville, Toledo, and Saragossa. Renouard, in his *History of Medicine*, styles the subsequent period, from the close of the fourteenth century to the present, the "age of renovation." Medicine, thus far an art based upon experience and biased by erroneous theories, now began to advance by successive discoveries in anatomy, physiology, and pathology to the standard of a science. Printing insured the dissemination of each progressive step. The Italian schools succeeded the Arabian. Mondino, of Bologna, dissected before the class in 1315, and wrote imperfectly on anatomy. To Andreas Vesalius, professor at Padua, who published his great work in 1543, anatomy owes its origin and permanent impetus. Vesalius was followed by Eustachius, Fallopius, Sylvius, Pacchioni, and others whose names now exist in anatomical nomenclature. In A. D. 1622 Aselli of Milan described the lacteals; in 1628 Harvey announced the circulation of the blood; in 1661 Malpighi of Bologna detected the movements of the red blood-globules; in 1690 Leeuwenhoek of Delft demonstrated the capillaries. The researches of Vieussens, Haller, Meckel, and Scarpa, the separation of the cerebro-spinal and ganglionic nervous systems by Bichat, the treatise of Sénac (in 1749) on the action and diseases of the heart, of Avenbrugger (in 1761) on percussion of the chest, the great work on pathology by Morgagni in 1762, the recognition of nerve origins, of the ganglia, and different faculties in the brain by Willis and others, the writings of Sydenham and Huxham, the discovery of vaccination by Jenner in 1796, are a few of the very many scientific truths which warrant us in speaking of medicine as a science. The status of medicine was again elevated. The barber-surgeons of Paris were abolished by law in 1743, in London in 1745. Clinical teaching was inaugurated at Padua in 1758. Schools of medicine were established both in Europe and in America. During the nineteenth century this devotion to the development of technical and scientific investigation, rather than to speculation, as the true basis of the treatment of disease, has steadily increased, and warrants the belief that we are erecting a system of scientific medicine. This has also been designated an age of "rational empiricism" in medicine, since skill in treatment is largely cumulative from past experience, yet rendered intelligible and certain by a clear discernment of the laws of life, of the functional activities which constitute health, and of their perversion in disease. Histology, physiology, microscopy, micro-chemistry, pathology, physiological medicine, pharmacy, and therapeutics are fields of incessant work and progress. The physical exploration of the chest, the study of Bright's disease, the discovery of anæsthesia, the recognition of the dependence of many if not most diseases—malignant pustule, erysipelas, tuberculosis, tetanus, and many others—on the presence of micro-organisms, the improved treatment of wounds by aseptic and antiseptic methods, the elaboration of the specialties, are some of the many results. Correct and intelligent diagnosis, study of morbid anatomy and etiology, and an accurate knowledge of the physiological effects of remedies, are sought as the only substantial basis for the treatment of disease, while its prophylaxis by the use of preventive inoculations is a brilliant anticipation which may possibly be realized in the future.

Among the best medical dictionaries available to the English-reading student may be mentioned those of Dunglison (21st ed. Philadelphia, 1893); Duane (Philadelphia, 1893); Gould (Philadelphia, 1894); and the more elaborate works of Billings (2 vols., Philadelphia, 1890); Foster (4 vols., New York, 1893); and the lexicon now (1894) in course of publication by the New Sydenham Society of London.

Medicine, Forensic: See JURISPRUDENCE, MEDICAL.

Medicine Hat: a growing town of Assiniboia, Canada; on the Canadian Pacific Railway, 660 miles W. of Winnipeg, on bottom-lands of the South Saskatchewan river (see map of Canada, ref. 9–F). It formerly had the name of Leopold. The origin of the present name is not known. In the vicinity are lignite beds and the petroleum district of Galt. Pop. 1,000. M. W. H.

Medicine Lodge: city; capital of Barber co., Kan. (for location of county, see map of Kansas, ref. 8–E); on the Atch., Top. and S. Fé Railroad; 91 miles W. of Winfield. It is in an agricultural and stock-raising region, and has two newspapers. Pop. (1880) 373; (1890) 1,095; (1900) 917.

Medick, Purple: See LUCERNE.

Medill', JOSEPH: journalist; b. in New Brunswick, Canada, Apr. 6, 1823; removed in childhood to Massillon, O.; studied law; founded in 1849 a Free-soil paper at Coshocton; established at Cleveland in 1852 a Whig paper, *The Forest City*, which in the following year was merged in *The Leader*; was in 1854 one of the organizers of the Republican party in Ohio; went to Chicago soon after, and with two partners bought in May, 1855, *The Tribune*, a paper with which he has since been identified. He was in 1870 a member of the Illinois constitutional convention, and was the author of the minority representation clause; was appointed in 1871 a member of the U. S. civil service commission, and elected mayor of Chicago. He spent a year in Europe (1873–74), and on his return purchased a con-

trolling interest in *The Tribune*, of which he became editor-in-chief. D. in San Antonio, Tex., Mar. 16, 1899.

Medi'na (Arab. Medinet-el-Nabi, City of the Prophet): 132 miles N. E. of Jemb or Yambu, its port (see map of Persia and Arabia, ref. 6–D). It is a handsome, well-built town, situated at the edge of the great Arabian desert on the east side of the mountain range which runs N. and S., parallel to the Red Sea. It is protected by a stone wall over 40 feet high with 30 towers and 3 gates, one of which, the Egyptian Gate (Bab-el-Misri), is exceedingly beautiful. Its importance is derived from the fact that Mohammed is buried here. His tomb, close outside the great mosque El Haram, is visited annually by over 60,000 pilgrims, though the visit is considered not incumbent, but only meritorious. Near by are the tombs of his daughter Fatima and of the Caliphs Aboubekr and Omar. The mosque—according to Burckhardt, 165 paces long and 130 wide, its dome upheld by 400 columns, lighted by 300 lamps which burn night and day—was burned in 1508 and rebuilt in 1514 by Kaid Bey, Sultan of Egypt. Mussulmans do not agree as to whether Mecca or Medina has the greater sanctity. Medina has ninety-two names, all referring to the holy character of Mohammed. The inhabitants are intelligent and sedate, and not so military in their bearing as those of Mecca. Pop. 80,000. See HEJIRA and MOHAMMED; also Burton's *Pilgrimage to El Medinah and Meccah* (3 vols., 1856); and especially Burckhardt's *Travels in Arabia* (1829).

E. A. GROSVENOR.

Medina: village (located in 1805, incorporated in 1832); Orleans co., N. Y. (for location of county, see map of New York, ref. 4–D); on Oak Orchard creek, the Erie Canal, and the N. Y. Cent. and Hud. Riv. Railroad; midway between Buffalo and Rochester. It is an important agricultural and orcharding center; contains 6 quarries, which show rare fossil formations, of the celebrated Medina sandstone, 7 churches, an academy with library founded in 1850, several flour-mills, 5 iron-foundries, and furniture and paper-pail factories; derives good water-power from the creek; and has a State bank with capital of $50,000, a national bank, and a monthly and 2 weekly newspapers. Pop. (1880) 3,632; (1890) 4,492; (1900) 4,716.

EDITOR OF "RECORD."

Medina: village (settled in 1818); capital of Medina co., O. (for location of county, see map of Ohio, ref. 2–G); on the Cleve., Lorain and Wheel. and the Pitts., Akron and West. railways; 28 miles S. W. of Cleveland. It has several flour, saw, and planing mills, foundry and bending works, hollow-ware factory, and a large manufactory of bee supplies, and contains a national bank with capital of $75,000, a State bank with capital of $25,000, and a semi-monthly and two weekly newspapers. Pop. (1880) 1,484; (1890) 2,073; (1900) 2,232.

EDITOR OF "MEDINA COUNTY GAZETTE AND NEWS."

Medina, JOSÉ MARIA: politician; b. in Honduras about 1815. He was acting president of Honduras after the death of Guardiola, Mar., 1862, and again in June, 1863. Supported by the influence of the Guatemalan conservatives, he was elected president of Honduras Feb. 15, 1864, and re-elected 1866 and 1870. Until 1871 he maintained peace, but the country was brought to bankruptcy by wild financiering, and probably peculation in connection with the scheme for building an interoceanic railway. There was a war with Salvador, Feb.–May, 1871; in 1872 Honduras, Salvador, and Guatemala made war on Honduras; Medina was defeated, and in August was deposed and imprisoned by his own troops. Released after some time he revolted against Leiva in Dec., 1875, but was defeated in Feb., 1876; at the end of 1877 he was arrested for another attempt at revolt, condemned to death by a court martial, and shot at Santa Rosa, Feb. 8, 1878. HERBERT H. SMITH.

Medi'na-Sido'nia: town; in the province of Cadiz, Spain; 25 miles S. S. E. of Cadiz (see map of Spain, ref. 26–D). It was built by the Moors, is situated on a steep eminence surrounded by walls, contains a fine Gothic cathedral and the ruins of a magnificent castle, and has an imposing appearance; it is, however, a gloomy and comparatively an insignificant town. Pop. (1887) 11,705.

Medinet Habu: a Christian village at West Thebes in Upper Egypt, dating from the fifth century, which gave its name to a mass of ruins representing two temples. The larger one dates from the twentieth dynasty, and was intended as a memnonium of Ramses III., being devoted to the preservation of his memory and renown. Its mural decorations are of great ethnological value on account of the care taken to reproduce the racial characteristics of the peoples against whom Ramses III. waged war. Other inscriptions are important to the history of the times. The smaller temple dated originally from the eighteenth dynasty, but it was extended by the Ptolemies and even by the Roman emperors, especially Antoninus. CHARLES R. GILLETT.

Meding, OSCAR: novelist, whose pseudonym is *Gregor Samarow*; b. at Königsberg, Prussia, Apr. 11, 1829; studied law at Königsberg, Heidelberg, and Berlin; became an advocate and afterward held office in the Prussian administration, but in 1859 entered the public service of Hanover, in which he rose to the position of councilor of state, and was intrusted with several confidential missions by the king. In 1870 he gave his support to the Prussian Government, and after residing in Switzerland and Stuttgart settled in Berlin, where he applied himself to the work of writing novels based on his own experiences. Of these works may be mentioned *Um Zepter und Kronen* (1872–76); *Die Römerfahrt der Epigonen* (1873); *Höhen und Tiefen* (1879–80); a cycle of romances relating to Russian history (1881–83); and *Die Saxoborussen* (1885). Besides these, he has published *Memoiren zur Zeitgeschichte* (1881–84) and a short biography of the Emperor William I. under the title of *89 Jahre in Glaube, Kampf und Sieg* (1886). F. M. COLBY.

Mediterranean, The [from Lat. *mediterra'neus*, midland, inland; *me'dius*, mid + *ter'ra*, land]: the large sea bounded by the continents of Europe, Asia, and Africa, 2,200 miles long, 700 miles broad to the E. of Sicily, and covering an area of 977,000 sq. miles, excluding 40,000 miles of island surface. It has a very irregular shape, forming many gulfs, as those of Lyons, Genoa, Taranto, Lepanto, Koron, Kolokythia, and Salonica on the shores of Europe; on the shores of Asia, Adramyti, Smyrna, Adalia, and Iskanderun; on the shores of Africa, Sidra and Cabes; and bearing different names in the different localities—as, for instance, the Tuscan, Ionian, Adriatic, and Ægean seas. It is in general a deep sea, the average being 4,393 feet. The greatest depths are W. of Sardinia (12,238 feet), between Crete and Egypt (10,974 feet), and between Sicily, Greece, and Barca (13,018 feet at lat. 35° 5′ N. and lon. 18° 8′ E.). It is nearly cut in two by a shallow region between Sicily and Tunis. It communicates E. with the Black Sea through the Strait of Constantinople, and W. with the Atlantic through the Strait of Gibraltar. A strong current sets into the Mediterranean in the middle of the Strait of Gibraltar on the surface, but below and at the sides the current is outward. The Dardanelles current is always toward the Mediterranean. It also receives the waters of several large rivers, the Ebro, Rhône, Po, and Nile. A much greater evaporation takes place in the Mediterranean than in the Atlantic or in the Black Sea, owing to the hot winds which blow over it from Northern Africa, while the Pyrenees and the Alps prevent the cold winds from Northern Europe from reaching it. The temperature and saltiness of the waters of this sea vary much more in different parts than is the case with the open ocean. There is very little tide, owing to the narrowness of the strait which connects it with the ocean. The prevailing winds are in spring S. E. and S. W., and during the rest of the year N. E. and N. W.; they often rise suddenly and blow with great violence. See *The Mediterranean* (1854), by Rear-Admiral William Henry Smyth.

Medlar [M. Eng. *medler*, from O. Fr. *mesler*, medlar-tree, deriv. of *mesle*, *mesple*, medlar < Lat. *mes'pilum* = Gr. *μέσπιλον*, medlar]: popular name of the fruit of the medlar-tree of Asia and Europe (*Mespilus germanica*), belonging to the order *Rosaceæ*. This is a small, sometimes thorny shrub or small tree, which is often cultivated. There are many varieties. The fruit is allowed to decay partially by the process called *bletting*, when its harshness disappears and it becomes edible. The Japan medlar is usually known by the Chinese name of LOQUAT (*q. v.*).

Revised by L. H. BAILEY.

Medley, JOHN, D. D.: bishop; b. in England in 1804; was educated at Wadham College, Oxford, and graduated in 1826 with honors; was several years vicar of St. Thomas's, Exeter, prebendary of the cathedral, and in 1845 was consecrated first Anglican bishop of the see of Fredericton, comprehending the province of New Brunswick, Canada. Here Bishop Medley built a cathedral of great architectural beauty at his own cost, where the services of the cathedrals of the

motherland were maintained. After the resignation of Dr. Oxenden, Bishop of Montreal and metropolitan, Bishop Medley was chosen to be metropolitan, and held the primacy of the Canadian Church until his death in 1892. His *Life*, by Canon W. O. Ketchum, D. D., of St. Andrews, New Brunswick, was published in 1893. Revised by W. S. Perry.

Medoc, mā′doc′: the name of a district of France stretching along the Gironde, from Ambés to Lesparre. It is about 40 miles long and from 5 to 12 miles broad. It is wholly covered with vineyards, which produce the most famous kinds of Bordeaux wine.

Medows, Sir William: soldier; b. in England, Dec. 31, 1738; entered the army in 1756; served with distinction in Germany 1760; went to North America in Sept., 1775, with the Fifty-fifth Regiment; afterward commanded the First Brigade of Grenadiers, distinguishing himself on several occasions; was wounded at Brandywine and at the capture of St. Lucia 1780; was made colonel of the Eighty-ninth Regiment, and sent as major-general to India 1781; was governor of Madras 1790–92; led the right wing of Cornwallis's army at the siege of Seringapatam 1792, where he displayed great courage and ability; became lieutenant-general Oct., 1793; was governor of the Isle of Wight for some years, and commander-in-chief in Ireland 1801–03. D. at Bath, Nov. 14, 1813.

Medra′no, Francisco, de: lyric poet. Almost nothing is known of his life. He was a native of Seville, and flourished in the end of the sixteenth and beginning of the seventeenth century. Aspirations of which we are ignorant carried him to Rome for a time; and when he had been unsuccessful he returned to his native land to die, in what year is unknown. His works were published at Palermo in 1617 as a kind of appendix to the imitation of Ovid's *De Remedio Amoris* by the Sevillian Pedro Venégas de Saavedra. Of all the Spanish imitators of Horace, Medrano is probably the best. His taste is excellent, his style is free from the gongorisms of his time, and the quasi-philosophical Horatian manner is admirably suited to his own character. The best edition of his poems is in vol. xxxii. of Rivadeneyra's *Biblioteca de Autores Españoles* (Madrid, 1872).

A. R. Marsh.

Medulla Oblongata: See Brain.

Medul′la Spinal′is [Lat., spinal marrow]: that part of the central nervous system which is inclosed in the spinal canal, extending from just below the foramen magnum, at the base of the skull, to a point usually opposite the upper part of the first and second lumbar vertebræ. It is a cylindrical, slightly flattened, cord-like mass of nervous matter, continuous at its upper end with the medulla oblongata, and terminating below in a conical extremity, its entire length being about 18 inches. In this course it gives off thirty-one pairs of spinal nerves, by means of which it is placed in communication with the whole of the body below the head. The spinal cord is inclosed by three membranes which lie within the bony canal of the spine — the *dura mater*, the *arachnoid*, and the *pia mater*. The structure and general arrangement of these membranes do not essentially differ from those of the same envelopes around the brain, one or two peculiarities, however, being worth noting. The dura mater has a firm attachment to the bone at its upper end, at the edge of the foramen magnum of the skull. From the pia mater covering the sides of the spinal cord spring numerous little processes having the shape of the teeth of a saw whose sharp points are attached to the inner surface of the dura mater; these fibrous processes constitute the *ligamentum dentatum*, and materially aid in maintaining the proper position of the cord within its sheath. Between the dura and the arachnoid only a little lubricating fluid is present, while under and within the meshes of the arachnoid, as elsewhere within the brain, lies the *cerebro-spinal fluid* in considerable though changing quantity.

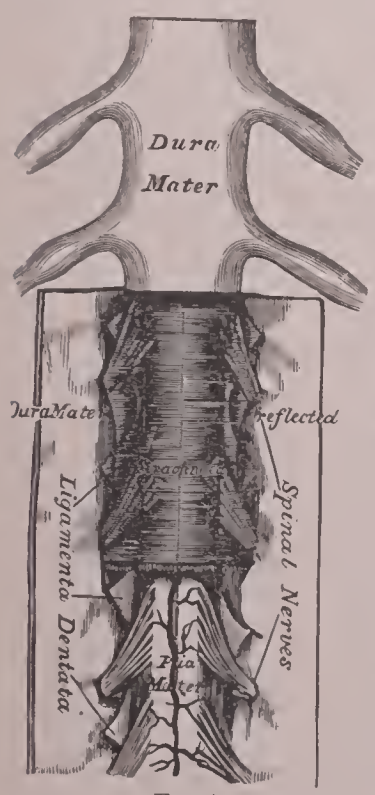

Fig. 1.

The spinal cord itself, like the other nervous centers, consists of certain elementary tissues; these are a supporting basis-substance, the *neuroglia*, the connective tissue derived from the pia mater, the nerve-cells, the nerve-fibers, and the blood-vessels. The special grouping of these elements gives form and character to different parts of the spinal cord. In general terms, it may be said that the spinal cord is made up in its central parts of *gray matter*—i. e. groups of ganglion-cells of different sizes, with nerve-fibers, blood-vessels, and delicate basis-substance; and in its outer peripheral parts of *white matter*—i. e. more or less coarse basis-substance, supporting medullated nerve-fibers and containing blood-vessels. On viewing a spinal cord whose membranes have been stripped off the following external appearances are presented: The cylindrical outline of the organ is made irregular by two swellings occupying those portions of the cord surrounded by the middle cervical and the lowest dorsal vertebræ—the so-called cervical and lumbar enlargements. Along the entire length of the front surface of the cord runs a line or deep mark, which after the removal of the pia mater is seen to be a real fissure or crack which penetrates quite deeply, and separates the organ into two equal halves. This, the *anterior median fissure*, is filled by the pia mater, containing the anterior spinal artery and its branches. On either side of the anterior median fissure very numerous delicate bundles of nerves arise from the spinal cord; these are the *anterior roots* of the spinal nerves. The median line on the posterior surface is not by any means so distinct behind as in front, and it is impossible to demonstrate a dorsal fissure without lacerating the tissue; the separation between the halves of the spinal cord posteriorly is a closely incorporated extension of the pia mater, and is called the *posterior median septum*. On either side of this are arranged the *posterior roots* of the spinal nerves, in the same manner as the anterior. The anterior and the posterior roots—physiologically distinct—pierce the dura mater, conjoin and mingle, and escape from side openings between the vertebræ as the spinal nerves. Just before joining the anterior root the posterior exhibits a swelling—the *ganglion* of the posterior root. At the upper part of the spinal canal the spinal nerves issue from the spine at a point corresponding to the level of their origin in the cord, but in the lower regions the nerves descend for some distance before reaching their canals of exit. Transverse sections of the cord (see Fig. 2) show that the white substance covers in the gray matter everywhere, except at a very narrow point behind where the gray matter reaches the pia mater. This piercing of the white substance by the gray enables us to divide the white substance into two unequal masses on each side —the smaller situated behind between the point of gray matter and the posterior median septum, constituting the *posterior column*, and the larger part, filling up the space in front of the point of gray matter and extending to the bottom of the anterior fissure, the *antero-lateral column*. The gray matter is irregularly developed in the cord and forms a figure like a rough letter H, whose forward arms are club-shaped. The tips of the lateral parts of the H constitute the *horns* of the gray matter, and the connecting bridge the *gray* commissure. The anterior horns are larger, more rounded than the posterior, and differ in structure. In them, particularly in the cervical and lumbar enlargements of the cord, are the largest ganglion-cells known; these "multipolar" elements present a multitude of delicate branching processes of two kinds—the richly branched *protoplasmic* processes and the delicate straighter *axis-cylinder* process. The former ramify within the gray matter, breaking up into extensions of in-

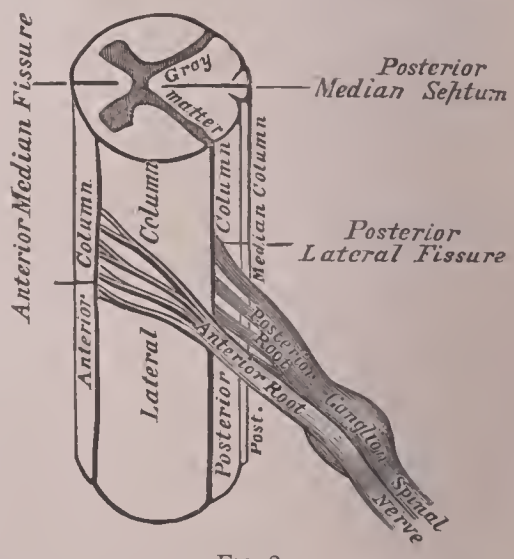

Fig. 2.

creasing delicacy, the latter is continuous with a nerve-fiber, the axis-cylinder of which it becomes. The majority of the anterior root-nerves are connected with the nerve-cells of the anterior horns, although some fibers included within these bundles are connected with more remotely situated elements of the cord. In the cervical and lumbar parts of the cord the ganglion-cells are especially numerous, being arranged within the anterior horns as *outer*, *middle*, and *inner* groups. In the cervical and upper dorsal region additional aggregations of smaller ganglion-cells exist in the inner side of the gray matter, nearly on a level with the commissure; these constitute the *column of Clarke*. The posterior horns possess relatively very few ganglion-cells, those which exist being oval and provided with few processes. The posterior nerve-roots do not, as far as we know, directly communicate with these ganglion-cells; the rootlets enter the white matter a little to the inner side of the point of the posterior horn, and send fibers in several directions—into the posterior horn, upward and downward in the posterior column. The central parts of the spinal cord consist of an *anterior commissure*, lying at the bottom of the fissure, and composed largely of medullated nerve-fibers. Just back of this band of white matter lies the *gray* commissure, the center of which is occupied by a round or oval hole—the *central canal* of the spinal cord—lined by columnar epithelial cells, or filled up by their *débris*. This canal extends from the lowest end of the cord to the fourth ventricle in the medulla oblongata, and is the remains of the primary neural canal of early fœtal life.

Physiology.—During the first twenty-five years of the nineteenth century the spinal cord was looked upon as a bundle of nerves extending from the brain to the external parts, the brain sending nervous force through the passive cord to

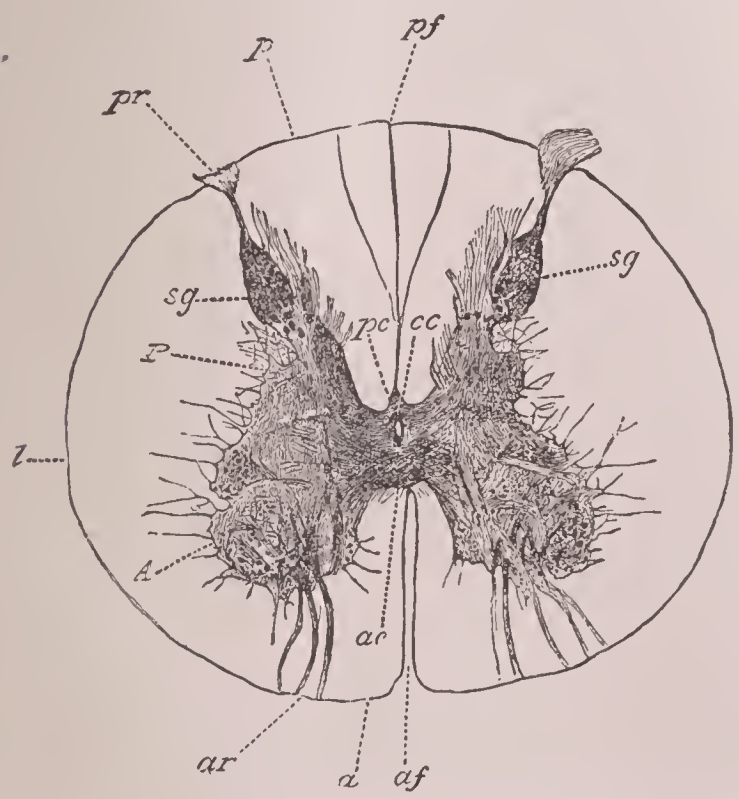

FIG. 3.—Transverse section of spinal cord from the cervical region: *A* and *P*, anterior and posterior horns of gray matter, surrounded by *a*, *l* and *p*, the anterior, lateral, and posterior columns of white matter; *af*, anterior median fissure; *pf*, posterior median septum; *ar* and *pr*, anterior and posterior roots of spinal nerves; *ac*, anterior or white commissure; *pc*, posterior or gray commissure; *cc*, central canal; *sg*, specialized neuroglia, constituting substantia gelatinosa of posterior horn.

the muscles. Later researches made it evident that the cord possesses independent energy which includes all the attributes of a high nervous center, even, according to some, a degree of volition and consciousness. While many points concerning the anatomy and the physiology of the spinal cord must be regarded as far from definitely determined, the complex nature of the functions of the cord must be recognized when we appreciate its multiple *rôle* as a conducting organ for sensory impressions and motor excitations, as a source of nervous force, and, in a degree, as a co-ordinating organ. *Sensory impressions* received from the periphery of the body reach the cord by the *posterior roots* (which are purely sensory), and are then conducted, directly or indirectly, upward to the perceptive centers in the brain. If we imagine the path as one continuous nerve-fiber, we should say that it extends from the right forefinger to the right posterior column of the cord, ascends on that side to the medulla oblongata (some fibers of the sensory path probably having crossed in the cord to the posterior column of the opposite side), from which, after a complex and by no

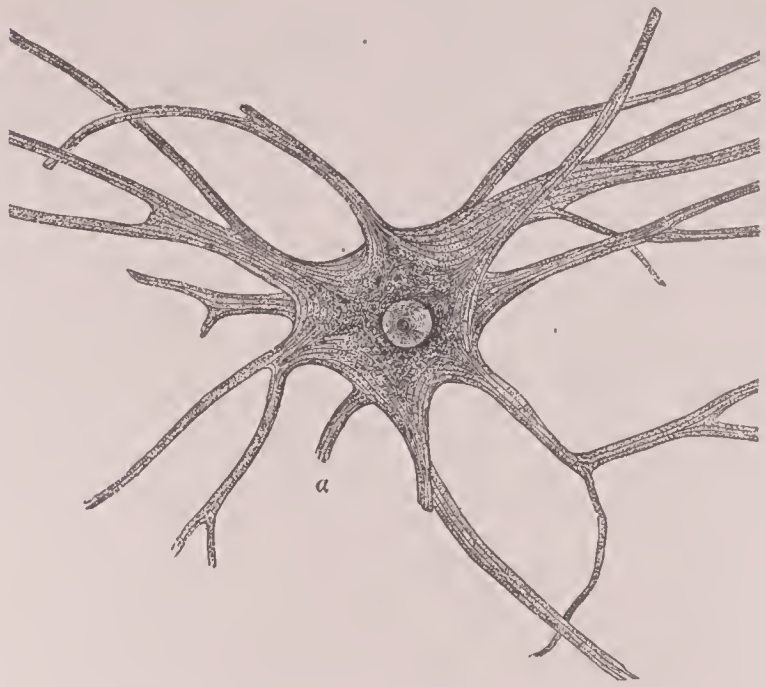

FIG. 4.—Multipolar nerve-cell from anterior horn of gray matter of spinal cord: *a*, the broken axis-cylinder process which becomes continuous with a nerve-fiber; the remaining processes belong to the richly branching protoplasmic group.

means fully known course, the impressions cross the parts of the left brain which perceive and appreciate sensations. *Motor excitations* or impulses pursue quite a different course, in an inverse direction. A motor impulse destined to move the right forefinger starts from the left side of the brain, descends through the left half of the basal parts of the encephalon, until it reaches the lower edge of the medulla oblongata near its junction with the spinal cord, where it suddenly passes across the median line into the right half of the spinal cord, descends in the right half of that organ, issues out of the right *anterior horn*, from which come the nerves of the arm, and follows these nerves to cause contraction of the muscles which move the right forefinger. In general the motor paths or nerves decussate within a definite limited area, the so-called decussation of the pyramids of the medulla oblongata. The motion referred to in the above illustration is a voluntary motion—one starting from the supreme cerebral ganglia—but the spinal cord furnishes involuntary movements of great variety and force originating within itself; it is consequently a source of power, a center for reflex motions. Simple and convincing proof of this assertion is had by watching the movements of a frog whose head has been cut off. The legs of the animal separately move when the creature is touched, and complex movements of jumping, removing irritations by means of two legs, are done just as well as when the animal was perfect. These movements all occur after some irritation of a sensory nerve, never spontaneously; they are consequently called reflex movements. A reflex movement may be defined as the result of a direct transformation (by ganglion-cells) of a sensory impression into motor impulse; in this sense reflex actions occur in every nervous center, great or small. Examples of reflex spinal actions in health are found in the involuntary movements produced by tickling, burning, etc. In diseased conditions certain convulsions are reflex spinal movements, and in some cases of palsy of the legs most extensive and violent movements are commonly observed in the affected limbs. The spinal cord may also be spoken of as a co-ordinating center for certain coarse movements. By co-ordinating center is meant a mass of gray matter whose ganglion-cells act in such a way, harmoniously and simultaneously, as to produce an exact movement. The performance of an exact movement, as walking, must be learned by repeated trials, but when the ganglion-cells have acquired the habit of acting together (education), they so act without the watchful and directing influence of volition; e. g. we start walking by a volitional impulse, but continue walking by spinal action, quite inattentive to what our legs are doing. Thus it is with very many complex movements of daily life. The spinal cord probably possesses a capacity to receive and retain impressions which reach it by sensory nerves.

This property of the ganglion-cells of the spinal cord, as well as of the ganglion-cells of other centers, has been termed retentivity, or it may be spoken of (as by a few authors) as the memory of the spinal cord. In proof of this may be adduced the performance of various acts without volitional interference and outside of consciousness—the execution of complicated movements by decapitated cold-blooded animals, and the well-known possibility of educating the spinal cord. Impressions are stored up and kept ready for use in the gray matter of the spinal cord as well as in that of the brain.

In conclusion, one word may be added about centers for certain actions in the spinal cord. Some ganglion-cells are grouped, and exert an influence over particular nerves destined for the control of special organs; thus nerve-fibers supplying the blood-vessels of the face and eyeball are connected with the upper cervical region of the spinal cord. Movements of the parts within the pelvis (bladder, uterus, etc.) are under the control of a part of the lumbar spinal cord and parts just above it; these are respectively the cilio-spinal and the genito-urinary centers. The spinal cord furthermore exerts an influence upon the organs contained in the chest and abdomen, and also, probably, upon the nutrition of tissues in general.

Revised by G. A. Piersol.

Medum (in Egyptian *Metun*): a locality in Lower Egypt; about 30 miles S. of Memphis; noted as containing some of the most ancient monuments of the country. The pyramid of Medum, called the "false pyramid" by the natives, was never completed. It rises in three parts. It is conjectured that it belonged to Snofru of the fourth dynasty. Just to the N. are several mastabas ornamented in archaic style, which belonged to relatives of that Pharaoh. From one of these mastabas came the sitting statues of Rahotep and Nefert, rightly adjudged to be among the finest efforts of Egyptian sculpture. This region and the neighboring Fayum have been explored by Flinders Petrie, who devoted several volumes to the results of his researches. See his *Medum, Hawara, Kahun, Illahun* (London, 1890–92).

Charles R. Gillett.

Medusæ [Mod. Lat., named from *Medu'sa*, one of the Gorgons = Gr. Μέδουσα. So called from the resemblance of its tentacles to Medusa's snaky locks]: a term given to the free-swimming Cœlenterates, commonly called jellyfish. These all have a disk-like or umbrella-shaped body, the proboscis, at the end of which is the mouth, corresponding to the handle, while the radiating divisions of the digestive cavity correspond to the ribs which support the cloth. The common name jellyfish is most apt, so far as the jelly is concerned, for these forms are scarcely more solid than the water in which they float. They swim by means of contractions of the umbrella, and they kill their prey by means of the many poisonous cells (nettle-cells) which cover certain portions of the body. Around the margin of the umbrella occur sense organs (eyes and ears), while below these depends a fringe of tentacles like the fringe on a parasol. Two great groups of medusæ are recognized, which, though so similar in external appearance, are widely different in structure. In the one belonging to the Hydrozoa (*q. v.*) the digestive layer of the body (entoderm) extends clear to the mouth. Most of the medusæ of this group are the sexual stages of the Hydroids, the asexual stage of which is firmly fixed to some submarine support. To this group belong the only fresh-water medusæ known. Some have been recorded from the Central African lakes, while one suddenly appeared in the *Victoria regia* tanks in the Kew Gardens in London. These forms may be recognized at once by the fact that the aperture of the umbrella is partially closed by a circular membrane (see the figures in Hydroida), whence the name Craspedote medusæ often applied to them. In the other group (Acraspedia) this membrane is lacking, and there is a throat lined by the outer body layer, leading from the mouth to the digestive cavity. For an account of the alternation of generations, the reader is referred to Acalephæ. See also Hydrozoa and Scyphozoa. The literature of the medusæ is large. We may mention A. Agassiz, *Catalogue of Acalephs of North America* (1865); L. Agassiz, *Contributions to Natural History of the United States* (1857–62); Haeckel, *System der Medusen* (1879–81); and papers by Brooks, Fewkes, Macready, etc. J. S. Kingsley.

Meek, Alexander Beaufort: jurist and journalist; b. at Columbia, S. C., July 17, 1814; graduated in 1833 at the University of Alabama; was admitted to the bar in 1835, and became editor of a Democratic newspaper; served three months in 1836 in the Seminole war, and on his return became attorney-general of Alabama; edited *The Southron* 1839; was (1842–44) judge of the court of Tuscaloosa County; law-clerk to the solicitor of the U. S. Treasury 1845; U. S. district-attorney for Southern Alabama 1846–50; a journalist of Mobile 1848–53; went in 1853 to the Legislature, where he originated the free-school system of Alabama; became in 1854 judge of the city court of Mobile; was Speaker of the House of Alabama 1859; was a fine chess-player, and author of a legal digest (1 vol., 1842); *The Red Eagle* (New York, 1855); *Songs and Poems of the South* (1857); *Romantic Passages in Southwestern History* (1857); and an unpublished *History of Alabama.* D. at Columbus, Miss., Nov. 30, 1865.

Meek, Fielding Bradford, M. N. A. S.: palæontologist and geologist; b. at Madison, Ia., Dec. 10, 1817; became at an early age interested in the study of the Silurian fossils, which are very abundant there; at majority, engaged in commercial pursuits, continuing, however, his scientific studies. In 1848 and 1849 he was employed as an assistant in the U. S. geological survey of the upper Mississippi country, under D. D. Owen. From about 1852–58 he worked as an assistant of Prof. Hall at Albany on the palæontology of New York, and meanwhile spent two summers in connection with the State geological survey of Missouri. In 1853, assisted by Dr. F. V. Hayden, he made a valuable collection of vertebrate and other fossils from the *Mauvaises Terres* or Bad-lands of Dakota for Prof. Hall. In 1858 he settled in Washington, D. C., and investigated and reported on organic remains brought in by exploring expeditions. The results of his labors were published jointly with others; his minor papers on paleontology and geology were various *Reports* and *Transactions*; the most important was *A Report on the Invertebrate Cretaceous and Tertiary Fossils of the Upper Missouri Country* (Washington, 1876, liv., 629 pp., 45 pl.). D. Dec. 28, 1876, at the Smithsonian Institution.

Meeker, Joseph Rusling: See the Appendix.

Meeks, Eugene: See the Appendix.

Meerschaum, meer'shawm [= Germ., liter., sea-foam; *meer*, sea + *schaum*, foam. Perhaps a corruption of Tartaric name, *myrsen*]: a compact mineral with a smooth surface; soft when first dug out of the earth, but hardening to 2·0 and 2·5. In composition it approaches silica, 60·9 per cent.; magnesia, 26·1 per cent.; water, 12 per cent. It is obtained from localities in Turkey, Asia Minor, Morocco, etc., where it is used as a substitute for fuller's earth; its principal use, however, is as a material for the bowls of tobacco-pipes.

Meerut, or **Mirat**: one of the seven great divisions or provinces of the Northwest Provinces, British India; lying between lats. 27° 38′ and 30° 57′ N., and meridians 77° 7′ and 78° 42′ E. It comprises the six districts of Dehra-Dun, Saharanpur, Muzaffarnagar, Meerut, Bulandshahr, and Aligarh. Area, 11,319 sq. miles. Pop. (1891) 5,324,910. The province extends in a narrow strip from the lower Himalayas over the marshy *terai* at their base into the *doab* or alluvial plain between the Ganges and Jumna. Except the *terai* and some small saline deserts adjacent, and the immediate banks of the Ganges, the country is fertile and well-watered either naturally or by irrigation. It exports large quantities of wheat, barley, millet, rice, cotton, and cane-sugar. It is traversed by the railway from the Punjaub to Allahabad. The district of Meerut is in the center of the province about the city of Meerut. Area, 2,379 sq. miles. Pop. 1,350,000. It is the most populous, fertile, and prosperous of the districts of the province. M. W. H.

Meerut: city of the Northwest Provinces of British India, and capital of the district and division of the same name; 38 miles N. E. of Delhi, near the right bank of the Kali-Nadi, an affluent of the Ganges, and a station on the railway connecting Delhi and Lahore (see map of N. India, ref. 5–E). It is an ancient city and numerous ruins show its former splendor. At the time of its submission to the British in 1803 it was in decadence, but its selection as a military center caused its revival. It has little commerce except the local trade. Pop. (1891) 119,390. M. W. H.

Megaby'zos (in Gr. Μεγάβυζος): (1) one of the conspirators who slew the false Smerdis; (2) a grandson of the former, son of Zopyrus, and one of the generals of Xerxes, whose daughter Amytis he had married. He was afterward commander in Syria and Egypt, where he was victorious over

the Athenians and Egyptians. On a hunt he gained the ill-will of Artaxerxes, and, though his life was spared, he was banished to Crete, whence he returned after five years, and was forgiven. D. at Susa in extreme old age. J. R. S. S.

Meg'acles (in Gr. Μεγακλῆς): a name that recurs frequently in the illustrious family of the Alcmæonidæ at Athens—(1) The first bearer of the name was the son of Alcmæon and Archon of Athens, in 612 B. C. (2) Megacles, the grandson of (1) and a son-in-law of Clisthenes, tyrant of Megara, took part as a conservative in the partisan politics at the time of Solon; but in 560 B. C., when Pisistratus became tyrant, he and the entire family of the Alcmæonidæ were forced into exile; later on they returned and twice forced Pisistratus into exile, but when Pisistratus had established himself firmly in the tyranny Megacles again went into exile. (3) A grandson of (2), maternal grandfather of Alcibiades; was a victor in the Pythian games, and twice ostracized. (4) Another grandson of (2), and uncle of Pericles on his mother's side. J. R. S. Sterrett.

Megalich'thys [Mod. Lat.; Gr. μέγας (stem μεγαλο-), great + ἰχθύς, fish]: the generic name of extinct rhomboganoid fishes whose bones are found in European Carboniferous strata. They were covered with huge bony plates, and their powerful jaws armed with immense teeth. These fishes seem to have possessed a crocodilian character, and are now represented by the much smaller garfishes of the U. S.

Meg'alo-Cas'tro: See Candia.

Megalon'yx [Mod. Lat.; Gr. μέγας (stem μεγαλο-) + ὄνυξ, claw]: the generic name of extinct Quaternary mammals from North and South America, allied to the sloths. The type, *Megalonyx*, was first discovered in the caves of Virginia, and named by President Jefferson in allusion to its large claws, the length of the terminal phalanx or bony support of the median claw being 7 inches, or more than one-third the length of the humerus of the same animal. Its remains have also been found at Bigbone Lick in Kentucky, and other localities. The typical species has received the name *Megalonyx jeffersoni*. Many other species of the genus occur in South America, principally in the southern part.

Megalop'olis [= Gr. Μεγαλόπολις, liter., Great City; μέγας, μεγάλη, great + πόλις, city]: city of Greece; on both sides of the river Helisson, an affluent of the Alpheus. It was founded by Epaminondas in 370 B. C., immediately after the battle of Leuctra, for the purpose of gathering the Arcadian communities, hitherto independent of each other, into a compact state, thereby forming a bulwark against Sparta. The city was laid out on a grand plan, being 50 stadia in circumference, with about 70,000 inhabitants, but it never acquired any considerable importance. It contained the greatest theater in Greece, of which remains are extant. Megalopolis was excavated by the British School at Athens in 1890–91. See Gardner, Loring, and others, *Excavations at Megalopolis* (London, 1892); see also *Journal of Hellenic Studies* (1892–93, pp. 319–337 and 356–358); *Mittheilungen, Athenische Abtheilung* (1893, pp. 215–219).
Revised by J. R. S. Sterrett.

Meg'alops [Mod. Lat., deriv. of Gr. μεγάλη, great + ὤψ, eye]: a name given to the last larval stage of crabs, in allusion to the relatively large size of the eyes.

Megalosau'rus [Mod. Lat.; Gr. μέγας (stem μεγαλο-) + σαῦρος, lizard]: a large carnivorous reptile from the Oolite and Wealden of England, belonging to the order *Dinosauria*, and exemplifying the carnivorous type of that order, as *Iguanodon* does the herbivorous. *Megalosaurus bucklandi*, the best-known species, was perhaps 30 feet in length, and attained a weight of 2 or 3 tons. The teeth are large, curved, pointed, and compressed; the crown is covered with smooth enamel, which rises along the margin of the tooth into a trenchant serrated edge. They are directed backward and set in sockets. The cervical vertebræ are little known, but appeared to indicate an upward curve in the neck, as in some mammals and birds. The dorsal vertebræ have the anterior face somewhat convex, the posterior concave. The bodies of the vertebræ are smooth and hour-glass-shaped, and the neural spines elongated. Both faces of the lumbar vertebræ are concave. The sacrals are five in number, and the caudals estimated at between thirty and forty. The humerus is hollow, but beyond that bone the structure of the fore limbs is unknown. They were, however, small in comparison with the hind limbs. In the pelvis the ilium was a broad, strong, arched plate, wide in front. The lower margin projects in thick, strong proesses, which receive the pubic and ischial bones. The ischium was slender and directed backward. The pubis projected downward and forward. The femur was more curved than in *Iguanodon*. It appears hollow like that of a bird. There were three well-developed toes on the hind foot, and the claws were strong and pointed. These animals lived upon the land, and probably moved mainly by means of their hind limbs. Remains of *Megalosaurus* have been found in the strata of the Mesozoic or Reptilian age in England, from the Lias to the Wealden; also in the Kimmeridge clay at Honfleur in Normandy, and in Oolite at Besançon, France. O. C. Marsh.

Megantic: a lake of Compton co., Quebec, near the boundary of Maine. It discharges through the Chaudière river into the St. Lawrence. It is 15 miles long by 2 or 3 broad, and is in picturesque surroundings. It is very full of fish. The surrounding country is being rapidly colonized. Lake Megantic town, at the N. of the lake, is a station on the Canadian Pacific Railway, 175 miles E. of Montreal. M. W. H.

Megapodes: See Megapodidæ.

Megapod'idæ [Mod. Lat., named from *Megapo'dius*, the typical genus; Gr. μέγας, great + πούς, ποδός, foot]: scientific name of a family of gallinaceous birds whose representatives are chiefly Australian, and there are commonly known as brush turkeys and mound-birds; they are nearly related to the curassows (*Cracidæ*) of South America, and the two form the group *Peristeropodes* of Huxley. The different types of the group vary much in external appearance, some

Nest of megapodius.

(*Megapodius*) reminding one of a rail or a tailless hen, while others (*Tallegallus*, etc.) rather resemble a turkey; the head and neck are sometimes (in *Megapodinæ*) thickly feathered, and sometimes (in *Tallegallinæ*) sparsely feathered or almost naked; the bill is more or less like that of the common cock; the gape not deep; the nostrils are subcentral or somewhat anterior; the tarsi unarmed; the hind toe on a level with the fore ones; the tail is very variable in its development. The different forms differ considerably in habits, but are all terrestrial birds; the *Tallegallinæ* live in small flocks; the *Megapodinæ* generally in pairs. The *Megapodinæ* are unique among birds in their nesting arrangements; they do not sit upon their eggs, but deposit them in mounds formed by themselves, and composed of sand, leaves, etc.; and in these a sufficient degree of heat is generated to hatch the eggs. The mounds are out of all proportion to the size of the birds, and sometimes measure from 30 to 50 feet in diameter and 14 feet in height. The young are *præcoces* in the fullest sense of the term, for they can run and fly as soon as hatched. See Brush-turkey. Revised by F. A. Lucas.

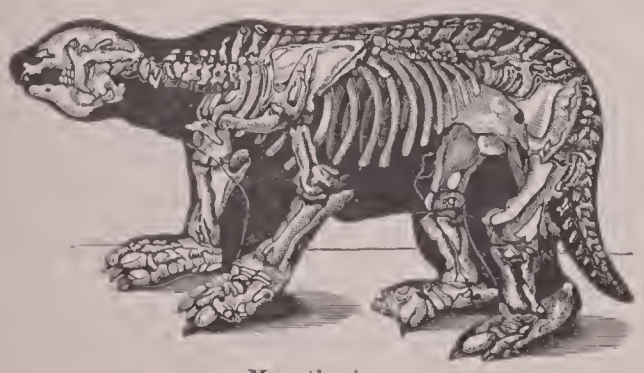
Meg'ara (in Gr. τὰ Μέγαρα): city of ancient Greece, and the capital of Megaris, a territory bounded by Attica, Bœotia, Corinthia, the Saronic and the Corinthian Gulfs. As early as the seventh and eighth centuries B. C. it was a prosperous and even wealthy city. It formed many colonies, of which Chalcedon and Byzantium were the most remarkable. It entered into rivalry with Athens, but had to yield in the contest, and became subject to that city. By its attempts to free itself from the Athenian supremacy it became one

of the causes of the Peloponnesian war, during which it suffered severely, and sustained losses from which it never recovered. Theognis the poet and Euclid were citizens of Megara. Revised by J. R. S. Sterrett.

Megas'thena [Mod. Lat.; Gr. *μέγας*, great + *σθένος*, strength]: a name given by Prof. Dana to the group of generally large mammals constituting the orders *Primates* (exclusive of man), *Feræ*, *Ungulata*, *Cetacea*, etc. The term in question alludes to the supposed superior life-force and specialization (so far as ways and means, mental as well as physical, are concerned) exhibited by them. The group is exactly equivalent as to its contents with the sub-class *Gyrencephala* of Owen, and, with the addition of man, to the super-order *Educabilia*. Theodore Gill.

Megas'thenes (Gr. Μεγασθένης): a Greek statesman and author in the service of Seleucus Nicator, one of the generals of Alexander the Great, who became monarch of Syria, Persia, and Bactria. He was sent as ambassador about B. C. 302 to the court of Sandracottos (Chandra-gupta), King of the Prasii, at Palibothra (Pataliputra) on the Ganges, supposed to be the modern Patna. He resided at this great capital many years, and wrote a work (*Ἰνδικά*, in four books) upon the history and geography of India, which was the foundation of nearly all that subsequent writers have communicated upon ancient India. The work of Megasthenes is lost, but an abstract of the work is given by Diodorus (ii., 35–42), and copious extracts, given by Strabo and other geographers, show him to have been an acute observer, though like most of the writers of his time he was fond of the fabulous, and of showing the relation of Greek and Indian myths. So he makes the Brahmans tell of the wanderings of Dionysos, whom they claimed as the civilizer of India. These fragments were edited by E. A. Schwanbeck, *Megasthenis Indica* (Bonn, 1846). See also Müller, *Fragmenta Historicorum Græcorum* (Paris, 1868–74), ii., 397–439. Revised by J. R. S. Sterrett.

Megathe'rium [Mod. Lat.; Gr. *μέγας*, great + *θηρίον*, wild animal]: generic name of certain Quaternary mammals. The genus *Megatherium* may be considered as typical of the extinct family of Edentates, *Megatheriidæ*. Their remains are more abundant in South than in North America, and indicate a former much greater development of the or-



Megatherium.

der of *Edentates* than now prevails. The tibia and fibula are co-ossified. The vertebræ of the tail are very large and powerful, and that organ, with the hind legs, seems to have formed a support for the heavy body, while the huge fore legs were employed in breaking the branches from trees or tearing them down for food. There are four toes in front, two behind. The teeth, five above and four below on each side, resemble those of the sloths. They grew from persistent pulps, and are deeply implanted in the jaw; they have a grinding surface of triangular ridges, and were fitted for masticating coarse vegetable food. The lower jaw is prolonged, and grooved in the symphysial region, and probably supported a powerful, muscular tongue. *Megatherium cuvieri*, from South America, exceeded the rhinoceros in size, its skeleton measuring 18 feet in length. The femur is three times as thick as that of the elephant. *M. mirabile* is a North American species, and its remains occur in Georgia and South Carolina. O. C. Marsh.

Megerle, Ulrich: See Abraham-a-Sancta-Clara.

Meghna: a river and estuary of Eastern India, into which flow the combined waters of the eastern branch of the Ganges and the Brahmaputra, forming the eastern branch of the Gangetic delta. The body of water is very great, but navigation is difficult because of constant changes in bars and islands. The mouth of the Meghna is said to be advancing to sea (4 miles in twenty-three years) and to the westward. The regular rise of the tide forms a wave 10 to 18 feet high, which rushes with great speed up the river and is much dreaded by boatmen. An occasional storm wave, due to cyclones, sweeps up the river. The last great wave of this sort was in 1876, when whole islands and the sea-face of the mainland were submerged, causing death directly to about 19 per cent. of the population of Noakhali district and the islands Sandwip and Hatia, and indirectly to about as many more by the cholera and other diseases resulting from it.
Mark W. Harrington.

Megrim: See Migraine.

Mehemet Ali Pasha: first Viceroy of Egypt; b. at Kavala, European Turkey, in 1769; the youngest of the sixteen children of Ibrahim Agha, an Albanian officer in the Ottoman service. He headed the contingent sent from Kavala to assist in expelling the French from Egypt, and having survived the land-battle of Aboukir (1799) he was appointed *binbashi* (colonel). Speedily obtaining ascendency over the other Albanians in the army, he, during the next six years, pursued a course of almost unparalleled cunning and duplicity, opportunely betraying or deceiving friend or foe, invariably reaping advantage from every dissension or intrigue, adroitly manipulating every foreign and domestic interest and faction, until in a revolt of the Albanians he was proclaimed, ostensibly against his will, Viceroy of Egypt. In this office he was confirmed by the sultan (July 9, 1805). During the next forty years his personal history and that of Egypt are identical. The Mamelukes were the scourge of Egypt, and it was impossible to crush them by war. He solemnly offered them his friendship, gathered their chiefs in his palace for a great festival of reconciliation, and then had more than 1,000 of his guests massacred in a narrow pass on their departure. Similar measures through the land annihilated the Mameluke power. He then organized an army after the European system, crushed the Wahabees, who had seized Mecca, and sent their chief, Abd-Allah-Ebn-Sououd, a prisoner to Constantinople (1818). Ordered by the sultan to assist in putting down the Greek revolution, he was able (1824) to send, under his son Ibrahim Pasha, a fleet of 167 vessels, carrying 17,000 men, against the Peloponnesus, which was subdued, but the fleet was destroyed at Navarino (1827). He confiscated private property, gained vast revenues from traffic in slaves, and became practically proprietor of Egypt, which he sought to develop to the utmost, that he might be able to maintain a powerful army and become independent. He laid out roads, cultivated cotton, indigo, and sugar, established some schools, and sought the friendship of the foreign residents. A quarrel with Abdallah Pasha of Acre furnished a pretext for the invasion of Syria, against which he sent his son Ibrahim Pasha (*q. v.*) with 24,000 men. Sultan Mahmoud, who at first had sanctioned the expedition, was soon terrified at the rapid progress of the Egyptians and ordered them to withdraw. Mehemet Ali, refusing and demanding investiture as governor of the joint Syrian pashalies, was declared an outlaw. Ottoman armies sent to enforce the sultan's will were defeated at Homs, Beilan, and Konieh. Great Britain and France, fearing the intervention of Russia, persuaded the sultan to yield. Mehemet Ali agreed to evacuate Asia Minor after appointment as governor of Syria (1833). During six years the European powers intrigued at both Constantinople and Cairo, France being favorable to Mehemet Ali and the rest of Europe against him. Troubles arose anew (1839), and the Ottoman army was destroyed at Nezib. Austria, Great Britain, Prussia, Russia, and the sultan signed a treaty and ordered the viceroy to evacuate Arabia and Syria within ten days. The four powers agreed to enforce this order, but, encouraged by France, Mehemet Ali refused to submit. Speedily deserted by France, he, after a desperate struggle, was compelled by Admiral Napier to accept conditions which left him nothing save the viceroyalty. That was declared hereditary in his family. The remainder of his life was uneventful. Falling into dotage, he died in Cairo, Aug. 2, 1849, and was succeeded by his son Ibrahim Pasha. Utterly unscrupulous, madly ambitious, with a veneering of European civilization, he is best described by Lamartine as "an adventurer of genius." E. A. Grosvenor.

Méhul, mā'ül', Étienne Henri: composer; b. June 22, 1763, at Givet, in the department of the Ardennes, France, in humble circumstances; went in 1779 to Paris with an introduction to Gluck, whose favor he gained, and under whom he studied; made a successful *début* as a composer

in 1791 by his opera *Euphrosine and Conradin*; achieved a most brilliant success by his composition of Chenier's song, *Chant du Départ*; became professor at the Conservatory; wrote forty-two operas. D. in Paris, Oct. 18, 1817. His most remarkable composition, besides the above-mentioned song, is his opera of *Joseph* (1807). The overture to the opera *La Chasse du Jeune Henri*, also characteristic, is often performed. See the *Biography* by Pougin (1889).

Meï, mā′ĕe, Lev (or **May**, Lyoff) Aleksandrovich: poet; b. in Moscow, Russia, Feb. 13, 1822, the son of an official of German origin. He was for a number of years in the service of the Government at St. Petersburg. While still a schoolboy he began to make creditable verses, and to the end of his life continued a most prolific writer. Besides translations, many of them remarkable, from eight foreign languages, and a modern rendering of *The Tale of the Troop of Igor*, he was the author of three historical dramas, *Tsarkaïa Nevesta* (The Bride of the Tsar. 1849), *Servilia* (1854), and *Pskovitïanka* (The Woman of Pskov, 1860), as well as of many shorter poems, some on biblical or classical subjects, others expressing with great skill and fidelity the life and character of the Russian people. D. in St. Petersburg, May 16, 1862. Meï was never a particular favorite of the public. He lacked individuality; also, partly owing to poverty, he wrote too much and too hastily. See his complete works (3 vols., St. Petersburg, 1863–65). A. C. Coolidge.

Meignan, mān′yaŭn′, Guillaume René: theologian; b. at Denazé, in the department of Mayenne, France, Apr. 11, 1817; was educated for the Church; was ordained a priest in 1840; held various minor charges, and was in 1862 appointed Professor of Biblical Theology at the Sorbonne; in 1863 vicar-general of the diocese of Paris; and in 1864 Bishop of Châlons; in 1882 was transferred to Arras; in 1884 promoted to the archbishopric of Tours. He published *Les Prophéties messianiques* (1858; 2d ed. 1878); *M. Rénan réfuté par les Rationalistes Allemands* (1863); *Les Évangiles et la critique au XIX^e siècle* (1864; 2d ed. 1871); *La crise Protestante en Angleterre et en France* (1864); *Le monde et l'homme primitif selon la Bible* (1869); *Instructions et conseils addressées aux familles chrétiennes* (1875); *Léon XIII. pacificateur* (1886); *Solomon, son règne, ses écrits* (1890); *Le Christ et l'Ancien Testament*; *Les Prophètes d'Israel: Quatre siècles de lutte contre l'idolatrie* (1892); besides a great number of minor essays. D. at Tours, France, Jan. 20, 1896. Revised by S. M. Jackson.

Meigs, Charles Delucena, M. D.: obstetrician; b. at St. George's, Bermuda, Feb. 19, 1792; received medical degree from the University of Pennsylvania 1817; settled in Philadelphia in 1817; made specialties of obstetrical practice and the diseases of women and children, in which he acquired a high reputation; was a professor in Jefferson Medical College 1841–61. He wrote several professional works, among which are *Midwifery* (1838); *Lectures on the Female* (1847); *Obstetrics*, a standard work (1849); *Childbed Fevers* (1854); he made valuable translations from French medical literature. He was the author of a *Memoir of Samuel George Morton, M. D.* (1854). D. in Delaware co., Pa., June 22, 1869. Revised by S. T. Armstrong.

Meigs, James Aitken, M. D.: clinician and physiologist; b. in Philadelphia, July 31, 1829; graduated at Jefferson Medical College 1851; became in 1856 librarian of the Philadelphia Academy of Natural Sciences; Professor of the Institutes of Medicine in Pennsylvania Medical College 1859–61; was Professor of the Institutes of Medicine in Jefferson Medical College 1868. He was the author of works chiefly on craniology and ethnology. D. in Philadelphia, Nov. 9, 1879. Revised by S. T. Armstrong.

Meigs, Montgomery Cunningham: officer and scientist; b. at Augusta, Richmond co., Ga., May 3, 1816; was educated at the University of Pennsylvania and U. S. Military Academy; graduated from the latter July 1, 1836; was appointed second lieutenant of artillery, which commission he relinquished in 1837 for the purpose of being transferred to the corps of engineers as brevet second lieutenant from date of graduation; became first lieutenant of engineers 1838, captain 1853. From 1836 to 1841 he was mainly engaged in the construction of Fort Delaware, of the Delaware breakwater, and in the improvement of the Delaware Bay and river; in charge of the construction of Fort Wayne, Mich., and Forts Porter and Niagara, N. Y., 1841–49; of Fort Montgomery, N. Y., 1850–52. From Nov., 1852, to 1860 he was engaged upon his great work of supplying the national capital with water from the Potomac river; the Washington aqueduct, by which the cities of Washington and Georgetown are now supplied, was designed and constructed under his personal direction, during which time he conducted the construction of the Capitol extension and its iron dome, as well as of the post-office extension. In Nov., 1860, he was sent to Florida to put Forts Jefferson and Taylor in a condition to resist attack; returning to Washington, he was by request relieved from other duties, Apr., 1861, and appointed chief engineer of the expedition for the relief of Fort Pickens; was appointed colonel of the Eleventh Infantry May 14, 1861, and the next day quartermaster-general U. S. army, with the rank of brigadier-general, and as such directed the equipment and supply of vast armies during the civil war, making frequent inspections of the operations of the quartermaster's department in the various armies in the field, being at Chattanooga throughout its investment, and engaged in the battle of Nov. 23–25, 1863; during Gen. Grant's operations in the Wilderness, May, 1864, was in charge of the base of supplies at Fredericksburg and Belle Plain; and during the appearance of the Confederate forces under Breckenridge and Early in front of Washington commanded a division composed of employees of the War Department. He was breveted major-general July 5, 1864. In Jan., 1865, he directed, at Savannah, Ga., the supply and refitting of Gen. Sherman's army, just arrived from Atlanta, and in March, at Goldsboro, N. C., directed the opening of communications for the supply of that army on its arrival there and at Raleigh. Visited Europe 1867–68, after which he inspected the operations of his department in Texas, California, Dakota, Wyoming, and Arizona; also the North Pacific Railway route to the Red River of the North. In 1875 he was sent to Europe particularly to inspect the organization of the staff departments (especially the quartermaster's) of European armies. Retired Feb. 6, 1882. D. in Washington, D. C., Jan. 2, 1892.

Meigs, Return Jonathan, Jr.; soldier and Senator; b. at Middletown, Conn., Nov., 1765; graduated at Yale in 1785; went to Marietta, O., with his father, Col. R. J. Meigs, in 1788; became a lawyer there, and was much engaged in border warfare; was made chief justice of the Ohio Supreme Court 1803–04; brevet colonel U. S. army, serving in Louisiana 1804–06; a judge in Louisiana 1805–06; U. S. district judge in Michigan 1807–08; U. S. Senator from Ohio 1808–10; Governor of Ohio 1810–14; U. S. Postmaster-General 1814–23. His governorship was remarkable for the active support which he and his State afforded the U. S. Government during the war of 1812–15. D. Mar. 29, 1824.—His nephew, of the same name, became a distinguished lawyer, and published a volume of *Law Reports* (1839), and with William F. Cooper prepared the *Code of Tennessee* (1858).

Meikong: a river of Indo-China. See Mekong.

Meilhac, Henri: See the Appendix.

Meinam, a river of Siam. See Menam.

Meineke, mī′ne-ke, August: classical scholar; b. in Soest, in Westphalia, Germany, Dec. 8, 1790; received his early education at the famous gymnasium of Schulpforta; studied under G. Hermann at Leipzig from 1810 to 1812, when he was appointed Professor of Greek and Roman Literature at the gymnasium at Jenkan; thereafter director of the gymnasium in Dantzic; and from 1826–57 director of the Joachimsthaler Gymnasium in Berlin. D. Dec. 12, 1870. Meineke's astounding philological activity was almost exclusively devoted to text critical editions of Greek authors, his work in the departments of Greek comedy and Alexandrian literature being particularly valuable. Among his many writings are *Fragmenta Comicorum Græcorum* (5 vols., 1839–57), the first volume containing the first complete and scientific survey of our knowledge concerning the development of Greek comedy, and the lives and works of its representatives; *Aristophanes* (2 vols., 1860); *Athenæus* (3 vols., 1859); *Analecta Alexandrina* (1843), a collection of learned monographs on the poets Euphorion, Rhianos, Alexander Ætolus, Parthenius, and others; *Theocritus, Bion* and *Moschus* (1856); Callimachus's *Hymns* and *Epigrams* (1861); the lexicon of *Stephanus Byzantius* (vol. i. 1849, the second never appeared); *Strabo* (3 vols., 1853); *Stobaeus* (6 vols., 1855–63); the histories of *Johannes Kinnamas* and *Nicephorus Bryennios* for the Bonn *Corpus scriptorum Byzantinorum*; *Horace* (1834), in which edition the so-called four-line strophe law, discovered independently by him and Lachmann, is consistently applied. See F. Ranke, *A. Meineke, ein Lebensbild* (Leipzig, 1871). Alfred Gudeman.

Meissen, mī'sen: town of Saxony; on the Elbe; 14 miles by rail N. W. of Dresden (see map of German Empire, ref. 4–G). It has a beautiful Gothic cathedral. St. Afra's School (founded in 1543), celebrated manufactures of porcelain, in which the so-called "Dresden china" is made (an industry begun in 1710); also manufactures of iron, machinery, jute, and cigars. Pop. (1890) 17,875.

Meissen, Heinrich, von (*Frauenlob*): poet; b. probably at Meissen about 1250. He was a traveling minnesinger, whom we meet at the courts and castles of many contemporary princes and nobles. Toward the end of his life he seems to have settled at Mentz, where he died Nov. 29, 1318. He was called Frauenlob because he extols in his poems the name Frau in opposition to the name Weib, which was used by other poets. He also wrote a long hymn in praise of the Holy Virgin, introducing in this and other poems the element of scholastic learning. The fact that in this style of poetry he was imitated by the later mastersingers is proof for the supposition that to Frauenlob we must trace the beginnings of the mastersong. (See Mastersingers.) Frauenlob was a poet of great technical talent, but an extremely vain man, whose conceit is not warranted by the meager contents of his poetry. Julius Goebel.

Meissner, mīs'ner, Alfred: poet; b. at Teplitz, Bohemia, Oct. 15, 1822; studied medicine at the University of Prague, and published his first volume of poems in 1845. Fearing that the publication of *Ziska*, an epic poem which he was then writing, would be prohibited in Austria, he went to Leipzig in 1846. Here he finished *Ziska*, which met with great success, but on account of its revolutionary spirit was not allowed to be sold in Austria. In order to escape extradition and punishment he went to Paris, where he became intimately acquainted with Heine. In 1848 he returned to Austria, where, on account of the revolutionary events of that year, a more liberal spirit had been inaugurated, and he was allowed to go free. During the remainder of his life he lived mostly in Prague and in Bregenz, at Lake Constanee. Though Meissner wrote several dramas and a number of novels which rank above the average, he is greatest as a lyric poet. Like Anastasius Grün and other Austrian poets of that time, Meissner finds the principal source of his poetical inspiration in the ardent longing for spiritual and political freedom from the fetters of mediæval feudalism and hierarchical despotism. Besides, we find in his poetry an element of melancholy, suggesting a decided influence of Lenau. The last years of Meissner's life were greatly embittered by the consequences of a most unfortunate literary partnership into which he had entered with a man named Hederich. Being ashamed to acknowledge this partnership publicly, he was forced not only to publish novels by Hederich under his own name, but also to meet, under the threat of exposure, the exorbitant pecuniary demands of this man. Nearly driven to madness, Meissner attempted suicide, and finally died, utterly broken down, at Bregenz, May 29, 1885.
Julius Goebel.

Meissonier, mā'sō'ni-ā', Jean Louis Ernest: genre and military painter; b. in Lyons, France, Feb. 21, 1815; pupil for a short time of Léon Cogniet, but obtained his art education in the main by the study of the old masters, especially those of the Dutch school. The first picture he exhibited was *The Visitors*, in 1834. He received a third-class medal at the Salon of 1840, second-class in 1841, and first-class in 1843 and in 1848. Received in 1846 the decoration of the Legion of Honor, and was made a grand officer in 1878; at the Paris Expositions of 1855, 1867, and 1878 he was awarded medals of honor; was elected in 1861 a member of the Institute. He was a member of all the principal art academies of Europe, and received various honors and orders at international exhibitions and from the sovereigns of different countries. D. in Paris, Jan. 31, 1891. His works are remarkable for their wonderful truth and exactness in detail, while they are painted with breadth and completeness of general effect. A number of his works deserve the name of masterpieces. His pictures have been sold for enormous prices, and most of them are in private collections in Europe and the U. S. *Napoleon III. at Solferino* (1864) is in the Luxembourg Gallery, Paris; *La Rixe* (1855) in Buckingham Palace, London; *Friedland—1807* (painted in 1876) in the Metropolitan Museum, New York.
William A. Coffin.

Meisterhans, mīs'ter-hans, Konrad, Ph. D.: classical scholar; b. at Andelfingen, canton of Zurich, Switzerland, Nov. 21, 1858; studied in Zurich and Paris; professor in the cantonal school at Solothurn, Switzerland; author of *Grammatik der attischen Inschriften* (1885; 2d ed. 1888); *Aelteste Geschichte des Kantons Solothurn bis zum Jahre 687* (1890).

Meistersinger: See Mastersingers.

Meistersong: See Mastersingers.

Mejía, mā-hee'ăă, Tomás: soldier; b. in Guanajuato, Mexico, about 1812. He was of pure Indian blood, and uneducated; rose from the ranks; fought against Taylor in the war with the U. S. 1846–47; subsequently supported the conservative or church party, and was conspicuous on its side in the civil wars 1857–61. In 1862 he joined the French and subsequently was one of the most trusted generals of Maximilian, to whom he was much attached. He was captured at the fall of Querétaro, and executed there with Maximilian, June 19, 1867. Herbert H. Smith.

Mejsnar, mās'năăr, Hynek Jaroslav: classical scholar; b. at Jilemnice, near Jičín, Bohemia, 1837; was professor at the gymnasium of Tábor; is professor at the academic gymnasium of Prague. He is best known as translator of Homer's *Odyssey* (1873–76); *Iliad* (1878–81); and *Hymns, Epigrams, and Batrachomyomachia* (1881). He also translated N. Nekrasov's and K. F. Rylejev's poems, Krylov's fables, and trilogy *Oresteia* (1883), etc. J. J. K.

Mek'hitar, or Mechitar: the founder of a congregation of Armenian monks, called after him Mekhitarists; b. at Sebaste in Lesser Armenia, Feb. 7, 1676. His true name was Manuk, but on entering a monastery in the vicinity of his native city in 1690 he received the name of Mekhitar, "comforter." He distinguished himself both for religious zeal and talent for learning, and in 1701 founded in Constantinople a congregation with the purpose of uniting the Armenian and Roman Catholic Churches. Compelled to leave Constantinople on account of the persecutions of the Armenian patriarch, he moved in 1703 to Modon, in the Morea, where, under the authority of the Venetians, who at that time held the country, he founded a monastery. Expelled from this place, too, by the war between Turkey and Venice, he repaired with his followers to the latter city, and having received the island of San Lazzaro, he built a new monastery here (1717). D. in the monastery Apr. 27, 1749. In their original aim of uniting the Armenian and Roman Catholic Churches, the Mekhitarists have not been very successful. They have branches in Italy, Germany, and Turkey, but United Armenians are scarcely found in Armenia proper. (See Armenian Church.) As a link of intercommunication, however, between their native country and European civilization they have developed a great and beneficial activity. Through them Armenia, its language, literature, and history have become known to Europe, and many of the best products of European learning and genius have become accessible to Armenians through their translations. See V. Langlois, *Notice sur le couvent arménien de l'île Saint-Lazare de Venise, et sur la congrégation mekhitariste* (Venice, 1863).
Revised by S. M. Jackson.

Mek'inez: town of Morocco; in lat. 33° 58′ N. and lon. 5° 35′ W. (see map of Africa, ref. 1–B). It is situated on a fertile plain covered with olive-groves. It is fortified, neatly built, and contains a magnificent palace built of marble and surrounded by beautiful gardens. The sultan resides there during the summer. A considerable trade and manufactures of leather and earthenware are carried on. Many of its inhabitants are connected with the court of the sultan. The town was formerly called Tákarat. Pop. estimated at 80,000.

Meklong': river and town of Western Siam, Indo-China. The river rises in the mountains between Tenasserim and Siam, is 250 miles long, is navigable for the lower 30 miles from Pra-Pri, is connected by a canal with the Menam near its mouth, and empties into the northwest angle of the Gulf of Siam. The town of Meklong, an important port, is on the river, 5 miles above its mouth. Pop. 10,000, mostly Chinese merchants and Siamese truck-growers and fishermen. Below the town is a strong fort. M. W. H.

Mekong', **Meikong**, or **Cambodia**: a river of Southeastern Asia, the greatest in Indo-China. Its upper course is not known with certainty, but it is believed to rise in Central Tibet, about lat. 34° N., lon. 94° W., but a few miles E. of the source of the Yang-tse-Kiang, traversing Eastern Kham (of Tibet) and Western Szechuan and Yunnan (of China), and entering Indo-China at the northwest angle of Tonquin, in about lon. 100° E. From here it goes S. until it passes lat. 22°, from which point its course is fully identified.

It passes first S. to lat. 20°, then E. through Luang Prabang to about lon. 102° E., then again S. to about lat. 18° N., thence E. again to lon. 104° E., thence, by a generally southerly course, to its mouth in the China Sea. Its greatest tributary is the Semoun from Siam, in about lat. 15° N. Below Khong, about lat. 14° N., begins a series of rapids and cataracts which make continuous navigation between the lower and upper river impossible. Below the cataracts of Khong navigation is possible without interruption to the mouth. At about 11° 30′ N. lat. the river receives the discharge of Tonlé-Sap, or Great Lake, lying 70 miles N. W. This lake is about 100 miles long, 20 miles in greatest breadth, and lies on the boundary between Siam and French Cambodia. At the junction of the Mekong and affluent of Great Lake is the important city of Pnom-Penh, and it is immediately below this city that the delta of the Mekong begins. The river then passes by many branches for 180 miles through the marshes of Cochin China, and empties into the ocean through four great mouths and innumerable smaller ones. As thus described, the Mekong has a course of over 2,600 miles, about that of the Amur, Hoangho, or Volga. Its basin includes about 350,000 sq. miles, which is small for its length. The stream is called by different names in different parts of its course. It is the Kiamdo-Chu of the Tibetans, the Lan-tsan-Kiang and La-Kao of the Chinese, the Mekwanmit of the Burman Laos, the Kien-long of the Siamese Laos, the Mekong or Namkong in Siam, and the Cambodia or Sangson in Cambodia. Its probable source is at an elevation of 15,000 or 20,000 feet, and its current above lat. 18° N. is generally rapid and turbulent. Below Khong the fall is so slight that the tides are felt as high up as Pnom-Penh, and sometimes to the extremity of the Great Lake and the foot of the cataracts of Khong. See Desgodin's *Missions du Thibet* (1872); Garnier, *Voyage d'exploration en Indo-Chine* (1873).

MARK W. HARRINGTON.

Mekran′, or **Makran′** (anc. *Gedrosia*): geographical name of Persian origin for the coast regions of Southwestern Baluchistan and Southeastern Persia. It is an arid and desolate region, traversed by chains of bare, rocky, or sandy hills running parallel to the coast, without permanent rivers. The climate is hot, and severe fevers are common. It is very sparsely inhabited, and is about equally divided between Baluchistan and Persia. It is inhabited by many mutually independent and jealous tribes.

M. W. H.

Me′la, POMPONIUS: geographer; b. at Tingentera in Spain; flourished in the first half of the first century of our era. He was the first Latin writer who composed a formal treatise on geography. His work, *De Chorographia Libri III.*, is still extant, though the text has suffered much. The first edition was published at Milan (1471); the best editions are those by Tzschucke (Leipzig, 1807), by Parthey (Berlin, 1867), and C. Frick (Leipzig, 1880). There is an English translation by Arthur Golding (London, 1585).

Revised by M. WARREN.

Melamet, DAVID: composer; b. in Prussia in 1861; was celebrated while a boy for his fine soprano voice, and made a concert tour when twelve years old. He studied in Berlin under Kullak, Tiersch, and Becker, and became a singer and chorus-conductor. He removed to New York in 1888, and became director of the Germania Männerchor. In 1889 he succeeded Fritz Fincke in Baltimore. In 1892 he won, with his *Columbus*, the prize which had been offered for the best cantata for the German Columbian celebration in New York.

D. E. HERVEY.

Melam′pus (in Gr. Μελάμπους): son of Amythaon and Idomene, and brother of BIAS (*q. v.*). In front of his house in the country stood an oak-tree in which a snake had built its nest. Servants killed the mother-snake, whose body Melampus reverently burned. The young snakes he reared as pets. In return therefor, as Melampus slept, the young snakes licked out and purified his ears, so that upon awaking he found that he understood the language of the birds, who thereafter instructed him in the prophetic art. After an interview with Apollo in the valley of the Alpheus, he became the most distinguished of soothsayers. See BIAS, PERO, PHYLACUS, and IPHICLUS.

J. R. S. STERRETT.

Melancholia: a form of emotional insanity. See INSANITY and DOUBTING INSANITY.

Melanch′thon (sometimes **Melanthon**), PHILIP: reformer and theologian; b. in Bretten, now in the grand duchy of Baden, Feb. 16, 1497. His father, George Schwarzerd (literally "Black earth," of which Melanchthon is simply the Greek translation), was a skillful and eminent manufacturer of military arms, who by his trade had attained a competency, and by his private virtues and decided religious character was widely known. His mother, Barbara Reuter, was the daughter of the burgomaster of the village. His grandmother was the sister of the renowned humanist John Reuchlin. From his earliest childhood he enjoyed rare advantages for instruction—first, under the supervision of his grandfather, and afterward of Reuchlin, who, in recognition of his attainments, translated his German name into Greek. Entering the University of Heidelberg in his thirteenth year, he resided with one of the professors, and was known familiarly among his fellow students as "the Grecian." Notwithstanding the distraction of private teaching, he took the degree of bachelor of arts when only a few months over fourteen. During this period he wrote his Greek grammar, published several years later. His ambition received a check the following year, when, notwithstanding his acknowledged attainments in scholastic philosophy, he was refused the degree of master of arts solely because of his extreme youth. This, with the insalubrity of the climate, from which he was suffering, determined his transfer in 1512 to Tübingen, where, after pursuing a wide range of studies—including Greek and Latin literature, philosophy, history, jurisprudence, medicine, and theology—he received his master's degree in 1514, and immediately began to lecture on the classics. In 1516 he published an edition of Terence, and for some years was a corrector of the press for publications of Reuchlin and others. In 1518 he declined calls to both Leipzig and Ingolstadt, and accepted a call, given on Reuchlin's recommendation, to Wittenberg. His youthful appearance caused much disappointment, until he delivered his inaugural address *On Matters to be Corrected in the Studies of Youth*, which completely won the hearts of his hearers, especially Luther. In his enthusiasm, Luther wrote: "I desire no other teacher of Greek so long as he lives." His lecture-room was continually crowded with eager students, the number frequently rising as high as 2,000. He enkindled much interest among the theologians in the study of Greek. His association with Luther led him constantly more deeply into the study of theology. In 1519 he accompanied Luther to the Leipzig Disputation, and, although only a spectator, became involved in a controversy with Dr. John Eck, when his letter to Œcolampadius, reporting the discussion, was published. During the same year he received the degree of B. D. He was gradually led to the work of a theological professor by his lectures on the New Testament writings. With great modesty he always protested that his sphere was that of the philologist and expounder of the classics rather than that of the theologian; but the demands of students, as well as of Luther, determined that he should especially devote himself to theology. His lectures on the Epistle to the Romans were published, without his knowledge, by Luther in 1522; but before they were published his prolegomena to the same lectures, as delivered to his students, had led to the publication of a small volume that proved to be the foundation of Protestant dogmatical theology. Recognizing the frequent recurrence of many of the same terms in the Epistle, he had prepared definitions of a number of them. Their publication by his pupils, in an imperfect form and without his knowledge and consent, demanded that an authorized edition should be prepared. This resulted in the *Loci Communes rerum theologicarum* of 1521. In them may be seen Melanchthon's great skill in presenting in the clearest and most accurate form the material derived from Luther. The latter declared that the book had more solid doctrine in it than could be found in any work since the days of the apostles, and that it was worthy of canonical authority. Melanchthon saw more than sixty editions issued from the press. He subjected it to two radical revisions. The former was in 1535 and the latter in 1543, the most noticeable variation being in the change concerning the freedom of the will, since he passed from the most absolute determinism in the edition of 1521 (*tollit itaque omnem libertatem voluntatis nostræ divina prædestinatio*) to the assertion of a synergism of the human will in conversion, that advanced in decision, until in 1548 he taught *Liberum arbitrium est in homine facultas applicandi se ad gratiam.* Other changes were determined either by his conciliatory attitude toward the Reformed or his willingness to compromise with a modified form of Roman Catholicism, as proposed in the *Interim* of 1548. The *Loci* in their three chief editions (Latin and German) are published with full introductions in vol. xxi. of Bretschneider and Bindseil's *Corpus Reformatorum.*

Besides his activity as professor and author, Melanchthon was more prominent even than Luther in what may be called ecclesiastical diplomacy, for which Luther's ardent temperament and directness unfitted him. His greatest work in this direction was his composition of the Augsburg Confession, upon the basis of material provided by him and Luther in common, and with Luther's revision and advice. (See Augsburg Confession.) The Apology of the Augsburg Confession and the appendix to the Smalcald Articles are also from his pen. He participated in the Diet of Spires of 1529 and the Marburg colloquy of the same year. Among other ecclesiastical conferences in which he was prominent were those with the representatives of the Church of England at Wittenberg in 1536, and in the same year with Baur and his associates, resulting in the Wittenberg Concord, in the Diet of Ratisbon (Regensburg) in 1540, and the Reformation of Cologne in 1543. He was entirely unequal to the occasion when, during Luther's absence at the Wartburg in 1521, religious disturbances arose at Wittenberg. Melanchthon in this sphere showed much vacillation, and was influenced by current events. This was particularly observable in his revisions (1540 and 1542) of the Augsburg Confession. Always desirous to improve his statements of doctrine, he seems to have not always discriminated between what he had written as a private theologian and what had been prepared for others to sign, and thus to become the confession of churches. The changes made in the Augsburg Confession, chiefly to make it more acceptable to the Reformed, led to the distinction between the *Invariata* and *Variata*, and occasioned violent controversies in the Lutheran Church. In a similar way, after Luther's death in 1546, when Lutheranism was in extreme peril as the result of the calamities of the Smalcald war, he was ready to concede the use of rites that had become distinctive of Roman Catholicism to secure the continuance of what he deemed evangelical teaching.

The frequent correspondent and adviser of Cranmer in his reformation in England, and the occasional correspondent of King Henry VIII. himself, he was repeatedly called to England, but declined. His influence, however, pervades the *Prayer-book*, the *Articles*, and the *Homilies*.

His last years were burdened with domestic afflictions, as well as by the disturbed condition of the Lutheran Church. He longed to be delivered from what he called the *rabies theologorum*. He died Apr. 19, 1560.

While Melanchthon was eminent as a classical scholar and as a lecturer and writer on philosophy, his chief distinction must always be as a theologian. This rests not upon any extensive investigations or attempts to solve difficulties, but almost entirely upon his extraordinary ability to state any truth presented for consideration in the clearest and simplest form. As Plitt remarks (*Einleitung in die Augustana*, i., 537), he was no systematic theologian in the proper sense of the term; instead of dealing with difficulties, he always sought to evade them; whatever the subject he undertook to treat, he presented it with transparent clearness. This has been stated in the often-quoted sentence, "Luther, the miner's son, dug the pure ore of truth out of the mountain, and Melanchthon, the armorer's son, forged it into a bright weapon." The misfortune of Melanchthon often forced him into positions in which he felt his weakness, and which were uncongenial to him. When there was no creative genius with a more powerful will to determine his course, as when he was by the side of Luther, his skill in what was purely formal did not protect him from errors in the material. Melanchthon, in turn, exerted much influence upon Luther. They supplemented each other. "If Luther was able to kindle, to rouse and elevate, and even ravish the heart, it was through Melanchthon's cooperation that the effect he produced received its abiding power, outlasting the change of moods; and thus what Luther gave was incorporated with the daily life, with quiet Christian enlightenment. In Melanchthon, Luther, the man of the people, had placed by his side the fine architectural and organizing spirit, who, gifted with a delicate moral tact, a circumspect and dialectic mind, and a power of unadorned but transparent and convincing representation, had the skill to give to the matter, born at first in the heart of Luther, an objective shape and the stamp of validity. Melanchthon, in particular, was the medium of extending the Reformation to the educated classes, to statesmen and learned men, who might easily have failed to recognize in Luther's sturdy language the matter that was of saving virtue to them." Dorner's *History of Protestant Theology*, Eng. transl., i., 116, *seq.*

The writings of Melanchthon fill twenty-four folio volumes of the *Corpus Reformatorum* (Halle, 1834–60). The first nine volumes contain his letters, to which Bindseil added in 1879 a volume of letters that were not included. These volumes are accompanied by the *Annales Vitæ*, a most minute chronological table of the chief events of his life. His biographies begin with that of his most intimate friend, Camerarius, 1566. Among the more recent are those of Köthe (1829), Matthes (1841), Ledderhose (1847), E. Schmidt (1861). In English we have Cox (1835) and Krotel's translation of Ledderhose (1855). See also Herrlinger's *Melanchthons Theologie* (Leipzig, 1879); Hartfelder's *Philip Melanchthon als Præceptor Germaniæ* (Berlin, 1889). See also German Theology.

Henry E. Jacobs.

Melanes'ia: one of three great ethnographic divisions of Oceania, being the part occupied by peoples with a black skin, while the natives of Micronesia and Polynesia are lighter in color. The Melanesian archipelagoes are, in order from the N. W. to the S. E., Bismarck Archipelago, the Solomon islands, the Santa Cruz islands, the Tucopia group, the New Hebrides, New Caledonia and the Loyalty islands, the Chesterfield islands, and finally the Fiji islands, where the population is so mixed with Polynesian that it may be indifferently attributed to Melanesia or Polynesia. The total area of these islands is 56,300 sq. miles, and the combined population 642,300, or about twelve persons to the square mile. The population of New Guinea or Papua is on the whole nearly allied to the Melanesians. If this is included the total area becomes 358,300 sq. miles, and the population 1,150,000. The Melanesians are closely allied to the Negritos, though there are great differences in language. They differ physically from the Polynesians, though there are striking resemblances in customs and languages. Probably considerable intermixture has taken place with the latter. The Melanesians are ugly, especially the women, but muscular, and good workmen. They have some simian characters fairly well pronounced; woolly but not crinkled hair; hairy bodies; narrow shoulders, and slender arms and legs, but large hands and feet; color a deep brown. They are less thievish than the Polynesians, and more energetic, though inferior in the making of weapons and canoes and in the art of navigation. See Coddrington, *The Melanesian Languages* (1885) and *The Melanesians: Studies in their Anthropology and Folklore* (1891).

Mark W. Harrington.

Melani'idæ [Mod. Lat., named from *Mela'nia*, the typical genus, from Gr. μέλας, μέλανος, black]: a family of fresh-water gasteropod molluscs in which the usually long or conical shell is covered with a thick, dark-colored epidermis. The foot is large, the proboscis short and stout, and the eyes near the base of the tentacles. The species are very numerous, especially in Southern Asia and in the Mississippi valley. Almost nothing is known of the structure or development of the various forms.

J. S. K.

Melanip'pus (in Gr. Μελάνιππος): son of Astacus of Thebes, who, when the Seven Heroes were attacking Thebes, was stationed by Eteocles opposite to Tydeus, whom he wounded mortally. Later in the fight Amphiaraus killed and beheaded Melanippus. Amphiaraus blamed Tydeus mostly for the war, upon which he had entered against his will, because he foreknew its issue. He therefore bethought him of a terrible vengeance. Being a seer, he knew that Athene was hastening from Olympus in order to cure Tydeus and make him immortal. In order to prevent this Amphiaraus gave the head of Melanippus to Tydeus, who still had strength enough to split open the skull and drink the brains, a deed which caused Athene to shrink back in horror. Amphiaraus was avenged, and Tydeus died.

J. R. S. Sterrett.

Mel'anism [from Gr. μέλας, -ανος, black]: a term used to denote the assumption of an abnormally dark or even black phase of color among animals; the opposite of albinism. It appears to be of such frequent occurrence in some animals, e. g. the rough-legged buzzard (*Archibuteo sancti joannis*) and black variety of the gray squirrel (*Sciurus carolinensis*), as to almost amount to Dichromatism (*q. v.*), while in others it is infrequent.

F. A. L.

Melanite: See Garnet.

Melan'thus (in Gr. Μέλανθος): son of Andropompus and King of Messenia. He was driven out of Messenia by the Heraclidæ, and took refuge in Attica. Xanthus, the King of Bœotia, was pressing the cowardly Thymœtus, the last King of Athens of the race of Theseus, and challenged him

to a duel for the possession of the town of Œnoë on the Bœotian frontier. Thymœtus refused to fight, but Melanthus took his place, and by the help of Dionysus killed Xanthus. Melanthus became King of Athens. In honor of the victory over Xanthus a sanctuary was erected to Dionysus Melanægis, and the festival of the Apaturia was established in honor of Zeus Apaturios. J. R. S. STERRETT.

Melba, NELLIE: See the Appendix.

Mel'bourne: the capital of the colony of Victoria, Australia; on the Yarra-Yarra river, 9 miles above its mouth in the basin of Port Philip; in lat. 37° 50′ S. and lon. 144° 57′ E. It was founded in 1837. In 1847 it had 10,955 inhabitants, and became the see of a bishop. In 1851 it had 20,400 inhabitants, and became the capital of the newly formed colony of Victoria. It had in 1891 491,378 inhabitants, nearly half of the population of the entire colony. This marvelous growth is mostly due to the discovery in 1851 of the gold-fields at Mt. Alexander and Ballarat, from 60 to 70 miles from Melbourne. Dec. 31, 1895, its population, including suburbs, was 452,258. In 1852 the shipping amounted to 1,657 vessels, of 408,000 tons burden. In the same year the value of imports rose from £1,056,000 to £4,044,000, and in 1853 to £14,000,000. In 1891 2,034 vessels, of 2,222,805 tons burden, entered, and 1,988, of 2,139,333 tons, cleared. In the same year the total value of imports amounted to £16,949,393, and that of exports to £14,558,658. The situation of Melbourne is very fine. Although the Yarra-Yarra does not admit large sea-going vessels on account of the bar at its mouth, railways have been constructed between Melbourne and Fort Philip, which is on a beautiful inlet of the Indian Ocean, safe and deep. The streets are all paved and provided with gas, electricity, and water. It is distinguished for its university, mint, museum, observatory, public library, hospital, and public gardens, and is an Episcopal see. M. W. H.

Melbourne, WILLIAM LAMB, Viscount: statesman; b. at Melbourne House, Derbyshire, England, Mar. 15, 1779; was educated at Eton and Cambridge; studied politics and jurisprudence at Glasgow; was called to the bar at Lincoln's Inn Nov. 23, 1804; entered Parliament and married Lady Caroline Ponsonby 1805. He attached himself to the Whig party, and continued a moderate opposition to the administrations of Perceval and Lord Liverpool; became Chief Secretary for Ireland on the accession of the Canning ministry Apr., 1827; succeeded to the title on the death of his father July 22, 1828; was a distinguished advocate of Catholic emancipation and of parliamentary reform; became Secretary of State for the Home Department in Earl Grey's cabinet Nov., 1830, and on the retirement of the latter July 9, 1834, succeeded him as First Lord of the Treasury and Premier; was dismissed in November of that year, but recovered his place in Apr., 1835, through the support of the House of Commons, and retained his position until Aug. 30, 1841. He was therefore the responsible head of the British Government at the accession of Queen Victoria and during the first four years of her reign, and contributed much to the education of his young sovereign in her royal duties. D. at Melbourne House, Derbyshire, Nov. 24, 1848.—His wife, CAROLINE PONSONBY, known in literature as Lady CAROLINE LAMB (she died before he succeeded to the title), a daughter of the Earl of Bessborough, b. Nov. 13, 1785, acquired great celebrity through her romantic attachment to Lord Byron, and her subsequent bitter quarrel with him. She wrote three novels—*Glenarvon* (1816); *Graham Hamilton* (1820); and *Ada Reis* (1823). D. in London, Jan. 25, 1828. See Torrens, *Memoirs* (1878); *The Greville Memoirs* (1875–85); and Justin McCarthy, *History of Our Own Times* (1878–80).

Mel'chites (royalists, Gr. Μελχίτης, from Semit. *melek*, king): (1) a name applied to the orthodox Christians of Egypt to distinguish them from the Jacobites (monophysites). The term was first employed in the fourth century, but especially after the Council of Chalcedon (451 A. D.), as a term of reproach, because of the charge that the decrees of the council were received simply because of the royal edict of the Emperor Marcian. Under the Mohammedan caliphs the term was taken to imply allegiance to the Eastern emperors, and still later to indicate Greek or foreign sympathies. In both cases it was an occasion for oppression to the orthodox, who were few in numbers. (2) An Eastern, Arabic-speaking branch of the Roman Church, worshiping according to the rites and ceremonies of the Eastern or Greek Church, but acknowledging the supremacy of the Roman see. The sect is found principally at Aleppo and Damascus, its patriarch residing at the latter place. It is supposed to have originated from the labors of Jesuit missionaries in the seventeenth century. It was found that the people were unwilling to abandon the customs of the Greek Church, and these they were allowed to retain in consideration of their acknowledgment of the authority of the Roman pontiff and acceptance of Roman doctrine. The laity partake of the sacrament in both kinds, using unleavened bread, and are allowed free use of the Scriptures; deacons and priests are allowed to marry before ordination, but bishops must be celibate. Their number has been estimated at between 30,000 and 40,000. C. R. GILLETT.

Melchizedek, mel-kiz'e-dek, or **Melchisedec** [= Lat. = Gr. Μελχισεδέκ, from Heb. *Malki-tsedhek*; liter., king of righteousness]: King of Salem and priest of the most high God; who met Abraham on his return from the rescue of Lot and slaughter of Chedorlaomer, brought forth bread and wine, and offered a banquet to Abraham and the King of Sodom in the valley of Shaveh, called "the king's dale," in the neighborhood of Jerusalem, after which he blessed Abraham, and received from him tithes of the spoil. (Gen. xiv. 18–20.) Being of unknown origin and end he typified Christ (Ps. cx. 4; Heb. vi. 20, vii. 1–21). Jewish traditions, recorded in the Targums as well as in many cabbalistic and rabbinical writings, identified him with the patriarch Shem, who, according to the current biblical chronology, was still living at that period. This was the prevalent Jewish opinion in the time of Jerome, was adopted by Luther and Melanchthon, and by Selden and Lightfoot among English writers. A sect of Christian heretics, called Melchizedekians, regarded him as an incarnation of the "great power of God," superior even to Christ. Others regarded him as an angel, as the Holy Ghost, or as the son of God, with which conception harmonized a Jewish belief that he was the Messiah. Revised by S. M. JACKSON.

Mele'ager (in Gr. Μελέαγρος): in Greek mythology, a son of Œneus, King of Caledon, in Ætolia, and Althæa, daughter of Thestius, husband of Cleopatra, daughter of IDAS (*q. v.*); a powerful hunter who was distinguished for his skill with the spear. He it was who killed the boar which Artemis had sent to ravage the fields of Caledon because Œneus had neglected to offer up to her a sacrifice. (See CALYDONIAN HUNT, THE). When Meleager was seven days old the Fates announced to his mother that the child would live as long as the stick of wood then burning in the fire was unconsumed. Althæa snatched the brand from the fire and preserved it carefully in a chest, but when Meleager had slain the brothers of Althæa (see ATALANTA) she burned the stick and Meleager expired at once. Thereupon Althæa and Cleopatra hanged themselves, and the sisters of Meleager wept so for his death that Artemis took pity on them and changed them into guinea-fowls (μελεαγρίδες). Ancient artists were fond of depicting Meleager and the Caledonian boar-hunt. A number of statues have come down to us. Chief among them are those in the Berlin and Vatican Museums. See Baumeister, *Denkmäler*, under *Meleagros* for a discussion of Meleager in art. J. R. S. STERRETT.

Meleager (in Gr. Μελέαγρος): poet; was a native of Gadara, in Palestine, and flourished under the last Seleucus, who died in 94 B. C. His first essay was in the line of cynical philosophy, for he was a disciple of his famous townsman, MENIPPUS (*q. v.*), and his satirical dialogues were much read and sedulously imitated; but he is chiefly known as a writer of love epigrams and as the compiler of a collection of short poems called the *Garland* (Στέφανος), made up from the works of some forty poets and arranged alphabetically according to the initial letter of each piece. Of this garland we have only stray flowers, together with the delightful introductory verses in which Meleager characterizes the different poets who were laid under contribution. His own poems, some 130 in number, are among the most attractive in the parterre of the Greek Anthology, except that a large proportion of them require a certain Greek elasticity of moral sense. They have been edited separately by Manso (1786), by A. C. Meineke (1789), and Graefe (1811); and Meleager's merits as a poet have been eloquently brought out by J. A. Symonds, *Studies of the Greek Poets*, c. xxii. See also Walter Headlam, *Fifty Poems of Meleager, with a Translation* (1890), and Susemihl, *Geschichte der alexandrinischen Literatur*, vol. i., p. 46. B. L. GILDERSLEEVE.

Meleagrid'idæ [Mod. Lat., named from *Melea'gris*, the typical genus, from Lat. *melea'gris* = Gr. μελεαγρίς, a kind of guinea-fowl]: a family of gallinaceous birds containing

the turkeys. They have a characteristic form in the large upraised body, long neck, and small head; the head and neck are destitute of feathers, but have scattered "hairs," and are more or less carunculated; an extensible fleshy process is also developed from the forehead; the bill is moderate; the nasal fossæ are bare; the tarsi armed with spurs in the male; the hind toe elevated; the tail (about as long as the wing) is truncate, and has more than twelve feathers. The breast-bone has a long, narrow keel (the "lophosteon") extending far backward, while from near the front on each side, and separated by a very deep notch from the sides of the anterior portion, a wing-like process (the "metosteon") both diverges and extends far backward, but is split into two parts, the external and internal xiphioid processes; the pelvis is peculiar in the extension of the post-acetabular area (or that behind the insertion of the legs), which is greater than the anterior. The family is at present limited to two species—(1) the common turkey, *Meleagris gallopavo*, and (2) the rare and beautiful turkey, *Meleagris ocellata*, of Honduras. The common turkey shows four local races or sub-species—*M. gallopavo*, of the Northern U. S.; *M. gallopavo osceola*, of Southern Florida; *M. g. mexicana*, of the Mexican uplands; and *M. g. elliotti*, of the Mexican lowlands and Southern Texas. The common domesticated bird is a descendant of the Mexican form and not of the common wild one of the U. S., which has even been considered a distinct species. In former geological epochs other species existed within the limits of the present U. S., the remains of two species (*Meleagris altus*, or *superbus*, and *M. celer*) having been found in the Post-pliocene of New Jersey, and of another (*M. antiquus*) in the Miocene beds of Colorado. Revised by F. A. Lucas.

Melegnano, mā-len-yaa′nō: town; in the province of Milan, Northern Italy; on the railway between Milan and Piacenza (see map of Italy, ref. 3-C). This little town is well built, having the aspect of a small city, and its trade in the produce of the neighborhood is very active. Its mediæval history is interesting, and in modern times it has been the theater of two important battles—one in which Francis I. defeated the Swiss mercenaries of the Duke of Milan in 1515, the other the victory of the French and Italian allies over the Austrians on June 8, 1859. Pop. 5,438.

Meléndez Valdez, mā-len′deth-vaal-deth′, Juan: poet; b. at the village of Ribera del Fresno, near Badajoz, Spain, Mar. 11, 1754. After studying the humanities and philosophy at Madrid and Segovia, he went in 1772 to Salamanca to prepare himself for the law. Here he made the acquaintance of the poet Cadahalso, who saw the poetic possibilities in the ballads which the youth had been writing in imitation of Gerardo Lobo. Under the influence of his new friend the young poet attempted to enlarge the range of his verse. In the meantime specimens of his work had come into the hands of Jovellanos, then living in Seville, and a friendly correspondence ensued between the two men. In 1780 he won his first public success with an eclogue, *Batilo*, on the charms of a country life, written for the Spanish Academy's third prize-competition in poetry held by that institution. The delightful freshness of this ("It smelt all of wild thyme"—*olía todo á tomilla*—said one of the judges) made it far superior to the artificial eclogue of his chief rival, Yriarte. In 1781 he went to Madrid and was received with great kindness by Jovellanos and his friends. Invited to write a poem for a brilliant function of the Academy of Fine Arts, he made a great success with his ode *Á las Artes*. In the same year he returned to Salamanca as Professor of the Humanities. This was the happiest and most productive period of his life. In 1784 he gained the prize offered by the city of Madrid for a comedy on the occasion of the celebration of the birth of twin heirs to the throne. The piece offered by him, *Las bodas de Camacho el rico*, founded on an episode in *Don Quixote* (part ii., chap. xx.), is modeled upon the pastoral dramas of Tasso (*Aminta*) and Guarini (*Il Pastor Fido*). When put on the stage it was not a success. In 1785 the author won great applause by a first collection of his poems. Soon after this began the troubled period of his life. He was tempted to take public office, secure as he supposed in the influence of his friends Jovellanos and the Prince of Peace. In 1789 he became judge in one of the courts of Saragossa; in 1791 he was given a place in the chancery of Valladolid; in 1797 he became *fiscal* of the court of alcaldes de Casa y Corte in Madrid. In 1797 also he published a new and much enlarged edition of his poems. The next year his friends in power fell and he with them. After several years of partial disfavor he unwisely attached himself to the new French rulers of Spain, thus bringing upon himself the hatred of his countrymen. In Oviedo on one occasion he was seized by a mob and barely saved from being shot. After the withdrawal of the French he hoped to retrieve himself, but fortune was against him, and in 1811 he fled to Southern France. Here he passed the rest of his life, an unhappy exile, whose only solace was the correction of his poems for a definitive edition. He did not even have the pleasure of seeing this printed, as he died at Montpellier, France, May 24, 1817, some three years before its appearance. Other editions are Paris (1832), Barcelona (1838), and in Rivadeneyra's *Biblioteca de Autores Españoles*, vol. lxiii. (Madrid, 1871). Quintana's *Life* of Meléndez Valdez is printed in vol. xix. of the same *Biblioteca* (Madrid, 1867). Meléndez Valdez is one of the most important figures in Spanish letters of the eighteenth century. A true poet, he surpassed almost all his contemporaries in intellectual culture, as well as in the instinctive perception of what constitutes poetic harmony and proportion. A. R. Marsh.

Meletius: Bishop of Lycopolis, a see which then stood second to that of Alexandria; originator of the Meletian schism of Alexandria, which was occasioned by his audacious assumption of episcopal functions in the see of Alexandria during the absence of its bishop. He was condemned by the Council of Nicæa, 325. He does not seem to have been heretical, but his followers, who were the beneficiaries of his arbitrary acts, became Arians.

Meletius: Bishop of Antioch: originator of the Meletian schism, which lasted from 361 to 381, when he died. Although personally orthodox, he had received ordination from Arian bishops, and was therefore unacceptable to the Catholic party in Antioch.

Mel'fi: town; in the province of Potenza, Southern Italy; lying in a most fertile region, about 28 miles from the town of Potenza (see map of Italy, ref. 7-G). The commerce and industry of this place are considerable. Melfi was a large town in 304 A. D., and its mediæval story is one of the most stormy of these turbulent times. In 1528 the French general Lautrec de Foix took Melfi after an obstinate resistance, and slew 18,000 of its inhabitants. It suffered from earthquakes in 1456, 1694, and 1851. Pop. about 11,760.

Melgar, māl-gaar′, Mariano: poet; b. at Arequipa, Peru, 1791. Disappointment in love gave a melancholy cast to his mind, and his verses are nearly all of a plaintive character. Many of them have been set to music, and they are among the most popular songs of the Spanish-American country people. Melgar joined the patriots during Pumacagua's rebellion, was taken prisoner by the Spaniards at the battle of Umachiri, and shot at Cuzco, Mar. 10, 1815. H. H. S.

Melgarejo, māl-gaă-rā′hō, Mariano: soldier and politician; b. at Cochabamba, Bolivia, in 1818. He rose from the ranks by skill and reckless daring, but was a hot-headed and unprincipled partisan, and during twenty years was involved in revolutions with almost every Bolivian president. In Dec., 1864, he succeeded in overthrowing the government of his brother-in-law, Gen. Achá, and had himself proclaimed president, or, practically, dictator. Counter revolutions at once began. In 1865 the insurgents occupied La Paz, but were beaten, and Melgarejo shot with his own hand ex-President Belzú, his rival (Mar., 1866). In 1865 he joined in the alliance against Spain, and in Aug., 1866, signed a boundary treaty with Chili, which, however, was not ratified by congress. Constant revolts ended in a great rebellion of the Indians against Melgarejo's tyranny. He was beaten in a hot battle in the streets of La Paz (Jan. 15, 1871), fled the country, and was killed at Lima, Peru, by his son-in-law, Gen. Sanchez, in a quarrel, Nov. 23, 1872. H. H. Smith.

Melicer'tes (in Gr. Μελικέρτης): son of Athamas and Ino, who fled with him in her arms when she was being threatened with death by Athamas because of her attempt to murder Phrixus and Helle, children of Athamas by Nephele. Ino leaped from the Scironian rocks into the sea with Melicertes still in her arms. Both mother and son escaped unhurt, and were changed into sea divinities, who were worshiped especially at Megara, on the Isthmus, and at Corinth. Ino was worshiped as Leucothea, and Melicertes as Palæmon. The Isthmian games, which were held in honor of Poseidon, were thought to have been first held on the occasion of the funeral of Melicertes. Melicertes is the Greek form of the Phœnician Melkart. J. R. S. Sterrett.

Melikoff, more properly **Loris-Melikoff**, Michael Tarielovitch, Count: soldier and statesman; b. at Lori, a town of Transcaucasia, Jan. 1, 1826, of Armenian descent; entered the army as colonel; commanded a regiment of light cavalry in the Crimean war, and was adjutant-general to the Grand Duke Michael, who commanded the army of the Caucasus, in 1877. Ardaban was taken in May and Kars in November, and after the war Loris-Melikoff was made a count. He still more distinguished himself as governor of Astrakhan by his measures against the plague, and as governor of Kharkov by his measures against the Nihilists. After the crisis of Feb. 17, 1880 (the blowing up of the dining-room in the imperial palace of St. Petersburg), he was made the chief of an extraordinary commission, with almost unlimited power, and afterward Minister of the Interior. D. at Nice, Dec. 24, 1888.

Mel'ilot [Lat. *melilotus*, honey lotus, from its sweet smell]: a name applied to various leguminous herbs of the genus *Melilotus*. *M. officinalis* (common melilot), *M. alba* (sweet clover), *M. cœrulea*, *arborea*, *Messanensis*, and others are cultivated in Europe, but not much in the U. S., as forage-plants. The fiber of some species is useful. These plants possess the rich odor so familiar in "sweet clover." The forage is eagerly eaten by cattle, and is of excellent quality, but is not very abundant.

Melinite: See Explosives (The Picrates).

Meliphag'idæ [Mod. Lat., liter., those belonging to the honey-eating family, named from *Meli'phaga*, one of the genera; Gr. *μέλι*, honey + *φαγεῖν*, eat]: a family of passerine birds, the "honey-suckers," distinguished by G. R. Gray in the following combination of characters: The form is thrush-like; the head well-shaped; the bill more or less long, curved, and usually acute at the tip, which is slightly emarginated; the nostrils placed in a large groove and generally covered by a membranous scale; the tongue is extensile, and furnished at the tip with a pencil of short fibers; the tarsi rather short and strong; the toes more or less long, the outer always united at its base; the tail long and broad. The species are quite numerous, and almost entirely confined to Australia and New Zealand, with the outlying islands; and of the ornis of the former country especially they form a characteristic feature. They vary in size from a large thrush to a small warbler. Gray divides the family into three sub-families—viz.: *Meliphaginæ*, with seven genera; *Melithreptinæ*, with two genera; and *Myzomelinæ*, with four genera.

Melito: Bishop of Sardis; flourished in the third quarter of the second century, and wrote, besides many other works, an apology for Christianity, of which some fragments are found in Routh, *Reliquiæ Sacræ* (vol. i., 113–153), and in Otto, *Corp. Apol. Chr.* (ix., 375–478). The *Apologia Melitonis*, of which a Syriac translation was discovered by Tattam and printed in Syriac by Cureton, with an English translation, *Spicilegium Syriacum* (London, 1855), is generally ascribed to Melito of Sardis, but on doubtful grounds. See Harnack, *Texte und Untersuchungen zur Geschichte der altchristlicher Litteratur* (Leipzig, 1882, vol. i., 240–278; Eng. trans. of the *Apology* and fragments in *Ante-Nicene Fathers*, vol. viii., 750–762). Revised by S. M. Jackson.

Mell, Patrick Hues, D. D., LL. D.: educator; b. at Walthourville, Liberty co., Ga., July 19, 1814. He spent two years at Amherst College, Mass.; became a Baptist minister, and soon after the organization of Mercer University by the Baptist convention of Georgia he became Professor of Ancient Languages in that institution. In 1857 he was called to the same chair in the State University; subsequently became vice-chancellor; resigned in 1872, but retained a professorship. For fifteen years he was president of the Georgia Baptist convention, and for nine years president of the Southern Baptist convention. Dr. Mell published several works which have been highly valued and extensively circulated—one on *Baptism*, one on *Corrective Church Discipline*, one on *Predestination*, an *Essay on Calvinism*, an *Argument on the Subject of Slavery*, a sermon on *God's Providential Government*, a treatise on *Parliamentary Practice*, and *Prayer as Related to Providence*. D. at Athens, Ga., Jan. 26, 1888.

Mellarosa: See Bergamot.

Mellon, Harriet: See St. Albans, Duchess of.

Me'lo, or **Mello**, Francisco Manoel. de: soldier and writer; b. at Lisbon, Portugal, Nov. 23, 1611; was educated by the Jesuits; rose to the rank of colonel in the Spanish army (Portugal being then subject to Spain), serving in the Netherlands and in Catalonia against the rebels who attempted to establish a separate kingdom. Of this movement he wrote (in Spanish) a history which has taken rank as a classic, *Historia de los movimientos, separación y guerra de Cataluña en tiempo de Felipe IV.* (Lisbon, 1645; published under the name *Clemente Libertino*; ed. by Ferrer, 2 vols., Paris, 1826–32; also in *Historiadores de sucesos particulares*, Madrid, 1851). He entered the service of Portugal when it declared its independence; was imprisoned nine years through the enmity of a powerful nobleman, who charged him with the murder of Francisco Cardoso, and spent many years in exile in Brazil. Through the intercession of the French court he was allowed to return to Lisbon, where he busied himself with literary work. D. at Lisbon, Oct. 13, 1665. He wrote a multitude of works, chiefly in Portuguese—enough to fill a hundred volumes, it is said—embracing essays, satires, poems, tragedies, and farces, few of which have been published, as well as historical works relating to Portugal and Brazil. His satirical poems, *Las tres musas de Melodino* (Lisbon, 1649), show the influence of his friend Quevedo. Revised by A. R. Marsh.

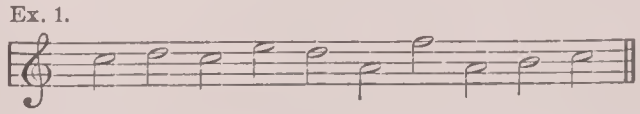
Melodeon: See Reed Instruments.

Melodra'ma [from Gr. *μέλος*, song + *δρᾶμα*, drama, liter., production, deriv. of *δρᾶν*, make, produce]: a name first bestowed upon the opera by Rinuccini, but now more frequently given to a non-operatic play of a semi-tragic or serious character, and marked by sensational, effective, or startling situations, and by exaggerated sentiment.

Melody [from O. Fr. *melodie* < Lat. *melo'dia* = Gr. *μελῳδία*, singing, melody, choral song; *μέλος*, song, tune + *ᾠδή*, song, words of a song]: in music, a connected series of single sounds, so arranged and linked together as to become capable of expressing some sentiment, and stirring up pleasurable, religious, patriotic, warlike, tragic, or other emotions. It is not every succession of sounds that can properly be called a "melody," for sounds in any number may be produced by voice or instrument which are unrelated, devoid of form, rhythm, accent, and symmetrical arrangement, and are therefore unmeaning, and incapable of awakening any feeling other than that of weariness. The music of the ancient Greeks appears to have been of a type not unlike this, however admired and extolled in its own day, when true melody was unborn, and music and noise were nearly akin. To our perceptions the music of the ancients seems to have consisted of a mere succession of intervals, selected without taste and refinement, and laid together without skill, design, or any trace of elegance and inspiration. The fragments that remain to us of such music, while valuable as curiosities and historical relics, are yet so sterile as to yield no indications of that connection of thought and richness in ideas which we look for now in what bears the name of "melody."

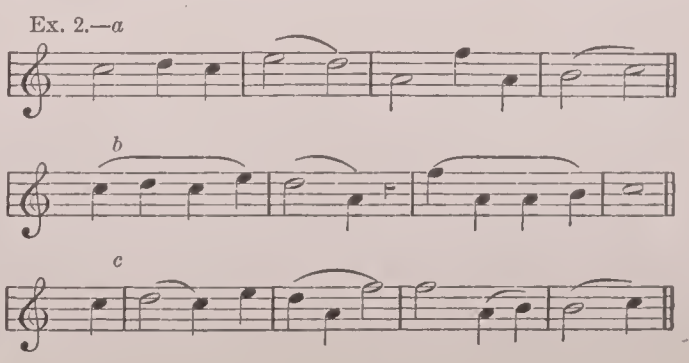
In the conception or formation of melody far more is implied than the mere arranging of several sounds or notes in any haphazard order of succession. Considerations of key and scale, mode, rhythm, time, accent, cadence, and rules affecting the progressions of certain intervals, are all to be taken into account if from any series of notes we would form a melodious strain, having in itself evidence of meaning and design. To illustrate this, we give in Ex. 1 a short train of notes, which, taken just as they stand, express little or nothing:

Ex. 1.



These same unmeaning notes, however, when molded into form and regularity by the application of rhythm, and by various changes of their time-values, as at *a*, *b*, and *c* in Ex. 2, are found to assume more or less of a melodious character:

Ex. 2.—*a*



Under still freer treatment, as at *a*, *b*, and *c* in Ex. 3, the dryness of the original notes entirely disappears, and the qualities of a simple but true melody are distinctly apparent:

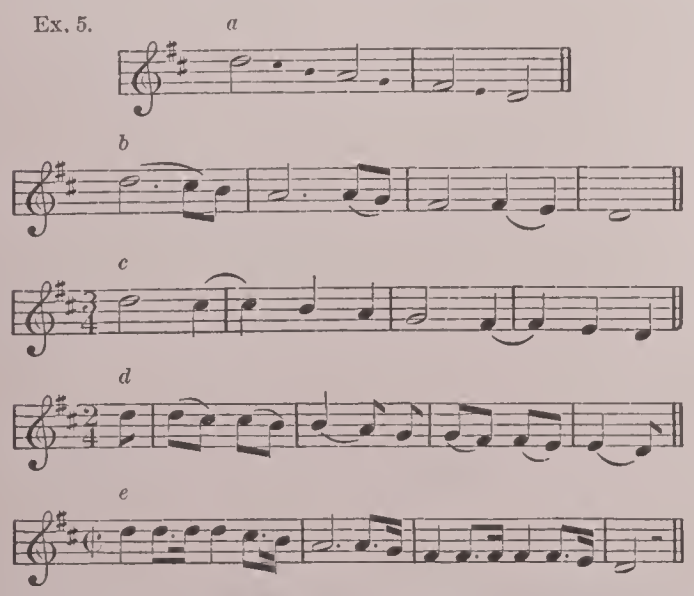
Ex. 3.—*a*

By dint of art and contrivance the most meager and limited series of notes may thus become the origin and source of many melodious ideas and progressions, often interesting and attractive, and suggestive also of still other ideas by the simple laws of association. In Ex. 4, at *a*, see a formula of only five notes, from which the melodies at *b*, *c*, and *d* are derived, and into which they may again be readily reduced:

Ex. 4.

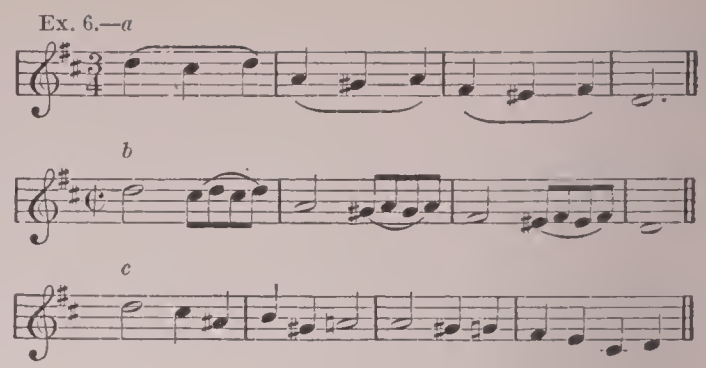
In the derived melodies given in the above examples no other notes have been used than those found in the rough formulas from which they spring. It will be observed, also, that those melodies have been produced chiefly by the addition of *rhythm* and of variations of the *times* of the original notes; but the field of invention is much enlarged, and the process of creating new melodies greatly facilitated, first, by filling up with notes the intervals made by skips in the original sketch, and using such notes as occasion serves. See Ex. 5, where at *a* the notes thus gained are marked by black dots, and several of the melodious forms obtained are shown at *b*, *c*, *d*, and *e*:

Ex. 5.



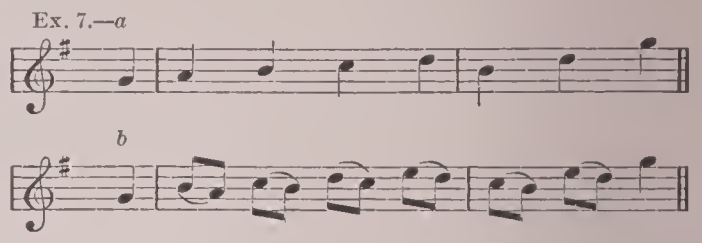
Second, by a judicious use of the semitone *below* any prominent note of the model, in the manner of an accidental leading-note, as in Ex. 6, at *a*, *b*, and *c*.

Ex. 6.—*a*



Third, by a similar use of the note *above*, as in Ex. 7, at *b*, where the progression may be compared with the plain notes at *a*:

Ex. 7.—*a*



Fourth, by the use of both the note above and the semitone below, by which means the plain notes at *a* in the last example may take such forms as appear at *a* and *b* in Ex. 8:

Ex. 8.—*a*

Fifth, by a discriminating use of a lengthened semitonic appoggiatura where the current of the melody naturally suggests it. See Ex. 9, where the plain notes at *a* are cast into form at *b*, and enforced by appoggiaturas. At *c*, the appoggiaturas are accompanied by suspensions and marks of emphasis:

Ex. 9.

Sixth, by the use of harmonic intervals in arpeggio form, either as the prevailing character of the melody, or as a passing relief to the ordinary motion when it consists of direct and contiguous intervals. It is to be observed, however, that as melodies of this kind consist chiefly of broken *chords*, their progressions must be such as are proper to those chords and in conformity with the rules of musical harmony. Instances of such melodies are given in Ex. 10, at *a* and *b*:

Ex. 10.—*a*

The observations thus made on the development of melody are to be taken, of course, rather as hints than rules. Melody is so dependent on the power of imagination and the existence of a creative talent as to render it far less amenable to laws and restrictions than the harmony by which it is accompanied. Revised by DUDLEY BUCK.

Melon [viâ O. Fr. from Lat. *me'lo, melo'nis*, clipped form of *melo'pepo, melopepo'nis* = Gr. μηλοπέπων, liter., apple-melon; μῆλον, apple + πέπων, kind of large melon]: a term applied to the fruits of various plants of the family *Cucurbitaceæ*, especially to *Cucumis melo*, the true melon or muskmelon, and to *Citrullus vulgaris*, the watermelon.

Muskmelons—The muskmelon is probably indigenous to India and adjacent parts of Asia, and there is some reason to suppose that it was also aboriginal in parts of Africa. It is now widely distributed, and it has run into numerous and very diverse forms. In fact, it is one of the most variable of all plants. The most serviceable classification of the many forms will be found to be approximately as follows:

1. *Cucumis melo*, var. *agrestis*, comprising the supposed wild forms of Oriental countries.

2. Variety *cantaloupensis*, the cantalopes, or melons distinguished by hard and more or less scaly, warty, or rough rind, often deeply furrowed. The name is derived from Cantaluppi, a former country-seat of the pope, near Rome, where these melons were early grown from Eastern sources. The cantalopes are prized in the U. S., particularly in the Southern States, where the name is sometimes used generieally (but erroneously) for all muskmelons. There are many cultivated forms.

3. Variety *reticulatus*, the netted melons, eommon in the Northern States, where early melons are essential, and known, as a class, by a more or less finely netted or rugose, but not deeply grooved rind.

4. Variety *saccharinus*, or sugar-melons, comprising a group of oblong melons represented in the U. S. chiefly by the pineapple class.

5. Variety *inodorus*, the seentless or winter melons. These are very little known in the U. S., although they are eommon in parts of Europe. They are hard-skinned green or yellow melons, which ripen late and keep until midwinter. Some of them are of good quality.

6. Variety *flexuosus*, serpent-melon or snake-cucumber. This is a strange variety in whieh the fruit is as long as one's arm and no thicker, with a very small core. It is grown mostly for curiosity, although it is edible.

7. Variety *acidulus*, or eucumber-melons of India, scarcely known in the U. S. The group comprises various sourish fruits of oblong or cylindrical form, yellow or mottled.

8. Variety *dudaim*, the curious Dudaim or Queen Anne's pocket melon, sometimes called vegetable pomegranate. The fruits are the size of a turkey's egg, beautifully mottled with yellow and brown, and exhaling a powerful and delicious perfume. They are grown for curiosity and for scenting wardrobes, but are not edible. This plant is sometimes sold by seedsmen as *Cucumis odoratissimus*.

9. Variety *chito*, the Chito melon, introduced into the U. S. under a variety of names, as vegetable orange, vine-peach, garden-lemon, melon-apple, and the like. The plant is slender, covering but a small space, and the fruits—the size of a hen's egg or an orange—are lemon-yellow with a clear white, slightly acid cucumber-like flesh. The little fruits are used for making pickles or eonserves.

10. Variety *erythræus*, or red Persian melons, not grown in the U. S.

The muskmelon is a popular fruit in North America, where it thrives over a wide territory because of the hot sunny summers. Varieties are grown in the Canadian provinces with entire success. In the year 1889 there were eighty-eight varieties of muskmelons on sale by North American seedsmen. The plant is very impatient of cold, and also of backward and poorly drained or hard soil. The seed should be put in the ground only after the weather is thoroughly settled. For early crops, especially in the northern parts of the U. S., the plants are often started in hotbeds or cold-frames in pots, boxes, or on inverted sods. The soil in which the crop is grown should be very rich and thoroughly tilled. All coarse new manures should be avoided. The plants are allowed to stand in hills, two to four together, 5 or 6 feet apart each way. Two to three pounds of seed is required for an acre. Some of the leading varieties are Nutmeg, Netted Gem, Osage, Hackensaek, Montreal Market, Christiana, and various cantalopes. The supposition that melons and cucumbers will mix when planted together is erroneous.

There are various diseases and enemies of the muskmelon. A downy mildew (*Plasmopara cubensis*) attacks the foliage, and should be treated with Bordeaux mixture. (See Fungicide.) The leaf-spot, due to a fungus of the genus *Phyllosticta*, which also attacks the shoots, can probably be checked by spraying with the Bordeaux mixture. A bacterial trouble, for which no remedy is yet known, is serious in many places. It attacks various parts of plants, but is usually a kind of damping off of the stems when the plants are young. Many insects feed upon the melon, although the plant seems to have no specific enemies. The melon-worm (*Phakellura hyalinitalis*) is confined mostly to the Southern States. The larva, a long green caterpillar, bores through the flesh of the melon. These worms feed upon the leaves while young, however, and in this stage they can be killed by Paris green. (See Insecticide.) The striped beetle (*Diabrotica vittata*), which feeds upon the young plant, can usually be repelled by sprinkling lime or plaster saturated with kerosene oil or turpentine about the plant; or a mixture of lime and sulphur may answer the purpose. If these repellents are not suecessful, Paris green should be sprayed upon the plant.

In 1890 there were 28,477 acres devoted to muskmelons in the U. S. upon the large truck-farms. This acreage was widely distributed, being largest in the Central States E. of the Mississippi, and in the territory tributary to New York city and Philadelphia. In the same year, also, 5,149 acres of muskmelons were grown for seed purposes.

Watermelons.—See Watermelon.

The Chinese preserving melon is the *Benincasa cerifera*, the hairy and resinous fruit of which is used for making conserves.

L. H. Bailey.

Melozzo da Forlì: See Forlì, Melozzo.

Melpom'ene [= Lat. = Gr. Μελπομένη, liter., singer, the singing one, fem. pres. partic. of μέλπεσθαι, sing]: one of the nine Muses—the Muse of Tragedy. As represented by Greek art she bears a mask, Heracles's club, or a sword, is shod with buskins, and wears on her brows a garland of ivy or vine leaves.

Revised by J. R. S. S.

Mel'rose: a village of Roxburghshire, Scotland; 31 miles S. E. of Edinburgh; containing the ruins of the celebrated Melrose Abbey (see map of Scotland, ref. 12–I). A Columbite monastery of Melrose stood at the place now known as Old Melrose, about 1½ miles to the E. of the village; but that building, which was not distinguished by any architectural magnifieence, was destroyed in the ninth century. The present abbey was founded in 1136 by David I., but destroyed in 1322 by the English under Edward II. It was rebuilt in 1326 by Robert Bruce and David II., but suffered severely in 1385 and 1545 by the English, and still more during the Reformation. While standing in its original splendor it was the finest structure in Scotland and a remarkable specimen of Gothie architecture; now it is only a ruin, though the church has been fairly well preserved.

Melrose: city; Middlesex co., Mass. (for location of county, see map of Massaehusetts, ref. 2–H); on the Boston and Maine Railroad; 7 miles N. of Boston. It contains 9 churches, public library founded in 1871, electric lights, public park, 3 public halls, 2 hotels, 2 club-houses, a national bank with capital of $100,000, a savings-bank, a monthly and 2 weekly newspapers, and manufactories of boots and shoes, sewing-machine needles, furniture, etc. Pop. (1880) 4,560; (1890) 8,519; (1900) 12,962.

Editor of "Journal."

Melton-Mowbray, mel'ton-mō'brĕ: a market-town, in the county of Leicester, England: at the confluence of the Wreake and the Eye; 15 miles N. E. of Leicester (see map of England, ref. 9–I). It has large breweries and tanneries, an important cattle-market, and a considerable trade in Stilton cheese. It is the center of a large and celebrated hunting district. Pop. (1891) 6,392.

Mel'vil, or **Melville**, Sir James, of Hallhill: courtier; b. at Raith, Fifeshire, Scotland, about 1535; went to France in early youth as page to Mary Stuart, who was betrothed to the dauphin; was for nine years a gentleman of the household to the Constable Montgomery, and was employed for three years at the court of the elector palatine; traveled in Italy; returned to Scotland when his former mistress had become Queen of Scots, and was appointed by her privy councilor and member of the royal household. He was closely connected with political affairs for several years, but having opposed the queen's inclination in favor of Bothwell after the murder of Darnley, he was obliged to consult his own safety by withdrawal from court. After the overthrow of the queen's party Melvil returned to court, enjoyed the confidence of the four suecessive regents who governed the country during the minority of the heir, and when King James assumed the direction of affairs was appointed a

privy councilor. When James succeeded to the throne of England, Melvil retired to his estate at Hallhill, where he died Nov. 13, 1617. His name had been nearly forgotten, when in 1660 a collection of manuscripts left by him was discovered in Edinburgh Castle, and found to contain important data concerning the reigns of Mary and James. They were published in 1683 by George Scott, under the title *The Memoirs of Sir James Melvil of Hallhill, containing an Impartial Account of the most Remarkable Affairs of State during the Last Age, not mentioned by Other Historians*, etc. This edition was incomplete; the first perfect edition was published in 1827–33 by the Bannatyne Club, which also printed Melvil's *Diary* (1829).

Melville: an island of British North America; situated in the Arctic Ocean between lats. 74° and 77° N., and between lons. 105° and 117° W., bounded W. by Fitzwilliam and Kellet Straits, S. E. by Melville Sound, and S. W. by Banks Straits. It was discovered in 1819 by Capt. Parry, who wintered here with his crew, and further explored in 1851 by Lieut. McClintock.

Melville, Andrew: clergyman and educator; b. at Baldovy, near Montrose, Scotland, Aug. 1, 1545; was educated at the University of St. Andrews, which he left in 1564 with the reputation of being "the best philosopher, poet, and Grecian of any young master in the land"; studied law and theology in Paris and elsewhere on the Continent; became a teacher at Poitiers (1566), and afterward (1569–74) was professor at Geneva, through the influence of Beza. Returning to Scotland in 1574 he was appointed principal of the University of Glasgow. In 1580 he was made principal of St. Mary's College, St. Andrews. In 1582 he preached the opening sermon before the Presbyterian General Assembly, boldly attacking the interference of the court with religious liberty, and headed a deputation which presented a remonstrance to King James at Perth. He was moderator of the General Assembly in 1587, 1589, and 1594; was made rector of the university in 1590; and was recognized as the most prominent member of the Scottish National Church. In May, 1606, James being King of England, Melville was summoned to London with other Presbyterian divines to confer upon Scottish ecclesiastical matters, and, having denounced the Archbishop of Canterbury for encouraging popery, was committed to the Tower 1607, where he remained four years. In 1611 he was released at the request of the Duke of Bouillon, who appointed him Professor of Theology at Sedan, where he died in 1622. He published a number of Latin poetical paraphrases of portions of the Bible, the best of which, the *Song of Moses*, is accounted an elegant production. His epigrams were very neat, and sometimes brought him into trouble, especially one written in ridicule of the chapel services at King James's English court. See his *Life* by Dr. Thomas McCrie (Edinburgh, 1819; 2d ed. 1823). Revised by W. J. Beecher.

Melville, George John Whyte: novelist; b. near St. Andrews, Scotland, 1821; entered the army in 1839; became captain in the Coldstream Guards 1846, and retired in 1849, but served again in the Turkish cavalry during the Crimean war. He wrote several novels, which became popular in both Great Britain and the U. S.; among them are *Captain Digby Grand* (1853); *Holmby House* (1860); *The Gladiators* (1863); *Sarchedon* (1871); and *Katerfelto* (1875). He also published a translation of the *Odes* of Horace and a volume of *Songs and Verses*. D. Dec. 5, 1878. Revised by H. A. Beers.

Melville, George Wallace: engineer-in-chief U. S. navy; b. in New York city, Jan. 10, 1841; was educated in public schools in New York, N. Y., and at the Brooklyn Polytechnic Institute; served an apprenticeship in an engineering establishment in Brooklyn; entered the U. S. navy July 29, 1861, as third assistant engineer; became chief engineer in 1881; and engineer-in-chief of the navy 1887, and was reappointed in 1891 for a term of four years. In the latter position he has contributed largely to the building up of the new U. S. navy. The most remarkable of his designs as an engineer is that of the triple-screw machinery for two swift cruisers. He has also developed a plan for increasing the speed of ships by lengthening the smoke-stacks. During the civil war he frequently volunteered for desperate service. In 1879 he joined the Jeannette expedition. (See De Long, George Washington.) After the Jeannette was crushed in the ice and he had conducted the crew of his own boat to safety, Melville conducted a search, amid the greatest hardships, for the crews of other boats. The story of this experience is told in his book *In the Lena Delta* (Boston, 1885). For his heroic conduct in these circumstances Congress in 1890 passed a special act advancing him one grade. C. H. Thurber.

Melville, Herman: novelist; b. in New York, N. Y., Aug. 1, 1819; shipped as a common sailor when eighteen years old; deserted in 1842 from a whaling-ship at the Marquesas islands, remaining four months a prisoner in Typee (Taipi) Valley, Nukaheva; escaped, and returned in 1844 to the U. S. He published *Typee* (1846); *Omoo* (1847); *Mardi* (1849); *Redburn* (1849); *White Jacket* (1850); *Moby Dick* (1851); *Pierre* (1852); *Israel Potter* (1855); *The Piazza Tales* (1856); *The Confidence Man* (1857); *Battle Pieces and Aspects of the War*, poems (1866); *Clarel*, a poem (1876); *John Marr and Other Sailors*, a story, privately circulated (1888); *Timoleon*, poems (1891). He married a daughter of Chief Justice Shaw of Massachusetts in 1847. In 1850 he removed from New York to Pittsfield, Mass. In 1860 he made a voyage around the world, and on his return held for some time a post in the New York custom-house. D. in New York, Sept. 28, 1891. Revised by H. A. Beers.

Membranous Angina: See Diphtheria.

Membré, măăn'brā', Zénobe, or Zenobius: missionary; b. in Flanders in 1645; entered the Franciscan order; went as a missionary to Canada in 1675; accompanied La Salle upon his expedition to the Western rivers 1679; remained at Fort Crèvecœur, on Lake Peoria, with Tonty, whom he aided in effecting a peace between the Iroquois and Illinois Indians; descended the Mississippi with La Salle 1681; returned to France the same year; wrote a narrative of the expedition, which was published by his cousin, Chrétien Le Clercq, in his work *Établissement de la Foi dans la Nouvelle France* (1691); became warden of a convent at Bapaume, France; returned to North America; accompanied La Salle in his final expedition to Texas by sea 1684, and remained in Fort St. Louis on Matagorda Bay, where, with other colonists, he was massacred by the Indians in Jan., 1689. Membré's narrative is based upon the official report of La Salle. It was plagiarized by Hennepin (1697), and by some authorities is ascribed to La Salle himself. See Parkman, *The Discovery of the Great West* (Boston, 1869); Sparks, *Life of La Salle* (Boston, 1844).

Memel, mā'mel: town of Prussia, founded in 1252; on the great fresh lagoon called the Kurisches Haff; 70 miles N. N. E. of Dantzic (see map of German Empire, ref. 1–K). It has a large and safe harbor, considerable ship-building, manufactures of ropes, sailcloth, and linens, distilleries, breweries, and iron-foundries, and a very important trade in corn, hemp, flax, timber, and amber. Pop. (1891) 19,282.

Memlinc, John: painter; b. at Damme, near Bruges, in 1450; date and place of death unknown, as also where he learned his art. He was a soldier for some time, and was taken into the hospital out of charity, in return for which he left to it his *Adoration of the Shepherds*, one of his finest pictures. He lived at Bruges, where he painted a *Virgin and Child with Saints*, a *St. Christopher* carrying the infant Christ across the river, the martyrdom of a saint, a crucifixion with the Virgin, St. John, and other saints; also the *Story of St. Ursula*. All these works are painted in tempera. W. J. Stillman.

Memnon: a name of several persons, the most remarkable of whom was the son of Tithonos and Eos, who after the death of Hector brought the Æthiopians to the assistance of Priam in the war against Troy. His adventures were the subject of the poem by Arktinos called the *Aithiopis*, according to which his armor was made by Hephaistos or Vulcan. Although of dark color, he was distinguished for his beauty. He killed Antilochos, the son of Nestor, in single combat, and was himself subsequently killed by Achilles. His mother, Eos, had in vain pleaded before Zeus against Thetis for the life of Memnon, her son, and was present with the daughters of the Sun at the fight. Ajax challenged him to single combat, and, Memnon being wounded, Achilles came and pierced him through the neck. The ancient works of art, however, represented a monomachia or single combat between Achilles and Memnon alone over the dead body of Antilochos. Eos carried in her arms the naked corpse of her son out of the battle-field. A flower, the *Paphlagonios*, was supposed to have sprung from the earth out of his blood. His body, according to some traditions, was burned on a pyre in the plains of Troy, and the ashes sent to his country or his sister Hemera, or to the Æsopos, where a mound was

erected for his grave, or else in the Trojan territory. His companions, the Æthiopians, or Negroes, always thus represented in ancient art, were changed into birds which contended at his pyre and frequented his grave. (For a discussion of Memnon in art, chiefly vase-paintings, see Baumeister, *Denkmäler*, under *Memnon*.) Other and later traditions make Memnon come to Troy with 20,000 Æthiopians and Susians and 20 war-chariots, by order of Teutamos, King of Assyria, and state that the palace or city of Susa was called Memnoneion, because Memnon had built it. The name of Memnon was connected at the period of the Roman empire with that of Amenhetp or Amenophis III., of the eighteenth Egyptian dynasty, about B. C. 1400, and attached to the northernmost of the seated colossal statues still remaining on the west bank of the Nile at Thebes, where they formed part of a dromos or row of statues leading to the pylon or gate of the Amenopheum, or palace of Amenophis in that quarter. The two statues still remaining amid the ruins of eighteen others, all made of a breccia sandstone, bear the name and titles of Amenophis III., and the most northern gave out sounds at sunrise when touched by the morning beams, supposed to be the salutations of Memnon to his mother, Eos or Aurora. The statue was said to have been broken in two by Cambyses (B. C. 525), and was called by the Thebans Phamenoph. The upper part appears really to have been thrown down by an earthquake B. C. 27, and continued so till A. D. 170, when it was set up and restored by brickwork, but ceased to give out sounds. In that interval seventy-two inscriptions were cut in Greek and Latin on it, recording the visits of Roman military officers, prefects, and others, some of which are dated, the earliest one mentioned being in the eleventh year of Nero (A. D. 64), and the last, A. D. 194. These record, sometimes in verses, the visit of the writer, and attest that he has heard the voice of Memnon. The most remarkable visit was that of the Emperor Hadrian and his wife Sabina (A. D. 130), recorded in verses by Julia Balbilla, a poetess in their suite. There has been much speculation as to the cause of the harp-like sound or tone given forth by the statue, which was heard emanating from the pedestal by several modern travelers in 1821 and later. It has been attributed to the expansion of the stone by the warmth of the sun, a phenomenon occurring occasionally in certain mountains, or to the frauds of the priests. Certain parts of Egyptian Thebes were named Memnoneia in honor of Memnon. Some historical personages of this name are known, as a Rhodian who revolted against Artaxerxes Ochos and fled to Philip, King of Macedon, but subsequently returned to the service of Persia, where he repulsed the first attempts of the Macedonians to establish their forces in Asia Minor, and became under Darius the commander-in-chief of the latter's forces, and fought against Alexander the Great the battle of Granicus (B. C. 334). His plans of the campaign were unfortunately not followed, and after an unsuccessful attempt to defend Ephesus and Halicarnassus, which he burned, Memnon retired to Mitylene, where he died B. C. 333. There was also a historian of this name, who wrote the local history of Heraclea of Pontus in the beginning of the second century A. D., and an Æthiopian people between the Nile and Astapus called Memnones, probably from their supposed resemblance to the hero of the Trojan war.

Revised by J. R. S. STERRETT.

Memno'nium [= Gr. Μεμνόνιον]: a building at Abydos (Egypt. *Abet*), located 8½ miles W. of the Nile in Upper Egypt (lat. 26° 12′ N). This designation, probably derived from the Egyptian *mennu*, monument, was first applied in the Alexandrian period. The building is described by Strabo (xxvii., i, 44) as one of great magnificence. It was quite different in purpose from the ordinary temple, being a mortuary sanctuary devoted to the memory of the builder and his ancestors. Its ground-plan resembles the letter L. It was begun by Seti I. and continued by Ramses II., as is shown by an inscription dating from the latter's first year. The most important information which it has furnished is found in the "Tablet of Abydos," engraved on one of the walls of an interior passageway. (For a copy of the original, see Meyer's *Geschichte des alten Aegyptens*, p. 10, plate). This tablet contains the names of seventy-six Pharaohs arranged in three rows, the lower of which is devoted to the name of Seti I., the same being repeated in the form of both prenomen and name nineteen times. This list is more important and complete than any other which the monuments have preserved (Karnak, sixty-one names; Saqqarah, forty-two; Temple of Ramses, eighteen), though the names actually given represent only a selection from the whole number. In the list given by Budge (*The Mummy*, p. 77 ff.) the name of Seti I. is the 178th in order, while this tablet makes it the seventy-seventh. An ancient temple is known to have stood here, which underwent repairs in the twelfth dynasty, but its remains are indistinct. Abydos was one of the oldest and most sacred places in Egypt, on account of its containing the reputed burial-place of Osiris. Here it was customary for all pious Egyptians to be buried, at least temporarily, in order to enjoy the benefits conferred by nearness to Osiris. The practice of setting up commemorative stelæ, or small chapels, even when the dead were deposited elsewhere, has made the place a mine of information concerning Egyptian biography and history. The tablet of Una, an official of the sixth dynasty, is a specimen of such monuments. It was found in the oldest necropolis (sixth to eleventh dynasty) just W. of the Memnonium. The necropolis dating from the twelfth and thirteenth dynasties is located to the N., and that employed after the nineteenth dynasty to the S. The pyramid tombs N. and W. of the temple are of peculiar interest, as showing the actual purpose of pyramidal structures. Abydos was reputed to have been a large city at one time, on the basis of the statements of Strabo, but there is little monumental evidence to support him; it was near the seat of the earliest culture, since This, or Thinis, the birthplace of Menes the first king, was only a few miles to the N. CHARLES R. GILLETT.

Memorial Day: See DECORATION DAY.

Memory [O. Eng. *memorie*, from O. Fr. *memoire* < Lat. *memo'ria*, deriv. of *me'mor*, mindful, remembering; cf. Eng. *remember*, from Lat. *rememora'ri*, to have brought back to one's mind]: a psychological subject which early attracted the attention of the ordinary man and of the professed philosopher. It is frequently discussed in current literature and daily conversation, and it has been investigated with success by modern scientific psychology. The earlier psychology consisted chiefly of descriptions of mental phenomena, obtained from introspection and observation. Descriptive psychology has been supplemented or developed in three important directions: (1) by investigation of the relations of body and mind; (2) by the study of disease; and (3) by experiment.

Descriptions of Memory.—From the Greek philosophy onward to the handbooks of psychology of the present day, a prominent place has been given to descriptions of the phenomena and conditions of memory. Those experiences are best remembered which are most recent, most interesting, best attended to, and most often repeated. The kind of memory possessed by an individual depends largely on his character, interests, and daily life. We may distinguish susceptibility, retentiveness, and readiness. The man of the world may have a good desultory memory, the daily gossip of society and of the newspapers may be readily picked up, repeated, and forgotten; whereas the student may remember chiefly those things which fit into his special study, but then they become a permanent part of his mental life. Many stories have been collected of extraordinary casual memory in persons who were not otherwise noteworthy. Thus we are told of servants, and even imbeciles, who could repeat pages in a language they did not know, on hearing them read once, or of a farmer who could remember the state of the weather on every day for forty-two years. Cases are known of remarkable memory in great men—Pascal, Euler, Leibnitz, and many more—and as great men are but few, we must conclude that good memory is more likely to be associated with genius than with mediocrity. Indeed, we may affirm without hesitation that good memory is a condition of successful accomplishment in any work. It has been noted that in childhood the memory is quick, but not retentive, whereas in old age new impressions are remembered with difficulty. Memory is closely related to other aspects of mental life. Thus we may say that we "remember" that acetate of lead is sweet, but we say we "know" that sugar is sweet. So also imagination, association of ideas, feeling, and action are closely connected with memory, and many aspects of memory can best be treated in connection with a general account of mental phenomena. See PSYCHOLOGY.

Physiological Basis of Memory.—Plato illustrated memory by a piece of wax which takes and preserves impressions, and this figure has been gradually developed as an actual fact of the nervous system. We may not like to explain states

of consciousness by their physiological conditions, but in the case of memory no reasonable psychological explanation has been proposed. To say that all our past experience is stored away in sub-consciousness and that the ideas strive to secure a place in consciousness would seem to be merely a figure of speech. We might nearly as well say that future sensations are in sub-consciousness struggling to arrive in distinct consciousness. From the point of view of scientific psychology we may best regard the physical world in the case of our sensations, and more or less permanent modifications of the nervous system as the cause of our memories, at least so far as retention is concerned. The principle of the inertia of matter is of such universal application that it does not seem to require an explanation. Bodies remain in their state of rest or motion until they are made to change that state by external forces. If the nervous system be modified in a given way, e. g. by a new series of sounds which in consciousness make a melody, the traces of the modification will remain until effaced by new impressions or the metabolism of the tissues. The inertia of the nervous system thus seems to account for both retention and effacement. Indeed, it even accounts for the details of memory, such as the more enduring retention of intense, interesting, or often repeated impressions, the better memory for recent events, the distinction between susceptibility, retentiveness, and readiness, the variations with age and state of health, etc. Physiological considerations also enable us to understand the close relations between memory and habit. When a movement has been often made it follows more readily, and may even take place without consciousness. The latent modifications of the nervous system which account for an acquired reflex movement may be regarded as similar to those which account for the retention of past experience. The facts of heredity, however obscure, must also in some way be due to the persistent modification of organic matter. Further, the known anatomical structure of the brain throws some light on the matter. We find there nerve-cells and nerve-fibers, and can picture to ourselves not only the more or less permanent modification of the parts, but also the gradual formation and deepening of paths which may represent association and recollection. It must, however, be acknowledged that we can only form general and schematic plans of the modifications and processes which condition retention and recollection. The actual alterations in the nervous system are not known from physiological observation and experiment; we have only hypotheses based on our general physical principles and on psychological observation of the facts of memory, and of course we do not know why given modifications of the nervous system are accompanied by given states of consciousness, nor why organic continuity is accompanied by self-consciousness and personal identity.

Diseases of Memory.—The dependence of memory on physiological conditions is further emphasized by the facts of pathology. A blow on the head may cause loss of memory, or a disease in a special part of the brain may cause a peculiar defect in memory. Pliny mentions the case of a man who forgot only the names of the letters after receiving a blow from a stone, and cases of *amnesia* of various sorts have attracted much attention. After an accident, the occurrences immediately preceding, say for an hour or two, may be entirely blotted from memory, and never recovered, or they may gradually return to mind. After severe illness the entire past life of the patient may be effaced—he must begin from the beginning and learn to read, etc. Sometimes, after complete amnesia, the past and its experiences return almost suddenly to consciousness. The most curious cases are those of alternating PERSONALITY (*q. v.*). A patient may forget his past life and become entirely different in interests and character; this may last for a while—weeks, or even years—and he may then return to his original personality and have no memory of the intervening period. The patient may in his ordinary condition be of good moral character, whereas he may be wayward or criminal in the secondary condition, or, on the contrary, his character may be improved in his secondary condition. Temporary lapse of memory occurs normally in sleep and is more marked in intoxication, in epileptic seizures, and in hypnotic trance. The memory may also be excited by disease, experiences being rehearsed in delirium which could not be recalled in health. In the case of APHASIA (*q. v.*), or loss of the power of speech, and *agraphia*, or loss of the power of writing, the localization of the brain lesion has been determined, and the various forms of the disease have thrown light on the normal processes of speech and memory. Under this heading may be mentioned an experience (paramnesia) which is scarcely a disease, as it seems to have occurred to nearly every one, the feeling that one is now living over again a past experience, usually accompanied by an emotion of mystery and weirdness. The phenomenon is probably sufficiently explained by some similarity of present surroundings to past experience.

Experiments on Memory.—We have seen that a satisfactory psychological explanation of memory has not been found, and that while its physical basis seems to account for the fact of retention, we are ignorant of the actual physiological processes concerned. However, exact observations and measurements of memory have been made which have enlarged our knowledge of the subject, and this on the side of psychology, not of physiology. It was known to Aristotle that when we regard a bright object and turn away the eyes, an after-image of the object persists. These after-images have been carefully studied and measured by many observers, and form a link between sensation and memory. Somewhat analogous to the after-image is the fact that a certain small part of immediately past experience always persists in consciousness. In fact, as Prof. James has remarked, the "present" of immediate experience is not a knife-edge, but a saddle-back, which experiments seem to show is in the neigborhood of ten seconds in width. What has happened during this interval is simultaneously in consciousness; thus in reading or conversation we take in the meaning of a sentence as a whole. We may next notice a peculiarly vivid form of memory, the so-called memory-image. If one has been searching for wild flowers, or working with the microscope, or watching machinery in motion, one may have very vivid images of the objects, and these persist for a long time and have many of the qualities of sensations. Then we have the power of calling up mental images of scenes. The individual differences in this respect have been studied by Fechner, Galton, and others with interesting results. Some people can call up a scene in imagination very vividly with the outlines, colors, etc., of the original objects, others can do this very imperfectly or not at all. With some the train of ideas is habitually accompanied by visual pictures, with others by sounds, with others by motor impulses, especially of speech. It should be noted that memory and imagination contribute a great deal to all our perceptions; thus in ordinary conversation what we hear is very largely supplied from our past experience. In this way illusions may occur—if one expect to see a ghost in a graveyard in the moonlight, one is quite likely to see a tombstone as a ghost.

Exact measurements have been made of the amount which can be remembered on one presentation, and of the number of repetitions required to learn by heart a series of impressions. Thus after a moment's exposure an observer could recognize and remember 6 letters, 4 disconnected words, or a sentence composed of 7 words. Ebbinghaus found that he could remember 7 meaningless syllables after a single reading. It required 16 readings to learn 12 syllables, 54 readings to learn 16 syllables, etc. There are considerable individual differences, and such experiments have been made on school-children with interesting results. Thus it has been found that there is a gradual increase in the "span of memory" with age and growth of intelligence, and the results can be used to measure attention and fatigue. Münsterberg has studied the part played by sight and hearing in memory. A series is best remembered when presented to two or more senses simultaneously. Thus in learning the letters a child should see them, and hear them, and name them, and write them. The rate of forgetting has been measured in several ways. Thus a light of a given intensity is shown to an observer and then a second light somewhat brighter or fainter, and what difference there must be in the lights in order that the observer may perceive the difference is determined. The interval between the two lights is then increased, and the greater "error of observation" measures the amount forgotten in a given time. Such experiments were first made by Weber, and have been extended by Wolfe and others. Another device is to measure the time required to learn a series of meaningless syllables. If the same syllables be used in a second experiment, the time is shorter, and the decrease in time may be used to measure the amount remembered. Thus in a series of experiments it was found that a saving of 58 per cent. in the time was secured after twenty minutes, 44 per cent. after one hour, 33 per cent. after one day, and 21 per cent.

after one month. We thus forget most rapidly at first: more is forgotten in the first hour than in the following month. It is commonly supposed that memory is strengthened by practice, but this is questioned by James, who has made experiments which do not show any improvement in retentiveness after practice.

Experiments have also been made measuring the time required for one idea to suggest another and for an act of memory. Thus it takes about half a second to name an object or a familiar color, whereas words, owing to the habitual association, can be named more quickly. The time required to name words in a foreign language measures familiarity with the language. It takes about a third of a second to add two numbers and about half a second to multiply them. Thus also has been measured the time required to remember in what country a city is situated, who is the author of a given work, etc. In this way individual differences may be determined, readiness and retentiveness compared, methods of education studied, etc. Ordinary accuracy of observation and recollection has been studied experimentally. Thus when a class of fifty-six college-students was asked what was the weather a week ago, sixteen answered clear; 12, rain; 7, snow; 9, stormy; 6, cloudy; and 6, partly stormy and partly clear. Such experiments, measuring the values of testimony, have important applications in the courts of justice and in other directions.

Bibliography.—Accounts of memory will be found in the standard handbooks of psychology, by James, Baldwin, Ladd, and Sully. An historical sketch by Burnham, with full references is contained in *The American Journal of Psychology*, vol. ii. Among special books on memory, see *Memory*, by Kay; *Das Gedächtniss*, by Fauth; and *Diseases of Memory*, by Ribot. Experimental papers are *Das Gedächtniss* by Ebbinghaus, and researches by Wolfe, Lehmann, Cattell, Müller and Schumann, Münsterberg and others, in *Philosophische Studien*, *Zeitschrift für Psychologie*, *Mind*, and *The Psychological Review*. See Aphasia, Mnemonics, and Psychology. J. McKeen Cattell.

Memphis [Gr. = Egypt. *Men-nefer*, pleasant dwelling; Coptic, *Memfe*, *Menfi*; Assyr. *Mempi*; Heb. *Moph* (Hos. ix. 6), or *Noph* (Isa. xix. 13, etc.)]: a city of Egypt; located near the apex of the Delta; the capital during the third to the fifth and the seventh and eighth dynasties. It was reputed on Greek authority (cf. Herodotus, ii., 99), to have been founded by Menes, but the Egyptian original (*Men-nefer*) does not appear till the sixth dynasty, when it was first applied to the pyramid of Pepi I. The "cities" of preceding Pharaohs had been built close to their pyramids and were unnamed; hence the city as a whole had a great north and south length and an immense area. During the Hyksos period the city lost its power, but it was revived and extended after the eighteenth dynasty. It was captured by the Ethiopian Pianchi and by the Assyrians. Strabo (xvii., i., 32) describes it as being large and prosperous. The Arabs deserted it, using it as a quarry for materials to build Cairo. Its destruction was not completed, however, till after the close of the twelfth century. About the middle of the nineteenth century Dr. Henry Abbott, an army-surgeon residing in Cairo, explored the site, and formed the valuable collection of antiquities now belonging to the New York Historical Society. Recently excavations have been renewed with some interesting results. At present the site is level with the ground and exposed to inundation, against which a dyke was erected in very ancient times. It is supposed that the intervening change of elevation has been insignificant. The center of the ruins is at *Mitrahineh* (29° 51′ N. lat.), whose mound is supposed to mark the great temple of Ptah (*Ḥā-ka-Ptaḥ*, House of the image of Ptah, the "sacred" name of the place). The city was also noted as the seat of the worship of Apis-Bulls (see Serapis), several of whose mummies are preserved in New York.

Charles R. Gillett.

Memphis: town; capital of Scotland co., Mo. (for location of county, see map of Missouri, ref. 1–H); on the Keokuk and West. Railroad; 45 miles W. of Keokuk. It is in an agricultural and stock-raising region; contains 7 churches, union school, business college, a national bank with capital of $50,000, 2 State banks with combined capital of $75,000, and 3 weekly newspapers; and ships large quantities of live stock. Pop. (1880) 1,418; (1890) 1,780; (1900) 2,195.

Editor of "Scotland County Democrat."

Memphis: city (laid out in 1820, incorporated as a city in 1831, had its charter repealed and was made a "taxing district" in 1879, and was reincorporated as a city in 1891); capital of Shelby co., Tenn. (for location, see map of Tennessee, ref. 7–A). It is at the head of navigation for large vessels on the Mississippi river, and on the Ches., O. and S. W., the Ill., Cent., the Kan. City, Ft. S. and M., the Kan. City, Mem. and B., the Little Rock and M., the Louisv. and Nash., the Mem. and Charleston, the St. L., Iron Mt. and S., the Tenn. Mid., and the Yazoo and Miss. Valley railways. It is the principal commercial point on the Mississippi river between St. Louis and New Orleans, is built on a bluff 80 feet above low and 40 feet above high water, has a waterfront of about 2 miles, with massive stone-paved wharves, and is the center of a large trade which is facilitated by its numerous railways and by regular steamboat connections with points on the Mississippi and other regions that naturally seek an outlet in the Gulf of Mexico. Its manufacturing interests are large, important, and rapidly increasing. The census of 1880 showed 138 manufacturing establishments, with $2,313,975 capital and 2,268 persons employed, which paid $845,672 for wages, and had products valued at $4,413,422; and that of 1890 showed 302 establishments, with $7,985,888 capital and 5,569 persons employed, which paid $2,874,526 for wages and $6,170,670 for materials, and had products valued at $11,800,455. The principal industries reported in 1890 were the manufacture of oil, cottonseed, and cake, 8 establishments, $1,511,632 capital, and $1,482,198 value of products; foundry and machine-shop products, 7 establishments, $1,308,750 capital, and $1,243,924 value of products; and lumber and planing-mill products, 10 establishments, $984,778 capital, and $1,462,733 value of products. The city is regularly and attractively laid out; has been provided with a thorough system of sewerage since the epidemic of yellow fever in 1878 (which bankrupted the city), and a water-service by the Holly system; has a steel railway-bridge across the Mississippi river, the third largest cantilever bridge in the world, opened May 12, 1892; and contains 4 national banks with combined capital of $2,250,000, 11 State banks with capital of $2,955,000, 3 other banks with capital of $720,000, 7 fire-insurance companies with capital of $780,000, and 3 daily, 15 weekly, and 2 monthly periodicals. In 1893 the city had a net debt of $3,132,100, a total assessed valuation of $39,637,950, and a tax-rate of $17.50 per $1,000. On June 6, 1862, a short engagement took place near Memphis, in which the Confederate fleet of eight vessels, under Commodore Montgomery, was defeated by the Union fleet of fourteen vessels, under Commodore C. H. Davis, and the city was thenceforth occupied by Union forces; in Aug., 1864, Gen. Forrest's Confederate cavalry entered and took several hundred prisoners. In 1879 the city became unable to meet its financial obligations and surrendered its charter. The Legislature designated the former city "the taxing district of Shelby County," and vested its control in a governing council of three commissioners, and a board of public works of five members. Under this council the improved system of sewerage was established, the debt compromised and funded, and the "district" brought into a condition that warranted its change into a municipality again in 1891. Pop. (1890) 64,495; (1900) 102,320.

Memphremagog, Lake: a beautiful sheet of water, extending from the village of Magog, Stanstead co., Quebec, Canada, to Newport, Orleans co., Vt.; 35 miles long and from 2 to 5 miles wide, and discharging its waters into the Magog river, a tributary of the St. Francis. Magog is connected with Montreal by the Canadian Pacific Railway, which reaches Newport viâ Mausonville, and with Newport, in summer, by a steamboat line; Newport is also connected with Sherbrooke, Quebec, by the Boston and Maine Railroad. The lake presents bold and striking scenery, and has on and near its shore many charming summer resorts. On its west side are Mt. Orford, over 3,500 feet above lake-level, and opposite Magog; Mt. Elephantis, to the S. W. of Georgeville, a village of summer residences; and Owl's Head, near the widening of the lake toward Newport. Among the places of special interest on the lake are Knowlton's Landing, on Sargent Bay, near the Bolton mineral springs; Kitteredge island, Gull Rock, and Black island, in the broad basin S. of Fitch Bay. Mausonville is on the Missisquoi river, in Brome County, Quebec, inland from the lake, W. of Owl's Head, and in a dairying and maple-sugar making region. Marbleton, in Wolfe County, Quebec, 25 miles from Sherbrooke, is the Canadian terminus of the Maine Central Railroad, and has extensive quarries of marble in its vicinity. Eighteen miles from Sherbrooke is Lake

Massawippi, extending from North Hatley S. through Stanstead County. It is a summer resort, and has excellent fishing within the shadows of the hills on its west side.
J. M. HARPER.

Mena, mā′năă, JUAN, de: poet; b. at Cordova, Spain, about 1411; studied at Salamanca and in Rome, and became Latin secretary and historiographer to John II., King of Castile. D. in 1456. He composed many verses in honor of his sovereign, the allegorical poems *Coplas de los Siete Pecados Mortales* and *La Coronación*, and an imitation of the *Divina Commedia* entitled *El Laberinto* (first printed in Seville, 1496). All these productions were extremely popular, and were printed in many editions soon after the introduction of the press into Spain, but they are no longer esteemed for poetic merit. In the literary history of Spain, however, Juan de Mena is important as one of the first imitators of Dante and introducers of that Italian influence which was powerfully felt by the best Spanish writers down to the seventeenth century. A collected edition of his works, under the title *Copilación de todas las obras de Juan de Mena*, was first printed in Seville, in 1528; and often since (e. g. Madrid, 1804, 1840). Revised by A. R. MARSH.

Menabrea, mā-năă-brā′ăă, LUIGI FEDERIGO, Count: statesman; b. at Chambéry, Sept. 4, 1809, of a Piedmontese family; studied mathematics at Turin; entered the Sardinian corps of engineers, and was appointed professor in technical science at the military academy and at the University of Turin while yet only a lieutenant. In 1848, having attained the rank of captain, he was employed in a diplomatic mission to the Italian duchies which were afterward annexed. He was elected a deputy, and served first in the ministry of War, then in the ministry of the Interior. In the war of 1859 against Austria he was chief of the staff. After the cession of Savoy and Nice to France the French Government endeavored to win him, as a native of Savoy, over to France, but he remained true to Italy, and Victor Emmanuel created him a senator. As chief of the engineering department he fortified Bologna, Piacenza, and Pavia; was made a lieutenant-general in 1860, and led the siege of Gaeta. In 1861 he became a member of the ministry of Ricasoli as Minister of the Marine, in which position he carried through several important reforms and devoted much interest to the building of the arsenal at Spezzia. In 1866 he was Italian plenipotentiary at the conclusion of peace between Austria and Prussia. In 1867, when the ministry of Rattazzi resigned, he formed a new cabinet, and took charge of the ministry of Foreign Affairs under difficult relations with France. In the Roman question he defended the rights of Italy against France, without suffering any breach to take place; he spoke for the annexation of Rome, but he imprisoned Garibaldi for his arbitrary intermeddling; thus he threaded his way between the hostile parties with great adroitness and without compromising the dignity of the Government. Only a few months after he entered office as president of the cabinet the imprisonment of Garibaldi brought him a vote of want of confidence in the house. He sent in his resignation immediately, but was induced by the king to remain and form a new cabinet. In May, 1869, the financial difficulties made another reorganization of the ministry necessary, but even after the accession of the new ministers Menabrea did not succeed in gaining the confidence of the house. On the opening of the session (Nov. 19, 1869) the Government proposed Mari for president, but Lanza was chosen, Menabrea resigned immediately, and Lanza became president of the cabinet. He was appointed ambassador at Vienna in 1870, at London in 1876, and at Paris 1882, where he continued to represent his Government till 1892. Menabrea was a mathematician and physicist. Prominent among his works are *Études sur la série de Lagrange* (Turin, 1844–47) and *Le génie italien dans la campagne d' Ancone et de la Basse-Italie* (Paris, 1866). His administration as president of the cabinet (only two years) brought order into the interior, and the relations of Italy to foreign countries were improved by his cautious policy. D. at Chambéry, May 25, 1896. F. M. COLBY.

Menado, me-naa′dō: town of Celebes, in the East Indian Archipelago; the capital of an important Dutch possession of the same name, comprising the whole northeastern peninsula of that island, and containing an area of 26,900 sq. miles, and a population of 540,000 (see map of East Indies, ref. 6–H). The high, volcanic surface of the territory is well adapted to coffee-culture; rice is also extensively grown. The value of exports of the district during one year amounted to 1,250,370 gulden. The town Menado has about 4,000 inhabitants. Revised by M. W. HARRINGTON.

Menai (men′ī) **Strait**: a narrow channel, 13 miles long and from 250 yards to 2 miles wide, between the island of Anglesea and Carnarvonshire, Wales, crossed by two bridges, the suspension and the Britannia bridge. At the entrance of the channel the tide sometimes rises 30 feet, and ordinarily from 10 to 12 feet. The navigation is difficult, but, as it saves time, the route is often chosen by vessels under 100 tons burden.

Menam′, or **Meinam′**: the principal river of Siam, of which it drains almost all of the western half. It rises in the mountains to the N. and N. W. of the kingdom, and after a southerly course of about 750 miles falls into the Gulf of Siam by a single estuary about 20 miles S. of Bangkok. It is a winding stream which in several cases subdivides into smaller streams, which reunite lower down. Its largest affluent is the Menam-Phe, which drains Central Siam and joins the main stream from the N. E. in the neighborhood of Ayuthia or Krung-Kao. Large ships can come up the Menam estuary to Bangkok. Small steamers can ascend to Ayuthia, about 50 miles farther up. Above this the river is navigable for small native craft to the rapids near Raheng, about 250 miles. MARK W. HARRINGTON.

Menamah, me-naa′măă: a city on the island of Bahrein, in the Persian Gulf, off the east coast of Arabia (see map of Persia and Arabia, ref. 6–G). It belongs to the British, and has 8,000 inhabitants. It is the center of the pearl-fishing industry of the gulf, and in the season is visited by many strangers. M. W. H.

Menander of Athens (Gr. **Μένανδρος**): one of the great chiefs of the New Attic Comedy; was born in 342, and was drowned in 291 B. C. while swimming in the harbor of the Peiræus. He was the son of aristocratic parents, and his uncle and trainer was ALEXIS OF THURII (*q. v.*), the famous poet of the Middle Comedy. He was rich, he was handsome, and it has been said that the only cross in his life was the cross in his eye. He had a house in town, a villa at the Peiræus, and his sweetheart, Glycera, was the type of all that is engaging in womanhood. Theophrastus and Epicurus gave him lessons in philosophy, and so well equipped for work and so happily circumstanced in fortune, he made a brilliant beginning in his art; but his early victory, gained when he was but twenty-one, was not matched by his subsequent career, and he was less favored by the public than were his rivals, especially PHILEMON (*q. v.*), though this comparative failure may have saved him from the weaknesses of the spoiled children of literature; but after his death the drama of Menander dominated the cultured world, and his verses were quoted and alluded to far into the Christian era. Plautus and Terence drew on him for sentiments and for plots, and of these Terence emulated his example so closely that he was called by Cæsar "a half but only half Menander." The ingenuity of his plots, the delicacy and penetration of his wit, the point and cogency of his maxims, the refinement of his language, and the sweetness of his temper made Menander a universal favorite, and his ideal still influences the comedy of situation and manners. Unfortunately, no play survives, and we are left to form our notion of Menander from imitations and quotations. Of his more than a hundred pieces, more than a thousand fragments have come down to us, not to speak of the hundreds of wise saws that have smuggled themselves in under his name. For the remains of Menander, see the collections of Meineke and of Koek. B. L. GILDERSLEEVE.

Menant, mā′năăn′, JOACHIM: Assyriologist; b. at Cherbourg, France, Apr. 16, 1820; studied law; became a magistrate of the civil tribunal at Havre, and acquired considerable celebrity as one of the earliest French decipherers of the cuneiform inscriptions of Assyria. He published, among other works, *Zoroastre* (Caen, 1844); *Recueil d'Alphabets des Écritures cunéiformes* (1860); *Éléments d'Épigraphie assyrienne* (1860; 2d ed. 1864); *Inscriptions assyriennes des briques de Babylone* (1860); *Inscriptions de Hammourabi, roi de Babylone au XVI^e siècle avant notre ère* (1863); *Exposé des Éléments de la Grammaire assyrienne* (1868); *Babylone et la Chaldée* (1875); and *Manuel de la langue assyrienne* (1880). He aided Prof. Jules Oppert in translating the *Grande Inscription de Khorsabad* (1865) and *Les Fastes de Sargon* (1863), and has published several learned essays in the *Journal* of the French Oriental Society.

Menasha: city; Winnebago co., Wis. (for location of county, see map of Wisconsin, ref. 5–E); on the Fox river at the outlet of Lake Winnebago, and on the Chi. and

N. W., the Chi., Mil. and St. P., and the Wis. Cent. railways; 18 miles N. of Oshkosh. It has a number of manufactories, a national bank with capital of $80,000, an incorporated bank with capital of $50,000, and two weekly newspapers. Pop. (1880) 3,144; (1890) 4,581; (1900) 5,589.

Menasseh ben Israel: See MANASSEH BEN ISRAEL.

Mencius, men'shŭs' [a Latinized form of the Chinese name *Mêng-tse*, *Măng-tse*, or *Mŭng-tse*, Mŭng the philosopher]: the most distinguished of the early Chinese philosophers after CONFUCIUS (*q. v.*); b. in the principality of Tsow (adjoining Loo, the native state of Confucius) about 371 B. C. The district city of Tsow-hien, in the department of Yenchow-foo and province of Shantung, claims the honor of being his native town, and there his lineal representative lives. He was in his third year when he lost his father, but his mother educated him so carefully and conscientiously that she is noted throughout China as the model mother. Thrice she changed her abode that he might be saved from the evil influences of unworthy surroundings. From his schoolboy days little is known of him until at the age of forty he emerged as a teacher of some note, with a large following of disciples. He acknowledged himself a disciple of Confucius, and Chinese critics consider it one of his greatest merits that he revived the influence and authority of that philosopher. He considered man good by nature, and his vices and miseries produced, like the stunted and distorted growth of a tree, by evil influences. The great problem, then, was to return to the original goodness, to set one's heart right. In politics he considered the interests of the people of prime importance, and emphasized the rights of the subject so strongly in opposition to those of the sovereign that he declared it righteous for a people to kill their ruler when he injured their welfare. Like Confucius, he traveled through the petty kingdoms into which China was then divided, setting forth his views, but met with little success, and the last fifteen years of his life were spent in retirement among his disciples. The date of his death is not certainly known, but it is stated that he was eighty-four years old when he died. His sayings are contained in the last of the *Four Books* which form the basis of all Confucian teaching. They were not admitted into the canon until near the end of the eleventh century. See Legge's *Chinese Classics* (vol. ii., London and Hongkong, 1861) and Faber's *Mind of Mencius*, translated by Hutchinson (London and Hongkong, 1880).

R. L.

Mendæans: See MANDÆANS.

Mendeléef, DIMITRI IVANOVITCH: chemist; b. at Tobolsk, in Siberia, in 1834; studied at the gymnasium there and at the University of St. Petersburg, where he became privat docent in 1856. After spending two years at Heidelberg, Germany, he became Professor of Chemistry at the Technological Institute of St. Petersburg in 1863, and professor in the university three years later. He is best known for his contributions to the periodic law (see CHEMISTRY). His *Principles of Chemistry* (1869) is one of the most suggestive text-books of chemistry. In 1882 he was awarded the Davy medal by the Royal Society of London, and in 1889 the Faraday medal by the Chemical Society. I. R.

Mendelssohn, men'dels-sōn, MOSES: metaphysician; b. at Dessau, in the duchy of Anhalt, Germany, Sept. 6, 1729, of Jewish parents; studied almost from infancy with the greatest energy, but under the hardest circumstances, the Bible, the Talmud, Maimonides, and afterward also modern literature, and became in 1750 tutor in a rich Jewish family in Berlin, and in 1754 bookkeeper in the firm. An accidental acquaintance with Lessing soon grew into an intimate friendship, and Lessing is said to have taken Mendelssohn as a model for his *Nathan*. He also associated with Nicolai, Abbt, and other literary persons, and began in 1755 to write for different periodicals. In 1763 his treatise on the *Evidence of Metaphysics* received a prize from the Academy of Berlin. In 1767 he published his *Phädon*, a dialogue on the immortality of the soul, which won a European celebrity. In 1783 appeared his *Jerusalem*; in 1785 his *Morgenstunden*, which exercised a considerable influence on his coreligionists. D. in Berlin, Jan. 4, 1786. A complete edition of his works was published by his grandson at Leipzig (1843–45). Mendelssohn possessed the gift of popularizing the philosophy of Leibnitz and Wolf, and of treating, after the model of English writers, religious, moral, æsthetical, and practical questions in a semi-philosophical common-sense manner. He must be considered the greatest of the so-called "popular philosophers" of the eighteenth century, and his theories concerning the beautiful, although based on antiquated psychological conceptions, had some influence on literary production, as may be seen, e. g., from his correspondence with Lessing. Mendelssohn was also one of the first who called attention to the almost forgotten philosophy of Spinoza. See Kayserling, *Moses Mendelssohn* (1882); Braitmaier, *Geschichte der poetischen Theorie und Kritik* (1889).

Revised by JULIUS GOEBEL.

Mendelssohn-Bartholdy, -băar-tōl'dĕ, FELIX: composer; b. at Hamburg, Feb. 5, 1809. His father, a wealthy Israelite, was a man of extensive learning and refined taste, and his mother was equally cultivated, being one of the brightest women in the best society of Berlin. He very early showed great talent for music under the instruction of his mother and of Madame Bigot; became the pupil of the romantic Berger for the piano, and of the severe Zelter for harmony; at eight years of age could read any music at sight, and write correct harmony. Although he had not the time to practice a great deal, yet such were the flexibility of his hands and the quickness of his musical faculty that he played perfectly the most difficult music. For his improvement and the entertainment of their guests, Mendelssohn's father hired for the boy a small orchestra, which he led with skill and great zeal at the home musical evenings. Aided by his talented sister Fanny, he often produced his own compositions before the large circle of artists and scholars frequenting his home; he thus became the musical prodigy and the bright center of their friendly interest. Up to 1826 his compositions showed less of the spontaneousness of genius than of skill in scholastic forms, which were the natural expression of a sensitive and not very self-asserting nature while under the dominion of the scientific Zelter. In that year, writing his *Midsummer Night's Dream*, he left the class-room, and revealed the leading quality of his originality, the graceful vivacity of his fancy. In 1829 he left Berlin to travel through Scotland, England, Germany, Italy, and France. In 1833 he was made musical director of the city of Düsseldorf. This office he kept only two years, and then moved to Leipzig, where he lived till his death, excepting during short periods of time—once to go to Berlin as director of music to the King of Prussia, and occasionally to visit England and various German cities to conduct performances of his works. By his strong personal influence, his intelligent direction of the concerts of the Gewandhaus, and the establishment of the conservatory, he made Leipzig the leading city of Germany for pure music. In recognition of his services the university conferred on him the degree of doctor of philosophy and of fine arts, and in 1836 the King of Saxony made him his honorary kapellmeister. In 1837 he married Cecile Jean Renaud, of Frankfort, whose grace, intelligence, and devotion were the happiness of the remaining ten years of his life. His continuous, laborious activity so much exhausted his sensitive organization that the death of his beloved sister Fanny (in 1847) was a blow from which he could not rally. A few months afterward he died of apoplexy (Nov. 4, 1847).

His nature united strong affections and a keen intellect, great energy, and mirth that was even frolicsome. One of his strongest traits was his unflagging pursuit of perfection; in every detail of every work he strove to express his best thought in the best form. He was too excitable and exacting to be a perfect conductor for the players given him in England and Berlin. In Leipzig, where enthusiasm was in the cause, his power seems to have been little short of magical in rousing his men and leading them to the heights of his conceptions. As a pianist he was one of the greatest of an age that counted such artists as Liszt, Madame Schumann, and Chopin. His execution was a rare union of fire, delicacy, and purity. Among his best known works may be mentioned the oratorio *Elijah*, which is more popular in England than any other oratorio excepting Handel's *Messiah*; the oratorio *St. Paul*, in which are happily united the grandeur of the ancient masters and the resources of modern art; the Forty-second Psalm; the *Midsummer Night's Dream*, a composition of extraordinary sprightliness and grace, probably the most striking work of its kind in the world; the concerto for the violin; the first concerto for the piano; the third symphony (in A minor), and the overture *Fingal's Cave*. His chamber-music, *Songs without Words* for the piano, and his vocal quartets and songs are among the purest and most charming contributions to the art. He seems to have had no dramatic power, or perhaps that side of his genius was undeveloped, for his efforts in opera are few.

See the *Life* by Moscheles (1873; Eng. trans. 1886); Hensel, *Die Familie Mendelssohn* (1879); the collections of Mendelssohn's *Letters* (1861 and 1863; Eng. trans. 1862–63); those to the Moscheles (1888); and *Selected Letters of Mendelssohn*, edited by W. F. Alexander (London, 1894) See also Grove's *Dictionary of Music and Musicians.*

Men'denhall, James William, Ph. D., D. D., LL. D.; clergyman and author; b. at Centerville, O., Nov. 8, 1844; graduated at Ohio Wesleyan University in 1864, and entered the Cincinnati Methodist Episcopal conference; was president of Fremont Collegiate Institute, Sidney, Ia., 1867–68; was transferred to North Ohio conference in 1869; was presiding elder about four years; was a member of the General Conference in 1884, 1888, and 1892; was elected editor of *The Methodist Review* in 1888 and was re-elected in 1892. His principal published works were *Echoes from Palestine* (1883); *Plato and Paul: or, Philosophy and Christianity* (1886). D. in Chicago, Ill., June 18, 1892.

Mendenhall, Thomas Corwin, Ph. D., LL. D.: physicist; b. near Hanoverton, O., Oct. 4, 1841; was self-educated in science, having received as a basis only a common-school education; in 1873 was elected Professor of Physics and Mechanics in the Ohio State University; in 1878 was called to the chair of Physics in the Imperial University of Japan at Tokio. Here he established a physical laboratory and founded a meteorological observatory, which later was merged into the general meteorological system established by the imperial Government. From measurements of the force of gravity at sea-level and at the summit of the extinct volcano Fujisan, he deduced a value for the mass of the earth that agrees closely with that obtained by Baily in England by another method. He aided in establishing the Seismological Society of Tokio, and in introducing a system of popular lectures. In 1881 he returned to the Ohio State University; in 1883 organized the Ohio State weather service, which he directed until 1884. In 1884 he became connected with the U. S. Signal Service at Washington, where he organized and equipped a physical laboratory, carried on observations of atmospheric electricity, and established the systematic gathering of data relating to earthquakes. In 1886 he resigned to become president of the Rose Polytechnic Institute at Terre Haute, Ind. In 1889 he was made superintendent of the U. S. Coast and Geodetic Survey, but resigned this post in July, 1894, to become president of the Worcester Polytechnic Institute, Worcester, Mass. He succeeded Francis A. Walker as President of the Boston School of Technology in 1897. In 1882 he was vice-president of the physical section of the American Association for the Advancement of Science, and in 1888 was chosen president of the association. He is a member of the National Academy of Sciences. In 1892 he was one of the two commissioners who represented the U. S. in the Bering Sea joint commission, and in the same year was appointed commissioner on the part of the U. S. to make a joint survey of the boundary between Alaska and British America; also commissioner to fix in connection with a representative of the British Government the boundary between Canada and the U. S., in the St. Croix river, and Passamaquoddy Bay. He has been chairman of the U. S. board of geographic names since its organization in 1890. Prof. Mendenhall has lectured extensively throughout the U. S., has contributed to many scientific periodicals, and besides monographs and special reports, has published *A Century of Electricity* (Boston, 1887).

Mendes (in Egypt. *Ded*, or *Pa-n-Ded*, House of the *ded* symbol): capital of the sixteenth nomos (district) of Lower Egypt and royal residence of the twenty-ninth dynasty, sacred to the ram of Mendes, which was, however, a he-goat, an incarnation of Osiris. The city name was written with a hieroglyphic sign (*ded*) which represented the spine of Osiris. According to some it was located 11 miles E. of Mansûra, but it is more probably to be identified with Tmey el-Amdîd, a little farther S. C. R. G.

Mendes, Catulle: poet and novelist; b. at Bordeaux, France, May 22, 1841. He went when quite young to Paris, and became very active in the group of young *parnassiens*, founding the *Revue Fantaisiste* (1849). He issued several volumes of verse, in which the concern for form is conspicuous: *Philomela* (1864); *Hesperus* (1869); *Contes épiques* (1870); *Odelette guerrière* (1871); *La Colère d'un franc-tireur* (1871); collected in 1878 as *Poésies.* He has also been an industrious writer in prose, producing dramas, novels, and short stories, marked by a search for strange effects and a prevalent erotic character. Among his novels and short stories are *Les Folies amoureuses* (1877); *Monstres parisiens* (1882); *Jeunes Filles* (1884); *Pour lire au bain* (1884); *Le Rose et le Noir* (1885); *L'Homme tout nu* (1885); *Grande-Maguet* (1888). Among his dramas are *Le Capitaine Fracasse* (1872); *Les Mères ennemies* (1882); *Le Châtiment* (1887); *Fiamette* (1889). A. G. Canfield.

Mendes Leal da Silva, men'dās-lā-ăal'daa-seĕl'vaă, José: poet and statesman; b. in Lisbon, Portugal, Oct. 18, 1820; d. at Cintra, Aug. 14, 1886. He began his literary career by articles in the *Diario* of the chamber of deputies. In 1846 he became secretary to the Duke of Terceira; in 1848 secretary to the conservatory, but lost this place in 1850. In 1851 he was elected a deputy, and soon after was for a time Minister of Foreign Affairs. From 1874 to 1883 he was ambassador to France; from 1883 to 1886 ambassador to Spain. As a poet he has had great popularity, his poems, *Canticos*, being first collected in 1858. His plays have had great success on the Portuguese stage: *Egas Moniz, A pobre das ruinas, O tributo das cem donzellas, Os homens de marmore, Os dous renegados, Pedro, A escala social*, etc. Particularly happy are the comedies *O tio André que vem do Brazil, O caçador*, etc. He published also several romances: *O flor do mar, O mosqueteiros da Africa, O Calabar.* His *Relaçoes de Portugal com a curia romana* (5 vols.) has scientific value. In 1845 he became a member of the Portuguese Academy. A. R. Marsh.

Men'dez-Pin'to, Fernão, or Fernam: traveler; b. at Montemor-o-Velho, near Coimbra, Portugal, about 1510; after various adventures in Europe he set out for the East Indies, and arrived in 1537 at Diu, on the west coast of India. His adventures lasted many years, and were narrated by him in a book published after his death, in which he states that he had spent twenty-one years in the East, had been thirteen times taken prisoner by the enemy, and seventeen times sold as a slave. His captivities had carried him from Egypt, Abyssinia, and Arabia through Persia, India, Burma, Malacca, Siam, Java, the Loochoo islands, Japan, China, and Tartary. Mendez-Pinto made four visits to Japan, one of which was in company with St. Francis Xavier, through whose influence he entered the order of Jesuits at Goa, devoting the large fortune he had acquired to the establishment of a seminary in Japan. Obtaining a release from his vows, he returned to Portugal in 1558 with letters of commendation from the viceroy at Goa. He resided at court several years; died at Almada, near Lisbon, July 8, 1583. His book, *Peregrinação de Fernam Mendez-Pinto*, was first printed in 1614, when it immediately became a favorite, and is now ranked among the Portuguese classics. It was translated into the principal languages of Europe.

Mendiburu, men-deĕ-boo'roo, Manuel, de: general and historian; b. at Lima, Peru, 1805. When a young student he joined the patriots in 1821, was captured by the Spaniards and kept a prisoner until the end of the war. Subsequently he held many civil and military offices; was Minister of War under Gamarra and of Finance under Echenique; and in 1851 was sent on a special mission to Europe. He had collected an immense quantity of material for a history of Peru, but modestly concluded that his abilities were not equal to the task of writing it. He therefore threw the notes into the form of a biographical dictionary entitled *Diccionario histórico-geográfico del Perú.* The first part, in eight volumes, includes the Inca and colonial periods; its publication was begun in 1874 and concluded after the author's death. It is by far the best work of its kind that has ever appeared in South America, and has been heartily praised by scholars; it is very full and contains much new material. The second part, which was to have come down to the present time, has never been published. Gen. Mendiburu died in Lima, Jan. 21, 1885. Herbert H. Smith.

Men'do, Andrés: ecclesiastic and author; b. at Logroño, Spain, in 1608: studied theology in the University of Salamanca; entered the order of Jesuits, and successively filled the positions of preacher to the court, secretary to the Inquisition, director of the schools of Oviedo and Salamanca, vice-provincial of Castile, and confessor to the Duke of Assuna, Viceroy of Catalonia. He died in 1685, having earned a great reputation for learning by his various writings, of which the principal are *Bullæ sacræ cruciatæ Dilucidatio* (Madrid, 1651); *De Jure academico* (Salamanca, 1655; 2d ed. Lyons, 1668); *De Ordinibus militaribus Disquisitiones theologico-morales* (Salamanca, 1657): several collections of sermons in Latin and Spanish; and *Statera*

opinionum benignarum in controversiis moralibus (Lyons, 1666). Revised by S. M. Jackson.

Mendocino, Cape: See Cape Mendocino.

Mendocino Indians: See Kulanapan Indians.

Mendota: city (founded in 1853); La Salle co., Ill. (for location of county, see map of Illinois, ref. 3–E); on the Ill. Cent. and the Chi., Burl. and Q. railways; 83 miles S. W. of Chicago. It contains 8 churches, 3 public schools, Blackstone High School, Wartburg Seminary (Lutheran, opened 1853), public library founded in 1870, 2 iron-foundries, a national bank with capital of $100,000, a private bank, and 4 weekly newspapers. It is in an agricultural region. Pop. (1880) 4,142; (1890) 3,542; (1900) 3,736.

Editor of "Bulletin."

Mendo'za: a western province of the Argentine Republic; bounded N. by San Juan, E. by San Luis, S. by the territories of Pampa and Los Andes, and W. by Chili. Area, as estimated by Latzina, 63,843 sq. miles, but careful surveys would probably reduce this to 55,000 sq. miles or less. The main range of the Andes forms the western boundary, the peak of Aconcagua being at the northwestern angle; spurs and lower ranges cover nearly the whole face of the province, subsiding to hills eastward; in the northwestern part there are extensive arid plateaus. Earthquakes are frequent, but only a few severe ones are recorded. The climate is so dry that in most places artificial irrigation is necessary for successful agriculture; some of the canals used were constructed by the Guarpe Indians before the conquest. Several rivers unite, on the eastern boundary, in the Desaguadero, which, farther S., is lost in marshes and salt lakes. Wheat, corn, and fruits are grown, the latter being dried and exported; but of late years vine-growing and wine-making have almost superseded other industries. In July, 1892, the estimated area in vineyards was 35,000 acres, and about 1,600,000 gal. of wine are exported yearly. Cattle are raised, principally for the Chilian markets, but the herds are not large as compared with other provinces. Silver and copper are mined on a small scale, and coal and petroleum are reported. Mendoza was settled in 1559 by Spaniards from Chili, who easily conquered the peaceful Guarpes. It formed part of the territory of Cuyo, attached to Chili until 1776, when it was united to the viceroyalty of La Plata or Buenos Ayres. Pop. (estimated, 1890) 160,000. The country population is mainly a mixed race, descended from Spaniards and Guarpe Indians.

Herbert H. Smith.

Mendoza: a city; capital of the province of Mendoza; situated at the foot of the eastern sub-ranges of the Andes; 654 miles from Buenos Ayres, and 2,550 feet above the sea (see map of South America, ref. 8–C). It is on the line of the Trans-Andean Railroad from Buenos Ayres to Valparaiso, and has a large trade, especially with the latter place; about one-tenth of the inhabitants are Chilians. Mendoza was founded in 1559 by Castillo, and was named after Garcia de Mendoza, who, at that time was governor of Chili. In 1816–17 San Martin massed his army here, previous to his celebrated march over the Andes into Chili. On Mar. 20, 1861, the city was destroyed by an earthquake; not even the streets were traceable after the disaster, and only some trees and an aisle of one of the churches were left standing. The shock occurred on the morning of Ash Wednesday, when the churches were filled with worshipers; about 13,000 people perished, and only 1,600 escaped. The new city was built a short distance from the ruins. Pop. (1892) about 20,000. Herbert H. Smith.

Mendoza, Andres Hurtado, de: See Hurtado de Mendoza, Andres.

Mendoza, Antonio, de: Spanish administrator; b. about 1485. He was a son of the second Count of Tendilla, and closely related to other distinguished persons of the same name. Charles V. having resolved to create a viceregal government for New Spain, or Mexico, Mendoza was appointed first viceroy in 1530, but did not reach the country until Oct., 1535. His rule was continued until Nov., 1549, and was, on the whole, wise and good; explorations were pushed toward the N. and N. W., mining-regions were developed, a mint was established, and Guadalajara, Valladolid, and other towns were founded; the irregular proceedings of former officeholders were punished, and a rebellion was put down. On the other hand, the burdens which already weighed on the Indian population were increased, and their misery was made greater at this time by a pestilence which swept over the country. Mendoza evaded the "new laws" which had been promulgated to regulate Indian labor, and which were fiercely resisted throughout Spanish America. Transferred to the viceroyalty of Peru, he reached Lima, Sept. 23, 1551, and died there July 21, 1552. During his short rule he commenced the Peruvian code of laws, known as the *Libro de Tasas*. Herbert H. Smith.

Mendoza, Antonio Hurtado, de: Spanish dramatist and poet; b. about 1600; d. in 1644. Little is known of his life. He lived much in Madrid in the company of the great poets of his day; was at one time a royal secretary, and again a secretary of the Inquisition. We have from him a number of plays, of which three are particularly good: *Cada loco con su tema ó el montañés indiano*, *Los Empeños de mentir*, and *El marido hace mujer y el trato muda costumbre*. The last was imitated with great success by the younger Moratín, and seems also to have been under the eyes of Molière when he wrote his *École des femmes*. Mendoza wrote also many ballads and lyrics, and a *Vida de Nuestra Señora*. His works were published in 1690 with the title *El Fenix Castellano, D. Antonio de Mendoza, renascido* (2d ed. Madrid, 1728). The three comedies mentioned above are reprinted in vol. xlv. of Rivadeneyra's *Biblioteca de Autores Españoles*. A. R. Marsh.

Mendoza, Diego Hurtado, de: statesman and writer; b. in Granada, Spain, in 1503, of high lineage. Being a younger son, he was destined for the Church; and to this end learned to speak Arabic in Granada, and then went to Salamanca to study Greek, Latin, and theology. While still a student there, as is commonly believed, he wrote his famous romance, *Vida de Lazarillo de Tormes, sus fortunas y adversidades*. This, the first example of the so-called *novelas picarescas*, while purporting to give the story of a little rascal, who by his native talent for lying and swindling rises from success to success, is in reality a satire upon those classes in Spanish society whose weaknesses made such successes possible. It seems to have been first published, without the author's name, in Antwerp in 1553. Its success was immediate and edition followed edition, certain passages prohibited by the Church, however, being cut out of most of the later ones. It also provoked continuations by greatly inferior writers. A so-called *Segunda Parte de L. de Tormes*, by an unknown hand, appeared in Antwerp in 1555; another *Segunda Parte*, by one Juan de Luna, a teacher of Spanish in Paris, in 1620. In the same year an imitation by Juan Cortés de Tolosa appeared, with the title *El Lazarillo de Manzanares*. The original was translated into many other languages (into English by David Rowland, 1586; again by James Blakeston, 1670). Mendoza seems soon to have found that his vocation was not ecclesiastical, for we next find him a soldier in the Spanish armies in Italy. Here his talents speedily brought him to the front, and in 1538 Charles V. appointed him ambassador in Venice. Here he mingled much with the scholars who were busied with the task of editing the Greek and Roman classics, and giving them to the world in printed form. He was a friend and patron of the great printers, the Aldi (see Manutius, Aldus); and he had made for his own library sumptuous copies of the manuscripts which Cardinal Bessarion had given to the Marcian Library. He thus became thoroughly imbued with the new humanistic culture of Italy; and after his return to Spain his great name and influence did much to diffuse this culture among his countrymen. The emperor, however, required his services as military governor of Siena, and he had to leave Venice. Later we find him the imperial representative at the Council of Trent (1542). Then, in 1547, he was sent to Rome as plenipotentiary to rebuke and overawe the pope. So well did he do this that for six years he was regarded as the head of the imperial party in Italy. In 1554, however, a change of policy on the part of Charles made it possible for Mendoza, already weary of his great responsibility, to return to Spain. The next year Philip II. came to the throne, and for some reason showed little liking for him. He had to go into a kind of exile at Granada, where he amused himself with writing poetry, either in imitation of the Latin poets or after the traditional popular manner of his own country. And here, later, he undertook in imitation of Sallust and Tacitus an account of the uprising of the Moors (1568–70), his famous *Guerra de Granada*, which, on account of its frankness and impartiality, could not be printed till long after its author's death (1st ed., incomplete, 1610; 1st complete edition 1776). In 1575 he was permitted to return to Madrid, but was

seized by a violent illness, and died a few days after his arrival, Apr., 1575. Besides the works mentioned above, we have from him some interesting letters, and an amusing, satiric *Diálogo entre Caronte y el ánima de Pedro Luis Farnesio, hijo del Papa Paulo III.* His works will be found in vols. iii., xxi., xxxii., and xxxvi. of Rivadeneyra's *Biblioteca de Autores Españoles.* See J. D. Fesenmair, *D. H. de Mendoza, ein span. Humanist des 16ten Jahrhunderts* (Progr. des Wilhelmsgymn., Munich, 1882 and 1884). Also K. Stahr, *Mendoza's Lazarillo de Tormes, etc.*, in *Deutsche Jahrbücher für Politik und Literatur* (Berlin, 1862).

Mendoza, Garcia Hurtado, de: See Hurtado de Mendoza, Garcia.

Mendoza, Iñigo Lopez, de: See Santillana, Marquis of.

Mendoza, Pedro, de: military commander; b. of noble family, in Gaudix, Granada, Spain, about 1487; fought with distinction in Italy, and is said to have profited greatly by the sack of Rome. After the return of Sebastian Cabot from the Rio de la Plata, Charles V. resolved to promote the colonization of that region, with the object of opening a new route to Peru. Mendoza offered to undertake the enterprise at his own expense, was named *adelantado* or governor of the new colony, and sailed from San Lucar Sept. 1, 1534, with fourteen ships and 2,650 men. The squadron touched at Rio de Janeiro, where the vice-admiral, Osorio, was killed on a vague suspicion of conspiracy. Arrived at the Rio de la Plata, Mendoza founded the first city of Buenos Ayres (Feb. 2, 1535) at one of the most inconvenient points on the coast. No attempt appears to have been made to pacify the Querendi Indians of the vicinity; repeated struggles with them followed, and the Spaniards, confined to their fort, suffered greatly from hunger. Ayolas, sent to explore the Paraná, founded on its banks the fort of Corpus Christi, to which a portion of the Buenos Ayres garrison was transferred. Disasters continued, and at length the governor in despair embarked for Spain, at the end of Apr., 1537. The ship, scantily provisioned, was reduced to famine; Mendoza became a lunatic and died before reaching Spain. The colony, under Ayolas and Irala, subsequently prospered. Asuncion was founded in 1537, and soon after Buenos Ayres was abandoned, to be refounded after many years. Herbert H. Smith.

Menede'mus (in Gr. Μενέδημος): (1) son of Clisthenes of Eretria in Bœotia. He began life as a soldier in Megara, but became interested in philosophy and studied under Plato and Stilpon. He transplanted the school of philosophy founded by Phædo in Elis to Eretria. Late in life he was accused of aiming to betray Eretria to Antigonus Gonatas, and went into exile. He left no writings. (2) A cynic philosopher of Lampsacus. (3) A rhetorician in Athens, 94 B. C. (4) A friend of Julius Cæsar. (5) A general of Alexander the Great. J. R. S. Sterrett.

Menela'us (in Gr. Μενέλαος): son of Atreus and younger brother of Agamemnon. After the murder of Atreus by Ægisthus, the two brothers went into exile, Menelaus going to the court of Tyndareus, King of Sparta, whose daughter, Helen, he afterward married. Through her he became King of Sparta. When Paris had carried Helen off to Troy, Menelaus journeyed thither in order to negotiate for the return of his wife, but in vain. Then, according to prenuptial agreement with the many suitors of Helen, he summoned them to war against Troy, himself being the commander of the Spartan contingent of sixty ships. At Troy, thanks to Hera and Athene, he became one of the most conspicuous figures. In a duel he was victorious over Paris, who was rescued by Aphrodite, but, owing to the treachery of Pandarus, Menelaus failed to get back Helen and her treasures. He protected the dead body of Patroclus from insult, and carried it out of the moil of battle back to the ships. He was one of those who entered the wooden horse. Upon his return voyage from Troy along with Helen, storms and winds drove a part of his ships to Crete, and five, including his own, to Egypt. He wandered about the Orient for eight years; he was everywhere received with kindness, and finally, in company with Helen, he reached Sparta on the day of the burial of Clytæmnestra and Ægisthus by Orestes. He thereafter lived in peace and comfort. On the occasion of the visit of Telemachus to Sparta Menelaus celebrated the marriage of his daughter Hermione to Neoptolemus, the son of Achilles. When on the island of Pharos he had forced Proteus (*q. v.*) to prophesy to him; he was informed that in view of the fact that he was a son-in-law of Zeus he would not die, but be translated to Elysium. He was more cruel than Agamemnon, and put Deïphobus, the son of Priam, to the most cruel tortures. He stood head and shoulders above Odysseus, spoke little, but always well and to the point. J. R. S. Sterrett.

Menendez de Avilés, Pedro: naval commander; b. in Avilés, Asturias, Spain, in 1519. He distinguished himself in privateering enterprises against the Moors and French; became captain-general in the navy; commanded the fleet which carried Philip II. to England 1554, the one which brought him re-enforcements to Flanders 1557, and that in which he returned to Spain in 1559; was twice general of the West Indian fleet, and acquired great wealth by his voyages; was imprisoned and fined for alleged irregularities in 1560, but regained favor, and in 1565 was named governor of Cuba and Florida, with the agreement that he should colonize the latter country. His preparations were hastened by the news that French Protestant colonies had been established on the Florida coast, and he sailed from Cadiz, June 29, 1565, with nineteen vessels and over 1,500 men. The ships were scattered by storms, and only seven united at Puerto Rico in August. Thence they sailed to Florida, and, after some preliminary skirmishing with the French ships, Menendez founded St. Augustine (now the oldest city in the U. S.) Sept. 8, 1565. Attacks on the post by French ships failed, and on Sept. 30 the Spaniards surprised and captured the French fort on St. John's river, slaughtering most of the garrison, "not as Frenchmen, but as heretics." Soon after the French ships met with repeated disasters, and most of those who had escaped the massacre at the fort gave themselves up, but they were butchered like the rest; in a few months hardly a Frenchman remained in Florida. The Spaniards established two other forts, but during the winter they suffered greatly from hunger and from Indian attacks; about 100 died and 500 deserted and left the colony. Subsequently large re-enforcements were received, and the colony prospered. Menendez made several voyages to Spain to bring over colonists and supplies, and he was active in the government of Cuba. He also pushed explorations northward, established a post on Port Royal Bay, now in South Carolina, visited Chesapeake Bay, and in 1570 sent a party of missionaries up the Potomac river; this mission was destroyed by the Indians, and in requital Menendez ascended the Potomac in 1572, and laid waste some of the Indian villages. In 1573 he finally returned to Spain, and was given command of the immense fleet which Philip was preparing against England and the Netherlands, but died soon after at Santander, Sept. 17, 1574. His letters from Florida to King Philip are extant, and have been used by modern authors. See Barcia, *Ensayo cronológico para la historia generál de la Florida* (1723); Parkman, *Pioneers of France in the New World* (1865); Gaffarel, *La Floride Française* (1875); Shea in *Narrative and Critical History of America*, vol. ii., p. 260, *et seq.*

Herbert H. Smith.

Menéndez y Pelayo, mā-nen'dāth-ee-pā-laa'yō, Marcelino: poet and scholar; b. in Santander, Spain, in 1857. His literary career began when he was less than twenty, with some articles in the *Revista Europea* for 1876, attacking the philosophical tendencies of Germany and the Spaniards who inclined to adopt them. Just before publishing these he had completed his studies in the University of Madrid, and a little later he went to Barcelona and to Paris for a considerable period in order to enlarge his scientific knowledge of literature. On his return to Spain he was appointed Professor of Spanish Literature in the University of Madrid, a special license from the Government being required because of his extreme youth. Soon after (1881) he was elected a member of the Spanish Academy. Menéndez y Pelayo is one of the most brilliant and most prolific writers of modern Spain. Though he has ostensibly allied himself with the conservative and extreme Catholic party, he is essentially a writer of humanistic rather than political or theological interests. A lover of beauty and of style, he returns lovingly to the perfection of the poets of the classical world, and prides himself on belonging to a Latin rather than a Germanic race. The work from his pen that has aroused the greatest discussion is perhaps the *Historia de los heterodoxos españoles* (3 vols., 1880–82), in which he defends the Inquisition and ranges himself among the antagonists of modern liberalism and modern science. This, however, was an immature work in spite of the remarkable erudition

it displays. He is more truly on his own ground when he is dealing with literary matters, and particularly the history of Spanish literature. Here belong *Estudios de crítica literaria* (1884); *Calderón y su teatro* (3d ed. 1885); *Horacio en España* (2d ed. 2 vols., 1885); *Historia de las ideas estéticas en España* (5 vols. in 9, 1884–91); *La ciencia española* (3d ed. 3 vols., 1887–89). In this connection should be mentioned also the *Antología de poetas líricos castellanos*, with learned introductions (1890, *seq.*; 4 vols. to 1893); and the monumental edition of the works of Lope de Vega, which Menéndez y Pelayo is editing for the Spanish Academy (1890, *seq.*). Besides these critical works he has also tried his hand with considerable success at poetry. Though he hardly passes beyond academic excellence here, no connoisseur can fail to be interested by the precision of his touch and the harmony and grace of his style. The best of his verse is to be found in the volume *Odas, epístolas y tragedias*, with an introduction by Juan Valera (1883). Deserving mention is *Horatius: Odas traducidas é imitadas* (1882). A. R. Marsh.

Meneptah [from Egypt. *Mer-n-Ptah*, beloved of Ptah; the *Amenephthes* of Africanus, and the *Amenophis* of Josephus]: the thirteenth son, coregent, and successor of Ramses II., and third king of the nineteenth Egyptian dynasty. The length of his reign is uncertain; monumental evidence does not extend beyond his eighth year. He left his name on many usurped monuments, but did little building of consequence. His only war was with the Libyans, whom he conquered. By many he has been identified with the Pharaoh of the Exodus in spite of chronological difficulties, on account of the fact that the earliest remains found at Pithom, one of the "store-cities" built by the Israelites, belonged to his father Ramses II., who is therefore identified with the Pharaoh of the Oppression. Curiously enough his mummy was not with the others found at Der-el-Bahari. See Her-Hor. Charles R. Gillett.

Menes [from Egypt. *Mena*, steadfast]: the first recognized human King of Egypt, being mentioned first in all the monumental lists of kings. Our information concerning him comes for the most part from Greek sources, as no contemporary monuments have been preserved. His native place was This, or Thinis (*q. v.*), the metropolis of the eighth nomos (district) of Upper Egypt, and he is said to have founded Memphis (*q. v.*). Manetho says that he waged war with the Libyans, and that he was finally killed by a hippopotamus. Herodotus (ii., 99) says that he founded the Temple of Ptah at Memphis; Diodorus (i., 94), that he arranged the worship of the gods; Ælian (*Hist. Anim.*, xi., 10), that he introduced the Apis-cult at Memphis; and Anticlides (cf. Pliny, *Hist. Nat.*, vii., 56–57, §§192–193) that he invented the alphabet. From native sources it is known that he received divine worship throughout almost all periods of Egyptian history, and the nomenclature of the kings as "King of Upper and Lower Egypt" seems to indicate that his special service was in the unification of the government of the whole land. Charles R. Gillett.

Mengs, Raphael: painter; b. at Aussig, Bohemia, in 1728. He formed his style by copying Raphael. His earlier works are in Dresden, but he painted chiefly in Rome and in Spain for Charles III., who appointed him his court painter. Although a foreigner he was elected president of the Academy of St. Luke in Rome. The ceiling of the Sala dei Papiri in the Vatican is one of his most important works. He painted in oil, in fresco, and also used pastel and gouache. D. in Rome in 1779. He was extremely industrious, and left innumerable works, besides many published treatises on art. W. J. Stillman.

Mêng-tse, or **Mŭng-tse**: See Mencius.

Menhaden, men-hā′den, **Moss-bunker**, or **Bony Fish**: a fish of the herring family, scientifically known as *Brevoortia tyrannus*, extensively caught along the Atlantic coast of the U. S. It is full of small bones, and is almost uneatable in the regular way, but for some years it has been the subject of an extensive and growing industry. The fish are put up as sardines, the bones being softened by subjection to steam. They have been long caught for their oil, which is abundant and is used in leather-dressing, rope-making, and for adulterating higher-priced oils. The refuse, called fish-guano, is a valuable fertilizer. The business of making this oil and guano is extensively carried on along the coasts of New England, Long Island, and New Jersey. See Bugfish and Fisheries. Revised by F. A. Lucas.

Meningi'tis [Mod. Lat., deriv. of *meninx*, from Gr. μῆνιγξ, membrane]: inflammation of the membranes enveloping the brain and spinal cord, termed cerebral, spinal, and cerebro-spinal meningitis, according as the inflammatory process is limited to the region of the cerebrum or brain, the region of the cord, or involves both. Acute cerebral meningitis results from injuries of the head, as fractures and diseases of the cranial bones, inflammation and suppuration of the middle and internal ear, from excessive mental labor, from perverted states of the blood, as in acute rheumatism, and from infectious fevers, such as erysipelas, pneumonia, and typhoid fever. The tubercular meningitis of children is the result of infection with the tubercle bacillus and the development of tubercles in the meninges. Spinal meningitis most often follows injury or disease of the vertebræ, less frequently is excited by rheumatic, gouty, and tubercular blood states. It may occur, as among soldiers in the field, from exposure in sleeping on the ground. Cerebro-spinal meningitis is usually epidemic, and is but one manifestation of a malignant febrile disease, the cerebro-spinal or spotted fever. In cerebral meningitis there are intense headache, active delirium, contracted pupil, flushed face, a slow pulse, sometimes convulsions, coma, paralysis, and death, due to exudation of inflammatory products upon the surface or within the ventricles of the brain. Chronic meningitis may be the cause of chronic headache, of epilepsy, idiocy, and insanity. In tubercular meningitis of children delirium may be absent, but the pain in the head is lancinating and intense, causing the utterance of shrill cries, constant motion of the head, sleeplessness, and peevishness. There are automatic movements of the extremities, and convulsions. General emaciation coexists, as this is a disease of delicate and bottle-fed infants or of children tainted with scrofula or actual tuberculosis elsewhere than in the brain. In spinal meningitis movement of the body develops intense pain over the length of the spine and in the extremities, and an incurvation or rigid arching of the back. Epidemic cerebro-spinal meningitis has, in addition to meningeal symptoms, febrile disturbance, great debility, and sometimes a peculiar purple eruption. Acute meningitis is treated locally by cold applications and counter-irritants, internally by remedies reducing the action of the heart. In secondary meningitis we treat the primary disease, the exciting cause. Tubercular meningitis requires improved hygiene, diet, tonics, and alteratives. Cerebro-spinal meningitis requires nourishing diet, tonics, and stimulants to resist the degenerated blood state, and opium to control pain. Revised by William Pepper.

Me'nippée, Satire: See Satire Menippée.

Menip'pus: Greek philosopher of the Cynic school; a native of Gadara in Syria; flourished about 250 B. C. His writings—a satirical medley of prose and verse—are lost, but his name survives as the model of Varro in his *Menippean Satires*, and as the forerunner of Lucian, in whose works he figures, and the title *Satire Menippée* is borne by a famous French work of the sixteenth century. B. L. G.

Menis'cus: a concavo-convex lens. It may be either a converging lens (thicker at the center) or a diverging lens (thicker at the edge). In other words, a meniscus is any lens the centers of curvature of whose faces are both on the same side, and whose two radii of curvature differ in length. See Lens. E. L. N.

Menkara: See Mycerinos.

Menno, or **Menno Simons**: See Anabaptists.

Mennonites: a body of evangelical Christians who, in relation to the constitution of the Church, to baptism, the taking of oaths, church discipline, accepting of civil offices, and the bearing of arms, are either entirely or almost in harmony with Menno Simons, after whom they are named. They are found in Switzerland, Germany, France, Russia, and North America. Originally, the followers of Menno in Holland were called by that name, but they have departed so far from his principles and practices that for more than a century they have preferred to style themselves Doopsgezinden, or persons who lay emphasis upon baptism. The Mennonites arose in Switzerland in 1525, under the leadership of Conrad Grebel at Zurich. Possibly the principles and practices of Grebel may have been in some way connected with those of sects of the Middle Ages, but hitherto no proof of this has been found. The immediate followers of Grebel were aware of no such connection, but asserted that since the days of the apostles true Christianity had not ex-

isted in the world. In the year 1647, more than a century after the death of Grebel, the notion was advanced that the Waldensians were the spiritual progenitors of the Mennonites, but it has now been surrendered by the most competent scholarship of the Doopsgezinden in Holland. Adherents of Grebel shortly appeared in the Netherlands, where they became very numerous. After the catastrophe at Münster in Westphalia, Menno Simons became their chief spokesman, and owing to his wisdom, industry, and prominence the entire party adopted his name. He was not their founder, however; he accepted the principles which the better portion of the brethren had previously defended, and acquired distinction merely by his ability and activity in promoting them.

The persecution that befell the Mennonites in Switzerland was more severe, perhaps, than any they were called to experience elsewhere. It continued through the whole of the sixteenth century. Toward the middle of the seventeenth century it was again renewed and lasted for a period of seventy years. Nearly all the churches were destroyed, and the unhappy Swiss believers were scattered in many lands. In 1682, when William Penn made an offer of religious liberty it was gladly accepted by them. The first society in North America was organized at Germantown, Pa., in 1683, and these were followed by many others from various portions of Germany. Divisions that originated in Switzerland about the year 1620 may be observed in Pennsylvania and other portions of the U. S. The followers of Jacob Amman of the Bernese Alps, who proscribed the use of buttons on clothing and the trimming of the beard and the like, were among the first to seek refuge in the U. S., and they are still a numerous body.

Mennonites exist at Nancy and Toul, in France, and in various towns in the Franche-Comté. In 1783 Mennonites of the German Baltic provinces emigrated in large numbers to Russia upon the promise of the Government that their scruples against bearing arms should be respected. In 1871 that promise was revoked and many of them quitted Russia for the U. S. Some of these are said to practice immersion in baptism, a practice probably due to their lengthy contact with the Greek Church, which still retains this mode. Among all other Mennonite sects the usual mode of baptism is said to be by pouring: the candidate kneels down and the bishop or minister takes water with both hands and pours it upon his head. This seems to have been the mode adopted at the outset.

The census of 1890 occasioned much surprise as to the number of Mennonites in the U. S. Prior to its appearance almost all authorities reported that there were 200,000 in America, of whom 175,000 were found in the U. S. and 25,000 in Canada. The census gives account of only 41,541 all told. It is possible that not more than the half of 25,000 could be counted in Canada. They are divided into twelve sects, as follows: Regular Mennonites, 17,078; Amish, 10,-101; Old Amish, 2,038; Apostolic (Amish), 209; Brueder-hoef, 352; Reformed, 1,655; General Conference, 5,670; Church of God in Christ, 471; Old Mennonites, 610; Bundes Conference der Brueder-Gemeinde, 1,388; Defenseless (Amish), 856; Mennonite Brethren in Christ, 1,113.

The history of these people in Holland, as elsewhere, has been marked by a variety of sects. The first division occurred during the life of Menno, when in 1554 the Waterlanders were excommunicated. The party that drove them out were themselves in 1566 divided into Flemish and the Frisian Mennonites. There were various other schisms until 1632, when Flemish and Frisians were again united. The Waterlanders were not troubled by divisions of this kind. They were the first to disclaim the name of Menno. After the opening of the eighteenth century the differences that had so long existed between the Flemish Mennonites and the Waterlanders began to fade away, and by the year 1800 all parties were again practically united under the designation of Doopsgezinden. In the year 1700 there were 160,000 of these people in Holland; in the year 1800 they had sunk to 30,000; in 1881 there were said to be 47,000. They have been greatly influenced by the progress of modern events. Having entered the current of modern life they retain but few of the peculiarities that distinguished Menno and the early Anabaptists (*q. v.*). Among these may be mentioned opposition to infant baptism; but it is said that the age of eight years has been fixed as the period of adult baptism. Most of their young people are received into the Church at that age. They still decline to make oath in courts of justice, and likewise maintain the congregational method of church government. There are few signs of the former separation from the world. Though the Doopsgezinden constitute only 1 per cent. of the population, they own at least 10 per cent. of the property and contrive to obtain more than 10 per cent. of the offices. Opposition to the bearing of arms was surrendered in the wars against Napoleon I. There has been a marked revival of religious life among them, as among many other churches of the Continent, since 1817. Most of the tendencies of modern theology are represented in their fold.

Literature.—No satisfactory history of the Mennonites has yet been produced. The *Historia Mennonitarum*, by H. Schyn, 1723 and 1729, is nothing but an attempt to prove that the Mennonites were derived from the Waldensians and not from the Anabaptists. Good materials for a history were brought together by Bloupet ten Cate, *Geschiedenis der Doopsgezinden* (1839–47, 5 parts). A useful work is Starck, *Geschichte der Taufe und Taufgesinnten* (1789); Jehring, *Historie von den Begebenheiten unter den Mennoniten* (1720); S. F. Rues, *Nachricht von den gegenwartigen Zustande der Mennoniten* (1720). The best authority is de Hoop Scheffer's article *Mennoniten*, in the second edition of Herzog's *Real-Encyclopaedie*, vol. ix., pp. 566–577.

William H. Whitsitt.

Menominee: city; capital of Menominee co., Mich. (for location of county, see map of Michigan, ref. 3–F); on Green Bay, at the mouth of the Menominee river, and on the Chi., Mil. and St. P. and the Chi. and N. W. railways; 52 miles N. N. E. of Green Bay. It has numerous saw-mills, and is an important lumber shipping-point. There are 2 national banks with combined capital of $200,000, and a monthly and 4 weekly newspapers. Pop. (1880) 3,288; (1890) 10,630; (1900) 12,818.

Editor of "Herald."

Menomoni: See Algonquian Indians.

Menomonie: city; capital of Dunn co., Wis. (for location of county, see map of Wisconsin, ref. 4–B); on Red Cedar river, and the Chi., Mil. and St. P. and the Chi., St. P., Minn. and Omaha railways; 23 miles N. W. of Eau Claire, 60 miles E. of St. Paul, Minn. It contains 7 brick-yards, 3 sawmills, foundry, machine-shop, sash and carriage factories, a national bank with capital of $50,000, 2 private banks, a bi-weekly and 4 weekly newspapers, and is an important shipping-point for lumber, flour, wheat, bricks, and other articles. Pop. (1880) 2,589; (1890) 5,491; (1900) 5,655.

Editor of "Dunn County News."

Men'on (in Gr. **Μένων**): (1) a King of Pharsalus, who was friendly to the Athenians during the Peloponnesian war. (2) A Thessalian, who was a leader of Greek mercenary troops on the expedition of Cyrus against the King of Persia, his brother. After the battle of Cunaxa Tissaphernes treacherously entrapped the Greek generals, and put them to death. Menon was among those who suffered, though he had planned to betray the Greeks.

J. R. S. S.

Menopo'ma [Mod. Lat.; Gr. *μένειν*, remain + *πῶμα*, lid, in reference to the permanent gill clefts]: a tailed batrachian peculiar to the fresh waters of North America (*Cryptobranchus alleghaniensis*), and commonly known as mud-puppy or hellbender. It has a large and flat head; two concentric series of minute teeth in the upper jaw, and one series in the under jaw; a branchial orifice on each side; rudimentary branchiæ; four limbs, the anterior having four and the posterior five short palmated toes; and a loose skin folded on the sides of the body. It attains a length of 18 inches, is dirty yellowish brown with dark mottlings, feeds chiefly on fish, worms, and mollusks, is fierce and voracious, and erroneously regarded as poisonous. It is common in the Ohio and tributaries. The species *C. fuscus* (Holbrook), found in Western North Carolina, is brownish white above and yellowish white below.

Revised by F. A. Lucas.

Menstruation: See Catamenia and Uterine Diseases.

Mensuration [from Lat. *mensura're*, measure, deriv. of *mensu'ra*, a measuring, deriv. of *mēti'ri*, *men'sus*, measure]: that branch of geometry which teaches how to find, by calculation, the lengths of lines, the areas of surfaces, and the volumes of solids. As the first of these cases comes under the head of Trigonometry (*q. v.*), the word mensuration has come to be applied to the measuring of areas and volumes solely. It shows how, by means of certain boundary-lines or dimensions of the figure, we can obtain the required area or volume. Thus if we are given the lengths of the sides of a rectangle expressed in terms of a unit of length, an inch or a foot, etc., the area is equal to the product of these num-

bers expressed in terms of a square inch or square foot, etc. Again, the area of a triangle is equal to half the product of the base into the height. From this we can derive the area of any plane figure bounded by right lines, as such a figure can always be broken up into triangles, the areas of which can be separately calculated. Among curved lines the area of a circle is equal to half the radius multiplied by the perimeter. Certain machines, called planimeters, have been invented for measuring areas on a plane. The best known is that of Prof. Amsler-Laffon. It consists of two rods hinged together. The extremity of one rod is fixed, while the free extremity of the other traces out the boundary of any curve that is limited in size only by the dimensions of the machine. A graduated roller attached to the latter rod gives, by the difference of its readings before and after the tracing has been accomplished, a number proportional to the area that has been gone round. For areas measured on the sphere, see SPHERE and LUNE.

The volume of a rectangular parallelopiped is the product of the length, the breadth, and the depth in terms of the cubes whose sides are units of length; the volume of a pyramid is one-third of the product of its height and the area of its base, from which we can find the volume of any solid bounded by planes, as such a figure can be decomposed into pyramids. In general, the determination of the length of curved lines, the area of plane surfaces bounded by curved lines, of the area of curved surfaces, and of the volume of solids bounded by curved surfaces, requires the aid of the integral calculus. For measurement on the earth's surface, see GEODESY and SURVEYING.

Mental Suggestion: See HYPNOTISM.

Mentana, men-taa'nă: a small place with an old castle, 13 miles to the N. E. of Rome, noted on account of the battle which took place here Nov. 3, 1867 (see map of Italy, ref. 6–D). The small army of volunteers under Garibaldi, numbering about 3,500 men, after defeating the papal troops at Monterotondo, was about to attack Rome, when on Oct. 28 and 29 the French fleet landed the detachment of Failly at Civita Vecchia. Garibaldi, who was before the Roman gate of St. Jean on Oct. 30, retreated to Monterotondo and Mentana, and began to intrench the latter position. On Nov. 2 he pushed one detachment toward Correse and another toward Tivoli. This latter fell in with 3,000 papal troops, followed by 2,000 French troops. The volunteers retreated to Mentana, and here began a fight which lasted four hours, in which they were completely defeated by the papal troops, aided by the French. On the retreat the volunteers met with the Italian army, which had entered the Papal States; they were disarmed, and Garibaldi himself was taken prisoner and carried to the fortress of Varignano, near Spezzia. In honor of this victory the pope instituted the Mentana medal, a silver cross with the inscriptions *Fidei et Virtuti* and *Hinc Victoria*, which was given to all who had participated in the battle. A monument was erected at Mentana in 1877 in honor of the Garibaldians who fell in the battle.

Men'tchikof, ALEXANDER DANIELOVITCH, Prince: soldier and statesman; b. in Moscow, Russia, Nov. 6, 1672, in humble circumstances, and apprenticed to a pie-baker; attracted the attention of Lefort by his spirited face; enlisted in the regiment of Preobashenski; discovered a conspiracy among the Strelitzes; distinguished himself at the capture of Azov; accompanied the czar on his journey to Holland and England; gained by degrees his confidence; became after the death of Lefort his most intimate friend and adviser, and was made a prince in 1707 and field-marshal in 1709. He was a man of superior talent, both as a statesman and as a military commander. He won the decisive battle of Kalisz 1706, contributed much to the victory of Poltava 1709, conquered Pomerania in 1712, took Stettin in 1713, and his influence was felt in all branches of the civil government of Russia. His rapacity was amazing; and when in 1713 he abandoned Stettin to Prussia without the consent of the czar, he was tried by a court martial; his general conduct underwent investigation, and he was sentenced to death. The czar changed this verdict to a heavy fine, and even appointed him governor of St. Petersburg, but he had lost his influence. Once more, however, he came into power on the accession of Catharine I. in 1725, and when in 1727 she was succeeded by the young Peter II., he obtained absolute control of the government of Russia. He was just about to marry his daughter to the czar when he was overtaken by a conspiracy headed by the family of Dolgoruki, Sept., 1727; his property was confiscated, and he and his family were banished to Berezov, in Siberia, where he died Jan. 30, 1730. —His great-grandson, ALEXANDER SERGEIVITCH MENTCHIKOF, naval officer, b. in 1787, was aide-de-camp to the Emperor Alexander in 1812–14, governor of Finland in 1831, Minister of Marine in 1836, and commander-in-chief during the Crimean war. He lost the battles of Alma and Inkerman, but defended Sebastopol with success for several months. He retired on account of ill-health, and was succeeded by Gortchakof. In politics he belonged to the Old Russian party, and was averse to all reforms. D. May 3, 1869.

Menton: town in the department of Alpes-Maritimes, France; beautifully situated on a bay of the Gulf of Genoa, and celebrated for its equable climate, being surrounded on the three sides by the Alpes-Maritimes, here between 3,000 and 4,000 feet high (see map of France, ref. 8–J). Although it has no regular harbor, it carries on a brisk trade in fruits, fish, and perfumeries. Pop. in 1896, 9,044. Close by are some famous bone-caves, 88 feet above the Mediterranean, which are rich in prehistoric remains.

Mentz (Germ. *Mainz*, Fr. *Mayence*. Cf. anc. name *Moguntia'cum*): city of Germany and an imperial fortress of the first rank; in the grand duchy of Hesse; on the left bank of the Rhine, nearly opposite the influx of the Main (see map of German Empire, ref. 5–D). It is surrounded on all sides by a system of strong fortifications consisting of fourteen immense bastions and four detached forts, which command both sides of the Rhine. Its streets are generally crooked and narrow, though since the conflagration in 1857 a large portion of the city has been rebuilt in a thoroughly modern fashion. It contains many interesting buildings—among which is the cathedral, a Romanesque structure with many Gothic details, of the fourteenth century—and many beautiful promenades and public places, such as the Gutenberg Place, with the magnificent bronze monument, by Thorwaldsen, of Johann Gutenberg, who was born and died here, and whose house stood until 1894. Among its manufactures, those of carriages, furniture, and musical instruments have great repute, and its trade is very considerable. Mentz was founded in the second century by the Romans and destroyed in the fifth by Attila, but was restored by Charlemagne. It soon became the see of an archbishop, and in course of time the archbishop became one of the three ecclesiastical electors of the empire. During the Thirty Years' war it was taken by the Swedes in 1631, was again captured by the Imperialists in 1635, and by the French in 1644. Pop. (1895) 76,300.

Menu: See MANU.

Menu'ridæ: See LYRE-BIRD.

Menzaleh: the name of a shallow, brackish lake in the northeast of the Egyptian Delta, which covers about 1,000 sq. miles, and abounds in fish. It is bounded on the E. by a part of the Suez Canal. The region was once fruitful, and was intersected by three (the Pelusiac, Tanitic, and Mendesian) branches of the Nile, and contained populous cities like Tanis, Avaris (Pelusium), Daphnæ (Tahpanhes), and Tennis. The obvious sinking of the surface of the ground, as evidenced by these changes, is intimately connected with a corresponding rise at the S. of the isthmus, and this in turn has an important bearing upon the earlier northern extent of the Red Sea and the probable place of crossing by the Israelites under Moses. See MIGDOL.

CHARLES R. GILLETT.

Menzel, men'tsel, ADOLF FRIEDERICH ERDMANN: historical and genre painter; b. at Breslau, Prussia, Dec. 8, 1815; is self-taught; is best known by his illustrations, which are principally pen-and-ink drawings or lithographs, and are of great excellence. His works in oil and in water-color are notable for admirable technical qualities. He is a member of Berlin, Vienna, and Munich Academies; was awarded a grand gold medal at the Berlin Exposition 1856; second-class medal, Paris Exposition, 1867; decoration of the Legion of Honor 1867. Several important works by him are in the National Gallery, Berlin. He is almost unknown in the U. S. Studio in Berlin. WILLIAM A. COFFIN.

Menzel, WOLFGANG: author; b. at Waldenburg, Silesia, June 21, 1798; served as a volunteer in the campaign of 1815; studied philosophy and history at Jena and Bonn;

was an enthusiastic disciple of Jahn, the founder of the German Turners; lived from 1820 to 1824 as a teacher at Aarau, Switzerland, but settled in 1825 at Stuttgart, where he devoted himself exclusively to literature, and died Apr. 23, 1873. His productions are very varied, comprising tales and romances—*Rübezahl* (1829), *Narcissus* (1830), *Furore* (1851); historical and mythological works and traveling sketches, sometimes consisting of several volumes, of which *Geschichte der Deutschen* (History of the Germans, 3 vols., 1824–25) was translated into English by G. Horrocks (London, 1849); and, finally, criticisms in the form of essays in the *Literaturblatt*, which he edited for many years, and also in the form of books, such as *Streckverse* (1823), *Die Deutsche Literatur* (1828), translated by C. C. Felton in Ripley's *Specimens of Foreign Literature* (Boston, 1840). Menzel was neither a great historian nor a great critic. While his historical writings retain a certain value as documents for the development of German patriotism in the nineteenth century, his critical works dealing with German literature are entirely antiquated. He gained for a while great notoriety by his attacks on Goethe and by the denunciation of the members of Young Germany, the sale of whose writings he caused to be prohibited. The religious and patriotic fanaticism of his critical writings prevented Menzel, however, from gaining permanent influence on German literature. Revised by JULIUS GOEBEL.

Mephistopheles: the name of a personification of the principle of evil, first occurring in the popular books and puppet-plays of the Middle Ages. Its etymology is uncertain, but most probably it is derived from a Hebrew root which signifies "one who loves lies."

Mercadan'te, SAVERIO; composer; b. at Altamura, Italy, 1797; was educated at the musical college of San Sebastio in Naples; first attracted attention in 1818 by a cantata performed at Naples; was appointed director of the Italian opera in Madrid in 1827; chapel-master at the Cathedral of Novara in 1833; director of the Conservatory of Naples in 1840; became entirely blind in 1862, and died at Naples, Dec. 18, 1870. He was a prolific composer, vivacious and graceful; none, however, of his fifty operas is now performed; and very few of his sacred compositions are in existence.

Mercantile (or **Commercial**) **Agencies**: institutions established for the purpose of obtaining information as to the character, personal responsibility, and financial standing of individuals, firms, or corporations.

The vast and rapid increase of population and the extension of railway, postal, and telegraphic communications brought new conditions and created the necessity for an organization to do promptly and systematically for the many what had formerly been done imperfectly by the individual merchant or banker receiving or extending credit. Among the earliest organizations to perform the functions of the modern mercantile agency were the Scottish trade protection societies, which began to spring up about the middle of the eighteenth century. These did not, however, aim to give the relative financial standing of merchants, but, like the BLACK LIST (*q. v.*), supplied such information with regard to bankruptcies, insolvencies, etc., as was needed for the protection of their members. The range of information supplied by these and similar organizations in Great Britain has been greatly extended, and includes statistics taken from the public records relating to assignments, trust deeds, bills of sale, judges' orders, protested bills, and other matters of interest to the mercantile community. In addition to this they have undertaken to collect bills and dividends for members, to investigate measures affecting trade, and to promote legislation favorable to commercial interests. These functions, however, are not assumed by mercantile agencies, as the term is understood in the U. S., where the aim is merely to afford means for ascertaining the credit of people engaged in business. The foundation of the system prevalent in the U. S. was laid in New York in 1840. In its assigned place the agency acts as a clearing-house for information affecting mercantile affairs and mercantile credit. The information is obtained from the business community through the same channels, and following, practically, the same system as was previously and still is employed by individual granters of credit, the agency being merely an enlargement of the individual system, but vastly strengthened by the experience of those who devote themselves to the administration of the details. It is essential that the mercantile world should investigate the moral and financial responsibility of those who assume business relations. Credit does not establish itself *per se*; it is determined by human action and personal judgment, but it should be decided by those competent to ascertain and analyze the facts and qualified to express properly the results of their investigations. The information obtained by the agency estimates the character and ability of persons engaged in business, the apparent success with which the undertaking is conducted, the capital invested, and such other conditions as may have a direct bearing or influence on credit. It is not *ex parte*, for opportunity is afforded all persons, firms, and corporations to state their own financial condition. The methods which apply to the obtaining of information in a single instance are practically the same in all, while the recorded information is subject to constant revision in a similar way. From the reports of investigators is deduced what is known and recognized as the "commercial rating." The names of the various merchants, with their business and rating, are issued quarterly in book-form, and are classified first by States and provinces, then by cities and towns, all arranged in alphabetical order.

The service of the agency is principally in the direct interest of its subscribers, who for a moderate consideration receive, upon application, the information desired, and also the use, for a limited time, of the current printed volume containing the names and ratings of those reported. The great agencies of the U. S. comprehend in their work the entire list of names of persons and business organizations known and recognized in the mercantile community, and to the accomplishment of this have established their offices in all commercial centers throughout the country, attaching to each a certain district—first, for the purpose of gathering, formulating, and distributing the necessary information through their own employees and correspondents, and, second, to give merchants in each section of the country equal opportunity to obtain the immediate benefits of the system. Thus a manufacturer in a small city or town in the interior has every facility for learning of the standing of dealers in his particular product in other places as readily as the merchant or banker of the larger city. The entire American continent is covered by these investigations, and through the extension of the system similar information is supplied with regard to the financial standing of those engaged in business in Europe and Australia. C. F. CLARK.

Mercantile Law [*mercantile* is from Lat. *merca'ri*, to traffic, trade]: is the body of special rules which govern merchants as distinguished from persons not engaged in trade, and mercantile as distinguished from ordinary transactions. Mercantile law constitutes a part of the national or municipal law of each state, and its rules are subject to change by local legislation; but historically it is a product of international usage. Its development has been singularly continuous, and its rules, as recognized and enforced by the principal modern states, are strikingly uniform. Many of the rules which govern international trade are regarded and treated as rules of international law (public or private), particularly in the case of maritime law.

The Ancient World.—The commercial customs of the ancient world, as worked out by Egyptians, Phœnicians, Greeks, etc., were incorporated by the Roman prætors into their provincial and city edicts, and were reduced to clear and simple form by the Roman jurists in their "law of nations" (*jus gentium*, see ROMAN LAW). When the Roman law reached its highest development, in the second and third centuries of the Christian era, the *jus gentium* and the older national law of Rome (*jus civile*) were fused into a single system. In this fusion the broader and more flexible rules of the *jus gentium* substantially replaced the strict and formal rules of the *jus civile*; and the Roman empire ceased to have or to require a separate body of commercial law because the whole law of property and of contracts had been *commercialized*—a fact which explains the dominant influence exercised by the Roman law in the development of mercantile law in the Middle Ages.

The Middle Ages.—Commerce, which had sensibly declined in the fourth and fifth centuries, shrank to very narrow proportions after the overthrow of the West Roman empire. During the early Middle Ages Byzantium was its chief commercial center; the "besant" was the European standard of exchange; and in the Byzantine trade between Europe and the East the rules of the Roman law continued to be observed. Toward the close of the ninth century some of the Italian cities began to assume commercial importance;

in the thirteenth century Italian coinage set the standard of value for Europe; Venice became the chief center of commerce with the East, and the trade between the Mediterranean ports and Northern Europe was largely controlled by the merchants and bankers of Lombardy. The mercantile customs of mediæval Italy—formulated by the statutes of the merchant guilds and incorporated in the statutes of the leading Italian cities; accepted by other cities, not only in Italy, but in Spain, Portugal, France, the Netherlands, Germany, and England; recognized and sanctioned in many cases by formal treaties, not only between the Christian states but also with Islam—became the law-merchant (*lex mercatoria, jus mercatorum*) of the mediæval world. From this source is derived the modern law of trade-marks; of partnership, open and silent, and of stock companies; of agency (see MANDATE) and brokerage; of banking, of negotiable papers (bills of lading and bills of exchange), and of bankruptcy; of shipping (maritime law), and especially of maritime loans (bottomry bonds, etc.), and of marine insurance. The institutions and rules of the law-merchant were drawn, in most cases, from the Roman law; but some Teutonic principles found their way (at first through the Lombard law, later through that of Germany and of England) into the general law of Europe; and the Roman rules themselves received important modifications. The most important and permanent changes were due to the fact that Roman commerce was carried on by slave labor, while modern commerce operates with voluntary service and free association. Certain variations from the Roman law, however, were due to the fact that mediæval trade was conducted on a smaller scale and in cruder forms than the commerce of imperial Rome, and in these cases the development of a more extensive commerce with more refined machinery has frequently resulted in a subsequent reception of Roman rules.

Two of the oldest statements of the mediæval law-merchant are (1) the *Charte d'Oléroun* or *Jugemens d'Oléron* (an island near La Rochelle), parts of which date back to the twelfth century, and which was not only received as authority in Flanders, Holland, and England, but was also incorporated in the North German *Waterrecht* (known later as the law of Wisby); and the (2) *Costumes de la mar*, known later as the *Libro del Consolat del Mar*, a compilation made at Barcelona, which was extensively circulated throughout Europe in the fourteenth century (especially in the Italian version, *Il Consulato del Mare*), and enjoyed the highest credit.

Modern Law.—The development of ocean commerce at the close of the Middle Ages relegated the Italian cities to a secondary position, but the law of commerce continued to develop essentially upon the lines of Mediterranean mercantile usage. The modern states of continental Europe have continued to treat commercial law (*droit de commerce, Handelsrecht*) as a distinct branch of the law, and they have generally adopted commercial codes. Such codes usually include maritime law and the law of negotiable papers and of bankruptcy, but in some cases these matters have received separate regulation. The first modern commercial codes were those of Louis XIV. (*Ordonnance de Commerce*, 1673; *Ordonnance sur la Marine*, 1681), which served as a basis for Napoleon's *Code de Commerce* (1808). The present French code has served as a model for the commercial codes of Belgium, Holland, Spain, Portugal, Italy, Greece, Roumania, Servia, and Turkey, and of many of the Central and South American republics. Germany, before 1861, had many separate commercial codes; these were superseded in that year by a federal code, which was introduced into Austria also. The present Russian code is largely based upon older Prussian legislation.

Great Britain and the U. S.—In the English common law, and in the statutes passed by the British Parliament, by British colonial legislatures, and by U. S. legislatures, there exist special rules for special forms of mercantile association (e. g. corporations, stock companies) and for special mercantile transactions; but neither in the British empire nor in the U. S. is there a separate and distinct body of commercial law. No such separate law has been developed, because, as was the case at Rome, the general law has been gradually commercialized. The recognition of mercantile custom in English judicial decisions dates back to a very early period; and the incorporation of the law-merchant into the English common law, although peculiarly associated with the names of Lord Chief Justice Holt and Lord Mansfield, has in fact kept pace with the development of European commerce.

MUNROE SMITH.

Mercap'tan and **Mercaptans** [from Mod. Lat. *mercu'rius*, mercury + Lat. *cap'tans*, pres. partic. of *capta're*, seize, intens. of *ca'pere*, take]: one of a class of compounds first made by Zeise in 1833. On account of its power of forming a well-characterized compound with mercury mercaptan received its name. It contains sulphur, carbon, and hydrogen, and is analogous to ordinary alcohol. If all the oxygen is removed from the latter and sulphur introduced in place of it, the product is mercaptan. The formulas of the two substances show this relation:

C_2H_6O.	C_2H_6S.
Alcohol.	Mercaptan.

Just as alcohol is a hydrate or a hydroxide, so mercaptan has a similar structure, being derived from the hydrocarbon ethane, C_2H_6, by the substitution of the group SH for one atom of hydrogen, as shown by the formula C_2H_5SH, alcohol being C_2H_5OH. Mercaptan is made by distilling a mixture of potassium ethylsulphate and potassium sulphydrate. It is a volatile liquid of extremely disagreeable odor. It has been shown that a quantity as small as $\frac{1}{460000000}$ milligramme of mercaptan can be detected by the olfactory nerves. This substance is now manufactured on a large scale, as it is required in the preparation of sulphonal. IRA REMSEN.

Mercati, mãr-kaa'tēē, MICHELE: physician and author; b. at San Miniato, in Tuscany, Apr. 8, 1541, belonging to a family which through several generations had distinguished itself by learning and literary accomplishments. He studied philosophy and medicine at Pisa, and after taking his degree, in 1561, he obtained employment from Pope Pius V. He founded the museum of natural history in the Vatican and laid out the botanical garden in Rome. When Cardinal Aldobrandini, whom he once accompanied on a mission, ascended the papal throne, under the name of Clement VIII. (1592), he was made his first physician, but died not long after, in Rome, June 25, 1593. He wrote *Instruzzioni sopra la Peste, Podagra, e Paralisi* (Rome, 1576); *Metallo Theca*, a description of the mineralogical department of the museum (published after his death); an essay on the obelisks found in Rome, and other works.

Merca'tor, GERARD (real name KRÄMER): geographer; b. at Rupelmonde, Flanders, Mar. 5, 1512; studied philosophy, mathematics, and the art of engraving at Louvain; first attracted attention by two superb globes he made in 1541 for Charles V.; moved in 1559 to Duisburg, where he was appointed cosmographer to the Duke of Cleve; published several valuable geographical works giving maps and descriptions of the world—Europe, France, Germany, and the British isles. D. Dec. 2, 1594. His principal works are *Tabulæ Geographicæ ad mentem Ptolemæi Restitutæ* (1578) and *Atlas, sive Geographicæ Meditationes* (1595). By those works he exercised a decisive influence, and contributed much to free the student of geography from the yoke which Ptolemy had laid upon him. When he became older, he became theological, and wrote *Harmonia Evangelistarum adversus Molinæum*, and other works which were put on the *Index Expurgatorius*, though they are really insignificant.

Revised by M. W. HARRINGTON.

Mercator, MARIUS: an ecclesiastical writer who flourished in the first half of the fifth century, and played a conspicuous part in the Pelagian and Nestorian controversies. Of his personal life very little is known. He is mentioned only by Augustine (Ep. 193; *Quæst. ad Dulcit.*, 3) and Posidius (*Indic. Lebr. August.*, 4), and it is doubtful whether he was a priest, a monk, or a layman. He was born in Africa. In 418, during the pontificate of Zosimus, he lived in Rome, and, having there become acquainted with the chief representatives of Pelagianism, he wrote two books against them, one immediately after the other. He sent them both to

Augustine, and received praise and encouragement from him; but they seem both to have been lost, unless the *Adversus novos hæreticos* be identical with the *Hypermesticon*, generally printed among the works of Augustine and generally ascribed to him. Ten years later on, in 428, he went to Constantinople—probably on some official mission, perhaps as the agent of Celestine I.—and there he spent a large portion of his life fighting the Pelagians. He wrote in Greek a memoir, *Commonitorium*, which he presented to the Emperor Theodosius II., the result of which was the banishment from Constantinople of Julian of Eclanum, Celestius, and other Pelagian leaders. He continued, however, to write against them, and in 431 they were formally condemned by the synod of Ephesus. He translated into Latin as well his own writings as other documents belonging to the controversy—several sermons by Nestorius, his epistle to Celestine, the *Symbolum Theodori Majis.*, Cyril's *Apologeticus advers. Orientales* and *Apologeticus advers. Theodoretum*, etc.—and those translations are of the greatest importance for the true understanding of the history of the Church during that period. For a long time, however, they were not known at all. It seems that they were used in the ninth century during the controversy between Gottschalck and Hincmar, and in the pseudo-Isidorian fabrications (whence arose the fable of an Isidorus Mercator), but after that time they were entirely forgotten or ignored until Holstenius, in the sixteenth century, again drew attention to them. The best edition of them is that by Baluze (Paris, 1684), reprint in Migne, *Pat. Lat.* xlviii.

Mercator, Nicholas: mathematician and mechanician; b. at Cismar, in Holstein, about 1620; studied philosophy and mathematics in Copenhagen and Rostock; visited England in 1660, and was made one of the first members of the Royal Society in London. He afterward settled in France, and was made superintendent of the construction of the fountains of Versailles, but, as he would not embrace Roman Catholicism, his salary was not paid him. He died in Paris in 1687. He published *Cosmographia sive descriptio cœli et terræ* (Dantzic, 1651); *Trigonometria ephoricorum logarithmica* (Dantzic, 1651); *Rationes mathematicæ subductæ* (Copenhagen, 1653); *Hypothesis astronomica* (London, 1664); *Institutiones astronomicæ* (London, 1676); besides several essays and memoirs in the *Transactions Philosophiques*. He also published a new edition of Euclid.

Mercator's Projection: that kind of projection used in making a chart in which meridians are represented by parallel straight lines, and circles of latitude by lines perpendicular to the meridians. Longitudes are plotted from a scale of equal parts, and latitudes from a varying scale so adjusted that the plot of a ship's course or of a rhumb shall be a straight line making with the meridians an angle equal to the course or the angle of the rhumb. The result is that the scale of the map increases from the equator toward either pole. The principle on which the projection is made is as follows: The length of a minute of longitude in any latitude is equal to the length of a minute of longitude at the equator multiplied by the cosine of that latitude. The length of a minute of longitude being represented by a constant distance, the length of a minute of latitude must be represented by the same distance multiplied by the secant of the corresponding latitude. A scale constructed according to this law is called a scale of meridional parts. (See Meridional Parts.) In projecting a chart of this kind, the earth is supposed to be a perfect sphere, and one minute of longitude at the equator, or one geographic mile, is taken as a unit. The parallels of latitude at the bottom and top, beginning at some meridian, are divided into equal parts, each of which contains some convenient number of minutes; the extreme meridians are divided into parts which continually increase in passing from the equator toward the pole, in accordance with the law heretofore explained; these parts are taken from a table of meridional parts (table iii., Bowditch's *Navigation*), each division corresponding to a convenient number of minutes, usually the same number that is employed on the parallel of latitude; the corresponding points are united by straight lines, and the outlines of continents, islands, oceans, and the like are then laid down from their known geographical positions, with such other information as may be useful to the navigator. If any two points on such a chart are joined by a straight line, and a right angle formed by drawing a meridian through one extremity, and a parallel of latitude through the other extremity, we shall have the triangle of Mercator's sailing. The side parallel to a meridian is the augmented latitude, the other side about the right angle is the longitude, and the angle at the base is the course. Revised by S. Newcomb.

Merced: city: capital of Merced co., Cal. (for location of county, see map of California, ref. 8–D); on the S. Pac. Railroad; 152 miles S. E. of San Francisco. It is in an agricultural and fruit-growing region, and has a large fruit-cannery, grain warehouses, planing-mill, machine-shops, 2 State banks with combined capital of $126,000, and a daily and 3 weekly newspapers. Pop. (1890) 2,009; (1900) 1,969.

Mercedes, mār-sā′dās: a town of the province of Buenos Ayres, Argentina; on the Western and Pacific railways; 61 miles W. of Buenos Ayres (see map of South America, ref. 8–E). It is the center of one of the richest sheep-grazing regions of the republic, and has a large trade in wool, etc.; there are several steam-mills, good schools, St. Patrick's College, etc. The town was originally a military post, established in 1779. Many of the inhabitants are descended from Irishmen who settled here in 1822. Pop. (1892) about 12,000. H. H. S.

Mercer: borough (founded in 1804); capital of Mercer co., Pa. (for location of county, see map of Pennsylvania, ref. 3–A); on the Neshannock creek, and the W. U. Y. and Pa. and the Pitts., Shen. and Lake Erie railways; 60 miles N. by W. of Pittsburg. It contains 2 public-school buildings, 3 national banks with combined capital of $250,000, and 2 weekly newspapers, and is in an agricultural, mining, stock-raising, and natural-gas region. Pop. (1880) 2,344; (1890) 2,138; (1900) 1,804.

Mercer, Hugh: military officer; b. at Aberdeen, Scotland, about 1721; was educated at the University of Aberdeen; became a physician, and served as assistant surgeon in the army of Prince Charles Edward, the Young Pretender, in 1745. In consequence of the failure of the rebellion he emigrated to America in 1747. He took part in Braddock's campaign, and was wounded in the battle of the Monongahela. He received a medal from the corporation of Philadelphia for his courage upon this expedition. In 1758 he was made lieutenant-colonel; accompanied Gen. Forbes to Fort Duquesne (Pittsburg), and commanded that post for some time. He then settled as a physician at Fredericksburg, Va.; was actively engaged in drilling and organizing the minutemen of Virginia in 1775 and the militia in 1776; was appointed colonel of the Third Virginia Regiment Feb. 13, 1776, and at Washington's request was chosen by Congress brigadier-general June 5, 1776. He commanded the attack at Trenton, and advised the night-march upon Princeton, in which he led the advance. He was mortally wounded Jan. 3, 1777, and died a few days later, Jan. 12.

Mercer, Jesse: b. in Halifax co., N. C., Dec. 16, 1769; moved to Georgia, and after being ordained to the Baptist ministry took pastoral charge of a church in Wilkes County in 1789; was an eloquent preacher, and perhaps did more to build up his denomination in the Southern States than any other one man. His collection of hymns, in a volume entitled *Mercer's Cluster*, is still in use in Southern Baptist congregations; wrote *History of the Georgia Baptist Association* (1836) and edited for many years *The Christian Index* of Georgia. He was one of the most prominent and useful members in the Constitutional Convention of 1798. Having acquired a considerable estate, and being without children, he founded by a liberal donation an institution of learning which was named Mercer University. This was at first established at Pennfield, but has since been moved to Macon, Ga. D. Sept. 6, 1841. See his *Memoir*, by C. D. Mallory. Revised by W. H. Whitsitt.

Mercersburg Theology: the name given to the movement within the German Reformed Church of the U. S. because it originated in the theological seminary of that body situated at Mercersburg, Pa., which grew out of the ideas and doctrines embodied in Dr. Schaff's inaugural address, as theological professor there, on the *Principles of Protestantism*, which was translated and indorsed in an introduction by the other theological professor, Dr. J. W. Nevin (1845). Its distinctive points were: 1. The Christo-centric idea of theology. 2. The Church, the body of Christ, like the human body, passes though various stages of development, in each of which it properly discards features of the previous stage (in this way mediæval Romanism was justified, and likewise its rejection by the Reformers). 3. A liturgical worship was commended. See *Life of John Williamson Nevin*, by Theodore Appel (Philadelphia, 1889).

Mer'cia: the largest and most powerful of the seven Saxon kingdoms in England; comprised the central part of the conntry from the Thames to Yorkshire. It was an independent state from 585 to 825, with the exception of a short period when it was subdued by Northumbria. In 825 it was conquered, and merged into the kingdom of Wessex.

Mercier, măr'si-ā', Honoré, LL. D.: politician; b. at St.-Athanase, Province of Quebec, Canada, Oct. 15, 1840; was educated at St. Mary's College, Montreal; and called to the bar in 1867. He edited *Le Courrier de St.-Hyacinthe* 1862–64; sat in the Dominion Parliament 1872–74; was solicitor-general, Province of Quebec, 1879; and on resignation of the Taillon administration, Jan. 27, 1887, formed an administration, in which he held the offices of Premier, president of council, commissioner of agriculture, and attorney-general. From 1883 till 1887 he was the head of the Liberal party. In 1891 he became commissioner of agriculture. He was member for St.-Hyacinthe in the Legislative Assembly 1879–90; and was member for Bonaventure County in the Legislative Assembly since 1890. He was appointed a Knight Grand Cross of the Order of Gregory the Great (Roman) 1888 and a Count of the Holy Roman Empire in 1891; also was an officer of the Legion of Honor, commander of the Order of Leopold, and received the degree of LL. D. from St. John's College, New York, Loyola College, Baltimore, Md., and Laval University, Quebec. D. in Montreal, Oct. 30, 1894. Neil Macdonald.

Mercier, Louis Auguste, M. D.: surgeon; b. at Plessis-Saint-Jean, Yonne, France, Aug. 21, 1811; graduated M. D. at the École de Médecine, Paris, in 1839; he devoted himself to the surgery of the urinary organs. Among his publications are *Recherches anatomiques, pathologiques et thérapeutiques sur les maladies des organes urinaires et génitaux* (Paris, 1841); *Recherches sur le traitement des maladies des organes urinaires* (Paris, 1856). S. T. A.

Merck, Johann Heinrich: critic; b. at Darmstadt, Germany, Apr. 11, 1741; studied at Altdorf and Göttingen; traveled extensively, and subsequently held several important positions in the civil and military service of his native country. Owing to the failure of some of his mercantile enterprises and to the sudden loss of five of his children he became despondent, and committed suicide June 27, 1791. In 1772 Merck founded the *Frankfurter Gelehrte Anzeigen*, a critical journal to which young Goethe and Herder contributed numerous reviews, and was one of the best contributors to Wieland's *Merkur* and Nicolai's *Allgemeine deutsche Bibliothek*. A man of highly refined literary taste, he exerted as a critic great influence not only upon Goethe, but also upon other contemporary writers and the development of German literature in general. See Merck's *Ausgewählte Schriften zur schönen Lit. und Kunst*, edited by Ad. Stahr (1840); *Briefe an und von J. H. Merck* (1838).
Julius Goebel.

Mercur, James: military officer and scientist; b. at Towanda, Pa., Nov. 25, 1842; graduated at U. S. Military Academy, and was promoted second lieutenant of Engineers, U. S. A., June 18, 1866; first lieutenant Mar., 1867, and captain Dec. 9, 1875; served as assistant engineer on the survey of the Northern and Northwestern lakes 1866–67; at the Military Academy as acting assistant and Assistant Professor of Natural and Experimental Philosophy 1867–72; with the engineer battalion as adjutant and commanding company 1872–76; as assistant engineer to Gen. Newton in removing the obstructions at Hell Gate, and upon other river and harbor works 1876–81; and charged with various works of river and harbor improvements and surveys in the Southern States and in New York harbor and vicinity 1881–84; Professor of Civil and Military Engineering at West Point from 1884 till his death, at Fort Monroe, Va., Apr. 21, 1896. He revised and enlarged Mahan's *Permanent Fortification* (1887), and is the author of *Elements of the Art of War* (1888), and *Military Mines, Blasting, and Demolitions* (1892).

Mercury: See Hermes.

Mercury [named from the god Mercury]: the planet which travels nearest to the sun at a distance of nearly four-tenths that of the earth. When near its greatest eastern elongations, which occur at intervals of four months, it may be seen in the west half an hour to an hour after sunset. Telescopic observation of Mercury has revealed very little of interest. Schröter, by careful study of the phases, concluded that the planet rotates on its axis in about 24h. 5m. 30s., but very little reliance can be placed either on this result or on the supposed inclination of the axis of Mercury to the plane of its orbit. Still, it is worth mentioning that in 1801 Harding discovered a streak on the southern hemisphere of Mercury, the careful observation of which resulted in his obtaining a rotation-period almost identical with Schröter's. The figure of Mercury shows no sensible compression. If Schröter's observations can be trusted, one mountain on Mercury has a height equal to $\frac{1}{125}$ of the planet's radius, or to about 12 miles; but later observers, using telescopes of the best modern construction, have failed so completely in recognizing the marks described by Schröter that great doubt necessarily rests on the accuracy of his conclusions. Mercury passes between the earth and sun more than three times in each year, and when, during one of these passages, Mercury is near his nodes he appears to pass across the face of the sun. Such an occurrence is called a transit of Mercury, and, though less important than a transit of Venus, is yet of interest to astronomers. Transits of Mercury occur at intervals of 13, 7, 10, 3, 10, 3, etc., years, always either in May or November. The following table shows the transits that will occur during the next half century, and the Atlantic times of middle of transit:

1894, Nov. 10	1h. 36m. P. M.
1907, Nov. 14	7h. 7m. A. M.
1914, Nov. 7	7h. 5m. A. M.
1924, May 7	8h. 34m. P. M.
1927, Nov. 10	45m. A. M.
1940, Nov. 11	6h. 22m. P. M.

Revised by S. Newcomb.

Mercury, or **Hydrar'gyrum** [*mercury* is so named from the god Mercury (*q. v.*), perhaps in allusion to the quickness and ease with which it flows in any direction; *hydrar'gyrum* is Mod. Lat., from Lat. *hydrar'gyrus* = Gr. *ὑδράργυρος*, mercury, quicksilver, liter., water silver; *ὕδωρ*, water + *ἄργυρος*, silver]: the only simple metal which is liquid at the ordinary temperatures. It occurs as a native metal, like gold, silver, copper, etc., and has been known to mankind from time immemorial. Its chlorides were also known of old—*corrosive sublimate* and the *red oxide* to the Arabians, and *calomel* to the alchemists. Its sulphide, *cinnabar*, has been used as a pigment from the most ancient times.

Occurrence and Preparation.—Besides the native metal, it occurs chiefly as cinnabar, its most abundant ore. The most famous localities in the U. S. are in California, New Almaden and New Idria, named after the two most productive European localities, Almaden in Spain, and Idria in Carniola. There are, however, numerous other undeveloped cinnabar-bearing regions in the Pacific States. Cinnabar is reduced to metallic mercury either by distilling with lime to combine with the sulphur, or by simply distilling in a current of air, which oxidizes the sulphur to sulphurous acid gas, leaving the mercury free. Metallic iron has also been used to combine with and retain the sulphur. The reduced liquid metal is sent into commerce in bottles of wrought iron closed with screw stoppers, containing about 75 lb. each.

Chemical and Physical Nature.—Pure mercury is almost silver-white, of mirror-like luster, which luster it preserves perfectly in air free from sulphur. Like silver, it is tarnished superficially by sulphurous emanations. Dust also may adhere and tarnish it, but it is readily restored to perfect brilliancy by straining, or even by pouring through a glass funnel, to which the dust or tarnish-films will adhere. The worst enemies to its purity are *other metals*, and ignorance of this fact often leads to the ruin or great deterioration in value of large amounts of mercury. No metal should ever be allowed to touch it except iron or platinum. The smallest proportion of some common metals, especially lead, tin, and zinc, and even copper to a less extent, causes it to tarnish constantly and lose its luster, and injures its perfect liquidity, making it somewhat viscous and adherent to other bodies, so that it will "drag a tail" behind when flowing over a surface, rendering it useless for nearly all its practical applications without purification by processes which are none too easy. In such cases, however, if the amount of base metal is minute, it may be removed by agitating with a diluted solution of perchloride of iron for some time. The mercury is thus "floured" or finely divided into globules, extending its surface so greatly that the base metal is soon converted into chloride and dissolved out. On washing then repeatedly with clean water, the globules will usually coalesce again. If some of them refuse to do so, it is best to add a minute quantity of amalgam of

sodium, which causes instant coalescence of the minutest globules. Mercury which gets into this state of fine division, so that it will not run together spontaneously, is lost in immense quantities in mining countries by being washed away in suspension in water and mingled with sand and "tailings." Mercury when pure has a density of 13·596 at 0° C. (32° F.). When it is frozen, which requires a reduction of temperature to about 39° F. below zero, according to Hutchins (= − 39·44° C.), it forms a tin-like mass, which is crystalline, but nevertheless malleable. It boils, when pure, at 357·25° C. (675° F.), yielding a transparent, colorless vapor 6·7 times as heavy as air. When exposed to the air at or near its boiling-point, it is slowly oxidized to the red oxide, which, when exposed again to a still higher heat, is decomposed into its elements.

Uses of Mercury.—The most important of these is in the working of the ores of Gold and Silver (*qq. v.*). It is also used in the amalgamation of the zincs of voltaic batteries, in making looking-glasses, in barometers, thermometers, steam-gauges and other pressure-gauges, in dental amalgams (with copper). In the laboratory it is a valuable agent in eudiometry (for confining gases), in mercurial pumps, and in other ways. It is used for preparing several important medicinal compounds.

Compounds of Mercury.—Several of the amalgams, or compounds of mercury with other metals, are useful substances. The dental amalgam, with copper, has already been mentioned. That with *tin* forms the coating on looking-glasses. Sodium-amalgam is used in the laboratory for a multitude of purposes, and in the arts in the amalgamation of the ores of the precious metals, and in the recovery of mercury which has been employed for this purpose. The two chlorides of mercury are known commercially as Corrosive Sublimate and Calomel (*qq. v.*). The protoxide or red oxide of mercury, known as *red precipitate* in medicine, is formed both by heating mercury in the air and by applying heat to the nitrate. The only other compound of importance is the sulphide, which, when artificially prepared, forms the beautiful pigment known as *vermilion*, and as found native is the mineral Cinnabar (*q. v.*).

Revised by Ira Remsen.

Medicinal Uses of Mercury vary in accordance with the different physiological effects of different preparations. These have therefore to be studied *seriatim*. There is, however, a general affection of the system called mercurialization, induced by the steady impregnation of the blood with the metal, which is essentially the same whatever be the preparation of mercury used. This will, then, first be considered. Physiologically, the symptoms of mercurialization are briefly as follows: There are first a metallic taste in the mouth, a soreness of the gums, with swelling and redness of the same, and a peculiar fetor in the breath. Next comes a tendency to increase of the secretions, especially of the saliva, to be followed by a general inflammation of the structures of the mouth, swelling of the salivary glands, excessive and foul-smelling salivary secretion, and accompanying fever. If the poisoning continue, this condition, known as salivation, may lead to most disastrous consequences. Ulcers, gangrene, caries of the teeth, and hæmorrhages may occur in the affected parts; and now also the general nutrition of the body will be profoundly disturbed. Diarrhœa, emaciation, grave impoverishment of the blood, with absorption of newly formed tissues, may result, establishing a state of general devitalization, from which the sufferer will but slowly recover. While in this condition the internal organs are liable to inflame, or, in common parlance, the individual is apt to "take cold." If the poisoning has resulted from breathing mercurial vapors, as in the case of artisans working with mercury, the symptoms of the mercurial infection are somewhat different. Salivation does not occur, but the poison attacks the nervous system, producing a peculiar trembling of the limbs, called "mercurial tremor." This may be so severe as to render the sufferer unable to stand, or even to use the hands for any useful purpose. Therapeutically, the induction of moderate grades of general mercurialization was formerly one of the commonest practices of the physician, being systematically resorted to in almost all inflammations, under the idea that thereby the inflammatory process could be checked, or at least controlled in severity, and the absorption of its morbid products hastened; but of late years this practice has been steadily losing favor, the treatment of inflammations without mercury apparently giving even better results than the mercurial system. Very many physicians therefore limit the medicinal use of general mercurialization to the single disease syphilis, in which its extraordinary power has been overwhelmingly demonstrated, but even here the old habit of continuing the use of the drug up till the production of actual salivation has been wholly abandoned, and the development of a slight sponginess and tenderness of the gums is recognized as the utmost physiological limit of therapeutic mercurialization.

Other special properties and uses of mercurial preparations are as follow: In general, the soluble or mercur*ic* compounds are intensely irritant, corrosive, and highly poisonous to all forms of life, animal and vegetable. When swallowed in poisonous dose they produce intense gastro-intestinal inflammation, with extremely severe burning pain, vomiting, purging, cramps, excessive prostration, and death. If the sufferer lives several days, salivation from absorption of the mercurial may occur. The antidote in mercuric poisoning is some form of albumen, as white of egg, milk, flour and water, but as the insoluble albuminates thus formed are again redissolved if left in the alimentary canal, the poison must be got rid of by emetics. The effects on the system are to be treated on general principles. The mercuric compounds used internally in medicine are mercuric chloride (corrosive sublimate), mercuric iodide (red iodide), and mercuric cyanide. These are employed in minute dose, largely diluted, to induce therapeutic mercurialization in syphilis, and in weak solution or in ointment as external applications in many forms of chronic skin disease, especially where depending on the presence of a parasite. Corrosive sublimate in exceedingly small doses is also used internally in certain digestive derangements with diarrhœa. In striking contrast with the mercuric are the mercurous compounds and preparations of the metal itself. Those used internally in medicine are mercurous chloride (calomel), mercurous iodide (green iodide), blue pill or blue mass (metallic mercury thoroughly rubbed into a pasty mass with confection of roses and liquorice-root), and mercury with chalk or "gray powder" (metallic mercury rubbed into a grayish powder with prepared chalk). These preparations have not the corrosive and poisonous properties of the higher compounds—a fact probably largely due to their great insolubility. Given in small repeated dose they are in some way slowly dissolved in the juices of the alimentary canal, become thus absorbed, and readily induce general mercurialization. They are accordingly much employed for this purpose in syphilis. In single large dose the tendency of the present group is to a cathartic effect, strongest in the case of calomel, weakest in mercury with chalk. When so operating the mercurial is itself discharged before there is time for its solution and absorption, and hence this mercurial purging is unattended by any general infection with the metal. The stools produced are yellow and green, apparently from the presence of bile—an indication that the cathartic action extends to the duodenum, and thus the bile contained in that part of the intestine is discharged *per rectum* instead of being reabsorbed. Calomel is much used, either alone or with other cathartics, as a purgative, and calomel, blue pill, and mercury with chalk often prove curative in many intestinal derangements, especially in that condition commonly called "biliousness"; but the philosophy of their curative action is not fully made out. Many other preparations of mercury are used for certain special purposes. Mercurial or blue ointment (metallic mercury rubbed thoroughly with lard and suet) is much used as a means of producing general mercurialization in syphilis, a small piece of the ointment being rubbed into the skin daily. It is also employed for purely local purposes in many skin diseases, and for the killing of parasites. A solution of mercuric oxide in oleic acid forms a more elegant preparation for the same purposes. Mercurous oxide (black oxide) and mercuric sulphide (cinnabar) are sometimes used to mercurialize in syphilis by the process of "fumigation," the compounds being volatilized by heat and allowed to precipitate upon the naked skin of the patient; calomel is also used for the same purpose. Mercuric oxide and ammoniated mercury (white precipitate) are used only externally as gently irritant applications to sluggish sores. *Citrine ointment*, containing mercury in the form of nitrate, is used for the same purposes. An acid solution of mercuric nitrate is a powerful caustic. Finally there should be mentioned the yellow sulphate, or "turpeth mineral," which is a prompt and non-nauseating but harsh and unequal emetic.

Revised by H. A. Hare.

Meredith, Edmund Allen: See the Appendix.

Meredith, George: novelist and poet; b. in Hampshire, England, Feb. 12, 1828; was educated in Germany; studied law, but early devoted himself to literature; has published novels and stories, including *The Shaving of Shagpat: an Arabian Entertainment* (1855); *Farina: a Legend of Cologne* (1857); *The Ordeal of Richard Feverel* (1859); *Evan Harrington* (1861); *Emilia in England*, now called *Sandra Belloni* (1864); *Vittoria* (1866); *Rhoda Fleming* (1865); *The Adventures of Harry Richmond* (1871); *Beauchamp's Career* (1875); *The Egoist* (1879); *The Tragic Comedians* (1881); *A Diana of the Crossways* (1885); and *One of Our Conquerors* (1890); also *Poems* (1851); *Modern Love and Poems of the English Roadside with Poems and Ballads* (1862); *Poems and Lyrics of the Joy of Earth* (1883); *Ballads and Poems of Tragic Life* (1887); and *A Reading of Earth* (1888). He succeeded Lord Tennyson as president of the British Society of Authors in 1892. See Le Gallienne, *George Meredith: some Characteristics* (with bibliography, 1890). Revised by H. A. Beers.

Meredith, Louisa Twamley: author; b. at Birmingham, England, July 20, 1812; received an artistic education; published in 1835 a volume of poems, and in 1836 *The Romance of Nature, or the Flower Seasons Illustrated*, both illustrated by her own pencil. In 1839 she married her cousin, Charles Meredith, and went to Australia. Five years later they settled in Tasmania. D. Oct. 21, 1895. She published *Notes and Sketches of New South Wales* (1844); *My Home in Tasmania* (1852); *Some of My Bush Friends in Tasmania* (1859); *Over the Straits* (1860); and *Loved and Lost*, a volume of verse, illustrated by herself.

Meredith, Owen: See Lytton.

Meredith, William Ralph: See the Appendix.

Meres, Francis: author; b. in England about 1565; was author of *Tamia Palladis, or Wit's Treasurie* (1597); *Wit's Academy: a Treasurie of Goulden Sentences, Similies, and Examples* (1634); and of a translation of the *Sinner's Guide*, by Fray Luis de Granada (1598–1614). The first-named work was a "comparative discourse of our English poets with the Greek, Latin, and Italian poets," which became popular as a schoolbook, and is celebrated as containing the earliest critical references to Shakspeare. Meres died Jan. 29, 1647.

Merganser [Mod. Lat., from Span. *mergánsar*; *mergo*, diver (<Lat. *mer'gus*, diver) + *ánsar*, goose < Lat. *anser*]: a name given to several birds of the family *Anatidæ*, differing from the true ducks in having a slender bill, slightly hooked at the tip, armed with little recurved processes which serve as teeth. This style of bill has earned for the mergansers the popular name of saw-bill. Another common name in the U. S. is sheldrake. The mergansers are expert divers and feed on fish. The males are handsome birds with a striking plumage of black and white. The largest species is the goosander (*Mergus merganser*), common to the Old and New Worlds. The handsomest species is the hooded merganser (*Lophodytes cucullatus*), in which the male has a large, compressed fan-shaped crest of black feathers, with a triangular white mark on the hinder portion. The females are more or less brown in plumage. F. A. Lucas.

Merger [O. Fr. infin. of verb, from Lat. *mer'gere*, sink, cause to be swallowed up]: in law, the absorption or extinguishment of one estate, right, or interest by another of a higher grade, when both become vested in the same person in one and the same right. The doctrine finds its principal application in the law of real estate. Whenever a greater and a less estate unite in the same person, without any intervening estate, the lesser estate is absorbed by, or swallowed up in, the greater. Thus if a tenant for years or for life acquire the reversion in fee simple, the estate for life or years is merged in the fee and disappears forever. What remains is only the fee simple, not at all enlarged or altered in character, it is true, by the absorption of the particular estate. (See Landlord and Tenant.) So if the mortgagee of an estate acquires the equity of redemption, merger will take place and he will become vested with the entire estate. The same result will follow if the mortgagor takes an assignment of the mortgage or becomes otherwise vested with the mortgagee's interest. It is a general principle that whenever a legal and an equitable estate in the same land unite in the same person, the latter is extinguished. In courts of equity, however, the doctrine will be ignored whenever a merger would work injustice or frustrate the lawful intentions of the parties. If the several estates by act of the law unite in the same person, but not in the same right or interest, no merger will occur. If, therefore, an executor who has a reversion in his own right acquire a term of years in his capacity as executor, the two estates will not merge.

Instances of the application of the doctrine of merger occur also in other branches of the law. Thus if a contract of specialty, as a bond, be given by a debtor, binding him to the payment of a debt founded upon simple contract, the remedy upon the specialty supersedes or extinguishes that upon the original agreement, inasmuch as the substituted obligation is of a higher nature. For a like reason the recovery of judgment upon a claim arising out of simple contract extinguishes the original ground of indebtedness, and the only subsequent remedy available is an action upon the judgment; but no merger will take place when both securities are of the same character or degree. Thus one chattel-mortgage would not extinguish another.

The term "merger" is also employed in the English law in a somewhat different sense from those which have been hitherto illustrated. Thus it is there a rule that when a felony has been committed which entitles the party injured to bring a civil action for redress, as well as to institute a criminal prosecution, the remedy by action is merged in the remedy by prosecution, or, as it is briefly expressed, the trespass is merged in the felony; but this does not mean that the civil remedy is extinguished, but only that it is superseded or postponed until the criminal proceedings are terminated. After the end of the prosecution the action is maintainable. This rule is established in order that the party injured may be induced to prosecute the public offense, which he might avoid doing if he were first permitted to recover satisfaction for his private injury. The fact that private persons generally act as criminal prosecutors in England makes this rule important. In the U. S., where the prosecution of criminal offenses is generally committed to special public officials, the English rule has been generally abolished.

In criminal law it was formerly held that a merger would occur where the same act was within the definition both of a misdemeanor and a felony, or both of a felony and of treason. In such cases the lower offense was said to merge in the higher, so that the act could be punished only as a felony in the one case or as treason in the other. This doctrine has, however, been very much restricted in England, where it originated, and it has at present little or no place in the U. S., where the distinction between felonies and misdemeanors has been generally broken down by statute. On the general subject, see *American and English Encyclopædia of Law*, article *Merger*. George W. Kirchwey.

Mergui, or **Merghi**; the southernmost district of Tenasserim, Burma, British India; consisting of a territory stretching along the coast of the Bay of Bengal from lat. 9° 58′ to 13° 24′ N., and an innumerable multitude of small islands known as the Mergui Archipelago. The islands are all high and mostly naked, but rich in edible birds' nests, tortoise-shell, and pearls. The territory of the mainland produces sapan-wood and ivory, and is rich in tin and zinc. It is occupied by two mountain ranges which run nearly parallel to each other, and between which the Tenasserim winds its way to the sea. The coast-land between the sea and the mountains presents in some places fine rice-plains, but is mostly mangrove swamps. The mountain country may be described as one continuous forest. Of the total area of the province, 7,810 sq. miles, only 73 sq. miles are under cultivation. Pop. 60,000. The capital is Mergui, situated on an island in the delta of the Mergui river, in lat. 12° 26′ N. It has a good harbor and some trade, but with the exception of the house of the governor, the hospital, and the barracks, it contains only miserable houses. Pop. 12,000, consisting of Burmese, Siamese, and Chinese settlers.

Merian, Maria Sibylle: naturalist and artist; b. at Frankfort, Germany, Apr. 2, 1647. She was the daughter of a Swiss engraver, and in 1665 married an artist of Nuremberg named Graff; but she is universally known as Madame Merian. She early distinguished herself for her knowledge of botany and entomology, and especially for her studies of insect life and drawings illustrating the metamorphoses of various species; in this she was assisted by her two daughters. In company with one of these she visited Surinam, 1699–1701, bringing back large collections of drawings; the daughter made a second trip to that country in 1702. In 1705 she published *Metamorphoses insectarum Surinamensium*, with numerous large plates of South American insects in different stages. This was republished in French after

her death, together with a similar work on the insects of Europe. Madame Merian's drawings were, for the time, remarkably accurate, and many of her observations, which had been questioned, have since been confirmed. D. at Amsterdam, Jan. 13, 1717. HERBERT H. SMITH.

Merian: the name of a family of artists: (1) MATTHÆUS "the elder," b. at Basel, 1593; studied at Zurich and traveled in the west of Europe; married a daughter of Dirk de Bry, a famous engraver of Flanders. At about the age of thirty he settled in Frankfort as engraver on copper, and afterward started a publishing-house, which was continued by his heirs. Among his works are seventy-eight plates of the ceremonial of *Baptism of Frederick of Wurtemberg*; 400 *Emblematic Plates*, with flowers and landscapes; *Bible Stories*, 200 plates; *The Dance of Death*, from paintings at Basel. His most important work is the immense series of plates of the cities, towns, villages, and castles of Germany and France, known with the accompanying text as Zeiller's *Topographiæ*. The twenty volumes of this work contain hundreds of plates of great merit, as simple renderings of fact, interesting for their historical record, and of value as specimens of simple art. The great Hollar is said to have worked on this series, and his own large topographical landscapes (see HOLLAR) are only the perfecting of the style which Merian introduced. D. at Schwalbach, 1650.—(2) MATTHÆUS "the younger," son of the above; b. at Basel, 1621. He was rather a painter than an engraver, but seems to have aided his father, and to have managed the business after his death.—(3) CASPAR or GASPAR, son of Matthæus the younger. He was an engraver, and signed some of the large plates of Zeiller's *Topographiæ* as above.—(4) MARIA SYBILLE, daughter of Matthæus the elder. (See separate article on this artist.)—(5) JAN MATTHÆUS, son of Matthæus the younger, miniature-painter.—(6) DOROTHEA MARIA GRAFF, daughter of Maria Sybille; b. 1678; painter of flowers and insects. D. 1741.—(7) JOHANNA MARIA HELENA, sister of the last; painter of flowers and insects. RUSSELL STURGIS.

Mer'ida (anc. *Augus'ta Eme'rita*): town in the province of Badajoz, Spain; on the Guadiana; 36 miles by rail E. of Badajoz (see map of Spain, ref. 17–C). During the Roman empire it was the capital of Lusitania and a magnificent city; it is still interesting for its remains of that time, among which are the superb bridge over the Guadiana, 2,575 feet long and containing eighty-one arches, and the triumphal arch of Trajan in the middle of the city. Of the magnificent aqueduct from the laguna of Albuera thirty-seven enormous piers are still standing, with ten arches in three tiers built of brick and granite. Of the circus, measuring 1,356 by 335 feet, eight rows of seats still remain. Pop. 7,390.

Merida, mā'-rĕĕ-dăă: a city of Venezuela; capital of the state of Los Andes; on an elevated plain partly surrounded by peaks of the Sierra Nevada; 310 miles W. S. W. of Caracas and 5,300 feet above the sea (see map of South America, ref. 1–C). Two small rivers, one on each side of the city, unite below to form the Chama, which flows to Lake Maracaibo. The scenery is extremely grand, varying from the luxuriant green of the plateau to rugged mountains, some of which are crowned with snow. The climate, owing to the elevation, is temperate (mean temperature, 61° F.) but subject to frequent and rapid changes. Merida has a lively trade, the principal exports being coffee, cacao, and sugar. The so-called University of Merida, founded in 1810, is properly a theological seminary. The city dates from 1558; it was partially destroyed by earthquakes in 1644, 1812, and 1894. Since 1778 it has been a bishop's see. Pop. (1891) 10,747. HERBERT H. SMITH.

Merida: capital of the state of Yucatan, Mexico; on a plain, 22 miles by railway from its port of Progreso on the Gulf of Mexico (see map of Mexico, ref. 7–K). It was founded by Francisco de Montejo in 1542, on the site of the Maya city of Thó; the latter is still the Maya name of the place. The cathedral, several monasteries, now used for secular purposes, and many dwellings date from the sixteenth century, and were built from material furnished by Maya structures. The city is laid out with straight and wide streets, and has a central square or park. The climate is hot, and at times unhealthful; yellow fever is a frequent visitor. From an early period Merida has been a noted intellectual center; at present it has faculties of theology, law, medicine, etc., forming a university, and numerous other educational institutions. Its modern commercial activity is largely due to the trade in sisal hemp. Pop. (estimated, 1892) 53,000. HERBERT H. SMITH.

Meriden: city; New Haven co., Conn. (for location of county, see map of Connecticut, ref. 10–G); on the N. Y. and N. E. and the N. Y., N. H. and Hart. railways; midway between New Haven and Hartford. It is noted for its manufactures, which include silver-plated ware, Britannia metal goods, hardware, cutlery, steel pens, glassware, cabinet organs, malleable iron, iron and brass castings, machinery, etc. The census returns of 1890 showed that 236 manufacturing establishments (representing 52 industries) reported. These had a combined capital of $13,695,409; employed 7,655 persons; paid $4,191,536 for wages and $4,883,757 for materials; and had products valued at $11,933,992. The city is the seat of the State Reform School, and has 3 libraries (High School, State Reform School, and Y. M. C. A.) with over 12,000 volumes, 3 national banks with combined capital of $1,400,000, 2 savings-banks, a trust and safe-deposit company, and 1 monthly, 2 daily, and 2 weekly periodicals. Pop. (1880) 15,540; (1890) 21,652; (1900) 24,296; town, including city (1890), 25,443; (1900) 28,695. EDITOR OF "JOURNAL."

Meridian: city; capital of Lauderdale co., Miss. (for location of county, see map of Mississippi, ref. 7–H); on the E. Tenn., Va. and Ga., the Mobile and Ohio, and the Queen and Cresc. railways; 85 miles E. of Jackson, 135 miles N. by W. of Mobile, Ala. It is in an agricultural region, chiefly producing cotton; contains Meridian Academy (Methodist Episcopal), Meridian Normal College, and East Mississippi Female College (Methodist Episcopal South); and has 2 national banks with combined capital of $230,000, a savings-bank with capital of $50,000, 2 daily, 5 weekly, and 2 monthly periodicals, and several large factories. Pop. (1880) 4,008; (1890) 10,624; (1900) 14,050.

Meridian Circle: See TRANSIT.

Meridian of a Place [*meridian* is from Lat. *meridia'nus*, pertaining to noon, deriv. of *meri'dies*, midday, noon]: the intersection of the earth's surface with a plane passing through the place and the earth's axis. It is a N. and S. line. If the plane of the meridian of a place is prolonged to intersect the celestial sphere, the line in which it cuts that sphere is the celestial, or astronomical, meridian of the place. The *magnetic meridian* of a place is the intersection of the earth's surface with a vertical plane passed through the axis of a freely suspended magnetic needle at the place. The angle between this meridian and the true meridian is called the *declination* or *variation* of the needle. See EARTH.

Merid'ional Parts: parts of the meridian, as used in Mercator's system, extending from the equator, and computed for all latitudes differing by a minute up to some limit, usually 83°. These parts are tabulated, and are used in this form for projecting charts and for solving problems in Mercator's sailing. The method of computing a table of meridional parts is as follows: Starting from the equator and taking a geographical mile as a unit, the length of the first minute of latitude is the natural secant of 1′, the length of the next minute is the secant of 2′, the length of the next minute is the secant of 3′, and so on; hence the distance from the equator to lat. 2′ is equal to sec. 1′ + sec. 2′, the distance from the equator to lat. 3′ is equal to sec. 1′ + sec. 2′ + sec. 3′, and so on. The results obtained in this way are only approximate, and the process of computation is somewhat tedious. Other methods of computation have been devised that are more accurate, and at the same time of easier application; but the method just given shows more clearly the nature of the table in question. The best method of computing a table of meridional parts is from the formula

$$M = 7915'\cdot70447 \log \cot \tfrac{1}{2}(90° - L),$$

in which L is any latitude, and M the corresponding meridional part. See Coffin's *Navigation*.

Mérimée, mā'rĕĕ'mā', PROSPER: author; b. in Paris, Sept. 28, 1803; studied law and was admitted to the bar, but did not practice; held various positions in the civil service; succeeded M. Vitet in 1831 as inspector of the archæological and historical monuments of France; entered the Academy in 1844; was made senator in 1853. Besides a number of traveling sketches, originally reports to the minister of his professional researches, such as *Voyage dans le Midi de la France* (1835), *Voyage dans l'Ouest de la France* (1836), *Voyage en Auvergne et dans le Limousin* (1838), and *Voyage en Corse* (1840), he wrote several valuable archæological and historical works—*Monuments Historiques* (1843), *Pein-*

tures de l'Église Saint-Savin (1844), *Histoire de Don Pedro I., Roi de Castille* (1843), *Épisode de l'Histoire de Russie* (1854), *Mélanges Historiques et Littéraires* (1855). He made his appearance in literature in 1825 with *Théâtre de Clara Gazul*, which was followed in 1826 with *La Guzla*, a collection of lyrical poems. Both were published simply as translations, the former from the Spanish, the latter from the Illyrian, and for many years the secret remained undiscovered; but their influence in propagating the taste and the ideas of the romantic school in France was nevertheless considerable. Afterward followed a series of novels or small romances, often based on some historical data, and delineating the character of the nation and the age with wonderful precision and vividness. *Colomba* and *Carmen* (1840) may be mentioned as his masterpieces in this style. He died Sept. 23, 1870. After his death a very intimate but somewhat peculiar correspondence with an unknown lady was published, under the title *Lettres à une Inconnue*; an autobiography was also found. See A. Filon, *Mérimée et ses amis* (1894). Revised by A. G. Canfield.

Merino Sheep: See Sheep.

Meri'ones (in Gr. Μηρίονης): a son of Molus and grandson of Deucalion. He went as lieutenant to his uncle Idomeneus, the commander of the eighty ships that formed the Cretan contingent in the war against Troy. He was one of the bravest of the heroes; he was the possessor of the helmet of Amyntor, and excelled especially in archery and spear-casting. On his return from Troy his ship was driven by storms to Sicily, but in time reached Crete, where he was worshiped as a hero. J. R. S. S.

Mer'ioneth: county of North Wales; bordering on Cardigan Bay. Area, 669 sq. miles. It is covered with mountains, the highest peak of which, Arran Mowddy, rises 2,955 feet. The soil is poor, and suited only for pasturage, but some lead and copper are found, and considerable limestone and slate. Pop. (1901) 48,786. Capital, Dolgelly.

Merivale, Charles, D. D., D. C. L., LL. D.: historian; b. in Bloomsbury, London, Mar. 8, 1808; was educated at Harrow, Haileybury, and St. John's College, Cambridge, where he was a fellow and tutor; graduated in honors 1830, and was university preacher (1839–41), Hulsean lecturer (1862), and Boyle lecturer (1864–65); rector of Lawford 1848–70; chaplain to the Speaker of the Commons 1863–69; and in 1869 became Dean of Ely. He wrote *The Fall of the Roman Republic* (London, 1853); *History of the Romans under the Empire* (1850–62, 7 vols.; latest ed. 1890, 8 vols., a standard work); *Conversion of the Roman Empire* (1864); *Conversion of the Northern Nations* (1865); a translation of the *Iliad* in rhymed verse (1869); *A General History of Rome* (1875); and *Lectures on Epochs of Early Church History* (1879), etc. D. at Ely, Dec. 27, 1893.
Revised by S. M. Jackson.

Merivale, Herman, C. B., D. C. L.: statesman and author; elder brother of Charles Merivale; b. in 1806; was educated at Harrow and Trinity College, Oxford, and graduated with high honors in 1827; became a fellow of Baliol College; was called to the bar at the Inner Temple 1832; was Professor of Political Economy at Oxford 1837–42; Under Secretary for the Colonies 1848–60; was perpetual Under Secretary for India; author of *Five Lectures on the Principles of a Legislative Provision for the Poor in Ireland* (1838); *Lectures on Colonization and Colonies* (London, 1841, 2 vols.), the most elaborate and complete work on the subject; *Historical Studies* (1865); *Life of Sir Henry Lawrence* (1873). D. in London, Feb. 9, 1874.

Meriwether, Lee: See the Appendix.

Merle: See Blackbird.

Merlin: a little hawk of Europe, *Falco æsalon*. It is swift and courageous, as well as docile in confinement, and hence it was once extensively employed for hawking at small game. It is represented by the pigeon-hawk in the U. S. See Falcon.

Merlin, Ambrosius: an ancient Welsh prophet and enchanter, traditionally stated to haved lived in the fifth century A. D. The legendary history of Merlin is given by Geoffrey of Monmouth in his *Historia Brittonum*, where he is represented as having sprung from the intercourse of a Welsh princess with a demon, and to have been the adviser of Kings Vortigern, Uterpendragon, and Arthur. He figures largely in all the Arthurian poems from Spenser to Tennyson. A collection of prophecies ascribed to him was printed in French in 1498, another in English in 1529, and a third in Latin at Venice in 1554.—Another Merlin, called *Caledonius*, or "the Wild," was said to have lived at Strathclyde in Scotland in the sixth century, and his grave is still shown at Drummelzier on the Tweed, where he was killed on returning from an incursion into Northumbria. He seems to have been a copy of his Welsh prototype, and his prophecies are almost identical with those of the former. An ancient metrical *Life* of this Merlin, consisting of 1,500 lines, was published by the Roxburghe Club.
Revised by H. A. Beers.

Mermaid [M. Eng. *mermayde*; *mere* < O. Eng. *mere*, lake, sea + *mayde* > Mod. Eng. *maid*]: an imaginary marine being, having the form of a woman to the waist, and ending in the tail of a fish. Mermen, the males of this supposed species, are also described. The probability is that the appearance of the dugong or some other marine animal in places where it was not well known may have given rise to the stories regarding this fabulous being. The sirens, nereids, and water-nymphs of poetry are all forms of the same creature.

Merobau'des, Flavius: a poet; flourished in the fifth century. He was a Spaniard and a Christian, and from an inscription of the year 435 (Corpus VI., 1724) we learn that he was a distinguished soldier and rhetorician and a privy councilor of the emperor. Four of his poems, formerly attributed to Claudian, can be found in Jeep's edition of Claudian, vol. ii., pp. 201–208 (Leipzig, 1879). See also Teuffel, *Römische Lit. Gesch.*, p. 464. M. W.

Meroë: the name given by Cambyses to the Ethiopian city Saba in honor of his sister who died there. It was situated on the Nile, between the fifth and sixth cataracts, in Upper Nubia (16° 44′ N. lat.). (Cf. Josephus, *Antiq. Jud.*, ii., 10; Strabo xvii., i., 5.) After the decay of Napata (*q. v.*) to the N., it became the Ethiopian capital, the chief place of an independent kingdom, in the tenth and ninth centuries B. C. The Greek tradition that Meroë furnished the original of Egyptian civilization is wrong, being based, probably, on limited observation and temporary relations. Amenophis I. (Amenhotep) of the eighteenth dynasty led a warlike expedition into Nubia, and penetrated as far as Meroë. The pyramids of the region were of late construction, dating from 600 to 100 B. C., and are simply formal imitations of those of Egypt. The name was also applied to the ancient kingdom of which Meroë was the capital, and whose kings, "So" and Tirhaka, invaded Egypt. It also survives as the name of a wretched village on the ancient site. The Isle of Meroë is the name of a tract in South Nubia, having an area of 577,480 sq. miles, between the Nile and its tributary, the Atbara. See Lepsius, *Letters from Egypt*, Eng. trans., p. 150. Charles R. Gillett.

Me'rom: the biblical name (Josh. xi. 5) for *Huleh*, a lake in Northern Palestine; triangular in form, the apex pointing S., about 4 miles long, and at its greatest breadth 3½. The best description of it is in Macgregor's *Rob Roy* (1866).

Merop'idæ [Mod. Lat., named from *Me'rops*, the typical genus, from Lat. *me'rops* = Gr. μέροψ, bee-eater]: a family of birds, popularly called "bee-eaters." (See Bee-eater.) They have the head moderate; the bill longer than the head, curved, and acutely pointed at the tip; the gape is not deep; the nostrils are basal, rounded, and partly hidden by the short bristles; the tarsi are very short; the toes long; the tail is long and broad. The species comprises tropical or sub-tropical birds, confined to the Old World. Three genera are generally recognized—viz.: *Merops*, with about twenty species; *Melittophagus*, with six species, peculiar to Africa; and *Nyctiornis*, with seven species, in the Indian mainland and archipelago, as well as Africa. They feed upon insects generally. Revised by F. A. Lucas.

Merostom'ata: the group of Arthropods which includes the Horseshoe Crabs (*q. v.*) and their fossil allies, the Eurypterida. They derive their name from the fact that the basal joints of the legs are used as chewing organs. These forms have the body divided into an anterior cephalothorax and a posterior abdomen. The former bears two pairs of eyes and six pairs of walking legs, some or all of which terminate in pincers. The abdominal appendages are adapted for respiration. Formerly classed with the Crustacea, these forms are now known to be more closely allied to the scorpions and spiders. For the most recent discussion of their affinities, see Kingsley, *Embryology of Limulus* in *Journal of Morphology* (1893). J. S. Kingsley.

Merovin'gian: the first Frankish dynasty in Gaul. The name is derived from Merwig or Merovæus, who was supposed to have founded a Frankish empire on the soil of Gaul in the middle of the fifth century, which Clovis (*q. v.*) or Chlodwig greatly extended and perfectly consolidated. The most characteristic events in the history of the Merovingian dynasty are the perpetual division and subdivision of the empire in Austrasia and Neustria; the horrible feuds originated by the rivalry and hatred of Brunehild and Fredegonda, and so vividly depicted by Augustin Thierry in his *Récits Mérovingiens* (1839); and the establishment of a peculiar office, that of *major domus*, which occasioned the overthrow of the dynasty. In 752 Pepin the Short, *major domus* to Childeric III., confined the king in a monastery and seated himself on the throne by the aid of the pope. Pepin was a man of enormous energy, of great courage, and with a subtle understanding of time and circumstances. He felt that the dire emergencies of the country demanded a vigorous ruler, and he understood that in the eyes of the people the clergy could legitimatize even a revolution. He consequently induced Pope Zacharias to become a member of the conspiracy, and Boniface crowned and consecrated him. Thus the Carlovingian succeeded the Merovingian dynasty. See Franks, The.

Merriam, Augustus Chapman, Ph. D.: scholar; b. at Locust Grove, N. Y., May 30, 1843; was educated at Columbia College, where he has filled successively the positions of tutor of Greek and Latin, Adjunct Professor of Greek, and Professor of Greek Archæology and Epigraphy. He was director of the American School of Classical Studies at Athens 1887–88, and during that time the excavations under his direction determined the birthplace of Thespis. In 1890 he was elected president of the New York Society of the Archæological Institute. D. at Athens, Greece, Jan. 19, 1895. His principal works are *The Phæacians of Homer* (1880); *The Greek and Latin Inscriptions on the Obelisk Crab in Central Park* (1883); *The Sixth and Seventh Books of Herodotus* (1885); *Law Code of Gortyna in Crete, Text, Translation, Comment* (1886); report as director of Athens school (1889). C. H. Thurber.

Merriam, Clinton Hart, M. D.: naturalist and biologist; b. in New York city, Dec. 5, 1855; was educated at the Sheffield Scientific School of Yale University; was appointed naturalist of the Hayden survey in 1872, and assistant U. S. fish commission in 1875; since 1886 has been chief of the division of ornithology and mammalogy, U. S. Department of Agriculture. In 1891–92 he was one of the Bering Sea commissioners. He has devoted himself particularly to the study of the geographic distribution of animals and plants in North America, and is the leading authority on North American mammals. His work, which has consisted largely in accumulating facts bearing on the subjects above named, is not to be measured by his published works. Since 1883 he has described about 125 new species of mammals from North America. Among his papers are *Birds of Connecticut* (1877): *Mammals of the Adirondacks* (1884); *Biological Survey of the San Francisco Mountain Region and Painted Desert of Arizona* (1890); *Geographic Distribution of Life in North America* (1892); and *Results of the Death Valley Expedition* (1893). F. A. Lucas.

Merriam, Henry Clay: See the Appendix.

Merrill: city; capital of Lincoln co., Wis. (for location of county, see map of Wisconsin, ref. 3–D); on both sides of the Wisconsin river, and on the Chi., Mil. and St. Paul Railway; 20 miles N. of Wausau. It contains a high school, 4 grammar schools, 11 churches, free public library with 5,000 volumes, 2 national banks with combined capital of $160,000, and 3 weekly and 2 monthly periodicals. It is in an agricultural and hardwood-timber region, and is principally engaged in lumber-manufactures. Pop. (1890) 6,809; (1900) 8,537.

Merrill, Frederick J. H.: See the Appendix.

Merrill, George Edmands: See the Appendix.

Merrill, George Perkins, M. S., Ph. D., F. G. S. A.: geologist; b. at Auburn, Me., May 30, 1854; was educated at the Maine State College and Wesleyan University, Middletown, Conn.; was assistant in Chemistry in Wesleyan University 1879–80; became curator of geology, National Museum, Washington, D. C., in 1880; has been Professor of Geology and Mineralogy in the Corcoran Scientific School of Columbian University, Washington, D. C., since 1893. He is the author of *Stones for Building and Decoration* (New York, 1891); *Handbook and Catalogue Collection of Building and Ornamental Stones in the United States National Museum*; *Report of Smithsonian Institute* (1885–86); *Handbook for the Department of Geology, United States National Museum*; *Report of the Smithsonian Institute* (1890); and numerous scientific papers.
C. H. Thurber.

Merrill, Selah, D. D., LL. D.: explorer; b. at Canton Centre, Conn., May 2, 1837; entered the class of 1859 at Yale College, but did not graduate; received, however, the honorary degree of M. A. from the same institution; preached in several places; was chaplain in the civil war (1864–65); has been specially active in explorations in Palestine, being archæologist of the American Palestine Exploration Society (1874–77) and U. S. consul in Jerusalem (1884–86, 1890–93), the results of which he has incorporated in numerous articles and in several works, including *East of the Jordan* (New York, 1881; 2d ed. 1883); *Galilee in the Time of Christ* (Boston, 1881); *Greek Inscriptions Collected in the Years 1875–1877 in the Country East of the Jordan, etc.* (New York, 1885); *The Site of Calvary* (1886). G. P. F.

Merrill, Stephen Mason: See the Appendix.

Merrimac: town; Essex co., Mass. (for location of county, see map of Massachusetts, ref. 1–I): near the Merrimack river, and on the Boston and Maine Railroad; 6 miles N. E. of Haverhill, 46 miles N. by E. of Boston. It is connected with Amesbury, Haverhill, and Newburyport by electric railway; has a public library founded in 1876, and a weekly newspaper; and is principally engaged in the manufacture of carriages and felt boots. Pop. (1880) 2,237; (1890) 2,633; (1900) 2,131. Editor of "Budget."

Merrimack River: a stream of New Hampshire and Massachusetts; formed by the union of the Pemigewasset and Winnipiseogee at Franklin, N. H. It flows southward into Massachusetts, where it curves toward the N. E., and reaches the ocean in lat. 42° 48′ 27″ N., lon. 70° 48′ 46″ W. On its banks are the thriving cities of Concord, Manchester, and Nashua, N. H., and Lowell, Lawrence, Haverhill, and Newburyport, Mass. It is a navigable tidal stream as far as Haverhill, 15 miles. At its mouth there is a shifting bar which impedes commerce. The river below the dam at Lawrence has valuable fisheries, but its chief industrial importance is from the immense water-power it affords.

Merriman, Mansfield: civil engineer; b. in Southington, Conn., Mar. 27, 1848; graduated in 1871 at the Sheffield Scientific School of Yale College, which also conferred upon him the degree of C. E. in 1872, and of Ph. D. in 1876. From 1872 to 1875 he was engaged in surveying and engineering work: from 1875 to 1878 he was instructor in the Sheffield Scientific School; from 1878 to 1881 Professor of Civil and Mechanical Engineering, since 1881 has been Professor of Civil Engineering in Lehigh University, Pennsylvania. During 1880–85 he was acting assistant, U. S. Coast and Geodetic Survey, having charge of triangulation in Pennsylvania. He is the author of the following books: *Continuous Bridges* (1876); *Elements of the Method of Least Squares* (1877); *The Figure of the Earth* (1881); *Text-book on the Method of Least Squares* (1884); *The Mechanics of Materials* (1885); *A Text-book on Roofs and Bridges* (1888); *Treatise on Hydraulics* (1889); *A Text-book on Retaining Walls and Masonry Dams* (1892); and *Introduction to Geodetic Surveying* (1892).

Merritt, Anna Lea: See the Appendix.

Merritt, Wesley: soldier; b. in New York city, June 16, 1836; graduated at the U. S. Military Academy, and entered the army as brevet second lieutenant of dragoons 1860; was appointed captain Second Cavalry 1862. In the early part of the civil war he had much valuable experience on the staff of cavalry commanders, and in Apr., 1863, accompanied Stoneman's raid to Richmond; was appointed a brigadier-general of volunteers in June, and breveted major U. S. army the week following for Gettysburg, where he commanded the reserve cavalry brigade, as also in the subsequent operations up to Apr., 1864. In the Richmond campaign of 1864 he commanded a division under Sheridan, participating in all the battles of that campaign, and was breveted lieutenant-colonel for gallant and meritorious services at Yellow Tavern, and colonel for the same at Hawes's Shop, Va. In command of a cavalry division in the Shenandoah campaign, he took part in various skirmishes and the battles of Opequan, Cedar Creek, Winchester, and Fisher's Hill, where he won the brevet of major-general; again at Five Forks, Sailor's Creek, and final surrender was distinguished, and promoted

to be major-general from date of Five Forks; and was breveted brigadier and major-general, U. S. army, Mar., 1865. He served in various departments till Feb., 1866, when he was mustered out of the volunteer service; became lieutenant-colonel July, 1866; colonel July, 1876; brigadier-general Apr., 1887; superintendent of U. S. Military Academy 1882–87; commanded the department of the Missouri 1887–91 and 1895–97, the department of Dakota 1891–95; major-general Apr. 24, 1895; in command of the East Apr. 11, 1897; commanded U. S. forces in the Philippines in 1898, and on his return again assigned to the department of the East.

Merry, Robert: poet; b. in London in Apr., 1755; was educated at Harrow and at Christ's College, Cambridge; studied law at Lincoln's Inn; bought a commission in the Guards in 1775, but soon sold it; lived from 1784 to 1787 at Florence, Italy, where he became a member of the famous Della Crusca Academy; contributed to *The Florence Miscellany*, and returning to London began to publish plays and poems under the pseudonym *Della Crusca*. Their style was imitated by many writers, and thus gave occasion to Gifford to satirize the "Della Cruscan school" in his *Baviad*. Merry married in 1791 Miss Elizabeth Brunton, an actress, with whom he went to the U. S. in 1796. He brought out in Philadelphia a play entitled *The Abbey of St. Augustine* (1797). D. in Baltimore, Dec. 14, 1798.

Revised by H. A. Beers.

Mersey: a river of England which rises in the north part of the county of Derby, flows in nearly a westerly direction, expanding at Runcorn into a broad estuary, on the north side of which is Liverpool; below this it joins the Irish Sea. This estuary is from 1 to 3 miles broad, and is about 16 miles long; on its Cheshire side is the entrance to the Manchester Ship-canal, and underneath it is a tunnel connecting Liverpool and Birkenhead by railway, which has been in operation since Jan. 20, 1886. The Mersey, with the estuary, has an entire length of about 70 miles, and is navigable to its junction with the Irwell, its principal affluent.

Mersin: chief port of Southeastern Asia Minor; in the vilayet of Adana (see map of Turkey, ref. 6–G). Its roadstead is exposed and has a shifting bottom. The town is attractive, with wide, clean streets; water abounds, and in the environs are numerous gardens and villas. Its exports of carpets, cotton, wool, sesame, linseed, and castor-beans are important. Pop. 8,000. E. A. G.

Merson, mãr'sōṅ', Luc Olivier: historical painter; b. in Paris, May 21, 1846; pupil of Pils; was awarded the Grand Prix de Rome in 1869; a first-class medal at the Salon of 1873; first-class at the Paris Exposition of 1889; received the decoration of the Legion of Honor in 1881. His compositions are most artistically conceived, and his work possesses qualities of a high order. *St. Isidore* (1879) is one of his finest works, and *Repose in Egypt*, the Holy Family resting by night in the desert—exhibited at the Salon of 1879—is owned by S. A. Coale, St. Louis, Mo. Studio in Paris. William A. Coffin.

Mer'thyr Tyd'vil: parliamentary borough and market-town of South Wales; on the borders of the counties of Brecknock and Glamorgan; on the Taff; 24 miles N. by W. of Cardiff, its port (see map of England, ref. 11–E). It is for the most part meanly built, but since 1850 it has been greatly improved. The industries arise entirely from the collieries and iron-works in the vicinity, as Merthyr is the center of the Glamorganshire coal-fields. Pop. (1891) 58,080.

Merton, Walter, de: founder of Merton College; b. at Merton, in Surrey, England, or at Basingstoke, Hampshire, early in the thirteenth century; was educated at the priory at Merton; took holy orders; obtained several benefices; was appointed Lord Chancellor 1261; deprived of his office by the barons 1263; reappointed 1272, but resigned in 1274, having been appointed Bishop of Rochester. He was reputed a man of great learning. D. Oct. 27, 1277, and was buried in Rochester Cathedral. Chancellor Merton established at Basingstoke, where his parents were buried, a hospital for poor travelers and indigent ministers, and founded Merton College at Oxford (Jan. 7, 1264), gave it a further endowment in 1270, and saw it completed in 1274. Its distinctive feature was that it was a literary, not a sacerdotal, institution, and that the students were prohibited from taking vows. It became the archetype upon which most subsequent colleges at Oxford were modeled, and celebrated its sex-centenary in 1864.

Meru, or **Sumeru** [Sanskr.]: in Hindu mythology, a fabulous mountain which forms the central axis of the universe and round which all planets revolve. It is 84,000 yojanas (about 1,344,000 miles) high, is wider at top than at bottom, is the abode of Brahmã, and supports the Devalokas (*q. v.*) and the Brahmalokas. Its eastern side is composed of gold, its southern side of lapis lazuli, its northern of crystal, and its western of silver, and each is the abode of one of the four regents or kings who ward off the assaults of the Asuras or demons who live beneath the mountain. The Ganges flows from heaven on its summit, and thence descends in four streams to the surrounding worlds. Mt. Meru plays an important part in the Buddhist cosmogony. R. L.

Mer'ula (*Marlani*), Georgios: classical scholar; b. at Alessandria, near Milan, 1424; was educated by the famous Philelpho; opened a school in Venice in 1464; was called back to Milan by Louis Sforza in 1482, occupying the post of historiographer of the city. D. Mar., 1494. He was a man of excessive vanity, and engaged in polemical controversies with his contemporaries, notably Politiano. He issued the *editio princeps* of Martial (1470); *The Comedies* of Plautus (1472); edited Cicero, *de finibus*, *pro Ligario*; and wrote learned commentaries to Juvenal, Statius, Ausonius, and others. Alfred Gudeman.

Merula (*van Merle*), Paul: classical scholar; b. at Dordrecht, Holland, Aug. 19, 1558; was a member of a very distinguished family; after several years of travel he practiced law at The Hague. He succeeded in 1592 to the chair of History at the University of Leyden, made vacant by Justus Lipsius, and was appointed librarian in 1598, after the death of Douza. He retired to Rostock because of ill-health, but died soon after his arrival July 20, 1607. He was the first editor of the fragments of *Ennius*, with valuable notes (1595); of *Eutropius*; author of a *Life of Erasmus*, and of many geographical works and treatises on Roman antiquities. Alfred Gudeman.

Merv (anc. *Margiana*): oasis in the province of Transcaspia, Russian Central Asia; situated in lat. 37° 30′ N. and lon. 62° E.; 250 miles N. of Herat and 360 miles S. of Khiva; area, 2,000 sq. miles; pop. 150,000 to 200,000; formed by the Murghab, and surrounded W., N., and E. by the most arid parts of the Kara-Kum desert, while to the S. it communicates with the valley of the Herirud of Afghanistan. The Murghab rises on the northern side of the Paropamisus, runs parallel to the Tejend, and likewise loses itself in the Kara-Kum desert, having spent its waters on the formation of Merv. The inhabitants of this oasis are Turcomans of the Tekke tribe. The great fertility of the country made Merv at times a marvel of prosperity, but at present the Tekkes feel it necessary to add to the productions of their agriculture and manufactures (arms, silverware, superior carpets, felts, coarse cloths, etc.) by pillaging their neighbors. In ancient times the oasis contained a wealthy and extensive city, as shown by its ruins. The present town of Merv has sprung up since the extension of the Transcaspian railway through the oasis. It is the railway station, and has a population of 3,000.

Revised by M. W. Harrington.

Méry, mā'ree', Joseph: poet and satirist; b. at Aygualades, near Marseilles, Jan. 21, 1798; was educated at a seminary, but was expelled on account of his atheistical opinions, and after a reckless and quarrelsome career, in the course of which he fought in duels, violated the press laws, and spent some time in prison, he went to Paris in 1824 and published in collaboration with Barthélemy *La Villéliade*, a satire on the Villèle ministry, and a number of verses dedicated to the Bonaparte family. He also worked on the *Némésis*, a satirical journal, and produced a variety of romances, dramas, and poems, some of which acquired great popularity. D. in Paris, June 17, 1866. Among his poetical works are *Mélodies poétiques* (1853) and *Napoléon en Italie* (1859). Of his romances may be mentioned *Scènes de la vie Italienne* (1837); *Les Nuits de Londres* (1840); *Un amour dans l'avenir* (1841); *Héva* (1843); and a collection of *Nouvelles nouvelles* (1853). His dramatic writings include *L'essai du mariage* (1855); *Les deux Frontins* (1858); *La fiancée aux millions* (1864); and many others, together with librettos for several operas. F. M. Colby.

Meryon, mā'ri-ōṅ', Charles: engraver; b. in Paris, France, Nov. 23, 1821; entered the naval school at Brest, and in 1839 began a naval career of seven years, during which he rose to the rank of lieutenant. In his voyages in the Medi-

terranean and the Pacific he had used freely a natural power of drawing from nature, and from 1846 to 1850 he studied art in a formal way, but gave up painting because his eye for color was defective. He began to make careful engravings of the buildings of old Paris, selecting those remarkable for picturesque effect, but not treating them in the swift and suggestive way common to etchers; his work was rather severe and exact than free, and it is difficult to say how far he used the burin to help out the effect of his etchings. His work obtained little recognition, and he could hardly support life by it. Melancholy and despondency overcame him; in 1858–59 he was confined in the asylum for the insane at Charenton, near Paris; and in 1866 his mind had failed so much that it was necessary again to confine him. He died at Charenton, Feb. 14, 1868. His chief work is contained in a series of *Eaux-Fortes sur Paris*, twelve large plates, with a number of smaller decorative pieces. The best known of these twelve plates are *La Morgue*, *L'Abside de Notre Dame*, *Tourelle de la Rue de la Tixéranderie*. Besides these he made other etchings of Paris, some from buildings in Bourges, some after drawings which he had brought home from Greece and from New Zealand and other islands of the Pacific, and a very few to order, of which much the most important is a panoramic view of San Francisco made from small daguerreotypes. RUSSELL STURGIS.

Merzlïakov', ALEKSEÏ FEDOROVICH: poet; b. in Perm, Russia, in 1778. In 1793 he was sent to Moscow, where he studied at the university at which he afterward taught, in time becoming full professor of Russian eloquence and poetry. His first verses appeared in print as early as 1794, and for the rest of his life he continued to contribute to different papers and reviews. Although in theory he was a strict adherent of the so-called classic school, the simplicity and feeling in some of his shorter poems have kept them popular to the present day. He was also the author of religious odes, many of which possessed merit, as well as of a number of translations, chiefly from the Latin and the Greek, likewise from Tasso, Alfieri, and other Italian poets. See his complete works (2 vols., Moscow, 1867). D. July 26, 1830. A. C. COOLIDGE.

Mesa, La: See LA MESA.

Mescala, or **Mezcala**, māz-kaa'lăă: a river of Mexico; rising in the state of Tlaxcala, flowing through Puebla and Guerrero, and lower down forming the boundary between Guerrero and Michoacan; its general course is westerly, but on reaching the Sierra Madre it turns suddenly southward through that range and reaches the Pacific near lon. 102° W. It takes various local names, as *Atoyac* in Puebla, *Rio de las Balsas* in Guerrero, and *Zacatala* near its mouth, where it is navigable for some distance; the entrance, however, is obstructed by sandbars, and the little port of Zacatala has no commercial importance. The Mescala has comparatively few dangerous rapids, but the current is very swift and strong; various plans have been proposed for its canalization. At present it is important only for gold washings along its lower course, and locally for its fisheries. It gives its name to the small town of Mescala in Guerrero. HERBERT H. SMITH.

Mescalero: See ATHAPASCAN INDIANS.

Mescalpa: See GRIJALVA.

Mesenceph'alon: See BRAIN.

Mes'entery [Gr. *μέσος*, mid, middle + *ἔντερα*, intestines, bowels]: a double fold of the peritoneum which attaches the small intestine to the spinal column, but so loosely as to allow much freedom of motion. The corresponding support of the large intestine is the *mesocolon*, with the *mesorectum*. The mesentery contains between its folds numerous blood-vessels, nerves, lacteals, and lymphatics, and the ganglia known as mesenteric glands, which are connected with the lymphatico-lacteal system. It is about 4 inches wide, and extends nearly the whole length of the intestine. See PERITONITIS.

Me'sha: King of Moab in the reigns of Ahab, Ahaziah, and Jehoram, tributary to the kingdom of Israel, to which he annually paid "a hundred thousand lambs (2 Kings iii. 4) and a hundred thousand rams with their wool." On the death of Ahab (i. 1; iii. 4) he revolted, and Jehoram made an alliance with Jehoshaphat, King of Judah, against him. The two kings overran Moab with the exception of one stronghold, which Mesha successfully defended after offering his first-born son as a burnt-offering to his god Chemosh (iii. 27). An inscribed tablet of this king, the MOABITE STONE (*q. v.*), which commemorates the deliverance hinted at in 2 Kings iii. 27, was discovered in 1868 at Dibon.

Mesh'ed, or **Mashhad**: the capital of the province of Khorassan, Persia; on an elevated but fertile plain in lat. 36° 17′ N. and lon. 59° 37′ E. (see map of Persia and Arabia, ref. 2–J). To some extent Meshed derives its importance from the circumstance that it contains the mausoleum of Imâm Riza, who was the founder of the great Mohammedan sect of the Shiites. This mausoleum and the mosque built over it, with its gilded domes and minarets, its doors of silver, its rails of gold, and forests of columns of marble and porphyry, is among the most magnificent buildings of the East, and is annually visited by thousands of pilgrims. Besides being a so-called holy city, Meshed is a great trade-center. Caravans are coming and going every day, carrying loads of costly merchandise from India, China, Persia, Arabia, and Europe. In several branches of industry its own manufactures are celebrated; its carpets, shawls, light silks, and sword-blades have a high reputation; also certain kinds of earthenware, glass, and porcelain. Pop. estimated at from 50,000 to 80,000. Revised by M. W. HARRINGTON.

Mes'mer, FRANZ, or FRIEDRICH ANTON: physician; b. at Itzmang, on the Lake of Constance, May 23, 1733, or, according to others, at Meersburg, in Suabia, in 1734. He was educated at Dillingen and Ingolstadt, studied medicine at Vienna, took the degree in 1766, and began his famous magnetic cures in 1772; went to Paris in 1778; made an enormous sensation and a great fortune, but lost his reputation here by the unfavorable report made on his method by a royal committee of the greatest French physicians and scientists; practiced for some time in London, though with less success; returned to Germany, and died almost entirely forgotten at Meersburg, Mar. 5, 1815. Mesmer gave his name to the whole class of phenomena now known under the term HYPNOTISM (*q. v.*), the older term mesmerism having covered a great number of theories and supposed facts, which only the recent scientific work in hypnotism has put in order. Revised by J. MARK BALDWIN.

Mesmerism: See HYPNOTISM.

Mesocarp: See DRUPE.

Mesonero Romanos, RAMON, de: writer and scholar; b. in Madrid, Spain, July 10, 1803; d. there in Apr., 1882. He began life by succeeding to his father's business in Madrid, but his literary instincts were strong, and he gradually gave way to them. In 1831 he made his literary *début* with a *Manual de Madrid* (3d ed. 1844), at once a guide to the topography and monuments of the city, and a collection of remarkably skillful pictures of the peculiar life there. This had appeared under the pseudonym *El Curioso Parlante*; and under the same name he published his *Panorama matritense* (2 vols., 1832–35); *Escenas matritenses* (4 vols., 1836–42); *Tipos y carácteres* (1843–62). In 1836 he founded, and for some years conducted, the *Semanario pintoresco español* (8 vols.). In 1842 he published *Recuerdos de viaje por Francia y Bélgica*. In 1845 he was attached to the Biblioteca Nacionál in Madrid, and from that time on turned more and more to scholarly labors. He edited several volumes of the dramatists for Rivadeneyra's *Biblioteca de Autores Españoles*, and contributed critical or biographical notices to several others. In 1861 he published a scholarly history of early Madrid, *El antiguo Madrid*. After his death a volume of his literary remains appeared, *Algo en prosa y verso* (1883). A collected edition of his works, *Obras*, was printed in Madrid in 1881. A. R. MARSH.

Mesopota'mia [= Lat. = Gr. *μεσοποταμία* (sc. *γῆ*, land), the country between the rivers; *μέσος*, mid, + *ποταμός*, river]: the name generally applied since the third century B. C. to the territory inclosed between the Tigris and Euphrates, and 33° 30′ and 37° 30′ N. lat. It is called by the Arabs *el Jezireh*, *the Island*. The whole region is now part of Asiatic Turkey, constituting the vilayet of Mesopotamia. The northern part is rendered hilly by spurs of the Taurus; all the rest is a low, level plain, consisting mainly of dry steppes. The soil is fertile along the rivers where irrigation is employed, but elsewhere affords scant pasturage. Kurds inhabit the north, but the great majority of the inhabitants are Arabs. Anciently it was well cultivated and prosperous, being traversed by the main commercial routes uniting Central and Western Asia. E. A. GROSVENOR.

Mesothorax: See ENTOMOLOGY.

Mesozo'a [Mod. Lat., from Gr. μέσος, middle + ζῷον, animal]: a name introduced by van Beneden for certain problematical animals, from the fact that he regarded them as occupying a position intermediate between the Protozoa, or single-celled, and the Metazoa, or many-celled animals. The forms included are almost microscopic in size, and are either thread-like or spindle-shaped. They live as parasites in cuttle-fishes, Echinoderms, and certain worms. The bodies are remarkable in consisting of very few cells, and these are arranged as an outer layer covering a central mass of one or several inner cells. All organs, except cilia for locomotion, are lacking. They have neither mouth, nervous system, nor muscles. The central cells produce the eggs which go through quite a peculiar history. As to the position of these forms opinions differ, but the weight of the evidence goes to show that they must be regarded, not as primitively simple forms, as thought by van Beneden, but as degenerate worms, coming from that group which naturalists call Plathelminthes. Two distinct groups are recognized, the Orthonectida and the Dicyemida. None has been found in America. J. S. Kingsley.

Mesozo'ic Era [*mesozoic* is from Gr. μέσος, middle + ζωή, life]: the second of the three great divisions of geologic time characterized by known forms of life. It was preceded by the Palæozoic era and followed by the Cenozoic, and has sometimes been called the era of reptiles. In the chronologic system of most European geologists, it includes the Triassic, Jurassic, and Cretaceous periods; in the system adopted by the U. S. Geological Survey it includes the Jura-Trias and Cretaceous periods. See Geology and Paleontology. G. K. G.

Mesquit-grass: a name given in the Western U. S. to rich pasture-grasses of the genera *Bouteloua*, *Aristida*, and some others. They are of great value to stock-raisers, but are of less value for hay-making.

Mesquit-tree: a small, thorny and gnarled tree of Texas, New Mexico, Arizona, and Mexico, the *Prosopis juliflora* of the family *Leguminosæ*. Its hard wood affords good fuel, and its branches yield abundantly a gum which is a good substitute for gum arabic. It appears sparingly in commerce, and is called mesquit-gum. The long pods abound in a thick, sweet, edible pulp. Both bark and wood are rich in tannic acid, and are excellent materials for use in tanning hides. Another mesquit is the *Prosopis pubescens* (screw mesquit); its beans are eaten by the Indians, and the wood is of great value on the southwestern desert plains. It is a shrub or small tree, considerably resembling the above.
Revised by Charles E. Bessey.

Messalina: See Claudius.

Messa'na (in Gr. Μεσσήνη, now *Messina*): a city on the eastern coast of Sicily, near the straits that bear its name. In 729 B. C. Chalcis in Eubœa sent a colony to the place, whose old name Zancle or Danele they retained. In 494 B. C. exiles of Miletus and Samos were invited to settle in Zancle, but by the advice of Anaxilas, tyrant of Rhegium in Italy (colonized partly by Messenians), the newcomers took possession of the city, which soon thereafter came into the power of Anaxilas who, being a Messenian, renamed it Messene (Doric Messana) after his unfortunate mother-country. It later became Messina (*q. v.*). J. R. S. Sterrett.

Messapian Language: a language which survived in Calabria, Southeastern Italy, until the first century B. C., and is known to us through a few inscriptions written in a special form of the Greek alphabet. It belongs to a group of languages which in early times occupied the entire southern and southeastern part of Italy, and was spoken by a population known under the various names Messapii, Iapygii, Pœdiculi, Peucetii, Dauni, Sallentini, Bruttii, etc. The most probable view concerning the historical connection of this group associates it with the Illyrian (Albanian) of the opposite shore of the Adriatic. See Th. Mommsen, *Unteritalische Dialekte* (1850); *History of Rome* (vol. i.); W. Deecke, *Zur Entzifferung der messapischen Inschriften* (*Rhein. Mus.* vols. xxxvi., xxxviii., xl.); H. Nissen, *Italische Landeskunde* (vol. i., 1883). See Italic Languages.
Benj. Ide Wheeler.

Messe'ne (in Gr. Μεσσήνη): a city in Messenia founded by the Thebans, under the lead of Epaminondas, in 369 B. C., at the foot of Mt. Ithome, after the power of Sparta had been finally broken. The new city was peopled by the descendants of those who had emigrated 300 years before, and the country flourished anew as an independent state until conquered by the Romans in 146 B. C. The ruins of the walls are universally admired. J. R. S. S.

Messe'nia (in Gr. Μεσσηνία): a state of ancient Greece embracing the southwestern part of the Peloponnesus; bounded on the N. by Elis and Arcadia, on the E. by Laconia, and on the S. and W. by the sea. See Messene and Messenian Wars. J. R. S. S.

Messenian Wars: wars between Messenia and Sparta. *First War* (from 743–724 B. C.).—Spartan maidens who were visiting the temple of Artemis on the frontier were carried off by Messenian youths, and when Teleclus, King of Sparta, demanded them back, he was killed. About the same time the herds of the Messenian Polyehares were driven off and his son was slain. Then, as the Spartans refused to deliver up the flocks, Polychares killed every Spartan he could find. The war began by the massacre of the inhabitants of the frontier town Ampheia by the Spartans. A pitched battle was of uncertain issue, though the Spartans gradually forced the Messenians to fortify themselves on Mt. Ithome. The Delphic oracle promised victory to the Messenians if a virgin of royal blood should be sacrificed. Aristodemus slew his own daughter, became king, and for a while was victorious over the Spartans, who by bribery obtained another oracle favorable to themselves, whereupon Aristodemus killed himself upon the grave of his daughter and Ithome fell. Many of the Messenians escaped to foreign countries, but those who remained were reduced to the condition of serfs and ground down by taxes. *Second War* (from 685–668 B. C.).—It was caused primarily by the hard lot of the Messenian serfs or Perioeci. The leader was Aristomenes, a man of royal blood, who from Mt. Eira made repeated invasions into Spartan territory, and distressed the Spartans so much that they applied to Athens for a leader. The Athenians sent the poet Tyrtæus, whose martial songs revived the drooping courage of the Spartans. Aided by the treachery of Aristocrates, King of Arcadia and ally of the Messenians, the Spartans won a decided victory (see Aristomenes), and most of the Messenians emigrated to Rhegium in Italy, and afterward possessed themselves of Zancle in Sicily. (See Messana.) *Third War* (from 464–455 B. C.).—A terrible earthquake in 464 B. C. gave the oppressed Messenian serfs a coveted opportunity for insurrection. Once again they fortified themselves on Mt. Ithome. At the request of Sparta the Athenians sent troops under Cimon to aid in putting down the insurrection, but after a time the Athenians were rudely dismissed by the Spartans. After a long siege the Messenians were allowed to withdraw on condition of perpetual exile. The Athenians located the most of them in Naupactus.

Messiah [from Heb. *māshi'aḥ*, anointed (deriv. of *māshaḥ*, anoint), hence Messiah, Christ, whence Gr. Μεσσίας, whence Lat. *Mes'sias*, Messiah]: the name in the sacred Scriptures and in the usage of Jew and Christian ascribed to that holy Person in whom the hopes of redemption center. מָשִׁיחַ in the Old Testament, used as an adjective, is applied to the high priest (Lev. iv. 3; vi. 22, etc.) as the one anointed with the holy oil; but as a substantive, to the theocratic king (1 Sam. ii. 10; Ps. xviii. 50, etc.), and so by the reflection of the poets to the patriarchs as the ancestors of the theocratic king (1 Chron. xvi. 22; Ps. cv. 15); and thus by eminence to that Person in whom the functions of priesthood and royalty culminated (Ps. ii. 2; cx. 1, 4; Dan. ix. 26). In the New Testament, ὁ Μεσσίας is used in John i. 42; iv. 25, but generally מָשִׁיחַ is rendered by its Greek equivalent Χριστός, which with the article refers to Jesus as the expected Messiah, but without the article, especially in the Epistles, became a proper name of Jesus Christ, the historical Messiah. In the New Testament it is easy to separate the person of Christ from his redemptive work and the last things; but this can not be carried out in the Old Testament, because the person of the Messiah is ever involved in the future redemption, and the last things embrace both advents. Hence we must treat of the Messiah under the more general head of *Messianic Prophecy*, which may be defined as the prediction of the fulfillment of redemption through the Messiah or the divine ideal of redemption presented in the Old Testament. This ideal or prediction was gradually unfolded, and is associated with historical epochs and great names in Israel's history. It is found not only in utterances respecting the future, but also in divine words subsequently revealed in reference to the past, in ideal statements concerning the present, and in institutions.

Primitive Messianic Ideas.—(1) Gen. i. 26–30 states that mankind was made in the divine image with the destiny of dominion over nature—the goal of creation was a godlike race inhabiting and subduing the earth. The whole plan of the world's history, which includes redemption after sin entered, is here indicated. Ps. viii. 3–9 repeats this idea. The fulfillment is realized through Christ, the Son of man, through whom mankind attains the original end of creation (Col. iii. 10; Eph. iv. 24; Heb. ii. 5–10). (2) Gen. iii. 15, the Protevangelium, predicts the ultimate victory of the seed of the woman over the serpent, but not without suffering. This victorious seed primarily is the human race, and this promise is the *Magna Charta* of human history. The seed, however, culminates in Christ, the representative of the race, through whom the victory is attained. The serpent and his seed represent all forces of evil (John viii. 44; Rom. xvi. 20; 1 Cor. xv. 25; Rev. xii. 9 f.; xx. 2 f.). (3) After the flood, in the promise and covenant with Noah, hope for the future is assured (Gen. viii. 21–22; ix. 8–11); mankind is not again to be cut off; the conditions necessary for man's destiny or redemption are thus guaranteed. (4) In Gen. ix. 25–27 is set forth the threefold development of the human race, determined by their descent from Noah's sons. To the descendants of Ham is given servitude; to those of Japheth, wide dominion; to those of Shem, the blessing or special favor of God. This last is unfolded in the choice of Israel and culminates in Christ. If v. 27 represents God dwelling in the tents of Shem (so many commentators) then the divine line of Messianic promise here begins, a line promising the advent of Jehovah, which is carried forward in the manifestations of the Angel of Jehovah, in Jehovah's dwelling above the cherubim, and in the predictions of Jehovah's coming in judgment and to abide with his people. The fulfillment is in the incarnation (John i. 14; Eph. ii. 22; Rev. xxi. 3). (5) Abraham's blessing (Gen. xii. 1–3; xiii. 14–17; xv. 4–5; xvii. 6–8; xxii. 15–19), renewed to Isaac and Jacob (xxvi. 3–5; xxvii. 27–29; xxviii. 13–15), unfolds the Protevangelium. It is a divine call with the institution of a covenant relation and a promise which includes a promised seed, a promised land, and a blessing to all nations. The seed—a generic term representing the seed of the woman—in its unity is fulfilled in Christ (Gal. iii. 16), but as a collective, with a multitude of members, nations, and peoples, like the stars and sand, it is fulfilled in the children of Abraham by faith (Rom. iv. 6; Gal. iii. 29). The land was primarily Canaan, but ultimately it is the spiritual Canaan, the heavenly Jerusalem (Heb. xi. 10, *seq.*; Rev. xxi.). The blessing is realized in salvation through Christ. (6) The patriarch Jacob on his death-bed divides the promised land among his sons, singling out Judah as the one through whom the covenant blessings especially unfold (Gen. xlix. 8–12). He will be of resistless might against his enemies, receiving also the homage of his brethren. The peoples will obey him as ruler, while he enjoys the luxuries of peace. The fulfillment began in the leadership of Judah in the conquest of the land, and was continued in the glory of the Davidic dynasty, but is fully realized only in the Lion of Judah (Rev. v. 5), who is the great conqueror (Eph. iv. 8; Col. ii. 15), to whom all will render homage (Phil. ii. 10 f.), and who will be enthroned amid the glories of eternal peace in heaven (Rev. xxi.–xxii.).

Messianic Prophecy of the Mosaic Age.—(1) In Ex. iv. 22 f. Israel is placed in the endearing relationship of sonship, even that of first-born son, to Jehovah. This idea, repeated in Deut. xxxii. 6–10 and Hos. xi. 1, is unfolded in the promise made to David where his seed is placed in a similar relation (2 Sam. vii. 14; comp. also Ps. ii. 7), and is fulfilled in Jesus, the well-beloved and only begotten Son of God (Matt. iii. 17; John iii. 16, *et al.*), and through him it becomes the blessed right of all believers (John i. 12; 1 John iii. 2). (2) In Ex. xix. 3–6 the foundation of the idea of the kingdom of God is laid, and the third element of Abraham's blessing is unfolded. Israel redeemed from Egypt is constituted by a covenant relation a kingdom of priests and a holy nation unto Jehovah. Priesthood and royalty thus are given to the people. The former finds representation in the Levitical and Aaronic priesthood (Num. xxv. 12, *seq.*). They unite in fulfillment in the Priest-King, the Messiah, and through him they become the inheritance of each believer in the Church (1 Pet. ii. 9; Rev. i. 6; xx. 6). (3) The prophecies of Balaam (Num. xxiii.–xxiv.) picture Israel as a unique nation dwelling apart, of countless numbers, irresistible in might, and enjoying rich and beautiful possessions, with God for their King, directly revealing his will among them. Out of Israel emerges a victorious royal dynasty, indicated in a star and scepter, permanent and enduring, while other nations crumble and pass away. These prophecies prefigure the glory and triumph of the Messianic kingdom, and by implication the sovereignty of the Messiah (Rev. xxii. 16). (4) In Deut. xviii. 15–18 there is the promise of a prophet like unto Moses, unto whom Jehovah will give his words and require that he be obeyed. According to some, the context demands that *prophet* should be taken as a collective noun, referring primarily to a line of prophets; others find reference only to a specific prophet. In either case the idea here set forth finds full realization only in Christ, through whom came "grace and truth" (John i. 17), and who fulfilled both the law and the prophets, saying, "But *I* say unto you" (Matt. v. 17, 21, 27, 34, 39), and the New Testament properly finds this prophecy fulfilled in him (Acts iii. 22–26). (5) In addition to these words associated with the patriarchal and Mosaic periods of history, there are also the sacrificial institutions, which typified a means of reconciliation with God, and are fulfilled in the priestly and atoning work of Christ (1 Cor. v. 7; Eph. ii. 14, 16; Heb. viii.–ix.; 1 Pet. i. 17, *et al.*).

Messianic Prophecy of the Time of David.—A new era begins with the organization of the kingdom of David, and the establishment of the religious and political center at Jerusalem. The desire of David to build Jehovah a house is the occasion of a fundamental prophecy (2 Sam. vii. 12–16). The promise to or covenant with David is that his seed shall be established as a house or dynasty, to whom will be granted, (1) to build a house for Jehovah; (2) to have an everlasting kingdom; (3) to be a son to Jehovah, chastised for sin and yet retained with everlasting mercy. In the first of these is involved the promise of the dwelling of God in the tents of Shem (if we adopt that reading, see above), the Shekinah of the tabernacle, and the fulfillment is in Solomon's temple (1 Kings v. 5), in the incarnation (hence Christ calls his body the temple, John ii. 19–21), and in the abiding presence of Christ and the Holy Spirit in believers or the Church (Matt. xxviii. 20; 1 Cor. iii. 16; 2 Cor. vi. 16; Eph. ii. 20); in the second is taken up Jacob's prediction concerning Judah and Balaam's of the star and scepter, and it forms the basis of all subsequent expectations concerning the personal Messiah, in whom and in whose kingdom it finds its ultimate fulfillment; in the third is infolded the sonship of the people (see above, Ex. iv. 22, 23), and the fulfillment is that already mentioned (see above) with the aditional idea of mercy and chastisement, relatively realized in God's dealings with Solomon and subsequent kings, but ultimately in the suffering Messiah, through whom mercy was first made sure forever, when he received the chastisement of his Father God for the redemption of his race (2 Cor. v. 21; Gal. iii. 13; 1 Pet. ii. 24). In David's last words (2 Sam. xxiii. 1–7) is expressed the confidence of the full realization of this covenant.

Based upon this Davidic covenant are certain passages in the Psalter which express the idea of its fuller realization, and thus are prophetic of the future. (1) Ps. xviii., describing the special interposition of God in behalf of David, and then his exaltation and the subjugation of his enemies, the extension of his rule to distant nations and the praise of God among them for the wonders he has wrought, foreshadows typically a future divine purpose through a king that is Christ and a kingdom under his rule here on earth (Rom. xv. 9). (2) Ps. cx. cites a divine oracle and oath, and upon these as a basis represents the Messiah going forth to battle, engaged in the struggle, and triumphant. He is a priest-king after the order of Melchizedek, the Lord of David exalted to a position of peculiar dignity at Jehovah's right hand, while he subdues all his enemies under his feet. The priesthood and royalty of the people here unite and find representation in a single person (see above, Ex. xix. 3–6). The fulfillment is in the priestly and kingly rule of Christ (Matt. xxii. 41–45; Acts ii. 34–36; Heb. i. 13; vii. 17, *seq.*; x. 12–13; Eph. i. 20; 1 Cor. xv. 25; Rev. xix. 11–16). (3) Ps. ii. represents a conspiracy against Jehovah and his anointed, who is established by Jehovah as King of Zion and according to divine decree recognized as his son, and to whom is promised worldwide dominion and the complete subjugation of enemies. The fulfillment is in the triumph of Christ, even through death, over those who conspired against him (Acts iv. 25–28), in his resurrection (Acts xiii. 33), in his heavenly enthronement (Heb. i. 5), and in the extension of his kingdom even now being realized. (4) In Ps. xlv. the king is represented as of divine majesty and as espousing a royal bride, a daughter of the nations.

This is typically prophetic of the exaltation and divine sonship of Christ (Heb. i. 8–9), and of his relation to his Church (Eph. v. 25; Rev. xix. 7–9). (5) Ps. lxxii. expresses aspirations for the king and their realization in righteousness. Mercy and peace everywhere prevail; the kingdom extends over the whole earth; the soil yields its abundance; and all nations unite in grateful tributes of praise and adoration. (6) Ps. xvi. unfolds the idea of the ideal man (see above, Gen. i. 26) as one who, having Jehovah as his portion, will triumph over death. This is actually realized in Christ's resurrection (Acts ii. 27).

Messianic Ideas of the Prophets.—After the death of Solomon, owing to the division of the kingdom and the degeneracy of the people, the prophets recognize that the purpose of Israel's choice can not be realized without a divine chastisement or judgment. This appears in various calamities, and especially in present or impending foreign invasion and captivity. After the judgment the redemption of a chosen remnant is announced, a saved and spiritually transformed community of reunited Judah and Ephraim, gathered to their land, which likewise is transformed, becoming most blissful, a paradise, where all dwell in everlasting security, with Jehovah in their midst, and where also Gentiles share in their blessings. Guilt, judgment, and redemption are the elements of the prophetic messages. These appear in the blessings and curses of the Pentateuch (Ex. xxiii. 20–33; Lev. xxvi.; Deut. xxvii.–xxviii.); and the Song of Moses (Deut. xxxii.) is a prototype of all propheey. The future redemption is accomplished by the advent of Jehovah, the work of his Spirit and the personal Messiah. The fulfillment is in the person and work of Christ, and extends from the first to the second advent. Temporal features usually typify spiritual. The eaptivity typifies the bondage of the race in sin. The saved community are the redeemed of the New Testament, and the land is the heavenly Canaan. The prophets vary in their outward presentation of Messianic ideas according to their individual character and historical circumstances. After the exile, while the notion of a judgment is still prominent, the thought of a captivity has disappeared. We give the prophets and contemporary Messianic Psalms in chronological order (there is not, however, entire agreement among scholars in reference to the date and division of some of these).

Pre-exilian Prophets.—(1) Joel (we follow Briggs, Delitzsch, and Orelli in placing Joel earlier than Amos; many modern critics, with much probability, regard his prophecy as post-exilian). The prophet declares the advent of Jehovah (*a*) (ii. 28–32) in the outpouring of the prophetic spirit, with wonders in heaven and on earth heralding judgment, and with deliverance in Jerusalem for all calling upon his name. (*b*) The advent in judgment is described (chap. iii.) as an assembly of all nations with confusion of multitudes and fearful natural phenomena, with the result of Jehovah's dwelling on Mt. Zion, Jerusalem being inviolable, the land of marvelous fertility, a fountain coming forth from the temple; likewise there shall be signal divine forgiveness. In the New Testament fulfillment is claimed for the day of Pentecost (Acts ii.), and the words and imagery are applied to the Gospel call and salvation (Rom. x. 12, 13), and to Christ's second advent (Matt. xxiv. 29). These New Testament applications show clearly that Christ assumed the place of Jehovah. See also Rev. vi. 12; xiv. 14 ff.; xvi. 16; xxii. 1.

(2) Amos (chap. ix.) sees judgment about to befall Israel, after which a remnant will be sifted out; the ruined house of David will be restored; the old or promised territory will be repossessed: and the land will be of wonderful fruitfulness, where Israel shall abide forever. Acts xv. 16 sees a fulfillment in the erection of the kingdom of Christ and the gathering of the Gentiles.

(3) The ideal of Hosea is that after severe chastisement and rejection set forth in the parable of the adulterous wife and her children (i.–iv.), and figured even under death (vi. 1; xiii. 14), the people of God, in great multitudes (i. 10) united under David, their king (i. 11; iv. 5), shall return unto Jehovah (iii. 5; v. 15–vi. 3; xi. 10 f.; xiv), becoming his faithful bride (ii. 16, 19 f.), and enjoying a land from which the curses of sin—war, wild beasts, and unfruitfulness—have been removed (ii. 18, 21–23). The apostle Paul (Rom. xi. 25 f.) sees a fulfillment in the reception of the Gentiles into the Church (comp. also 1 Pet. ii. 10). The bride of Jehovah reappears in the Church as the bride of Christ (Eph. v. 22, *seq.*; Rev. xxi. 9).

(4) The author of Zech. ix.–xi. (probably a contemporary of Hosea) represents the Messianic king as meek and lowly, and yet victorious; the weapons of war are destroyed and the king reigns in peace over the earth (ix. 9 f.; comp. Matt. xxi. 5). Ephraim and Judah are restored by Jehovah in exultation to their own land, where they walk in the name of the Lord (ix. 9–x. 12). In xi., under the transactions of the shepherd, is symbolized the mutual rejection of Jehovah and Israel by each other, which typifies the rejected Messiah of the New Testament. Comp. Matt. xxvii. 5.

(5) Isaiah (ii. 1–5 and also Micah iv. 1–7) represents the temple mount as exalted, and as a source of divine instruction sought by all nations with the result of universal peace. In iv. 2 ff. the land becomes wonderfully fruitful; Jerusalem is thoroughly cleansed from all iniquity, and is the abiding-place of Jehovah, who creates a refuge for his people, the holy remnant. A corner-stone is likewise laid there worthy of all confidence (xxviii. 16). Zion is the quiet habitation of Jehovah, the glorious judge, warrior, and king, who is its protection in the place of streams and navies, against all hostile powers (xxxiii. 10–24). On the temple and Jehovah dwelling on Mount Zion, see above, 2 Sam. vii. 12, *seq.* On the corner-stone, comp. Ps. cxviii. 22, and see Matt. xxi. 42; Acts iv. 11; Rom. x. 11; 1 Pet. ii. 6, *seq.* Jehovah's dwelling upon Mt. Zion is based upon the placing of the ark there by David, which is commemorated by Ps. xxiv. 7–10, a typical prophecy, further unfolded by Isaiah. Ps. xlvi. and xlviii. belong to the period of Isaiah and express similar thoughts of the security of Mt. Zion. The Messianic person is distinctly brought out by Isaiah—(*a*) vii. 14–16, as a wonderful child, called Immanuel, the bearer of the divine deliverance, but until his maturity distress will continue in the land. (Comp. Matt. i. 20–25.) (*b*) ix. 1–7. A wonderful light shines on the northern frontier, which exalts that people as highly as they had previously been brought into contempt as the first of the Jews to go into exile; a great deliverance, transcending that of Gideon in the day of Midian, is wrought, a child of the house of David is born, named Wonderful Counselor, Divine Hero, Everlasting Father, Prince of Peace, who reigns on the throne of David in righteousness for ever. (Comp. Matt. iv. 15–16; xi. 23; Luke x. 15.) (*c*) xi. A twig comes forth from the stump of Jesse; a shoot from his roots bears fruit. The sevenfold gift of the Spirit rests upon him, endowing him to fulfill his work of judging the poor with spiritual discernment and the wicked with the word of his mouth. Girded with righteousness and faithfulness, he establishes universal peace in the earth, in which the animal kingdom shares. He becomes the standard of the nations; a deliverance like that of Egypt takes place; the ransomed assemble from all lands, marching up on highways of redemption. Matt. ii. 23 applies the נֵצֶר of our passage with the corresponding צֶמַח of Jer. xxiii. 5; xxxiii. 15; Zech. iii. 8; vi. 12, to the Nazarene, as the one who grew up in that obscure place to which the line of David had wandered as a shoot from a neglected stump. (Comp. John. i. 32; xii. 32; Rom. viii. 22; xv. 12; Rev. i. 16.) The nations share in Messianic blessings. Chap. xviii. 7 points to the conversion of Ethiopia; xix. 18–25 represents Egypt and Assyria as united with Israel as the people of God, speaking the holy language and serving Jehovah with altar and sacrifices; xxiii. 18 predicts the consecration of the merchandise of Tyre.

(6) Micah, with predictions of divine judgment upon Israel, announces the elevation of the temple mount (iv. 1–4; see Isa. ii.), and the restoration of the scattered of Israel (ii. 12; iv. 6, *seq.*, 10; vii. 12), who will be purified (v. 10–15) and their sins forgiven (vii. 18, *seq.*), and who will be a blessing and destruction among the nations (iv. 13; v. 7–9), and over whom Jehovah will reign in Mt. Zion forever (iv. 7). Micah presents the Messianic king after the manner of Amos, referring to the exaltation of the Davidic dynasty (iv. 8); after the manner of Hosea, placing a leader at the head of the returning people (ii. 13); after the manner of Isaiah, in the ruler, the great deliverer, in whom the ancient promises will be fulfilled, coming forth from little Bethlehem (v. 2–6. See for fulfillment Matt. ii. 5, *seq.*).

(7) Zephaniah announces after the judgment the deliverance of a purified remnant in whose midst is Jehovah as a king rejoicing and resting in love (iii. 17). This remnant also will be a name and a praise among all the peoples of the earth (iii. 19, *seq.*) and nations from the most distant parts of the world will worship Jehovah (iii. 9, *seq.*). With Zephaniah belong Ps. lxxvii., describing the adoption of the nations into the city of God, and Ps. lxxx., a prayer for protection.

(8) The Messianic prophecies or ideals of Jeremiah are as follows: (1) Ch. iii. 14–17, Jehovah the Saviour marries his exiled people, selecting one from a city and two from a tribe, restores them to Zion, setting over them shepherds after his own heart. (Comp. John xxi. 15–17.) Rachel, weeping for her children (xxxi. 15, *seq.*), is comforted with the promise that they will come again out of the land of the enemy (Matt. ii. 18). Jehovah will sow both the house of Judah and the house of Israel in their own land again (xxxi. 27, *seq.*; comp. Hos. ii. 23). They will come together out of the land of the north, and inherit the goodly heritage of the host of the Gentiles (iii. 18; comp. Hos. i. 11). Jehovah makes with them a new covenant (xxxi. 31, *seq.*), the law being written in the heart, so that all shall know him. (Comp. Hos. ii. 18, *seq.*) New institutions are established (iii. 17), entire Jerusalem is called the throne of Jehovah instead of the ark, and all nations gather into it (Rev. xxi. 2; xxii. 3, *seq.*). The whole city and suburbs become holy as the temple (xxxi. 38–40), even the hill Gareb, the abode of the lepers, and the valley of Hinnom, the place of refuse. (2) The sprout of Isa. xi. 1, *seq.*, is taken up and clothed with new ideas. He is called the righteous branch, Jehovah our righteousness (xxiii. 5, *seq.*), as the bearer of divine righteousness, and so the New Jerusalem bears the same name as the divine throne (xxxiii. 16; comp. Isa. vii. and Ex. xvii. 15). The exodus from Egypt is no more remembered for the greater exodus from all countries of the dispersion to the land of their inheritance. Jehovah will surely fulfill his covenant with David and the Levites; the monarchy and priesthood will become eternal (xxxiii. 17, *seq.*). With Jeremiah belong Ps. lxxxix. and cxxxii., which set forth the inviolability of the Davidic covenant.

The Exilian Prophets.—(1) Ezekiel presents many of the same elements as his forerunners. Jehovah as a faithful shepherd will accomplish a restoration (xi. 17; xxxiv.) which is likened to a transplanted cedar twig becoming an immense tree (xvii. 22, *seq.*), to a resurrection of the dead (xxxvii. 1–14; see above, Hosea); Ephraim and Judah will be united (xxxvii. 15–22). The people will be purified, receiving a new and obedient heart (xi. 19; xxxvi. 26–29; comp. Jer. xxxi. 31, *seq.*). David will be their king (xxxiv. 24; xxxvii. 24). A new covenant of blessings will be made and all ills banished from the land (xxxiv. 25–31; xxxvi. 35; comp. Hos. ii. 18–21, *seq.*; Isa. xi. 6–9, *et al.*), and Jehovah will dwell among his people (xxxvii. 27). The powers of the world—Gog and Magog—will vainly endeavor to destroy them (xxxviii.–xxxix.; comp. Rev. xx. 7–10). There is a prolonged description of a new temple, a new arrangement of worship, the wonderful fertility of the land, and division of territory among the tribes (xl.–xlvii.; comp. Rev. xxi.–xxii.). Sodom and Gomorrah will also find a place with the people of God (xvi. 53–63).

(2) Isa. xxi.–xxvii. These chapters present a divine judgment upon the world and the redemption of God's people, who, restored to Mt. Zion, will unite with all nations in a feast provided by Jehovah (xxv. 6; xxvii. 12, *seq.*). The pious dead will be raised (xxvi. 19); death and sorrow will be abolished forever (xxv. 7, *seq.*; comp. Rev. xxi. 4; 1 Cor. xv. 54). The feast is the prototype of the Gospel feast of the New Testament. Isa. xxxiv.–xxxv. belongs also here, describing the removal of all physical and moral evils at the advent of Jehovah.

(3) In the Psalter is a group of Psalms (xxii., xl., lxix., and lxx.), typically prophetic of Christ, describing suffering. These most probably are based upon the experience of faithful persecuted servants of God like Jeremiah, and especially those of the period of the exile. The most important of these is Ps. xxii. The Messianic features of these Psalms taken together are: (*a*) Cruel reproaches of malicious enemies (Ps. lxix. 26; xli. 7–8; xxii. 7–8; comp. Matt. xxvii. 39, *seq.*). (*b*) He is persecuted because of his consecration to the divine will as the acceptable sacrifice (Ps. xl. 6–8; comp. Heb. x. 8, *seq.*; Ps. lxix. 7–12; comp. Matt. xxvii. 27–30; John ii. 17; vii. 5; Rom. xv. 3). (*c*) The sufferings are the stretched body, feverish frame, intense thirst, offering of gall and vinegar, division of his garments, agonizing cry, and broken heart (Ps. xxii. 1, 12–18; lxix. 20–21; comp. Matt. xxvii. 39, *seq.*). (*d*) Notice also the traitor and his doom (Ps. xli. 9; comp. John xiii. 18; Ps. lxix. 23, *seq.*; comp. Acts i. 20 and Ps. cix. 8). (*e*) Observe also the praise of the delivered one and the worldwide significance of the sufferings (Ps. xxii. 22; comp. Heb. ii. 12; Ps. lxix. 30, *seq.*; xl. 9; comp. John xvii. 4). These Psalms prepare the way for the suffering servant of Isa. liii.

(4) Isa. xl.–lxvi., belongs to the period of the exile. These chapters form an organic whole, into which are woven previous Messianic references about the person of the Servant of Jehovah. This Servant, like the Seed and the Son of the Pentateuch and Psalter, is a generic term referring primarily to Israel, but culminating in the Messiah. Jehovah calls him from the womb to be his servant, and anoints him with his Spirit. He is the gentle preacher and saviour of the poor, the meek, and broken-hearted. He restores the remnant of Israel, is a covenant of the people, a light of the Gentiles, Jehovah's salvation to the end of the earth (xlii. 1–9; xlix. 5–8; lxi. 1–3; comp. Matt. xii. 17–21; John viii. 12; Heb. viii. 6; ix. 15; Luke ii. 32; iv. 18, *seq.*). He is a suffering servant (chap. liii.), without form or majesty, despised and rejected of men, a man of sorrows and acquainted with grief. He is a sufferer, bearing his people's sorrows, pierced for our transgression, crushed for our iniquities, and his stripes were for our healing and peace. (Comp. Ps. xxii. 16; lxix. 26; Zech. xii. 10; Gal. iii. 13; 1 Pet. ii. 24.) All were wandering sheep. Jehovah laid on him, the uncomplaining lamb, the iniquities of all. (Comp. John i. 29; Acts viii. 32; 1 Pet. i. 19; Rev. v. 6; vii. 14, etc.) His contemporaries did not consider this, but assigned him his place with the wicked and with the rich in his death. (Comp. John xix. 38–41. He suffers as a substitute, a trespass-offering, and then reaps his reward in his exaltation, his spoils of victory, and his prosperous ministry. (Comp. Heb. ii. 10–13; Matt. xx. 28; John x. 11–17; Rev. i. 18; Heb. xii. 2.) Chap. lv. gives the Messianic invitation to the free grace of the Gospel (Rev. xxii. 17). The sure mercies of David, the everlasting covenant, are offered in him who is the witness, prince, lawgiver of the people. (Comp. John xviii. 37; Rev. i. 5; iii. 14; Acts v. 31; xiii. 34.) The seed of the righteous servant enjoy the riches of the Gentiles as they become the priests of Jehovah and minister clothed in the garments of salvation; righteousness and praise spring forth before all nations (lxi. 9–11), who come up to the holy places from the most distant parts (xlix. 12). Hunger and thirst, the violent heat of the sun, together with all sorrow and mourning, are banished from the land (xlix. 10; lxi. 3; comp. iv. 3; Rev. vii. 16–17).

The advent of Jehovah is no less prominent. In xl. 3–11 we see the herald of the advent. Zion and Jerusalem become evangelists. Jehovah comes as the gentle shepherd. This is applied to the Baptist and Jesus in Matt. iii. 3. (Comp. John x. 1–18; Luke xv. 3–7.) In liv. 5, *seq.*, and lxii. 5 Jehovah takes Israel as the wife of his youth and rejoices over her as his bride; and in lx. 1, *seq.*, he becomes the light and glory of his people, instead of the sun and moon (Rev. xxi. 23–26). So in lxii. 1, *seq.* the righteous of Zion and her salvation becomes a bright and shining light to the nations; she is called by a new name (Rev. ii. 17), becomes a crown of glory in the hand of the Lord, and is named Hephzibah and Beulah. Jerusalem is rebuilt with precious stones (liv. 11, *seq.*; comp. Rev. xxi. 18–21); her walls are salvation and her gates praise; they are open day and night, while kings and nations enter therein (lx. 11, *seq.*; Rev. xxi. 25), and great is the peace of her children as they are taught of Jehovah (liv. 13; comp. John vi. 45; 1 Thess. iv. 9; 1 John ii. 20). In lix. 15–18 Jehovah appears as a warrior armed with vengeance for his enemies and redemption for his people. He pours out his Spirit as water upon the offspring of the people (xliv. 3–5; comp. lix. 21), and puts his words in their mouth for ever, and they spring up as willows by the watercourses, while the Gentiles claim to belong to Jehovah and enroll themselves as his people. The call goes forth to the ends of the earth, and the oath is sworn "that unto me every knee shall bow and every tongue shall swear" (xlv. 22, *seq.*), and the sons of the stranger come to the holy mount, offering their sacrifices in the house of prayer for all nations (lvi. 6, *seq.*; comp. Rev. viii. 3–5; Heb. xiii. 15, 16). Chap. lxv. 17–27 predicts the creation of a new heaven and earth, as well as of a new Jerusalem, in which there is no more weeping or crying, but length of days, prosperity, and communion with God, in which the animal kingdom shares (2 Pet. iii. 13; Rev. xxi. 1). Ch. lxvi. now describes the final catastrophe and glories. On the one side all flesh assemble in one immense congregation every Sabbath, as at the great feasts, before the throne (Rev. v. 11, *seq.*; vii. 9–12, etc.); on the other side, the carcasses of transgressors are cast out into the unquenchable fire and to the never-dying worm. Comp. Matt. xxv. 41, *seq.*: Rev. xx. 10, *seq.*; xxi. 8, *seq.*

The Post-exilian Prophets.—(1) Haggai predicts that heaven and earth will be shaken, kingdoms overthrown, and

the instruments of war destroyed (ii. 6, 22). The nations will bring their choicest treasures into the house of Jehovah, and the latter glory of the house will be greater than the former (ii. 7–9). Zerubbabel, the servant of Jehovah, will become his signet (ii. 23).

Ps. xciii.–xcix. are probably to be connected with the building of the second temple, and thus with Haggai and Zechariah. Their theme is the advent or reign of Jehovah, and they belong to the divine line of prophecy which finds fulfillment in Christ.

(2) Zechariah (i.–vii.) presents Jehovah as a wall of fire round about Jerusalem, and a glory in her midst (ii. 5, *seq.*; comp. Isa. iv. 5; Jer. iii. 17). Jehovah dwells in the midst of Jerusalem, which is inhabited by old men and little children (viii. 3, *seq.*). The prophet develops also the thought of the future personal Messiah, whom he calls the Branch (iii. 8; vi. 12; comp. Isa. xi. 1; Jer. xxiii. 5). In his day the iniquity of the land will be removed (iii. 9); in him the priestly and royal offices will unite, and he will be the source of the divine Spirit (vi. 9–15 compared with iv.).

(3) In Zech. xii.–xiv. Jehovah's shepherd is smitten by the sword (xiii. 7–9), in consequence of which Jehovah's hand is turned in protection over the little ones (Matt. xxvi. 31–32; Mark xiv. 27; John x. 15); while the house of David and the inhabitants of Jerusalem upon whom the spirit of grace and supplication has been poured, looking upon Jehovah's representative whom they have pierced, mourn greatly (xii. 10–14). A fountain for sin and uncleanness is opened in that day, and the land is purified (xiii. 1, *seq.*). Nations besiege Jerusalem, and are overthrown through disease, panic, and divine intervention (xii. 1–9; xiv. 1–15; comp. Joel iii.; Ezek. xxxviii.–xxxix.). The remnant of the nations goes up yearly to worship Jehovah the King at the Feast of the Tabernacles (xiv. 16). Even the bells of the horses and every vessel in Jerusalem will be as holy as the high priest's tiara, and no unclean person will enter it any more (xiv. 20, *seq.*; comp. Jer. xxxi. 38–40; Rev. xxi.–xxii.).

(4) Malachi introduces the herald of the advent, "my messenger" (iii. 1), "Elijah the prophet" (iv. 5)—who is John the Baptist, according to Matt. iii. 1–12; xi. 10; xvii. 11; Luke vii. 27—turning the hearts of parents and children to one another. The coming one is הָאָדוֹן (the Lord), and the Malakh Jehovah, both terms referring to Jehovah, the divine Messiah. The advent is in judgment as the refiner's fire and fuller's lye, purging the sons of Levi, to offer acceptable sacrifices. It is a day of fire, burning up the wicked as stubble, while to the god-fearing the Sun of righteousness arises with healing in his wings. (Comp. Ps. lxxxiv. 11; Isa. lx. 19; Deut. xxxii. 11.) This divine Messiah is Jesus Christ (Matt. iii. 11–12).

(5) Daniel (whose book in its final form belongs to the Maccabean period) describes the Messianic kingdom, the stone cut out of the mountain, as destroying and supplanting the kingdoms of the world (ii. 25–44), and the Messiah in the form of "one like unto the Son of man" receiving everlasting dominion and glory and the homage of all nations (vii. 13, *seq.*). Daniel likewise typically predicts the cutting off of the Messiah, the ending of the Old Testament worship, and the destruction of Jerusalem (ix. 26, *seq.*; comp. Matt. xxiv. 15). He also declares that there will be a resurrection of the dead, and a day of judgment when the righteous shall receive their inheritance and shine as the stars forever and ever (xii. 2–4; comp. Rev. xx. 12–15).

The fulfillment of these prophecies in their final or Messianic meaning began with the birth of Jesus Christ, and continues throughout these latter days of the dispensation of grace until the second advent in glory at the end of the world. This distinction of advents is not made in the Old Testament, but first by the advent itself and the prophecies of Christ and his apostles. Hence while the first advent fulfills all those references on the divine side to the outpouring of the Spirit, the establishment of a new covenant with new institutions of salvation, and the growth of the kingdom under Jehovah's favor, and on the human side to the more humble features, as of the prophet-like Moses, the suffering servant of Jehovah, etc., yet the great mass of Messianic prophecy is referred by the New Testament writers to the second advent—on the divine side in judgment, on the human side in glory, and yet the human and the divine lines, which in the Old Testament remain ever apart, converge in Jesus Christ the God-man at his first advent, who in his first state of humiliation and his final state of glory either has fulfilled, or is yet to fulfill, all the law and the prophets.

LITERATURE.—Recent works on this subject especially to be mentioned are Briggs's *Messianic Prophecy* (New York and Edinburgh); von Orelli's *Old Testament Prophecy of the Consummation of God's Kingdom* (trans. from Germ., Edinburgh); Delitzsch's *Messianic Prophecies in their Historical Succession* (trans. from Germ., New York and Edinburgh); Riehm's *Messianic Prophecy* (trans. from Germ., New York and Edinburgh). This last contains a full list of recent literature on the Messiah. C. A. BRIGGS.
Revised by EDWARD LEWIS CURTIS.

Messi'na: province of Sicily. It occupies the northeastern corner of the island, and has an area of 1,246 sq. miles, with 500,000 inhabitants. It is mountainous, but the valleys are very fertile, and produce excellent wheat, flax, hemp, wine, oil, and fruit. Sulphur abounds.

Messina: a large seaport-town in the province of Messina, Sicily. It lies in lat. 38° 17′ 38″ N., lon. 15° 35′ E., and rises amphitheater-like from the sea, backed by the rocky extremity of the Siculo-Calabrian Apennines (see map of Italy, ref. 9–G). The harbor of Messina, the largest and safest in the kingdom of Italy, is deep, spacious, well furnished with quays, and defended by a fort and citadel. The annual amount of shipping it receives is over 4,000 vessels, of 1,130,000 tons burden, the imports being wheat, cotton, and woolen goods, hardware, etc.; the exports, fruit, wine, oil, essences, and silks. Messina, having suffered so often from earthquakes and bombardments, now consists in the main of fine new buildings, with well-paved streets and spacious squares, flanked by stately palaces and adorned with fountains and statues. The university was founded in 1549. There are many noteworthy churches, and the old cathedral is one of the most interesting monuments of the city, the exterior being very quaint and curious, and the interior decorated with the rarest marbles, porphyry, jasper, lapis-lazuli, etc. The city is the seat of an archbishopric, and has a university founded in 1549. For the earliest history of Messina, see MESSANA. It suffered severely during the Punic wars and during the Roman civil wars, also from the Goths and the Saracens, the latter being expelled by the Normans in the eleventh century. In 1282 12,000 Frenchmen perished here in the terrible Sicilian Vespers. In 1783 the town was almost totally destroyed by an earthquake. In 1848 Messina threw off the Bourbon yoke, but was reduced to submission after an obstinate and destructive resistance. In 1860 it was freed by the forces of Garibaldi. The climate of Messina is delightful, and the views are magnificent. Pop. of commune (1892) 141,000; of city proper, about 90,000.

Messina, Strait of (Ital. *Faro di Messina*, Lat. *Mamerti'num Fre'tum*): a narrow channel of water connecting the Ionian and the Tyrrhene seas, and dividing Sicily from Calabria. Its length is 26 miles, its greatest width 12 miles, its least 2 miles. The tide is most irregular in this strait, the eastward current being vastly stronger than the westward, and the flood and ebb succeed each other with great rapidity. For a curious phenomenon witnessed here, see FATA MORGANA. See also SCYLLA.

Messis, Metsys, or Matsys, QUINTYN: painter; b. at Antwerp in 1450. He began by working in iron. The gates of a well near the cathedral at Antwerp first attracted attention to his talent. The College of Louvain then ordered a balustrade of him, but the immense fatigue of this work proved too much for a fragile constitution, and, being confined to his bed, he occupied himself by painting images for distribution to the lepers. He afterward taught himself the art of painting in order to marry a woman who was unwilling to wed any one but a painter. A triptych painted for the wood-carvers' guild in Antwerp, representing Christ surrounded by holy women, with the martyrdom of St. John the Evangelist, and Herodias with the head of St. John the Baptist, on the side compartments, is one of his principal works. His portraits were highly prized; those of Erasmus and of Egidius are especially good. He died in 1529. His son John, also a painter, was his pupil. W. J. STILLMAN.

Messiter, ARTHUR HENRY: See the Appendix.

Mestizo, mes-tee'zō [= Span.: Fr. *métis* < Vulg. Lat. **mixti'cius*, deriv. of *mix'tus*, mixed]: in Spanish America, a half-breed, the offspring of a white father and an Indian mother. The white characters usually predominate. The offspring of an Indian father and a quadroon mother (three-fourths white, one-fourth Negro, the latter by the female side) or a quinteroon mother produces what is called a brown

mestizo. A mestizo-claro is the offspring of an Indian father and a mestizo mother.

Mészáros, măs'aar-osh, Lazar: soldier: b. at Boja, Hungary, Feb. 20, 1796; was educated first for the Church, then for the bar, but followed in 1813 the summons of the emperor, Francis I.; entered the Austrian army as a volunteer; served in the campaigns of 1814–15; rose slowly, but acquired a solid reputation in the army, and was made a colonel in 1844. When, in 1848, Count Batthyani formed a separate Hungarian ministry, he chose Mészáros as head of the military department, and although he at first opposed the separation of the Austrian and Hungarian armies, he organized the Hungarian army with great rapidity and skill when the decision was taken. After the declaration of independence (Apr. 14, 1849), he left the ministry and received an active command, and after Görgey's surrender at Vilagos (Aug. 13, 1849) he fled to Turkey; was sentenced to death by an Austrian court martial, and hanged in effigy at Vienna. He afterward lived in France, England, and the U. S. D. at Eywood, Herefordshire, England, Nov. 16, 1858.
Revised by J. J. Král.

Meta, mā'tăă: a river of Colombia and Venezuela, rising in the Eastern Cordillera and flowing E. N. E. to the Orinoco; length about 750 miles, of which about 180 miles are in Venezuelan territory. The Meta is properly formed by the confluence of the Humadea, Negro, and Upia, almost directly E. of Bogotá. It is navigable for steamboats to Cubuyaro, over 400 miles; portions of its lower course are a mile wide. H. H. S.

Metaline: a substance intended for application to all kinds of machinery where friction is encountered, obviating the necessity of oil or other lubricant. Its appearance is that of a soft, dark, metallic compound. It is prepared originally in the form of a fine powder, and is then molded into any shape required by hydraulic pressure. After molding it may be cut or turned to suit any form of application. It is usually applied to journal-boxes in the form of cylindrical plugs or disks from $\frac{1}{8}$ to $\frac{5}{16}$ of an inch in diameter, inserted in holes bored near together over the whole inner surface. In small bearings, such as spindle-bolsters and the journals of sewing-machines, it is pressed into longitudinal slots or creases. Several varieties of metaline are manufactured, differing in composition and adapted to use under the various conditions encountered in running machinery, such as steel on brass, steel on cast iron, etc.
Revised by Ira Remsen.

Met'allurgy [from Gr. *μεταλλουργός*, working in metals, miner; *μέταλλον*, mine, metal + *ἔργον*, work]: the science and art of preparing metals from their ores. In very ancient times the word probably included all the operations of mining, smelting, and the subsequent manufacture of the metal into articles of use. Mining has for many centuries been recognized as an entirely distinct and different calling, though metal-working, such as copper-beating and founding, gold and silver smithing, and blacksmithing, continued for a much longer time to be regarded as metallurgical. As these became more commonly practiced, they were looked upon as mechanical trades, each of which, with the expansion of metal-working, attained a separate existence and took a separate name. As the word is now used by those who follow the calling, the metallurgist is strictly one who prepares metals from their ores, and performs in addition such other operations as are necessary to the production of a finished raw material. Thus in the metallurgy of iron is included not only the smelting of the ores, but also the manufacture of wrought iron and steel from the first product, and such processes of refining as are necessary to obtain the different marketable grades of iron and steel. Only in a few instances does the metallurgist carry his work so far as to produce a finished article ready for immediate use, thus adding metallurgical engineering to the productive branch of his calling. These exceptions are nearly all confined to the manufacture of bulky and low-priced goods, when economy requires the immediate union of the smelting-works and the finishing-shop. The production of railway iron is the most prominent example of this practice. On the other hand, true metallurgical establishments are frequently producers of finished articles which properly belong to chemical manufactures and other branches of technical industry, such as sulphuric acid, arsenic, paints, etc., but these are by-products, obtained from substances occurring in the ore which yields the metal, and their manufacture belongs to other branches of technology than metallurgy. From the foregoing it will be seen that while the meaning of the word metallurgy has in the process of time become restricted to the mere production of metals, instead of its old application to all the arts of working in metals, the practice of the metallurgist has extended so as to embrace the work of the chemist and the manufacturer of products which in former times were not classed as metallurgical.

The minerals from which the useful metals are obtained form only a very small part of the earth's mass, so far as known. The basic elements of the remainder include such metals as sodium, potassium, etc., which, though employed to a limited extent, are not technically classed among the useful metals. The list of the latter has, however, been greatly extended by the increasing use of metals in modern civilization. At present, iron, copper, lead, zinc, tin, silver, gold, mercury, nickel, antimony, aluminium, bismuth, and perhaps platinum, may, either on account of common use, employment as currency, or importance of application, be ranked among the useful metals; while cadmium, arsenic, potassium, sodium, and magnesium have found some application, though a very limited one in the case of the last. Other metals, like cæsium, cerium, etc., have been made for the purposes of chemical study or for cabinet curiosities.

The science of metallurgy includes the processes for obtaining all the metallic elements, but in practice the *art* of metallurgy is restricted to the production of the useful metals alone, the preparation of the others being the work of chemical manufactories. Those minerals which contain enough metallic base to make its extraction profitable are called *ores*, and as the question of profit is dependent upon local circumstances, a given mineral may be an ore in one country and not in another. It is rare to find an ore consisting entirely of the metal-bearing mineral, other non-metalliferous minerals being nearly always mixed mechanically with it. This oreless rock is technically known as the gangue, and it plays a very important part in metallurgy, frequently compelling the choice of operations that are not favorable to the complete extraction of the metal, or that are costly for some other reason. Two general kinds of gangue are distinguished: First, earthy gangue, which is either acid, from a preponderance of silica, or basic, when lime, magnesia, alumina, and iron most frequently occur. In this case two methods of removing the associated rock may be used. One is mechanical, the ore being crushed fine and passed through machines which cause a separation of the heavy ore from the lighter gangue by virtue of their different specific gravities; or by subjecting the crushed ore to some uniform force which affects the two minerals differently. This work, however, is usually allotted to mining operations, and is one of its important auxiliary operations called ore-dressing. The smelter receives the dressed product. The other mode of separating the gangue is by fusion with fluxes. A flux is any substance which will make the ore fusible and fluid at temperatures which are within our control. Practically, the operations of the metallurgist are confined to the treatment of compounds containing silica for the acid, and usually lime, magnesia, alumina, or iron for the base. Other acids and bases occur, but they play a very subordinate part, and are always accompanied by one or more of the above. The art of fluxing therefore simply consists in adding silica when the bases predominate in the ore, and one of the above bases when the contrary is the case. Its difficulties lie entirely in the fact that the proportions must be properly adapted to the metal under treatment and the temperature required. The second kind of gangue is one that consists of a metal-bearing mineral, with which is associated the mineral containing the object of the metallurgist's labors. A distinction has to be made between these two sorts of gangue—partly for the reason that the latter is always basic, and partly because it is often impossible to separate the two metalliferous minerals by mechanical means; and these ores therefore usually come into the metallurgist's hands just as they are received from the mines. Many type-processes of metallurgy have been invented to surmount the difficulties presented by such a metalliferous gangue. Among metals occurring in this manner the most frequent examples are tin, copper, lead, nickel, gold, silver, and others in pyrite (a bisulphide of iron). Most ores consist of both earthy and metalliferous minerals, and therefore require both mechanical and chemical processes for their treatment. While the ores present a great variety of combinations, three general classes may be

recognized by the character of the negative element combined with the metal. They are—(1) Native metals, in which no acidifying element occurs, the metal itself being found uncombined in nature. These native metals are, however, rarely pure, but are generally alloyed. They are gold, silver, copper, platinum, and bismuth. (2) Sulphides, or compounds of the metal with sulphur as the negative element; and in this class may be ranked the compounds in which arsenic and antimony occur, as they come under the same general mode of treatment. Copper, lead, silver, mercury, antimony, nickel, and zinc form such compounds. (3) Oxides, which form the largest and most important class. Iron, copper, lead, tin, zinc, and all the rarer metals belong to it. Many metals occur in two or in all three of these classes, and the division here made refers only to their common occurrence and the mode of treating their ores. The general character of the processes by which a metal is extracted from its ores is not governed by the metal itself, but by the negative element with which it is combined. The metal may decide the adoption of a particular class of operations or apparatus, but the native metals may all be obtained by mechanical dressing or by simple fusion; the sulphides must all be melted with some substance that will combine with the sulphur and leave the metal free, or else they must be roasted and then treated like oxides; and the oxides of the useful metals are all reducible to metal by heating them with carbon or other reducing agents. In carrying out these different processes a great variety of reactions are employed, but only those of a general character will be spoken of here. Three grand modes of producing these reactions are employed, the dry, the wet, and electrolysis. In the first the fluidity necessary for the free action of the substances employed is obtained by heat; in the second by solution in a liquid; and in the third by the electric current. Two of these modes are frequently combined in the treatment of an ore. So far as is known, the dry method is the oldest; the wet followed as the more progressive part of the art, having grown out of the establishment of chemical science; while the employment of the electric current has developed from the creation of the application of electric science to technical work. It has created a new branch of metallurgy called electro-metallurgy, which occupies a conspicuous place in the production of copper and aluminium, and has some promise with zinc. The wet modes of operation simply repeat the reactions of the laboratory, and are therefore more under control and better understood than those of the dry method.

The metallurgy of the native metals consists usually in a combination of mechanical and chemical processes. When the ore occurs in a vein, as copper, and sometimes gold and silver, the vein-rock must be crushed fine; and the most common apparatus for this work is the stamp-mill. A stamp is a heavy pestle, of which the head is iron and the stem may be either iron or wood. It is supported between guides, and rests upon an iron seat or die placed in a mortar, and the crushing is performed by raising the stamp and allowing it to fall upon the ore, which is introduced upon the die, while a constant stream of water passes through the mortar. Stamp-mills form a very important part of the metallurgical apparatus used in the western part of the U. S., and their management includes many important questions of theory and practice. The side of the mortar contains a sieve of the proper degree of fineness, and as soon as the ore has been sufficiently crushed it is carried through the sieve by the water-current. It now consists of metallic grains mixed with, but no longer attached to, particles of rock. The succeeding operations are intended to effect the separation of the metallic grains, either by means of gravity or by taking up the metal (in the case of gold and silver) in mercury. Several modes of utilizing the force of gravity are employed. One of the most common is to run the stream of slime (the ore and water) over coarse blankets. The metal, being heavier than the rock, sinks to the bottom of the stream, and is caught in the meshes of the blankets, from which it is afterward removed by washing them in a tank of water. A similar separation will be obtained if the slime runs over a flat, shallow trough without blankets, provided the force of the current is not sufficient to wash off the metal after it has once settled upon the trough. Many other mechanical methods of separation are employed. When mercury is used, as in the case of gold and silver ores, the operation is known as amalgamation; and it is not yet positively decided whether this is a mechanical or a chemical act, but it is probable that both of these forces are included. The mercury may be used either as a shallow bath, into which the gold sinks by virtue of its greater specific gravity, or it may be distributed in a thin layer over copper plates. The former method is most employed in Europe, and the latter in America. Agitation of the mercury and slime by a percussive movement of the vessel which contains them, or by causing ripples and low falls in the stream, is thought to increase the efficiency of the operation. A large part of the gold and all of the platinum obtained is found in sands and deposits of gravel. In this case the stamp-mill is not needed, the mining being so managed that the sand is conveyed in a current of water through the separating or amalgamating machinery. Platiniferous sands are first concentrated on blankets, as above described; the concentrated sand is carefully washed by hand: the gold removed by amalgamation; and the product, which contains about 75 per cent. of platinum, is sold to manufacturing chemists, who prepare the marketable metal. Of the metals so far considered, native copper and platinum are obtained only by washing, gold and silver by washing or amalgamation. Bismuth differs from the foregoing in having so low a fusing-point that it is more economical to melt the metal out of the ore by the operation called "liquation" than to crush and dress it. The ore is therefore placed in inclined iron tubes holding about 25 lb., and heated to redness, when the metal flows out.

Next to these processes in point of simplicity is *the metallurgy of the oxides.* These ores include the most important metals known, such as iron, copper, lead, tin, and zinc. With the exception of iron, all of these are used pure in the arts, and the mode of treating the ores is to heat or fuse them in direct contact with the fuel. The affinity of carbon for oxygen is so strong at high temperatures that the elements in the ore are dissociated, the oxygen uniting with the fuel and passing off as a gas, leaving the metal to run out in a fluid state, or in the case of zinc allowing it to escape volatilized, to be subsequently condensed. This simple operation is one of the oldest in the art, and the time of its discovery is unknown. It is certain, however, that one of the oldest form of metallurgical apparatus is the shaft-furnace, which is especially adapted to satisfy the conditions of this operation. A shaft-furnace is either round, in section, or consists of four vertical walls containing within them a space which is usually much higher than it is wide or deep. Fire being made within it, the ore fluxes, and fresh fuel are thrown in at the top, and combustion is maintained by driving a steady current of air in at the bottom. The especial characteristic of this apparatus is that the ore and fuel being in immediate contact, and the amount of air being limited, the carbon of the fuel must satisfy its affinity for oxygen by extracting and combining with that contained in the ore, producing the reaction known as reduction. This affinity is so strong that most ores give up their oxygen at comparatively low temperatures, and reduction occurs while they are still in the upper part of the furnace. As the materials at the bottom are melted by the higher heat there and flow out, the reduced ore descends by its own weight until it is in turn melted and collected in the bottom of the furnace, from which it is removed by tapping or opening a small hole in the furnace-wall. Oxides of copper, lead, and tin may be smelted in one operation to metal in furnaces of this kind, which vary from 2 to 30 feet in height. Ores of iron, which are more refractory—that is, do not give up their oxygen with the same ease—require higher furnaces, technically called blast furnaces, the extreme limits of which, in civilized countries, are 25 and 100 feet, while barbarous nations still employ very rude furnaces of 2 or 3 feet in height. See BLAST FURNACE.

Zinc differs from the other oxides in being volatilizable at high temperatures, and it is therefore obtained by distillation. The ore is ground fine, mixed with a pure carbon-fuel, like coal or anthracite, and placed in a tube made of fire-clay. This is heated to whiteness, at which temperature the carbon attracts the oxygen of the ore, leaving the zinc to distill off as metal. In front of the tube are placed condensers of clay and sheet-iron, in which the metal collects.

The metallurgy of the sulphides is more complicated than that of either of the above classes. The metals of this class are (1) volatilizable and (2) non-volatilizable. The former include mercury and zinc. The compound of mercury and sulphur—cinnabar—is not stable at high temperatures if sufficient air is present, the sulphur oxidizing and leaving

the metal free. The ore is therefore heated to redness with access of air, when the mercuric sulphide distills off, and in doing so breaks up into mercury and sulphurous acid. The vapor is passed through large chambers, where the metal condenses and runs out. Sometimes the dissociation of the mercury and sulphur is aided by mixing iron or lime with the ore, as these have a stronger affinity for sulphur than the metal. The sulphide of zinc, called blende, is converted to oxide by roasting, which consists in heating it in contact with the air, whereby the sulphur is driven off as sulphurous acid. In some metallurgical processes, however, the aim of roasting is to produce a sulphate, which may be subsequently extracted by leaching. It is then treated like the oxide, as above described. In the treatment of the non-volatilizable metals three general processes are followed: (1) Roasting and reaction; (2) roasting and reduction; (3) precipitation. The first two depend upon the removal of the sulphur by roasting; and this operation has a furnace especially adapted to its requirements which is in all respects the exact opposite of the shaft-furnace, although in a modified form the latter is also occasionally employed in roasting operations. The apparatus usually employed is called a reverberatory furnace, and consists of a horizontal chamber with a low roof, having a fireplace on one side and a chimney on the other. The ore is placed in the chamber, which is called the hearth. The flames produced in the fireplace pass through this chamber, and are deflected by the low, arched roof upon the ore. Openings are made in the sides for the admission of air and for the purpose of working the charge. In this furnace the amount of air is in excess of that required by the fuel, so that the ore is subjected to oxidation. The oxide of sulphur, being a gas, passes off, leaving the remainder of the ore as a solid oxide. Various modes of utilizing this reaction are in use, depending upon the individual characteristics of the metals. When pure sulphide of silver is roasted, metallic silver, and not the oxide, remains; but in the majority of other cases the residue is partly or wholly an oxide. Roasting and reaction is performed by interrupting the oxidation when only partially finished, thoroughly mixing the half-roasted ore, piling it up, closing the furnace-doors to prevent the entrance of air, and heating the charge to such a temperature that the sulphur still remaining will combine with the oxygen absorbed by the ore. In this way both the sulphur and the oxygen are removed without giving the metal an opportunity to reoxidize, and metal is accordingly the result. Lead and copper ores are treated in this way. Roasting and reduction consists in allowing the oxidation of the ore to become complete, and then treating the product as above described for the oxide class. Lead, copper, antimony, and nickel are obtained by this method. Precipitation consists in melting the sulphide ore with some substance which has a stronger affinity for sulphur than the metal already combined with it. Lime, zinc, and iron are such substances, but the first requires too high a temperature for perfect action, and the second is too dear. Iron is the only reagent that is of universal application for this purpose. It may be used either as metals, oxide, or silicate, and the cinder made in iron-works is frequently employed. The unroasted ore is melted with the iron or cinder and the fluxes necessary to make the gangue fusible. A shaft-furnace is theoretically the best apparatus for the work, since no waste of iron by oxidation can take place in it. The reverberatory is frequently used, because in it the sulphur can be partly removed by roasting at a low heat, and the operation finished by melting the residues with iron.

The outline of metallurgical practice here given relates only to the most general principles. It is rare that an ore can be smelted at once to metal of purity sufficient for its immediate use in the arts. Sometimes the baser metal contains considerable quantities of the precious metals, which must be separated by further working. A refining process is almost always applied to the crude metal obtained from its ores; and very often the process of smelting is lengthened by making each operation incomplete, and thus obtaining the metal by a gradual elimination of the elements combined with it. The reason for this is that the impurities are always more volatilizable or more oxidizable, or their oxides are more reducible, than the metal itself, and by repeatedly subjecting the compound to operations which affect its constituents in different degrees a complete separation is effected. It is found to be much easier to eliminate these impurities from some compound of the metal than from the latter when fully reduced. For this reason the metal is often combined with some element that admits of perfect subsequent separation; and this compound is then passed through the purifying operations, in which there is a gradual concentration of the metallic base. The element employed for this purpose is sulphur. Oxides of copper are often turned into sulphides by adding some sulphide ore, like pyrite, to them, instead of reducing them at once to metal, which would not only cause serious loss in the slag, but also give an impure product in the case of impure ores. The general belief that sulphur is the smelter's greatest enemy is therefore unfounded. It is often his chief dependence, and purposely added in his operations. A rich ore is usually smelted without concentration. Of poor ores there are two kinds. The ore may contain a rich mineral mixed with a great preponderance of gangue; and when mechanical concentration is not admissible, such ores are usually melted raw, with fluxes to make the gangue fusible. The product is the metalliferous mineral without the gangue, and the process can then proceed on this rich product with greater care. The other case is that of an ore which contains a great deal of metalliferous mineral, but of low grade. Such ores are usually subjected to some process like roasting, by which part of the mineral is obtained in a condition that will admit of its removal by the fluxes in the first fusion.

The products of the fusion of an ore are threefold: (1) That containing the metal. This may be either metallic or a "matte" when it contains sulphur, or "speise" when it contains much arsenic or antimony. (2) That containing the gangue and fluxes; it is the stony part of the ore melted to a glass, and is called slag when the bases are chiefly non-metallic, and cinder or scoria when the base is chiefly a metallic oxide. (3) The gaseous products, which, besides the products of combustion, contain the oxygen of the ore and such other constituents of it as are volatile.

Metallurgy is rapidly advancing as a science in consequence of the great aid given by the progress of chemistry. At the present day the most prominent question is the use of the electric current and the economical use of fuels. The best construction of furnaces, the use of gaseous fuel (which permits the employment of refuse carbonaceous materials), the heating of the blast to increase the effect of the fuel used, the utilization of the half-burned carbon which exists in furnace-smoke, and the direct production of metals from their ores in one or two operations, are all phases of this important problem; and these things are now chiefly occupying the attention of metallurgists. Great care is also taken in large works to make useful every element in the ore that has a market value. To this end metallurgical establishments are now large manufactories of sulphuric acid, arsenic, iron and copper vitriol, such paints as zinc white, smalt, etc. The most noticeable instance of this economy is the manufacture of sulphuric acid from pyrite, which is a bisulphide of iron. No less than 1,500,000 tons of this ore are burned for this purpose yearly in Europe, producing about two-thirds its weight of acid. Pyrite almost always contains at least a trace of silver, and in England large quantities of the burned ore are treated for silver, of which it contains about three-fourths of an ounce per ton. After extracting the silver, a moderate part of the residue is sold to the iron-works and made into iron. This is probably the most complete utilization of an ore known.

The *wet method* of treating ores consists in bringing the metal into solution, and then precipitating it by some agent. When the ore is an oxide or contains a native metal, the solution may be effected by treating it with an acid which will dissolve the metal; sulphides may also be treated in this way by first roasting them. Sulphuric and hydrochloric acids are those usually employed, but they are too dear in most localities, and the use of purchased acid is limited. Examples of such treatment are mostly confined to the metallurgy of gold, platinum, copper, and bismuth. The acidification of the metal is sometimes accomplished by heating it with some substance containing the acid. Thus silver is frequently chlorinated by heating the roasted ore with salt, which contains chlorine. The resulting chloride of silver may then be extracted by solution in strong brine, or it may be treated with iron, which reduces the chloride to metal, and mercury, which amalgamates the metal as fast as formed. The most usual mode of accomplishing solution is employed with the sulphides, which are carefully roasted in such a manner that the product is not an oxide, but a sulphate of the metal to be extracted. This is accomplished by regulating the temperature employed,

and when the material operated on contains sulphides of several metals, a proper management of the operation will give a product containing oxides of the metals which are not desired, and a sulphate of the one which is to be extracted. The roasted material is then treated with water which dissolves the sulphate, leaving the oxides; and the metal is then precipitated by some reagent. Copper precipitates silver, and iron precipitates copper. This operation is employed in the metallurgy of silver when the ores are pure; but the ore itself is not treated directly in this way, the gangue being first removed by fusion, and the roasting applied to the resulting matte. Copper, silver, and nickel are the metals most frequently extracted by the wet way, but it is also applied to gold, platinum, and bismuth. For poor ores it is usually much cheaper than the dry method, but when the ore is rich, or if the gangue is a substance soluble in acid, the use of acid and labor may be so great as to make the dry method preferable.

In *electro-metallurgy* the electric current is utilized for the reduction of ores or the separation of metals. Its widest application in the former direction is in the manufacture of aluminium (see ALUMINIUM), where the introduction of electrolytic methods has so cheapened cost that the metal is now available for common use. The most conspicuous example of the separation of metals is furnished by modern copper metallurgy. In many ores copper is associated with a small quantity of the precious metals. The ordinary wet methods did not admit of paying separation of the silver from the metallic copper produced unless the latter contained more than 30 oz. of silver to the ton. The electrolytic method is much cheaper, and therefore adds a somewhat important source to silver production. The crude metallic copper as it comes from the hands of the copper-smelter—being in recent years the product of the Bessemer converter—is cast into flat slabs or anodes, which, after being covered with bagging, are suspended in vats containing an acidulated solution of sulphate of copper. Copper sheets are alternately hung between the argentiferous copper anodes, they acting as cathodes. By the passage through the vats of an electric current the copper is dissolved from the anodes, and is redeposited on the cathodes, the silver remaining behind with whatever impurities the coarse copper may have contained. Very large quantities of argentiferous copper are annually treated by this method in the U. S. and in Europe.

The electrolytic method is also rapidly becoming the standard in the refining and parting of silver, the process being based on the selective power of nitric acid, by which the silver is dissolved and reprecipitated with less electromotive force than the usually accompanying metals, bismuth, lead, and gold. The silver to be treated is cast into plates which are covered with linen bags, and are introduced as anodes into the vats containing dilute nitric acid. Rolled plates of fine silver are used as cathodes. The current causes the silver to dissolve, and it is deposited on the cathodes at the rate of 4·2 lb. per hour per electric horse-power. The current used has an electromotive force of $1\frac{1}{3}$ to $1\frac{1}{2}$ volts for each vat. The two works at St. Louis and Pittsburg alone treat together daily 70,000 oz. of silver.

Metals [from Lat. *metal'lum*, metal, mine = Gr. *μέταλλον*, mine, metal; the most probable source of the word is the Semitic, cf. Heb. *mātal*, to forge]: elementary bodies especially characterized by their peculiar and generally high luster, known as the metallic luster; by very great opacity; and, with few exceptions, by their high specific gravity. The *opacity* of even the thinnest films is perfect, except in the case of gold, which is so malleable that it can be beaten into films through which a greenish light is found to pass. The *color* of the metals is generally white, although of various tints; zinc and lead having a bluish, bismuth a reddish, and calcium a yellowish tint. Gold is yellow, and copper red. The metals have generally a high *specific gravity*, but potassium, sodium, and lithium are lighter than water, while magnesium and aluminium have a specific gravity of 1·75 and 2·56 respectively. Of the others, the more important vary from arsenic at 5·88 to platinum at 21·5 in the form of fine wire. The specific gravity of malleable metals is decidedly increased by compression. *Malleability*, or the property of flattening more or less under pressure of blows, is possessed by a large number of the metals. Gold has been beaten into films only $\frac{1}{200000}$ of an inch thick; silver is also very malleable, and so are copper, tin, and platinum, although in an inferior degree. Iron, lead, nickel, cadmium, and mercury, when frozen, are more or less malleable; bismuth is very slightly malleable in small globules; while antimony, arsenic, cobalt, and manganese are brittle. Zinc is rather brittle at ordinary temperatures, but between 120° and 150° C. it can be rolled into sheets, which remain malleable when cold. At a higher temperature, 210°, it becomes very brittle again. Hammering and rolling render malleable metals more or less brittle, but their malleability can be restored by heating them strongly and slowly cooling them. This process is called *annealing*. Related to malleability is *ductility*, the property of being drawn into wire; but as this depends partly on the power of resisting a strain, or tenacity, the most malleable metals are not necessarily most ductile; the order being as follows, beginning with the most ductile: iron, copper, platinum, silver, gold, zinc, tin, lead. Metals are drawn into wire by pulling them through holes in steel plates. If they become brittle during this operation, they must be annealed. In *conductivity* the metals vary greatly. Silver is the best conductor of heat, and bismuth one of the poorest. Silver is likewise the best conductor of electricity.

Conductivity of Heat.—Silver, 1,000; copper, 736; gold, 532; tin, 145; iron, 119; lead, 85; platinum, 84; bismuth, 18. The *linear expansion* of metal rods by heating from 0° to 100° C. is expressed by the following fractions: iron, $\frac{1}{819}$; gold, $\frac{1}{682}$; copper, $\frac{1}{584}$; silver, $\frac{1}{524}$; lead, $\frac{1}{351}$; zinc, $\frac{1}{333}$. Platinum expands only $\frac{1}{1167}$, and this being very nearly the rate of expansion of glass, it is found that platinum wires can be inserted into fused glass without any danger of cracking the glass on cooling. The fusibility of the metals covers a very wide range, mercury being liquid at ordinary temperatures, and platinum requiring the heat of the oxyhydrogen blowpipe for its liquefaction. Osmium is the most refractory of the metals, volatilizing without fusing at a temperature capable of volatilizing platinum.

Fusing-points of Metals.

Mercury	39·44° C.	Antimony	425° C.
Tin	227·8	Silver	1,023
Cadmium	228	Copper	1,091
Bismuth	258	Gold	1,102
Lead	325	Cast iron	1,530
Zinc	412		

Nickel, cobalt, manganese, and palladium require the highest forge heat; molybdenum, tungsten, and chromium only agglomerate in the forge; titanium, iridium, rhodium, and platinum are infusible except at the temperature of the oxyhydrogen blowpipe. Wrought iron and platinum become soft before melting, and pieces of iron or steel can therefore be united by pressure while in this pasty state, and porous platinum sponge can be made solid. This is called *welding*. *Volatility*, or the property of assuming the gaseous state, is known to be possessed by most of the metals, and is probably a property of them all. It is especially characteristic of certain of them, which volatilize at comparatively low temperatures. Thus mercury yields a sensible amount of vapor at 20° C., and at 350° boils; zinc, cadmium, and magnesium volatilize rapidly at a red heat; and even gold and platinum may be vaporized before a properly arranged oxyhydrogen blast. Arsenic passes off in vapor without fusing. In *hardness* the metals vary at ordinary temperatures from the fluid mercury and soft, waxy potassium to the exceedingly hard chromium and manganese capable of scratching glass and hardened steel. The *crystalline form* of some of the metals has been determined; some being found naturally crystallized, as gold, copper, and silver; others being deposited in crystals by the galvanic battery, as tin; by sublimation, as arsenic; or by fusion and gradual cooling, as bismuth. Zinc, arsenic, antimony, and bismuth crystallize in forms belonging to the hexagonal system; tin is tetragonal; gold, silver, platinum, mercury, copper, lead, and iron are isometric.

The metals are found both free and combined in nature. Gold and platinum almost invariably occur free, for it is a disputed question whether the gold so generally found in iron pyrites is combined with sulphur or not. Mercury occurs mainly as sulphide, and sometimes metallic. Silver is often found native, but more generally as sulphide, and with sulphides of antimony, arsenic, copper, and lead; also largely as chloride. Copper mainly as sulphide, generally with sulphide of iron, also very commonly as carbonate and oxide, and in a few localities large deposits of native cop-

per are found. The iron ores are the oxides and carbonate; sulphide of iron furnishing sulphur, sulphuric acid, and green vitriol, but not being generally accounted an iron ore. Lead occurs mainly as sulphide, but the carbonate is also an important ore. Tin is found as oxide; the sulphide is a less esteemed ore, although abundant in the English mines. The most valuable zinc ores are the carbonate and sulphide; the oxide is less abundant. Nickel and cobalt occur chiefly as arsenides and sulphides; bismuth, antimony, and arsenic are found combined with sulphur, and also native, in sufficient quantities to be worked.

There are forty-nine of the elements universally considered as metals, tellurium, which is sometimes reckoned as the fiftieth, being generally classed among the *metalloids* with selenium, to which it bears close relations. Gold, silver, mercury, lead, copper, iron, and tin were known to the ancients. Potassium was discovered by Davy in 1807 while acting upon potash with a powerful galvanic battery, and this led to the discovery of sodium, lithium, and the metals of the alkaline earths. Rubidium, cæsium, thallium, and indium were discovered by the use of the spectroscope, indium being the last metal discovered. Gallium was discovered by Lecoq de Boisbaudran Aug. 27, 1875, during the spectroscopic examination of zinc-blende from the Pierrefitte mine, valley of Argeles, Pyrenees. It gives a violet line at 417, and a faint band about 404, and is a white, moderately hard metal, closely allied to zinc.

The metals have been variously classified, according to the purposes to be served by the grouping. To express their electrical relations they were arranged in succession, beginning with the most electro-positive metals, the alkali-metals, and ending with the most electro-negative, the noble metals; the noble metals being those whose oxides are reduced by heat alone—viz., gold, silver, mercury, and the metals of the platinum group. They are also classified according to the properties of their oxides, some forming powerful bases, as the oxides of metals of the alkalies and alkaline earths, with the lower oxides of most of the other metals; others form only acid oxides, as arsenic and antimony, and the higher oxides of chromium, manganese, and iron; while others, like sesquioxide of aluminium, may sometimes play the part of acids and sometimes of bases.

The classification of the metals according to their equivalence or combining power is the most accurate for the general purposes of modern chemistry. This method of classification assumes the atomic weight of hydrogen as the unit for the relative combining weights of the elements, which are then placed in groups whose members have equivalent combining proportions, and also possess certain properties in common.

1. *Monad Metals.*—The *alkali metals*, potassium, sodium, lithium, cæsium, and rubidium, which form only one chloride each. Silver, although differing widely from the alkali metals in general, is a monad, and yields an alum closely related to potash alum.

2. *Dyad Metals.*—Barium, strontium, and calcium, whose oxides are called the *alkaline earths*, form a group together. Glucinum, yttrium, erbium, lanthanum, and didymium, all rare metals, whose oxides are called earths, form a second group. Zinc and cadmium, with magnesium, which is analogous in many of its compounds to zinc, although it was formerly reckoned among the alkaline earths, form a third group. The elements of each of these groups form only one chloride. Mercury and copper constitute a fourth group, and form each two chlorides.

3. *Triad Metals.*—Indium, forming only a trichloride, and thallium and gold, forming each a mono and a trichloride, belong here. Thallium, however, has strong analogies to the alkali metals, and indium is capable of forming an alum with ammonium.

4. *Tetrad Metals.*—Platinum, palladium, iridium, rhodium, ruthenium, and osmium are classed together, and all form tetrachlorides, as well as dichlorides, excepting rhodium, which forms a dichloride and a trichloride, but is retained here from analogy. Tin and titanium form a second group of tetrads. Lead is considered quadrivalent, because it yields a plumbo-tetrethide with the hydrocarbon radical ethyl. Zirconium and thorinum form tetrachlorides. Iron, aluminium, manganese, cobalt, nickel, and cerium are also considered as tetrads, although their proper position is on some accounts doubtful.

5. *Pentad Metals.*—Arsenic and antimony form trioxides and pentoxides, and bismuth is grouped with them from its analogy to antimony. Vanadium is regarded as a pentad on account of its analogy to phosphorus in some of its combinations. Tantalum and niobium have been shown to form pentachlorides.

6. *Hexad Metals.*—Chromium forms a hexfluoride, and uranium is reckoned as a hexad from compounds similar to those of chromium. Tungsten forms a hexchloride, and molybdenum, being analogous to it, is considered hexadic.

Specific Gravities of Metals at 15·5° C.

Platinum (in thin wire)	21·50	Cobalt	8·54
Gold	19·50	Manganese	8·00
Uranium	18·40	Iron	7·79
Tungsten	17·60	Tin	7·29
Mercury	13·59	Zinc	6·86–7·1
Palladium	11·30–11·80	Antimony	6·80
Lead	11·45	Arsenic	5·88
Silver	10·50	Aluminium	2·56–2·67
Bismuth	9·90	Magnesium	1·75
Copper	8·96	Sodium	0·972
Nickel	8·80	Potassium	0·865
Cadmium	8·70	Lithium	0·593
Molybdenum	8·63		

Revised by CHARLES KIRCHHOFF.

Metal-work: the manipulation and treatment of metals and the making of metal objects of any kind, for use or ornament; also the objects so made. Ordinarily the term is not used for matters of pure utility; thus we do not hear of machinery or of barbed-wire fences or of brass faucets and stop-cocks as *metal-work*; the term is applied rather to the *making* of things that are more or less ornamental, and to the *things* themselves. It is in that sense that it is used in this article.

Metals are given the forms desired by several different processes, as by *casting*, by *hammering*, by *stamping*, by *filing* or otherwise cutting away some part of the substance, by *rolling*, as when sheet-metal is wanted, by *drawing*, as wire. Moreover, the forms so produced are further modified by CHASING (*q. v.*), and the surfaces are treated either by chasing or by ENGRAVING (*q. v.*). Parts are put together by means of welding and soldering, and by means of rivets and screws. The colors of metals are changed or modified by *alloyage*, that is, by melting two or more metals together (see ALLOY); by applying a thin film of one metal to the surface of another, as in *silver plating* and in *gilding*; by exposure to washes and "pickles," which give different tints to bronze castings; and by chemical changes of a simpler kind, such as the formation of oxides and sulphides on the surface. Moreover, color effects can be got by DAMASKEENING (*q. v.*), or inlaying one metal in another; by NIELLO-WORK (*q. v.*), by the Japanese process imitated in the West of hammering different colored metals together to produce a veined or mottled surface; and by the corrosion or mechanical roughening of parts in contrast with the brightness or smoothness of others. Painting, too, of different sorts can be applied to metals, and enameling can be applied with perfect ease. Each metal allows of certain kinds of ornamental treatment, and is less adapted to others.

Hammer-work: (1) *Wrought Iron.*—The singular property that iron has of keeping in a soft condition when above red heat, though still far below the fusing-point, is its special fitness for being shaped by hammering. It has also the property of uniting readily and strongly one mass of hot iron with another when the two are brought together and hammered one into the other. Pieces so united are said to be *welded* together, and iron treated by hammering when hot is said to be *forged*. Iron-work produced by these means, especially when elaborate and of many parts, or very delicately worked, is called *wrought iron*. Nearly all the artistic work in iron, in all ages and all parts of the world, has been wrought iron. We know little of the iron-work of the ancients; it has perished, and it does not seem to have been important as decorative art; but that of the Middle Ages is of the greatest interest. As the smiths of the time had no machinery to facilitate and hasten their work, everything had to be done by sheer hammer-work; the pieces of iron were shaped, drawn out, flattened, curved, united in one, split apart and spread into branches, formed into efflorescent sprays, and these grouped in anthemions—all by the hand of man, aided only by simple tackle for lifting and lowering, and by pincers and hammer, and now and then by punches and dies of home manufacture. The gates, the window-grates, hinges and locks, bars and bolts, made in this way by patient handiwork, became almost of necessity

the medium of whatever power of fantastic design the smith possessed. Such power of design was inherited, too, from ancestors, and taken up from teachers and masters, who had worked in an equally spontaneous way all their lives, and whom the son and pupil hoped to excel; and in no department of decorative art is the early time more admirable and enviable than in this of simple smith-work. With each improvement made in the industrial arts of iron the fine arts of iron have grown more feeble.

Hammer-work: (2) *Repoussé-work.*—The practice of beating up patterns in relief in thin plates of metal requires that the artist's eye should be upon the work as it grows, while the hammer-strokes must be plied from the other side, the reverse. For this purpose a singular tool is used, called sometimes a snarling-iron. It is a bar of iron fixed strongly at its larger end, tapering toward the other or free end, which is turned up at the point. An assistant pounds steadily upon the bar at a convenient distance from the fixed end; its elasticity then causes the turned-up thin point to strike a series of slight blows upon the under side of the plate of metal which the artist holds firmly above it. In this way, as the plate is moved about, the relief pattern slowly takes shape. Such *repoussée* or *repoussé*-work, as called by the French term generally used in English, is done in gold and silver very commonly, nearly all the relief ornaments in old silver plate being of this character, and purely ornamental disks and plaques being common in the seventeenth and eighteenth centuries of art. At the same epoch it was done in copper on a very large scale, cooking-vessels, water-pots, and all sorts of bowls and dishes were made of sheet-copper worked exclusively with the hammer. It is done in bronze by the Orientals; the Japanese have exquisite work of this sort, both simple and elaborate. Lead has been treated in this way, and, at the other end of the scale of hardness, so has steel. In modern times old work of this sort has been imitated and even surpassed in delicate finish as well as in boldness. Works of art of immense size have been carried out chiefly by hammer-work: the most ancient bronze statues of the Greeks were shaped in this way, and the practice has been revived in modern times.

Hammer-work Helped by other Processes.—It is customary to carry out the design and to diversify the surface of hammer-wrought metal by means of sharp-pointed and edged tools applied directly, and also by stamps and dies. Wrought iron is worked upon while hot by tools with chisel-edges, and also with the sharp point; of course, only very simple patterns are possible, such as zigzags and crosses, and the impression of gouge-shaped tools producing little arcs of circles, and punches of circular form. For more elaborate patterns and all reliefs, such as the simple leafage which one sees in rich Gothic hinges and the like, a die is used into which the hot iron is forced by blows of the hammer. *Repoussé*-work is retouched by the chasing-tool, and that in a most elaborate fashion. (See CHASING.) In the eighteenth century, which was, in Europe, the great time for goldsmiths' and silversmiths' delicate and minute work, watch-cases, smelling-bottles, *étuis*, or small boxes of a decorative sort were made of thin plates of precious metal worked in high relief by the hammer and then chased with surprising elegance. The back of a watch would be a bas-relief containing a dozen or more human figures well and delicately modeled, with a suggested landscape for the background, and a decorative border of scroll-work; and such a watch commanded no very exorbitant price. *Engraving* may be used also to decorate hammer-work (see ENGRAVING); indeed, it is probable that the burin as well as the chasing-tool has been used on the gold and silver *repoussé*-work described above. In antiquity the bronze *cistæ* or caskets for toilet articles and the like were made of thin sheets of bronze hammered into the simple forms of circular and elliptical cylinders, and received their chief ornamentation from the graver. The touch of the sharp tool on the hot iron though often spoken of as engraving can hardly be considered so: the graver removes some part of the metal, which is hardly feasible in hot iron, and the impressed lines and patterns on wrought-iron hinges, lock-plates, etc., are rather chased than engraved, but actual chiseling in the cold iron has been done, and even on a large scale. Japanese decorative objects are often finished in this way, and the famous wrought-iron pillar of the Koutab mosque in old Delhi seems to have been sculptured as if it were bronze or a still softer metal. Oriental bronzes offer many such examples of graver-work in the cold metal.

Cast-work: (1) *Cast Iron.*—This material is not pure iron, but has much carbon combined with it and also mixed with it, and is more brittle and harder than wrought iron. It does not give very clean and sharp castings, and it is too hard to be tooled after casting, as is done with bronze, for instance. Therefore, cast iron has never been a recognized medium for works of fine art, although several attempts have been made to produce artistic castings. This is notably in the case of what is called *Berlin iron* or *Berlin jewelry*, which originated in Germany at the time of Napoleon's supremacy, when gold jewelry was given to the nation and it became a fashion to wear the inexpensive substitute. These castings were of surprising delicacy, but more recent work of the same sort is inferior. Another noteworthy attempt has been the casting of large statues and groups by French founders since 1875, some of which have approached real excellence. *Brass* also, and *latten*, which is not really different from brass, are used for castings, and generally the cast parts are subsidiary to larger works in sheet-metal. The most important use of casting in the arts is in the case of *bronze*. This is an alloy of copper with tin, or with tin and lead, or tin and zinc, or all three, sometimes having small proportions of still other metals. Tin alone with copper makes the hardest and finest bronze; the proportions are generally about nine parts copper to one of tin, there being no fixed rule. Bronze has always been the especial material for artists; from early civilization to the nineteenth century it has been in use for medals and medallions, bas-reliefs, statues, and decorative objects. It gives a beautifully sharp and delicate casting, and allows of great refinement of finishing work upon the surface, so that it can be brought to a full realization of the artist's conception; then it bears perfectly exposure to the weather, soon losing its golden primitive color and taking a greenish tinge which comes from a chemical change in the external particles, and is called the *patina*. Moreover, as many bronzes are not meant for exposure out of doors, the patina is often given by artificial means, and many tints of green and brown and yellow, olive and buff, and silver gray are produced by means of "pickles" or strong acid mixtures. Some Eastern bronzes are colored to resemble a crystalline surface, shot with little *spiculæ*; others are mottled and spotted, but these surfaces are applied to vases and dishes in the main, and to those of plain outline and simple form. Bronze bowls and other vessels, arms, weights, lamps, mirrors, and the like are found among very early Egyptian and Assyrian deposits. Bronze statuary and relief sculpture come down to us in perfect condition from Grecian times, from the Roman imperial epoch, from the Byzantine empire, and from the Middle Ages and later times; some of it is hammered and riveted, but by far the greater part is cast-work. Most of the works of art in this material have been lost to the world because of the intrinsic value of the bronze. Thus of the enormous number of large bronze statues and groups which are known to have existed in Rome and the other cities of the empire, not half a dozen have been preserved, apart from the great collection found in a single villa at Herculaneum, and now exhibited in the Naples Museum. In like manner very many pieces of even the fifteenth and sixteenth centuries have been melted down, and to this day newly found antiques are in imminent danger of being cut up and sold by ignorant finders. There is no doubt that valuable pieces are being destroyed in this way every year in all the lands surrounding the Mediterranean.

Stamped Work.—Much the most important kind is that of medals and coins struck with a die. (See MEDAL and NUMISMATICS.) Other instances of stamped work have been named under *wrought iron*. Apart from this, stamps are used chiefly in silverware and the finer vessels of pewter and other cheap metals. Small ornaments in relief are produced in this way with good results.

Filing and chiseling are used in all kinds of metal-work, and are not the chief formative processes in any.

Rolling is only an alternative of hammering in cases where a flat sheet or a continuous bar or strip is required. The flat sheet-metal used in ancient cists was made, as armor was made, by the hammer; bars and the like were made, as was also wire, by hammering the metal into a groove in the anvil. Modern processes of passing between rollers are merely cheaper and quicker ways of doing the same thing on a large scale.

Drawing, as wire, is of the same nature, but a modification of wire-work is that called damaskeening, which is strictly inlaying metal upon metal.

As regards the purposes to which metal-work is put in the way of decorative art, it is customary to make many divisions and subdivisions; thus gold and silver plate is divisible into ecclesiastical and domestic, and there is also the intermediate variety of college and corporation plate, much studied in England, where more remains than on the continent of Europe; and the purely artistic, not at all useful work put upon medallions, *repoussé* plaques, and the like; and also the pieces worn or carried upon the person, such as buttons and buckles, *étuis* and *vinaigrettes*, to all which varieties the large department of jewelry must be added. (See JEWELRY.) In like manner in wrought-iron work are included not merely the gratings and crestings of architectural purpose, but also arms and armor in all their variety, steel being substituted for iron.

There are certain ornamental processes which though not metal-work themselves are closely allied to it, such as NIELLO and ENAMEL (*qq. v.*). Their use is practically limited to gold and silver ware, except that in cases where enamel is the chief decorative appliance, the design of the whole piece being based upon the effect of the enameling, the metal basis may be of brass or other inexpensive metal. The filling of engraved lines with black or red wax, as in monumental brasses (see BRASSES, MONUMENTAL), is inlaying and not essentially metal-work. RUSSELL STURGIS.

Metamerism [prefix *μετα-*, corresponding to, duplicating, from Gr. *μετά*, with + Gr. *μέρος*, part]: in zoölogy, that condition exhibited by various types, like Annelids, Arthropods, and Vertebrates, in which the body can be reduced to a series of similar parts. Thus in an earthworm the body is composed of a series of essentially similar segments arranged one after the other, each segment containing portions of the nervous, excretory, digestive, muscular, and circulatory systems. In the Vertebrates this metamerism is at first sight not so evident, but it is readily shown to exist, and upon its presence some of the modern advances of our knowledge of the relationships of the Vertebrates to the lower forms depend. J. S. KINGSLEY.

Metamerism, in chemistry: See ISOMERISM.

Metamor'phism [Gr. *μετά*, after, beyond, over + *μορφή*, form]: a term extensively employed in the science of geology to indicate all those changes in the mineralogical composition and structure of rocks, whereby they are rendered harder and more crystalline (or at least not less so) than in their original condition. In its broadest sense the term metamorphism might apply to all chemical and structural changes which go on in rocks, but by common consent it is restricted to the above given meaning, and thus contrasted with the terms *weathering* and *decomposition*, which are used to cover those changes tending to make rocks less crystalline and more soluble.

The two contending cycles of rock-history, *decomposition* under atmospheric conditions, and *recomposition* under conditions of high temperature and pressure, have long been recognized. At the earth's surface crystalline masses become hydrated or combine with carbon dioxide, thereby disintegrating into soil; the *débris* thus formed is spread out in sedimentary deposits, which, when deeply buried, become recrystallized into hard and resistant rocks.

Metamorphic Rocks.—The fact of metamorphism on a large scale was clearly appreciated by Hutton, who, over a hundred years ago, in his *Theory of the Earth*, described it, while considering heat as its all-sufficient cause; the term itself science owes to Lyell. For a century the processes it embraces have received an ever-increasing amount of study and attention from geologists.

Metamorphic rocks are regarded as occupying an intermediate position between those of igneous and those of sedimentary origin; they are such as owe their component minerals and structures, in great part at least, to the recrystallization of pre-existing rocks without fusion. They include most of the so-called CRYSTALLINE SCHISTS (*q. v.*), which are in part demonstrably of igneous, and in part of sedimentary origin, although a still larger number are so profusely altered as to leave their original character in doubt.

Kinds of Metamorphism.—One of the most apparent as well as earliest recognized distinctions among metamorphic rocks is to be found in the presence or absence of an apparently effective cause of metamorphism. It was early recognized that various intrusive igneous masses had produced a direct change by hardening and recrystallizing the rocks around them. As these changes surrounded the entire intrusive mass, and as their intensity was seen to be proportional to the proximity of the eruptive rock, the efficiency of the latter as the metamorphosing agent was hardly to be questioned. Such cases were therefore called *contact* or *local* metamorphism, in contradistinction to those which disclose no such active agent. These latter, which generally involve much greater areas than the comparatively narrow zones of alteration surrounding igneous intrusions, have been called cases of *general* or *regional* metamorphism. In many instances the effects of this latter kind of metamorphism are so like those produced by contact action that igneous masses have been assumed as existing below the surface. In the majority of cases, however, no such assumption will account for the facts.

Within recent years the energy developed by the great mechanical movements within the more disturbed zones of the earth's crust has been recognized as an efficient cause of the metamorphism of rocks on a vast scale. The faulting, folding, and shearing of great rock-masses has generated heat, stimulated circulation, and developed new minerals and structures. Thus new rocks are developed from old ones, and the completeness of the change is, in the main, proportionate to the intensity of the earth's movement. Such metamorphism has been called *dynamical* or *dislocation* metamorphism. The vast and complex problems which it involves have as yet only just begun to be investigated in detail.

Agents of Metamorphism.—Whether the primary exciting cause of metamorphism be the intrusion of igneous masses or the dislocation of the rock strata, the three most active and necessary agencies in producing the changes called metamorphic are (1) heat; (2) moisture, or some other mineralizing agent; (3) pressure. Heat and pressure both greatly increase the chemical action of igneous solutions, while even a small amount of some substance, like fluorine, chlorine or boron, capable of forming volatile compounds, facilitates the formation of new minerals.

Another important factor in metamorphism is the presence of a thick mass of overlying material which prevents the free escape of heat and volatile substances, and thus gives them their maximum efficiency.

The *result* of metamorphism in a given case depends of course not merely on the nature and intensity of the metamorphosing agents, but also on the kind of rock acted upon. Limestone, sandstone, slate, and eruptive rock will yield very different products when subjected to the same metamorphosing influences.

The metamorphic action on a given rock-mass may be designated as macro-structural (cleavage or jointing), micro-structural (crushing and recementation of the constituents), or chemical (formation of new minerals). In most cases all three of these occur simultaneously. The separate consideration of the action of each of the three metamorphosing agencies, as well as of the three kinds of changes which they produce, would carry us far beyond the space available for this article. They are well described by Sir Archibald Geikie in his article on *Geology* in the ninth edition of the *Encyclopædia Britannica*, and in his *Geological Text-book*.

Origin of the Metamorphosing Agencies.—Heat: In the case of contact metamorphism the necessary heat is furnished by the intruding igneous mass; in the case of dynamic metamorphism it is produced by friction in the rocks undergoing the disturbance, and in part also by the escape of heat from below through the fissures formed. *Moisture*: Water is present in all rocks, even the most compact and impermeable. The so-called quarry-water (*eau de carrière*) is well known to all practical stone-workers. Its amount varies greatly with the porosity of the rocks, but it is always present. This furnishes the necessary moisture in the case of contact metamorphism, although it is well known that igneous rocks also contain large quantities of water and other volatile substances. In the case of dynamic action the crushing and faulting of rock-masses of course greatly facilitates the presence and circulation of water. *Pressure*: Great thicknesses of overlying strata may furnish a pressure which greatly increases the chemical activity of solutions. In disturbed regions the strains to which the rocks are subjected are very efficient agents of metamorphism, as is shown by the intensity of the changes, being proportional to the amount of disturbance.

Experiments Relative to Metamorphism.—Much has been learned as to the nature and processes of metamorphism by experimentation. Foremost among the investigators in this field are Hall, Scheerer, Rogers, and Daubrée.

G. H. WILLIAMS.

Metamor'phosis: in zoölogy, the term applied to those changes exhibited by various animals in their growth from the egg to the adult condition in which they pass through forms apparently very dissimilar. Possibly the most familiar example is that afforded by the butterfly, where the caterpillar, the first stage, becomes transformed into the chrysalis, and this, in turn, into the winged form. (See ENTOMOLOGY.) These three stages at first sight are very unlike. Metamorphoses are very common in all groups of animals except the vertebrates, and in many cases they are seized upon by the evolutionist as indicating the affinities and lines of descent of different groups. In this, however, great care has to be exercised, for there is much evidence to show that not all the stages passed through are reminiscences, so to speak, of ancestral conditions, but are complications introduced at a later period into the life-history.

J. S. KINGSLEY.

Metaphor [from Lat. *meta'phora* = Gr. μεταφορά, deriv. of μεταφέρειν, carry over, transfer; μετά, over + φέρειν, carry]: a figure of speech in which an ordinary term is displaced by one which suggests merely a portion of its characteristics, thereby instituting a comparison between the two circles of ideas suggested by the two terms, on the basis of something they possess in common, disregarding what is peculiar to each. It may therefore be regarded as an abbreviated or implied simile. Thus the metaphor *an iron will* implies the simile *a will strong as iron*; *the ship plows the sea* implies the simile *the ship cuts the water as a plow cuts the soil.* The substituted term usually replaces the general and remote with the concrete and familiar. The purpose of the substitution is in general to stimulate the imagination.

The substitution or transference is not merely or principally a feature of rhetoric or style. It represents a deeply rooted tendency of natural speech, which plays an important *rôle* in shaping the historical development of the meaning and use of words. When the substituted or metaphorical term becomes through persistent use the ordinary or regular, a permanent step has been taken in the development of language; thus the metaphorical use of the Latin *spiritus*, breath, in the sense of spirit, becomes in the French *esprit* a permanent fact of language. See METONYMY and SYNECDOCHE.

BENJ. IDE WHEELER.

Metaphysics [from Gr. τὰ μετὰ τὰ φυσικά, liter., the (essays) after the ones about (external) nature, the subjects treated after physics (in Aristotle's essays), but later taken to mean the subjects higher than or above physics (μετά, after, beyond, above; φυσικός, pertaining to φύσις or nature)]: a system of thought aiming to explain the universe by one or more general principles. The problem of metaphysics is the discovery of the deeper nature of things, the last truth which comprehends all the partial truths of the different sciences, physical and mental.

Conceptions of Metaphysics.—The various systems of philosophy which have been propounded in history all deal ultimately with the metaphysical question of "first cause" or "ground" of things, and they may be classed under four heads, according as they have conceived the problem and the method of solving it. These four conceptions or types of thought may be called (1) the Aristotelian, (2) the German, (3) the Scottish, (4) the Herbartian conceptions, respectively:

1. *The Aristotelian Conception.*—Aristotle conceived the problem of metaphysics to be the explanation of the reality which lies deeper than the "physics"—i. e. deeper than all empirically ascertained knowledge, whether it be the truths of psychology or those of physical and natural sciences. To him metaphysics is the doctrine of the underlying, the permanent, the cause which itself has no cause. This view had to Aristotle, situated as he was historically, two main points of application. In Socrates the separation of truth, knowledge, opinion (δόξα) from reality, essence (οὐσία) had appeared. Socrates distinguished concepts from reality, and aimed so to verify and define concepts as to make them universally true to reality. Plato widened the breach between knowledge and reality by distinguishing *ideas* (ἰδέα) as metaphysical essences of which knowledge in consciousness and things in the world were types and imperfect reflections. The problem presented to Aristotle therefore was twofold—i. e. to explain knowledge and to explain reality. Aristotle aimed to combine these opposites in a view which found in knowledge the true reflection of reality, and this involved the identification of reality with the particular things of nature, which were the objects of knowledge. This general position of Aristotle appears in the three leading doctrines of his metaphysics: (1) His doctrine of the relation between the individual and the universal. Aristotle held, against Plato, that reality resided not in the general notion or idea, but only in the particular thing in which the idea is realized. Hence metaphysics, as a science of what is universal, must find its material in the natural sciences—in the world as it is given in experience. (2) The doctrine of "matter and form" by which he distinguishes between reality as matter and idea as form. The "thing" in nature is matter from the point of view of fact, but form from the point of view of thought—i. e., of the meaning, use, development—which thought attributes to it. Things are particular in themselves (matter), but universal according as they enter into a system (form). In order, therefore, to a true system, a universal form, there must be particulars—material things—which embody it. (3) The doctrine of "mover and moved," which though less essential in its development, illustrates the same dual problem and its solution. Matter he made the static element, without dynamic property or movement; movement came from the "mover," which, however, was not divorced from the thing moved, but pertained to it as a higher category of its existence in the world of forms or concepts. All of these positions show the unity of Aristotle's thought, and at the same time the elements of the problem of metaphysics as conceived in the Socratic school.

2. *The German or Ontological Conception.*—It is evident that a system of metaphysics might be constructed from either of the two points of view which Aristotle endeavored to combine; being may be asserted at the expense of knowledge, on one hand, giving an *ontological* system, or knowledge may be emphasized at the expense of being, on the other, giving a *gnosiological* system. The great systems of German metaphysics down to Hegel (Kant, Schelling, Fichte in part) are of the former character, which as a type of thought may therefore be said to have flourished, apart from the rise of the Oriental mystical systems, mainly in Germany. It takes up the tradition of Plato and the philosophers of the Eleatic school, who postulated a principle of being (τὸ ὄν) from which the world of things—knowledge included—might be deduced. Such a principle is capable of a twofold construction, however. It may be conceived in terms of the mind's object, i. e. the external world or matter, and so become *Materialism*; or it may be conceived in terms of the mind which perceives its object—the object being in some way a manifestation of mind. In this case we have some form of *Idealism.* It is this last type of doctrine which the German systems have developed. Materialism has had little avowed support as a conscious metaphysical system. Idealism, in Germany, has been mainly of the ontological character. In Fichte it became more subjective and ethical in its interpretation of being, and in Hegel reached a reconciliation of the two points of view which reversed the terms of Aristotle's attempt to accomplish a similar reconciliation. In Hegel the true is the universal; but it is an outcome, an ideal, a goal of nature; its reality is its progress in the phenomenal world. In Aristotle the true is the particular, the thing in the world; but it is form as well as matter, and only in its systematic interpretation does its final truth, its *ideality*, its meaning, become evident.

3. *The Scottish or Gnosiological Conception.*—The other alternative mentioned goes back to Socrates; the alternative which emphasizes the subjective side of the process of knowledge and attempts to find justification for the world in the nature of thought and the soul. This view may take the form of an analysis of the mind's object so thoroughgoing that only the mind which knows is left; in which case we reach a form of *subjective idealism* in contrast with the objective or ontological idealism already described; this type of thought is associated with the name of Berkeley; or—and this is the tradition of the Scottish school founded by Reid—the mind may be held to have in it the direct witness not only of its own existence and reality, but also of that of things or truths outside of it. On this view metaphysics either becomes Natural Realism, a form of rational psychology based on so-called "intuitions" of the mind—which is not metaphysics at all—or it takes the character of an avowed dualism in the structure of the universe. Natural realism of a theological character has been the prevailing philosophy in the U. S. It also held sway in Britain as a sort of unavowed support to the association psychology, until the German metaphysics found footing both in England and in Scotland.

4. *The Herbartian Conception.*—The most important and widely current conception—except possibly the second mentioned above—goes by the name of Herbart, also a German philosopher. It is a conscious return to the type of solution found in Aristotle; except that it goes further back and lays under contribution something of the method of Socrates. The first task of metaphysics, on this view, is to rectify and justify concepts. This can be done only by an adequate criticism, both of thought and of experience. Only on the basis of such a patient criticism and mutual adjustment of claims can philosophy proceed at all. The true question is: What *must we think* about cause, self, change, reality, God, that our thought may be consistent and our lives true? Knowledge can not, in the last analysis, contradict experience, for experience, in the last analysis, is knowledge. So the real must ultimately be reached through such knowledge as is undoubtedly the full teaching of experience interpreted consistently with itself. In this basis Herbart reached a doctrine of atoms or "reals" which had the properties both of objective existence and of presentation—a view which is the historical outcome of such a conception of the problem—i. e. the atomism of Leibnitz and the "real beings" of Lotze. Metaphysics, then, builds itself upon all science and takes light from every source. This conception commends itself to scientists and to philosophers to whom the disposition to speculate is not considered the metaphysician's highest endowment. It is becoming the dominant conception in America. See Ladd, *Introduction to Philosophy*; Ormond, *Basal Concepts in Philosophy*; Bowne, *Metaphysics*.

Divisions of Metaphysics.—The indications now given from the historical point of view may serve to show the divisions of subject-matter in this topic. Metaphysics is related to general philosophy as part to whole. Philosophy includes not only the ultimate questions propounded by metaphysics, but, further, the justification of the partial truths in science and life upon which metaphysics must rest. Philosophy has three departments of inquiry: *Gnosiology*, or epistemology, devoted to an analysis of the nature and validity of knowledge; *Cosmology*, the detailed theory of the world as an orderly whole, involving the united results of the sciences of nature and life; and *Ontology*, the final synthesis or construction of the concepts of gnosiology (the soul, subject and object, etc.), and cosmology (problems of space, time, design, etc.) in a final doctrine of being. This last is accordingly metaphysics, properly so called. See Idealism, Materialism, and Philosophy. J. Mark Baldwin.

Metargon: See the Appendix.

Metastasio, mā-tăăs-taa′sĕĕ-ō, Pietro: poet; b. in Rome, Jan. 3, 1698. His father, Felice Trapassi, of Assisi, was a pork-butcher, and he was himself as a boy apprenticed to a jeweler. His beauty, however, and his readiness at song and improvisation attracted the attention of the jurisconsult and critic Gravina, who adopted him, Grecized his name into Metastasio, had him carefully educated, and when he died (1718) left him a considerable sum of money. He had already, at the age of fourteen, written a tragedy, *Giustino*, and been received among the Arcadians with the name *Artino Corasio* (Apr. 15, 1718). He soon spent his inheritance, however, and had to seek his living in Naples (1720), in the office of the advocate Castagnola, who made him promise to refrain from poetry. He could not keep this promise, but wrote anonymously the tragedy *Endimione*, then the *Orti Esperidi* (1722). In the latter of these pieces the famous Marianna Benti-Bulgarelli, known as *la Romanina*, took the part of Venus; and soon after she fell deeply in love with the author and took him to live with her. They went to Venice, then to Rome, where Metastasio attracted the attention of the Countess Althann, who obtained for him the position of *Cæsarian poet* at the court of Vienna. In 1730 he settled in Vienna, leaving *la Romanina* in Rome. She died in 1734, and showed that she had not forgotten him by bequeathing him her fortune, which he resigned in favor of her husband. He lived in great honor at the Austrian court, under Charles VI. and Maria Theresa, perhaps the most famous poet in Europe at that time. He was very intimate with the Countess Althann, and is said to have married her secretly. Many famous men were among his friends, he belonged to numerous academies and learned societies, and his literary pre-eminence was universally acknowledged. In his last years, however, he wrote little, and that uninterestingly. He died in Vienna, Apr. 12, 1782.

Metastasio's fame rests chiefly upon his lyrical dramas, or melodramas in the accurate sense of that term, of which he wrote a large number. Though the fundamental principle is the same in all of these, yet they fall into several groups, according to the period of his life in which they were written. The earliest, like those already mentioned and like the *Galatea*, the *Didoni Abandonata* (1724), the *Catone* (1727), the *Artaserse* (1730), hardly deserve the name of plays, being really only *azioni drammatiche*, in which a theme is employed in order to string together lyrical and musical numbers. With the *Adriano* (1731) begins a new manner, that of the melodrama proper, in which there is something of true dramatic structure, though here, too, music, rather than action, really determines that structure. Here belong the *Demetrio*, *Issipile* (1732), *Demofoonte*, *La Clemenza di Tito* (1734), and *Attilio Regolo* (1740–50)—the last of which is generally regarded as Metastasio's masterpiece. The pieces of the last period of his life are few and mediocre. Besides the dramas, he wrote also many lyrics—*canzonette* (of which he was a master), sonnets, idyls, elegies, etc. He wrote also various interesting bits of poetical criticism, and many letters of a literary character. The best edition of Metastasio's works is that of Paris, 1780–82, but there are many fairly good besides—e. g. in 20 vols. (Mantua, 1816–20), and in 16 vols. (Florence, 1819). The *Lettere* are to be found in two collections: G. Carducci, *Lettere disperse e inedite di P. M.* (Bologna, 1883), and C. Antona-Traversi, *Lettere disp. e ined. di P. M.* (Rome, 1886). For his *Life*, see A. Mussafia, *Pietro Metastasio* (Vienna, 1882); Vernon Lee, *Studies of the Eighteenth Century in Italy* (London, 1880); O. Tommasini, *P. Metastasio e lo svolgimento del melodramma italiano* (in *Scritti di storia è critica*, Rome, 1891).

A. R. Marsh.

Metas'tasis [= Lat. = Gr. μετάστασις, removal, change, departure, deriv. of μεθίστασθαι, be removed, depart; μετά, over + ἵστασθαι, be put]: in pathology, the sudden removal of a disease to a distant part, as when the disease called mumps is transferred from the parotid to the ovaries or to the testes. There are also metastatic abscesses, dependent upon the transference of bacteria from a primary focus of suppuration to distant parts by the blood. Tumors give rise to secondary nodes at a distance in similar manner, a small part of the original tumor being carried to the distant part where it grows. William Pepper.

Metatheria: See Eutheria.

Metayer [Fr. *métayer*: Provenç. *meytadier* < Lat. **medieta′rius*, deriv. of *medi′etas*, mean, middle]: a name applied to the peasants of continental Europe, and especially those of France and Italy, that farm their land on shares. This form of tenure was common all through the Middle Ages and to the end of the eighteenth century, but is falling into disuse. It is thought that the metayers were originally emancipated serfs, who, having neither land nor capital of their own, were fain to till the lands of another on such terms as they could get. The landlord furnished the land, the metayer furnished the labor; the landlord usually received half the produce in France, two-thirds in Italy. Tenures of this kind had a permanent character, and in this respect offered some of the advantages of private land ownership; but the system did not give the fullest stimulus to personal effort or to the improvement of the soil by the use of capital. The laborer was unwilling to do extra work when half of the surplus produce would go to the landlord. The landlord was unwilling to invest capital (beyond the necessary minimum which custom demanded), when half the benefit of such capital would go to the laborer. In these respects the English land system was better than the continental system, since in England, under a system of money-rents, the tenant obtained the whole immediate profit from his exertions, and the landlord the whole permanent benefit from the investments of fixed capital, so that each was stimulated to do his best. A. T. Hadley.

Metazo'a [Mod. Lat.; from Gr. μετά, after + ζῷον, animal]: a term given, in contrast to Protozoa, to the great majority of the animals, which differ from the Protozoa in the fact that they are composed of many cells, and these cells are further differentiated into tissues and organs, while in the Protozoa each cell performs all the functions of life.

Metel'lus: the name of a Roman family belonging to the plebeian gens Cæcilia. It first became known in history during the first Punic war, when Lucius Cæcilius Metellus was elected consul in 251 B. C. Its most conspicuous members were (1) Quintus Cæcilius Metellus Macedonicus, who defeated the Macedonians in 148 B. C. and the Achæans

in 146 B. C. With Q. Pompeius he was censor in 131 B. C. (they were the first plebeians to hold this office), and proposed that all citizens should be required to marry. His name became proverbial as an example of human happiness.—(2) QUINTUS CÆCILIUS METELLUS NUMIDICUS, who fought successfully in 108 B. C. against Jugurtha, King of Numidia, but was superseded by Marius, at that time his legate.—(3) QUINTUS CÆCILIUS METELLUS CELER, who was prætor in 63 B. C., when Cicero was consul, and contributed much to the suppression of the conspiracy of Catiline.

Revised by G. L. HENDRICKSON.

Metemone: See GALABAT.

Metempsycho'sis [Mod. Lat. = Gr. *μετεμψύχωσις*, transmigration of souls; *μετά*, after, beyond, over, across + *ἐμψυχοῦν*, animate, vivify; *ἐν*, in + *ψυχή*, soul]: the transit of the soul from one stage of being or life to another, commonly called transmigration. As the belief that the soul after death appears again in animals or in men and women is spread all over the world, it would appear to be anthropologically innate, and to be the first form in which the idea of immortality occurs to man. The early Egyptians saw in it an explanation of the sufferings endured by many men on earth, which sufferings were otherwise inexplicable. Their entire religion was based on this doctrine, that man is a fallen angel, once an equal of the gods. He is to be judged after death, and if his life on earth has been evil he must renew his earthly existence, if not as a human being, as an animal, according to his crimes. It was in India, where the problems of metaphysics and ethics as connected with ontology and the destiny of the soul were elaborated to the last degree on a pantheistic basis, that metempsychosis was most ingeniously and extensively developed. All the problems of fate, free will, and human suffering were easily explained by the doctrine that the soul, an emanation from God, passed from life to life, and that the sins committed in one existence were expiated in another. It was even held that the account was kept so closely that a soul might pass thousands of years or *kalpas* in one or other of the heavens as a reward for good deeds or self-inflicted suffering, and yet be obliged to return to earth or hell to expiate as an animal, man, or demon, certain sins. (See BUDDHISM and KARMA.) To the pure theism of the early Jews and Arabs, or of the Shemitic race, who simply held that God directly made and willed all things, the idea of metempsychosis was utterly opposed. According to the latter, the soul is guided by laws which lie far behind the highest conceivable idea of a God; according to the former, God distinctly makes all laws with full self-consciousness. Consequently, the Old Testament contains no trace of the transmigration of souls. After the building of the second temple, however, foreign speculation and superstition flowed in on them freely. The *Gilgul Neshamoth*, or theory of metempsychosis, forms an important doctrine in the Cabbalah, and ere long a mass of wild and beautiful legends arose to illustrate it. The rabbis held that David had been Adam, and is to come again as the Messiah, and that Simeon had been Japheth. Many fanciful ideas sprung up in the Hebrew theory of transmigration—e. g. that when a woman had a soul which had been that of a man she could not bear children until God had breathed into her some part of a woman's soul. The Greeks derived the doctrine of metempsychosis from teachers who had taken it from Egypt or India. Thales had taught it at an early period, and it was subsequently greatly developed by Pherecides, Pythagoras, and Plato. The Greek mysteries were, in fact, not only a school in which metempsychosis was taught, but an indispensable grade or lodge through which all of the aspirants must pass before they could be purified and pass on to higher stages of existence. Pindar, setting forth the Orphic doctrines, teaches that the soul must thrice lead a pure life before it could be fully set free; and Plato, refining on all the theories of his predecessors, believed (or rather argued for) the principle that souls had pre-existed, and that on earth they assumed shapes corresponding to their character. What with purification, penance, and intervals of a mere ghost-existence apart from the body, Plato assumed that 10,000 years must pass before the soul would attain divinity. But Aristotle, however, in many passages of his writings, combats the doctrine of metempsychosis on the ground that the soul is the efficient and final cause of the body, and hence that it is suited only to the body that it makes and not to some other body that it happens to enter. There is every reason for believing that there were few religious or spiritual systems of antiquity which did not eventually include metempsychosis, strange as it appears at the present day. The Epicureans denied it, but it appears to have been generally inculcated as one of the deepest doctrines of the mysteries. The Neo-Platonists, who believed in magic, as in all the wild deductions from a theory of a universal soul and life, of which man was a part, assumed the doctrine of metempsychosis as a natural inheritance. Gnostics and Manichæans welcomed it, and the more speculative or mystical of the Church Fathers found in it, as the Egyptians had before them, a ready explanation of the fall of man and the doctrine of evil spirits. All are "dreeing their weird," or undergoing penance for sins. This considerable step toward reconciling the existence of suffering with that of a merciful God was distinctly set forth by Porphyry and Origen, and passed from the East, with all the strange heresies of "illumination," in all probability, through such institutions as the Cairene House of Light and the Knights Templar, into the doctrines of the obscure sects of the Middle Ages in Europe. The Taborites, an extreme branch of the Hussites, are said to have believed in transmigration, and this view has been thoroughly set forth by George Sand in *Consuelo*. The Druids taught it, and of late years poetical philosophers or true poets have found in its inexhaustible fitness for romantic pictures and incidents subjects for their pens. It has also become familiar to a wide public since 1885 through the writings of Madame Blavatsky and the members of the Theosophic Society.

Revised by W. T. HARRIS.

Metencephalon: See BRAIN.

Me'teorite, Meteor'olite, or **A'ërolite** [*meteorite* is from Gr. *μετέωρος*, in the air, suspended on high; *μετά*, beyond + *ἀείρειν*, raise; *meteorolite* is from Gr. *μετέωρος* + *λίθος*, stone; *aërolite* is from Gr. *ἀήρ*, air + *λίθος*, stone]: terms used synonymously to denote a solid body that has fallen from the heavens. They are not to be confounded with those small luminous bodies that flash across the sky every bright night, visiting us in large numbers at stated periods, and called *shooting stars*; for these last are doubtless composed of very attenuated matter, and are never known to leave any solid residue behind them. (See METEORS.) A genuine meteorite may flash across the sky, become visible, and yet pass on without sending to the earth any evidence of its true character; but very frequently it falls to the earth, and forms a permanent addition to our globe. These bodies have been observed to fall in all ages of the world; and doubtless the earliest account we have of any one of them is to be found in Joshua x. 11; at any rate, the phenomenon referred to in that verse can be interpreted by reference to some of the more modern falls of meteoric stones; but one of the most remarkable falls recorded in ancient history is that of the Thracian stone mentioned by Pliny in the fifty-eighth chapter of his second book of natural history. It fell near Ægospotamos in Thrace 467 years before Christ. Pliny describes it as being as large as a cart; he describes it also as being of a burnt color. It was held in veneration by the inhabitants of the country, and the time of its fall served to fix the period of certain important events, as evidenced by the following statement to be found in the *Parian Chronicle*: "From the time when the stone fell at Ægospotamos, and the poet Simonides, who died at the age of ninety during the archonship of Theagenides at Athens, is 205 years." Another ancient and memorable meteorite is now at Mecca; for the celebrated black stone, *Hajar el Aswad*, that forms an object of adoration of the pilgrims to the Kaaba at Mecca, is doubtless one of these bodies; and some think, with very good reason, that the image which fell down from Jupiter (referred to in Acts xix. 35), and was worshiped by the Ephesians, was also an aërolite.

To give an idea of the phenomena accompanying the fall of these bodies, we shall furnish a short statement of those connected with the fall at L'Aigle, France, in 1803, and that in Guernsey co., O., in 1860. At the time of the fall of the L'Aigle meteorite the atmosphere was clear and calm, and many persons observed a brilliant fiery ball passing rapidly through the atmosphere; and a few moments after there was heard a violent explosion, or rather succession of explosions, lasting five or six minutes, the first two or three sounds resembling those of cannon, and subsequent ones that of musketry, then a rumbling noise like the beating of a drum; all these noises being produced by the original explosions and subsequent reverberations. The noise appeared to proceed from a small rectangular cloud, parts of which

from time to time were thrown off by the successive explosions; the noises were heard in an area of over 100 miles, and the area over which the stones fell was about 6 miles long by 3 miles broad. Of the Guernsey fall we have no very definite account of the meteorite during its flight through the atmosphere. This occurred also in the daytime, a little after one o'clock, when three or four distinct explosions were heard, like the firing of heavy cannon, with the interval of a second or two after each report. This was followed by sounds like the firing of musketry in quick succession, which ended with a rumbling noise like distant thunder; and this continued two or three minutes. The first reports were so heavy as to produce a tremulous motion like heavy thunder, causing the glass in the windows to rattle; the sound was so singular that it caused excitement and alarm, many supposing it an earthquake.

There was a fall of meteorites in Iowa on Feb. 12, 1875, from which many fragments, in all not less than 500 lb. in weight, were secured. Iron masses assumed to be of meteoric origin are known to exist which weigh many tons, and it may be readily believed that the larger detonating and stone-producing meteors are, when they enter the air, as large as these irons. On the other hand, the smallest shooting stars, especially the telescopic ones, are probably not greater than small pebbles or grains of coarse sand. The apparent size of all meteors is magnified by the surrounding flame and by irradiation, and does not therefore indicate the real size of the meteoric body.

Fracture in the Air.—The meteorites coming from a single meteor must before entering the air have been in close company, and probably were coherent. The resistance of the air is a sufficient cause for breaking the body into fragments. At the close of the flight these fragments usually are distributed over areas miles in extent. Upon them we often find evidences of successive fractures. One surface may show by its smooth form continued melting. On an adjacent surface may be an accumulation of melted matter, with clear evidence on its margin of its having come from the other side. Another surface may show a mere accumulation of melted matter, while its own material is not changed. Another surface may be more or less browned as with smoke, with some or all of its margins exhibiting a delicate rounding of the black crust of the adjacent surfaces, showing the fracture to have taken place while the crust was soft. Still other surfaces are so slightly discolored that it is impossible to decide whether the fracture may not even have been subsequent to the fall, while numerous cracks extending into the stony mass show that the disintegration was still in progress. All these peculiarities are shown in some Iowa meteorites mentioned above. This breaking is shown peculiarly by the fragments of a meteor that fell in India in 1861, which were picked up at places 3 or 4 miles apart, and which fit to one another. Moreover, some of the fitting surfaces had the usual black crust, while others were unaltered.

Structure of Meteorites.—The meteorites contain no elements, so far as we know, which have not been found on the earth, but these elements are compounded differently from those of any terrestrial minerals. Iron is always present, usually in metallic form and combined with nickel. The stones from different meteors differ much in their structure, though they may be grouped in a few well-marked classes. In general, the meteorites resemble the igneous more than the other rocks of the earth's crust. The iron masses have a crystalline structure, which is revealed by polishing a surface and etching it with acid. The lines developed by the acid are called the *Widmannstätten figures.*

Gases in the Meteorites.—If fine chips of meteoric iron, or powdered fragments of the stony meteorites, be placed in a vacuum and then heated moderately, they yield up gases consisting of oxygen, carbon, hydrogen, and nitrogen. These gases seem to have been absorbed at some former time by the meteor, probably by the iron of the meteor. The spectrum of these gases corresponds to the spectrum of the light of a comet's coma and tail.

Meteorites are of two kinds, stony and metallic, the latter being composed mostly of iron. The general character of *the stony variety* is (1) great variety in size, from that of a pea to many cubic feet; (2) irregularity of form, with rough and indented surfaces; (3) they are coated with a black crust or varnish, which doubtless arises from the fusion of the surface by the intense heat developed during the rapid passage through the atmosphere; (4) their specific gravity is between 3 and 4; (5) the minerals constituting the mass are principally of the class belonging to the pyroxenes and olivenes, always containing more or less metallic iron alloyed with nickel and cobalt. There are one or two meteorites supposed not to contain this metallic iron, but it is very doubtful if such be really the case. There are other minerals associated with them; the most interesting and constant are schreibersite (a phosphuret of iron and nickel) and triolite (a sulphuret of iron). A fragment of one of the Guernsey County meteorites gave for its composition—

	Per cent.
Olivene	56·884
Pyroxene	32·416
Nickeliferous iron	10·690
Schreibersite	0·002
Triolite	0·015

Iron Meteorites.—This class simply represents the metallic particles found in the stony meteorites, increased to several pounds and even tons in weight, as exemplified by the Cranborne iron in the British Museum or the Texas iron (of less weight) in the Yale University Museum. All of the irons that are known, except three or four, have been discovered some time after their fall, this not having been observed, their composition being the only guide as to their origin. There have, however, been three of them seen to fall, and these constitute the three most valuable specimens of this class. They are the following:

Agram	1751
Dickson co., Tenn.	1835
Braunau	1847

The iron meteorites have the same irregular shape as the stony ones, with a specific gravity of 7 and 7·8, with a composition of which the three following irons are types:

PARTS.	Tazewell, Tenn.	Oldham co., Ky.	San Gregorio, Mex.
Iron	84·10	91·61	95·01
Nickel	15·22	8·09	4·40
Cobalt	0·43	0·25	0·51
Copper	0·06	trace	trace
Phosphorus	0·19	0·05	0·08

In the interior of these irons it is not uncommon to find nodules of sulphuret of iron, phosphuret of iron and nickel, and graphite. When polished the surface of the metal is very brilliant, and in some cases remains so; in others the surfaces are rapidly rusted.

Origin of Meteorites.—It was at one time supposed that these masses of stones and iron originated in the atmosphere or were ejected from terrestrial volcanoes. Another theory, advanced by Terzago, and subsequently by Laplace (adopted by Berzelius and others), and sustained in part by his mathematical calculations, is that they were projected from the moon, but these crude notions have been long since exploded. It is now fully understood that they form a few specimens of countless small bodies or fragments, invisible in the most powerful telescopes, which are moving like planets or comets in eccentric orbits around the sun. We know nothing of them except when one happens to encounter the earth. Revised by S. Newcomb.

Meteorol'ogy [Gr. *τὰ μετέωρα*, things in the air (see Meteorite) + *λόγος*, reason, discourse]: the science which treats of the atmosphere. It falls naturally into two branches, meteorology proper and Climatology (*q. v.*). Meteorology proper treats of the weather and its causes, and of the physical laws involved, including the instruments by which the phenomena are observed. The instruments are discussed under their proper headings. Meteorology has a practical and a theoretical aspect. The practical aspect is the one which will be treated here, as of most interest to those who are not professional students of meteorology. For those who wish to pursue their studies further, the bibliographical references at the end of this article will serve as a guide.

Ancient meteorology included everything supposed to be aërial, embracing some things now known to be astronomical, as comets and meteors. As it lacked the means of accurate observation it came to rely on pseudo-observations, and by the Middle Ages had become thoroughly astrological. A new and better era was begun by the invention of the thermometer (before 1597) and barometer (1643), due to the happy intuitions of Galileo, who started the work of striking off the intellectual fetters imposed by Aristotle 2,000 years before. Two hundred years were spent in developing these instruments and inventing new ones, in gathering the enormous harvest of facts rendered possible

by them, and in drawing the plain deductions from these facts, when a new era was initiated by the use of the synchronous weather-map. We are now in the weather-map period of the history of meteorology, and although we have been but a short time in this period the advance made by the science has been enormous.

The weather-map is a chart on which are graphically represented meteorological data taken simultaneously over the entire area it represents. To make the map useful for forecasting the data must be collected and transferred to the chart with the least possible delay—within two or three hours of taking the observations, if possible, and within four at the outside. The happy idea of simultaneous observations was not a new one, but the immediate collection of the data could not be put into operation until the successful trial (1835) of the electric telegraph and its extension to a considerable number of widely separated plans (1847). In 1856 Prof. Joseph Henry began the use of the first *immediate* weather-map. It was a wall map with movable symbols, posted in the Smithsonian Institution. From the map Prof. Henry deduced certain conclusions concerning the weather which he sent to Congress. In 1857 Le Verner, in France, began the publication of an international bulletin (a statement of current meteorological data, but not reduced to chart form), and from these he began predictions for the ports in 1860. On Sept. 16, 1863, he printed the weather-map for that day, and distributed it to his correspondents. This was the first current weather-map published, and the series has been continued since without interruption. It gives daily the air-pressure and winds for Central and Western Europe.

In the meantime the disturbances incident to the civil war had interrupted the orderly advance of meteorology in the U. S. It was resumed by Prof. Cleveland Abbe, then director of the Cincinnati astronomical observatory, who in 1869, with the gratuitous assistance of the Western Union Telegraph Company, began the collection and use of telegraphic reports from the adjoining States; and on Feb. 2, 1870, Mr. Armstrong, the local manager for the telegraph company, undertook under Prof. Abbe's direction, the making of current weather-maps and their multiplication by a manifold process. These maps were continued until Oct. 10, 1870, and were the first current weather-maps in the U. S. The official series of weather-maps in the U. S. began with tri-daily maps on Nov. 1, 1870. They were in manuscript, and were made both in Washington and Chicago. They were multiplied by a manifold process, and were first printed May 2, 1871, at Washington. The next series of official weather-maps was that of the British Meteorological Office, which first appeared in printed form in the bulletin for Mar. 23, 1872. The number of series has gradually increased since, until in 1894 there were eighteen of them issued by as many official weather services, besides about seventy daily issued at local stations in the U. S. In size they vary from 16 by 22 inches (U. S.) to 4 by 5 inches (British). In Japan they are issued three times daily (as formerly in the U. S). In the U. S., and in Russia, they are bi-daily. The remaining fifteen are daily, and all, except the Australian, are issued on Sunday. The hours of observation are early in the morning, and—for the bi-daily—early in the evening. At all stations of the U. S. there were 8,830 maps issued on June 1, 1893, of which 6,257 were morning maps and 2.573 evening maps. This makes a total issue of about 3,000,000 maps per year.

In what follows, reference is always made to the Washington map unless otherwise specified. The maps issued at other U. S. stations differ in some details from the Washington map, and the maps of the other national services, although occupied with the same meteorological elements and serving the same purposes, differ in many details.

The observations are taken at 8 A. M. and 8 P. M., in 75th meridian time. This is what is called Eastern time, and is closely the local time of Philadelphia and nearly that of Washington. It is about seven o'clock local at Chicago, St. Louis, and New Orleans; about six o'clock for Helena, Denver, Santa Fé, and El Paso; and about five o'clock for San Diego, Los Angeles, San Francisco, and Portland. The observations are taken as nearly simultaneously, and as nearly in the same way, with as similar instruments as possible. They are collected at Washington, reduced to maps, the forecasts made, and the maps published within about three hours from the time of observation.

The pressures of the atmosphere as shown by the barometer are reduced to sea-level before they are entered on the map. The reduction employed is in part founded on general physical principles (Ferrel, *Recent Advances in Meteorology*, pp. 392–402), and in part on an empirical adjustment, such that it makes a consistent map. In the elevated plateaus of the interior and mountain stations these reductions are somewhat uncertain and occasionally introduce illusory appearances on the weather-map, but with the reductions now used (due to Prof. H. A. Hazen) those misleading phenomena are reduced to a minimum. These reductions are made in order to render strictly comparable observations taken at widely separated points. If they were not made the topographic effects on air-pressure would be the chief ones visible, and those due to weather changes would be masked. Any other level could be taken as the basis of the map (as a plane 1,000 feet above sea-level, or 2,000 feet), or instead of the actual pressures reduced the variations from the average pressure for the day might be employed; but the method actually used, though not free from objections, is now universally employed on weather-maps, and its faults have become familiar to forecasters. Slight culminations or hollows of air-pressure on the elevated plateaus and mountains of the West are to be treated with suspicion, but high or deep ones are reliable.

When the barometric pressures have been entered on the map, lines are drawn passing through all points having the same pressure. These are called *isobars*, or lines of equal pressure. They are usually made for each tenth of an inch of pressure, as 29·5, 29·6, 29·7, etc., and are drawn as shown in the diagram. If one station has the reduced pressure of 29·79 and the next to the E. has 29·83, it is evident that the isobar of 29·8 must pass between them, and will be at about a quarter of the distance from the first to the second, at the point A. It will not pass between the first and the one to the S. of it, because they are both below 29·8, but will between the latter and the one to the E. of that, as the last is 29·86—and at the point B, about half way between the two, connecting now A and B, with a sweep suggested by its previous and following course—and we have the isobar of 29·8 for that part of the map. With practice the isobars and other lines can be drawn with rapidity and precision, but one rule should be always remembered: these lines, from the fluidity of the air, will always be in free and easy sweeps, and will never make a sharp angle.

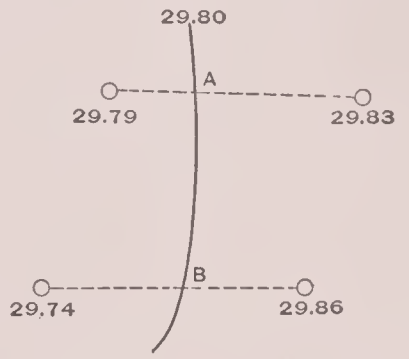

DIAGRAM 1.—Drawing of isobars.

The resulting isobaric map will look like a contour map in geography, presenting certain slopes from lower pressure to higher and descents from higher to lower, the one often ascending to a rounded area of highest pressure, the other terminating in a rounded area of lowest pressure—each covering a considerable area.

The culmination of highest pressures is one of the most important features of the map, and a key to the meteorological situation. It is called an *anti-cyclone*, but, from its resemblance to a hilltop on a topographic map, it is also called, familiarly, a *high*. Such a high is appearing in the northwest corner of map No. 4, inclosing the unusually high pressures of 30·6 or more. A high defines an area of fair weather with dry air and gentle winds. The air of a high is relatively cool, but the absence of clouds and humidity gives the sun's rays unusual power in the afternoon, and the free radiation to the sky makes it unusually cold toward morning. The high is therefore the region of extreme daily changes in temperature. The air of the high is dry, tonic, and agreeable, but it is also the region of extreme heat and cold and of untimely frosts, and if it remains long it means drouth and failure of crops.

The area of lowest pressures is called a *cyclone*, or, for topographic reasons and to avoid the common associations of violence with this word, a *low*. From the low the pressure ascends in all directions. The low is the area of warmth, cloud, moisture, rain, and high winds. Though it brings close, warm, muggy, humid weather, and is consequently depressing and disagreeable, its influence is benign, for it brings the rain and keeps the air stirred, preventing the stagnation so characteristic of a long drouth. The low is even more a key to the meteorological situation than is the high. The maps Nos. 1 to 4 show the successive positions

of a low, the path of which is marked out (especially on No. 4) by the stream of arrows. This low brought high winds to the Great Lakes, but little rain. Lows are often called *storm-areas.*

After the isobars come the *isotherms*, or lines of equal temperature. They are usually drawn for each 10° F., making an isotherm for −10°, 0°, 10°, 20°, etc. (See the broken lines on maps No. 1 to 4.) They are not reduced for elevation. They usually run poleward toward a low, and equatorward from a high. Near a low is sometimes an area of rapidly warming weather—especially in front and sun, because its direction is contrary to that taken by the sun in its diurnal course. For all cyclones or lows in the northern hemisphere the spiral inflowing of the winds is in a contra-clockwise direction; for the same storms in the southern hemisphere the direction of spiral inflow is clockwise. In the case of the anti-cyclones or highs, the air pours out from the center with a slight clockwise turn in the northern hemisphere, and contra-clockwise in the southern.

The velocity of the winds is not represented on these maps, though it is on foreign maps, usually by the number of feathers on the wind-arrows. The wind is usually gentle

a little to the S. Correspondingly there is a colder area in front of and below a high. These, when they represent a change of 20° or more, are marked out by a row of red dots (shown in the accompanying illustrations as large black dots). Such an area of "colder" is seen on each of the maps Nos. 2 to 4, and on No. 3 it is divided into two. *Isocheimal Lines* connect places having the same mean winter temperature, and *Isocrymal lines* connect places having the same mean temperature for the coldest months in the year.

The winds are presented on the maps by arrow-heads at the stations, the arrows flying with the wind. If, as at Duluth, the arrow points S. E., the wind is a northwest one. A careful examination of the maps will show, what is true on the average, that the wind flows spirally into the low, and that the direction of the inflow is contra-clockwise (the clock lying on its back, with face up). It is also called sinistral, because to a man standing at the center it would wind from the right hand to the left; also against the with highs and fresh with lows, but there are many exceptions to this. Some lows have such gentle winds that they would not attract attention, while some highs have high winds on some part of their margins, generally on the side next the nearest low when the latter is intense and not far off. These are questions of intensity, and lows vary from extreme gentleness to the intensity of the hurricane.

The criterion for intensity on the weather-map is the crowding of the isobars. When they are near together the winds are high, and when far apart the winds are gentle. The perpendicular distance between two successive isobars (or, more properly, the length of the line of force as defined in physics) is called the pressure *gradient*, and the above relation may be stated as a rule: the shorter the pressure gradient the stronger the wind.

The relations of direction of wind to the center of the low can be stated as a rule or law. When it is cloudy and humid and the wind is fresh, so that it is certain that the

low is sufficiently intense to be considered a storm, then the rule is—stand with your face to the wind and the low center is to your right hand, a little behind you. This is called Buys-Ballot's law, after an eminent Dutch physicist.

The cloudiness is indicated by the changes in the station-circle on the map. In maps Nos. 1 to 4 ○ means clear, ◑ fair or partly cloudy, ⊕ cloudy. The low usually has a cloud-cap, which is likely to extend farther forward or eastward of the center of the low than behind or westward, and more to the S. than to the N.

The symbol for rain is ●, a dark circle, that for snow ◍. The rain often precedes the low, especially in the S. E. quadrant; the snow may either replace the rain, or it may occur to the rear of the low, and toward the high.

ciple in the theory of gases that any gas or vapor, in the presence of another, acts as if the other was not present, provided it does not enter into chemical combination with the other. Hence the vapor of water in the atmosphere forms what is in many respects an independent atmosphere. This vapor atmosphere is called the *hydrosphere*, and meteorological conceptions are somewhat clearer if the hydrosphere is considered as a whole and by itself before consideration is given to its interaction with the dry atmosphere.

The fact of prime importance concerning the atmospheric water is that it undergoes all of its changes of state (vapor, liquid, and solid) within the range of actual meteorological temperatures, and that it is the only element of the atmosphere that does so. Water and ice evaporate into vapor, and this

No. 2.—Weather-map for Eastern U. S., Nov. 21, 1893, 8 P. M.

These are the elements of the weather-map, briefly stated. They will be discussed more in detail in what follows. It only remains here to state one general principle of the highest importance in the use of the weather-map. It is this: The weather in temperate regions drifts eastward with about the speed of a passenger train. There are, however, many variations in the paths and speed of highs and lows; changes in intensity of all the elements also often occur. The skill of the forecaster consists largely in detecting the signs of these changes, and this skill is the result of long practice.

The Hydrosphere.—Before passing on to a discussion of the mechanism of storms, it is necessary to consider what is, according to present meteorological theory, the chief source of energy in storms—in fact, the element without which we would have no storms. It is a fundamental principle condenses again into liquid water and into ice. Each change involves a change of energy. When water is evaporated, heat is taken up and removed from the immediate surroundings, thus lowering their temperature; when water is condensed, this heat is restored, raising the temperature. A heat-unit is the amount of heat required to raise a kilogramme of water a degree centigrade. To evaporate a kilogramme of water at freezing requires 607 such heat-units, and at boiling 537. The result is that, by evaporation and condensation of water, the atmosphere becomes a heat-engine, with the sun's rays as the chief source of heat, and the patches in the cloud-layers, where active condensation is taking place, as the cylinders. The vapor is pouring into the hydrosphere at every point where it comes into contact with a liquid or solid surface, at all times and at all temperatures. Evaporation takes place even from a surface of ice

without visible transition through the liquid state. It is more free from a surfaee of turf than from a water surface, and more free from the latter than from a surface of moist bare soil. It is more free at higher temperatures, in the sun than in the shade, in summer than in winter, in the tropics than in higher latitudes. Evaporation also depends on the amount of moisture in the air, being the more free the drier the air. Wind favors evaporation, as also does the purity of the water evaporated. Evaporation also depends slightly on the air-pressure; it increases with decrease of pressure.

When the moleeules of water free themselves from the trammels under whieh they were held when in the liquid or the solid state, they tend, aside from the influence of gravity, to spread equally in all directions. Their motion as gaseous partieles is rapid, so that this spread is a very quick one.

The vapor of water in the air is called *humidity* of the air. There is a limit to the amount of this vapor which the air can eontain. When the vapor has reached this point the air is said to be saturated. If more vapor is forced into the air, the surplus condenses, and the temperature at whieh condensation begins is ealled the *dew-point*. The amount of moisture in the air at any time, measured either by its pressure or tension as a part of the hydrosphere or by the number of grains in each cubic foot of air, is called the *absolute humidity*. The ratio between the amount of moisture aetually in the air and the amount which would saturate the air at its present temperature is called the *relative humidity*. The relative humidity shows whether the air is moist or dry, and is naturally never greater than unity whieh marks saturation—at least never under natural conditions; certain artificial eonditions seem to cause supersaturation. The lower the temperature, the lower the dew-point and the smaller the absolute humidity at saturation. In cold weather the relative humidity is often 1; in hot weather, rarely. When the relative humidity is low, water evaporates rapidly from the soil or from reeeptaeles, furniture shrinks, the skin is likely to chap, and fine wrinkles gather on the faee. When the relative humidity is high, plants look bright and freshen up, animals appear more comfortable, and furniture swells and ereaks.

The hydrosphere is a shallower envelope for the earth than is the dry atmosphere. It thins out rapidly toward mountain-tops and toward the poles. It is also irregular, variable, and stratified. The irregularities are produeed by night and day, sunshine and shadow, clear weather and elouds. The variations are due to mueh the same eauses. The stratifieation depends on the principles of condensation, as follows:

The humidity spreads in all direetions until it reaehes some plaee already saturated, when eondensation takes plaee. This may be due to the chilling of the air in contact with any free surfaee cooled below the dew-point, when there is a deposit of dew, hoar frost, or frost-work (see DEW), or it may be due to the chilling of the air by elevation and consequent expansion, in which case cloud is formed, or the water-moleeules themselves may, in their journeys, pass the elevation at whieh the temperature is that of the dew-point, in which case a thinner cloud may be formed. (See CLOUDS.) At the preeise level or isothermal plane where the temperature is that of the dew-point, a stratum of cloud will be formed, but the release of heat by condensation of vapor and the action of the sun's rays on the upper surface of the cloud now make this air warmer than below, and the condensation has removed some of the moisture, so that the next cloud-layer can be formed only at a considerably greater elevation. Above this may come a third layer and possibly more, so that a distinct, though transient, layering is set up.

A fog is a eloud at the earth's surface, and is the result of a supersaturation due to chilling.

We have now followed the molecule of water from the time it left the mass of ice or liquid water until it is recondensed as dew or the element of a cloud. These partieles may now agglomerate until raindrops, hailstones, or snowflakes are formed, when they fall to the earth as precipitation. (See RAIN, HAIL, and SNOW.) A part of the precipitation flows off the surfaee to streams, then to rivers and the sea; a part percolates into the soil to appear at a distance in springs, or to be evaporated gradually from the surfaee; a part is utilized in organic or inorganic changes; and a part is evaporated sooner or later from the surface of the earth. The amount utilized in each way depends on the sort of precipitation, the character of the surfaee and soil, and the character of the vegetation at the plaee of fall. In any case, the moleeule which falls is likely, by the aid of streams and winds, to be earried far to leeward before it falls again.

Experiments indicate that dust plays an important part in the condensation of atmospheric moisture, which condenses most readily on free surfaces, and such surfaees are afforded by motes and particles of dust floating in the air. These extremely small, solid masses fall with excessive slowness through the air, and the resistanee of the air causes them soon to assume a uniform veloeity, which may be but a fraction of a foot per day. They also show a tendency to make more or less distinet layers or strata in the air, those of about the same size tending to oecupy the same stratum. This is a tendency common also to sediments in water.

Lows or Cyclones.—The air, like other gases, and even liquids, shows a strong tendency to form vortiees, which are transitory beeause of friction. In a frictionless fluid they would be indestructible. The tumultuous whirls from a faetory chimney or from the crater of a smoking volcano, the perfeet whirls formed by a smoker, or by the puffs of a locomotive at starting, illustrate these whirls beeause the moving air is outlined by the smoke that moves with it. The eddy of a windy street-corner is a stationary one due to the obstruction; those seen in the movement of flakes in a windy snow-storm are not stationary, but are very transient.

A more complete type of aërial whirls is found in the little whirlwinds formed over a dusty road or field of stubble on a hot afternoon. The sun's rays heat up the ground, and thus the air in contaet with it, until the latter becomes hotter, and consequently lighter, than the air immediately above. If the field is uneven the projeeting points conduet the lighter air up their sides, thus giving it enough momentum to send it on its way upward, and the general effect on looking across the field is that of a tremulous motion over the whole of it. If there is no such aid to its start upward, the lighter and warmer air remains below until it gets force enough to aseend without help. Under these conditions a horizontal view through the air gives a more or less perfeet mirage—a phenomenon which ean sometimes be seen over a hot street as perfeetly as over a desert. When this air breaks its bonds it is likely to do so at one point, and there is a sort of drainage upward, resulting in a somewhat orderly inflow below and a eonsequent whirl, whieh on the road is soon exhausted, but on the desert may last for a large part of an hour.

The whirls just mentioned are due to heated air alone, and when the supply of hot air is intereepted or exhausted they come to an end. If the whirl were very large and moist air should flow in, then a continuous souree of energy —the condensation of moisture—would be added, and the whirl would be persistent. Such is the so-called convective theory of eyelones, and though this theory is not satisfaetory at all points, it is the only consistent and generally accepted explanation of these phenomena.

The convective or aspiration theory of storms is as follows: An unequal heating of the air sets up at some plaee a motion upward. The air rushes in below to take the plaee of that which rises; above, the air is chilled by expansion, condenses some of its moisture to form a cloud-cap, then flows out from the center above. The height to which the air rises is very small—probably not a hundredth of the horizontal diameter of inflowing winds. Thus a eyclone is a flat, horizontal vortex, a hundred times as broad as thick, lying flat on the earth and moving as a whole eastward, with inflowing winds on its lower and outflowing on its upper surface.

That the air flows in spirally and not radially, as might be expeeted, is due to irregularities of inflow, and that the spiral is contra-cloekwise in the northern and clockwise in the southern hemisphere is due to the rotation of the earth. Ferrel has shown (*Pop. Treat. on Winds*, pp. 77–88) that any body in motion horizontally over the surfaee of the rotating earth has a tendency to defleet to the right in the northern hemisphere and to the left in the southern. If the center of the low is at C (diagram), the decrease of pressure there will cause a particle of air at A to pass radially along A B toward C; but the earth's rotation causes the deflection B D, and the particle actually reaches

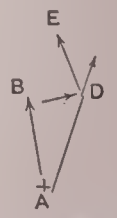

DIAGRAM.—Cause of sinistral spiral motion in lows.

D. From this point the suction, so to speak, of the center would cause the particle to move to E, but the earth's rotation, and now also the momentum from the motion from A to D, will cause its actual path to be to the right hand of D E, and so on.

Thus the particle of air passes in a spiral path to the center of the cyclone. Meantime its velocity is increased as it approaches the center. This is due to the law of "preservation of areas," or, as it is called in astronomy, Kepler's second law. In meteorology it is sometimes so efficient that, combined with the action of inertia (the so-called centrifugal force), it causes the particle near the center to circulate around the axis without ever reaching it, thus causing a partial vacuum about the axis—a feature of importance in Ferrel's theory of tornadoes.

To obtain a clear idea of the mechanism of a cyclone, as above explained, let us follow in imagination a particle of air from the time it enters until it leaves such a vortex. Lying on the extreme margin of a cyclone, it is caught in the suction action of the center, and starts slowly toward it. Its course is at first along a radius, but the deflective effect the speed becomes less and less, until finally it is thrown out at the margin of the cyclonic disk, and comes to rest in a position decided by other than cyclonic laws.

The low has a cap of cloud. This cap is not placed centrally over the low, nor is it symmetrical. It is usually more marked on the advancing or eastern side and on the southern side of the low, and is thickest and lowest at some point a little S. E. of the center. From here it thins out in all directions, but most rapidly toward the rear. The extreme edges, especially in front, are long streaks or fingers of cirrus, and are at great elevations.

The precipitation (rain and snow) is usually greatest where the cloud is densest—that is, somewhat ahead and to the right hand of the center of the low. Snow in squalls and flurries often falls to the rear of a low, especially if it is crowded by a high. The area of precipitation varies enormously with individual storms, and the heaviest rainfalls usually occur with secondaries, to be mentioned hereafter.

Cyclones have an eastward motion in temperate latitudes which has been variously attributed to the general drift of the surface air, to the higher currents or anti-trades, and to

of the earth's rotation soon comes in play, and it bends its path to the right of the center. Then comes into action the centrifugal force and the law of preservation of areas, and its path about the center becomes constantly smaller and more circular, while its speed becomes greater. Meanwhile it gets gradually into the central region where aspiration is active, and its spirals begin to rise. Eventually it passes the median plane of the cyclone, the suction weakens, and is finally reversed, the spirals become wider and wider, self-propagation due to the fact that the rain and cloud center is a little in advance of the center of low pressure. They are disposed to follow habitual paths, but this regularity of path is by no means to be relied on in the case of any individual cyclone.

The movement of the cyclone over the station of an observer gives rise to a well-marked series of phenomena lasting from one to three days. The barometer gradually falls, reaches a minimum, then rises rather more rapidly than it

fell. The thermometer gradually rises until the center of the low is passed, when it falls faster than it rose. The fingers of the cirrus are first seen extending up from a point on the western horizon. They gradually extend, and are followed by a sheet of cloud which grows denser and descends lower until the rain-center has passed the meridian, when the weather clears more rapidly than it clouded. The weather thickens and it becomes more and more rainy until the rain-center has passed the meridian, when the rain passes off more rapidly than it came on.

The most interesting series of phenomena, however, are those of the wind. The cyclone brings with it a series of winds of its own, which pass along with it and so gradually sweep over any station in its path. In the resulting and successive changes in wind-direction which are possible, there are three distinct cases depending on whether the storm-center passes to the N. or S., or centrally, over the station. If the center passes to the N., the wind starts in as southerly, passes through westerly, and ends as a northerly wind. It thus takes a clockwise change, or that with the sun. This is called *veering*. If the center passes to the S., then the wind passes from southerly to northerly through the E., or against the sun, which is called *backing*. If the center passes over the station, the wind is southerly when it is coming on and northerly when it is going off. There is no veering or backing, but the wind simply reverses with a longer or shorter interval of relative calm. This is a remarkable phenomenon in violent cyclones, in which cases the calm center or "eye of the storm" is especially large and well marked. Vessels have found the eye of the storm, with its tremendous choppy seas but no wind, to be about as destructive as the winds themselves.

If a line is drawn through a center of low-pressure and in the direction of motion, then we have a right-hand half and a left-hand half of the storm. In the northern hemisphere the right hand (or generally southern) half of a violent storm is the more dangerous because the air there moves with the velocity of the cyclonic wind *plus* the velocity of progression of the storm as a whole. The left-hand half is the less violent half because the velocity of the air there is that of the wind *minus* that of progression.

If a line be also drawn through the center, but perpendicular to the preceding, the storm is divided into four quadrants, of which the front right-hand one is the most dangerous, most cloudy, and most rainy.

Storms.—The larger storms (or atmospheric disturbances accompanied with precipitation) are the more intense lows or cyclones; the smaller ones are secondaries or minor whirls (in size not intensity) in the general whirl of the cyclone.

One path of storms comes up from the West Indies. This is the path of hurricanes. Another comes up from the Philippine islands. This is the path for typhoons. These are both violent cyclones of tropical origin. (See HURRICANE.) Typhoons are also known in the vicinity of the Friendly islands in the South Pacific and in the vicinity of the Mascerene islands in the western part of the Indian Ocean. The habitual paths of storms in the southern hemisphere are not yet known except for small areas.

The *secondaries* are minor whirls, often imperfect as whirls, which are imbedded in the general whirl of the cyclone, and most generally in the right-hand anterior quadrant. They are most common in extensive and humid lows, and appear generally in the hotter moist seasons and in the hotter hours of the day. They are local in character and brief in duration. Among them are TORNADOES, THUNDERSTORMS, HAILSTORM, and CLOUDBURST (*qq. v.*). They afford a large percentage of the rainfall of warm seasons—the more the nearer the tropics are approached. In the tropics these minor disturbances appear to form locally, and independently of any general storm.

Highs or Anti-cyclones.—In the highs the air descends from above and flows out. The outflowing winds here take also a spiral direction, but with dextral turn (in the northern hemisphere) or opposite to that taken in cyclones. The curvature of the spiral is here gentle and the velocity generally slight. The motion of anti-cyclones is generally less rapid and more erratic than that of cyclones. They appear in the W. and disappear in the E., like cyclones, but their paths are usually on more southerly latitudes; while the cyclones usually leave the continent by the way of New England or the provinces, the highs usually leave by the Middle Atlantic coast.

Gales are not unusually associated with highs, though they are generally at a distance from the center; are most frequent when a high is not far distant from a preceding low, and are not accompanied with much precipitation. The Texan NORTHER (*q. v.*) is a gale due generally to an anti-cyclone in higher latitudes. A COLD WAVE (*q. v.*) is a phenomenon of the advancing edge of a winter high following closely on an unseasonable low. Where the cold wave is accompanied by a fall of fine, cold-weather snow, in sharp acicular crystals with a high wind, it becomes a BLIZZARD (*q. v.*), which is dangerous.

Vertical Change.—The pressure of the air decreases with elevation in free air or on mountains, but the change is modified somewhat by temperature. The pressure at sea-level supports a column of mercury about 30 inches long. At 1,000 feet elevation (temperature 40°) it is 28·90 inches. At 8,000 feet it is only 22·14 inches. The rate of fall decreases with increase of elevation. The temperature falls with elevation in the free air, but at a rate which varies with the season, the cloudiness, and the humidity. The sun's rays are hotter at an elevation, but the air is thinner and less warmed up by the sun. Glaisher, in his remarkable balloon ascent of Sept. 5, 1862, with the temperature of 59° F. at the ground, found it 41° at a height of 1 mile; 32° at 2 miles; 18° at 3 miles; 8° at 4 miles; and 2° at 5 miles. The cirrus clouds are formed of ice particles, and the temperature where they are found must be considerably below freezing, or the sun would melt them. Their average height is above 29,000 feet in middle latitudes. Hermite's pilot-balloon probably went to the height of 10 miles, and the automatic thermometer registered —58° C., or —72° F., though with a break in the record and some doubts as to interpretation. The absolute humidity at 1,000 feet in balloons is on the average 88 per cent. of that on the ground, at 10,000 feet 31 per cent., and at 20,000 feet 11 per cent. On mountains the percentages were somewhat greater at higher elevations—for instance, 16 per cent. at 20,000. The wind increases in velocity with ascent, reaching a maximum at a moderate elevation, perhaps 4,000 to 5,000 feet.

Periodic Changes.—The diurnal rotation of the earth causes a well-known series of periodic changes. The air-pressure usually undergoes a double variation of small amplitude, with maxima between 9 and 11, morning and evening, and minima between 3 and 5 in the afternoon and early morning. This appears to be a tidal phenomenon. The temperature has a single maximum early in the afternoon, and a minimum at about sunrise. This is simply a result of solar and terrestrial radiation, and is dependent for the amplitude on the state of the sky and other sheltering conditions. The diurnal curve of absolute humidity runs fairly parallel to that of temperature at extra-tropical coast stations. Inland, however, and in the tropics, the afternoon maximum is cut out by rising currents of warm air, due to the heating by the sun. There results a double variation, with maxima morning and evening. The diurnal curve of relative humidity runs in a direction the reverse of that of temperature on which it depends.

The clouds show a distinct diurnal variation, but it is obscured and complex because it depends on the kind of cloud. For instance, the cumulus cloud is a day cloud, and is most common on summer afternoons. The clearest times of day are about sunset and sunrise. The wind shows a distinct diurnal change in velocity, being highest in the afternoon and lowest toward morning. It also shows diurnal changes in direction, which vary with the topography. The best-known case is that of land and sea breezes, occurring on coasts in the tropics and elsewhere, where it becames heated inland during the day. This wind pours in from the sea in the daytime and seaward at night.

The annual changes are even better marked and known. In the interior of continents the annual change of air-pressure is well marked with a maximum in winter and a minimum in summer. On the oceans and coasts it is usually slight and irregular. The changes in temperature and in the elements depending on it—as wind, clouds, and precipitation—are well known, as they make the seasons which so profoundly affect all human activity. The maximum hot weather usually occurs about the middle of July, and the maximum cold about the middle of January. Spring comes in the U. S. both from the S. and from the W., and autumn departs in much the same way.

Many other periods have been suspected and investigated without entirely satisfactory results. A period agreeing with the sun's rotation—between 26 and 27 days—bids fair to commend itself eventually. The change of the weather with the sun-spot period (averaging 11·1 years) also appears

to be proven, but the relation is apparently of a complicated character, giving different results at different stations. Yet the coincidences are too numerous to be rejected as without significance.

Lunar periods—whether the revolution of the moon (27 or 28 days), the lunation (about 29 days), the saros (18 years 11 days), or the meteoric cycle (19 years)—have all failed to get a foothold in scientific respect, though much time has been put on them, and they appear theoretically probable. Weather periods depending on individual planets have entirely failed to commend themselves to scientific students, though many paradoxes rely on them for forecasts which have received some popular approval and confidence. Even purely astrological meteorology has its adherents.

Other and longer periods have been suggested—as 35 years and 100 years—and striking coincidences can be found for them, but they prove elusive when the attempt is made to inspect them more closely. In general, there is reason to believe that weather changes run in cycles, because this is the method of nature, especially in the phenomenon of fluids, but it appears also probable that the periods of the weather are very numerous, and generally mutually incommensurable. As a matter of experience, no cycles have proved useful in predicting the weather excepting only the diurnal and annual ones.

alluded to. Some of the leading principles for the U. S. may be stated as follows:

1. Lows appearing in view to the W. of the meridian of Lake Huron generally direct their course across the Great Lakes; those appearing in view to the E. of this meridian usually pass up northward in a path parallel to the Atlantic coast. All usually leave the vicinity of the U. S. on the latitude of New England or the provinces.

2. Highs usually take a more erratic course, with more varying velocity. They usually leave the U. S. on the latitudes of the Middle Atlantic coast.

3. Lows are more intense, better defined, and run on more southerly courses in the cold than in the hot season. In July and August they are especially weak, ill-defined, and erratic. The highs are more inclined to become stationary in summer than in winter.

4. The lows from the West Indies are the most violent. Next to these the most violent are from the high N. W. Those from the W., S. W., and Gulf are generally gentle, and the last usually afford abundant precipitation.

5. Severe local storms generally occur to the S. of a very moist and unseasonably warm low, especially if the latter extends a trough of low pressure to the southward.

Many local signs, crystallized into the form of popular weather proverbs, are of use in predictions. This is espe-

No. 4.—Weather-map for Eastern U. S., Nov. 22, 1893, 8 P. M.

Forecasts for short periods ahead (thirty-six hours generally in the U. S.) are made by nearly all the official weather services by means of the weather-map. The general principles on which such forecasts are made have already been

cially true of the sunset signs, as they indicate the character of westward or approaching weather.

The verification of predictions is difficult. With the best means available the forecasts of the Weather Bureau give a

verification of 85 or 90 per cent. The precipitation is especially important in public estimation, but the exact time and place of its occurrence are especially hard to forecast. Verified by the same methods, the popular paradoxes in weather forecasts get only about 50 per cent., but a generous public forgets their failures and remembers their successes.

Experimental Meteorology.—This science is considered one of observation rather than of experiment, yet it has an experimental side of great interest. The electric spark, differing from lightning only in magnitude, can now be easily made. The cloudy condensation of aqueous vapor can be produced with the aid of artificial dust particles, and so controlled as to reproduce the color phenomena of the sky, though not the different species of clouds. Weyher (*Am. Met. Journal*, vii., 17) has succeeded in mechanically producing, on a small scale, whirls and vortices, which represent familiar forms of natural whirlwinds and waterspouts. These lack the self-perpetuating power of water vapor in the presence of strong contrasts of temperature, as found in nature, but Espy thought he had a means of obtaining this by a great fire under suitable meteorological conditions. He tells, in his second congressional report, of the burning of a cane-brake in Florida one hot afternoon, which resulted in, or was at least soon followed by, a cloud-formation and a heavy shower. His theory was that the fire caused a stationary whirl of relatively small magnitude, but large enough to raise a mass of moist air so high that it was chilled by expansion, and condensed and dropped its surplus moisture.

A series of experiments on the production of rain was authorized by Congress, and conducted by R. G. Dyrenforth, in Texas, in the years 1891 and 1892. Powerful explosions were produced on the earth and in the air, with results which to the experimenter and his aids appeared favorable, but to many onlookers, especially to those whose scientific training made them most competent to judge, they appeared unfavorable. It was generally agreed that the methods were expensive and noisy, and that an explosion in a cloud might bring down a few drops of rain, but further than this there was no general agreement. A secret method of rain-making, said to be due to an Australian named Melbourne, was tried in the western part of the U. S. during the summers of 1892 and 1893, with more favorable results. See also CLIMATE, FLOODS, LIGHTNING, RAIN, WEATHER BUREAU, etc.

LITERATURE.—The literature of meteorology is very large. Among current journals may be mentioned: *American Met. Journal* (Ann Arbor and Boston, since 1884); Symons's *Monthly Met. Magazine* (London, since 1866); *The Quarterly Journal* of the Royal Met. Society (London); and the *Met. Zeitschrift* (Berlin). The later books in English are: Waldo, *Modern Meteorology* (1893); Abbe, *Deductive Methods in Meteorology* (with Rep. Chief Sig. Off., 1889), and *Met. Apparatus and Methods* (with Rep., 1887); Ferrel, *Popular Treatise on Winds* (1889), and *Recent Advances in Met.* (with Rep. Chief Sig. Off., 1885); Greely, *American Weather* (1888); Abercromby, *Seas and Skies in Many Latitudes* (1888), and *Weather* (1887); Scott, *Elementary Meteorology* (1883); Swainson, *Handbook of Weather Folklore* (1873). For meteorological tables, see Hazen, *Met. Tables* (1888); *Smithsonian Met. Tables* (Misc. Coll., 844, 1893); and the very complete and authentic *Tables mét. internationales* (Paris, in three languages, 1890). Harrington's *Met. Work for Agricultural Institutions* (Exp. Stations, Bull., No. 10, 1892) contains many suggestions for meteorological work. The meteorological bibliographies of the Signal Service and Weather Bureau afford a guide to the literature generally. The weather-maps of the U. S. meteorological service (now about 20,000 in number) and international maps of the same service afford a very large mass of material for work.

MARK W. HARRINGTON.

Meteors [from Gr. *μετέωρος*, in the air. See METEORITE]: a term used to denote many different objects and phenomena, generally of short duration, that have their place in the atmosphere. Thus there are *aërial meteors*, as winds, tornadoes, etc.; *aqueous meteors*, as fogs, rain, snow, hail, etc.; *luminous meteors*, or those due to the action on light of elements in the air, as rainbows, halos, parhelias, mirages, etc.; *electrical meteors*, as lightnings, auroras, etc.; and *igneous meteors*, as shooting or falling stars, star-showers, bolides or fireballs, aërolites or meteorites, etc. In present usage the term *meteor* is generally limited to the last group, or to the igneous meteors.

Upon any clear night a person looking upward will from time to time see a bright star-like point of light appear in the sky, move rapidly several degrees in a right line across the heavens, and as suddenly disappear, the whole flight lasting usually only a fraction of a second. This is a *shooting* or *falling star*. On certain nights these shooting stars have been seen in immense numbers. Thus on the morning of Nov. 13, 1833, they came so thickly as to be described as a fiery snow-storm. On Nov. 12, 1799, Nov. 13, 1832, Nov. 14, 1866, Nov. 14, 1867, Nov. 14, 1868, Apr. 4, 1095, Oct. 24, 1366, Nov. 27, 1872, and on many other nights that could be named, they came by thousands. On the night of Aug. 10–11 every year three or four times the usual number are to be seen. The brighter of these displays are called *star-showers*.

Varieties of Meteors.—The shooting stars are of all degrees of brightness. Some are so faint that one looking at them can not be certain that he sees anything, and some are visible only in a telescope. Others may be brighter than the planets, or even than the moon. These are called *bolides* or *fireballs*, or by older writers *flying dragons*. Sometimes they are seen in full daylight. The larger fireballs often explode into fragments, the parts chasing one another across the sky or scattering in different directions. In some cases terrific explosions, as of distant and numerous cannon, are heard over all the region a few minutes after the disappearance of the body. These are called *detonating meteors*. At times from these detonating meteors come down stony fragments, scattering themselves over a region miles in extent, and usually striking the ground with enough force to bury themselves in soft earth 1 or 2 feet. These fragments are called *aërolites* or *meteorites*. See METEORITES.

Height.—By observers near each other the track of a shooting star is seen in the same part of the heavens; but when two observers see the same track from two stations 50 or 100 miles apart, it appears in different parts of the sky. Hence the actual altitude can be determined. It is found that they are not seen higher than about 100 miles from the earth, and they rarely come lower than 30 miles unless they send down fragments. While they are thus very far above the region of clouds, they are still more distinct in place from all other astronomical phenomena, excepting, perhaps, the auroras and twilight.

Numbers.—Shooting stars are seen on any clear, moonless night. One person would on the average see not less than eight per hour, but the number increases through the night, so that about three times as many can be seen just before dawn as in the evening hours. A large group watching together can see five or six times as many as one person, or an average, at midnight, of 40 or 50 per hour.

Trains.—Many of the shooting stars leave behind them a bright cloud of phosphorescent light. Often this disappears in a fraction of a second or in two or three seconds. Frequently, however, a bright one leaves in its path a narrow bar of light several degrees long. This contracts in length and broadens, sometimes changing into a small round cloud, which slowly floats away; but usually it retains its elongated form, and after a fraction of a minute is seen to lose its straightness. If it lasts several minutes, the cloud gets twisted forms, the result, no doubt, of winds in the upper air and of currents produced by the meteor itself. One such train lasted forty-five minutes, and they have been reported as lasting more than an hour.

Color.—The meteors and their trains have various colors—white, green, blue, yellow, scarlet, etc. Those which are seen on Nov. 13 of various years leave a bluish train. The body and train of a large meteor may give in its various parts all these colors.

Duration of Flight.—The duration of the flight is generally less than a second of time, but the brighter ones may last several seconds. The fireball of July 20, 1860, was in sight over half a minute, which was, however, an extreme instance, for its path was very long. It was first seen over the State of Michigan, and last seen when it was 200 or 300 miles E. of New York city.

Velocity.—Some meteors move through the air with a velocity of 8 or 10 miles, and some with a speed of 40 or more miles, a second. The mean velocity is about 30 miles a second, or 100 times that of a cannon-ball.

Meteors are Astronomical Phenomena.—It is now universally admitted by astronomers that igneous meteors are caused by small bodies which have been traveling about the sun in their orbits, and striking the earth's atmosphere are burned by the intense heat due to the concussion and friction. These bodies before they come into the air are called *meteoroids*.

Meteoric Showers.—On the morning of Nov. 13, 1833, from about three o'clock till daylight, large numbers of shooting stars were seen throughout the western hemisphere. The very important fact was noticed that wherever the observer might be, the paths of the meteors across the sky were always directed from a point in the constellation Leo, and that this point kept its place among the stars notwithstanding the earth's rotation. This fact could be explained only by assuming that the paths of the meteors through the air were straight lines parallel to each other, and were directed from the constellation Leo; also that the meteors were of cosmical not of terrestrial origin. Further research established that there had been star-showers on the following earlier dates:

Nov. 13, 1833;	Oct. 19, 1202 (O. S.);
" 12, 1799;	" 17, 1101 "
" 9, 1698;	" 15, 1002 "
Oct. 28, 1602 (O. S.);	" 14, 934 "
" 25, 1533 "	" 15, 931 "
" 23, 1366 "	" 13, 902 "

These dates show a cycle of about thirty-three years, with a change of date of about three days in a century, the apparent change of twelve days in the seventeenth century being due in the main to the difference between old and new style. The cycle, the change of date, and the radiation all implied that the meteors belonged to a group of bodies revolving about the sun in similar elliptic orbits. It was also found that only five possible orbits could explain the cycle and the radiation, and that one, and only one, of these explains the change of date. This is an orbit whose period is $33\frac{1}{4}$ years, inclination 17° 45′, eccentricity about $\frac{9}{10}$, and motion retrograde. According to expectation, the meteors appeared again in thousands on the morning of Nov. 14 in 1866, 1867, and 1868.

The swarm was looked for in 1899 and 1900, but for some unexplainable reason did not appear.

Comet 1866 I.—A comet passed its perihelion in Jan., 1866, which has an orbit very nearly identical with the common orbit of the meteors as thus determined. The comet is traveling with the group, and near the head of it.

Comets 1366.—A star-shower occurred in Oct., 1366. Two or three days afterward a comet appeared in the northern heavens, and traveled along the track of the meteors. A week later a second comet followed along the same path. Probably both were members of the group.

Dimensions of the Leonid Meteor Stream.—These meteors, because of their radiation from the constellation Leo, are called *Leonids.* The denser part of the stream of meteors is traversed by the earth in from one to three hours, which implies an actual thickness of 20,000 to 50,000 miles. It takes three or four years for the stream to pass the node, which implies a length of many hundreds of millions of miles. The breadth in its own plane is unknown. The numbers seen per minute in the middle of the brighter of these star-showers imply that the meteoroids have in the center of the stream, as they travel through space, a mean distance from their near neighbors of from 25 to 50 miles.

The August Meteors and Comet 1862 III.—There are shooting stars every year on Aug. 9–12, numbering on the morning of the 10th or 11th, with a clear, moonless sky, 200 or 300 per hour for four observers. They radiate from the constellation Perseus, and are hence called *Perseids.* The comet 1862 III. has an orbit that very nearly cuts the earth's orbit at the point where the earth is on Aug. 10. If a stream of meteoroids were moving with this comet, as the Leonids move with comet 1866 I., they would appear like the Perseids, the radiant being in the same place in Perseus. Hence it is reasonable to assume that the Perseids and comet 1862 III. have like orbits.

The Biela Comets and the Andromedes.—A comet of short period, making three circuits in 20 years, was discovered in 1772, and observed in 1805, 1826, 1832, 1845, and 1852. It 1845 it was seen to be separated into two parts, about 150,000 miles from each other. In 1852 the two comets were about 1,200,000 miles from each other. Since that time they have never been seen. The earth's orbit came very close to the comet's orbit, the earth crossing the comet's path at first early in December, but afterward, owing to the action of Jupiter on the comet, late in November. Shooting stars were seen in considerable numbers Dec. 7, 1798, and Dec. 8, 1838, and at the latter time were observed to radiate from Andromeda; they are hence called *Andromedes.* From this same point in the sky any meteoroids traveling along the orbit of the Biela comets, and coming into the air, would be seen to radiate. On Nov. 24 and 27, 1872, large numbers of Andromedes were seen in Europe and America, forming on Nov. 27 a star-shower of brilliant character. The whole forms a stream, more or less intermittent, hundreds of millions of miles in length. See COMET.

The April Meteors and Comet 1861 I.—Shooting stars in large numbers have been observed in certain years on Apr. 20, radiating from a point in the constellation Lyra. They are hence called *Lyriads.* They seem to be connected with the comet 1861 I. in the same way as the star-showers with the comets already described. Brilliant displays of shooting stars were seen in China on this day B. C. 687 and B. C. 15, and in Europe A. D. 1095 and A. D. 1122, which probably were Lyriad meteors.

Numbers of Sporadic Meteors.—Meteors which do not belong to a group are called sporadic. By considering the number of such meteors visible each hour, their distribution over the sky, and the average relative velocity of the meteoroids in space—all of which can be determined with a certain degree of accuracy—we find that there are in the region through which the earth is traveling 10,000 or 15,000 meteoroids in each volume of the size of earth. In other words, each meteoroid that would, in coming into the air, under favorable circumstances, furnish a meteor-track visible to the naked eye, occupies an average space equal to a cube whose edge is 200 or 300 miles. The number of the meteoroids that enter the atmosphere daily is not less than 10,000,000. If we include those smaller meteors which can be seen only in the telescope, that number may be multiplied twenty or forty fold.

Theory of the Meteors.—The preceding facts lead to the following theory of meteors, which is now universally accepted. A meteoroid is a small solid body describing its long elliptic orbit about the sun, like any comet. The number of such small bodies is so great that every day many millions of them come within 4,000 miles of the earth's center, the number being but little increased by the earth's attraction. They are entirely invisible until, at a height of less than 100 miles from the ground, they enter air dense enough to resist their motion and create light. Their velocity being enormous, generally from 10 to 400 miles a second, an intense heat is developed by the air directly in front of the body. The anterior surface is in consequence melted away, the melted matter being wiped off by the air. This streams back, forming in part the apparent flame, and the train of the meteor proceeds many miles before it is entirely destroyed. Under favorable circumstances of velocity, chemical and mechanical constitution, and size, the meteoroid is not entirely scattered, but, breaking up into fragments, comes to the ground in a shower of stones. These stones often show traces of the flow of melted matter, also evidences of successive fractures, and even the partially developed cracks which with further action would have become fractures; but for this action of the air in arresting and destroying the meteoroids, we should be intolerably pelted with them. The meteorites are all evidently fragments, not separate formations. They are in the heavens, to some extent at least, grouped in streams along the orbits of known comets, and hence have some common origin with them. The continuity of these streams, the double and multiple character of Biela's and other comets, and the steady diminution of comets in brilliancy at successive returns, seem to argue a continuous breaking up of the comet into fragments by some cause—probably by the sun's heat. The meteoroids, however, are not constituents of either the comet's coma or its tail.

LITERATURE.—The literature of this subject is extensive. See, in particular, the various articles in *The American Journal of Science,* in the *Astronomischen Nachrichten,* in the *Monthly Notices* of the Royal Astronomical Society, and in the annual reports of the luminous meteor committee of the British Association for the Advancement of Science; also, the following separate works: Schiaparelli, *Note e Riflessioni sulla Teoria astronomica delle Stelle cadenti* (Florence, 1867), or its German translation by Boguslawski (Stettin, 1871); Kirkwood, *Meteoric Astronomy* (Philadelphia, 1867); and *Comets and Meteors* (Philadelphia, 1873).

Meters, in prosody: See METRES.

Meters: appliances for measuring; especially any instrument for recording the quantity or force of a fluid actuating it. For a full description of the meter used for measuring illuminating gas, see GAS-LIGHTING; for the water-meter,

see WATER-METER. In electricity the meter is a device for measuring, for commercial purposes, the energy developed in an electric circuit. The measure of electrical activity in practical units is the *watt*, which is the product of the current flowing and the difference of potential existing between the terminals or extreme limits of the circuit under consideration. By Ohm's law this is the equivalent of the square of the current multiplied by the resistance of the circuit. These statements hold only in cases in which the activity is due to a steady current. When alternating or variable currents are used the expression is more complicated. The *energy developed* is the product of activity and time, and the practical units are the *watt-hour* and the *kilowatt-hour* (1,000 watts for one hour). In the early days of electric lighting the horse-power hour was the prevailing unit. This, which is equal to 746 watt-hours, has been abandoned. Electric meters are from the nature of the case *watt-meters*, under which title some details of the construction of the best-known types will be found. It may be said that the most successful forms are those in which a small electric motor, so designed as to revolve with a speed proportional to the activity of the circuit, actuates a counting device. The latter, which should be direct-reading, generally consists of a set of dials similar to those upon gas-meters. Recording ammeters have also been used as electric meters to some extent. Another form is the zinc voltameter, which has been found a fairly accurate device for measuring the energy supplied to glow-lamp circuits, etc. See ELECTRICITY, ELECTRIC LIGHTING, AMMETER, GALVANOMETER, and WATT-METER. E. L. NICHOLS.

Method in Education: See the Appendix.

Methodism: the system of doctrines, polity, and worship of the religious body called Methodists. The title "Methodists" was applied to Wesley and some of his Oxford associates not in derision, but as expressive of the regularity of their religious habits, especially their punctual devotion to the ritualistic services of the Church, for the members of the Oxford "Holy Club," as it was called, were not only extremely "High Church," but exceedingly "ritualistic." They were distinctively the "ritualistic party" of their day, notwithstanding the very simple practical character and comparative disregard for ritualism which the Methodistic movement subsequently assumed. The little society, formed in 1729, grew slowly, and consisted in its sixth year of only fourteen members, the most memorable of them being John and Charles Wesley and George Whitefield. (See WESLEY.) The departure of the Wesleys to America terminated the history of the "Oxford Methodists" and the existence of the "Holy Club." The return of the two brothers to England, however, revived the denominational epithet, for by the next year (1739) they and Whitefield had spread a religious sensation over much of the United Kingdom. They were excluded from the pulpits of the national Church, and had to preach in the open air, and in many places they and their adherents were denied the Eucharist at the church altars. They were therefore compelled to unite their followers in "societies," to give them the sacraments, and provide for them places of assembling and worship. The year 1739 is considered the true epoch of Methodism. In that year Wesley began the erection of his first chapel at Bristol, opened his famous "Old Foundry" in London, and formed in the latter city his first "society," which he says (in the introduction to his *General Rules*) was the "rise of the United Society"—that is to say, of organized Methodism. In the same year "bands" were formed, for the first time, in the city of Bristol, and it is the date of the first publication by the brothers of their *Hymns and Sacred Poems*, the beginning of that Methodistic psalmody which has spread over most of the Protestant world, and which has been the chief liturgy of the denomination.

Thus had the "great Methodistic movement" begun. It soon extended over Great Britain and into Ireland. Additional "societies" were continually formed; *General Rules* were prepared for them by John and Charles Wesley jointly. These "Rules" are the recognized "terms of membership" throughout the Methodist communion, and they expressly declare that no other "condition" than such as they define "is previously required of those who desire admission to these societies." They are singularly liberal, being "remarkable," says a Methodist writer, "as containing not a single dogmatic condition of communion." They are thoroughly practical, requiring as the "only condition" "a desire to flee the wrath to come and be saved from sin," and the exemplification of this desire, first, by the avoidance of certain specified vices; secondly, "the doing good of every possible sort, and as far as possible, to all men," especially in certain specified respects. Wesley, though at first, as he acknowledges, a "High Churchman," and as strict a "ritualist" as the Anglican Church possessed in his day, had now become one of the most liberal of men. Throughout the remainder of his life he refers often to the liberality of the terms of membership in his societies, and demands of all good men the sacrifice of sectarian bigotry and cooperation in practical religion. Though he now formed "societies," not churches technically or strictly considered, yet when, many years later, he prepared a form of organization for the Methodist Episcopal Church in the U. S., he still retained the *General Rules* as presenting the only condition of membership, and inserted in a separate part of the book an abridgment of the Anglican Articles, not as an obligatory symbol to be virtually subscribed, but as a merely indicative standard of the best theological opinions. Members of the Church were to be amenable not so much for their individual opinions as for making strife and trouble in the denomination by them. It can not be questioned that John Wesley was not only immeasurably in advance of his own age, but also far in advance of ours in "evangelical liberality."

The societies rapidly increased, and Wesley and his few clerical coadjutors were soon compelled to organize more thoroughly their converts if they would not labor in vain. The societies were therefore divided into "classes" of about twelve persons each, and placed under the inspection of select "leaders." They met weekly, sang, prayed, and related their Christian experience. The "class meeting" has since been the germ of almost every Methodist church in the world. Each member contributed a penny a week and a shilling a quarter for the support of the cause, and thence arose the whole financial system of Methodism. The clerical laborers could not supply the increasing local societies; laymen of natural talents were therefore recognized, first as "exhorters," and then as "local preachers," to conduct their public services in the absence of their clerical guides. (See MAXFIELD, THOMAS.) Wesley soon called out some of his ablest "local preachers" into the general field, to travel and preach continually, like himself, his brother, and Whitefield; and thence arose the lay *itinerant ministry*—one of the greatest factors in the Methodist movement throughout the world. To give regularity to the labors of these lay evangelists, they were assigned to different sections of the kingdom; thence came the famous Methodist "circuit"—of incalculable service, especially in the early frontier settlements of the New World, for it sometimes put under the regular ministrations of one or two "itinerants" parishes 500 miles in extent. Over a given number of these circuit preachers presided a select itinerant, and thence arose the "district," with its "presiding elder" in North America, its "chairman" in Great Britain. This officer assembled the preachers and other "official members" of each circuit four times a year, for the better regulation of their work; thence arose the "quarterly conference"; a similar gathering from all the circuits of a district constituted the "district conference"; the yearly gathering of all the preachers of all the districts, for the revision of their entire work and its redistribution for the ensuing year, made the "annual conference." The latter, however, preceded, chronologically, the other forms of "conference," Wesley having held the first session in 1744. In the U. S. the great territorial range of the denomination has since 1792 rendered necessary a quadrennial session called the "general conference," composed since 1812 of delegates from all the annual conferences.

Besides these peculiarities, Methodism has some minor functions or distinctions which have contributed much to its popular effectiveness. Its "love-feast" was borrowed, through its early Moravian associates (see WESLEYS), from the agapæ of the primitive Church. Bread and water are distributed among the assembly at the opening of its service, and the rest of the time is spent in the narration of Christian experience. The "band meeting" was also copied from the Moravians. Each sex met in its own bands; the "class meeting" has generally superseded this institution. The "watch-night" is usually celebrated on New Year's Eve, its services closing with silent prayer at midnight. It originated with the early Methodist converts among the Kingswood colliers. It had been their custom to close the old and hail in the new year with drunken orgies. Method-

ism reclaimed hosts of these poor people, who changed to this new and devout form their observance of New Year's Eve, and gave it to the denomination throughout the world. The lay "prayer meeting" is universal among Methodists, and has been claimed as original with them, at least in the modern Church. (Smith's *History of Methodism*, vol. i., book iii., chap. ii.) It is characterized by great freedom and fervor, and especially by its popular psalmody. Both sexes have equal liberty of prayer and exhortation in it.

The *theology of Methodism* may be said to be substantially that of the Church of England, though it eliminates the alleged Calvinistic teachings of the Thirty-nine Articles. Wesley was thoroughly Arminian, and his followers, with the exception of the Welsh Calvinistic Methodists, are universally such. The "minutes" of his early conferences record many discussions with his assembled preachers on theological subjects. Certain compilations from these documents, together with his sermons and his notes on the New Testament, are recognized as the theological standards of the English or Wesleyan Methodists. In the U. S. his abridgment of the Anglican Articles is the only authoritative Methodistic standard. It does not include his views of the "witness of the Spirit" and of "sanctification," which, though subjects of much interest to American Methodists, are left freely to individual opinion and discretion. These two doctrines have usually been considered, by outside critics of Methodism, as peculiar to its theology. Neither Wesley nor any subsequent authority of the denomination would admit them to be so. They consider them to be not only biblical, but generally admitted truths in Greek and Latin Christendom. Wesley did not even go as far in his teachings regarding the "witness of the Spirit" as many of the older Protestant theologians went in the doctrine of "assurance." According to him, the Spirit, not by any marvelous demonstration, outward or inward—"not by an inward voice, though He may do this sometimes"—gives the peaceful impression to the justified man that his sins are forgiven. To use his own words, "the Spirit so works upon the soul by His immediate influence, and by a strong though inexplicable operation, that the stormy wind and troubled waves subside, and there is a sweet calm; the heart resting as in the arms of Jesus, and the sinner being clearly satisfied that all his 'iniquities are forgiven and his sins covered.'" In his teachings on sanctification—or "perfection," a word which he used because the Scriptures use it—he taught not absolute moral perfection. "We are no more to expect any man to be infallible," he says, "than to be omniscient." A Methodist writer affirms that "perfection, as defined by Wesley, is not perfection according to the absolute moral law; it is what he calls it, *Christian perfection*—perfection according to the new moral economy introduced by the atonement, in which the heart, being sanctified, fulfills the law by love (Rom. xiii. 8, 10), and its involuntary imperfections are provided for by that economy without the imputation of guilt, as in the case of infancy and all irresponsible persons." See ARMINIANISM.

Although in the foregoing remarks historical references have been made chiefly to Wesleyan or English Methodism, nearly all that has been thus far said is applicable to the many divisions of the denomination; for one of the most noteworthy facts of Methodism is its essential unity. Whatever distinctive prefixes or affixes its numerous bodies may have adopted, they all hold to what they justly consider substantive Methodism. They have very generally the same practical system and interior regimen, and aim at the same type of spiritual life. They all have fraternal relations.

Wesleyan Methodists is the title of the British parent body. The outlines of its early development have already been given. During Wesley's life it was chiefly controlled by his patriarchal authority. He left, however, a *Deed of Declaration*, recognized in 1794 by the high court of chancery, providing for the government of the "connection" after his decease. By this deed the annual conference is composed of 100 traveling preachers, with power to fill vacancies in their number. They are the "legal conference," but the other traveling ministers attend their sessions and share in their debates, without the right of voting. The president of the conference is elected for one year by the "legal conference" and the preachers, but the "legal conference" can negative the nomination of the general body. He has during this term the general supervision of the denomination. The proceedings of the "district" and "quarterly conferences" (above noted) are subject to revision and amendment in the annual conference. Committees appointed by these minor bodies to prepare the principal business of the annual session meet about a week before the latter, and their measures are generally adopted by the "legal hundred." Wesleyan Methodism cannot, under Wesley's *Deed of Declaration*, have "lay representation," but it has nearly its equivalent in these committees, which are composed largely of laymen, and in the Representative Conference, a chamber composed of ministers and laymen, instituted in 1878, which meets previously to the legal conference or "pastoral session," and acts, subject to its ratification, upon matters of temporal and non-ecclesiastical import. Moreover, the draft of appointments of ministers to stations is submitted to the societies every year for the suggestion of desired changes, before its final adoption by the conference. No preacher, however, can be appointed to the same place more than three successive years. The Wesleyans report (1900) 3,174 traveling preachers and 703,138 church members. The parent conference employs in Great Britain and Ireland 2,457 regular ministers. Besides these, there were in 1900 in England alone 19,956 lay preachers. The number of church members in Great Britain and Ireland in 1900 was 510,337; and 7,652 Sunday schools were returned, with 134,812 officers and teachers, and 992,316 pupils. Their missions are carried on in Ireland, France, Switzerland, Austria, Italy, Spain, Malta, Egypt, India, Ceylon, China, South and West Africa, the West Indies, Honduras, and the Bahamas. These missions employ 3,456 paid agents, including 366 who are regularly ordained and are wholly engaged in the work of the Christian ministry. Besides, there are 6,133 lay workers who render important service gratuitously, while the number of church members is 47,372, with 13,625 on trial for membership. The children in the mission schools number 92,488. The parent connection has in Great Britain 743 day-schools, containing 160,787 pupils, with an average attendance of 129,905. The Wesleyans have conferences, affiliated and subordinate to that of England, in Ireland, France, South Africa, and West Indies. The conferences in Australia and New Zealand are now independent of the parent body, and form the Australasian Wesleyan Methodist Church, a body returning (1900) 775 ministers, 8,783 lay preachers, 3,438 churches, 118,984 members, 397 Sunday-schools with 21,618 officers and teachers and 214,734 pupils, with missions in the South Sea Islands and New Guinea. A union of all the various Methodist bodies in Australia under the name of the United Church of Australia is likely to be effected, negotiations to that end having (1901) reached a stage near completion. The Wesleyans publish a quarterly review, 8 monthlies, 6 weeklies, and several missionary and Sunday-school periodicals. Some of these are in their foreign fields; most of them are official, others are independent. They have 4 collegiate institutions, 4 theological schools, 2 important normal seminaries, and numerous academies or boarding-schools.

The *Calvinistic Methodists* arose from a difference between Whitefield and Wesley respecting the Calvinistic doctrines. Wesley, as we have seen, was thoroughly Arminian, Whitefield as thoroughly Calvinistic. After Wesley's celebrated sermon on "free grace" they pursued separate though parallel lines of public labor. Personally they became cordial friends again, but their followers were never reunited. The Calvinistic Methodists were finally organized in three denominations. The first was called *Lady Huntingdon's Connection*. Her ladyship was their liberal patron and their chief director. She purchased or built for them numerous chapels. Their pastors were settled, they used the liturgy of the national Church, but their system of government was essentially congregational. They early established a theological school, which still exists under the title of Cheshunt College. They have not shared the prosperity of the other Methodist bodies.

The second body of Calvinistic Methodists, the *Whitefield Methodists*, no longer exist as a "connection" or denomination, but some of their early churches survive among the independent congregations of England.

The third and greatest result of Calvinistic Methodists bears the title of the *Welsh Calvinistic Methodists*. Welsh Methodism was independent of English Methodism, both in origin and organization. Its first "societies" were formed in 1735. The chief founders were Howell Harris, Griffith Jones, Daniel Rowlands, and Thomas Charles, the last named surviving long enough to shape the later history of the denomination. Its first "association" was held in 1742, two and a half years prior to the English Methodist Confer-

ence, under Wesley, in London. In 1811 it was more thoroughly organized, and in 1864 the organization was completed by the constitution of the General Assembly. The Church is Presbyterian in doctrine and polity, and is a member of the Presbyterian Alliance. The latest statistics (1900) are: In Wales, 1,572 chapels and 879 other buildings apart from chapel houses and manses, 158,114 communicants, 319,261 hearers, and collections for the year of £283,903. In the U. S. they had in 1900, 89 ministers, 158 churches, 12,152 members, and 13,954 officers and pupils in Sunday-schools.

The *Wesleyan Methodist New Connection* is the title of an organization originally composed of 7 preachers and about 5,000 seceders from the parent connection, who for certain alleged grievances withdrew in 1797, under the leadership of Alexander Kilham, an able preacher, who had been expelled the preceding year for his zealous advocacy of liberal changes in the system of government which Wesley had established. The New Connection adopted equal lay and ministerial representation in its conference. It extended into Ireland, and for a considerable time was the refuge of members of the elder body who were dissatisfied with their restricted liberties. The ministry of this denomination (1900) comprises 209 traveling and 1,122 local preachers, and its membership is 41,043. It has 672 churches, and 490 Sunday-schools with 10,903 officers and teachers and 83,578 pupils.

The *Primitive Methodists* form one of the most important branches of the great Methodist family. Lorenzo Dow introduced the camp-meeting from the U. S. into England about 1807. William Clowes, a Wesleyan local preacher, approved and labored in these "open-air" assemblies. Hugh Bourne, a layman, but an influential chapel trustee, saw in them an important means of reaching multitudes of the common people who could not otherwise be brought under religious influence. He defended them in a pamphlet; counter publications were issued by the preachers of Burslem and Macclesfield circuits. No small agitation ensued, and in 1807 the conference denounced camp-meetings, and "disclaimed connection with them." In 1808 Bourne was expelled from the connection; two years later Clowes was also expelled. They continued, however, their "out-door meetings," organized their converts in classes, and in 1810 established the Primitive Methodist connection. It retained the doctrines and internal discipline of Wesleyan Methodism, and attempted to restore the primitive simplicity of the latter in dress, manners, and living. It revived Wesley's custom of "out-door preaching," and licensed women to preach. Its church government is notably liberal toward the laity, two-thirds of its annual conference being laymen. The Primitive Methodists have done much good among the neglected classes of England; they have also established several foreign missions. They have in 1901, 1,100 ministers, 198,874 members, 59,929 teachers and 460,783 pupils in Sunday schools, and 4,575 chapels, providing sittings for 1,042,335 hearers. In the U. S. they have 74 ministers, 90 churches, and 6,549 members.

The *Primitive Wesleyans of Ireland* must not be confounded with those of England, above noticed. The Irish body was distinguished by its partiality to the Established Church in Ireland, and originated in that partiality. As early as 1795 the British conference allowed its preachers to administer the sacraments to their people, under specified restrictions. The Irish conference (a branch of the former) voted in the next year that it was not expedient for the preachers within its territory to avail themselves of this concession. About twenty years later (1816), in compliance with an extensive demand of the people, the concession of the parent conference was adopted. In a vote of 88 members there was a minority of 26 which sturdily insisted that their people should still resort to the Established Church for the sacraments. This, it was argued, was Wesley's design down to his death regarding all his societies, except those of America, where the Anglican establishment had ceased to exist. Adam Averell, one of the most commanding members of the Irish conference, withdrew from the connection, leading with him the minority and about 10,000 members. Wesleyan Methodism lost by this schism at least one-third of its numerical strength in Ireland. The Irish Primitives had no great success, and in 1878 they returned to the parent body.

Besides the above, there are minor sects of Methodists in England, among which may be mentioned: (*a*) The *Independent Methodists*, who, beginning with one church at Warrington in 1797, were soon associated with churches in Manchester and Macclesfield, and formed a union in 1805 at Manchester. The annual meeting of 1808 at Macclesfield comprised churches from eight places. Each church controls its own affairs by the entire membership or by representatives. They have no salaried ministers. Local societies have various names, such as Independent Methodist, Free Gospel Church, Christian Brethren, Benevolent Methodist, Christian Lay Church. Their joint name was changed in 1843 to *The United Free Gospel Churches*, and they include (1901) 153 chapels and missions, 8,377 members, 372 ministers, and 26,194 Sunday-school pupils. (*b*) The *Protestant Methodists*, chiefly seceders from the Wesleyan societies of Leeds, who became disaffected in 1828 because the societies placed an organ in one of their chapels. More than 1,000 communicants, including 56 class-leaders and 28 local preachers, combined in the schism. (*c*) The *Wesleyan Methodist Association*, originated in 1835 by a secession chiefly under the direction of Rev. Dr. Samuel Warren, who with his followers opposed the introduction of theological schools among the Wesleyans. Though Wesley himself had proposed such means of ministerial education, it was assumed by the seceders that they were incompatible with the genius of Methodism, and would be adverse to its prosperity. The *Protestant Methodists* of Leeds united with these Association Methodists in 1836. (*d*) The *Reformed Methodists* originated in an extraordinary proceeding of the parent Wesleyan conference in 1849, when six of its members, some of them eminent men, were arraigned before that body and half of them reproved, the other half expelled, under an accusation of disguised hostility to the conference and of secret co-operation with the Wesleyan Methodist Association. It was alleged by the accused and their many friends that the action of the conference was precipitate, and violated the legal formalities in such cases required. It excited profound agitation throughout the connection, and no less than 100,000 Wesleyans seceded. These last-mentioned three bodies were consolidated in 1857 under the title of the *United Methodist Free Churches*. They have adopted a "liberal" system of church government, admitting laymen to their annual conference or assembly, and giving independent jurisdiction to the circuits over their interior or local affairs. They report (1900) 436 traveling and 3,379 local preachers, 91,717 members, and 195,429 Sunday-school pupils. (*e*) The *Bible Christians*, sometimes called Bryanites from William O'Bryan, a Methodist of Cornwall, who preached on independent lines in unevangelized parishes for about six years, and then organized the first society in 1815 in Devonshire. The first conference was held at Baddash Launceston, in Cornwall, Aug. 17–26, 1819, and was attended by twelve preachers. Here the question whether women should preach was discussed and decided affirmatively. They report (1900) 291 traveling and 1,858 local preachers, 34,883 members, and 57,939 Sunday-school pupils. (*f*) *The Wesleyan Reform Union*, formed in 1859, a remnant of the schism of 1849 (who were unwilling to be merged in the United Methodist Free Church), numbering, in 1900, a membership of 7,187, Sunday-school pupils 20,025, with 18 salaried and 496 unsalaried preachers. It will be observed that secession has played a conspicuous part in the history of English Methodism. The frequency of this evil is attributable largely to the ardent popular elements which it has been the task of the denomination to gather and improve, but still more perhaps to the restricted and rigid ecclesiastical system which Wesley's *Deed of Declaration* has entailed upon the parent body. Every schism in the history of Methodism has been occasioned by ecclesiastical or economical provocations; no theological defection or controversy has ever seriously disturbed the denomination in any part of the world.

Methodism has had its chief mission in the New World, where by its peculiar practical system, especially by its ministerial "itinerancy," it has spread the provisions of religion coextensively with the ever-extending emigration, until it has become the largest Protestant denomination of the U. S.

The *Methodist Episcopal Church* is the title of the earliest Methodist organization in the U. S. Philip Embury, with other Wesleyan emigrants from Ireland, began to hold meetings for preaching and prayer in New York city as early as 1766. In the next year Capt. Thomas Webb, a British officer, who like Embury had been a Wesleyan local preacher in England, visited the little flock, and preached to them in his regimentals, exciting much popular interest. The captain also preached on Long Island, in New Jersey,

Philadelphia, Delaware, and Maryland, and is honored as one of the chief founders of American Methodism. Embury's congregation increased rapidly in New York. In 1767 they worshiped in a rigging-loft, which was thronged, and in 1768 they built the famous old "John Street chapel," supposed to be the first Methodist church erected in the Western hemisphere, though about the same time Robert Strawbridge (another Irish Wesleyan) began to preach, formed societies, and built a small chapel on Sam's Creek, Frederick co., Md. Some Methodist authorities still consider it doubtful which had priority, Embury or Strawbridge; the Church generally, however, recognizes the date of Embury's labors (1766) in New York as the epoch of American Methodism. In 1769 Wesley sent over two of his itinerants, Pilmoor and Boardman, who labored successfully in and about New York and Philadelphia. They were followed in 1771 by Wright and Asbury. The latter became the representative character and most effective bishop of the denomination, and did more for its outspread and permanence than any other man in its history. In 1773 Wesley sent over two more itinerants, Rankin and Shadford; and this year is also memorable for the session of the first Methodist conference in North America. It was held in Philadelphia, and reported 1,160 members of society and 10 preachers—the same number of the latter as constituted Wesley's first conference in England twenty-nine years before. Notwithstanding the disturbed condition of the country during the ensuing Revolutionary war, the cause prospered, and in 1784 enrolled 15,000 communicants. There were now 84 preachers, traveling 46 "circuits," for by this time a considerable native ministry had been raised up. Hitherto, the Methodists had been dependent on the colonial English Church for the sacraments, none of their own preachers having yet been ordained; but in this year Wesley ordained two of his English itinerants, Whatcoat and Vasey, to the function of presbyters, and consecrated Rev. Dr. Thomas Coke as a bishop, and sent them to America with authority to organize the scattered societies as a distinct Church, under the title of "The Methodist Episcopal Church in the U. S. of America." He sent with them a printed liturgy and formulas for ordinations, the sacraments, marriage, burial of the dead, etc., abridged from the *Book of Common Prayer*, and substantially the same as those still in force in the Methodist *Book of Discipline*. Coke and his two presbyters assembled a general conference about Christmas at Baltimore, where the plan appointed by Wesley was adopted, and Asbury (at Wesley's suggestion) was ordained successively deacon, presbyter, and bishop. Wesley was led to these extraordinary measures by the abolition of the authority of the English Church establishment in the colonies, by the urgent demand of his American people for the sacraments, and by his repeated failure to obtain relief for them in the ordination of some of his preachers by the Bishop of London.

A consolidated and distinct Church had at last come into existence in North America. It retained the ecclesiastical system of English Methodism, as well as its theology, except that its chief administration was placed in the hands of bishops. As it rapidly extended over the continent its annual conferences were multiplied, until in 1792 regular "general conferences" were created, meeting quadrennially, and comprising all the traveling preachers who could attend. It was found necessary at last, by the growth of the ministry, to make the general conference a *delegated* body. It assembled as such, for the first time, in 1812, at the Old John Street church, New York. The ratio of delegates to the number of traveling preachers has been necessarily changed from time to time. Lay representation in the general conference was granted in 1872, when not more than two lay delegates were admitted from each annual conference. In 1900 the number of lay delegates was made the same as that of the ministerial delegates, and the general conference now consists of one of each order for every forty-five ministers in the annual conferences.

The quadrennial general conference is the supreme assembly of the Church—legislative, judicial, executive. It elects the bishops, who are, in fact, but its executive agents; it makes all laws except minor local regulations, which are left to the annual conferences: it tries judicial appeals from the annual conferences; it is itself under constitutional restraints, called "Restrictive Rules," which can be suspended or changed only by the concurrence of specified majorities in the general conference and in all the annual conferences. American Methodism has now a quarterly conference for each circuit; a district conference, wherever desired, for all the circuits which are under the care of each presiding elder; annual conferences for larger sections of the country, embracing often considerable portions of one or more States; and a general conference, comprehending all the annual conferences. The work of the denomination is thus under periodical supervision in a series of sessions extending from a quarter of a year to four years. The preachers are appointed at the annual conferences for one year, but they can be reassigned for any number of years to the same appointment. The bishops make these appointments, aided by the presiding elders; the latter can be continued six years on the same district. The bishops are required by an organic law of the Church to travel at large. The whole nation is their common diocese. The denomination has a powerful publishing institution called the "Book Concern," with above $3,000,000 capital. It has two large establishments—one in New York, the other in Cincinnati—with branches and depositories in other cities from Boston to San Francisco. It issues a bi-monthly review, two monthly magazines (one in German), a monthly Sunday-school journal, several weekly Sunday-school and tract papers in different languages, and thirteen weekly religious newspapers. There are also over twenty unofficial or independent religious journals issued in various parts of the Church. Its theology and ecclesiastical economy have been sufficiently indicated in the preliminary remarks of this article. Though the denomination maintains episcopacy and the two ministerial orders of deacons and presbyters, it does not claim for them divine right or scriptural obligation. It regards them only as expedient for its own peculiar working system. Episcopacy it esteems merely as an office, not as an "order." The English Methodists have neither bishops nor deacons, but the American Methodists recognize the Wesleyans as a genuine Church. Wesley did not believe that any particular system of church polity is *enjoined* in the Holy Scriptures, and the claim of any denomination to validity *as* a Christian Church does not rest, in the estimation of Methodists, on its form of organization, but on theological and moral grounds.

One of the most momentous events in the history of the Methodist Episcopal Church was its division, by the separation from it of all the conferences (save one) in the slaveholding States, and their organization as the METHODIST EPISCOPAL CHURCH SOUTH (*q. v.*). It would be impossible here to enter into the arguments, pro and con, of this great ecclesiastical controversy, nor is it desirable. Later national events have extinguished the chief cause of the strife, and fraternal and conciliatory measures have been taken by both parties, and organic reunion is a subject of serious if not hopeful discussion. Both churches have since the civil war had signal success.

There were in 1900 in the Methodist Episcopal Church 150 annual conferences and missions, 22 bishops, 16,059 traveling preachers, 14,126 local preachers, 2,929,674 lay members, 19,341 Sunday-schools, with 1,568,883 pupils and 205,429 officers and teachers, 27,230 churches and 11,189 parsonages, and property in churches and parsonages amounting to $136,964,660. It has 56 universities and colleges, 8 colleges and seminaries for women, 25 theological schools, 60 classical seminaries, and 99 foreign mission schools. It has foreign missions in Mexico, South America, Sweden, Norway, Denmark, Germany, Switzerland, Italy, Bulgaria, Africa, India, Japan, China, Korea, and Malaysia. In Africa it has 2 conferences (Liberia and Congo); in China 2; in Germany 2, with a publishing-house and a theological seminary; in Sweden 2; and 1 conference each in Mexico, Finland, Norway, Switzerland, Italy, and Japan. It has 5 conferences in India, where, particularly in the north, very successful work is now in operation. Its home missions are numerous and very fruitful, especially among the German and Scandinavian population. Besides the German conferences already mentioned in the U. S. and Germany, its German domestic work includes 276 missionaries, 42,222 members and probationers, 21,614 pupils in Sunday-schools, 309 churches and chapels, valued at $1,743,821, 3 colleges, 2 orphan asylums, a weekly journal, a Sunday-school periodical, and a monthly magazine. The Scandinavian domestic missions have 235 missionaries, 272 churches, 26,030 members and probationers, 15,254 pupils in Sunday-schools, with church property valued at $1,133,094, a weekly journal, and a weekly Sunday-school paper. The total sum contributed for home and foreign missions in 1900, including the receipts of the woman's societies, was $1,987,368.43.

The foreign missions returned in 1900 a total of 182,957 church members. The order of deaconesses was officially recognized and organically connected with the Church in 1888. The organization of the young people of the Church for Christian work was formally introduced into the *Discipline*, in 1892, by the adoption of the Epworth League. See EPWORTH LEAGUE.

The *Methodist Protestant Church* arose from a controversy in the Methodist Episcopal Church against the alleged exclusively clerical government of the denomination. The seceders opposed episcopacy and demanded lay representation. They organized at a convention held in Baltimore, Md., in 1830, which in a session of about twenty days formed a constitution, retaining the doctrines and essential discipline of the elder Church, but excluding episcopacy and establishing equal lay and clerical representation in the government of the Church. At this convention there were 83 delegates representing 80 ministers and about 5,000 members; and at their first general conference in 1834 they reported nearly 500 preachers and about 27,000 members. Its annual conferences have presidents elected by ballot. It has a delegated general conference, composed of laymen and preachers sent from its annual conferences. They were themselves divided by the controversy on slavery into the Methodist Protestant Church of the Northwestern States, and the Methodist Protestants of the Southern States; in 1858 the Northern branch assumed the title of the *Methodist Church*, proposing to combine under this name the various Methodist sects which have rejected episcopacy. The two branches were reunited in 1877 under the old title Methodist Protestant Church. They have (1900) 59 annual conferences, 1,645 traveling and 1,135 local preachers, 177,066 members and 4,250 probationers, 2,001 churches, and 1,881 Sunday-schools, with 16,680 officers and teachers, and 126,031 pupils. They have publishing-houses at Baltimore and Pittsburg, and colleges at Yadkin, N. C., Bowdon, Ga., Adrian, Mich., Kansas City, Mo., and Westminster, Md., the last named having also a theological department.

The *Wesleyan Methodist Church* originated chiefly in the anti-slavery controversy; the question of lay representation, however, became one of the motives of its organization. Some of the most zealous anti-slavery preachers in the Methodist Episcopal Church called a convention at Utica, N. Y., in 1843, where the new Church was formed on a basis identical in theology and internal discipline with that of the elder body, but excluding episcopacy and presiding elders, and providing lay representation. They have annually elected presidents of conferences and stationed chairmen of districts. Their preachers are appointed by a committee, the conference having authoritative revision of the appointments. Local preachers as well as laymen have representation in the annual and general conferences. At the time of the organization of this body it reported 6,000 members, with 300 preachers, traveling and local. It reports (1900) 595 ministers, 506 churches, and 17,201 members. A late Sunday-school report gives 471 schools, with 1,948 officers and teachers, and 17,290 pupils. Its publishing-house is at Syracuse, N. Y.

The *African Methodist Episcopal Church*, whose members are sometimes called *Allenites*, was organized at Philadelphia in Apr., 1816, under the guidance of Richard Allen, afterward Bishop Allen. They considered themselves disparaged and oppressed in the Methodist Episcopal Church, and, finding no redress, formed themselves into an independent body, consecrated Allen as their first bishop, and adopted a system of government substantially the same as that of the parent Church. The Church has grown rapidly, and has (1900) 65 annual conferences in the U. S., Africa (4), West Indies (3), and British America (3), 14 episcopal jurisdictions, 5,439 traveling and 8,409 local preachers, 663,706 members, and 20 colleges, with 165 teachers and 5,237 students; together with a publishing-house in Philadelphia, a quarterly review, and other periodicals.

The *African Methodist Episcopal Zion Church* originated in a secession of Negroes from the Methodist Episcopal churches of New York city in 1820. They retained all the distinctive features of the parent Church, but elected their bishops quadrennially until 1880, when the tenure of the office was made for life or during good behavior. These officers were not consecrated by formal ordination previously to 1888, at which time a provision requiring the laying on of hands was inserted in the ritual. They report (1900) 9 bishops, 3,200 itinerant preachers, 1,906 churches, 520,000 members, more than 600 Varick Societies of Christian Endeavor, with upwards of 20,000 members. They have a college and several high schools, maintain a publishing-house at Charlotte, N. C., and publish a quarterly and several weekly periodicals.

The *Colored Methodist Episcopal Church in America* consists mostly of former African members of the Methodist Episcopal Church South. After the civil war the colored members of the Methodist Episcopal Church South desired a separate organization; this desire was acceded to, and the new Church was accordingly formed on Dec. 16, 1870, at Jackson, Tenn. It has (1900) 1,427 churches, 2,039 ministers, and 204,317 members, with 5 episcopal districts and as many bishops; maintains several high schools; has a publishing house at Jackson, Tenn.; and publishes one weekly journal and several Sunday-school papers. In its theology and polity it is a copy of the Methodist Episcopal Church South, and the latter extends to it parental care, without trenching on its independence. It includes but a fragment of the former numerous African membership of the Methodist Episcopal Church South; some of these remain in the latter, some have joined the Methodist Episcopal Church, and thousands have been absorbed in the two African Episcopal Churches above mentioned.

The *United Brethren in Christ*, though bearing the same name as the Unitas Fratrum, or Moravians, have no relations with the latter, but are Methodists, and are often called *German Methodists*. In theology and polity they are nearly identical with the Methodist Episcopal Church, having bishops, a general conference, and annual conferences. They date from 1765, when their first society was organized by Philip William Otterbein. Their first annual conference was held in Baltimore in 1789, but their present organization was formed and their name adopted at the conference held in 1800. They report (1900) 1,846 ministers, 4,112 churches, and 223,972 members, with extensive domestic missions and foreign missions in Japan and West Africa. They have a publishing-house at Dayton, O. The *United Brethren in Christ* (*Old Constitution*), numbering about 800 churches and about 26,000 members, are those who since 1889 refuse to acknowledge the revised and amended confession and constitution of that date, and maintain that the old constitution is the only organic law of the Church.

The *Evangelical Association* is also an organization of German Methodists, sometimes called *Albrights*, from the name of their principal founder, Jacob Albright. They were organized in 1800, and their first general conference was held in 1816. They have (1900) 27 annual conferences, 877 traveling preachers, 1,617 churches, and 96,345 members. Their publishing-house is at Cleveland, O. This Church suffered a division in 1894, when the *United Evangelical Church* was formed. The latter body has (1901) 493 itinerant and 215 local preachers, 1,003 organized congregations, and 62,523 members.

The *Free Methodist Church* was formed at Pekin, Niagara co., N. Y., in 1860, chiefly by friends of two preachers of the Methodist Episcopal Church who were expelled from the Genesee conference. They disclaim episcopacy, but have an elective *superintendent*, whose term of service is four years, and insist on congregational singing, excluding instrumental music; on free seats in the congregation; on extempore preaching; on plainness of dress and living; and especially on the doctrine of Christian perfection. They have (1900) 975 ministers, 857 churches, and 26,353 members. *The Free Methodist*, a weekly journal, is published in Chicago.

The *Methodist Church, Canada*, is the final resultant of the union of several distinct organized bodies of Methodists effected at the united general conference in Belleville, in Sept., 1883. Sporadic Methodism existed in Canada as early as 1780, but its first organic planting was in 1791 by the Methodist Episcopal Church, when William Losee was appointed to Kingston circuit under Jesse Lee, presiding elder of the New England district of the New York conference. A steady increase for twenty years resulted in 1811 in two districts, Upper and Lower Canada, with 3,117 members. The war of 1812–15 reduced the membership nearly one-half. The Canadian annual conference was formed in 1824, and in 1828, the general conference approving, the *Methodist Episcopal Church in Canada* was organized. Meanwhile during the war (1812–15) and the years following the missionaries and societies of the *British Wesleyan Church* appeared, soon followed as early as 1824 by those of the *New Connection Methodists*, the *Bible Christians*,

and the *Primitive Methodists*, all from England. In 1832 a union of the Methodist Episcopal Church in Canada and the British Wesleyans was prematurely formed on the English basis, but broken again in 1834–35, when the former reappeared, though numbering at this time only one-twelfth as many as the Wesleyan body. In 1840 the Canadian and British Wesleyans were separated, but reunited in 1847 as the *Wesleyan Methodist Church in Canada*. In 1874 the Wesleyan Methodist Church in Canada, the New Connection Methodists, and the Wesleyan conferences in the Maritime Provinces united as the *Methodist Church of Canada*. Finally, in 1883, a basis of union having been agreed upon, the Methodist Church of Canada, with 1,216 ministers and 128,644 members, the Methodist Episcopal Church in Canada, with 259 ministers and 25,671 members, the Primitive Methodist Church, with 89 ministers and 8,090 members, and the Bible Christian Church, with 79 ministers and 7,398 members, united under the title of *The Methodist Church, Canada*. They have (1900) 2,032 ministers and ministerial probationers, 2,290 local preachers, 284,901 members, 3,405 Sunday-schools with 33,023 officers and teachers and 267,654 pupils, and 1,850 Epworth Leagues with 74,920 members; 533 home and foreign mission stations, 3 book and publishing houses, 4 periodicals, and 10 educational institutions.

Among the Negro settlers of Canada about the year 1834 certain ministers of the African Methodist Episcopal Church organized societies, and about 1838 these societies were organized into the Canadian annual conference of that Church. The *British Methodist Episcopal Church* was organized Sept. 26, 1856, at Chatham, Ontario, in accordance with a privilege granted in answer to a memorial presented by the Canadian annual conference of the African Methodist Episcopal Church to the general conference of that body the same year. It was united with the African Methodist Episcopal Church in 1884.

The following tables will supplement the statistics given in the preceding account:

BRITISH METHODISTS.

DENOMINATIONS.	Ministers.	Lay preachers.	Church members and probationers.
Wesleyan Methodists:			
Great Britain	2,202	19,956	481,061

Revised by JOHN F. HURST and WILLIAM H. LARRABEE.

Methodist Episcopal Church South: a division of the Methodist Episcopal Church in the U. S. formed in 1846. The subject of slavery was discussed with painful interest in 1844 at the General Conference in New York and measures were adopted in the interest of peace for a separation of the Church into two distinct organizations. This is concisely set forth in an account of the organization of the Methodist Episcopal Church South, inserted in the *Discipline* of 1846 as follows: "In the judgment of the delegates of the several annual conferences in the slaveholding States, the continued agitation of the subject of slavery and abolition in a portion of the Church, the frequent action on that subject in the General Conference, and especially the proceedings of the General Conference of the Methodist Episcopal Church of 1844 in the case of the Rev. James O. Andrew, D. D., one of the bishops, whose wife owned slaves, produced a state of things in the South which rendered a continuance of the jurisdiction of that General Conference over the conferences aforesaid inconsistent with the success of the ministry in their proper calling. This conviction they declared in solemn form to the General Conference, accompanied with a protest against the action referred to, assured that public opinion in the slaveholding States would demand, and that a due regard to the vital interests of Christ's kingdom would justify, a separate and independent organization. The developments of a few months vindicated their anticipations. The Church in the South and Southwest, in her primary assemblies, her quarterly and annual conferences, with a unanimity unparalleled in ecclesiastical history, approved the course of the delegates, and declared her conviction that a separate jurisdiction was necessary to her existence and prosperity. The General Conference of 1844 having adopted a *Plan of Separation* and provided for the erection of the annual conferences in the slaveholding States into a separate ecclesiastical connection, under the jurisdiction of a Southern General Conference, the delegates of the aforementioned conferences in a published address recommended that a convention of delegates from the said conferences, duly in-

structed as to the wishes of the ministry and laity, should assemble at Louisville, Ky., on the first day of May, 1845. The convention met, delegates having been formally appointed in pursuance of this recommendation, and after a full and minute representation of all the facts in the premises, acting under the provisional *Plan of Separation*, declared by solemn resolution the jurisdiction hitherto exercised by the General Conference of the Methodist Episcopal Church over the conferences in the slaveholding States *entirely dissolved*, and erected the said annual conferences into a separate ecclesiastical connection, under the style and title of *The Methodist Episcopal Church South*, the first General Conference of which was held in the town of Petersburg, Va., on the first day of May, 1846." By this measure were severed from the parent Church 1,474 traveling preachers, 2,550 local preachers, 330,710 white members, 124,811 Negro members, and 2,978 Indian mission converts, making an aggregate of 462,428. The *Plan of Separation* was conceived in the most fraternal spirit, and its acceptance by the South was urged by such distinguished Northern men as Drs. Olin, Elliott, and others, who believed that the Church in the South would be ruined if Bishop Andrew were deposed from the episcopate (as virtually proposed in the pending resolution), and in the North if he exercised his episcopal functions in the Northern conferenees.

The Southern conferences organized according to the provisions of the *Plan of Separation*, and at the first General Conference (in 1846) Joshua Soule, senior bishop of the Methodist Episcopal Church, and Bishop Andrew adhered to the Southern branch, and were recognized in their episcopal character; and William Capers, D. D., and Robert Paine, D. D., were elected and consecrated as their colleagues. Lovick Pierce, D. D., was appointed to bear the fraternal regards of the conference to the General Conference of the Methodist Episcopal Church which met in Pittsburg in 1848, but that conference declined to receive him in his official character, and repudiated the *Plan of Separation* as null and void. A refusal to divide the Church property with the Southern Church led to litigation, which was finally terminated by a decision of the Supreme Court of the U. S., which recognized the validity of the *Plan* agreeably to the claim of the Methodist Episcopal Church South. The court affirmed that according to its provisions "the religious association known as the Methodist Episcopal Church in the U. S. of America, as then existing, was divided into two associations or distinct Methodist Episcopal churches, as in the bill of complaint is alleged." At first the bishops of the Methodist Episcopal Church (North) declined to exercise their functions in the South; but during the civil war (1862–65) and since, in obedience to the instructions of their General Conference, they have organized annual conferences in all parts of the South, as have also the "Afriean" and "African Zion" connections, thus taking from the Methodist Episcopal Church South a large part of its colored members, of whom it numbered nearly 200,000 in 1860. At the General Conference of the Methodist Episcopal Church in 1872, messengers were appointed to bear fraternal greeting to the General Conference of the Methodist Episcopal Church South, which met in Louisville in 1874. The manner in which these messengers fulfilled their mission and were received by the conference was highly creditable to both parties. The conference responded fraternally to their communications, and authorized the bishops to appoint commissioners to bear fraternal greetings to the General Conference of the Methodist Episcopal Church, which met in 1876, and to adjust existing difficulties between the two connections. The venerable Dr. Lovick Pierce, who served on a similar errand in 1848, was appointed (in connection with Dr. James A. Duncan, president of Randolph-Macon College, and Chancellor Garland, of Vanderbilt University) to lead this fraternal commission, but was too feeble to attend. Since this conference perfect fraternity has existed between the two churches. The adjustment of all existing difficulties in the way of fraternity was referred to a joint commission of ten members (five from each Church), which met at Cape May, N. J., in Aug., 1876. The action of this commission was indorsed by the next succeeding General Conferences of both churches. Though all the Arminian Methodists in the world agree in the great essentials of Methodism, yet there is considerable difference in matters of polity, which render organic union difficult, but do not interfere with fraternal intercourse. The two Methodisms, e. g., differ as to the relative powers of the bishops and the general conference—the Methodist Church South holding that the bishops are a co-ordinate branch of the government, and can not be *deposed* by a *delegated* general conference, except as they may be excommunicated by regular process of trial; which was the vexed question that divided the Church in 1844. The Methodist Episcopal Church has made an addition to the terms of membership not sanctioned by the Methodist Episcopal Church South, and altered the general rule on slavery, which the Methodist Episcopal Church South has canceled as not being in the *General Rules* as drawn up by John Wesley. There are also minor differences in the organization and powers of district and quarterly conferences.

As the great theater of the civil war covered the region occupied by the Methodist Episcopal Church South, it suffered greatly thereby. Churches, parsonages, seminary buildings, etc., were destroyed or alienated from the Church in many places; thousands of its members perished; and after the surrender the greater part of its Negro membership was taken into other folds. The Church rallied its fortunes with wonderful energy. The statistics for 1900 report 47 conferenees and missions, 6,227 traveling ministers, 11 bishops, 5,151 local preachers, 1,470,520 members, total of ministers and members, 1,481,898; churches, 14,572, valued at $23,012,400, on which an indebtedness exists of $631,055. There are under the control of the church 147 schools and colleges, which report 1,126 teachers, 17,205 pupils, endowment funds to the amount of $2,890,515, and property valued at $5,698,950. The contributions from missions were $400,850. The publishing-house, located in Nashville, is a magnifieent institution; it is supervised by a book committee appointed by the General Conference, and managed by two book agents. It employs an editor of books and of *The Christian Advocate*, a weekly sheet, the organ of the General Conference; and also a Sunday-school secretary, who edits a Sunday-school magazine, *The Sunday-school Visitor*, and other publications in that department. There are many other weekly papers issued in various parts of the connection. A theological and literary *Quarterly Review* is published at Nashville. The board of missions has its bureau in the publishing-house; it employs three secretaries, and superintends the missions in China, Japan, Korea, Mexico, Brazil, Cuba, and among the Indians. The foreign missions return 10,959 church members. The domestic missions are managed by the several annual conferences within whose bounds they are located. The property formerly held by the Church for the colored people has been legally transferred (as also the members for the most part) to the Colored Methodist Episcopal Church in Ameriea. The Vanderbilt University (located at Nashville, Tenn.), the largest and best-endowed institution of learning in the South, is wielding a powerful influence in the Church. The Church Extension Society supplies destitute places with comfortable houses of worship. See *Disciplines*, *General Minutes*, and *Journals* of the General Conferences of the Methodist Episcopal Church and Methodist Episcopal Church South; Redford's *Organization of the Methodist Episcopal Church South*; Myers's *Disruption of the Methodist Episcopal Church*; Howard's *Reports of the Supreme Court*; McTyeire's *Manual of the Discipline* and *History of Methodism*; Summers's *Commentary on the Ritual of the Methodist Episcopal Church South*; Peterson's *Handbook of Southern Methodism*; and the article on METHODISM.

Methodists: See METHODISM.

Methoma'nia [from Gr. *μέθη*, strong drink, drunkenness + *μανία*, madness, mania]: See DIPSOMANIA.

Methyl Alcohol, Methyl Hydrate, Carbinol, Pyroxylic Spirit, or **Wood-naphtha** ($CH_4O = CH_3OH$) [*methyl*, from Gr. *μέθυ*, spirit, wine + *ὕλη*, wood, is a word clumsily constructed to represent *wood-spirit*]: a liquid found associated with acetic acid in the watery product from the distillation of wood; it may also be formed (1) by treating methyl chloride with potassic hydrate; (2) by distilling oil of wintergreen, which is chiefly methyl salicylate, with potassic hydrate.

Preparation of Commercial Wood-spirit.—The crude watery liquid (*pyroligneous acid*) obtained by the distillation of wood is redistilled; the first tenth which passes over is rectified over slaked lime, whereupon considerable ammonia is given off; sulphuric acid is then added, which fixes the remaining ammonia and precipitates some tarry matter: the liquid is redistilled and rectified several times over quicklime. Oak-wood yields about 2 gal. crude wood-spirit to the cord. The crude product has a strong aromatic odor,

and turns brown on keeping. It contains considerable quantities of acetone, methyl acetate, ethyl acetate, and lignone or xylite, which is the dimethyl acetate of ethylene.

The purification of crude wood-spirit is effected by saturating it with fused calcic chloride, with which the methyl alcohol forms a compound which is not decomposed by a temperature of 100° C. It is then heated over a water-bath as long as anything volatile is given off. It is then distilled with water, and the product is rectified over quicklime. A purer product is obtained when the crude product is distilled with strong potash or soda lye previous to the treatment with calcic chloride. To obtain perfectly pure methyl alcohol an ether of methyl, as the oxalate, must be first prepared from the wood-spirit.

Properties.—Methyl alcohol is a colorless, mobile liquid, having a purely spirituous odor, like that of common alcohol. Sp. gr. = 0·8142 at 0° C. It boils at 66°–66·5°, It burns with a pale flame, and is used as a substitute for alcohol in spirit-lamps. It mixes with water, alcohol, and ether, and dissolves fixed and volatile oils and most resins. It unites directly with some substances, forming compounds like the alcoholates, in which it takes the place of water of crystallization; with calcic chloride it forms $CaCl_2.2CH_4O$; with anhydrous baryta, $BaO.2CH_4O$; with potassium and sodium, KCH_3O and $NaCH_3O$. By oxidation it is converted into formic acid, $CH_4O + O = HCHO_2 + H_2O$. Calcic hypochlorite (bleaching-powder) converts it into chloroform.

Impurities.—The impurities of ordinary wood-spirit are aldehyde, acetone, and very small quantities of other substances. Acetone is the most objectionable impurity, if the alcohol is to be used in the preparation of aniline colors.

Metics (in Gr. Μέτοικοι): the foreigners who resided in Athens. In 309 B. C. they numbered 10,000. They had to choose a protector from among the Athenian citizens to represent them in all official acts. In return for this protection the men paid a capitation tax of 12 drachmæ (about $2.40), while widows paid 6 drachmæ. Neglect to pay this tax was punished with sale into slavery, as was also the illegal assumption of the active rights of citizenship. They might not marry free-born Athenian women, nor own real estate, but still they had to pay the extraordinary war taxes. In solemn processions they acted as bearers of parasols and vases. In return for special services to the state they might be advanced to the position of *Isoteleis*, which freed them from the capitation tax and from the necessity of having patrons, and put them on an equal footing with the free-born citizens as far as regarded the owning of real estate and the performance of liturgies, but did not confer upon them the right to vote. J. R. S. STERRETT.

Me'tis (in Gr. Μῆτις): a daughter of Oceanus and Tethys. She was the personification of wisdom, and was the first wife of Zeus, who swallowed her because of a prophecy that her child would dethrone its father. In this way it came about that Athene was born from the head of Zeus himself, and Metis ceased to be dangerous to him. J. R. S. S.

Metonic Cycle: See CYCLE.

Meton'ymy [from Lat. *metony'mia* = Gr. μετωνυμία, liter., change or transfer of name; μετά, over, across + ὄνομα, name]: a figure of speech in which an ordinary term is displaced by one which naturally suggests it, on account of some constant relation, as of cause and effect, occasion and result, or of contact in time, place, or use. Thus an action-name is used to denote the concrete result of an action, as *union*, in the sense of a united body, or to denote an object which conditions the action, as *dwelling* in the sense of *house*. So the name of a poet is used for his works, the name of an inventor for his inventions, of a discoverer for his discovery, of a king for his people, of a general for his army, etc. Other relations determine the metonymy in, e. g., *throne* for *king*, *house* for *audience*, *cuisine* for *cooking* or *food*, etc. As in the case also of metaphor (see METAPHOR), these occasional transfers of terms often result in permanent changes of signification; thus *beads*, prayers, has been permanently transferred to a mechanism used in connection with prayer. See METAPHOR and SYNECDOCHE.

BENJ. IDE WHEELER.

Mètre, or **Meter** [from Fr. *mètre*, meter, from Gr. μέτρον, measure]: the linear base of the metric system of weights, measures, and moneys. Theoretically, it is the $\frac{1}{10000000}$th part of the quadrant of a terrestrial meridian; actually, it is the length of a bar of platinum designed to represent that dimension (3·280899 feet = 39·37079 inches), now deposited in the Palace of the Archives of France in Paris. See METRIC SYSTEM.

Metres, or **Meters** [from Gr. μέτρον, measure, measure in poetry, metre]: the adaptation of speech to measurement by rhythmical units. Particular results of the process are called *metres*, the science of meter is called *metric*, and the art of composing meters is called *versification*. For general principles and definitions, see PROSODY, RHYTHM, QUANTITY, and VERSE.

I. DACTYLIC METRES.—The fundamental foot is the dactyl (– ◡ ◡), which may be replaced by the spondee (– –). The most common verses are—

1. *Hexameter*, composed of two cola, with cæsura between. See HEXAMETER.

2. *Pentameter* (so called), composed of two catalectic trimeters, with invariable cæsura (diæresis). Rhythmically this verse is a hexameter. The true pentameter is rare and even doubtful. It is confined to lyric poetry, and is usually not truly dactylic.

3. *Tetrameter*, used in Greek and Latin chiefly in lyric systems, and in Latin to form distichs with hexameters, as,

Quo nos cumque feret melior fortuna parente,
Ibimus, o socii comitesque.

4. *Trimeter.* — The trimeter and trimeter catalectic (– ◡ ◡ – ◡ ◡ –) are important elements of longer verses, but are scarcely used in Greek as independent verses. In Latin the trimeter catalectic alternates with the hexameter in the first Archilochian stanza, as,

Diffugere nives, redeunt jam gramina campis
Arboribusque comæ.

5. *Dimeter.*—The *versus adonius* of Sappho, sometimes called a dactylic dimeter, is logaœdic:

– ◡ ◡ — ◡, risit Apollo.

In English, feet containing three syllables with stress on the first are usually read rather as tribrachs, or at least are triseme; so that the so-called spondees are usually read as trochees. Still the name "dactylic" is used of this kind of meter. Though it is not very common, every variety of it occurs from the monometer, or single foot, to the hexameter with the last foot complete (– ◡ ◡). Each verse presents the three varieties: acatalectic, catalectic *in disytlabum*, catalectic *in syttabam*, as in these hexameters:

Now with a sprightlier springiness bounding in triplicate syllables.
Welcome once more to a home that is better perchance than the old one.
Would there be sorrow for me? there was love in the passionate shriek.

II. ANAPÆSTIC METRES.—The fundamental foot is the anapæst (◡ ◡ –), which may be replaced by the spondee (– –) or the dactyl (– ◡ ◡); but four shorts must not fall together. The rhythm is especially adapted to the march; hence the dipody, representing a single step of both feet, is the measure.

1. *Tetrameter* (*Catalectic*).—This verse, exclusively used in certain parts of ancient comedy, consists of a dimeter and a catalectic dimeter, with cæsura (diæresis) between. The last entire foot is always an anapæst. The scheme, therefore, is

◡ ◡ – ◡ ◡ – ◡ ◡ – ◡ ◡ – ‖ ◡ ◡ – ◡ ◡ – ◡ ◡ – – – ⏑

Ἄγε δὴ φύσιν ἄνδρες ἀμαυρόβιοι, φύλλων γενεᾷ προσόμοιοι.

2. *Dimeter and Hypermeter.*—In both tragedy and comedy a series of dimeters with an occasional monometer, closing with a catalectic dimeter (called *paræmiac*), is often used, forming a *system* or *hypermeter*, which is recited continuously, as if it were one long verse. Hence the end of each colon except the last is treated exactly as the end of the first colon of the tetrameter, having none of the privileges of a verse-end:

ὦ μέγα σεμνὴ Νίκη, τὸν ἐμὸν
βίοτον κατέχοις
καὶ μὴ λήγοις στεφανοῦσα.

These systems are used sometimes as marches, sometimes in dialogue between the chorus and actors, and in comedy it often forms the close (ἔκθεσις) of a passage of tetrameters. The acatalectic dimeter has cæsura in the middle.

The catalectic dimeter, or parœmiac verse, was also used continuously in songs to be sung by soldiers as they marched.

There is also a looser lyric composition, in which the parœmiac may be used several times in succession. In both the latter cases the spondee may be used anywhere.

Sometimes a passage of dimeters is divided into several systems, the end of each being indicated by the parœmiac.

In Latin the parœmiac is not employed as in Greek, the tetrameter is little used and is sometimes acatalectic.

In English the most usual verse is the tetrameter, that is, *four feet*, called "dimeter" in the ancient languages, as,

When the lowlands shall meet thee in battle array.

Or, with rhyme between half-verses, and parœmiac close:

Not a soul of them all could the dangers appall
Of the hazardous *pons asinorum*.

Occasionally other verses are used, containing from two up to seven feet. The rhythm is more readily produced than the dactylic, as the latter requires an initial stress that is often inconvenient.

III. Trochaic Metres.—The fundamental foot is the trochee (– ⏑), which may be replaced by the tribrach (⏑ ⏑ ⏑), the irrational choree (– >, ⏑ ⏑ >), the light dactyl (– ⏑ ⏑, – ⏑⏑), and, in lyric poetry, the triseme syllable (–̆). The measure is the dipody (– ⏑ ÷ ⏧; Lat. also – ⏧ ÷ ⏧). The rhythm is light and lively.

1. *Tetrameter.*—The complete tetrameter was little used, but the catalectic was much employed in certain parts of Greek comedy and (especially the older) tragedy, and also in the Latin drama. It consists of a dimeter and a catalectic dimeter, usually, though not always, separated by cæsura (diæresis):

– ⏑ – ⏧ | – ⏑ – ⏧ ‖ – ⏑ – ⏧ | – ⏑ – ∧

The substitution of two shorts for one long, and in Latin the admission of irrational feet into the odd places, lend the verse great variety of form. (See Iambic Meters.) Examples:

χρημάτων ἄελπτον οὐδέν ἐστιν οὐδ' ἀπώματον.

In qua civitate tandem te arbitrare vivere.

Hipponax used a tetrameter scazon with long penultimate syllable.

2. *Dimeter and Hypermeter.*—Sometimes, especially as the close (ἔκθεσις) of a passage of tetrameters, a series of continuously recited dimeters terminating with a catalectic dimeter, thus forming a system or hypermeter, was employed, especially in Greek comedy. In Latin the catalectic dimeter (or tetrapody) without irrational feet occurs with other verses, as,

Tunditur dies die.

3. *Tripody or Ithyphallic.*—This is a colon, chiefly used in asynartete verse. It is no doubt sometimes a dimeter with syncope (παρέκτασις). Thus, ζώϊον κάκιστον may be either – ⏑ – ⏑ – ⏑, or – ⏑ – ⏑ ⌙ – ∧.

In English there is a considerable variety of trochaic verses, but the most common is the octameter (corresponding to the classical tetrameter). Its cola are usually separated into distinct verses, as,

Tell me not in mournful numbers,
Life is but an empty dream.

But sometimes the two run continuously, as in *Locksley Hall*:

In the spring a young man's fancy lightly turns to thoughts of love.

It is impracticable to place the stronger stress uniformly on the odd feet in English, nor is it probable that this was done by the ancients.

IV. Iambic Metres.—These are the metres in which the fundamental foot is the iambus. The movement of the verse is more vigorous than the trochaic, and can not be treated as trochaic with anacrusis, though the form would be the same. For a detailed treatment, see Iambic Metres.

V. Ionic Metres.—The fundamental foot is the *ionicus a minori* (⏑ ⏑ – –), or the *ionicus a majori* (– – ⏑ ⏑). Resolution (⏓) and contraction (⏑⏑) often occur, and by anaclasis (ἀνάκλασις, breaking up) the first of the two shorts may be placed between the two preceding longs; that is, the dichoræus (– ⏑ – ⏑) may be substituted for the *ionicus a majori* whether the verse begins with anacrusis (⏑ ⏑) or not. The movement is plaintive, and can scarcely be sustained in English.

1. *Dimeter.*—This verse, with or without anaclasis, is occasionally used in the Greek drama. Sometimes syncope occurs. The schemes therefore are—

(*a*) ⏑ ⏑ – – ⏑ ⏑ – –
(*b*) ⏑ ⏑ – ⏑ – ⏑ – –
(*c*) ⏑ ⏑ – – ⏑ ⏑ ⌴, or ⏑ ⏑ – – ⏑ ⏑ – ∧̄,

with some other variations. Scheme (*b*) is much used in the late Anacreontics, with occasional reversion to scheme (*a*):

(*a*) ἐν ἁμίλλαισιν ἀνάγκας.
(*b*) ἐσορᾷς τάδ' ὦ Διὸς παῖ.
(*c*) ἀχαλίνων στομάτων.

2. *Trimeter.*—The trimeter is rare, occurring a few times in Greek lyrics and in an ode of Horace (iii., 12) in connection with dimeters, forming a sort of system. Most of the passages where the dimeter and trimeter are found in lyrics allow (if some of them do not require) division into other verses than these.

3. *Tetrameter Catalectic, or Galliambic.*—The original form of this verse was—

⏑ ⏑ – – ⏑ ⏑ – – ‖ ⏑ ⏑ – – ⏑ ⏑ –

which by anaclasis became—

⏑ ⏑ – ⏑ – ⏑ – – ‖ ⏑ ⏑ – ⏑ – ⏑ –

By resolution and occasional contraction in both these schemes the verse assumes many forms. There is difference of opinion which of the two forms was felt to be fundamental, but there is reason to believe that sometimes the one was intended and sometimes the other. There is occasional reversion to the original form in one colon or the other. The extant examples, though the verse is of Greek origin, are almost entirely confined to the celebrated *Attis* of Catullus (Ode lxiii.), beginning—

Super alta vectus Attis celeri rate maria.

⏑ ⏑ – ⏑ – ⏑ – – ‖ ⏑ ⏑ – ⏑ ⏑ ⏑ ⏑ ⏓

The second colon here is not ⏑ ⏑ – | ⏑ ⏑ ⏑ | ⏑ ⏓ with iambic rhythm, though this seems the true scansion in some verses. The movement of these verses of Catullus is wild and weird to suit the subject-matter.

The *Boadicea* of Tennyson is often erroneously called galliambic.

Other ionic verses (such as the Sotadean, – – ⏑ ⏑ | – – ⏑ ⏑ | – – ⏑ ⏑ | – – ∧̄, nearly always with anaclasis) are of little importance.

VI. Choriambic Metres.—The foot is the choriambus (choree or trochee + iambus, – ⏑ ⏑ –). The difference between ionic and true choriambic rhythm results from the opening foot. Real choriambic meter is very rare, and is confined to lyric poetry. So-called choriambic verses are usually (according to some, *always*) logaœdic, the seeming choriambus being –⏑ ⏑ ⌙ or –⏑ ⏑ –, as in Hor. Od. i., i., 1:

Mæcenas atavis edite regibus,
– > –⏑ ⏑ ⌙ ‖ –⏑ ⏑ – ⏑ ⏓

or Hor. Od. i., xviii., 1:

Nullam, Vare, sacra vite prius severis arborem.
– > –⏑ ⏑ ⌙ ‖ –⏑ ⏑ ⌙ ‖ –⏑ ⏑ – ⏑ ⏓

These are the *asclepiadeus minor* and *major*. (See Logaœdic Meters.) The triseme syllable always closes a word; hence a pause may often be used (–⏑ ⏑ – ∧) in reciting.

VII. Antispastic Metres.—"Choriambic" verses sometimes begin with a δισύλλαβον ἀδιάφορον (two either long or short syllables, ⏓ ⏓). These syllables are now called a *basis*. When they form an iambus (⏑ –) the ancients divided thus, ⏑ – – ⏑ | ⏑ – – ⏑ | , and called the meter *antispastic* (ἀντισπαστικός, from ἀντίσπαστος, drawn in opposite directions), and the foot (⏑ – – ⏑) *antispast*. The metre has no real claim to recognition.

VIII. Cretic Metres.—The fundamental foot is the cretic (– ⏑ ÷), which derived its name from the frequent use of the rhythm by the ancient Cretans in dance melodies. By resolution the first pæon (– ⏑ ⏑ ⏑) and the fourth pæon (⏑ ⏑ ⏑ ÷) become its substitutes. In Latin the form – > – is allowed. The rhythm is confined to lyric poetry. The verse chiefly used is the tetrameter, as,

ἦλθες οὐ πρίν γε δεῖν, ἴσθι σαφές, ἀλλ' ὅμως.
– ⏑ – – ⏑ – – ⏑ ⏑ ⏑ – ⏑ –

Te sequor, quin vocas spectatores simul.
– ⏑ – – ⏑ – – > – – ⏑ ⏓

In English the rhythm is impracticable, and even in the music of modern times its use is very rare. It is difficult

for us to avoid making it trochaic with triseme syllables, – ◡ ⌞ – ◡ ⌞, or with pauses, – ◡ – ∧ – ◡ – ∧. Sometimes seeming cretics are really trochaic.

IX. Bacchic Metres.—The feet are the bacchius (◡ ⏑ ⏑) and the antibacchius (⏑ ⏑ ◡). If the first long be removed from a cretic verse (see VIII.) a rhythm based on the bacchius results, and if a long be prefixed the antibacchic rhythm results; but both are called simply bacchic. Except in Latin comedy (where three longs may form the foot) the meter is little used, as,

τίς ἀχώ, τίς ὀδμὰ προσέπτα μ' ἀφεγγής.
◡ – – ◡ – – ◡ – – ◡ – –

Verses of various lengths occur. Sometimes the last long is omitted. Occasionally a seeming bacchic verse is really trochaic with triseme syllables. The context must be considered. The rhythm marks intense interest.

X. Dochmiac Metres.—The measure is the complex foot, ◡ ⏑ ⏑ ◡ ⏑, called dochmius (δόχμιος, aslant), probably from its peculiar, abnormal rhythm. By the use of irrational syllables for the shorts and two shorts for the longs, the foot assumes about twenty different forms in actual use. The movement denotes extreme agitation resulting usually from overwhelming grief. Dochmii are found only in Greek lyric poetry (κομμοί and ᾠδαὶ ἀπὸ σκηνῆς), and are sometimes mixed with bacchii or iambi in the same verse; and often dochmiac verses are mixed with iambic trimeters. Examples of a dipody and a monopody are:

ἰὼ δυσκάθαρτος Ἄιδου λιμήν,
τί μ' ἄρα τί μ' ὀλέκεις.
◡ ⏑ ⏑ ◡ ⏑ ◡ ⏑ ⏑ ◡ ⏑
◡ ◡ ◡ ◡ ◡ ◡ ⏑

To reduce the rhythm to ordinary triple time it has been proposed to read verses like the second one cited ◡ ◡ ◡ ◡ ◡ ◡ ⏑, which makes the fundamental form ◡ – ⏑ ◡ ⏑ ∧. The foot ◡ – seems to occur in other meters in Pindar; but both there and in the doehmius it is better to treat it as in the case of syncope in modern music, and read ◡ ⏑. The treatment of iambi and bacchii mingled with dochmii will depend on the view taken of the dochmii themselves, and metricians disagree.

XI. Logaœdic Metres.—Logaœdic rhythm is a modified form of the trochaic. The relative stress of the ictus-syllable is thought to have been less marked than in ordinary trochees. Logaœdic metre was much used in the lyric parts of the Greek drama and by some of the lyric poets, and many of the verses were borrowed, and in some cases modified, by Horace, and a few by Catullus. For a detailed treatment of this metre, with illustrative examples, see Logaœdic Metres.

XII. Dactylo-epitritic Metres.—The rhythm is a combination of dactyls with epitrites (⏑ ◡ ⏑ –). The cola of either sort may be catalectic. The elements most in use are ⏑ ◡ ◡ ⏑ ◡ ◡ ⏑ –, ⏑ ◡ ◡ ⏑ ◡ ◡ ⏑, ⏑ ◡ ⏑ –, ⏑ ◡ ⏑, which are combined in various ways. Anacrusis is sometimes found. There is difference of opinion as to the correct scansion. In practice it is best to make the dactyls and spondees of the dactylic elements, and the trochees and spondees of the epitritic elements, all equal to each other by slight change of the tempo of the trochees. One favorite method is to read the trochees ⌞ ◡. The rhythm is confined to Greek lyric poetry, and was much used by the tragedians and Pindar. Samples are:

ἀλλ' ἐπεύξασθαι μὲν ἐγὼν ἐθέλω.
⌞ ◡ – – | – ◡ ◡ – ◡ ◡ –
ὀξυκόμαν κε βαθὺν πόντον περάσαις.
– ◡ ◡ – ◡ ◡ –, – | ⌞ ◡ – –

The name (ἐπίτριτος = containing one and a third) "epitritrite" is derived from the fact that apparently the spondee is one and a third times the length of the trochee, or θέσις : ἄρσις :: 3 : 4; but the ancients always spoke of metrical forms from the standpoint of the words (μέρη λέξεως) rather than the rhythm.

XIII. Asynartete Metres.—Asynartete (ἀσυνάρτητος, unconnected) verses are composed of heterogeneous members. In Greek there were a good many, but most of them are represented by very few fragments. In Horace the following occur:

1. *Greater Archilochian.*

– ⏑ – ⏑ – | ⏑ – ◡ ‖ – ◡ – ◡ – ⏑
Solvitur acris hiems grata vice veris et Favoni.

The last two syllables may be ⌞ ⏑, but the trochees should not be read with triple ratio (⌞ ◡). Some make the dactyls cyclic.

2. *Elegiambic* (Archilochian).

– ◡ ◡ – ◡ ◡ ⏑ ‖ ⏑ – ◡ – ⏑ – ◡ –
Sribere versiculos amore percussum gravi.

Hiatus and syllaba anceps are allowed before the diæresis.

3. *Iambelegic* (*Horatian*).—This is like the preceding with the cola interchanged:

⏑ – ◡ – ⏑ – ◡ ⏑ ‖ – ◡ ◡ – ◡ ◡ –
Deformis ægrimoniæ duleibus adloquiis.

The elegiambic and iambelegic may each be read as two verses.

XIV. The Saturnian Verse.—This verse was used by the Romans before Ennius introduced the Greek dactylic hexameter. We have only a few short inscriptions and some fragments composed in it, and there is a dispute whether the stress is determined by the quantity or by the word-accent, as in English. According to the first theory the fundamental scheme is

◡ ⏑ ◡ ⏑ ◡ ⏑ ⏒ ‖ ⏑ ◡ ⏑ ◡ ⏑ ⏒
Dabúnt malúm Metélli Naévió poétæ.
The queen is in her parlor, eating bread and honey.

According to the other theory (letting ⏑ denote an accented or half-accented syllable, and ◡ an unaccented syllable), the scheme is

⏑ ◡ ⏑ ◡ ◡ ⏑ ◡ ‖ ⏑ ◡ ⏑ ◡ ⏑ ◡
Dábunt málum Metélli Naévió poétæ.
In her parlor the queen sits, eating bread and honey.

Under either theory the verse exhibits many licenses.

Milton W. Humphreys.

Metric System: a system of weights and measures designed to remove the confusion arising out of the excessive diversity of weights and measures prevailing in the world, by substituting in place of the arbitrary and inconsistent systems actually in use a single one constructed on scientific principles and resting on a natural and invariable standard. The proposition for the creation of such a system originated in 1790 with Prince Talleyrand, then Bishop of Autun. He recommended the length of the pendulum beating seconds in latitude 45° as a suitable linear basis, and introduced into the National Assembly of France a decree embodying this proposition and providing for a scientific determination of the exact length of this pendulum by a commission to be composed in equal numbers of members of the French Academy of Sciences and of the Royal Society of London. This decree, with some modification, was adopted, and the king, Louis XVI., was requested to open a correspondence on the subject with the King of Great Britain, which he did; but, owing to the temper and the public troubles of the times, this overture met with no response. Similar applications to other nations were more successful, and in subsequent proceedings, Spain, Italy, the Netherlands, Switzerland, Denmark, and Sweden participated by sending delegates to an international commission. The system itself was, however, matured by the labors of a committee of the Academy of Scienees, embracing Borda, Lagrange, Laplace, Monge, and Condoreet, five of the ablest mathematicians of Europe. Their report, dated Mar. 19, 1791, after considering the comparative fitness, as a standard of length, of the pendulum and of the earth itself in some one of its natural dimensions, decided in favor of the latter, and recommended as the standard unit of linear measure $\frac{1}{10000000}$th of the quadrant of a terrestrial meridian. The report was communicated to the Assembly and received its sanction. Committees of the Academy were then charged with the duty of making the necessary determinations of the standard units, including those of capacity and weight as well as that of length. An arc of the meridian passing through Paris and extending from Dunkirk to Barcelona was measured trigonometrically by Delambre and Méchain, an operation of immense labor which occupied seven years; the object being to ascertain with the greatest exactness the length of the linear base, called the meter. It was resolved to make the unit of volume equal to the capacity of a cubical vessel measuring one-tenth of a meter on its edges; and the standard of weight, the actual weight of distilled water which should fill such a vessel at the temperature of maximum density. The weight of a given volume of water under these conditions was made a

subject of elaborate investigation by a committee of the Academy, and in conformity with the results obtained the standard unit of weight, called the *gramme*, was fixed at $\frac{1}{1000}$th part of the standard weight above mentioned, which, being 1,000 grammes in weight, is called the *kilogramme*.

On the fourth day of the month Messidor, in the seventh year of the republic "one and indivisible," the international commission above referred to, after having carefully tested the accuracy of the standards prepared by the committees of the Academy, proceeded in a body to the Palace of the Archives in Paris, and there deposited the standard meter, a simple bar of platinum, which represents the linear base of the system, and the standard kilogramme, a simple cylinder, also of platinum, which represents the unit of metric weights. The value of these units had, however, been ascertained much earlier with an accuracy sufficient for all practical purposes: and by a law passed on Aug. 1, 1793, the metric system was established as the only legal system of weights and measures for France and the French colonial possessions. The system has since been successively adopted by Holland, Belgium, Spain, Portugal, Italy, the German empire, Greece, Roumania, British India, Mexico, New Granada, Ecuador, Peru, Brazil, Uruguay, the Argentine Confederation, and Chili. Switzerland, without adopting the system in full, has given to all her standards metric values, and Denmark has done the same for her standard of weight. Austria has adopted the system for custom-house purposes, and Turkey has introduced a metric measure of length. In Great Britain the use of metric denominations in business transactions has been made legally permissible; but, by a singular inconsistency, the metric weights and measures themselves are not allowed to be kept in tradesmen's shops and employed in actual commerce. In the U. S., metric weights and measures were legalized by an act of Congress passed July 27, 1866, and at the same time the bureau of weights and measures at Washington was directed to prepare and furnish to the executive authorities of the several States authenticated standards for the verification of metric weights and measures used in commercial affairs. The aggregate population of the countries in which the metric system has been established by law amounts to nearly 350,000,000; of those in which it has been partially introduced, to about 70,000,000; and of those where its use is legally permissible, to 70,000,000 more. It has thus been adopted by largely more than half of the civilized and Christian world.

The question whether the prototype meter of the archives is really, with great severity of exactness, $\frac{1}{10000000}$th part of a terrestrial quadrant is regarded as a futile one, and of no great practical importance from the point of view of metrology; the fact being that we are not sufficiently well acquainted with the figure of the earth to warrant the adoption of it as a basis for a system of measurement.

The desirability of settling all doubts as to the stability of the system and the permanency of its unit-bases, as well as of providing authenticated copies of the prototype standards to be distributed to the governments of all metric nations, and of securing such standards against the danger of alteration in all coming time, led to the assembling at Paris, in the year 1870, of an international commission to consider and adjust all questions connected with this subject. In this commission, thirty independent powers were represented. The deliberations of the commission, interrupted by the war of that year between France and Germany, were subsequently resumed, and resulted at length in an international convention providing for the maintenance at Paris of an International Bureau of Weights and Measures, to be supported by *pro rata* contributions from all the signatory powers, and charged with the care of the prototype standards, and with the duty of constructing and verifying copies of those standards not only for the powers interested but for other governments, or even for corporations and individuals who should apply for them and should be willing to pay the expense attending their construction and comparison. This convention was signed in Mar., 1874, the diplomatic representative of the U. S., Mr. Washburne, being, by consent and direction of the President, one of the signers. It was resolved by this commission that the prototype meter and the prototype kilogramme of the archives shall be recognized and perpetuated forever as the true bases of the system, without regard to any doubtful questions which have been raised as to the exactness of their correspondence with their theoretic values.

The units of the metric system are five—viz.: 1. The meter (the unit of length) = 3·280899 feet = 39·37012 inches.

2. The are (the unit of surface) = the square of the meter = 119·60332 sq. yards.

3. The liter (the unit of capacity) = the cube of one-tenth of a meter = 0·26418635 gal. = 1·0567454 quarts = 2.1134908 pints.

4. The stere (the unit of solidity) = one cube meter = 35·336636 cubic feet = 1·308764 cubic yards. This unit has fallen into general disuse.

5. The gramme (the unit of weight) = 15·43234874 grains troy.

Each unit has its decimal multiples and submultiples; that is, weights and measures ten times larger or ten times smaller than the unit of the denomination preceding. These multiples and submultiples are indicated by prefixes placed before the names of the several fundamental units. The prefixes denoting multiples are derived from the Greek language, and are *deka*, ten; *hecto*, hundred; *kilo*, thousand; and *myria*, ten thousand. Those denoting submultiples are from the Latin, and are *deci*, tenth; *centi*, hundredth; and *milli*, thousandth.

The unit of itinerary measure is the kilometer, which is equal to 0·62138 mile.

The unit of land measure is the hectare, equal to 2·47114 acres.

The unit of commercial weight is the kilogramme, equal to 2·20462125 lb. avoirdupois.

The system of French moneys is connected with that of metric weights by the creation of a coin of standard silver (nine parts pure silver and one of alloy) to represent the monetary unit, called the franc, having the weight of exactly 5 grammes; the coins of higher and lower denominations being multiples and submultiples of this. As in the coinage system of France gold and silver are equally standard metals, it is necessary that their relative values, weight for weight, should be determined by an arbitrary ratio. This ratio is fixed by law at $15\frac{1}{2}$ to 1; and accordingly the twenty-franc piece of gold, commonly (though not legally) called the napoleon, has the weight of twenty times 5 grammes divided by $15\frac{1}{2}$, which is equal to 6·4516 grammes of standard gold. See UNITS and WEIGHTS AND MEASURES.

Revised by E. L. NICHOLS.

Metrodo'rus (in Gr. Μητρόδωρος): (1) a philosopher of Chios (330 B. C.); (2) an Epicurean of Athens (277 B. C.); (3) a rhetorician and statesman of Scepsis under Mithridates Eupator (140 B. C.); (4) a philosopher of Stratonicea (110 B. C.); (5) a freedman of Cicero; (6) a writer of epigrams in the time of Constantine the Great. J. R. S. S.

Met'ronome [Gr. μέτρον, measure, measure in poetry and music + νέμειν, deal out, distribute, divide]: in music, an instrument for the measurement and regulation of time. As the directive terms usually prefixed to musical compositions, such as *adagio*, *lento*, *andante*, *allegro*, etc., can only give to the performer an approximate idea of the rate or velocity intended by the composer, various means have been employed to indicate the speed with more precision. The metronome, invented by John Maelzel, a mechanician in the service of the Emperor of Austria, and brought into use in the early part of the nineteenth century, is a simple but ingenious contrivance by which any degree of slowness or rapidity can be marked, and practically shown with the greatest exactness. The instrument is small and portable, in form between that of the pyramid and the obelisk, and consists of an inverted steel pendulum (8 or 9 inches long), on which is a sliding weight which may be moved up or down the pendulum, and thus brought opposite to any of the figures on a graduated scale in its rear. The pendulum is moved by simple wheelwork, and makes a loud tick for every vibration. The sliding weight determines the rate of vibration. If it is near the point of suspension, the motion will be rapid: and the rapidity decreases in proportion as the weight is moved toward the remote end. In practical use the object is to ascertain how many minims, crotchets, etc., of a given piece of music are to be performed in one minute. The numbers on the scale have therefore reference to a minute of time—i. e. when the weight is placed at 50, fifty beats or ticks will occur in each minute; when at 100, one hundred beats in a minute, etc. The rate at which any piece of music is to be played is thus easily found when the metronome mark is placed by the composer at the beginning. For example, ♩ = 50, means that when the sliding weight is placed at that figure on the graduated scale, the

pendulum will vibrate *once for every minim* in the music, and that there will be fifty minims (or their value in other notes) in a minute of actual or clock-time.

Metropolis City: city (founded in 1839 on the site of Fort Massac, built by the French and Indians about 1700); capital of Massac co., Ill. (for location of county, see map of Illinois. ref. 12–F); on the Ohio river, and the St. L., Alt. and Terre Haute Railroad; 156 miles S. E. of St. Louis. It is in an agricultural region; has high school, graded schools, 6 churches for white people and 2 for colored, public library, and a monthly and 2 weekly newspapers; and contains saw and planing mills, pipe-foundry, wheel and wagon material works, flour-mills, stave, heading, and veneer factories, and pottery-works. Pop. (1890) 3,573; (1900) 4,069.

Metsys, QUINTIN: See MESSIS.

Mettam, CHARLES: See the Appendix.

Metternich, met'er-nich, CLEMENS WENZEL NEPOMUK LOTHAR, Prince: statesman; b. at Coblentz, May 15, 1773; studied jurisprudence at Mentz and Strassburg; was employed by the Austrian Government in diplomatic service at The Hague in 1794, but returned to Vienna after the conquest of the Netherlands by the French; married in 1795 the granddaughter and sole heiress of Prince Kaunitz; was employed at the Congress of Rastadt (1797–99), and went in 1801 to Dresden as ambassador, in 1803 to Berlin, and in 1806 to Paris; on Oct. 8, 1809, was made Minister of Foreign Affairs, and on May 25, 1821, chancellor of the empire, which positions he held till Mar. 13, 1848. With great shrewdness he kept Austria out of the great conflict of 1813 until she could make her own conditions for her participation, and at the Congress of Vienna (1814), of which he was unanimously chosen president, he procured for Austria a great extension of territory and a prominent position in Germany and Italy. For the next thirty years he actually stood at the head of the continental politics of Europe, and by the congresses of Aix-la-Chapelle (1818), Carlsbad (1819), Vienna (1820), Laybach (1821), Verona (1822), Münchengratz (1833), Töplitz (1835), etc., and by the aid of the Holy Alliance, he succeeded in suppressing almost every national or liberal movement in Europe. He completely worked out his system within the boundaries of Austria, which by censorship, police, etc., was almost hermetically shut out from the rest of Europe. Nevertheless, on Mar. 13, 1848, the revolution in Vienna compelled the prince to flee for his life. He resided in London till Nov., 1849, when he returned to Vienna, where he lived in retirement till his death July 11, 1859. A collection of his writings (*Denkwürdigkeiten*) has been published and an autobiography (8 vols., Vienna, 1880–84).

Metz: a city and fortress of Germany; in Alsace-Lorraine; on the Moselle (see map of German Empire, ref. 6–C). The town is beautifully situated on both sides of the river, which divides into several arms, surrounded by mountains, and is one of the strongest fortresses in the world. Seven strong forts—Plappeville and St.-Quentin to the W., St.-Eloy to the N., St.-Julien to the N. E., Les Battes to the E., Quenlen to the S. E., and St. Privat to the S.—crown the hills around it. It is the seat of the highest authorities of Lorraine, of a bishop, of a civil and commercial tribunal, etc., and has an academy, a college, two seminaries, a school of artillery, a museum with collections of Roman antiquities, coins, and pictures, a library containing 30,000 volumes, and an arsenal. The most important public buildings are the Cathedral of St. Stephen, a Gothic structure, begun in the thirteenth century, the nave finished in 1392, the choir in the sixteenth century, with a tower 387 feet high, containing a bell weighing 260 cwt.; the Church of St. Vincent, begun in the thirteenth century; the Church of St. Eucharius, built in the twelfth century; and the Palace of Justice, built in the eighteenth. The esplanade has beautiful walks; opposite stand magnificent barracks. Brushes, fur, felt, leather, paper, soap, silk, woolens, embroideries, drugs, etc., are manufactured, and a brisk trade is carried on in wine, timber, corn, and hides. Pop. (1890) 60,186.

Metz, whose ancient name was *Divodurum* or *Mediomatrica*, was destroyed by Attila in the fifth century, then became the capital of Austrasia, fell, on the division of the empire of Charlemagne, to Germany, and was established as a free imperial city, governed by a count in the name of the emperor. In 1444 the French besieged the city without taking it, but in 1552 Henry II. gained possession of it under pretense of bringing aid to the Protestant German princes. The Emperor Charles V. besieged it in vain from Oct., 1552, to Jan., 1553. By the Peace of Westphalia in 1648 the authority of France over Metz, as well as over Toul and Verdun, was acknowledged and guaranteed. By the war of 1870–71 the state of affairs was entirely changed. The fortress, which had been much strengthened by Napoleon III., formed the principal point of support for the imperial army drawn up along the German frontier, and after the first defeats at Weissenburg and Wörth it served as a retreat for the largest part of the army, numbering more than 180,000, under Marshal Bazaine. Prince Frederick Charles inclosed Metz with an army of 200,000 men, and thus the memorable siege began which ended with the surrender both of army and fortress. On Oct. 27, 1870, the capitulation was concluded, according to which the fortress was to be occupied by the Germans, and the French army to go to Germany as prisoners of war. The French army, including the sick and the national guard, comprised 173,000 men, with 6,000 officers and 3 marshals. The war material, worth 80,000,000 francs, comprised 800 cannon, furniture for 85 batteries, 66 mitrailleuses, 300,000 muskets, an enormous number of sabers and cuirasses, 2,000 wagons, etc.; 53 eagles and colors were taken. By the Peace of Frankfort (May 10, 1871) Metz was ceded to the German empire, and the German military administration has strengthened the fortress. See BAZAINE.

Metzger, KARL ALBERT EMIL: geographer; b. at Coblentz, Germany, Oct. 19, 1836; was gazetted second lieutenant in the Prussian engineers (pioneer corps) in 1856, but the following year he resigned and entered the Dutch service, going to Java, and entering the trigonometrical survey department. From 1865 to 1875 he was actively engaged in trigonometrical work in Java, when he returned to Europe, settled in Stuttgart, and devoted himself to geographic studies. He had an intimate knowledge with the far East, and was a frequent contributor to scientific journals. His principal work was his *Weltlexicon* (1888), or gazetteer of the world, intended for those interested in commerce and industry. D. July 6, 1890. M. W. HARRINGTON.

Metzu, GABRIEL: painter; b. at Leyden, Holland, in 1615; d. in 1659. He formed his style on that of Terburg and Gerard Dow, but surpassed both in drawing. He left many genre pictures of great excellence, of which the Louvre possesses the most famous examples, viz.: the portrait of *Admiral Tromp*, *A Soldier Offering Refreshments to a Lady*, *A Chemist Reading near a Window*, and *The Fruit-market at Amsterdam*. W. J. S.

Meun, mön, JEAN, de (JEAN CLOPINEL): poet; b. at Meun-sur-Loire, France, about 1250. He studied in the schools at Paris, and while still thus engaged (1277) he took up the ROMANCE OF THE ROSE (*q. v.*) where it had been left by Guillaume de Lorris and completed it, though in a very different spirit. Later he wrote several other works, though of far less repute than his first. In 1284 he translated for Jean de Brienne, Count d'Eu, the *De re militari* of Vegetius; later still, the *Letters of Abélard and Héloïse*, the *Marvels of Ireland* of Giraud de Barri, the book of the English monk Aelred on *Spiritual Friendship*, and the *De Consolatione philosophiæ* of Boethius. Between 1291 and 1296 (?) he wrote his poetic *Testament*, full of criticisms on his contemporaries, but also of sincere piety. He became a person of wealth and distinction. He died before Nov., 1305. See the *Histoire littéraire de la France*, vol. xxviii., pp. 391–439. A. R. MARSH.

Meur'sius, JOHANNES (Dutch, *De Meurs*): classical scholar; b. at Loozduinen, near The Hague, on Feb. 9, 1579; studied philology; traveled much, and became Professor of History at Leyden in 1610, afterward of Greek, but left Holland, disturbed by the political broils in his country, and accepted a position at the Academy of Soröe in Denmark, where he died Sept. 20, 1639. He was one of the most learned men of his age, and his *Glossarium Græco-barbarum* (1614) and *Athenæ Batavæ* (1625), as well as his numerous monographs relating to the Greek literature, mostly reprinted in Gronovius's *Thesaurus Antiquitatum Græcarum*, are still of interest. He also edited Lycophron's *Alexandra*, Apollonios Dyscolos, Philostratus, and the works of some of the Byzantian historians. His works were edited by Lamie (12 vols. fol., Florence, 1741–63). Revised by A. GUDEMAN.

Meurthe-et-Moselle, mört'ā-mō-zel': a department of Northeastern France; formed on Sept. 11, 1871, after the Franco-German war. It comprises an area of 2,025 sq.

miles; consists of the arrondissements Briey, Lunéville, Nancy, and Toul, and contains some of the most beautiful scenery and some of the most fertile soil in France. Vine-culture is the chief occupation; half of the surface is occupied by vineyards. Capital, Nancy. Pop. (1896) 466,417.

Meuse, Fr. pron. möz: department of Northeastern France, comprising an area of 2,405 sq. miles. It extends along both sides of the river Maas, which is inclosed between two ranges of low hills running parallel with it. The valley is very fertile and produces wheat and good wine: cattle, horses, swine, and bees are reared. The hills contain iron, limestone, and gypsum. Capital, Bar-le-Duc. Pop. (1896) 290,384.

Meuse, or **Maas**: a river of Europe which rises in France, in the south of the department of Haute-Marne. Proceeding N., it crosses the northwest corner of the department of Vosges, traverses the departments of Meuse and Ardennes, and in the wild mountainous region still known as the Forest of Ardennes pours through a wild, romantic gorge; on reaching Givet it enters Belgium, and at Namur, where it receives on the left its largest tributary, the Sambre, almost doubling its volume, changes its course to N. E., and passes Liège, where it is augmented by the Ourthe. At Bommel it draws so close to the Rhine as to be brought into communication with it; resuming its western course and finally turning N. W., it joins the left bank of the Waal, one of the arms of the Rhine, and gives its name to the mighty accumulated flood of these streams. Proceeding W. the Meuse is divided near Dordrecht into two great rivers, one of which bends round to the N., and reaches Rotterdam; the other branch continues W.; and shortly after the two branches again unite and discharge themselves, amid shoals and quicksands, into the North Sea. Total length, 600 miles, of which 460 are navigable.

Mexia: town (founded in 1873); Limestone co., Tex. (for location of county, see map of Texas, ref. 3–I); on the Houston and Tex. Cent. Railroad; 80 miles S. of Dallas, 181 miles N. W. of Houston. It is in an agricultural region; is a shipping-point for cotton, hides, and live stock: and has an academy, 2 public schools, 6 churches, a national bank with capital of $50,000, a private bank, 3 weekly newspapers, flour, planing, and saw mills, canning-factory, carriage and wagon shops, and tin and sheet-iron works. Pop. (1880) 1,298; (1890) 1,674; (1900) 2,393.

EDITOR OF "LEDGER."

Mexican Antiquities: the relics of races inhabiting Mexico before the advent of Europeans. The Toltecs, Aztecs, and other well-known Nahuan peoples followed one another in their occupation of Mexican territory, building and deserting their cities and monuments. Preceding and alternating with them were other nations and tribes of less note. The most striking of the many existing features of pre-Columbian culture in Mexico are the ruins of cities, temples, and monuments. The dismantled remnants of a chain of colossal structures extends from Chihuahua on the N. to Honduras on the S., the best-preserved examples occurring S. of the valley of Mexico. The degree of preservation is, however, not a reliable index of the original stability and perfection of the structures, as some were in ruins when the conquerors landed, and others were so situated that they were exposed to devastation by the Europeans and were totally demolished. Tenochtitlan, Cholula, and Tezcuco, centers of Nahuatl culture and power, were, with the downfall of these peoples, leveled with the ground, while Teotihuacan, Xochicalco, and Mitla, already in ruins, are still standing.

The mural remains of Mexico are often characterized by great massiveness, although they never exhibit pronounced megalithic features. The plan of the buildings was often complex, and the area covered large. The masonry was well constructed of stones laid in mortar. Grout and sun-dried bricks were also extensively used in some sections. The true arch was unknown; doors and windows were bridged by wooden lintels, by slabs of stone, or by smaller stones overlapping.

The walls are often covered with elaborate figures in low-relief and sculptured columns; and slabs and masses of stone, some of enormous size, are found. The Almaraz monolith, discovered on the site of San Juan Teotihuacan, weighs upward of 18 tons. The pottery is varied in form, rich in color, and abounds in æsthetic and symbolic designs. Each section has its distinctive groups of ware, indicating the strong individuality of the tribes and nations. Implements of stone flaked and polished are numerous, and the number of minor carvings, statuettes, charms, and ornaments is very great. Objects of metal are common, and some elaborate ornaments in gold and gold-copper alloy have been preserved. Iron had not come into use.

The most striking features of many of the ruins are pyramids and pyramidal masses of earth, cement, and masonry. This was not so during the period of occupation, as these structures were the nuclei of clusters of ceremonial buildings and of dwellings, traces of which have, as a rule, disappeared. The largest is that of Cholula, which in its present much-altered state is upward of 1,400 feet square at the base and is nearly 200 feet in height. They were built in a great variety of forms, and of such materials as were at hand. They were frequently finished with cement or faced with neat masonry, and were furnished with terraces and stairways, and the truncated summits were generally occupied by public or religious structures. In no case were they simple pyramids serving exclusively as monuments or as receptacles for the dead, as did the pyramids of other countries.

Casas Grandes.—The ancient ruins of Northern Mexico are closely related to the better-known ruins of New Mexico and Arizona. Cliff ruins are found in the mountains, and deserted pueblos are scattered over the valleys of Chihuahua. The most noted example of the latter class is known as the Casas Grandes, in the northwestern part of the state. The principal ruin consists of three or more clusters of rectangular apartments connected by obscure walls, and occupying an area of about 250 feet in width by 800 feet in length. The walls appear to be composed of cement or grout, a mixture of earth, gravel, and cut straw, which was built up in sections by pouring the plastic material into movable boxes of the thickness of the wall, the boxes being moved along when the contents had properly set, just as the Chinese do at the present day. The heavier walls are five feet thick at the base, and still stand to a height approximating three stories. Neither the period of occupation nor the people concerned are known, as the site is said to have been deserted when first visited by the whites. Many less important ruins, mostly reduced to mere heaps of *débris*, are scattered about. Stone was used in localities where it could readily be obtained.

Quemada.—Five hundred miles farther S. in Zacatecas are the ruins of Quemada, of which nothing is known as to period or people, and the relation of these remains to those of other sections is not well made out. The pueblo has been extensive, and evidently was the center of a flourishing community. Its situation resembles that of many of the pueblos of the north, occupying a somewhat precipitous but irregular mesa-like elevation, from 200 to 500 yards wide and half a mile long. It was inclosed where approach was easy by heavy walls of masonry. The plan of the pueblo is irregular, conforming to the topography of the site. The walls, terraces, inclosures, columns, temples, and pyramids, are substantially constructed of uncut, flag-like stones laid in reddish mortar tempered with straw. There are indications of plastering, but no carving or other ornamental work; and no arches, doors, or windows have been noted.

Tula, Tenochtitlan, Texcoco.—Between Quemada and Tenochtitlan, the center of the Nahuan empire, there are numerous interesting remains. Tula, the most northern center of culture with which any historic people is definitely associated, is said to have been a Toltec city of early date and great importance, but explorations conducted by Charnay and others develop little of an architectural kind, and the few relics found may apparently as readily belong to Aztec as to Toltec culture.

On the sites of Tenochtitlan, the Aztec capital, now Mexico, and Texcoco, the Acolhuan capital, its rival, almost nothing is left of the splendid structures of the pre-Spanish period. Two of the most notable pieces of sculpture in America, the Calendar stone and the composite idol, the god of war and the goddess of death, were dug up on the site of the present cathedral of Mexico where the great Teocalli, reached by 120 steps, once stood; and farther out toward the lake excavation discloses layer after layer of art remains representing successive occupations, the lower characterized by the rudest kind of pottery. At Texcoco, on the eastern side of the lake, there are still meagre traces of a number of structures, probably pyramids, and numerous carvings on stone and minor relics of clay.

On the hill of Texcocingo, a few miles beyond Texcoco, there are unique remnants of ancient chambers, and foun-

tains and stairways and statuary carved in the solid rock. The hill itself, several hundred feet in height, was in the period of Nezahualcoyotl fairly remodeled by the cunning chisel of the sculptor, and masked and crowned with artificial structures.

Among the ruins of San Juan Teotihuacan, 25 miles N. of Mexico, are two massive pyramids which overlook the crumbling ruins of a once-extensive city, the history of which is almost wholly lost. Aside from the pyramids, the most striking feature is the so-called street of the dead, a broad highway over half a mile in length, bordered by ruined temples, *teocallis*, and other structures. The larger pyramid stands a little to the E. of the highway, and is surrounded by earthen walls and low mounds. It is about 200 feet high, and about 735 feet square at the base; the summit is truncated, and measures 60 by 90 feet. The smaller pyramid is about 140 feet high, and approximates 500 feet square at the base, the flattened summit measuring about 40 by 60 feet. These structures appear to be composed of somewhat heterogeneous materials, having been finished with coatings of cement, and possibly to some extent with facings of stone. There are signs of narrow terraces, and originally spacious stairways probably led up to the temples that crowned the summits. At the south base of the smaller pyramid the roadway expands into a large plaza, near the center of which is a small mound; at the base of this lies a much-mutilated idol of large size and another, found among the mounds on the west side of the court, has been removed to the Muséo Nacionál.

Cholula.—Next in interest to Teotihuacan is Cholula, a more recent center of Toltec power, situated some 60 miles to the S. E. of Mexico and a few miles W. of the city of Puebla. The pyramid found here is one of the most noted aboriginal structures in America. It was stormed and taken by Cortés, by whom the native temple crowning its summit was destroyed and replaced by a Roman Catholic church. It rises abruptly from the plain on the E. to the flat summit, and descends on the W. in a number of terraces, now not clearly defined. Excavations on the N. and E. show a mixed construction, a succession of accumulations composed of adobe bricks, earth, and cement.

Xochicalco.—The ruins of Xochicalco, about 65 miles S. W. of the city of Mexico, are exceedingly interesting. The principal structure is situated upon the summit of an oblong conical hill 2 miles in circumference and 400 feet high. This is surrounded by stone terraces and pierced by mysterious galleries and chambers not yet satisfactorily explored. Like the hill of Texcocingo, this "hill of flowers" was probably at one time fairly remodeled by art and covered with walls and buildings. The summit is level, and is said to measure 280 feet by 328 feet. It is surrounded by a wall, and occupied by a number of ruins, the principal of which is a pyramidal structure 58 by 68 feet at the base, and retaining a height of 20 feet or more. The walls are built of large, accurately dressed blocks of porphyry, brought apparently from a distance of several miles; they contract from the base to a height of perhaps 8 feet; above this they rise vertically for 4 or 5 feet, and then expand in a wide cornice. Above this are remnants of a second story, and it is said that originally there were several stories. the full height being given traditionally as 65 feet. The effect thus suggested would have a close general resemblance to that of the remarkable pyramid of Papantla near the Gulf coast, 150 miles N. W. of Vera Cruz. The entire surface is covered with mythic figures sculptured in low-relief. This structure, which has decided points of resemblance to other important architectural remains in Mexico and Central America, is not assigned, even traditionally, to any particular people.

Mitla.—According to Charnay the remains at Mitla, 15 miles S. E. of Oaxaca, are now reduced to three pyramids and six palaces. The best-preserved group consists of three buildings surmounting low mounds of earth and stone, and forming three sides of a square court. The opposing structures on the E. and W. are nearly obliterated, but that on the N. is well preserved. This building has a T-shaped plan, and was entered from the court by three doorways. The entrance is into a court 36 feet wide and 130 feet in length, along the middle of which is a row of tapering porphyry columns, six in number, that once supported the roof. The walls are faced outside with neatly cut stone in large blocks, laid to form sunken panels of varying size, in which by means of stucco a series of tasteful geometric decorative patterns have been worked. The floor is paved with flat stones, and the inner surface of the walls is of unhewn stone; both were originally plastered. The pyramids are reduced to shapeless mounds. According to Zapotec tradition, Mitla was a great religious center.

Oaxaca furnishes a number of less important groups of ruins, as at Monte Alban, Zachila, and Tehuantepec.

The state of culture attained by the most advanced of the Mexican nations was that of well-advanced barbarism, and if we are to judge by the originality and apparent virility of their genius, there is a strong probability that had they been left alone to work out their destiny they would have passed gradually into the succeeding stages of civilization and enlightenment.

Authorities.—Lord Kingsborough, *Antiquities of Mexico* (1830, etc.); Bancroft, *The Native Races of the Pacific States* (5 vols., 1875); Charnay, *The Ancient Cities of the New World* (1860); Bartlett, *Narrative of Explorations* (1854); Chavero, *Mexico, á traves de los siglos*; Nadaillac, *Prehistoric America.*

W. H. Holmes.

Mexico [from Aztec *Mexitl*, name of a tutelary divinity; Span. *Estados Unidos Mexicanos*, Mexican United States]: a federal republic of North America, occupying the whole width of the continent between the U. S. on the N. and Guatemala and British Honduras on the S. E.; limited on the E. by the Gulf of Mexico and the Caribbean Sea, and on the W. and S. W. by the Pacific Ocean. The main portion, which has been aptly compared to a cornucopia in form, is about 1,950 miles in extreme length from N. W. to S. E., and 750 miles wide in the northern part, dwindling to 140 miles at the Isthmus of Tehuantepec. Besides this main body the republic includes the two peninsulas of Lower California on the N. W., nearly separated by the Gulf of California, and Yucatan, a northerly projection of the southeastern end, between the Gulf of Mexico and the Caribbean Sea. Owing to these peninsulas the coast-line is very extensive, aggregating over 6,000 miles.

Topography.—The main portion of Mexico is essentially a high plateau, framed and traversed by mountain ranges and descending by terraces to more or less extensive strips of lower land on the coasts. The plateau, in Mexico and Puebla, is about 8,000 feet in average height above the sea; thence it falls northward to 3,600 feet at El Paso del Norte. On the western side it is bordered by an almost unbroken mountain chain, the Sierra Madre, which enters the republic from Arizona and traverses it in a S. S. E. direction. In its northern part the axis of this range is at least 250 miles from the western coast, descending to it by a series of terraces, but sharply cut down on the eastern or plateau side; farther S. it is much nearer the ocean. Several rivers cut through the Sierra Madre, forming deep valleys or cañons. The mountains on the eastern side of the plateau are parallel to the Gulf coast and at no great distance from it; but they form rather a series of groups than a connected range. The highest peaks are southward, in Vera Cruz, where the Cofre de Perote attains 13,415 feet. Between lats. 19° 30′ and 18° 30′ an irregular line of mountains, sometimes called the Cordillera de Anahuac, may be traced E. and W. across the country; it does not form a continuous chain, but it embraces all the highest masses and all, or nearly all, the active volcanoes of Mexico. Beginning at the W., the most remarkable peaks are the Nevado de Colima, 14,365 feet, and the Colima volcano, 12,743 feet (these two nearly in the line of the Sierra Madre); the isolated recent volcano of Jorullo in Michoacan; the group formed by Popocatepetl (an active volcano), 17,798 feet, and Ixtaccihuatl, 16,076 feet; Malinche, 13,575 feet; Orizaba (an extinct volcano, also on a line with the eastern border of the plateau), which, according to Scovell and Bunsen, rises to 18,314 feet, being the highest mountain in Mexico, and, with the probable exception of Mt. St. Elias, the highest in North America; and, finally, the active volcano of Tuxtla, near the Gulf coast, S. E. of Vera Cruz. Between and near these mountains there are evidences of plutonic action in numerous extinct craters; and it is noticeable that the volcanic Revillagigedo islands in the Pacific and the Greater Antilles in the West Indies lie in the same line. S. of the Cordillera de Anahuac the whole of Southern Mexico is essentially mountainous, though the ranges are to some extent broken in the Tehuantepec Isthmus; the axes of the ranges, as well as the coast-lines, trend E. and W. Parallel to the Pacific coast the Sierra Madre del Sur is continued into Guatemala. The plateau falls gradually northward, and is divided by subordinate ranges into well-marked basins, which, in turn, are

varied with hills. The best known of these basins is that called the Valley of Mexico or Anahuac, about the city of Mexico; it is over 7,500 feet above the sea, completely inclosed and partly occupied by several small lakes. The *Bajio* of Guanajuato is somewhat similar in character, and there are other basins to the N. W. and N. E. In Northern Mexico the Bolson de Mapimi occupies Southeastern Chihuahua and the adjacent parts of Coahuila and Durango. It is a vast basin, probably at one time the bed of a great inland lake, and still containing shallow bodies of alkaline water which often dry up entirely; but most of the Bolson is completely dry and uninhabitable, forming the Chihuahua desert. The rivers of the plateau have cut deep cañons, as in Jalisco, or wide valleys, as on the eastern side, and along these the lowlands of the coast are often continued far into the interior. The traveler in Mexico is seldom out of sight of high hills or mountains; and the endless variety of surface, with the corresponding differences of vegetation, make Mexico one of the most picturesque countries in the world.

The narrow peninsula of Lower California is little more than a rocky continuation of the Sierra Nevada. Yucatan, except in its southern part, is low; and the northwestern part (Campeachy), with Tabasco, contains a wide strip of forest-covered alluvium.

Islands.—Most of these are near the coast, and unimportant; the most notable are Cozumel, E. of Yucatan; Tiburon and Guarda, in the Gulf of California; and the Tres Marias, off San Blas. The outlying Revillagigedo group, in the Pacific, is sterile and nearly or quite uninhabited.

Harbors.—The Pacific coast has several excellent harbors, including the fine bays of Acapulco and San Blas and the smaller one of Mazatlan. The Gulf ports are all more or less open, and some are mere roadsteads. Vera Cruz, the most important port of the republic, has only a small harbor, imperfectly sheltered by a reef, and during northers ships have frequently been wrecked before the city. An extensive breakwater, now (1894) in course of construction, is intended to furnish an effectual shelter.

Rivers and Lakes.—The rivers of Mexico generally rise on the plateau or among the mountains, rapidly descend to the eastern or western lowlands, and, after passing through a small extent of alluvial land, enter the Gulf or the Pacific. They are therefore essentially highland streams, generally small, swift, obstructed by rocks, falls, and rapids. A few only are navigable for short distances, especially the Grijalva and its branch, the Usumacinta, in Tabasco. The former is regularly ascended by small steamers to San Juan Bautista, 90 miles, and during floods considerably farther; and the latter is said to be navigable for 150 miles, but is very crooked. The Rio Grande del Norte or Rio Bravo, on the confines of the U. S., is 1,500 miles long, or much longer than any exclusively Mexican river; but it is navigable only for a short distance and for vessels of light draught. The Pánuco, on the northern boundary of Vera Cruz, forms, with its connecting channels and lagoons, a waterway of some importance; and numerous small rivers of Vera Cruz, Tabasco, and Campeachy admit light-draught vessels near their mouths. Yucatan has no rivers of importance. On the Pacific side the largest rivers are the Lerma, or Rio Grande de Santiago, flowing through Jalisco and forming a deep cañon, and the Mescala, or Rio de las Balsas, which rises in Puebla and reaches the ocean on the confines of Guerrero and Michoacan. Neither of these is navigable; the scheme for improving the Mescala as a means of interoceanic communication is probably impracticable. The rivers of Sonora, though of considerable length, are useless as waterways. The Colorado enters the northern end of the Gulf of California, flowing for a short distance through Mexican territory. The largest Mexican lake is the beautiful Lago de Chapala, on the confines of Jalisco and Michoacan. Various small lakes are scattered over the plateau, the most important being those about the capital, MEXICO (*q. v.*). The swampy depressions of the Bolson de Mapimi hardly deserve the name of lakes. Of the many lagoons along the Gulf coast the most important are the Laguna de Terminos, in Campeachy, and the Laguna Madre, in Tamaulipas.

Geology.—The very complicated geology of Mexico has been studied only in fragments, and no clear general statement of it can yet be given. The higher mountains, especially of the Sierra Madre, are formed of granite, which passes under the general surface of the plateau; but it is here covered and in great part hidden by a tangle of eruptive and metamorphic rocks—porphyries, basalts and trachytes, schists, and crystalline limestones—and these contain the richest mineral deposits. The recent volcanic action along the east and west belt of the Cordillera de Anahuac has resulted in extensive deposits of lava and ash. In the northern and eastern parts of the plateau lower spaces, between the mountains, are largely occupied by unaltered limestones and sandstones, mostly of Mesozoic age. Generally the coast belts show metamorphic and eruptive rocks; but in some places, principally along the Gulf, there are Quaternary deposits or recent alluviums. Yucatan appears to be largely formed of Tertiary limestones. For *Minerals*, see below.

Earthquakes, though frequently felt in Southern and Western Mexico, are seldom severe, and have never, within historic times, been very destructive.

Climate.—From the snow-clad peaks to the hot and moist coast lands and the dry northern deserts, Mexico presents every possible gradation of climate; but, owing to the terraced character of the plateau edges, three zones of temperature are pretty clearly defined in the inhabited lands. Mexicans distinguish these as the *tierra caliente*, hot or tropical land, extending to about 3,000 feet in the latitude of Mexico; *tierra templada*, temperate, 3,000 to 6,000 feet; and *tierra fria*, cold, above 6,000 feet. The latter embraces all the higher parts of the plateau, and is cold only in a relative sense, the climate being, in fact, very mild and equable; at Mexico city, for example (7,350 feet), the mean temperature is about 60° F., commonly descending to 45° or 40° in the early morning, but seldom to the freezing-point. At higher elevations and farther N. the temperature is of course more severe. The *tierra templada*, especially on the terraces facing the Gulf, is called, with reason, the "paradise of Mexico," combining as it does a balmy climate with the most magnificent scenery and a wealth of semi-tropical vegetation. In the coast regions of the *tierra caliente* the mean temperature varies at different points from 75° to 85° F. In general, the winter months are characterized by a somewhat lower thermometer, less frequent rains, and on the Gulf side by frequent "northers," or storms from the N., very destructive to shipping and accompanied by a sudden lowering of temperature. During the summer months the heat in many parts of the *tierra caliente* is oppressive; and at some of the ports—notably Vera Cruz, Progresso, Tampico, Acapulco, Mazatlan, and Guaymas—is nearly always accompanied by epidemics of yellow fever; these rarely extend to the *tierra templada*, and never to the *tierra fria*. Most of Eastern and Southern Mexico has an abundant rainfall. The rainy season, where it can be distinguished, generally extends from May to September; but along the Gulf no part of the year can be called dry; and in parts of Tabasco and Campeachy there is a second rainy season in January and February. The northern and northwestern states, with Lower California, are deficient in moisture except in favored places; and the great Bolson de Mapimi is so dry that much of it is uninhabitable without irrigation. See CLIMATE.

Vegetation.—No country in the world shows so many variations in the aspect of plant life as Mexico. In a few hours' ride one may pass through pine-forests, oak glades, weedy slopes, plains or ravines bristling with cacti, tangled scrub, heavy tropical jungle, and bright-green alluvial meadows; and each of these seems, for the time being, to cover the whole country. The very irregular distribution of the climate zones is evident when one finds in the heart of the plateau valleys filled with tropical growth or fields of sugar-cane, while above them may tower pine-clad mountains and snowy peaks. Sometimes the types of vegetation are strangely combined; thus in the mountains of Guerrero palm-trees grow side by side with pines at the level of 7,500 feet. Broadly speaking, the plants of the *tierra caliente* are tropical in character, those of the *tierra templada* are semi-tropical, and those of the *tierra fria* resemble the temperate flora of the U. S. True forest is generally confined to the mountain-sides and to some alluvial flats along the coast, especially on the Gulf side; the latter is tropical jungle, and the range upward extends to woods principally of oaks, and finally to the high pine-forest. The coast lands, where not alluvial, are generally occupied with a low, scrubby growth, with numerous cacti and spiny plants; and this is prevalent over much of Yucatan. The plateau is commonly more or less open. The number of useful indigenous plants is very great. They include mahogany, tropical cedar, ebony, rosewood, and a large number of other cabinet woods in the lowlands, besides oak and pine in the mountains; rubber, copal, and various gums; jalap, cassia, ipecacuanha, and many other medicinal species; logwood, arnatto, indigo, cartamo,

and other dyes; and vanilla. Two species of *Agave* are particularly valuable, and both are now cultivated on a large scale: the *A. americana*, or the maguey-plant of the high plateau, the juice of which, fermented, is chicha, a national beverage; and the henequen-plant of the lowlands, yielding sisal hemp, now the principal product of Yucatan. There are numerous other vegetable fibers, but little utilized.

Zoölogy.—Mexico, as a whole, is included in the neotropical zoölogical region (see AMERICA, SOUTH), and is generally united with Central America as a sub-region, the Central American. This sub-region, however, is not very clearly defined; in fact, the animals of Mexico, as a whole, closely resemble those of Brazil, differing only in a certain proportion of species and genera. There are the same or very similar monkeys, jaguars, armadillos, rodents and opossums, toucans, parrots, humming-birds and trogans, serpents, insects, and land-shells; and the same types of fishes and alligators are found in the rivers. Owing to the great variety of surface and elevation the fauna is exceedingly rich and varied, though the larger species tend to extinction. As the boundary of the neotropical region nearly corresponds with the northern limit of Mexico, there is naturally a mingling of forms with those of temperate North America. In the hot lands, for example, the jaguar ranges into Texas; and the buffalo formerly roamed over the high plains of Northern Mexico. All the European domestic animals have been introduced.

Cochineal-culture, formerly very important in the southern states, is now almost abandoned, the dye being largely superseded by chemical substances; in 1891 less than $150,000 worth of cochineal was exported. The pearl-fisheries of the Gulf of California were formerly very productive, and are still important.

Minerals.—In mineral wealth Mexico stands in the first rank, and her riches are practically inexhaustible. Nearly all the metals exist; but among them silver is so prominent that it has absorbed much of the enterprise of the country, and may be said to have shaped its history. Among the Aztecs gold, being easily obtained in placer mines, was the chief precious metal, and it first attracted the cupidity of the Spaniards; but as the conquest extended from Mexico toward the N. rich silver districts were discovered in quick succession, the most renowned being those of Guanajuato, San Luis Potosí, Zacatecas, and Durango. These attained an immense development in the seventeenth and eighteenth centuries, when enormous fortunes were made in them and fortunate proprietors sometimes purchased titles of nobility bearing the names of their mines. In 1800 Humboldt estimated that the Veta Madre, or main lode of Guanajuato, had yielded one-fifth of the silver then current in the world. The Valencia mines are said to have produced $226,000,000 from 1776 to 1826, and the Catorce mines of San Luis Potosí yielded $150,000,000 in seventy-seven years. Thousands of mines have been abandoned, especially in Guanajuato, but new ones are constantly being opened. At present the great silver regions are Zacatecas, San Luis Potosí, Chihuahua, Coahuila, Guanajuato, and Hidalgo; but there are mines in nearly all the states. The most common method of reduction is the *beneficio de patio* or mercury process, invented by Bartolomé de Medina in 1557. The hyposulphate or leeching process is now employed in several of the northern districts, and some ores are exported to Germany for smelting. The silver ores generally contain a percentage of gold, and most of the gold now obtained in Mexico is a surplus product of the silver mines. Placer-gold mines are profitably worked in Mexico, Michoacan, Guerrero, and some of the northern states. Cinnabar is widely distributed, but during the colonial period the extraction of mercury was restricted by law in order to protect the Spanish mines; and it is only of late years that the deposits have been worked, principally in Morelos, Guerrero, and San Luis Potosí; owing to the great demand for mercury in silver reduction, these mines bid fair to be largely developed. Lead occurs principally in connection with silver ores, but also separate, especially in Hidalgo and Querétaro, where it is extracted to some extent. Copper deposits are said to be very extensive, notably in Michoacan, Chiapas, and Sonora, but they are generally neglected; the mines of Lower California yield 5,000 tons yearly. Tin, zinc, platinum, bismuth, antimony, etc., have been reported, but have never been utilized. Iron (magnetic ore principally) occurs in immense and very rich beds. The celebrated Cerro del Mercado, near the capital of Durango, is a hill 640 feet high, composed almost entirely of iron ore, which averages 70 per cent. of metal; it is calculated that the hill contains 300,000,000 tons. This and other deposits hardly less rich have been worked only on a small scale, owing principally to the lack of transportation and of coal. Beds of the latter have lately been reported from Coahuila, Sonora, Michoacan, Puebla, Oaxaca, Guerrero, Nuevo Leon, etc. The Coahuila coal is now exported to the U. S. in considerable quantities. That of Sonora is anthracite, and is believed to be very valuable. Efforts are being made (1894) to develop the beds of Puebla and other states. Sulphur exists in large quantities in the volcanic craters; salt is obtained in the coast lagoons and in mines of the northern states, and asphaltum and petroleum are said to be found in paying quantities. Marble of fine quality is mined in Mexico, Nuevo Leon, etc., and appears to be widely distributed. The beautiful Mexican onyx (a semi-transparent alabaster) is quarried in Puebla, and is largely used in the manufacture of ornamental objects. Many kinds of precious stones are reported, but the only ones of importance at present are opals; these are extensively exported, and the best are of fine quality and often very large; the most productive mines are in Querétaro and Guerrero.

Calculations of the amount of precious metals which have been produced by Mexico are always defective. The records of mints and other sources show an output from 1521 to 1891 of $3,570,370,247 in silver and $276,970,173 in gold, but these are probably very far below the true totals. (See *Mints and Coinage* below.) Mining enterprise is now (1894) more active than at any previous period. The aggregate annual product of gold and silver is estimated at from $40,000,000 to $42,000,000. Bancroft calculates that the entire mineral product of Mexico reaches $67,000,000 annually. About 240,000 men are regularly employed in the mines.

Political Divisions, Area, and Population.—Mexico has an area of 767,005 sq. miles, and a population (1895) of 12,578,861. It is divided into twenty-seven states, two territories, and a federal district. The following table exhibits the situations and areas of the several states, with their population, in 1895:

STATES.	Area in sq. m.	Population.
GULF STATES:		
Yucatan	35,203	298,039
Campeachy	18,087	88,121
Tabasco	10,072	134,794
Vera Cruz	29,201	855,975
Tamaulipas	32,128	208,102
PACIFIC STATES:		
Chiapas	27,222	315,120
Oaxaca	35,382	882,529
Guerrero	24,996	417,621
Michoacan	22,874	889,775
Colima	2,272	55,677
Jalisco	31,846	1,107,863
Sinaloa	33,671	258,845
Sonora	76,900	191,281
CENTRAL STATES:		
Puebla	12,204	979,723
Tlaxcala	1,595	166,803
Morelos	2,773	159,800
Mexico	9,247	837,368
Hidalgo	8,917	548,039
Querétaro	3,556	227,223
Guanajuato	11,370	1,047,238
Aguas Calientes	2,950	103,645
NORTHERN STATES:		
San Luis Potosí	25,316	570,814
Zacatecas	24,757	452,720
Durango	38,009	294,366

Coahuila	63,569	235,638
Chihuahua	87,802	266,831
TERRITORIES:		
Lower California	58,328	42,245
Tepic	11,275	148,776
Federal district	463	484,608
Totals	767,005	12,578,861

Of this population about 4,500,000 are Indians, descendants of the ancient inhabitants of the country; 5,000,000 are mestizoes or persons of mixed white and Indian (and sometimes Negro) blood; and 2,400,000 are of European (mostly of Spanish) race. Some of the Indians, as the Otomí tribes, show little aptitude for civilization, and others, in the northern states and territories, are practically independent. In general both the Indians and mestizoes show a desire to advance themselves, and frequently they attain the highest social and political positions; President Juarez, for example, was a pure-blooded Indian.

Mexicans are often accused of indolence and lack of enterprise. Considering the great progress which the country has made since 1870, these defects can hardly be charged on

the nation as a whole, though they doubtless exist in some individuals. The long civil wars retarded improvements, encouraged lawlessness, and made the peasant careless of a future whose course he could not foresee. To some extent, at least, they fostered independence and self-reliance, and the many political exiles brought back to their country the advanced ideas which they had gathered abroad. The better class of Mexicans are brave, liberty-loving, intelligent, and quick to adopt new customs. They are hot partisans, but are beginning to see the necessity of majority rule. Slavery is not merely abolished, but its influence is now hardly felt; workmen are well treated and respect themselves, and class distinctions are hardly known. Above all the people are optimistic, and have a thorough belief in their country and its future. Gambling and the lower forms of sport—the bull-ring, cock-fighting, etc.—still have a strong hold on the people, but intelligent men are waking up to the harm which they produce.

Government.—The constitution of Feb. 5, 1857, is in force, but has been several times amended. It is very similar to that of the U. S. The states are free and sovereign in the control of their internal affairs. The federal executive is a president, chosen for four years by indirect popular suffrage. He may be re-elected. In case of his death or absence his place is filled by the president of the senate for the preceding month; formerly the succession was vested in the president of the Supreme Court. The president is assisted by a cabinet of seven secretaries, appointed and removable by him. Congress now consists of a senate and house of deputies. There are two senators from each state and two from the federal district, elected for four years, half the seats falling vacant every two years. Deputies are elected for two years in the ratio of one for every 40,000 inhabitants. The eleven justices of the Supreme Court, with the fiscal and attorney-general, are elected by popular suffrage for terms of six years. The constitution guarantees freedom of speech and religion and freedom of the press, subject only to the regular action of the laws. The great improvement of the country is shown in the marked decrease of crime; the laws are now effectually administered in all except the wildest regions. Brigandage, once the scourge of Mexico, has been nearly extinguished by the action of the severe but salutary law which condemned every brigand to death and made his trial a summary one. The army has been reduced (1894) to about 40,000 men. By the addition of the permanent and general reserves it can be increased to 160,000. The navy is very small.

Religion and Education.—Most Mexicans are Roman Catholics, and until 1857 the Roman Catholic was the state religion. Ecclesiastics had great influence in political affairs, and the Church controlled education and absorbed much of the wealth of the country. Church and state are now absolutely separated, and the laws assure perfect freedom of worship. By the law of Sept. 25, 1873, it was declared that the nation recognized no state religion. Marriage is a civil contract. Monastic orders are prohibited, and (at least in the larger cities) the clergy must wear secular dress in the streets. Ecclesiastical institutions are not allowed to acquire real estate. Public schools are supported by the national and state governments, and are unsectarian. Primary education is compulsory in most of the states, and all classes show a commendable desire to have their children taught. In 1898 there were in the republic 12,358 schools of all grades, with 828,078 pupils. The National University, opened in 1553, has been abolished, its place being taken by schools of law, medicine, and engineering, which are in a flourishing condition. There are various other institutions for higher education in Mexico and in the state capitals supported by public or private means and by the Church. The principal libraries, museum, art school, observatory, etc., are at the federal capital. Literature, as in other Spanish-American countries, has been somewhat unequally developed. In history and the kindred studies of archæology, ethnology, and bibliography Mexican scholars stand deservedly high, but in natural sciences, poetry, and fiction few names of note have appeared. Musical talent is general, and both music and drama are well supported.

Mints and Coinage.—The silver *peso* or dollar is the standard of value; it weighs 27,073 grammes, or 417·7903 grains, 9,027 parts in 10,000 being pure silver. The gold 20-peso piece weighs 522·2340 grains, 875 parts in 1,000 being pure gold; the proportionate value of these, and the value of the silver peso in foreign exchange is of course subject to fluctuations. There are eleven Government mints, which are leased to private individuals, but are subject to inspection. Any person may have gold or silver coined at these mints on the payment of 4·618 per cent. on gold and 4·41 per cent. on silver coins. The total amount coined during the fiscal year 1899–1900 was—silver, 19,979,000 pesos; gold, 698,740 pesos; besides 10,694 pesos in copper cents. A large amount of coin, especially silver, is exported, and the peso is current in many Spanish-American and even Asiatic countries. Counterfeit coins are frequent in the rural districts. Ten or twelve private banks issue banknotes, but no Government paper-money is in circulation.

Weights and Measures.—The metric systems have been introduced, and are coming into general use in large places. In the interior the old Spanish weights and measures are still generally used. The *libra* (pound) is equal to 0·46 kilog.; the *arroba* is 25 *libras*. The *vara* (yard) is 0·837 meter, or 2 ft. 8·9 in.; the league is 6,666⅔ varas.

Finances.—On June 30, 1892, the public debt was officially stated as follows (in Mexican dollars):

External debt, £16,500,000 (at par)	$82,500,000
Internal debt—	
Consolidated 3 per cent.	31,642,850
Railway bonds (Government lines)	22,689,875
Railway debts	15,926,608
Other debts	21,640,177
Total	$91,949,510

In 1900 the outstanding gold debt amounted to £22,628,920; outstanding silver currency bonds to 140,000 dollars. The internal debt July 30, 1899, was 114,542,648 dollars silver, the floating debt 953,619 dollars silver. About 58 per cent. of the revenue is derived from import and export duties, 35 per cent. from internal taxation, and the rest from mints and other sources. The revenue of late years has increased steadily, while expenses have been much reduced; in the fiscal year of 1891–92 the revenue exceeded the expenditures for the first time in the history of the republic. Owing to the fall in the price of silver, the financial conditions since then have been less favorable; but they have been met by a rigid system of economy. In 1899–1900 the revenue was 64,261,078 dollars, the expenditure 58,309,934 dollars. It should be remembered that Mexico has granted in railway subsidies, from 1870 to June 30, 1892, no less than $93,500,000, of which nearly $65,000,000 had been actually paid up to the latter date. In fifteen years $522,000,000 has been expended in public improvements, while the country has met its other obligations.

Means of Communication.—The first railway line—that from Vera Cruz to Mexico, noted for its magnificent scenery and remarkable engineering works—was completed in 1872. Since then, and especially since 1880, the republic has shown great activity in railway building. In 1892 the total length of all Mexican lines in operation was 6,330 miles. These include the Mexican Central, from Mexico to El Paso, and the National, from Mexico to Laredo (these two bringing the capital into connection with the railway system of the U. S.); the Inter-oceanic, from Vera Cruz to Acapulco, etc. Most of these have been built by the aid of Government subsidies with foreign or native capital. The federal Government is now (1894) engaged in the construction of a line across the Isthmus of Tehuantepec. The republic has about 19,000 miles of common roads, some of them good but the greater part execrable, especially in the mountain districts. The lack of bridges is especially vexatious to the traveler by diligence or on horseback, as he is often detained for days by swollen streams. In 1892 there were 31,842 miles of telegraph, mostly national or state property. The telephone, electric light, and tram-cars have been introduced in larger places.

Agriculture.—On the higher lands maize and beans are the most important agricultural products, and the food-staples of the poorer classes; wheat and other cereals grow well in some places, but are not extensively cultivated. Maguey is largely grown in many places, and city markets are regularly supplied with pulque by a special railway service on some lines. In the *tierras templadas* and *calientes* the principal crops, besides maize and manioc, are coffee of excellent quality, especially in Vera Cruz and Colima; tobacco in Vera Cruz, Jalisco, Oaxaca, etc.; cacao in Tabasco and Campeachy; rice in Morelos and the Gulf States; henequen in Yucatan; and sugar-cane in nearly all the states. The cultivation of tropical fruits on a large scale has been undertaken along the Gulf coast, the crops going to the New

Orleans market. Cattle, sheep, and goats are largely bred in some of the northern states.

Manufactures.—The cotton-factories of Puebla, Jaliseo, Vera Cruz, Coahuila, Tlaxcala, and the federal district now employ about 25,000 operatives, and the annual product—principally coarse *manta* or sheeting—is valued at $15,000,000. Carpets, woolen underwear, and cloths are now produced on a considerable scale. There are numerous flour-mills and distilleries, a few breweries, soap-factories, paper-mills, powder-mills, tile-factories, etc. Vera Cruz is the principal center for the manufacture of cigars and cigarettes, though they are made all over the country. The peculiar broad-brimmed Mexican hats, saddles, silver ornaments, jewelry, etc., are generally made at small establishments, but they are of fine quality and the aggregate product is very considerable; to these may be added furniture, clothing, books, etc. The handiwork peculiar to the Indians should be mentioned. It includes various kinds of terra-cotta and glazed pottery, often highly artistic and much prized; feather-work, hammocks, artificial flowers, etc.

Commerce.—The total exports for the fiscal year 1892–93 were valued at $87,509,221, Mexican money. They included the following items:

Silver coin	$27,170,865	Hides	$2,067,156
Silver	6,732,801	Tobacco	1,459,690
Silver ore	10,940,750	Gums	703,572
Argentiferous lead	7,402,641	Ixtle	617,300
Copper	860,379	Vanilla	969,612
Henequen	8,893,071	Woods	1,673,738
Coffee	8,727,119		

The exports, including precious metals, at present largely exceed the imports as recorded. The U. S. receive about two-thirds of the exports and furnish more than half the imports; much of the remaining trade is with England. See Mexico in the Appendix.

History.—Before its discovery by the Spaniards Mexico was occupied by several Indian races, the Nahuas (Aztecs, etc.) being dominant in the southern part of the plateau, with their principal towns about the lakes in the valley of Mexico. (See Aztecs and Mexican Antiquities.) The exploration of the Gulf coast by Grijalva (1518) was followed by the Spanish invasion of the country (1519) and the taking of the Aztec capital, Tenochtitlan, in 1521. (For events of the conquest, see Cortés, Hernando, and Montezuma.) The Spanish colony of New Spain, thus formed, was erected into a viceroyalty, and rapidly became the richest European possession in the New World, with the single exception of Peru. From the new capital at Mexico conquest was pushed over the whole plateau and both coasts, and eventually far into the present territory of the U. S. The first viceroys ruled all the Spanish possessions in North America from the southern boundary of Costa Rica to Florida, as well as the West Indies and the Spanish East Indies. Gradually their authority was restricted in the outlying territories, and in the eighteenth century the East Indies and Guatemala, or Central America, were entirely separated. New Spain was divided into the three "kingdoms" of New Spain, New Galicia, and New Leon, corresponding to Southern, Northwestern, and Northeastern Mexico, to which were added the Territories of Texas, New Mexico, and California, with an undefined extent northward. This vast territory was subdivided into many "intendencies," the bases of the modern states. In the latter part of the eighteenth century the northern part was separated as the "Provincias Internas," though it was reunited to Mexico after the independence. The viceroys ruled with great splendor, and the country experienced no greater disturbances than a few Indian wars and descents of buccaneers on the coast. Enormous fortunes were amassed in the silver mines, in the East Indian trade, which centered at Acapulco, and often by speculation and bribery in office; but commerce was heavily fettered to protect the Spanish monopolies. All important civil and ecclesiastical offices were absorbed by Spaniards. The Creoles or whites born in the country had few privileges, and suffered from unjust and heavy taxation and oppressive laws; and the Indians and mestizoes were kept in a state of degradation and semi-servitude. To these grievances must be added the restrictions on literature and education, the tyranny of the Inquisition, the lack of security for personal liberty, and the venality of the courts. Hatred of the Spaniards naturally produced a desire for independence which found its opportunity in the disturbed state of Spain during the Napoleonic wars. On Sept. 16, 1810, a revolt broke out near Querétaro headed by the priest Hidalgo. It soon assumed formidable proportions, and for a time threatened to drive the Spaniards out of the country, but after several bloody battles it was suppressed and the leaders were shot. (See Hidalgo.) Small bands of insurgents kept up the struggle in the mountains, and the invasion of the northeastern provinces by Mina (1817) did much to foster the spirit of independence. Still loyalty to Spain was by no means dead, and when (1821) a young army officer named Iturbide advanced the plan of an independent Mexican empire under a Spanish Bourbon prince, it was eagerly seized upon even by the avowed republicans, and generally by the army. Iturbide and Guerrero marched on Mexico, and the last viceroy was forced to give in his adhesion to their plan. Spain refused to ratify this treaty with "rebels," and the first Mexican congress made Iturbide himself emperor (June, 1822). This outcome of the struggle was bitterly opposed by the old republicans. After a troubled reign of less than a year Iturbide was deposed and a republic was formed. (See Iturbide.) The term of the first president, Victoria (1824–28), was generally prosperous, but soon after it ended the republic was plunged into civil war, and for many years was subject to the military dictatorship of Santa Anna (*q. v.*). During this period Texas seceded and joined the U. S., leading to a war with that republic (1846–47) which terminated in the cession to the U. S. of all the territory N. of the Rio Grande, and California. The final deposition of Santa Anna (1854) opened the way to the reformed constitution of 1857, but this change involved the long and bitter struggle of the "Reform war," 1857–60. (See Comonfort and Juarez.) The triumph of the reform party under the Indian statesman Juarez was hardly accomplished before France interfered in the affairs of Mexico (1861), and after two years of war made the ill-fated Maximilian emperor. (See Maximilian.) The U. S. finally forced the French to withdraw, leaving Maximilian to his fate. He was soon defeated and shot by the republicans (1867), and Juarez, who had bravely upheld the constitution even when driven from the country, was reinstated, and ruled until his death. Under him the constitution of 1857 was cemented, and the modern era of progress and prosperity was inaugurated. Gen. Porfirio Diaz first attained the presidency in 1877 through a short civil war, but he has ruled with wisdom and firmness, and still (1901) holds the office. See also Spanish-American Literature.

Authorities.—History: Mora, *Méjico y sus revoluciones* (3 vols., 1836); Alaman, *Historia de Méjico* (5 vols., 1849–52); H. H. Bancroft, *History of the Pacific States* (*Mexico*), 6 vols., 1886–88 (a very complete bibliography in vol. i.); also *Popular History of the Mexican People*; Prescott, *Conquest of Mexico*; Noll, *A Short History of Mexico* (1890). Zoölogy and botany: The *Biologia Centrali-Americana*, edited by Godman and Salvin (in course of publication, 1894). General works, travels, and geography: Janvier, *Mexican Guide*; A. R. Conkling, *Guide to Mexico* (1866); *Hamilton's Mexican Handbook* (1883); Bureau of the American Republics, *Handbook of Mexico* (1890); H. H. Bancroft, *Resources and Development of Mexico* (1893); the works of Cubas, Orozco y Berra, Charnay, and Bandelier (on antiquities); Humboldt, Chevalier, Castro, and Brantz Mayer; the travels of Ward and Ober.

Herbert H. Smith.

Mexico: a state of the republic of Mexico; centrally situated in the southern part of the plateau, bordering on Querétaro, Hidalgo, Tlaxcala, Puebla, Morelos, Guerrero, and Michoacan. Area, 9,247 sq. miles; pop. 837,368 (these figures do not include the capital and federal district, which are surrounded by the state). Capital, Toluca. The surface is much broken by mountains of the Anahuac system. On the southern border the giant masses of Popocatepetl and Ixtaccihuatl are in plain sight from the city of Mexico; on the E. the irregular range called the Sierra Nevada separates the valley of Mexico from the plateau of Puebla; on the W. there are other high mountains; and the central range, called the Sierra de las Cruces, culminates in the Nevado de Toluca (14,020 feet), and divides the valley of Mexico from the somewhat similar but higher basin of Toluca. Some of the southeastern valleys are within the *tierra caliente*—i. e. below 3,000 feet—and grow sugar-cane and other tropical products. The silver mines of the state are very productive; mercury, gold, sulphur, and marble of excellent quality are mined. Cereals and maguey (for pulque-making) are the principal products of the higher lands. Mexico is one of the principal manufacturing states, making cotton and woolen cloths, glass and porcelain, saddlery, hats, etc. Public instruction receives much attention.

H. H. Smith.

Mexico (Span. *México*, or *Méjico*): capital and largest city of the Mexican republic; in the federal district; lat. 19° 25′ 45″ N., lon. 99° 5′ 15″ W., and about 7,350 feet above the sea (see map of Mexico, ref. 7–G). The valley of Mexico, in which it is situated, is an inclosed basin, 50 miles long by 35 miles broad, containing six shallow and more or less brackish lakes, some of them now little more than swamps. Formerly these lakes were larger and partly confluent. The site of the city was originally a marshy island in Lake Texcoco. Here, according to their own accounts, the Aztecs settled in 1325, calling their *pueblo* Tenochtitlan and sometimes Mexitl (apparently an appellation of the war-god, Huitzilopochtli), whence the modern name. The island was partially protected from floods by a dike, and was approached by causeways. The chiefs of Tenochtitlan became, during the fourteenth century, dominant over the southern part of the plateau. Opinions differ as to the extent of their power; but the drift of modern research is to reject the idea of an Aztec empire; probably the pueblos and tribes of the plateau remained in a state of semi-independence, though Tenochtitlan extorted tribute from them; some, as Tlaxtala, were certainly free. The Aztec capital was taken by the Spaniards in 1521, after most of the low buildings composing it had been destroyed. (See CORTÉS, HERNANDO.) Cortés made the mistake of building his capital on the ruins of the old city, though there was plenty of high ground near. The waters of the lakes have receded, and the city is now several miles from the nearest of them, though still approached by causeways over low and often swampy ground; canals, bordered by vegetable and flower-gardens, connect the outskirts with Texcoco and Chochimilco; the city drainage, heretofore, has been into the former lake. Having no outlet, these lakes swell with the summer rains, forcing back the polluted water into the city; during the colonial period the waters frequently rose so high as to flood the streets to a depth of several feet, and this during long periods. The inundations have practically ceased, partly owing to the natural decrease of the lakes and partly to the expensive dikes, and to a huge drainage canal which was constructed in the seventeenth century; but these did not dispose of the city sewage. Built on a sub-soil of swamp and without proper drainage, Mexico has always been an unhealthful place, especially in the poorer quarters; intestinal diseases and swamp fevers are very common, and there have been frequent epidemics of typhoid and typhus. Water quickly gathers in very slight excavations, so that it is impossible to dig cellars; the resulting dampness, together with the rarefied atmosphere at this elevation, often induces pulmonary complaints, especially among strangers. It has frequently been proposed to drain away all the lakes, at an enormous expense, and this may eventually be done. Works initiated under Maximilian had for their primary object the disposal of the city sewage, and secondarily the regulation of the level of the lakes. After many interruptions these works were essentially completed in 1894. They include a canal nearly 30 miles long and a tunnel of nearly 7 miles. With these and other sanitary measures, it is believed that the health of the city will be greatly improved. There are two fine aqueducts, bringing a somewhat inadequate water-supply from the hills; that of Chapultepec follows, very nearly, the line of an Aztec aqueduct. Mexico is regularly laid out, with moderately wide streets which cross each other at right angles, and are usually well paved and lighted; tram-cars run through the principal ones to several suburbs. The usual central square (now adorned by a garden) is faced by the cathedral, which is on or near the principal Aztec temple (*teocalli*). The present building was begun in 1573 and consecrated in 1645, though then far from complete; it is regarded as the finest church edifice in Spanish America, and the interior is elaborately decorated, some of the paintings, it is said, being by Murillo. Another side of the square is occupied by the Government palace, on the site of that of Montezuma; it was the residence of Cortés (partly burned by rioters in the seventeenth century, but rebuilt) and of the viceroys. It now contains the principal Government offices, senate chamber, hall of ambassadors, etc., and the Government pawn-shop, an important institution. Other buildings of interest are the offices of the Inquisition (now turned into a medical school), the mint (the oldest in the republic), custom-house, convent of Santo Domingo, various churches, and the numerous charitable institutions. Iturbide's palace, a very large structure, is occupied as a hotel. The Panteon contains many elaborate monuments, the finest being that in honor of Juarez. The better class of dwellings are solidly built of stone, with interior courts; living-rooms are generally on the second floor. The National Museum is especially rich in antiquities, including the sacrificial stone, hideous idols, etc., found near the site of the *teocalli*, and sculptures from the southern states and Yucatan; the mineral collection is very complete. There are several libraries, the most important, and perhaps the most valuable in America, being the Biblioteca Nacional, with 155,000 volumes (in 1892) and a priceless collection of historical manuscripts. The Academy of San Carlos contains more valuable paintings by old masters than any other art-gallery in America. There are excellent astronomical and meteorological observatories; several scientific schools receive Government aid, and are doing good work; and schools of law, medicine, pharmacy, engineering, technology, fine arts, music, etc., take the place of the old university. The city and federal district are well supplied with good public and private schools of all grades. The principal outdoor resorts are the Alameda, a public park and promenade with superb trees; the Paseo de la Viga, along a canal of that name; and the Paseo de Bucareli, continued to Chapultepec in the Paseo de la Reformas, and adorned with a fine bronze equestrian statue of Charles IV. and monuments to Columbus, Guatemotzin, and Cortés. Mexico is now connected by rail with most of the states and the U. S., and is a center of manufactures and commerce. Much of the trade is in the hands of foreigners. Pop. (1895) 344,377. The federal district has an area of 463 sq. miles, and a population of 484,608; it includes, besides the city, the towns or suburbs of Tacubaya, Guadalupe, Tlolpam, etc. H. H. SMITH.

Mexico: city; capital of Audrain co., Mo. (for location of county, see map of Missouri, ref. 3–H); on the Salt river, and the Chi. and Alton and the Wabash railways; 108 miles N. W. of St Louis. It is the seat of Hardin College (Baptist, opened 1872), and has a military academy, a national bank with capital of $50,000, 2 State banks with combined capital of $250,000, and 2 daily, a monthly, and 3 weekly periodicals. The industries comprise the manufacture of flour, fire-brick, wagons, and plows. Pop. (1880) 3,835; (1890) 4,789; (1900) 5,099. EDITOR OF "LEDGER."

Mexico: village; Oswego co., N. Y. (for location of county, see map of New York, ref. 3–G); on the Salmon creek, near Lake Ontario, and the Rome, Water. and Ogdensburg Railroad; 17 miles E. of Oswego. It contains 4 churches, 3 district schools, an academy, a weekly newspaper, and flour and grist mills, carriage-factories, corn-canneries, butter-dish factory, and agricultural-implement works. Pop. (1880) 1,273; (1890) 1,315; (1900) 1,249.
EDITOR OF "INDEPENDENT."

Mexico, Gulf of: a vast inland sea, corresponding in many ways with the Mediterranean; nearly surrounded by the U. S. and Mexico, and partially shut off from the Atlantic by the island of Cuba. It is connected with the Atlantic by two comparatively shallow channels known as the Straits of Florida and the Yucatan Channel. The former has a maximum depth of 344 fathoms and a cross-section of 11 sq. miles; the latter, with a greatest depth of 1,164 fathoms, has a cross-section of 110 sq. miles. These measurements, together with other data, obtained by the U. S. Coast and Geodetic Survey, show that only a part of the Gulf Stream comes from the Gulf, instead of the whole of it, as has been long supposed. The area of the Gulf, cutting it off by a line from Cape Florida to Havana, is 595,000 sq. miles. The 100-fathom line marking the true continental border is distant from the present shore about 6 miles at Cape Florida, 120 miles on the west coast of Florida and the north coast of Yucatan, and 130 miles opposite Louisiana and Texas. Should the surface of the Gulf be lowered 100 fathoms, 208,000 sq. miles, or one-third of its area, would be added to the land. The greatest depth is 2,119 fathoms. A submarine plateau to the N. W. of the center of the Gulf, and below 2,000 fathoms, is known as Sigsbee's Deep, after its discoverer. The northern part of the Gulf has been filled with sediment from the Mississippi, and many facts indicate that the bottom in that region is slowly subsiding on account of the weight of the silt deposited upon it. See also GULF STREAM. Consult *Report of Superintendent of United States Coast and Geodetic Survey for 1883–84*, pp. 619–621. ISRAEL C. RUSSELL.

Meyer, ADOLF BERNHARD, M. D.: ethnologist and ornithologist; b. at Hamburg, Germany, Oct. 11, 1840; was educated there and at the Universities of Göttingen, Vienna, Zurich, and Berlin. From 1870 to 1873 he traveled in the

Philippine and Malay islands; since 1874 he has been director of the Royal Zoölogical and Anthropo-Ethnographic Museums of Dresden. Dr. Meyer's contributions to ornithology and ethnology are numerous, and have appeared in the publications of the leading scientific societies of Europe. Besides these he has, as director, issued sixteen volumes of memoirs and reports of the Dresden Museum. Among his other works are *Abbildungen von Vogelskelette* (4to, parts 1–21, 1879–94); *Die Hirschgeweihsammlung zu Moritzburg* (folio, 62 plates, 1883–87); *Unser Auer-, Rackel-, und Birkwild und seine Abarten* (folio, with atlas of 17 plates, 1887); *Album von Celebestypen* (1887); *Album von Philippinentypen* (1885–89, with 82 plates); and *Gurina im Obergailthal* (Kärnthen, folio, 14 plates, 1885). F. A. Lucas.

Meyer, Eduard, M. D.: ophthalmologist; b. at Dessau, Nov. 13, 1838; studied at the Universities of Halle, Berlin, and Paris, graduating M. D. at Berlin in 1860; settled in Paris, in 1863, to practice his specialty. In 1869 he published *Maladies des yeux*, a work that has passed through a number of editions and has been translated into German, English, Spanish, Italian, and Russian. In 1882 he became coeditor of the *Revue generale d'ophthalmologie*. S. T. A.

Meyer, Georg Hermann, von, M. D.: anatomist and physiologist; b. at Frankfort-on-the-Main, Aug. 16, 1815; studied in the Universities of Heidelberg and Berlin, under Tiedemann and J. Müller, graduating M. D. from the latter school in 1837; in 1840 was privat docent in the University of Tübingen; in 1844 accepted the position of prosector at the University of Zurich, subsequently becoming Professor of Anatomy. His contributions to physiological anatomy are very valuable. Among his works are: *Lehrbuch der physiologischen Anatomie des Menschen* (Leipzig, 1856); *Die Statik und Mechanik des menschlichen Knochengerüstes* (Leipzig, 1873); *Unsere Sprachwerkzeuge und ihre Verwendung zur Bildung der Sprachlaute* (Leipzig, 1880).
S. T. Armstrong.

Meyer, Gustav, Ph. D.: philologist; b. at Gross-Strehlitz, Silesia, Nov. 25, 1850; studied at the University of Breslau; from 1871 to 1874 was teacher in the Gymnasium at Gotha; in 1876 became privat docent in Prague; since 1877 has been Professor of Comparative Philology at Graz in Steiermark; is a member of the Imperial Academy of Vienna; is author of *Die mit Nasalen gebildeten Präsensstämme* (1873); *Zur Geschichte der indogerm. Stammbildung und Declination* (1875); *Griechische Grammatik* (1880; 2d ed. 1886); *Albanesische Studien* (3 vols., 1883–92); *Essays und Studien zur Sprachgeschichte und Volkskunde* (1885); *Reiseskizzen aus Griechenland und Italien* (1886); *Albanesische Grammatik* (1888); *Griechische Volkslieder in deutscher Nachbildung* (1890); *Etymologisches Wörterbuch der albanesischen Sprache*. He is the first authority in the field of Albanian philology. Benj. Ide Wheeler.

Meyer, Heinrich August Wilhelm, Th. D.: Bible commentator; b. at Gotha, Jan. 10, 1800; studied theology in Jena; was pastor at Osthausen (1822), Harste (1831), Hoya (1837), Neustadt (1841); after 1848 he resided in Hanover, and there died June 21, 1873. As early as 1832 his labors as an exegetical commentator upon the New Testament were recognized in Germany as uniting sound learning and the most searching criticism with an orthodox, conservative faith. From that day to the period of his death he was constantly putting forth new editions, masterpieces of exegesis. Unable to finish the New Testament himself, because the wonderful sale of his commentary had obliged him to make these frequent revisions, which were of the most thorough and candid character, he gave Thessalonians to Revelation to others. An English translation of his commentary appeared at Edinburgh under the supervision of Rev. W. P. Dickson, of the University of Glasgow, and Rev. F. Crombie, of St. Mary's College, in twenty volumes, 1873–82, of which there is a greatly improved American edition (11 vols., New York, 1884–88). Revised by S. M. Jackson.

Meyer, Johann Georg, called **Meyer von Bremen**: genre-painter; b. in Bremen, Oct. 28, 1813; d. in Berlin, Dec. 6, 1886. He was a pupil of Düsseldorf Academy; settled in Berlin in 1852; became Professor of the Academy there 1863; was a member of the Amsterdam Academy. He was awarded a medal at the Centennial Exhibition, Philadelphia, 1876. His pictures, almost all of small size, brought high prices during his lifetime, and many of them are owned in the U. S. *The Letter* is in the Wolfe collection, Metropolitan Museum, New York. W. A. C.

Meyer, Julius Lothar, von, Ph. D.: chemist: b. at Varel, in Oldenburg, Aug. 19, 1830; studied medicine in Zurich and Würzburg, then chemistry, mathematics, and physics in Heidelberg and Königsberg; graduated at the University of Würzburg in 1857, his thesis being *Die Gase des Blutes*; taught in the forestry academy of Neustadt-Eberswalde after 1866, in the Carlsruhe Polytechnic Institute after 1868, in the University of Tübingen after 1876, and in that of Göttingen after 1885. D. at Göttingen, Apr. 14, 1895. He contributed many technical papers to chemical periodicals. S. T. Armstrong.

Meyer, Leo, Ph. D.: comparative philologist; b. at Bledeln, in Hanover, July 3, 1830; studied at Göttingen and Berlin; in 1862 became assistant professor at Göttingen; since 1865 has been Professor of German and Comparative Philology at Dorpat in Russia (Livonia); is the author, among other works, of *Gedrängte Vergleichung der griechischen und lateinischen Deklination* (1862); *Vergleichende Grammatik der griech. und lat. Sprache* (2 vols., 1861–65; vol. i., 2d ed. 1884); *Die gotische Sprache* (1869); *Griechische Aoriste* (1879). Benj. Ide Wheeler.

Meyer, Ludwig, M. D.: alienist; b. at Bielefeld, Germany, Dec. 27, 1827; studied in the Universities of Bonn, Würzburg, and Berlin, graduating M. D. from the latter in 1852; began his psychiatric studies in the Berlin Charité Hospital, later going to the Hamburg general hospital; in 1866 was elected professor at the University of Göttingen, and became director of the asylum for the insane. His papers on various topics connected with insanity have been published in the *Zeitschrift für Psychiatrie* and the *Archiv für Psychiatrie*. S. T. Armstrong.

Meyer, Paul: philologist; b. in Paris, Jan. 17, 1840; has been Professor of the Languages and Literatures of Southern Europe at the Collège de France since 1876, director of the École des Chartes, and member of the Académie des Inscriptions et Belles-Lettres. He is also secretary of the Société des Anciens Textes Français, has been one of the editors of the *Romania* since its foundation in 1872, and was one of the first editors of the *Revue critique d'histoire et de littérature*, begun in 1866. Besides many papers in periodicals, such as the two just mentioned, the *Jahrbuch für romanische und englische Literatur*, the *Mémoires de la Société de linguistique de Paris*, the *Bibliothèque de l'École des Chartes*, etc., which are important for the study of the Provençal and Old French languages and literatures, he has also published in separate volumes a number of editions of mediæval texts and other works. Among these are *Barlaam und Josaphat* (1864), an Old French poem, with H. Zotenberg; *Le Roman de Flamenca* (1865); *Les derniers troubadours de la Provence* (1871); *Recueil d'anciens textes bas-latins provençaux et français* (1874–77, not yet complete); *La Chanson de la croisade contre les Albigeois* (2 vols., 1875–79); *Daurel et Beton* (1880); *Girart de Roussillon* (1884), a translation; *Fragments d'une Vie de Saint-Thomas de Cantorbéry* (1885); *Alexandre le Grand dans la littérature française du moyen âge* (2 vols., 1886); *L'Histoire de Guillaume le Maréchal* (vol. i., 1891); *La Chansonnier français de Saint-Germain-des-Prés* (vol. i., 1891), with G. Raynaud. E. S. Sheldon.

Meyer, Victor: chemist; b. in Berlin, Sept. 8, 1848; studied in Berlin; became Professor of Chemistry in Stuttgart 1871, in Zurich 1872, in Göttingen 1885, in Heidelberg 1889; has made exhaustive researches in organic chemistry. Is author of *Pyrochemische Untersuchungen* (with Lauger, 1885); *Die Thiophengruppe* (1888); *Ergebnisse und Ziele stereochemischer Forschung* (1890); *Lehrbuch der Organischen Chemie* (with Jacobson, 1891); *Tabellen zur qualitativen Analyse* (with Treadwell, 3d ed. 1891); *Aus Natur und Wissenschaft* (1892).

Meyerbeer, mī'er-bār, Giacomo (Italianized form of Jakob Meyer Beer: composer; b. in Berlin, Sept. 5, 1791. His father, James Beer, a wealthy Jew, who appreciated culture and had a fondness for art, gave his three sons, Michael, Wilhelm, and Jakob, the full advantages of education. Giacomo (or Jakob) had a genius for music, and enjoyed the benefit of the best teaching that could be commanded. In 1806 he was admitted to Vogler's select school at Darmstadt, and in close intimacy with Karl Maria von Weber, who had already composed operas, he studied hard and successfully for two years. At this time Meyerbeer composed an oratorio, *Gott und die Natur*. In 1812, under Vogler's auspices, the opera of *Jephthah* was produced at

Munich. It failed, and the disconcerted composer, dropping dramatic music for a time, returned to the piano, and achieved great distinction in Vienna. A second opera, *Die Beiden Kalifen*, failed. Italian music alone was popular, and Meyerbeer went to Italy to learn the methods of the Italian school. Thenceforward his labor was successful. His *Romilda e Costanza* (1812) at Padua, his *Semiramide* (1819) at Turin, his *Emma di Resburgo* (1820) at Venice, were received with praise. In 1822 *Margaret of Anjou* was brought out triumphantly at the Scala in Milan. The next year *L'Esule di Grenata* was produced with Lablache and Pisaroni. In 1824 the *Crociato* was received with immense favor at Venice. This closed the first period in the composer's career. The second period opened in Paris, with *Robert le Diable*, which was brought out in 1831, and roused unprecedented enthusiasm, not in Paris only, but in Germany and all over Europe. *The Huguenots* followed in 1836, and added new laurels to Meyerbeer's fame, it being the first of what may be termed "historical" as distinguished from the purely romantic lyric drama. The appearance of *The Huguenots* made an epoch in operatic art. Thirteen years passed before the *Prophète* was completed. In 1854 came *L'Étoile du Nord*, five years later *Dinorah*, also known as *Le Pardon de Ploermel*, both works inferior in dignity to the two preceding. *L'Africaine*, the work of years, waited long for an opportunity, and was not produced till 1865, a year after the composer's death, which occurred in Paris, May 2, 1864. See the *Life*, by Blaize de Bury (1865) and that by Henri Mendel (1868).

Meyersdale, or **Dale City**: borough; Somerset co., Pa. (for location of county, see map of Pennsylvania, ref. 6–C); on the Casselman river, and the Balt. and Ohio Railroad; 113 miles S. E. of Pittsburg. It is in an agricultural and mining region, and has flour and planing mills, iron-foundry, furniture-factory, stoneware-works, large lumber interests, and two weekly newspapers. Pop. (1880) 1,423; (1890) 1,847; (1900) 3,024.

Meynert, Theodor, M. D.: alienist and neurologist; b. at Dresden, Saxony, June 15, 1833; graduated M. D. at the University of Vienna in 1861; in 1865 was docent for the Anatomy of the Brain; in 1866 was prosector of the Vienna Insane Asylum; in 1870 director of the psychiatric clinic and Extraordinary Professor of Psychiatry at the university; in 1873 elected Professor of Neurology; in 1885 made a privy councilor. He was president of the Psychiatric Association, vice-president of the Vienna Medical Society, and a member of the Imperial Academy of Sciences of Vienna. His researches on the anatomy of the brain and his writings on medico-psychological subjects have been of great value in advancing this department of medical science. Among his publications are *Zur Mechanik des Gehirnbaues* (Vienna, 1874); *Psychiatrie Klinik der Erkrankungen des Vorderhirns* (Vienna, 1884). He was coeditor of *Psychiatrisches Centralblatt* from 1871–78, and of *Jahrbücher für Psychiatrie* for 1879. D. May 31, 1892.

S. T. Armstrong.

Meyr, Melchior: author; b. at Ehringen, in the Ries, a fertile plain included by the Franconian and Suabian Jura, Bavaria, June 28, 1810; studied at Munich and Heidelberg; devoted himself to literature; lived in Berlin 1840–52, afterward alternately at Munich and Ehringen, where he died Apr. 22, 1871. His best-known productions are *Duke Albert* (1852); *Stories from the Ries* (1856); *Charles the Bold* (1862); and *New Stories from the Ries* (1871). In the *Stories from the Ries* he gives a series of exquisite pictures of the peasant life of his native country, which rank among the best village tales written in the German language.

Revised by Julius Goebel.

Mey'rick, Frederick: theologian; b. at Ramsbury vicarage, Wiltshire, England, Jan. 28, 1827; educated at Trinity College, Oxford, where he was successively scholar, fellow (1847–60), and tutor (1851–59), and has since held the university office of select preacher (1855–56, 1865–66, 1875–76). He was the chief founder of the Anglo-Continental Society; published *The Practical Working of the Church in Spain* (1851); *The Moral and Devotional Theology of the Church of Rome* (1857); *The Outcast and the Poor of London* (1858); *Is Dogma a Necessity?* (1883); *The Doctrine of the Church of England in Holy Communion Restated* (1885; 3d ed. 1891); *The Church in Spain* (1892); and controversial writings against Roman Catholicism; has contributed to Dr. Smith's *Dictionary of the Bible*, to the *Speaker's Commentary*, to the *Pulpit Commentary*, and to Hodder and Stoughton's *Theological Library*. Editor of the *Foreign Church Chronicle and Review*; was examining chaplain to the Bishop of Lincoln (1868–85); principal of Codrington College, Barbados (1886–87); since 1868 has been rector of Bickling, Aylsham, Norfolk. Revised by S. M. Jackson.

Meyrick, Sir Samuel Rush, LL. D.: archæologist; b. in London in 1783; was educated at Queen's College, Oxford, and became an advocate in the ecclesiastical and admiralty courts, but devoted his chief attention to archæological studies, and contributed innumerable papers to *The Gentleman's Magazine*. His specialty was the collection and illustration of ancient arms and armor, of which he ultimately formed a large collection. Among his works were *The History and Antiquities of the County of Cardigan* (4to, London, 1810); *The Costume of the Original Inhabitants of the British Islands* (1815); *A Critical Inquiry into Ancient Armor* (1824; improved ed. 3 vols., 1844), with more than 100 colored plates; and *Engraved Illustrations of Ancient Arms and Armor, a Series of 154 Etchings* (by Joseph Skelton) *of the Collection at Goodrich Court* (2 vols., 1830). The prints in the last-named work are valuable, but there is little archæological accuracy in the text of any of his publications. D. in London, Apr. 2, 1848. Revised by Russell Sturgis.

Mezeray, māz'rā', François Eudes, de: historian; b. near Falaise, Normandy, in 1610; began his literary career as a poet, but turned soon to historical studies, and published in 1643 the first volume of his *Histoire de France*, which procured for him the patronage of Richelieu, who gave him a pension of 4,000 livres and the title of historiographer. His *Abrégé chronologique de l'Histoire de France* (1668) is considered better than the principal work. D. in Paris, July 10, 1683.

Meze'reon [from Fr. *mézéréon*, from Arab. and Pers. *māzariyūn*, camellia]: in materia medica, the bark of shrubs belonging to the genus *Daphne*, especially *D. mezereum*, *D. laureola*, and *D. gnidium*. They are natives of Europe and Asia, sometimes seen in cultivation in the U. S. They are of the order *Thymeleaceæ*. The bark has strongly irritant-narcotic properties. It was once extensively employed in medicine, and now has a limited use in cases of rheumatism and other diseases. The fresh bark will quickly blister the skin.

Revised by H. A. Hare.

Mézières, mā'zi-ãr': a fortified town; the capital of the department of Ardennes, France; on the Meuse, opposite Charleville, with which it is connected by a bridge. It is 155 miles by rail N. E. of Paris (see map of France, ref. 2–G). In 1520 it was successfully defended by Bayard against Charles V., and his banner is still preserved in the hotel de ville. The anniversary of the deliverance of the town, Sept. 27, is still observed. The present fortifications were planned by Vauban. The school of military engineering originally founded here was successively transferred to Metz and Fontainebleau. The iron industry has gradually been concentrated at Charleville. Pop. (1891) 6,551; (1896) 7,453.

Mézières, Alfred Jean François: critic; b. at Réhon, Moselle, France, Nov. 19, 1826. He studied at the École Normale Supérieure, and then at the French school in Athens, obtaining the degree of docteur-ès-lettres in 1853. In 1854 he was made Professor of Foreign Literatures at Nancy; in 1863 he was given a similar position at the Sorbonne, having already served some time there as *suppléant*. In Jan., 1874, he was elected to the Académie Française to succeed Saint-Marc Girardin. His studies were chiefly in Italian, English, and German literature, and most of his publications have had to do with one or the other of these. We may mention *Étude sur les œuvres politiques de Paul Paruta* (1853); *Shakespeare, ses œuvres et ses critiques* (1861); *Prédécesseurs et contemporains de Shakespeare* (1863), like the preceding crowned by the French Academy; *Contemporains et successeurs de Shakespeare* (1864); *Dante et l'Italie nouvelle* (1865); *Pétrarque, d'après de nouveaux documents* (1867); *La société française, etc.* (1869); *W. Goethe, les œuvres expliquées par la vie* (2 vols., 1872–73). Mézières has contributed much literary criticism to the *Revue des Deux Mondes* and *Le Temps*. Since the Franco-German war he has interested himself in politics as a moderate republican. In 1881, and in 1885, he was elected deputy. Of his more recent publications may be mentioned *En France: XVIII^e et XIX^e siècles* (1883), and *Hors de France: Italie, Espagne, Angleterre, Grèce moderne* (1883).

A. R. Marsh.

Meziriac, me-zĕĕ'rĕĕ'ăăk', Claude Gaspar Bachet: classical scholar; b. in Bourg, France, Oct. 9, 1581. He be-

longed to the Jesuit order, but subsequently became an apostate and married. He was one of the most learned men of his time; is now chiefly known as the author of a commentary to the *Heroides* of *Ovid*, a work full of recondite learning. The first edition (1626) is one of the rarest of books, a second was, however, issued in two volumes by Haye du Sauzet (1716). A. G.

Mezzo, med'zō [Ital., liter., middle, half: Span. *medio*: Portug. *meio*: Roman. *miez*: Fr. *mi* in *midi*, *parmi*, etc. < Lat. *medius*, mid, in the middle]: in music, a term of diminution, signifying the half, middle, or mean between two things of a positive nature or description. Thus a mezzo-soprano voice is one whose range is between the soprano and alto. Mezzo forte (or *m. f.*) is rather loud, and mezzo piano (or *m. p.*) rather soft. Mezzo voce, in like manner, implies the use of only half of the usual force of the voice.

Mezzofan'ti, Giuseppe Gaspardo: linguist; b. at Bologna, Italy, Sept. 17, 1774. At the age of fifteen, besides Greek and Latin, he already knew many foreign European languages. Having entered the priesthood (1797), he was appointed Professor of Oriental Languages and librarian at Bologna. In 1831 he removed to Rome; in 1833 succeeded Angelo Mai as chief keeper of the Vatican library; and in 1838 was made a cardinal. He is said to have spoken over fifty languages, but this faculty was not combined with any great measure of intellectual power. D. in Rome, Mar. 15, 1849. His books and papers became the property of the library of Bologna. There exists but a single printed work of his, an eulogy pronounced in 1819 upon his old master in Greek, Emmanuele da Ponte. See his *Life*, by Charles William Russell (1858; 2d ed. 1863).

Mezzotint Engraving: See Engraving.

Miako, mĕĕ-aa'kō: a Japanese name meaning "metropolis," and therefore synonymous with *Kioto*, frequently applied to the old capital of Japan now called *Sai-kio*, or "Western capital," to distinguish it from Tokio (literally, "Eastern capital"), the present capital of the country.

Miall, Edward: politician; b. at Portsmouth, England, in 1809; was educated at the Protestant Dissenters' College at Wymondley; became an Independent minister at Ware, and afterward preached at Leicester; removed to London in 1840 and established *The Nonconformist*; in 1844 aided in establishing the British Anti-Church Association, later known as the Liberation Society; was an unsuccessful candidate for Parliament in 1845 and 1847; was elected for Rochdale July, 1852; lost his seat 1857; represented Bradford in 1869–74. Mr. Miall was a conspicuous parliamentary advocate of manhood suffrage and an opponent of all religious endowments. He published *Views of the Voluntary Principle* (1845); *Ethics of Nonconformity* (1848); *Title-deeds of the Church of England to her Parochial Endowments* (1861); *Politics of Christianity* (1863); and *Wayside Musings and Reminiscences* (1865). D. Apr. 29, 1881. See the *Life* by A. Miall (1884).

Miami (mī-aa'mĕĕ) **River**: a river in Dade co., Fla.; formed in the Everglades by outlets of Lake Okeechobee. It flows into Biscayne Bay. At its mouth is a fine grove of cocoa-palms.

Miami River: a stream of Ohio; rises in Hardin co., runs in a southwest course, passing the cities of Troy, Dayton, and Hamilton. It is a rapid stream, flowing through a beautiful, fertile, and populous valley, and joining the Ohio below Cincinnati. It is 150 miles long, and furnishes much water-power. Its ultimate source is 1,335 feet above tide. A canal extends along the river.—The Little Miami is a smaller, unnavigable stream, flowing through a fertile and hilly region to the E. of the Miami, and reaching the Ohio 6 miles above Cincinnati.

Miamis: See Algonquian Indians.

Miamisburg: village; Montgomery co., O. (for location of county, see map of Ohio, ref. 6-C); on the Great Miami river, the Miami and Erie Canal, and the Cleve., Cin., Chi., and St. L., and the Cin., Hannibal, and Dayton railways; 10 miles S. of Dayton, the county-seat, 50 miles N. of Cincinnati. It is in a tobacco-growing region, has excellent water-power, and contains several mills and factories, 2 national banks with combined capital of $200,000, and 2 weekly newspapers. Pop. (1880) 1,936; (1890) 2,952; (1900) 3,941.

Miami University: an educational institution at Oxford, Butler co., O.; incorporated in 1809; opened as a grammar school in 1818, and as a college in 1824. It derives its origin from a grant of the township of Oxford, made by Congress to the State of Ohio in 1802, to be held in trust for educational purposes. During the years 1873–84 the institution was closed. The university is non-sectarian, governed by a board of eighteen trustees appointed by the Governor of the State, and receives an annual appropriation from the Legislature. Its library contains 16,000 volumes. President, Rev. David S. Tappan, D. D.

Miantonomoh: sachem of the Narragansett Indians and nephew of Canonicus; assumed the government about 1636, and in that year concluded an alliance with the government of Massachusetts. He aided the colonists in the Pequod war 1637, and was friendly to Roger Williams and other early settlers of Rhode Island, to whom he made grants of land. Having engaged in war with Uncas, sachem of the Mohegans, he was taken prisoner, carried to Hartford, and by the advice and consent of the commissioners of the United Colonies was returned to Uncas to be executed. He was taken to the spot where he had been defeated, Great Plains, near Norwich, and there was put to death by the tomahawk by a brother of Uncas. A simple monument, erected in 1841, marks his grave.

Miao-tse, or **Meao-tse** (literally, sons of the soil): aboriginal tribes who early appear in Chinese history, and who formerly occupied extensive tracts in Central China, especially in the neighborhood of the Tung-ting Lake, but who have been driven by the advancing Chinese into the more inaccessible mountain regions of the S. and S. W., chiefly Kwei-chow and Kwangsi, where they still maintain a practical independence, though in the period Kien-Lûng (1736–95) many tribes were compelled by the presence of superior Chinese forces, which had fallen upon them unawares, to accept Chinese sovereignty. Some have gradually become assimilated to the Chinese, and a few have risen to position among the mandarins. They are divided into about fifty clans, ranged in several larger divisions, known as the Red, the White, the Blue, and the Black Miao, from the color of their dress. Their numbers are unknown.

Physically they are of smaller stature than the Chinese, have regular features, and seem to be ethnically affiliated to the Siamese family. They are skillful hunters, but engage to some extent in the cultivation of the soil. Like the Li of Hainan the young people do their own match-making. Disputes among them are settled by the arbitration of the elders. R. Lilley.

Miaoulis, mĕĕ-ow'lis, Andreas Vokos: revolutionist; b. at Hydra, Greece, in 1770, where he received his surname Miaoulis from his commanding a felucca (Turk. *miaoul*). He devoted himself and his property to the Greek revolution (1821), was made commander-in-chief of the fleet, and by his invincible courage and fertility in expedients gained several brilliant successes over greatly superior Ottoman and Egyptian forces. With self-sacrificing loyalty to the national cause he resigned in favor of Lord Cochrane, and continued to serve as a simple captain. Afterward he was reinstated in his office by Capodistrias, the president of Greece, but opposed the latter's Russian tendencies, joined the opposition, and became much involved in the political controversies of the time. He was a member of the deputation which went to Munich (1832) to offer the Greek crown to King Otho. D. at Athens, June 24, 1835, and was buried at the Piræus, near the supposed grave of Themistocles.
E. A. Grosvenor.

Miasma, or **Malaria**, or **Paludism** [*miasma* is Mod. Lat., from Gr. *μίασμα*, stain, pollution, defilement, deriv. of *μιαίνειν*, stain, taint, pollute]: a term which is said to have been used, with a signification similar to that which it has to-day, as long ago as the time of Hippocrates, who, in his treatise *On Airs*, attributes various diseases to a mixture of the blood with vitiated air. Not long ago the generally accepted teaching of medical writers was not more definite or rational than this; for miasma (malaria) was regarded as an imponderable emanation, usually from marshy grounds, which obtained access to the blood by way of the lungs, and thus poisoned the body. The word miasma has had somewhat different significations at different times: thus it has been used to indicate injurious emanations from the soil or from dead or living vegetable or animal organisms, being synonymous with effluvia. Again it has been applied (especially in Paris) to the influence on health of persons afflicted with infectious diseases. Probably the best modern definition of miasma—excluding that which rests upon a bacterio-

logical basis (to be spoken of later)—describes it as that element in the cause of diseases peculiar to certain locations (usually marshy), which is found in the air of such places, and which is known only by the effects of its operation.

Formerly the production of malaria was loosely attributed to the soil; but in recent years it has been attributed first to the vegetable contents of soil and afterward to minute fungous growths—bacteria. Prof. Léon Colin, of Val-de-Grâce, has proposed the term "telluric intoxication," as more accurately fitting the idea intended by the words malaria or miasm, namely, that certain diseases were produced by the action of air coming from soil, the energy of which is not expended upon vegetation; at present neither this term nor the idea it conveys has much standing in medical circles. The same may be said of the idea that malaria or miasm is derived from decaying vegetable matter. However reasonable these ideas may appear to some conservative students of the causation of disease, and however imperfectly established may appear the hypothesis that malarial diseases are caused solely by invasion of the body by bacteria, this is the view of almost all modern writers on the subject. In 1879 Prof. Tommasi Crudeli, of Rome, and Prof. Klebs, of Prague, found a microscopic fungus in the lower strata of the air of a malarial region in Italy, and in the soil and stagnant waters, which they named *bacillus malariæ*. This organism they cultivated in various media, and separated the solid part of the product of their culture from the liquid by filtration and repeated washing. They then injected the solid residue, properly diluted, under the skin of healthy dogs, and produced in them what the experimenters regarded as typical intermittent fever. This explanation of the causation of malarial fever has recently been to a great extent supplanted by the opinion, first advanced by Laveran, that there is always present in the blood of patients with malarial fever a peculiar organism (hæmatozoön) not found in any other disease. This organism, which is regarded as a parasite, has been carefully studied by Prof. Osler and Prof. Councilman, of Johns Hopkins University, and Prof. Dock, of the University of Michigan. The different forms and phases of malarial fever are (according to this theory) associated with various forms and stages of development of the organism which is sometimes called the *Plasmodium malariæ Laveran*.

These germs are found in the blood-cells, and also free in the blood-fluid. They are seen to have very different shapes, but all the shapes are quite characteristic. The most striking forms are globular masses containing pigment granules, and those of a fairly round shape, with or without one or more flagella. In some cases they are seen to have a body depressed on one side like a saucer, presenting, when seen on edge, the appearance of a crescent. Laveran objects to the use of the term *plasmodium*, on the ground that it is botanically inaccurate, and he prefers to call his germ a *hematozoaire*.

The germ theory of the nature of malaria, though ably supported by the writers named and other observers, has not yet been fully accepted. Prof. von Jaksch, of Prague, a most competent authority, states—after referring to the various bacteriological theories—that the contradictory statements of recent writers show that the question as to the specific cause of intermittent fever is not yet satisfactorily solved—a conclusion which the facts fully bear out. The fact that malarial fevers occur very frequently in the neighborhood of marshy regions has led to the use of such terms as "marsh miasm" and "paludal fever"; but malarial fevers are by no means confined to moist ground; for they have raged with great severity in arid districts, as when the British army, under the Duke of Wellington, was operating in Estremadura and near Ciudad Rodrigo in the Spanish Peninsula. The Campagna near Rome is also a dry region in which malarial fevers are very common. Still miasma, or malaria, is in general most active in the neighborhood of moist ground in which decaying vegetable matter is present. It is also often liberated from soil which has long been undisturbed, as when canals are made or streets are dug up.

The common belief of medical writers is that malaria effects an entrance into the human system by the air-passages; and the very obscurity of this process and the multiplicity of the symptoms, and the vague character of some of the phenomena attributed to malaria, probably serve at times as a cloak to conceal inability properly to diagnosticate cases of other diseases. That which is typical of miasmatic or malarial fevers is the regular repetition of a series of the following phenomena: a chill, a rise of temperature, a sweat, and a period of comparative freedom from any of these symptoms. The various forms of intermittent and remittent fevers will be described under these titles, it will suffice here to merely mention them as the results of miasmatic or malarial influences. Beside these, disturbances of the digestive apparatus, of varying degrees of severity and diarrhœa, as well as nervous disorders, dysentery, etc., are attributed by medical writers to the same agency.

The action of miasm is best combated by all measures calculated to elevate and maintain at a normal standard the vital functions—good food, good air, cleanliness, good habits, and courage. Removal from suspected regions, and the administration of certain drugs, chief among which is quinine, will often cut short the progress of pronounced cases of malarial intoxication, while other cases end in death or permanent disability. CHARLES W. DULLES.

Micah: one of the minor Hebrew prophets; b. at Moresheth, near Gath. He lived in the latter half of the eighth century B. C., and was a contemporary of Isaiah. Mic. iii. 12 is quoted in Jer. xxvi. 18 to justify the latter in foretelling the destruction of Jerusalem. Micah's prophecies are written in a vivid, poetical style, and refer chiefly to the fate awaiting the two Hebrew nations. The style is not unlike that of Isaiah. Micah deals with social and popular rather than political sins. He named Bethlehem as the birthplace of the Messiah (Micah v. 2).

Micas [*mica* is Mod. Lat. in form, from Lat. *mi'ca*, crumb, grain, but evidently connected in meaning with *mic'are*, shine]: a group of very interesting and widely spread minerals, belonging to the Unisilicates, and containing silicic acid, with varying proportions of the alkalies, magnesia, lime, and protoxides of iron, with the sesquioxides of aluminium, iron, and manganese, usually a little flourine, and more rarely titanium. Titanium occurs to the extent of 7 or 8 per cent. in the rare mica *astrophyllite*, which also contains zirconia. *Lepidolite*, which is confined to a few localities, and the very rare *cryophyllite* contain an important percentage of lithia, with a little rubidia and cæsia. The micas occur generally in thin, shining scales, usually transparent, but opaque in some very dark varieties of *biotite* and *lepidomelane* (an iron-potash mica). More rarely, some of the micas are found in large plates, and occasionally six-sided prisms. Unless decomposed they are distinguished by a very easy cleavage, splitting readily into extremely thin, elastic laminæ, and showing usually a pearly luster on the cleavage faces. The most important micas are *phlogopite*, *biotite*, *lepidolite*, and *muscovite*. Phlogopite, or *magnesia mica*, contains magnesia as well as potash, among the protoxides, with very little of the oxides of iron. It is orthorhombic, with an optic-axial divergence of 3°–20°. It is light colored, usually yellowish brown, and very liable to alteration. Phlogopite occurs chiefly in serpentine, crystalline limestone, and dolomite. Biotite (*magnesia-iron mica*) is hexagonal, generally dark green or black, and is similar in composition to phlogopite, but with 5–10 per cent. of sesquioxide of iron; sometimes much more. Lepidolite is very interesting, because it contains the rarer alkalies. Muscovite (*potash mica*) contains principally potash among the protoxide bases, with some soda, and among the sesquioxides alumina, with generally 2 or 3 per cent. of sesquioxide of iron. It is orthorhombic, and has an optic-axial divergence of 44°–78°. Muscovite includes nearly all common mica, and is a constituent of granite, gneiss, and mica-schist; it is also found sometimes in shales and other sedimentary rocks in small scales, and may occur in eruptive rocks and granular limestone. Being usually of light color, quite transparent, and very tough, it becomes valuable when found in plates of considerable size, and is then used in stoves for doors, etc. There are very few localities where marketable mica is found, the supply for the U. S. being almost confined to mines in Haywood, Yancey, Mitchell, and Macon cos., N. C., where the mineral is found in granite rock with coarse feldspar, and to Grafton co., N. H., where the Palermo mine is now the principal source of sheet mica. It has also been mined to some extent in South Dakota, Wyoming, and New Mexico, but not in quantities nor of high quality. In recent years the production has amounted to about 75,000 lb., valued at $100,000. A considerable quantity is imported into the U. S. from Canada, the principal deposits being in Ottawa County. American dealers in mica have lists of 193 sizes, ranging from 1½ by 2 inches to 8 by 10 inches as the standard sizes. The preparation of ground

mica for use in the manufacture of wall-paper has become a separate industry. See BIOTITE.

Revised by CHARLES KIRCHHOFF.

Mica-schist: a metamorphic, stratified, schistose, crystalline rock, always foliated in texture, and composed of variable proportions of mica and quartz. It gradually passes in one direction into gneiss and in another into quartz-schist. *Argillaceous mica-schist*, according to Cotta, may be regarded as "an imperfect mica-schist, or as a somewhat crystallized clay-slate."

Michael Angelo: See MICHELANGELO.

Michaëlis, KAROLINA: See under VASCONCELLOS, JOAQUIM ANTONIO FONSECA, de.

Michae'lis, JOHANN DAVID: theologian: b. at Halle, Germany, Feb. 27, 1717; studied theology, Oriental languages, and biblical archæology under his father, who was professor at the university; traveled in Holland and England, and was appointed professor in 1745 at the University of Göttingen, where he died Aug. 22, 1791. His works, the results of immense learning and great acuteness, are very numerous, and contributed much to a fuller understanding of Holy Writ, especially the Old Testament. His theological standpoint may be indicated as a transition from the old orthodoxy to the subsequent rationalism, and on his age he exercised a considerable influence. His principal works are *Introduction to the New Testament* (2 vols., Göttingen, 1750), translated into English by Bishop Marsh (6 vols., London, 1823), and *Commentaries on the Laws of Moses* (6 vols., Frankfort, 1770–75), translated into English by Alexander Smith (1810, 4 vols.). Of great importance is also his *Supplementa ad lex. hebr.* (1786, 2 vols.), which contains excellent contributions to the knowledge not only of the language, but also of the antiquities and history, of the Old Testament. See his *Autobiography*, ed. by J. M. Hassencamp (Rinteln, 1793), and *Correspondence* (3 vols., Leipzig, 1794–96).

Michaelmas: the festival of St. Michael the Archangel, celebrated on Sept. 29.

Michael Palæologus: See BYZANTINE EMPIRE.

Michalce, mikh'ăăl-ets, MARTIN: poet; b. at Litoměřice (Leitmeritz), Bohemia, in 1484; was educated in schools of the Bohemian Brethren; was ordained pastor at Brandejs n. O. in 1531, officiated as superintendent of various communities of the Brethren in Bohemia and Moravia; became a member of the supreme council, and was elected bishop in 1537. D. in 1547. He was a talented and eloquent speaker, and he wrote a number of polemical tracts and numerous *songs*, thirty-one of which are contained in the Brethren's hymn-book.

J. J. KRÁL.

Michaud, mĕĕ'shō', JOSEPH FRANÇOIS: journalist and historian; b. at Albens, Savoy, June 19, 1767; went to Paris in 1791; wrote in the *Gazette Universelle*, *Postillon de la Guerre*, and *Courrier Républicain*, three royalist papers, and showed himself a stanch defender of the monarchy; founded in 1794 the *Quotidienne*; was condemned to death Oct. 27, 1795, for his anti-Revolutionary opinions, but succeeded in getting the verdict annulled; was banished to Cayenne by the Directory, but escaped and hid himself among the Jura Mountains, where he wrote his popular poem, *Le Printemps d'un Proscrit* (Paris, 1804; 2d ed. 1827); returned to Paris under the consular government, but continued to adhere to the cause of the Bourbons; formed, with his brother and Giguet, a publishing firm, and devoted himself principally to historical studies, though he once more, after the Restoration, took up journalism and renewed the *Quotidienne*. His principal historical works are *Histoire des progrès et de la chute de l'empire de Mysore* (2 vols., 1801); *Histoire de Croisades* (3 vols., 1812–22); *Correspondance d'Orient* (7 vols., 1833–35); *Collection de Mémoires pour servir à l'Histoire de France depuis le XIII^e siècle* (32 vols., 1836–39). He also participated in the production of the edition of the *Biographie Universelle*, published from 1811 to 1828. D. at Passy, Sept. 30, 1839.

Revised by B. B. HOLMES.

Michaux, mĕĕ'shō', ANDRÉ: botanist; b. at Satory, near Versailles, France, Mar. 7, 1746; was the son of a rich farmer, and was bred to agriculture; studied botany under the Jussieus; in 1779 sent many British trees to France for culture; botanized in Spain in 1780, and collected seeds for French cultivators; was in Asia 1782–85, whence, after many adventures, he returned with a rich supply of seeds and plants; was 1785–97 the French agent in North America for the collection of useful trees and shrubs for naturalization in France; made near Charleston, S. C., and New York (in Bergen co., N. J.), large nurseries for arboriculture. In 1796 he returned to France, but suffered shipwreck and the loss of all his effects. After waiting in France in poverty and hunger for the arrears of his pay, he started in 1800 upon Baudin's expedition to Australia, but at the Mauritius left the expedition and went to Madagascar, where he died Nov. 13, 1802. His principal works are a *Treatise on the Oaks of North America* (in French, 1801; Germ. trans. 1802), and a *Flora Boreali-Americana* (1803).

Michaux, FRANÇOIS ANDRÉ, M. D.: botanist; son of André Michaux; b. at Versailles, France, in 1770; for a time was his father's assistant in the U. S., and was himself sent in 1802, and again in 1806, to study the botany of the Mississippi valley and collect useful seeds. He published a *Treatise on the Naturalization of American Forest Trees* (1805); a *Journal* of his travels (Paris, 1804; Eng. trans. London, 1805); a work on the Bermudas (1806); *North American Sylva* (in French, 1810–13; in English, the trans. by Hillhouse, 1817–19; completed by Nuttall and others 1842–50). In 1816 Michaux was received into the French Academy of Sciences. D. at Vauréal, France, Oct. 23, 1855.

Michel, mĕĕ'shel', FRANCISQUE: scholar; b. at Lyons, France, Feb. 2, 1809; d. in Paris, May 21, 1887. In 1839 he became Professor of Foreign Literatures in the Faculty of Bordeaux, and retained the position until his death. He was one of the most distinguished students of mediæval literature, especially Old French, in Europe. He edited a large number of important Old French texts, among them: *Tristan, recueil . . . des poèmes relatifs à ses aventures, etc.* (2 vols., 1835–39); *Lais inédits des XII^e et XIII^e siècles* (1836); *Le chanson de Roland* (1837); *Le Roman du St. Graal* (1841); *Girartz de Roseilho* (1856); *Le Roman de la Rose* (2 vols., 1864). He also published a number of works dealing with the mediæval period, among them: *Histoire des races maudites de la France et d'Espagne* (2 vols., 1847); *Histoire des tissus de soie au moyen âge* (2 vols., 1852–54); *Le pays basque, etc.* (1857); *Les Écossais en France et les Français en Écosse* (2 vols., 1862).

A. R. MARSH.

Michel, GEORGES: landscape-painter; b. in Paris, France, in 1763; d. there in 1843. His pictures, long unnoticed, have come into prominence in artistic circles by their being included in exhibitions with the works of Millet, Rousseau, Corot, and their contemporaries, but they have no claim to rank with them in merit. His compositions are almost all of the same general character and are almost monotone in color.

W. A. C.

Michel, JULIUS, M. D.: ophthalmologist; b. at Würzburg, Germany, July 5, 1843; studied medicine in the Universities of Würzburg and Zurich, graduating M. D. at the former in 1866, and serving as Horner's assistant at the latter for several years; established himself in Leipzig in 1872; in 1873 was elected Extraordinary Professor of Ophthalmology in the University of Erlangen, where he remained until 1879, when he accepted the same chair in the University of Würzburg. Among his published works are *Die histologische Structur des Iris-stroma* (Erlangen, 1875); *Die Prüfung des Sehvermögens und der Farbenblindheit beim Eisenbahnpersonal und bei den Truppen* (Munich, 1878); *Lehrbuch der Augenheilkunde* (Wiesbaden, 1884). He was editor of the *Jahresbericht über die Leistungen und Fortschritte im Gebiete der Ophthalmologie* for 1877.

S. T. ARMSTRONG.

Michel, LOUISE: revolutionist; b. at Vroncourt, Haute-Marne, France, in 1839; won distinction by her musical and poetical talents; opened a school in Montmartre, Paris, in 1860; in 1870, during the Commune, fought on the barricades in the uniform of the National Guard; was taken prisoner at Versailles and sentenced to death, but the sentence was commuted to transportation to New Caledonia for life; returned to Paris on the granting of amnesty to political prisoners in 1880. Her continued activity and communistic undertakings led to her imprisonment in 1883 and in 1886. Later she took up her residence in London. She has published *Memoirs* (1886), and a novel, *The Microbes of Society*.

C. H. THURBER.

Michelangelo, or **Michelagnolo**, or **Michelangiolo**, of the family of Buonarrota Simone, generally called MICHELANGELO BUONARROTI: sculptor and painter; b. at Caprese,

in Tuscany, Mar. 6, 1475. He was apprenticed to Ghirlandajo (Domenico Bigordi) in his early youth, and received admittanee when about fifteen years old to the strange, informal academy of fine art which Lorenzo the Magnificent, chief of the Medici, had allowed to form itself in his gardens at San Marco in Florenee. Here he attracted Lorenzo's attention and was aided by him, but the great patron died in 1492. It was probably at about the same time that were executed the two bas-reliefs now in the Buonarroti Museum at Florence, the unfinished and confused eomposition called *The Centaurs* and a *Madonna and Child* with emblematic figures in the baekground. Almost immediately after this he was at work upon a statue of Hereules larger than life, which statue must have been finished before he was twenty, and which was thought worthy, thirty years later, to be a present to King Franeis I. That statue is lost, but a marble statuette of a kneeling angel with a candlestick, in the Church of San Domenico at Bologna, is known to be of this epoch, and the beautiful statue of St. John the Baptist, in the Berlin Museum, is with probability considered a work of Miehelangelo's boyhood. The strong tendency toward pure form as a means of expression, seen in this rapid and almost total abandonment of painting for sculpture, remains a lifelong eharaeteristic. The profound knowledge of the human form, and the almost perfect mastery of its movements and aspects, gained at so early an age, mark him as one of the very greatest technical artists whose works are known.

He had made a hurried visit to Venice and had dwelt some months in Bologna and a year in Florence, eonstantly at work upon sculpture, most of which has disappeared, when Cardinal di San Giorgio called him to Rome, whieh city he first reached in June, 1496. The statue of Bacchus, of the National Museum at Florenee, was sculptured during the following two years, but his other doings at this time are not recorded. The beautiful so-ealled cupid of the South Kensington Museum is generally admitted to be his work, and is thought by many to be of this time; it represents a vigorous youth kneeling on one knee, the left hand held high seems to hold a bow, the right to seize an arrow on the ground; he seems about to shoot downward from a height, and is rather a hunter than a cupid. In 1498 Michelangelo undertook one of the noblest sculptures of his life, the *Pietà*, or group of the Madonna holding the dead Christ upon her knees, which is in St. Peter's chureh at Rome. This is perhaps the only pieee which the artist ever signed; it bears the words Michael Angelus Bonarotus Floren Faciebat, cut in large capitals on the belt whieh passes over the shoulder and aeross the breast of the Virgin. The beautiful *Madonna and Child* in the cathedral at Bruges, in Belgium, almost certainly a work of this artist, is probably a work of the same time.

It should be observed that it was Michelangelo's habit to work the marble himself; contemporary witnesses state that he did even the rough first shaping, at least in some cases. This would be neeessary when he did not have full-size models before him; and it is doubtful if he made such models, or anything more than small sketch-models for study and experiment. It had not then become the custom for sculptors to bring the clay models to absolute completeness that workmen might copy it in the marble, leaving only the final touches for the sculptor. In fact, no accurate process of pointing was in use. Miehelangelo's practice differed from that of his contemporaries only in boldness and unhesitating certainty.

In 1501 the artist returned to Florence, and was at once occupied with the famous *David*, the eolossal statue whieh was finished in 1504, and which had stood for 320 years in the open air at the door of the Palazzo Vecchio, when, about 1875, it was put under cover in the Academy of Fine Arts. This noble work is a study of the forms of adolescenee, and is bold in its recognition of all that is awkward and immature in the youthful body. The action is of the moment of preparation before the sling is whirled and the stone dismissed. A great undertaking of this time was a whole series of apostles for the cathedral of Florence; one only was begun, the *St. Matthew*, whose rough-hewn effigy, half detaehed from the block as if a bas-relief, is in the Florence Academy. The five statuettes of the Pieeolomini altar in the Cathedral of Siena belong to these years, also the model of a bronze *David*, sent to France and set up in the court of the Château of Bury, but now lost, and most probably the two *tondi*, or round bas-reliefs, each of the *Madonna and Child*, one of which is in the National Museum at Florence and the other in the Royal Academy in London. At this time was painted, for Angelo Doni, the one existing movable picture whieh is known to be by Michelangelo, the round *Holy Family* in the Tribune at Florence. It is extremely characteristic of the artist: St. Joseph, an old man, sits behind the Virgin who is seated on the ground, and who takes the child from her husband over her right shoulder without turning round, and with a free and vigorous movement of both arms; the background is occupied with nude figures grouped upon a low stone wall; there is no landscape and no architectural adornments of any kind. An immense painting was undertaken at this time for one wall of the great hall in the Palazzo Veechio; the cartoon only was made, and this was destroyed a few years later; its subject was a number of soldiers surprised while bathing, and hurrying to dress and arm themselves. Most of the year 1504 must have gone to this cartoon, and at the close of that year the artist was called to Rome again, and began a task whieh was to harass him for many years and to remain unachieved, the great monument of Pope Julius II. That vigorous and warlike pope had been elected at the close of 1503; at his command Michelangelo sketched a gigantic strueture "eighteen cubits by twelve," three stories high, including forty statues, some of them colossal, besides basreliefs and ornaments. Half of the year 1505 was spent in mere superintendence of quarrying at Carrara; early in 1506 he hurried from Rome to his home in Florence, believing that the pope cared no longer for the tomb, and would not pay his expenses. The pope tried persuasion and threats to bring him back, and even letters to the rulers of Florence, and at last in Nov., 1506, Michelangelo yielded, met the pope in Bologna, and began work upon a eolossal seated bronze statue of Julius, which occupied him for eighteen months, and was destroyed four years later in a revolt. Then began another exhausting struggle with authority and a four-year task, though this one ended in a triumph and in a gigantic work of art, whieh has been preserved as a permanent possession of Europe. Pope Julius insisted upon the painting of the vaults of the chapel whieh had been built by Pope Sixtus IV. in the Vatiean —a plain room 130 feet long, 44 feet wide, and nearly 70 feet high. The walls had already been adorned with large freseoes by Botticelli, Ghirlandajo, Luca Signorelli, and Perugino, most of which still remain, and with portrait-figures of popes, but the vaulted roofs were now to be deeorated. In spite of great unwillingness to leave sculpture for so vast a work of painting, Michelangelo put up his scaffolding and began; at the close of 1509 the scaffolding was struck so that the half-finished work could be seen; at the close of 1512 the roof was shown again, and this time in the state in which it has remained since, not quite complete it is thought, but a marvel of figure-drawing and of composition, perhaps the greatest achievement in painting in Europe. A very simple architectural framework is painted on the smooth vault, and this affords bases for grouped caryatides, pedestals for single seated figures, seats for larger figures of prophets and sibyls, medallions filled with small compositions, and frames in the flat middle of the ceiling for nine pietures of Bible story; fourteen lunettes and the smaller vaults above them are filled in like manner with huge groups, so that there are in all perhaps 300 human figures, draped and undraped, most of them larger than life and many of them gigantic. In this great work Michelangelo had little help from other artists, for it appears that he had little power of bringing around him men who should work in harmony with him. The human figures, with their conventional drapery, and the slightest indieated architeetural setting, form the whole decoration; there is no other ornament. Then, as there is no landscape, no costume, and almost no incident in this giant work of art, so there is no depth and richness and little variety of color. Michelangelo was not in the usual sense a eolorist, but a modeler of plastic form, to which he gave only so much flesh color, such gray, dull yellow, and dusky blue in the drapery, and such negative stone-gray for the architecture, as would suffiee to keep his work from being a monochrome.

For the next ten years there is a singular and confused record of constant diversion of the great sculptor's and painter's thoughts from the work, which he alone could do, to building, which others could have done better. The rule with the great men of the Renaissance had been, "Great in one art, great in all." The assumption was that he who could handle form and color, who had the eye trained to see as artists see, the hand practiced to execute, and the spirit

alert to deal with tangible and visible realities, must needs be good in all ways. If he could model a great statue he could cut a die or build a church; even more, he would be thought fit for employment as engineer, civil or military. Accordingly, among the more complex and specialized arts of the sixteenth century, the same was expected of Michelangelo. Pope Leo X., who had begun to reign in 1513 and who was one of the Medici, was in Florence at the close of 1515 and decided to employ him on the front of San Lorenzo, the church which still stands with its brick wall as bare as if months of the precious life of a great artist had not been wasted in thought for it. A new contract was made with the executors of Pope Julius for his tomb, planned on a much smaller scale, and statues to form part of this were kept in hand; a model was made for the front of San Lorenzo, and once more many months were spent in the marble quarries. Then came a plan for building a library at San Lorenzo, and next a scheme for decorating the new sacristy of the same church, and putting up tombs of powerful members of the Medici family. Only an orderly and peaceful life and perfect system would have enabled the artist to achieve all that was thrust upon him, but his masters seem to have decreed that he should not have those advantages. They struggled with one another and countermanded their own orders, and while all Italy was contending for the artist's services, felt free, each in his turn, to put him to trivial tasks which he could not decline. *The Risen Christ* of the Church of Sta. Maria sopra Minerva in Rome is the one important piece of sculpture known to have been completed during these years—a life-size figure, concerning which the most contrary opinions are held by modern critics. It is peculiar in being wholly nude, the slight drapery of metal being put on at a later time. Like the Christ of *The Last Judgment*, it is a muscular and powerful man, and many critics think it lacking in proper sentiment. The same year that this was set up (1521) Leo died, and Adrian's short reign came in, to be followed in 1523 by that of Clement VII. Clement was another member of the Medici family, and the work of San Lorenzo was to be pushed accordingly.

There is no doubt that four or five tombs were proposed, instead of two only, and that the two Medicean popes, Leo and Clement, were to be honored in this way. The two tombs which were finished are in memory of comparatively unimportant princes of the family. No monuments of art in Europe are better known by photographs and engravings than these, or have been more fully described and criticised. As works of associated sculpture they are of enormous importance, but their architectural value is slight, and the sacristy itself is not a very successful piece of decorative building.

The statues made about this time for the tomb of Julius II. can not now be identified with certainty, except two of bound captives, which are in the Louvre. Other figures, made perhaps for that tomb or perhaps for the front of San Lorenzo, seem to belong to this epoch of the artist's life; such are the four male figures of the Boboli gardens, and the so-called *Victory* and the so-called *Adonis* of the National Museum at Florence. The *Victory* is a most impressive and vigorous group, but unfinished and capable of many different explanations. The year 1527 brought with it a revolution in Florence, and three years of fortifying, administering, and exile for Michelangelo; then came submission to the Medicean tyranny again, the production of the *Apollo*, in the Florence National Museum, and work continued on the sacristy at San Lorenzo, until it and its contents reached nearly the condition in which we see them.

The Medicean monuments were not finished as we see them till 1534; in that year Paul III. was elected pope, and in the following year Michelangelo was made chief architect, painter, and sculptor to the Vatican. This meant a further diminution of the work to be done for Pope Julius's tomb, for which the giant *Moses*, now in the Church of S. Pietro in Vincoli, had been sculptured—enough by itself, as Pope Paul declared, to grace his predecessor's tomb—and the immediate undertaking of the vast fresco of *The Last Judgment* at the northern end of the Sistine chapel. There were four years of pretty steady work upon this great labor, and at Christmas-time, 1541, when the artist was nearly sixty-seven years old, it was shown to the people of Rome. It can hardly be judged now; the painted drapery added by Daniele da Volterra, the fading of colors, the smoke and dust of many years, have stripped the fresco of the tints and the gradations that it was meant to have had. The composition of lines and masses can still be judged, in part, and the absence here as in the roof paintings of any source of interest but the one of the human body in vigorous action, and the combinations of form which this alone can give. The next great work which he undertook has suffered still more, and is now scarcely to be considered the handiwork of Michelangelo—the frescoes of the chapel built by Paul III. in the Vatican, close to the Sistine chapel. These two paintings, the *Crucifixion of St. Peter* and the *Vision of St. Paul*, were in hand from 1542 for seven years. Except for this work, architecture took up most of the old man's thought and strength. The Farnese Palace, a favorite undertaking of Pope Paul III., owes its completion to him; the two structures on the Campidoglio are his, and in his seventy-second year he became architect of St. Peter's church, then not very far advanced. He labored at this great task until his death, but his successors have greatly changed the church from what he meant it to be, and the cupola itself is the principal result of his labors on the church. This indeed is a triumph; no other European dome is so beautiful; and there seems little reason to doubt that its beauty is due to Michelangelo himself. He was peculiarly one who worked alone and without consultation or aid; moreover, the wooden model which was certainly made in the artist's time, and which was followed in its main lines by the builders, has been most thoroughly discussed and the claims of all disputing artists fully weighed. Michelangelo himself saw built only the drum or cylindrical wall below the cupola; but we are safe in giving him the credit for the whole of this lovely conception, which can only be judged rightly from without by those who will pass around the western and northern sides of the great church and look at the whole mass from the rising hillside of the Vatican gardens. Within as well as without the cupola is of unsurpassed beauty. Michelangelo has, however, no high rank as an architect, for the power of conceiving a graceful form, without much capacity to give it organic and constructional life and with little knowledge of details, is not a very rare nor a very exalted gift. His influence on the development of architecture was bad, or was at least not good, not calculated to oppose the evil tendencies of his time in Italy.

As painter and as sculptor his position is very exalted. Great differences of opinion exist, naturally, about his works of art; the lovers of Greek art do not bow to his powerful but often inaccurate modeling and drawing; the lovers of painting in its noblest form, as at Venice, can not find the fullest enjoyment in his frescoes; the admirers of the refinement and transcendental feeling of the true Renaissance can not worship the man whom they rightly regard as the leader and embodiment of the Decadence. In the second half of the nineteenth century there seems to be nowhere a school which is founded upon the study of Michelangelo's work; that remains, in its highest reach, the object of wonder and admiration as of the most wonderful achievement known to us of grave and somber thought expressing itself with almost unsurpassed technical skill, individual in the extreme, true *fine art*, as being the creation of the mind which had previously saturated itself with knowledge of nature, but still causing far more astonishment than love, and more fitted to stimulate than to teach.

Throughout his life, but especially in his later years, Michelangelo wrote sonnets and other poems, most of them of abstract subject, religious, mystical, or philosophical. The text of these had been known before 1863 only in an extremely falsified condition, for the great man's nephew, Michelangelo the Younger, had rearranged and almost recomposed the poems. All old editions of the poems and all translations of them and conclusions drawn from them are therefore worthless, and the student must go to Guasti's edition (Florence, 1863) until a still more critical one shall be published. The letters published by Milanesi (Florence, 1875) are also accessible now as never before; but it appears that the most unreasonable difficulties are thrown in the way of students wishing to consult the original documents in the Casa Buonarroti in Florence, and therefore the student is still at the mercy of two editors.

During his last years Michelangelo remained stanch to his duties as architect of St. Peter's, and resisted numerous temptations to undertake work elsewhere. He kept much of his strength till the end, and was incapacitated for but a short time, dying in Rome, Feb. 18, 1564.

BIBLIOGRAPHY.—The latest book on Michelangelo is John Addington Symonds's *The Life of Michelangelo Buonarroti*

(2 vols., London, 1893). In this documents not before accessible have been used. The book is inadequate in its critical appreciation of fine art, but is valuable and trustworthy, and contains useful illustrations. Charles Heath Wilson, *Life and Works of Michelangelo Buonarroti* (2d ed. London, 1881), is of great importance because of the minute examination made by the author of the frescoes in the Sixtine chapel. There are many other books on this subject, and a sufficient list of the important ones is given in vol. i. of Mr. Symonds's work. RUSSELL STURGIS.

Michelet, mĕesh'lā', JULES: historian; b. in Paris, Aug. 21, 1798, and educated at the Lyceum of Charlemagne, in which he was elected professor in 1821. After the revolution of 1830 he was appointed chief of the historical section of the royal archives, and in 1838 Professor of History and Morals at the Collège de France. In 1851 he lost his position, both at the archives and at the university, as he refused to take the oath of allegiance to Louis Napoleon. D. at Hyères, Feb. 9, 1874. Of his historical writings, the most important are *Histoire de France* (16 vols., 1833–67); *Histoire de la Révolution* (7 vols., 1847–53); *Précis de l'Histoire moderne* (1827); *Histoire Romaine* (2 vols., 1831); of his polemical writings are *Les Jesuits* (1843); *Du Prêtre, de la Femme, de la Famille* (1844); *Le Temple* (1846); *Pologne et Russie, Légende de Kosciusko* (1851); *Principautés danubiennes* (1853); of his miscellaneous writings, *L'Oiseau* (1856); *L'Insecte* (1857); *L'Amour* (1858); *La Femme* (1859); *La Montagne* (1868); *Nos Fils* (1869).—His second wife, ATHANAISE MICHELET, who survived him, assisted him in these latter works.

Michelet, KARL LUDWIG: philosopher; b. in Berlin, Dec. 4, 1801; studied first law and afterward philosophy, and was appointed Professor of Philosophy at the University of Berlin in 1829. The study of Aristotle was enriched by his *Ethik des Aristoteles* (1827) and *Examen critique de l'ouvrage d'Aristote, intitulé Métaphysique* (1836), which was crowned by the French Academy. On German philosophy he wrote *Geschichte der lezten Systeme der Philosophie in Deutschland* (1837); *Schelling und Hegel* (1839); *Entwickelungsgeschichte der neuesten deutschen Philosophie* (1873). His own standpoint—a modern reconstruction of Neo-Platonic Christianity—is principally developed in his *Die Persönlichkeit des Absoluten* (1844); *Der historische Christus* (1847); *Die Zukunft der Menschheit* (1852); *Naturrecht oder Rechtsphilosophie* (2 vols., 1866). D. Dec. 16, 1893. See his autobiography, *Wahrheit aus meinem Leben* (1884).

Michelozzi, mĕe-kā-lōt'sĕe, MICHELOZZO: seulptor and architect; b. toward the end of the fourteenth century in Florence, where he died at the age of sixty years. He worked with Donatello, whom he helped at Naples with the Brancacci monument. He built for Cosmo dei Mediei the palace now known as the Palazzo Riceardi; he followed this patron into exile to Venice, where he built the Library of St. George for the Benedictine monks, and made many designs for private and public works. On his return to Florence with Cosmo he repaired the Palazzo della Signoria, which Arnolfo had designed; he built the Dominican convent of St. Mark, finished in 1452; construeted the Tornabuoni palace, and, by order of Piero dei Mediei, designed a chapel in the Church of the Virgine Annunziata. A statue of *Faith* in the Baptistery in the same city is his work. At Bosco he designed the Capuchin convent; at Mugello the palace of Caffaggiuolo; and at Fiesole the Mozzi palace and the church and convent of St. Jerome. Michelozzi also designed and made a model for a hospital for pilgrims, which Duke Cosmo ordered to be erected at Jerusalem at his expense, and at the order of the duke he constructed an aqueduct for Assisi, and ereeted a beautiful fountain there. At Perugia he restored the convent and designed the ancient eitadel. When Francesco Sforza bestowed a palace in Milan on Cosmo, Michelozzi was sent to enlarge and ornament it with sculpture. The chapel of St. Peter, Martyr, in St. Eustorgio, of Milan, is also his work. W. J. STILLMAN.

Michie, PETER SMITH: officer and educator; b. at Breehin, Scotland, Mar. 24, 1839; his family removed to Cineinnati, O., in 1843; he graduated at the U. S. Military Academy June 11, 1863; was promoted first lieutenant Corps of Engineers Junc 11, 1863, and captain Nov. 23, 1865. He served during the civil war in the operations against Charleston and in the siege of Fort Wagner June, 1863, to Jan., 1864; was chief engineer northern district, department of the South, and of the district of Florida Jan. to Apr., 1864, being engaged in the battle of Olustee. He was assistant engineer Army of the James May to Aug., 1864, and chief engineer Army of the James and departments of Virginia and North Carolina Aug., 1864, to Mar., 1865; was assistant inspector-general Twenty-fifth Army-corps Mar. to July, 1865, being engaged in the action at Drewry's Bluff, assault and capture of Fort Harrison, and in charge of the construction of lines of works, the Dutch Gap Canal, and the engineering operations of the left column of the Army of the Potomac in the pursuit and capture of Gen. Lee at Appomattox Courthouse. He was made brevet captain and major for gallant and meritorious conduct during the Richmond campaign of 1864, lieutenant-colonel for the Appomattox campaign, and brigadier-general of volunteers for meritorious serviees in 1864; was on duty at the Military Academy as assistant professor in the departments of engineering and chemistry 1867–71; appointed member of commission to Europe to collect information on fabrication of iron and steel June to Nov., 1870; Professor of Natural and Experimental Philosophy at the U. S. Military Academy Feb. 14, 1871; was a member of board of overseers of Thayer School of Civil Engineering; was the author of works on analytical mechanies, hydro-mechanies, and wave-motion, and of the *Life of General Upton*. D. Feb. 16, 1901. JAMES MERCUR.

Michigan [from Indian *Mitchi Sawgyegan*, liter., Lake Country]: one of the U. S. of North America (North Central group); the thirteenth State admitted to the Union.

Seal of Michigan.

Location and Area.—It is situated between 41° 42′ and 47° 32′ N. lat. and 82° 24′ and 90° 31′ W. lon., and covers an area of 58,915 sq. miles, of which 1,485 sq. miles are water surface. It consists of two peninsulas, of which the lower, resting on Ohio and Indiana, and bounded on all other sides by the lakes and their connecting waters, extends 300 miles toward the N., with an average breadth of 200 miles; while the upper, resting with its southwest border on Wiseonsin, stretches eastward between the lakes to St. Mary's river, the outlet of Lake Superior, with a length of over 300 miles and an average width of 50 or 60 miles.

Physical Features.—During the glacial epoch the whole of Michigan was buried beneath several thousand feet of ice, which flowed in a southerly direction, and which greatly modified the previous topography. In the lower peninsula, where the rocks, eroded by glacial action, lie deeply buried, the relief of the land, as now seen, is almost wholly the result of the deposition of clay, gravel, sand, and bowlders by glaciers and by the streams flowing beneath the ancient ice sheet or issuing from its margin. The direction of the streams also was determined by inequalities of the surface left when the ancient glaciers retreated. Imperfect drainage has left thousands of lakes filling depressions in the surface, and in thousands of instances shallow lakes have been filled with marl and peat, and now form swamps or have been drained, and furnish rich soils for vegetable gardens. Over considerable areas there are no surface streams, the rainfall being conducted away by percolation. Beneath the general covering of glacial deposits there is a system of stream channels, excavated in hard rock, traces of which may sometimes be recognized at the surface or discovered by wells and borings, but it has no immediate relation to the present surface drainage. In the lower peninsula there are several summits which attain elevations of from 100 to 700 feet above the lakes, but these are seldom abrupt, and are scarcely distinguishable in the generally monotonous topography. Through the central portion of the peninsula, from Saginaw Bay, S. W., there is a broad, low tract of country which would be transformed into a strait, leaving the country to the N. as an island should the waters of Lakes Michigan and Huron be raised 75 feet. A high-water stage of the Great Lakes, which came later

than the glaciers, left beaches at elevations of several hundred feet above the present lake surfaces, and spread fine clays over the submerged borders. These ancient lake ridges may be easily recognized in both the lower and upper peninsulas. On the Lake Michigan shore of the lower peninsula are large tracts of drifting sand forming dunes, which travel inland in the direction of the prevailing winds.

Geology.—The rocks below the superficial deposits of the lower peninsula are sandstones, limestones, and shales, ranging in age from the coal-measures downward to the Upper Silurian. Beneath these, but not coming to the surface, are still older Palæozoic strata. The Trenton limestone underlies the entire peninsula at a depth in the central part of about 2,000 feet. At an early date in the deposition of the strata a central basin was formed by subsidence, which was filled as its bottom was lowered, so that the younger rocks, the coal-measures, occur in a somewhat circular area, about which the older rocks come to the surface as concentric rings. Owing to the existence of a central basin, the brines and salt deposits included in the rocks at the time of their formation have not been flooded out. In the eastern half of the upper peninsula the geological strata are a continuation of those existing in the lower peninsula, the sandstone cliffs along the southern shore of Lake Superior forming the northern part of the basin referred to. The western portion of the upper peninsula, however, presents a marked contrast with the rest of the State. The hills rise to an elevation of from a few hundred to about 1,300 feet above the lake, but their ruggedness has been much softened by glacial erosion. Among the boldest topographic features is Keweenaw Point, which projects into Lake Superior as a long ridge, with an elevation of from 800 to 900 feet, and owes its prominence to numerous dikes and sheets of igneous rocks which have withstood erosion. The characteristic rocks of this region belong to the Algonkian period, which includes the copper and iron bearing rocks, and to the Archæan, including the granites. With these rocks is found a reddish sandstone of the Cambrian period, which has been quarried for building purposes.

Mineral Resources.—According to the U. S. census of 1890, Michigan in 1889 produced 40·34 per cent. of all the iron ore mined in the U. S., Alabama and Pennsylvania coming next with 10·82 and 10·75 per cent. respectively. In 1899 the Michigan mines produced 9,146,157 long tons, valued at $13,707,899, 37·1 per cent. of the total production of the U. S. Minnesota, Alabama, and Pennsylvania ranked next with 33, 10·3, and 9 per cent. respectively. The mines are in three ranges: the Marquette range, of which the most important mines are those of Ishpeming; the Menominee range, of which the principal mine, the Chapin, has a yearly output second only to that of the Norrie; and the Gogebic range, of which the Norrie is the leading mine. Until 1889 Marquette was the most important port for the shipment of iron ore, but in that year the lead passed to Escanaba, and finally in 1897 to Two Harbors, Minn. The shipments from these two ports in 1899 aggregated 7,693,951 long tons, more than one-third of the total shipment of the Lake Superior region. Only a very small part of its iron-ore product is smelted within the State, and that in charcoal-plant furnaces, which in 1899 produced 134,443 long tons of pig-iron. The U. S. produces a third of the world's copper, and of the output of the U. S. Michigan furnishes a third. Its copper mines are all situated on the peninsula jutting out into Lake Superior, and terminating in Keweenaw Point. The total production of copper in the Lake Superior region in 1899 was 147,400,338 lb. Some of the leading mines with the amount of their production were: Tamarack, 18,565,602 lb.; Quincy, 14,301,182 lb.; Oceola, Kearsarge, and Tamarack, Jr., 11,358,049 lb.; Franklin, 1,230,000 lb.; Atlantic, 4,675,882 lb.; and Wolverine, 4,756,646. The annual report of the Calumet and Hecla Mining Company for the fiscal year ending April 30, 1899 shows a product of 49,312 tons of refined copper. The metal is found in the rock as free copper, and is separated by crushing and washing. The brine and salt stored in the rocks underlying the State have been reached by wells. These wells vary in depth from 850 to 2,200 feet, and the salt-bearing rocks lie deepest in the western part of the State. In 1898 the wells of the State yielded 5,263,564 barrels, valued at $1,628,081, out of a total product for the U. S. of 17,612,634 barrels, valued at $6,212,554. Of the gypsum produced in Michigan, which forms about half the yield of the entire country, the larger part comes from Kent County, where, in the neighborhood of Grand Rapids, there are deposits not far below the surface covering an area of 10 or 12 sq. miles. About a third of the gypsum produced in the State is calcined into plaster-of-Paris, while the remainder is sold as land plaster. The quarries at Grindstone City supply the best quality of stone for wet grinding. Sandstone is quarried in considerable quantities for building purposes in the upper peninsula, where the supply is unlimited and of fine quality.

Soil and Productions.—Owing to the commingling of the *débris* of many kinds of rocks, the soils of Michigan are of varied composition, and in large areas very fertile. The following summary from the census reports of 1880 and 1890 shows the extent of farm operations in the State:

FARMS, ETC.	1880.	1890.	Per cent.*
Total number of farms	154,008	172,344	11·9
Total acreage of farms	13,807,240	14,785,636	7·1
Value of farms, including buildings and fences	$499,103,181	$556,190,670	11·4

* Increase.

The manufacture of beet-sugar has been successfully introduced, giving employment to 23,000 persons and producing more than 34,000,000 lb. of sugar in 1900.

The following table shows the acreage, yield, and value of the principal crops in the calendar year 1900:

CROPS.	Acreage.	Yield.	Value.
Corn	1,080,235	38,888,460 bush.	$14,388,730
Wheat	1,219,969	9,271,764 "	6,397,517
Oats	917,971	33,689,536 "	8,759,279
Rye	71,306	1,041,068 "	499,713
Barley	37,858	904,806 "	425,259
Buckwheat	22,160	310,240 "	158,222
Potatoes	171,453	16,630,941 "	4,324,045
Hay	1,339,238	1,727,817 tons	16,218,657
Totals	4,860,190	....	$51,171,422

On Jan. 1, 1899, the farm animals comprised 412,462 horses, value $23,752,433; 2,567 mules, value $166,161; 463,698 milch-cows, value $15,162,925; 338,120 oxen and other cattle, value $9,043,695; 1,389,073 sheep, value $4,972,882; and about 700,000 swine, value $5,000,000: total value, $58,098,096.

The fruit-crop is varied. The apple-crop in particular is large, varying between the extremes of 1,500,000 and 5,000,000 barrels annually. The peach belt of the State lies chiefly under the lee of Lake Michigan. The yearly peach crop is from 500,000 to 1,000,000 bush. Allegan, Kent, and Van Buren Counties are the chief producers. The various kinds of small fruits are largely cultivated.

Lumber.—According to the U. S. census of 1890, Michigan in 1889 produced 19·75 per cent. of all the lumber cut in the U. S., or an amount about equal to the combined product of Wisconsin and Minnesota, the two States which stand nearest to it on the list. When lumbering began in Michigan the State possessed enormous wealth in its pine-forests, which were found N. of a line running nearly W. from Port Huron, and which are estimated to have contained 150,000,000,000 feet of lumber. For the marketing of this lumber there existed the most ample facilities, the logs being floated down the rivers and their tributaries swollen by spring rains, and the lumber being shipped from lake ports. So rapidly has this process been carried on that of the once apparently inexhaustible pine supply of the State, nine-tenths have been already cut. The total production for the year 1899 was 2,338,575,135 feet, and 1,454,578,000 shingles. The abundance of lumber has given an impetus to the manufacture of furniture, nearly $10,000,000 being invested, fully half of the amount in the factories at Grand Rapids.

Fisheries.—The fisheries of Michigan give employment to over 4,000 men, and yield annually about 35,000,000 lb. of fish. Two-thirds of the catch of the State consists of trout and whitefish, of which Lake Michigan yields nearly half, while the rest is furnished in equal proportions by Lake Superior and Lake Huron. To replenish the lakes and streams a board of fish commissioners has established hatcheries at Detroit, Paris, Glenwood, and Sault Ste. Marie, and the Federal Government has established others at Alpena and Northville.

Climate.—The climate is intermediate between that of the relatively moist New England and that of the relatively dry Dakotas. It has also some features peculiar to its position. In the spring the Great Lakes, the waters of which warm up more slowly than the land, serve to hold back the

summer temperatures. Hence spring comes late and with a rush, its actual duration being extremely short, sometimes not more than a fortnight. May Day in Michigan is almost invariably cold and raw. In the autumn, the lakes, whose waters cool slowly, prolong the autumn and give several weeks of cool, stimulating, and beautiful weather, which may extend well into December, and sometimes is prolonged beyond Christmas. Moreover, the extremes of temperature are cut down at both ends, so that the weather is not likely to be either so cold in winter or so hot in summer as it is in adjacent States. The accompanying tables give the average and the extreme temperature for certain selected stations, where observations were taken for the number of years indicated:

* Principally from observations made at the State Agricultural College of Michigan. † Period of observation.

The number of storms that pass over the State in the course of a year is large. If maps were drawn for a number of years, showing, in black, the path of each storm, the successive maps would become blacker and blacker, and the blackest path would be in the vicinity of Alpena. The following table gives the average number of low-area storms crossing centrally over the State each month during the decade 1883–92, and shows also their distribution among the three indicated divisions:

STATIONS.	Jan.	Feb.	Mar.	Apr.	May.	June.	July.	Aug.	Sept.	Oct.	Nov.	Dec.
Upper peninsula	2·6	1·6	2·0	1·2	1·7	1·7	2·4	2·0	2·0	2·4	2·6	1·7

* Reference for location of counties, see map of Michigan.
† Formed from parts of Iron, Menominee, and Marquette in 1891.
‡ In Lake Superior. Annexed to Keweenaw County in 1897.
§ Annexed to Charlevoix and Leelanaw Counties in 1896.

Principal Cities and Towns, with Population in 1900.—Detroit, 285,704; Grand Rapids, 87,565; Saginaw, 42,345; Bay City, 27,628; Jackson, 25,180; Kalamazoo, 24,404; Muskegon, 20,818; Port Huron, 19,158; Battle Creek, 18,563; Lansing (capital) 16,485; Ann Arbor, 14,509; Manistee, 14,260; Ishpeming, 13,255; West Bay City, 13,119; Flint, 13,103; Menominee, 12,818; Alpena, 11,802; Sault Ste. Marie, 10,538; Marquette, 10,058; Pontiac, 9,769; Ironwood, 9,705; Adrian, 9,654; Escanaba, 9,549; Traverse City, 9,407; and Iron Mountain, 9,242.

Population and Races.—In 1870, 1,184,059; 1880, 1,636,937; 1890, 2,093,889 (native, 1,550,009; foreign, 543,880; males, 1,091,780; females, 1,002,109; white, 2,072,884; colored, 21,005, of whom 15,223 were of African descent; 120 Chinese, 38 Japanese, and 5,624 civilized Indians); 1900, 2,420,982.

Commerce.—Michigan has a large foreign commerce, chiefly with Canada, the exports including iron ore, copper, salt, building-stone, lumber, grain, fish, meats, fruit, carriages, and railway cars. The U. S. customs districts and ports of entry are Detroit, Grand Rapids, Huron, Michigan City, and Superior, and during the calendar year 1900 the combined imports amounted in value to $5,556,054, and the exports to $32,590,586.

Finance.—In 1899 the State debt, including trust funds, amounted to $6,630,996.39. The financial report for the year ending June 30, 1899, showed balance on June 30, 1898, $1,216,212.61; receipts from June 30, 1898, to June 30, 1899, $4,576,874.98; expenditures during same period, $4,391,031.71; leaving a balance, June 30, 1899, of $1,402,055.88. The assessed valuation in 1900 was $1,105,100,000.

Banking.—On Sept. 5, 1900, there were 83 national banks, with a combined capital of $11,471,532.60, surplus and undivided profits of $4,844,733.41, and individual deposits of $54,065,246.36. There were, June 30, 1900, 194 State banks, capital $12,945,100, surplus and profits $5,390,312, and deposits $102,448,609; and 48 private banks, capital $617,603, surplus and profits $128,378, and deposits $3,442,350.

Means of Communication.—The first railway built in Michigan was the one between Port Lawrence, O. (now Toledo), and Adrian, which was opened for traffic in 1836. In 1837 the Legislature authorized the construction by the State of three railways, traversing the State from E. to W., of which the central had been built from Detroit to Kalamazoo, and the southern from Monroe to Hillsdale, when in 1846 they were sold to private corporations. The two railways reached Chicago in 1852, within a few hours of each other. The progress of railway construction is shown by the following figures, giving the number of miles of track within the State at the end of each decade: 1840, 104; 1850, 380; 1860, 770; 1870, 1,739; 1880, 3,823; 1890, 6,957. On June 30, 1899, the total mileage was reported at 8,097·31.

A coast line of over 1,600 miles affords unequal facilities for water transportation. Of the 2,784 craft engaged in carrying the 53,500,000 tons of freight transported on the Great Lakes in 1889, about 1,000 belonged to Michigan. In 1892, vessels numbering 33,860, with 24,785,000 registered tonnage, passed through Detroit river, and 12,580 vessels, with 10,647,203 registered tonnage, passed through St. Mary's river and canal. The only other canal in the State, 3 miles long and without locks, connects the northern end of Portage Lake with Lake Superior.

Churches.—The census of 1890 gave the following statistics of the religious bodies having each a membership in the State of 5,000 and upward:

DENOMINATIONS.	Organizations.	Churches and halls.	Members.	Value of church property.
Roman Catholic	406	409	222,261	$3,671,350
Methodist Episcopal	1,085	1,042	86,958	3,739,850
Baptist	395	415	34,145	1,858,419
Lutheran, Synodical Conference	137	116	27,472	488,880
Presb. in the U. S. of America	236	246	25,088	2,214,636
Congregational	331	346	24,582	1,533,055
Protestant Episcopal	189	204	18,034	1,645,551
Lutheran, Michigan Synod	62	62	11,041	157,270
German Evan. Synod of N. A.	50	50	10,926	242,450
Lutheran, General Council	70	70	8,710	153,350
Christian Reformed	44	52	7,782	174,100
Evangelical Association	134	136	6,677	188,450
Reformed Church in America	45	53	6,609	262,800
Lutheran, Joint Syn. of Ohio, etc.	21	21	6,217	125,700
Disciples of Christ	73	75	5,788	160,650
United Brethren, Old Constitution	164	164	5,602	119,550
Free-will Baptist	128	127	5,135	277,275
United Brethren in Christ	138	137	5,201	133,250

Schools.—For primary education the townships are divided into school districts, each with a board of three members chosen at the school meeting. In 1899 there were 7,973 school-houses, and 15,564 teachers, and a school enrollment of 498,665 out of a total school population of 713,740, with an average daily attendance of about 350,000. The total revenue for school purposes was $6,660,800; the total expenditure, $5,883,369. The average expenditure per pupil, based on daily attendance, was $16.81. The primary-school fund had its origin in the grant made by Congress of a section in each township for educational purposes. In many of the more populous districts the schools have been graded, the statistics of 1892 showing 572 graded school districts. To encourage grading the law permits two or more contiguous districts to unite to establish a graded school. High schools are but graded schools of a more advanced character, the line between the grammar school and the high school being drawn, as a rule, at the end of the eighth grade. The educational system of the State culminates in the University of Michigan, a State institution managed by an elected board of regents, and having in 1898–99 about 200 professors and instructors and 3,059 students. The Normal School, at Ypsilanti, the Agricultural College, at Lansing, and the Mining-school, at Houghton, complete the list of State educational institutions. There are also a number of colleges in the State supported by religious denominations.

Libraries.—According to a U. S. Government report on public libraries of 1,000 volumes and upward each in 1891, Michigan had 139 libraries which contained 733,377 bound volumes and 80,734 pamphlets. The libraries were classified as follows: General, 47; school, 36; college, 14; college society, 1; law, 2; medical, 1; public institution, 7; State, 1; social, 24; scientific, 2; garrison, 1; not reported, 3.

Post-offices and Periodicals.—In Jan., 1901, there were 2,173 post-offices, of which 305 were presidential (11 first-class, 46 second-class, 148 third-class), and 1,968 fourth-class. There were 1,066 money-order offices, and 60 money-order stations. The newspapers and periodicals comprised 77 daily, 5 tri-weekly, 21 semi-weekly, 604 weekly, 1 bi-weekly, 6 semi-monthly, 89 monthly, 3 bi-monthly, and 5 quarterly publications: total, 790.

Charitable, Reformatory, and Penal Institutions.—The first charitable institution organized in the State was the School for the Deaf, established at Flint in 1851. The school had in 1900 431 pupils and 18 instructors. The blind were also admitted to this school until 1880, when a School for the Blind was established at Lansing. An institution peculiar to Michigan is the State Public School at Coldwater, established in 1874 to afford a temporary home to dependent and ill-treated children who, if between the ages of two and twelve and sound in body and mind, may be sent there by the superintendents of the poor under the order of a judge of probate. In 1891 there were 198 children in the school and 1,352 in homes which had been secured for them, and where they continue to be wards of the State. There is a Soldiers' Home at Grand Rapids. The Legislature of 1893 made provision for a Home for the Feeble-minded and Epileptic. The State has also made generous provision for the insane. In three asylums, located at Kalamazoo (opened in 1859), at Pontiac (opened in 1870), and at Traverse City (opened in 1878), the total number of patients in 1892 was 2,748. A law of 1893 provided for a fourth asylum to be located in the upper peninsula. For such criminals as might become insane the Asylum for Insane Criminals was established at Ionia in 1885, but in 1891, upon provision being made for the transfer to it of the dangerous insane, its name was changed to the Michigan Asylum for Dangerous and Criminal Insane. The State Prison at Jackson was established in 1839. The State House of Correction and Reformatory, established at Ionia in 1877, was designed for younger and less hardened male offenders, but it has no distinctive reformatory features and differs from the State Prison chiefly in the exclusion of life-prisoners. In both institutions the prisoners are employed in various kinds of manual labor in the immediate service either of the State or of contractors. A third prison, corresponding to these, established at Marquette in 1885, is known as the State House of Correction and Branch of the State Prison for the Upper Peninsula. The number of inmates in the three prisons in 1892 was 768. The State Board of Corrections and Charities, consisting of four members appointed by the Governor for eight years, one every second year, and of which the Governor is *ex officio* a member, is intrusted with the duty of

inspecting the charitable, reformatory, and penal institutions of the State, as also county jails and asylums, and of reporting annually to the Governor the results of such inspection, together with such recommendations as it may deem proper. An agent of the board may be appointed by the Governor in every county, charged with the duty of advising the courts in regard to juvenile offenders, of seeking suitable homes for children who have become wards of the State, and of exercising oversight over those who have already been placed in homes.

Political Organization.—The Legislature is composed of two houses, the Senate and the House of Representatives, the former having 32 and the latter 100 members, elected in both cases from single districts. During its term of two years the Legislature, unless specially convened by the Governor, has but a single session, which begins on the first Wednesday in January of the year following the election of its members. To the Governor the constitution intrusts a qualified veto power, the duty of enforcing the laws, including the right as commander-in-chief to make use of the militia for the purpose, the authority to remove for cause a large number of appointed and elected officers, and the pardoning power. In the thirty-three judicial districts into which the State is divided circuit judges are elected for terms of six years, whose duty it is to hold at least two terms of court yearly in each of the counties belonging to their circuit. The Supreme Court consists of five justices elected for terms of ten years, one being elected every second year, and each acting as chief justice during the last two years of his term. The right to vote is given to male citizens of the U. S., including those who have declared their intention to become citizens, who are twenty-one years of age and have resided in the State three months and in the township or ward ten days preceding the election. The right of women to vote and to hold office is limited to school districts. The constitution prescribes that every sixteenth year the question of general revision shall be submitted to the voters.

History.—The early French missionaries and traders, diverted from the more direct route by the hostility of the Iroquois, moved westward by way of the Ottawa and French rivers and Georgian Bay, establishing settlements at Sault Ste. Marie and at St. Ignace, about thirty years before Cadillac's appreciation of the strategic importance of its position made him in 1701 the founder of Detroit. The town was surrendered to the English Nov. 29, 1760, within two months of the fall of Montreal. Two and a half years later it narrowly escaped falling into the hands of Pontiac at the head of a general movement on the part of the Indians to check the encroachment of the whites. In the Revolutionary war Detroit was the base of British operations in the Northwest, and their retention of it for thirteen years after the conclusion of peace resulted from their unwillingness to abandon that region to the U. S. Forming part at first of the Northwest Territory, organized by the ordinance of 1787, and belonging after the division of the latter in 1800 to the Territory of Indiana, Michigan was in 1805 organized as a separate Territory. Its first executive, Governor Hull, surrendered Detroit to the British in Aug., 1812, but the disaster was retrieved in the following year in consequence of Perry's victory at Put-in-Bay. Under the able rule of Lewis Cass, Governor from 1814 to 1831, emigration, hitherto held in check by danger from Indians, bad roads, and erroneous views in regard to the soil, streamed into the Territory. It was under the administration of Stevens T. Mason who, though but nineteen years of age, was appointed territorial secretary upon the resignation of Cass to enter Jackson's cabinet, and who acted as Governor during nearly the whole remaining period of territorial existence, that Michigan organized itself as a State and applied for admission into the Union. Its admission was retarded by its border controversy with Ohio, Michigan claiming that the boundary should be the continuation from the west boundary of Ohio of a line running due E. from the most southerly point of Lake Michigan, and hence reaching Lake Erie S. of Toledo. A proposition made by Congress to admit the State on condition that it should relinquish to Ohio the territory in dispute and accept in its stead a considerable addition of territory on the northwest, being the greater part of what is now known as the upper peninsula, was first rejected, but shortly afterward accepted, and on Jan. 26, 1837, the State was admitted. The constitution of 1835 was revised in 1850, when, among other changes, judges and heads of departments were made elective.

GOVERNORS OF MICHIGAN.

Under French Dominion.

Samuel Champlain	1622–35
M. de Montmagny	1636–47
M. d'Aillebout	1648–50
M. de Lauson	1651–56
M. de Lauson (son)	1656–57
M. d'Aillebout	1657–58
M. d'Argenson	1658–60
Baron de Avangour	1661–63
M. de Mesey	1663–65
M. de Courcelles	1665–72
Count de Frontenac	1672–82
M. de la Barre	1682–85
M. de Nonville	1685–89
Count de Frontenac	1689–98
M. de Callieres	1699–1703
M. de Vaudreuil	1703–25

S. census, etc.

RICHARD HUDSON.

Michigan City: city; La Porte co., Ind. (for location of county, see map of Indiana, ref. 1–D); on Lake Michigan, and the Lake Erie and W., the Louis., New Alb. and Chi., and the Mich. Cent. railways; 50 miles E. of Chicago. It contains 15 churches, a central and 5 ward public schools, St. Mary's Academy (Roman Catholic), St. John's and St. Luke's parochial schools (Lutheran), the Northern Indiana State Prison, a sanitarium, a U. S. life-saving station, electric street-railway, a beautiful public park on the lake front, a national bank with a capital of $250,000, a State bank with capital of $50,000, and 2 daily and 3 weekly newspapers. The city has an extensive trade in lumber, salt, and iron ore. Its manufactories include foundries, planing-mills, railway-car factory, glass-works, and several chair-factories. Pop. (1880) 7,366; (1890) 10,776; (1900) 14,850. EDITOR OF "NEWS."

Michigan, Lake: a lake of the Laurentian system, communicating with Lake Huron by the Straits of Mackinac. From the maps of the U. S. Lake Survey it has been computed that Lake Michigan, including Green Bay, has an area of 21,729 sq. miles. It is somewhat smaller than Lake Huron, and ranks third in the series of Great Lakes. Its mean surface elevation is 582 feet above the sea, and is the same as the level of Lake Huron. Its maximum depth is 870 feet; the bottom of the basin is therefore some 300 feet below sea-level. Its shores are low, unpicturesque, and without embayments except at the N., where Green Bay indents the western and Grand Traverse Bay the eastern shore. About its southern and eastern borders there are immense accumulations of sand which has been thrown ashore by the waves and currents, and drifted inland by the wind. In this way heavy forests have sometimes been buried, as may be seen at Sleeping Bear bluffs and other localities.

The level of the lake undergoes many changes, due to variations in the direction and force of the wind, seasonal and secular variations in rainfall and evaporation, fluctuations in atmospheric pressure, etc. The average differences of level as shown by twenty years' observation do not exceed 1·3 feet, but protracted gales blowing steadily in one direction may cause a rise or fall of several times this amount. A tide in the lake was detected from observations made by the U. S. Lake Survey at Chicago, having an amplitude of 1½ inches for neap and about 3 inches for spring tide. The

lake has an important influence on the climate of its shores, as its waters are warmer than the air in winter and cooler in summer. The effect of this amelioration of climate is shown by the abundance and rich flavor of the fruits of Michigan. Like its sister lakes, Lake Michigan abounds in fish, and is an important commercial highway. See also St. Lawrence River. Israel C. Russell.

Michigan University: an institution of learning at Ann Arbor, Mich. Congress, in the year 1826, set apart two townships in the Territory of Michigan for the future foundation of a university, which was accordingly established by the first Legislature of the new State Mar. 18, 1837, though not opened until Sept. 20, 1841. It is supported by the State, and open to students of both sexes on the payment of a small matriculation fee and of an annual charge of from $20 to $35. James B. Angell, LL. D., has been its president since 1871. To the original academic institution a medical department was added in 1850, a law department in 1859, and subsequently a school of pharmacy, a homœopathic medical college, and a dental college. The department of literature, science, and the arts embraces nine regular courses of four years and a graduate course. In that department courses in civil, mining, mechanical, and electrical engineering are given. The total number of instructors in 1899–1900 in the various departments was 158; the number of students was 3,700. The libraries contain about 145,000 volumes. A fine observatory was erected by citizens of Detroit in 1854. The grounds of the university embrace 55 acres, and the buildings were erected at a cost of $700,000. The university fund, derived from the sale of lands, annually yields about $38,500. A sixth-of-a-mill tax levied by the State for the university yielded (1899) about $240,000. The Legislature at each session for many years has made generous appropriations for the university. The annual expenditure averages about $325,000. The government is in the hands of eight regents, elected by the popular vote of the State.

J. B. Angell.

Michipicoten, mish-i-pi-kō'ten (great mushroom, according to Lacombe): name of a river, harbor, bay, and island in or emptying into northeastern Lake Superior, and forming parts of Ontario. The river is the outlet of many lakes, and descends through them by a series of rapids and cascades into the Bay of Michipicoten. It has clear and abundant water, except in summer; abounds in trout, sturgeon, and other fish, and forms with Moose river a boat route from Lake Superior to Hudson Bay, over at least thirty-nine portages. It requires sixteen days to reach Moose Factory, at the mouth of Moose river. At the mouth of Michipicoten river was the Michipicoten House of the Hudson Bay Company—one of its largest fortified posts, established at an early date, and long the busiest place on Lake Superior. Fifty miles S. W. is the island of Michipicoten, 25 miles long E. and W. by 10 broad, rocky, inhabited, cut up by fiords on the south side, culminating in an elevation of about 800 feet above the level of the lake. It has inexhaustible supplies of native copper. M. W. Harrington.

Michmash, mik'mash: a town of Palestine; in the tribe of Benjamin; 9 Roman miles N. of Jerusalem. It was a point of great strategical importance, and played a conspicuous part in several of the wars of the Israelites (1 Sam. xiii., xiv.; Isa. x. 28). It became the seat of government under Judas Maccabæus (1 Macc. ix. 73). It is now a small village, called Mukhmash. S. M. J.

Michoacan, mĕĕ-shō-ăă-kaan' (often written *Mechoacan*): a southwestern state of Mexico; bounded N. W. by Colima and Jalisco, N. by Guanajuato and Querétaro, E. by Mexico, S. by Guerrero, and S. W. by the Pacific. Area, 22,874 sq. miles. Pop. (1895) 889,795. Capital, Morelia. Somewhat N. of the middle the state is traversed from E. to W. by forest-covered monntains, which, farther W., in Jalisco, join the Sierra Madre. None of them is snow-capped, and the highest point in the range and in the state appears to be Tancitaro (about 11,500 feet). N. of these extend the plains and rolling country of the plateau about Morelia, generally open lands, dotted with lakes; of these, the largest are the Lago de Chapala (*q. v.*), on the border of Jalisco, and the Lago de Patzcuaro. S. of the mountains the country is extremely varied, long ridges descending toward the coast and separating fertile valleys of the *tierra templada* and *tierra caliente*. In the southeast, and S. of the principal mountain range, there is an arid basin, covered with lava and cinders, and containing the isolated recent volcano of Jorullo (*q. v.*). The climate, except in some parts of the coast land, is healthful, and in the interior is like that of a perpetual spring. The state is abundantly watered, the two largest streams being the Mescala and Lerma, respectively on the southern and northern frontiers. The soil is so fertile that this has been called the "garden of Mexico." The principal crops are maize on the plateau, coffee in the middle valleys, and sugar-cane and cotton (for home consumption only) in the hot lands. Cattle-raising is an important industry in the high lands. This is not one of the great mining states, but gold, silver, and copper to the amount of about $2,000,000 annually (Mexican money) are extracted, and a number of other minerals are reported. Manufactures, as yet in their infancy, consist mainly of woolen and cotton cloths and small hand-works.

Herbert H. Smith.

Michon, mĕĕ'shōṅ', Jean Hippolyte: preacher and author; b. at La Roche Fressange, Corrèze, France, Nov. 21, 1806; was educated in the College of Angoulême; studied theology in the Seminary of St. Sulpice, in Paris; was ordained a priest in 1830; preached with great success in Bordeaux, Angoulême, Périgueux, Paris, and other places; accompanied de Saulcy twice to the East, in 1850 and in 1863; was made an honorary canon of Bordeaux and Angoulême. D. at Montauzier, Charente, May 8, 1881. His numerous works belong to apologetics or archæology, or to that new science he has designated as "graphology." The first group comprises *La femme et la famille dans le catholicisme* (1845); *Apologie chrétienne au XIX^e siècle* (1863); *Vie de Jésus* (2 vols., 1865); the second, *Statistique monumentale de la Charente* (1844–48); *Monographie du château de la Rochefoucault* (1848); *Solution nouvelle de la question des lieux saints* (1852); *Voyage religieux en Orient* (2 vols., 1854); the third, *Système de graphologie* (1874); and the semi-monthly review *Graphologie*. See Varinard, *Jean-Hippolyte Michon, sa vie et ses œuvres* (Paris, 1883).

Mickiewicz, mits-kyev'ich, Adam Bernard: poet; b. at Novogródek, Lithuania, Dec. 24, 1798; studied at Minsk and Wilno; was appointed teacher of Latin and Polish at the gymnasium of Kovno, and published in 1822–23, at Wilno, two volumes of poems, *Poezye* (containing ballads, hymns, and the epic *Gražyna* and the *Dziady*), which at once gave him rank among the greatest poets of Poland, and decided the contest between the old classical and the new romantic school. A journey to the Crimea (1825) gave rise to a series of sonnets, *Sonety krymskie* (Moscow, 1826). For participation in Zan's conspiracy he was banished to the interior of Russia, and here he wrote the great patriotic epic *Konrad Wallenrod* (St. Petersburg, 1828). Having received permission to make a tour of Europe, he went to Germany and Italy, and finally settled in Paris (1832). There he published *Księgy narodu polskiego* (Books of the Polish Nation, Paris, 1832), in which he describes the mission of Poland in a biblical style. His greatest work, however, is the modern epic *Pan Tadeusz* (Paris, 1834), in which the poet, like a modern Homer, faithfully portrays Lithuanian life in 1812. In 1840 he was appointed Professor of the Slavonic Languages and Literature at the Collège de France, and his brilliant lectures attracted much attention; but afterward he became concerned in various fanatical religious and political plans designed by Towiański, and his lectures were suspended. In 1849 he edited *La Tribune du Peuple* (a daily). In 1852 Napoleon III. made him librarian at the arsenal in Paris. In 1855 he was sent by the emperor on a secret mission to Constantinople. D. in that city Nov. 28, same year. He was buried at Montmorency, Paris. Mickiewicz is justly considered the greatest of all Slavonic poets.

Revised by J. J. Král.

Micmacs: See Algonquian Indians.

Microbacteria: See Fermentation.

Microbes: minute living beings, instrumental in the production of fermentation and decay, and of many contagious diseases affecting man and the lower animals. See Bacteria and Bacteriology.

Micrococcus: the general name applied to minute spherical bacteria, many of which produce diseases in plants and animals. The name is also applied to a particular genus of the spherical bacteria. See Bacteria and Fermentation.

Micrococci.

Mi'crocosm [Gr. μικρόκοσμος, little world]: a name applied by the astrological philosophers of the Middle Ages to man, who was conceived of as the epitome or miniature representation of the universe, which was

named by them *Macrocosm*, or the great world. This theory, a very ancient one, was believed to explain the supposed influence of the stars upon the events in the history of the human race and of individual men.

Microfarad: See FARAD.

Microm'eter [Gr. *μικρός*, small + *μέτρον*, measure]: an apparatus for measuring small distances. The term is usually limited to a contrivance placed in the field of view of a telescope or microscope. Gascoigne in 1640 first suggested the idea of measuring distances in the field of view of a telescope by separating mechanically the edges of two brass plates placed in the focus of the eyepiece. Auzout and Picard in 1666 described a micrometer in which silver wires take the place of the brass edges. Felix Fontana in 1775 substituted spiders' web for the silver wires, which seems to be, in connection with the previous suggestions of Bradley, the incipient idea of the modern position micrometer. A fixed micrometer is mentioned by Cassini, and Cavallo used a strip of mother-of-pearl ruled to $\frac{1}{200}$th of an inch. Roemer hints at the heliometer with two object-glasses in 1675, and Bouger first calls it by that name in 1748; but it remained for Dolland in 1753 to construct a heliometer with a divided object-glass.

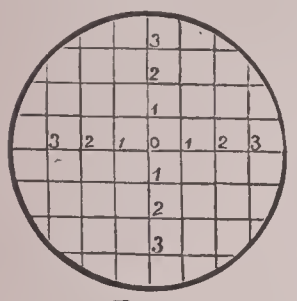

FIG. 1.

The simplest form of micrometer is the reticulated micrometer shown in Fig. 1, which consists of a network of lines whose distances apart are known. The apparent size of an object in the field of view then becomes known by noting how many divisions of the micrometer are occupied by its image. Scales ruled on glass, such as shown in Fig. 2, are sometimes substituted for the reticule. These lines are rendered visible at night by artificial light. For the observation of very faint objects, Prof. Rood suggests (*American Journal of Arts and Sciences*, 3d series, vol. vi., p. 44) an inexpensive scale micrometer made as follows: A dead black surface is formed on a thin plate of silver. Lines are ruled through the blackened surface, ending at the edge of the plate. The plate is then put in the focus of the eyepiece, so as to obscure less than half the field of view. The lines are illuminated by the light of a distant lamp or diffused light, which reaches them through an opening cut in the telescope tube between the observer's eye and the ruling on the silver plate. The ring micrometer is a circular metallic ring fixed in the focus of the telescope such as shown in Fig. 3.

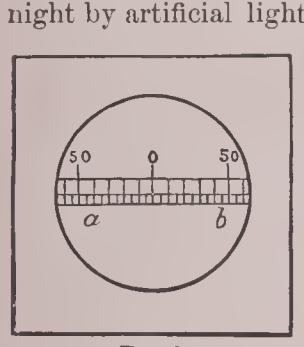

FIG. 2.

FIG. 3.

The Filar Micrometer.—This is the micrometer now most commonly used in astronomical instruments. It is called filar because its essential feature is a system of fine spider lines, having the appearance of threads. In a rectangular frame, *a a a a*, slide two rectangular forks, *b b b* and *c c c*, which can be moved by the screws *f f* by turning the graduated heads *g g*, which are graduated usually into 100 equal parts; at *a* and *a* are two pointers. If the head is turned so that 100 divisions will pass the point *a*, obviously we move one of the forks

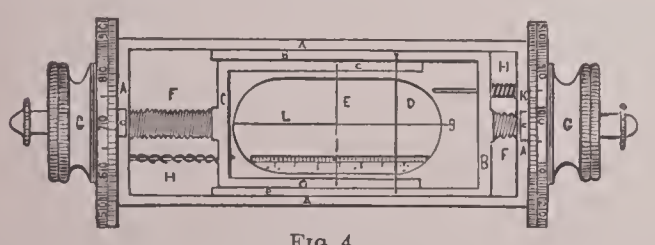

FIG. 4.

a distance equal to the distance between the threads of the screw *f*. The forks carry two spider-lines, *e* and *d*. The distance apart of any two points in the field of view may be determined by making the line *e* bisect one of them, and the line *d* the other, and at the same time having the line joining them parallel to *l*. For every entire revolution of the screw *f* the line *e* or *d* passes over a single tooth of the comb *c*. By noting the number of teeth included between the lines *e* and *d*, and also noting the readings of the pointers *a* and *a*, the exact distance between the two points becomes known, expressed in terms of the distance between the threads of the micrometer screw *f f*, which has usually about 100 threads to the inch. One division on the head of the micrometer screw would in this case correspond to $\frac{1}{10000}$th of an inch. When the filar micrometer is attached to a graduated circle, so that it can be rotated around the axis of a telescope, as shown in Fig. 5, it is called a position micrometer. The spider-lines are illuminated by lamplight at night.

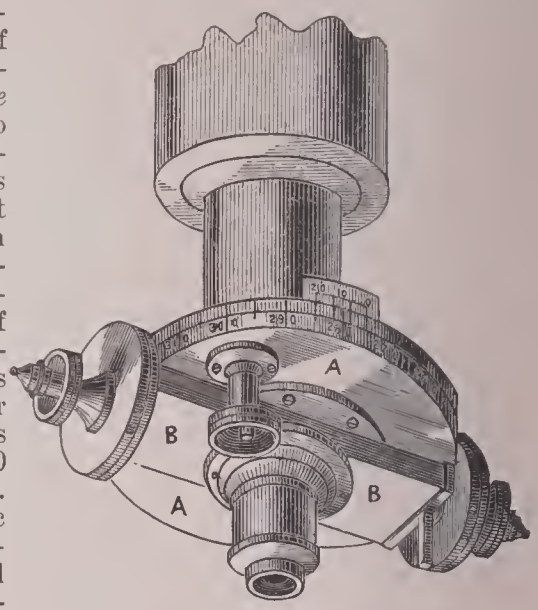

FIG. 5.

The Double-image Micrometer.—In this form the images of two objects are made to coincide in the field of view, either by the motion of the two halves of a divided object-glass of a telescope, in a line parallel to the line of section, or by the separating of the two halves of a simple eye-lens. The motion in either case is effected by proper micrometer-screws, and the displacement of the lenses necessary to effect a coincidence gives the data necessary to determine the angular distance between two objects. The first form of instrument is called the heliometer, and is superior to the position micrometer in that much larger distances can be measured. The second form is known as the double-image eyepiece micrometer. Either the reticulated or the filar micrometer may be used with the microscope, but one of the best microscope micrometers is that known as Jackson's micrometer, and shown in Fig. 6 and 7, where *a* is a frame containing a glass plate on which a scale of fine lines is ruled. This scale can be moved by a screw *s*, so that when placed in the focus of the eyepiece *b c* any desired line of the scale may be made to bisect any point in the field of view. The distance between two points may easily be determined in terms of the scale divisions.

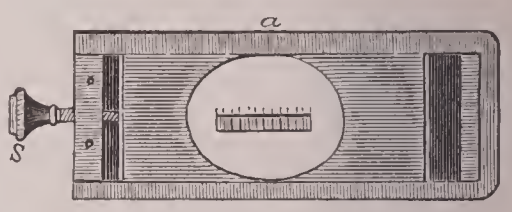

FIG. 6.

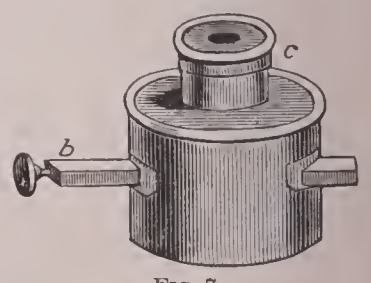

FIG. 7.

See for discussion of errors of micrometers Chauvenet's *Manual of Practical Astronomy*. For a very complete description of various forms of micrometers see *The Encyclopædia Britannica*, article *Micrometer*, by David Gill. For index of literature on micrometer, and descriptions of, see Dr. Philipp Carl on *Die Principien der astronomische Instrumentkunde* (Leipzig, 1863).

Revised by S. NEWCOMB.

Microne'sia [Gr. *μικρός*, small + *νῆσος*, island]: one of the three grand geographic, or more properly ethnographic, divisions of Oceanica, comprising the Marianne, Caroline, Marshall, and Gilbert groups, and those lying to the N. and N. E. of the Mariannes, with a combined area of about 1,300 sq. miles, and an estimated population of 91,000, or seventy per square mile. The Micronesians are closely allied to the Polynesians, but quite distinct from the Melanesians. There

is apparently some negrito mixture, and also considerable Malayan intermingling, but there are also traces of a race of still clearer complexion. M. W. Harrington.

Microphone: a device for increasing the amplitude of the minute sound-waves received by the telephone and thus to intensify the effect in the telephonic receiver. The name is generally applied to apparatus in which the change in the electrical resistance of graphitic carbon with varying pressure is utilized. Numerous forms of the microphone have been described, of which the carbon button invented by Edison has come into general commercial use in telephonic transmission. This button consists of a layer of pulverized carbon between two metallic disks. To one of these, which is free to move, is attached the stylus of the telephone transmitter, the motions of which vary the pressure upon the powdered carbon. This carbon button is placed in circuit with a battery and with the primary coil of an inductorium. To the secondary circuit of this induction coil is connected the line and the receiving telephone. This simple device has greatly increased the practicability of telephonic transmission to a distance. E. L. Nichols.

Micropyle: See Entomology.

Mi'croscope [Gr. *μικρός*, small + *σκοπεῖν*, look at, view]: Those objects which are too minute to be seen by the unaided vision are brought into view by the instrument called *microscope*. The period at which the microscope first became generally known was about the year 1590, Zacharias Jansens and his son having made the instrument at that time. Fontana (1618) and Stellati (1685) also made use of the microscope, and the latter published a description of the anatomy of the bee, including its minute structure. With the simple microscope (a single lens) Swammerdam, Leeuwenhoeck, and others made many discoveries; in fact, it would seem that the simple lens served to establish the immense value which this instrument was destined to render, and has rendered, almost every department of science. The form of single microscope used by Dr. Nathaniel Lieberkuhn (1740) consisted of a small lens placed in the center of a polished concave speculum of silver, thus allowing a brilliant light to be reflected upon the surface of the object. (Fig. 1.) Leeuwenhoeck's discoveries were made with a single lens mounted between two plates, each plate pierced with a hole. The objects were fastened to needles or plates of talc, which could be brought into position by means of screws. As each instrument was arranged for only two or three objects. Leeuwenhoeck had a large number of such simple microscopes. From the time of Zacharias Jansens (1590) to the period when uncorrected instruments were being abandoned, many forms of microscopes were constructed by men of science and by opticians in England, France, Germany, and Italy. Prominent among those to whom the development of the microscope is due are Adams, Baker, Hill, Delabarre, and Wollaston. The great difficulty which beset these early microscopists was the *spherical and chromatic aberrations* of the lenses, by which the image formed was distorted in figure and surrounded by a colored fringe. Wollaston and Fraunhofer directed their attention to the improvement of these defects, which resulted in the celebrated Wollaston doublet called by its inventor "periscopic microscope," and the combination by Fraunhofer of two glasses in juxtaposition, forming a single achromatic object-glass (1816). Euler as early as 1776 discovered the achromatic objective. The value of clear definition had now become so established that the greatest scientists of the day were engaged upon the subject of achromatism, both theoretically and practically. In 1829 Mr. Jackson Lister effected one of the greatest improvements in the construction of the object-glass, using a plano-concave lens of flint glass and a double convex of crown. These two lenses were cemented together by Canada balsam.

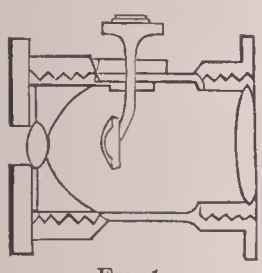

Fig. 1.

By a *simple* microscope is understood a single lens or set of lenses, by means of which the object is viewed directly. The ordinary hand-magnifier or pocket-lens is an example. Here one, two, or three lenses may be employed. A more convenient form consists in having the simple microscope mounted upon a stand provided with an arm made to move up and down by means of a rack and pinion or other device. The steadiness attained by this addition enables much useful work to be accomplished, such as dissecting animal and vegetable tissues, studying in a rough way fragments of rock, plants, etc. Hand-magnifiers, to be serviceable, must range in focal length between 2 inches and half an inch. High powers on this plan are generally known as the Coddington lens, Stanhope lens, and Wollaston doublet. It seems that the Coddington lens was really invented by Sir David Brewster, its present name having been given to it by Mr. Carey, who constructed one for Mr. Coddington, and supposed that he was the originator. This Coddington lens consists of a sphere of glass with a groove cut all around it and filled with dark, opaque material; the definition is good, and the instrument is used in collecting specimens for study with the larger microscopes, or where a rapid view is desired of many objects. Under the head of *compound* microscopes may be included those furnished with an object-glass and an eyepiece, or ocular, which further amplifies the image formed by the object-glass. A stand furnished with stage or object-carrier, quick and slow motions for focusing, with many accessories, constitutes the complicated though easily managed modern instrument.

In order fully to comprehend the optical arrangements of the microscope it seems best to consider very briefly some of the laws of optics which are immediately connected with it, and, as lenses are the chief parts to be looked into, to begin with their study. "A lens is a piece of glass or other transparent substance having its two surfaces so formed that the rays of light in passing through it have their direction changed, and are made to converge or diverge from their original parallelism, or to become parallel after converging or diverging." When a ray of light passes in an oblique direction from one transparent medium to another of a different density, the direction of the ray is changed both on entering and leaving; this influence is the result of the well-known law of refraction, that a ray of light passing from a rare into a dense medium is refracted toward the perpendicular, and *vice versa*. (Fig. 2.) The ray *k e* falling perpendicularly on the piece of glass at *e* is continued in a straight line to *h*. Now, if the same ray should take the course *a e*—that is, obliquely—instead of passing in a straight line *a e m b*, it will be turned out of its course, or refracted, to *d*, which is nearer the perpendicular *a' k h*. *a e* is the incident ray, and the angle *a e k* the angle of incidence with the perpendicular *k h*. From *e* to *d* is the refracted ray, and the angle *d e g* is the angle of refraction to the perpendicular. After the change in the course of the ray has taken place in the glass, we find that when the ray is allowed to pass out from the glass, as at *d c*, another bending takes place, by means of which the course is made parallel with the incident ray *a e*, only its course is shifted a little to one side. With any radius, as *d e*, describe a circle from the center *e*; then the angle of incidence *a e k* is measured by the arc *a a'*, and the arc *g' d* measures the angle of refraction *g e d*. The line *a k* equals the sine of the angle of incidence, and *d g* equals the sine of the angle of refraction. The sine of the angle of incidence (in a given transparent medium) has always the same ratio to the sine of the angle of refraction with all degrees of obliquity of the incident ray.

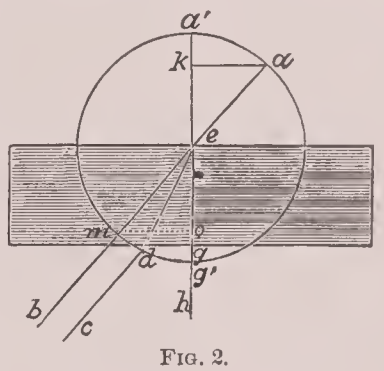

Fig. 2.

Lenses are of various forms, and change the course of light passing through them according to their special figure. In Fig. 3 are represented the different shapes of lenses. *a* is simple, parallel glass, *b* a meniscus or concavo-convex lens, *c* a double concave, *d* a plano-concave, *e* a double convex, and *f* a plano-convex. In the optical construction of the microscope, convex and concave lenses are chiefly employed, the convex being the most important form, as the concave is used more for the purpose of correcting the errors which exist in simple convex glasses. The course of parallel rays when they pass through a convex lens is changed, and brought to a point called a focus, *the principal focus*, and the distance from the center of the lens to this point is the focal length. Diverging rays are rendered parallel in their

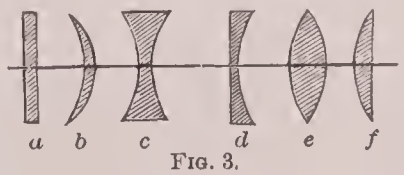

Fig. 3.

passage through a convex lens, and the focal distance for a double convex will be one-half that of a plano-convex having the same curved surface. The focal length depends upon the curvature of the lens and its index of refraction, so that a lens of crown glass will have a longer focus than one of flint with the same curvature. The principal focus, in general terms, may be considered as the distance of its radius for a double convex lens (that is, in its center of curvature), and at twice the distance of its radius for a plano-convex, parallel rays being understood as passing through in both cases. A concave lens refracts light in exactly the opposite manner from convex; hence parallel rays are caused to diverge, etc. By means of a convex lens a great number of rays proceeding from some point of an object are united in one point; each ray carries with it the image of the point from which it proceeded; therefore, all the rays united form an image of the object, and the image is brighter in proportion to the number of rays united. "If an object be placed at twice the distance of the principal focus, the image, being formed at an equal distance on either side of the lens, will be of the same dimensions with the object." (Fig. 4.) As the object approaches the lens, the image increases both in size and distance from the lens; and as the object is withdrawn from the lens, the image is smaller and closer to the glass. The smaller the image the more brilliantly it is illuminated; and, on the other hand, the light decreases as the image increases in size. Images formed by simple lenses are usually imperfect in two respects; they are distorted, and they are surrounded by a colored fringe. These defects are due to the spherical form in which the lenses are ground, as practically such curves as the ellipse and hyperbola can not be accurately made. The rays of light, then, in passing through a convex lens, are not *all* brought to the same focus, but those on the periphery come to a point first—i. e. nearest to the lens—and then those rays passing through closer to the center, afterward or farther from the lens. (Fig. 5.) This phenomenon to which the distortion of the image is due is called spherical aberration. A concave lens has precisely the same defects, but of an opposite character; hence, as will be seen further on, by combining the convex and concave a compound lens is obtained in which figure-distortion is greatly reduced. Chromatic aberration is due to the fact that the light, which consists of rays of different degrees of refrangibility, in its passage through the lens has the more refrangible rays brought to a focus first, and those of less degree at a greater distance from the lens. (Fig. 6.) Chromatic aberration can be corrected by the combination of two media of opposite form and of different refracting and dispersing power. By thus neutralizing the dispersion the refraction is not entirely overcome, but it is modified. With a lens of crown glass, double convex, index of refraction 1·519, dispersive power 0·036, focal length 4⅓ inches, cemented to a concave lens of flint, index of refraction 1·589, dispersive power 0·0393, focal length 7⅔ inches, the combined focal length 10 inches, an image free from color will be produced, which

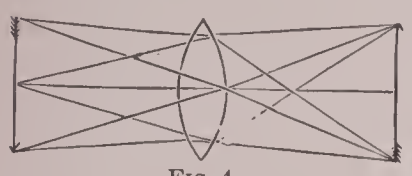

Fig. 4.

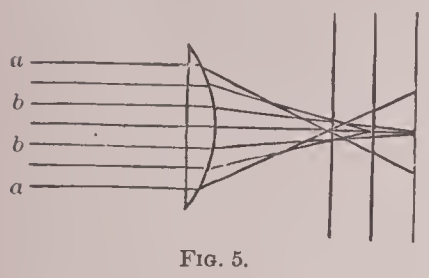

Fig. 5.

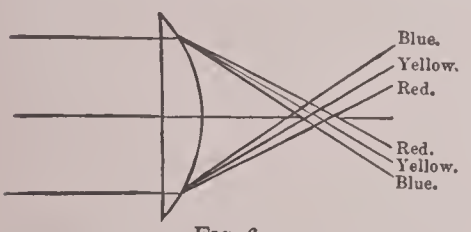

Fig. 6.

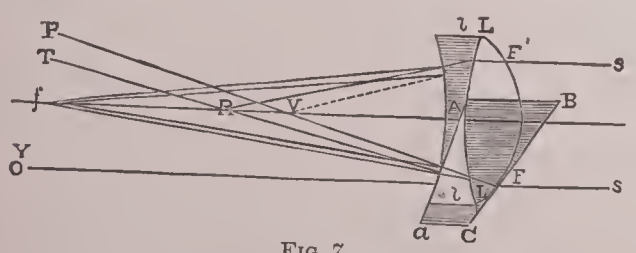

Fig. 7.

can be better understood from Fig. 7. L L is a double convex of crown glass, and *l l* is a concave of flint glass. The ray S falling on the lens L L at F is refracted just as it would be were it to fall on a prism A B C whose faces touch the lens at points of entrance and emergence of the ray. The ray S F goes on to form the spectrum P T, with F V, the violet ray, crossing the axis *f* V, and going to the upper end of the spectrum, and the red ray going to the lower end of the spectrum T. The flint-glass lens, however, *l l*, or the prism A *a* C, instead of allowing the rays to take the course indicated above, unites the rays F V, F R at *f*, refracting the ray S F without color from S F Y to F *f*. The ray S′ F′ is refracted in the same manner to *f*.

The Magnifying Power of a Lens.—In order that an object may be seen, it must be at such a distance as to form an image of some appreciable size upon the retina; and it must furthermore be sufficiently illuminated to produce an impression. The apparent size of an object depends upon the angle which it subtends to the eye, or the angle formed by two lines drawn from the extremities of the object to the center of the eye. (Fig. 8.) The lines from A and R form twice the angle at the center of the eye that O and W do; therefore the object O W seems one-half the size of A R. The angles formed as just described are called the visual angles. The eye can receive rays of a certain character only to produce distinct vision, and the rays must be parallel or slightly divergent, so that the crystalline lens may form an image of the object upon the retina. The distance or limit of distinct vision ranges from 6 to 10 inches; and when an object is brought closer to the eye, although it appears larger, it becomes more and more indistinct as the distance decreases, due to the fact that the rays which enter the eye are becoming more and more divergent. When a convex lens is interposed between a near object and the eye, it reduces the divergence of the rays forming the pencils issuing from it, and in this manner enables the rays to enter the eye so that an image may be formed upon the retina. (Fig. 9.) The more important laws of optics relating to the microscope will be considered as the various parts of the instrument are described.

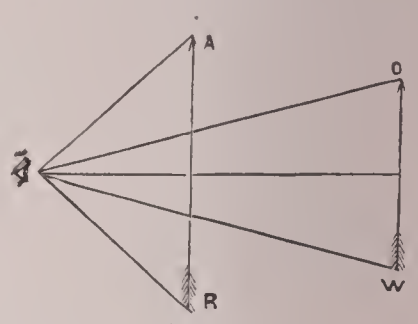

Fig. 8.

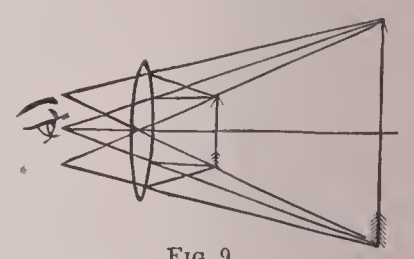

Fig. 9.

In the simple microscope, as has been seen, several lenses may be used, but they all act as a single glass; now, in the compound microscope, there are two parts, the object-glass, which may be a single lens, and the eyepiece or ocular, and this can also be a single lens. (Fig. 10.) The object-glass C D forms an enlarged and inverted image A′ B′ of the object A B, and the eye-glass L M receives the diverging rays from this image, as if from an object, and brings them to the eye at E. so that the object appears greatly magnified, on the same principle as the simple instrument. The magnifying power can be varied by changing the power of the objective, of the eyepiece, and by altering the distance between object and object-glass, eye-glass and object-glass. By approaching the object to the objective, and moving the ocular to a greater distance from the object-glass, the image is increased in size; and, conversely, by increasing the distance from object to object-glass, and lessening that between the latter and eye-glass, the image is reduced in size. In order that a greater portion of the object may come within range of the eyepiece, and so be made visible, a third lens (F F, Fig. 11) is placed between the objective and the eye-glass. As the third lens limits the circle of light or field of view which is seen in looking into a microscope, it is

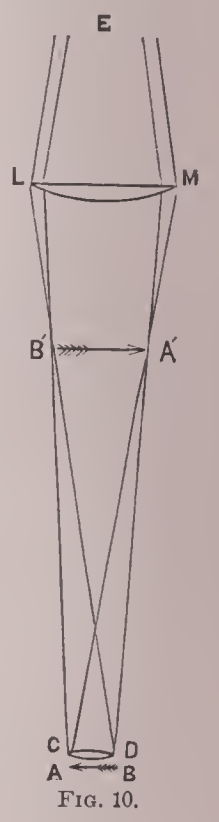

Fig. 10.

called the *field-glass*. The eye-glass and field-glass together are considered as one, and termed eyepiece or ocular. The Huyghenian is the most usual form of eyepiece, and consists of two plano-convex lenses (Fig. 12, E E and F F) with their plane surfaces toward the eye. The lenses "are placed at a distance equal to half the sum of their focal length, or, to speak with more precision, at half the sum of the focal length of the eye-glass and of the distance from the field-glass at which an image of the object-glass would be formed by it. A stop or diaphragm B B must be placed between the two lenses in the visual focus of the eye-glass, which is, of course, the position wherein the image of the object will be formed by the rays brought into convergence by their passage through the field-glass. Huyghens devised this arrangement merely to diminish the spherical aberration, but it was subsequently shown by Boscovich that the chromatic dispersion was also in great part corrected by it."

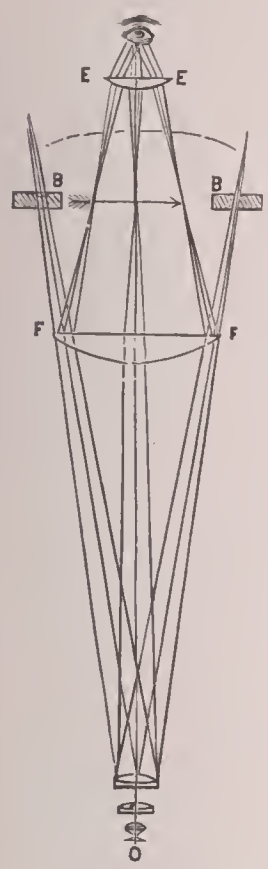

FIG. 11.

The *object-glass*—which, as has been stated, may be a single lens—is of the utmost importance; it is this part of the instrument that requires the greatest amount of care and skill in construction, and therefore requires special attention. The distortions known as spherical and chromatic aberration are the obstacles to be overcome in the construction of the object-glass. Now, it has been shown that, by combining a double convex lens of crown glass with a plano-concave of flint, the spherical and chromatic errors may be remedied—not in a single combination of flint and crown glass, but by means of two or more so-called achromatic lenses. To Joseph Jackson Lister is due the discovery by means of which the errors in the object-glass may be almost if not entirely overcome. Lister's result, which was communicated to the Royal Society in 1830, may be stated as follows: Plano-convex achromatic lenses, of the form shown in Fig. 13, are most easily constructed. When the convex and concave lenses have their inner surfaces of the same curvature cemented together, much less light is lost by reflection than if the lenses are not cemented. Every such plano-convex combination has some point *f*, not far from its principal focus, from which radiant light falling upon the lens will be transmitted free from spherical aberration; the point *f* is called the *aplanatic focus*. The incident ray *f d* makes, with the perpendicular *i d*, an angle considerably less than the emergent ray *e g* makes with the perpendicular at the point of emergence. The angle of emergence is nearly three times as great as the angle of incidence, and the rays emerge from the lens nearly parallel, or converging to a focus at a moderate distance from the lens. If the radial point is now made to approach the lens so that the ray *f d e g* becomes more divergent from the axis as the angles of incidence and emergence become more nearly equal to each other, the spherical aberration becomes negative or over-corrected; but if the radiant point *f* continues to approach the glass, the angle of incidence increases, and the angle of emergence diminishes and becomes less than the angle of incidence, and the negative spherical aberration produced by the outer curves of the compound lens becomes again equal to the opposing positive aberrations produced by the inner curves which are cemented together. When the radiant has reached this point *f'* (at which the angle of incidence does not exceed that of emergence so much as it had at first come short of it), the rays again pass the glass free from spherical aberration. The point *f'* is called the shorter aplanatic focus. For all points between the two aplanatic foci *f* and *f'* the spherical aberration is over-corrected, or negative; and for all radiant points more distant than the longer aplanatic focus *f*, or less distant than the shorter aplanatic focus *f'*, the spherical aberration is under-corrected, or positive. These aplanatic foci have another singular property. If a radiant point in an oblique or secondary axis is situated at the distance of the longer aplanatic focus, the image situated in the corresponding conjugate focus will not be sharply defined, but will have a coma extending outward, distorting the image. If the shorter aplanatic focus is used, the image of a point in the secondary axis will have a coma extending toward the center of the field. These peculiarities of the coma, produced by oblique pencils, are found to be inseparable attendants on the two aplanatic foci. These principles furnish the means of entirely correcting both chromatic and spherical aberration, and of destroying the coma of oblique pencils, and also of transmitting a large angular pencil of light free from every species of error. Two plano-convex achromatic lenses (A M, Fig. 14) are so arranged that the light radiating from the shorter aplanatic focus of the anterior combination is received by the second lens in the direction of *f''*, its longer aplanatic focus. If the two compound lenses are fixed in this position, the radiant point may be moved backward or forward within moderate limits, and the opposite errors of the two compound lenses will balance each other. Achromatic lenses of other forms have similar properties. It is found in practice that larger pencils free from errors can be transmitted by employing three compound lenses, the middle and posterior combinations being so united as to act as a single lens, together balancing the aberrations of the more powerful anterior combinations. (Fig. 15.)

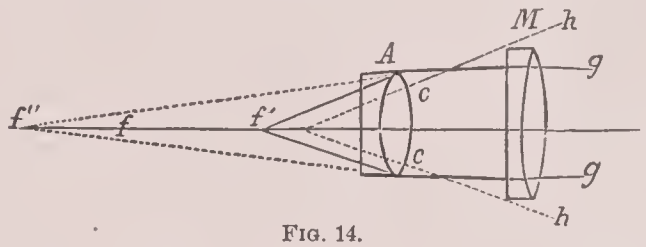

FIG. 14.

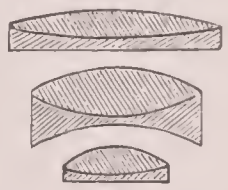

FIG. 15.

In many objectives it is required that there should be what is termed a large "angle of aperture," by means of which the definition is much improved. "The angle of aperture is that angle which the most extreme rays that are capable of being transmitted through the object-glass make at the point of focus." A much larger quantity of light passes through a lens of high angular aperture. The lenses constructed upon the principles given are termed *dry lenses*—i. e. a layer of air is between the objective and the front of the combination; for higher powers, however, the *immersion system* is now generally used, which is simply the intervention of a drop of water between the object and the lens, and consequently the rays of light from the object pass through water instead of air. The interposition of the water seems to prevent reflection of certain rays which would otherwise be lost; and therefore with the immersion system a greater amount of light can pass into the glass. Immersion lenses, as a rule, can not be used dry, although objectives have been made by Tolles, Wales, and other opticians that work both as wet or dry. Some makers construct two fronts, one for *dry* and the other for *wet* focusing, the middle and posterior combinations remaining the same in both instances.

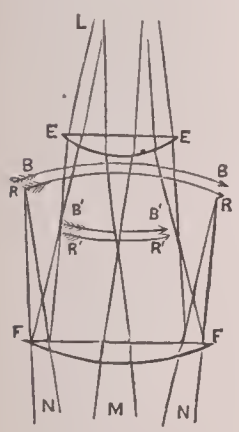

FIG. 12.

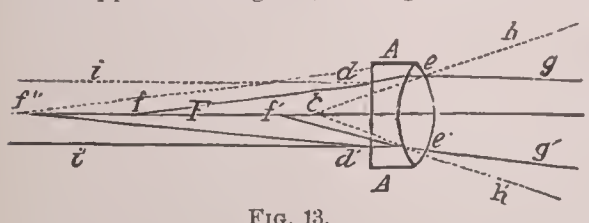

FIG. 13.

The great perfection obtained by opticians has rendered imperfect the performance of certain higher powers when different thicknesses of glass are used for covering the object. The discovery was made by A. Ross that a very marked difference exists in the precision of the image according as the object is viewed with or without the thin cover.* A correction for this has been effected by Ross by giving to the

* Microscopical objects are examined upon plates of glass 1 inch by 3 inches, and covered with a disk or square of thin glass; this cover is for the purpose both of protecting the object and of preventing the formation of moisture or deleterious vapors from reaching the exposed portion of the objective.

front pair of the objective an excess of positive aberration, by under-correcting it, and by giving an excess of negative aberration to the middle and posterior combinations. When the lenses are adjusted for an uncovered object, by bringing the anterior combination closer to the middle and posterior, a certain amount of positive aberration can be produced which will neutralize the negative aberration caused by the covering glass. A *screw-collar* is added, therefore, to those lenses which require the change in the position of the front lens, and in this manner the different thicknesses of glass covers are easily disposed of.

Objectives are named according to their magnifying power. Unfortunately, there is no uniform system upon which the lenses are constructed. In Great Britain and the U. S. lenses are called 1-inch, ½-inch, ¼-inch, etc. On this principle it is supposed that 10 inches is considered the standard for distinct vision, and therefore the 1-inch object-glass would produce an image at 10 inches distance enlarged 10 diameters,* the ½-inch (at the same distance) 20 diameters, the ¼-inch 40 diameters, etc. Lenses made in France and Germany are named according to an arbitrary system adopted by the maker himself; and Hartnach, of Paris, simply gives a series of numbers, 1, 2, 3, 4, etc., to designate the various powers. The eyepieces of American and English manufacture receive the letters of the alphabet to distinguish them; the A eyepiece magnifiying 5 diameters; B, 10; C, 15, etc. Hence the 1-inch objective with A eyepiece gives a power of 50 diameters; ½-inch, 100 diameters. Continental eyepieces are named 1, 2, 3, in just the same manner as are the objectives. Low-power objective glasses are those of longer focus than the ½-inch; medium, $\frac{1}{10}$ths, ¼th, and ⅓th; high, from ⅛th to $\frac{1}{15}$th, which is about the highest.

Reference has been made, in a general way, to the *stand*, which carries the eyepiece and object-glass, together with the object. In nearly all modern stands *coarse* or rapid adjustment is effected by milled heads, which move the tube by means of rack and pinion, while the *fine* adjustment is made by a delicate screw (also provided with milled head), which acts upon a lever, and this lever moves the nose carrying the objective. The stage or object-carrier likewise is frequently given freedom of motion both laterally in the direction of the optical axis of the instrument, while at the same time it can be made to rotate concentrically. Below the stage is what is termed the sub-stage, into which can be fitted the achromatic condenser, polariscope, and various other accessories. The sub-stage is provided with centering screws, rotation, and vertical motion. The various accessories of so much value to the microscope can be best studied in the larger works devoted to the special subject.

Revised by E. L. Nichols.

Microscopy: the use of the microscope and the preparation of objects to be examined by it. (See Microscope.) The use of the microscope in medicine is confined to the examination of solids and fluids of the body. It is of the utmost importance in distinguishing the changes which are produced in the body in various diseases, and the diagnosis of diseases by such changes. Perhaps the greatest use of the microscope which has been made in recent years is in the recognition during life of the pathogenic bacteria, and in this way diagnosing disease. Thus in the case of consumption the earliest proof of the presence of the disease may be obtained by the examination of the expectoration and the detection in this of the tubercle bacilli. Of scarcely less importance is its use in the examination of the urine and other secretions of the body. It has also an important part to play in medical jurisprudence, especially in the examination of stains for the presence of blood. In the examination of fluids they are either placed in their natural state under the microscope, or they are treated before examination in various ways with the view of rendering certain substances in the fluids more easily recognizable. Frequently in the examination of fluids, particularly urine, it is better to allow it to stand for some time until the solid substances contained in it have settled, and then to examine the sediment. The examination is rendered still easier by the use of the centrifugal machine which separates the solid matter. In the examination of the tissues of the body they may either be torn apart with needles and the cells examined, or they may be divided into very thin sections, and these sections examined. The sections are prepared on an instrument called the microtome. A certain degree of consistency must be given them in order to render it possible to divide them into these thin sections. This may be done either by freezing the tissue and then cutting it, or by subjecting the tissue to the action of alcohol or other hardening fluids. The sections so prepared may either be examined without further change, but better results are usually obtained by treating the sections with suitable coloring fluids, which have the effect of rendering certain of the constituents more easily visible.

W. T. Councilman.

* As the image is enlarged equally in all directions, ten diameters would represent a space occupied by the image 100 times greater than the original object. The simple form of writing magnifying power is, × 10, which means magnified ten diameters. When very high magnifying power is used, the expression in diameters is more convenient than superficial measurement.

Microzyma: See Fermentation.

Micyllus (Molsheym), Jacob: classical scholar; b. in Strassburg, Alsace, Apr. 6, 1503; studied under Melanchthon; was appointed director of the Latin school of Frankfort in 1524. After a stay of eight years, he was compelled to resign owing to an anti-humanistic propaganda of certain Lutheran Reformers, and accepted a professorship of Greek at Heidelberg in 1533, but meeting the same opposition here, he again returned to Frankfort in 1537, where the classicists had finally triumphed. Ten years later he was recalled to Heidelberg. With the powerful aid of the Margraves Frederick II. and Otto Heinrich, he and Melanchthon reorganized the university on a firm humanistic basis, elevating it to a high position among the learned institutions of Europe. D. Jan. 28, 1558. As an author, Micyllus is deservedly celebrated for his elegant Latin poems, published after his death by his son, under the title *Silvae* (1564). Of his philological works, which now possess only an historical value, may be mentioned his editions of *Ovid*; the so-called fables of *Hyginus*, his master-piece; *Vita Euripidis, de tragœdia et eius partibus*; a Latin translation of *Lucian* (1538); translations of *Germania*, *Histories and Annals of Tacitus*, one of the earliest translations of a classic author into German; a commentary to Boccaccio, *De genealogia Deorum*. See I. Classen, *J. M., als Schulmann, Dichter und Gelehrte* (Frankfort, 1859).

Alfred Gudeman.

Mi'das (in Gr. Μίδας): in Greek mythology, son of Gordius and King of Phrygia. He was the leader of the Phrygians from Europe to Asia Minor. His name alternated with that of Gordius (*q. v.*) in the Phrygian royal family. There were three Midases and four Gordiuses, and both names continued to live in *Gordium* and *Midiæum*. One of the Midases entertained hospitably the drunken Silenus. He thus promoted the worship of Dionysus, and became the center of a number of popular myths. Thus Dionysus gave him the power of transforming everything he touched into gold, but the gift proved a terrible curse. The man would have starved to death had not the god helped him a second time. By bathing in the river Pactolus the auriferous power was transferred from the body of Midas to the waters of the river, and they became henceforth productive of gold. He was merely the type of the immensely wealthy king in the times before Crœsus. Another time he was chosen umpire in a musical contest between Apollo and Pan. He gave the prize to the latter, and the angry god punished him by changing his ears into those of an ass. Midas concealed the deformity under a Phrygian cap, but one of his slaves, a barber, happened to discover the secret. Unable to keep it to himself, and yet not venturing to tell it to anybody, the slave dug a hole in the soil, and whispered the secret into the hole, which he filled with earth, but the reeds which grew upon the spot always sang when the wind blew among them, "Midas has ass's ears." The original Midas was a Silenus or Satyr, and the ass's ears were but the ears of the Satyr, and afterward became familiar in the Attic drama and in art. (See Marsyas.) For an excellent discussion of this whole subject, see Perrot and Chipiez, *History of Art in Phrygia*, etc. (London, 1892, pp. 1–231), where the literature will be found cited.

Mid'delburg: capital of the province of Zealand, Netherlands; situated on the island of Walcheren; 4½ miles by rail N. E. of Flushing (see map of Holland and Belgium, ref. 8–C). It is a handsome town, and has many public squares and interesting buildings, among which the town-hall is the most remarkable, built by Charles the Bold in 1468, and ornamented with twenty-five colossal statues of Counts and Countesses of Flanders. The commerce of Middelburg has greatly declined, but it has some manufactures of cotton, and an active inland trade. The town is mentioned in the middle of the twelfth century, and received its charter in 1225. The brilliant point in its history is the

defeat of the Spaniards in 1574, after a siege of two years. The wars between France and Great Britain in the beginning of the nineteenth century nearly ruined the town. Pop. (1888) 16,455.

Middelburg, Paul: mathematician: b. at Middelburg, island of Walcheren, Netherlands, in 1445; studied at the University of Louvain; took holy orders, and was appointed chaplain at the Church of St. Bartholomew in his native city; but, preaching a little too zealously against ignorance, drunkenness, gluttony, and other habits of that day, he was expelled from the city, and returned to Louvain, where he lectured with great success on mathematics. Chosen by the grand council of Venice to the chair of Mathematics in Padua, he afterward became physician to the Duke of Urbino, on whose recommendation he was appointed Bishop of Fossombrone in 1494 by Pope Alexander VI. With Julius II. and Leo X. he stood in great favor, and presided over the fifth Lateran Council (1512–18). D. in Rome, Dec. 15, 1534. He was one of the first to urge the necessity of reforming the calendar, showing in his learned work *Paulina, de recta Paschæ Celebratione, et de die Passionis Domini nostri Jesu-Christi* (fol., 1513), that the great Easter festival was not celebrated on the day determined by the Council of Nice, but sometimes a whole month earlier or later. Some of his many other writings treat the same subject, such as the *Epistola ad Universitatem Lovaniensem: De Paschate recte observando* (1487), which occasioned a long controversy, during which he published *Epistola apologetica magistri Pauli de Middelburgo, alumni universitatis Lovaniensis*, in answer to a criticism by Pierre de Rivo, Professor of Theology at Louvain.

Middle Ages: the term generally used to designate that great historical period lying between the ancient and modern epochs of the world's civilization, and separating them from each other as young manhood separates youth from mature manhood.

1. *Chronology.*—Concerning the exact date of the beginning and end of the mediæval period differences of opinion exist, some authors regarding the triumph of the Franks over the remnants of the Roman power in Gaul at the battle of Soissons (486 A. D.), others the overthrow of the West Roman empire in 476 A. D., and still others the accession of Charlemagne in 768 A. D., or the dissolution of the Frankish empire in 843 A. D., as the opening events. Some consider the discovery of America, others the discovery of printing, most the German Reformation, and a few the Westphalian Peace (1648), as marking the close. Those historians who consider ancient history to comprehend the world's history down to the dissolution of the Roman state begin the Middle Ages with the overthrow of the Roman power by the Germans and the settlement of the Vandals, Goths, Anglo-Saxons, Franks, and Burgundians upon Romanic soil in the last half of the fifth century; while those who regard Teutonic history in its more specific light, and consider each nationality as having its own childhood, youth, manhood, and old age, are inclined to look upon the life of the Teutonic peoples down to the dissolution of the Frankish European empire (see Franks) as the period of their wardship, and hence to set the beginning of the following period of young manhood or middle age between the years 814 and 843 A. D.; while, as regards the boundary of the epoch on the other side, very nearly all are agreed that the great events of the fifteenth and sixteenth centuries—viz., the discovery of printing, the discovery of America, the employment of gunpowder, the development of the absolute monarchy in the state, and the Reformation in the Church—designate the point where the spirit of civilization was throwing off its mediæval and taking on its modern form.

2. *Events.*—The cardinal events of the Middle Ages were—

(*a*) The reaction of the spirit of nationality against the artificial union of the Frankish European empire, producing the treaty at Verdun in 843 A. D. between the different sovereigns of the Carlovingian house, whereby the empire was divided into three independent kingdoms, corresponding in their territorial extent very nearly to the geographical basis of three distinct types of nationality, which had been for three and a half centuries developing themselves, and which may be termed from that time forward Italian, German, and French.

(*b*) The reaction of individuality against the authority of law imposed from without, which may be termed a great *series* of events rather than an event, realizing themselves all through the mediæval period, and splitting Europe up into a multiplicity of petty sovereignties, standing closed and hostile over against each other, blockading trade and intercourse, and producing unceasing intestine strife.

(*c*) The great invasion of the Scandinavian Vikings (836–912 A. D.), striking the deathblow to the tottering Carlovingian powers, already threatened by the Saracens in the S. and the Magyars in the E., compelling the members of this dynasty, in their impotence to defend their lands and peoples, to give way to stronger arms and cleverer genius, occasioning thus the elevation of the Capetians to the throne of France, changing Germany into an elective monarchy, and delivering emperorless Italy over to three-quarters of a century of most fearful intestine struggles.

(*d*) The settlement of the Northmen upon the territory of Northern France, founding there the dukedom of Normandy, accepting the culture of the Romanized Franks both in state and Church, setting the great North into connection with the Continent, and opening it up to the influences of Christianity and the civilization of the Romanic world; and then from this continental basis making conquest both of England (1066 A. D.) and Southern Italy (1029–85 A. D.), and founding independent kingdoms upon Anglo-Saxon and Italian soil.

(*e*) The crusades, eight in number, reaching chronologically from the year 1096 to 1270 A. D. In this great European movement, in which the chivalrous type of Christianity, beginning with the consecration of King Clovis's sword to the service of the Church, culminates, the peoples of Europe, especially those of Romanic nationality, impelled chiefly by the power of religious fanaticism, threw themselves back upon Asia with the nominal purpose of freeing the Holy Sepulcher from the desecrations of the Turks. In 1099 A. D. Jerusalem was captured and a European kingdom erected in Palestine, which existed with changeable fortune for nearly two centuries. In 1291 A. D. the last remnants of European sovereignty in Syria were extinguished, but the influence which the movement and its results exercised upon the course of European civilization was all-guiding and permanent. Six millions of men perished in these undertakings. Among these the nobility as a class suffered far the most severely, both in loss of life and property. From some districts this class was almost entirely obliterated. Moreover, the establishment of a political connection with Asia had led to the establishment of an intercourse and trade which enriched the burgher class as much as the wars had impoverished the nobility. The effect of this change in the conditions of property upon the political constitution of Europe was most marked. The political power passed over more and more to the cities and the burgher class, and the old feudal constitution began to be undermined. The results as regards the Church were of a double nature. Its temporalities had been immensely increased, in that it fell heir, for the most part, to the property of those who perished in these great religious adventures, having been made the guardian of the same during the absence of the owners; and its moral power entered upon the period of its decline, not only because the increased wealth of the Church led to luxurious living on the part of the clergy, but because also that power of religious fanaticism and unreflecting devotion upon which the Church of that age so much rested had been broken of its intensity and exhausted. The crusades were, after all, powerful elements in opening the way for the absolute monarchies and the Reformation.

(*f*) Lastly, the re-establishment of the Carlovingian imperium by Otho the Great (962 A. D.), under the name of Holy Roman Empire of the German Nation, thus bringing, both for weal and for woe, the German and the Roman into direct contact with each other, and paving the way for that great conflict between pope and emperor for the supremacy over European Christendom which, of all the movements of the Middle Ages, was the most continuous, important, and heavy with results. (See Franks.) The clergy had ever regarded the Carlovingian imperium as their own creation. In it European Christendom had found its point of unity. No wonder, then, that they sustained it to the last, and when it fell, felt themselves compelled to look for a new center and a new head. What more natural than that all eyes should be turned toward the Bishop of Rome? From the moment of the dissolution of the Carlovingian imperium the watchword had been the establishment of the "papal monarchy," and the withdrawal of the Church, with its property and its *personnel*, from under the jurisdiction

of the secular powers to unite it under the sovereignty of the pope, both as regards temporal and spiritual matters. In this way it would make good that which had been lost in the dissolution of the imperium—viz., the principle of unity in European Christendom. During the century and a quarter between the treaty of Verdun (843 A. D.) and the re-establishment of the empire by Otho (962 A. D.) this had been the reigning idea in the Church; and the chief reason why it did not then come to realization was the lack of a mighty personality upon the papal throne, by the power of whose genius that which lay in the consciousness and desire of the Church might be made an objective reality. This power was attained when Hildebrand became first the manager and maker of popes, and then pope himself under the title of Gregory VII. The creation of the college of cardinals with the sole power of electing the pope, and the laws against marriage and simony, were the chief means made use of in the establishment of the European papal monarchy. These measures, or something with the same nominal purpose, were indeed, to a certain extent, justified by the needs of the time. The conflict between the emperors and the nobility of Rome over the papal appointment had been productive of such confusion and bloodshed as to become an offence to all Christendom, while the unchastity and venality of the clergy had risen to a fearful height. These measures, though nominally taken for the purpose of correcting abuses (a fact which justified them fully in the eyes of the unthinking masses), were attended by far more wide-reaching results, and were used for the execution of a far more wide-reaching plan in the mind of Gregory and his assistants. He had conceived the relationship of the Church to the state to be that of the soul to the body, and meant to realize in the world of fact the forms of his idea. By the constitution of the college of cardinals he would withdraw the papal office from under the influence both of the secular princes and the laity, and place it under the immediate control of the narrow ecclesiastical aristocracy of the Roman diocese. It was not meet that the body should choose the organ through which the soul realized its will. By the forbiddance of priestly marriage he would cut the bond of blood and interest which connected the servants of the Church with society at large, and make the clergy the complete and willing executors of the papal will; and by the laws against simony he would withdraw the bishops and abbots from their feudal relationship to the secular princes in whose territories their bishoprics and cloisters lay, and bring the property for which they owed feudal service to the state under the complete and independent ownership of the Church. It was one of the most daring attempts to unsettle and transform the relationships of property which the world has ever known. Borne by the power of such personalities as Gregory VII., Alexander III., Innocent III., and Boniface VIII., the cause of the papacy and the universal Church monarchy was for two and a half centuries, from the beginning of the eleventh to the middle of the fourteenth, powerfully and successfully pushed forward upon the road of universal European sovereignty. By the help of the great German dukes, who were ever striving for more independence of the imperial power, the triumph over the mightiest secular lord of Christendom, the Roman German emperor, was secured, while England, Scotland, Poland, Hungary, Aragon, and the Two Sicilies became little more than fiefs of the papal throne. It was Philip the Fair of France (1285–1314 A. D.) who first opposed with success this growing and threatening power. Through force and intrigue the papal seat was removed by him from Rome to Avignon (1307 A. D.), and became thenceforth a luxurious court devoted to pleasure and the interests of French politics. From this time forth the moral influence of the papacy and of the Church declined from year to year; and the scientific discoveries and revival of learning in the fifteenth century, and the Reformation in the sixteenth, lifted society above that stage of its civilization where the Church can absorb the state.

3. *Spirit and Genius of the Middle Ages.*—From the above-mentioned facts it is not difficult to generalize a conception of the spirit and genius which brought them forth. Defiant self-reliance upon rude physical force in regard to the attainment of all things temporal, and superstitious subjection to a sacerdotal order in regard to things unseen, unknown, and represented as eternal; narrow selfishness in regard to the duties and functions lying near and in the common course, connected with the most chivalrous devotion to the mystical, the undefined, and the distant; the direst immorality and disobedience to law and order, coupled with the most exaggerated and enthusiastic religiosity; bold adventuresomeness without defined purpose; fancy and imagination without reflection; faith without reason; devotion without humanity—these are some of the contradictions which characterize the mediæval spirit. Those great cathedral piles testify not only to the power of the imagination and devotion of the age, but also to the undervaluation of the human sufferings and sacrifices through which they were founded and builded.

4. *Institutions of the Middle Ages.*—This spirit and genius incorporated itself in the two all-comprehending institutions, the feudal state and the hierarchical Church. The spirit of the age was far too objective to conceive of the authority of law as based upon the common consciousness of the governed. The individual felt no internal behest to observe the rights of his neighbor any further than he had by contract or promise agreed to do so. Personal contract, varying in the details of its terms with time, place, and circumstances, occupied thus the proper ground of universal political law. Under such an order the common man could only protect himself by contracting for his protection by some great man, whose land and people furnished him the means of protection. The cost of such protection to the common man was the surrender of his own land to the ownership of the lord, retaining only the possession of the same as a fief, and rendering certain tributes or services to the lord for such possession and protection. The vassals of the same lord were connected with each other not directly, but only through their feudal relation to a common lord, and different lords only through their feudal relation to a common superior or by *contract* with each other, and so on until the sovereign lord of the land was reached—the apex of the feudal pyramid; only the pyramid was inverted, with the greatest weakness where the greatest strength ought to be. These actual relationships were legalized through the ratification obtained mediately or immediately from the kingship and the imperium, in which latter office the sum and substance of all authority was theoretically held to exist as the immediate gift of God to one man through his vicegerent upon earth—the pope. The practical result of such a system was anarchy in the state. In regard to the Church, the same externality of idea manifests itself in the conceptions of authority and grace. The sum and substance of all authority and grace were conceived as proceeding from Christ to the chief of his apostles, to whom the pope was successor; by the latter dealt out again upon the bishops in their consecration, and then by these in turn upon the priests and laity. The power to bind and to loose, to damn and to save, became thus, according to this conception, the property of a close corporation, which by the power of excommunication from the company of the saved upon earth, with all its attendant consequences upon the social and political status of the individual, and of the threats of eternal punishment hereafter, held the souls of men in a state of spiritual subjection of a most degrading nature. The practical result of such a system was spiritual despotism in the Church.

Men have been wont to call the Middle Ages "Dark Ages." On the contrary, they are full of light. In them the great questions of the relationship of individual right to political right, of local government to central government, and of ecclesiastical government to secular government, were raised and drawn into conscious consideration. Had the European empire of Charlemagne been perpetuated, Europe might have become a second China, but would never have been what it is—viz., the source of the civilization of the modern world. The unceasing conflicts of the Middle Ages between private right and public law, local government and central government, state authority and Church authority, were necessary to bring men out from under the monotony of slavish subjection to the artificial, external, Church-state system of the Carlovingian empire, and develop them by the antagonism of thought and will into the power of producing systems more reflected and more free. See FEUDAL SYSTEM.

Middleboro: town; Plymouth co., Mass. (for location of county, see map of Massachusetts, ref. 4-J); on both sides

of the Namasket river, and on the N. Y., N. H. and Hart. Railroad; 10 miles E. of Taunton, 34 miles S. by E. of Boston. It is one of the oldest towns in the county; derives excellent power for manufacturing from the river, which has three falls, comprises several villages, and has several churches and public schools, an academy, gas and electric light plants, a free public library (founded 1874) containing 6,000 volumes, a national bank with capital of $50,000, a savings-bank with deposits of over $750,000, and two weekly newspapers. For many years the town has been noted for its manufactures, which include shoes, woolen goods, lumber, varnish, marble, shovels, and needles. Pop. (1880) 5,237; (1890) 6,065; (1900) 6,885.

Middlebury: village; capital of Addison co., Vt. (for location of county, see map of Vermont, ref. 5–A); on Otter creek, and the Cent. Vt. Railroad; 33 miles N. N. W. of Rutland, 35 miles S. of Burlington. It is in an agricultural region, and has excellent water-power, six productive marble quarries, and several large lime-kilns. It is the seat of Middlebury College, and contains three libraries (Ladies', Sheldon Art Museum and Library, and Middlebury College) with nearly 25,000 volumes, a national bank with capital of $200,000, a weekly newspaper and a monthly college publication, and flour-mills, pulp-mills, and iron-furnace. Pop. (1890) 1,762; (1900) 1,897. Editor of "Register."

Middlebury College: an institution of learning at Middlebury, Vt., established in 1800. It is coeducational and purely collegiate, its curriculum being partially elective and leading up to the degrees of A. B. and B. S. The (eighth) president, Ezra Brainerd, LL. D., was inaugurated in 1886. The faculty numbers eleven, the departments of instruction being mental and moral science, natural history, physics and chemistry, mathematics, Greek, Latin, English, modern languages, history, and political science. The main buildings are the chapel, with lecture-rooms and laboratories, Starr Hall, the main dormitory, Painter Hall, containing the library and the gymnasium, Battell Hall, for young women. Of these buildings, the first three are of stone and are surrounded by a beautiful park of 30 acres.

C. B. Wright.

Middle C: in music, the note standing a fifth above the F or bass clef and a fifth below the G or treble clef. Its place is therefore on the added-line between the bass and treble clefs. It takes its name from this circumstance, and also from its midway position on the general scale. The C clef, whether placed on the third, fourth, or any other line, is always representative of the note or sound called "middle C," and the lines and spaces above and below are named accordingly.

Middle English: See English Language.

Middleport: village; Niagara co., N. Y. (for location of county, see map of New York, ref. 4–C); on the Erie Canal, and the N. Y. C. and Hud. Riv. Railroad; midway between Buffalo and Rochester. It is in a fruit-growing region, ships large quantities of general produce, has a ship-yard and dry-dock, and contains saw and planing mills, paper-mill, grist-mill, foundries, furniture-factory, large fruit canning and evaporating works, and a creamery. Pop. (1880) 771; (1890) 1,217; (1900) 1,431. Editor of "Herald."

Middleport: village; Meigs co., O. (for location of county, see map of Ohio, ref. 7–G); on the Ohio river, and the Col., Hock. Val. and Tol. and the Ohio Cent. railways; 2 miles S. of Pomeroy, the county-seat. It is in an agricultural and coal-mining region, and has important manufactures, large river commerce, a national bank with capital of $50,000, and two weekly newspapers. Pop. (1880) 3,032; (1890) 3,211; (1900) 2,799.

Middlesborough: municipal, parliamentary, and county borough; in the county of York, England; at the mouth of the Tees; 50 miles N. of York (see map of England, ref. 5–I). It has very important iron and steel works and considerable exports of coal, besides ship-yards, chemical-works, salt and soda works, wire, nail, and tube works, marine engineering works, sawmills, and manufactures of ropes and sailcloth. The public buildings include a town-hall, a market-house, and a royal exchange. The docks, opened in 1842 and extended in 1875, have 1,700 feet of quays, and can accommodate vessels of 3,000 tons burden. Middlesborough was founded in 1830, and in 1831 it had a population of 154; in 1841, of 5,463. In 1850 iron ore was discovered in Eston Hills, and in 1881 the population of the municipal borough had increased to 55,288. In 1901 it was 91,300.

Middlesex: a county of England; bounded S. by the Thames, and E. and W. by its two affluents, the Colne and the Lea. Area, 283 sq. miles. A great part of the county consists of grazing lands and market-gardens, which supply London with milk, hay, and vegetables. Pop. (1901) 792,-225.

Middleton: town of Annapolis co., Nova Scotia; 102 miles W. N. W. of Halifax (see map of Quebec, ref. 2–B). It is a station on the Windsor and Annapolis Railway, and northwestern terminus of the Nova Scotia Central Railway, near the historic Annapolis river. There are rich iron and copper mines in the vicinity, and near it are the attractive Nictaux Falls. Pop. (with environs) 2,000. M. W. H.

Middleton, Conyers, D. D.: theologian and classical scholar; b. at Richmond, Yorkshire, England, Dec. 27, 1683; graduated at Cambridge 1702, and became a fellow of Trinity College 1706. He was for years engaged in an acrimonious quarrel with Richard Bentley (see Monk's *Life of Bentley*); wrote *A Letter from Rome showing an Exact Conformity between Popery and Paganism* (1729); became principal librarian of Cambridge (1722); was Woodwardian Professor of Mineralogy 1731–34. His best-known works are an uncritical and highly eulogistic *Life of Cicero* (1741); *Introductory Discourse* (1747); and the *Free Inquiry* (1748), violent attacks on ecclesiastical miracles. D. at Hildersham, July 28, 1750. Cf. Leslie Stephen, *English Thought in the Eighteenth Century*. Revised by A. Gudeman.

Middleton, Thomas: dramatist; b. probably in London about 1570; studied law at Gray's Inn; became a dramatic author; assisted Rowley, Massinger, Fletcher, and Ben Jonson in the composition of some of their plays, and produced several dramas, among which are *A Mad World, my Masters*, *Women beware Women*, *A Trick to Catch the Old One*, *The Changeling*, and *The Spanish Gipsy*. In 1623 he wrote a very clever satirical comedy (*A Game of Chess*) on Prince Charles's unsuccessful wooing of the Spanish infanta. The performance of the play was stopped by royal order, but the action against the author was afterward dropped. His plays were edited by Rev. Alexander Dyce (5 vols., 1840) and by Bullen (8 vols., London, 1886). D. July, 1627.

Revised by H. A. Beers.

Middleton, Thomas Fanshaw, D. D.: bishop and Bible scholar; b. at Kedleston, England, Jan. 26, 1769; was educated at Christ's Hospital and at Pembroke Hall, Cambridge; took orders in the Church of England 1729; became archdeacon of Huntingdon 1812, and was consecrated May 8, 1814, at Lambeth, first Bishop of Calcutta, in which city he arrived Nov., 1814; died there of fever July 8, 1822. He was an elegant scholar, and as a writer is remembered for his *Doctrine of the Greek Article, applied to the Criticism and Illustration of the New Testament* (London, 1808; 5th ed. 1858). A volume of his sermons, charges, and tracts was published in 1824. See his *Life*, by Rev. C. W. Le Bas (2 vols., London, 1831). Revised by S. M. Jackson.

Middletown: city (settled in 1650, incorporated in 1784); formerly a port of entry, and one of the county-seats of Middlesex co., Conn. (for location of county, see map of Connecticut, ref. 9–H); on the Connecticut river opposite Portland, with which it is connected by an iron railway bridge, and on the N. Y., N. H. and Hart. Railroad; 15 miles S. of Hartford, 24 miles N. E. of New Haven. The city is pleasantly situated, is laid out with broad, tree-shaded streets, and has daily steamboat communication with New York and Hartford, the river being navigable here for vessels drawing 10 feet of water. Valuable freestone and feldspar and the rare columbite are found in the vicinity, silver and lead were formerly mined, and gold has been found. The city is the seat of Wesleyan University (Methodist Episcopal, opened 1831), of the Berkeley Divinity School (Protestant Episcopal, opened 1847), the Connecticut Hospital for the Insane, and the Connecticut Industrial School for Girls; contains 5 libraries (the University, Divinity School, Insane Hospital, Industrial School, and the Russell) with about 75,000 volumes, 4 national banks with combined capital of $1,069,300, a State bank with capital of $600,000, and 2 savings-banks with surplus of $500,000, and 2 daily and 2 other periodicals. Pop. (1880) 6,826; (1890) 9,013; (1900) 9,589.

Editor of "Penny Press."

Middletown: town; Newcastle co., Del. (for location of county, see map of Delaware, ref. 3–M); on the Phila., Wil. and Balt. Railroad; 25 miles S. by W. of Wilmington, the county-seat, 52 miles S. W. of Philadelphia. It is in the

great peach-growing region of Maryland and Delaware, and has carriage, harness, and agricultural-implement factories, fruit curing and canning works, 2 national banks with combined capital of $160,000, and 2 weekly newspapers. Pop. (1880) 1,280; (1890) 1,454; (1900) 1,567.

Middletown: city (incorporated in 1888); Orange co., N. Y. (for location of county, see map of New York, ref. 7–J); on the Wallkill river, and the Erie, the N. Y., Ont. and W., and the N. Y., Sus. and West. railways; 24 miles W. S. W. of Newburg, 66 miles N. N. W. of New York. It is in an agricultural and dairy region, is the seat of the New York Homœopathic Hospital for the Insane, and has 12 churches, graded high school, 12 other public schools, 2 libraries (Leonora S. Bolles Memorial and Public School), 2 national banks with combined capital of $260,000, a savings-bank, and a monthly, 3 daily, and 5 weekly periodicals. There are silk and handkerchief mills, woolen-hat factories, and saw and file works. Pop. (1880) 8,494; (1890) 11,977; (1900) 14,522. EDITOR OF "PRESS."

Middletown: city; Butler co., O. (for location of county, see map of Ohio, ref. 6–C); on the Miami river, and the Cin., Ham. and Day., the Cleve., Cin., Chi. and St. L., the Cin. and Day., and the Middle. and Day. railways; 32 miles N. of Cincinnati. It has the Holly system of water-works, gas and electric lights, 2 national banks with combined capital of $550,000, an incorporated bank with capital of $50,000, and 2 daily and 2 weekly newspapers. There are 7 paper-mills, 2 tobacco-factories, 2 paper-bag factories, foundry, planing-mill, and flour-mills. Pop. (1880) 4,538; (1890) 7,681; (1900) 9,215. EDITOR OF "JOURNAL."

Middletown: borough (founded in 1756, incorporated in 1828); Dauphin co., Pa. (for location of county, see map of Pennsylvania, ref. 5–G); at the junction of Swatara creek with the Susquehanna river, and on the Penn. and the Phila. and Reading railways; 9 miles S. E. of Harrisburg. It is in an agricultural region, has good water-power from Swatara creek, and had the first furnace in America for the manufacture of blister steel, erected about 1793. It has water, gas, electric-light, and electric street-railway plants, brownstone and limestone quarries, tube and iron works, iron-furnaces, railway-car shops, furniture-factory, tannery, and large lumber interests, the Frey Orphan School, a national bank with capital of $85,000, a State bank with capital of $50,000, and a daily and two weekly newspapers. Pop. (1890) 5,080; (1900) 5,608. EDITOR OF "JOURNAL."

Midge [M. Eng. *migge* < O. Eng. *mycge*: O. H. Germ. *mucca* > Mod. Germ. *mücke*, moth; cf. Gr. *μυῖα*]: a name applied in England to several dipterous insects resembling gnats and mosquitoes in their habit of feeding upon the blood of men and animals. Some are of the family *Chironomidæ*, which has representatives in North America. In the U. S. the name is especially given to the wheat midge, *Cecidomyia tritici*, a most destructive insect, which lays its eggs in the blossoming ears of wheat. Deep plowing destroys many of them by burying their cocoons in the earth, and late-sown spring wheat generally blossoms so late as to escape their ravages. For gall midges, see GALL INSECTS.

Midhat Pasha: statesman; born of humble parents in 1822 in Constantinople, where he was educated. He early entered the civil service of the Ottoman Government and gave proofs of executive ability. He visited England and France in 1819. The following year he was made a pasha. He was at various times governor of Uskup, Bulgaria, and Salonica. In each province he constructed roads, built bridges, favored industry, and with a firm hand put down lawlessness and crime. The reactionary party always looked upon him with disfavor; hence his appointment as grand vizier in Mar., 1873, was considered a significant event, as was his speedy removal from that office. He was the real chief among the conspirators who deposed Abd-ul Aziz (May 30, 1876) and Murad V. (Aug. 31, 1876). Made grand vizier (Dec. 23, 1876) by the new sultan, Abd-ul Hamid II., he was an object of suspicion as instrumental in the overthrow of two sultans, and held office only till Feb., 1877, when he was dismissed and banished. He spent some time in Paris, where he published *La Turquie, son passé et son avenir* (1878). Soon after he was made governor of Smyrna, and then of Syria. In 1881 he and several other pashas were accused of murdering Sultan Abd-ul Aziz. At the trial he was convicted and condemned to death, but on the representations of Great Britain this sentence was commuted to imprisonment for life. D. May, 1884, in Arabia. E. A. GROSVENOR.

Midianites: an ancient Arabian race, the descendants of Midian, the fourth of the six sons of Abraham by Keturah (Gen. xxv. 2). They were idolaters. They appear to have dwelt mainly to the S. of Moab. The Sinaitic peninsula was a part of their territory, and the Tawarah Arabs, now dwelling there, are supposed to be their descendants. Moses dwelt in the land of Midian and married a daughter of a priest of Midian (Ex. ii.). Midianites joined Moabites in desiring Balaam to curse Israel (Num. xxii.). They oppressed Israel and were signally defeated by Gideon (Judg. vii.–viii.). Revised by S. M. JACKSON.

Midland: city; capital of Midland co., Mich. (for location of county, see map of Michigan, ref. 6–I); at the junction of the Tittabawassee and Chippewa rivers, and on the Flint and Pere Marq. Railroad; 18 miles W. of Bay City. It contains 7 churches, 4 public schools, and 2 weekly newspapers, and manufactories of lumber, shingles, hoops, pails and tubs, salt, and bromine. Pop. (1880) 1,529; (1890) 2,277; (1900) 2,363. PUBLISHER OF "REPUBLICAN."

Midlothian: See EDINBURGHSHIRE.

Midnapur: district and city of the Bardwan division, Bengal, British India. It is the southernmost of the districts of Bardwan, and extends from the Hugli estuary on the E. to Chota Nagpur on the W. Area, 5,082 sq. miles. Pop. about 2,500,000. The central and southeast portions are a densely populated plain, while the northern plain is dry, and the northwest contains the Mehals jungle, an undulating, picturesque country, alive with wild beasts and serpents, and almost uninhabited. The cultivated portions are but little above sea-level, and suffer much from floods from the rivers and cyclonic inundations from the coast. The city is 62 miles S. of Bardwan, and about the same distance W. of Calcutta, on the Kusi river and terminus of the High Level Canal (see map of N. India, ref. 8–I). It is very subject to fevers and endemic cholera. It is a center for work carried on by missionaries from the U. S. Bronze and copper utensils are manufactured in large numbers, and the sale of these, as well as the commerce in indigo and silk for the district, is centered in a great bazaar in this city. Pop. 35,000. MARK W. HARRINGTON.

Mid'rash [from Heb. *midhrāsh*, commentary, explanation]: a general name for the study and amplification of the Bible as current in the Jewish schools during the times of the Mishnāh and Talmud. As the Bible was regarded as the source of all ritual and ethical laws and practice, and of all religious and philosophical ideas, it became necessary to deduce new ordinances, new principles, and new doctrines from its wording. This the Midrash did by comparing parallel passages, by making use of allegorical explanations, and by casuistical deductions from real or fancied peculiarities of expression. The oldest Midrash busied itself not only with Haggadah (see TALMUD), but also with Halachah. Halachah, which was not derived from the biblical word, was called Mishnāh. The oldest Midrashic works belong to the period of the Tannaim, the teachers who lived from 100 B. C. to about 200 A. D., though the redaction which we now possess was made later. These are the *Mechilta* to Exodus, the *Sifrā* to Leviticus, and the *Sifrē* to Numbers and Deuteronomy. The Midrash thus became also a sort of running commentary on the Bible. In course of time this use of the Midrash gradually usurped the place of the older and more general use. It came to denote almost exclusively the Haggadah. As such it was based largely upon the religious and ethical discourses delivered in school and synagogue, and follows the biblical pericopes. Though certain rules (*Middōth*) were laid down which were to govern this exposition, still the greatest latitude was allowed. The Midrash was not intended to be an exposition of the Bible in our sense of the word. It sought to find in the Bible an indication, however slight, for the principles or ideas it wished to express. The lives of the patriarchs and of other great men in Hebrew history, eschatalogical and mythological ideas, the Divine Being, and philosophical problems of all sorts, formed the subject-matter of the later Midrashim. They are full of anecdotes, bright and witty sayings, and a truly Eastern wealth of imagery. It is impossible to tell how early such Midrash collections were made. The word Midrash occurs in the Bible (2 Chron. xiii. 22, 24, 27). The book of Chronicles itself, when compared with the books of Samuel and Kings, is a sort of historical Midrash. The same method of exegesis is to be found in the New Testament (Matt. xxii. 31; Gal. iii. 16; iv. 22; Rom. x. 6–8), in the Hellenistic Jewish literature, in the Apocrypha, the TARGUMIM (*q. v.*), and

the pseudepigraphic writings of the time. Both Talmuds are full of it. A whole branch of Jewish literature has for its object the collection and arrangement of the later Midrash. See JEWISH LITERATURE.

LITERATURE.—Zunz, *Die Gottesdienstlichen Vorträge der Juden* (2d ed. 1892); Steinschneider, *Jewish Literature* (London, 1857, pp. 5, *seq.*); Karpeles, *Geschichte der Jüdischen Literatur* (Berlin, 1886, i., pp. 332, *seq.*); D. Hoffmann, *Zur Einleitung in die halachischen Midraschim* (Berlin, 1887); Schürer, *Gesch. des Jüd. Volkes im Zeitalter Jesu* (Leipzig, 1886, i., p. 108; ii., p. 278); Hamburger, *Real-Encyclopädie für Bibel und Talmud*; Strack, *Midrasch*, in Herzog-Plitt *Real-Encyclopädie* (ix., pp. 752, *seq.*); Theodor, *Composition der agadischen Homilien*, in Grätz's *Monatsschrift*, vol. xxxviii.; Lerner, *Anlage und Quellen des Bereschit Rabba* (Frankfort-on-the-Main, 1882); J. H. Weiss, *Zur Gesch. der Jüd. Tradition* (vols. ii. and iii., Vienna, 1871–83); Jellinek, *Beth Hamidrasch* (Leipzig, 1853–57; Vienna, 1873–77); A. Wünsche, *Bibliotheca rabbinica* (Leipzig, 1881–92).

RICHARD GOTTHEIL.

Midriff: See DIAPHRAGM.

Midway: town; Woodford co., Ky. (for location of county, see map of Kentucky, ref. 3–H); on the Louis. and Nash., and the Queen and Cresc. railways; 14 miles W. of Lexington. It is in the blue-grass region, is noted for its breeding-farms for thoroughbred horses and shorthorn cattle, ships large quantities of grain and tobacco, and has the Kentucky Female Orphan School, two State banks with combined capital of $115,000, and a weekly newspaper. Pop. (1880) 950; (1890) 1,185; (1900) 1,045.

Midwifery: See OBSTETRICS.

Mierevelt, mee'rā-velt, MICHAEL JANSON: painter; b. at Delft, Holland, May 1, 1567; studied painting under A. Montfort at Blockland, and became one of the most celebrated portrait-painters of his time. Albert, Archduke of Austria, established him at his court, allowing him complete liberty to practice his own religion, Mierevelt being a Mennonite. He left Delft only to paint the Counts of Nassau, whose portraits are excellent examples of his skill. It is said by Sandvart that no less than 10,000 portraits were produced by Mierevelt. D. July 27, 1641. W. J. S.

Mieris, FRANZ: painter; b. at Delft, Holland, in 1635. He studied under Gerard Dow, and became famous at an early age. The Austrian archduke invited Mieris to establish himself at Vienna, offering him a pension besides his own price for all his pictures, but a love of independence prompted the artist to refuse this offer. The Grand Duke of Tuscany having generously paid him for several works, Mieris presented him with his own portrait, now in the Uffizi at Florence. The Louvre possesses nine of his highly finished works. D. in Rome in 1690. W. J. S.

Mifflin, THOMAS: soldier; b. in Philadelphia in 1744 of Quaker stock; was educated at Philadelphia College; became a merchant, and in 1772–73 was in the Legislature; was sent to the Continental Congress in 1774; joined the Revolutionary army, thus severing his connection with the Society of Friends; was made quartermaster-general; rose to be brigadier-general in 1776, and major-general in 1777, serving with great honor; was replaced by Gen. Nathaniel Greene in the quartermaster's department in 1778; in consequence of charges of mismanagement resigned his commission, which Congress refused to accept; was sent to Congress in 1782, becoming its president in 1783; was speaker of the State Legislature in 1785; was in the convention of 1787 which formed the U. S. Constitution; was president of the Pennsylvania executive council 1788–90; president of the State convention of 1790; Governor 1791–1800. D. at Lancaster, Pa., Jan. 20, 1800.

Mifflinburg: borough (founded in 1792); Union co., Pa. (for location of county, see map of Pennsylvania, ref. 4–F); on Buffalo creek, and the Penn. Railroad; 9 miles W. by S. of Lewisburg, the county-seat. It is in an agricultural, limestone, and iron ore region, and has steam flour and planing mills, furniture, carriage, sleigh, and buggy factories, 2 oil-factories, and 2 weekly newspapers. Pop. (1880) 1,168; (1890) 1,417; (1900) 1,436.

EDITOR OF "TIMES."

Migdol [= Heb. watch-tower]: a locality mentioned (Ex. xiv. 2, etc.) as near the place where the Israelites crossed the Red Sea. The word indicates the necessity of guarding a ford where a shallowing of the waters due to natural causes rendered the land liable to incursions by predatory bands from the East. The existence of a Migdol (Magdolum) on the Roman itinerary N. of the middle of the Isthmus of Suez gave nearly all of its probability to the now exploded theory of the Exodus route proposed by Brugsch Bey. See MENZALEH.

CHARLES R. GILLETT.

Mignard, meĕn'yaar', NICHOLAS: painter; b. at Troyes, France, in 1603; d. in Paris in 1668. He studied painting under Boucher, but afterward was much influenced by the works of Primaticcio. On his way to Rome, where he spent two years, he stopped at Avignon to paint a ceiling, and fell in love with a young girl, whom he married subsequently. On his return he established himself at Avignon, thus acquiring the designation of Mignard of Avignon, to distinguish him from his brother, Mignard "the Roman." He was patronized by Cardinal Mazarin, and through him received an order to paint a portrait of the king, after which he painted the portraits of all the members of the court, including the Princess of Elbœuf as St. Cecilia. He also painted two pictures for the Chartreuse of Grenoble, and was appointed professor of the Academy of Painting. Louis XIV. intrusted him with the decoration of his ground-floor apartment at the Tuileries, and was so much pleased that he commissioned him to paint another room, but Mignard soon died through overwork. W. J. STILLMAN.

Mignard, PETER: painter; b. in 1610; brother of Nicholas Mignard. His father desired him to become a doctor, but at the age of fifteen Peter painted the portraits of his medical professor's family in one picture, thus showing his artistic proclivities. After studying under Boucher, and later under Vouet, he was attracted to Rome, where he lived with Dufresnoy, who had been his fellow pupil, and who continued to direct his studies. He visited Venice and many other Italian cities, and on his return to Rome received an order to paint the pope, Alexander VII. He spent twenty-two years in Rome, then was recalled to Paris by Louis XIV. Mazarin introduced him to the royal family, and the cupola of the Val-de-Grâce was assigned to him to decorate. Subsequently he did decorative work in St. Eustache, in the small gallery at Versailles, and elsewhere. He was elected president of the corporation of St. Luke, which he helped to revive. Louis XIV. held him in great favor, ennobled him, and on the death of Lebrun made him court painter and director of the royal manufactories. He became member, professor, rector, director, and chancellor of the Royal Academy of Painting and Sculpture, all in one day. His paintings at the Val-de-Grâce and at St.-Cloud are his most remarkable works. The Louvre contains seven of his pictures. He was also an engraver. D. in Paris in 1695.

W. J. STILLMAN.

Migne, meeñ, JACQUES PAUL: publisher; b. at St.-Flour, Cantal, France, Oct. 25, 1800; studied theology at Orleans; was ordained priest in 1824, and appointed curate at Puiseaux; went in 1833 to Paris and founded the Ultramontanist journal *L'Univers*, which he sold in 1836 and founded at Petit Montrouge, near Paris, the Imprimerie Catholique, which soon became one of the most remarkable industrial establishments in France. From this office issued *Collection des Orateurs Sacrés* (100 vols., 1846–68); *Patrologiæ Cursus Completus* (390 vols.); *Encyclopédie Théologique* (171 vols.). In the establishment were also manufactured organs, statuary, pictures, and all kinds of church utensils. D. in Paris, Oct. 25, 1875. Revised by S. M. JACKSON.

Mignet, meĕn'yā', FRANÇOIS AUGUSTE MARIE: historical writer; b. at Aix, Provence, France, May 8, 1796; was educated at Avignon; studied law at the Academy of Aix at the same time with Thiers; removed to Paris in 1822; produced a dissertation on feudalism and the institutions of St. Louis; then followed *Histoire de la Révolution Française* (1824); 13th ed. 1880); *Histoire de Marie Stuart* (1851; 6th ed. 1884); *Vie de Franklin*; *Antonio Perez et Philippe II.* (1845; 5th ed. 1881); *Charles Quint, son abdication, son séjour et sa mort au monastère de Yuste* (1854; 10th ed. 1882); *Éloges Historiques* (1864; 5th ed. 1884), and other works; was in 1830–48 director of the archives of the foreign ministry; member of the Institute and of the Academy, and commander of the Legion of Honor, etc. D. in Paris, Mar. 24, 1884. See Trefort, *Mignet und seine werke* (Budapest, 1885).

Mignonnette, min-yŭn-et' [= Fr., dimin. of *mignon*, darling]: popular name of an herb, sometimes half shrubby; a native of North Africa; universally cultivated for its delicious fragrance. Its botanical name is *Reseda odorata*,

and it belongs to the order *Resedaceæ*. WELD (*q. v.*) also is a species of *Reseda*.

Migraine, Megrim, or **Hemicrania** [*migraine* is derived through Fr. and Late Lat. from Lat. *hemicrania*, Gr. *ἡμικρανία*; *ἡμι-*, half + *κρανίον*, skull]: paroxysmal headache, usually one-sided, with nausea, and disorders of vision. The disease is often hereditary, and usually begins in youth. It is most frequent in women and the neurotic. It is noteworthy that many celebrated men have suffered from it. Often no cause can be found, but it is quite frequently dependent upon eye-strain, disorders of the uterus and ovaries, adenoid growths in the pharynx, and diseased conditions of the nose. The attacks are precipitated by certain foods, by emotional excitement, and sometimes apparently without cause. The attacks may occur at regular intervals, so that the patient can foretell the very hour of onset, though more often the recurrence is irregular. The duration varies from some hours to several days. In the simplest form there is one-sided headache with nausea, followed by vomiting and relief. In some patients remarkable visual phenomena precede an attack. There may be simple blurring of vision, subjective flashes of light, or bright zigzag lines (fortification spectra). More rarely there are distinct illusions of animals, as dogs and cats, or even distinct landscapes. Transient hemianopia may occur. Disorders referable to the other special senses are rare. There is sometimes numbness and tingling of the arm, face, and tongue. Rarely transient muscular weakness in the arm is present. There may be loss of speech during the attack. The pain usually begins in a small spot on the forehead, or temple, and spreads thence over one side of the head. It may finally involve the whole head and neck. The face on the affected side may be pale and later flushed. The disease is not dangerous. It often ceases of itself at middle life. Treatment depends on removal of the cause and personal hygiene. W. PEPPER and C. W. BURR.

Miguel, Dom MARIA EVARISTO: prince; b. in Lisbon, Oct. 26, 1802; the third son of John VI., King of Portugal, by the Spanish princess Carlotta Joachima; went in 1807 to Brazil with his parents, fleeing from the French armies. Here he grew up entirely neglected. When he returned to Europe in 1821 he could neither read nor write. At ten years of age he was a drunkard; at fifteen his debaucheries and atrocities amazed the people. He was, nevertheless, his mother's favorite, and seems to have returned this love, while he hated his father and brother, and considered them as strangers. Soon after the return of the royal family to Portugal he began to form conspiracies against his father; open revolt followed. The plan was to depose the king, and, if necessary, to kill him; but he fled on board a British man-of-war, and by his escape Dom Miguel's plan was foiled. The prince was banished from Portugal May 12, 1824. On May 10, 1826, John VI. died, and, in order to prevent a civil war, the eldest son, Dom Pedro, Emperor of Brazil, resigned the Portuguese throne in favor of his daughter, Maria da Gloria, and offered her hand to Dom Miguel. He assented, made oath on the constitution, and entered on his regency during the minority of Maria; but he soon broke his oath, subverted the constitution by the aid of the clerical party, dissolved the constitutional Cortes, assumed absolute power, filled all the dungeons of the country with the liberals, and ruled Portugal for several years by terror, while he gave himself up to the wildest dissipation. In 1832 Dom Pedro arrived at Oporto with a Brazilian fleet. In 1833 he conquered Lisbon, and on May 26, 1834, Dom Miguel was brought to Genoa by a Portuguese man-of-war, having agreed never to re-enter Portugal. As soon as he arrived at Genoa, however, he protested against the agreement, but the only result of the protest was that he lost his pension from Portugal, and all his property was confiscated. He afterward married a German princess. D. at Brombach, Baden, Nov. 15, 1866.

Mikado, mĕĕ-kaa'dō [Jap. *mi*, exalted + *kado*, gate. Cf. title *Sublime Porte* applied to the Sultan of Turkey]: the title usually applied by foreigners to the hereditary ruler of Japan. It is, however, rarely heard in Japan itself, having passed away with the abolition of the feudal system. Mikado denoted first the imperial court, and then, by a common Oriental figure, it passed over to the person of the emperor. The Japanese prefer to use the title of *Tenshi* (i. e. Son of heaven), or *Kotei*, the Japanese equivalent of Chinese Hwang-ti or Imperial Ruler, as more in harmony with the modern system of government. Mikado has therefore become a merely historical or literary term, associated with the odes of the *Man-yoshu* and with courtly romances like the *Genji Monogatari*. J. M. DIXON.

Mikhaïlov, A.: See SHELLER, A. K.

Mikhaïlov, mĕĕ-kaa'ĕĕ-lof, MIKHAIL LARIONOVICH: Russian writer; the son of an official and of a Khirgiz princess; b. in the Ural Mountains in 1826. In 1844 he went to St. Petersburg, but was unable to pass the entrance examinations to the university, though he followed the lectures for a while as an outsider. From time to time he sent poems, mostly translations, to the newspapers, and in 1851 he published his best story, *Adam Adamovich*, which made him a reputation. In the following year he settled down to a regular literary career, writing for different journals, and especially for the *Sovremmenik* (Contemporary), to which he contributed tales, serious articles (among them one on the poets and novelists of the U. S.), and many translations, particularly from Heine. From 1858 to 1861 he traveled in Europe, but on his return was arrested for his connection with certain proclamations, tried, and sent to Siberia. There he died in 1865. His translations from Heine were published in 1858, and his works in 1859 (2 vols., St. Petersburg). A. C. COOLIDGE.

Mikhaïlovskiï-Danilevskiï, ALEKSANDR IVANOVICH: Russian historian; b. in 1790; studied at the University of Göttingen, and after his return to Russia was given a position in the ministry of Finance. In the following years he served in the campaigns against Napoleon, and he was present at the Congress of Vienna. From 1815 to 1818 he traveled in the suite of the Emperor Alexander; was major-general under Diebitsch in the war against the Turks (1829). D. Sept. 21, 1848. He was the author of histories of the war of 1806–12 against the Turks, and the military operations against the French, in which he took part. The latter books have been translated into German. Mikhaïlovskiï's style is excellent, but he is often partial and inaccurate. His complete works appeared in seven volumes (St. Petersburg, 1849–50). A. C. COOLIDGE.

Miklosich, mik'lō-zich, FRANZ, von, Ph.D.: founder of Slavic philology; b. at Luttenberg, in Steiermark, Nov. 20, 1813; in 1848 was elected member of the Reichstag; from 1850 to 1886 was Professor of Slavic Philology at Vienna; in 1862 was made life-member of the Reichsrath. His chief works are *Vergleichende Grammatik der slavischen Sprachen* (4 vols., 1852–74); *Lexicon Palæoslovenico-Græco-Latinum* (1862–65); *Ueber die Mundarten und die Wanderungen der Zigeuner Europas* (1872–77); *Etymologisches Wörterbuch der slavischen Sprachen* (1886). D. in Vienna, Mar. 7, 1891. BENJ. IDE WHEELER.

Miklucho-Maclay, NICHOLAS, von: traveler and naturalist; b. in the Ukraine in 1846. In 1865 he went to Germany, where he pursued his studies at Heidelberg, Jena, and Leipzig, and met Dr. Haeckel, with whom in 1867 he visited the Canary islands and Morocco. In 1869 he visited the Red Sea and Asia Minor. He had already decided to devote himself to an investigation of New Guinea, and in 1870 he started for that almost unknown land. From that time until not long before his death he was almost constantly traveling, his longest stay in any place being two years or more at Sydney, Australia. He was in New Guinea 1871–72, 1874, 1877, 1879–80, 1881, and 1883. He also traveled through the Malay Peninsula in 1874–75, the Caroline and Admiralty islands in 1876, and East Melanesia in 1879. His publications were very numerous, but are scattered. The most of them appeared under the auspices of the Imperial Geographical Society of St. Petersburg, or in the Dutch *Nat. Tijdschrift* of Batavia. These writings related to geography, anthropology, linguistics, and zoölogy. His name did not readily lend itself to expression in western languages, and he himself varied in the German form for it. He sometimes signed himself N. von Maclay. The name is sometimes written Miklukho-Maclay and Miklucha-Maklai. D. Apr. 15, 1888. MARK W. HARRINGTON.

Mikovec, mik'ō-vets, FERDINAND BŘETISLAV: dramatist and archæologist; b. at Sloup (Pirkstein), Bohemia, Dec. 24, 1826; was educated at Česká Lípa and Prague; made a special study of Bohemian history and archæology, and contributed numerous essays to Bohemian and German magazines. In 1848 he was politically active in the Bohemian and Servian commotions, returned to Prague in 1849, but went to Leipzig where in 1850 he published a German translation of the letters of John Huss, the Bohemian martyr and

Reformer. In 1851 he established at Prague a magazine devoted exclusively to belles-lettres, the *Lumír*, then the only one of its kind in Bohemia. He wrote two successful tragedies, *Záhuba rodu Přemyslovského* (The Extinction of the Premyslides, Prague, 1851) and *Dimitri Ivanovič* (Prague, 1856), and left two other dramas in MS. In 1858 he became editor of the *Starožitnosti a památky země české* (Bohemian Antiquities). D. at Prague, Sept. 22, 1862.

J. J. Král.

Mil'an (Ital. *Milano*): large town of Northern Italy; in lat. 45° 28′ N., lon. 9° 11′ E., lying in the center of the great fertile plain of the Po, between the Alps and the Apennines, the Adriatic and the Ligurian Seas (see map of Italy, ref. 3–C). The Olona, a small stream, washes its southern wall, and the town is connected by navigable canals with the Adda, and, through the Ticino, with the Po. Railways centering in an imposing station unite Milan with all the large towns of Italy. The circumference of the city, following the walls, which nearly inclose it, is about 8 miles; it has fourteen gates, the most striking being the Porta Sempione on the N. W., at the entrance of the great Simplon road, whose construction is here commemorated by a magnificent triumphal arch begun in 1807. In the center of the city is the Piazza del Duomo, which has been greatly enlarged, and from which tramways and omnibus lines extend in all directions. The streets of Milan generally are broad and clean; the palaces, though sometimes of immense size, lack the mediæval grandeur of those of Florence.

Churches.—Milan is the seat of an archbishopric, and is celebrated for its fine churches. Of the 240 existing in the middle of the eighteenth century, Maria Theresa and Joseph II. suppressed 117; others have been abandoned since, so that the present number is about 80. The Cathedral of Milan, an Italian Gothic structure, is one of the most splendid temples in the world, being exceeded in size only by St. Peter's and the Cathedral of Seville. It was begun in 1366 (Heinrich Arler, of Gmunden, being the architect, according to some—Matteo da Campione, according to others), and was in great part completed by 1500. Under Napoleon the work was actively resumed in 1805, and further decorations and repairs are constantly going on. The interior of this cathedral is 477 feet in length, 186 feet in breadth; height of nave 158 feet, of dome 214 feet, of tower 360 feet. The nave is supported by fifty-two columns, the four sustaining the dome being 10 feet and the others 8¼ feet in diameter, canopied niches with statues taking the place of capitals; the pavement is of mosaic; the vaulting, painted to imitate carved stone, has been injured by dampness, and is unworthy the rest of this wonderful edifice. The roof is a forest of Gothic turrets, 98 in number, decorated with exquisite carvings; the exterior of the cathedral is adorned with 2,000 statues, the interior with 700. Passing over other very noteworthy churches, that of St. Ambrose, founded in 387 by the illustrious archbishop himself, is of the greatest interest to the architect, the antiquarian, and especially to the lover of early Christian art. Near Santa Maria della Grazie, in which are very interesting frescoes, etc., is the convent containing that ruined masterpiece of art, Leonardo da Vinci's *Last Supper*.

Art-galleries, Libraries, etc.—The Brera Gallery alone contains more than 400 oil-paintings, many of great excellence, besides admirable frescoes, etc. In the same building is an archæological museum and the National Library, founded by Maria Theresa in 1764, and enlarged by private donations, libraries from suppressed monasteries, etc., until it now counts 250,000 volumes. The famous Ambrosian Library, founded by Cardinal Borromeo, has also risen to 160,000 volumes, besides about 10,000 manuscripts, some of the greatest rarity. The adjoining Gallery of Art contains, among its countless treasures, invaluable original drawings and manuscripts by da Vinci. In addition to public collections, Milan has 26 private picture-galleries of more or less interest. There are 15 museums of natural history, 14 of medals and antiquarian objects generally.

Public Institutions.—The charitable and educational institutions are on a most liberal scale, and admirably managed. The schools, academies, musical conservatories, etc., have a high reputation. The theater La Scala is the second largest in Italy and one of the largest in Europe. The public gardens and the Bastione di Porta Venezia furnish charming promenades, and the drive through the Corso and around the walls is most agreeable. Among the noted edifices in the city should be mentioned the Victor Emmanuel Gallery, or arcade. It represents a Latin cross, 960 feet long, 48 broad, and 85 in height, with a cupola 165 feet high. The roof consists of two glass vaults, one 6 feet above the other. This gallery is entered from the Piazza della Scala through a superb Corinthian arch of granite, extends to the Piazza del Duomo, and contains about 100 brilliant shops. The municipality has spent large sums of money, besides the cost of the ground, on the new cemetery outside the Porta Garibaldi.

Commerce and Industry.—The geographical position of Milan secures it an immense inland trade, chiefly in grain, rice, cheese, silk, and cotton; it also exports much country produce. It is the chief financial and banking center of Italy, and has very important manufactures of silks, velvets, woolens, gloves, machinery, art-furniture, and porcelain.

History.—At the time of its conquest by the Romans (220 B. C.) Milan was the largest town of Cisalpine Gaul. Cicero and Marcus Brutus were afterward among its governors, and in the third century it almost rivaled Rome. It was Christianized very early—tradition says by St. Barnabas—and was made illustrious in the fourth century by the good and great St. Ambrose. It suffered severely from the barbarians in 452, and in 558 was destroyed by a nephew of Vitiges, who, according to Procopius, slew 300,000 of its inhabitants. After many vicissitudes Milan in the eleventh century became once more independent and had a population of 300,000. Its moral and intellectual prosperity rose with its material wealth. The celebrated Archbishop Aribert offered every encouragement for the education of the young, and from her schools of philosophy, medicine, etc., Milan sent forth her professors to Burgundy, to France, and to Germany. After this followed a series of disastrous wars, ending with the destruction of the city by Frederick Barbarossa in 1162. It was, however, rebuilt with marvelous rapidity, and in 1176 the Milanese, aided by the neighboring towns, defeated Frederick at Legnano. In 1227 they were once more crushed by Frederick II. In 1259 an attempt was made by the terrible Ezzelino to get possession of the city, which failed, and from that time till 1447 it was governed by the ducal house of the Visconti. The so-called Golden Ambrosian republic, of three years' duration, was followed in 1450 by the dukedom of the Sforza, which lasted till 1500. From that time Milan continued for the most part under a foreign yoke, French, Spanish, or German, until 1796, when the French entered Milan and Napoleon made it the capital of the Cisalpine republic. In 1814 the Austrians took possession of the city and promised a liberal government, but pursued an entirely opposite policy. Insurrections broke out (1815, 1821, 1833), each followed by arrests, imprisonments, executions; and a state of chronic conspiracy existed until the "Glorious Five Days' Revolution," which began on Mar. 18, 1848, and terminated in the expulsion of the Austrians. After four months the enemy returned victorious. A new but disastrous insurrection was attempted in 1853. On June 8, 1859, Milan welcomed the Franco-Italian army within her gates, and Victor Emmanuel as the sovereign of her choice. The city is at present highly prosperous. Pop. of commune (1892, estimated) 426.500.

Milan: town; capital of Sullivan co., Mo. (for location of county, see map of Missouri, ref. 1–F); on the Chi., Burl. and Q. and the Quincy, Om. and Kan. City railways; 250 miles N. W. of St. Louis. It is in the center of the blue-grass region; raises fruit, grapes, and berries in abundance; has large farming and stock-growing interests; and has deposits of coal, fire-clay, mineral paint, and good building-stone in the vicinity. Farming, coal-mining, and manufacturing are the principal industries. Pop. (1880) 1,117; (1890) 1,234; (1900) 1,757. Editor of "Republican."

Milan: city; Gibson co., Tenn. (for location of county, see map of Tennessee, ref. 6–B); on the Louisv. and Nashv. and the Ill. Cent. railways; 93 miles N. E. of Memphis. It has six churches, a college, a high school, a weekly newspaper, and steam cotton-gins, saw and flour mills, barrel-factory, and fruit-canning works. Pop. (1880) 1,600; (1890) 1,546; (1900) 1,682. Editor of "Exchange."

Milan I., Obrenovitch: King of Servia; b. Aug. 22, 1854; son of Milosch Yephremovitch; was a student in the Lycée Louis-le-Grand, when, on the assassination of his cousin, Prince Michael III., he succeeded (July 2, 1868) as Prince Milan IV., and (Aug. 22, 1872) on reaching the age of eighteen he personally assumed the reins of government. He declared war against his suzerain, the sultan, in 1876,

but his army under the Russian general Tchernaïeff was always ignominiously beaten and only the intervention of Russia imposed peace and saved Servia from serious loss of territory. Participating shortly after in the Russo-Turkish war, the independence of Servia was recognized by the Treaty of Berlin (July 13, 1878). Servia declared itself a kingdom (Mar. 6, 1882), and Milan took the title of Milan I. On the union of Eastern Roumelia and Bulgaria (Oct., 1885), Milan invaded Bulgaria, but was speedily expelled, and his army disastrously defeated at the battle of Slivnitza, fought on Servian soil. Only the intervention of Austria stopped the progress of the Bulgarians. Milan abdicated (Mar. 6, 1889), proclaiming his son Alexander king under a regency till the attainment of his majority. Some time after he renounced the rights of his rank and nationality, taking the title of Count Takovo. Milan married (Oct. 17, 1875) Natalie, the daughter of the immensely wealthy Russian Col. Keschko; was divorced illegally Oct. 24, 1888, and reconciled to his wife Mar. 7, 1893. E. A. Grosvenor.

Milanés y Fuentes, mĕĕ-laă-nās'ee-foo-ān'tās, José Jacinto: poet; b. at Matanzas, Cuba, Aug. 16, 1814. His family was poor, and in early life he was a clerk at Matanzas and later a blacksmith's assistant at Havana; mainly by self-instruction he obtained a fair education, and about 1833 some of his verses were published, attracting an immediate and wide attention. In 1838 he published a tragedy, *El Conde Alarcos*, which is confessedly one of the best dramatic works of Cuban authorship. Soon after, through the influence of Delmonte, he obtained a position as secretary of a railway company, which placed him in comparatively easy circumstances. A mental disease which attacked him in 1842 was not alleviated by a journey in the U. S. and Europe in 1848–49; he sank into helpless melancholia and died at Matanzas, Nov. 14, 1863. After Heredía, Milanés is the most popular of the Cuban poets. A collected edition of his works was published at Havana, 1846, and a more complete one in New York, 1865. Herbert H. Smith.

Milá y Fontanals, mĕĕ-laa'ee-fōn-taa-naals', Manuel: scholar; b. at Villafranca del Panades, near Barcelona, Spain, May 4, 1818; d. in Barcelona, July 16, 1884. After studying law (licentiate, 1841), he gave himself entirely to the history of literature—especially that of Catalonia and Spain—and in 1845 was made Professor of Literature in Barcelona. For many years he was the most eminent representative in the Spanish Peninsula of the scientific study of the Romance languages and literatures. Among his works may be mentioned *Romancerillo catalán* (1843; 2d ed. 1882); *De los trovadores en España* (1861); *De algunas representaciones catalanes* (1864); *De la poesía heróico-popular castellana* (1873); *Principios de literatúra general* (1874); *Estudios de lengua catalana* (1875); *Notas sobre la influencia de la literatúra italiana en la catalana* (1877); *Poètes lyriques catalans* (Montpellier, 1878). He wrote many learned articles also for the *Romania* and other journals. A new edition of his works, edited by M. Menéndez y Pelayo, is in course of publication in Barcelona (vol. i., 1888; vol. ii., 1889).

A. R. Marsh.

Milaz'zo: seaport-town; in the province of Messina, Sicily; on the Gulf of Milazzo; about 27 miles W. of the city of Messina (see map of Italy, ref. 9–G). This town stands partly on the shore and partly on a high promontory. The harbor is sufficiently large and deep to receive ships of war. The exports consist chiefly of oil, wine, salt fish, linseed, dried fruits, etc. Milazzo (anc. *Mile*) was founded by the Zanclei more than 700 years before our era, and has shared the general vicissitudes of the island. It has been the theater of many battles, the last in 1860, when Garibaldi, July 20, obtained a brilliant victory over the Neapolitan troops, followed by the surrender of the fortress of Milazzo and the city of Messina. Pop. (1881) 7,971.

Milburn, William Henry, D. D.: lecturer and preacher; b. in Philadelphia, Pa., Sept. 26, 1823; removed in childhood to Jacksonville, Ill.; studied at Illinois College, notwithstanding a partial loss of sight; became a Methodist itinerant preacher at the age of twenty, chiefly in the Southern States; was settled for a time at Montgomery, and afterward at Mobile, Ala.; became a popular and eloquent lecturer and was six times chaplain to Congress, and in 1893 was chosen as chaplain to the U. S. Senate; went to Great Britain in 1859, and lectured with success in the principal cities. On his return he was ordained in the Protestant Episcopal Church, but returned in 1872 to Methodism. He is widely known as "the blind preacher," and has published *Rifle, Axe, and Saddle-Bags* (1857); *Ten Years of Preacher Life* (1859); and *Pioneers and People of the Mississippi Valley* (1860). Revised by A. Osborn.

Mildews [*mildew* is from O. Eng. *meledēaw* : O. H. Germ. *militou*, probably meaning, originally, honeydew; Germ. *mehlthau* has then suffered corruption under influence of *mehl*, meal; cf. Goth. *miliþ*, honey : Gr. μέλι : Lat. *mel*]: the general name applied to many microscopic fungi, now pretty well restricted to two families of parasitic plants distingnished as the Downy Mildews (*Peronosporaceæ*) and the Powdery Mildews (*Erysipheæ*).

In Great Britain the rust of wheat and other cereals is called mildew, but this usage does not prevail in the U. S. (See Rusts.) The mildew of cloth exposed to dampness, consisting of reddish, brownish, blackish, yellowish, or even greenish patches, is caused, at least in part, by minute fungi of various kinds (e. g. *Cladosporium herbarum*, *Penicillum glaucum*, *Aspergillus glaucus* and *A. roseus*, *Papulospora sipedonioides*, etc.). The large genus *Botrytis*, of the so-called imperfect fungi, are often known as mildews. They attack dead or languishing plants, e. g., the lettuce mildew, *Botrytis vulgaris*.

The Downy Mildews (*Peronosporaceæ*) consist of branching unseptated threads which grow in and through the tissues of their hosts. Certain branches protrude through the breathing pores of the host (Fig. 1), and produce great numbers of spores (summer spores, or conidia). These spore-bearing branches (conidiophores) occur in such great numbers that they give the surface a downy appearance, whence the popular name, Downy Mildews.

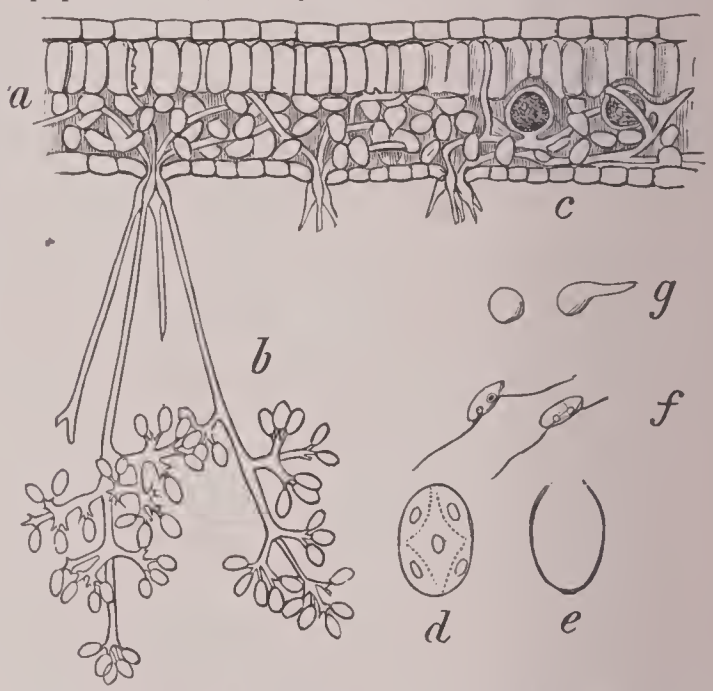

Fig. 1.—Downy mildew of the grape: *a*, diagrammatic section of affected grape-leaf; *b*, branches bearing conidia; *c*, two resting spores; *d*, germinating conidium; *e*, conidium after the escape of zoöspores; *f*, active zoöspores; *g*, zoöspores at rest, and germinating (all magnified).

The summer spores germinate quickly, either by sending out a tube which develops directly into the threads of a new plant (as in lettuce mildew), or by each one breaking up internally into a number of active bodies (zoöspores) which swim about (in dewdrops and films of moisture on leaves) for a time, and then become rounded and covered with a cell-wall, after which each sends out a tube, which develops into a branching thread. This latter method of germination is characteristic of the downy mildew of the grape.

The resting spores are formed within the tissues of the host, by the fertilization of an enlarged globular cell (the oögone), by a slender cell (the antherid), resulting in the formation of a thick-walled cell (Fig. 1, *c*). These resting spores (oöspores) remain for some time in the decaying tissues of the host and then germinate by forming zoöspores, as in the second kind of conidia described above, eventually giving rise to a new generation of the parasite.

About 100 species of Downy Mildews are known. Formerly these were all placed in the single genus *Peronospora*, but five genera are now recognized as follows:

Phytophthora.—Conidiophores at first simple, afterward branched; conidia producing zoöspores; resting spores thin-walled. The most important species is *P. infestans*, the

cause of the potato rot. (See Rot.) Another species is the bean mildew or blight (*P. phaseoli*), which attacks the leaves, stems, and pods of Lima beans.

Sclerospora.—Conidiophores simple; conidia producing zoöspores; resting spores thick-walled. Represented in the U. S. by *S. graminicola*, which attacks the leaves of "foxtail" grasses (*Setaria*).

Plasmopara.—Conidiophores with lateral branches; conidia forming zoöspores; resting spores thin-walled. The downy mildew of the grape (*P. viticola*, Fig. 1) belongs here. It attacks the leaves, young twigs, and berries, and is often harmful.

Bremia.—Conidiophores dichotomously much branched; conidia germinating by an apical tube. The single species is the lettuce mildew (*B. lactucæ*), which attacks garden lettuce and many wild plants related to it.

Peronospora.—Conidiophores dichotomously much branched; conidia germinating by a lateral tube. Radish mildew (*P. parasitica*) attacks the leaves and flowers of radishes (often greatly enlarging and distorting the latter), and many other crucifers. The so-called onion rust is a downy mildew (*P. schleideni*) which attacks and destroys the leaves.

The Powdery Mildews consist of delicate, white, septate threads which grow upon the epidermis of higher plants, here and there sending out a short "sucker" which penetrates the epidermal cells. Many vertical branches are

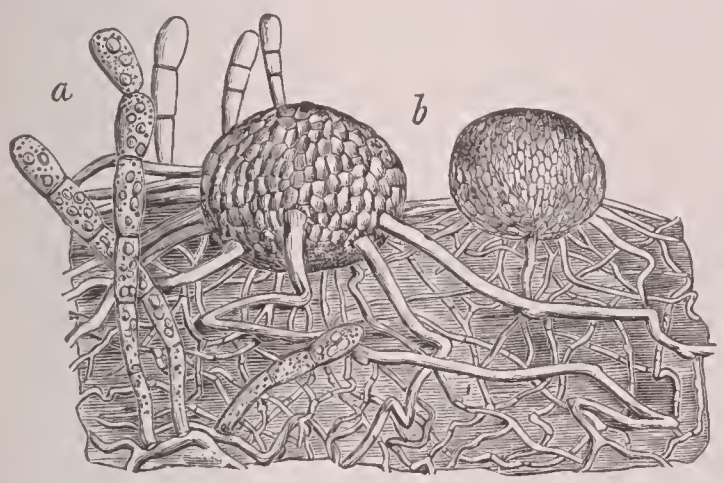

Fig. 2.—Portion of a leaf affected with powdery mildew, showing threads on the epidermis: *a*, conidia; *b*, sporocarps.

produced, which break up into spores, whose great numbers give a white powdery appearance to the surface (Figs. 2 and 3). These spores (summer spores, or conidia), which are

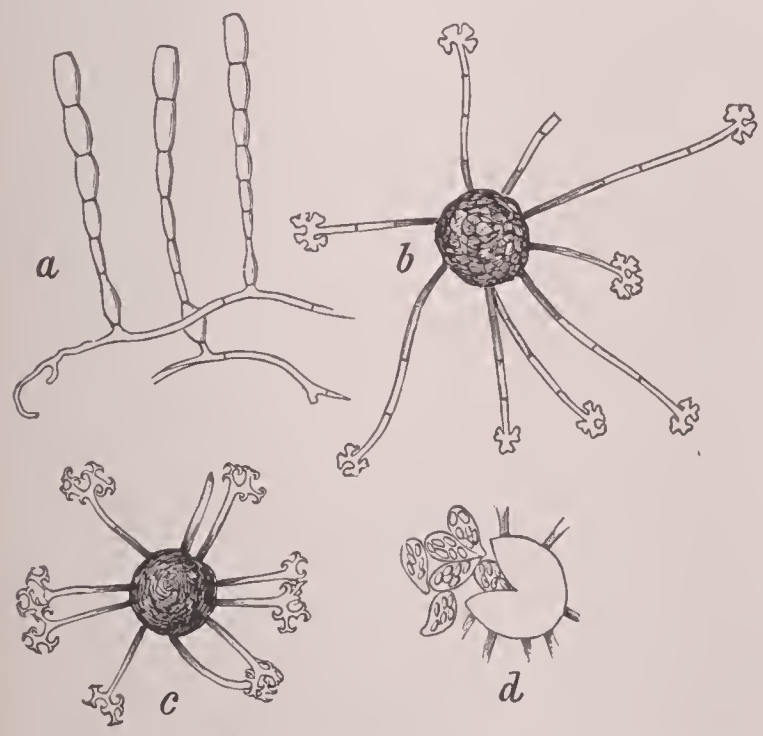

Fig. 3.—*a*, conidia of powdery mildew (*Erysiphe graminis*); *b*, sporocarp of cherry mildew (*Podosphæra oxycanthæ*); *c*, sporocarp of lilac mildew (*Microsphæra alni*); *d*, same ruptured, all magnified about 100 times.

capable of quick germination, soon produce more mildew upon unaffected areas, and thus rapidly spread the parasite. A little later the globular fruits (sporocarps) are produced, within which are the long-lived sac-spores (Fig. 3, *d*), which live through the winter and thus propagate the parasite the next season.

There are somewhat more than 100 species, distributed among half a dozen genera, as follows:

Erysiphe.—Spore-sacs several; appendages simple threads. Abundantly represented by the pea mildew (*E. communis*), often destructive to garden peas, attacking both leaves and pods, and the powdery mildew of composites and verbenas (*E. cichoracearum*), frequently very injurious to cultivated verbenas, sunflowers, asters, etc.

Uncinula.—Spore-sacs several; appendages coiled at the tip. Grape leaves and fruits are often seriously injured by the powdery grape mildew (*U. necator*), which is probably the same parasite as that known in Europe as *Oidium tuckeri*. Maple-leaves are often attacked by a species (*U. aceris*), and willows by another (*U. salicis*).

Microsphæra.—Spore-sacs several; appendages dichotomously branched at the tip. Most commonly represented by the lilac mildew (*M. alni*, Fig. 3, *c*), which covers the leaves in autumn with a dirty white mould-like growth. It attacks also honeysuckles, elms, walnuts, and many other trees and shrubs.

Phyllactinia.—Spore-sacs several; appendages needle-shaped. Represented in the U. S. by but one species (*P. suffulta*), the powdery mildew of magnolias, hawthorns, ashes, elms, birches, alders, hazels, beeches, etc.

Sphærotheca.—Spore-sac single; appendages simple threads. The hop mildew (*S. humulis*) is often destructive in hop-fields. Rose mildew (*S. pannosa*) is frequently troublesome in greenhouses, appearing as a white powdery growth upon the leaves. Another species (*S. mors-uvæ*) is the powdery mildew of the gooseberry.

Podosphæra.—Spore-sac single; appendages dichotomously branched at the tip. The principal species in the U. S. is *P. oxycanthæ* (Fig. 3, *b*), the powdery mildew of cherry, plum, and apple leaves, which is especially harmful to young trees.

Various remedies and preventives have been used for the mildews with more or less success. The fumes of sulphur are effective for the powdery mildews. Spraying with ammoniacal copper carbonate, or some of the copper sulphate solutions (Bordeaux mixture, eau celeste, etc.), has been found effective in both the powdery and the downy mildews.

Charles E. Bessey.

Mile [O. Eng. *mīl*, from Lat. *mi'lia*, *mil'lia*, mile, deriv. of *mil'le* (*pa'suum*), a thousand (paces); cf. Germ. *meile*, Fr. *mille*]: the name for a great number of lineal measures, each remotely derived from the Roman mile. Among the principal miles are the following:

English and U. S. statute mile	= 1·
Roman mile	= ·9193
English nautical or geographical mile	= 1·153
German, four English nautical miles	= 4·611
Scotch mile	= 1·127
Irish mile	= 1·273
German short mile	= 3·897
" long "	= 5·753
Prussian mile	= 4·680
Danish "	= 4·684
Swedish "	= 6·648

The geographical mile is one minute of the earth's equator. Our statute mile was fixed in Queen Elizabeth's time at 5,280 feet, and has not since been changed.

Revised by S. Newcomb.

Milelli, mĕĕ-lel'lĕĕ, Domenico: poet; b. at Catanzaro, in Calabria, Italy, in 1841. Destined for the priesthood, he turned aside to literature, and that of the most pagan kind. In 1864 he wrote an ode to Ugo Foscolo, which was translated into English, and then back into Italian by a writer ignorant of its origin. The list of his poetical works is long: *In giovinezza* (1873); *Gioconda* (1874); *Hiemalia* (1874); *Odi pagane* (1879); *Povertà* (1879); *Discerpta* (1881); *Il rapimento di Elena* (1882); *Canzoniere* (1884); *Verde antico* (classical translations, 1885). He has also published under the pseudonym *Conte di Lara* a book of *Rime* that has been very popular. He is one of the most extreme of the so-called *Veristi*, and many of his utterances have brought upon him the severest denunciations. A. R. M.

Miles, Nelson Appleton: soldier; b. at Wachusettville, Mass., Aug. 8, 1839; entered the volunteer service as cap-

tain in the Twenty-second Massachusetts Volunteers Sept., 1861; was distinguished at Fair Oaks and at Malvern Hill; became adjutant-general of a brigade; was appointed Sept. 30, 1862, colonel Sixty-first New York Volunteers, which he commanded at Fredericksburg; was severely wounded at Chancellorsville; was appointed brigadier-general May 12, 1864; was distinguished in the Richmond campaign of 1864; appointed brevet major-general Aug., 1864; major-general of volunteers Oct., 1865; colonel of Fortieth Infantry U. S. army July 28, 1866; transferred to the Fifth Infantry Mar. 15, 1869, and commissioned brevet brigadier and brevet major-general U. S. army Mar. 2, 1867; brigadier-general U. S. army Dec., 1880; major-general Apr. 5, 1890. He commanded several military departments, and has distinguished himself by his success in suppressing Indian outbreaks. He was in command of the U. S. troops stationed in Chicago during the riots in July, 1894. On Oct. 5, 1895, assumed command of the army. JAMES MERCUR.

Milet de Mureau, mēē'lā'de-mü'rō', LOUIS MARIE ANTOINE DESTOUFF, Baron: soldier and statesman; b. at Toulon, France, June 26, 1756, of a noble family from Lorraine; entered the army in 1771, and was made a captain in 1779. As a member of the States-General he usually voted with the right, but returned soon to active service as commander of the artillery of the army of Italy. In 1792 he was called to Paris to edit the journals of Pérouse, and performed the task with great ability (*Voyage de la Pérouse autour du monde pendant les années 1785–88*, Paris, 1797–98, 4 vols.), though it presented peculiar difficulties, as the revolutionary government wanted the text changed in favor of the Revolution. In 1799 he was for a short time Minister of War, during the empire prefect of the department of Corrèze, and under the Restoration president of the board of administration of the Hôtel des Invalides. Napoleon refused to give him any command, but made him a baron. D. in Paris, May 6, 1825.

Mile'tus (in Gr. Μίλητος): one of the most flourishing cities of Ionia, on the Sinus Latmicus, opposite to the mouth of the Meander. It existed as a town at the time when the Greeks planted their first colonies in Asia Minor; but on the arrival of the Ionians under Neleus all the male citizens of the ancient population (Carians or Leleges) were massacred. Miletus soon became one of the most powerful maritime and commercial places of the Mediterranean. It monopolized the trade of the Euxine; it sent its vessels into the Atlantic; it formed a great number of prosperous colonies, such as Abydos and Lampsacus on the Hellespont, Cyzicus on the Propontis, Sinope and Amisus on the Euxine, and others in Thrace, the Crimea, and on the Borysthenes. It continued to flourish under the Lydian and Persian rule, but after its unsuccessful revolt against Persia in 500 B. C. under HISTIÆUS (*q. v.*), its strength was broken. Darius treated it with great severity. Most of the inhabitants were massacred, and the rest were transported to Ampe, at the mouth of the Tigris. The place was then given up to the Carians; and when the Persians were compelled, 479 B. C., to retire from the coast of Asia Minor, it revived. It gave some signs of life during the Peloponnesian war by throwing off the Athenian yoke; it afterward attempted to resist Alexander the Great, and continued a place of commercial consequence until destroyed by the Turks. Its site is now occupied by Balat or Palattia, described as "a fever-stricken place." See Rayet and Thomas, *Milet et le Golfe Latmique* (Paris, 1877). J. R. S. S.

Miley, JOHN, D. D., LL. D.: minister and educator; b. in Butler co., O., Dec. 25, 1813; educated at Augusta College, Kentucky; entered the Methodist Episcopal ministry in 1838; was pastor 1838–48; professor in Wesleyan Female College, Cincinnati, 1848–50; pastor 1850–73; and Professor of Systematic Theology in Drew Theological Seminary since 1873. He has published *The Atonement in Christ* (1879) and *Systematic Theology* (2 vols., 1892–94). J. F. H.

Milfoil: See YARROW.

Milford: town (originally known as Wepowage, site purchased from the Indians Feb. 12, 1639, settlement independent till 1643, then merged into the colony of New Haven); New Haven co., Conn. (for location of county, see map of Connecticut, ref. 12–F); on Long Island Sound at the mouth of the Wopewaug river, and the N. Y., N. H. and Hart. Railroad; 10 miles S. W. of New Haven. It contains 5 churches, public high school, Elmwood School for boys (opened 1884), lyceum with library (founded 1858), soldiers' monument (dedicated 1888), 2 ancient burying-grounds, and a savings-bank. At the 250th anniversary of its settlement (1889) a memorial bridge across the river at the head of the gorge, built of granite, with a tower, and granite blocks inscribed with the names of early settlers on its copings, was dedicated. The industries of the town comprise the manufacture of shoes, straw hats, fish oil, and bone fertilizers, and the cultivation of oysters. Pop. (1880) 3,347; (1890) 3,811; (1900) 3,783.

Milford: town (founded in 1794); Kent co., Del. (for location of county, see map of Delaware, ref. 5–N); on both sides of the Mispillion river, and on the Phila., Wil. and Balt. Railroad; 96 miles S. of Philadelphia. It is in an agricultural, fruit-growing, and fruit-curing region; is a shipping-point for general produce; contains 6 churches, 2 public schools, a preparatory school, and 2 weekly newspapers, and has considerable ship-building interests. Pop. (1880) 1,240; (1890) 2,565; (1900) 2,500.

EDITOR OF "PENINSULAR NEWS AND ADVERTISER."

Milford: town; Worcester co., Mass. (for location of county, see map of Massachusetts, ref. 3–F); on the Charles river, and the Boston and Albany, the Grafton and Upton, and the N. Y. and N. E. railways; 30 miles S. W. of Boston. It is one of the largest boot and shoe manufacturing centers in the U. S., and has, besides, manufactories of machinery and straw and cotton goods. There are 2 national banks with combined capital of $385,000, a savings-bank, a public library (founded 1858), and 2 daily and 3 weekly newspapers. Pop. (1880) 9,310; (1890) 8,780; (1900) 11,376.

EDITOR OF "JOURNAL."

Milford: village (settled in 1833); Oakland co., Mich. (for location of county, see map of Michigan, ref. 7–K); on the Huron river, and the Flint and Pere Marq. Railroad; 43 miles N. W. of Detroit. It is in an agricultural region; has good water-power and manufactories of foundry products and farming implements, and contains 4 churches, 2 public schools, and a weekly newspaper. Pop. (1880) 1,251; (1890) 1,138; (1900) 1,108. EDITOR OF "TIMES."

Milford: town (incorporated in 1794); Hillsborough co., N. H. (for location of county, see map of New Hampshire, ref. 10–E); on the Boston and Maine Railroad; 50 miles N. W. of Boston. It is in a granite-quarrying and dairying region; contains a high school, public library (founded 1868), a national bank with capital of $100,000, a savings-bank, and a weekly newspaper, and manufactures hosiery, knitting cotton, picture and mirror frames, and furniture. It is a popular summer resort. Pop. (1880) 2,398; (1890) 3,014; (1900) 3,739. EDITOR OF "FARMERS' CABINET."

Milford Haven: a deep inlet of the Atlantic, on the southwest coast of Wales (see map of England, ref. 12–B). It is about 15 miles in length; average width 2 miles; has deep water, and is one of the best ports of the British dominions.

Milhau, mēē'lō', or **Millau**: town; in the department of Aveyron, France; on the Tarn, half a mile below the influx of the Dourbie (see map of France, ref. 8–F). It is beautifully situated, surrounded with picturesque hills covered with vineyards and forests. It has large tanneries and manufactures of gloves, and carries on a considerable trade in leather, wool, and timber. During the religious wars it was one of the chief strongholds of the Calvinists, but its castle was demolished by Louis XIII. Pop. (1896) 18,754.

Miliary Fever: See SWEATING SICKNESS.

Miličević, mil-i-chev'ich, MILAN: author; b. at Ripanj, near Belgrade, Servia, May 7, 1831; studied theology; became a teacher in 1850, obtained a state office in 1852, and was appointed secretary to the Servian Minister of Education in 1861. He has published important geographical and ethnological works: *Knježevina Srbia* (The Principality of Servia, Belgrade, 1876); *Život Srba seljaka* (Servian Peasant Life; in the *Glasnik*, 1867 and 1873); *Selo Zloselica, etc.* (Belgrade, 1880); *The Kingdom of Servia* (Belgrade, 1884); also some stories of Servian life, *Jurmusa i Fatima*, etc., and *Zimnje večeri* (Winter Evenings, Belgrade, 1879). In 1865 he translated Hilferding's *Pišma ob istorii Serbov i Bolgar* (Notes on the History of the Servians and the Bulgarians). J. J. KRÁL.

Milicz of Kremsier: reformer; one of the most influential precursors of Huss; b. at Kremsier, a village near Olmütz, in Moravia, in the beginning of the fourteenth century, probably in 1325. In 1350 he took holy orders; in

1360 he was made canon of the Cathedral of St. Vitus, in Prague, and in the same year he was appointed secretary to the Emperor Charles IV., whom he accompanied to Germany. In 1363 he resigned all his positions, retired to some lonely place in the Bohemian Forest, and then returned to Prague, where he began to preach to the poor people in the streets—not in Latin, but in Bohemian. He caused a great sensation, as a sermon in the native tongue was at that time something altogether unheard of, but he also made a deep impression; and he actually succeeded in cleaning out one of the most obnoxious streets of Prague, the Benatki, and inducing the fallen women who had inhabited it to enter the charitable institution called the Jerusalem, which he had established for their benefit. It soon began, however, to dawn upon him that the root of the evil was in the Church herself—in her corruption, in her vices—and it gradually became clear to him that Antichrist had come, and that radical and sweeping reforms were indispensable. In 1367 he repaired to Rome to confer with the pope; but when he announced, by a placard on the gate of St. Peter's, that he was going to preach on the presence of Antichrist, he was arrested by the Inquisition. He was, however, soon after released and allowed to return to Prague by Urban V., who treated him with great kindness. From 1369 to 1372 he again preached in Prague, but in the latter year dissensions arose between him and his brother-priests in Prague, and they formally accused him of heresy before the pope. He was summoned to Avignon to defend himself, which he did successfully, but he died there, before the verdict was announced, June 29, 1374. His *Libellus de Antichristo* is still extant. Revised by S. M. Jackson.

Military Academies: academies for training men for service as military officers. As they now exist they are of quite modern origin. In modern times many circumstances have combined to make war far more a matter of science and skill, and less a matter of brute force and courage, than formerly. Hence the great necessity for a thorough preparation of officers, upon whose character and ability the results of war, with all its momentous consequences, must very greatly depend. As the peculiar instruction and training required can not be furnished by the ordinary educational institutions, special schools have been judged necessary, and have been carefully organized by the most enlightened nations. Only the principal military schools of some of the great military powers are here noticed.

Great Britain.—1. *The Royal Military Academy* at Woolwich, instituted in 1741, for the purpose of educating candidates for commissions in the artillery and engineers. The education is chiefly technical. Admission is by open competitive examinations, conducted by the civil service commissioners. The candidates pass a preliminary examination in mathematics, French or German, English writing and composition, geometrical drawing, and geography, after which they pass the decisive examination in the following subjects: I. Mathematics (compulsory), mechanics, analytical geometry, conic sections, Latin, French, German (optional). II. Greek, English history, physics, chemistry or physical geography, and geology. III. English composition, free-hand and geometrical drawing. The candidates select only four of the subjects in group I., and one in group II., taking all of group III. Age of admission, sixteen to eighteen years. The course of instruction lasts two years, and embraces mathematics, fortification, artillery, military drawing and reconnoissance, French or German, elementary chemistry and physics, drills, and exercises; certain voluntary subjects being allowed to be taken up at the option of the student. At the end of the first year the courses of the engineers and artillery are conducted separately, the highest choosing the engineers. The cadets pay an annual contribution, which, however, is not the same for all, being greatest for sons of civilians, less for sons of military and naval officers, and least for sons of deceased officers whose families are in pecuniary distress; the queen's cadets pay nothing. At present there are 202 cadets and about thirty professors and instructors, besides the governor and his staff. On graduation the cadets are commissioned lieutenants in the engineers or artillery.

2. *The Royal Military College* at Sandhurst, instituted in 1799, for the purpose of affording a special military education to candidates for commissions in the cavalry and infantry. Admission is as for the Royal Military Academy, and the preliminary entrance examination is quite the same. The decisive entrance examination includes the following subjects: I. Mathematics, Latin, German, French. II. English history, Greek, higher mathematics, physics, chemistry or magnetism and heat, physical geography and geology. III. English composition, free-hand and geometrical drawing. The candidates select three of the subjects in group I., one in group II., taking all of III. Age of admission seventeen to twenty years. The course is one year, and embraces military administration, army organization, minor tactics, fortification, military reconnoissance, drill, riding, and gymnastics. The cadets pay an annual contribution, varying in amount, as in the Royal Military Academy. The number of students is now 300, with about thirty professors and instructors, in addition to the staff of government. On graduation the cadets are commissioned lieutenants in the cavalry or infantry.

3. *The Staff College* at Sandhurst, organized in 1858, is for the instruction of officers in the duties of the staff of an army. Admission is wholly by competitive examination, open to officers of all arms of the service, including artillery and engineers. Candidates must have served five years, have certain certificates from their superiors, and be under thirty-seven years of age. The subjects of the competitive examination are mathematics, military history and geography, French, German (for officers of the Indian staff corps, Russian or Hindustani), and fortification, military drawing, and minor tactics; mathematics, one language, military topography, and minor tactics are obligatory; the remaining subjects are at the option of the candidate. The course lasts two years, and embraces fortification and artillery, topography and reconnoissance, military history and geography, military administration and law, French, German, or Russian (one language only), lectures in applied sciences (voluntary), riding. Much time is devoted to practical outdoor work, including orientation and tactical discussions. The number of students is sixty-four, with fifteen professors and instructors, exclusive of the staff of government. Upon graduation the officers are assigned to staff duty (in some arm other than their own) for four months in the camp at Aldershot, after which they return to their ordinary regimental duties, and are available for assignment to staff duty.

4. Great Britain has also the *Royal Military College of Canada* (Kingston), the *Royal School of Military Engineering* at Chatham, the *Advanced Class of Artillery Officers* at Woolwich, the *School of Gunnery* at Shoeburyness, and the *School of Musketry* at Hythe.

France. 1. *The Polytechnic School at Paris.*—This celebrated school was founded in 1794, but received its organic law in 1799 from La Place, then Minister of the Interior under Napoleon. It is a scientific school, giving a preparatory education for several branches of the public service—viz., the engineers, artillery, and staff, the department of powder and saltpeter, the navy and marine artillery, the naval architects, the hydrographical engineers, the corps of roads and bridges (*ponts et chaussées*), the corps of mines, the telegraph department, the tobacco department, and for other branches requiring an extensive knowledge of mathematics, physics, and chemistry. Admission is wholly by competitive examination. Age of admission, sixteen to twenty-one years, or, if in the army, not over twenty-five years. The candidate must have the degree of bachelor of science or of bachelor of literature, and is examined in French, resolution of triangles, figure and color drawings, algebra and analytical geometry, descriptive geometry, physics and chemistry, and German. The course lasts two years, and embraces analysis, descriptive geometry and stereotomy, mechanics and machines, physics, chemistry, astronomy, geodesy, architecture and public works, topography, military art and fortification, composition and French literature, German, history, figure, landscape, and color drawing. The number of pupils is about 520, with about 40 professors and instructors, exclusive of the staff of government. Pupils pay a certain amount annually, but aid is given by the state to those needing it. On graduation, those who enter the army or navy are commissioned second lieutenants.

2. The *Special Military School* at St.-Cyr (organized in 1808) is intended for the instruction of those destined to become officers of infantry, cavalry, and the marine corps. Age of admission, seventeen to twenty-one, whether in the army or not. Admission is wholly by competitive examination in the following subjects—viz., arithmetic, algebra and plane trigonometry, geometry, descriptive geometry, mechanics, cosmography, physics, history, geography, German, English (voluntary). Candidates must have the degree of

bachelor of science or of literature. The course of study lasts two years, embracing topography, fortification, legislation and administration, artillery, military history and minor tactics, geography, and military exercises. There are about 950 pupils, with 42 professors and instructors, and 26 military officers of instruction in drill, etc., exclusive of the staff of government and administration. On graduation those who pass are commissioned second lieutenants, the rest complete their service in the ranks.

3. The *Superior War School* in Paris, instituted as the *Staff School* in 1808, reorganized in 1875 for the purpose of educating officers in the duties of the general staff. The candidates are lieutenants or captains of the army (exceptionally also of the marine corps or naval artillery), who have served at least five years, without limit as to age. Admission is by competitive examination in the following subjects: Army organization and military history, minor tactics, German, administration, artillery, fortification, geography, topography and riding, including a written solution of a problem in minor tactics, and one in administration, and a topographical map. The course is two years, embracing military history, strategy and tactics, applied tactics, general staff duty, administration, fortification, telegraphy, geodesy, geology, topography, and hygiene. There are now about 163 pupils, with 25 instructors and professors, and 8 visiting lecturers, besides the director and his staff.

4. France has also the *School of Artillery and Engineers* at Fontainebleau, the *Cavalry School* at Saumur, the *Military Orphan School* at La Flèche, the *Medical School* in Paris, the *School of Military Hygiene* at Lyons, the *Gymnastic School* at Joinville-le-Pont, the *School of Musketry* at Châlons, the *Infantry School* at St.-Maixent, the *Artillery and Engineer School* (for non-commissioned officers) and the *Military Administration School* at Versailles.

Prussia. 1. The *Cadet Schools.*—There are seven of these schools—viz., a senior cadet school at Lichterfelde, near Berlin, and six junior cadet schools, preparatory to the senior, situated at Potsdam, Culm, Wahlstatt, Bensberg, Ploen, and Oranienstein. Their purpose is to educate and train youths, particularly for the military service, thus insuring a supply of efficient officers for the army. Admission is by examination, not competitive, but fixed for every particular age. The classes of the junior schools are arranged to correspond to a Real school, with the classes sexta, quinta, quarta, lower tertia, upper tertia, the ages of the pupils ranging from ten to fifteen years; candidates may enter any one of these classes. The full course in the junior schools is five years, and embraces religion, German, Latin, French, English, mathematics, physics, history, geography, natural history, drawing, and writing. On graduation the pupils enter the senior cadet school. The full course at the latter is five years, with the classes lower secunda, upper secunda, lower prima, upper prima, and selecta. The course embraces religion, German, Latin, French, English, mathematics, history, physics, chemistry, drawing, writing; and in the selecta military sciences (ordnance, minor tactics, fortification, topography, drawing, and service duties) and French. Those who complete the upper secunda may pass the ensign examination at once, or enter the selecta (if sufficiently developed physically) or the prima (if not); those who fail enter the army in the ranks. Those who complete the lower prima pass the ensign examination, or enter the selecta or upper prima. Those who complete the upper prima take the graduating examination and enter a war school. The graduates of the selecta may pass the officers' examination without attending a war school. In each junior school there are about 200 pupils, and in the senior school over 800. Cadets in all these schools pay a certain sum, but state aid is given as circumstances require it.

2. The *War Schools.*—These schools are eight in number, situated at Glogau, Potsdam, Neisse, Engers, Cassel, Hanover, Anclam, and Metz, and are designed for the instruction of those intended for officers of all arms. The conditions for entrance are the commission of ensign (officer aspirant), five months' service with troops, and not over 24¼ years of age. The course of instruction lasts nine or ten months, and is subdivided into a theoretical and a practical course; the former (limited to the forenoon) embraces tactics, fortification, science of arms, military surveying and drawing, and military correspondence; the latter (generally in the afternoon throughout the course) embraces drill, gymnastics, swimming, fencing, riding, musketry practice, and service duties. The pupils who pass the graduating (officers') examination are commissioned second lieutenants.

3. The *War Academy* in Berlin. This is designed to furnish an education in the higher branches of military science to officers of the army, to prepare them for general staff duty, and to furnish a supply of well-trained officers for the higher commands. Admission is by competitive examination, open to all officers who have served three years with troops (without limit as to rank or age), and who are characterized on their qualification lists as good duty officers with troops, in sound health, of established character, studious in habit, and free from pecuniary difficulties. The entrance examination includes minor tactics, ordnance, fortification, surveying, history, geography, algebra, geometry, and French. The course lasts three years, and embraces minor tactics, ordnance, fortification, geodesy, general history, general, physical and military geography, mathematics, history of strategy, physics, military history, military administration, surveying, general staff duty, chemistry, military hygiene, military law, history of literature, sieges, French, and Russian. Part of the course is voluntary. Practical instruction in the field is also given, particularly during yearly *rides of instruction* in minor tactics, surveying, general staff duty, etc. There are about 300 pupils. During the vacations, at the end of the first and second years, the officers are detailed on general staff duty in arms other than their own, and on graduation they return to their own regiments, being afterward selected for the general staff as required, lieutenants being promoted to captains out of turn.

4. Prussia has also an *Artillery and Engineer School* at Charlottenberg, near Berlin, a *Military Riding School* at Hanover, a *School of Musketry* at Spandau, a *School of Gunnery* at Tegel, near Berlin, and two *medical schools* in Berlin.

Austria, Russia, Italy, Spain, and other powers have their systems of military schools, of which those of Austria and Russia are noticeable.

The United States. 1. The *Military Academy* at West Point, N. Y. The conception of a military academy in the U. S. dates back to 1776, when a committee was appointed by the Continental Congress to "prepare and bring in a plan of a military academy at the army." No further action appears to have been taken. Washington invited the attention of Congress to the subject in 1793, and in 1796 recommended the institution of a military academy. The result was, finally, the act of Mar. 16, 1802, founding the Military Academy. Between 1802 and 1812 there were in all only six instructors at West Point, of whom only from two to four were present at the same time, and there were only eighty-nine graduates. The uniform of the cadets, nearly the same as now worn, was prescribed by a general order in 1816.

Although owing much to the efforts of its two first superintendents, and especially to Col. Jonathan Williams, the real initiation of the academy, as it has since been, dates from the appointment of Brevet Major (afterward Gen.) Sylvanus Thayer of the Corps of Engineers, who assumed command July 28, 1817. He established the office of commandant of cadets; introduced the division of classes into sections, transfers between the sections, and weekly class reports showing weekly progress, and by a system of daily marks indicating the individual progress of cadets. The check-book controlling the expenses of the cadets, the extensive use of the blackboard, and the essential parts of the regulations now governing the academy are due to him. Ten months of the year were allotted to academic duties, and two months to those of camp. He inculcated by precept and example that spirit of devotion to duty and unquestioning, prompt obedience to lawful authority which still distinguish the graduate of West Point.

In the appointment of cadets it has been admitted as a principle that the sons of those who have lost their lives in the defense of the nation should have preference. The custom of appointing cadets from districts naturally arose in accordance with the tendency to distribute all appointments under the general Government in proportion to representation, and was converted into a law in 1843. The monthly pay of cadets was $28 in 1802, $24 in 1845, $30 in 1857, in 1864 about $50; the pay in 1885 was $540 a year. A board of visitors, to attend the annual examinations and report on the condition of the Academy, provided for in 1816 by regulation from the War Department, was first assembled after Maj. Thayer became superintendent. Discontinued by the act of 1843, it was again authorized by act of Aug. 8, 1846, the members to be selected by the President from half the number of States annually, alternating with the other half;

the number of members was reduced to seven in 1868; and to this number were added in 1870 two Senators and three members of the House of Representatives, to be designated respectively by the President of the Senate and the Speaker of the House. The aggregate amount appropriated from 1864 to 1884 was $6,180,331.07; from 1885 to 1892 (both inclusive), $3,287,700.31; the largest being that for 1890, which was $902,766·69, and included the appropriation for a new gymnasium and a new academic building.

Present Organization.—The general commanding the army has, under the War Department, supervision and charge of the academy. The staff of government and instruction consists of (1) the superintendent,* directing the studies and exercises, and exercising command over all persons belonging to the academy, and commanding the military post. The military staff includes an adjutant, quartermaster, commissary of subsistence, treasurer, surgeon, and assistant surgeon. (2) The commandant of cadets, an officer of the army, who is the instructor of artillery, infantry, and cavalry tactics, and is charged with the discipline and administration, and commands the battalion of cadets. He has eight assistants, likewise army officers. (3) Seven commissioned professors, one professor detailed from the judge-advocates of the army, an instructor of practical military engineering, and an instructor of ordnance and gunnery, taken respectively from the Engineer and Ordnance Corps; these (the superintendent and commandant included) constitute the academic board. There are about forty-three assistant professors and instructors, including those in tactics, and one swordmaster. Except seven professors, all officers and instructors of the academy are officers of the army detailed for the duty, usually for a period of four years. The academic board examines candidates for admission and cadets, recommends text-books, maps, models, etc., draws up programmes of instruction, etc., grants diplomas, etc. For the purpose of discipline and tactical instruction the cadets are organized as a battalion of four companies, each under the supervision of an instructor of tactics, with officers and non-commissioned officers selected from the cadets themselves. Usually cadet officers are selected from the first class,† sergeants from the second class, and corporals from the third class. There are also a cadet adjutant, quartermaster, sergeant-major, and quartermaster-sergeant. The position of cadet officers affects their relation to other cadets only when on duty as officers.

Admission.—Each congressional district and Territory and the District of Columbia are entitled to have one cadet at the academy. The appointments are made by the Secretary of War at the request of the Representative or delegate in Congress from the district or Territory, of which the person appointed must be an actual resident. The President also appoints ten cadets at large. Candidates must be between seventeen and twenty-two years of age, at least 5 feet in height, and free from any infectious or immoral disorder, and from anything which may render them unfit for military service. They must be well versed in reading, writing, and orthography, arithmetic, elements of English grammar, descriptive geography, particularly of America, and history of the U. S. Those admitted are required to sign articles binding themselves to serve the U. S. eight years from date of admission, unless sooner discharged. An oath of allegiance to the U. S. is also required.

The course of study embraces the following subjects: (1) Infantry, artillery, and cavalry tactics and military police and discipline; (2) mathematics, including algebra, geometry, trigonometry, mensuration and surveying, descriptive geometry, analytical geometry, differential and integral calculus; (3, 4, and 5) English, French, and Spanish languages; (6) drawing, comprising topography, with pencil, ink, and colors, etc.; (7) heat, chemistry, electricity, mineralogy, and geology; (8) natural and experimental philosophy, comprising mechanics with applications, acoustics, optics, and astronomy; (9) ordnance and gunnery; (10) history, geography, and ethics; (11) law, including general principles, international law, Constitution of the U. S., etc., Rules and Articles of War, courts martial; (12) practical military engineering, etc.; (13) military and civil engineering and the science of war. By a system of numerical marks the proficiency of a cadet's daily recitations is measured; and these are taken into account in making up the merit rolls in each branch, as well as in the general class standing.

Discipline is very strict—more so than in the army, and probably than in any other similar institution. The aim is to inculcate habits of prompt and cheerful obedience to lawful authority, of neatness, order, and regularity, and of thoughtfulness and attention in the discharge of duty. A scrupulous regard for one's word is also required. The system of punishment for offenses is remarkable for inflexible enforcement rather than for severity. Besides demerit marks, which count in making up the class standing, cadets are further liable to three classes of punishment: (1) privation of recreation, etc., extra duty, reprimands, arrests, or confinement to room or tent or in the light prison, reduction to ranks of officers and non-commissioned officers; (2) confinement in dark prison; (3) suspension, dismission with the privilege of resigning, public dismission. Punishments of the first class are inflicted by the superintendent or with his approval; that of the second class by sentence of a court martial, except in case of mutinous conduct or breach of arrest. Monthly statements of conduct and progress in studies are sent to parents or guardians.

Upon graduating, the class is divided by the academic board into three sections of varying and unequal numbers, according to class rank; the highest, usually very small and sometimes wanting, is recommended for promotion in any corps in the army; the second, for any corps except the engineers; the third, in any corps except the engineers and the artillery. Commissions for the rank of second lieutenant are then usually conferred by the President.

2. The U. S. has also the *Engineer School* at Willets Point, N. Y., the *Artillery School* at Fort Monroe, Va, the *Infantry and Cavalry School* at Fort Leavenworth, Kan., the *Light Artillery and Cavalry School* at Fort Riley, Kan., and the *War College* at Newport, R. I. JOHN P. WISSER.

Military Law: See MARTIAL LAW and COURT MARTIAL.

Military Orders: See KNIGHT, KNIGHTS TEMPLAR, etc.

Militia [= Lat. military service, soldiery, deriv. of *mī'les, mi'litis*, soldier]: that portion of the military strength of a nation enrolled for discipline and instruction, but local in its organization, and engaged in active service only in cases of emergency. Originally the term was synonymous with the cognate derivative "military," as embracing the whole body of national troops, whether embodied for actual service or relegated to industrial pursuits. It is the organized national reserve in contradistinction to the regular army and the *levée en masse* of a country, and therefore comprehends the "volunteer" organizations of Great Britain and the U. S., the National Guard of France, the Landwehr and Landsturm of Germany, and similar organizations in the other European states.

In Great Britain alone, of the European states, is reliance placed upon voluntary enlistment for maintaining the various militia organizations in time of peace, and for recruiting the regular army both in peace and war. The British militia system originated in the Anglo-Saxon *fyrd*, and in the warlike feature of the ancient *posse comitatus*. The fyrd was overshadowed by the feudal system, was revived in the struggle between the crown and the barons, and was superseded by the "trained bands" created by James I. These were in turn suppressed, and at the Restoration the existing system, in its essential features, was established. Under it the Government appoints lords-lieutenant of counties, empowered to call out, embody, and command the "regular militia" and to appoint its officers. The quota for each county is established by Government, and in the failure of voluntary enlistment a levy by ballot would be made upon all non-exempted inhabitants of the county; but practically these quotas are kept up in time of peace by volunteers. This force assembles at stated periods for military exercise, and can be "embodied" in any national crisis. Most of the regiments were embodied in the Crimean war, and many of them during the Indian mutiny. They may not be sent out of the kingdom unless they volunteer, and then only by provision of Parliament; but this exemption does not apply to a portion, about one-quarter of the whole force, called the "militia reserve." The militia of the United Kingdom in 1893–94 comprised 140,308 men, of whom 123,744 were classed as "effectives." The volunteers, how-

* Up to July 13, 1866, the superintendent was an officer of engineers, of which corps the academy itself formed part. By the act of that date the superintendency was thrown open to all branches of the service. See ENGINEERS, CORPS OF.

† The classes are numbered in inverse order of the years of their service at the academy—that most recently entered being the fourth, etc.

ever, constitute the great national reserve. First organized in 1804, they in 1813 numbered over 400,000 effectives, but diminishing in numbers as danger became less imminent, they were absorbed in the local militia. A revival of military spirit was, however, initiated in 1859, and in 1894 the strength of this force, including the yeomanry cavalry, was 274,549. By furnishing paid adjutants and drill-masters to these corps, granting them certain pecuniary allowances, arming the men, and employing a staff of inspectors under the immediate direction of the War Office, the Government maintains this force in a very creditable condition of efficiency; but, excepting the yeomanry cavalry, it "may not be employed in time of civil disturbance." All of it, however, may be embodied for active service anywhere in Great Britain in case of invasion.

In Switzerland there is, nominally, at least, no standing army, but a corps of educated officers is maintained; every citizen is held to military service, and is taught its exercises in the schools; and the war-strength of the country is divided into a "regular force" of about 80,000, a reserve of about 50,000, and a Landwehr organization.

In the U. S. the militia becomes national only when called into the actual service of the Federal Government. Durthe Revolutionary war, 1775–83, the Federal armies consisted of State troops adopted by Congress, and this system of maintaining a military force prevailed till after the present Union was formed. Although eminently qualified for military service by the experiences of the French and Indian wars, Continental militia, as such, played no prominent part in the Revolutionary struggle. Available only for brief periods, it was deficient in discipline, and therefore uncertain under fire; and it was mainly to the regular troops, or "Continental line," that the revolting colonies were indebted for national independence. The following table, compiled from records of the New Hampshire Historical Society, exhibits the number of troops, Continental and militia, furnished by the thirteeen original States:

STATES.	Continentals or regulars.	Militia.
Massachusetts	67,907	15,155
Connecticut	31,939	7,792
Virginia	26,678	5,620
Pennsylvania	25,678	7,357
New York	17,781	3,304
Maryland	13,912	4,127
New Hampshire	12,497	2,093
New Jersey	10,726	6,055
North Carolina	7,263	(?)
South Carolina	6,417	(?)
Rhode Island	5,908	4,284
Georgia	2,679	(?)
Delaware	2,386	376
Totals	231,971	56,163

Under the Constitution, Congress has power to provide for the organization, equipment, and discipline of the militia, and for its government while in the service of the U. S.; and the States are prohibited from keeping troops in time of peace except under congressional consent; but the appointment of the officers and the authority for training the militia according to the discipline prescribed by Congress is expressly reserved to the respective States. Congressional enactments for maintaining a uniform system of militia throughout the Union require the enrollment in each State of all non-exempted able-bodied male citizens, resident, between the ages of eighteen and forty-five; establish the manner of organization; prescribe as the system for its discipline and field exercises that obtaining for the time being in the regular army; and provide for arms, pay, pensions, etc. Though the necessity of a *well-regulated* militia to the security of a free State is recognized in the Constitution, the arguments of statesmen and the logic of facts have alike failed to secure that attention demanded by the gravity of the subject. Since 1795 there has been no general revision of the system. The militia code is obsolete in many particulars, and in some of the States general enrollments are unknown, and in others the stated musters for exercise are mere burlesques upon military discipline. A judicious system would secure an effective military reserve of over 3,000,000 men; but as a matter of fact the only existing militia worthy of the name is found in the uniformed volunteer organizations maintained in many of the States as "National or State Guards," and these forces do not aggregate an effective force of over 50,000.

The President is commander-in-chief of the militia of the several States when called into the actual service of the U. S., and is empowered to call out these forces, by orders to such officers of the militia as he may choose to address, in event of invasion, actual or imminent, and in cases of insurrection or rebellion against the authority of the U. S. or any one of the States thereof; and he may continue the militia in service for a period not exceeding nine months. While so employed the troops receive the pay, rations, etc., of regular soldiers, are subject to the Rules and Articles of War, and their officers take precedence in rank next after officers of like grade in the regular service or in such volunteer organizations as may also be in the service of the U. S. The efficiency of this system was first tested in the war of 1812–15, in which some of the militia rendered most valuable service, particularly in defense of positions, but much embarrassment was caused to the national Government by pretensions in some of the States—1st, that the State executive could decide whether or not to furnish quotas called for; 2d, that the militia could not be sent out of the U. S., or even beyond its own State; and 3d, that it was exclusively under the command of its own officers, and subject only to the *personal* command of the President. These pretensions arose of course only in localities where the war was unpopular, but they have never been quieted by statute. The troops in the civil war demonstrated that citizens make thorough soldiers, but the lesson of that and all other modern wars has been that civilians are not so transformed by prestidigitation. The armies in the field at the close of the civil war were veteran troops, regulars in all but name; and the time that was required for the drill and discipline of militia and volunteer forces after pressing necessity for their immediate employment had arisen would all have been saved if these men could have been drawn from an efficient military reserve. The war of 1812 repeatedly exhibited the melancholy spectacle of large bodies of U. S. troops marching to the battle-field without understanding a single principle of elementary tactics; and the first draft of national militia (call of Apr. 15, 1861) in the civil war was practically worthless; before they could be fully organized and reasonably disciplined their terms of service began to expire, and their only actual service fittingly terminated in the disaster of the first Bull Run.

From the *Final Report of the Provost-Marshal-General United States Army* it appears that the total number of militia, volunteers, and drafted men received into the service of the U. S. during the civil war was 2,690,401; that there were actually 1,000,516 men in the field when hostilities ceased, of whom about 978,000 were volunteers or conscripts; and that the national enrollment exhibited, at the same time, an available reserve of 2,254,063 men. From the same authority is compiled the following exhibit of militia, called for and accepted as such, during the war:

STATES.	Call of Apr. 15, 1861, for 75,000 militia for three months' service.		Call of Aug. 4, 1862, for 300,000 militia for nine months' service.		Militia for 100 days, mustered into service between Apr. 23 and July 18, 1864.

* Accepted for three months.

Revised by JAMES MERCUR.

Milk [O. Eng. *meolc*, *meoluc* : O. H. Germ. *miluh* (> Mod. Germ. *milch*) : Icel. *mjölk* : Goth. *miluks*; cf. Lat. *mul'gere* : Gr. ἀμέλγειν : Sanskr. √*marj*, stroke, rub]: the characteristic secretion of the mammary glands which supplies the natural nourishment for the young of all mammals. Under normal conditions it is an opaque, white liquid, often tinged with yellow or blue. It is heavier and more viscous than water, and, when fresh, has a faint, pleasant odor and an agreeable, sweetish taste. When first drawn it is nearly neutral, often giving the amphoteric reaction, i. e. it reacts acid with blue litmus and alkaline with red litmus; usually the acid reaction is most marked. Human milk is nearly always alkaline, and milk from carnivorous animals acid. In a short time milk becomes decidedly acid, owing to the conversion of milk-sugar into lactic acid. Milk when fresh is a mechanical mixture in the form of a thin emulsion of butter-fat and milk serum. All milks, from whatever source, have the same general properties and contain the same proximate principles, the only difference found between milks from different races of animals or from different individuals of the same race being caused by slight variations in the proportion of the several constituents.

Cows' milk, on account of its great importance as human food and because it has been more thoroughly studied than any other, will be considered as typical of all milks. It is white or yellowish white, the yellow tint being imparted by the butter-fat, as closely skimmed milk uniformly has a bluish-white, opalescent appearance. A highly colored milk is characteristic of some breeds of cows, especially the Guernsey, and to a somewhat less extent the Jersey, the intensity of the color varying considerably with individual animals of all breeds. The color is affected by the food and by the period of lactation, it being more marked when cows are in good pasture than when they are fed dry fodder, and higher in the earlier stages of lactation than toward the end. Its specific gravity ranges from about 1·028 to 1·038, according to the amount and character of the solids which it contains; the average is about 1·032.

Microscopic Appearance.—Under the microscope milk appears to be a transparent colorless liquid, in which are suspended an immense number of yellowish translucent globules having a high refractive power and a pearly luster. These globules, which constitute the fatty portion of the milk, vary greatly in size, the diameter ranging from about ·001 mm. for the smallest to about ·01 mm. for the largest; the average diameter is about ·004 mm. The number of globules varies from less than 1,000,000 to over 5,000,000 in a cubic millimeter of milk, from which it is estimated that a single drop of good milk will contain from 150,000,000 to 200,000,000. The number gradually increases, and at the same time the size diminishes, as the period of lactation advances, there being usually two to four times as many at the end of the lactation period as at the beginning. Breed characteristics are also marked, although individual variations are very great within the breeds. So far as the subject has been studied, the globules in Jersey and Guernsey milk have been found the largest and those in Ayrshire and Holstein milk the smallest. On account of the greater facility with which large fat globules separate from the serum, the size of the globules is an important factor in butter-making, especially when any system of gravity creaming is used; the difference, however, practically disappears when the centrifugal cream-separator is used.

It was formerly supposed that the fat globules were inclosed in a thin membrane, which is ruptured by churning, thus permitting the globules to adhere, forming granules of butter; this hypothesis was supported by the fact that ether fails to dissolve fat from fresh milk when the two are shaken together, but dissolves it readily if a little acid or alkali is first added to the milk, the explanation being that the membrane was destroyed by the acid or alkali, thus permitting the solvent to come in contact with the fat. As all of the phenomena indicating a membrane may be duplicated in artificial emulsions where no membrane can exist, and as the globules in milk may be divided by agitation at temperatures above the melting-point of the fat without changing their appearance or properties, it is fair to assume that milk is a simple emulsion and that the globules of fat are free, being prevented from running together or being dissolved by the surface tension of the liquid around them.

Yield of Milk.—The yield of milk depends chiefly upon the individual characteristics and the breed of the animal, and is influenced by age of cow, period of lactation, and food. The average yield of dairy animals throughout the U. S., including all breeds and all conditions of treatment, is between 3,000 and 4,000 lb. per year. The Holsteins lead all other breeds in quantity of milk produced. *The Advanced Registry* contains names of a number of animals that have records of over 20,000 lb. per year, and one cow is reported to have produced 30,318½ lb. in 365 days, an average for the whole year of over 83 lb. per day; her maximum yield was 112 lb. 7 oz. in one day. This cow weighed 1,365 lb.; the average weight of milk would therefore equal her own weight every 16½ days. The Ayrshires are also heavy milkers, but are not so remarkable in this respect as the Holsteins. With proper care the yield of milk increases as the cow grows older, until seven or eight years old, when a maximum is reached. The greatest flow is usually obtained within a few weeks after calving, and then gradually diminishes until the end of lactation. A generous ration rich in albuminoids is conducive to a large milk yield.

Products of Milk.—For cream, butter, cheese, etc., see Butter and Cheese.

Chemical Constituents of Cows' Milk.

In most analyses of milk only two direct determinations are made, viz., the total solids, obtained by evaporating the water and drying the residue at 100° C. to constant weight, and the fat, which is that portion of the total solids that is soluble in anhydrous ether. More complete analyses show that both the fat and the solids not fat are mixtures of several compounds having widely different properties.

Butter-fat is a mixture of several neutral fats or glycerides (glycerol salts or ethers of fatty acids). Nine fatty acids have already been obtained by the saponification of butter-fat, and it is likely that still others will be found when better methods for separating the insoluble acids have been devised. The acids found in butter, in combination with glycerol, are, according to Kirchner, oleic, palmitic, stearic, butyric, caproic, caprylic, capric, myristic, and butic. The first five mentioned are the most important, and are the only ones which will be considered in this place, as only minute quantities of the others are found in butter. The glycerin compounds of these acids are

Olein, $C_3H_5(C_{16}H_{31}O_2)_3$, a constituent of all animal and vegetable fats. When pure, it is nearly colorless and liquid at temperatures above the freezing-point. It yields 95·7 per cent. of oleic acid.

Palmitin, $C_3H_5(C_{16}H_{31}O_2)_3$, occurs in many animal and vegetable fats. It is a white solid, melting at 62·8° C.; it yields 95·28 per cent. of palmitic acid.

Stearin, $C_3H_5(C_{18}H_{35}O_2)_3$, is found in all solid animal fats. It is a white solid, melting at 55° C.; it yields 95·73 per cent. of stearic acid.

Butyrin, $C_3H_5(C_4H_7O_2)_3$, is a heavy oily liquid, having a rancid odor and a disagreeable taste. It yields 97·4 per cent. of butyric acid.

Caproin, $C_3H_5(C_6H_{11}O_2)_3$, is a colorless liquid, with properties similar to butyrin. It yields 90·1 per cent. caproic acid.

Oleic, palmitic, and stearic acids derived from the corresponding glycerides are insoluble in water, and are not volatile; they comprise about 87·5 per cent. of the butter-fat. The proportion of each has not been accurately determined. Butyric and caproic acid are soluble in water and volatile; they comprise about 7 per cent. of the butter-fat.

All of the fats used in the adulteration of butter are composed of olein, stearin, and palmitin, glycerides which yield upon saponification fatty acids which are insoluble and not volatile. The estimation of the soluble and volatile acids is therefore the best means of detecting spurious butters.

The specific gravity of butter-fat at 15° C. is, according to Fleischmann, ·93 when referred to water at 4° C.; its melting-point ranges, according to the amount of liquid and solid glycerides, from 29° C. to 41° C., with an average of about 33° C. The properties of butter-fat, viz., color, specific gravity, melting-point, and amount of volatile acids, are to a considerable extent dependent upon the breed of cow, the character of the ration, and the period of lactation.

The solids not fat in milk consist of protein matter (casein and albumen), milk-sugar, and salts (ash), with minute quantities of other organic compounds (galactin, lactoglobulin, urea, creatin, fibrin, cholesterin, and citric acid). The solution of the solids not fat in water constitutes the milk serum.

The Nitrogenous Portions of Milk.—(1) *Casein*: Under normal conditions casein is the most abundant protein body found in milk, to which it is peculiar, as it has not with

certainty been identified anywhere else. It differs from other albuminoids in containing phosphorus, and in being precipitated by rennet. Its composition, according to Hammarsten, is as follows: Carbon 53, hydrogen 7, nitrogen 15·7, sulphur 0·8, phosphorus 0·85, and oxygen 22·65 per cent. Little is known concerning its molecular structure. Its solutions turn the plane of polarized light to the left. When dry it is a white solid, very slightly soluble in pure water or in solutions of neutral salts—readily soluble in water made slightly alkaline, the solution being neutral or slightly acid, also soluble in water to which carbonate of lime is added, the carbonic acid being liberated. If the solution in lime-water be carefully neutralized with dilute phosphoric acid, neither the casein nor the phosphate of lime, which is present in considerable quantity, appears to be precipitated. This solution has the opalescent appearance of closely skimmed milk; it is therefore probable that the white color of milk is to some extent due to the casein and phosphate of lime which it contains. It is questionable if in these cases, or in milk, the casein is in perfect solution; it seems more probable that it is diffused through the liquid in the form of a thin jelly. It is, however, to all practical purposes, a complete solution, and will be so considered in this article.

Casein solutions are not coagulated by boiling, although the surface becomes covered with a tough skin, which is renewed when removed. It is precipitated unchanged by saturating its solutions with sodium chloride or magnesium sulphate. It is precipitated from neutral solutions by all mineral acids, the precipitate being again dissolved when an excess of acid is added. The coagulation (souring) of milk when it is left undisturbed for a few hours is caused by the formation of lactic acid from the milk-sugar by the growth of the lactic ferment. The most characteristic property of casein, which distinguishes it from all other albuminoids, is that utilized in the manufacture of cheese, viz., its coagulation by rennet. This reaction occurs only in solutions containing salts of lime and at temperatures between 15° C. and 60° C. Casein and alkaline albuminate have many properties in common, but their identity has not been fully established. Normal milk contains about 3 per cent. of casein, the range in individual cases being from about 2 to 4 per cent. We are indebted for most of our knowledge concerning the properties of casein to the researches of Schmidt, Soxhlet, and Hammarsten.

(2) *Albumen* is found in all milk. Its properties are similar to the albumen of eggs and that of the blood serum. It is soluble in water. It is not precipitated from its solution by dilute acids and not by rennet. When warmed to 70°–75° C., it is coagulated. Normal milk contains an average of about 0·6 per cent. of albumen. Colostrum milk, on the other hand, contains a much higher percentage, the amount sometimes reaching 20 per cent.

(3) *Lactoglobulin* was discovered independently in cows' milk by Sebelien and Emmerling at about the same time. Only small quantities of it occur in normal milk, usually not over 1 milligramme per liter, but in colostrum milk several per cent. have been found. It may be separated from whey by carefully adding sodium hydrate to neutral reaction and then saturating with magnesium sulphate. Its solutions are coagulated by heating to 67°–76° C. It is similar to, but not generally considered identical with, the paraglobulin of blood.

(4) *Galactin*, or lactoprotein, belongs to the group of peptones, and occurs even in fresh milk, which on the average contains about 0·1 per cent. It is not precipitated by boiling, nor by acids, but is precipitated by mercuric nitrate, alcohol, tannin, and other reagents, which precipitate peptones.

(5) *Fibrin.*—The presence in milk of a small quantity of a nitrogenous principle having similar properties to blood fibrin was first mentioned by Babcock. The evidence upon which his conclusions are based may be thus summarized: First. The peculiar grouping of the fat globules of milk after it is drawn, which is analogous to the grouping of the blood corpuscles of blood, both of which phenomena are prevented by the addition of substances which interfere with the coagulation of fibrin. Second. The decomposition of hydrogen peroxide by milk, which reaction, although much less marked than with blood fibrin, is of the same nature, in that it is prevented by first heating the milk to boiling. This reaction may be modified by applying tincture of guiacum and hydrogen peroxide to a filter-paper that has been moistened with fresh milk and then dried at ordinary temperatures; the paper will be colored faintly blue wherever any clots of fibrin occur. Clots of fibrin are heavier than the milk serum, and, as they usually contain globules of fat, offer considerable resistance to creaming. The inclosed fat globules are usually sufficient to float the small clots which accumulate in the cream, and cause this to give a stronger reaction for fibrin than the skim milk or even the whole milk from which it is derived. When a centrifugal cream-separator is used, the fibrin clots are mostly collected upon the sides of the bowl, and form a large proportion of the slime found in the separator-bowl after it has been used. This slime often give nearly as strong reaction for fibrin as blood.

In consequence of the resistance which fibrin clots offer to creaming, any condition which prevents their formation should facilitate the separation of cream, and such appears to be the case so long as the means employed does not at the same time tend to separate the casein or other constituents of the milk. For instance, the addition of small quantities of caustic soda or potash to milk gives a very rapid and efficient creaming. The rapid cooling of the milk directly after it is drawn delays the coagulation of the fibrin and facilitates creaming. Close creaming by the deep-setting system is best explained by this fact.

Normal milk appears to contain about one-thousandth as much fibrin as blood, or on the average about ·0003 per cent. This amount, small as it is, on account of its great tendency to coagulate and adhere to the sides of the creaming vessel, may materially affect the practical work in the creamery. When the quantity is much increased, spontaneous coagulation of the milk takes place without the development of acid. The examination of a few milks which coagulated in this way showed in every case that the amount of fibrin was abnormal, at least so far as this is indicated by the decomposition of hydrogen peroxide.

(6) *Creatin and urea*, substances belonging to the amide group, have been separated from milk; but they never occur except in minute quantities, and have no influence upon the quality of the milk.

Milk-sugar, lactose, lactin ($C_{12}H_{22}O_{11} + H_2O$), is a peculiar carbohydrate found in all milks, and in no other animal secretion. According to Bouchardt it also occurs in the ripe fruits of *Achras sapota*. When pure it is a white solid, crystallizing in the rhombic system with one molecule of water, which it gives up slowly at 100° C.; it is easily and completely removed at 130°–140° C.; at 170°–180° C. it loses the element of water, being changed into lactocaramel, a brown amorphous solid. The dry crystals are hard and gritty between the teeth, and have only a slightly sweet taste. It is soluble in 6 parts of cold water and in 2·5 parts of boiling water; it is insoluble in absolute alcohol and in ether. With pure yeast it does not undergo the alcoholic fermentation, but by the action of certain micro-organisms the sugar is so changed that the alcoholic fermentation takes place. Upon this depends the production of *koumiss*. It readily undergoes the lactic fermentation, being changed into lactic acid, and to this is due the ordinary phenomenon of the souring of milk. Milk-sugar is usually manufactured from whey, a waste product obtained in the manufacture of cheese, by evaporation and crystallization. It is used in infant and invalid foods, as well as in pharmaceutical preparations.

Citric Acid.—One of the most interesting discoveries connected with the composition of milk is that it contains a small amount of citric acid. Soxhlet first called attention to the fact that the amount of lime dissolved in milk could only be explained by the presence in milk of an organic acid. Later Henkel, in Soxhlet's laboratory, succeeded in separating citric acid from milk, and showed that it was a normal constituent of all milks. This acid is the same as that in lemons. On the average about 0·1 per cent. of it is contained in milk, so that the milk of a good cow would contain each day more citric acid than a large lemon. This acid is in combination with the ash constituents, otherwise it would render the milk distinctly acid, and probably cause the coagulation of the caseine. The quantity in milk appears to be independent of the nature of the ration.

The Ash—Mineral Constituents.—The mineral constituents of milk are: Potassium oxide, K_2O; sodium oxide, Na_2O; calcium oxide, CaO; magnesium oxide, MgO; ferric oxide, Fe_2O_3; phosphoric pentoxide, P_2O_5; sulphur trioxide, SO_3; and chlorin, Cl.

The metallic oxides are mostly combined with phosphoric acid and Cl, but as these are not sufficient to neutralize the alkalis, the remainder must be united with organic acids.

The SO_3 and a portion of the P_2O_5 in the ash are derived from organic compounds in the milk. The ash amounts to about 0·7 per cent. of the milk.

The total solids in cows' milk vary from 11·64 per cent. to 19·34 per cent., averaging about 13 per cent.

In the graphic table given below are grouped together all of the constituents mentioned, in proportions which represent approximately the average composition of cows' milk. Moreover, as the same constituents enter into all milk, it is typical for milk in general. It is safe to say that milk is uniformly poor. Other breeds have their characteristics more or less pronounced, and there are in all breeds certain families noted either for the quantity or quality of their milk production.

The table in the preceding paragraph gives the averages of analyses of milks from different types of cows. The analyses are taken from Koenig's tables, and represent the average of hundreds of cows in each class mentioned.

The analyses made during the ten years ending 1889 at the milking trials of the British Dairy Farmers' Association

TABLE SHOWING THE COMPOSITION OF MILK.

Milk	100	Butter-fat	3·6	Olein, Palmitin, Stearin, Myrestin, Butin, trace	Glycerides of insoluble and non-volatile acids.	3·3	Fat 3·6	Total solids 12·7

				Chlorin	0·100			
				Water				87·3
								100·0

the individual variations in the composition of cows' milk show wider differences than is found between the average composition of milks from different races of animals.

The Proportion of Milk-constituents.

The average composition of normal cows' milk derived from nearly 800 analyses collected by Koenig from all parts of the world, including milk from all breeds of cows kept under a great variety of conditions, is as follows:

COMPONENT PARTS.	Mean.	Maximum.	Minimum.
Specific gravity	1·0315	1·0370	1·0264
Water	87·17	90·69	80·32
Fat	3·69	6·47	1·67
Casein	3·02	4·23	1·79
Albumen	0·53	1·44	0·25
Sugar	4·88	6·03	2·11
Ash	0·71	1·21	0·35
Total solids	12·83	19·78	9·31
Solids not fat	9·14		

The circumstances which contribute to the wide variations shown will be considered under the following heads:

1. *Individuality and Race.*—In almost every herd of dairy cows will be found some animals which give poor milk, measured by the amount of fat which it contains, and others which give milk much richer than the average; so persistent are these traits under all natural conditions that the individual tendency of the animal is recognized as the most important factor which contributes to the quality of milk produced. These peculiarities may be intensified and, to a certain extent, established by careful breeding through several generations, until they become family or breed characteristics which, within certain limits, may be depended upon. In this way the Channel island cattle

Analyses of Milks from Different Breeds.

PARTS, ETC.	Channel island cattle (Guernsey and Jersey).	Shorthorn.	Dutch cattle, Holstein-Fries., Oldenburg, etc.	Ayrshire.
Water	85·70	87·20	87·85	86·93
Fat	4·65	3·45	3·42	3·58
Casein	3·66	3·21	3·40	3·42
Sugar	5·05	5·45	4·61	5·43
Ash	0·94	0·69	0·72	0·64
Total solids	14·30	12·80	12·15	13·07
Solids not fat	9·65	9·35	8·73	9·49
Number of analyses	47	63	73	41

(Jerseys and Guernseys), noted for the uniformly rich milk which they produce, have been developed. On the other hand, the Holstein cattle bred through many generations toward quantity of milk with little regard to its quality, have come to be the greatest milk-producers, although the

give the following averages for yield and composition of milk from different breeds (*Agr. Gazette*, Nov. 18, 1889):

BREED.	Number of cows.	Yield of milk per day, lb.	Per cent. of solids.	Per cent. of fat.	Per cent. of solids not fat.
Shorthorns	119	43·13	12·87	3·73	9·14
Shorthorns	31	45·80	12·89	3·81	9·08
Jerseys	118	27·87	14·36	4·56	9·80
Jerseys	43	28·41	14·94	5·47	9·47
Guernseys	49	28·30	14·00	4·77	9·23
Guernseys	14	31·15	14·46	5·03	9·43
Dutch	7	43·31	12·11	3·26	8·85
Ayrshires	13	34·26	13·43	4·15	9·28
Devons	2	30·12	14·34	4·90	9·44
Red polled	3	43·10	12·72	3·60	9·12
Welsh	1	46·00	12·74	4·16	8·58
Kerrys	3	23·50	14·22	4·40	9·82
Crosses	26	39·12	12·91	3·69	9·32

The averages for these breeds in 1888 and 1889 show a marked improvement in the general quality of dairy cattle, due to intelligent breeding and selection. The possibilities in this direction are still further shown in the figures below, which are the averages for the prize winners in the same show in 1892 (*London Live Stock Journal*, Oct. 21, 1892):

BREED.	Number of cows.	Yield per day, lb.	Per cent. of solids.	Per cent. of fat.	Per cent. of solids not fat.
Shorthorn	3	59·4	12·90	3·72	9·18
Jersey	3	29·6	15·49	6·18	9·31
Guernsey	2	38·5	14·31	5·41	8·90
Ayrshire	2	40·5	13·64	4·22	9·42
Kerrys and Dexters	3	30·3	13·39	4·40	8·99
Dutch	1	61·8	12·85	3·86	8·99
Polled Aberdeen	1	60·3	13·74	4·99	8·75

The individual variations within each breed are very wide, so that it by no means follows that a cow will give rich milk because she is a Jersey or a Guernsey, or poor milk because she is a Holstein or an Ayrshire. Even in the above trial from selected cows the range in quality is large. Each of the 3 shorthorn cows entered gave practically the same amount of milk, still the per cent. of fat in their milk ranged from 2·91 to 4·30; the 3 Jerseys, with a difference of less than 1½ lb. of milk per day, had a difference in per cent. of fat from 5·20 to 7·84; and the milk from the 3 Kerry cows varied from 3·70 to 5·11 per cent. of fat. The individual variation within the breeds is much greater than is found between these animals, selected as they have been for this trial on account of their superiority either in yield or quality of milk. As a rule, phenomenally rich milk is not given by those cows or breeds that are noted for their large yields. Very few analyses of cows' milk are recorded that have

shown more than 10 per cent. of fat, and in nearly all cases where this has occurred the cows have either been sick or were at the time giving very small quantities of milk. So far as known, there is no case on record of a cow giving as much as 15 lb. of milk per day that contained over 9 per cent. of fat. A number of butter records have been reported that would require from 15 to 25 per cent. of fat in the milk yielded during the trial, provided the butter was of standard quality; but no such record is accompanied by analyses of either the butter produced or of the milk from which it was made.

2. *Period of Lactation.*—The time after calving during which a cow continues to give milk without going dry is known as the period of lactation. Occasionally cows are met with that give milk continuously from one calving to the next, but such cases are not common. Usually cows go dry from four to eight weeks before calving. Cows which have been spayed or that are farrow often give milk for years continuously. An average period of lactation is about 300 days. Cows generally yield the maximum quantity of milk soon after calving, the amount diminishing with more or less regularity from this time until the flow ceases, or becomes too small to be obtained with profit. As this period advances, the composition of the milk gradually changes. As a rule, both the fat and the solids not fat increase slightly, but many cases are found where one or both of these constituents diminish. The following table, compiled from tests given in the *Tenth Annual Report* of the New York agricultural experiment station for 1891, shows the nature of these changes. There were fourteen animals experimented upon, the breeds represented being Holstein, Ayrshire, Jersey, Guernsey, American Holderness, and Devon. The first month represents the time from calving to the first day of the following month, and is of course much affected by the nearness to calving. The table shows the general averages for the breeds for the first ten months of lactation. Under the heading casein is included the total nitrogenous matter of the milk:

MONTH OF LACTATION.	Yield of milk, lb.	Total solids, per cent.	Fat, per cent.	Casein, per cent.	Sugar, per cent.	Ash, per cent.	Solids not fat, per cent.
1.....	245·0	14·09	4·86	3·53	5·00	0·69	9·23
2.....	587·3	13·13	4·13	3·05	5·20	0·72	9·00
3.....	586·7	13·04	4·07	3·23	5·01	0·71	8·97
4.....	547·9	13·36	4·22	3·42	5·06	0·70	9·14
5.....	538·7	13·56	4·23	3·32	5·29	0·70	9·33
6.....	503·3	13·90	4·35	3·61	5·24	0·73	9·55
7.....	510·4	14·08	4·39	3·51	5·42	0·74	9·69
8.....	471·2	14·00	4·39	3·51	5·35	0·74	9·61
9.....	470·4	14·17	4·51	3·80	5·13	0·71	9·66
10.....	418·6	14·41	4·46	3·81	5·39	0·73	9·95

3. *The Milking.*—The first portion of milk drawn at any milking contains much less fat than the last portion, the difference being sometimes as much as 10 per cent.; but otherwise there is very little variation from the beginning to the end of the milking. The following analyses of the first and last half-pints from the same milking illustrate this point:

MILKINGS AND STRIPPINGS.	COMPOSITION OF MILK.			COMPOSITION OF MILK SERUM.	
	Water.	Solids.	Fat.	Water.	Solids.
First milk.....	88·17	11·83	1·32	89·35	10·65
Strippings.....	80·82	19·18	9·63	89·43	10·57
First milk.....	88·73	11·27	1·07	89·69	10·31
Strippings.....	80·37	19·63	10·36	89·66	10·34
Average for first milking.	.....	.....	.....	89·52	10·48
Average for strippings...	.....	.....	.....	89·55	10·45

The interval between milkings also appears to have considerable influence, the milking which follows a short interval usually being richer in fat than that obtained after a long interval. As a rule, three milkings per day not only result in a larger yield of milk than two milkings, but in milk richer in fat.

The manner in which the milking is done has a decided influence upon the per cent. of fat. Some milkers always obtain richer milk than others from the same cow. In a trial at the Wisconsin agricultural experiment station between two milkers with 4 cows, the test continuing for several days, the average per day for each milker was for A, 72·3 lb. milk with 4·20 per cent. of fat; for B, 80 lb. of milk with 4.68 per cent. fat. There was not a single change that was not in favor of B. When a cow was milked fast and slow by the same milker, the fast milking in every case gave the richer milk, the difference in some cases being over 1 per cent. of fat; an average of tests continuing over several days with 6 cows being per day for the fast milking 169 lb. milk with 4·63 per cent. fat; for the slow milking, 165·4 lb. milk with 4·23 per cent. fat. When cows were milked in an unusual manner, the milk obtained was much poorer than the average. A cow which gave milk testing on the average about 5 per cent. of fat, gave, at four successive milkings when milked one teat at a time, milk which tested 2·9, 5·00, 4·06, and 3·78 per cent. of fat. Another cow tested in the same way gave, when milked two teats at a time, milk testing 4 per cent. fat, when milked one teat at a time 2·7 per cent. fat. The greater the departure from the usual method of milking the poorer was the milk obtained. When milking-tubes were used, the milk obtained tested only 2·92 per cent. fat, while hand-milking of the same cows gave milk testing 4·72, the test being with 6 different cows and continued with 3 of them over a period of 7 days. The greatest difference with any cow was 1·93 per cent. fat when milked with tubes and 5·47 per cent. fat when milked by hand. These observations seem to indicate that the elaboration of the milk is more active at the time of milking than at other times, and that it depends to a considerable extent upon the nervous condition of the animal. The best results are always obtained by regularity and kindness.

4. *Food.*—There is a common notion that the kind of food fed has a marked influence upon the per cent. of fat in the milk produced. The results, however, in careful trials, at numerous experiment stations in the U. S. and in Europe, indicate that no rule that will apply to all cows can be stated, as it has been found that some animals respond favorably to one ration and others to another. The only point upon which all agree is that a generous ration made up of such feedstuffs as are relished by the animal is most conducive to good results. Among those feeds which have the reputation of increasing the fat in milk may be mentioned palm-nut meal, cocoanut-meal, sugar-meal, and corn-germs; the first two are not used to any extent as feeds in the U. S., the sugar-meal is a waste product from the manufacture of starch and glucose from corn, and the corn-germs a waste product from the hominy-factories. Foods rich in fat have no tendency toward increasing the fat in milk. The following rations are typical of the best dairy practice in the U. S. The amounts are for cows of 1,000 lb. weight in full milk: (*a*) Pasture with 5 to 8 lb. of a mixture of equal parts of corn-meal and wheat-bran. (*b*) Hay (mixed clover and timothy), 20 lb.; wheat-bran, 6 lb.; oat-straw, 6 lb. (*c*) Corn silage, 40 lb.; clover-hay, 8 lb.; wheat-bran, 6 lb.; corn-meal, 3 lb. (*d*) Clover-hay, 12 lb.; oat straw, 8 lb.; corn-meal, 6 lb.; wheat-bran, 3 lb.; cotton or linseed meal, 2 lb.

Colostrum is the milk secreted for a short time after parturition. It has a yellow color, is much more viscous than normal milk, has a salty taste, a peculiar odor, and generally a slightly acid reaction. Owing to the large amount of solids which it contains, its specific gravity is high, rarely falling below 1·040, and in extreme cases reaching 1·080. Under the microscope there are shown, in addition to the globules of fat, numerous granular bodies of variable shape, ·005–·025 mm. in diameter, containing minute globules of fat. These bodies, which are peculiar to colostrum milk, are known as "colostrum cells"; they have been generally supposed to be cast off epithelium cells from the udder, but more recently are considered to be white blood-corpuscles that have undergone fatty degeneration. These cells rapidly diminish in number from the first milking, and usually disappear within three or four days. The composition of colostrum is very variable, no two samples being alike. Its most marked peculiarity is the high per cent. of albumen, this being from ten to thirty times as large as in normal milk; the casein and ash are also high, while the sugar and fat are usually low. The following analyses by Engline illustrate this fact:

CONSTITUENTS OF COLOSTRUM.	First milking after calving.	Fifth day after calving.
Specific gravity.....	1·071	1·033
Total solids.....	27·70	13·15
Fat.....	3·11	3·94
Casein.....	5·20	2·86
Albumen and globulin	15·50	1·12
Sugar.....	1·85	4·55
Ash.....	2·04	0·68

The average composition of the first milking as given by Koenig is:

Water	74·05 per cent.
Total solids	25·95 "
Casein	4·66 "
Albumen	13·62 "
Fat	3·43 "
Sugar	2·66 "
Ash	1·58 "

Other Milks.—*Human milk* differs from cows' milk chiefly in containing less protein matter and more sugar. It is whiter than cows' milk, and usually has an alkaline reaction when fresh. The curd formed by the addition of rennet or acids is not as firm as that from cows' milk. Its average composition, as derived from over 100 analyses compiled by Koenig, is—water, 87·41 per cent.; casein, 1·03 per cent.; albumen, 1·26 per cent.; fat, 3·78 per cent.; milk-sugar, 6·21 per cent.; ash, 0·31 per cent.

Mares' milk is poor in fat and protein, and rich in sugar. *Asses' milk* is very similar in general composition to human milk, and where obtainable is used in preference to cows' milk for infants. *Sheep's milk* is very rich in fat and other solids; it is used quite extensively in some parts of Europe for the manufacture of cheese of high grade. *Goats' milk* is very similar to cows' milk, but contains on the average a little more protein and fat. The average composition of these milks, according to Koenig, is:

VARIETIES.	Water.	Casein.	Albumen.	Fat.	Milk-sugar.	Ash.
Mares' milk	90·78	1·24	0·75	1·21	5·67	0·35
Asses' milk	89·64	0·67	1·55	1·64	5·99	0·51
Sheep's milk	80·82	4·97	1·55	6·86	4·91	0·89
Goats' milk	85·71	3·20	1·09	4·78	4·46	0·76

Preservation of Milk.

Nearly all the changes in milk which cause it to become unsuitable for food are caused by the growth of micro-organisms, the germs of which are introduced into the milk after it is drawn. These germs fall into the milk from the udder and the skin of the animal during milking, and from the air, which always contains immense numbers of them, especially in stables where the milking is done, or are deposited upon the vessels in which the milk is handled. Scrupulous cleanliness may reduce their number, but even with the greatest care it is impossible to exclude them entirely from the milk used for domestic purposes. These germs multiply rapidly in milk, and within a few hours or at most within a few days, according to the conditions under which it is kept, the original properties of milk become entirely changed. The most common change is that known as souring, manifested by an acid taste and coagulation of the casein. There are several kinds of organisms that produce this change, which consists in the transformation of the milk-sugar into lactic acid. Only a portion of the sugar is changed in this way, as the development of the organisms is hindered by the acid formed, and ceases entirely when the acid amounts to about 1 per cent. Other organisms produce different changes, such as slimy, ropy, and bitter milk, as well as numerous taints. As it is impossible to exclude germs from milk, it is necessary, in order to preserve it unchanged for even a few hours, either to provide conditions which are unfavorable to the growth of organisms or to destroy them before the milk has become unsuitable for food. Nearly if not all of these organisms grow most rapidly at temperatures between 30° and 40° C. (86°–104° F.), decreasing rapidly as the temperature falls and ceasing at the freezing-point; at temperatures below 4° C. (40° F.) there is very little change. This suggests that the most practical way of keeping milk from day to day, or where fresh supplies can not be obtained at frequent intervals, is to cool it to as near the freezing-point as possible.

Antiseptics.—Certain mild antiseptics, among which may be mentioned boracic acid, borax, and salicylic acid, have been recommended, and to a considerable extent used, for the preservation of milk for domestic purposes. All such substances interfere more or less with the action of the digestive organs, and usually aggravate diseases of the kidneys; their use is not to be recommended, and under no circumstances should milk preserved in this way be used as food for infants or invalids. The use of the antiseptics mentioned has been prohibited in France and Germany and very generally condemned by boards of health everywhere.

Sterilized or Pasteurized Milk.—A large demand has grown up in cities for milk that has been heated in closed vessels to temperatures ranging from 65° to 80° C. for a sufficient time to kill the organisms contained in it; the best results are obtained when the milk is reheated twenty-four to forty-eight hours after the first heating, the jars being kept closed. Such milk will keep without undergoing the usual fermentations to which milk is subject so long as the cans containing it are kept closed and access of germs prevented; it will, however, soon sour after the cans are opened. The flavor of milk prepared in this way is slightly different from fresh milk, but is not objectionable; its use for invalid and infant food is rapidly increasing. The greatest objection made to it is that the cream which separates is not readily mingled again with the whole mass, especially if the cans have been kept in one position for a considerable time.

Condensed milk is prepared by evaporating milk at low temperatures *in vacuo* to about one-third of its original volume. Most of the manufacturers add a considerable quantity of cane-sugar to the milk after it is condensed. Inclosed in air-tight cans, it may be kept indefinitely and transported to all parts of the world. Diluted with about two parts of water, it is the best substitute for fresh milk. The following analyses, compiled by Dr. Koenig, show its average composition:

CONSTITUENTS OF CONDENSED MILK.	Mean of 36 analyses.	Milks to which sugar was added, mean of 64 analyses.
Water	58·99	25·61
Protein	11·92	11·79
Fat	12·42	10·35
Milk-sugar	14·49	13·84
Cane-sugar	.....	36·22
Ash	2·18	2·19

The Use of Pure Cultures.—The aroma of butter and the characteristic flavors of the different varieties of cheese are now quite generally recognized as being due to changes in the constituents of milk brought about by the action of certain species of bacteria. It is therefore important that milk and cream for dairy purposes be kept under conditions favorable to the growth of bacteria which contribute to the best results. Very successful experiments in butter-making have been made by introducing pure cultures of these bacteria into the cream and allowing them to develop before churning. In Denmark some large creameries have been operated upon the plan of first sterilizing the cream by heat and then introducing the desired culture. Butter of superior quality is being made in this way. Little has yet been done with pure cultures in the manufacture of cheese, but undoubtedly the most promising field for improvement lies in this direction.

Methods of Analysis.

The estimation of the fat and the total solids is sufficient to show the value of milk for technical purposes and to detect the usual adulterations. More detailed analyses comprise the estimation of the casein, albumen, milk sugar, and ash. The other constituents mentioned on previous pages are rarely determined, as, so far as is at present known, they play no important *rôle* in the dairy industry.

Estimation of Total Solids.—The simplest method of making this determination consists in evaporating upon a water-bath from 2–3 grammes of milk, in a flat-bottomed platinum or nickel dish 5 cm. in diameter, that has been previously weighed, and drying the residue at 100° C. until of constant weight. A little ignited asbestos placed in the dish before weighing absorbs the milk and greatly facilitates the drying by exposing a larger surface. Clean, ignited sand has been extensively used instead of asbestos for this purpose, but the latter is to be preferred. The weight of the dry residue represents the total solids in the amount of milk taken.

Estimation of Fat.—The principle involved in all of the gravimetric methods is to extract the fat from the dried residue with anhydrous ether, and after evaporating the ether in a tared dish to weigh the residual fat. Many methods of accomplishing this have been devised. That in use at the Wisconsin agricultural experiment station, which admits of the use of the same sample of milk for the estimation of both solids and fats, is as follows: A hollow cylinder 2 inches long and $\frac{3}{4}$ inch in diameter, made from finely perforated sheet copper or tin (if of copper, it should be plated with nickel or silver to prevent oxidation), is nearly filled with ignited asbestos and weighed. From 2 to 5

grammes of milk are run on to the asbestos, which quickly absorbs it. The cylinder is then dried at 100° C. until of constant weight. The difference between the first and second weight gives the total solids. When dry the cylinder is placed in a continuous extraction apparatus, and the fat extracted with ether, which, being received in a weighed flask, is dried and weighed. The Adams method, quite generally adopted by English chemists, consists in absorbing the milk upon coils of fat-free filter-paper, which, after being dried, are extracted with ether as described above.

Besides the gravimetric method for the estimation of fat, several others based upon different principles have been quite extensively used. Among these may be mentioned Soxhlet's areometric method, which depends upon the specific gravity of the ether solution, which separates when definite quantities of milk, caustic potash, and ether are mixed together. The method is accurate, and has been very extensively used in Europe. Feser's lactoscope and the pioscope depend upon the optical properties of milk. They are very simple of manipulation, but can not be depended upon for accurate work.

Since 1888 a number of simple volumetric methods designed for dairymen and others not versed in chemical manipulation have been introduced. The most prominent of these, which give accurate results, are Short's, Patrick's, the Leffman, and Beam and Babcock's methods. The latter is extensively used by dairymen for testing the value of their cows, and is being very generally introduced in creameries and cheese-factories throughout the U. S. for the purpose of making dividends upon the "relative value plan." This method is described as follows:

Apparatus.—The test-bottles (Fig. 1) for this test should contain not less than 40 cubic cm. up to the neck. The graduated neck should be about 10 cm. long and 5 or 6 mm. in diameter; the graduated portion should contain 2 cubic cm. and be divided into 50 equal parts, each of which represents ·2 per cent. of fat when 18 grammes of milk are taken for the test. The pipette for measuring milk (Fig. 2) has a mark at 17·6 cubic cm., and will deliver approximately 18 grammes of average milk. The acid graduate (Fig. 3) has a single mark at 17·5 cubic cm. The centrifugal machine for whirling the bottles should be so arranged that the drum carrying the bottles will make from 700 to 1,000 revolutions per minute. The diameter of this drum should not be less than 15 inches and need not exceed 20 inches. Commercial sulphuric acid having a specific gravity of 1·82 to 1·83 is required for the test.

Fig. 1.

Fig. 2.

Fig. 3.

Making the Test.—The milk is first carefully mixed by pouring from one vessel to another, and the proper amount is measured into the test-bottle with the 17·6 cubic cm. pipette, and 17·5 cubic cm. of H_2SO_4 added from the acid measure. The bottle is then shaken until the contents are thoroughly mixed; considerable heat is evolved, the contents being changed to a dark-coffee color. While still hot the test-bottles are placed in the centrifugal machine and whirled for four or five minutes, when the fat is found in a clear layer resting upon a dark liquid. Sufficient hot water is then poured into the bottles to fill them to about the 7 per cent. mark, after which they are whirled again for about a minute, when the reading can be taken. The method is applicable to the estimation of fat in cream, skim-milk, buttermilk, and in cheese.

Estimation of Casein and Albumen.—These are usually determined together by multiplying the nitrogen by 6·25. The nitrogen is most easily determined by the Kjeldahl method.

Sugar may be determined after precipitating the casein and albumen by titration with Fehling's solution, or more quickly with the polariscope. When the other constituents are determined the sugar may be found by difference with sufficient accuracy for most purposes.

Ash.—From 5 to 10 grammes are dried in a platinum or porcelain dish and the residue burned in a muffle-furnace at low redness until all of the organic matter is destroyed.

Detection of Adulterations.

The usual adulterations of milk are the abstraction of fat and the addition of water. Owing to the wide variations in the amount of fat which different milks contain, it is impracticable to determine by any method whether a portion of the cream has been removed from the sample of milk if the source of the milk is unknown. It is therefore necessary for the better protection of the public against frauds of this kind to prohibit the sale of any milk as pure which contains less than a minimum amount of fat, which is fixed by law. In most places this limit is placed at 3 per cent. of fat; in Massachusetts and some other States it is 3·5 per cent. Any milk which falls below the established standard is supposed to be skimmed, and the person who offers such milk for sale as pure violates the law, and may be punished, although the poor quality of the milk may be caused by poor cows and not by dishonesty on his part.

The variation in the amount of solids not fat in milk is much less than that of the fat. In mixed milks the solids not fat are usually above 9 per cent. and rarely fall below 8·5 per cent. in milks from individual cows. In Great Britain and in most of the U. S. where standards are established the minimum for solids not fat is placed at 9 per cent. Skim-milk contains a trifle more solids not fat than pure milk, while milks to which water has been added contain less. If, therefore, a sample of mixed milk is found which contains less than the established standard of solids not fat, it is considered to be watered. The judgment in regard to a watered milk turns entirely upon the amount of solids not fat, and has nothing to do with the amount of fat which the milk contains. A milk may therefore contain a higher per cent. of fat than is required by law and still be condemned as watered if the solids not fat are below standard.

In States where there is no legal standard for the solids not fat, no arbitrary rule can be given for determining a watered milk. Frauds of this kind may, however, be detected in the following manner: Whenever the solids not fat fall much below 9 per cent. it is a suspicious circumstance, and a sample of milk from the same herd, taken at the time of milking by an authorized person, should be tested in the same way. If in this sample, which is known to be genuine, the per cent. of solids not fat is found to be about the same as in previous trials, it is probable that the milk has not been tampered with at any time. If, however, the per cent. of solids not fat in the samples taken at the farm are up to the required standard, it is strong evidence that water had been added to the milk which tested low.

The usual methods of analysis already described are too complicated, and require too much time for the use of milk-inspectors, who often have large numbers of milks to examine in a single day. The method generally employed by them is to determine the specific gravity of the milk with a delicate lactometer and the per cent. of fat by some of the rapid volumetric methods. From the data thus obtained the total solids and the solids not fat can be calculated with sufficient accuracy.

The *lactometer* is a hydrometer especially adapted to the examination of milk; many kinds are in use, all of which have the same general form, viz., a narrow stem to which is attached an elongated bulb weighted at the bottom so as to float in an upright position with the stem partially submerged. The depth to which the lactometer sinks depends upon the specific gravity of the milk in which it is placed, a heavy milk causing it to rise higher above the milk than a light one. The lactometer generally used in the U. S. is graduated from 0° to 120°, 0° being the point to which the instrument sinks in pure water at 60° F. and 100° the point to which it sinks in a liquid having a specific gravity of 1 029, this being assumed to be the lowest specific

Fig. 4.—Quevenne's lactometer.

gravity compatible with pure milk. The scale of this lactometer is intended to show the per cent. of milk having a specific gravity of 1·029 which the sample examined contains. This, however, it does not do, as the addition of cream to milk, thus rendering it richer, affects the reading in the same way as the addition of water. For this reason, and also because it is necessary when the readings are to be used in connection with the per cent. of fat for the calculation of the total solids to know the specific gravity of the milk, the Quevenne lactometer is to be preferred. The scale of this lactometer expresses in thousandths the difference between the specific gravity of the liquid tested and water, the specific gravity of water being 1. The specific gravity is easily derived from the reading by dividing it by 1,000 and adding 1 to the quotient. To illustrate: a reading of 33 on this lactometer is equivalent to a specific gravity of 1·033. The scale of the ordinary lactometer may be converted into the Quevenne scale by multiplying by ·29.

Among the formulas used for the calculation of total solids from the specific gravity and per cent. of fat may be mentioned those of Fleischmann and Babcock. Fleischmann's formula is—

$$\text{Total solids} = 1{\cdot}2f + 2{\cdot}665\,\frac{100\,S - 100}{S}.$$

Babcock's formula is—

$$\text{Solids not fat} = \left(\frac{100\,S - Sf}{100 - 1{\cdot}0753} - 1\right) \times (100 - f)2{\cdot}6.$$

In both of these formulas f = per cent. of fat in milk and S = specific gravity of milk at 15° C. Both tables are given to aid in calculations.

A simple formula which does not require the use of tables is

$$\text{Solids not fat} = \frac{L + {\cdot}7f}{3{\cdot}8},$$

in which L = reading of Quevenne lactometer and f = fat.

S. M. BABCOCK.

Milk-fever: a name applied to a short febrile attack which sometimes attends the beginning of the milk-secreting process, a few days after childbirth. It is often a mild form of infection and may be ushered in by profound and rather alarming chills, but is unimportant except as sometimes simulating the onset of puerperal fever, for which it is occasionally mistaken. Farmers and veterinarians apply the name to puerperal peritonitis of the lower animals, and to a severe form of cerebro-spinal meningitis which sometimes attacks cows after calving. The last-mentioned disease is treated by cathartics, mercury, aconite, and heat to the spine; the former, by opium, aconite, mercury, and hot abdominal fomentations. Revised by W. PEPPER.

Milk-mirror, The: See ESCUTCHEON.

Milk-sickness: an acute disease endemic in sparsely settled parts of the U. S.; affecting cattle primarily, and human beings as a result of eating the flesh or drinking the milk of affected cattle. In cattle it is called *trembles* and *slows*. It is probably infectious in nature, but no particular micro-organism has been discovered. The symptoms in cattle are marked muscular weakness, tremor, vomiting, and a peculiar fetor of the breath. In man the disease comes on suddenly and presents similar symptoms. Fever, coated tongue, great fetor of breath and vomiting, with profound weakness, are the characteristics. Fortunately, the disease is much less frequent than formerly. The treatment should aim at control of the fever and relief of urgent symptoms, with supporting remedies to prevent exhaustion. W. P.

Milk-snake: a popular name for a harmless snake found in the eastern parts of the U. S. See KING-SNAKE.

Milk-sugar: See CHEESE and MILK.

Milk-tree: popular name for any tree the trunk of which when incised yields a milky fluid fit for food. Such are the cow-tree, found in the Caraccas islands; the kiriaguma, or *Gymnema lactiferum*, of Ceylon, used for domestic purposes; and the tabayba dolce, or *Euphorbia balsamifera*, of the Canary islands, which yields a wholesome juice resembling sweet milk.

Milkweed Family: the *Asclepiadaceæ*; a large group (1,700 species) of milky-juiced dicotyledonous herbs, shrubs, and trees, with opposite leaves, gamopetalous flowers, free bicarpellary ovaries, and mostly united stamens. They are widely dispersed, especially in the warmer portions of the earth. In the U. S. there are about 100 species, more than half of which (the common milkweeds of fields and lowlands) belong to the genus *Asclepias*. Many species are grown for ornamental purposes, especially the species of ASCLEPIAS (*q. v.*), *Vincetoxicum*, *Ceropega*, *Hoya*, and *Stapelia*. The last are leafless cactus-like plants from South Africa. Their flowers are showy, but have an offensive smell.

CHARLES E. BESSEY.

Milky Way: See GALAXY.

Mill, JAMES: philosopher; b. at Logie Pert, Forfarshire, Scotland, Apr. 6, 1773; was educated at the University of Edinburgh, and was licensed as a preacher in the Scottish National Church 1798, but abandoned that career in consequence of a change of religious opinion; became a tutor in the family of Sir John Stuart, whom he accompanied to London in 1802, and settled in that capital as an author. He edited *The Literary Journal*; became intimately connected with Jeremy Bentham, residing in his house and expounding his opinions to the English public; wrote an elaborate *History of British India* (3 vols., 1817–18), which procured him an important post in the office of the East India Company; was one of the chief contributors to *The Westminster Review* (1824); published a treatise on *Political Economy* (1821–22); wrote largely for the *Encyclopædia Britannica* on political and social subjects, and was author of a remarkable philosophical work, *An Analysis of the Phenomena of the Human Mind* (2 vols., 1829). In this work the principle of "association," stated by Hartley, received a penetrating application to the whole range of psychological problems. The "association psychology" was thus expounded and the foundation laid for its great and acute development by later British writers, notably Spencer and Bain. D. June 23, 1836. Revised by J. M. BALDWIN.

Mill, JOHN STUART: philosopher, logician, and political economist; son of James Mill, philosopher; b. in London, May 20, 1806. His father took sole charge of his education, and conducted it in a way to secure a precocious development. Mill says of himself: "I have no remembrance of the time when I began to learn Greek; I have been told that it was when I was three years old." At eight he was reading Herodotus, Xenophon, and Plato; and during the next four years he read the works of the leading Latin authors and the Greek poets, dramatists, orators, and philosophers, even to Aristotle's *Rhetoric*. In the same period he was grappling with the problems of the calculus and higher mathematics, and finding his recreation in reading history and books of experimental science, interspersed with earnest conversations with his father as they took long walks together. In his fourteenth year he was taken through a complete course of political economy, with the help of such books as were then published and of discussions with his father. Up to this time he had been excluded from participation in the ordinary sports of children and from association with other boys. When about fourteen he left England for a year, spent mostly in the south of France. There he imbibed a taste for mountain scenery, took lessons in fencing and other forms of bodily exercise, attended lectures on science, and studied the higher mathematics under private tuition. He carried home with him a strong and permanent interest in continental liberalism, which qualified his subsequent political views. He received the impress of his father's religious skepticism to such a degree that he confesses, "I am one of the very few examples in this country of one who has not thrown off religious belief, but never had it. I looked upon the modern exactly

as I did upon the ancient religion, as something which in no way concerned me." On his return from France he assisted his father in preparing for the press a work on political economy. Soon after he studied law with John Austin, a disciple of Bentham. All his associations identified him with Bentham's school of philosophy, to which he claims to have given the title "*utilitarian*." When seventeen years old his father secured for him an appointment from the East India Company, in whose service he remained for thirty-five years, rising steadily from the lowest grade of clerk to the highest post in his department, that of examiner of India correspondence. The same year (1823) *The Westminster Review* was established by Bentham and his followers as a radical organ in politics and religion. Young Mill began at once contributing to its pages, and made it for many years the chief medium for publishing his literary efforts. From 1835 to 1840 he was its principal conductor. When only twenty-one he edited Bentham's great work *On Evidence*, adding notes and supplemental chapters of his own. With the bringing out of his *System of Logic, Ratiocinative and Inductive*, in 1843, he became prominent as a strong, bold, radical writer on philosophical subjects. This work embodied the peculiarities of empirical philosophy and association psychology. After having previously treated parts of the subject in a series of essays, he published in 1848 his full treatise, entitled *Principles of Political Economy, with some of their Applications to Social Philosophy*. This work, like the *Logic*, has passed through several editions in England and the U. S., and has a place among the standard works on the subject. On the dissolution of the East India Company in 1856, Mill, thrown out of his office, turned his attention altogether to literary labors. He published in 1859 a work *On Liberty*, which strikes at the despotism of public opinion over individual freedom of thought. In the same year was issued a collection of his *Dissertations and Discussions, Political, Philosophical, and Historical*, which had previously appeared in *The Westminster* and *Edinburgh Reviews*; also an essay entitled *Thoughts on Parliamentary Reform*, in which he advocated the extension of suffrage without distinction of sex on the basis of educational qualifications. In 1865 Mill was returned to Parliament, but his career in that body disappointed his constituents and the public generally. His chief prominence was in advocating the measure to admit women to the suffrage, which failed. In the new election he was rejected, and retired from public life. During his remaining years his residence was in the south of Europe, near Avignon, varied by spending some time twice a year in the neighborhood of London. He devoted his time to miscellaneous literary work, the fruits of which were in part presented to the public under his own eye and in part reserved for posthumous publication. Of the latter, his *Autobiography* and *Essays on Theism* are worthy of special notice. In 1830, when in his twenty-fifth year, he formed the acquaintance of a Mrs. John Taylor, and was drawn into an almost idolatrous devotion toward her. She shared in his literary work, and he says, rather extravagantly, "What I owe, even intellectually, to her is in its detail almost infinite." In 1851 that "most valued friendship of his life" was consummated by a formal marriage. His wife died at Avignon in 1859, after which he fixed his residence near her grave. There, with her eldest daughter, he cherished her memory as a "religion," and endeavored still to regulate his life with supreme regard to her approbation till his own death, on May 8, 1873. Besides the works above noticed, Mr. Mill gave to the public the following—viz.: *Considerations on Representative Government* (1861); *Utilitarianism* (1862); *Auguste Comte and Positivism* and *Examination of Sir William Hamilton's Philosophy* (1865); *England and Ireland* (1868); *The Subjection of Women* (1869); *Chapters and Speeches on the Irish Land Question* (1870). His *Autobiography* appeared soon after his death, in 1873, and the *Three Essays—Nature, The Utility of Religion*, and *Theism*, in 1874. A clear and candid presentation of Mill's views and character is given in a little memorial published in 1873, which is made up of twelve distinct sketches by H. R. Fox Bourne, Herbert Spencer, J. E. Cairns, Henry Fawcett, and others well acquainted with the man and familiar with his writings. Also see the biographies by Bain (1882) and Courtney (1889). The influence of J. S. Mill upon British philosophy was extraordinary, especially at Oxford, before the rise of the Neo-Hegelian movement represented by Green. The association psychology became the orthodox system, ministering as it did to utilitarian ethics and to a positivistic agnosticism in metaphysics and religion. Moreover, by his system of inductive logic, Mill emphasized the tendency to natural science conceptions and made easy the introduction of the views of Comte. Mill is the founder of the inductive or empirical logic. See INDUCTION and LOGIC.

Revised by J. MARK BALDWIN.

Millais, mil'lā', Sir JOHN EVERETT: portrait, genre, and landscape painter; b. at Southampton, England, June 8, 1829. He studied in the Royal Academy, London, where in 1843 he won a silver medal for his *Pizarro Seizing the Inca of Peru*, and a gold medal in 1847 for his *Benjamites Seizing the Daughters of Shiloh*; became a Royal Academician 1863; was created baronet in 1885; won a second-class medal at the Paris Exposition of 1855; medal of honor at the Exposition of 1878; was made an officer of the Legion of Honor 1878; member of the Institute of France 1883; member of the Academies of Antwerp, Edinburgh, Madrid, and Rome. In 1847–48 he formed one of the small group of British painters called the Pre-Raphaelites who had John Ruskin as their champion, but he did not long adhere to the peculiar theories of art held by that brotherhood. He was the leading portrait-painter in London, and some of his pictures, such as *A Huguenot* (1851), *Yes or No* (1875), and *Effie Deans* (1877), have achieved a widespread popularity through engraving and other reproductive processes. He succeeded Lord Leighton as president of the Royal Academy. D. at London, Aug. 13, 1896. WILLIAM A. COFFIN.

Mil'lard, DAVID: clergyman and author; b. in Ballston, N. Y., Nov. 24, 1794; became a minister of the "Christian" denomination 1815; was pastor of a church at West Bloomfield, N. Y., 1818–32, and at Portsmouth, N. H., 1837–40; published *The True Messiah Exalted* (1818; 2d ed. 1825); edited for several years a monthly magazine called *The Gospel Luminary*; visited Palestine in 1841, and published *A Journal of Travels in Egypt, Arabia Petræa, and the Holy Land during 1841–42* (1843); settled again at West Bloomfield, and was from 1845 to 1867 Professor of Biblical Antiquities and Sacred Geography at Meadville Theological Seminary. D. at Jackson, Mich., Aug. 3, 1873. See the *Life* by his son, Rev. D. E. Millard, 1874.

Millard, HARRISON: See the Appendix.

Millau: See MILHAU.

Millbury: town (set off from Sutton in 1813); Worcester co., Mass. (for location of county, see map of Massachusetts, ref. 3–F); on the Boston and Albany and the N. Y., N. H. and Hart. railways; 6 miles S. of Worcester, the county-seat. It contains 7 churches, 15 graded and 2 district schools held in 7 buildings, a national bank with capital of $200,000, a savings-bank with deposits of over $800,000, a town library (founded 1864) containing over 7,000 volumes, and a weekly newspaper. There are 5 woolen, 2 edge-tool, a hosiery, a linen shoe-thread, an electric-car, and a loom-heddle manufactory, indigo dye-works, 2 foundries, machine-shop, and sash, door, and blind, and wood-turning factories. In this town Thomas Blanchard constructed the first machine for turning irregular forms, the principle of which has never been improved. Pop. (1880) 4,741; (1890) 4,428; (1900) 4,460. D. EDMUND MARCH.

Milledgeville: city (formerly the State capital); capital of Baldwin co., Ga. (for location of county, see map of Georgia, ref. 4–H); on the Oconee river at the head of navigation, and on the Cent. of Ga., the Ga., and the Mid. Ga. and Atlantic railways; 39 miles E. N. E. of Macon. It is the seat of the Georgia Normal and Industrial College for Girls, the Middle Georgia Military and Agricultural College (a branch of the State University) and the Georgia State Lunatic Asylum. It is in a cotton-growing region, and has water-works, electric lights, a State bank with capital of $50,000, a weekly newspaper, and oil, machinery, pottery, and brick works. Pop. (1880) 3,800; (1890) 3,322; (1900) 4,219.

EDITOR OF "UNION-RECORDER."

Milledoler, mil'dol'er, PHILIP, D. D.: college president; b. at Rhinebeck, N. Y., Sept. 22, 1775; graduated at Columbia College in 1792; became pastor of the German Reformed church in Nassau Street, New York, in 1794, of the Third Presbyterian church in Philadelphia 1800–05, of the Rutgers Street Presbyterian church, New York, 1805–13, of the Collegiate Reformed Dutch church 1813–25, and from 1825 to 1840 was president of Rutgers College, New Jersey. He was one of the founders of the American Bible Society. D. on Staten Island, N. Y., Sept. 22, 1852.

Millena'rians, or, less commonly, **Chiliasts**: those who hold that the second advent of Christ precedes the end of the world, and that at his coming the pious dead will be raised and will reign with him upon the earth for a thousand years, the so-called millennium of Rev. xx. 1–7. This theory has always had believers and advocates in the Christian Church, but never has received confessional sanction. In the first century those who accepted it were called Chiliasts. The ablest work in English against it is by Rev. David Brown, *The Second Coming of our Lord* (London, 1846). An elaborate work upon eschatology in general, on the millenarian side, is by G. N. H. Peters, *The Theocratic Kingdom* (3 vols., New York, 1884). S. M. Jackson.

Millennium, or, less commonly, **Chiliasm** [*millennium* = Late Lat.; Lat. *mil'le*, thousand + *an'nus*, year; *chiliasm* is from Gr. χιλιασμός, deriv. of χίλιοι, thousand]: the thousand years of the Messiah's reign on earth supposed to be taught in Rev. xx. 1–7. There are two theories to which all the numerous theories on this subject may be reduced: 1. The literal, according to the Jewish form of which, as taught first 200 years B. C., the Messiah shall reign in Jerusalem, and the Jews restored to Palestine shall enjoy remarkable and continuous prosperity; and in its Christian form, the so-called Chiliasm, as found in Papias and others, Christians no less than Jews shall share these temporal blessings with the Jews. These views persisted in the Church and were revived by the radical party among the early Protestants, but the sober sense of the Church was against them. 2. The spiritual theory declares that the number 1,000 is used in Scripture as denoting an indefinite large number. So the thousand years of Rev. xx. 1–7 is not to be taken literally, but as figurative of that long period of spiritual prosperity which the Church shall enjoy before the coming of Christ and the end of time. S. M. Jackson.

Millepeds [Lat. *mil'le*, thousand + *pes*, *pedis*, foot]: See Myriapoda.

Millepore [Lat. *mil'le*, thousand + *po'rus*, pore]: name of a genus of Hydroidea, which unlike most hydroids produces a sort of coral which is smooth and branching, and has very small cells occupied by the polyps. These cells are unlike those of the true coral in that they are divided by horizontal partitions. On account of the presence of these partitions the millepores and their allies formerly were grouped with a number of fossil forms in which similar partitions or "tables" exist, in an order, *Tabulatæ*. The investigations of Hickson have shown that at least one species of millepore produces medusæ (see Hydroids), which, however, never become separated from the parent stock. The species of millepore are few, and they play but a minor part in the formation of coral reefs. The stag-horn coral, so common in tropical waters, is *Millepora alcicornis*. J. S. Kingsley.

Miller, Charles Henry: See the Appendix.

Miller, Cincinnatus Heine, known in literature as Joaquin Miller: poet; b. in Wabash District, Ind., Nov. 10, 1841. In 1854 he went to Willamette Valley, Ore., and soon after to the California mining-regions. In 1860, after studying law, he was admitted to the bar in Oregon; in 1863 edited the Eugene *Democratic Register* for a short time; in 1866 was elected district judge of Oregon, and served in that position four years; settled in New York about 1874, having made a visit to Europe in 1870. He wrote *Songs of the Sierras* (1871); *Pacific Poems* (1873); *Songs of the Sun Lands* (1873); *Unwritten History* (1874); *The Ship in the Desert* (1875); *First Families of the Sierras*, a novel (1875); *Adrianne, a Dream of Italy* (1876); *One Fair Woman*, a novel (1876); *Songs of Italy* (1878); *Shadows of Shasta* (1881); *The Gold-seekers of the Sierras* (1884); and *Songs of the Mexican Seas* (1887). His novel *The Danites* (1881) was successfully produced as a play. He afterward became a journalist at Washington, D. C., and in 1887 removed to Oakland, Cal. Revised by H. A. Beers.

Miller, Hugh: geologist; b. Oct. 10, 1802, at Cromarty, Scotland; lost his father when he was five years old, but received, nevertheless, a very conscientious and careful education by his two uncles; acquired an extensive and well-digested knowledge of English language, history, and literature, and developed early that power of acute observation which afterward made him celebrated in literature and science. He did not care, however, to attend a university. In 1819 he was apprenticed to a stone-mason, and he worked at this trade steadily till 1836, though devoting all his leisure hours to geological researches and to reading. In 1829 he published a volume of *Poems written in the Leisure Hours of a Journeyman Mason*, and became a frequent contributor to different periodicals. In 1836 he received a second-accountantship in a branch bank at Cromarty, married, published his *Scenes and Legends of the North of Scotland*, and during the Non-intrusion controversy in the Scottish Church his *Letters to Lord Brougham* on the Auchterarder case brought him prominently before the public. In 1840 he went to Edinburgh as editor of *The Witness*, a Free Church organ, and it was in the columns of this paper he first published *The Old Red Sandstone, or New Walks in an Old Field*, which made a great sensation, not only on account of the important geological discoveries it contained, but also by its exact reasoning and finished style. He also published *First Impressions of England and its People* (1847); *Footprints of the Creator* (1850); *My Schools and Schoolmasters* (1854), an interesting sketch of his education; *Testimony of the Rocks* (1857), etc. Least satisfactory were his attempts to establish perfect harmony between the details of religious doctrines and scientific views. His denial of the universality of the Deluge and of the literal meaning of the word "day" in the first chapter of Genesis aroused much suspicion among his coreligionists, and even met with some severe criticism; while, on the other hand, his assertion that the entire type of organic being was changed by each geological period did not escape the sneers of the scientists. During this hard work, continued through many years without flagging, his brain at last gave way, and he shot himself at Portobello, near Edinburgh, Dec. 26, 1856. See Peter Bayne, *The Life and Letters of Hugh Miller*, London.

Miller, James Russell, D. D.: clergyman and editor; b. at Frankfort Springs, Pa., Mar. 20, 1840; was educated at Westminster College, Pennsylvania; was pastor of the United Presbyterian church, New Wilmington, Pa., 1867–69; of the Bethany Presbyterian church, Philadelphia, 1869–78; of the Broadway Presbyterian church, Rock Island, Ill., 1878–80; of the Holland Memorial Mission, Philadelphia, 1881; and co-pastor of the same organized as an independent church. Since 1880 he has been editor for the Presbyterian board of publication, and has also published *Week-day Religion* (1880); *Home Making* (1882); *In His Steps* (1884); *Silent Time* (1886); *Come ye Apart* (1887); *The Marriage Altar* (1887); *Practical Religion* (1888); *Bits of Pasture* (1890); *Making the Most of Life* (1891); *Mary of Bethany* (1891); *Dew of thy Youth* (1891); *The Every Day of Life* (1892); and numerous smaller books, and pamphlets and leaflets.

Miller, Joaquin: See Miller, Cincinnatus Heine.

Miller, Joseph, known as Joe Miller: actor and reputed humorist; b. in England in 1684; was a comic actor in London, somewhat celebrated for his ready wit, and died there Aug. 16, 1738. The collection entitled *Joe Miller's Jests*, published the year after his death (1739), was really made by the publisher, John Mottley (1692–1750), and contained little or nothing really derived from Joe Miller.

Miller, Joseph Nelson: See the Appendix.

Miller, Lewis: See the Appendix.

Miller, Orest Fedorovich: writer and professor; b. in Reval, Russia, in 1833; studied at the University of St. Petersburg, where in 1861 he was appointed teacher of Russian literature, particularly of its beginnings. In 1865 he published *The Slav Question in Life and Knowledge*; in the following year *Lomonosov and the Reforms of Peter the Great*; in 1869 *Ilïa Muromets i Bogartyrsvo Kievskoe* (Ilïa Muromets and the Heroism of Kiev)—his best-known work, a study of the Russian popular myths. He is also the author of *The Slav World in Europe* (1877); *Lectures on Russian Literature after Gogol* (3d ed. 1887); and other works. Miller is one of the foremost of the Slavophils, although not an extremist. A. C. Coolidge.

Miller, Patrick: one of the numerous inventors of steam-navigation; b. at Dalwinston, Dumfriesshire, Scotland, about 1730. He was a wealthy country gentleman, fond of mechanical experiments; made some improvements in artillery; began in 1785 some experiments in ship construction and propulsion upon a loch near his estate, and published in 1786 a pamphlet giving an account of a vessel he had invented. In this pamphlet he stated his conviction that the steam-engine could be employed to work the wheels. In 1788 he, with the aid of James Taylor, propelled a boat 5 miles an hour by a steam-engine. The experiment proving unsatisfactory for several reasons, it was abandoned, but

after the successful experiments of Fulton his claims to the invention were put forward. D. at Dalwinston, Dec. 9, 1815.

Miller, Samuel Freeman, LL. D., D. C. L.: jurist; b. at Richmond, Ky., Apr. 5, 1816; was educated at Transylvania University; became a physician, and afterward a lawyer. In 1848 he became an advocate of the emancipation of the slaves, and in 1850 removed to Iowa; was successful as a lawyer; declined all public offices until 1862, when he was appointed one of the justices of the U. S. Supreme Court. He held this office till his death, and for many years was the senior justice of the court. Among his notable official acts were the opinions on the Louisiana slaughter-house cases, in which he defined the differences between the rights of the general Government and those of the States; and on the Kilbourn-Thompson case, where the constitutional authority of Congress as a co-ordinate branch of the Government was for the first time defined; and the motion before the Electoral Commission in 1877, which led to the judgment that Congress had no authority to go behind the returns of the legal officers of a State. At the centennial celebration of the adoption of the Federal Constitution by the convention in Philadelphia, in 1887, he was the principal orator. D. at Washington, D. C., Oct. 13. 1890.

Miller, Warner: politician; b. in Oswego co., N. Y., Aug. 12, 1838; graduated at Union College in 1860; became a teacher in the Fort Edward collegiate institute, but when the civil war broke out he enlisted as a private in the Fifth New York Cavalry. He fought under Gen. Sheridan, and attained the rank of lieutenant. He was a delegate to the national Republican conventions of 1872 and 1888; was elected to the New York Assembly in 1874 and 1875, and to Congress in 1878 and 1880. On July 16, 1881, he was elected U. S. Senator from New York for the unexpired term of Thomas C. Platt, who had resigned. Mr. Miller's term expired in 1887. He was nominated by acclamation for Governor of New York by the Republican convention Aug. 28, 1888, but was not elected.

Miller, William: founder of the sect of Millerites; b. at Pittsfield, Mass., Feb. 15, 1782; settled in Poultney, Vt., 1804; served as a captain of volunteers on Canadian frontier during the war of 1812; moved in 1815 to Low Hampton, Washington co., N. Y., and in 1831 began to announce the speedy second coming of Christ, which, by his interpretation of the biblical prophesies, he fixed for the year 1843, at which time the world would be destroyed. In a few years his converts in the U. S., Canada, and Great Britain numbered many thousands, and were popularly known as Millerites, though they styled themselves Second Adventists. (See Adventists.) D. at Low Hampton, N. Y., Dec. 20, 1849. See his *Life*, by Sylvester Bliss (Boston, 1853), and by James White (Battle Creek, Mich., 1875).

Revised by S. M. Jackson.

Miller, William Hallowes, F. R. S.: mineralogist; b. in Wales in 1801; graduated at Cambridge in 1826; became fellow and tutor of St. John's College; succeeded Dr. Whewell as Professor of Mineralogy 1832; was appointed in 1843 on a royal committee to superintend the construction of parliamentary standards of length and weight in place of those destroyed by fire in 1834, and undertook the restoration of the standard of weight, which he finished in Mar., 1854. He served in 1867 on a commission to inquire into the condition of the exchequer standards, and in 1870 on the international commission upon the metric system. He published in *The Philosophical Magazine* and the *Proceedings* of the Royal Society many important papers on mineralogy and crystallography, for which he received in 1870 one of the royal medals. He was for many years secretary, and subsequently president, of Cambridge Philosophical Society, was foreign secretary of the Royal Society 1856–73, and was a member of the principal scientific societies in Europe. D. May 20, 1880.

Millerites: See Adventists and Miller, William.

Millersburg: village; capital of Holmes co., O. (for location of county, see map of Ohio, ref. 4–G); on the Cleve., Akron, and Columbus Railway; midway between Cleveland and Columbus, and 80 miles from each city. It is in an agricultural region, with coal-fields and iron mines in the vicinity, and has 7 churches, 2 union schools, electric lights, 2 weekly newspapers, and flour and planing mills, tile and brick works, foundry and machine-shops, and furniture-factory. Pop. (1880) 1,814; (1890) 1,923; (1900) 1,998.

Editor of "Holmes County Farmer."

Millersburg: borough; Dauphin co., Penn. (for location of county, see map of Pennsylvania, ref. 5–G); on the Susquehanna river, and the Northern Cent. Railway; 26 miles N. of Harrisburg. It is in an agricultural region, and near the famous Lykens coal-fields; is an important coal-shipping point; and has manufactories of lumber, axles, wheels, taps and dies, brooms, and carpets. Pop. (1880) 1,440; (1890) 1,527; (1900) 1,675.

Editor of "Herald."

Miller's Thumb, or **River Bullhead**: a small fish of the cold streams and lakes of Northern Europe. Its scientific name is *Cottus gobio*. It lies quiescent on the bottom among stones, making a quick spring when disturbed. It is very destructive to the eggs of trout. Numerous similar species of *Cottus* are found in the cold brooks of Northern America. See Cottidæ. D. S. J.

Millet [from Fr. *millet*, dimin. of *mil* (whence Eng. *mill*, millet): Ital. *miglio* < Lat. *mi'lium*, millet; cf. Gr. μελίνη and O. Eng. *mīl*]: any one of numerous grasses of several distinct genera and species. The *Milium effusum*, found throughout Europe and Northern Asia and in the Northern U. S., is a slender grass of the tribe *Paniceæ*, 4 to 6 feet high, which has never been cultivated, but is abundant in the woodlands both of Great Britain and North America. The true, cultivated millet of ancient and modern times belongs to a third genus, *Panicum*, which embraces no less than 850 species. *Panicum miliaceum* is sown chiefly for forage, though the seeds yield a very nutritious flour. The Hungarian, German, and Italian millets are now classified by botanists under the genus *Setaria*. It is these coarse setarias which are known as millet in the U. S., where the crop is grown chiefly for forage, and is made into hay. The requisites for successful culture of this millet are a moderately rich, well-tilled soil, and a fine and closely compacted seed-bed. The seed should not be sown until the ground is thoroughly warmed, June 1–15. It is sown broadcast and lightly brushed in. Millet requires a large amount of moisture from frequent showers in order to make its best growth, but it will not do well on a wet or sodden soil. It is a plant of very quick growth, and is usually cut within two months after seeding, or as soon as the seed-heads have appeared, and before the seed has hardened. The process of cutting and curing is the same as for hay from other grasses. Millet hay is less nutritious and less palatable than that of the finer meadow-grasses, but since it furnishes a large amount of fairly nutritious forage and is easily and quickly grown on new soil, it is a favorite crop in those localities where permanent meadows have not yet become established. If the plant is allowed to become ripe before cutting, the forage is less digestible and less palatable, and the ripened or partially ripened seed contains a diuretic principle which makes its use as a fodder objectionable, particularly for horses.

Revised by H. H. Wing.

Millet, mēē'yā', Aimé: sculptor; b. in Paris, Sept. 27, 1819; studied under David d'Angers; began to exhibit in 1842, and attracted great attention in 1857 by a statue, *Ariane*, which was bought for the museum of the Luxembourg. Of his other works may be named the *Mercure*, in the Louvre, and *La Jeunesse effeuillant des roses*, on the tomb of Henri Murger, the poet of bohemian life, and an *Apollo and Pegasus* for the Paris Opera, and especially the colossal equestrian statue of Vercingetorix at Alise-Sainte-Reine, in Burgundy. He became an officer of the Legion of Honor in 1870. D. in Paris, Jan. 13, 1891.

Mil'let, Francis Davis: genre and portrait painter; b. at Mattapoisett, Mass., in 1846; was a pupil in the Royal Academy of Antwerp, where he won medals in 1872 and 1873; studied also in France and Italy; elected a member of the Society of American Artists 1880; National Academician 1885; vice-president of National Academy 1891; member of the American Water-color Society and Royal Institute of Painters, London; was awarded a second-class medal at the Paris Exposition of 1889. His pictures represent life in England during the eighteenth century, and scenes in ancient Rome, Pompeii, and Greece. He is a writer of fiction and descriptive articles in the magazines, and made a high reputation as the correspondent of the London *Daily Telegraph* in the Turco-Russian war. He illustrates his own articles. His *Between Two Fires* (engraved in *The Century Magazine* for Sept., 1892) was purchased by the Chantrey Bequest at the Royal Academy Exhibition, London, in 1892, and one of his best works, *An English Inn*, is

in the Union League Club, New York. Studios in New York and at Broadway, Worcestershire, England.

WILLIAM A. COFFIN.

Millet, mĕĕ'lā', JEAN FRANÇOIS: genre and landscape painter; b. at Gréville, Manche, France, Oct. 4, 1814; d. at Barbizon, Seine-et-Marne, Jan. 20, 1875. He was a pupil of Mouchel and of Langlois at Cherbourg, and of Paul Delaroche in Paris; was awarded second-class medals at the Salons of 1853 and 1864; first-class at the Paris Exposition 1867; decoration of the Legion of Honor 1868. He was well trained in academic study, but desiring to get inspiration from nature by direct contact with the scenes he wished to paint, he went to live in the country. He was poor, and for a long time his pictures brought him but slight pecuniary return, but toward the end of his life they began to be appreciated by collectors who had formerly been unable to see any merit in them. Since his death his works have been praised by artists and critics and sold at very high prices, one of his best-known pictures, *The Angelus*, (1859) having brought $100,000 at auction in Paris in 1889. This picture was exhibited in the principal cities in the U. S., but was finally purchased by a French amateur, M. Chauchard, and taken back to Paris. It has been called Millet's masterpiece, but it is by no means the best of his works. If this title is to be given to any of them, it undoubtedly belongs to *The Gleaners* (1857) which was bought from its owner, M. Bischoffsheim, by Madame Pommery, of Reims, in 1889, and presented to the Louvre, where it now is. Millet was one of the greatest artists of modern times. The list of his best works includes, besides the two already mentioned, *The Sower* and *The Water-carrier*, both in the collection of Mrs. W. H. Vanderbilt, New York; *The Grafter* (William Rockefeller, New York); *Peasant Leaning on his Hoe* (M. Van den Eynde, Paris); *The Sheep Park* (M. Bellino, Paris); *The Turkey-keeper* (C. A. Dana, New York); *The Churner* (F. L. Ames, Boston); *Buckwheat Threshers* (not carried to completion, Quincy Shaw, Boston); *The Planters* (Quincy Shaw, Boston); *The Potato Harvest* (W. T. Walters, Baltimore); *Breaking Flax* (W. T. Walters, Baltimore); and *Death and the Woodcutter* (owned in France). The most complete work on Millet is *Vie et Œuvre de J. F. Millet*, by Alfred Sensier (Paris, 1881). WILLIAM A. COFFIN.

Mil'li-Casso'ne, GIANNINA: poet and *improvisatrice*; b. at Teramo, Abruzzi, Italy, in 1827. She is said to have composed verses when but five years old; at the age of seventeen found a literary guide in de Martinis. Having heard the poet Regaldi improvise, she was seized with an impulse to emulate him, in which she was encouraged by Regaldi himself. She gave public improvisations in the Abruzzi, in Calabria, and finally at Naples under the protection of the learned Giulio Genoino. In the same way she made a tour through the Two Sicilies, was honored with two silver medals, and in Rome with a medal of gold. Her name was not generally known throughout Italy until after 1857, when she began her poetical excursions through Tuscany and Upper Italy. In 1860 she met with the greatest success at Turin, then the royal residence; and a pension was bestowed upon her by the minister de Sanctis. In 1869 she was appointed inspector of the elementary schools for girls of Southern Italy. A normal school for young women was afterward established in Rome, and she was appointed superintendent, a position she held till her marriage with Ferdinando Cassone, schools-inspector at Caserta. Her first published verse was entitled *Qual è il più bel pregio della donna* (1854). Later her poems were collected in two volumes (1862–63). Revised by A. R. MARSH.

Milligan, WILLIAM, D. D.: theologian; b. in Edinburgh, Mar. 15, 1821; graduated at St. Andrews (1839); was minister at Cameron, Fifeshire, and afterward at Kilconquhar 1844–60; Professor of Divinity and Biblical Criticism at the University of Aberdeen from 1860. He was principal clerk to the General Assembly, and moderator of Assembly in 1882. D. in Aberdeen, Dec. 11, 1893. Among his published works are *Words of the New Testament as Altered by Transmission and Ascertained by Modern Criticism* (with Dr. Roberts, Edinburgh, 1873); *The Resurrection of our Lord* (London, 1881, and subsequent editions); *The Revelation of St. John* (Baird lecture, 1885, published 1886); a Commentary on the *Gospel by John* (with Dr. Moulton, in Schaff's *Popular Commentary*, New York and Edinburgh, 1880); *Revelation* (in same series, 1883); *Elijah: his Life and Times* (in the Men of the Bible Series, 1889); *The Book of Revelation* (Expositor's Bible Series, 1891); *The Ascension and Heavenly Priesthood of our Lord* (London and New York, 1892); *The Resurrection of the Dead* (1894). W. J. B.

Milliken's Bend: post-village of Madison parish, La.; on the Mississippi river; 15 miles above Vicksburg, Miss. In June, 1863, near this place, a Confederate force of 2,500, under Gen. H. McCullough, attacked a body of colored troops, numbering 1,400, and part of an Iowa regiment, under Gen. E. S. Dennis, but with the assistance of gunboats from Admiral Porter's fleet they were repulsed.

Mills, ALBERT LEOPOLD: See the Appendix.

Mills, CHARLES KARSNER, M. D.: alienist and neurologist; b. at Falls of Schuylkill, Pa., Dec. 4, 1845; graduated M. D. at the University of Pennsylvania in 1871; was Professor of Physics in the Wagner Institute, Philadelphia, from 1870 to 1873, and lecturer on Physics in the Franklin Institute from 1872 to 1873; was lecturer on Electro-therapeutics and Nervous Diseases in the Philadelphia School of Anatomy and Surgery in 1876, lecturer on these subjects in the University of Pennsylvania in 1877, and in 1887 was made lecturer on Nervous and Mental Diseases in that institution. He is the editor of a *System of Nervous Diseases*, and is a well-known author of papers on his specialty in medical journals.

S. T. ARMSTRONG.

Mills, CLARK: sculptor; b. in Onondaga co., N. Y., Dec. 1, 1815. His first trade was that of a millwright, his second that of a plasterer. From this he proceeded to sculpture, which he began to practice in Charleston, S. C. He was self-taught, had never been in Europe or seen the works of the masters in his art. His first work was a bust of John C. Calhoun, which the city of Charleston purchased and placed in the town-hall in 1846. This led to other portrait-busts of local celebrities. In 1848 he was invited to furnish the design for an equestrian statue of Andrew Jackson for the Government. The result was the statue on Lafayette Square, near the White House, in Washington, chiefly remarkable for the poise of the horse on its hind legs. The next performance was the colossal statue of Washington at the battle of Princeton, also in Washington, which was unveiled Feb. 22, 1860. The casting of the colossal statue of Liberty, after Crawford's design, for the dome of the Capitol, was finished in 1863. D. in Washington, D. C., Jan. 12, 1883. Revised by RUSSELL STURGIS.

Mills, DAVID, LL. B.: politician; b. in Oxford, Kent co., Ontario, Mar. 18, 1831; graduated at Michigan University; studied law and was called to the bar in 1883. He was superintendent of schools for Kent County 1856–65; was employed by the government of Ontario to define the northwestern boundary of the province in 1872, and was one of the counsel employed in the argument before the British Privy Council in 1884. He was elected a member of the council of public instruction for Ontario in 1875; had a seat in the Parliament of Canada 1867–96; was Minister of the Interior 1876–78. He became a Senator and Minister of Justice in 1897.

Mills, ROBERT: architect and engineer; b. in Charleston, S. C., Aug. 12, 1781; studied architecture in Washington, under Benjamin H. Latrobe, the original designer of the Capitol; designed and supervised the erection of several important buildings in Philadelphia. The single-arch bridge of 740 feet spanning the Schuylkill river attests his originality and skill as an engineer. The custom-houses in New London and Middletown, Conn., and in New Bedford and Newburyport, Mass., the marine hospitals in Charleston and New Orleans, and the State penitentiary of Louisiana were all built according to his designs; so, also, was the Washington Monument in Baltimore. After completing other important works he returned to South Carolina in 1820, and was made State architect and engineer. In 1837 he was recalled to Washington, where he was appointed by President Jackson the architect of the general Government, and held this office during the administrations of Jackson and Van Buren, designing and supervising the erection of the Treasury building and General Post-office building. The Patent-office building also was erected under his supervision. The design for a national Washington Monument was made by him, but his plan for a circular colonnade around its base was not carried out, and only the bare obelisk was erected (1848–84). He published *Statistics of South Carolina* (1826), accompanied by a folio atlas; *American Pharos, or Lighthouse Guide* (1832); and a *Guide to the National Executive Offices* (1842). D. in Washington, D. C., Mar. 3, 1855.

Revised by RUSSELL STURGIS.

Mills, Samuel John: "father of foreign missions in America"; b. at Torringford, Conn., Apr. 21, 1783; entered Williams College in 1806, and in Sept., 1808, was the prineipal organizer of a society of undergraduates who eontemplated beeoming missionaries in foreign lands. This was the first organization in behalf of that object in America. He graduated in 1809; spent some months at Yale College studying theology and seeking adherents to his missionary projeet; entered Andover Theological Seminary in 1810, and associated himself with Messrs. Judson, Nott, and Newell in memorializing the General Association of Massachusetts, then in session at Bradford (June 28, 1810), upon the subject of missions, an aet whieh resulted in the formation of the American Board of Commissioners for Foreign Missions. He was licensed to preaeh in 1812, and ordained in 1815; spent three years in missionary labors in the Southern States, and two years in New York and other great eities, engaged in promoting the formation of the Ameriean Bible Soeiety and the Ameriean Colonization Society, as well as other missionary organizations, and was sent by the Colonization Soeiety, along with Rev. Ebenezer Burgess, to Western Africa, to select a site for a eolony. They proceeded first to England to confer with British philanthropists (1817), and aecomplished their objeet in Afriea in the following year, in what is now Liberia, but on the return voyage Mills died at sea, June 16, 1818. See his *Memoir*, by Rev. Gardiner Spring (New York, 1820).

Mills, Sebastian Bach: pianist and teaeher; b. at Cirencester, England, Mar. 13, 1838; was educated by his father in the strict English cathedral school. Then he studied in the Leipzig Conservatory, and on graduation made a sueeessful eoneert tour in Germany; removed to New York in 1857, and took a leading position as a eoneert pianist. He was for many years a familiar and favorite pianist, and has played with all the great orehestral soeieties. In 1866 and 1867 he made an extended concert tour with Parepa and Carl Rosa under the Bateman management; but gradually he retired from publie life, and has devoted himself exclusively to teaching. His compositions are almost exclusively for the piano, and belong to the brilliant bravura school, of whieh he was a fine exponent.

D. E. Hervey.

Mill Springs: post-village of Wayne co., Ky.; on the Cumberland river. During the eivil war, on Jan. 19, 1862, the Federal troops, 28,000 strong, under Gen. George H. Thomas, and the Confederate troops, 10,000 strong, under Gen. George B. Crittenden, met in battle about 5 miles from this plaee. The latter were led by Gen. Felix K. Zollicoffer, who was killed, and his forees defeated with a loss of 190 killed, 60 wounded, and 89 prisoners. Of the Federal force 38 were killed and 194 wounded.

Milltown: a post-village of Charlotte co., New Brunswick; on the St. Croix river; contiguous with St. Stephen, and directly opposite Milltown, a post-village ineluded in the limits of the eity of Calais, Me., with which it is connected by bridges (see map of Quebec, ref. 6–G). Immense quantities of lumber are sawed and shipped here. There are eighteen gang sawmills on the Canada side alone, besides an edge-tool factory and other works. Milltown has an aeademy, three churehes, a eireulating library, and several schools. Pop., with St. Stephen, about 4,000.

Revised by M. W. Harrington.

Millville: city; Cumberland eo., N. J. (for loeation of county, see map of New Jersey, ref. 7–B); on the Maurice river, here navigable, and the W. Jersey Railroad; 40 miles S. of Philadelphia. It eontains 12 churches, high school (building completed in 1894 at a cost of $25,000), 15 public sehools, public library and reading-room (founded 1864), gas and electrie lights, eleetric railway connecting the city with Bridgeton, the county-seat, a national bank with capital of $100,000, manufactories of iron, glass, and cotton, and 3 weekly newspapers. North of the city is Union Lake, 7 miles long, on the banks of which is an extensive public park. Pop. (1880) 7,660; (1890) 10.002; (1900) 10,583.

Editor of "Republican."

Milman, Henry Hart, D. D.: historian; b. in London, Feb. 10, 1791; was the son of Sir Franeis Milman, M. D., an eminent physician (1746–1821). He was edueated at Eton and Brasenose, Oxford; became a fellow 1815; took priests' orders 1816; was Bampton lecturer 1827; Professor of Poetry at Oxford 1821–31; rector of St. Margaret's, Westminster, and canon 1835; dean of St. Paul's 1849. D. at Sunninghill, Sept. 24, 1868. His chief works are a prize poem, *Apollo Belvedere* (1812); *Fazio*, a successful tragedy (1815); *Samos*, a poem (1818); *The Fall of Jerusalem*, a poem (1820); *The Martyr of Antioch*, and other poems (1821); *Bampton Lectures* (1827); *History of the Jews* (1829); *History of Christianity to the Abolition of Paganism* (1840); *History of Latin Christianity* (1854–55); a sumptuous edition of *Horace* (1849); an edition of Gibbon's *History of the Decline and Fall*, with notes, etc. His *Poetical and Dramatic Works*, of which a collected edition appeared in London, 1839, in 3 vols., attracted much attention in their time, but are now forgotten with the exception of a few hymns. His historieal writings at first encountered mueh criticism—chiefly on aecount of the strongly pronounced liberal Church views on which they were based.

Revised by W. S. Perry.

Milmore, Martin: sculptor; b. at Sligo, Ireland, Sept. 14. 1844; emigrated with his family to Boston in 1851; entered the studio of Thomas Ball in 1860; modeled an alto-relief of an ideal subjeet entitled *Phosphor*; made busts of Sumner, Longfellow, Tieknor, and other distinguished eitizens; reeeived in 1864 a commission to exeeute granite statues of Ceres, Flora, and Pomona for the Horticultural Hall at Boston, a task which oeeupied him two years; designed in 1867 a bronze statue for the soldiers' monument at Forest Hill Cemetery, Roxbury, and subsequently was employed by the eity of Boston to exeeute an army-and-navy monument, whieh was placed on Boston Common. D. in Boston, July 21, 1883.

Revised by Russell Sturgis.

Milne, John, F. G. S., F. R. S.: geologist and seismologist; b. in Lancashire, England, in 1848. He distinguished himself as a student at the Royal School of Mines, London; traveled in Ieeland; was engaged 1873–74 in mining in Newfoundland; visited, with Dr. Beke, Northwest Arabia, and finally in 1875 accepted a position as Professor of Mining and Geology under the Japanese Government, a post whieh he still holds. Much of his time has been devoted to seismology, on which he is the recognized authority. He founded the Seismologieal Soeiety of Japan in 1886, and is author of the volume on *Earthquakes* in the Natural Seienee Series.

J. M. Dixon.

Milne, William, D. D.: missionary; b. at Kinnethmont, Aberdeenshire, Scotland, Apr., 1785; went to China as a missionary in 1812; visited the chief islands of the Indian Arehipelago, and established himself at Malaeca, whence he circulated throughout Eastern Asia the Scriptures, as well as religious books in Oriental languages written and printed by himself. He published *The Indo-Chinese Gleaner*, a quarterly magazine, aided in translating the Bible into Chinese, and wrote *Retrospect of the Protestant Mission to China* (Malacca, 1820). D. in Malaeca, May 27, 1822. See his *Life and Opinions*, by Rev. Robert Philip (London, 1839).

Milne-Edwards, Alphonse, M. D.: geologist and naturalist; son of Henri Milne-Edwards, naturalist; b. in Paris, Oct. 13, 1835; graduated as doctor of medicine 1859; became professor in the Paris Sehool of Pharmacy in 1865, and member of the Legion of Honor in 1868; officer in 1884; sueeeeded his father in 1876 as professor at the Musée. He is the author of many important papers on zoölogy, and particularly on the anatomy of fossil birds, most of which have appeared in *Annales de Science Naturelle* and *Comptes Rendus*. His *Recherches Anatomiques, Zoologiques et Palæontologiques sur la Famille des Chevrotains* (1864) is an important work, but his masterpieee is *Recherches Anatomiques et Palæontologiques pour servir à l'Histoire des Oiseaux fossiles de la France* (1866–72).

Revised by F. A. Lucas.

Milne-Edwards, Henri, M. D.: naturalist; b. at Bruges, Belgium, Oct. 23, 1800; was the son of an Englishman; took his medieal degree in Paris 1823; beeame Professor of Natural History at the Lycée Henri IV.; Professor of Natural History at the Musée 1841; Professor of Zoölogy 1862; dean of the Faculty of Seiences; member of the Academies of Sciences and of Medicine; commander of the Legion of Honor, etc. Author of *Anatomical Researches Concerning Crustaceans* (1828); *Handbook of Materia Medica* (1832); *Elements of Zoölogy* (1834–35; new eds. 1840, 1851); *Natural History of Crustaceans* (1837–41); a new edition of Lamarck's *Natural History* (1838–45); *Leçons sur la Physiologie* (10 vols.), and of a great number of valuable scientific papers. D. July 29, 1885. Revised by F. A. Lucas.

Milner, John, D. D., F. S. A.: archæologist and polemical writer; b. in London, Oct. 14, 1752; was educated at Douay; became a Roman Catholic priest in 1777; became in 1803 titular Bishop of Castabala and vice-apostolic of the Midland district of England, but was expelled from his office by the English Catholic board in 1823. D. at Wolverhampton, Apr. 19, 1826. He was author of *History and Antiquities of Winchester* (Winchester, 1798–1801, 2 vols.; 3d ed. 1839, with his *Memoir*); *Letters to a Prebendary* (1800; 8th ed. Derby, 1843); *Ecclesiastical Architecture of England during the Middle Ages* (London, 1811; 3d ed. 1835); *The End of Religious Controversy* (1818; 11th ed. Dublin, 1859); and a *Vindication* of the same (1822). See his *Life*, by F. C. Husenbeth (Dublin, 1862).

Revised by S. M. Jackson.

Milnes, Richard Monckton: See Houghton, Baron.

Mi'lo [Gr. Μῆλος, whence Lat. *Me'los*]: a Greek island; the most southwesterly of the Cyclades; 14 miles long from E. to W. and 8 miles from N. to S.; 63 miles E. from Peloponnesus. Entirely volcanic, it is crescent-shaped, the vast crater forming an excellent harbor. It is rich in sulphur, vitriol, and alum. Exceedingly fertile and prosperous 150 years ago, it has been rendered sterile and almost depopulated by volcanic action and poisonous exhalations. The former population of 20,000 has shrunk to about 2,000, many of whom are sickly and deformed. Antiquities abound. The celebrated statue called *The Venus of Milo*, now in the Museum of the Louvre, was dug up here by a peasant in 1820, and was acquired for 6,000 francs by the French Government. E. A. Grosvenor.

Milo (in Gr. Μίλων): athlete of Croton, in Southern Italy; son of Diotimus. He was one of the most noted athletes of antiquity, having won the prize as wrestler in six Olympian, seven Pythian, ten Isthmian, and nine Nemean games. He was distinguished for his appetite also; at Olympia he lifted and carried on his shoulders a four-year-old ox across the race-course, then slew and ate it on the same day. He flourished about 510 B. C. He found his death by trying to split with his hands a log that had been opened by wedges. The wedges fell out, his hands were caught in the log, and he was torn to pieces by animals. J. R. S. Sterrett.

Milo, Titus Annius Papinianus: Roman politician; b. early in the first century B. C. Little is known of his life till he became tribune of the people in 57 B. C., when, as a partisan of Pompey and friend of the exiled Cicero, he incurred the enmity of Clodius. The followers of Milo and Clodius fought daily in the streets of Rome, and after Cicero returned from exile the contest became even more embittered. In Jan., 52 B. C., the rival parties met at Bovillæ, and Clodius was murdered by one of Milo's bodyguard. Cicero defended his partisan, but was deterred by intimidation from delivering his oration, *Pro Milone*, and was unable to prevent the conviction of the accused. He was condemned to exile and went to Massilia. Returning to Italy in 48 B. C. to take part in the rebellion incited by Marcus Cælius, he was killed near Thurii. F. M. Colby.

Milrea', or **Milree'** [from Portug. *milreis*, a thousand reals; *mil*, thousand + *reis*, plur. of *real*, a real < Lat. *rega'lis*, royal]: called also *corão* or *crown*; a Portuguese and Brazilian coin and money of account. The Portuguese milrea is worth about one U. S. dollar; the Brazilian is 51‡ cents of the money of the U. S.

Milti'ades (in Gr. Μιλτιάδης): general; b. at Athens; was the son of Cimon, a citizen of that place; succeeded his brother Stesagoras as tyrant of Chersonesus, and joined Darius Hystaspis in his campaign against the Scythians. Together with the other Greeks he was left in charge of the bridge over the Danube, and when Darius did not return at the appointed time he recommended the destruction of the bridge, while the Ionians, on the advice of Histiæus, insisted on its preservation. Afterward he conquered Lemnos, which was a Persian possession, and when the Persian fleet, after the capture of Miletus, approached Chersonesus, he fled and repaired to Athens. Here he was chosen commander against the Persian force, which, under Datis and Artaphernes threatened Athens, and defeated it in the memorable battle of Marathon (490 B. C.). A new armament which the Athenians placed under his command he used for an expedition against Paros for merely private purposes. He was arraigned, and condemned to defray the whole cost of the armament, and as he could not pay this enormous fine, he was thrown into prison, where he died from a wound he had received during the campaign. His son Cimon afterward paid the fine, and a monument was raised in honor of him on the plain of Marathon.

Revised by J. R. S. Sterrett.

Milton: city; capital of Santa Rosa co., Fla. (for location of county, see map of Florida, ref. 2–C); on the Blackwater river, and the Louis. and Nash. Railroad; 20 miles N. E. of Pensacola. It is in a cotton, fruit, wool-growing, and lumbering region, and has iron-foundries, dry dock, ship-yards, interior and coasting trade, and a weekly newspaper. Pop. (1880) 1,058; (1890) 1,455; (1900) 1,204.

Milton: town (settled in 1640, incorporated in 1662); Norfolk co., Mass. (for location of county, see map of Massachusetts, ref. 5–I); on the Neponset river at the head of navigation, and the Old Colony Railroad; 7 miles S. of Boston, with which it also has street-railway connection. It is the seat of Milton Academy (non-sectarian, chartered 1798); contains the Blue Hills which gave their Indian name to the State, 30 public schools, public library (founded 1871) with over 10,000 volumes, 4 churches, a national bank with capital of $200,000, and a weekly newspaper; is engaged in market-gardening, building-stone quarrying, ice-harvesting, and the manufacture of paper, chocolate, and water-crackers. The town contains the residences of many Boston business men. Pop. (1880) 3,206; (1890) 4,278; (1900) 6,578.

Editor of "News."

Milton: borough (founded in 1797, incorporated in 1817); Northumberland co., Pa. (for location of county, see map of Pennsylvania, ref. 4–G); on the Susquehanna river, the Pennsylvania Canal, and the Phila. and Read. and the Penn. railways; 62 miles N. of Harrisburg. It contains 9 churches, 22 graded schools, library (High School), 2 national banks with combined capital of $200,000, a trust and safe-deposit company with capital of $125,000, and 3 weekly and 2 other periodicals. There are railway-car works, rolling-mills, axle-forge, bolt and nut works, nail-factories, washer-works, large steam tannery, agricultural-implement works, 4 machine-shops, 2 planing-mills, 2 iron-foundries, sawmills, and fly-net factory. The borough was destroyed by fire in 1882. Pop. (1880) 2,102; (1890) 5,317; (1900) 6,175. Editor of "Miltonian."

Milton, John: poet; b. in Bread Street, Cheapside, London, Dec. 9, 1608; received a very careful education, first under a private tutor, then at Christ's College, Cambridge, which he entered Feb. 12, 1625. He was originally destined for the Church, but, reared in a family of Puritan cast, and consequently opposed in many points to the English Church of that time, he gave up this plan, and when in 1632 he left Cambridge he returned to his father's house in Horton, a village in Buckinghamshire, whither the family had retired on an independency. Here he studied classical literature and philosophy with great energy, being by nature a studious and industrious man; cultivated music, in which both he and his father were quite proficient; and composed the *Sonnet to the Nightingale*, *L'Allegro*, and *Il Penseroso*, the elegy *Lycidas*, and the two masques *Comus* and *Arcades*; the first collected edition of his poems was not published, however, until 1645. After his mother's death in 1637 he went abroad, visited Leyden, Paris, and Rome, and made the acquaintance, among others, of Grotius and Galileo. His Latin verses and other scholarly attainments, his personal beauty and noble disposition, introduced him to learned and elegant society, and made him friends. On his return home after an absence of fifteen months, he settled in London, the household at Horton having been broken up in the meantime, and took a few pupils, sons of relatives and friends, under his tuition; but soon he became deeply entangled in the turbulent controversies, religious and political, which filled that period of English literature, and for twenty years the poet of *L'Allegro* and *Comus* was engaged as a most violent and intolerant, though candid and eloquent, controversialist. His first polemical onset was an attack on the Established Church (1641–42). Five treatises belong to this contest—namely, *Of Reformation*, *Of Prelatical Episcopacy*, *The Reason of Church Government*, *Animadversions*, and *Apology for Smectymnuus*. In 1643 he married Mary Powell, but she left him after one month on account of the "spare diet and hard study" she found in his house. Four tracts on divorce followed (1644–45)—namely, *The Doctrine and Discipline of Divorce*, *The Judgment of Martin Bucer*, *Tetrachordon*, and *Colasterion*, in which he maintained that moral incompatibilities justify

divorce. The couple became reconciled afterward, and lived together until the death of the wife in 1653; she bore him three daughters. In 1644 he also published two other essays, *On Education* and *Areopagitica, a Speech for the Liberty of Unlicensed Printing*, which latter treatise is his most eloquent piece of prose writing. After the execution of Charles I. (Jan. 30, 1649) he wrote three powerful pamphlets (1649–50) in order to defend the acts of the English people in its struggle with its king—namely, *The Tenure of Kings and Magistrates*, *Eikonoclastes*, and *Pro Populo Anglicano Defensio contra Salmasii Defensionem Regiam*; and to this group of writings belongs also his controversy with Dumoulin (1654–55), comprising three pamphlets, among which was *Defensio Secunda*. The attack on Salmasius made a great sensation in Europe. It was written at the demand of Parliament, as in 1649 Milton had been appointed secretary in the ministry of Foreign Affairs by Cromwell. This position he held till the Restoration in 1660, though he became entirely blind in 1654, and could work only by the aid of a reader and a scribe. After the Restoration he was compelled to keep himself concealed for some time, and even after the Act of Oblivion he continued to live very secluded. On Nov. 12, 1656, he married Catharine Woodcock, but she died fifteen months after in childbed. In 1663 he married his third wife, Elizabeth Minshull, but his home was not a happy one. A severe regularity and haughty solitude characterized his life; studies and literary compositions occupied his time. *Paradise Lost* was published in 1667; *History of Britain* in 1670; *Paradise Regained* and *Samson Agonistes* in 1671; *Of True Religion* in 1673. A Latin manuscript, *De Doctrina Christiana*, which shows his very heterodox conceptions of different points of Christianity, was not published till 1825. He died Nov. 8, 1674, and was buried in the Church of St. Giles, Cripplegate, beside his father. At its first appearance *Paradise Lost* made no great impression. The author received £5 for the first 1,300 copies; the second edition was not published until 1673. The widow of Milton sold in 1681 her interest in the work for £8. Among others, see Masson's *Life of Milton*, 6 vols., 1858–80. The most complete edition of Milton's prose works is that in Bohn's library (1848–53, 5 vols.). The best edition of the poetical works is that by Mitford (London, 1851, 8 vols.). See ENGLISH LITERATURE.

Revised by H. A. BEERS.

Milton College: a coeducational institution at Milton, Wis., connected with the Seventh-day Baptist denomination. It was opened in 1844 as an academy, and in 1867 was chartered as a college. It furnishes both preparatory and collegiate instruction in three courses of study—classical, scientific, and English. There is a department of music. The buildings, apparatus, and libraries are valued at more than $50,000. The college has a faculty of eleven. Rev. W. C. Whitford, D. D. is president.

Milwaukee: city; capital of Milwaukee co., Wis. (for location, see map of Wisconsin, 7–F): on Lake Michigan, and the C. and N. W., the C., M. and St. P., and the Wis. Cent. railways; 80 miles N. of Chicago; area, 23 sq. miles.

It is located on a beautiful bay running inland about 3 miles, stretching 6 miles from headland to headland, part of which is being converted by the U. S. Government into a harbor of refuge for the Great Lakes. The Milwaukee river flows through the main portion of the city almost due S. till it nears the lake, when it turns abruptly S. E. About half a mile from its mouth it is joined by the Menomonee from the W., and still nearer the lake by the Kinnickinnic from the S. W. The spacious harbor and miles of dockage have been utilized by numerous steamboat lines, and the most intimate connection is kept up between Milwaukee and all the important cities of the Great Lakes. The lake also furnishes Milwaukee with the cheapest kind of transportation for the iron, copper, and lumber of Northern Michigan, Wisconsin, and Minnesota, and for the great coal mines of the Middle States. Part of the city between the river and lake lies 80 feet above the bay; and on the west side of the Milwaukee river the ground rises 125 feet above the lake, furnishing most admirable locations for residences. It is a city of wide streets and commanding views, while in its residence part it is remarkable for its fine shade-trees and spacious lawns, and the absence of fences gives it the appearance of one large park. There are seven public parks aggregating 456 acres on the lake shore, Milwaukee river, and other portions of the city and suburbs. At the Soldiers' National Home, 2 miles W. of the city, there are large and expensive buildings, where 2,000 disabled veterans are cared for, and surrounding which there are 400 acres of land which are thrown open and used as a park. The county courthouse is a large structure built of Lake Superior sandstone at a cost of over $400,000. There have recently been erected a new U. S. Government building at the cost of $1,500,000, a new city hall which cost $1,000,000, and a new public library and museum building costing $600,000; also a large and well-equipped Emergency Hospital belonging to the city. The Industrial Exposition Building, where an annual exhibit is held, cost over $300,000. The Layton Art Gallery, with a fine collection of paintings, the Union Railway Station and that of the Chicago and Northwestern are tasteful and substantial structures. Among the church edifices worthy of special mention are St. Paul's Episcopal, Norman architecture; Immanuel Presbyterian, Gothic; St. James's Episcopal, Gothic; and the Church of Gesu, Gothic—the last, built by the Jesuits, is the largest and most expensive church in Wisconsin, and has two spires, one 250 and the other 200 feet high. There are over 130 churches, including 38 Lutheran, 10 Baptist, 28 Roman Catholic, 19 Methodist Episcopal, 9 Congregational, 8 Presbyterian, and 7 Protestant Episcopal. Milwaukee is the seat of a Roman Catholic archbishopric and of a Protestant Episcopal bishopric. There is a good public-school system with 50 schools and an enrollment of 33,194 pupils. The annual cost of the schools is $714,000. The Roman Catholic and Lutheran Churches have a large number of parochial schools, which, with a few other academies, have an enrollment of 21,131. There is a normal school under the regents of the State, and 3 high schools under the city school board. Milwaukee College for women was established in 1849; it is now known as Milwaukee Downer College, and has fine buildings on a beautiful site of 10 acres near the Lake Shore. The Roman Catholics and Lutherans have large colleges in the city and suburbs. The Convent de Notre Dame, the mother-house in the U. S., owns and occupies an entire square near the center of the city. The Woman's Club of Milwaukee owns a valuable property, called the Athenæum, which is used as a headquarters for the club's social, literary, and benevolent meetings. There is a large number of charitable and benevolent institutions, among which are 3 homes for the aged, and orphan asylums, 10 hospitals, 15 relief and aid associations, 50 benevolent societies of various kinds, and 2 industrial schools. There are over 100 social, literary, national, and athletic clubs, such as the Milwaukee Club, the Calumet Club, Recreation Club, St. Andrew's Society, Chess Club, Deutscher Club, Iroquois Club, Whist Club, Bon Ami Club, Old Settlers' Club, Phœnix Club, Curling Club, etc., some of which occupy costly buildings of their own. The Turner societies are strong and wealthy, and have done much to promote physical culture. Milwaukee has long been famous as a musical center, and its Musical Society, Arion Club, and Cecilian Choir have done much to raise the musical standard. Including those connected with churches, there are in Milwaukee about 50 musical societies. The valuation of the real and personal property of the city, as assessed for taxation, is $158,174,873, while the tax levy for city purposes is $3,177,313. The bonded debt of the city is $6,090,500, a large part of which is for the water-works, which the city owns and from which it derives a handsome revenue. There are 7 daily, one of which is in the Polish language, 5 semi-weekly, 36 weekly, 5 semi-monthly, and 15 monthly periodicals. There are 2,572 manufacturing establishments, employing $106,594,752 capital and 60,455 persons, paying annually $28,871,313 for wages, and receiving $158,136,847 for products. The greatest number of hands employed is in the manufacture of iron, steel, and machinery, then follow leather, clothing, beer, knit goods, stoves, tinware, and furnaces, car-building, iron and steel, furniture, malleable iron, brick, and meat-packing. The annual values of the chief productions are: Iron, steel, and machinery, $17,398,774; beer, $15,418,000; packed meats, $14,391,488; leather, $12,424,526; malt, $6,476,251; clothing, $5,136,600; tin, $4,296,477; malleable iron, $4,157,700. The healthfulness of the city has improved every year, and now the annual deaths number but a fraction over 13·88 per 1,000. The sewers emptying into the Milwaukee river at one time were sources of disease, but a tunnel has been constructed from the lake to the river above the city, and now the water of the river is kept pure by being flushed continually from the lake. Milwaukee has one of the best electric street-railway systems in the country, connecting all parts of the city

with each other and with the neighboring towns and villages. Pop. (1880) 115,578; (1890) 204,468; (1895) 249,290; (1900) 285,315. JOHN JOHNSTON.

Mīmāṁsā: a Sanskrit word signifying "discussion"; its common use is to designate the Hindu philosophical system of Jāimini, and in this sense it is an abbreviation for *Pūrva-* or *Karma-mīmāṁsā*, "Prior discussion" or "Discussion concerning religious observances," as distinguished from the Vedānta system, which is otherwise known as the "Later discussion" or "Discussion concerning Brahman," the *Uttara-* or *Brahma-mīmāṁsā*. In both systems the subjects of the ancient Brahmanical speculations are methodically elaborated, and the two thus form a coherent whole in so far as the first is practical and the second theological: the first, a system of ritualistic precepts; the second, in connection with the idealistic monism of the older Upanishads, a doctrine of salvation by knowledge. The two systems refer each to the other, and are accordingly doubtless of synchronous origin. That the Mīmāṁsā is reckoned as one of the six Indic philosophical systems is due chiefly to this connection with the Vedānta, and, secondarily, also to the form of its discussions (see below).

The aphorisms of Jāimini, called the Mīmāṁsā-sūtras, form the oldest and most important work of this school. Like the sūtras or aphorisms of the other systems, they are so brief and obscure as to be quite unintelligible without a comment. Their most famous commentator was Çabara-svāmin, who wrote not long after the birth of Christ (Bühler's *Manu*, p. cxii.). The composition of our sūtras—and accordingly also of the Vedānta-sūtras—may be referred to the beginning of our era or to a date a little earlier.

The purpose of the Mīmāṁsā is to give the rules for the interpretation of the Vedic texts that concern themselves with the Brahmanic ritual; but these texts do not set forth the ceremonies completely and clearly, and they are everywhere mingled with discussions of the mystic significance of this or that sacrificial act or utensil; and the Brahmanical sacrificer was taught to expect the most dreadful consequences from the smallest mistake in the performance of his ceremonies; he therefore had a real need for such a compendium as the Mīmāṁsā-sūtras; for these attempt to resolve all doubts respecting the details of the sacrifice, and to reconcile the contradictions of the Vedic texts—contradictions which really exist, but which are, according to the Mīmāṁsists, only apparent. Moreover, as this system treats of the rewards held out for the correct performance of the sacrifices, it has become an epitome of the lore of the Brahmanical scriptures.

The existence of God is not recognized by the Mīmāṁsā; but this fact does not interfere in the least with the belief in the deities of the Indic popular religion; in all the Indic systems, in fact, the gods are merely beings who, by merit won in previous existences, have raised themselves in the scale of being to a divine rank in which they are loftier and happier than men; but they are not immortal; the after-effect of their merit once exhausted, they are liable to shift to other and lower forms of existence. If, in the absence of a divine source of revelation, accordingly, we ask upon what authority the doctrine concerning sacrifices and their results may rest, the Mīmāṁsists reply: "Upon the *Veda*; and the *Veda* needs no ulterior authority, being itself eternal and uncreated; and treats only of things that have existed from all eternity, and that carry their own proofs with them."

The Mīmāṁsā is not of a properly philosophic character; its inclusion among the six philosophical systems, Vedānta, Sānkhya, Yoga, Nyāya, Vāiçeshika, is due in part to the form of its exposition. The contents of the *Veda*, e. g. are classified in certain definite categories: (1) Positive precepts; (2) texts and formulas; (3) names of ceremonies; (4) prohibitions; (5) explanatory statements of acts enjoined or forbidden. Further, the discussions proceed in a manner that presupposes an advanced state of the study of logic. The established scheme contains five members: (1) Proposition; (2) doubt of its correctness; (3) false view of the subject; (4) refutation of the same by the correct argument; (5) result of the discussion. Moreover, for the establishment of Mīmāṁsā doctrines, really philosophical questions are sometimes discussed. Most notable is the discussion of the eternity of sound, and of the question whether the connection of sound and sense is natural (*φύσει*) or conventional (*θέσει*). (See Ballantyne, *Christianity contrasted with Hindu Philosophy*, London, 1854, pp. 176–195.) The doctrine of the sources of knowledge is so treated in the Mīmāṁsā that a greater number is recognized than in the other five systems—namely, perception, inference, authoritative tradition, analogy, self-evidence, and several others.

Dr. Fitzedward Hall, in his *Contribution toward an Index to the Bibliography of the Indian Philosophical Systems* (Calcutta, 1859), enumerates eighty-five Sanskrit works on Mīmāṁsā. In India, next to Jāimini and Çabara-svāmin, the most esteemed authority upon Mīmāṁsā was Kumārila-svāmin, who wrote his glossary to Çabara-svāmin's comment at the beginning of the eighth century. The Mīmāṁsā-sūtras were published with the commentary in the *Bibliotheca Indica* (2 vols., Calcutta, 1873–85); a good modern compendium, the *Jāiminīya-nyāya-mālā-vistara*, was edited by Th. Goldstücker (London, 1865), and by Pandit Çivadatta in the Ānandāçrama Sanskrit Series (Poona, 1892).

Although the Mīmāṁsā doctrines have been of great importance for the intellectual and religious life of India, the system has never been an attractive one for Occidental students. In 1826 H. T. Colebrooke published his essay on the Mīmāṁsā (reprinted in his *Miscellaneous Essays*, London, 1873); and this was the only treatise of the subject published in a modern European language and worth mentioning until the appearance of G. Thibaud's edition and English translation of the *Artha-saṁgraha* (Benares Sanskrit Series, 1882). This translation and the introduction thereto constitute the best English account of the principal contents of the system. R. GARBE.

Mime [from Lat. *mīmus* = Gr. *μῖμος*; cf. *μιμεῖσθαι*, imitate, mimic]: a development of the Sicilian farce. The word is still used as a synonym for an actor on the mimic stage. In its special application the mime represents the imitation of a definite situation or a typical character, and differs from the antique comedy of the early period by the lack of a chorus and the lack of an elaborate plot. The credit of introducing the mime into literature is ascribed to Sophron, who flourished in Syracuse about the middle of the fifth century B. C., and whose influence on the form of Plato's dialogues is a matter of literary tradition. The dramatic idyls of Theocritus doubtless owe much to Sophron's pattern, and some of the dialogues of Lucian may be called mimes, but the whole department has been brought nearer to us by the recent discovery of the *mimiambi* of HERONDAS (*q. v.*). In Rome the mime was early popular. It was introduced from Sicily by way of Magna Græcia, and developed from a rude ballet in character until it ceased to be a mere intermezzo, absorbed the comic elements of the *fabulæ Atellanæ*, and became a regular afterpiece. The height of the mime was reached in the time of Cæsar, and Decimus Laberius and Publilius Syrus are its most distinguished representatives. For an interesting description of the Roman mime, see Ribbeck, *Geschichte der römischen Dichtung*, vol. i., p. 220 foll. B. L. GILDERSLEEVE.

Mimicry: the general fact of imitation. The word is used in several more technical senses.

Mimicry in Biology.—Biologists recognize under this phrase a great class of cases of close resemblance in form, color, or habits, between insects or animals, and even between these and inanimate objects, which serve to render these creatures indistinguishable by friend or foe. In their coloration, insects—butterflies are a notable example—take on the colors of various flowers, leaves, mosses, etc., and thus avoid detection; or the colors of poisonous insects, and so share their immunity; or the shape of harmless knots, twigs, etc., and so escape attention; or the colors of conspicuous things, and so attract their mates and victims. The phenomena, of which these instances are only examples, fall thus into two classes—*protective mimicry*, the animal escaping his enemies by these deep-going organic subterfuges, and *aggressive mimicry*, the animal deceiving others thus to support himself and to destroy his enemies. Taken together the facts furnish a convincing proof of the evolution process; for no explanation is adequate except that afforded by the law of natural selection. See EVOLUTION.

Mimicry in Psychology.—In psychology the term is applied to all cases of imitation of one being by another in which the mental state of the imitator is in a measure involved. There is (1) *expressive mimicry*, referring to all the facts of organic pantomime by which one creature expresses himself by gestures, movements, etc., which another understands and responds to. It is probable that the imitations of monkeys, parrots, etc., had their origin in such a common

tendency to become gregarious by getting rudimentary forms of expression, the original movements being useful either to the individual or to the flock. Men show the same tendency to pantomime, as is seen clearly in idiots, imbeciles, and diseased persons. The loss of this gesture imitation is called *amimia* by the pathologists. Looked at theoretically as a kind of imitation, it is nearest the biological type. (2) *Conscious mimicry*, ordinarily called "conscious imitation." It applies to the fact of an innate tendency to imitate movements, actions, etc., seen early in infants. (3) *Social mimicry*, the tendency so universal and so binding upon us all to act, believe, think, dress, etc., as custom, habit, and social life dictate. These influences are summarized under the phrase "social suggestion." (See IMITATION and SUGGESTION.) On biological mimicry, see Poulton, *The Colours of Animals* (London, 1893), and on psychological mimicry, Tarde, *Les Lois de l'Imitation* (Paris, 1892).

J. MARK BALDWIN.

Mimo'sa [Mod. Lat., from Gr. *μῖμος*, imitator, mimic. So called from its imitating animal sensibility]: name of a genus of leguminous trees, shrubs, and herbs which gives name to the great sub-family *Mimoseæ*, distinguished by having regular flowers. The genus includes at least ten species which have decidedly sensitive leaves. (See SENSITIVE PLANT.) Of these, the *Mimosa pudica* is the most remarkable, and the only one familiar in cultivation. Most of the numerous species are tropical, many are African, many American, of which no less than fifteen occur in the southern and southwestern parts of the U. S.

Min: an Egyptian deity, worshiped principally at Koptos as the patron of travelers through the Hammamat valley to the Red Sea, and guardian of the Hammamat quarries. He was primarily regarded as the god of the desert, but the Greeks identified him with Pan. C. R. G.

Mi'na [= Lat., from Gr. *μνᾶ*, a measure of weight (originally Assyrian), a weight of silver, a sum of money; cf. Heb. *māneh*, a weight, *mina*, deriv. of *mānāh*, divide, measure out]: in Greek money and weights, a standard equivalent to 100 drachmæ and forming the sixtieth part of a talent. The value varied according to the talent used. (See TALENT.) The Attic mina is generally stated to have been worth $17.61 U. S. money; it was a money of account, and was not coined. Revised by J. R. S. STERRETT.

Mina, mee'năă, FRANCISCO ESPOZ Y: soldier and revolutionist; b. at Ydoein, near Pamplona, Spain, July 17, 1782; joined his nephew (see MINA, FRANCISCO JAVIER) in 1809 in organizing the mountaineers into guerrilla bands to oppose the French invasion. In the following year he succeeded to the command, and soon became the most efficient of the numerous partisan leaders of Northern Spain. In 1812 he received a commission as general, and was appointed commander-in-chief of Aragon; became "political chief" of Navarre 1813; contributed to the victories of Salamanca and Victoria; blockaded Pamplona 1812–13, and retired to private life on the restoration of Ferdinand VII. The despotic measures of that king, however, induced the two Minas to head an insurrection, but, having failed in an attack upon the citadel of Pamplona, Sept. 25, 1814, he sought refuge in France. In 1820 he took part in the constitutional revolution of Riego, becoming captain-general of Navarre; suppressed the royalist insurrection in Catalonia 1822; became captain-general of Catalonia Jan., 1823; capitulated to the French at Barcelona Nov. 1, 1823, and proceeded to England. In 1830 he was again engaged in an unsuccessful revolt against Ferdinand VII. in Navarre, and again escaped to England. In 1834 he was recalled to Spain to defend the liberal government established in the name of the young Queen Isabella against the Carlists, and took command of an army corps, but with indifferent success. Resigning in 1835, he died at Barcelona, Dec. 24, 1836.

Mina, FRANCISCO JAVIER, nephew of Francisco Mina: soldier; b. at Otan, near Monreal, Navarre, Dec. 3, 1789. He studied for the priesthood, but in 1808 headed a band of guerrillas against the French; was captured by the latter in 1810 and remained a prisoner until 1814, when he joined his uncle against Ferdinand VII. and was driven with him over the border into France. Thence he went to England and the U. S. to obtain subscriptions and recruits for an expedition in aid of the patriots in Mexico. With 200 men he landed at Galveston, Tex., in Nov., 1816, but was soon forced to retire. At New Orleans he organized a fresh force; landed in Tamaulipas, Apr., 1817, and at the head of less than 500 men fought his way into the center of Mexico. He showed great courage and generalship, and repeatedly defeated the Spanish forces; his generous policy won him many adherents, and his force increased to nearly 2,000 men. The movement was badly timed, however; the Mexican patriots were disheartened at this period by the crushing reverses which they had undergone; the support which they might have given to Mina was withheld, and his recruits gradually fell away. After sustaining himself for some months in Guanajuato, Mina was captured by surprise, and was tried and shot before the fort of Los Remedios, where some of his adherents still held out, Oct. 27, 1817. The fort was taken by the Spaniards in Jan., 1818, closing this episode of the Mexican revolution. See Bancroft, *Hist. of the Pacific States* (Mexico, vol. iv., p. 659); Robinson, *Memoirs of the Mexican Revolution* (1820). HERBERT H. SMITH.

Mi'na Bird [also *mina*, from Hind. *mainā*, starling, mino]: a member of the starling family (*Sturnidæ*) common in Southern India; its scientific name is *Gracula religiosa*. It is about 10 inches long, of a glossy purplish black, with a white patch on the primaries. A curious wattle on each side of the head, back of the eye, is orange colored; the bill and feet are yellow. It is very lively and intelligent, and when trained is considered the best talker among the birds, far surpassing any parrot. It is also a good singer. Allied species occur in Ceylon, Burma, and some parts of the Malay Archipelago. F. A. LUCAS.

Minaev, mĕĕ-naa'yef, DMITRIĬ DMITRIEVICH: poet, son of Dmitriĭ Ivanovich Minaev (1808–76), likewise a poet, though of little importance; b. in Simbirsk, Russia, Oct. 21, 1835. For a number of years he contributed to different papers and reviews humorous or satirical pieces, attacking the abuses of society with all the vivacity that characterized the Russian writers of the great reform period (from 1860 to 1870). He will, however, rather be remembered for his numerous translations from foreign authors, among others the *Ruy Blas* and *Hernani* of Victor Hugo; Marlowe's *Faust*; Byron's *Childe Harold*, *Don Juan*, and *Manfred*; Shelley's *Prometheus Unbound*, etc. A. C. COOLIDGE.

Minard, CHARLES JOSEPH: engineer; b. at Dijon in 1781; was educated at the École Polytechnique, and entered the administration of Ponts et Chaussées in 1800. He became division inspector in 1839, inspector-general in 1846, and retired in 1857. Among his numerous works were *Cours de construction des ouvrages qui établissent la navigation des rivières et des canaux* (1841); *Notions élémentaires d'économie politique appliquées aux travaux publics* (1850); and *Des embouchures des rivières navigables* (1855). He also published numerous pamphlets on technical questions relative to transportation. D. at Bordeaux, Oct. 24, 1870.

Minaret [from Span. *minarete*, from Arab. *manārat*, lantern, lighthouse, turret, deriv. of *minār*, candlestick, lamp, lighthouse; cf. *nār*, fire, and *nawwir*, illumine]: the slender, lancelike shaft of brick or stone which rises from close outside one of the corners of a Mussulman mosque. It terminates far above the roof in a tapering cone, and is ascended from inside by a very narrow spiral staircase. At varying heights it is surrounded by one or more projecting galleries, whence the MUEZZIN (*q. v.*), protected by a parapet or railing, calls to prayer. Many minarets are most graceful, ethereal structures, and the conception—considering the fact that they are used especially in countries often convulsed by earthquake—is one of the most daring in architecture.

E. A. GROSVENOR.

Minas, mee'năăs: an inland department in the southern part of Urnguay, surrounded by Treinta Tres, Rocha, Maldonado, Canelones, and Florida. Area, 4,230 sq. miles; pop. (1891) 23,466. The surface is much broken, and, in the N., mountainous. The name (meaning mines) refers to its supposed mineral wealth, but no mines have been successfully worked: cattle-raising and, to a small extent, the cultivation of grains are the only industries. The population is said to be very lawless. Minas, the capital and chief town, was founded in 1783, and has a population of about 5,000. H. H. SMITH.

Minas Geraes, mee'năăs-*zhā*-raa'*ās*: a state of Brazil; lying inland from the southeastern coast; surrounded by Bahia, Espirito Santo, Rio de Janeiro, São Paulo, Matto Grosso, and Goyaz. Area, by the best attainable estimates, 211,917 sq. miles. The principal mountain ranges are the Serra do Mar, on the eastern boundary; the Serra da Mantiqueira, running northward through the middle of the

state; the Serra da Canastra, on the W.; and a cross range, the Serra das Vertentes, joining the Mantiqueira and Canastra chains and separating the head waters of the rivers São Francisco and Paraná. Itatiaia, the highest peak in Brazil (8,900 feet), lies at the extreme southern angle; and there are several other points over 5,500 feet high. Between the mountains, especially in the western part, there are lower, rolling or hilly lands, properly extensions of the Brazilian plateau. The region between the Canastra and Mantiqueira ranges is drained by the upper part of the river São Francisco, which rises in this state; it consists mainly of open lands suitable for grazing, which is the principal industry, is thinly populated, and is still one of the most neglected parts of Brazil; but it has great natural capabilities, and since the opening of navigation on the upper São Francisco it has given promise of rapid development. (See São Francisco.) The mountainous northeastern region contains large areas of untouched forest lands, rich in valuable woods, but as yet almost unknown except to roving Indian tribes. The principal rivers are the Jequitinhonha and Doce. By far the greater part of the population is gathered in the southern part, where, among the mountains, there are many fertile valleys and slopes, well adapted for coffee-culture; this is now one of the great coffee-producing states. Southern Minas Geraes has a good system of railroads, connecting with those of São Paulo and Rio de Janeiro. Coarse cotton cloths, beer, saddlery, etc., are manufactured on a considerable scale. The captaincy of Minas Geraes was separated from Rio de Janeiro in 1709. As the name indicates, it was long noted for its mines, especially its gold and diamond washings. It is still the principal mining state in Brazil, but only a few of the gold deposits are profitably worked, and diamond-mining is nearly abandoned. The quartz crystals called Brazilian pebbles, largely used in the manufacture of spectacles, etc., are obtained from this state; sapphires and rubies are found in conjunction with the diamonds, and many other valuable minerals have been discovered, but not extracted on a large scale. Pop. (estimated, 1894) 3,604,622. Capital, Ouro Preto. See Saint-Hilaire, *Voyage dans les provinces de Rio de Janeiro et de Minas Geraes* (1830); Gerber, *Noções geographicas e administrativas da provincia de Minas Geraes* (1863); Burton, *Explorations of the Highlands of the Brazil* (1869). Herbert H. Smith.

Mincio, min'ehō: a river of Northern Italy which issues from the southern extremity of Lake Garda, passes by Mantua, and joins the Po 8 miles below this city after a course of 50 miles. It is navigable for barges from its union with the Po to Mantua. Its waters are much used for irrigation.

Minckwitz, Johannes: poet and philologist; b. at Lückersdorf, Lusatia, Jan. 21, 1812; studied at Leipzig; became professor extraordinary in the University of Leipzig in 1861. He published *Lehrbuch der deutschen Verskunst* (1844; 6th ed. 1878); *Gedichte* (1847); *Taschenwörterbuch der Mythologie aller Völker* (1852; 6th ed. 1883); *Lehrbuch der rhythmischen Malerei der deutschen Sprache* (1855); *Der illustrierte neuhochdeutsche Parnass* (1860); *Der Künstler* (1862); *Vorschule zum Homer* (1863); *Die Weisen des Morgenlands* (2d ed. 1865); *Dem neuen Kaiser* (1871). D. in Heidelberg, Dec. 29, 1885.

Mind [O. Eng. *mynd*, *gemynd*: O. H. Germ. *minna*, memory, love: Goth. *gamunds*, memory; cf. Lat. *mens*, *men'tis*, mind, Gr. *μένος*, mind, strength of spirit, Sanskr. *man*, think]: as contradistinguished from *matter*, free, self-determined being; hence it exists in the form of atomic individuals, and not, as is the case with matter, in that of mere mechanical or quantitative aggregates. Wherever we observe activity which is in conformity to an end or purpose, we attribute it to mind. Mind contemplates its potentiality or lack or need in the form of an idea, and uses means to realize it, while material things, although having potentialities, do not act with conscious purpose. Taken generally, material things are limited or constrained from without—conditioned through others—while spiritual beings are always free and self-conditioned, at least formally, originating their own limitations, first as ideas or purposes theoretically, and then realizing them by practical activity or will. Pure matter, devoid of all self-determination, is perhaps mere empty space—pure chaos; pure mind or absolute self-determined being is God. Between these ultimates lie the world of nature and that of man, the former containing material beings that manifest various degrees of self-determination—from the crystal through the plant up to the animal; the latter containing the world of man or human history, which is the revelation of self-determination or mind in its progressive emancipation from matter, the humblest human soul being immortal and potentially free, though involved in manifold external complications with circumstance. Historically, it was Anaxagoras who first announced mind (*νοῦς* = reason) as the simple self-existent essence of things, that which sways matter. Besides this general signification of the term *mind*, in which it is a synonym of spirit, and corresponds to the German term *Geist*, including the several activities of feeling, volition, and thought, the word mind is used in a narrower sense to imply only the theoretical activity or the Intellect—the activity of cognition. Aristotle's *ψυχή* is identical with mind in the first-mentioned sense, if we interpret it as including the *νοῦς ποιητικός*. In the second book of the *De Anima* in his careful manner he defines soul (*ψυχή*) to be "the first entelechy of a physical organic body having life potentially." By "first entelechy" he means a self-determining or free being in its undeveloped first stages, when it *has* not unfolded, but *may* unfold, its capacities—hence a formally free being; the "second entelechy" is the actually self-developed free being. According to this definition, soul would seem to be correlative of body. But he proceeds in the third book to describe the creative reason (*νοῦς ποιητικός*) as possessing independent and eternal existence apart from body, thus apparently making the term soul apply to God as well as to mixed earthly natures. In opposition to the theory of the speculative philosophers and theologians, represented by such names as Plato, Aristotle, Leibnitz, Hegel, St. Augustine, Thomas Aquinas, Duns Scotus, and Meister Eckhart, the materialists repudiate the co-ordination of mind with matter, or the subordination of matter to mind, and explain mind as a function of matter. Psychology with them, accordingly, falls into a department of physiology. From Democritus and Empedocles, and their gifted expounder Lucretius, down to Hartley and Bain, this unpopular doctrine has found in every age its hardy advocates. Physiological investigations into the conditions under which mind is active in its various phases have doubtless been of great benefit to psychology, and more is to be expected from this source in the future. Notably, in certain practical spheres—for instance, in the medical treatment of the insane—we have profited by adopting the physiological theory. John Stuart Mill, holding the doctrine of sensation as the original form of mental activity, defines matter to be "the permanent possibility of sensation," and likewise mind to be "a series of feelings with a background of possibilities of feeling"—definitions which point toward Berkeley's theory of immaterialism. Another class of thinkers are found in open hostility to the theological and speculative view first mentioned, although they do not adopt the physiological view of mind. The early commentators of Aristotle were divided—some, like Themistius, holding that individual men are immortal; others, like Alexander Aphrodisias, holding that only God is immortal; the lower faculties of the soul, memory, feeling, the discursive intellect, etc., called by Aristotle the passive reason (*νοῦς παθητικός*), are mere dispositions connected with the animal faculties, and therefore perishable with the body. The creative reason (*νοῦς ποιητικός*) was conceded to be immortal and independent of matter, but only as One, the deity or the world-soul, while men, who participate in this pure activity, lose their individuality at death with the lapse of sense-perception, memory, reflection, fancy, etc., which furnished the individual attributes. The adoption by Averroës of this doctrine, subversive of all claims on the part of man as man to essential participation in the divine life, made an epoch in the history of thought. The dangerous predicament of the Church upon the revival of learning, and the study of Aristotle through Arabian commentary and translation, aroused the mightiest thinkers of the period of scholasticism, and Christian theology at length settled its dogmas upon a firm foundation beyond the power of the subtle metaphysics of the Arabians. The great question regarding mind was this of the relation of the particular individual to the universal soul; and there is no second problem of equal importance to man.

The philosophy of mind must verify its theories by their application to the interpretation of human institutions. The nature and destiny of mind is revealed in those gigantic products of the united endeavor of entire peoples—the work of the will rather than of the intellect, embodied in the state, the Church, civil society—with unmistakable tracings, while the scientific theories, born of individuals, are the field

of interminable disputes. Psychology as a science has been taken by some to include the entire realm of the philosophy of mind; by others it has been understood to include only the subjective manifestation of mind, or, still more limited, the self-conscious phase of it. (See PSYCHOLOGY.) An outline of the entire philosophy of mind as treated by one of the most comprehensive and profound of modern thinkers includes the following departments; A. Subjective Mind falls under three heads—I. Anthropology, or the science of those phases of mind beginning with its enthralment in nature and its struggle for individuality; these are (*a*) the peculiar qualities and processes arising from race, climate, age, sex, sleep, sensation, passions, etc.; (*b*) feeling, the interaction between consciousness and the unconscious life of instinct, ideas for the most part remaining obscure and in the form of mere impulses; (*c*) symbolism and language, the mind creating for itself a conventional medium in which it fixes the products of its thinking activity for the sake of communication, combination of the individual with the race, and self-contemplation. The human mind thus frees itself from animal impulse and elevates itself to consciousness. II. Phenomenology of mind is the science of the process by which mind comes to recognize free self-determining intelligence as the presupposition and logical explanation of the objective world. It begins (*a*) with the consideration of immediate consciousness of objects, and traces the history of its (*b*) discovery of their relativity and the origin of their properties and attributes in their mutual relations, until (*c*) it arrives at the conviction that the objects of sense-perception are mere phases or manifestations of forces which are in a state of perpetual transition into each other, originating and annulling individual things, leaving no permanent material beings, but only an abstract internal power, of which the phenomenal world is a manifestation. The thought of a genesis of difference and distinctions from an abstract force in which all concrete distinctions have vanished is the thought of a self-determining or self-duplicating entity, a manifestation by means of self-opposition; and this radical idea that underlies the thought of force is the idea of a universal that exists as a particularizing process. Here may be recognized the thought or concept of the personal Ego or of mind. Hence all distinctions among objects in the outer world are traced ultimately to mind as their Creator, and this investigation has found the substance underlying objects and identified it with the Ego or a thinking subject. III. Psychology, considered as a special department, is the science of mind as subject; it considers the subjective factor of knowledge and investigates its forms. It treats (*a*) of theoretical mind as sense-perception, representation and pure thought; (*b*) of the emotional activity of mind; (*c*) of the practical activity, or the will. B. Objective Mind includes the world of human history and the organized institutions of man—(*a*) the family, (*b*) civil society, (*c*) the state. C. Absolute Mind (*νοῦς ποιητικός*) includes (*a*) the phase of manifestation of the divine mind to sense-perception in the form of the beautiful in art; (*b*) the revelation of the divine to the will in the form of the good as set forth in religion; (*c*) the systematic exposition of the divine mind as the ultimate truth in the form of science, culminating in theology or philosophy.

WILLIAM T. HARRIS.

Mindanao, min-dăă-naa′ō: the southeasternmost of the Philippine islands, the largest next to Luzon, and the least known; between 5° and 10° N. lat. and 122° and 126° E. lon. It is shaped like a calabash, with the handle to the W. and the mouth to the N. It is a part of the old Spanish colony of the Philippines. Area, 37,500 sq. miles. The census of the population submitted to Spain gave in 1887 a count of 209,086. The independent population is much larger, and is estimated at 400,000, giving a total of about 600,000, or 160 per sq. mile. It is the most densely populated of the group. The surface is very mountainous; the highest known mountain is Apo, near the Gulf of Davao, on the south coast; height, 10,300 feet. The very numerous volcanoes, though essentially modern, as shown by the lavas, are now inactive. Earthquakes are very frequent, but generally slight, though very destructive ones sometimes occur. The island is rising along the western coast. Streams and lakes are numerous, but generally small. The Palangui or Grande carries 2 fathoms for 80 miles from its mouth. There is a dry and wet season each year, but their occurrence depends on the topography. The southwestern slopes are wet and the northeastern dry during the southwest monsoon, and the reverse for the northeast monsoon. During the wet season local storms are frequent, and typhoons occasionally, though rarely, pass over the island. The soil is extremely fertile. The surface is closely covered with fine forests abounding in useful woods, resins, and gums. The fauna is tropical and rich. A rare and little-known species of wild cattle exist in swamps in the interior which have the same appearance for cattle that the turnspit has among dogs. The inhabitants are negritos, the aborigines, few in number, generally vagabonds, sometimes slaves; Infedels, under which the Spaniards included the independent interior tribes, Indonesian, resembling the Dyaks and Battas, wild, man-hunters, but scrupulously honest, numbering about 300,000; Malays, along the coast, especially on the S. E., N. W., on the interior lakes, and in the valley of the Grande; Mohammedans, predatory, resembling the inhabitants of the Sulu islands, submissive along the coast, but independent inland, numbering about 100,000; Visayas, who are submissive, Catholics, the descendants of native colonies from the Visaya islands, numbering 120,000; and the Chinese, who are increasing rapidly in number, are scattered along the coasts and in the towns, and are devoted to agriculture and trade. The Spaniards are few in number, mostly at Zamboanga, a fortress and the end of the handle. This island was the first of the Philippines seen by Magellan (1521), and since that date Spanish conquest had been under way with varying success. The most difficult peoples to deal with are the Malays. See PHILIPPINES in the Appendix.

MARK W. HARRINGTON.

Mind and Body: See the Appendix.

Mind-cure: the cure of bodily ailments through mental influences without use of medicines or other treatment. The influence of mind on body is now recognized to a degree in therapeutics; but no systematic or scientific formulation is yet possible. The therapeutic uses of HYPNOTISM (*q. v.*) show that the dwelling of the attention upon certain ideas tends to bring about the usual physical effects. This is now known as SUGGESTION (*q. v.*), and extends to all mental conditions to some degree. It is only an aspect of this general fact that strong belief in certain physical effects, predicted and strongly suggested by another, should have some influence in producing them, especially in minor functional and nervous troubles. It should be distinctly understood, however, that reputable physicians will have nothing to do with any mind-cure which is based on appeals to credulity or professes to go beyond the slight moral influences auxiliary to regular medical treatment. The various forms of mind-cure exploited under the names of "Christian science," "personal magnetism," "cure by will power," etc., are, apart from the slight suggestive influence mentioned, nothing short of frauds; and the case is made worse when it is remembered that the professors of such power are usually either schemers, who make money by preying upon the credulity of others, or enthusiasts of too little medical information to know one disease from another.

J. MARK BALDWIN.

Mindeleff, COSMOS: archæologist; b. in 1863 of Russian parents, who settled in the U. S. in 1861. His father, Dimitry Mindeleff, had more than a national reputation as a chemist and inventor. The son graduated at a private school at the age of fifteen, and at once engaged in business. In 1882 he became connected with the bureau of ethnology, and since that time has been engaged in the study of the aboriginal architecture of the pueblo region. In 1886 he published the first description of the snake-dance of the Tusayan (Moki) Indians that appeared in a scientific publication. In collaboration with his brother Victor he took part in the preparation of a report on pueblo architecture, which was the first comprehensive and scientific treatment of that subject. This appeared under the title *A Study of Pueblo Architecture: Tusayan and Cibola*. In 1891 he prepared plans for the repair and preservation of the famous Casa Grande ruin in Arizona. He published the first report on aboriginal remains in the valley of the Rio Verde, Arizona. He is perhaps best known as a modeler of archæologic and topographic subjects.

J. W. POWELL.

Minden: town; in the province of Westphalia, Prussia; on the Weser; 40 miles W. of Hanover (see map of German Empire, ref. 3–E). It is an old town, closely built, with few open places or interesting buildings. The Roman Catholic church, however, has a tower which dates back to the eleventh century, and illustrates the first stage in the development of the Gothic spire. The town was formerly

strongly fortified, and has been the scene of some hard fighting; now the place of its fortifications is occupied by manufacturing suburbs. It has manufactures of soap, chemicals, glass, tobacco, beer, brandy, and hosiery. Pop. (1891) 20,223.

Minden: city (founded in 1876); capital of Kearney co., Neb. (for location of county, see map of Nebraska, ref. 11–E); on the Burlington Route and the St. Jos. and Gr. Is. railways; 128 miles W. of Lincoln. It is in an agricultural region, and contains 8 churches, 2 public-school buildings, wagon and milling works, and 3 weekly newspapers. Pop. (1880) 98; (1890) 1,380; (1900) 1,238.

EDITOR OF "GAZETTE."

Mindo'ro: one of the larger of the Philippine islands; S. and W. of Luzon; on the China Sea; in lat. 13° N., lon. 121° W.; area, 3,800 sq. miles; pop. estimated at 40 per. sq. mile, or 150,000. The Spanish domination is limited to a narrow strip of coast, and the interior is perhaps the least known of the group. It has suffered much from the depredations of the Sulu pirates. M. W. H.

Mind-reading: See MUSCLE-READING and HYPNOTISM.

Mincola: town; Wood co., Tex. (for location of county, see map of Texas, ref. 2–J); on the Int. and Gt. N., the Mo., Kan. and Tex., and the Tex. and Pac. railways; 77 miles E. of Dallas, 110 miles W. of Shreveport, La. It is in a cotton-growing region, is an important commercial distributing point, and has a high school, private bank, and two weekly newspapers. Pop. (1880) 1,175; (1890) 1,333; (1900) 1,725.

Mineralogy [Lat. *minera'lis*, pertaining to a mine, mineral (deriv. of *mi'nera*, mine) + Gr. λόγος, discourse, reason]: the science which treats of the chemical and physical properties, relations, occurrence, and classification of minerals; the word *mineral* denoting any homogeneous, inorganic, natural product, not gaseous, and not the immediate result of organic processes. A mineral may be the indirect and altered product of organic life, like coal, which results from the alteration of the once organic wood, or amber, which is an altered vegetable resin; but fossil bones, shells, etc., are not to be classed as minerals. Minerals are distinguished by their chemical properties, their form, structure, luster, color, hardness, specific gravity, etc.

Chemistry.—The exact composition of a mineral is ascertained by quantitative analysis; the nature of its constituents by qualitative analysis, the blowpipe reactions being especially useful in determining minerals, from their simplicity and certainty. Every one of the elements occurs in the mineral kingdom, and a mineral may consist of one element or of a combination so complex that no present system of chemical notation will give a satisfactory representation of its composition. Like any other chemical compounds, minerals are to be regarded as combinations of atoms and molecules, and in writing the formulas for these the ratios of the elements present are calculated in three ways. The *atomic ratio* is the ratio between the number of atoms; thus for the aluminium, silicon, and oxygen in Al_2O_3,SiO_2 it is 2 : 1 : 5. The *oxygen ratio* is the ratio between the number of atoms of oxygen in the different oxygen compounds present. In Al_2O_3,SiO_2 the O ratio of the Al_2O_3 and SiO_2 is 3 : 2. The *percentage ratio* is the number of parts in 100, and is deduced from the ratio between the atomic weight of the compound and that of each constituent. The atomic weight of Al_2O_3 is 51·5 (old system); of O_3 it is 24; hence 51·5 : 100 : : 24 : 46·6, the percentage of oxygen. For Al_2 (at. wt. = 27·5) we have 51·5 : 100 : : 27·5 : 53·4, the percentage of aluminium. The at. wt. of Al_2O_3,SiO_2 is 81·5, and that of SiO_2 is 30; hence 81·5 : 30 : : 100 : 36·8, the percentage of SiO_2 in the compound. The atomic ratio of the constituents may be calculated from their percentage ratio by dividing the latter by the atomic weight of each constituent. In Al_2O_3 the percentage ratio of Al and O is 53·4 : 46·6; hence $53{\cdot}4 \div 13{\cdot}75 = 3{\cdot}93$, and $46{\cdot}6 \div 8 = 5{\cdot}82$, from which we obtain the ratio 3·93 : 5·82, or nearly 2 : 3, the atomic ratio of the aluminium to the oxygen. The ratio of any constituents in a compound may also be obtained by comparing the amounts of oxygen in the percentages of the constituents. Thus in Al_2O_3,SiO_2 the percentage of $SiO_2 = 36{\cdot}8$, of $Al_2O_3 = 63{\cdot}2$. In 100 of SiO_2 there are 53·33 of oxygen; hence $36{\cdot}8 \times {\cdot}5333 = 19{\cdot}625$; 100 of Al_2O_3 contain 46·6 O; hence $46{\cdot}6 \times {\cdot}632 = 29{\cdot}45$; then 19·625 : 29·45 : : 2 : 3, and since SiO_2 contains 2O and Al_2O_3 3O, the result shows that the compound contains one of silica and one of alumina, or has the formula Al_2O_3,SiO_2. The atomic ratio is therefore of use in obtaining the formulas of minerals.

Compounds containing two kinds of elements are called *binary*, and one element is regarded as negative to the other. A *ternary* compound contains three kinds of elements, which are so combined as to form a base and an acid. Thus MgO,SiO_2 contains the base of MgO and the acid SiO_2, or the *basic* element Mg, the *acidic* Si, and the *acidific* O. The *replacing power* of the elements is in proportion to their combining power, reckoned in number of atoms of the acidific element, oxygen, sulphur, or whatever it may be. In accordance with this principle, if R represent any basic element, $R_{\frac{2}{3}}O$ may be written for R_2O_3, and may then replace RO in a compound.

According to the new system of chemistry, in the formulas of ternary compounds the acid and base are not written separately, as $2MgO,SiO_2$, but the symbol of each element is written by itself—Mg_2SiO_4. Regarding certain elements as negative to the others, it is held that each element has power to fix a certain number of atoms of a more negative element. The elements are divided into two classes—perissads (περισσός, odd), which combine with one another in the ratios 1 : 1, 1 : 3, 1 : 5, taking hydrogen as the unit; and *artiads* (ἄρτιος, even), with combining ratios 2 : 2, 2 : 4, 2 : 6, taking the same unit.

In some classes of compounds it is held that only a part of the oxygen present serves to unite the acidic element to the base. For example, in the formula MgO,SiO_2 we have Si combining with 2O, equivalent to 4H, and Mg with 1O, equivalent to 2H. The *tetrad* Si has then four bonds of attraction, and the *dyad* Mg two; O is likewise a *dyad*. Hence we may represent the combination of Si, Mg, and 3O by the graphic formula $O = Si \langle^{O}_{O}\rangle Mg$, the dashes representing so many bonds of attraction, and indicating that only 2O unite the Mg and Si, one O being combined with Si alone. Dana writes this formula $SiO \parallel O_2 \parallel Mg$. The formula $2MgO,SiO_2$ may be represented similarly by $Mg \langle^{O}_{O}\rangle Si \langle^{O}_{O}\rangle Mg$; by $Mg = O_2 = Si = O_2 = Mg$; or, as Dana writes it, $Si \parallel O_4 \parallel Mg_2$. These formulas are written on the principle that the number of atoms of uniting oxygen is equal to the number of bonds of attraction of the basic or acidic element, according as the former or latter has the smaller number. The formulas are similar for sulphur, tellurium, and selenium compounds, and for ternary fluorides.

Form and Structure.—Some minerals occur only in an amorphous state, never showing any signs of crystallization, but the majority are at times well crystallized or distinctly crystalline. Any crystal can be referred to one of seven systems, in which the crystal faces are determined by their position in regard to a set of assumed axes intersecting within the crystal. In six of these systems there are three axes, and in one of them four. See CRYSTALLOGRAPHY.

The crystalline form is very useful in distinguishing minerals, because it is an established fact that the angle between any two faces of a crystal will, under similar conditions, always be the same for the same minerals, subject to slight variations corresponding to changes in the composition of the varieties of the mineral. The similar faces may vary greatly in size, so that one or more faces may almost or entirely disappear, but the angles between the similar faces will remain the same.

Isomorphism, or the property of similar substances to crystallize in very similar forms, admits of their mutual replacement in crystallized minerals, this replacement being often accompanied by a slight change in the angles of the crystals. Thus lime, magnesia, the protoxides of iron and manganese, and oxide of zinc, are isomorphous bases, and yield very similar crystals when combined with the same acid. Hence the close relation between the forms of calcite, dolomite, and the related minerals. *Dimorphism* is the property of the same substance to crystallize in two different systems, or two different types of the same system; thus carbonate of lime appears in the hexagonal system as rhombohedral calcite, and in the orthorhombic as aragonite. *Trimorphism* and *polymorphism* refer to crystallization in more than two forms. *Pseudomorphism* is the assumption by one mineral of the peculiar form of another, but the second mineral always retains its own internal structure and physical characteristics. Pseudomorphs may result from the deposition of one mineral upon another, followed by the removal of the first mineral by solution, and subsequent filling up of the mold thus formed

with the material of the second mineral; by filling up of the cavity left by previous removal, through solution or otherwise, of the first mineral from its matrix; by alteration of the original crystal through removal or addition of some components; or, lastly, by simple molecular change within the mineral, which is possible only in case of dimorphous substances, as in the alteration of andalusite into cyanite.

A distinction is made between crystallized and crystalline minerals, the latter not showing free or partially individual crystals. If a crystalline mineral does not even show recognizable individuals, it is called cryptocrystalline. Crystalline minerals are classified, according to their structure, into *granular*, *lamellar*, *scaly*, *radiated*, and *fibrous*.

Lamellar structure is described as *parallel*, *divergent*, etc.

In amorphous minerals there is no trace of crystalline form or special characteristic of structure due to individual crystals, although an intermittent deposition of the mass composing the mineral may have occasioned differences of color, hardness, and texture. The majority of the solid amorphous minerals are the result of a gradual change from a gelatinous state, or of rapid cooling from a melted condition, but many of them are the result of the alteration of pre-existing minerals.

Cleavage, or the tendency to split in certain directions, is characteristic of most crystallizable minerals, and is of great use in determining minerals, the cleavage planes being always the same for the same mineral, no matter what the modifications of the crystal. Thus *calcite*, whether occurring as a rhombohedron or a hexagonal prism, will cleave always parallel to the faces of the type rhombohedron of calcyte; *fluorite*, whether occurring in cubes, octahedrons, or any other form of the isometric system, will always cleave parallel to the faces of the octahedron. Cleavage takes place parallel to certain planes, but there may be two or more sets of cleavage-planes in the same crystal, and in this case the cleavage will be easier parallel to one set of planes than to another, but will always be easiest parallel to the same planes. Thus *orthoclase*, in the monoclinic system, has a very perfect cleavage parallel to the base of the prism, a less distinct cleavage parallel to the clino-pinacoid, faint parallel to the ortho-pinacoid, and only in traces parallel to one face of the prism. Some minerals are devoid of cleavage, especially the amorphous minerals and native malleable metals, while the cleavage of some minerals, like mica and gypsum, is so perfect that they can be easily split into very fine laminæ. Other minerals have a distinct cleavage, which may be very hard to obtain, as in quartz, while some, like argentite, show scarcely any traces of cleavage.

Fracture differs from cleavage in not being parallel to fixed planes. It is classified as conchoidal, even, and uneven, according to the shape, and smooth, splintery, earthy, and hackley (like broken copper), according to the nature of the resulting surface.

Hardness.—Minerals vary in hardness, from the liquid hydrocarbons and water to the diamond. Hardness does not usually vary much for the same mineral, and is therefore a valuable aid in determining minerals. Its degree is ascertained by reference to the following scale, beginning with the softest: 1, talc; 2, gypsum; 3, calcite; 4, fluorite; 5, apatite; 6, orthoclase; 7, quartz; 8, corundum; 9, diamond. A mineral scratched easily by apatite, and easily scratching fluorite, would be fixed at 4·5.

According to their *tenacity*, or resistance to blows and cutting edges, minerals are classified as *brittle*, *sectile*, *malleable*, and *flexible*, the latter being *elastic* or *non-elastic*. It has been shown that the degrees of tenacity depend properly upon the elasticity of minerals.

Specific gravity is confined to narrow limits in its variations for the same minerals, and is of importance in distinguishing them.

Magnetism, or the power of affecting the magnetic needle, is possessed by a few minerals containing the magnetic oxide or sulphide of iron, and *magnetite* sometimes possesses polarity.

Electricity is developed in all minerals by friction; certain minerals become electric by pressure, cleavage crystals of calcite showing positive electricity when pressed between the fingers; others show electrical disturbance on warming, and are called *thermo-electric*. When opposite kinds of electricity are simultaneously developed at opposite parts of such crystals, they are said to possess polar thermo-electricity, and certain of these crystals are *hemimorphic*, or have different faces at their opposite ends. Tourmaline affords a very striking example of polar thermo-electricity.

Optical Properties.—All transparent crystals not belonging to the isometric system (anisometric) possess *double refraction*, or divide into two rays a ray of light passing through them. (See Refraction, Double.) A ray of light passing through a doubly refracting crystal may escape double refraction if it passes through in certain directions, according to the crystalline system. These directions are called the *optical axes*. In crystals belonging to the tetragonal and hexagonal systems there is one optical axis, parallel to the vertical axis, and such crystals are called *uniaxial*. The other systems are *biaxial*, and the optical axes lie in one of the three planes passing through any two of the crystallographic axes, and are usually symmetrically situated with reference to the crystallographic axes in the same plane. The angle between the optical axes is called the optic-axial angle. A line bisecting the acute optic-axial angle is called the *acute bisectrix*, or simply *bisectrix*, and one bisecting the obtuse angle and which is at right angles to the acute, is the *obtuse* or *conjugate bisectrix*. The optic-axial angle may vary widely for different varieties of the same mineral, but the position of the bisectrix is nearly constant.

The emerging doubly refracted rays are *polarized*, but this phenomenon disappears when the light passes in the direction of an optical axis, and in the case of easily cleavable minerals we can readily determine whether they are uniaxial or biaxial by examining thin laminæ between two crossed Nicol's prisms or other suitable apparatus, because uniaxial crystals cleave best parallel to the base, and hence normal to the optical axes, while very cleavable biaxial crystals cleave best parallel to the base or one of the pinacoids, and would have neither of the optical axes normal to the laminæ. See Polarization.

Sections of doubly refracting crystals of proper dimensions exhibit colored rings when examined by convergent polarized light, owing to the interference of the rays. Uniaxial crystals show one set of rings, intersected by a dark cross; biaxial crystals, one or two systems of elliptical rings, crossed by a dark band. A section of a quartz crystal vertical to the optical axis exerts double refraction in a peculiar way, the rays progressing not in direct oscillations, but with varying velocity in circular oscillations, producing what is called *circular polarization*.

Certain crystals sometimes show double refraction, especially *senarmontite*, *diamond*, *boracite*, *analcite*, and *alum*. This is owing sometimes to incipient alteration: sometimes perhaps to pressure exerted by gases within the crystal; sometimes to interposed layers of some doubly refracting mineral; and sometimes perhaps to a lamellar structure of the mineral itself, which produces the same results as a system of glass plates, and has given the name of *lamellar polarization* to the phenomenon.

Some crystals transmit light of different colors and intensity in different directions. This property is called *pleochroism*, and belongs more or less to all crystals with unequal axes. Colorless crystals cause only variation in the intensity of the light—colored crystals in the color also. Uniaxial crystals are *dichroic*, and biaxial crystals *trichroic*. The phenomenon is closely connected with double refraction, as the two rays suffer different absorption, and in general the more refracted ray also suffers the greater absorption. The phenomenon is observed by means of the *dichroscope*.

Labradorite, chrysoberyl, and other minerals show a peculiar change of color in reflected light, attributed partly to the presence of microscopic lamellæ and scales of foreign minerals, partly to very minute fissures in the mass of the mineral. *Asterism*, sometimes resulting in the appearance of a star, as in certain sapphire crystals, sometimes as a changeable streak of light across the fibers of certain varieties of gypsum, etc., is allied to the above phenomenon.

Luster, Color, and Translucency.—Minerals are divided according to their *luster*, or appearance in reflected light, into two grand classes, *metallic* and *non-metallic*, and the non-metallic again into adamantine, vitreous, greasy, pearly, silky, and lusterless or earthy. *Color* is always the same, and characteristic in the case of some minerals, as metals, pyrites, the sulphides, certain metallic oxides, and salts; others are white or colorless and transparent, like ice, quartz, many silicates, etc., but these may be colored by mechanical admixture or isomorphous combination of colored constituents. The colors of minerals vary greatly, and so does their translucency, the native metals and minerals with me-

tallic luster being generally quite opaque, even in very thin films.

Phosphorescence is induced in some minerals, as diamond and calcined barite, by exposure to daylight; in others, topaz and fluorite, by warming, by electricity, or by mechanical disturbance, as pressure, cleaving, etc. The *taste*, *smell*, and *feel* of minerals are additional means of distinguishing them.

Classification.—For a long time mineralogy as a systematized science was in a very confused state, minerals and rocks (often only aggregates of different minerals) were confounded together, and widely different minerals were placed in the same classes. Cronstedt, about 1758, pointed out the difference between a rock and a mineral; de Lisle soon after applied crystallography to the study of minerals, and finally Mohs produced a natural system, founded chiefly on external characteristics. In the early part of the nineteenth century Berzelius introduced chemistry in classifying minerals, and at the present day chemistry, combined with crystallography, forms the basis of the generally accepted systems of mineralogy. Dana's system of mineralogy, as given in the fifth edition of his work on the subject, an unexcelled example of research and judgment, may be cited in illustration of the chemical grouping of minerals combined with crystallography. He first arranges the elements into three series, beginning with the more basic, then the more negative, and finally the eminently negative: *Series I. Gold group*, gold, silver; *iron group*, platinum and allied metals, mercury, amalgams, copper, iron, zinc, lead; *tin group*, tin. *Series II. Arsenic group*, arsenic, antimony, bismuth; *sulphur group*, tellurium, sulphur, selensulphur; *carbon-silicon group*, diamond, graphite. *Series III.* Chlorine, bromine, iodine, fluorine, oxygen. The gold group also includes hydrogen and the alkali metals; the arsenic group, phosphorus, nitrogen, and probably boron; the iron group, calcium, magnesium, aluminium, cobalt, nickel, zinc (chromium, manganese, lead, in part, etc.); the tin group, titanium and zirconium. The general subdivisions are then as follows: I. native elements; II. compounds, the more negative element an element of Series II. (1) Binary—sulphides, tellurides of metals of the sulphur and arsenic groups; (2) binary—sulphides, tellurides, selenides, arsenides, etc., of metals of the gold, iron, and tin groups; (3) ternary—sulpharsenites, sulphantimonites, sulphobismuthites. III. Compounds, the more negative element belonging to Series III., Group I.: chlorides, etc. IV. Compounds, the more negative element of Series III., Group II.: fluorides. V. Compounds, the more negative element of Series III., Group III. Oxygen compounds: (1) Binary—oxides; (2) ternary, the basic element of Series I., the acidic of Series II., the acidific of Series III. (1) Silicates; (2) columbates, etc.; (3) phosphates, etc.; (4) borates; (5) tungstates, etc.; (6) sulphates, etc.; (7) carbonates; (8) oxalates. VI. Hydrocarbon compounds. The silicates may serve as an example of the further arrangement into groups and species. First, they are divided into anhydrous and hydrous silicates, and each of these into bisilicates, unisilicates, and subsilicates. In the anhydrous silicates the oxygen ratio for bases and silica is for the bisilicates 1 : 2; unisilicates, 1 : 1; subsilicates, 1 : less than 1. The bisilicates are arranged into groups: amphibole group, crystallization orthorhombic or clinohedral; angle of prism not 120°: beryl group, hexagonal; pollucite group, isometric. The amphibole group has sub-groups: *pyroxene sub-group*, angle of prism, 86–88°; composition, RO,SiO_2 or $(3RO,R_2O_3)3SiO_2$, and when both RO and R_2O_3 are present, ratio of $3RO:R_2O_3 = 3:1$ to $1:2$. *a*, Orthorhombic; *b*, monoclinic; *c*, triclinic. *Spodumene sub-group*, angle of prism, 86°–88°; composition $(3RO,R_2O_3)3SiO_2$, and $3RO:R_2O_3 = 1:4$. *Amphibole sub-group*, angle of prism, 123°–125°; *a*, orthorhombic; *b*, monoclinic.

The sulphides, etc., of the gold, iron, and tin groups may serve for further illustration. There are three divisions: (1) *Basic*, atomic ratio between the sulphur, arsenic, etc., and the basic metal is less than one to one; (2) *Proto*, with the ratio 1 : 1; (3) *Deuto*, ratio 2 : 1. The *Proto* division has four groups: (1) *Galena group*, isometric, holohedral; (2) *Blende group*, isometric, hemihedral; (3) *Chalcocite group*, orthorhombic; (4) *Pyrrhotite group*, hexagonal. The *Deuto* division has two groups: (1) *Pyrite group*, isometric; (2) *Marcasite group*, orthorhombic.

Revised by CHARLES KIRCHHOFF.

Mineral Oil: See PETROLEUM.

Mineral Point: city; Iowa co., Wis. (for location of county, see map of Wisconsin, ref. 7–D); on the Chi., Mil. and St. P. Railway; 36 miles N. E. of Dubuque, Ia., 45 miles W. S. W. of Madison. It is in a farming, stock-raising, and lead-mining region, and has lead and zinc furnaces, iron-foundries, planing and grist mills, oxide-of-zinc works, national bank (capital $100,000), private bank, and two weekly newspapers. Pop. (1880) 2,915; (1890) 2,694; (1900) 2,991.

Mineral Springs: See SPRINGS, MINERAL WATERS, and WATER.

Mineral Waters: waters such as contain unusual quantities of various salts in solution, or sometimes simply very pure water. In the latter case they are not properly called mineral waters. Springs that are found in localities where soluble substances occur in the earth are likely to contain some of these substances in solution. Such natural solutions have long attracted the attention of mankind, and are used medicinally to an enormous extent, under the impression that they have curative powers that are not possessed by solutions of the same kind made artificially. In some cases a water owes its reputation to its temperature alone; in other cases to the presence of substances that unquestionably produce effects upon the system; in others still to the presence of minute quantities of rare substances, the names of which produce a psychological effect, thus influencing the body indirectly.

Mineral waters are classified into (1) *thermal waters*; (2) *common salt or muriated saline waters*; (3) *alkaline waters*; (4) *sulphated saline waters*; (5) *iron or chalybeate waters*; (6) *sulphur waters*; (7) *earthy and calcareous waters*; (8) *alum waters.*

(1) *Thermal waters* are valued for their high temperature, from 27°–65° C. Examples of springs of this kind are the Hot Springs of Arkansas and Virginia, in the U. S., and those of Bormio, Gastein, Pfäffers, and Ragatz, in Europe.

(2) *Common salt or muriated saline waters* contain common salt or sodium chloride as the principal constituent. Such waters are very common. The Saratoga waters contain common salt together with a number of other substances. In the table are given the results of analyses of some of these waters. The analyses were made by Prof. Charles F. Chandler, of New York. Other well-known springs belonging to this class are those of Middlewich, Harrogate, Leamington, and Cheltenham, in England; Kissingen, Homburg, Pyrmont, Kreuznach, Wiesbaden, and Baden-Baden, in Germany.

(3) *Alkaline waters* contain sodium carbonate with more or less free carbonic acid and sometimes with a large quantity of sodium chloride. Some of the Saratoga waters belong to this class, as is shown by the table (on next page) of analytical results. Other celebrated waters of this class are Vichy, Apollinaris, Salzbrunn, Vals, Ems, Selters.

(4) *Sulphated waters*, as the name implies, contain sulphates, and these are either sodium or magnesium sulphate, or both. In some cases sodium carbonate and chloride are also present. They are often called "bitter waters." Prominent among such waters are Hunyadi Janos, Epsom, Friedrichshall, Scarborough, Carlsbad, Marienbad, etc.

(5) *Iron or chalybeate waters* contain iron in some soluble form. The waters of Schwalbach, Spa, Tunbridge Wells, and Alexisbad are examples of comparatively pure chalybeates, that is to say, of waters that contain some salt of iron but are otherwise comparatively pure. Several of the Saratoga waters contain iron in addition to the other constituents, and the same is true of the waters of Pyrmont, Petersthal, and St. Moritz.

(6) *Sulphur waters* contain either sulphuretted hydrogen, H_2S, or the sulphides of sodium, potassium, calcium, or magnesium. Those of Harrogate and Aix-la-Chapelle are renowned in Europe, while in the U. S. there are numerous examples, among which are the White, Red, and Salt Sulphur Springs of Virginia, the White Sulphur Springs of Ohio, and the Richfield, Sharon, Chittenango, and Florida Springs of New York State. The sulphuretted hydrogen gives these waters a sweetish taste and a very peculiar odor, which some consider offensive. These waters have the property of blackening silver.

(7) *Earthy and calcareous waters* contain large proportions of the carbonate and sulphate of lime. Some of the most important of these abroad are found at Wildungen, Weissenburg, St. Arnaud, and Couran. Again it is to be noted that several of the Saratoga waters are rich in carbonate of lime.

(8) *Alum Waters.*—In several localities waters occur charged to a greater or less extent with alum. These waters

frequently contain free sulphuric acid. The Rockbridge Alum Spring and the Church Hill Alum Spring, in Virginia, are examples of this class.

Among waters that can not properly be classed under any of the above heads may be mentioned Buffalo lithia water and strontia water.

In 1899 there were 541 commercial mineral springs in the U. S. The total product was 39,562,136 gal., at a valuation of $6,948,030. IRA REMSEN.

Mineral Wax: See PARAFFIN.

Mineral Wool, or **Silicate Cotton**: thread-like filaments which have the appearance of wool or cotton when massed together; produced by the action of steam or air under pressure upon vitreous or scoriaceous substances when in the molten state. As an article of commercial value the material first came into use in 1871, it having been produced in that year at Osnabruck, Germany. The production of it in the U. S. began about four years later, and subsequently in England. In the various processes of smelting ores of metals the compressed air necessary to accelerate combustion sometimes escapes from the furnaces through the tapping-hole or tuyeres in such a way as to separate the cinder into shot-like particles, which in tearing themselves from the fluid stream draw out threads of various length and fineness. Most furnacemen are familiar with such freaks of the blast, so that the material in this sense has but little novelty, and it is to be noticed that as a result of this occurrence the only patent which seeks to protect the article at all does not claim the product as such, but the method of manufacture. John Player, of Norton, near Stockton-on-Tees, England, was the inventor of the process as practiced at the present time.

The slag of blast-furnaces is the cheapest and most abundant substance which can be utilized for the manufacture of the article. This, however, is only a coincidence, and furnace-slags in every case can not be utilized, for some of them contain too large a proportion of silica to make fine and pliable fibers, while others are so basic, owing to the high percentage of lime, that they will not draw out satisfactorily. Besides, when there is an excess of lime, the tendency is for the fibers to become caked or solidified, there not being sufficient acid present to give stability and permanence to them. An objection to the use of mineral wool made from slag is that it generally contains sulphides of calcium, potassium, and sodium which are soluble in weak acids and in water containing alkalies, and to some extent also in warm water. When such a sulphur-bearing material is used on pipes or boilers there is a danger of its becoming wet from leaks or from external moisture, and the sulphur thus brought into solution to attack the iron. Cases of corrosion from this cause are, however, very rare, and it is contended that so long as the heat is kept on the pipe no dampness will reach its surface. In order to produce a non-sulphur-bearing mineral wool a plant has been put in operation to melt down such rock-mixtures as are free from the obnoxious element and are of the proper composition to form a cinder of a specific character. By mixing together four parts of orthoclase feldspar and six parts of dolomitic limestone a cinder is obtained which runs fluid and is susceptible of conversion almost entirely into fibers of a stable nature. In treating slag 2 lb. of shot are made to every pound of fiber, while in the case of cinder prepared from minerals the proportion is about 2½ lb. of fiber to 1 lb. of shot. These different products are named "slag-wool" and "rock-wool," the chief distinction between them being the presence of sulphides in the former, while the latter is free from them. As a general thing, the color of mineral wool is white. The fibers of mineral wool act as a medium to prevent the circulation of the air; which being accomplished, the passage of heat is retarded. By reason of its porosity the material also forms a most effective barrier to the transmission of sound. The indestructible character of the fibers makes mineral wool available for all purposes of insulation. Insects or vermin find in it nothing wholesome to eat, while its glassy nature forbids their making homes in it.

Miner's Inch: a unit for measuring water frequently employed in mining regions. It may be roughly defined to be the quantity of water which flows from a vertical standard orifice an inch square when the head on the top edge of the orifice is 6 inches. The mean discharge from such an orifice is 1½ cubic feet per minute. The actual value of the miner's inch varies, however, in different localities. In California it ranges from 1·20 to 1·76 cubic feet per minute, according to the arbitrary definitions adopted. For example, at Smartsville an orifice 4 inches deep and 250 inches long, with a head of 7 inches above the top edge, is said to furnish 1,000 miner's inches. In Montana a vertical rectangle an inch deep is generally used, with a head of 4 inches, and the number of miner's inches is said to be the same as the number of linear inches in the rectangle. An orifice through which a given number of miner's inches of water is furnished is called a module. The important feature to be observed is that the head should be kept nearly constant over the module, and in order to insure this many automatic appliances have been devised. For the sake of uniformity it is much to be desired that water should be sold by a constant unit, such as per cubic foot per hour, instead of by the miner's inch. MANSFIELD MERRIMAN.

Minersville: borough; Schuylkill co., Pa. (for location of county, see map of Pennsylvania, ref. 5–H); on the Schuylkill river, and the Phila. and Read., the People's, and the Schuyl. and Lehigh Val. railways; 4 miles W. of Pottsville, the county-seat. It is principally engaged in coal-mining, and has improved water-works, iron-foundries, electric lights, public library, and two weekly newspapers. Pop. (1890) 3,504; (1900) 4,815. EDITOR OF "FREE PRESS."

Miner'va [= Lat. < O. Lat. *Menerva*, appar. for **Menesva*, deriv. of **menes-*; Gr. *μένος*, mind, strength of spirit: Sanskr. *manas-*, strength, mind. See MIND]: in the Roman

mythology, the goddess of reason, and so of all invention, of the arts, and of science. With this original conception of the goddess were blended at a later time certain warlike attributes, arising from the identification of Minerva with the ATHENA (*q. v.*) of the Greeks. The oldest sanctuaries of the goddess were situated on the Capitol, the Aventine, and the Cælian Mons. On the Capitol she possessed a cella in the triple temple of Jupiter Capitolinus, to the right of the god. The temple of Minerva on the Aventine was the headquarters of the earliest association of artists in Rome, the *scribæ* and *histriones* (poets and actors), whose organization dated from the time of Livius Andronicus. The principal festivals in honor of the goddess took place on the 19th of March and June, i. e. the fifth day after the ides, *Quinquatrus*, and while the name indicates that the celebration was originally only on that day, it was eventually extended to five days (described by Ovid, *Fasti*, iii., 809–48). It was the first day's celebration which gave to this festival its characteristic tone, and it was shared in by school children and teachers, as being under the special guardianship of Minerva; by women and girls, who worshiped her as the patron of all the domestic arts, such as spinning, weaving, etc.; by artisans of various kinds, notably fullers and cobblers, and by all those whose occupations were distinctively literary or artistic, such as poets, painters, sculptors, etc. The fact that this festival touched so many spheres of life made it a popular one even down to late imperial times. The remaining days of the feast, from the end of the republic on, were devoted to the worship of Minerva as the warlike daughter of Jupiter (a character which was given to her from identification with the Greek Athena), and they were occupied chiefly with gladiatorial exhibitions. The lesser *Quinquatrus*, on June 19, was a festival of pipers (*tibicines*), and was observed with much riotous celebration. In the course of time more characteristics of the Greek Athena were introduced into the worship of Minerva. Thus the founding of a temple to her by Pompey from the spoils of his Eastern conquests seems to have been due to the analogy of the Greek Athena Niké, and the later identification of Minerva with the senate house is apparently due to the Athena *Βουλαία* at Athens. The Emperor Domitian claimed to be under the special guardianship of Minerva, and to her he dedicated two temples, slight remains of one of which, in the Forum of Nerva, still survive. Besides the artistic representations of Minerva, which did not differ from those of Athena, there was an ancient and very sacred image of the goddess called the Palladium which had been brought to Rome from Troy after the destruction of the latter city, and was preserved with great care in the temple of Vesta. See Preller, *Röm. Mythologie* (i., p. 289 ff. Cf. index in vol. ii.). G. L. HENDRICKSON.

Mines and Mining: Mining in its widest sense is the winning of useful minerals, or metals, when the latter are found native. Among the useful minerals are included, by statisticians, mineral oils, natural-gas, mineral springs, and building-stones, which are included by the U. S. Geological Survey in its reports of the product of the mineral industry of the U. S. Mining engineering embraces the study of deposits (see ORE DEPOSITS) of useful minerals, the search for workable deposits, and the final preparation of the material extracted by mechanical means prior to its treatment by metallurgical processes for the extraction of the marketable product. The act of excavation may be termed mining in its narrower sense. The aim is extract with the maximum profit at the minimum of risk to life and property.

The search for deposits of useful minerals is conducted by methods varying with their character. The simplest means is to dig a series of trenches at right angles to the supposed course of the deposit, or if the covering be too heavy to sink a number of test pits. When the mineral is inbedded deposits, shafts or borcholes are sunk or tunnels are driven. In the case of deposits of magnetic-iron ore, the dipping-needle is employed. For salt, oil and natural-gas boreholes are usually sunk, occasionally to great depth.

The methods of mining pursued depend upon the location of the deposit, the character of the mineral, its value, the nature of the rock in which it is imbedded, and the extent and position of the deposit. When the mineral is exposed at the surface, or is covered only by a shallow layer of soil, quarrying is resorted to. Modern machinery for the removal of earth has been so much improved that stripping of the ore deposit or bed can be carried to considerable depth. Open-air work is carried on in this manner in a number of iron mines in New York, New Jersey, and Minnesota, and in the anthracite-coal regions of Pennsylvania. It has been employed in a conspicuous manner in the diamond mines of South Africa and Brazil, and in the great pyrites deposits of Spain and Portugal. This method possesses the advantage of permitting of very cheap extraction, but is hampered with growing difficulties with increasing depth. Surface mining plays a very important part, however, in the working of alluvial deposits. A very large part of the gold produced in the world and the greater part of the tin ore mined is obtained through surface mining. It has led in the U. S. to the development and application on a grand scale of what is called *hydraulic* mining to the recovery of gold from alluvial deposits. See GOLD.

Mining, as usually understood, deals, however, with the extraction of the useful mineral by underground operations. A multiplicity of conditions must determine how they must be conducted to produce the best results. Conspicuous among these is the character and the position of the deposit itself. First of all means of ingress and egress must be provided. These serve at the same time for the removal of the mineral and of accumulated water, for ventilation, and for the delivery into the mines of timber, filling material, and supplies.

Whenever it is possible the deposit is attacked by a tunnel, since it saves hoisting and pumping and in many instances greatly facilitates ventilation. Below the superficial drainage a vein or bed must be reached by a shaft or a slope, with a series of horizontal adits, spaced conveniently apart, which lead to the mineral mass at different levels.

If we imagine an inclined tabular deposit, such as a metallic vein usually is, and as a coal-bed may be, it would seem cheapest to run down in it by means of a slope dug in the material itself. That process, in fact, turns out the valuable matter at once, and might more or less pay for itself while in operation; but as a shaft or slope is the most important of all the preparatory works, usually being intended to endure, and requiring substantiality for the incessant needs of hoisting and pumping, it is necessary to make such a construction solid, and therefore a slope in a vein must be supported by flanking masses devoted to that object alone. In a coal mine this sacrifice is not of much importance, but in a metallic one it might be a greater loss than the slight advantage of a slope would compensate for. Moreover, a slope to a given level is longer and more irregular than a shaft sunk vertically in the country-rock; the development of hoisting-ways, cables, pump-rods, pipes, etc., is therefore greater and the service more inconvenient. The usual method, particularly when some capital is at command, is to sink a vertical shaft so as to strike the deposit in depth.

Supposing, then, that a vertical shaft for the attack of a vein has been sunk, and as deep down at once as various reasons will allow, it is next put into connection with the deposit by means of the cross-cuts, which are galleries sloping a little toward the shaft for drainage and rolling. These, like the shaft, should be ample for the circulation expected, and spaced apart vertically, say 100 feet. The cross-section of a shaft adapted to hoisting, pumping, and ladders, or a man-engine, all together, may be 20 by 30 or more, and the section of galleries for single track about 6 by 6 feet. From where the cross-cuts pierce the vein next are run gangways to right and left in the vein itself. These make the different levels; and as they are permanent ways for rolling, they have the same dimension as the cross-cuts, and like them and the shaft are strongly timbered. Finally, these levels being put into communication by slopes in the vein—200 feet apart, for example—the mineral mass is seen to be subdivided into a set of parallelopipeds 100 by 200, and presenting each four disengaged angles on which they may be easily attacked for the prosecution of exploitation. This finishes the preparatory work, and it remains to be said that such interior preparation should always be kept up and urged in advance of the exploitation proper, so as to explore the vein for at least a year's work in prospect.

Exploitation is the taking out of the parallelopipeds so prepared and exposed. If such a parallelopiped be attacked on an upper corner by miners, who with pick, drill-bar, and shovel delve into and break away the mass beneath them, such is called underhand stoping, which is now rarely practiced. Overhand stoping is where the workmen attack one of the lower angles of a parallelopiped. In this case the miners, all of them, are, as it were, undermining the whole parallelopiped; the one in advance is directly on the timbering of the gangway beneath him; the refuse

is piled up behind on this timbering, and the other miners follow standing on that or on trestles, so that the profile of attack becomes and shows like a stairway upside down.

When the vein matter itself does not furnish enough refuse, it is usual, in the case of minerals of considerable value, to send waste rock down into the mine from the surface, or procure it by excavations outside of the vein. When the vein lies flat it is evident that the same profile of steps may be laid out for the attack; but then, also, a larger style may be adopted with advantage, and particularly in coal-beds, where it is always an object to get out the material in ample dimensions. In this case either longer steps are designed, with several miners on each face, or the long-wall method is applied. This, which is common now even in beds of coal 9 to 10 feet thick, where strong propping is attainable, consists in attacking a long, straight line of face with all the miners abreast. They prop behind them, and if there is refuse sufficient to fill up in rear, they do so, reserving open rolling ways to the shaft. This method is convenient for every element of interior economy, such as rolling, ventilating, lighting, overseeing, etc. If filling can not be procured adequate to replenish the vacancy, then what little there may be is built into pillars or walls, and the ground is allowed to sink upon these, or even completely down if the rolling-ways can be kept open by hacking into the roof.

The exploitation of thick veins is effected by different dispositions. For example, when there is abundant filling they may be attacked from below upward, taking out horizontal slices, which are successively filled; or, again, where caving is allowable, they may be taken from above downward, each slice being treated like a horizontal bed, without filling. Finally the method by pillars and galleries is applicable anywhere. That title ordinarily refers to an exploitation in which the pillars of the mineral are used for support alone, and are supposed to be left and abandoned utterly. This relinquishes one-third to one-half the material in the earth, and is the worst possible almost, though in thick veins of cheap ore or coal sometimes the only one possible. It is combined often, however, with a subsequent robbing of the pillars, whereby it becomes more economical and rational. The robbing involves caving, of course, and when the creep of the caving can be commanded nicely the method is as exhaustive as any.

All the foregoing, except underhand stoping, applies to coal-mining, but this last is at the same time a larger and yet a more delicate kind of mining than metallic. Coal-mining differs from other mining principally because the fronts ought to be larger, because there is comparatively little refuse in ordinary coal-beds, and because the generation and ignition of fire-damp in fiery mines exact peculiar lighting, particular ventilation, and besides a disposition of works which admits of handling large quantities economically. This consideration leads to disposing the main plan in boundaries, with walls of coal left between, and also to the well-known style of pillar-and-stall exploitation. In this the pillars are long strips left between the stalls, which are headings run into the coal, directed so as to take an easy grade, and out of which the coal is entirely won. The pillars are intended to be subsequently cut through and robbed out; in the meantime there is in each front or breast quite a seclusion from outside damage. The perfection of an exploitation is to get out all the valuable material, and nothing else, with rapidity and with safety and comfort to the miners.

With softer materials the actual work of extraction by the miner consists in cutting a deep groove under the mineral to be won, sometimes supplemented by vertical cuts and prying off the body thus loosened. In harder material blasting is resorted to. See BLASTING.

Interior Transportation.—From the fronts down to the gangways the matters are sent in barrows, sledges, shutes, or cars. In the main ways there are always railways; the tracks are narrow and the rails light, but laid best on sleepers, as above-ground. The cars may be iron or wood; they must have a low center of gravity; wheels close together, for the curves are short, and encumber with the least possible dead weight. The motors are men and boys, mules, small horses, stationary engines with endless chains to take trains, locomotives, or electric motors. Examples of great drains used as canals for subterranean transportation are also familiar.

Hoisting.—At the mouth of the shaft is planted a great derrick, usually made with four uprights, on top of which are two large sheaves or pulleys to bend the cables from the shaft to the winding-drums or reels. The cables are hemp, aloes, iron or steel wire, and either round or flat; they are terminated with an end of chain, which is hooked to the buckets, skips, or cages. The cages, now so prevalently used, are simple elevators, which carry one or more cars; they are guided by vertical strips of timber fixed to the sides of the hoisting-way for that purpose, and these also serve in connection with the safety-catches, which are attached to all cages, particularly if miners are hoisted in them. Safety-catches are of various patterns; the best are probably those with toothed eccentric wheels, which, when the cable breaks, encrust themselves into both lateral flanks of each guide. The best winding apparatus is for round cables conical drums, and reels for flat. The operation of hoisting is for many reasons delicate, and the engines ought to be sensitive. The best hoisting system of these is composed of two horizontal cylinders, without any fly-wheel if possible.

Pumping.—In the Cornish type the pumps of a deep mine are composed of a series of lifts, each more than 100 feet high. All the pumps are force-pumps with plungers, except the lowest, which is a lift-pump, more convenient for following the sinking of the shaft or being moved about. One main rod of wood and iron stretches from top to bottom of the shaft, and to this are fixed by spurs or shoulders the rods of the force-pumps. The weight of the main rod is almost always greater than that of the column to lift; therefore the work of the engine is limited to lifting that rod, which when released sinks and moves the plungers. In the U. S. practice favors the use of direct acting pumps.

Ventilation is either natural or artificial. Many circumstances may cause a natural draught between two orifices, such as difference of level, difference of section, variety of exposure, and prevailing winds. Artificial ventilation is produced by pneumatic machines, the cheapest of which is the old Hartz blower; by fans, such as Guibal's and Fabry's; by furnaces, a common and cheap method, but dangerous in fiery mines; and by jets of steam. The use of compressed air in the drills of mines assists ventilation, but not so much as might be imagined. On the whole, it is found preferable to ventilate by drawing out the air, rather than by forcing it in; and this course is particularly advantageous in coal mines, because by rarefying the air, instead of condensing it, the fire-damp is more freely liberated to be wafted away. As for the distribution of the air, a general principle is to carry the current low down at first, directing it afterward through the works upward, and split it into numerous untainted streams, until it reaches the upcast. The directing and modifying of the currents is effected by doors and air-shutes in the mine-ways. Most miners who perish by explosion in coal mines are victims not of the fire-damp, but of the choke-damp, or carbonic acid, after the catastrophe, particularly if the doors and ventilating-flues are disabled; therefore, in these dangerous mines the means and potentiality of ventilation are vitally important.

Milling at coal mines consists only in breaking, picking, screening, and washing the coal. The breakers are toothed cylinders; the screens are revolving screens, with different-sized apertures for sorting the lumps as they pass through; the washing is done in large jigs or cisterns, where the coal, like metallic ore in smaller apparatus of the same kind, is subjected both to a current of water and to a movement of vertical oscillation of the same impelled by pistons. Masses of metallic ore when first extracted and dumped are first broken by hammers or sledge-work in a pile-driver frame; then treated by jaw-crushers and cylinder rolls, sometimes toothed, then transmitted to the stamps, which are of various patterns, the most powerful being regular steam-pestles working direct from the steam-cylinder. The metallic mud thus obtained is concentrated further by washing in jigs, shaking-tables, cloth-rollers, and the slimes are finished off in sluices and long tailing labyrinths. It is advantageous, even in the cheaper metals, to carry slime-washing far, and in the preparation of coal, washing tends to come more and more in vogue.

Mining Surveying.—No engineer ought to be content without accurate and adequate maps of his underground works. The main ways are surveyed with a transit, the narrower ones and the fronts of work with a compass and half circle suspended from a cord stretched at convenient points. The vertical and horizontal angles and linear measurements being referred to three co-ordinate planes, it is easy therefrom to make maps, sections, and elevations,

or to solve any problem of underground projection, by the ordinary methods of descriptive geometry or trigonometry.

Revised by CHARLES KIRCHHOFF.

Minghetti, min-get'tē, MARCO: statesman; b. in Bologna, Italy, Sept. 8, 1818; studied physical and social science, and as soon as he was of age traveled extensively in Italy, France, and Germany. In 1846 he pronounced a discourse at Bologna on the corn-law reform in England, declaring himself in favor of free trade. His next work was a *Dialogue on the Philosophy of History*. In 1854 he published an essay on the *Decay of the Fine Arts* and a eulogy on Gastano Recchi; in 1859 a treatise entitled *Della Economia publica, delle sue attinenze con la morale e col diritto*, which is the most remarkable of his works. Meanwhile, Minghetti had established in 1846 a journal, *Il Felsineo*, which gave him great consideration at Bologna. In 1847 he was invited to Rome as member of the Consulta della Finanze. In 1848 he was named by Pius IX. Minister of Public Works, but on the defection of the pope from the liberal cause Minghetti left the ministry and hastened to the Lombard camp, where he was appointed captain on the staff of Charles Albert. After the battle of Goito he was created major, and after that of Custozza (1848) he was decorated by the hand of the king himself. Rossi invited him to form a part of his constitutional ministry. Minghetti arrived in Rome on the very day of the assassination of his friend, and at once published an indignant protest against the infamous crime. Pius IX. desired Minghetti to take the place of the murdered minister, but he refused, and returned to the Piedmontese army. After the battle of Novara the gave himself up to his private studies, taking part in politics only when it was necessary to sustain the policy of Cavour. In 1858 he went to Egypt and Sinai; in 1859 he was appointed by Cavour secretary-general of foreign affairs, and contributed powerfully to secure the annexation of the duchies and of the Romagna. After the peace of Villafranca he became a member of the assembly of the Romagna, and upon the annexation he was elected member of Parliament from Bologna. In 1860 Minghetti was named Minister of the Interior; in 1862 Minister of Finance, and at the same time president of the council; in 1864 he effected a loan of 700,000,000 francs, and with the concurrence and aid of Peruzzi brought about the famous September convention which transferred the capital of the kingdom of Italy to Florence. In the Menabrea ministry Minghetti was at the head of the agricultural and commercial department, and from 1873 to 1876 he was at the head of the cabinet—first as Minister of Finances, afterward as Minister of Foreign Affairs. He published *Opusculi Letterari ed Economici* (1872); *Le Donne Italiane nelle Belle arti al Secolo XV. e XVI.* (1877); *La Chiesa e lo Stato* (1878). D. in Rome, Dec., 1886. *Miei Ricordi* (3 vols.) appeared after his death.

Mingrelia: down to 1804 an independent principality of Transcaucasia; in that year became subject to Russia. It corresponds to the ancient *Colchis*, and its capital, Izgaur or Iskuriah, situated on the Black Sea, is identified with the ancient *Dioscurias*, a colony of Miletus. The Mingrelians, numbering (1890) about 214,000, are closely related to their neighbors the Georgians.

Minho, meen'yō [Portug.: Span. *Miño*], or **Entre Douro e Minho**, en'trā-doo'rō-ā-meen'yō (between the Douro and the Minho, rivers which bound it on the S. and N. respectively): a former province of Portugal; bounded N. by Spain, E. by Traz os Montes, S. by Beira, and W. by the Atlantic. Area, 2,807 sq. miles. It is the most populous, the richest, and the best cultivated province of the kingdom. Everywhere are fertile valleys, rich meadows, fields, and vineyards. The products are fruit, wine, oil, figs, oranges, barley, rye, and wheat. Chief town, Oporto. Pop. (1881, official estimate) 1,014,768.

Miniature [from Fr. *miniature*, from Ital. *miniatura*, deriv. of *minia're*, to paint with *minium* or red-lead < Lat. *minia're*, deriv. of *mi'nium*, red-lead. The modern change of meaning to include the idea of smallness may be by confusion with Lat. *mi'nimus*, Ital. *minimo*, etc.]: a very small picture of any kind. Some writers have included in the term small sculptures, medallions, wax models, and the like, but this is unusual. Miniatures in the usual sense, i. e. of small pictures, belong generally to one of two classes, viz.: (1) The paintings in manuscripts. (2) The paintings, usually portraits, on paper, cardboard, ivory or vellum, or in vitrifiable colors, on porcelain or enameled metal plates, which were introduced in the sixteenth century, became fashionable in the seventeenth, and went out of common use when photographic portraits became common, about the middle of the nineteenth century.

A collection of fifty-eight illustrations of the *Iliad*, exhibited in the manuscript room of the Ambrosian Library at Milan, is of peculiar value because the writing on the back of the pictures, by its character, fixes the date very nearly. This approximate date is 400 A. D., a time when classic art was in a state of degeneracy. It is suspected, however, that the miniatures have been copied from much earlier works. The Vatican Vergil of about the same date is stated to contain fifty pictures. A few Greek manuscripts of about the same epoch are known in which are miniatures of great beauty. Several of these have been copied in color and with great care in Labarte's *Histoire des Arts Industriels*; the manuscripts themselves are accessible to students in the great libraries of Vienna, Paris, and the British Museum. (See ILLUMINATED MANUSCRIPTS.) Greek manuscripts of the tenth, eleventh, and twelfth centuries, such as are generally called Byzantine, give us also some idea of the pictures which earlier books must have contained. It is quite evident that many of these pictures are copied from those of the great times. Others seem to be rather original conceptions of the time when they were painted. Byzantine painting is known to us chiefly by means of these miniatures, and by the mosaics which remain in churches. See MOSAIC.

In Ireland in the sixth and seventh centuries there was a very remarkable development of decorative and representative art. The manuscripts of this time contain very decorative miniatures, some of which, however, are extremely barbarous in expression of faces and in drawing. Another surprising development of art at an early epoch is that of the time of Charles the Great (Charlemagne). The manuscripts of his reign contain some splendid pictures, worthy of comparison with work of a much later and more generally artistical epoch. Both the Irish and the Carolingian miniatures, as well as the early English ones of a period not much later, are more generally conventional portraits of Christ or of some one of the evangelists; but there are occasional pictures of incident, like the very spirited picture given by Westwood in the *Palæographia Sacra Pictoria*, and taken from a splendid ninth-century Bible in the National Library in Paris. This represents St. Jerome about to take ship; behind him is Rome, a fortified city, with a draped figure armed with spear and shield—perhaps a reminiscence of some ancient statue of the goddess Roma; the saint himself is in his bishop's robe; the ship is of classic type. Much of this is an echo of some much older painting, but the picture is full of vigor and interest.

Miniatures of the later Middle Ages are to be found in Gospels, Psalters, and church-service books, and their number and character are fixed by tradition. Thus opposite the page devoted to St. Barbara appears a picture of the saint with her tower in a pleasant landscape; in corresponding place is St. Christopher bearing the infant Christ; or St. George killing the dragon while the sultan's daughter in an old Eastern costume kneels in the distance, and beyond is a towered city. A Crucifixion, a figure of the Saviour in the act of benediction, a group of the Virgin and Child and St. Anne, the mother of the Virgin, have each its appointed place in these elaborate service-books. These are full-page pictures, but the books are generally small. Miniature-painting in books reached its greatest elaboration in the work of Jean Fouquet, who died about 1480, and of such Flemish painters as decorated the Grimani Breviary in the Venice Library. These artists have left elaborate pictures, with landscape, many figures, free and vigorous action. The well-known and generally respected traditions of the art, that no shadows shall be cast, but everything modeled in pure color, are now, at least, disregarded, as in the borders of many late miniatures, and in some of the pictures of the *Brevario Grimani*. Mediæval miniature-painting went through its last stage in the brilliantly colored pictures which the practiced illuminators knew how to make out of early wood-cuts in outline. Some of these are richly painted in vivid colors and touched with gold, so that the frontispiece of a printed book of the sixteenth century would not be known for a wood-cut but that other copies of the same book exist with the same print uncolored.

Portrait miniatures began to be fashionable almost exactly as pictures in manuscripts ceased to be painted in the sixteenth century. Under Henry VIII. in England very small circular portraits painted in water-color and in oil,

chiefly on cardboard and on paper, were very common, and the painters were well paid. Some of these miniature portraits have even been ascribed to the great Holbein, but without sufficient evidence. A little later, under Elizabeth, Nicholas Hilliard was the favorite miniature-painter, and he was succeeded by Isaac Oliver. These were the most famous artists in this line about the English court, but other portrait-painters worked in small as well as in life-size, and a great number of round and oval portraits, from 2 to 3 inches in diameter, were produced, many of which are preserved. The fashion was a little less prevalent on the Continent during the sixteenth century, but in the seventeenth this was reversed, and the splendid court of Louis XIV. led all Europe into a custom of having portrait and other miniatures set in lockets, mounted in the tops of sweetmeat-boxes and snuff-boxes, or richly framed for hanging up. The introduction of enamel-painting gave great impetus to the custom, for enamel-painting is of all processes the most fit for such a purpose, because of its brilliancy of color, the ease with which gold can be introduced into it, and its perfect durability. Of the enamelers the most famous was Jean Petitot, who worked in England under Charles I., but soon returned to France, where he lived till nearly the close of Louis XIV.'s reign. It is probable that many existing enamel miniatures are improperly ascribed to Petitot, but it is quite certain that many are his, and his work, continued through a long life, set up the standard for such painting, for its quality has never been surpassed. Under the reigns of Louis XV., Louis XVI., and Napoleon, it still remained a fixed custom to present costly snuff-boxes with the portrait of the sovereign set in the lid to ambassadors and other persons to whom honor was to be done. A common way to make a money gift to any one thought to need such help was to present to him a miniature portrait of the giver and a *rouleau* of gold "to pay for having it mounted." There is constant mention of that proceeding in the memoirs of the time. Besides portraits, pictures of incident, sometimes very free in subject, were set in snuff-boxes, patch-boxes, and the like. Moreover, porcelain boxes were made, the hinge and rim of the cover being of gold or silver-gilt, and the porcelain of these boxes painted with delicate landscape and figure subjects. The little round portraits painted on ivory, even as late as 1840, and in a few cases still more recently, preserve a faint tradition of what was once a marvelous extravagance of demand and supply in one department of fine art.

Bibliography.—For miniatures in manuscripts, see the bibliography under Manuscripts; for the miniatures of the sixteenth century and later, see Bradley, *Dictionary of Miniaturists* (3 vols., 1888–89), and J. L. Propert, *History of Miniature Art* (1887). Russell Sturgis.

Minicoy, Minucoy, or **Minakai**: a small island between the Laccadives and Maldives, separating the eighth parallel channel of the navigators from that of the ninth parallel, politically belonging to the former group, and hence to Kananur of the Malabar coast, but ethnographically to the latter. It is a coral formation, crescent shaped; about 5 miles long, with a total area of 2½ miles. The population in 1881 was 3,915, giving the enormous density of 1,566 per square mile, or that of a continuous village. The inhabitants are Mohammedans. Mark W. Harrington.

Minié, mē̆e′ni-ā′, Claude Étienne: soldier and inventor; b. in Paris in 1814; early entered the army as a volunteer; fought in Algeria; was made a captain in 1849; became a teacher in gunnery at the school of Vincennes in 1852, and went in 1858 to Egypt as superintendent of a factory of firearms and director of a musketry school at Cairo on the invitation of the viceroy, who gave him the title of general. In 1849 he brought out his invention of the rifle-ball that bears his name. It is cylindrical, conical in the front, hollow in the rear, and provided with a ridge of thin iron, which by being pressed into the grooves of the barrel when the ball is forced through, gives to this a much higher precision and range. His invention was the first application of the principle of expansion in the construction of firearms. D. Dec. 14, 1879.

Min'ims, or **Min'imi,** Order of the [*minims* = Lat. *mi'nimi*, plur. of *mi'nimus*, least]: a monastic order founded by St. Francis de Paul in Calabria in 1436, confirmed by Sixtus IV. in 1474, and given its present name by Alexander VI. in 1493. Its founder called them the Hermits of St. Francis of Assisi. In Paris they were called Bons Hommes; in Spain, Fathers of Victory, because Ferdinand the Catholic ascribed to their prayers his victory at Malaga over the Moors; in German, Pauliner. The name Minim (least) is derived from the humility of their bearing—this being one of their characteristics. They were forbidden to eat flesh, likewise eggs, butter, cheese, and milk; bread, water, and oil alone formed their sole dietary, and fasts were numerous and severe. Besides monks there were nuns and tertiaries. At first the order spread rapidly, but now it has only a few monasteries in Italy, and still fewer nunneries. See Louis Dony d'Attichy, *Histoire générale de l'ordre sacré de Minims* (2 vols., Paris, 1824). S. M. Jackson.

Mining: See Mines and Mining.

Ministers: See Diplomatic Agents.

Minium: See Lead.

Miniver: See Ermine.

Mink [of uncertain etymology]: a name given to certain animals belonging to the weasel family (*Mustelidæ*) and the genus *Putorius*, especially *P. lutreola* of Europe and North Asia, and *P. vison* of North America. The former is a smaller animal, with a much finer fur than the American mink. Still the mink of North America, especially northward, yields fine and high-priced furs. The mink is 15 to 18 inches long, of a rich glossy brown with a white patch on the chin, or sometimes a white line down the throat. Minks frequent small streams and forests and mountains, swim well, and catch fish, frogs, mice, and birds. They are easily bred in a half-domesticated state. They are easily trapped, being neither suspicious nor cunning. They are very destructive in poultry-yards, often taking up their abode near them.

Minks.

Minneapolis: city; capital of Ottawa co., Kan. (for location of county, see map of Kansas, ref. 5–G); on the Solomon river, and the Atch., Top. and S. Fé and the Union Pac. railways; 23 miles N. W. of Solomon City. It is in an agricultural and stock-raising region, and has grist and saw mills, foundry and machine-shop, carriage and other factories, and 4 weekly and 3 monthly periodicals. Pop. (1880) 1,084; (1890) 1,756; (1900) 1,727.

Minneapolis [Dakota *minne*, water + Gr. πόλις, city]: city (settled in 1849, incorporated in 1867, enlarged by annexation of the city of St. Anthony in 1873); capital of Hennepin co., Minn. (for location of county, see map of Minnesota, ref. 9–E); on both sides of the Mississippi river, at the Falls of St. Anthony, and on the Burl. Route, the Chi. and N. W., the Chi. Great W., the Chi., Mil. and St. P., the Chi., St. P., Minn. and Om., the Great N., the Minn. and St. L., the Minn., St. P. and St. Ste. M., the N. Pac., the St. P. and Duluth, and the Wis. Cent. railways; 10 miles N. W. of St. Paul. It is on a broad esplanade, which commands a fine view of the falls; has an area of 55⅜ sq. miles; is regularly laid out, with straight avenues averaging 80 feet in width; and has several beautiful lakes, including the famous Minnetonka, and the celebrated Falls of Minnehaha, within easy access. The lake region, affording excellent boating, bathing, hunting, and fishing, is becoming a popular summer and autumn resort. The city is the seat of the State University (chartered in 1851) and of the Augsburg Theological Seminary (Lutheran, opened in 1869), and contains 167 churches, 62 public-school buildings, an academy,

2 female seminaries, a medical college, a conservatory of music, a free public library (building cost $350,000) with over 112,631 volumes, 4 opera-houses, 18 miles of boulevard drives, 1,194 acres of lands devoted to public parks, and 2 large cemeteries. Among notable buildings are the city and county building (cost $4,000,000); Northwestern Guarantee Loan (cost $1,250,000); New York Life Insurance (cost $800,000); and the Masonic Temple (cost $400,000). The census returns of 1890 showed that 2,649 manufacturing establishments (representing 162 industries) reported. These had a combined capital of $40,763,718; employed 26,453 persons; paid $14,439,005 for wages and $50,116,362 for materials; and had products valued at $77,146,451. The principal industry, according to the amount of capital employed, was the manufacture of flour and grist mill products, which had 18 establishments, and $9,960,997 capital, paid $946,958 for wages and $24,703,703 for materials, and had products valued at $27,758,790. Next was sawed lumber, with 20 establishments and $8,577,304 capital, which paid $1,002,949 for wages and $4,894,257 for materials, and had products valued at $7,215,293. Then followed agricultural implements, 7 establishments, $2,382,318 capital, $173,370 wage and $205,573 materials payments, and $848,466 value of products; planing-mill products, 22 establishments, $2,188,093 capital, $803,243 wage and $1,231,398 materials payments, and $2,411,682 value of products; and foundry and machine-shop products, 36 establishments, $1,374,924 capital, $509,280 wage and $413,785 materials payments, and $1,411,721 value of products. The taxable valuation of the city in 1893 was $140,624,490, the tax levy amounted to $2,995,301, and the city owned property valued at $18,512,330. The net debt Jan. 1, 1894, was $6,637,573, including a water debt of $1,230,000. There were 7 national banks, combined capital $5,450,000, 15 State banks, of which 13 reported combined capital $2,655,000, and 2 other banks, and 6 daily, 43 weekly, 6 semi-monthly, 27 monthly, and 2 quarterly periodicals. Pop. (1880) 46,887; (1890) 164,738; (1895) 192,833; (1900) 202,367. EDITOR OF "NORTHWESTERN MILLER."

Minnedo'sa: a town of Manitoba, on the Little Saskatchewan, an affluent of the Assiniboine; 135 miles W. N. W. of Winnipeg, on the Manitoba and Northwestern Railway (see map of Canada, ref. 9–H). It is a flourishing business place in a region of excellent farming land which is rapidly filling up with colonists. Pop. 1,500. M. W. H.

Minneha'ha [Dakota, liter., laughing water]: a waterfall in Hennepin co., Minn., celebrated for its beauty. Here the small river Minnehaha leaps 60 feet down a limestone precipice. It is half a mile from the Mississippi and near Minneapolis. The interesting legend of an Indian maiden leaping this fall when thwarted in her love for an Indian brave has been finely treated by Longfellow in *The Song of Hiawatha*.

Minnesingers [from Germ. *minnesinger*, *minne*, love (< O. H. Germ. *minni*) + *singen*, sing]: the name of that class of German poets, belonging chiefly to the nobility, who, from the latter part of the twelfth to the close of the thirteenth century, cultivated lyric poetry as an art. Although this name was applied to this class of poets by Hartmann von der Aue, and used during the later Middle High German period, it was lost during the subsequent centuries, and finally was reintroduced by Bodmer, who revived the interest in the study of these poets by the publication of a collection of their poems (1758). The origin and growth of the minnesong coincides with the development of the German chivalry during the twelfth century, though it is incorrect to regard the minnesong a product of the French influence which at that time made itself felt in the social life of the German courts and castles. The oldest specimens of the minnesong which originated in Austria do not indicate the least trace of such foreign influence. Their resemblance in contents and language to the popular song recorded in the fourteenth and fifteenth centuries makes it, on the contrary, quite evident that the oldest minnesong developed from the popular German love-song, of which we possess unfortunately no documents previous to the middle of the twelfth century. While we have thus in Austria a German minnesong of purely native origin (Kürenberg, Burggraf von Regensburg, etc.), we can observe in the western part of Germany the rise of a more artistic minnesong, which is due to the influence of Provençal and French models. The imperfect rhymes prevailing in the old Austrian songs are now gradually being replaced by perfect ones; the structure of verse and strophe is regulated by artistic principles, and instead of the old monostrophic song we now find the poets combine a number of strophes into one poem. Besides, we may notice how the views of the fashionable court society, the strict rules of chivalrous etiquette which form the basis of the troubadour poetry, also became the conditions upon which the artistic minnesong rests. Now the German knight, like his French model, addresses his lamentations to some married noble lady, whose servant he becomes, whose name he dare not betray, and whose favor, if ever attained, he had to enjoy secretly, amid great dangers, as she was being watched very closely. Under these conditions there was little room left for the descriptive element of poetry, since the poet was restricted to the depiction of a very few situations. With the exception of the *Tagelieder*, in which the parting of the lovers in the morning after a clandestine meeting is more or less dramatically described, there is to be found a great monotony in the minnesongs of this kind. We are compensated, however, for this defect and the consequent introspectiveness of most minnesongs by the graceful expression of tender and deep sentiments, and by conceptions concerning womanhood and love, which in their sublime idealism are distinctly German and far surpass the frequently frivolous tone of the troubadour songs.

The earliest representatives of this artistic minnesong are Heinrich von Veldeke and Friedrich von Hausen. They have numerous followers, the most prominent of whom are Heinrich von Morungen and Reinmar der Alte. In the latter poet, who lived at the Austrian court, we may probably see the model, if not the teacher, of Walther von der Vogelweide, whose earliest minnesongs show in thought and style a great similarity to those of Reinmar. Walther, who was the greatest lyric poet of the Middle Ages, soon felt the burdensome narrowness and monotony of the minnesong, as well as the apparent immorality of the whole minnedienst, and we can follow him in his poems opposing the unnatural artificiality of the minnesong and claiming the right of healthy nature. In his best songs Walther again approaches the simplicity of the popular love-song, which he ennobles by the means of his exquisite art. The decline of the minnesong sets in with Walther's death. While some of the minnesingers, like Ulrich von Lichtenstein, carry the old traditions to a ridiculous extreme, a number of poets, like Tannhäuser, Steinmar, Neifen, and others, continue the opposition inaugurated by Walther, ridiculing the sentimentality of the minnedienst, and finally dissolving the whole fabric of minnepoetry. The songs of Neidhart von Reuenthal who, assuming the air of a minnesinger, sings the praise of peasant girls and makes the villages near Vienna the scene of his love adventures, must also be classed among the opposition to the artificial minnepoetry of Reinmar and Ulrich von Lichtenstein. With the close of the thirteenth century the minnesong has practically died out or become petrified among the mastersingers, the inheritors of the highly developed metrical form and other artificialities of the last minnesingers.

BIBLIOGRAPHY.—The poems of the minnesingers have been handed down to us in a number of good manuscripts, among which the so-called *Mannessische*, now in Heidelberg, is the costliest and most famous. It has been reprinted in the large edition of the minnesingers by F. von der Hagen. The minnesingers previous to Walther may be found in the classical edition *Des Minnesangs Frühling*, by Lachmann and Haupt. JULIUS GOEBEL.

Minnesota [named from Minnesota river]: one of the U. S. of North America (North Central group); the nineteenth State admitted into the Union.

Location and Area.—It is bounded N. by the Dominion of Canada, E. by Lake Superior and Wisconsin, S. by Iowa, and W. by North Dakota and South Dakota. The west part of the north boundary is the parallel of 49° N. lat.; the Iowa line is the parallel of 43° 30′ N. lat. The extreme longitudes are the meridians of 89° 39′ and 97° 5′ W. The area of the State, including all marginal waters except those

of Lake Superior, is 84,286·53 sq. miles (53,943,379 acres). The geographic position of Minnesota is almost central in the continent of North America, and her drainage reaches the Atlantic by way of Hudson Bay, the Gulf of St. Lawrence, and the Gulf of Mexico.

Seal of Minnesota.

Physical Features. — In the north central part of the State is a plateau, the highest points of whose surface are 1,750 feet above sea-level. From this height the general surface slopes gradually in all directions toward the boundaries, but curving upward in both the northeastern and southwestern corners, so as to give still higher elevations. The granite pinnacles of the Giant Mountains N. of Lake Superior reach a height of 2,200 feet, while the Coteau des Prairies gives to several southwestern counties an elevation of some 1,800 feet. The slopes, of very unequal area, are each quite uniform in declivity. The average elevation of the whole State is 1,275 feet above sea-level. The feature which most conspicuously breaks the general uniformity of surface is the great trough formed by the valley of the Mississippi in the S. E., the valley of the Red River of the North, and, intermediate and continuous with them the broad valley of the Minnesota river, making a big V with its salient thrust well into the southern part of the State. The highest point in this trough is 975 feet.

The Itasean plateau contains the sources of four river systems, each draining one of the great slopes. The Red River of the North, receiving the waters flowing from the western slope, discharges them into Lake Winnepeg and ultimately into Hudson Bay. The area thus drained is 15,107 sq. miles. The northern slope is less extensive, occupying an area of 10,330 sq. miles, traversed by numerous short streams emptying into the Rainy river or into the chain of lakes forming a considerable part of the northern boundary of the State. The ultimate outlet is into Hudson Bay. The eastern slope is smallest in area, covering only 8,552 sq. miles, and has the greatest angle of declivity, the lowest land in the State being found near Fond du Lac, where the St. Louis empties into Lake Superior. This system is understood to embrace a number of streams flowing S. E. directly into Lake Superior. The head waters of the Mississippi river spring from the heart of the Itasean plateau, in the lake named by Schooleraft "Itasca." They flow first northerly, then curve eastward through a great chain of lakes, and describe more than a half circle before striking out in a main southerly course for the Gulf of Mexico. After receiving the St. Croix 20 miles below St. Paul, the Mississippi forms the eastern boundary of the State, and leaves it at an elevation of 620 feet above sea-level. The flow of the Mississippi, like that of most of the rivers of the State, is on the drift till its descent of the Falls of St. Anthony, whence it follows a deeply eroded preglacial channel. Of numerous tributaries the Minnesota is by far the most important. The area drained by the Mississippi is 45,566 sq. miles, more than half of the State. The Mississippi, the Minnesota, and the Red are the only rivers that are navigable, and navigation has almost ceased on the last two. In the extreme southern part of the State are found the head waters of the Cedar and the Des Moines, which, flowing southerly, at length reach the Mississippi. The Rock river empties into the Missouri. The total area drained by these streams is 4,731 sq. miles.

It is estimated that the surveys of the State when completed will enumerate 10,000 lakes. They are of all sizes, from Red Lake, with an area of 340 sq. miles, down to inconsiderable ponds. At least three-fourths of the lakes are found in the "morainic till" which forms the surface of the greater part of the State. A smaller number, generally shallow, but often extensive, lie in the "modified drift." A very few, like Lakes Traverse and Big Stone, in the Minnesota trough, and Lake Pepin, in the Mississippi valley, are mere enlargements of river beds. The remainder are the rock lakes, lying along the northern boundary and in the triangle, where they display bold and tortuous shores.

Geology.—From the reports of the State Geological Survey, which has been prosecuted since 1872 under the auspices of the University of Minnesota, the following statement, in which the local terminology is employed, has been gathered: An ancient Archæan axis traverses the State centrally from N. E. to S. W. On the opposite flanks of this axis the later rocks are laid in belts approximately parallel, though they are much more extensive on the southeastern flank. These belts in order are—(1) The Taconic, embracing two systems, (*a*) the Animikie, which has at its base the quartzite seen at Pakegama Falls, New Ulm, and in Pipestone County, and (*b*) the Keeweenawan or copper-bearing traps of the Lake Superior region; (2) the St. Croix series, displayed extensively in the bluffs of the St. Croix and Mississippi rivers, being of Cambrian age; (3) the Lower Silurian, extending from the St. Peter sandstone upward to the Hudson river formation, seen in the interior of the State; (4) a feeble representation of the Upper Silurian; and, (5) nonconformable upon the last, the lowermost members of the Devonian, viz., the Corniferous, and doubtfully some traces of the Hamilton. All these systems and formations are clearly made out in the S. and E., but in the N. W. they lie deep under the drift. Later than all the foregoing, Cretaceous strata were deposited with discordant stratification on their outcropping edges. The State as a whole lies under a heavy mantle of drift, which is deepest in the western half and thins out gradually, to disappear in the triangle N. of Lake Superior and in the ancient rocky valley of the St. Croix and the Mississippi. The principal rock exposures are found in these denuded areas. In the western half of the State exposures are few and widely separated, the principal being those of the upper Minnesota valley and the quartzites of the extreme southwestern counties. As a general fact, the great drift sheet consists of that confused mixture of sand, gravel, and clay known as till, and believed to be the immediate product of glacial action. Along the river valleys, however, are found extensive areas of stratified sand and gravel, evidently deposited in water on a foundation of till. In some cases these deposits form narrow terraces, in others they widen out into plains. Extensive beds of stratified sand and gravel are also found outside of river gorges, and they constitute a large portion of the surface drift in the Leaf Hills, the Mesabi Range, and in the Coteau des Prairies. These drift materials are the subsoil of the State, and mingle with other elements to form also the surface soil. There is very little stony ground. The top covering of the soil, commonly known as "black dirt," varies in depth from a few inches to several feet. The color and richness of this coating are due to the residuum of immemorial prairie-fires, or, in the forest regions, to the accumulations of decayed vegetation.

The stratified clays of the drift are wrought into bricks of many degrees of color and hardness. Excellent pottery is made from the finer clays, and kaolin and other materials for crockery are found on the Cretaceous area.

Clean, sharp sand for building purposes is generally abundant, and the pure white sands from the St. Peter formation are pronounced unsurpassed for glass-making. Building-stones are found in great variety, and may be classified as follows: (1) Crystalline, as in the granites at St. Cloud; (2) quartzite, as in the red jasper of the southwestern counties; (3) dolomites, as in the beds at Frontenac; (4) dolomitic limestone, as quarried at Red Wing and Kasota; (5) limestone, as in the Trenton beds about Minneapolis; and (6) sandstones, as found at Hinckley, Dresbach, and Jordan.

The Archæan formations of the State contain iron mines of phenomenal richness and accessibility. The region known as the Vermilion Iron Range extends both E. and W. from Tower. From this range in 1899 were produced 1,643,984 long tons of high-grade ore, mostly suitable for Bessemer steel. Another range of iron-bearing rock lies at the base of the Palæozoic in the Taconic formation, known as the Mesabi Range. This region extends from the Pokegama Falls of the Mississippi river easterly 145 miles. The ore is soft hematite, very free from impurities. Extensive mining is carried on by means of steam shovels, which lift the ore directly from the bed to the railway cars. The production in 1899 was 6,517,305 long tons. The total shipments of iron ore from Minnesota mines in 1899 were 8,161,289 long tons.

Productions.—The great geographic extent of the State, the richness of soil, and the abundance of water give rise to a varied and abounding flora. The valley of the Minnesota, occupying less than one-fifth of the area, contains 1,174 flowering plants. Contrary to a common belief, Minnesota is a country of forest rather than of prairie. About 52,000 sq. miles are, or have been, wooded, the remaining 32,000 sq. miles being prairie.

The timber of the woods of the Coteau des Bois region consists chiefly of oak, elm, bass, and maple. In the north half of the State are found white and yellow pine, white cedar, spruce, tamarack, and birch. The winter climate is too rigorous for the peach and the cherry, but the hardier varieties of the apple are grown, and many varieties of the native plum are being propagated. Small fruits, including the grape, flourish in great abundance and excellence. Nowhere are the usual garden vegetables grown in greater perfection than in the black soil of this State.

The buffalo and antelope, which were once plentiful, have disappeared, but in the great forest to the N. are elk, moose, bear, deer, and rarely the beaver. Grouse, partridge, and quail still survive the war of the pot-hunter. There are few waters that are not well stocked with valuable species of fish. The State has an efficient game law, and a State fish commission is engaged in restocking lakes and streams.

The following summary from the census reports of 1880 and 1890 shows the extent of farm operations in the State:

FARMS, ETC.	1880.	1890.	Per cent.
Total number of farms	92,386	116,851	+26·5
Total acreage of farms	13,403,019	18,663,645	+39·2
Value of farms, including buildings and fences	$193,724,260	$340,059,470	+75·5

The following table shows the acreage, yield, and value of the principal crops in the calendar year 1900:

CROPS.	Acreage.	Yield.	Value.
Corn	963,476	31,794,708 bush.	$9,220,465
Wheat	4,905,643	51,509,252 "	32,450,829
Oats	1,662,978	41,907,046 "	10,057,691
Rye	53,151	1,036,444 "	435,306
Barley	324,788	7,275,251 "	2,764,595
Buckwheat	9,564	143,460 "	81,772
Potatoes	106,618	8,636,058 "	2,590,817
Hay	1,227,021	1,423,344 tons	9,892,241
Totals	9,253,239	.....	$67,493,716

On Jan. 1, 1900, the farm animals comprised 459,673 horses, value $25,256,763; 8,248 mules, value $489,858; 672,540 milch-cows, value $21,285,891; 564,463 oxen and other cattle, value $13,700,354; 419,218 sheep, value $1,333,113; and about 600,000 swine, value $5,000,000; total value, $67,065,979.

Climate.—The climate of the mid-temperate zone is in Minnesota modified and ameliorated by local conditions. It is rare that an abundant rainfall in the growing season is not followed by dry weather favorable to harvesting. The winters are dry, with moderate snowfall. The high latitude gives a long day in the growing season. Fair weather is the rule for the whole year, so that Minnesota has been a favorite resort for invalids needing to live out of doors. Malarial diseases are unknown.

The average temperature for the year of the central part of the State is 44·6°, for the summer 70·5°, and for the winter 16·1°. The average precipitation for the year is 28·75 inches; the mean height of barometer, 30·00; and the lowest winter temperature in 1893 was —26° F.

The record of observations made at Minneapolis (lat. 45° N., lon. 93° 14′ W.) by William Cheney, voluntary observer, U. S. Weather Bureau, Department of Agriculture, shows the average temperature and precipitation by months from 1865 to 1893 inclusive:

MONTHS.	Temperature, average for 29 years.	Rainfall in inches, average for 28 years.
January	8·72°	1·218
February	14·23	1·206
March	24·76	1·484
April	43·65	2·419
May	57·23	3·516
June	67·03	4·282
July	71·38	3·304
August	68·22	3·776
September	58·79	3·413
October	45·76	1·858
November	29·16	1·307
December	15·70	1·249

The average temperature of the year at this station is 42·05 (twenty-nine years); the average summer temperature, 68·88°; the average winter temperature, 12·88°; and the average rainfall per year, 29·032 inches (twenty-eight years).

Divisions.—For administrative purposes Minnesota is divided into eighty-four counties, as follows:

COUNTIES AND COUNTY-TOWNS, WITH POPULATION.

COUNTIES.	* Ref.	Pop. 1890.	Pop. 1900.	COUNTY-TOWNS.	Pop. 1900.
Aitkin	6-E	2,462	6,743	Aitkin	1,719

* Reference for location of counties, see map of Minnesota.

Principal Cities and Towns, with Population in 1900.—Minneapolis, 202,718; St. Paul, 163,065; Duluth, 52,969; Winona, 19,714; Stillwater, 12,318; Mankato, 10,599; St. Cloud, 8,663; Faribault, 7,868; Red Wing, 7,525; Brainerd, 7,524; Rochester, 6,843; Fergus Falls, 6,072; Little Falls,

5,774; Owatonna, 5,561; Austin, 5,474; New Ulm, 5,403; Crookston, 5,359; Albert Lea, 4,500; Hastings, 3,811.

Population and Races.—In 1850, 6,077; 1860, 170,023; 1870, 439,706; 1880, 780,733; 1890, 1,301,826 (native, 834,470; foreign, 467,356; males, 695,321; females, 606,505; white, 1,296,159; colored, 5,667, of whom 3,683 were persons of African descent, 94 Chinese, 2 Japanese, and 1,888 civilized Indians); 1900, 1,751,394.

Industries and Business Interests.—The census returns of 1890 showed that 7,505 manufacturing establishments reported. These had a combined capital of $127,686,618, employed 79,629 persons, paid $38,189,239 for wages and $118,481,941 for materials, and had products valued at $192,033,478. The leading manufacture is that of spring wheat-flour, and its chief seat is in Minneapolis, where the immense water-power of the Falls of St. Anthony is mostly thus utilized. The daily capacity of its mills is 46,800 barrels, and the output of the year 1892 was 9,750,470 barrels, of which 3,337,205 barrels were exported directly from the mills to foreign markets. A considerable manufacture of flour is growing up in Duluth, attracted by the convenience of shipment directly by water. Lumber, chiefly pine, holds the next place to flour. The total cut of pine in 1892 was reported as 1,091,917,003 feet. The greater part of this was manufactured into lumber in the State, Minneapolis holding the leading place, with Duluth as second. Next in importance and of considerable magnitude are foundries and machine-shops, builders' supplies, meat-packing, agricultural implements, furniture, printing, car-building, boots and shoes, and paper.

Banking.—On Sept. 5, 1900, there were 83 national banks with combined capital of $12,682,040, individual deposits of $45,805,379.48, and surplus and profits of $3,671,687.91; and 188 State banks with combined capital of $6,654,800, individual deposits of $28,130,738, and surplus and profits of $1,442,940. There were also 47 private banks, 6 loan and trust companies, and 11 savings-banks, with combined capital of $2,992,507, deposits of $16,277,189, and surplus and profits of $751,029.

Commerce.—Minnesota has two U. S. customs districts and ports of entry—Duluth, on Lake Superior, and Minnesota City, with the chief office at St. Paul, on the Mississippi river. During the calendar year 1900 the imports of merchandise at Duluth aggregated $96,400 in value, and the exports $3,659,241; and the imports at Minnesota City $1,581,390, and exports $357,778; total imports, $1,677,790; exports, $4,017,019; total foreign merchandise trade, $5,694,809.

Finance.—The assessed valuation is about $700,000,000. State tax rate (1898), $1.50 per $1,000. In the year ending July 31, 1900, the receipts of the State aggregated $9,015,168.24, and the expenditures $6,845,830.72, leaving balance of $2,169,337.52. The total debt, all funded, on July 31, 1900, was $1,279,000.

Means of Communication.—With some exceptions the railways may be considered as radiating from a center in the "twin cities," St. Paul and Minneapolis. Their aggregate mileage on June 30, 1899, was 6,560·26 miles. The 3 per cent. tax on gross earnings, in lieu of all other taxes, amounted to $1,443,992.13. Minnesota has no canals. The rivers furnish over 2,500 miles of navigation, and Lake Superior, penetrating to the heart of the State, gives water communication eastward to the seaboard.

Churches.—The census of 1890 gave the following statistics of the principal religious bodies having a membership of 5,000 and upward each in the State:

DENOMINATIONS.	Organizations.	Churches and halls.	Members.	Value of church property.
Roman Catholic	465	445	271,319	$3,514,325
Lutheran, United Norwegian	405	388	49,541	608,200
Methodist Episcopal	534	532	30,837	1,725,843
Lutheran Synodical Conference	217	178	30,398	443,700
Lutheran, General Council	220	223	27,609	616,720
Lutheran, Norwegian Evan.	164	147	21,832	267,950
Baptist	194	194	14,698	1,107,839
Presb. in the U. S. of America	167	173	13,732	1,292,670
Congregational	175	177	13,624	1,114,800
Protestant Episcopal	171	173	11,142	931,100
Lutheran, Hauge Synod	55	55	6,534	99,345
Evangelical Association	134	134	6,181	170,550
German Evan. Synod of N. A.	53	53	5,567	97,900

Schools.—The system of public instruction consists of (1) the common schools and the normal schools for supplying them with teachers; (2) the graded schools, including the high schools; and the State University. These institutions are organically affiliated and are unique in presenting a complete system of secularized school instruction, in which tuition is absolutely free of charges, from A B C to the doctorate of philosophy.

The State superintendent is at the head of the system. County superintendents have immediate supervision of the common schools. The graded schools are supervised by local superintendents. Most of the high schools are subject to the visitation of the State high school board, which controls the distribution of a State fund to such approved schools as undertake to prepare students for the university. In 1898–99 there were 6,940 schools; the school property was valued at $14,800,000. There were 11,250 teachers—2,306 men and 8,944 women: the average pay a month was, for men $41, for women $29.50. The total revenue for school purposes was $5,550,437, and the expenditure $5,172,110. There were 384,063 children enrolled; average daily attendance, 237,145. School was held 159 days. The expenditure per pupil, based on the average daily attendance, was $21.81. The permanent school fund derived from the sales of public lands granted by the general Government amounted in 1899 to $696,842. Under a "local-option" law textbooks are generally supplied to pupils of common and graded schools at public expense.

Libraries.—According to a U. S. Government report on public libraries of 1,000 volumes and upward each in 1891, Minnesota had 56 libraries which contained 304,668 bound volumes and 35,690 pamphlets. The libraries were classified as follows: General, 12; school, 19; college, 9; law, 2; theological, 2; medical, 1; public institution, 2; Y. M. C. A., 1; social, 5; scientific, 2; and historical, 1.

Post-offices and Periodicals.—In Jan., 1901, there were 1,660 post-offices, of which 148 were presidential (3 first-class, 18 second-class, 127 third-class) and 1,512 fourth-class. There were 782 money-order offices and 50 money-order stations. The newspapers and periodicals comprised 36 daily, 4 semi-weekly, 560 weekly, 1 tri-monthly, 1 bi-weekly, 19 semi-monthly, 58 monthly, 1 bi-monthly, and 3 quarterly publications; total, 683.

Charitable, Reformatory, and Penal Institutions.—A legislative act of 1883 established a State Board of Corrections and Charities, and formed all of these institutions into an aggregate, the board having charge of the whole system. Each institution is under the immediate supervision of a board of trustees or managers, excepting the schools for the deaf, dumb, and blind, which are grouped into an Institute for Defectives. The whole number of inmates in 1900 was 5,730, and the total expenditure in the 13 charitable and penal institutions was $969,337. The hospitals for the insane are at St. Peter, at Rochester, and at Fergus Falls. The Institute for Defectives is at Faribault, and the School for Dependent and Neglected Children at Owatonna. The Soldiers' Home occupies a beautiful site on the Mississippi river in Minneapolis. The reformatory institutions are the State Prison at Stillwater, the State Reformatory at East St. Cloud, and the Reform School at Red Wing.

Political Organization.—The constitution comprises a bill of rights, a frame of government with the usual tripartite division of functions, and separate articles on elective franchise, finances, and education. The executive department comprises a Governor, Lieutenant-Governor, Secretary of State, auditor, treasurer, attorney-general, land commissioner (the auditor), commissioner of statistics (the assistant secretary of State), superintendent of public instruction, public examiner, State librarian, commissioner of labor statistics, insurance commissioner, inspector of illuminating oils, seven inspectors of logs and lumber, five inspectors of steam-boilers, and about 7,000 notaries public. Besides the regents of the State University, the Governor appoints the members of seventeen boards and commissions. The Legislature meets biennially, and remains in session for 90 legislative days. The 80 counties are divided into 54 districts, each of which elects one Senator and one or more Representatives, of whom the whole number in 1894 was 114; Senators are elected for four years, Representatives for two. The Legislature is prohibited from passing special acts when a general law can be made applicable, and no bills can be introduced in the last twenty days of a session excepting by a special message from the Governor. The Governor may veto any item or items of an appropriation bill while approving the remainder. The judiciary has the usual gradation of courts. All judges and clerks of courts of record are elected, judges for six years, clerks for four years. Minnesota being a "code State," the distinction between actions at law and suits in equity is abolished, and there is but one

form of action, called "a civil action." The franchise is extended to males twenty-one years old and upward who have resided in the U. S. for one year, in the State for four months, and in the election district for ten days, providing they are citizens of the U. S., foreigners who have declared their intentions of becoming citizens, civilized half-breed Indians, and civilized Indians examined in any district court and pronounced capable. Women of legal age may vote for school officers and measures, and may hold school offices. All voters must have been registered previously. A modification of the Australian ballot system is in use. Elections are held on the first Tuesday after the first Monday in November in alternate even-numbered years. The legal rate of interest is 7 per cent.; the rate allowed by contract, 10 per cent.

History.—The most conspicuous of the early missionaries and fur-traders who penetrated the territory was Father Hennepin, who in 1680 discovered the falls, to which he gave the name of his patron saint, Anthony of Padua. Deserving of mention also was Capt. Jonathan Carver, who set out in 1766 to explore the new lands which under the treaty of 1763 had passed from France to England. The part of Minnesota E. of the Mississippi became U. S. territory by the treaty of 1783, and was included in the "Northwest Territory," organized under the ordinance of 1787. It was later part of Indiana, Michigan, and Wisconsin territories successively.

The lands W. of the Mississippi came into possession of the U. S. by the Louisiana purchase, and were included successively in the territories of Upper Louisiana, Arkansas, Missouri, and Iowa. The expedition of Lieut. (later Gen.) Zebulon Pike in 1805 furnished to the Government and to the people the first definite and authentic information of the climate, soil, and natural resources of the region. Later military explorations enlarged and confirmed Pike's reports. In 1819 the Government took measures which resulted in the completion of a military post, later known as Fort Snelling, at the junction of the Minnesota and Mississippi rivers. For the use of the garrison a sawmill was built at the Falls of St. Anthony, 7 miles above, in which in 1823 machinery for flouring was set up.

In 1827 a body of Swiss refugees from Lord Selkirk's colony at Pembina, on the Red River of the North, appeared at Fort Snelling, and were allowed to cultivate lands belonging to the post. These were the first white settlers. In the decade 1830–40 a post of the America Fur Company was established at Mendota, near Fort Snelling, by Henry Hastings Sibley, later first Governor of the State. In the same period the scientific explorations of Featherstonehaugh, Mather, Nicollet, Frémont, Cass, and others were prosecuted, and such missionaries as the Ponds, Riggs, Williamson, and Boutelle began their labors. By them the Dakota language was reduced to writing. In 1837 the Chippewa title to the lands E. of the Mississippi was extinguished, and thereupon pioneers swarmed in to take up farms and cut pine lumber on the St. Croix. In 1841 the Catholic missionary Father Galtier erected a small log chapel on the site of the city, which took its name, St. Paul, from that given to the edifice.

Congress passed an act creating the Territory of Minnesota on Mar. 3, 1849. In 1851 21,000,000 acres of land were acquired of the Dakotas by the treaty of Traverse de Sioux. The influx of settlers was immediate and rapid, and industry and trade increased at a prodigious rate, which later was but slightly checked by the disasters of the panic year of 1857. In 1858 Minnesota was admitted to the Union as a State, with an area much reduced, under a constitution closely modeled on those of States previously created out of the Northwest Territory.

The Dakotas in selling their lands in 1851 reserved a considerable territory on the Upper Minnesota, toward the southwestern corner of the State. Exasperated by the encroachments of settlers, the extortions of traders, and the mismanagement of Government agents, the Sioux in Aug., 1862, raided the adjacent settlements. In the course of thirty-six hours, as stated by Neill, some 800 whites were murdered. As soon as possible a military force was organized under Gen. H. H. Sibley, which after a series of affairs and two considerable battles at Birch Coolie and Wood Lake, captured or dispersed the savages. Of the leaders, thirty-eight were executed on one scaffold at Mankato Dec. 26, 1862.

In the course of the civil war Minnesota furnished 11 regiments of infantry, a regiment of heavy artillery, 3 batteries of field-artillery, 4 regiments or battalions of cavalry, and 2 companies of sharpshooters, in all 25,052 men, equal to one-seventh of her population.

GOVERNORS OF MINNESOTA.

Territorial.	
Alexander Ramsey	1849–53
Willis A. Gorman	1853–57
Samuel Medary	1857–58
State.	
Henry H. Sibley	1858–60

WILLIAM W. FOLWELL.

Minnesota River [*Minnesota* is from Dakota *minne*, water + *sota*, muddy]: a stream which rises in Big Stone Lake, on the boundary between Minnesota and South Dakota, traverses the State of Minnesota, flowing first S. E. and then N. E., reaching the Mississippi 5 miles above St. Paul. It flows through the Coteau des Bois, or Big Woods, a great forest of deciduous trees, and is navigable 300 miles in high and 45 in low water. Total length, 470 miles.

Minnesota, The University of: a public institution for superior education in Minneapolis, Hennepin County, established by territorial statute 1851, confirmed by the State constitution adopted in 1857. The present charter dates from 1868, and the first collegiate work was begun in 1869.

The government is vested in a board of regents consisting (1) of nine members appointed for six years and (2) of three members *ex officiis*—the Governor of the State, the State superintendent of public instruction, and the president of the university. Tuition is free in the non-professional departments. Both sexes are admitted. There is no dormitory system. No honorary degrees have been or can be conferred. The libraries contain over 55,000 volumes. The laboratories are extensive and well equipped. The geological survey of the State was intrusted to the university in 1872 and has since been in successful progress. The first volume of the final report was published in 1884, the second in 1888.

The endowment consists of 202,083 acres of lands granted by the national Government, or the proceeds of the sales thereof. Over half of the lands have been sold and the amount of the permanent fund was, in 1899, $1,307,219. The current-expense fund is hereafter to come mainly from a share—three-twentieths of one mill—of the general State school tax.

In the early years the university was obliged to maintain a "preparatory" department. The plan of organization adopted in 1870 provided for the gradual elimination not only of the preparatory department, but also of the first two years of the usual college work, thus relegating all secondary instruction to the affiliated high schools of the State. The last preparatory class was dropped in 1887, but a considerable time must elapse before the university may safely throw more work on those schools. By the mediation of a State high school board, charged with the management and distribution of a State fund to such high schools as will undertake to prepare students of both sexes free of charges for tuition for the university, eighty high schools are brought into close filiation with the university, and the system of public instruction unified and completed.

The following colleges or departments have been organized and are in operation: The College of Science, Literature, and the Arts; the College of Agriculture; the College of Engineering, Metallurgy, and the Mechanic Arts; the College of Law; the Colleges of Medicine, Dentistry, and Pharmacy. The number of students in all departments in Jan., 1900, was 3,410, and the faculty numbered 246.

WILLIAM W. FOLWELL.

Minnetarees: See SIOUAN INDIANS.

Minnewaukon, or **Devil's Lake**: a body of water in the northern part of North Dakota, on the 48th parallel of N. lat. It is about 40 miles long, and 12 miles wide in its broadest part. Its water is of a deeper tint than that of the surrounding fresh-water lakes, and is so brackish as to be unfit to drink.

Minnow [M. Eng. *menow* < O. Eng. *myne* (cf. dial. Mod. Eng. *minny*, minnow)]: a name applied to many small fresh-water fishes of the family *Cyprinidæ*. The English minnow is *Leuciscus phoxinus*, a very common little fish of the brooks, with blunt head, small scales, and the males brightly colored in spring. In the U. S. the name is extended to some 200 small fishes, species of *Hybognathus*, *Notropis*, *Leuciscus*, *Rhinichthys*, etc. They are used as live bait in pike and pickerel fishing, and are important as affording food to larger and better fishes.

Revised by D. S. Jordan.

Mino da Fiesole, mee'nō-daa-fē̆e-es'ō-lā: sculptor; b. in Italy about 1430. He went to Rome at an early age, but he had already attained a prominent position in his art, for he was commissioned to adorn with bas-reliefs the marble altar of St. Jerome for Sta. Maria Maggiore. The monument of Paul II. was intrusted to him, and was considered at the time the most beautifully ornamented of any of the papal tombs. He then made a tabernacle to contain the holy oil for St. Maria in Trastevere, and in Sta. Maria sopra Minerva, the tomb of Francesco Tornabuoni, the marble statue on which was much admired. After this he returned to Fiesole and settled there, producing innumerable works for the convents and churches of Florence, and monuments, of which the one to the Markgraf Hubert of Magdeburg is one of the finest. Prato, Perugia, and Volterra also possess examples of his art. D. in 1486. W. J. Stillman.

Minonk: city; Woodford co., Ill. (for location of county, see map of Illinois, ref. 4–E); on the Atch., Top. and S. Fé and the Ill. Cent. railways; 29 miles N. of Bloomington, 53 miles N. E. of Peoria. It has valuable coal mines, brickyards, tile-works, steam flour-mills, grain elevators, and 2 private banks. Pop. (1890) 2,316; (1900) 2,545.

Minor: See Infant.

Minor: Robert Crannell: See the Appendix.

Minor: Virginia Louisa: See the Appendix.

Minor'ca [Span. *Menorca*; from Lat. *mi'nor*, less, the lesser. Cf. Majorca]: the second largest and easternmost of the Balearic islands; situated in the Mediterranean, 27 miles E. N. E. of Majorca, and belonging to Spain; is about 35 miles in length and 17 broad. Area, 301 sq. miles. Pop. 35,000. It is mountainous, its highest point, Mt. Toro, rising 1,148 feet. It produces oil, wine, hemp, and fruits. The *Hedysarum coronarium*, or zulla, is extensively cultivated for fodder. Sweet potatoes are also raised here and exported to Algeria. The caper plant is abundant. The island has manufactures of wool, hemp, flax, etc. Among the principal exports are wheat and cattle. The island is less fertile than Majorca; lead, copper, and iron are found, but the scarcity of fuel prevents extensive working of them. Superior marbles and porphyries are found here, also lime and slate. The coast contains numerous creeks and bays, especially on the north side. The chief town, Port Mahon, the capital, situated on the southern coast of the island, has a spacious, safe, and strongly fortified harbor capable of accommodating a whole fleet of men-of-war. Minorca has also the ports of Addaya, Fornells, Nitja, and Ciudadela, which was formerly the capital, and has a cathedral and several convents, also woolen manufactures. The island has been declining in business and population since it passed from English into Spanish hands (1803). A considerable emigration is taking place to Algeria, where the Minorcans are called Mahonais. Revised by M. W. Harrington.

Mi'norites [from Lat. *minor*, lesser. Cf. Lat. name *Fra'tres Mino'res*, lesser brothers]: the name given by St. Francis of Assisi to his original order. (See Franciscans.) The name is still borne by some congregations of that great order or group of orders.

Minority Representation: See Representation.

Minor Mode, **Minor Scale**: See Mode and Scale.

Mi'nos (in Gr. Μίνως): a King of Crete, to whom the Cretans traced their laws and political institutions; said by Homer and Hesiod to have been a son of Zeus and Europa, a brother of Rhadamanthus, father of Deucalion and Ariadne. He was on familiar terms with his father Zeus, in whose sacred grotto he lived for nine years, being instructed by his father in the science of laws. His laws were therefore promulgated in the name of the god. Minos died and was buried in Sicily, whither he had gone in pursuit of Dædalus (*q. v.*). After his death he became one of the judges in Hades. Later poets and mythologists speak of two Kings of Crete of the name of Minos, probably in order to establish harmony between the many contradictory myths which clustered around the name. See Pasiphaë and Minotaur.

J. R. S. Sterrett.

Minot, George: jurist; b. at Haverhill, Mass., Jan. 5, 1817; graduated at Harvard in 1836 and at Harvard Law School in 1838; finished his law studies under Rufus Choate; was admitted to the bar in 1839, and became distinguished in his profession. He was associate reporter of the decisions of Judge Woodbury of the first circuit court; published in 1844 his *Digest of the Decisions of the Supreme Court of Massachussetts* (45 vols., with *Supplement*, 1852); edited the *English Admiralty Reports* (9 vols., 1853–54); aided Richard Peters, Jr., in editing the first 8 vols. of the *United States Statutes at Large* (1848), for which he prepared the *Index*, and was the editor of that important publication for the ten years preceding his death, which occurred at Reading, Mass., Apr. 16, 1858.

Min'otaur [from Lat. *Minotau'rus* = Gr. Μινώταυρος; Μίνως, husband of Pasiphaë + ταῦρος, bull]: in Grecian mythology, a monster with the body of a man and the head of a bull, the offspring of Pasiphaë, the wife of Minos, and Poseidon's bull. Minos shut the monster up in the Cnossian labyrinth, where it was fed on criminals and on the youths and maidens paid as a tribute by Athens, until it was killed by Theseus, with the help of Ariadne. The monster has been frequently represented by Greek artists in its early adventures, inclosed in the labyrinth, and fighting with or subdued by Theseus. The Minotaur was identical with the Moloch of the Phœnicians in form and in the fact that human sacrifice was offered to it. The slaying of the monster by Theseus means that Greek civilization (Theseus) put an end to human sacrifice. Revised by J. R. S. Sterrett.

Minot's Ledge, or **Minot's Rocks**: a portion of the extensive reefs called Cohasset Rocks, lying off Cohasset, Mass., the southeastern promontory of the coast of Boston Bay, E. S. E., and 14 nautical miles from the city. A granite lighthouse with fog-bell is situated on the outer rock. See Lighthouse.

Minsk: government of Russia, on the upper part of the Dnieper. Area, 35,293 sq. miles. The watershed between the basin of the Niemen, flowing to the Baltic, and the basin of the Dnieper, flowing to the Black Sea, is formed by a narrow plateau and a range of low hills seldom reaching the height of 1,000 feet. Otherwise, the ground is low and level; the soil often sandy, often marshy; the climate in winter very severe. Extensive forests cover much of the land. Rye, flax, and hemp are raised, sheep and horses are reared, and tar, timber, and potash are produced. Pop. (1897) 2,156,343.

Minsk: town of Russia; capital of the government of Minsk, on the Svislocz, a tributary of the Beresina; 436 miles by rail W. S. W. of Moscow (see map of Russia, ref. 7–C). It has many good educational institutions and is the seat of the provincial government, but its trade and manufactures are unimportant. It is mostly built of wood. Pop. (1897) 91,113, including about 20,000 Jews.

Minstrels [from O. Fr. *menestrel*, by analogy of dimins. in *-el*, from Mediæv. Lat. *ministra'lis*, servant, retainer, jester, singer, deriv. of Lat. *minis'ter*, servant, liter., inferior, deriv. of *minus*, less]: the name applied during the Middle Ages in England, Scotland, France, and Normandy to strolling musicians who sang to the harp verses composed by themselves or others, and usually accompanied their songs with dancing, mimicry, and other devices to *minister* to the amusement of royal or noble patrons. There can be little doubt that they were the direct successors of the skalds and gleemen of earlier Scandinavian and Teutonic antiquity, and connected, though more remotely, with the "bards" who figured so largely among the Celtic and Gothic tribes. They were, however, no longer the custodians of the national epics, like the Minnesingers (*q. v.*), nor even permanently attached to the noble families as genealogists, but had begun to degenerate into jesters. The last representative of the earlier type of warrior-minstrels was probably Taillefer, who at the battle of Hastings rode before Duke William, tossing up and

catching his sword, and singing the song of Roland. By the time of Edward IV. the nobler occupations of the minstrels had given place to masquerading and playing at mysteries, and in the thirty-ninth year of Elizabeth a statute was passed classing minstrels and "jugglers, bearwards, fencers, common players of interludes, tinkers, and peddlers" as "rogues, vagabonds, and sturdy beggars," and to be punished accordingly. From that period nothing more is heard of minstrelsy as a profession. In modern times the name has been employed in a double sense. The comic singers of Negro and other melodies are known as "minstrels," while the same term is often employed in a complimentary sense nearly as the equivalent of "poet." Of the latter conception Scott's *Lay of the Last Minstrel* is a good example.

Mint [O. Eng. *minte*, from Lat. *menta*, from Gr. *μίνθη*, mint]: the name of various fragrant labiate plants, especially those of the genus *Mentha*. Of these the Peppermint and Spearmint (*qq. v.*) are the most important. The whole genus and other plants of the order possess aromatic qualities. The European pennyroyal (*M. pulegium*), bergamot mint (*M. citrata*), and others have considerable use in domestic medicine, and some are employed in cookery.

Mint Family: a large and well-defined group (*Labiatæ*) of dicotyledonous, mostly herbaceous plants, with opposite leaves, and with gamopetalous, mostly two-lipped flowers, four or two stamens, and superior four-lobed ovary. They are distributed throughout all parts of the earth, and number 2,700 species, of which about 150 are natives of the U. S. Many are grown in gardens and greenhouses, e. g. species of *Salvia*, *Coleus*, *Perilla*, *Æolanthus*, etc. Many domestic medicines are obtained from species of this family, as peppermint, horehound, hyssop, lavender, rosemary, sage, thyme, pennyroyal, catnip, balm, etc. Charles E. Bessey.

Minto, Earl of: See the Appendix.

Mints and Minting [*mint* is from O. Eng. *mynet*, coin: O. H. Germ. *muniza* > Mod. Germ. *münze*, mint, coin, from Lat. *mone'ta*, mint, coined money (deriv. of *Mone'ta*, surname of Juno, in whose temple money was coined) > O. Fr. *moneie*, whence Eng. *money*]: A mint is a factory of coin conducted under the sanction of public authority. The use of the precious metals, as measures of value and mediums for effecting the exchange of commodities, dates from the earliest period in the history of the human race of which any record exists. Originally, gold and silver passed by weight in the form of lumps, buttons, wedges, and spikes. With the progress of civilization, increase of barter, and the extension of commerce came the necessity for individual pieces of metal of uniform fineness, weight, and value, in form for convenient use, and bearing in effect the certificate of the supreme authority as to such fineness, weight, and value, and to pass by tale or count. The best authorities are generally agreed in according the invention of coins to the Lydians, and the period of their first use to about the seventh century B. C. Their introduction enabled the weighing of bullion in ordinary business transactions to be dispensed with, and placed the unskilled multitude upon an equality in the use of money with the skilled few. The use of coins rapidly spread, aiding materially in the exchange of commodities, and powerfully promoting intercourse between the different countries of the world.

In describing the processes of minting those in use in the mints of the U. S. may be taken as typical of all others.

The mints and assay-offices are under the supervision of a director, whose headquarters are in the Treasury Department at Washington, and who is subject to the general direction of the Secretary of the Treasury. The former are located at Philadelphia, San Francisco, Carson City, and New Orleans; and the latter at New York, St. Louis, Denver, Col., Boisé City, Ida., and Charlotte, N. C.

The various operations and processes to which bullion is subjected may be summarized as follows:

(1) *The preparatory melting*, usually with protective or refining fluxes, as the case may be; (2) *the assay*, which determines the precise proportion of fine gold or fine silver in each case, and also whether both metals are present and require parting; (3) *the parting process*, often called *refining*, since it takes the silver out, and leaves pure gold and pure silver as the separate products; (4) *the alloying of the metal*, so as to make ingots or thin bars of standard fineness, and the casting of such ingots; (5) *the assay of ingots*, to determine whether they are of the legal or standard fineness for coinage; (6) the various manipulations by which such standard ingots are converted into coin.

Conversion of Bullion into Standard Ingots.—As a general rule, all bullion when received is subjected to a preparatory or "deposit" melting, for the purpose of freeing it from all earthy matter and adhering substances, as well as to render the mass homogeneous preparatory to assay. Samples for assay are taken for gold from the cast bar, and from silver while the bullion is in a fused condition. The weight of the bullion after deposit-melting is that with which the depositor is credited and the melter and refiner charged. The bullion, if not of sufficient fineness and otherwise in condition to admit of being brought to the legal standard for coinage—nine parts pure metal and one of copper—is subjected to purification by melting and the use of protective and refining fluxes. If gold bullion contains silver, or silver bullion contains gold, in quantities sufficient to defray the expense of separating the two metals, it is subjected to the parting operation, which is based on the fact that silver is soluble in both nitric and sulphuric acid, while gold is not affected by either. If the metal to be parted is not present in quantity sufficient to equal the expense of the operation, it passes off in the coins, but without valuation. In the gold coins the law permits one-tenth of the alloying metal to be composed of silver. Tests made by the assay commission show that the silver in gold coins is almost inappreciable, amounting to but a trace, while out of five examinations made for gold contained in silver coins the highest limit was 1 part in 5,000. The most economical proportion of the two metals for the parting operation is 2 oz. of silver to 1 oz. of gold.

The bullion, having been freed from all foreign substances and base metals, or separated where gold and silver are associated in the same bullion, is alloyed with copper and brought to the legal standard for coinage. It is then cast into ingots and assayed, and if found to be sufficiently within the deviation from standard or "tolerance" allowed by law, is transferred to the coiner, who by a series of operations converts it into coin.

The Conversion of Ingots into Coin.—The principal operations and processes to which ingots of standard fineness are subjected in their manufacture into coin may be classified as follows:

(1) *The rolling*, which reduces the ingots to strips or fillets of a thickness proper for the denominated coins. (2) *The annealing*, which is rendered necessary to preserve the ductility of the metal during the rolling operation. (3) *The drawing*, whereby any want of uniformity in the thickness of the strips is corrected. (4) *The cutting*, or forcing from the strips "planchets" or blanks of the size and shape of the coin. (5) *The adjusting*, or weighing separately of each blank, and bringing those above standard within the working limit of deviation by filing. (6) *The milling*, which presses up the edge of the blank in order to protect the surface of the coin. (7) *The cleaning*, whereby all oxidation is removed from the face of the blank. (8) *The coining*, or impressing upon the blanks the devices and inscriptions prescribed by law.

When ingots are received by the coiner from the melter and refiner, and the weight noted, they are taken to the rolling-room, and passed through heavy iron or steel rolls, each melt being kept and passed through separately. At each successive rolling the rolls are brought together by means of a screw, their adjustment or proximity to each other being indicated upon a dial which is regulated by the workman in charge. Successive rolling hardens or renders brittle the strips, and necessitates annealing in order to preserve their ductility. The length of time required to anneal gold is from one to one and a half hours, and for silver about twenty minutes. The first annealing having been completed, the strips are passed a few times through the finishing-rolls, and after a second annealing are ready for the drawbench. The pointed end of the strips are inserted between the drawplates, and drawn through a small pair of perpendicular steel rolls by means of a treadle and an endless chain. Two drawings are necessary for each strip. In the first a slight reduction is made, and in the last the drawplates are carefully adjusted to the thickness of the coin. A few strips are then passed through, from both ends of which blanks are cut and weighed, and if the weight is found to conform to the working tolerance, the drawing of the entire lot is proceeded with.

The strips are then taken to the cutting-press and planchets cut therefrom. This operation consists in passing the strip across a conical steel bed, while a punch just fitting the bed operates on the upper side of the fillet and forces a piece

of the exact size and shape of the punch through the sharp bed beneath. The punch, operated by steam, moves with great rapidity, and cuts from 150 to 280 pieces a minute. The number of pieces that can be cut from ingots is as follows:

GOLD.

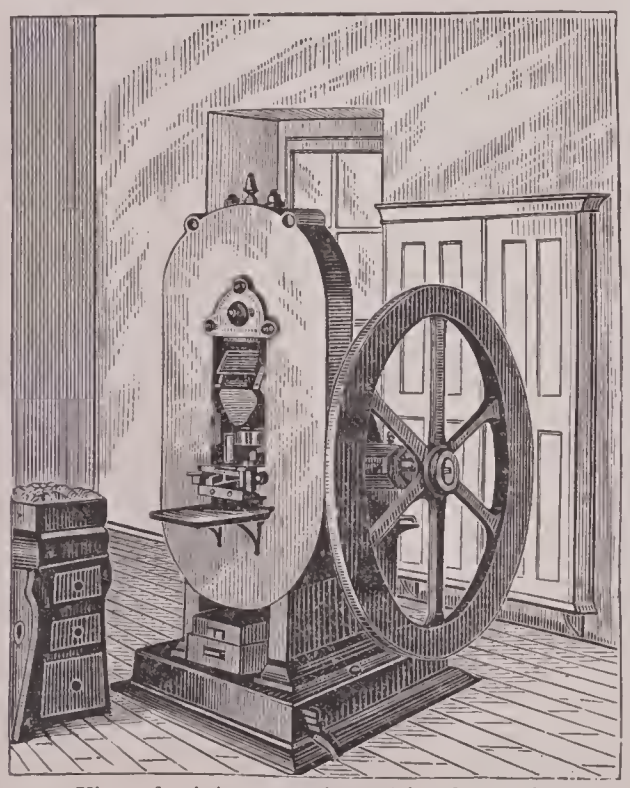
From one double-eagle ingot	.....	40 pieces.
" " eagle "	.....	60 "
" " half-eagle "	.....	75 "
" " three-dollar "	.....	136 "
" " quarter-eagle "	.....	100 "
" " dollar "	.....	632 "

SILVER.

From one standard-dollar ingot	.....	33 pieces.
" " half-dollar "	.....	60 "
" " quarter-dollar* "	.....	70 "
" " dime "	.....	354 "

The perforated strips, denominated "clippings," and the blanks, are sent to the cleaning-room for the purpose of removing all dirt and grease adhering to them from previous operations. The clippings are returned to the melter and refiner and remelted, and the planchets or blanks delivered to the adjusters.

A blank, or counterweight, adjusted to a small fraction exceeding the legal weight of the coin is furnished to each adjuster, with which the weight of all the blanks is tested, those heavier than the counterweight being carefully filed upon the edge until they are adjusted to a perfect counterpoise. The adjusted planchets are then returned to the forewoman, and under her supervision five of the most experienced adjusters prove the work, and if any planchet is found outside of the prescribed limit it is readjusted. Those of less weight than the counterweight are kept in separate pans and tested by a second counterweight, which is a slight fraction *below* the standard weight of the coin. In the case of gold coins, which are the standard of value and unlimited legal tender, each blank is adjusted by hand before being milled and stamped. The blanks for the dollar, which is a legal-tender coin, are also adjusted by hand, while those for the subsidiary or over-valued silver coin, the half dollar, quarter dollar, and dime, are not so adjusted, the drawbench being relied on to insure the necessary uniformity as to thickness and correspondence of the blanks to their respective legal weights. The law allows on all coins a



View of coining-press in position for work.

certain deviation from standard weight. (See *Tolerance*, below.) This deviation, however, is seldom reached, the coiner fixing a limit within the legal deviation, which is known as the "working tolerance." All pieces found below the "working tolerance" are designated "condemned lights," and returned to the melter and refiner. The remainder, known as "heavies," "lights," and "standards," are kept separate until they reach the weigh-room as *coin*, when they are united in proper proportions, and made up into drafts for delivery by the coiner to the superintendent, who is acting treasurer. The subsidiary silver coins, half dollar, quarter dollar, and dime, are weighed separately, and all above or below the legal tolerance rejected.

The adjusted blanks are now ready for the milling operation, which is done by a machine containing a circular plate, the outer edge being of steel; the plate revolves within a strong band of the same material. The revolution of the inner disk carries the blank through the intermediate space between the working disk and fixed band, and this, being somewhat less than the diameter of the piece, presses up the edge of the planchet as it revolves. One revolution carries the piece through the mill and completes the operation. The milled planchets, more or less oxidized, before being brought to the proper condition for blanching, must be entirely coated with oxide of copper. To insure this, they are annealed to a cherry-red heat, and when removed from the furnaces are placed in a colander, dipped for a few moments into a diluted solution of sulphuric acid, and thence into pure water, in order to rinse off the acid. This leaves the blanks thoroughly cleaned, and after being dried by shaking in a large iron sieve or revolving riddle filled with sawdust, they are ready for the stamping operation.

This last and most important operation is performed by the coining-press. As each blank descends to the bottom of the tube a pair of steel fingers seize it and carry it forward between the dies. While the dies are closing upon it and stamping both the obverse and reverse inscriptions simultaneously, the steel fingers return for another planchet, and, conveying it to the dies, push the coined piece into a box beneath the press. The coined pieces are collected from the presses and taken to the weigh-room, where they are made up in drafts for delivery to the superintendent. The speed of the coining-presses is estimated at from 75 to 120 pieces a minute, and the pressure exerted in stamping the coins ranges, according to their denomination, from 45 to 280 tons.

Tolerance.—The law allows a tolerance or deviation from the standard fineness of $\frac{1}{1000}$th in the gold coinage and $\frac{3}{1000}$ths in the silver. But in practice the assayer does not avail himself of even one-half the tolerance, as the aim is to have the coinage as near the exact standard as possible, which is not the practice followed by some foreign mints. The margin of fineness of gold coin in the British mint is placed at 2 parts in 1,000, though but a small part of this margin is actually used.

The following statement exhibits the standard weight of the gold and silver coins of the U. S., and the legal tolerance or deviation allowed on single pieces:

DENOMINATION.	Standard weight, grains.	Legal deviation, grains.
Gold.		
Double eagle	516	$\frac{1}{2}$
Eagle	258	$\frac{1}{2}$
Half eagle	129	$\frac{1}{2}$
Three dollar*	77·4	$\frac{1}{4}$
Quarter eagle	64·5	$\frac{1}{4}$
Dollar*	25·8	$\frac{1}{4}$
Silver.		
Half dollar	192·9	$1\frac{1}{2}$
Quarter dollar	96·45	$1\frac{1}{2}$
Twenty-cent piece*	77·16	$1\frac{1}{2}$
Dime	38·58	$1\frac{1}{2}$

* These coins have been abolished by act of Congress.

These deviations are intended for the protection of the mint officers, and are not taken advantage of in the preparation of the coins, which are made as close to the standard weight as practicable. In weighing a number of pieces together, when delivered by the coiner to the superintendent, and by the superintendent to the depositor, the law provides that the deviation from the standard weight shall not exceed in the case of gold coins $\frac{1}{100}$th of an ounce in $5,000 in double eagles, eagles, half eagles, or quarter eagles; while on silver the deviation is $\frac{2}{100}$ths of an ounce in 1,000 standard dollars, half dollars, or quarter dollars, and $\frac{1}{100}$th of an ounce in 1,000 dimes. The uniform practice at the mints is that each delivery of coin made by the coiner to the superintendent shall conform to the standard weight, no advantage being taken of the limit or tolerance allowed in weighing a large number of pieces together.

From each delivery of coins by the coiner to the superin-

* The quarter-dollar ingot is now made to yield a double row of blanks, or 140 pieces to the ingot.

tendent a certain number of pieces are indiscriminately taken, sealed up, and placed in the pyx, for the annual trial or test of the coinage, which is made in February of each year by a commission constituted by law for that purpose; and if it appears by such examination and test that the reserved coins do not differ from the standard fineness and weight by a greater quantity than is allowed by law, the trial is considered and reported as satisfactory; but if any greater deviation from the legal standard or weight appears, the fact is certified to the President of the U. S., and if on a view of the circumstance he shall so decide, the officer or officers implicated in the error are thenceforward disqualified from holding their respective offices.

Wastage.—In the various processes to which bullion is subjected at the mints more or less loss occurs, particularly by volatilization in melting and refining, and is accounted for under the term "wastage." The operative officers are charged and credited with all bullion delivered to and returned by them, and are allowed a credit for actual "wastage" incurred, provided it does not exceed the legal allowance, which in the case of the melter and refiner is $\frac{1}{1000}$th of the whole amount of gold, and one and a half thousandths of the whole amount of silver delivered to him since the last annual settlement; and in the case of the coiner, one-half of $\frac{1}{1000}$th of the whole amount of gold and $\frac{1}{1000}$th of the whole amount of silver delivered to him by the superintendent. The actual wastage is, on the average, much within the limit fixed by law.

Great care is taken to recover from time to time all the minute particles of bullion remaining in the residuum fluxes, flues, etc. These are mostly recovered in the form of "sweeps," which are sold to bullion-smelters at about 60 per cent. of the value of the bullion contained.

Mint Values.—Gold is valued in the coinage at the rate of $25\frac{8}{10}$ths grains troy, nine-tenths fine, or $23\frac{22}{100}$ths grains of pure metal to the dollar. For silver the valuation in the standard dollar is at the rate of $412\frac{1}{2}$ grains troy, nine-tenths fine, or 371·25 grains of pure metal to the dollar. In the subsidiary silver coins it is valued at the rate of $385\frac{8}{10}$ths grains troy, nine-tenths fine, or $347\frac{22}{100}$ths grains pure metal to the dollar.

Charges.—Charges which are estimated to equal but not exceed the average expense of each operation required to bring gold and silver bullion into a condition for coinage are fixed from time to time by the director of the mint with the approval of the Secretary of the Treasury. The subjects of charge are deposit melting, parting, toughening, refining, copper alloy, bar charge. In the charge for deposit melting exceptions are made for standard gold bullion, fine gold bars, U. S. gold coin of less than legal weight, foreign coin of U. S. standard or above to be converted into coin, fine silver bars over $997\frac{1}{2}$ fine, unless they contain gold, and mint or U. S. assay-office bars redeposited. Gold bullion, including foreign gold coin, is received at the mints at Philadelphia, San Francisco, and Carson City, and the assay-office, New York, for coin or bars. Silver bullion is received only for bars or by purchase for Government account, and all coinage of silver is for Government account. At the mint in Denver, operated as an assay-office, and the assay-offices at Boisé City and Charlotte, the identical bullion is returned to the depositor in the form of unparted bars bearing upon them the U. S. stamp of fineness, weight, and value.

Subsidiary Coins.—The subsidiary silver, as well as the minor or token coins (bronze one-cent and copper-nickel three and five cent pieces), are manufactured on Government account only, the public treasury purchasing the bullion and metals required therefor, defraying the expense of manufacture, wastage, and transfer to the various treasury-offices, and realizing the seigniorage or gain on such coinage. Gold coins are receivable at the Treasury of the U. S. at their denominational value, when not reduced in weight by natural abrasion after a circulation of twenty years as shown by the date of coinage, more than one-half of 1 per centum, and at a ratable proportion for any period less than twenty years. For the silver coins no legal limit of abrasion or wear is provided, but when mutilated or defaced, such coins are purchased at the mints at their bullion value when presented in sums of $3 and upward.

Under the title of "bullion fund" a part of the public moneys are placed at the different coinage mints and at the assay-office, New York, out of which depositors are paid for their bullion, in coin or bars, as soon as the value thereof has been ascertained by assay (generally three days thereafter), and on payment being made the bullion so deposited becomes the property of the U. S.

Revised by O. C. Bosbyshell.

Minu'cius Felix: See Felix, Marcus Minucius.

Miu'uet [from Fr. *menuet*, so called from the short steps taken in it, deriv. of *menuet*, smallish, pretty, dimin. of *menu*, small > Lat. *minu'tus*, whence Eng. *minute*]: in music, a species of dance-tune formerly in common use. Its movement was rather slow, graceful, and stately. The minuet was written in triple measure, and always began with a full bar. It consisted of two divisions or parts, each containing eight bars, and both divisions were repeated. Minuets also, not intended for dancing, and of considerable rapidity of movement, are now often found as constituent parts of overtures, symphonies, sonatas, and other formal pieces. In such cases the minuet generally comprises two strains of sixteen bars each, with repetitions. Another strain, called the "trio," follows directly, and after the trio the former part of the minuet is repeated.

Min'uit, or **Minnewit**, Peter: founder of New York; b. in Wesel, Rhenish Prussia, about 1580, belonged to a distinguished family, and had been deacon in the Walloon church at Wesel, but had resided some years in Holland when, Dec. 19, 1625, he was appointed by the Dutch West India Company first governor and director-general of New Netherlands. He landed on Manhattan Island May 4, 1626; purchased the island from the Indians for sixty guilders; built Fort Amsterdam, and governed the colony with energy and success until Aug., 1631, when he was recalled. Having put into the port of Plymouth, England, through stress of weather, on his homeward voyage, Apr., 1632, his ship was attached at the suit of the New England Council on an accusation of illegal trading, but was released in May. Minuit had lost favor with the West India Company, through a charge of having countenanced land monopoly, and after unsuccessful efforts to regain his position offered his services to the Swedish Government to found a colony in North America. The great chancellor Oxenstiern having patronized the project, a Swedish West India Company was formed, and Minuit sailed from Gothenburg, Sweden, in 1637, with a body of Swedes and Finns; ascended Chesapeake Bay, and in Mar., 1638, began to build Fort Christiana, 2 miles from the confluence of Minqua's Kill with the South river, near the present city of Wilmington, and called the country New Sweden. This was the first permanent European settlement on the Delaware, and the colony remained in the hands of Sweden until captured by the Dutch in 1655. D. at Fort Christiana in 1641.

Min'yas (in Gr. Μινύας): a rich mythical King of Orchomenos, in Bœotia, and the founder of the Minyan race. His genealogy is variously given. He was the first to build a beehive treasure-house, the ruins of which were excavated by Schliemann in 1880–81–86. The daughters of Minyas refused to take part in the worship of Dionysus when first it was being introduced into Bœotia, and they were finally punished by being changed into bats and owls. See Müller, *Orchomenos und die Minyer* (Breslau, 1844). J. R. S. S.

Miocene Period [*Miocene* is from Gr. μείων, less + καινός, recent]: the division of geologic time following the Eocene period and preceding the Pliocene. In the chronologic system adopted by the U. S. Geological Survey for the geologic atlas of the U. S., the Miocene and Pliocene periods of earlier classifications are included in the Neocene Period (*q. v.*).

Miquel, mē'kel', Johann: statesman; b. at Neuenhaus, Hanover, Feb. 21, 1828; studied law at Heidelberg and Göttingen 1846–49, and settled at Göttingen as an advocate. Enthusiastic for the unity of Germany, he worked with great energy for the national idea, but thereby, and by some papers on the financial condition of Hanover, incurred the enmity of the Government. He gained the confidence of the people, however. In 1864 he was elected a deputy from three different places, and in the second chamber of the Hanoverian Diet he occupied an influential position. He espoused the policy of Bennigsen. In 1865 the city of Osnabrück elected him burgomaster. After the annexation of Hanover to Prussia in 1866, he exerted himself zealously in order to strengthen the newly established connection, and it was in no slight degree due to his influence as a member of the North German Diet and the Prussian House of Deputies that the policy became liberal and the South German states entered into intimate relations with the

North German Confederation. His office of burgomaster he resigned in 1870, to accept that of director of the Diskontogesellschaft of Berlin; in 1876 he again became burgomaster of Osnabrück; in 1880 burgomaster of Frankfort-on-the-Main and a member of the House of Peers; in 1887 he entered the Reichstag; and in 1890 became Prussian Finance Minister.

Miquelon: an island S. of Newfoundland, belonging to France. See ST.-PIERRE.

Mirabeau', HONORÉ GABRIEL RIQUETTI, Count: revolutionist; b. at Bignon, near Nemours, in Provence, France, Mar. 9, 1749. His father (b. Oct. 5, 1715; d. July 13, 1789) was one of the theoretical philanthropists of the eighteenth century, a propagandist of the physiocratic system, and the author of *L'Ami des Hommes* (1755), and of *La Philosophie rurale* (1763). He was hot-headed and tyrannical, and is said to have used fifty-four *lettres de cachet* in order to maintain peace in his family. Young Honoré, with his herculean body, ugly face, violent passions, and turbulent manners, was a special object of dislike to the father, in spite of the eminent power of intellect which he showed very early. He received a military education at Paris, and was a lieutenant of cavalry in his seventeenth year; but, although he pursued his military and mathematical studies with energy, his life was so wild that in 1768 his father had him shut up in the island of Ré for six months. After serving for some time in Corsica, he settled on one of the family estates in Limousin, where (June 22, 1772) he married the young Marie Émilie de Covet. He did not live happily with his wife, and after a period of semi-exile in the country, where he wrote his earliest extant work—the *Essai sur le Despotisme*—he was again imprisoned by his father (Sept., 1774), this time in the Château d'If, in the Bay of Marseilles, whence he was removed some time after to Fort Joux, near Pontarlier, in the Jura Mountains. From this place he eloped with the young Marquise Sophie de Monnier, the wife of a friend whose trust he betrayed. He fled first to Switzerland, then to Amsterdam, where he earned a living by doing hack-work for the booksellers. In May, 1777, he was arrested and confined in the dungeon of Vincennes till Dec. 13, 1780. While there he wrote *Essai sur les Lettres de Cachet* (Hamburg, 1782), a number of other works, and a multitude of passionate letters to Sophie, published at Paris in 1793. Nevertheless, as soon as he was liberated he quarreled with her, and he now tried by a law-suit to compel his wife to return to him. He pleaded his case himself, and, although he lost it, he made a deep impression by his powerful eloquence. During a residence in London he wrote in 1785 *Considérations sur l'Ordre de Cincinnatus*. On his return to France he attacked the financial system of Calonne. In 1786 he was sent on a secret mission to Berlin, the fruits of which were *De la Monarchie Prussienne sous Frédéric le Grand* and *Histoire Secrète de la Cour de Berlin*, but he proved himself unfit for the career of a diplomatist. As he failed to obtain any further diplomatic appointment he continued his attacks on the Government by his *Dénonciation de l'Agiotage* (1787) and *Suite de la Dénonciation* (1788), which by their violence prevented his election to an office he was seeking, and forced him to live for a time in retirement at Tongres. On the convocation of the States-General he first tried to be elected by the nobility, but was rejected, and afterward entered the Assembly as a member of the third estate. From this moment and up to his death he was the leading statesman of France. It was he who established the third estate as the dominant power in the States-General, and it was he who established the States-General as the dominant power in the government of France. Thus he started the Revolution, and when it became too violent he turned around and tried to stem its course, defending the royal prerogatives and the monarchical principle, but upholding, on the other hand, civil liberty and constitutional government. He was opposed alike by the obstinacy and timidity of the court and the fanaticism of the radicals. He wished to become minister, but was prevented by an act of the Assembly decreeing that no member of that body could enter the ministry. From May, 1790, he entered into close relations with the court, which paid his debts in reward for his services. His popularity waned, but he still swayed the Assembly by his eloquence. The activity which he developed as leader of the Assembly and president of the Jacobin Club was enormous, but the exertion, in connection with his reckless life, suddenly broke his strength. On Mar. 27, 1791, he spoke in the Assembly for the last time; on Apr. 2 he died. He was buried in St. Geneviève, the Pantheon, whence his corpse afterward was removed to his family estate, in order to give room for that of Marat. The most complete account of his life is found in *Mémoires biographiques, littéraires et politiques de Mirabeau* (8 vols., 1834), published by his natural son, Lucas de Montigny. The best edition of his works is that by Blanchard (1822, 10 vols.), but it does not contain his *Monarchie Prussienne*.

Revised by F. M. COLBY.

Miracle-plays, Mysteries, and Moralities: three forms of dramatized story that preceded the rise of the modern drama. The sources of the drama lie deep in the Church services of the Middle Ages. The liturgy of the early Christian Church was a symbolic drama, which laid especial emphasis upon the incidents of highest tragic value in the Christian story. When the doctrine of transubstantiation was accepted in the ninth century, the symbolic tragedy became a genuine tragedy, since Christ was believed to dwell as a real presence in the host, and the death of Christ became a tragic motive of the first importance.

The tragedy of the liturgy became the germ of the modern drama. Zealous priests sought by a concrete presentation of the crucifixion, burial, and resurrection to bring the story home to the multitude. Very soon, as introductory to the crucifixion, plays of the arrest and trial were acted on the days preceding Good Friday. Thus arose, within the services and in intimate connection with the liturgy itself, a minor cycle of mysteries—i. e. plays pertaining to the mystery of redemption.

The Christmas Cycle.—There soon appeared another cycle dependent upon the many festival days that follow Dec. 25. Christmas, established about 350 A. D., drew to itself many heathen customs of Rome and of the Germanic tribes; these customs entered largely into the Christmas plays. The proximity of Christmas and Epiphany (Jan. 6) gave rise to two weeks of sacred holiday, and made possible another minor cycle of plays, *The Salutation by the Shepherds*, *The Adoration by the Magi*, *The Slaughter of the Innocents*.

The Creation Cycle.—These minor cycles readily formed a major cycle through the insertion of plays representing incidents of Christ's life. The play of *The Judgment* was added as an epilogue. A sermon attributed to St. Augustine was dramatized as the play of *The Prophets*, and became a fitting prologue. When this play of *The Prophets* was displaced by scenes from the Old Testament, beginning with the creation, the creation cycle was complete.

The earliest plays—of about the tenth century—were formed from the biblical dialogue as given in the Vulgate; they departed but slightly from the liturgy, and were practically the same in all countries of Roman Catholic faith. Artistic development was more rapid in the Latin nations. In Germany the Christmas plays developed late, and were curiously affected by Northern superstitions. In France they began early, but later, through fusion with the low comedy inherited from the Romans, gave rise to grave scandals; thus *The Feast of the Ass* sprang from the part played by Balaam in the play of *The Prophets of Christ*.

The Continuous Play.—As these plays were the favorite medium of literary expression, expansion followed, and the desire arose to combine the plays of several days into a continuous play; but such representation withdrew the plays from their dependence upon the liturgy, and established them as an independent drama. Extant plays of this intermediate kind date from the tenth to the fourteenth century. Together with the fusion of liturgical plays into a continuous drama came many other changes tending toward the secularization of the mystery. Slowly the vernacular superseded the Latin; first for the parts of the common people, then throughout the play. The continued play wearied the audience; diversion was supplied by devil-play and jest; thus, in the English cycles, Noah and his wife have a conjugal quarrel, and the shepherds jest about the singing of the angels. Each step of development carried the cyclic play further from the simple biblical dialogue of the liturgical play, and made its presence in the Church more objectionable.

The Stage.—The stage necessities of the play hastened its departure from the Church. At first no special platform was used. The cross with Christ was lifted up. Mary made her lamentations, of which many forms are still extant in German, and the priest explained the significance of the scene. Christ was placed in the sepulcher (which still exists in many old English churches) there to lie until

Easter morning. When the play grew in importance a platform was built in the nave. As scenes multiplied the platform lengthened, that each scene might have an independent station, until, in the minor cycle, hell was near the door, heaven in the sanctuary, and the nave was occupied by the incidents of earthly life. Clearly the play must move to the market-place for further expansion.

In fact many causes contributed to expel the cyclic play from the Church. The play had admitted many comic elements and popular superstitions; these called forth stern prohibitions in 1210 from Pope Innocent III., in 1225 from the Council of Treves, in 1252 from Alfonso X. of Aragon. Then also the audiences, as well as the stage, had outgrown the cathedral. The cyclic play moved to the market-place, but the simple liturgical play retained its place in the Church services until the time of the Reformation.

The Secular Mystery.—With the secularization of the mystery its national history begins. In Italy it became the care of the monasteries, which vied with each other in costly representations. In Spain it united with the pastoral drama, departing widely from the liturgical form and content. In Germany the mastersingers' guild wrote complicated plays for the artisan guilds. In France the mysteries passed to the care of the Puy, a species of literary society that spread throughout the north and west of France. The plays were patronized by the nobility, and finally became the property of the Confrérie de la Passion, which established the first theater in Paris in 1402 and played sacred dramas until forbidden in 1548. In all continental countries the immense stage, divided into many stations, was a common feature. Enormous crowds assembled—in Reims in 1490 16,000 persons—and the plays continued either three or eight days. The expense was great, and was met by donations, city appropriations, and sometimes by an admission fee.

In England the development of the cycle was unique, and greatly influenced by the royal entry and the Corpus Christi procession. As early as 1313 cities greeted a visiting monarch with stationary tableaux, representing incidents in the life of Christ. Similar tableaux, placed on floats, were carried by the representatives of the guilds in the Corpus Christi procession from its institution by Pope Urban IV. in 1264. In England the tableaux of the mute mystery were displaced by the spoken play. Each pageant wagon halted at designated stations, where the populace, seated in separated audiences, heard in succession each play of the cycle.

The Craft-guild Cycles.—Of the craft-guild cycles of English plays there are still extant the York cycle of forty-eight plays; the Woodkirk, of thirty-two plays; the Chester, of twenty-five plays; and two plays of the Coventry. The Beverley cycle is lost, as are probably a few others, of which, however, very little is known. A cycle of forty-eight plays, known as the Coventry, but probably the property of some company, has also been preserved, together with several single plays which probably were written for holiday occasions. The interrelations among the cycles have not been fully made out, but it would seem that there was an early York cycle and that this became the type which other cities followed, obtaining their plays sometimes from York, sometimes from neighboring cathedrals, or from independent sources. Later additions brought this early York cycle up to forty-eight plays.

The expense of the guild plays was borne by the guilds, each setting forth its play at its own expense, or as collaborator with one or more of the weaker guilds. If a guild were reluctant to incur expense, the city often compelled it to contribute, since the play was to the honor and profit of the city. The pageant wagon was a permanent structure, and often figured with its belongings as a considerable asset of the guild. It consisted of a platform on wheels, draped to the ground, and surmounted by a canopy. Possibly the platform was of two stories when both heaven and earth were represented. Hell-mouth led to the space beneath the platform, where the devils dwelt hard by the necessary stage machinery. Sometimes the action abandoned the wagon for the street. There are scanty evidences of scene-shifting in the plays, but the stage appliances were of the most rudimentary character.

The life of the craft mysteries of England extends, roughly speaking, from the latter part of the thirteenth to the middle of the sixteenth century. The Protestant Reformation condemned the mystery. In England the cyclic plays were easily put down, but stern laws were necessary to force the abandonment of Church plays. In Roman Catholic countries the mystery lingered in rural districts, though shorn of its former glory. Indeed, it still survives at Oberammergau, in the Bavarian highlands.

The Miracle-play.—Miracle-plays drew their material from the lives and legends of saints. They never formed true cycles, since they were independent of the liturgy, and possessed no continuity among themselves. The miracle-play was short—the French plays of about 1,500 lines—complete in itself, and was usually played by some lay association, school, or guild, in honor of its patron saint. In Germany the miracle-plays of the fourteenth century led to the German historical drama. In France the miracle-play, together with the mystery, was cultivated by secular literary associations, whose productions were called, without much distinction, mysteries or miracles; thus the *Miracles de Notre Dame*, forty in number.

In England the mysteries were known as miracle-plays. There are no true miracle-plays extant in English. Mention is made of a play of St. Catherine as early as the twelfth century; others mentioned are Fabian, Crispin and Crispian, St. George, etc., but tableaux and plays are often called indiscriminately pageants, so that it is not easy to determine what were spoken plays. The play of *The Lord's Prayer* (York), the play of *The Sacrament* (Croxton)—both of the fourteenth century—and *The Creed* play (York) of the first half of the fifteenth century, may be classed as plays akin to miracles.

The miracle-play fell, with the mystery, under the ban of the Reformation, but is still occasionally acted in Catholic lands.

The Morality.—The morality arose from the desire to express abstract conceptions dramatically for purposes of moral instruction. The morality was the outcome of an attempt to use the drama as a vehicle of allegory. In what country moralities were first written is unknown. In France they abounded in the fifteenth century, and lent themselves easily to the satire of society, even touching occasionally the foibles of Church and state. Their usual length was about 1,500 lines, but one, *The Just Man and the Worldling*, contained 36,000 lines.

Early English Moralities.—The earliest English moralities, *The Castell of Perseverence*, of about 3,500 lines, *Mind, Will, and Understanding*, and *Mankind*, are of the first half of the fifteenth century. The general structure of these earliest moralities is the same. They trace the life of man from birth to death. As a youth he follows evil counselors; as an old man he sorrows for the sins of his youth, and through confession is reconciled to God.

Other types of the morality and of the allegorical play existed. The so-called Coventry cycle of mysteries introduced as personages Pity, Justice, and Peace. In the fifteenth century the interludes were composed on mystery themes, but in the sixteenth century became moralities. These later moralities often contained comic elements. The "Vice" was introduced as a companion to the devil. From the popular Vice the Elizabethan clowns have, it is supposed, their origin. Another variety of the morality might be called the didactic morality; of such are the *Interlude of the Four Elements*, and the interlude in praise of learning called *Wyt and Science*.

Summary for England.—The progress of dramatic development in England can be summed up as follows: First, the liturgical mystery, with the development of the cyclic play within a century after the establishment of the Corpus Christi procession. Co-ordinate with the mystery is the rise of the occasional miracle-play. Second, allegory, which had been dominant in poetry since the thirteenth century, fashioned the morality in the fifteenth century. Third, the court introduced the pastoral and farce of France, and supported companies of professional players. The universities and inns of court produced plays of Latin models. With the suppression of the mystery by law the play-loving populace sought permissible material for plays from other sources. The morality flourished apace. The chronicle history arose. Traveling companies, under the patronage of noble lords, cultivated sedulously every species of drama that met the popular taste. Such a company built the first theater in London before 1576. The subject is more fully discussed in the writer's *Studies in the English Mystery Plays* (Yale doctoral thesis, 1892). The most important collections of plays are:

English.—Chester Mysteries (2 vols., Shakspeare Society, 1843–47); *Ludus Coventriæ* (Shaks. Soc., 1841); *The Towne-*

ley Mysteries (Surtees Society, 1836); *York Plays* (Oxford, 1885); *Digby Mysteries* (New Shaks. Soc., 1882); Marriott, *A Collection of English Miracle-plays and Mysteries* (Basel, 1838); Sharp, *A Dissertation on the Pageants or Dramatic Mysteries anciently performed at Coventry* (Coventry, 1825); *The Presentation in the Temple* (Abbotsford Club, 1836); Smith, *The Book of Brome* (Norwich, 1886); *Hawkins's English Drama* (3 vols., Oxford, 1773); Bale, *Scriptorum Illustrium Maioris Brytanniæ Catalogus* (Basel, 1557–59); Pollard, *English Miracle-plays* (Oxford, 1890).

French.—*Miracles de Notre Dame* (6 vols., Société des Anciens Textes Français); *Le Mistère du Viel Testament* (Soc. des Anciens Textes Français); Jubinal, *Mystères inédits du XV^e^ siècte* (2 vols., Paris, 1837); Gaston Paris and Gaston Raynaud, *Le Mystère de la Passion d'Arnoul Greban* (Paris, 1878); Monmerqué and Michel, *Théâtre français au moyen âge* (Paris, 1839); Luzarch, *Adam, drame anglo-normand du XII^e^ siècle* (Tours, 1854); Arnoul and Simon Greban, *Les Actes des Apôtres* (3 vols., Paris, 1541).

German.—Hoffman von Fallersleben, *Fundgruben für Geschichte deutscher Sprache und Literatur* (Breslau, 1837); Mone, *Schauspiele des Mittelalters* (Carlsruhe, 1846); Grein, *Alsfelder Passionspiet* (Cassel, 1874); *Oberammergauer Passionspiel* (Leipzig, 1880); Weinhold, *Weihnachtsspiele und Lieder aus Süddeutschland und Schlesien* (Gratz, 1853).

Liturgical.—Méril, *Origines latines du théâtre moderne* (Paris, 1849); Milchsack, *Die Oster- und Passionspiele* (Wolfenbüttel, 1880); Wright, *Early Mysteries and Latin Poems of the Twelfth and Thirteenth Centuries* (London, 1838); Sepet, *Les Prophètes du Christ* (Bibliothèque de l'École des Chartes); Halliwell, *Reliquiæ Antiquæ* (2 vols., 1843); Coussemaker, *Drames titurgiques du moyen âge* (Paris, 1861); Sepet, *Le Drame chrétien au moyen âge* (Paris, 1878).

Miscellaneous.—A. d'Ancona, *Sacre rappresentazione dei secoli 14–16* (3 vols., Florence, 1872); *Autos sacramentates desde su origen hasta fines del siglo XVII.* (Madrid, 1884, 8vo) in *Biblioteca de Autores españoles* (vol. lviii.).

CHARLES DAVIDSON.

Miracles [viâ O. Fr. from Lat. *mira'culum*, wonderful work, miracle, neut. dimin. of *mi'rus*, wonderful. Cf. *mira'ri*, wonder at]: the general designation for the "signs," "wonders," and "mighty deeds" recorded in the Scriptures of the Old and New Testaments as wrought by God in connection with the revelation of his will and the establishment of Christianity. Their nature and relations to Christianity have formed a subject of profound interest and much discussion, especially in modern theology.

1. *Definition.*—A miracle may, in general, be said to be an unusual event in physical nature wrought by direct action of God working for a moral end. More accurately, it is defined as "an event in the physical world wrought by God independently of the sequences through which he ordinarily works." It is the production, by the exercise of God's power, of a definite effect which could not otherwise have taken place. This definition assumes the reality of the distinction between nature and the supernatural. It is based in the theistic conception of the world. While it views the universe as the work of God, it does not conceive of his power and efficiency as all transferred to the forces and laws of nature or as restricted to its established uniformities. There must be neither a pantheistic confounding of God with nature nor a deistic separation of him from it. It does not move on as an independent and inflexible mechanism. While God is above nature as its Creator, he is also immanent in its forces and order, which rest in and on his abiding and omnific will. God and nature do not stand to each other in merely external relation, but he is in ever-living communication with it. "He upholds all things by the word of his power." "He is above all and through all and in all." "In him we live and move and have our being." Physical nature can be rationally viewed only as subordinate to the life and moral welfare of man, whose creation in the image of God and with given dominion alone explains and justifies the material system. The physical world is not for itself, but for the higher designs of the divine administration. This is the conception which the Scriptures themselves give of God's relation to the world and the interests for which he has adjusted its system and guides its history. The miracle can be fairly defined and interpreted only under this conception.

Miracles are not to be thought of, as often represented in older statements, as "violations or suspensions of the laws of nature." Hume and others have under this view sought to discredit their possibility and place them beyond proof. They are in no such antagonism to nature, and do not clash with its proper order. They are due to a special and direct exertion of the divine will-power, without annulling any natural force or its sequences of cause and effect. God inserts his direct power for its own effect. The reality may be fairly illustrated in the operation of human will-power. When this, through science and skill, inserts its directive touch in nature's ongoings and turns water or electricity into driving forces for industry or commerce, or shapes the transparent glass into lenses for bringing the distant stars into view, no law of nature is violated. The new result is accomplished by special free causation. When this free power lifts a hand or casts a stone into the air, the law of gravitation is not infringed or suspended—every particle of matter in hand or stone still gravitating as before. When the sons of the prophets cut down a stick and cast it into the water and the ax-head swam (2 Kings vi. 6), neither the specific gravities of the water or iron were altered, nor was the law of gravitation annulled.

2. *The Place of Miracles.*—This can be rightly seen only in the light of the teleological principle. God has a purpose in the world, and miracles manifestly have their place with respect to this in connection with the moral good of mankind, and especially in connection with the redemptive economy with which the Scriptures associate them. They are no part of the natural system with which science deals, and belong not to any necessity for the order or completion of the physical cosmos; hence no objection can be raised against them as derogatory to God in implying such a failure in his creative wisdom and power as to require the help or correction of after-intervention. It is only when we recall the great truth that through the aggregate natural world God is aiming at a moral product in the free life of man, and, further, that there is such a thing as *sin* which has disturbed the true life, order, and happiness of humanity and created a need of God's coming forth for relief and help, that we see the true position and import of miraculous action. It is part of the supernatural administration in a redemptive economy and in conducting the world on to its true design. It centers in Christ, marking and manifesting his work. All the miracles of the Old Testament stood in this relation, belonging to the preparatory mediatorial history which opened the way for the advent of the Messiah. Those of Christ himself were the appropriate manifestations of his supernatural person. Those of the apostles were from the same source. Special periods in this unfolding redemption were particularly marked with them. In the Mosaic period, when the authority and supremacy of Jehovah needed assertion and display, and again in the days of Elijah and Elisha, when the truth of monotheism required vindication against the encroachment of idolatry, they appear in striking prominence. Around the person and ministry of Jesus Christ, the eternal Word made flesh as the Saviour of men, the full presence and action of miraculous power culminated and accomplished its work. When the full provisions of redemption were wrought out and the new kingdom of grace was certified by miraculous activities, the miracle as a special extraordinary event ceased and disappeared in the regularly constituted supernatural action of established grace through the Word of the Gospel under the power of the Holy Spirit. The miracle is never to be considered as something isolated, apart from the supreme divine purpose with respect to humanity. It can be understood only as associated with the work of God as Redeemer.

3. *Their Credibility.*—The same degree of credibility must attach to miracles as attaches to the idea of the superiority of moral order and spiritual good over the mere mechanism of nature. If there is no invincible improbability that God as Holy Love should give to man information as to his duties and the conditions of his welfare beyond that which may be gathered by reason, and, further, should make known a way of forgiveness of sin and redemption from its bondage and misery, concerning which nature is silent, there can surely be no insuperable improbability of supernatural revelation. Such revelation is itself intrinsically miraculous. As history and ethnology unquestionably show that men, outside the circle of special revelation, have striven for more light as to human duty and destiny and salvation from the woe of moral evil, there is plainly no antecedent incredibility that such instruction and help should be given by an almighty and loving Crea-

tor. Whether miraculous revelation has been given is a question of fact. As such its proper proof is simply adequate testimony. Hume's claim, so often refuted, that no amount of testimony can prove a miracle, is sophistical and unreasonable.

4. *The Possibility of a Miracle.*—Evidently the writers of the Old and New Testaments felt no trouble on this point. Their reason and piety never doubted that if God, acting in his eternal freedom, love, and sovereignty in his own world, wished to teach or help his servants, bringing them salvation in emergencies, he could do it. This was the deep innermost faith of their souls, and their whole view of the world was in harmony with this. Of an order of nature obstructing God's will or power they never dreamed; but in modern and recent times much objection on this ground has been made to the possibility of a miracle. Though the objection is variously shaped, all its forms amount to this one contention, that the uniformity of nature's system is so fixed and inflexible under the reign of physical force and law as to allow no room for such an occurrence; but nature is utterly misrepresented when its ongoing of cause and effect is said to exclude free-will causation for divine miracles. Undoubtedly there is law in nature, but such law as opens nature to the easy entrance of will-power into its movements. It is not a system of unyielding mechanism in unbending rigidity, foreclosed forever against all the power of freedom, both human and divine, but one, in fact, infinitely elastic and plastic to the touch and handling of will-force for effects which the system, if left alone, could never produce. Such the world must be, in order to be man's fit dwelling-place and to serve the interests of his life. It is placed under his dominion and submitted to his use; and there is not an hour in which the human will is not turning nature into new forms and events which millenniums of ages of untouched nature could never produce. Nowhere is this better known than under the full light of science, in whose name this objection is so often falsely made. Human free will is changing the face of the earth. Steam vessels and railways and telegraphs and telephones and phonographs, in which the mightiest as well as the most subtle forces are used as servants, are some of the "physical miracles" of the *human* will—wrought, too, upon the *basis* of the very uniformities and laws which are, in the objection, said to bar off the will-power of God from miraculous action.

5. *The Proof of Miracles.*—If proved at all, they must be proved, like other facts, by the testimony of proper witnesses. The accounts of these "signs," "wonders," and "mighty deeds" are woven in with the very warp and woof of the history of the Christian redemption. They are of a piece with the revelation idea which runs in transparent clearness through it all. The biblical history is found, in fact, to yield to no history in the world in the clearness and accuracy of its statements. No historico-critical investigation has ever been able to impeach the credibility of the testimonies to the miracles without discrediting the entire history in which they form an integral part. They were given with a calmness and veracity that remained unshaken in the face of danger, persecution, and death. If such testimony is worth nothing, no testimony on earth is of valid force, and may be arbitrarily set aside; but objection is made that the witnesses were uncritical and disposed toward the marvelous, or that, at best, though they reported honestly the external events as they appeared, they could not, as spectators, see behind the phenomena and trace them up to the direct hand of God. As to the first part of the objection, it is in point to say that they were ready to accept miracles only as they were to accept the reasonable truth that God is present in supreme power in the world, and at hand with the help for his people which great moral emergencies required. As to the second, if mere spectators could give only their *opinion* as to the cause of the wonder, the suggestion is inapplicable to the testimony which Christ gave to the miracles which he himself wrought, whose knowledge could connect them infallibly with the divine power. Moreover, is it possible to repudiate the miracles as false perceptions or misinterpreted phenomena, or legends or myths of the religious temper of those far-away times, and still hold to the generic supernaturalism of the whole redemptive idea, the divine call of Israel, the inspiration of prophecy, the incarnation of the Son of God, the aggregate "wonder" of his life and teaching, or the crowning miracle of the resurrection and the living Christ of history since? The subordinate supernaturalism of the miracle-records is so integral a part of the whole redemptory revelation that they inevitably stand or fall together. To repudiate the possibility or reality of the incidental phenomena logically carries with it a repudiation of the entire supernaturalism of Christianity, as is constantly illustrated in the case of deniers of the Gospel miracles; but as long as Bible Christianity stands, belief in miracles must form a part of Christian faith.

6. *The Evidential Value of Miracles.*—This has been differently estimated at different times. In the early Church, Middle Ages, and early Protestant theology, apologetics made large use of them as proof of the divine authority of Christianity; but since the rise of modern pantheistic and deistic philosophies, and the recent development of physical science with its emphasis on the conservation of force and the reign of law in nature, energetic and persistent assault has been made upon the biblical miracles, and the appeal to them has been less used—not because not valid but as less available. Opponents of Christianity have represented them as not the triumphant proof of its truth, but the greatest impediments to its reception. Hence apologetics have tended to rest the proof more on other forms of evidence. They are thus often thrown into the background, as tenable indeed *by* faith, but not its support or warrant; but this persistent and many-sided assault and depreciation have stimulated Christian thought to deeper study and led to profounder views of the real import and significance of miracles and of their position in the redemptory economy. The change not only corrects the false forms of statement which long allowed them to be thrust into untrue antagonism to nature, but holds them in closer and more living relation to the whole divine activity for the spiritual regeneration of man, and especially emphasizes their indissoluble union with the very life and work of the Mediator as God manifest in the flesh. In evidential value they are thus entirely separated from the useless prodigies of pagan superstitions which presented no moral or divine reason for their occurrence, and they stand out clearly as called for by the grandest necessities and interests of humanity. The miracles of Christ—and all the Christian miracles are parts of the redemptive activity of which he was the center—are not simply credentials externally attached to his ministry for authentication of his mission and the truth of his teaching, but are the normal or natural manifestations of his supernatural person, the incarnate Son of God acting in the presence of men. They are distinctively redemptive in relation and character. They exhibit him *at* his redeeming work, testifying to him in the relation in which he presents himself as the Saviour of men, the Light and Life of the world. They are parables of his person, types of his work. They are thus the true "signs" of a Saviour, and the fitting witnesses to the divine character of Christianity. While these may not convince those who do not believe in the supernatural, they are yet just the crowning evidences for the confidence of those who do believe. While men may stumble at these miracles, no one could be satisfied to accept a Saviour who does not have these very tokens of supernatural power and office about him.

M. Valentine.

Mira de Mescua, mec'raă-dā-mās'kwaă, or **Amescua**, Antonio: poet and playwright; b. at Guadix, Spain, about

1570. He became archdeacon of the Church in Guadix, but subsequently was patronized by the famous Conde de Lémus, who as viceroy in Naples (1610) had Mira de Mescua and other notable writers with him, to give distinction to his court. Returning to Spain, the poet became a court chaplain at Granada, and subsequently chaplain-of-honor to Philip IV. in Madrid. D. in Madrid in 1635. He was much admired by his contemporaries both for his lyrics and his plays, and he obtained the somewhat peculiar honor of having his works largely pillaged by more famous writers. Among these were Calderón and the French Corneille, the latter of whom in the *Héraclius* used our author's *Rueda de la fortuna*, and in the *Don Sanche d'Aragon* his *Palacio Confuso*, attributing it wrongly, however, to Lope de Vega. The works of Mira de Mescua have never been collected and are hard to get at. A few of his lyrics are printed in vol. xlii. of Rivadeneyra's *Biblioteca de Autores Españoles* (Madrid, 1857), and five of his plays are to be found in vol. xlv. of the same collection. Eighteen of his plays are printed in the now very rare *Comedias escogidas de los mejores ingenios* (1652–1704). A. R. Marsh.

Miraflores, mē̆e-rä̆a-flō′rāz: a village of Peru, near the seashore; 6 miles S. of Lima, between that city and Chorrillos (*q. v.*). Previous to the Chilian invasion it was the residence of many wealthy Peruvians. After their defeat at Chorrillos (Jan. 13, 1881) the Peruvians formed a second line of defense at Miraflores; it was attacked by 13,000 Chilians, Jan. 15, and carried after a bloody battle, thus opening the way to Lima. It was burned by the Chilians. H. H. S.

Miraflo′res, Manuel de Pando, Marquis of, and Count of Villapaterna: statesman; b. in Madrid, Spain, Dec. 24, 1792; was educated for the public service, in which he spent more than fifty years; was ambassador at London 1834, at Paris 1838–40, and at Vienna 1860; seven times president of the senate, often a cabinet minister, and Premier in 1846 and 1863. In 1868 retired to private life. D. in Madrid, Mar. 17, 1872. The marquis was decorated with nearly all the grand orders of merit in Europe, and was an active member of the Spanish Academy of History. He wrote several treatises in favor of Isabella's right of succession to the throne, a biography of Louis Philippe (1851), valuable *Memoirs* of his own life, and a *History of the First Seven Years of the Reign of Isabella II.* (2 vols., 1843–44), and published numerous speeches and fugitive writings.

Mirage, mē̆e-rä̆azh′ [Fr., deriv. of *mirer*, look at (in the reflexive form), *se mirer*, look at one's self in a glass, be reflected, reflect < Mod. Lat. *mira're*, look at]: a term including those aërial and marine reflections generally known as mirage, looming, and Fata Morgana. These are all analogous phenomena, due to the refraction of light, to its total reflection, or to a combination of both. These are—(1) mirage of the desert; (2) mirage at sea; (3) looming; (4) a combination of ordinary mirage at sea and looming; (5) Fata Morgana. The first, mirage of the desert, presents the appearance of reflection in a smooth surface of water, the inverted image of trees, etc., being seen beneath the real objects. It is due to the refraction, and finally to the total reflection, of the rays of irregularly reflected light, sent back to the eye from the object. The heated sand of the desert rarefies the lower strata of air, while the upper strata are condensed by the chilling due to the radiation of its heat. The strata of different densities mingle slowly in consequence of the stillness of the air. Fig. 1, *a b c d e f*

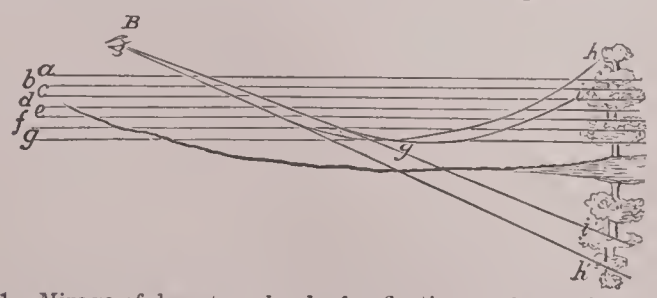

Fig. 1.—Mirage of desert: *a b c d e f*, reflecting surfaces where strata of air touch; *g*, angle of total reflection; B, eye of observer; *h i*, pencils of rays from object; *h′ i′*, points where pencils focus in reflection.

g, represents the boundaries of strata of air, which decrease in density from above downward. Every point of the tree sends out divergent rays of irregularly reflected light, by means of which it is visible. The direct rays from the tree to B make it visible to the eye at B. The ray *h*, which under ordinary circumstances would never reach the point B, meets in its downward course strata of continually decreasing density, and becomes less and less inclined to the parallel layers of air, till at *g* the angle of total reflection is reached and the rays are bent upward (see Reflection of Light), and enter the eye in the direction of *h′*B; and so with *i* and all other rays. An object is always seen in the direction by which the rays sent from it enter the eye; an inverted image is therefore formed by the portion of each pencil of rays proceeding from the tree, which is bent back to the eye as by a mirror. Second, mirage at sea is explained in exactly the same way, except that the conditions are reversed. The lower strata of air are chilled by the waters of the ocean, and increase in density from above downward; the rays which produce the image curve convexly, or in the opposite direction. (Fig. 2.) Third, looming is due to refraction alone; a portion of the pencil of rays which proceed from the point *h* (Fig. 3) reaches the

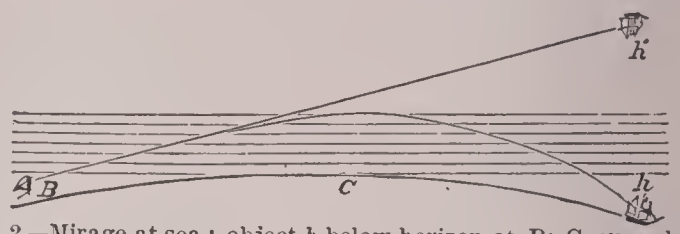

Fig. 2.—Mirage at sea; object *h* below horizon at B; C, curved surface of the earth.

Fig. 3.

eye direct, and produces the image of the real object, while another portion is refracted, and produces an erect image above the real one. Fourth, a real, inverted, and erect picture of the same object is sometimes projected upon the retina of the eye at the same time a portion of each pencil of rays proceeding from the body reaches the eye direct, producing the image of the real object; another portion is simply refracted, as in Fig. 3, producing an erect image; while a third portion is first refracted and then totally reflected, forming an inverted image. In 1822 Capt. Scoresby recognized the ship Fame by her inverted image in the air, though she was 17′ below the horizon. The whole of Dover Castle has been seen as if lifted over an intervening hill by the refraction of the rays of light from its surface, and in this case the image from the looming was so vivid as to obscure the hill which really lay between the castle and the observer's eye. Lateral images are sometimes formed by reflection of the rays from vertical columns of air having different densities. Two boats, one real, the other a reflection, have been seen side by side upon the Lake of Geneva at the same moment. Mirage is most common when there is a marked difference between the temperature of air and water; it is most frequent in the morning or in summer and autumn, when the air is laden with mist. It is seen oftener by an eye placed close to the surface of the water, less perfectly at a height of 6 or 8 feet, and almost never at 24 feet or more above the level of the sea. Dr. Wollaston obtained three images of an object seen through a square glass vessel containing successive layers of sirup, water, and spirit. Fifth, the phenomenon called Fata Morgana, or castles of the fairy Morgana, is occasionally seen upon the Calabrian coast while looking westward toward the Straits of Messina. (See Fata Morgana.) On still mornings, when the sun, rising behind the Calabrian Mountains, strikes upon the sea at an angle of 45°, the air is rapidly heated; the strata slowly intermingle, and present a series of reflecting surfaces which multiply images on the opposite Sicilian shore. The water is supposed at the same time, by the action of the tides, to possess a slight convexity. There are three forms of this mirage—the marine Morgana, where each object is reflected again and again in an inverted position and at different angles on the surface of the water; the aërial Morgana, when they are thus reflected in the air; and a third form, in which the aërial images are fringed with prismatic hues. Gigantic reflections of men and animals are sometimes observed to flit over the scene. The Calabrians hail the appearance of this beautiful but short-lived spectacle with delighted cries of "Morgana!

Morgana!" This phenomenon is not confined to the Calabrian coast, though the meteorological conditions, the topography of the ground, and the conformation of the coast in this place render its appearance more frequent and more beautiful than elsewhere. In all these reflections there is apt to be a wavering in the defining lines, and sometimes the whole image is tremulous like an object seen through a current of heated air.

Miramichi, mir-a-me-shee', **River**: a large river of New Brunswick, discharging its waters by a deep estuary into Miramichi Bay, an arm of the Gulf of St. Lawrence. The river is navigable to Newcastle by large ships, and higher up by smaller vessels. Salmon and many other valuable fish are taken here in great quantities.

Miramions: See GENEVIÈVE, DAUGHTERS OF ST.

Miramon', MIGUEL: soldier; b. in Mexico city, Sept. 29, 1832. He was the son of a distinguished officer of French descent; entered the military school of Chapultepec in 1846; served as a volunteer against Scott, and was taken prisoner; was commissioned in the army 1852, and as captain and colonel fought against Alvarez 1854–55, until the triumph of the latter. He served for a time under Alvarez and Comonfort, but his sympathies were with the reactionists. In Dec., 1855, he deserted with his regiment, and took a leading part in the revolt at Puebla Jan.–Mar., 1856. When Comonfort captured the city, Miramon was degraded to the ranks. In October of that year he headed another revolt at Puebla, and with a few hundred men defended the city during a siege of forty-three days against 4,000 troops, finally escaping before the surrender. Subsequently he took Cuernavaca, and in Jan., 1858, joined Zuloaga, who had revolted at Mexico, and assisted in driving Comonfort from the city. For this he was made brigadier-general. The reactionists were now in the ascendency, but Juarez maintained a constitutional government at Vera Cruz. Miramon, at the head of Zuloaga's forces, gained several victories in the central states, occupied San Luis Potosí, and was promoted to the rank of major-general (1858). The electoral junta chose him for president in the place of Zuloaga Jan. 2, 1859. He declined at first, but Zuloaga eventually resigned after appointing him successor *ad interim* (Feb. 2). The new president made an unsuccessful attempt against Vera Cruz, which was still occupied by Juarez. During his absence Degollado, at the head of a constitutionalist force, attacked Mexico, but was defeated at Tacubaya by Marquez (Apr. 11, 1859). Miramon, who had returned to the capital on the same day, issued a written order to shoot all the prisoners of the rank of officers, a command which was executed by Marquez. This "massacre of Tacubaya" horrified the nation and greatly weakened Miramon's influence. Juarez gained correspondingly, and in April his government was recognized by the U. S. During 1859 the reactionists were generally successful in the central and northern states, and in Feb., 1860, Miramon again laid siege to Vera Cruz, but abandoned it Mar. 21. In May he defeated Uraga at Guadalajara; but thereafter the Juarists gained ground. Miramon was defeated in Guanajuato in August, shut in at Mexico, and finally routed by Ortega at the battle of Colpulalpam Dec. 22, 1860. Two days after he abandoned the capital, which soon surrendered, reached the coast after several narrow escapes, and took refuge on a French ship. He proceeded to Europe, where he had an interview with Napoleon III., and probably entered into his plans for a French invasion of Mexico. Early in 1862 he appeared at Vera Cruz, which was then held by the forces of the Triple Alliance; but the British admiral refused to let him land. Later he adhered to Maximilian, who gave him the rank of grand-marshal and made him minister to Berlin. In 1866, after the French had withdrawn, he returned and was given high command, and with Maximilian himself undertook the defense of Querétaro. At the fall of that city he was captured, and was shot with the ex-emperor June 19, 1867. H. H. SMITH.

Miranda, or **Guzman Blanco**: a state of Venezuela; bounded N. by the Caribbean Sea, E. by Bermudez, S. by Bolivar, and W. by Zamora and Carabobo; area, 72,499 sq. miles; pop. (1891) 526,633. The northern third is mountainous, and contains many fertile valleys, the richest agricultural regions of the republic. The remainder lies in the LLANOS (*q. v.*), and supports immense herds of cattle. The Orinoco and its branch, the Apure, form the southern boundary, and are the principal outlets of the pastoral zone. Miranda is the richest and most populous state of Venezuela, and contains the oldest settlements. The most important exports are hides, tallow, live cattle, coffee, tobacco, cacao, and goatskins. Capital and largest town, Ciudad de Cura. The island of MARGARITA (*q. v.*), with the neighboring islets, is included in this state. HERBERT H. SMITH.

Miranda, mĕe-raan'daă, FRANCISCO ANTONIO GABRIEL: revolutionist; b. at Caracas, Venezuela, June 9, 1756. He served as captain and licutenant-colonel in the Spanish army in Spain, Guatemala, Florida, and the West Indies, and about 1782 was expelled for alleged contraband trading. Subsequently he fought with the French auxiliaries against the English in North America, and after 1785 was in St. Petersburg, where the favors which he received from Catharine II. gave rise to scandalous but unproved stories. In 1790 he joined the French republican army, was general of division and held high commands on the Rhine and in Germany. About this time he began to scheme for the independence of Spanish South America. To this end he founded in London a secret society, the Gran Reunión Americana, all the members of which were pledged to work for the independence of Spanish America. Bolivar, San Martin, the Carreras, Caro, Madarriaga, O'Higgins, and others, who were afterward prominent in the South American revolution, were initiated, and the effects of the organization were very great and far-reaching. Aided by funds from private sources, he went to New York, where he organized a small expedition, and made a descent on the Venezuelan coast in Aug., 1806; but few Venezuelans joined him, and after part of his men had been captured he was driven to take refuge in Trinidad, whence he returned to England. After the breaking out of the Venezuelan revolution he returned to that country with Bolivar (Dec., 1810), was received with enthusiasm, and soon after was given command of the patriot army. His operations were generally successful, and at the beginning of 1812 the revolution in Venezuela seemed assured. Serious reverses, however, followed the disastrous earthquakes of Mar. 26–May 1, and Miranda was made dictator. For a time he held the royalist leader, Monteverde, in check, but the fall of Puerto Cabello convinced him that further resistance was hopeless, and on July 25 he signed a capitulation. Miranda himself fled to La Guayra with the intention of leaving the country, but on July 31 he was arrested there by Bolivar and others and—treacherously as some charge, unavoidably as others claim—was delivered over to the Spaniards. In violation of the treaty they sent him a prisoner to Spain, where he died in captivity at Cadiz, July 14, 1816. See Briggs, *History of Don F. Miranda's Attempt* (1809); Baralt, *Historia de Venezuela*. vol. ii. (1841); Mitre, *The Emancipation of South America* (translation of Pilling, 1893). H. H. SMITH.

Mirdites: a peculiar and primitive people of Albania; a sort of military aristocracy, occupying a tract about 40 miles square, included between 40°–41° N. lat. and 17°–18° E. lon., nearly surrounded by the Drin. Orosch, a mountain fastness, is the residence of their prince. They never intermarry, but capture their wives from their Mussulman neighbors and give their own daughters to other Christian tribes. They number about 20,000, are nominally Roman Catholics, and are brave, faithful, and hospitable. See Tozer's *Highlands of Turkey*, vol. i. E. A. GROSVENOR.

Mir'iam [from Heb. *Miryām*, liter., rebellion, whence Gr. Μαριάμ, Μαρία, whence Eng. *Mary*]: the sister of Moses, according to Josephus, the wife of Hur and the grandmother of Bezaleel, who built the tabernacle. She led the chorus of women triumphing over the Egyptian discomfiture (Ex. xv. 20, 21); joined her brother Aaron in murmuring against the divine exaltation of Moses, and showed her jealousy and dislike of Moses's Ethiopian wife, for which conduct she was punished with temporary leprosy (Num. xii.). She died at Kadesh (Num. xx. 1). In the Arabic traditions she is often confounded with the Virgin Mary.

Miri Lake: See LAGOA DOS PATOS.

Mirkhond', or, more fully, **Muhammad bin Khavandshāh bin Mahmūd**: historian: b. at Nishapur, Persia, in 1433; d. at Herat in July, 1498. His great work, the *Rauzat-ussafa, or The Garden of Purity, containing the Histories of Prophets, Kings, and Khalifs*, as it is fantastically entitled, was begun about the year 1474. It gives the history of the world from the creation nearly to his own times, and comprises seven volumes. Many manuscripts of this work are found in the libraries of London, Paris, Berlin, and Vienna. Portions of it have been edited by Jaubert,

Jenisch, Mitscherlich, Wilken, and Vullers; it was translated into French by Silvestre de Saey, Jourdain, Langlès, and Defrémery; into Latin and German by numerous authors; and into English by David Shea (1832), W. H. Morley (1848), Rehatsek and Arbuthnot (1892, etc.).

Revised by A. V. Williams Jackson.

Mirrors [M. Eng. *mirour*, from O. Fr. *mireor* > Fr. *miroir*, deriv. of *se mirer*, be reflected. See Mirage]: solids, usually in the form of plates having a smooth surface, capable of reflecting light. They have been a part of the furniture of the toilet from a period of very high antiquity. The earliest mirrors were formed of polished mineral substances or of metals, but after the invention of glass that substance naturally superseded most others in the construction of mirrors. The backs of glass mirrors were sometimes coated with lead, but about three centuries ago the process of covering glass with an amalgam of mercury and tin came into use in Venice, and has been since employed. The process, substantially the same now as when first introduced, consists in spreading out upon a solid horizontal table a sheet of tinfoil, which is first rubbed and afterward covered to a sensible depth with mercury, so that the superior surface may remain liquid. The mercury is prevented from flowing by means of slight ledges placed around the sheet. After having been scrupulously cleaned on its lower surface the glass to be coated is advanced horizontally along the layer of mercury, its lower edge being depressed below the surface, so as to exclude air and to remove impurities. When in proper position it is left resting on the mercury, and by tilting the table the superfluous fluid is allowed to flow off, being caught in a trough provided for the purpose at the margin of the table. A uniform pressure is then applied to the glass, and it is allowed to remain for some time in this condition, after which it is carefully lifted, the amalgam adhering to it, and is placed with the amalgamated surface uppermost. Some weeks' rest is required to allow the amalgam to harden, and sometimes a mirror will not "dry" for months.

The preparation of mirrors by quicksilver is objectionable on many accounts, the principal of which is the injurious effect of the vapors on the health of the workmen. Quicksilvered mirrors are also liable to various faults, such as a flowing of the mercury in drops, carrying the amalgam with it, forming streaks (known as worms); also a crystallizing of the amalgam when exposed to light (called blindness). These disadvantages of the quicksilvering process have turned the attention of manufacturers to the use of pure silver for backing mirrors. Von Liebig in 1836 was the first to notice that aldehyde would reduce silver from ammoniacal solutions, depositing it upon glass or porcelain in a continuous film. Subsequently, other chemists proposed other reducing agents. The first application of the process on a large scale was made by Drayton, who patented it at Brighton, England, Nov. 25, 1843. He used different essential oils as reducing agents, but his glasses were used only for a short time; they soon became spotted. The next attempt was made by Petitjean, who obtained a patent in 1855; and this seems to have been more successful, his process, with slight modifications, being still in use. The materials and proportions required by one of the various modifications of Petitjean's process, used on large plates, are as follows: (1) 1 lb. crystallized nitrate of silver to be treated, while stirring, with 12 liquid ounces of ammonia 26° B. After cooling and crystallization, 6½ pints distilled water are to be added, and the solution filtered. This solution will keep for any length of time. (2) The reducing solution is to consist of pure crystallized tartaric acid dissolved in four parts of water; and this is said to improve with age.

The advantages claimed for the silver over the quicksilver process are: (1) Harmlessness to the workmen; (2) facility and expedition, the whole operation being completed in a few hours; (3) possibility of repairing damaged parts; and (4) superior power of reflection. A silver mirror reflects about 20 per cent. more light than one of quicksilver, and reflects objects more truly in their natural colors. The durability of silver mirrors is still an open question. They are all liable, after a time, to become spotted, and unless this difficulty be overcome it is hardly probable that the silver process will ever completely supersede the quicksilver. For the optical properties of mirrors, see the article Reflection of Light.

Mirut: city and division of Northwest Provinces, British India. See Meerut.

Mirzapur': town; Benares division, Northwest Provinces of British India; the capital of a district of the same name, on the right bank of the Ganges (see map of North India, ref. 7–G). The district of Mirzapur, comprising an area of 5,224 sq. miles, extends along the Ganges and the Sone between lats. 23° 50′ and 25° 30′ N., and between lons. 82° 11′ and 83° 39′ E. The city of Mirzapur is a very busy and lively place, the most important cotton-market of India, with an extensive industry in cottons, woolens, and silks. From the river it looks very magnificent with its flights of marble steps leading from the temples down to the waters, but the interior consists mostly of mud huts. There are, however, many fine European residences. About 4,000 persons are employed in the manufacture of shell-lac. Brassware and carpets of a very fine description are also made. Pop. (1891) 84,130. Revised by M. W. Harrington.

Misdemeanor: See Crime, Felony, and Infamous Crimes.

Mishawaka: town; St. Joseph co., Ind. (for location of county, see map of Indiana, ref. 1–E); on the St. Joseph river, and the Chi. and Gr. Trunk, the Elkhart and West., and the Lake Sh. and Mich. S. railways; 4 miles E. of South Bend, 90 miles E. by S. of Chicago. It is one of the oldest towns in Northern Indiana, the first dam on the St. Joseph river and the first iron-furnaces being erected here; has excellent water-power, water-works, electric lights, electric street-railway, and a monthly and two weekly newspapers; and is noted as a manufacturing point, especially for the production of windmills, wagons, plows, and other farm implements, furniture, pulleys, transmission systems, wool and felt boots, horse-collars, church organs, church altars and carvings, paper, wood-pulp, flour, beer, etc. Pop. (1880) 2,640; (1890) 3,371; (1900) 5,560.

Editor of "Enterprise."

Mishna: See Talmud.

Misiones, mĕĕ-si-ō′nās: a territory forming the extreme northeastern portion of the Argentine Republic; bounded N. E. and S. E. by Brazil, S. W. by the province of Corrientes, and N. W. by Paraguay. The area actually held by Argentina is about 22,000 sq. miles. In addition to this the Argentine Government claims an easterly extension of the same region, comprising about 15,500 sq. miles, now held by Brazil (state of Santa Catharina), and known as Upper or Brazilian Misiones. The disputed region is (1894) the subject of arbitration by the President of the U. S. Misiones lies between the upper Paraná, with its tributary, the Yguassú, and the upper Uruguay. The surface is much varied, but without high mountains; there are large tracts of forest and others of open lands adapted for pasturage. Cattle-raising, the gathering of mate or Paraguay tea, and timber-cutting are the principal industries. Misiones was included in the region formerly called Guayrá. From 1633 to 1767 it was the site of large and flourishing Jesuit missions, said to have contained a population of 130,000 in 1735. After the expulsion of the missionaries they fell to decay; in 1817 the villages were ravaged and burned by the Portuguese, and the country was almost depopulated. Ruins of the Jesuit buildings still exist, half covered with forest. Pop. of the Argentine portion, 11,000; of the disputed territory, 5,000. Chief town, Posadas. H. H. Smith.

Misisagas: See Algonquian Indians.

Misrepresentation: in law, an untruth, by statement or conduct, which induces the formation of a contract. Fraudulent misrepresentation having been dealt with under the head of Fraud (*q. v.*), the present article will be confined to innocent misrepresentation. This sort of misstatement can never be made actionable as a tort, and it is the general policy of English common law to exclude it from affecting a contract with which it is connected, unless the parties have made it a term thereof. Special classes of contracts, like those of Insurance (*q. v.*), are exceptions to this rule. Any material representation, however innocent, renders them voidable.

In the sale of chattels, however, a misrepresentation which is not a term must strike at the very root of the contract in order to avoid it at law—that is, there must be a complete difference in substance between the subject-matter of the contract as it was represented and as it was. For instance, if the purchase of a horse is induced by an honest misrepresentation as to its soundness, the buyer will have no relief, though both vendor and purchaser erroneously thought they were dealing about a sound horse, unless the

representation was a warranty. Accordingly, a person who began examining a horse which was to be sold at auction the next day without warranty, and upon being told by the owner, "You have nothing to look for; I assure you he is perfectly sound in every respect," desisted from the examination, saying "If you say so, I am satisfied," and later bid off the horse at auction, was held bound to take and pay for him, although he was in fact unsound, no bad faith on the part of the vendor being charged. (*Hopkins* vs. *Tangueray*, 15 Common Bench Reports 130.) For the effect of a misrepresentation which amounts to a WARRANTY, see the article under that head. An innocent misrepresentation may be introduced into the contract as a condition, in which case its untruth will entitle the party to whom it is made to a discharge from the agreement. The following is an example: The owner of a ship agreed with the owner of coal that she was then in the port of Amsterdam, and would proceed to Newport and load, and carry a cargo of the coal to Hongkong. It turned out that the ship was not then in Amsterdam, and this innocent misstatement, being a condition of the contract, entitled the owner of the coal to be discharged from all liability thereon. *Behn* vs. *Burness*, 3 Best and Smith 750.

In equity, however, a contract obtained by a material false representation can be set aside at the instance of the party to whom it was made, although it was made innocently, or he can successfully resist an action for the specific performance of such a contract, on the ground that no man ought to take advantage of his own false statements. Pollock *On Contracts*, chs. ix. and x.

FRANCIS M. BURDICK.

Mis'sal [from Late Lat. *missa'le* (also *li'ber missa'lis*, mass-book), liter., neut. of *missa'lis*, pertaining to the Mass, deriv. of *mis'sa*, mass. See MASS]: the service-book of the Roman Catholic Church, a volume containing the prayers, hymns, etc., used in the performance of the Mass. There are several missals in use. Each of the Eastern rites has one or more peculiar liturgical services, and in the Latin rite, up to the time of the Council of Trent, there were many variations in the celebration of the Mass; but the council fixed the present Roman missal as the standard liturgy, permitting, however, a few local liturgies to be retained, but at present the Roman missal is almost universally employed. The earliest specimens of this kind of books were the so-called *Libri Sacramentorum*, or *Sacramentaria*, which date back to the time of Gelasius I. The missal, such as it was finally fixed for the Roman Catholic Church by the Council of Trent, is nothing but a revision of those *Libri Sacramentorum*. Editions of the missal in the original Latin have often been printed; as, for instance, in Paris, 1739, and Berlin, 1841. See LITURGICS.

Mission Indians: See SHOSHONEAN INDIANS; also YUMAN INDIANS.

Missions [from Lat. *mis'sio*, a sending, deriv. of *mit'tere*, send]: organized work for the propagation of religious doctrines, especially of the doctrines of Christianity. Islam and Buddhism have both made use of missions for the propagation of their tenets. With the former, however, force has been so prominent a feature that the essential element of all true mission work—persuasion by preaching and teaching—has been largely lost sight of. Buddhist missions have more nearly corresponded to Christian missions. See BUDDHISM and MOHAMMEDANISM.

I. HISTORY OF CHRISTIAN MISSIONS.—This may be divided into three periods: apostolic and early Christian, mediæval, and modern or post-Reformation. The mediæval missions are both Roman Catholic and Eastern; the modern are Roman Catholic, Protestant, and Greek Orthodox.

1. *Apostolic and Early Christian Missions.*—These cover the period of the spread of Christianity from the time of Christ until about 500 A. D. This period belongs more distinctively to Church history, and covers a style of work essentially different in character from that of the present day. It was chiefly the work of individuals, and was the development of the type first given by the apostle Paul in his journeys. During it the Gospel was spread throughout the whole of Southern Europe, Great Britain, Northern Africa and Ethiopia, and as far east as Persia, and perhaps even China.

2. *Mediæval Missions.*—These cover the period of about 1,000 years, from 500 A. D. until the Reformation. They approach more nearly to the modern conception of missions, in which the Church in its different branches undertakes the work as a whole, employing individuals. The chief place in it belongs to the Roman Catholic Church, although this is the period of the work carried on by the Nestorian Church, when its missionaries carried the Gospel throughout Central Asia to India, founding there the Syrian Church of Malabar, and into China. The Roman Catholic Church missions of the Middle Ages took their start from Ireland, and included in their scope England, Scotland, and Northern Europe. Still the effects of the early methods were seen in the predominating influence of individuals, as Columba of Iona, Columban, who established his monastery in 590 among the Vosges Mountains in Eastern Gaul; St. Ansgar, the apostle of Scandinavia; St. Cyril and St. Methodius among the Slavs; and St. Adalbert of Prague among the Magyars. Monte Corvino penetrated to China, and Raymond Lull preached in North Africa. The work of these men partook largely of the nature of a proselytizing crusade rather than of an organized work of missions, as the term is used now.

3. *Modern or Post-Reformation Missions.*—(*a*) *Roman Catholic.*—The immediate effect of the Protestant Reformation was to stimulate the activity of the Roman Catholic Church, and the next century and a half witnessed some of the most romantic and adventurous mission enterprises ever known. What the Church was losing in Europe she sought to gain elsewhere; and the discovery of America and the voyages of the Portuguese in the East offered a free field. Mexico was entered in 1522 by the Franciscans, followed by the Dominicans and Jesuits. The West Indies were occupied, and South America was secured by the conquest of Peru in 1533. In 1586 came the famous Jesuit mission to Paraguay, when indefatigable workers sought first to reconvert the Spaniards as a necessary means to reaching the Indians. The first mission to Canada was started by the Jesuits in 1608 at the mouth of the St. Croix. Then came the Recollects or Reformed Franciscans, and until the French and English wars resulted in the establishment of English power, the work extended chiefly among the Abnakis (Abenaquis) and Hurons, with many thrilling experiences of devoted self-sacrifice. It was in the East, however, that the greatest achievements of Roman Catholic missions appeared. As early as 1510, following the lead of Vasco da Gama, missionaries penetrated to India, and the first bishopric was established at Goa. In 1542 Francis Xavier began from that place a series of journeys and missions whose story is one of the most fascinating in the annals of missionary enterprise. Xavier was followed by Robert de Nobili, who lacked his predecessor's Christian simplicity, and filled with zeal for baptisms countenanced accommodations to heathen ideas and customs which proved disastrous. China's first missionary of this period was Barreto, who stopped at Canton in 1555 on his way to Japan. The first baptism was in 1584, and the success of these Jesuits, especially under the lead of Ricci, was phenomenal, until in 1664 there were nearly 270,000 Christians. Persecution followed, and by the middle of the eighteenth century Christian life was almost extinct, though Christian families remained. Japan showed more of success. As early as 1582 there were 200,000 Christians and 250 churches. The seventeenth century opened with persecution, in which was manifested the most resolute heroism of martyrdom, closing with the massacre of 37,000 at Simbara, the Mount of Martyrs, and here, as in China, active life died, though many concealed Christians remained. The remaining field, made notable by the work of the Roman Catholics, was Africa, where in the Portuguese possessions, especially near the mouth of the Congo, the converts were numbered by the ten thousands. Under the influence of the Portuguese rule, however, everything was lost.

During the nineteenth century the Roman Catholic Church has continued to extend its work, taking up in some instances the lines that were broken by persecution. Its missionaries have also labored with varying success among the other Christian Churches of Western Asia to bring them back to allegiance to the pope. Work among distinctively heathen peoples has been pushed in Africa, notably Uganda, Madagascar, China, Japan, and the East Indies. In no one of these sections have they met with anything like the success of the early Roman Catholic missionaries. Statistics of their missions are vague and unsatisfactory.

(*b*) *Greek Orthodox Church of Russia.*—This is the only branch of the Christian Church, aside from the Roman Catholic and Protestant, that has undertaken any aggressive missionary work, and this has confined its efforts to Japan. Its missionaries began operations in Northern Japan in 1870,

and have steadily pushed their work until in 1893 they reported 164 churches, 19 native pastors and 159 evangelists, 21,239 church members, and 1,182 baptisms during the year.

(c) *Protestant Missions.*—The Reformation brought at first little of interest in foreign work to the evangelical churches. The previous influence of Huss and Wycliffe had been for home rather than foreign development, and the same principles were carried out by Luther and his successors. It is true that Erasmus dwelt upon the necessity of providing the Turks with the Scriptures, and Luther thought that they ought to be prayed for, but beyond that there seemed no hope of successful work. Under the influence of Calvin, Admiral Coligny, about the middle of the sixteenth century, inaugurated a Reformation enterprise in Brazil, and at about the same time Gustavus Vasa sent a mission to the Lapps of Europe. None of these, however, amounted to much. In the latter part of the seventeenth century Hans Egede, a Norwegian pastor, opened up work in Greenland, and about the same time Ziegenbalg and Plütschau went as the first Protestant missionaries to India under the auspices of what was known as the Danish-Halle Mission. At about the same time the Unitas Fratrum, formed 200 years before by the union of the followers of Huss, some Waldenses, and Moravians, were led by the influence of Count Zinzendorf to commence their great work, which has continued in the van of mission enterprise. In 1732 Dober and Nitschmann set out for St. Thomas in the West Indies, and in 1749 David Zeisberger became the apostle of the Delawares. Prior to this the settlement of New England called the attention of the English people to the needs of the Indians, and King James, announcing that zeal for the extension of the Gospel was a special motive for colonizing, was followed by Cromwell in 1649 with the creation of the first missionary society, the Corporation for the Propagation of the Gospel in New England. The first missionary of this new work was John Eliot, followed by Mayhew and the Brainerds. The charter of the East India Company, granted by King William III. in 1698, contained provisions for a missionary and educational as well as ecclesiastical establishment. In 1701 the Society for the Propagation of the Gospel in Foreign Parts was organized, but rather as a colonial than a foreign missionary society, though it did some work among the natives of the various English colonies. Thus the evangelical churches were waking up to the demands upon them, and it needed only the genius and consecration of some man to start a general work. That man was Carey, a Baptist shoemaker and minister, who began his work by the publication of an *Inquiry into the Obligations of Christians to use Means for the Conversion of the Heathens.* In 1793 came the beginning of the little Baptist Missionary Society, and in November of that year Carey landed at Calcutta.

Modern Protestant foreign missions may fairly be said to have begun with the work of Carey. The influence of his preaching and example was felt all over England, Scotland, and America, and extended to the continent of Europe. One after another the different branches of the Church entered upon the work, until before twenty-five years had passed all the leading ones had missionaries in every quarter of the globe.

The first field to attract attention was the islands of the Pacific. The difficulty of reaching them and the opening up of India led Carey thither. The London Missionary Society, however, carried out the idea, and the first mission to those islands started in 1800. The progress both of interest in the Churches and of occupation of territory can, in the space allowed, be best set forth in chronological tables.

1. The order of establishment of the most important societies, together with the fields occupied by them, also in chronological order:

1649. New England Company (England): Indians of North America.
1691. Christian Faith Society (England): Aid to Christian workers, especially in India and Mauritius.
1698. Society for the Promotion of Christian Knowledge (England): Publication and colporteur work in many lands.
1701. Society for the Propagation of the Gospel (England): British colonies—India, Africa, East Indies, Japan.
1721. Danish Missionary Society (the successor of the Danish-Halle Mission): India, Greenland. (Home mission to the Santals, Loventhal's, and Red Karen missions, branches from this.)
1732. Unitas Fratrum, or Moravians (Germany): West Indies, Greenland, South America, Africa (South and Central), Central America, Australia, Central Asia, Labrador, Alaska.
1792. Baptist Missionary Society (England): India, Africa, Congo, China, Japan, Palestine.
1795. London Missionary Society (England, Congregational): South Sea islands, Tahiti, etc.; Africa (East and South), West Indies, Madagascar, China, New Guinea.
1797. Netherlands Missionary Society: East Indies.
1799. Church Missionary Society (Church of England): Africa (East and West), India, New Zealand, Palestine, China, Persia, Japan.
1799. Religious Tract Society (England): Publication and colporteur work all over the world.
1804. British and Foreign Bible Society: Publication and distribution of Scriptures all over the world.
1809. London Society for Promoting Christianity among the Jews: Europe, Asia, and Africa.
1810. American Board of Commissioners for Foreign Missions (U. S.): At first undenominational, now practically Congregational; India, Hawaiian islands, Turkey, China, Persia, Africa (East and West), Micronesia, Japan, Mexico, Spain, and Austria.
1814. American Baptist Missionary Union (U. S.): Burma, India, Africa, Congo, China, Japan.
1814. Wesleyan Methodists (England): India, Africa (South), West Indies, New Zealand, South Seas, China.
1815. Basel Missionary Society (Germany): Africa (South), India, China.
1816. American Bible Society: Publication and distribution of Scriptures all over the world.
1816. General Baptists (England): India.
1819. Methodist Episcopal Church (U. S.): Africa (West), South America, India, China, Bulgaria, Europe and Mexico, Japan, Korea, Malaysia.
1819. Leipzig Missionary Society (Germany): India.
1822. Paris Evangelical Missionary Society (France): Africa (South and West), Polynesia.
1824. Methodist Church of Canada: Japan.
1824. Berlin Missionary Society (Germany): Africa (South), China.
1826. American Tract Society: Publication and general colporteur work in all lands.
1829. Established Church of Scotland (Presbyterian): India, Africa (East), China.
1829. Rhenish Missionary Society (Germany): Africa (South), Dutch East Indies, China.
1835. Swedish Missionary Societies (four in number): Africa (South), India, Russia, Alaska.
1835. Protestant Episcopal Church (U. S.): Africa (West), Greece, China, Japan, Haiti.
1836. North German Missionary Society (Germany): Africa (West).
1836. Gossner Missionary Society (Germany): India.
1836. Reformed Church (German, U. S.): Japan.
1836. Free Baptists (U. S.): India.
1836. Reformed Presbyterians, General Synod (U. S.): India.
1837. Presbyterian Church (U. S., at first connected with American Board 1810): Syria, Persia, Africa (West), India, Siam, China, Japan, South America, Mexico, Guatemala, Korea.
1839. Lutheran General Synod (U. S.): India, Africa.
1840. Edinburgh Medical Missionary Society (Scotland): Trains physicians for other boards, and employs missionaries in Japan and Syria.
1840. Presbyterian Church of Ireland: India, China.
1840. St. Chrischona Pilgrim Mission (Germany): Started a mission in the Sudan, which was broken up; now educates men for other boards.
1841. Welsh Calvinistic Methodists: India.
1842. Reformed Presbyterian Church (Scotland): Syria.
1842. A number of English and Scotch societies for work among the Jews.
1842. Norwegian Missionary Society: Africa (South), Madagascar.
1843. Free Church of Scotland: India, Africa (East and South), New Hebrides, Syria, Arabia.
1844. African Methodist Episcopal Church (U. S.), Africa, West Indies.
1844. Presbyterian Church of Canada: New Hebrides, Trinidad, China, India.
1844. South American Missionary Society (England): Terra del Fuego and cities of both coasts.

1845. Methodist Episcopal Church South (U. S.): China, Mexico, Brazil, Japan.
1845. Methodist Protestant Church (U. S.): Japan.
1845. Southern Baptist Convention (U. S.): Africa (West), China, South America, Mexico, Japan, Italy.
1845. Wesleyan Methodists' Connection (U. S.): Africa (West).
1846. Ermelo Society (Holland): East Indies.
1847. Seventh-day Baptists (U. S.): China.
1847. Presbyterian Church of England: China, India.
1847. United Presbyterian Church of Scotland: West Indies, Africa (West and South), India, China, Japan.
1849. Foreign Christian Missionary Society (Disciples, U. S.): Turkey, India, Japan, China.
1849. American and Foreign Christian Union (U. S.): Commenced work in Roman Catholic countries, which was handed over to the American Board. Gives aid.
1849. Herrmansburg Society: Africa (East and South), India, Australia, New Zealand.
1849. Mennonites (Holland): East Indies.
1850. Melanesian Mission (England): Southern Pacific.
1853. United Brethren in Christ (U. S.): Africa (West).
1853. Hawaiian Evangelical Association: Micronesia.
1856. Java Comité (Holland): Java.
1858. Reformed Church (Dutch, U. S.; at first connected with American Board): China, India, Japan.
1858. United Presbyterian Church (U. S.): Egypt, India.
1858. United Methodist Free Churches (England): Australia and New Zealand, Africa (East and West), China.
1858. Christian Literature Society (England): India.
1858. Dutch Missionary Society (Holland): Java.
1859. Reformed Presbyterian Church (U. S.): Turkey.
1859. Methodist New Connexion (England): China.
1859. Utrecht Missionary Society (Holland): Java.
1859. Dutch Reformed (Holland): Java.
1859. Finland Missionary Society: Africa (South).
1860. Universities Mission (England): Africa (East).
1861. Strict Baptists (England): India.
1861. Woman's Union Missionary Society (U. S.): India, Japan.
1862. Presbyterian Church (South, U. S.): China, Brazil, Mexico, Greece, Japan, Africa, Congo.
1865. China Inland Mission (England): China.
1867. Friends (England): India, Madagascar, China, Turkey.
1868. Woman's Board (U. S.), connected with American Board. This was the pioneer of the numerous woman's boards connected more or less closely with almost all the general boards.
1869. Lutheran General Council (U. S.): India.
1870. Primitive Methodist Church (England): Australia and New Zealand, Africa (West and South).
1871. United Original Secession Church (Scotland): India.
1874. Free Churches of French Switzerland: Africa (South).
1875. Associate Reformed Synod of the South (U. S.): Mexico.
1876. Cumberland Presbyterian Church (U. S.): Japan, Mexico.
1878. Evangelical Association (U. S.): Japan.
1880. Salvation Army: India.
1881. Congregational Churches of Canada: Africa (West).
1881. German Baptist Brethren (U. S.): Scandinavia, India.
1881. International Medical Missionary Society (U. S.): Trains medical missionaries.
1881. North Africa Mission (England): Barbary States of North Africa.
1882. Breklum Missionary Society (Germany): India.
1884–86. Several Baptist (colored) societies for work in Africa.
1885. Bible Christians (England): Australia and New Zealand, China.
1886. American Christian Convention (U. S.): Japan.
1886. Baptist Churches of Canada: India.
1889. Seventh-day Adventists (U. S): Africa, Pacific islands, Europe.
1889. German Evangelical Synod (U. S.): India.
1890. Universalist Convention (U. S.): Japan.

This list is by no means complete. It is, however, sufficiently so to give a correct idea of the spread of missionary interest in Christian countries. There are a large number of other bodies, more or less fully organized, employing some missionaries. The Unitarian Association supports two missionaries, and does some publishing in Japan, and has some work in India. There are several individual enterprises, like F. S. Arnot's work in Garenganzi in Central Africa, and P. Z. Easton's work in Persia. There are also a number of aid societies, and a large number of Bible societies and publication societies.

2. Turning to the opening of foreign fields, the following list gives the order in which the principal countries of the world have been occupied:

1649. North America: The New England Company, organized by royal charter for work among the Indians.
1705. India: The Danish-Halle Mission of the Lutheran State Church, later the Danish Mission Society. Also the Baptist Missionary Society of England, founded by Carey in 1792.
1721. Greenland: Danish Mission Society.
1733. West Indies: Moravians.
1735. South America: Moravians (north coast).
1737. Africa (South): Moravians.
1797. South Sea islands: London Missionary Society.
1804. Africa (West): Church Missionary Society.
1807. China: London Missionary Society.
1807. Burma: English Baptists.
1811. Persia: Henry Martyn. 1834, American Board.
1812. Java: Netherlands Missionary Society.
1812. Ceylon: English Baptists.
1814. New Zealand: London Missionary Society.
1818. Madagascar: London Missionary Society.
1819. Syria and the Levant: American Board.
1819. Egypt: Church Missionary Society.
1819. Hawaiian islands: American Board.
1823. Argentine: American Board.
1824. New Hebrides: London Missionary Society.
1825. Australia: London Missionary Society.
1828. Siam: Netherlands Missionary Society and London Missionary Society.
1828. Greece: Protestant Episcopal Church (U. S.).
1830. Abyssinia: Church Missionary Society.
1834. Fiji, Samoa, etc.: Wesleyan Methodists of England.
1836. Brazil: Methodist Episcopal Church (U. S.).
1836. Assam: American Baptist Missionary Union.
1843. Palestine: Church Missionary Society.
1844. Africa (East): Church Missionary Society.
1852. Micronesia: American Board.
1859. Japan: May, Protestant Episcopal Church; October, Presbyterian; November, Reformed (Dutch)—all U. S.
1861. Chili: American and Foreign Christian Union.
1872. Mexico: Presbyterian Church (North). Work had been done by the American Bible Society and Mr. Riley.
1877. Africa (Central, Tanganyika): London Missionary Society.
1881. Africa (Barbary States): North Africa Mission (England).
1884. Korea: Presbyterian Church (North) and Methodist Episcopal Church (U. S.).
1885. Arabia: Church Missionary Society.

There have been numerous efforts to enter Tibet, Afghanistan, and Nepal, in Central Asia, and there are portions of Africa yet closed to missionaries, but in 1894, with these exceptions, there is no section of the world where missionary enterprise has not penetrated. These various enterprises have met with very different success. In almost every case the opposition was intense. In the South Seas missionary after missionary lost his life. In India the hostility of the people was strengthened by the opposition of the East India Company. In Burma imprisonment and suffering attended the first efforts. Africa seemed to offer an almost impenetrable barrier; for a long time little more was accomplished than the establishment of a few churches on the coast, and when an entrance was effected the climate proved deadly. The Mohammedan lands of the East met the first missionaries with all the force of Moslem bigotry. There were, however, exceptions, as in the Hawaiian islands; and in some of the South Sea islands and in Burma the bitter opposition at the beginning resulted in wonderful progress. So of later years, long continued labor has been followed by special success among some of the lower castes of India, especially the Telugus and Sweepers.

II. Methods of Missions.—The methods of missions from the time of the apostles to the close of the eighteenth century were very simple: The preaching of the Gospel, the

gathering of converts into churches, and the placing of these churches under the care of foreign educated preachers. There was little or no effort to develop local Christian life into self-direction. There was instruction, but very little education. With the entrance upon the work of the English and German churches, especially the former, a new idea was brought in. They realized that it was utterly beyond their power to reach the countless millions of heathendom themselves, and that they must look to the natives of the different fields to do what they could not do. They realized, too, that a Christian church to be strong must be self-propagating, and in order to that it must be independent. The result was that other duties took rank almost equally with preaching, viz., translation of the Scriptures, education, medical work, woman's work, and organization.

Translation of the Scriptures.—It was the experience of the early missionaries in every field that the great mass of the people were grossly ignorant. In the Pacific, in Africa, and in parts of India many of the languages were not even reduced to writing. Accordingly, the first thing to be done after getting a colloquial use was to find some way of expressing the sounds by signs. The achievements in this line have bordered on the marvelous. A brief summary may be found in the article BIBLE. Even when these languages already had a written form, or the form had been provided, it was no easy task to perfect a translation. What word should be used as the name of God, how indicate spirit, grace, sin, salvation, to races who had never had any adequate idea, or even any idea at all, of them? An illustration of the difficulty is found in the fact that up to 1894 it is not decided just what term to use for God in the Chinese versions. In other cases translations already existed, but in archaic and incomplete form. These must be put into modern language.

Education.—Wherever missions have gone schools have been established whose prime object was to enable converts to read and understand the Bible. With the development of Christian churches other needs have come in. Preachers and teachers must be trained to do work that is beyond the power of the missionary. For this a better, more thorough, and complete education is necessary, and high schools and theological seminaries were established. Community life brought still other needs. Persecution cut off some converts from their employments. To support them was to pauperize them. They must be trained to some means of gaining a living. In most lands life is very circumscribed, labor is degrading, and, except in the most simple forms, employment not easily found. Many of the trades do not exist at all, and what there are, are of the most primitive sort. The entrance of Christian thought and life creates not so much a distaste for existing methods of work and life as a reaching out after something better. To fail to satisfy this is to crush out hope and ambition, without which there can be no genuine growth. Thus there has been developed in the early history of every mission field, in greater or less degree, a complete system of education, including primary, intermediate, and high schools, colleges, and theological seminaries. These have mostly been on the same general plan as schools in the U. S. and Europe, and there has been a marked development in industrial education, especially in Africa. This development of education has given rise to the sharpest controversies in regard to mission methods. Some have maintained that the original idea of limiting missionary education to the most elementary topics, except for the training of preachers and teachers, should be preserved; others, claiming that mission work contemplates Christian communities and social and civil life, as well as the conversion of souls, have advocated a much broader plan.

Medical Work.—No one department probably has been more aggressive or has opened more fields hitherto closed than this. It developed into a distinct feature with the establishment of the Edinburgh Medical Missionary Society in 1840. Since then the advance has been rapid, and in 1893 there was a large force of medical missionaries in every field. Their work has been especially valuable in China, Africa, Persia, and Turkey. In most cases they work in connection with the regular societies, very few being employed by medical societies.

Woman's Work.—The conception of special work for the women of heathen lands to be carried on by women practically originated with Mrs. Doremus, of New York, the founder of the Woman's Union Missionary Society. In 1891 there were between sixty and seventy regularly organized societies. A few work independently, but most work in connection with some one of the general boards. They pay special attention to education for girls and women, house to house (zenana) work among the women, and medical work.

Organization.—(A) *At Home.*—The management of the entire work is committed to boards or societies, chartered by the State to hold property and, in general, conduct the financial affairs involved. These boards are of three kinds: (1) directly connected with some denomination or church, and under its control; (2) indirectly so connected and only morally bound to consult them; (3) absolutely independent of all ecclesiastical relations. The Presbyterian boards belong to the first; the Church Missionary Society to the second; the American Board and the German societies to the third. These boards sometimes act directly, sometimes through executive committees, and employ a force of paid officials. Their work includes the collection of funds and their apportionment to the foreign fields; the selection of missionaries; the furnishing of information to the churches; the holding of property, and the decision of questions of policy on the field. They are composed of prominent men of the different professions and in business well qualified to conduct large affairs. Their financial standing is of the highest.

(B) *On the Field.*—This is both missionary and native.

(*a*) *Missionary.*—The missionaries in a given section of country are generally formed into a mission. This mission meets periodically for the discussion of plans of work, the preparation of estimates, the apportionment of receipts from the board, the assignment of missionaries, and any other business that may come up. The mission is again subdivided into stations (large places where one or more missionaries reside) and out-stations or sub-stations (places of less importance where mission work is carried on, generally through native agents). With the exception of the sum total of expenditures in a single year, and the establishment of general principles, the decision of the mission in its annual meeting is generally final. It ordinarily decides the location of a missionary. The salary he is to receive is decided by the board on the basis of information from the mission, and in accordance with the general principle that he shall receive enough so as to live moderately, but comfortably, without expecting to lay by for future use.

(*b*) *Native.*—As soon as a number of converts are gathered in any place they are usually formed into a church or congregation. Their ecclesiastical position is in most cases regulated by that of the missionaries, though with many there is considerable freedom allowed. As the community grows there are organized Sunday-schools, general schools, and the various forms of community life. As a rule, natives are not members of the mission proper, but are consulted by the missions in the general conduct of the work. There are cases, chiefly in Episcopal missions, where they are members of the missions. In some sections circumstances have arisen which necessitated the formation of civil communities. This has been especially the case in Moslem countries, owing to the peculiar laws. In several communities there have been formed native societies for the conduct of mission work in remote sections—e. g. the Hawaiian Evangelical Society, Home Missionary Societies in Japan, etc. The question of the ecclesiastical relation of native churches on mission fields to the churches supporting the mission has been generally recognized as a very difficult one. In many cases, notably Japan, there is a great desire to break away from all organic connection with what are to them foreign churches. The idea of national churches in Japan, India, China, and elsewhere has gained a strong hold upon the communities. In Turkey the situation is peculiar. The missionaries, debarred from work among the Moslems, turned to the Armenians, seeking to reform the old Church. The Armenian hierarchy sought to crush out the new ideas by persecution with the result of forming distinctively Protestant civil communities according to Turkish law. As the work has progressed the leaven of evangelical ideas has entered the old or Gregorian Church, and many look forward to a reunion of the two in the future.

With the development of the work and its fuller organization, missionaries become less evangelists, more educators and leaders in community and church life.

III. RESULTS.—Any estimate of the results of foreign missions must include many factors. 1. Statistics of converts, churches, native laborers, schools and scholars, copies of the Bible and religious books distributed. 2. Obstacles overcome to the acceptance of the Gospel. 3. The degree of Christian life developed.

1. *Statistics.*—Complete statistics are not at hand. There is no agreement among the societies as to how they shall be reported and a great diversity as to the completeness of the returns from the fields. Using, however, the best sources available, *The Missionary Review of the World*, the American Board *Almanac*, and the tables prepared by Dean Vahl, of Denmark, the following estimates may be considered as approximately correct for 1893:

Communicants, 1,250,000; adherents (persons identified with Christian churches, though not communicants), 2,500,000, exclusive of children.

There are no returns of churches. The number of organized congregations, based upon the number of stations and out-stations, is perhaps 20,000.

Native preachers and teachers, 55,000.

Schools (secular), 19,000; scholars, 790,000.

Sunday-schools, 25,000; scholars, 2,000,000.

Volumes of scriptures distributed in a single year, 3,000,000.

2. *Obstacles to the Acceptance of the Gospel Removed.*—Among these may be mentioned the opening up of China, Japan, and Korea; the discoveries in Africa; the abolishment of the death penalty in many countries; the breaking down of much of the power of caste in Southern Asia; the heavy blows to the slave-trade. In all of these there have been other influences as well, but missions have had a prominent place, due to the personal character of the missionaries and their influence with governments, to medical work, to relief rendered in times of famine and distress, as well as to the direct influence of preaching and teaching. There has been no appreciable effect upon Mohammedanism, unless the renewed activity of Islam be such. Confucianism remains unmoved in general. Buddhism and Hinduism have felt the results of missionary preaching most, as indicated by the development of the Brahmo Somaj and similar movements. The great apparent advance of missions has been among the more ignorant fetich and nature worshipers. There is, however, evidently a very decided weakening of the power of the great religions over thinking men, but whether they are turning to Christianity or to infidelity is as yet in most cases a problem. Often they throw off all religion, although most admit intellectually the superiority of Christianity.

3. *The Degree of Christian Life Developed in the Native Communities.*—This is after all the crucial test. Figures of converts, etc., amount to very little, except as they may be indicative of the character of the communities. A few points may be noted: (1) The growth in self-support. Wherever missions have been successful the native churches are increasing by assuming the entire expense of their church and educational life. Peculiar circumstances have delayed at times, but in general the progress in this particular has been most marked. (2) The position occupied among the surrounding communities. This no figures can show, and outside reports from travelers are very apt to be incorrect. Native Christian communities are not as a rule prominently located. We may, however, cite such travelers as Miss Bird (now Mrs. Bishop) and such officials as the governor-generals of India and the various American ambassadors and consuls, who almost without exception have borne witness to the high character of the Christian communities. Another indication is found in the demand for their members for places of responsibility. (3) The very general effort, even at much self-denial, to extend the work of giving the Gospel to others.

Literature.—The bibliography of foreign missions is very large. By far the most complete attempt in this line is the bibliography prepared by the Rev. Samuel Macauley Jackson, and published as an appendix to the *Encyclopædia of Missions* (New York, 89 pp. 8vo in solid nonpareil; it goes down to the close of 1890). A supplementary list to it was prepared by the Rev. James S. Dennis, D. D., and published in *Foreign Missions after a Century* (New York, 1893). Of minor importance are *Book Department of the Student Volunteer Movement for Foreign Missions* (Chicago) and *A Select Catalogue* (Presbyterian Board of Publication, Philadelphia). The most important books of general reference are *The Encyclopædia of Missions*, with maps, bibliography, and statistical tables, edited by Rev. Edwin Munsell Bliss (2 vols., New York, 1891); *Manual of Modern Missions*, J. T. Gracey, D. D. (New York, 1893); *Short History of Christian Missions*, George Smith, LL. D. (Edinburgh, 1890); *Outline of the History of Protestant Missions*, Dr. Gustav Warneck, translated from the German (Gemmell, Edinburgh, 1884); *Report of the Centenary Conference in London*, Rev. James Johnston (New York, 1888); *Oriental Religions and Christianity*, F. F. Ellinwood, D. D. (New York, 1892); *Medical Missions, their Place and Power*, John Lowe (London, 1890). There are also a large number of historics of special fields and of the different societies, biographies of eminent missionaries, books on the different religions, travels in mission lands, etc. E. M. Bliss.

Mississippi [named from Mississippi river]: one of the U. S. of North America (South Central group); the seventh State admitted into the Union.

Location and Area.—It is bounded on the N. by Tennessee, on the E. by Alabama, on the S. by the Gulf of Mexico (including all islands within 6 leagues of shoreline) for 78 miles westward to the mouth of Pearl river, and from a point about 75 miles above the mouth of that river by the 31st parallel of N. lat., and on the W. by Louisiana and Arkansas. Its extremes are between 30° 25′ and 35° N. lat., and 88° 12′ and 91° 36′ W. lon.; area, 46,810 sq. miles (29,958,400 acres), of which 470 square miles are water surface.

Seal of Mississippi.

Physical Features.—The small streams which fall into the Tennessee river in the northeast corner of the State are bordered by massive walls of limestone. W. of this the Cretaceous formations crop out. W. of these, Tertiary formations prevail. The bottom-lands of the Mississippi, Sunflower, and Yazoo rivers, and the tributaries of the latter, as well as the Gulf coast for about 30 miles back, belong to the Quaternary, or alluvial, era. To this era belongs the Orange sand, the most striking feature of the State's geology, for its presence on the surface is so general as to make its absence exceptional. It is chiefly made up of rounded, siliceous sand, colored, and more or less indurated, by the hydrated peroxide of iron. On the Pontotoc ridge it is either of a glaring deep red, as in Itawamba County, or of a dull iron-rust color; in the region of the long-leaf pine it is of a delicate rose tint, and sometimes of a bright yellow, crimson, or purple; elsewhere it becomes white, and even bluish. With a large increment of iron, in some places the tendency is to concrete into a ferruginous sandstone, occasionally in such masses and solidity as to afford good building material. These indurations are generally found capping hills and ridges, some of which rise in steep isolated hillocks from the level surrounding country as high as 150 feet, forming curious landmarks which indicate the former surface level. In some places these conglomerates are tubular, of singular regularity of dimensions and mold, with the appearance of newly made iron castings, often 4 to 5 feet in length, and with a bore from a quarter of an inch to 4 inches in diameter. Such hills are further crowned, generally, with clumps of short-leaved pine, not visible elsewhere in the same vicinity. The average thickness of this Orange sand stratum varies from 40 to 60 feet, but 100 is not at all infrequent, and it has been found as thick as 200 feet. The useful materials of this formation are the ferruginous sandstone, much of which can be used in rough masonry, and large beds of pipe-clay of great purity, and potter's and crucible clays. The Tertiary beds afford lignite, or brown coal, to some useful extent, mineral fertilizers of value and convenience, potter's and fire-brick clays, and limestone (rotten), chiefly for burning. The mineral deposits of Mississippi are relatively of small consideration, however, in the sum of its natural advantages. In nearly all sections of the State artesian wells may be found, varying in depth from 600 to 900 feet, and waters of decided mineral and medicinal character are of wide occurrence, such as alkaline and saline chalybeates, containing iron, lime, magnesia, and often soda. Among these medicinal waters, those of Cooper's Wells, Greenwood Springs, and Castalian Springs are of the highest repute.

The highest land in Mississippi lies in the northeast, and

from thence it slopes gradually to the Mississippi river and to the Gulf of Mexico. Running N. and S. through the center of the State is a broad low ridge, which divides the tributaries of the Mississippi river from those of the Pearl, Tombigbee, and Pascagoula rivers. This ridge terminates near Vicksburg in a high bluff. W. of this watershed the country is broken up by several narrow ridges and valleys of denudation which finally fall away into the Yazoo delta. E. of the central ridge are vast prairies of exceeding fertility. On the table-land constituting the ridge are immense forests and much cultivated land. In the pine-woods region in the southern portion of the State the land is rolling. Thus, while in Mississippi there are no high elevations, the land is generally rolling and much broken, and in some places the ridges rise to the height of 800 feet. The State is mainly drained by the Mississippi river and its tributaries, the Big Black, Homochitto, and the Yazoo with its affluents, the Sunflower and the Tallahatchie. The Tombigbee flows through the eastern portion of the State, while the Pearl with its tributaries, and the Pascagoula, with the Chickasawha, drain the southeast. In the extreme northeast the Tennessee river separates the State from Alabama for 15 miles. Portions of the Yazoo delta are subject to overflow at times of extreme high water.

The useful materials found in the different formations represented may be conveniently grouped in the natural order in which they occur. In the Carboniferous rocks which occupy the extreme northeastern portion of the State are found limestones, both common and hydraulic, sandstones, used for building purposes, and materials for glass. In the Cretaceous system marls, limestones, and building-stones occur. The Cenozoic occupies by far the greater portion of the State, if we except the Orange sand formation which is of almost universal occurrence, and in this formation are found isolated beds of lignite and several kinds of clay, used in the manufacture of pottery and fire-brick.

Soil and Productions.—The State has a great variety of soils, most of which in their virgin condition are very fertile, and there are still large areas of the cultivated lands that produce good crops without the aid of fertilizers. The most fertile land in the State is the Yazoo delta, an elliptical body of land in the extreme western portion of the State, extending north from Vicksburg. E. of this is a belt running N. and S. known as the bluff formation and brown-loam table-lands, that is nearly as fertile as the Yazoo delta. These are doubtless the most desirable lands in the State for general agricultural purposes. The yellow-loam lands, lying E. of these and N. of the central portion of the State, are among the less productive lands, though portions of this section are quite fertile. The northeastern prairie region, with its rich, black, calcareous soil, has always been noted for having many of the best farming lands of the State, and during the civil war was known as the "Egypt of the Confederacy." These lands are still rich in all the elements of plant-food, and their fertility is easily maintained by the growth of such leguminous crops as melilotus, red clover, alfalfa, Japan clover, and cow-peas. The lands in the extreme northeastern portion of the State are similar to the yellow-loam lands. Extending from Vicksburg across the State to the Alabama line is a belt, from 18 to 45 miles wide, with several kinds of soil, a large proportion being prairie. Most of the soils in this belt are fertile. The large body of land S. of the central prairie belt, known as the pine-woods region, is either sandy loam with clay subsoil or sandy subsoil, the former being the predominating soil in the northern and the western portions of the belt. The southern portion of this belt is almost entirely covered by its virgin growth of pine, while its northern and western portions furnish conditions favorable for cultivation and improvement; and on these lands are some of the finest truck-farms in the State. Except the pine lands in the extreme southern portions of the State and the yellow-loam lands in the north central portion, the soils are unusually rich in plant-food and may easily be kept in a high state of cultivation.

Mississippi has still a vast area covered by virgin forests. Over the Androzoic and the Cenozoic formations the oak is the most common deciduous tree. In the central and northern portions of the State the red oak, the scarlet, the black, the willow, the chestnut, and the water-oak are common on the lowlands. The rock-chestnut oak is found on the higher lands in the delta. Black jack is found on all poor lands in all portions of the State. Other deciduous trees are walnut, butternut, dogwood, black gum, sweet gum, beech, sycamore, cottonwood, magnolia (three species), red maple, ironwood, locust, black and white mulberry, alder, and hickory (four species). Among the evergreens are the long and short leaf pine, pitch pine, cypress, and live oak. Among the more common fruits are the grape, apple, peach, pear, plum, and apricot. Thousands of acres are used for the cultivation of strawberries and tomatoes along the line of the Illinois Central Railway S. of Durant, and large quantities of these fruits are also grown on the line of the Mobile and Ohio Railway between West Point and Booneville. In the southern counties figs, oranges, olives, and other semi-tropical fruits flourish. The land throughout the State is capable of producing almost every variety of farm crop. The Yazoo delta is renowned as the best cotton land in the world, and the State stands third in the Union in the production of this staple. The northeastern portion is especially adapted to the growing of cereals, grasses, clovers, and other forage crops; and the farmers of this section are largely engaged in stock-raising and dairying.

The animals of the chase now found in the State are the deer, black bear, raccoon, gray and black wolves, gray and red foxes, mink, weasel, muskrat, beaver, opossum, squirrel (seven kinds), and rabbit. Wild turkeys, quail, woodcocks, wild pigeons, ducks, and geese are plentiful. Paroquets are found as far N. as Natchez, while mocking-birds and other birds of song and beauty abound throughout the State. Gulls, hawks, vultures, and turkey buzzards are common. Alligators, lizards, and watersnakes inhabit the swamps and marshes, and rattlesnakes are found occasionally in the uplands. Fish are abundant along the Gulf coast and in the Mississippi river, the most important being the giant catfish, pickerel, black bass, buffalo, redfish, pompano, sea-trout, Spanish mackerel, and red snapper.

The following summary from the census reports of 1880 and 1890 shows the extent of farm operations in the State:

FARMS, ETC.	1880.	1890.	Per cent.
Total number of farms	101,772	144,318	+41·8
Total acreage of farms	15,855,462	17,572,547	+10·8
Total value of farms, including buildings and fences	$92,844,915	$127,423,157	+37·2

The following table shows the acreage, yield, and value of the principal crops other than cotton in the year 1900:

CROPS.	Acreage.	Yield.	Value.
Corn	2,293,818	25,231,998 bush.	$14,634,559
Wheat	4,248	40,781 "	34,256
Oats	170,718	2,390,052 "	1,099,424
Potatoes	5,259	347,094 "	288,088
Hay	57,098	99,922 tons	994,224
Totals	3,031,141	.....	$17,050,551

On Jan. 1, 1900, the farm animals comprised 203,492 horses, value $8,903,707; 164,713 mules, value $9,743,925; 244,103 milch-cows, value $5,052,932; 273,706 oxen and other cattle, value $3,719,121; 215,748 sheep, value $335,490; and about 1,500,000 swine, value $5,500,000; total value $33,254,475.

Cotton Production and Manufacture.—Cotton is the largest and most valuable crop, the total area devoted to its cultivation in 1899 being 2,784,286 acres, which produced 1,203,739 bales. The total value of this crop to the producers was $44,175,897, an average of $36.72 per bale, or $15.11 per acre. In 1890 nine establishments were engaged in the manufacture of cotton goods. They employed 1,184 persons, 1,352 looms, 57,004 spindles, and used 17,366 bales of cotton. The capital invested was $2,053,743, and the total value of the production was $1,333,398. In 1900 ten mills were reported in operation and seven building. There were 2,427 looms and 81,890 spindles. The manufacture of cotton-seed oil and meal also employs many factories.

Climate.—The summer season is long and hot, but generally healthful, except in the Yazoo delta region in the western part of the State. The temperature rarely reaches 98°, the normal mean temperature for the summer months being 80·1°. The winters, comparatively short, are damp and somewhat colder than in the corresponding latitude on the Atlantic coast. A minimum temperature of 9° is rare in the northern part of the State, while along the Gulf coast the temperature seldom falls below 28°. The average rainfall for the State at large is about 56 inches, with a fall of 62 inches near the southern coast, and a little less than 54 inches in the northern portion. It is distributed throughout the year in a most favorable manner for the agriculture

of the State. The following table gives a summary of the temperature and rainfall:

MONTHS.	Mean temp.	Mean maximum temp.	Mean minimum temp.	Maximum.	Minimum.	Rainfall, in inches.
January	45·8°	70·7°	19·8°	76°	9°	5·5
February	50·5	73·4	25·2	78	15	5·31
March	56·4	79·6	23·8	83	19	6·15
April	64·7	85·8	39·2	88	30	6·43
May	72·3	90·4	47·2	91	40	4·15
June	79·1	95·2	56·6	97	43	4·25
July	81·3	94·4	64·6	99	60	3·84
August	80·0	93·2	59·4	95	56	3·96
September	74·4	90·0	51·2	93	43	3·81
October	65·2	85·4	36·6	88	34	2·82
November	53·7	78·2	25·2	80	19	4·64
December	47·5	73·2	24·0	77	13	5·13

Divisions.—For administrative purposes Mississippi is divided into seventy-five counties, as follows:

COUNTIES.	*Ref.	Pop. 1890.	Pop. 1900.	COUNTY-TOWNS.	Pop. 1900.
Adams	8-E	26,031	30,111	Natchez	12,210

Totals		1,289,600	1,551,270		

* Reference for location of counties, see map of Mississippi.

Principal Cities and Towns, with Population for 1900.—Vicksburg, 14,834; Meridian, 14,050; Natchez, 12,210; Jackson, 7,816; Greenville, 7,642; Columbus, 6,484; Biloxi, 5,467; Yazoo, 4,944; McComb, 4,477; Hattiesburg, 4,175; Water Valley, 3,813; Aberdeen, 3,434; Canton, 3,404; Wessen, 3,279; West Point, 3,193; Laurel, 3,193; Greenwood, 3,026.

Population and Races.—In 1860, 791,305; 1870, 827,922; 1880, 1,131,597; 1890, 1,289,600 (native, 1,281,648; foreign, 7,952; males, 649,687; females, 639,913; white, 544,851; colored, 744,749, of whom 742,559 were persons of African descent, 147 Chinese; 7 Japanese, and 2,036 civilized Indians); in 1900, 1,551,270.

Finance.—The assessed valuation of taxable property in 1900 was $188,716,159; of this $57,400,336 was on personal property. The total State debt on Oct. 1, 1900, was $2,903,088.41. The revenue for the year ending Sept. 30, 1900, was $1,916,491.70; cash balance, Oct. 1, 1899, $333,765.80; available funds, $2,250,257.50; the expenditure was $1,627,855.57; cash balance Oct. 1, 1900, $622,401.93.

Banking.—On Sept. 5, 1900, there were 12 national banks with aggregate capital of $980,000, deposits of $3,878,626.52, and surplus and profits of $663,788.47; and on June 30, 1900, the State banks numbered 101 and had an aggregate capital of $4,279,496, deposits of $12,547,103, and surplus and profits of $1,351,872.

Means of Communication.—On June 30, 1899, there were fifteen lines of railways, aggregating 2,714·73 miles. The total valuation of railroad, express, and telegraph property was $26,338,476, on which the taxes were $171,200.35. Of these railways, the Illinois Central, the Mobile and Ohio, and the Yazoo and Mississippi Valley traverse the State from N. to S.; and the Memphis and Charleston, the Kansas City, Memphis and Birmingham, the Alabama and Vicksburg, and the New Orleans, Mobile and Texas cross it from E. to W. On the western border of the State the Mississippi river, for a distance of more than 500 miles, affords facilities for an immense shipping interest. In addition to this, the State has five or six small rivers, which aggregate more than 700 miles of navigable waters, that give facilities for shipping in a limited way. Mississippi also has about 100 miles of Gulf coast, and at Ship Island, opposite Biloxi, there is the best and most important deep-water harbor on the Gulf.

Churches.—The census of 1890 gave the following statistics concerning the principal religious bodies:

DENOMINATIONS.	Organizations.	Churches and halls.	Members.	Value of church property.
Baptist, colored	1,385	1,391	136,647	$682,541
Baptist South	1,125	1,126	82,315	689,451
Methodist Episcopal South	903	884	74,785	903,563
Methodist Episcopal	398	395	31,142	245,624
African Methodist Episcopal	122	256	25,439	226,242
Colored Methodist Episcopal	293	292	20,107	230,290
Roman Catholic	67	67	11,348	321,525
Presbyterians in the U. S.	208	184	11,055	415,315
African Methodist Episcopal, Zion	64	64	8,519	22,975
Cumberland Presbyterians	135	119	6,353	108,650
Disciples of Christ	111	109	5,729	55,422
Protestant Episcopal	68	63	3,560	322,960
Methodist Protestant	75	75	3,147	16,175

Schools.—The report of the State to the U. S. Commissioner of Education for the year 1896–97 showed: Number of children of school age (five to twenty), 552,467; enrolled in the public schools, 367,579; average daily attendance, 223,900; number of public schools, 6,510; teachers, 7,903—male, 3,649; female, 4,254; average monthly salaries, male, $32.18; female, $26.69; revenue for public schools, $1,214,630; expenditures, $1,165,840; value of school property, $1,636,055. The higher institutions of learning supported by the State are the State University, Agricultural and Mechanical College, Industrial Institute and College (for white girls), Alcorn University and Agricultural and Mechanical College (colored), and State Normal School (colored). The appropriations to these institutions added to the cost of public schools made a total expenditure by the State for education of about $1,300,000. A comparison of statistics shows that Mississippi ranks first among the Southern States and eighth in the U. S. in the amount expended for education in proportion to the valuation of property, and second in the Union in the per cent. of population enrolled in the public schools. In addition to the public schools, there are in the State 233 high schools, academies, and colleges under private or denominational control, with 22,859 pupils. Tougaloo and Rust Universities for colored youth, Mississippi College (Baptist), and Millsaps College (Methodist) are the principal denominational institutions in the State. Whitworth College, organized in 1859, has for many

years been the largest college for women in the State under private or denominational control.

Libraries.—According to a U. S. Government report on public libraries of 1,000 volumes and upward each in 1891, Mississippi had 31 libraries, which contained 130,314 bound volumes and 16,125 pamphlets. The libraries were classified as follows: General, 3; school, 7; college, 10; college society, 2; law, 1; public institution, 1; State, 1; scientific, 1; society, 3; and not reported, 2.

Post-offices and Periodicals.—In Jan., 1901, there were 1,988 post-offices, of which 49 were presidential (8 second-class, 41 third-class) and 1,936 fourth-class. There were 409 money-order offices. There were 14 daily, 1 tri-weekly, 5 semi-weekly, 181 weekly, 1 tri-monthly, 11 semi-monthly, and 11 monthly publications; total, 224.

Charitable, Reformatory, and Penal Institutions.—The following institutions are supported wholly or in part by the State: Institute for the Instruction of the Blind, at Jackson, established in 1848. Literary studies, music, and industrial arts are taught. Among the latter are sewing, knitting, and bead-work to the girls, and mattress, broom, and chair making to the boys. Only white pupils admitted. Institution for the Education of the Deaf and Dumb, at Jackson, established in 1853, for whites and colored. Pupils are instructed by both the sign and the oral method. Literary and industrial branches are taught. State Lunatic Asylum, at Jackson, established in 1853. East Mississippi Insane Asylum, at Meridian, established in 1882, for whites. Two public hospitals, one at Vicksburg and the other at Natchez, are supported jointly by the State and by the county and city in which they are respectively located. The Protestant Orphan Asylum was founded in 1816. It has since been managed by women, and is now under the auspices of ladies of the Protestant and Hebrew congregations of Natchez. In this asylum about fifty children are sheltered and educated. Benevolent orders, schools, and charitably disposed persons throughout the State contribute to its support. Each county has its jail and poorhouse, and some have convict farms, to the owners of which the able-bodied prisoners are leased and thus made to support themselves. The chief penal institution of the State is the penitentiary at Jackson. In it a leasing system similar to that adopted in the counties has prevailed for years, and has caused the penitentiary to be a source of revenue instead of expense to the State. By the constitution of 1890 this system was abolished. About 125 convicts, unable to labor on farms, railways, or levees, are confined within the walls and kept at work manufacturing furniture, wagons, clothing, shoes, and other articles.

Political Organization.—The constitution of 1890 provides that the Governor shall be chosen in the following manner: On the first Tuesday after the first Monday of Nov., 1895, and on the first Tuesday after the first Monday of November in every fourth year thereafter, an election shall be held in the several counties and districts created for the election of members of the House of Representatives, and the person receiving the highest number of votes cast in any such district shall be holden to have received as many electoral votes as the district is entitled to members in the House of Representatives. The election commissioners transmit the returns of said election to the Secretary of State who must deliver them to the Speaker of the House within one day after he shall have been elected. The Speaker opens and publishes them in the presence of the House of Representatives, and said House ascertains and counts the vote of each electoral district and decides any contest that may be made concerning the same. The person found to have received a majority of all the electoral votes and also a majority of the popular vote is declared elected. If no person shall receive such majorities, then the House of Representatives shall choose the Governor from the persons who shall have received the highest number of popular votes, the vote to be recorded in such a manner as to show for whom each member voted. All other State officers are elected in a similar way. The Governor is ineligible as his immediate successor in office, and the treasurer and auditor of public accounts are ineligible to immediately succeed themselves or each other. The House of Representatives is composed of 133 members chosen every four years by the qualified electors of the several counties and districts. The Senate is made up of forty-five members chosen at the same time and in the same manner as the Representatives. All male inhabitants, except idiots, insane persons, and Indians not taxed, who are citizens of the U. S., twenty-one years old and upward, who have resided in the State two years and in the election district or in the incorporated city or town, in which he offers to vote, one year, and who have never been convicted of bribery, burglary, theft, arson, obtaining money or goods under false pretenses, perjury, forgery, embezzlement, or bigamy, and who have paid on or before the first day of February of the year in which they shall offer to vote all taxes which may have been legally required of them, and which they have had an opportunity of paying according to law, for the two preceding years, are declared to be qualified electors. In addition to the foregoing qualifications, an elector must be able to read any section of the constitution of the State; or be able to understand the same when read to him, or give a reasonable interpretation thereof.

History.—Hernando De Soto, a daring Spanish adventurer and explorer, was the first European to enter the limits of the present State. Crossing the eastern boundary near the present city of Columbus, he proceeded in a northwesterly direction to the Chickasaw Bluffs on which the city of Memphis is built. There, in May, 1541, he reaped the only lasting fruit of his wanderings in the fame which he acquired as the discoverer of the Mississippi river. A year or so later his body was sunk to rest beneath its waters. In honor of his memory the State has given his name to the county and the county-seat in it nearest to the point at which he made his great discovery. Marquette and Joliet, French explorers, passed down the river to the mouth of the Arkansas in 1673, and La Salle, another indomitable French explorer, floated down the Mississippi to the Gulf of Mexico, and claimed all the country drained by it and its tributaries for the King of France under the name of Louisiana (in 1682). The first colony in the State was established by M. d'Iberville in Feb., 1699, at Biloxi, and settlements were soon made at several other points. Until 1712 the Louisiana colony was a royal province, with Bienville, the brother of d'Iberville, as its governor. Crozat, a wealthy French merchant, was then granted the proprietorship, but gladly relinquished it to the West India Company in 1717, which in turn relinquished it to the crown in 1732. From that time till ceded to the English in 1763 it was again a royal province. Among the most important events of the period of French possession were the massacre of the garrison at Fort Rosalie and the consequent extermination of the Natchez tribe of Indians. In two campaigns against the Chickasaws the French were themselves signally defeated.

Negro slaves were first imported in 1720. Owing to misrule, the thriftlessness of the settlers, and other causes, the colony never prospered; and after sixty-four years of French rule there were but 500 settlers, white and black, in all the province. Under the English better government was established, favorable treaties with the Indians were made, and liberal land grants were offered. Immigration of a better class of settlers at once set in, and the colony, then called British West Florida, flourished until 1780, when it was subjugated by Galvez, the Spanish Governor of Louisiana. By the treaty of 1783 the independence of the U. S. was recognized, and the 31st degree of north latitude was made its southern boundary. West Florida was given to Spain, and 32° 28′ was claimed as its northern boundary until by special treaty in 1795 with the U. S. the 31st parallel was established as the dividing line. Under Spanish rule the colony continued to prosper with Natchez as the capital. Tobacco, indigo, and cotton were the exports. In 1798 the section of country between 31° and 32° 28′ from the Chattahoochee river to the Mississippi river was organized as the Mississippi Territory, with the capital at Natchez; but in 1802 the capital was moved to Washington, 6 miles E. of Natchez. Georgia still claimed all this territory, and for a while there was much confusion in land titles; but in 1800 by act of Congress the Georgia claim was adjusted, and Mississippi raised to the second grade of territorial government, entitled to a representative in Congress. Its population then was about 10,000. In 1804 the boundary was moved northward to the Tennessee line, and in 1812 the strip of coast S. of the 31st parallel, between the Pearl river and the Perdido river, was added to the territory. Great excitement prevailed in the territory during the Creek war and that of 1812, and its development was much retarded for a few years, as cotton could not be exported on account of the British blockade. On Dec. 10, 1817, Mississippi was admitted as a State, and Alabama Territory was organized out of what was supposed to be the eastern half of the Mississippi territory. Fourteen counties lying S. of the railway which now connects

Meridian and Vicksburg then comprised the State, for the Choctaws and Chickasaws still owned all the land N. of that line. By treaties with the Choctaws in 1820 and 1830 they were induced to move to the Indian Territory, and in 1832 a similar treaty was made with the Chickasaws. The site for the new capital, named Jackson, in honor of Gen. Andrew Jackson, was chosen in 1821. In 1832 a new constitution was adopted. The State had increased rapidly in wealth and population from its admission. Railways and telegraph lines were introduced, and the cotton crop in 1834 netted $15,000,000; but the loose banking system then prevalent culminated there, as in other States, in the financial panic of 1837. From this heavy reverse the people of the State rapidly recovered, and continued to prosper till the outbreak of the civil war. Mississippi heartily favored the annexation of Texas and the war with Mexico; and no troops won greater honor in that war than did the First Mississippi Regiment under Col. Jefferson Davis. The ordinance of secession was adopted Jan. 9, 1861, and one month later Jefferson Davis, of Mississippi, was elected president of the Southern Confederacy, established at Montgomery, Ala. In the war which followed Mississippi contributed her quota of men and means to uphold the Confederacy. In or on her borders were fought the fierce battles of Shiloh, Iuka, Corinth, Chickasaw Bayou, Port Gibson. Champion Hills, Vicksburg, Harrisburg or Tupelo, and Brice's Cross Roads, and much of her best territory was devastated by the Union armies. On May 22, 1865, Gov. Clarke was sent a prisoner to Fort Pulaski, and on June 13 Judge W. L. Sharkey was appointed provisional governor of the State. On Oct. 2 following delegates to Congress were elected, but were refused admission to that body. By the Reconstruction Act of 1867 Mississippi and Arkansas were united in the fourth military district. In Jan., 1868, a constitutional convention, composed of delegates elected under the Federal Registration Act, was assembled; but the constitution prepared was defeated at a general election in June, and B. G. Humphreys was re-elected Governor. On June 15 he was expelled by military force from his office, and Adelbert Ames appointed in his stead. On Nov. 30, 1869, the constitution of 1868, with the obnoxious clause disqualifying Confederate soldiers from holding office stricken out, was resubmitted to the people, and almost unanimously adopted. Members to Congress from the State were admitted to their seats Feb. 24, 1870. The election in 1873 of Adelbert Ames as Governor was very objectionable to the white people of the State. Taxes had become exorbitant, while property had ruinously depreciated. Under his administration race conflicts also became frequent. A convention of taxpayers assembled in Jackson in 1875 to institute measures of reform, but their petitions to the Legislature were unheeded, and bills introduced for the correction of evils were defeated by the Negro members. Gov. Ames intensified race prejudices by attempting to organize a body of Negro militia to preserve the peace. The November elections of 1875 resulted in the return of a white majority to the Legislature; and in Mar., 1876, articles of impeachment were drawn up against Gov. Ames. He resigned his office on condition that the articles be withdrawn. A. K. Davis, Lieutenant-Governor, and T. W. Cordozo, State superintendent of education, both colored, were also impeached, but were permitted to resign. John M. Stone became Governor, and the State rapidly regained prosperity. In 1890 a new constitution was adopted.

GOVERNORS OF MISSISSIPPI.

Territorial.	
Winthrop Sargent	1798–1802
Wm. C. C. Claiborne	1802–05
Robert Williams	1805–09
David Holmes	1809–17
State.	
David Holmes	1817–19
George Poindexter	1819–21
Walter Leake	1821–25
David Holmes	1825–27
Gerard C. Brandon	1827–31
Abraham M. Scott	1831–33
Hiram G. Runnels	1833–35
Charles Lynch	1835–37
Alexander G. McNutt	1837–41
Tilghman M. Tucker	1841–43
Albert G. Brown	1843–48
Joseph W. Matthews	1848–50
John A. Quitman	1850–51
John J. Guion (acting)	1851
James Whitfield	1851–52
Henry S. Foote	1852–54
John J. McRae	1854–58
William McWillie	1858–60
John J. Pettus	1860–62
Jacob Thompson	1862–64
Charles Clarke	1864–65
W. L. Sharkey (prov'l)	1865–66
Benj. G. Humphreys	1866–70
James L. Alcorn	1870–71
Ridgley C. Powers	1871–74
Adelbert Ames	1874–76
John M. Stone	1876–82
Robert Lowry	1882–90
John M. Stone	1890–96
Anselm J. McLaurin	1896–1900
A. H. Longino	1900–

S. D. LEE.

Mississippi River [Indian, Algonkin, *Missi Sepe*, Great River; first spelled by the discoverers Mesasippi]: the great river of North America; popularly called the Father of Waters. It was discovered by De Soto in 1541. It drains a territory of 1,246,000 sq. miles, which is inhabited by a population of over 30,000,000 (1890). The mean annual rainfall over the whole basin is 30⅘ inches. Taken in connection with its principal tributary, the Missouri (which should have been considered the extension of the parent stream), it is one of the longest rivers in the world, the distance from the headwaters of the Missouri to the mouth of the Mississippi being 4,200 miles. The Mississippi has its source in the numerous lakes in the northern part of the State of Minnesota, the stream having been traced to its origin in Lake Itasca in lat. 47° 14′ N. and lon. 95° 15′ W. Its length is 2,800 miles, although the direct line distance from its source to its mouth is but about 1,660 miles, where it empties into the Gulf of Mexico in lat. 29° N. and lon. 89° 10′ W.

Slope.—The fall or slope of the river in the navigable portion above the mouth of the Ohio is about 6 inches per mile except at the Des Moines and the Rock Island Rapids, where the total fall is 24 feet and 22 feet respectively. The Falls of St. Anthony, 78 feet (including the rapids above and below), at Minneapolis marks the head of navigation. A canal has been constructed for passing the Des Moines Rapids, but boats are able to pass the Rock Island Rapids, as they extend over a distance of 14 miles of river. Below the mouth of the Ohio river the high and low water slopes are as follows:

SLOPE OF MISSISSIPPI RIVER, CAIRO TO NEW ORLEANS.

STRETCH.	Distance in miles.	Fall at high water.	Fall at low water.	SLOPE IN INCHES PER MILE.	
				High water.	Low water.
		Feet.	Feet.	Inches.	Inches.
Cairo to Memphis	230	100	88	5¼	4⅓
Memphis to Helena	76	30	42	4⅘	6⅘
Helena to Lake Providence	236	79	72	4	3⅝
Lake Providence to Vicksburg	57	15½	26	3½	5½
Vicksburg to mouth of Red river	166	42¼	39½	3	2⅞
Mouth of Red river to New Orleans	192	35½	4½	2¼	¼

Width.—The width of the river is greatest in its middle portion. Above the mouth of the Missouri there are many islands, and the total width of the Mississippi is about a mile as high up as Lake Pepin. This is an expansion to the width of 2 to 3 miles for a distance of about 20 miles, not far below the head of navigation. Below the mouth of the Missouri the width reduces to from half a mile to a mile, an average retained as far down as Red river; but occasionally the river widens out as much as a mile and a half. From Red river to the mouth the width averages but little over half a mile, and is quite uniform.

Stability of Banks.—Above the mouth of the Ohio the Mississippi river is similar to other inland streams. It flows in a tolerably stable bed; the variations in depth are not extraordinary; the changes in width are not excessive; and the banks are fairly stable. Below that point, however, the deposits which form its banks are composed of alternate layers of sand and mud or clay (the sand having been deposited by running water, and the mud having been deposited in comparatively still water); and the sand layers are readily washed out, thus causing the banks to cave off rapidly whenever the current sets against them. The slope is also great enough to create high velocities, and the result is a very unstable channel, constantly shifting laterally, and causing the river to develop into a serpentine form, one bend following

another continuously almost all the way from Cairo to New Orleans. Below the mouth of the Red river, however, the slope is reduced, and the banks become tolerably stable. The banks cave off along the outer sides of these great curves or bends, causing them to develop more and more until finally two adjacent bends meet and a "cut off" is made. This concentrates a fall which had been distributed over some 15 miles upon a much shorter distance, and thus the river here is given an abnormal velocity and energy together with new directions of flow, so that the old *régime* of the river is disturbed for many miles above and below. The convex bank in a bend is built up with sand deposits as rapidly as the concave bank caves off, so that the river does not usually become any wider in the bends on account of the caving. The wide places in this part of the river are generally on the stretches intervening between the bends, and are called crossings, because steamboats must cross over here from the deep water on one side of the river to the deep water upon the other in the next bend, the deepest water always being next to the concave or wasting bank.

Depth.—In those parts of the river where the bends are fully developed the variation in depth is enormous. If the water could all be drawn off from the channel it would be seen to be composed here of a series of crescent-shaped trenches in the bends, with almost perpendicular sides at the outer banks, but with very low slopes toward the inner side. These successive horseshoe-shaped depressions would always be turned with the horns pointing toward each other, alternately curved in opposite directions. Intervening between these horns would be sand-ridges, some 50 feet or more in height, which are the principal obstructions to navigation, and which it is the object of the improvement of the river to remove to some degree. Below the mouth of Red river the depth is always sufficient for navigation, but above that point there is more or less trouble at low stages. As the river narrows in the lower part of its course it becomes correspondingly deeper, its depth being in many places over 100 feet at ordinary stages.

Sediment.—Below the mouth of the Missouri the river is always very highly charged with sediment of a yellowish appearance. A large proportion by weight of this sediment is very fine sand. From daily measurements of volume of water and proportion of sedimentary matter passing New Orleans in the year 1880 (*Report* Miss. Riv. Com. 1882), it appears that for that year the total discharge of the river was 18,400,000,000,000 cubic feet. The average proportion of sediment by weight was $\frac{1}{1600}$. There was no high water during this year, therefore it is probable that the mean annual discharge of the river is about 21,000,000,000,000 of cubic feet, or sufficient to cover the whole Mississippi basin to a depth of 7½ inches; in other words, one-fourth of the rainfall over the basin passes off to the Gulf at the mouth of the river. If account is taken of what passes off through the Atchafalaya, 10 to 15 per cent. must be added to this. The average annual amount of solid matter delivered into the Gulf is therefore about 400,000,000 tons, or a volume a mile square and 360 feet high. This is spread by the Gulf currents over a very large area, and accumulates very slowly at the South Pass, which is the navigable outlet. A very much smaller amount of sediment (not over 2 per cent.), composed of coarser sand, is rolled or pushed along upon the bed of the river. This material is moved intermittently in the form of "sand-waves." These waves are strongly developed, being from 1 to 10 feet high and about 100 to 300 feet from crest to crest. The slope is very gentle on the up-stream side and very steep on the down-stream side. A given particle of sand is rolled or pushed up the low slope on the upper side and falls over and assists in building up the lower side. In this way these waves move gradually down stream at the rate of from 10 to 50 feet a day. They are only developed in the main channels where there is a decided current, but are found in both shoal and deep water. The most significant movement of sediment, however, is a discontinuous one of particles of sand in suspension. On account of the widely varying areas of cross-section the velocity of the water varies greatly. Where the velocity is more rapid, sand is taken from the bed and banks, thus increasing the size of this section, and deposited in the next enlarged section below, where the current is slack, reducing its area.

There is no such condition of the water as was formerly spoken of as "surcharged with sediment." The more rapid the flow and the more violent the vertical movements in the "boils" and "eddies" which result from the flow over the sand-ridges at the bottom, the greater is the proportion of sediment carried, the variable element being composed almost wholly of sand.

Velocity.—The mean velocity of the flow is from 1 to 6 miles per hour for different stages and sections. For any given stage, the same volume passing all sections, the mean velocity must vary inversely as the areas of the cross-sections. At low stages the large areas are in the narrow bends where the water is deep, and the small sections are in the wide crossings where the water is very shallow. The greatest velocity at low stages, therefore, is found on the sandbars, the slope also being concentrated at these points. The river is now washing off the crests of these bars in its effort to attain to a uniform cross-section and uniform velocity. At high stages the direct reverse is the case, the river then being engaged in cutting out the engorged sections in the bends and filling up the wide reaches where the sandbars lie. Evidently, if any given stage should continue long enough, a channel of nearly uniform sectional area would be created. To facilitate this desirable result the wide reaches are artificially narrowed, so that the river may have a tendency to exert a continual scouring action upon the bottom.

The Alluvial Basin.—Above the mouth of the Ohio the river flows through a chasm in limestone formations, from 1 to 10 miles wide, cut out by a monstrous glacial and preglacial river, which drained all the northern part of the continent. The limestone bluffs are from 200 to 300 feet above the low-water stage, but the intervening bottom-lands are largely subject to overflow. Those above overflows are sandy plains formed as great sandbars by the once gigantic stream. Those now subject to overflow have been formed by the later alluvial deposits, and are very fertile. Below the mouth of the Ohio the river flows through a region wholly formed by its own deposits. Numerous borings made for this purpose have established the fact that the alluvial basin below Cairo was once an estuary, or arm of the Gulf, and that it has been raised, along with the entire southern portion of the continent, about 100 feet, and then filled to its present height by the sediment carried down by the river itself. The width of this alluvial region varies from about 20 to about 70 miles. It is divided into three great basins, called respectively the St. Francis Basin, on the W., the Yazoo Basin, on the E., and the Tensas Basin, on the W. When not confined to the channel by levees, the natural course of a great flood is to spread so as to cover entirely all these basins. They then act as great reservoirs and storage grounds, although there is a slow movement of the water through them. They greatly delay the high-water stages on the lower portion of the river and lengthen out the period of the flood by fully four weeks at New Orleans. The Yazoo and Tensas basins have been closed against the entrance of floods by levees; the St. Francis Basin is open (1894), but is in process of being closed.

Great Floods.—On the upper river (above the mouth of the Ohio) the greatest floods come in April, May, or June. On the lower river they come in February, March, or April, and come mostly from the Ohio river. The following table gives the more prominent flood data for different points on the river:

LOCALITY.	Maximum rise in feet.	Low-water discharge in cub. ft. per second.	Ordinary high-water discharge in cub. ft. per second.	Extreme high-water discharge in cub. ft. per second.	Ratio of ordinary high to low water discharge.
St. Louis.....	41	40,000	600,000	1,000,000	15
Cairo	52	100,000	1,200,000	1,600,000	12
Memphis.....	37	100,000	1,100,000	1,200,000	11
Helena.	48	120,000	1,200,000	1,560,000	10
Lake Providence ..	41	160,000	1,100,000	1,200,000	8
Vicksburg	53	200,000	1,200,000	1,500,000	6
Mouth of Red river.	48	220,000	1,300,000	1,600,000	6
New Orleans.....	18	250,000	1,000,000	1,200,000	4

Very important deductions can be made from the figures in this table. It will be seen that the increase of stage at high water is much less at Memphis and Lake Providence than at points above and below. These localities are opposite the great basins of the St. Francis and the Yazoo, respectively. The St. Francis Basin always takes off a large portion of the water in time of flood and transports it through the swamps, it not yet having been leveed out. The Yazoo Basin is fully leveed, and in 1892 resisted a moderate flood without any breaks, for the first time, although this basin has been leveed for a quarter of a century. The flood

made large crevasses on the west side, however, opposite this basin, and thus obtained relief. When both of these basins and also the Tensas Basin have been efficiently leveed, the flood stage along their fronts will approximate closely to that at the junction points Cairo, Helena, and Vicksburg, but at these points the maximum stages given in the table are not for a great flood, as no great flood has ever been so confined to the channel. The lower end of the river has never carried in the channel more than 1,200,000 cubic feet per second. In several recent floods about 1,600,000 cubic feet per second has passed the mouth of the Red river in the channel. To enable it to escape down the river, crevasses in the levees have always occurred. To enable this amount of water to pass New Orleans in the river, a great enlargement of the channel must be effected. Temporarily, at least, this increased area of cross-section must be provided at the surface, which means levees very much higher on this portion of the river than have ever yet been built. See LEVEES.

The Atchafalaya Problem.—The Atchafalaya river was formerly the lower end of the Red river, and such it has again come to be. The Mississippi developed a bend toward the W., the Red river became a tributary to the Mississippi, its former channel silted up, finally becoming choked with "rack-heaps." These were cleared out many years ago to improve this stream for navigation, and it immediately began to enlarge its channel. It may be seen that the distance to sea-level is much shorter by this route, and hence the slope is correspondingly greater. It has now developed into a large river, carrying in time of flood in 1890 over 450,000 cubic feet per second. It is feared that since there is still a high-water connection between the Red-Atchafalaya river and the Mississippi, their channel may enlarge sufficiently to carry the whole river, thus leaving New Orleans on an arm of the sea. Another evil effect of this enlargement has been to drown out the plantations in Western Louisiana, which were the finest in the State, but are now entirely abandoned. The further enlargement of the Atchafalaya is now (1894) being provided against by building artificial sills in its bed near the junction with the Red river, and by means of a dam to force Red river to find its outlet again in the Mississippi. This would make the Red a tributary and the Atchafalaya an outlet of the Mississippi, as was formerly the case. At low stages the Red-Atchafalaya river is now entirely severed from the Mississippi, and it has been found practically impossible to maintain an open channel between them by artificial means at extreme low water.

The Improvement of the River.—This work divides itself into three kinds: bank protection, levee building, and contraction works. The banks are protected from caving by first grading them down by water-jets to a suitable slope, and then covering these with mattresses composed of small trees of willow and cottonwood, woven together with wire. These mattresses reach from near high water to the bottom of the river, and often are supplemented with others in the bottom extending out from the bank, all of them being held in place by rock ballast and piles. They immediately fill up with silt, and are very efficient in preventing further caving.

The levees are built near the river banks because the land here is higher, and the most valuable land for cultivation is near the river. If they were placed farther back the waste land in front of them would be soon covered with cottonwood-trees and thick undergrowth, so that this area would be worthless for discharging flood waters; but because the levees are placed near the unprotected banks they often cave off, and others are built a little farther back. These levees are earthen embankments from 5 to 20 feet in height and low slopes on each side. They are sure to be washed away if the water runs over them, and this is the common cause of failure. The levees have mostly been built by a special levee-tax collected from the lands benefited, by commissioners of certain "levee districts" organized under special State enactments. For several years, however, Congress has appropriated money for this purpose, and this money has been allotted in such a way as to supplement and encourage the local assessments. Some $7,700,000 has now (1894) been spent by the U. S. Government in this way.

The contraction works consist of transverse spar and longitudinal training dikes made of wooden piles and porous aprons or wattlings of small willow-trees, so placed as to check the flow of the water somewhat, without wholly deflecting the current, thus causing the water to drop its heavier sediment where fills are desired. In this way the river can be made to build for itself new banks, and to narrow the wide reaches in its channel with great certainty and at a moderate expense. When so narrowed the low-water depth becomes sufficient for navigation from natural scour. These dikes do not reach to the high-water stage, so that at high water there is the original width for discharge. These artificially filled areas soon grow up in timber, however, and this effectually stops nearly all flow. The piles are driven by the aid of a water-jet, and they are protected from washing out by means of foot-mattresses weighted down with stones, as described for the bank protection. This work has all been done under the auspices of the Mississippi River Commission, which was appointed under act of Congress in 1879. It is composed of three members of the Engineer Corps of the U. S. army, one engineer from the U. S. Coast and Geodetic Survey, two civil engineers, and one lawyer. The headquarters of the commission are in St. Louis, and their annual reports are full of valuable detailed information of every possible phase of the work under their charge, well illustrated, and can be had on application. Nearly $14,000,000 have (1894) been spent on contraction works and bank protection. The results are very satisfactory and full of promise.

The jetties at the mouth of the South Pass were constructed by Capt. James B. Eads, under a special contract with the U. S. Government in 1874. They have proved a perfect success in every way, and provide now a navigable channel about 30 feet deep at all seasons. The predicted shoaling at their outlet has not occurred, most of the sediment brought down by the river being carried off by Gulf currents. See JETTIES.

Reservoirs and Equalization of Volume.—One of the greatest causes of sandbar construction is the great variation of volume. The river in time of flood builds up the wide reaches, since here the current is slackened at such stages. To add more volume to the river at these times is but to intensify the evil effects of such stages. It is very desirable, therefore, to reduce flood volumes and to increase low-water volumes. Reservoirs at the head-waters, which will store up flood water and deliver it back to the river at low stages, are therefore helpful. Their effect is quite inappreciable in reducing the flood stage, but they materially add to the dry-weather flow. The proposed enlargement of the Illinois and Michigan Canal, which will deliver a continuous flow from Lake Michigan, will also help out the scouring action of the low-water flow. The effect of reservoirs, several of which have now been built on the head-waters in Minnesota, is too small, however, to make their construction as a means of river improvement economical. Far more can be accomplished with the same money by contraction works.

Effect of Regularization and Improvement.—The effect of a perfected levee system would be to bring under cultivation a very large area of country now considered worthless. The uncertainty as to future flood volumes and the stages consequent upon a confined channel are so great, however, that great devastation from crevasses caused by the river overtopping the levees will continue for many years to come. The banks will never be fully protected from caving, and the channel will always be very unstable, and will shift more or less in position. The wide sections will be gradually reduced in width, and the intervening bars lowered by natural scour. The effect of the levees is to increase the height of the bars so long as the very unequal widths are uncorrected, for a confined river means higher flood stages, and the higher the stage the higher the bars are built up in the wide reaches. Therefore the regulation of the width and the protection of the banks should precede the building of levees. The popular demand for levees, however, has reversed this order, and the levees have been constructed far in advance of the other works.

The ultimate increase in low-water depths for navigation is much smaller than generally supposed. It is not probable that, after the river is fully regulated in accordance with what now seems the best standard width (3,000 feet), the navigable depths at the lower stages will exceed 12 feet up to Vicksburg, 10 feet to Memphis, 8 feet to Cairo, 6 feet to St. Louis, 5 feet to Keokuk, and 3 feet to St. Paul; yet if these moderate depths could be assured at all seasons, the commercial advantages to the country would more than repay for the cost of the work. See RIVERS, LEVEES, and FLOODS; also the *Annual Reports of the Mississippi River Commission*, 1879 to date; Humphrey and Abbot's *Physics*

and Hydraulics of the Mississippi River; Corthell's *History of the Mississippi River Jetties*; *Great Floods on the Lower Mississippi*; and also *Protection of the Lower Mississippi Valley from Overflow*, by the author of this article, in *Journal of the Association of Engineering Societies*, vols. ii. and iii. respectively. J. B. JOHNSON.

Mississippi Scheme: a banking and commercial scheme which ended in a wild speculation and collapse. It was started in Paris in 1717 by John Law (see LAW, JOHN) under the patronage of the regent. Its primary object was to relieve the French finances from the burdensome debt and disorder consequent on the expensive wars of Louis XIV. Law established a private bank, and managed its affairs so skilfully that its paper was soon accepted by the public with perfect confidence, and in 1718 it was transformed into a royal bank. Then a commercial company was chartered entitled "The West India Company," of which also Law was director-general. To this company the whole province of Louisiana, watered by the Mississippi and its branches, was granted. Subsequently it was intrusted with the collection of the taxes and of the king's revenues, and thus it had a monopoly of almost the entire commercial and financial operations of the nation. Meantime the bank issued its notes freely till the paper currency amounted to 2,700,000,000 livres, but these notes were kept from depreciation by accepting them at a premium over specie in payment for the shares of the company. This increase of currency, with a promise of large dividends, rapidly advanced the price of shares, and the whole nation was possessed with a frenzy of speculation. All classes, prince and peasant, clergy and laity, men and women, were affected alike. The rush of stock-jobbing business in the streets of Paris was enormous. The speculations culminated at the close of the year 1719, when the company's shares sold for thirty or forty times their original value, and money was so abundant that the bank loaned at 2 per cent. There was, however, a drain of specie from the bank, as the shrewd ones attempted to put their new-made fortunes into forms of fixed value. To check this drain ineffectual edicts were passed to restrict payments in coin, to limit the amount of specie which one might hold, and to fix the value of the notes. The royal bank was incorporated with the company in Mar., 1720, and on May 21 a Government edict was issued reducing the value of bank-notes and of company shares one-half. This burst the bubble at once, and universal bankruptcy and distress ensued. This scheme stands a striking illustration of the fallacies that a nation's debt can be paid or its prosperity increased by a mere increase of its money circulation, and that paper money can be made stable and safe on some general security without respect to its convertibility. The leaders of the scheme were probably deluded with the rest.
Revised by C. K. ADAMS.

Mississippi, University of: a collegiate institution in Lafayette co., Miss.; chartered in 1844; opened Nov. 6, 1848. It was founded on a grant by Congress to the State of one township of land in 1819, the proceeds of which amounted to over $544,000, on which the State pays to the university interest at 6 per cent.; Congress granted another township of land in 1894. The institution possesses twelve plain but commodious brick buildings. In 1900 there were 18 instructors, 270 students, and 1,520 alumni. Courses lead to the degrees of A. B., B. S., and Ph. B. The library contains 16,000 volumes. The presidents have been: George F. Holmes 1848–49; Aug. B. Longstreet 1849–56; F. A. P. Barnard 1856–61; John N. Waddel 1865–74; Alexander P. Stewart 1874–86; Edw. Mayes 1886–91; Robert B. Fulton, 1892–. R. B. FULTON.

Missolon'ghi, or **Mesolonghi**: the most important town of Western Greece; in the government of Ætolia, on the Gulf of Patras (see map of Greece, ref. 16–J). It is well fortified, and famous for the valor with which it twice met the besieging Turks during the war of independence, in 1822 and 1826. Lord Byron died here Apr. 19, 1824. Pop. 6,000.

Missoula: city; capital of Missoula co., Mont. (for location of county, see map of Montana, ref. 5–D); on Clark's fork of the Columbia river, and the N. Pac. Railroad; 145 miles W. of Helena, the State capital. It is in an agricultural, lumbering, and fruit-growing region; has extensive mines and rich grazing land in the vicinity; and contains a flour-mill, hospital, and 2 daily and 4 weekly newspapers. Pop. (1880) not in census; (1890) 3,426; (1900) 4,366.
EDITOR OF "MISSOULIAN."

Missouri [named from Missouri river]: one of the U. S. of North America (North Central group); the eleventh State admitted into the Union.

Location and Area.—It lies wholly W. of the Mississippi river, between lats. 36° and 40° 30′ N. and lons. 89° 2′ and 95° 44′ W. from Greenwich; is bounded N. by Iowa, E. by Illinois, Kentucky, and Tennessee, S. by Arkansas, and W. by Indian Territory, Kansas, and Nebraska; extreme breadth E. to W., 318 miles; average breadth, 244 miles; area, 69,415 sq. miles (44,425,600 acres), of which 680 sq. miles are water surface.

Seal of Missouri.

Physical Features.—The State is divided into two unequal portions by the Missouri river, which crosses it from W. to E., and forms also its northwestern boundary. The portion S. of the Missouri is of very varied surface, the southeastern portion being low and partially swampy; above this, on the Mississippi, the highland bluffs begin and extend to the mouth of the Missouri. In the southwestern portion of the State the Ozark Mountains—or rather hills—render the whole region exceedingly broken and hilly, the isolated peaks sometimes rising from 500 to 1,000 feet above their bases, and then sinking into very beautiful and sometimes fertile valleys. The numerous river-bottoms and valleys formed by the tributaries of the Osage and Missouri rivers are moderately fertile, but they are generally subject to overflow. Farther N., in the basin of the Osage and above it, the land is mostly rolling prairie, with occasional forests: the immediate valley of the Missouri has a rich alluvial soil, and abounds in large forest trees. The principal rivers are the Mississippi, which bounds the State on the E. and has a direct shore-line of 470 miles (with windings, about 500 miles), and the Missouri, which forms the western boundary of the State for nearly 200 miles, and, turning eastward at the mouth of the Kansas river, flows in an E. S. E. direction across the State, then, flowing N. E., enters the Mississippi 20 miles N. of St. Louis. The Little river, which crosses the southern boundary of the State before entering the Mississippi, and the Meramec, are the only considerable streams discharging their waters into the Mississippi S. of the Missouri. N. of that river Salt river is the largest of these tributaries, but the Cuivre or Copper river, Perruque or Wig creek, Dardenne creek, Fabius, Wyaconda, and Little Fork rivers are streams of moderate size. The Missouri receives numerous large affluents in the State: on the south side are Lamine river, Osage river, and its tributary the Little Osage, Sac river, Grand river, Pomme de Terre river, Big Niangua, Auglaize, Maries creek, and Gasconade river; on the north side, the Nishnabatona, Nodaway, Platte, Grand, Chariton, Roche Percé, Cedar, and Loutre rivers, and Yellow creek.

Geology and Mineralogy.—The geology of Missouri may be briefly summed up as follows: Quaternary deposits in the S. E., extending over a triangular tract from the point where the Current river crosses the southern boundary of the State to the Mississippi river, and comprising the counties along and near the river in the whole swamp region to a point near Benton; the same formation extends through the immediate valley or bottom lands of the Missouri to and beyond the point where it leaves South Dakota. There are no Tertiary, Cretaceous, Triassic, or Jurassic rocks in the State. The next is the Carboniferous or coal-measures, which either as Upper or Lower Carboniferous cover 23,100 sq. miles of the surface of the State, occupying in general the western, northwestern, and northern portions of the State. These include the four subdivisions of the Upper Carboniferous formation and six successive deposits of the Lower Carboniferous, comprising an unclassified sandstone, and the St. Louis, Keokuk, and Chouteau groups of limestones and sandstones, most of them rich in fossils. Adjoining these coal-measures are two considerable tracts

of Devonian rock, one in the southwest, the other in the northeast, portion of the State; a narrow belt of it also follows the eastern edge of the Carboniferous deposits in all their devious lines, and extends S. E. to the immediate vicinity of St. Louis. The Hamilton and the Onondaga groups, both mainly limestones, are the only strictly Devonian rocks in the State. The Upper and Lower Silurian formations come next, and occupy a tract almost 200 miles in width, and extending from the Missouri river to the southern line of the State, and also crop out in the immediate bottomlands of the Mississippi above the mouth of the Missouri. Four groups of the Upper Silurian are found here—viz., Oriskany sandstone, Lower Helderberg or Delthyris shale, Niagara group, and Cape Girardeau limestone. Of the Lower Silurian formation there are three groups, belonging to the Trenton period—viz., the Cincinnati group, represented mainly by Hudson river shale; the Galena group, receptaculite limestone; and the Trenton group, composed of Trenton, Black river, and Birdseye limestones. There are also three groups of the magnesian limestone series, consisting of magnesian limestones, saccharoidal and other sandstones, and Potsdam limestones, sandstones, and conglomerates. Below these, and around the head-waters of the affluents of the St. Francis and White rivers, there are frequent outcrops of Eozoic or archaic rocks—greenstone, porphyry, and granite. Much of the limestone of the coal-measures, as well as some of the other formations, is cavernous, and there are numerous caves of great extent and beauty in the central and western portions of the State.

During the year ending June 30, 1892, there were 1,144 mines of all kinds in operation, and the output showed a marked increase over that of the preceding year, but prices were lower. The production of lead and zinc was valued at $5,056,504; of coal, $3.825,828; and of iron, $234,606. In 1899 the Galena-Joplin district of southwestern Missouri and southeastern Kansas yielded 255,088 short tons of zinc, and 23,888 short tons of lead, the total value of the product being $10,715,307. The iron output, chiefly from the Iron Mountain in St. François County, was in 1899 22,720 long tons, valued at $42,203. The mineral output has decreased somewhat in recent years, but a distinct revival is taking place, especially in the older mining districts. The coal-area was estimated at 26,700 sq. miles, and yielded in 1899 3,025,814 short tons, valued at $3,591,945: of granite the most extensive quarries were at Graniteville, Iron County, and Granite Bend, Wayne County, and the product in 1899 was valued at $151,688. The sandstone output was valued at $57,662, and that of limestone at $977,399. There are rich deposits of refractory, potters', and sedimentary clays in St. Louis County, and valuable mineral springs in Pike, Saline, Cedar, Lawrence, Randolph, and Mercer Counties.

Soil and Productions.—The soil is divisible into five classes: (1) The alluvial deposits of the southeast part and of the bottoms of the Missouri river, which are exceedingly fertile; (2) the black-soil prairies of the northwest part; (3) the part prairie and part rolling land of the eastern part, N. of the Missouri river, which contains the best tobacco lands of the State; (4) a good fruit, wheat, and corn tract in the southwest part; (5) the extensive tract between the southwest part and the swampy lands in the southeast, which contains heavily timbered hills and some very rich valleys. Most of North and Northwestern Missouri is prairie, though with belts of timber along the streams. The bottoms are generally heavily timbered with cottonwood, hickory, black walnut, hackberry, burr, and red oak. W. of Howard County the Missouri river counties have heavy bodies of fine timber, interspersed with prairies. E. of Howard County there are belts of hardwood timber from 10 to 20 miles wide, including ash, oak, walnut, sugar-maple, hickory, elm, etc. Along the Osage river and in all the southern counties are heavy tracts of good timber, chiefly white, black, yellow, and post oak, black jack, black hickory, sassafras, dogwood, cedar, etc., and nearer the Arkansas border extensive tracts of pine. Yellow poplar, sweet gum, cypress, oak, catalpa, tupelo, black gum, and black walnut are the principal forest trees of the southeast.

The following summary of the census reports of 1880 and 1890 shows the extent of farm operations in the State:

FARMS, ETC.	1880.	1890.	Per cent.
Total number of farms	215,575	238,043	+10·4
Total acreage of farms	27,879,276	30,780,290	+10·4
Total value of farms, including buildings and fences	$375,633,307	$625,858,361	+66·6

The following table shows the acreage, yield, and value of the principal crops in the calendar year 1900:

CROPS.	Acreage.	Yield.	Value.
Corn	6,453,943	180,710,404 bush.	$57,827,329
Wheat	1,507,737	18,846,713 "	11,873,429
Oats	901,291	24,695,373 "	5,679,936
Rye	9,607	134,498 "	68,594
Barley	713	14,830 "	6,674
Buckwheat	108,677	10,106,961 "	3,537,436
Tobacco	10,580	7,406,000 lb.	666,540
Potatoes	108,677	10,106,961 bush.	3,537,436
Hay	2,145,748	2,768,015 tons.	19,237,704
Totals	11,336,973		$91,435,078

On June 1, 1890, there were reported 25,191,788 poultry of all kinds, and the egg product of the census year was 53,147,418 dozen. The dairy product in the same period was: butter, 43,108,521 lb.; cheese, 288,620 lb.; and milk, 193,931,103 gal. The wool clip in 1890 was 4,040,084 lb., a little more than half of the clip of 1880. The production of beeswax in 1889–90 was 75,670 lb., and of honey, 4,492,178 lb., the latter being an increase of 3,771,098 lb. over the crop of 1879–80.

The farm animals on Jan. 1, 1900, comprised 724,597 horses, value $24,891,718; 165,026 mules, value $7,210,321; 659,731 milch cows, value $18,868,307; 1,387,615 oxen and other cattle, value $36,981,329; 597,619 sheep, value $1,854,711; and about 4,000,000 swine, value $20,000,000; total head, 7,534,588; total value, $109,806,386.

Climate.—The climate is generally healthful, excepting in the river-bottoms and the swampy districts of the southeast, but it is subject to great extremes. The summers are long and hot, and the winters very cold, with strong and piercing winds. The following is a summary of reports of observations, furnished by the U. S. agricultural experiment station at Columbia, showing the mean temperature and the average rainfall of the State during 1893:

MONTHS.	Mean temperature.	Average rainfall in inches.
January	25·5°	0·45
February	27·9	1·98
March	40·5	2·86
April	53·9	7·84
May	61·8	5·89
June	72·6	4·61
July	77·3	4·91
August	72·8	2·20
September	69·9	3·92
October	56·7	0·99
November	40·9	1·59
December	35·2	0·95

The highest temperature of the year was 107°, at New Hartford and Harrisonville on Sept. 14, and the lowest was −20°, at New Boston on Feb. 5. The precipitation ranged from 18·30 inches, at Lexington in July, to nothing, at Louisiana and West Plains in January, and at Conception and Tindall in October.

Divisions.—For administrative purposes the State is divided into 114 counties and one city (St. Louis) as follows:

COUNTIES AND COUNTY-TOWNS, WITH POPULATION.

COUNTIES.	* Ref.	Pop. 1890.	Pop. 1900.	COUNTY-TOWNS.	Pop. 1900.
Adair	1-G	17,417	21,728	Kirksville	5,966

* Reference for location of counties, see map of Missouri.

Principal Cities and Towns, with Population in 1900.—St. Louis, 575,238; Kansas City, 163,752; St. Joseph, 102,979; Joplin, 26,023; Springfield, 23,267; Sedalia, 15,231; Hannibal, 12,780; Jefferson, 9,664; Carthage, 9,416; Webb, 9,201; Moberly, 8,012; St. Charles, 7,982; Nevada, 7,461; Independence, 6,974; Chillicothe, 6,905; Aurora, 6,191; Kirksville, 5,966; Columbia, 5,651; De Soto, 5,611; Brookfield, 5,484; Trenton, 5,396; Louisiana, 5,131; Mexico, 5,099; Marshall, 5,086; Clinton, 5,061.

Population and Races.—In 1860, 1,182,012; 1870, 1,721,295; 1880, 2,168,380; 1890, 2,679,184 (natives, 2,444,315; foreign, 234,869; males, 1,385,238; females, 1,293,946; whites, 2,528,458; colored, 150,726; comprising 150,184 of African descent, 409 Chinese, 6 Japanese, and 127 civilized Indians); 1900, 3,106,665.

Industries and Business Interests.—The census returns of 1890 showed that 14,045 manufacturing establishments reported. These had a combined capital of $189,236,422; employed 142,924 persons; paid $76,327,907 for wages; and had products valued at $323,897,688. Manufacturing was principally carried on in Kansas City, St. Joseph, St. Louis, and Springfield, which cities together reported 8,086 establishments, employing $159,564,369 capital and 113,256 persons, paying $65,261,837 for wages and $147,463,005 for materials, and receiving $274,367,662 for products. This summary showed an increase since 1880 of 4,761 establishments, $105,160,529 capital, 67,625 persons employed, $45,200,820 paid for wages and $65,149,242 paid for materials, and $148,508,021 in value of products. In 1890 the principal industries, according to the amount of capital employed, were the manufacture of malt liquors, $16,293,974; foundry and machine-shop products, $10,912,341; clothing, $5,701,009; saw and planing mill products, $5,694,929; tobacco, $4,681,840; paints, $3,498,107; slaughter-house products, $3,274,671; and flour and grist mill products, $1,401,760. During the fiscal year ending June 30, 1893, the collections of internal revenue in the State were: on the manufacture of distilled spirits, $3,207,444; tobacco, $3,556,943; fermented liquors, $2,122,201; oleomargarine, $64,854; and penalties, $23,146; total, $8,974,595.

Commerce.—Missouri has three interior ports to which foreign merchandise can be transported without appraisement at receiving ports, Kansas City, St. Joseph, and St. Louis; and during the year 1900 the aggregate value of foreign merchandise imported at these ports was $4,480,283.

Finance.—On Jan. 1, 1899, the State bonded debt was $3,642,000. Under the constitution the State must pay at least $250,000 of its debt annually. The actual valuation of taxable property was $2,397,902,945, and the assessed valuation was $1,093,091,204, of which $337,632,192 are credited to St. Louis. The railway and telegraph property in the State was assessed at $103,361,000.

Banking.—On Sept. 5, 1900, there were 67 national banks, with combined capital of $17,950,000; surplus and profits of $8,545,405.14; and deposits of $64,448,555.54. On June 30 there were 510 State banks, capital $18,592,225, and 90 private banks, capital $924,370, with deposits aggregating $88,660,622.

Means of Communication.—The first railway in the State was opened with 38 miles of track in 1852. On Dec. 31, 1892, there was an aggregate of 6,403 miles of single track and 7,970 miles of single, double, and siding tracks. Only six counties are without railway facilities. The cost of the road-beds and equipments was $288,180,000; the capital stock and funded debt amounted to $1,102,955,141; the earnings were $140,377,068; and the operating expenses $99,735,881. The total mileage in 1899 was 6,826·58. The earnings in 1900 were reported at $17,296,880. The Mississippi and Missouri rivers are spanned by several iron railway bridges, the former at Hannibal, La., St. Louis (2), and Cairo; the latter at St. Joseph, Atchison, Kansas City, Glasgow, Boonville, St. Charles, and Belle Fontaine.

Churches.—The census of 1890 gave the following statistics of the principal religious bodies:

DENOMINATIONS.	Organizations.	Churches and halls.	Members.	Value of church property.
Roman Catholic	442	437	162,864	$4,070,370
Baptist	1,636	1,607	121,985	2,386,898
Disciples of Christ	1,120	889	97,773	1,632,531
Methodist Episcopal South	1,230	1,141	86,466	2,046,389
Methodist Episcopal	905	876	58,285	1,835,840
German Evan. Synod of N. A.	124	124	25,676	575,560
Cumberland Presbyterian	393	333	23,990	571,362
Lutheran Synodical Conference	118	113	22,121	613,940
Baptist, colored	234	238	18,613	400,518
Presbyterian in the U. S. of A.	207	210	17,272	1,328,700
Presbyterian in the U. S.	143	120	10,363	753,490
African Methodist Episcopal	87	126	9,589	281,289
Protestant Episcopal	111	90	8,828	952,600
Congregational	80	79	7,617	650,344
Baptist, General	166	162	6,654	22,675
Baptist, Free-will	108	105	4,752	59,825
United Brethren in Christ	105	98	4,361	47,825

Schools.—In 1900 there were 981,722 children of school age (six to twenty years) in the State, of whom 668,018 were enrolled in the public schools, and 416,364 were in average daily attendance. There were 10,326 school buildings, 13,782 teachers—5,979 men, and 7,803 women—and school property of all kinds valued at $17,020,880. The public-school fund aggregated $6,734,315: the total expenditure of the year was $7,048,826. In 1890 there were 4 public normal schools, 13 commercial and business colleges, 64 endowed academies, seminaries, and other private secondary schools, 12 colleges for women, 27 universities and colleges, and 13 schools of medicine, 4 of theology, 2 of law, and 2 of pharmacy. The State University at Columbia includes an agricultural college and a school of mines. The main building, constructed in 1840–42, and containing recitation-rooms, chapel, etc., and library of 40,000 volumes, was destroyed by fire Jan. 9, 1892, but has been rebuilt and much enlarged.

Libraries.—According to a U. S. Government report on public libraries of 1,000 volumes and upward each in 1891, Missouri had 105 libraries, containing 561,905 bound volumes and 96,278 pamphlets. The libraries were classified as follows: General, 10; school, 34; college, 27; college society, 1; law, 2; theological, 3; medical, 2; State, 1; Y. M. C. A., 2; social, 12; scientific, 3; historical, 2; I. O. O. F., 2; Masonic, 1; mercantile, 1; and not reported, 2.

Post-offices and Periodicals.—In Jan., 1901, there were 2,993 post-offices, of which 158 were presidential (5 first-class, 24 second-class, 129 third class), and 2,835 fourth-class. There were 1,156 money-order offices, and 114 money-order stations. Of newspapers and periodicals there were 84 daily, 4 bi-weekly, 9 semi-weekly, 780 weekly, 13 semi-monthly, 143 monthly, 3 bi-monthly, and 9 of quarterly publication; total, 1,045.

Charitable, Reformatory, and Penal Institutions.—These comprise the State lunatic asylums at Fulton, opened 1851, at St. Joseph, opened 1874, and at Nevada, opened 1887; a county insane asylum at St. Louis; a State penitentiary at Jefferson City; State School for the Deaf and Dumb at Fulton, opened 1851; State School for the Blind at St. Louis, opened 1851; a day school for the deaf at St. Louis, opened 1879, and supported by the city; and many hospitals, orphanages, homes, refuges, and other institutions under the control of various religious organizations.

Political Organization.—The elective franchise is given to every male citizen of the U. S. and to every male person of foreign birth who has declared his intention to become a citizen of the U. S. not less than one year nor more than five years before he offers to vote, who is over the age of twenty-one years, and has resided in the State for one year and in the county, city, or town for at least sixty days immediately preceding the election at which he offers to vote. U. S. soldiers and marines, paupers, criminals convicted once until pardoned, felons, and violators of suffrage laws convicted a second time, are excluded from voting. The Governor is elected for four years, and is ineligible for re-election. The Senate consisted in 1894 of 34 members, chosen for four years, and the House of Representatives of 140 members, chosen for two years; the number of the latter varies with the changes in population and the decennial apportionments. All laws, excepting the general appropriation act, unless an emergency clause is incorporated in it, take effect ninety days after final adjournment. The Legislature holds biennial sessions, limited to seventy days. The judicial authority is vested in a Supreme Court, of five judges, elected by the people for ten years, one being elected every two years, and the oldest in commission being chief justice; a circuit court with one judge in each judicial circuit; county and probate courts with one judge for each; special circuit, criminal, and criminal correction courts in the city of St. Louis (which is coextensive with the county of St. Louis); and the usual minor courts and officers. The constitution provides that the State tax, exclusive of that necessary to pay the bonded debt, shall not exceed 20 cents per $100 of taxable property; that whenever the taxable property in the State shall amount to $900,000,000, the rate shall not exceed 15 cents; that no county, city, town, or other subdivision of the State shall become indebted to an amount exceeding in any one year the income provided for such year, without the assent of two-thirds of the voters thereof voting on the measure, nor in such cases shall an indebtedness be created to an amount, including existing indebtedness, exceeding 5 per cent. of the taxable property therein; and that there be set aside annually at least 25 per cent. of the State revenue, exclusive of the interest and sinking fund, for the support of the public schools.

History.—The present State of Missouri was known as Upper Louisiana. Under this name its lead mines began to be known as early as 1720, and settlements were made not long after at St. Louis, Cape Girardeau, and (probably about 1735) at Ste. Genevieve. In 1763 it was ceded to Spain with the rest of the Louisiana or Mississippi river country, while all E. of the river came into the possession of the English. In 1775 St. Louis (which was founded by Laclede, Feb. 15, 1764), had attained some reputation as a fur-dépôt and trading-station, and had about 800 inhabitants, and Ste. Genevieve about half as many. New Madrid had been founded some time before. In 1800 Spain ceded her provinces on the Mississippi to France, and the French Government sold them to the U. S. in 1803. The U. S. Government divided the purchased region into the Territory of Orleans and the district of Louisiana, the latter including most of Arkansas, Missouri, Iowa, Minnesota, and Dakota, and most of Kansas and Nebraska. On Mar. 10, 1804, Capt. Amos Stoddard, of the U. S. army, succeeded Delassus, Spanish commandant at St. Louis, and the authority of the U. S. in Missouri dates from that day; during the same year this region was erected into the Territory of Louisiana, and St. Louis made the capital. In 1810 the population of the territory was 20,845, of which all but 1,500 were in the present limits of Missouri. In 1812, Louisiana becoming a State, the name of the Territory was changed to Missouri Territory. In 1817 the Territorial Legislature applied to Congress for liberty to prepare a State constitution preliminary to admission into the Union. This application led to a protracted struggle in Congress on the question of the admission of Missouri as a slave State. It was finally settled by the MISSOURI COMPROMISE (*q. v.*). A convention met in St. Louis June 12, 1820, and agreed upon a constitution; the State was admitted to the Union by presidential proclamation Aug. 10, 1821. Its subsequent progress was very rapid. The people of the western portion of the State, in 1858–59, had taken sides in the Kansas troubles, and armed bodies of men, known as Missouri "border ruffians," had penetrated into Kansas and committed many outrages there. A convention was called in Missouri on Feb. 28, 1861, which decided in favor of remaining in the Union. Another constitutional convention met in St. Louis Jan. 6, 1865, and adopted a new constitution, providing for emancipation and the changes induced by it. This constitution was further modified in 1870, and a new one adopted Oct. 30, 1875.

GOVERNORS OF MISSOURI.

Alexander McNair	1820–24	Joseph W. McClurg	1869–71
Frederick Bates	1824–26	Benj. Gratz Brown	1871–73
John Miller	1826–32	Silas Woodson	1873–75
Daniel Dunklin	1832–36	Charles H. Hardin	1875–77
Lilburn W. Boggs	1836–40	John S. Phelps	1877–81
Thomas Reynolds	1840–44	Thomas T. Crittenden	1881–85
M. M. Marmaduke (acting)	1844	John S. Marmaduke	1885–87
John C. Edwards	1844–48	A. P. Morehouse (acting)	1887–89
Austin A. King	1848–53	David R. Francis	1889–93
Sterling Price	1853–57	William J. Stone	1893–97
Trusten Polk	1857	Lon V. Stephens	1897–1901
Hancock Jackson (acting)	1857	Alex. M. Dockery	1901–
Robert M. Stewart	1857–61		
Claiborne F. Jackson	1861		
Hamilton R. Gamble	1861–64		
Willard P. Hall	1864–65		
Thomas C. Fletcher	1865–69

S. census; Reports of the U. S. Department of Agriculture; *Mineral Resources of the United States*.

WILLIAM F. SWITZLER.

Missouri Compromise: a name given to a law of Congress which may be regarded as one of the principal landmarks of the history of the U. S. during the nineteenth century. Upon the introduction into Congress, in the session of 1818–19, of a bill providing for the admission of Missouri as a State, but prohibiting slavery therein, the opposition on the part of the Southern members became violent and menacing, and after long and brilliant debates a compromise was effected, chiefly by the influence of Henry Clay. Missouri was admitted as a slave State, and at the same time an ordinance was enacted (Feb. 28, 1821) that from all the territory W. of Missouri and N. of the parallel of 36° 30′ (the southern boundary of the new State) slavery should be forever excluded. This agreement subsisted until virtually repealed by the bills which established the Territories of Kansas and Nebraska in 1854, when the question, thus reopened, became the cause of civil war in Kansas between the partisans of liberty and slavery. This measure determined the formation of the Republican party (1854), precipitated the anti-slavery issue, and led to the civil war of 1861–65, by which the whole question was set at rest.

Missouri Indians: See SIOUAN INDIANS.

Missouri River [*Missouri* is from Indian words meaning "muddy water"]: the principal tributary of the MISSISSIPPI RIVER (*q. v.*). It is formed in Southwestern Montana by the union of the Jefferson, Madison, and Gallatin rivers; flows N. and E. through Montana; then in a southeasterly direction traverses North and South Dakota, and flows between Nebraska and Kansas on the W. and South Dakota, Iowa, and Missouri on the N. E. and E. until it reaches Kansas City, whence it flows E. through Missouri to its junction with the Mississippi, 20 miles above St. Louis, in lat. 38° 50′ 55″ N., lon. 90° 14′ 45″ W. Its length to the source of the Madison river, which rises in National Park, is about 3,000 miles. It is a turbid and swift stream, navigable in high water to Fort Benton, Montana, or even to the Great Falls, and in low water to the mouth of the Yellowstone, near the boundary between North Dakota and Montana. The Great Falls are 40 miles above Fort Benton. They consist of four cataracts separated by rapids, with a total fall of 357 feet in 16½ miles. About 145 miles above this point the river passes through the Gate of the Rocky Mountains, a gorge with perpendicular walls rising 1,200 feet directly from the edge of the stream, and extending thus for a distance of nearly 6 miles. In its lower course the river flows through a narrow alluvial valley of great fertility. Its chief tributaries are the Milk, Dakota, Big Sioux, Little Sioux, and Grand on the left, and the Yellowstone, Little Missouri, Cheyenne, White, Niobrara, Platte, Kansas, and Osage on the right.

Missouri, University of the State of: a non-sectarian institution of learning founded at Columbia, near the center of the State of Missouri, in 1839. Academic work began in 1841, a normal department was established in 1867, the College of Agriculture and Mechanic Arts and School of Mines and Metallurgy were added in 1870, the latter being located at Rolla; the department of law was added in 1872, medicine in 1873, engineering in 1877, and the experiment station in 1887. The experiment farm and the horticultural grounds are close to the campus.

The endowment bearing interest at 5 or 6 per cent. is $1,200,000. The buildings, equipment, and grounds (including farm and gardens) are worth $1,000,000. The Federal Government contributes yearly to the Morrill and experiment station funds. The endowment is held by the State, which pays interest and makes liberal appropriations. From Feb., 1891, to Mar., 1893, these amounted to $1,525,000, but this sum includes interest for four years and $650,000 of war tax refunded to Missouri and given by her as additional endowment to the university. There are sixteen buildings. All departments are open to women. The institution is the head of the public-school system of Missouri, and aids in helping forward the elementary and secondary schools. In 1899–1900 the university had 70 professors and other teachers, and 1,181 students. President, R. H. Jesse, LL. D.

R. H. JESSE.

Missouri Valley: town; Harrison co., Ia. (for location of county, see map of Iowa, ref. 5–D); on the Chi. and N. W., and the Sioux City and Pac. railways; 6 miles E. of the Missouri river, 20 miles N. of Council Bluffs. It contains 7 churches, 3 public schools, improved water-works, electric lights, district fair-grounds, and 2 daily and 2 weekly newspapers; and has flour-mills, brick and tile works, machine-shops, large railway repair-shops, carriage-factory, stove-foundry, and wood-working plants. Pop. (1880) 1,154; (1890) 2,797; (1900) 4,010.

Mist: See FOGS.

Mistake: in law, an unintentional act or omission having legal consequences (*mistake of fact*), or an intended act or omission having unintended legal consequences (*mistake of law*). It is true in law as it is in the other concerns of life that a person committing a mistake must generally bear the consequences of his error. The law does not undertake to rectify the mistakes of normal juristic persons (i. e. of persons having legal capacity), nor to avert from them or from others the consequences of their blunders. Thus one who goes upon the land of another, believing it to be a part of his own domain, is guilty of trespass equally with him who maliciously intrudes upon his neighbor's premises; and, on the other hand, the man who innocently incloses a part of his neighbor's land, believing it to be his own, acquires by lapse of time, even without his knowledge and against his own will, the same indefeasible title which an intentional wrongdoer would have gained by the same acts. This is only another way of saying that the law does not ordinarily look to the intention with which an act is done, but only at the act and its consequences. It is only in that limited class of cases in which the intent of the party or parties is an essential part of the transaction that the law will relieve from the consequences of a mistaken expression of such intent. The principal, if not the only, cases in which this occurs are those of contracts, of conveyancing, of the making and revocation of wills, of money paid under mistake, and of crimes.

Before entering upon a consideration of the topic of consent as related to these several classes of cases, it will be necessary to refer briefly to the different treatment which the law accords to mistakes of fact and of law respectively. The rule, as generally stated, declares that relief will be given against mistake of fact, but not against mistake of law. Neither branch of this statement is true without a good deal of qualification. We have already seen that in most transactions mistake, even of fact, is altogether without effect. On the other hand, there are many cases in which a mistake of law will have the effect attributed by the rule only to mistakes of fact. This occurs, for example, where the mistake is due to ignorance of particular private rights; or where two parties have made an agreement and instructed a third to put it in legal form, and the latter, owing to ignorance of law, fails to express the real intention of the former; or where the mistake is as to foreign law. It is true, however, that mistakes of law are generally remediless, and that it is only in exceptional cases that the law will afford relief from their consequences. This result is commonly attributed to the supposed existence of a legal presumption that every one knows the law; but this statement is as far from being an expression of a legal fact as it is from being an actual fact. There is, indeed, a rule of law that in certain cases ignorance of law excuses no one, but there is no rule that every one must be taken to be cognizant of the law. The nature of the distinction here referred to between mistakes of law and of fact will more clearly appear in connection with the several classes of cases in which mistake is a matter of legal recognition.

Contracts.—Mistake does not *of itself* affect the validity of contracts at all. It is an almost universal rule that a man is bound by an agreement to which he has expressed his assent in unequivocal terms; but mistake may be such as to prevent any real agreement from being formed, in which case the agreement is void both at law and in equity. The essence of contract is a mutual understanding and agreement as to the matters included in the transaction. Where this element is lacking, or where the agreement is only apparent and does not really exist, there is no contract.

Accordingly, it is only fundamental error, going to the very root of the transaction, which will have the effect of vitiating the agreement. Such error may be mistake (1) as to the nature of the transaction, (2) as to the person of the other party, or (3) as to the subject-matter of the agreement. The first of these kinds of mistake (which must be of very unusual occurrence) may be illustrated by the case of a person who, without negligence on his part, signs an obligation or document of one kind believing it to be an obligation or document of another kind. The court will in such cases allow the mistaken party to avoid the obligation unintentionally assumed by him. In the second place, every

person has a right, consciously and of his own free will, to choose the persons with whom he deals. If A addresses an order for goods to B, C can not, by filling the order, thrust himself into the position of a contracting party with A. Even though A has accepted the goods, under the mistaken belief that they were supplied by B, he does not become liable to C upon the contract. The third case, of mistake as to the subject-matter of the agreement, is of more frequent occurrence. It happens where the parties agree for the purchase and sale of an article, and there is a mutual mistake as to the article intended; or where the person or property to which the agreement relates is no longer in existence, but both parties are ignorant of that fact. This branch of the rule may be summed up in the statement that where both parties to an agreement are under a mistake as to a matter of fact essential to the agreement, the agreement is void.

In all cases in which mistake has the legal effect of avoiding the contract, the party seeking to escape the consequences of the mistake may invoke the aid of both the legal and the equitable tribunals. If the contract is still executory he may repudiate it, or if he have paid money under it he may sue and recover it. In equity he may resist specific performance, or may sue for a decree declaring the contract void.

There is another class of cases arising in contract, where the mistake does not go to the very existence of an agreement, as in the cases above considered, but where a genuine agreement of the parties has been perverted by a mistake in the form of expression adopted by them. In such cases there is no remedy at law, but where the mistake is mutual the courts of equity will rectify it, either negatively, by refusing to compel the party injured by the mistake to perform the contract, or positively, by reforming the contract so as to make it express the true intent of the parties. For this purpose the court will, if necessary, take parol evidence to guide it in arriving at this intent.

Deeds, etc.—Indeed it is by the exercise of this equity jurisdiction in the reformation of written instruments that the consequences of mistake have most generally been averted. This jurisdiction is even more frequently exercised in the case of deeds, mortgages, bonds, and sometimes even to reform, or rectify, negotiable instruments. In all of these cases equity will reform the careless or perverted expression of the written instrument so as to make it conform to the real intention at which the parties aimed but failed to express. In this class of cases, however, as in the case of the rectification of a written contract, above referred to, the mistake must be mutual in order to procure the reformation demanded.

It should be added that the equity tribunals make far less account of the distinction between mistakes of fact and of law than do the law courts, and that a mutual fundamental mistake of the parties as to the law will usually secure the intervention of equity.

Wills.—In the making and revocation of wills the question of intention is again, as in the case of contracts, fundamental. No writing can take effect as a testament unless the will of the alleged testator accompanies it. It is this *will*, or intention, which gives to the written instrument all its force and validity. Consequently, if this intention be wanting, as where a person executes the wrong paper as a will, or goes through the form of executing a will without intending that the paper so executed shall have the effect of a will, the probate courts will give relief by refusing to allow probate of the instrument. It will be observed that in the cases above supposed the testamentary *will* is entirely lacking. Where, however, a will has actually been made, although it bears manifest improprieties and errors in expression upon its face, there is ordinarily no direct and certain remedy. Equity can not *reform* a will as it reforms a deed or a contract. The same result is, however, often attained by the application by the court of the generous principles of interpretation and construction which prevail in the case of wills. (See INTERPRETATION.) So, on the other hand, the courts will admit to probate a will which has been destroyed by the testator, where it is made to appear that it was destroyed by mistake, or without the intention to revoke.

Money paid by Mistake.—This is perhaps the most frequent and familiar case of mistake against which the courts afford relief. They do this by permitting the party who made the mistaken payment to bring an action against the payee for the recovery of the money paid out. Though the action is in form an action in contract, and is usually so described, it is essentially an equitable remedy administered on equitable grounds by the courts of common law. (See QUASI-CONTRACT.) The theory on which a recovery is allowed is that it would be against conscience for the defendant to retain the money paid to him by mistake; but the mistake must be of a material fact, and it must be an unqualified error. Money paid with knowledge that the payee is not entitled thereto can not be recovered. The law will not permit one who knows or believes that a claim is not well founded to make the voluntary payment thereof a reason for shifting his position from that of defendant to that of plaintiff. However, where the party making the payment had had full knowledge of the facts but had forgotten them, he is entitled to bring his action. On the other hand, where the party making the payment received an equivalent, or, perhaps, any consideration for the payment, even a genuine mistake will not avoid the transaction.

It is the general rule in this class of cases that the remedy will be afforded even where the parties can no longer be put *in statu quo*, but this rule does not apply where the negligence of the plaintiff has rendered it impossible to restore the payee to the position occupied by him before the payment was made.

It may be added that it is the rule in England, and generally, though not universally, in the U. S., that money paid under a *mistake of law* can not be recovered. There seems to be no reasonable ground for this discrimination, which is probably based on the mistaken notion, above referred to, of the existence of a rule that all persons are presumed to know the law.

Crimes.—The rule which refuses to allow a person to escape the consequences of his legal errors finds a reasonable and proper application in the domain of criminal law. Here it would be in the highest degree dangerous to allow a wrongdoer to plead his ignorance of the law which he has violated. Such ignorance, accordingly, is in no case an excuse for the offense committed, though it may, under certain circumstances, be relevant to the question of the wrongdoer's intention or state of mind. Ignorance or mistake of fact, however, will usually be taken into account, and will relieve the wrongdoer from the consequences of his mistake in all cases where *knowledge* is of the essence of the crime charged. Thus if A, shooting at a person whom, upon reasonable grounds, he supposes to be a burglar, kills a person who is not a burglar, he is in the same situation as if he had killed a burglar. On the other hand, there are many statutory crimes where no provision is made for the element of innocent intention due to ignorance of a fundamental fact. Thus if A abducts B, a girl under fifteen years of age, from her father's house, believing in good faith and on reasonable grounds that B is eighteen years of age, A commits the offense of abduction, although if B had been eighteen years of age she would not have been within the statute.

For a fuller treatment of the whole subject, see Pollock *On Contracts*; for the special topics, see Anson *On Contracts*, Keener *On Quasi-contracts*, Story *On Equity Jurisprudence*, Jarman *On Wills*, and Stephen's *Digest of Criminal Law*.

GEORGE W. KIRCHWEY.

Mistassini [Cree, *Mista-ssini*, or Great Rock]; a lake of Labrador, in lat. 51° N., lon. 72° W., just N. of the "Height of Land" or watershed and on the Hudson Bay versant. It receives considerable drainage from the north, and empties, through Rupert river, 120 miles long, into James's Bay. It is of very irregular form, with many long islands running N. E. and S. W. Reports of its size vary much, but an exploring expedition in 1884 found it about 100 miles long and only 13 or 14 broad, while at some points it had great depth. A smaller lake lies parallel to it and not far eastward. This region has a rigorous winter, but it is picturesque, abounds in game and fish, and has a good soil with some agricultural possibilities. See Bell, *Information regarding Lake Mistassini* (Montreal, 1884). M. W. H.

Misteli, FRANZ JOSEF, Ph. D.: philologist; b. at Solothurn, in Switzerland, Mar. 11, 1841; was educated at the Universities of Zurich and Bonn; was a teacher in the gymnasiums of St. Gallen and Solothurn, and since 1874 has been Professor of Comparative Philology at Basel. He is a member of the Finnish-Ugrian Society of Helsingfors and of the Hungarian Academy of Budapest; is author of various articles on subjects relating to comparative philology and speech-philosophy in the Steinthal-Lazarus *Zeitschrift für Völkerpsychologie*; also of *Ueber griech. Betonung* (1875);

Erläuterungen zur allgemeinen Theorie der griech. Betonung (1875); reviser of the new edition of Steinthal's *Charakteristik der hauptsächlichsten Typen des Sprachbaues* (1860, 1893). BENJ. IDE WHEELER.

Mistletoe [O. Eng. *misteltān*, liter., mistletoe sprig; *mistel*, mistletoe + *tān*, twig]: a parasitic dicotyledonous shrub, of the family *Loranthaceæ*, with opposite leaves, reduced diœcious flowers, and a single inferior one-celled ovary. The mistletoe of the Old World is *Viscum album*, a common parasite upon apple-trees in England, rarely upon oaks. The yellowish-green foliage is in great demand for Christmas decoration. The American mistletoe resembles the foregoing, but belongs to the genus *Phoradendron*. One species (*P. flavescens*) is common from New Jersey to Southern Indiana, Missouri, and southward, upon many trees, forming pale-green clumps from 2 to 4 feet in diameter. This species is used for Christmas decorations in the U. S. Several other species occur southwestward and in California.
CHARLES E. BESSEY.

Mistral [Fr.; Provenç. *mistraou*; Ital. *maestro*, the master]: a norther or land wind on the southern shore of France, cold, dry, gusty, and sometimes violent, injurious to vegetation, and hard to endure. It is most frequent and violent in winter, and is felt along the coast from the mouth of the Ebro to the head of the Gulf of Genoa, but it extends inland and becomes most violent in Provence and Languedoc, especially over the delta of the Rhône. In the lower Rhône valley it occurs every two or three days, and at Marseilles it blows on the average 175 days in the year. It is so violent as sometimes to overturn railway trains. It resembles the Bora of Istria and the norther of Texas. M. W. H.

Mistral, mēēs'trăăl', FREDERIC: poet; b. at Maillane, Bouches-du Rhône, France, Sept. 8, 1830. After studying law at Avignon, he returned to his little native town, and set himself to writing in the dialect of Southern France, which in the hands of Jasmin had begun to recover its former prestige as a literary language. He speedily allied himself with other young men who were cherishing the same aims; and in 1854 he was one of the seven founders of the famous society of Felibrige. After numerous lesser efforts, he published in 1859 a work in the revived tongue that at once made him famous. This was the half-pastoral, half-mystic narrative poem *Mirèio*—full of the color and the sentiment of Provence. So great repute did this work give Mistral that in 1861 the French Academy decreed him its chief poetic prize. Fame, however, did not change the course of his life. He remained at Maillane, writing much both in verse and prose for the *Aïòli*, the *Armana prouvençau*, and other organs of the coterie. In 1867 he brought out a second narrative in verse, *Calendau*, which shows the results of his studies in mediæval Provençal literature. From this time, indeed, his interests gradually became more scientific. The founding of the Société des Langues Romanes at Montpellier, in which he was actively interested, was a sign of the same tendency among all the best of the group to which he belonged. In 1876 he published a collection of his shorter poems under the title *Lis Isclo d'or*. For some time, however, he had been at work upon a great philological task, intended of course to advance the cause he was devoted to—his *Tresor dóu Felibrige*, or dictionary of the dialects of Provence (2 vols., 1878–86). An interesting romance, *Nerto* (1884), dealing with mediæval life in Southern France, showed, however, that he had not wholly given up literature for erudition. This has been followed by a tragedy, *La Rèmo Jano* (1890), on the much-maligned Joanna I. of Naples. There have been many editions of *Mirèio*, and three translations into English (C. H. Grant, Avignon, 1867; H. Crichton, London, 1868; Harriet W. Preston, Boston, Mass., 1872). The original text was accompanied by a French version in prose, and one in French verse has been published by E. Rigaud (Paris, 1880). It has been rendered into several other languages. A. R. MARSH.

Mitchel, JOHN: patriot; son of a Presbyterian minister; b. at Dungiven, County Derry, Ireland, Nov. 3, 1815; graduated at Trinity College in 1836; studied law and practiced for several years at Banbridge; contributed to the local newspapers and the Belfast *Chronicle*; was editor of the Dublin *Nation* for several years; wrote *Hugh O'Neil* (1845), which brought him to public notice; in 1848 started *The United Irishman* in the interests of the advanced Young Ireland party, and with the leaders was arrested, convicted of felony, and transported for fourteen years, but escaped in 1853; went to New York city, where he started *The Citizen*, advocating slavery, but gave it up, and started *The Southern Citizen* at Knoxville, Tenn., which failed; resided at Paris till the war broke out; returned to Richmond, edited *The Enquirer* in the interests of the South, and also lost two sons in its forces; returned to New York and established *The Irish Citizen*, which soon failed; went to Ireland in 1874, where, unmolested, he was elected and returned to Parliament from Tipperary; being declared ineligible, he was again returned to Parliament, but further action was rendered unnecessary by his death, at Cork, Mar. 20, 1875. He also wrote *Jail Journal* (1854); *The Last Conquest of Ireland—Perhaps* (1861); edited the poems of Thomas Davis and James C. Mangan; and wrote a continuation of McGeoghegan's *History of Ireland*. See the *Life* by William Dillon (2 vols., 1888).

Mitchel, ORMSBY MCKNIGHT, LL. D., F. R. A. S.: astronomer and soldier; b. in Union co., Ky., Aug. 28, 1810; graduated at West Point in 1829. He was promoted second lieutenant of artillery, served as Assistant Professor of Mathematics at West Point until 1831, and in garrison until 1832; resigned Sept. 30, 1832; studied law, was admitted to the bar, and practiced in Cincinnati until 1834, when he was elected Professor of Mathematics, Natural Philosophy, and Astronomy at Cincinnati College. He held this position until 1844. Through his influence an observatory was erected on Mt. Adams, within the city limits, and he procured for it in Europe a telescope and other apparatus. After his death the observatory was rebuilt on Mt. Lookout, and was given his name. He served as adjutant-general of Ohio 1847–48. The great work of Prof. Mitchel's life was the stimulus given to astronomy by his popular lectures, which were the direct cause of the establishment of observatories at Albany, Clinton, and Allegheny City. He established in July, 1846, a popular scientific journal entitled *The Sidereal Messenger*; in it, and in a school edition of Burritt's *Geography of the Heavens*, which he prepared in 1849, Prof. Mitchel published his observations upon double stars. In 1848, acting upon a suggestion of Prof. Sears C. Walker, he invented a chronograph for automatically measuring and recording right ascensions by electro-magnetic mechanism, nearly at the time a similar apparatus was constructed by Mr. Locke. In 1849 he devised a declinometer, or apparatus for the accurate measurement of large differences of declinations. During the ensuing five years (1854–59) many zones of faint stars were observed by its means, and nearly 50,000 observations were accumulated. Among the other achievements of Prof. Mitchel may be mentioned his discovery that certain stars were double, notably Antares; his numerous unpublished observations of nebulæ, solar spots, double stars, and comets (chiefly made in 1848–49); and the invention of an apparatus for finding the personal equation. In Aug., 1859, he accepted the post of director of the Dudley Observatory at Albany, N. Y., which had been erected in accordance with plans furnished by him five years before. In 1861 he tendered his military services to his country, was made brigadier-general of volunteers Aug. 9, and ordered to the department of Ohio. He distinguished himself by a forced march into Northern Alabama, seizing the railway between Corinth and Chattanooga, was made major-general Apr. 11, 1862, and given the command of the department of the South in September; but while making energetic preparations for the coming campaign was seized with yellow fever, and died at Beaufort, S. C., Oct. 30, 1862. His principal publications were *The Planetary and Stellar Worlds* (1848) and *The Orbs of Heaven* (1851). See the *Life* by his son (Boston, 1887). Revised by JAMES MERCUR.

Mitchell: city; capital of Davison co., S. D. (for location of county, see map of South Dakota, ref. 7–F); on the Chi., Mil. and St. P. and the Chi., St. P., Minn. and Om. railways; 65 miles W. by N. of Sioux Falls. It is in an agricultural region; has manufactories of chemicals and well-boring machinery, and a daily, 4 weekly, and 2 monthly periodicals; and is the seat of Dakota University (Methodist Episcopal, opened 1885). Pop. (1880) 320; (1890) 2,217; (1900) 4,055.
EDITOR OF "REPUBLICAN."

Mitchell, ALEXANDER FERRIER, D. D.: a professor and author; b. at Brechin, Forfarshire, Scotland, Sept. 10, 1822; was educated at the University of St. Andrews; has been minister at Dunnichen 1847–48; professor in the College of St. Mary and University of St. Andrews, of Hebrew, 1848–68, and of Ecclesiastical History and Divinity since 1868; was convener of the Church of Scotland's Jewish mission 1856–74; since 1860 has been convener of the Westminster

minutes committee; since 1880 convener of the Pan-Presbyterian council on *Desiderata* of Presbyterian history; is member of Scottish text and history societies; honorary member of the American Society of Church History; a representative to all the councils of the Reformed Churches; and moderator of the General Assembly 1885. He has published *The Westminster Confession of Faith: a Contribution to the Study of its History* (Edinburgh, 1866; 2d ed. 1867); *The Wedderburns and their Work* (1867); *Minutes of the General Assembly, 1644–49, with Introduction* (1874); *Introduction to Black-letter Edition of Archbishop Hamilton's Catechism* (1882); *The Westminster Assembly: its History and Standards* (Baird lectures for 1882; London, 1883); *Catechisms of the Second Reformation* (London, 1886); *Reprint, with Introduction, of the First Protestant Treatise in Scottish Dialect* (Edinburgh, 1888); *Register of Knox's Congregation in Geneva*; *Introduction to the Records of the General Assemblies in Edinburgh, 1846–47*; and many historical articles in reviews and cyclopædias.

C. K. Hoyt.

Mitchell, Donald Grant (*Ik Marvel*): author; b. at Norwich, Conn., Apr. 12, 1822; graduated at Yale in 1841; passed three years on a farm; traveled in Europe; studied law in 1846 in New York; published *Fresh Gleanings* (1847); *The Battle Summer* (1849), a record of his observations in 1848 in Paris; *The Lorgnette* (1850); *Reveries of a Bachelor* (1850); *Dream Life* (1851); was U. S. consul at Venice 1853–55; *Fudge Doings* was published in 1854; in 1855 he settled upon a farm near New Haven, Conn.; published (1863) *My Farm of Edgewood*; *Wet Days at Edgewood* (1864); *Seven Stories* (1865); *Doctor Johns*, a novel (1867); *Rural Studies* (1867); *Pictures of Edgewood* (1868); *About Old Story-tellers* (1876); *Out of Town Places* (1884); *English Lands, Letters, and Kings* (1889–90).

Revised by H. A. Beers.

Mitchell, Hinckley Gilbert, A. M., Ph. D., D. D.: minister and educator; b. at Lee, Oneida co., N. Y., Feb. 22, 1846. He was educated at Falley Seminary, Wesleyan University (A. B. 1873; A. M. 1876), Boston University, School of Theology (B. D. 1876), and at Leipzig University (Ph. D. 1879). After serving as pastor of a Methodist church at Fayette, N. Y., 1879–80, he taught Latin and Hebrew at Wesleyan University 1880–83; was instructor 1883–84, and since 1884 has been professor of Hebrew and Old Testament in Boston University. He has published *Hebrew Lessons* (1884); *Amos: an Essay in Exegesis* (1893); *Hints for Bible Students: The Pentateuch* (1893); a translation of *Theology of the Old Testament*, from the French of Ch. Piepenbring (1893).

A. Osborn.

Mitchell, Margaret Julia: actress; b. in New York city in 1832. She is best known as Maggie Mitchell. She began her stage career by playing child's parts in the Old Bowery theater. In 1851 she appeared successfully as Julia in *The Soldier's Daughter* at Burton's Chambers Street theater, New York. In 1854 she played Constance in *The Love Chase*, at the Chestnut Street theater, Philadelphia. She produced *Fanchon* at the Olympic theater, New York, in 1862, and acquired a great reputation by its performance. Other successful parts on the same lines were Mignon, Little Barefoot, and the Pearl of Savoy. She married her manager, Henry Paddock, Oct. 15, 1868.

B. B. Vallentine.

Mitchell, Maria, LL. D.: astronomer; b. at Nantucket, Mass., Aug. 1, 1818, of Quaker parentage; assisted her father, William Mitchell, in his favorite astronomical studies; gave special attention to study of nebulæ and of comets; received in 1847 a gold medal from the King of Denmark for the discovery of a comet; was afterward employed upon the Coast Survey and *The Nautical Almanac*; removed with her family to Lynn, Mass.; became in 1865 Professor of Astronomy in Vassar College; and was a member of various learned societies. The degree of LL. D. was conferred upon her by Hanover College in 1852, and by Columbia College in 1887. D. in Lynn, Mass., June 28, 1889.

Mitchell, Silas Weir, M. D.: neurologist, novelist, and poet; b. in Philadelphia, Feb. 15, 1829; son of John Kearsley Mitchell, D. D.; was educated at the University of Pennsylvania and at Jefferson Medical College, where he graduated in 1850; was greatly interested in natural history, and carried on a series of investigations regarding snake poisons, publishing in the *Smithsonian Contributions to Knowledge* in 1860 his researches upon the characteristics of rattlesnake venom, and in later years various monographs on allied topics. He was appointed an acting assistant surgeon in the army in the hospital for injuries, etc., to the nerves, in Philadelphia in 1863; here he made the observations on injuries of the nerves and their consequences that have given him a worldwide reputation. In 1871 he published a little work, *Wear and Tear, or Hints for the Overworked* (5th ed. 1887). *Injuries of the Nerves and their Consequences* appeared in 1873 (Philadelphia and London); *Lectures on the Nervous System* in 1881, 2d ed. 1885 (Philadelphia and London); *Fat and Blood* in 1885. He has published several volumes of poetry and fiction, including *Hephzibah Guinness* (Philadelphia, 1880); *The Hill of Stones, and other Poems* (Boston, 1882); *In War Time* (1884); *Roland Blake* (Boston, 1886); *A Mosque and other Poems* (Boston, 1887); *Hugh Wynne, Free Quaker* (1897); and *The Adventures of François* (1898).

Mitchell, Sir Thomas Livingstone, D. C. L., F. R. S.: explorer; b. in Stirlingshire, Scotland, in 1792; entered the British army in Portugal at the age of sixteen; was aide-de-camp to the Duke of Wellington, and afterward on the staff of the quartermaster-general till the end of the Peninsular war; was sent back to Spain as a member of Sir Henry Torrens's survey of the fields of battle; in 1827 was appointed deputy surveyor-general of New South Wales, and ultimately became surveyor-general, filling that post until his death. In that capacity he conducted four daring expeditions into the great deserts of Australia; discovered Mt. Byna, the vast region called Australia Felix, the Red, Peel, Nammoy, and Victoria rivers, explored the courses of the Darling and Glenelg rivers, and mapped out a practicable route between the colonies of Victoria and South Australia. He published in 1838 an account of his first three expeditions, and in 1848 his *Journal* of the heroic but unsuccessful effort to reach the Gulf of Carpentaria from Sydney. He also published several elementary geographical and military treatises, and an account of a "boomerang propeller" invented by him for steam vessels. He was knighted in 1839; made a colonel in 1854. D. at Park Hall, near Sydney, Oct. 5, 1855.

Mite: See Acarus.

Mitford, Mary Russell: author; b. at Alresford, Hants, England, Dec. 16, 1786; published in early life some volumes of poems, and then became a successful and highly popular prose-writer. The greater part of her life was spent near Reading. Her principal works are *Our Village*, a series of pleasant sketches (5 vols., 1824–32); *Belford Regis, Country Stories, Recollections* (1852); *Atherton and other Tales* (1854); and a number of dramas, of which *Rienzi* (1828) was the most successful. D. at Swallowfield, Jan. 10, 1855. See her *Life and Correspondence*, edited by Rev. A. G. K. L'Estrange (3 vols., 1878), and his *The Friendships of Mary Russell Mitford* (1882).

Revised by H. A. Beers.

Mitford, William: historian; b. in London, Feb. 10, 1744; was educated at Queen's College, Oxford, where he studied little but Greek; retired to his Hampshire estate, and often sat in Parliament; became Professor of History in the Royal Academy; wrote *An Inquiry into the Principles of Harmony in Languages* (2d ed. 1804) and *History of Greece* (5 vols., 1784–1815), once regarded as a standard work, but long since superseded. It is written from the aristocratic standpoint. The best edition (8 vols. 8vo, 1838) has the notes of his brother, Lord Redesdale. Mitford died at Exbury, Feb. 8, 1827.

Mithras [= Gr. Μίθρας, Pers. *Mithra*; cf. Sanskr. *Mitra*, name of a god, liter., the friendly one]: originally the Persian god of light, who was afterward identified with the sun-god. As such he was the god of wisdom as well as of everything good, and overcame the demons of darkness and of evil. By degrees he became the chief god of the Persians, though in most ancient times he was not so reckoned. In Roman times his cult was introduced into Greece and Rome, chiefly through the pirates whom Pompey conquered. Mysteries were connected with the worship of Mithras. The intrant had to pass through eighty degrees of trial before he could be initiated into the mysteries. In numerous works of art Mithras is represented as a young man in Asiatic costume kneeling upon the back of a prostrate bull, whose head he pulls back with his left hand, while with his right he plunges a sword into the bull's breast.

J. R. S. Sterrett.

Mithrida'tes (in Gr. Μιθριδάτης): a Persian name common throughout the Orient. It was the name borne by

most of the kings of Pontus.—Mithridates I. (337–302 B. C.) submitted to Alexander the Great, and was killed by Antigonus.—Mithridates II. (302–266 B. C.) withstood the successors of Alexander, and increased the kingdom.—Mithridates III. fought the Gauls.—Mithridates IV. conquered and annexed Sinope.—Mithridates V., Euergetes (156–121 B. C.), received a great part of Phrygia from the Romans for service rendered in the third Punic war.—Mithridates VI., surnamed Eupator, or more generally The Great (121–63 B. C.), b. at Sinope, the capital of the kingdom, in 134 B. C.; succeeded his father in 121 B. C.; conquered during the first period of his reign the territories along the northern coast of the Euxine as far as Chersonesus Taurica; incorporated the kingdom of Bosporus farther to the W.; turned then to the countries S. of the Euxine, attacked Cappadocia and Bithynia, and met here with the Romans. Three wars ensued, known in the history of Rome as the Mithridatic wars—namely (1) 88–85 B. C.; (2) 83–82 B. C.; and (3) 74–66 B. C. They are fully described under Sulla, Lucullus, and Pompey, and ended with the complete defeat of Mithridates, who retreated behind the Euxine, and killed himself at Panticapæum, where he was besieged by his own son, Pharnaces, in 63 B. C. Nevertheless, the Romans considered him as the most formidable enemy the republic had ever had to contend with, and he was evidently a highly gifted man, both as a general and a statesman. He had received a Greek education and spoke twenty-two languages, and, although he was an Asiatic despot in all his measures and in his whole character, he had a fine taste for art and science. His collection of gems and his library of medical books were celebrated. See Reinach, *Mithridate Eupator* (Paris, 1890). J. R. S. Sterrett.

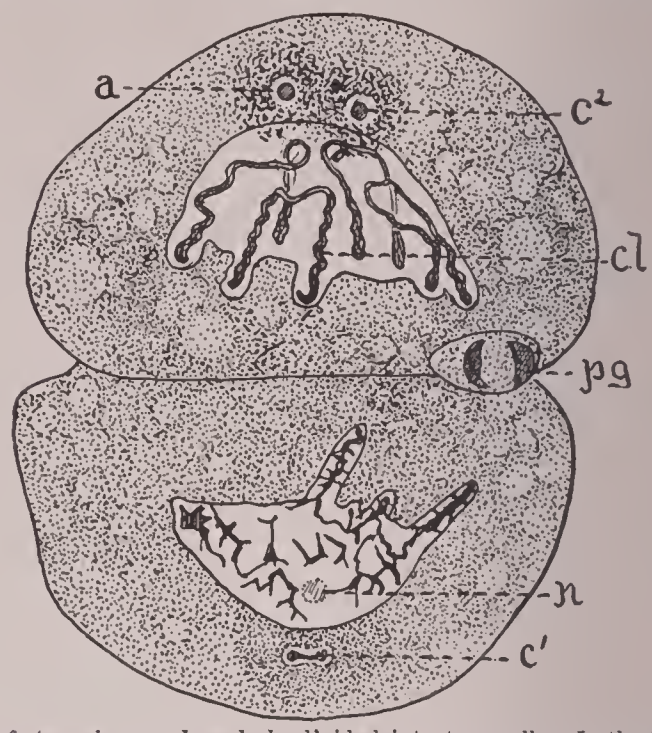
Mit'la, or **Mictlan'**: See Mexican Antiquities.

Mito: an old town and clan of Northern Japan; in the province of Hitachi and prefecture of Ibaraki (see map of Japan, ref. 6–E). The town lies 7 miles inland from the Pacific, and is five hours distant by rail from Tokio. The castle, a most picturesque spot, has not been dismantled, but the inclosure is now devoted to educational purposes. During the civil war of the restoration it was the scene of severe fighting, traces of which remain. Mito was ruled by a succession of able princes closely allied by blood to the Tokugawa shoguns, to whom they supplied regents in the case of a minority, and in some cases heirs, the last shogun, Keiki, being a son of the lord of Mito. It was and is a center of Confucianism and conservatism. A fine garden, constructed by Rekko, the most famous of its princes, is now the public garden; that formerly attached to the Mito residence in Tokio is the finest in the empire. Pop. 19,000. There are manufactures of cloth and household utensils.

J. M. Dixon.

Mito'sis: a term introduced by Flemming for indirect cell-division, called by Schleicher karyokinesis. In outline the process is as follows: Each cell of animal or plant (see Cell) consists of different kinds of protoplasm arranged in a subcentral *nucleus* and in extra-nuclear protoplasm or *cytoplasm*. Most characteristic of the nucleus is a peculiar substance known as chromatin, from the readiness with which it takes histological stains. This chromatin, in the resting nucleus in the shape of a network, is supported in a secondary network of non-stainable material, the *linin*, and the interstices of these networks are occupied by the nuclear fluid. In the cytoplasm there exists likewise a network of firmer material, in the meshes of which is more fluid material. Besides these two long-known portions, recent investigations have shown the existence in the cytoplasm of a distinct structure, the *pole-body* or *aster*. This consists of a central portion or *centrosome* surrounded by a clear space or *archoplasm*, and outside this a denser mass of granules, frequently arranged in a radiating manner around the centrosome, the whole presenting a starlike appearance, justifying the term aster.

In the ordinary or mitotic cell-division the aster apparently takes the initiative. Lying as it does on one side of the nucleus, it divides into two equal portions, each of which moves a quarter way around the nucleus until the new asters come to lie at opposite poles. At the same time the starlike appearance is being formed around each centrosome, while on one side the rays from the two stars intermingle, giving rise eventually to a spindle-shaped figure between the two. The appearance has well been compared to the "lines of force" exhibited by iron filings between the poles of a horseshoe magnet. In the meantime the nuclear structures are exhibiting changes. The network of chromatin becomes converted into a long filament which is coiled like a wreath. Then the filament becomes thickened, and finally it breaks into V-shaped loops, the number varying with different species. While this is going on the nuclear wall, separating the nucleus from the cytoplasm, breaks down, and at last the chromatin loops become ar-



Egg of *Ascaris megalocephala* divided into two cells. In the lower the nucleus is in the resting stage and the chromatin is irregularly distributed; the centrosome (c^1) is beginning to divide. In the upper cell the centrosome has divided, while the chromatin loops (*cl*) have formed. *a*, archoplasm; c^1 c^2, centrosomes; *cl*, chromatin loops; *n*, nucleolus; *pg*, polar globule.

ranged in a plane around the spindle. The next step is the equal division of the loops. Each splits lengthwise, the split beginning at the folded end. As it progresses one half of each loop moves along the threads of the spindle toward one centrosome, and the other half travels in a similar manner toward the other. When these loops have reached their respective poles, the spindle threads break and are withdrawn, while the loops unite again into a wreath, and then become modified into the nuclear network of the new nucleus. A new nuclear wall forms, and, after these steps are complete, a constriction appears in the cytoplasm which results in its division into two cells.

Recent investigations have shown this division by mitosis to be almost universal. The direct or amitotic division occurs comparatively rarely. In this case all the strange steps outlined above are lacking, the cell and its nucleus are simply drawn apart like so much plastic matter.

The meaning of mitosis has not yet been placed beyond a doubt. There is evidently some important function to be fulfilled by such a complicated process to bring about an equal division of the chromatin, and upon these phenomena several theories of Heredity (*q. v.*), notably that of Weismann, have been based. It is noticeable that amitosis takes place only in fully differentiated tissues. The literature of mitosis in the last two decades has reached enormous proportions. The most recent summary of our knowledge is to be found in O. Hertwig's *Die Zelle und die Gewebe* (Jena, 1893), where full references to the literature will be found.

J. S. Kingsley.

Mitrailleuse: See Machine and Rapid-fire Guns.

Mitre, mee'trā, Bartolomé: general, politician, journalist, and author; b. at Buenos Ayres, Argentine Republic, June 26, 1821. His father, a schoolmaster, educated him carefully, and before he was eighteen he began to make his mark in literature. The persecutions of Rosas forced the family to emigrate to Montevideo, where young Mitre served as an officer in the defense of the city during part of the "nine years' siege." The opposition to Argentine officers drove him in 1846 to Bolivia, where he was chief of staff to President Ballivian and director of a military school. After Ballivian's deposition (1847) he went to Peru, and thence to Chili; here he devoted himself to journalism. In 1851–52 he was banished to Peru for alleged complicity in revolts. He joined Urquiza in the campaign against Rosas, and took a prominent part in the battle of Monte Caseros (Feb.

3, 1852), when the dictator was overthrown. Urquiza, as the leader of the federalists, became president of the Argentine Confederation. Elected deputy, Mitre at once took the lead of the "unitarian" party, which aimed at the establishment of a strong central government and a free press, and through his influence Buenos Ayres set up a separate government (Sept. 11, 1852). Urquiza, at the head of the other states, made vain efforts to reduce Buenos Ayres to submission, and in 1859 appealed to arms. Mitre, then Minister of War for Buenos Ayres, took the field against him, and was defeated at the battle of Cepeda Oct. 23, 1859; Buenos Ayres was thus forced to re-enter the confederation. Mitre was immediately elected governor of the new state, and in this office he continued to resist Urquiza and his successor, Derqui. War again broke out, and on Sept. 17, 1861, Mitre defeated the federalist army of Urquiza at the battle of Pavon. The result was the dissolution of the old confederation. Elected president *ad interim*, Mitre called a constituent congress, which met at Buenos Ayres May 25, 1862, and adopted the present constitution of the Argentine Republic. Under it Mitre was duly elected president for six years in Oct., 1862. With him began an era of unparalleled prosperity. Paraguay having declared war on the Argentine in 1865, Mitre joined with Brazil and Uruguay in the triple alliance against that country, and until 1867 he commanded the allied forces. He was succeeded in the presidency (1868) by Sarmiento, who appointed him special envoy to Brazil. In 1874 he was again a presidential candidate, and, failing of election, headed a short-lived rebellion. Mitre was hardly less distinguished in literature than in politics. Besides poems, sketches, political writings, etc., he published two important historical works—the *Historia de Belgrano* (1857) and *Historia de San Martin* (3 vols., 1869). The latter, though in its inception a biography, is really a history of the war for independence in South America, and shows great research; an English abridged translation by Pilling bears the title *The Emancipation of South America* (London, 1892). In 1853 Mitre established at Buenos Ayres a daily newspaper, *La Nación*, which continued under his control, and is now the most important paper in South America. D. at Buenos Ayres, Jan., 1894. H. H. Smith.

Mitylene: See Lesbos.

Miv'art, St. George, F. R. S.: anatomist and zoölogist; b. in London, Nov. 30, 1827; was educated at Clapham Grammar School, King's College, London, and St. Mary's, Oscott. Although he studied law and was admitted to the bar in 1851, he devoted himself to science, and in 1862 became lecturer on Comparative Anatomy and Zoölogy at St. Mary's Medical School, London, a position he held until 1884. From 1874 to 1877 he was Professor of Biology at the Catholic University College, Kensington, and since 1890 he has been Professor of the Philosophy of Natural History at the University of Louvain, Belgium. Prof. Mivart has been vice-president of the Linnean and Zoölogical Societies of London, and has published many papers, chiefly anatomical, in the *Proceedings* and *Transactions* of these societies, and in the *Philosophical Transactions* of the Royal Society. Among his other works are *The Genesis of Species* (1870–71); *Lessons in Elementary Anatomy* (1872); *Man and Apes* (1873); *Contemporary Evolution* (1876); *The Cat, an Introduction to the Study of Back-boned Animals* (1881); *The Origin of Human Reason* (1889); *Monograph of the Canidæ* (1890); and *Types of Animal Life* (1893). He is widely known as an opponent of certain features of the Darwinian theory, denying that evolution is applicable to the human intellect. D. April 1, 1900. F. A. Lucas.

Mixed Mathematics: the application of mathematical principles to scientific investigations or to practical construction in the arts. The term is used in contradistinction to "pure mathematics," which is applied to the investigations of the purely scientific principles of mathematics.

Mixed Modes (in music): See Mode.

Mixes: See Indians of Central America.

Mizon, Lieut. L.: See the Appendix.

Mnemonics, nĕe-mon'iks [from Gr. *μνημονικός*, mnemonic, deriv. of *μνήμων*, mindful, remembering, deriv. of *μνήμη*, memory]: artificial systems intended to aid the memory. They were highly esteemed in antiquity, attracted much attention after the revival of learning, and still claim a share of popular interest. The systems depend on associations, usually of an artificial sort. The plan commonly used by the Greeks and Romans was to select a real or imaginary house, and impress on the mind the different rooms with their walls, windows, furniture, etc. In preparing a discourse each part (cf. the phrase "in the first place") was associated with a given room, and the subdivisions, etc., with the parts of the room; then the orator in delivering the discourse would imagine himself going through the rooms and seeing the parts with which he had associated his headings. Houses were also set apart for memory of different classes of facts, and symbols were "stored" up in them. Then the houses were combined to make a street or town. A different plan, approved by Winckelman and Leibnitz for the memory of dates, etc., is to associate letters with the numbers. The letters, usually consonants, corresponding to the numbers, are made into real or meaningless words by the addition of other letters, and the words are associated with the fact to be remembered. Thus if it be desired to remember that printing was invented about 1436, according to one system 1 = t, 4 = r, 3 = m, and 6 = g, and the combination *tremengous* can be formed and associated with printing because it was such an important discovery. Other systems consist of memorizing series of images, and especially memorial rhythms which are associated with the facts to be remembered. Or intermediate or additional associations, often of an absurd or startling character, are added. Systems of mnemonics will doubtless enable "the victims" to call up disconnected dates and facts which it might not otherwise be possible to remember; but it may well be doubted whether it be any advantage to keep such things in mind. There are some cases (e. g. the number of days in the months and the rhythm, "Thirty days hath September, April, June, and November") where an artificial aid may be worth the while, but the elaborate systems which have been proposed would seem to crowd the mind with useless furniture and interfere with logical and judicious memory. Bacon compared the feats of memory which can be performed by such systems with the exhibitions of rope-dancers, which may "cause admiration" but "can not be highly esteemed." True methods for cultivating the memory are logical ways of conceiving, classifying, and analyzing facts, and connecting them with central and permanent interests. J. McKeen Cattell.

Mnemotechnics [Gr. *μνήμη*, memory + *τέχνη*, art]: the art of memorizing, together with the artificial devices and systems for aiding the memory. Another and more common term is Mnemonics (*q. v.*).

Mnevis: the sacred ox or bull of Heliopolis, probably dedicated to the sun-god, Ra, as was the city (Strabo, xvii., i., 22, 27), or possibly to Osiris (Plutarch, *Isis*, § 33) as Osiris-Mnevis. His cult is supposed to have been similar to that of the Apis bull at Memphis (see Serapis), and to have furnished the prototype of the golden calf worshiped by Israel in the desert (Ex. xxxii.). See also Wilkinson, *Ancient Egyptians*, iii., 306–307. As to the color of the animal there is some uncertainty. Ancient authors speak of it as black, but on the basis of obscure inscriptions some suppose it to have been white. Charles R. Gillett.

Moa: supposed to have been the Maori name for the extinct gigantic birds of New Zealand, and now used as a common name for any species of Dinornis (*q. v.*).

Mo'abites [deriv. of *Moab*, from Heb. *Mō'ābh*]: descendants of Moab, the son of Lot by his eldest daughter (Gen. xix. 37). An idolatrous people, they were hostile to the Israelites, in spite of the relationship between them. The southern boundary of the Moabites was the brook Zered (the modern Wady el-Ahsy), which empties into the southeast corner of the Dead Sea. Their territory was about 20 miles from E. to W., and at one time extended as far N. (50 miles) as the mountains of Gilead. At the time of the Exodus they had lost about 30 miles of territory, having been driven S. of the Arnon by the Amorites. Subdued by David, they regained their independence after the dismemberment of the Hebrew kingdom, aided Nebuchadnezzar (604–561 B. C.) against the Jews (2 Kgs. xxiv. 2) and rejoiced in their overthrow (Ezek. xxv. 8–11; Zeph. ii. 8–10), which conduct induced the prophetic denunciations of Isaiah (xv., xvi., xxv. 10), Jeremiah (xxv. 21; xlviii.), and Amos (ii. 1–3), all of which were fulfilled, for they soon after disappear from history.

Moabite Stone, The: a stone or block which celebrated the achievements of one of the Moabite kings, Mesha (about 900 B. C.). It was of black basalt, 3 ft. 8½ in. high, 2 ft. 3½ in.

wide, and 1 ft. $1\frac{78}{100}$ in. thick, rounded at both ends, and inscribed with thirty-four lines of Hebrew-Phœnician writing. It was found Aug. 19, 1868, by the Rev. Mr. Klein at Dhiban (the ancient *Dibon*), just N. of the Arnon. Though broken to pieces afterward by the Arabs, six-sevenths of the inscription have been preserved, and two-thirds of the stone itself are now in London. This inscription proves that the Greeks added nothing to the alphabet which was brought to them from the East. The best edition of the text, with a translation and copious notes, is by Canon Driver in his *Notes on the Hebrew Text of the Books of Samuel, with an Introduction on Hebrew Palæography, and the Ancient Versions and Facsimiles of Inscriptions* (Oxford and New York, 1890, pp. lxxxiv.–xciv.). He thus translates it:

1. I am Mesha son of Chemoshmelek, king of Moab, the Da-
2. -ibonite. My father reigned over Moab for 30 years, and I reign-
3. -ed after my father. And I made this high place for Chemosh in QRHH, a high place of sal-
4. -vation, because he had saved me from all the kiugs (?), and because he had let me see my pleasure on all them that hated me. Omr-
5. -i was king over Israel, and he afflicted Moab for many days, because Chemosh was angry with his la-
6. -nd. And his son succeeded him; and he also said, I will afflict Moab. In my days said he th[us;]
7. but I saw my pleasure on him, and on his house, and Israel perished with an everlasting destruction. And Omri took possession of the [la-]
8. -nd of Mehedeba, and it (i. e. Israel) dwelt therein, during his days, and half his son's days, forty years; but [resto-]
9. -red it Chemosh in my days. And I built Baal-Meon, and I made in it the reservoir (?); and I built
10. Qiryathen. And the men of Gad had dwelt in the land of Ataroth from of old; and built for himself the king of I-
11. -srael Ataroth. And I fought against the city, and took it. And I slew all the [people of]
12. the city, a gazingstock unto Chemosh, and unto Moab. And I brought back (*or*, took captive) thence the altar-hearth of Davdoh (?), and I drag-
13. -ged it before Chemosh in Qeriyyoth. And I settled therein the men of SHRN, and the men of
14. MHRTH. And Chemosh said unto me, Go, take Nebo against Israel. And I
15. went by night, and fought against it from the break of dawn until noon. And I too-
16. -k it, and slew the whole of it, 7,000 men and . . . , and women, and . . . .
17. -s, and maid-servants: for I had devoted it to Ashtor-Chemosh. And I took thence the [ves-]
18. [-sels] of YAHWEH, and I dragged them before Chemosh. And the king of Israel had built
19. Yahaz, and abode in it, while he fought against me. But Chemosh drave him out from before me; and
20. I took of Moab 200 men, even all its chiefs; and I led them up against Yahaz, and took it
21. to add it unto Daibon. I built QRHH, the wall of Ye-arim (*or*, of the Woods) and the wall of
22. the Mound. And I built its gates, and I built its towers. And
23. I built the king's palace, aud I made the two reser[voirs (?) for wa]ter in the midst of
24. the city. And there was no cistern in the midst of the city, in QRHH. And I said to all the people, Make
25. you every man a cistern in his house. And I cut out the cutting for QRHH with the help of prisoner-
26. [-s of] Israel. I built Aroer, and I made the highway by the Arnon.
27. I built Beth-Bamoth, for it was pulled down. I built Bezer, for ruins
28. [had it become. And the chie]fs of Daibon were fifty, for all Daibon was obedient (to me). And I reign-
29. -ed [over] an hundred [chiefs] in the cities which I added to the land. And I buil-
30. -t Mehede[b]a and Beth-Diblathen, and Beth-Baal-Meon; and I took there the sheep-grazers (?),
31. . . . . sheep of the land. And as for Horonen, there dwelt therein . . . . and . . . .
32. . . . . Chemosh said unto me, Go down, fight against Horonen. And I went down . . . .
33. . . . . [and] Chemosh [resto]red it in my days. And I went up thence to . . . .
34. . . . . And I . . . .

Moaviah: See OMMIADES.

Moberly: city; Randolph co., Mo. (for location of county, see map of Missouri, ref. 3–G); on the Mo., Kan. and Tex. and the Wabash railways: 130 miles E. by N. of Kansas City. 148 miles W. of St. Louis. It contains the division headquarters and machine-shops of the Wabash railway system, 2 vitrified pressed-brick plants, flour and planing mills, machinery repair-shops, foundry, agricultural-implement works, and ice-factory, and has a national bank and 2 daily and 4 other periodicals. Pop. (1890) 8,215; (1900) 8,012.

EDITOR OF "MONITOR."

Mobile: city (founded in 1702, capital of the province of Louisiana till 1720, captured from the English by the Spanish in 1780, occupied by the U. S. troops in 1813, incorporated as a city in 1819, area reduced and name changed to Port of Mobile in 1870, rights of municipal government restored in 1887); capital of Mobile co., Ala., and only port of entry in the State (for location, see map of Alabama, ref. 8–A). It is on the Mobile river near its entrance into Mobile Bay, and on the Louisv. and Nashv., the Southern, and the Mobile and Ohio railways; 30 miles N. of the Gulf of Mexico, 140 miles E. of New Orleans. The city is built on a sandy plain rising from the river's bank, and in the suburbs are several attractive hills on which are many costly residences. It has a newly constructed, city owned water-supply from Spring Hill, 7 miles distant, from Clear Creek, 11 miles distant, and from artesian wells, struck in 1892. A complete sewerage system was constructed in 1900. Modern quarantine protective measures have relieved the people from all apprehension of danger from yellow fever. The harbor, formerly very shallow, has been improved by the U. S. Government, and vessels drawing 23 feet of water are admitted to the city wharves. Mobile has an extensive export trade, particularly in cotton and naval stores, lumber, rosin, turpentine, iron, and coal, and Western foodstuffs, machinery, etc., and an import trade chiefly in tropical fruits, sisal grass, and wood. In the calendar year 1900 the value of exports was $14,095,029, and of imports $2,934,071. The census returns of 1890 showed that 229 manufacturing establishments (representing 51 industries) reported. These had a combined capital of $1,450,373; employed 2,331 persons; paid $857,660 for wages and $1,433,136 for materials; and had products valued at $2,872,017. The principal industry according to the amount of capital employed was the manufacture of lumber, which had 9 establishments and $564,910 capital, employed 703 persons, paid $220,594 for wages and $513,376 for materials, and had products valued at $937,499. Then followed printing and publishing, foundry and machine-shop products, saddlery and harness, flour and grist mill products, tobacco, and ship-building. Market-gardening has become an important industry, having an average annual product valued at $500,000. The city has 52 churches, a Jesuit college at Spring Hill, Roman Catholic academy at Summerville, 9 other Catholic schools, Barton Academy, Alabama Medical College, 3 libraries (Public and Bar) with about 30,000 volumes, 4 orphan asylums, U. S. Marine Hospital, a port hospital, Providence Infirmary, U. S. Government building, 2 State banks, with combined capital of $250,000, 2 national banks with capital of $550,000, and 3 daily and 12 weekly periodicals. Pop. (1890) 31,076; (1900) 38,469.

EDITOR OF "REGISTER."

Mobile River: a stream formed by the confluence of the Alabama and Tombigbee rivers. A few miles below the junction it divides into two branches, of which the eastern is called Tensas, and both branches subdivide into several others, which meet in a common embouchure at the head of Mobile Bay. The total length of the Mobile river proper is 50 miles. The city of Mobile is on its west bank.

Moccasin [Indian, Algonquian, *makisin*], or **Water-moccasin**: a very venomous serpent of the Southern U. S., found in swamps and wet places, and even in water. It is 2 feet long, dark brown above and gray beneath. Its bite is justly dreaded. Its scientific name is *Ancistrodon* (*Toxicophis*) *piscivorus*. The name moccasin is also given to the copperhead (*Ancistrodon contortrix*).

Moccasin Flower: See CYPRIPEDIUM.

Mo'cha: town; in the province of Yemen, Arabia; on the Red Sea, in lat. 13° 19′ N. (see map of Persia and Arabia, ref. 10–D). It has a good, strongly fortified harbor, and is the most celebrated coffee-market in the world. Mocha is a comparatively modern city, probably much later than the establishment of Islamism. It became rapidly important as the place of export of the coffees of Yemen, hence called Mocha coffee. The place has lost its importance and decayed, especially since the British took possession of Aden. Pop. about 5,000.

Revised by M. W. HARRINGTON.

Mocha-stone: See CHALCEDONY.

Mocking-bird: a singing-bird (*Mimus polyglottus*) of the family *Turdidæ*, found in the warmer parts of North America. Its general color is ashy brown above, white below, with the outer tail feathers and bases of primaries white. It is a rare summer visitant in the more Northern States. The mocking-bird is reputed to be the best American songbird. Besides its own delightful song, it imitates the notes of most other birds. It readily learns to whistle tunes, but not to talk. The mocking-bird bears confinement well, especially if taken when young from the nest. Its song in the cage is often superior to that of the wild bird, but the

bird often becomes a nuisance from its persistent utterance of loud whistling notes. Revised by F. A. Lucas.

Mode, or **Mood**: See Verb.

Mode [viâ O. Fr. from Lat. *mo'dus*, measure, due measure, manner, mode, rhythm, melody]: in modern music, a certain scheme or arrangement of sounds in direct order from low to high, or *vice versa*, under which they are recognized by the ear as forming a complete and conclusive series extending over eight degrees, and having a distinctly marked beginning, progress, and ending. If the eight principal sounds comprised in the octave were *equidistant*, there could be only one such mode or system, inasmuch as a series of notes commencing on D or E, etc., would differ only in point of pitch (not in quality) from another series commencing on B or C; but as it is, we find in the octave five whole tones and two *semi*-tones; and it is also essential that these tones and semitones shall fall into a certain order to render the scale available in modern music. That order may be twofold—viz., major and minor—and these two forms of scales constitute the two *modes* now in use, the third above the tonic being in the one case major, and in the other minor. The pattern scale of the *major* mode, with the places of its two smaller intervals or semitones marked by slurs, is given in Ex. 1:

Ex. 1.

From no other starting-point but C can such a scale be formed by the use of the natural notes or intervals, inasmuch as the relative positions of the two semitones between the third and fourth and the seventh and eighth could not be preserved if we should begin on D, E, F, or any other degree of the scale. A scale in this mode may, however, be founded on any other degree by the use of such sharps or flats as may be found necessary to raise or lower the incorrect intervals, and thus bring them into conformity with the normal scale of C. (See Transposition.) The pattern scale of the *minor* mode (that of A), with the peculiar position of its two semitones, is shown in Ex. 2:

Ex. 2.

A scale such as this also can be formed from the natural notes only by beginning on A. But (as in the major mode) it may take its rise from any other degree of the scale by using the necessary sharps or flats to bring its intervals into correspondence with the model.

The distinction between the two modes springs chiefly from the dissimilarity of the respective thirds, sixths, and sevenths, which are all (in their natural or original form) one semitone greater in the major than in the minor mode. These intervals are therefore the characteristic and essential elements of the modes when those modes are viewed in their simple and normal condition. In the minor mode there is a certain peculiarity which does not appertain to the major—viz., a difference between the ascending and the descending scale—and also an indeterminate or equivocal quality in the sixth and seventh of the scale which is too subtle to be regulated by any fixed rule. In the ascending scale (see Ex. 2) it will be observed that the seventh is *minor*, and for that reason can not be a true and satisfactory "leading note" to the octave above. The interval of a whole tone thus existing between the seventh and the eighth is disappointing and repulsive to the cultivated ear, and especially so in final cadences. To obviate this, it becomes necessary to bring the seventh one semitone nearer to the octave by means of a sharp, thereby constituting it a leading note similar to that of the major mode. By this process we create a new difficulty by widening the distance between the *sixth* and the seventh into the interval of an augmented second. This also admits of adjustment by raising the sixth also a semitone, which places it now midway between the fifth and the seventh. With these modifications the ascending minor scale of A will stand as in Ex. 3:

Ex. 3.

It is a valid objection, however, to this sharping of the *sixth* that it renders the upper part of the minor scale identical with that of the major; for it is evident that by such a process every trace of a distinctively minor mode is obliterated. On comparing the altered minor scale at *a*, in Ex. 4, with the major scale at *b*, it will be seen that *from the fourth upward* there is no difference whatever:

Ex. 4.—*a*

For this reason composers of instrumental music often prefer the use of the natural to the sharped sixth; and this not only when the progression of the melody turns *downward* from the sixth, but also when it *ascends* to the sharped seventh and the octave. Some illustrations of this are given at *a*, *b*, and *c* in Ex. 5:

Ex. 5.

A similar difference of opinion and practice prevails also in regard to the *descending* scale in the minor mode. Ordinarily, the seventh and sixth are taken in their natural form—i. e. unchanged by sharps, etc.; but frequently the progression by the sharped seventh and the *natural* sixth is preferred, and in numerous cases is even imperative. In this form, as shown in Ex. 6, one of the strongest characteristic intervals of the mode is preserved—viz., the somber and plaintive effect of the sixth:

Ex. 6.

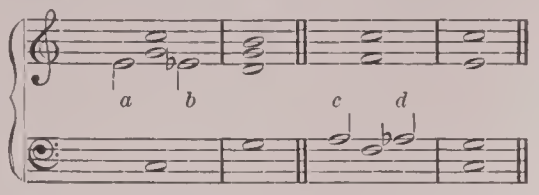
In this form of the descending minor scale a singularly beautiful effect is produced by a chain of thirds or sixths, as at *a* in Ex. 7, while no such effect is observable when the same movement is taken on the natural notes of the scale, as at *b*:

Ex. 7.—*a*

Mixed Modes.—In modern music much of the variety and beauty of the harmony often arises from the mingling of chords belonging to one of the modes with the regular progressions of a composition written in the other. This occurs most frequently when in the course of a piece in the *major* mode certain harmonies are borrowed from the corresponding *minor*, and are substituted for those which would naturally occur. By a skillful use of this device many of the most striking and expressive traits of the minor mode may be transferred and incorporated into the major mode, thereby enriching that mode with new and singularly beautiful effects, and also surprising the ear by a train of unexpected and graceful turns of the harmony, such as could not be produced by the ordinary progressions of either of the modes exclusively. The chief characteristic intervals of the modes are the third and sixth, with the diminished seventh of the minor. Those belonging to the *minor*, when judiciously transferred into music of the major mode, as passing harmonies, not implying or leading into other keys, give a new interest and coloring even to very commonplace ideas, and are also the source of the grandest as well as the most elegant and pathetic developments of modern musical art. In its simplest form this mixing of

modes occurs when, for instance, we change the *major* triad of the tonic or subdominant into the corresponding *minor*. Thus in Ex. 1 the tonic triad of C major at *a* is exchanged at *b* for the tonic triad of C minor; and at *c* and *d* a similar change takes place with the subdominant triad:

Ex. 1.



It is quite evident here that the harmony at *a* and *c* belongs to the scale or key of C *major*, while that at *b* and *d* is derived from C *minor*. On the same principle are to be interpreted such progressions as those in Ex. 2, where several intervals of one mode are exchanged for those of the other (major yielding to minor), as indicated by the accidental flats. N. B.—By *omitting* all the flats, the example will be reduced to a simple major harmony, and may be so played:

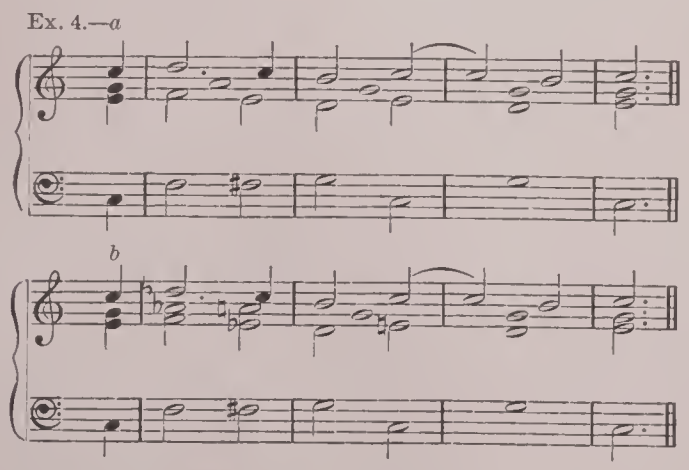
Ex. 2.

The superior richness of effect thus obtained by the mixture of modes will be still better apprehended by comparing the plain harmony of Ex. 3 at *a* with that at *b*, where two diminished sevenths are borrowed from the minor scales of F and C:

Ex. 3.

Compare also the passage at *a* in Ex. 4 with the harmony given at *b*, the mysterious beauty of which latter arises altogether from the adoption of two chords (in the first full bar) belonging to foreign scales:

Ex. 4.—*a*



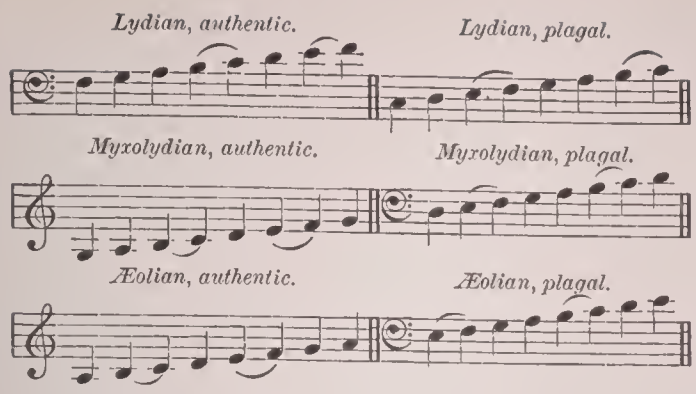
Ecclesiastical Modes are those on which, for many ages, the music of the Church was founded. Each of these scales consisted of five tones and two semitones in the octave, as in the modern diatonic scale. The notes, however, were taken in their natural order (i. e. without flats or sharps) from whatever degree of the scale the series might begin. The relative position of the two semitones to the five tones would therefore differ very much in the various scales, and music written in one scale could not be transposed to another without the loss of most of its distinguishing features. A scale beginning on C, for instance, was quite different in structure from another beginning on D or E, etc. There were, in reality, as many modes as there were scales; and with one exception they were unlike either the major or minor modes of our modern system. Each scale had its own peculiarity of form, and from that form resulted a certain quality or effect—solemn, tranquil, joyous, or plaintive—which constituted its special characteristic.

The ancient Greeks, amid their confused, bewildering, and almost unintelligible speculations concerning musical intervals and their mathematical proportions, finally classified or arranged them in these several species of octaves now called "modes." At first there appear to have been only four, and these were for the most part named after the nations to which their origin was referred. These four modes were the Dorian, Phrygian, Lydian, and Myxolydian (or mixed Lydian). The first of these began on D of the scale, the second on E, the third on F, and the fourth on G; and their scales were as in Ex. 1, with a semitone in every case falling between E and F and between B and C.

Ex. 1.

To these four modes were added by the Greeks two others called the Ionian and the Æolian, and subsequently the Hypo-Dorian (from ὑπό, below), the Hypo-Phrygian, Hypo-Lydian, Hypo-Myxolydian, Hypo-Ionian, and Hypo-Æolian, making in all twelve modes by *name*, though (as will be seen presently) several of them appear to be only duplicates. Of these modes, St. Ambrose in the fourth century selected the original four for use in the Church—viz., the Dorian, Phrygian, Lydian, and Myxolydian. And, as the plain-chant or *canto-fermo* in the early ages seldom exceeded a fourth or fifth in its compass or range of inflection, the limits of these scales were held to be sufficient for all the psalmody and liturgical demands of public worship. Eventually, however, the Church melodies were extended so as to embrace the remaining degrees of the octave, and in the course of time they assumed a character so nearly resembling what was afterward called the "florid style" as to require much more space than that afforded by the narrow bounds of the recognized modes. This led to the introduction by St. Gregory (200 years after St. Ambrose) of the other modes above mentioned, though with some modifications and under a different nomenclature. The old modes, including also the Ionian and Æolian, were called "authentic," or principal, while the added modes were styled "plagal," or subordinate: and on these twelve modes (or those most approved) the chants and other music of the Church were written. Hence the rise of the well-known "Gregorian tones" or chants, eight in number. These were short strains consisting of intonations (or introductory notes), reciting notes, mediations, cadences, and usually several terminations or "endings." The plagal modes always began on the fourth below the corresponding authentic, as if three notes below were added to the authentic, and the three upper ones omitted. In Ex. 2 all these modes, both authentic and plagal, are exhibited, and the different places of the semitones are marked, as before, by slurs:

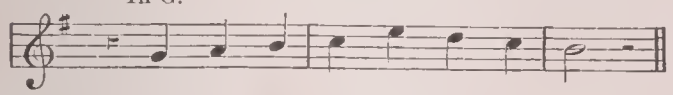
Ex. 2.



On noticing this example critically, it will be seen that several of the plagal scales are apparently mere duplicates of some of the authentic. Thus the Lydian plagal and the Ionian authentic are the same in *notes*, as are also the Myxolydian plagal and the Dorian authentic. It is not to be presumed, however, that these scales are in all respects identical. There is a probability, at least, that the Greeks made use of some kind of *temperament*, by which certain intervals of these similar scales were so far modified as to give them a special coloring or effect, and thus enable any one to recognize in them a real distinction. It is known also that the melodies, cadences, and general mode of treatment proper to the plagal were not also considered appropriate to the authentic; and thus a difference might exist, though the notes were in other respects the same. This may perhaps be better understood by observing that something similar often occurs even in modern music, an illustration of which is given in Ex. 3, where the *same train of notes* will be found to suggest different ideas, according as the notes are regarded as belonging to the key of C or that of G:

Ex. 3. In C.

In G.



There is also a further point of difference between authentic and plagal modes, which are alike in notes. Each mode was treated by the ancients as consisting of two parts or divisions, the lower and the upper. In the authentic, the lower division comprehended five degrees of the scale, and the remainder (beginning on the fifth) formed the upper division; but in the plagal the case was reversed—the lower division comprising only four degrees, while the upper (commencing on the fourth) contained five. The difference is shown in Ex. 4, where the divisions in two of the modes are marked by strokes:

Ex. 4. *Dorian, authentic.* *Dorian, plagal.*

From this it will be evident that the whole course of a melody in a plagal mode would give an impression essentially different from one in an authentic mode, even though the two should coincide in notes, and seem to form one and the same scale.

In some of the modes it was found expedient to correct the imperfection of the fourth and fifth by the use of an accidental flat or sharp. In Gregorian music the *flat* is often expressly written in cases where the note requires it; but it is probable that the *sharp* was in many cases used, though not actually written. See Grove's *Dictionary of Music and Musicians.* Revised by DUDLEY BUCK.

Mo'dena (anc. *Mutina*): a large town of Northern Italy, capital of the former duchy of Modena, which embraced the territory between Venetian Lombardy, the Pontifical States, Tuscany, and the Mediterranean, and the duchy of Parma and the kingdom of Sardinia (see map of Italy, ref. 3–D). The town itself, situated in lat. 44° 38′ N., lon. 10° 56′ E., lies in a low, moist, but healthful and fertile plain between the Secchia and the Panaro, with which rivers it is connected by canals. It is connected by canal with the Po and the Adriatic also. From the ramparts, now converted into a public promenade, the views are fine; the city itself is well built and the streets and squares are spacious. The Duomo was begun in 1099; adjoining it is the famous tower La Ghirlandina, 315 feet in height. The ducal palace, a vast and grand mediæval edifice, contains a picture-gallery with many fine works by the best Italian masters; a library of 90,000 volumes and 3,000 MSS.; a museum with 26,000 ancient medals; also archives of the greatest interest. Modena boasts many learned societies, and is conspicuous for her educational and charitable institutions. The university, founded in 1678, has nearly 300 students. There are manufactures of leather, silk, vinegar, and cast metals, and a large trade in agricultural produce. The history of this town may be traced to 200 B. C. Mark Antony besieged it without success. Cicero names it as one of the most splendid of the Roman cities. In the reign of Constantine it began to decline, and so rapidly that St. Ambrose in 387 speaks of it as "but the corpse of a city." Its mediæval history is stormy and changeful. In 1288 the Marquis Obizzo d'Este became ruler of Modena, and in 1291 also lord of Reggio. From this time, with a few brief intervals, the house of Este, in one or another of its branches, governed Modena and its dependencies until 1859. Among the most distinguished of its dukes should be mentioned Borso (1452), afterward also Duke of Ferrara, a true friend of peace and of the people; Alphonso I. (1476), a man of great genius and valor and the patron of Ariosto; Alphonso II., a brilliant and magnificent prince, whose court was made illustrious by the poet Tasso. Modena formed a part of the Cisalpine republic, but in 1814 was restored to Francis IV., who in 1831 dishonored himself by his faithlessness in the terrible affair of Ciro Menotti. Francis V. was driven out by his subjects in 1848, restored soon after by Austria, and obliged to fly a second time in 1859, soon after which Modena by a popular vote was annexed to the kingdom of Italy. Pop. (1892) 64,500.

Modes'to: town (founded in 1870); capital of Stanislaus co., Cal. (for location of county, see map of California, ref. 7–D); on Tuolumne river, and S. Pacific Railroad; 30 miles S. E. of Stockton. It is in an agricultural, wool-growing, and fruit-raising region, and in the center of the Modesto and Turlock irrigation district of 250,000 acres; contains 7 churches, gas and electric-light plants, a national bank with capital of $100,000, a State bank with capital of $175,000, and a savings-bank with capital of $20,000, and 2 daily and 3 weekly newspapers; and has manufactories of agricultural implements. Pop. (1890) 2,402; (1900) 2,024.

Modesty and Bashfulness: See the Appendix.

Mod'ica (*Sar Mohac, Motycat, Motuca*): a large town in the province of Syracuse, Sicily: in a fruitful valley surrounded by lofty hills; about 20 miles W. S. W. of Noto and about 10 miles from the sea (see map of Italy, ref. 10–F). The streets are narrow, but the buildings are good, and among them are some fine churches, a municipal palace, and a strong castle. The trade here is considerable, and the exports are wheat, barley, olive oil, hemp, etc. The chief interest of Modica for the traveler, however, consists in the remains of a troglodyte city not far distant in the direction of Spaccaforno. Pop. about 38,400.

Modjes'ka, HELENA: actress; b. in Cracow, Poland, Oct. 12, 1844. Her father was Michael Opido, a cultured man, who gave lessons in music. She manifested at an early age a taste for the stage, but did not adopt the profession, on account of family opposition. When seventeen years old she married Modrzejewska, a Government official in Cracow. When she went on the stage in the U. S. she abbreviated her name to Modjeska. In 1862 she made her first appearance in an amateur performance at Bochnia, a little town in Austrian Poland. Her success was such that a small company was organized, and, assisted by her younger sister, she played at the Government theater in Lemberg, Czernowce, and towns in Galicia. She returned to Cracow in 1865, and became the leading lady in the theater in that city. She received offers to play in France and Germany; the younger Dumas personally inviting her to appear in Paris as Marguerite Gautier in his *Dame aux Camélias.* She refused, preferring to remain in Poland. After her first husband's death, she married in Sept., 1868, Charles Bozenta Chlapowski. In Warsaw she played the heroines in the principal plays of Shakspeare, Goethe, Schiller, and Molière, and in new Polish dramas. She remained seven years in that city, and her repertory in her native tongue comprised 284 parts.

She left the stage in 1876 and went to the U. S., settling near Los Angeles, Cal., where she hoped to found a Polish colony. After studying English for a few months, she made her first appearance in the California theater, San Francisco, in 1877, as Adrienne Lecouvreur. Her success was immediate. She has since made a number of tours throughout the U. S. and in England, and also has visited Poland professionally. Beatrice, Imogen, Juliet, and Rosalind are her favorite Shakspearean characters, but she has achieved distinction as Mary Stuart and Camille. B. B. VALLENTINE.

Modulation [from Lat. *modula'tio*, deriv. of *modula'ri*, measure, regulate, modulate, deriv. of *mo'dulus*, dimin. of *mo'dus*, mode]: in music, the process by which, in any part of a composition, a transition is made from one key to another. Every piece of music, if regular, is written in some particular key, and to this several others are so nearly related that short excursions may be made into them from the original key. From a *major* key we may thus proceed to the keys of its dominant, subdominant, relative minor, and the relative minors of the dominant and subdominant —i. e. from the key of C major, for instance, we may proceed to the keys of G, F, A, E, and D, and from a *minor* key we may pass to the keys of its dominant and subdominant, its relative major, and the relative major of its dominant and subdominant; i. e. in the key of A minor we may modulate to the keys of E, D, C, G, and F. It is to be observed, also, that a transition may be made into any of these nearly related keys by the intervention of a single chord—viz., that containing the leading note and dominant of the new key. Transitions of this kind, being simple and easily effected, constitute what is called *natural* modulation. *Abrupt* modulation occurs when a transition is made into some more remote key, as from C major to A♭; or by a sudden change of the mode, as from C major to C minor, A minor to A major, etc. *Enharmonic* modulation takes place when one and the same note (with the harmony dependent upon it) is treated as equivocal or having two distinct relations, and therefore capable of progression in two entirely different directions. This occurs, for instance, when F♮ is assumed to be E♯, or when B♭ is regarded as A♯, and a transition is unexpectedly made in accordance with the *latter*, instead of the former quality of the note or chord. The modern tendency is toward remote modulation, and our ears have become so accustomed to it that much which would have horrified the composers and auditors before Beethoven's day is now accepted by us as only a mild and gentle stimulant. It is certain, however, that modulation should not be introduced *simply for the sake of modulating*, but for the purpose of illustrating some new phase of thought or emotion. To render this effective implies that the key of the piece should previously have become well defined and settled to the ear before such modulation is introduced. Otherwise the effect produced will be that of a restless uncertainty as to key and tonality. As "it is a poor rule that will not work both ways," the restlessness referred to might be exactly the purpose of the composer. Shifting modulations would then constitute the best means to that end. The student will find an admirable illustration of this idea in the first scene in Wagner's *Tannhäuser*. Revised by DUDLEY BUCK.

Module: in architecture, one-half the lower diameter of the column used as a scale of dimension for all the various parts of a classic order. The Italian architects of the middle of the sixteenth century, especially Vignola and Palladio, and later Scamozzi, sought to establish an exact canon of proportion and form for every detail of the five classic orders, based on comparative measurements of antique Roman examples. The *module* was taken as the unit, and divided into "minutes" or "parts"; twelve in the Tuscan and Doric orders, and eighteen in the Ionic, Corinthian, and composite; or, according to Sir William Chambers, into thirty minutes for all the orders. The height, projection, and thickness of every part of each order were specified in minutes and modules. This highly artificial system of proportions has never prevailed to any great extent outside of the text-books, though sometimes employed in detailed comparisons of different examples of the orders. See ARCHITECTURE and ORDERS OF ARCHITECTURE. A. D. F. H.

Modulus: See LOGARITHMS and IMAGINARY QUANTITIES.

Modulus of Elasticity: a constant number expressing a certain quality of an elastic solid. If a force is applied to elongate a bar of any material whose cross-section is 1, and whose length is L, the amount of elongation will depend upon the nature of the material and upon the intensity of the force. If the applied force is not too great, the bar will recover its original length when the force ceases to act; and the greatest strain to which a bar may be thus subjected and recover its original length is called the limit of the body's elasticity. If we denote the total elongation of the bar in question when acted upon by a force W, within the limit of the body's elasticity, by l, we shall have the relation

$$W = \frac{l}{L} \times E, \text{ or } E = \frac{WL}{l},$$

in which E is constant for each particular material; this constant is called the *modulus of elasticity*. See Mahan's *Civil Engineering*, Appendix, note D.

Moe, mō, JØRGEN ENGEBRETSEN: poet, folk-lorist, and clergyman; b. in the district of Ringerike, Norway, Apr. 22, 1813; received his first education in a public school, and was then privately prepared for the university. While receiving this tuition he gained the friendship of P. C. Asbjörnsen (see ASBJÖRNSEN, PETER CHRISTIAN), a friendship that was to be of the greatest importance not only for these two men personally, but for Norwegian literature and the study of folk-lore as well. Moe studied divinity at the university, graduated in 1839, and, after teaching school and preaching in different parts of Norway, was in 1875 appointed bishop of the diocese of Christiansand. Among his poems (*Digte*, 1850; 2d ed. 1856) are some of the most popular Norwegian romances and ballads. *I Brønden og i Kjærnet* (In the Well and in the Tarn, 1851) contains some exquisite stories for little children. Moe's chief importance lies in his activity as a gatherer and reteller of popular fairy tales. Moe made several journeys into the country to gather popular tales, first in 1835, then every year from 1841 to 1852. The full appreciation of the scientific and national value of these treasures that had been hidden among the people was only gained by Moe after he had seen the famous collection of the Grimm brothers. In 1842 he published, together with P. C. Asbjörnsen, the first installment of *Norske Folkeeventyr, samlede ved P. C. Asbjörnsen og Jørgen Moe* (1842–44; 2d ed., with a scientific introduction by Moe, 1852; 5th ed. 1874; translated by George Webbe Dasent, *Popular Tales from the Norse*, Edinburgh and New York, 1859; 3d ed. 1888). Of the sixty tales contained in the second edition of this book, thirty-one are by Moe. The influence these popular tales have had on Norwegian language, literature, and art, can hardly be overestimated; thus the present Norwegianizing of the language dates from the appearance of their work. Moe's *Samlede Skrifter* (Complete Writings) were published in two volumes by his son, Moltke Moe, in 1877. D. in Christiansand, Mar. 27, 1882. P. GROTH.

Moebius, PAUL JULIUS, M. D.: neurologist; b. at Leipzig, Germany, Jan. 24, 1853; studied medicine in the Universities of Leipzig, Jena, and Marburg, graduating M. D. from the former in 1876; in 1883 was appointed docent in his *alma mater*. He has given special attention to nervous diseases. He has been associate editor of *Schmidt's Jahrbücher* since 1885. Among his published works are *Die Nervosität* (Leipzig, 1882); *Allgemeine Diagnostik der Nervenkrankheiten* (Leipzig, 1886). S. T. ARMSTRONG.

Mö'en: an island of Denmark, in the Baltic Sea; separated from Seeland by Ulfsund, and from Falster by Grönsund. Area, 84 sq. miles. Pop. about 13,000. It is one of the most fertile and (on account of its elevated and diversified surface) one of the most beautiful of the Danish islands, presenting a row of bold bluffs toward the Baltic. Principal town, Stege.

Moeris [*Meri*, the lake, or *Mer-ur*, great lake, in the Paiom = Fayum, the lake]: an artificial reservoir covering 63 sq. miles, at the entrance (S. E.) of the Fayum region, in Egypt, constructed by Amenemha III. of the twelfth dynasty. By the ancients the construction was attributed to a king to whom the name Moeris was given. The lake can not be identified with the Birket el-Kurûn, the existing natural lake at the N. W. of the district, because the latter's low level (200 feet below the entrance through the Libyan Hills) would have rendered it useless for its purpose. It was employed for the storage of water in time of high Nile, for purposes of irrigation. Its destruction was due simply to the natural decay of the retaining embankments through lack of care. The region was explored and the line of embankments traced by Linant Bey (*Mémoire sur le lac Moeris*, 1843, and *Mémoires sur les principaux*

travaux d'utilité publique, pp. 47–88; Lepsius, *Letters from Egypt*, p. 92), and they are still to be seen. For ancient descriptions, see Herodotus (ii., 149 f.), Diodorus (i., 52), Strabo (xvii., i., 37), and Pliny (*Nat. Hist.*, v., 9, 50; xxxvii., 12, 76). These writers, however, do not agree with one another, and all their statements can not be true. Remnants of the two pyramids mentioned by Herodotus have been discovered in recent times. CHARLES R. GILLETT.

Mœ'sia: province of the Roman empire, corresponding to the present Bulgaria and Servia; bounded N. by the Danube, E. by the Black Sea, S. by the Hæmus (Balkan Mountains), and W. by the Save. Originally it was inhabited by tribes of Thracian race, with whom the Romans came in contact after the conquest of Macedonia, but it was not made a Roman province until the time of Augustus. It was then divided into Mœsia Inferior (Bulgaria) and Superior (Servia), fortifications were constructed along the Danube, and several Roman settlements were formed. Among its towns the most remarkable were Tomi on the Black Sea, whither Ovid was banished; Durostorum (Silistria) on the Danube; and Singidunum near the present Belgrade. In 250 A. D. began the invasions of the Goths, and in 395 several Gothic tribes settled in the country and received the names of Mœso-Goths. The country remained a province of the East Roman or Byzantine empire until, in the seventh century, the Slavonians and Bulgarians entered it and formed the kingdoms of Servia and Bulgaria.

Mœso-Goths: See ULFILA.

Moffat, ROBERT: missionary; b. at Ormiston, Scotland, Dec. 21, 1795; was by occupation a gardener; went to South Africa as a missionary in 1816, and passed fifty-four years in successful labors among the Bechuanas and other barbarous tribes, into whose languages he translated portions of the Bible, hymn-books, and other religious books. He published in 1842 *Labors and Scenes in South Africa*. He returned to England to live in 1870. A testimonial, amounting to £5,800, was presented to the venerable missionary in 1873, in recognition of his lifelong labors. D. at Leigh, Kent, Aug. 9, 1883. The wife of the explorer Dr. Livingstone was a daughter of Mr. Moffat. See J. S. Moffat, *Lives of Robert and Mary Moffat* (1885).

Mogador, or **Suera**: town of Morocco, on the Atlantic; about 130 miles W. of the city of Morocco (see map of Africa, ref. 2–B). It is regularly laid out and well built, and has an excellent harbor. It has extensive exports of wool, gum, wax, hides, gold-dust, feathers, and almonds. Pop. about 15,000, half of whom are Jews.

Moghilev: government of Russia; situated on the Dnieper, between lat. 52° and 55° N. Area, 18,551 sq. miles. The surface is a level or slightly undulating plain, of an elevation of from 600 to 900 feet, forming the watershed between the Dnieper and the Dwina; the soil is very fertile and the climate mild. Of the whole area, nearly one-half (46 per cent.) is under crops; nevertheless, considerable quantities of grain are usually imported, on account of the immense consumption of the distilleries. Grain, timber (especially masts), and cattle are largely produced, and carried on the Dnieper to the ports of the Black Sea. The cultivation of hemp is very important; hemp and hemp-seed oil are exported to Riga. Pop. (1897) 1,707,613.

Moghilev: capital of the government of Moghilev, Russia; on the Dnieper (see map of Russia, ref. 7–C). It is a handsome and well-built town, the see of a Greek bishop and a Roman Catholic archbishop, and the residence of many of the Russian nobility. It has many good educational institutions, several manufactures, and a lively export trade in grain, hides, leather, wax, and honey through the ports of the Baltic and those of the Black Sea. The preparation of skins is an old and famous industry of the place. Its cathedral, built in 1780, is a very fine building. Pop. (1897) 43,106, of whom two-thirds are Jews and the rest White Russians.

Moghilev: town in the government of Podolia, Russia; on the Dniester; 190 miles N. W. of Odessa (see map of Russia, ref. 9–B). It is a beautifully situated and thriving town, with about 18,500 inhabitants, of whom nearly one-half are Jews and the rest Little Russians. Grain, wine, spirits, timber, etc., are bought in Galicia and sold in Odessa, and manufactured goods are imported from Austria and sent to the interior of Russia. The Little Russians are mostly occupied with agriculture, gardening, wine-making, and mulberry-culture.

Mo'gul, Moghul, or **Mughal** [a corruption of Mongol]: the name generally applied by Europeans to members of that Mohammedan dynasty of Mongol descent which in the sixteenth century established itself in Hindustan under Baber, a descendant in a direct line from Timour or Tamerlane, and which here founded a great and powerful empire. The most remarkable of the rulers of this dynasty were Akbar (1556–1605), Jehangir (1605–27), and Aurungzebe (1658–1707), during which period the empire comprised almost the whole of Hindustan. In Europe these monarchs were generally known under the name of the *Great Mogul*, and the most extravagant stories of their riches and power were current. Their magnificence became proverbial, and hints at their wealth and splendor are frequent in all comic writers of that period of European literature. The title used by themselves was the Persian *shah*, and Persian was the official language. After the death of Aurungzebe the power of the dynasty rapidly declined, and at the beginning of the nineteenth century the Mogul empire was but a shadow of itself. When the British conquered India they gave the rulers of this dynasty a pension, but after the rebellion of 1857, in which it was implicated, the last Great Mogul was banished to Rangoon.

Mohacs, mō-haach': town of Southern Hungary, on the Danube; 37 miles by rail E. S. E. of Fünfkirchen (see map of Austria-Hungary, ref. 8–G); the center of a considerable trade in cattle, grain, wine, and other agricultural products, which are shipped hence to Vienna. Pop. (1890) 14,468. It is famous as the place where two of the most momentous battles in Hungarian history were fought (Aug. 29, 1526, and Aug. 12, 1687). In the former the young and chivalric king, Louis II., with an army of hardly 25,000 men, attacked, without waiting for the re-enforcements which approached under John Zapolya, a Turkish army of 200,000 men, under Solyman the Magnificent. After a protracted and desperate fight the Hungarian army was cut entirely to pieces, the king in his flight drowned in the Csellye, and a large portion of the country fell into the hands of the Turks. In the latter battle the Austro-Hungarian army under Charles of Lorraine completely defeated the Turks, and put an end to their dominion in Hungary.

Mo'hair [from O. Fr. *mouhaire* > Fr. *moire* (whence Eng. *moire*); cf. Arab. *mukhayyar*, a kind of coarse camelot or haircloth]: a name for the wool of the Angora goat and the fabrics woven from it. This kind of goods, formerly made only in the East and imported sparingly into Europe by way of Venice, is now extensively produced in Great Britain and other parts of Europe, and less extensively in the U. S. Mohair is combed like coarse wool or worsted and alpaca. It is mixed in many cases with cotton or silk. The raw material brings a high price.

Mohammad, SHAMS UD-DĪN: See HĀFIZ.

Moham'med, or **Ma'homet** [from Arab. *Muhammad*, a man's name, liter., praised, deriv. of *hamada*, to praise]: the founder of Islam; the prophet of the Mussulmans or Moslems; b. at Mecca, in Arabia, Aug. 27, 570. His family, Hashem, was poor, but his father, Abd-Allah, who died two months before his birth, belonged to the Koreish, the most distinguished of the Arabian tribes, to whom the guardianship of the KAABA (*q. v.*) was hereditarily intrusted. When six years old he lost his mother, Amina, and two years later his grandfather, Abd-el-Mouttalib. Adopted by his uncle, Abou-Talib, he accompanied him to Syria, where he met the monk Bahira or George, who in those early interviews exercised a large influence on his subsequent history. At the age of fourteen he was present with his uncles at the battle of Nakla between the Koreish and the Havazin, and picked up the arrows as they fell in the fight. Then he served as a shepherd and camel-driver for Abou-Talib (584–594), by the integrity of his conduct winning the surname of El Amin, the faithful. Employed by the wealthy widow Khadijah, the chief lady in Mecca, as her business agent, he so won her gratitude and esteem that, although fifteen years his senior, she offered him her hand and became his wife the following year. Mohammed proved a faithful and devoted husband. Their union was happy, save that of their seven children the three sons died in infancy. The years 596 to 610 were comparatively uneventful. Freed by his marriage from the necessity of daily labor, Mohammed was able to give full exercise to that religious sentiment which had always been dominant in his character. Every year he withdrew for long periods to Mt. Hira, near Mecca, and passed the time in meditation and prayer.

The religious condition of Arabia was most deplorable. The original monotheism of the Arabs had been supplanted by star-worship, demon-worship, snake-worship, and every variety of fetichism, often accompanied with debasing and inhuman rites and practices. Judaism and Christianity were indeed adhered to by certain tribes, but in such degraded and distorted forms as to be little preferable to the prevalent polytheism. None of those faiths could satisfy Mohammed.

The Arab historians state that on a Friday, the seventeenth day of the month of Ramazan, while in the cave of Hira, Mohammed saw in a dream the angel Namous (Gabriel) and heard himself saluted as prophet of God. These ecstatic visions were repeated at intervals in his subsequent life, attended by bodily convulsions resembling epilepsy. In them Gabriel revealed to him the successive chapters of the Koran (*q. v.*), which he committed to memory, as he could neither read nor write. These experiences he at first confided only to Khadijah, who became his immediate convert. During three years he preached in secret and made eight converts, his nephew Ali becoming the first male Mussulman. During nine years (613–622) he preached publicly, making few converts, often in peril of his life, enduring all manner of insult and persecution from the Meccans, and especially from the Koreish. Khadijah and Abou-Talib died in 619. In 620 he converted six men from Yatreb who had come in pilgrimage to Mecca. On their return home they advocated the new faith with success. Two years afterward (Mar., 622), Yatreb, in the person of seventy-five representatives, on the hill of Acaba, not far from Mecca, solemnly swore that it accepted Islam and acknowledged Mohammed as the prophet of God. He now chose twelve apostles, after the example of Christ, to propagate his religion. The Mussulmans of Mecca emigrated to Yatreb, leaving only Ali and Aboubekr with the prophet. Despite attempts at his assassination he succeeded a few months later in escaping (see Hejira) to Yatreb, which at once changed its name to Medinet-el-Nabi, City of the Prophet. A mosque was immediately begun, at the erection of which he labored with his own hands, and in which he preached his first sermon (623). Hostilities soon broke out between Mecca and Medina. The Mussulmans, 314 in number, defeated a thousand Koreish at the battle of Bedr (Jan., 624), but at the battle of Mt. Ohud (Jan., 625) were themselves defeated by Abou-Souphian, the leader of the Koreish, on account of disobedience to the prophet's orders. Medina was besieged (627), but Mohammed was able to divide his enemies, some of whom became his adherents. He signed a truce (628) for ten years with the Koreish, wherein it was stipulated that he might make the pilgrimage to Mecca the following year. This he did (629) accompanied by 2,000 Mussulmans. As the Koreish violated the treaty, he marched on Mecca with 10,000 men. The Koreish surrendered without fighting. The conqueror destroyed the 360 idols surrounding the Kaaba, and Abou-Souphian and all the inhabitants declared themselves converts to Islam. The negotiations he had undertaken with Abyssinia, Persia, and the Byzantine empire, were unsuccessful. During the years since the Hejira, Islam had made such constant and rapid progress as to have become practically the religion of Arabia; so when Mohammed again made the pilgrimage to Mecca, it was at the head of 100,000 Mussulmans (632). His constitution had been undermined four years previously by poison given him by a Jewess. Soon after his return to Medina he sickened and died June 8, 632. In the unconscious delirium of his last moments he talked of the angels and God.

The two charges brought against Mohammed are that he sanctioned and himself practiced polygamy—marrying fourteen wives after the death of Khadijah, ten of whom survived him—and that he sometimes employed artifice or the sword in propagation of his faith. Till the death of Khadijah, when he was forty-nine years old, the closest scrutiny reveals no flaw in his character. He was devotedly attached to his mother's memory, never forgot a kindness, and was unselfish and just. He was an able statesman and a skillful commander, intrepid in battle, generous and humane in victory. He put forth no extravagant claims concerning himself, always declaring that he was only an ordinary man, unable to work miracles, and that his sole commission was to proclaim the unity of God. Whether self-deceived or not, he was sincere. The better he is understood, the more favorable will be the verdict upon his life and work. Impartial investigation must pronounce him one of the greatest and most sagacious reformers the world has seen. See Davenport's *Apology for Mohammed and the Koran* (London, 1869); Gagnier's *La Vie de Mahomet* (Amsterdam, 1732); Muir's *Life of Mahomet* (London, 1861); d'Ohsson's *Tableau de l'Empire Ottoman* (Paris, 1787); Caussin de Perceval's *Essai sur l'histoire des Arabes* (Paris, 1847–48); Saint-Hilaire's *Mahomet et le Coran* (Paris, 1865); Sedillot's *Histoire des Arabes* (Paris, 1854); Bosworth Smith's *Mohammed and Mohammedanism* (London, 1874); Sprenger's *Das Leben und die Lehre des Mohammed* (Leipzig, 1861–65); Garcin de Tassy's *L'Islamisme* (Paris, 1874); Weil's *Mohammed der Prophet* (Stuttgart, 1843).

E. A. Grosvenor.

Mohammed: the name of four Ottoman sultans. Mohammed I. (1413–21), b. in 1379. When Bayezid I. died in captivity (1403), one year after the battle of Angora, and Tamerlane retired beyond the Oxus, the Ottoman empire remained in anarchy during ten years, while Bayezid's four sons, Souleïman, Musa, Isa, and Mohammed, disputed the throne. In 1413 Mohammed alone survived, and became sole ruler. His main effort was to restore the almost ruined empire to its former condition. Though his reign was filled with wars against the learned dervish Behreddin, the impostor Mustapha, Karamania, Persia, and Venice, he loved peace, and was a sagacious, just, and generous soveregin.—Mohammed II. el Fatih, the Conqueror, the Great (1451–81), b. in 1429; son of Murad II. Illustrious as general, statesman, and legislator, no other sultan is equally revered by the Ottomans. He was expert with the sword and bow, and possessed prodigious strength and courage. He knew Arabic, Greek, Latin, and Persian; was a poet and writer, and was well versed in geography and mathematics. He favored the arts and sciences, built hospitals, mosques, and schools, and founded the great Ottoman code, or fundamental law, the Kanoum-Namé; yet he was treacherous, cruel, and revengeful. He conquered Servia in 1459, the Peloponnesus in 1460, the empire of Trebizond and Wallachia in 1461, Karamania and Bosnia in 1463, Herzegovina in 1467, Negropont in 1470, the Crimea in 1476, Albania in 1479, and captured Otranto in 1480. He was successfully resisted by Hunyadi at Belgrade (1455), by Seanderbeg in Albania till the death of that hero (1467), and by the Knights of St. John at Rhodes (1480). His pre-eminent exploit was the overthrow of the Byzantine or Eastern Empire by the capture of Constantinople (May 29, 1453) after a fifty-three days' siege. That city he reorganized as capital of the Ottoman empire, guaranteeing the Christians many rights and privileges, and attracting inhabitants from abroad. He died May 2, 1481, while leading his army in an expedition, the object of which has always remained unknown.—Mohammed III. (1595–1603), b. in 1566; son of Murad III. and of the Venetian Baffa. On his accession he had his nineteen brothers bowstrung. An indolent and incapable prince, the empire rapidly declined during his reign. Insurrection followed insurrection, and the wars with Moldavia, Wallachia, the German empire, and Persia, were disastrous, despite the capture of Erlau and the Ottoman victory of Kerestes (Oct. 26, 1596), where 50,000 Germans and Hungarians perished.—Mohammed IV. (1648–87), b. in 1641; son of Ibrahim I. Indifferent to the empire, he devoted himself to hunting and pleasure. His reign, though signalized by two illustrious grand viziers of the Kupruli family, was disastrous. Its chief events were the completion of the conquest of Crete (1669), the terrible defeats of St. Gothard (1664), and Mohacs (1687), and the unsuccessful siege of Vienna (1683). The army, sharing the popular discontent, deposed Mohammed in 1687 and raised his brother Souleïman II. to the throne. Mohammed was confined in the seraglio, where he died five years later (1692).

E. A. Grosvenor.

Mohammedan Art: the art of the Mohammedan peoples. In it certain dominant traits, due largely to common religion, override the wide racial distinctions which separate the Aryan Persians and Indians from the Semitic Arabs and the Turks. The Mohammedans excel in many of the decorative arts, and in all branches of design display a special predilection for brilliant but harmonious color, and for surface ornament of extreme intricacy and minuteness of detail. Such ornament is generally composed of wholly conventional or geometric elements, except in Persia, where the Koranic prohibition of pictorial art is less rigidly construed than among the Arabs and Turks. In textile fabrics, especially rugs and carpets, in wall decoration by quarry ornament and encaustic tiling, in cabinet-work and inlays, in certain branches

of metal-work, and in manuscript illumination, the art of the Levantine Moslems, the Persians, and the Mohammedans of India, is particularly brilliant and worthy of study. In architecture each of these races has built up its national style out of materials and suggestions furnished by the peoples it has conquered; so that traces of Byzantine, Sassanian, Norman, and even classic art are found in all Saracenic, Persian, and Indo-Moslem works. In all these one detects the predominance of the idea of surface decoration, whether of inlay or carving, in marble or plaster or wood; the dependence on color rather than on architectural form for the chief effect, and the development of geometric motives as the basis of ornament. To this should be added a wholly original innovation in the decorative use of Arabic lettering, in relief or in color, to form borders and friezes of great richness and beauty.

The Arabs, who in the seventh century carried the conquering standard and faith of Islam from the gates of India to the Pillars of Hercules, were neither artists nor builders, nor even for the most part dwellers in cities, but nomadic tribesmen, and therefore compelled to make use of the arts and of the craftsmen of the lands they conquered. The Sassanians in Persia, the Copts in Egypt, the Byzantine Greeks in the Mediterranean countries, were their builders and decorators for centuries. The earlier Mohammedan works therefore partake of the character of the arts of widely diverse peoples, though these arts were transformed in time by the imperious control of the Arabic mind and Koranic restrictions. These facts explain the variety of style which distinguishes from each other the arts of the Egyptian Arabs, the Moors, the Turks, the Persians, and the several schools of Indo-Moslem art. The most characteristic manifestations of Arabian art, so called in distinction from the Moorish or Moresque art of Northwestern Africa and Spain, are to be found in Egypt, especially in Cairo, and in Syria. The splendid mosque of Omar in Jerusalem was built (637 A. D.) by Byzantine architects, but is quite unlike any Byzantine type. The same was true of the great mosque of El Walid at Damascus (705 A. D.), recently destroyed or seriously injured by fire. In Cairo also the earlier mosques and tombs were by Coptic architects; but, unlike the Coptic Byzantine churches, they presented a new model of design, consisting of many parallel rows of slight columns or piers bearing arches and supporting richly decorated wooden ceilings. The hall was preceded by an atrium or court, and the end of its central aisle was adorned by a *mihrab* or prayer-niche, indicating the direction of Mecca, as in the partly ruined mosques of Amron (642–720) and Ibn Toulam (876). In later mosques a domical hall or a cavernous vaulted chamber, open to the court, replaced the columnar areaded hall, its walls incrusted with colored marbles in rich designs (mosque of Barkouk, 1149, and of Hassan, 1356). In these and some others one sees, associated with the mosque proper, a whole congeries of schools, hospitals, and tombs in plans of great complexity. In the fourteenth century the general adoption of domes and minarets, under Persian influence, led to a great increase of architectural splendor. The mosques of Hassan (1356), El Muayed (1415), Sinan Pacha (1468), and Kait Bey (1463) are beautiful examples of this style of design, which is illustrated on a smaller scale by the tombs of the caliphs and of the Mamelukes. In all these the four-centered, pointed arch, the Saracenic "stalactite" corbeling, interlaced star-patterns and minute geometric detail, play an important part both in the external and internal decoration of walls, domes, and minarets. The Arabs particularly excel in cabinet-work of small pieces combined in intricate star-patterns, and in lattice-screens of spindle-work of great beauty and variety.

Moresque Art.—The art of Morocco and Tunis is not well known as that of the Moors in Spain, being much less accessible, and seldom comparable either in splendor or importance with the works of the Spanish Moors. Cordova, Seville, Toledo, Granada, Tarragona, and Segovia—all contain relics of the grandeur of the Moslem dominion which lasted from 710 until the final expulsion of the Moors in 1492. The mosque of Cordova, founded in 786, consists of 17 rows of 32 columns, each carrying superposed horseshoe arches, elaborately cusped, with a domical sanctuary built 200 years later. Many smaller mosques of this type exist in Spain, at Toledo, and elsewhere; but the most splendid products of Moorish architecture are palaces, of which the Alcazars at Seville, Segovia, and Malaga, and the Alhambra at Granada are the chief examples. The latter, built during the thirteenth and fourteenth centuries, has always been regarded as one of the wonders of the builder's art, on account rather of its superb decoration than of anything marvelous in its architectonic composition. Begun by Mohammed-ben-al-Hamar in 1238, enlarged in 1279, 1306, and 1348, it comprises two large and several smaller courts surrounded by halls and chambers of varied size and form, and embellished by arcades and fountains of great beauty. The building is one story high, without external regularity, entirely covered internally with rich and minute diaper-work in plaster, brilliantly colored and gilded except where the lower parts are revetted with a wainscot of enameled tiles. The arches are all cusped, the slender columns are of colored marble, and the windows filled with finely executed plaster screens or lattices. There is less of strictly architectural design here than in the buildings of Cairo, but an even freer use of detail in relief, gilding, and color. The influence of this sumptuous decoration was long felt upon the Gothic art of Spain, and even upon the Renaissance art which succeeded it.

Persian Art.—Among the Persians we find a highly original and vital development of style in architecture and decoration. Less ostentatious than the Hispano-Moresque, more rigidly constructive than the Egypto-Arabic, Persian architecture offers examples of imposing conceptions executed with exceeding refinement, and sumptuously decorated without sacrifice of dignity. The Persians appear to have excelled in the construction of vaults and domes from immemorial times, and the type of dome, slightly swelling and pointed, which they adopted for their mosques and tombs is encountered alike in Cairo and in India, where architecture owed much to Persian influences. Various mosques and tombs at Ispahan, Tabreez, Sultaniyé, etc., show a rich decoration of enameled and painted tiles, externally as well as internally—a branch of art for which the Persians have always been famous. The "green mosque" at Broussa (Turkey) may be considered a Persian work, its lining of rich blue-green tiling being wholly of Persian make. The round minaret, universal in Turkey and frequent in India, is also of Persian origin. Not only in tile-making, but in the weaving of rugs and carpets, Persian art displays surpassing excellence; especially in its skillful blending of rich colors broken into minute areas, never in large masses, as in those of Asia Minor. In calligraphy—an important branch of Moslem art—in the illumination of manuscripts, in the printing of calicoes, the Persians have never lost their supremacy. Belonging to the heretical sect of the Shieh, they interpret very broadly the Koranic prohibition of pictorial art, and Persian decoration consequently displays a freedom and resource, especially in its floral forms, not met with in Saracenic or Turkish design.

Turkish Art.—The Seljûkian Turks, who in 1453 under Mohammed II. finally overthrew Constantinople, after occupying for nearly a century the surrounding territory in Asia Minor and Thrace, followed the example of all other Mohammedan conquerors by adopting at once the arts of the conquered race. The Conqueror's mosque, the work of Christadoulos, a Byzantine Greek, was a modification of the St. Sophia type of domical construction and planning, a type which has persisted, with variations, in Turkish mosque designs down to the present time. The noblest example of this is the mosque of Sûleiman the Magnificent (*circa* 1550), while in Constantinople, Broussa, Damascus, and other cities are a number of other examples only inferior to this. The exteriors are more elaborate, the interiors plainer, than those of their Byzantine prototypes, to which the Turks have added minarets and cloisters, domical tombs, and many other accessories. The pointed arch, with voussoirs alternately light and dark, monumental doorways set in vast niches with stalactitic arches or heads, and picturesquely spreading wooden-eaved roofs, are features of Turkish architecture which has produced, besides mosques, some fine tombs and fountains, but it lacks the abandon and exuberance of Arabic, Moorish, or Indian art, and has suffered much from the influence, in the eighteenth century, of the most degraded forms of rococo design, due to the importation of Italian artists. The Turks excel, however, in needlework, rug-weaving, and some branches of metal-work and inlay.

Indian Art.—Northern India came under the Moslem sway at the end of the twelfth century, and the Pathan monuments of the next century in Delhi and Ajmere differ but little from the older Jaina colonnaded courts and halls. This is also true of many of the mosques and tombs of Ahmedabad, Mirzapur, and Birkej, though their domes and minarets ally them with the contemporary buildings of Per-

sia and Egypt. Still more nearly related to Persian models are the mosque and the bazaar at Kalburgah (Deccan), and the Jumma Muddjid and the tomb of Mahmûd at Bijapûr, in which the system of vaulting by domes on intersecting pointed groined pendentives at once recalls the mosque and the bazaar at Ispahan; but the most splendid works of Moslem art in India belong to the Mogul period (1494–1707), in which—especially at Agra and Delhi—the resources of Hindu and Saracenic design seem to have been combined with wonderful results. The Taj Mahal is one of the most beautiful buildings in existence. See INDIA.

Indo-Moslem art can not always be separated from Hindu (pagan) art in its minor products, such as rugs, carpets, brass-work, and wood-carving, in which racial rather than religious characteristics predominate. These works are all marked by a wonderful patience and minuteness of detail, and by rich and harmonious combinations of line and color.

Among the leading works of reference are Prisse d'Avennes, *L'Art Arabe*; Bourgoin, *Les Arts Arabes*; Texier, *L'Art moderne de la Perse*; Owen Joncs, *Grammar of Ornament* and *The Alhambra*; L. Parvillée, *L'Architecture Ottomane*; J. Fergusson, *Indian and Eastern Architecture*. A. D. F. HAMLIN.

Mohammedanism: the name commonly but improperly applied by Europeans to the religion taught by the prophet Mohammed. The name Islam (resignation, submission) is that given by the founder and invariably employed by its adherents. The latter deprecate being called Mohammedans or Mahometans, asserting they are followers of no human being, but are Mussulmans or Moslems (the resigned or submitted).

Knowledge, according to the Mussulmans, is derived either from the five physical senses or from tradition, thereby including both oral tradition and revelation, or from reason. No knowledge is derived from inspiration. The Koran, the gift of revelation, contains all the laws and doctrines considered of divine origin. This book is further expounded, in addition to its obvious meaning, by the Sunna, or oral tradition concerning the prophet's sayings, actions, and even his silence in certain circumstances; by the Idymay-ummeth, or explanations and legal decisions rendered by the apostles and chief disciples contemporary with or immediately subsequent to the prophet; and by the Kiyass, or later decisions, made during the early centuries of Islam.

The central, all-dominating idea of the faith is the unity of God. In the creed, "There is no God but God, and Mohammed is the prophet of God," the first clause is the all-important, and the second is added, not to exalt Mohammed, but simply that men may accredit his mission, and hence accept and believe whatever he taught as revealed to him concerning the deity. The theologic system, however, embraces many other doctrines. For convenience and definiteness two catechisms have been drawn up: one in Turkish, called *Exposition of the Mussulman Faith*, by Mohammed ben Pir Ali el Berkevi; and one in Arabic, by Nedjhm ud-din Nessefy, who died at Bagdad in 1142. These two catechisms do not disagree, but the latter is the authorized and universally accepted summary of orthodox Islam. With Oriental prolixity, and with scant regard to their logical order or relative importance, it sets forth fifty-eight doctrines or articles of faith, all of which are equally held by the orthodox. Some are sanitary rather than theological; some hardly more than definitions; some seem almost puerile, while others set forth the sublimest truths held in common by all monotheistic peoples.

Doctrines.—The existence of the world proves a creator. This creator is God. "There is only one God: he lives, is eternal, omnipotent, and omniscient; hears all, sees all; is endowed with will and action; in him there is neither form nor face nor limits nor numbers nor members nor parts nor multiplication nor division, because he is neither body nor matter, and has neither beginning nor end; he exists by himself, without generation or habitation, beyond the control of time, incomparable in his nature as in his attributes, which, while not distinct from his essence, do not constitute his being. God possesses the word. The word, eternal in its essence, has neither visible letter nor character nor sound, and its nature is the opposite of silence." "The Koran is the uncreated word of God, written in our books, engraved on our hearts, articulated on our tongues, heard by our ears, in which the sound of the word is received, and not the word itself, which is eternal and self-existent." The believer's future spiritual vision of God is demonstrated by reason and revelation. In the tomb sinners are tormented, there the faithful enjoy spiritual delights, and there all the dead, without exception, are questioned by the angels Munnker and Nekir as to their God, their religion, and their prophet. The resurrection of the dead, the balance wherein are weighed all actions committed during life, the daily record (*kitab*) of each individual, the examination on the day of judgment, the bridge (*al Sirat*), the celestial basin, and a never-ending paradise and hell, are all real and certain. There are twelve capital sins—polytheism, homicide, injury of another, adultery, desertion on the field of battle, magic, robbery of orphans, disobedience to parents, sacrilege at Mecca, usury and illegal gain, theft, use of wine—any of which God may pardon save polytheism. Through the intercession of the prophets guilty believers will not remain in hell forever. Faith is belief in and confession of all revealed by God; good works can be increased or diminished; not so faith, which is the same as Islam. The destiny of the elect and the damned is decreed by the Eternal, for predestination exists in the essence of God, and he never changes; but this predestination extends only to spiritual condition, does not include all mankind, and has no connection with one's moral, civil, or political condition; man is never deprived of free will. The prophets, envoys of God, have attested their mysterious mission by prodigies and marvels: of these Adam is the first: Christ is superior to all the others save Mohammed, the last and most eminent of all. The angels, God's messengers and servants, are without sex. The sacred books descended from heaven, were put into the hands of men, and are in order of rank the Koran, the Pentateuch, the Gospels, and the Psalms. The bodily ascent of Mohammed to the heaven of heavens is a fact. The saints possess the gift of miracles. The funeral prayer for one just dead is incumbent on the survivors. The use of the bath is obligatory on travelers. Date-juice is not a prohibited drink. Saints do not attain the same felicity as the prophets. No man is exempted from obedience to positive and prohibitive laws. The text of a sacred book must be understood in its literal sense. To lack faith in the sacred books, to be indifferent to sin, or to joke about religious matters or about worship, to distrust God, to have no fear of his threatenings or punishments, to put confidence in diviners or omens—all these things are infidelity. Prayers for the dead contribute to the repose of their souls. God listens to prayer and grants its petitions. Certain signs will announce the end of the world. Doctors of theology are not infallible. Human prophets are superior to angelic prophets, and men are higher than angels. The foregoing summary, together with nine doctrines concerning the rank, prerogatives, and limitations of the early caliphs and imams, gives briefly and in the same order the contents of the catechism of Omar Nessefy.

Ritual.—As to matters of ritual or required external observance, there are four systems all equally reputed orthodox, though differing in various details, founded by the imams Azam Ebu Hanifeh (d. 767), Schafiy (d. 849), Malek (d. 795), and Hannbel (d. 855). This ritual has been almost unmodified since the ninth century. Most Mussulmans are followers of Hanifeh, but the four systems are tanght side by side in the large theological seminaries. The external observances are five: purification or ablution, prayer, fast, pilgrimage, and the tithe. The manner whereby each shall be discharged is indicated with scrupulous and minute particularity. Purification does not deliver from sin, which can be washed away only by repentance and works of penitence, but no man is permitted to perform any religious act until himself and his garments are free from material defilement. Prayer must be made toward the KAABA (*q. v.*) five times every twenty-four hours, just before sunrise, at noon, in the afternoon, at evening, and during the night. The words are carefully prescribed as are also the prostrations, genuflections, and changes of position. Prayer is incumbent on every Mussulman, male or female, after the age of seven. Fast continues through the entire month of RAMAZAN (*q. v.*). This is obligatory after the age of fourteen. As to pilgrimage, see HADJ. The tithe, not really though nominally a tenth, is required only of the rich, or of those in easy circumstances, and is devoted to indigent coreligionists. Though these observances, save the fifth, are demanded from every believer, a variety of conditions may free from the performance of any or even of all. This discharge may be many times repeated, through months, during years, or even throughout a lifetime. Thus

poverty, sickness, physical defects, inability to provide for family necessities in case of absence, may and does dispense thousands from the hadj. These exemptions are specially frequent in the case of women, on account of their physical weakness or physical conditions of sex.

Moral Code.—This can hardly be separated from Mussulman theology, the two so trench upon and are so connected with each other. Its minutiæ are almost infinite. The vices specially denounced are hypocrisy, as in reading the Koran for pay or admiration; envy, as wishing that another may lose his property; obstinacy, covetousness, gluttony, and avarice. Love of the world is the initial principle of sin, and is folly, for real joy is only in heaven. One must not honor the rich simply for his wealth, or despise the poor, or seek out a neighbor's secret faults, or deceive another, or ever lose from sight the real motive for shunning vice. The foremost virtue is patience, whereby one endures misfortune and suffering without expressed or secret complaint; such patience is the necessary first fruit of Islam, inasmuch as the believer is entirely and joyfully submissive to God's will. Gratitude to and fear of God, trust in his mercy, aversion to merely worldly delights, are in close connection. Humility is requisite whereby one declares himself the least of the faithful. One should always think well of others, but judge himself severely. A promise must be strictly kept; one must never lie nor steal, or touch anything impure, or play games of chance. Friday should be especially esteemed, because Adam and Eve were created on that day. Kindness to animals is duty and wisdom, for each shall be judged not only by his conduct toward men, but toward brutes. One must watch carefully against any sin that may enter by any of "the seven doors," which might then become "the seven gates of hell." Those doors are the ears, eyes, tongue, hands, feet, stomach, and the organs of sex.

Charges against Islam.—The main charges are sensuousness, toleration or approval of slavery and polygamy, the position to which it is supposed to relegate woman, and that it has often been propagated by the sword. The first and last charges are well sustained. The doctrine of literal interpretation seems to necessitate that the glowing passages of the Koran be taken in strict literal sense. They are so understood by the vast majority of Mussulmans, have hence furnished a most powerful incentive in battle, and largely contributed to the diffusion of the faith. Yet many of their theologians assert that these passages are pictures or metaphors, the literal interpretation of which must mean "interpretation according to the idea contained." As to slavery and polygamy, Mohammed found them everywhere in Arabia. He destroyed neither, but restricted and ameliorated both. As to the third charge—so far as it can be divorced from considerations of polygamy—woman was elevated by Islam; not, indeed, to the highest dignity, but still to a position such as in Arabia she had never known before. The seclusion of woman is primarily the result of Oriental prejudice and ideas, not of Islam. Nowhere is the mother held in greater reverence than among the Mussulmans.

Fidelity to External Observances and Influence of the Moral Code.—Islam has many merely nominal adherents, and others apparently uninfluenced by its moral teachings. Moreover, by strange inconsistency, many zealous Mussulmans have adopted and openly maintain customs and ideas opposed to their prophet's teaching, and directly violating his commands. For example, Islam forbids castration and the employment of eunuchs, yet eunuchs abound in the palaces and mansions of wealthy Mussulmans. The fifty-second doctrine denounces faith in diviners, magicians, fortune-tellers, astrologers, and omens, yet belief in these things is universal among Mussulmans. Persistency in denying human free will is expressly declared impiety deserving of death, yet Kismet—the most absolute and all-embracing fatalism—is practically accepted by the Mussulman world. Mohammed declared, "No monasticism in Islam," yet the seventy-two orders of dervishes—really monks, though married—are its most fanatical, most revered, and perhaps most powerful supporters. Yet, after all this is granted, the fact remains that Islam does have a marvelous hold on its members, and that its external requirements are observed in general with marvelous fidelity. The rite of circumcision is never omitted. The Mussulman who does not make his purifications and stated prayers, who eats pork or indulges in wine, who does not scrupulously keep the fast and, if wealthy, give his alms, is the rare exception. The young Mussulman, educated abroad or in contact with Western or European customs, may be lax, indifferent, or skeptical, but the immense majority adhere to their religion and its practices with a tenacity probably never greater than to-day. Some of the virtues it enjoins they possess in higher degree than they do others, but the average Mussulman is patient, submissive, simple, unenvious, honest, temperate, hospitable, and kind.

Sects.—Mohammedan sects are exceedingly numerous, and many have become extinct. They are often spoken of as the "seventy-two heretical sects," but this estimate is far below the real number. While sometimes founded on interpretation of doctrines, as the Wahabees, they have generally arisen in partisanship, in adherence to the supposed claims of some individual leader, as among the Shiïtes. In the intensity of their sectarianism they have often been envenomed and fanatical almost beyond belief. See Ismaïlis, Karmathians, Motasalis, Nusairieh, Shiïtes, Wahabees, etc.

More than almost any other great religion, Islam seems held by its very nature within certain geographical boundaries. It might spread indefinitely E. and W. along an immense belt N. and S. of the equator, yet there are certain parallels beyond which it can hardly pass, or, if it passes, where it can never hold its own. Local in its self-imposed restrictions, it lacks capability of adjustment. Yet a modern school of Mussulmans claim that it is capable of adapting itself to all latitudes and civilizations. See the references under Mohammed, and Caliph, Ommiades, Shiïtes, Sunnites, and Dervishes. E. A. Grosvenor.

Mohammedan Schools: See the Appendix.

Mohave Indians: See Yuman Indians.

Mohawk River: the principal affluent of the Hudson, surpassing in volume that stream above its confluence. It rises in Lewis co., N. Y., and after a generally eastward course reaches the Hudson at Cohoes. It affords valuable water-power, and flows through a valley famed for its beauty.

Mohawks: See Iroquoian Indians.

Mohee'lev: same as Moghilev (*q. v.*).

Mohegans: See Algonquian Indians.

Mohl, Jules, von: Orientalist; b. at Stuttgart, Germany, Oct. 25, 1800; educated at Tübingen for the Lutheran ministry, but was early attracted to Oriental studies, Chinese, and especially Persian, in which he was destined to win renown. In 1823 he went to Paris, where, under the leadership of de Sacy, at this time was the great school for Oriental learning in Europe. He thus came under the influence of Ampère, Eugène Burnouf, and Abel Rémusat. In 1826 he received the appointment of a professorship of Oriental Languages at Tübingen, with permission to remain in Paris. At this time the French Government commissioned him to prepare an edition of Firdausī's *Shāh Nāmah* (see Firdausī), the first volume of which appeared in 1838. He worked also for a time in London and at Oxford. In 1847 he became Professor of Persian at the Collège de France, and in 1852 director of the Oriental department of the national printing-office. He was a member of the Institute, and was most closely associated with the Société Asiatique down to the time of his death, Jan. 4, 1876. His principal work is his edition of Firdausī's *Shāh Nāmah*, text and translation (*Le Livre des Rois par Firdousi*, 6 vols., Paris, 1836–68), incomplete at his death. An edition of the translation, in seven volumes, appeared after his death (Paris, 1876–78). Important also are his collected reports published posthumously under the title *Vingt-sept Ans des Études Orientales* (Paris, 1879).—His brother, Hugo von Mohl, b. at Stuttgart, Apr. 8, 1805; studied medicine and natural science at Tübingen, and was appointed Professor in Botany and director of the botanical garden in that city in 1835. D. Mar. 31, 1872. He was the most eminent vegetable anatomist of his day. His principal works are *Ueber den Bau und das Winden der Ranken und Schlingpflanzen* (1827); *Beiträge zur Anatomie und Physiologie der Gewächse* (1834); *Grundzüge zur Anatomie und Physiologie der vegetabilischen Zelle* (1851); and a large number of memoirs, the principal ones collected in his *Vermischte Schriften*.

Revised by A. V. Williams Jackson.

Möhler, mö'ler, Johann Adam: theologian; b. at Ingersheim, Würtemberg, May 6, 1796; studied theology at several of the most prominent universities of Germany, both Protestant and Roman Catholic; was ordained a priest of the Roman Catholic Church in 1819: became Professor of Theology at Tübingen in 1825, and at Munich in 1835. D. at Munich, Apr. 12, 1838. His principal works are *Die Einheit in der Kirche, oder das Princip des Katholicismus*

(1825), and his *Symbolik* (1832), which ran through many editions, and was translated into English in 1832 by Robertson. It is an exposition of the doctrinal differences between Roman Catholics and Protestants as set forth in their recognized creeds or *symbols*. It was answered by Nitzsch, Marheineke, and especially by Baur. The controversy which ensued rendered Möhler's position so painful that he sought a transfer to some other university. Chairs at Bonn and Münster were offered, but he finally accepted the call to Munich. Revised by JOHN J. KEANE.

Mohn, HENRIK: meteorologist and geographer; b. at Bergen, Norway, May 15, 1835; attended the cathedral school 1845–52; the university in Christiania 1852–58; was assistant observer at the astronomical observatory at Christiania 1860–66: has been professor in the university and director of the Meteorologieal Institute since 1866. He was a member of the international committee of the meteorological congresses of Rome, Vienna, and Munich. He was a director of the physical part of the Norwegian North Atlantic expedition with the Vöringen 1876–78, and member of its editorial committee. He was also a member of the international polar conference, and organized the Norwegian polar station at Bossekop. He received the honorary degree of Ph. D. from Upsala in 1877. His publications are numerous. Among them may be mentioned his *Atlas des tempètes de l'Institut Mét. de Norvège* (1870); the *Reports of the Norwegian Atlantic Expedition*, Astronomy, Geography (1882), Meteorology (1883), Depths, Temperature, and Circulation of the North Sea (1887); and especially his excellent *Grundzüge der Meteorologie* in Norwegian and German (1875; 4th ed. 1887), also translated into Russian, Spanish, Italian, and French. M. W. HARRINGTON.

Moir, DAVID MACBETH: physician and author; b. at Musselburgh, Scotland, Jan. 5, 1798; became in 1817 a successful practitioner of medieine at Musselburgh, where he was settled till his death. He soon became widely known as "Delta," from the letter Δ appended to his numerous poems in the periodical literature of that time. His *Legend of Genevieve* (1824), *Autobiography of Mansie Wauch*, a novel (1828), *History of Medicine* (1831), *Domestic Verses* (1846), and his lectures on *Poetical Literature* (1851) are all of value. D. at Dumfries, July 6, 1851. Revised by H. A. BEERS.

Moisture: See HUMIDITY.

Mojave Indians: See YUMAN INDIANS.

Mojós, or **Moxós**, mō-hōs': a race of Indians in Northern Bolivia, principally on the Mamoré, one of the great branches of the Madeira. Formerly they extended to the Guaporé, Itonama, and Beni, and were very numerous; their tribal relations were loose, each village being practieally independent; they subsisted principally by agriculture, wore long shirts made of bark, and were mild and friendly in disposition. When the Jesuit Cyprian Baraza came among them in 1674 they readily listened to his teachings, and fifteen large mission villages were established in their territory; one of these, Trinidad (founded 1687), is now the capital of the department of Beni. The descendants of the Mojós are devout Catholics; they are industrious, excel in light artistic work, and are much in demand as canoemen and rubber-gatherers. Physically they are a handsome race, and rather light colored for Indians. By their language they belong to the great Maypuré or Arawak stock, whieh once extended to the Bahama islands; the Guanás of Matto Grosso are closely allied to them. They are said to number about 30,000, but this includes other tribes which have mingled with them in the missions. The best existing grammar and vocabulary of their language is that of Father Marban (Lima, 1701). See Keller, *The Amazon and Madeira Rivers* (1875). HERBERT H. SMITH.

Mokanna: See HAKIM-BEN-ALLAH.

Mokrý, mok'rē, OTOKAR: poet and novelist; b. at Budějovice (Budweis), Bohemia, in 1854; studied law at Prague; is state notary at Vodňany, and editor of the *Laciná knihovna národní* (People's Cheap Library). He belongs to the romantic sehool. His poems, epic and lyrical, are collected in *Jihočeské melodie* (Melodies from Southern Bohemia, Prague, 1880); *Básně* (Poems, 1883); *Na dívčím kameni* (On the Maiden's Rock, 1885); *Dumy a legendy* (Reflections and Legends, 1888). His short stories, *Povídky a arabesky* (Short Stories and Arabesques, 1883) and *Povídky a drobné kresby* (Short Stories and Sketches, 1886), contain reminiscences of his travels in the South. J. J. KRÁL.

Molale: See WAIILATPUAN INDIANS.

Molasses, or **Treacle** [formerly *melasses* from Fr. *mélasse*, from Span. *melaza*, molasses < Lat. *mellā'ceus*, honey-like, deriv. of *mel*, *mel'lis*, honey]: a thick, dark-colored sirup, produced during the manufacture of sugar, consisting essentially of uncrystallizable sugar, water, coloring-matter, and various impurities. It is in part the product of the sugar-plantations (known as West India and New Orleans molasses), and in part comes from the sugar-refineries of other countries (sugar-house molasses). The latter is separated by the centrifugal process, by claying, and the other operations of sugar-refining. Molasses is used as a cheap substitute for sugar, especially by the poorer classes, and is imported in considerable quantities for the manufacture of RUM (*q. v.*). See SUGAR.

Molay, JACQUES BERNARD, de: the last grand master of the order of Knights Templars; b. in Burgundy about 1244. Little is known of his life till about the year 1298, when he became grand master. Philip IV., who was then reigning in France, viewed the order with suspicion and longed to get possession of its vast wealth. His hostility was increased when the management of the order was intrusted to so able a chief as de Molay, who soon won renown for himself and his comrades by his invasion of Syria in 1299 and his temporary conquest of Jerusalem. He was defeated, however, in 1302, and forced to take refuge in Cyprus. There he received an order from the pope at the instance of Philip commanding him to return to France. He obeyed the summons, was hospitably received by the king, and made an ostentatious entry into Paris, but Philip at once began active proceedings against the order. In Oct., 1307, de Molay was arrested, tortured, and forced to confess the guilt of the Templars; afterward recanting his confession, he was dragged to the stake and burned to death by a slow fire in Paris, Mar. 18, 1314. F. M. COLBY.

Molbech, CHRISTIAN: scholar; b. in Sorö, Denmark, Oct. 28, 1783; was connected with the Royal Library, was director of the Royal theater, and Professor of Literature at the university. His most important work is his dictionary, which, though out of print, is still a standard work. He was a diligent investigator and a voluminous writer, but lacked breadth and sympathy. D. June 23, 1857. Among his publications may be mentioned *Dansk Haand-Ordbog til Retskrivnings og Sprogrigtigheds Fremme*, etc. (1813); *Den danske Riimkrönike* (1825); *Henrik Harpestrengs Lægebog* (1826); *Den ældste danske Bibel-Oversættelse*, etc. (1828); *Dansk Ordbog*, etc. (1833; 2d ed., 2 vols., 1859); *Dansk Dialect-Lexikon*, etc. (1841); *Dansk Glossarium over forældede danske Ord . . . fra det 13de til det 16de Aarhundrede* (2 vols., 1857 and 1866). D. K. DODGE.

Molbech, CHRISTIAN KNUD FREDERIK: poet; son of Christian Molbech; b. in Copenhagen, July 20, 1821. From 1853 to 1864 he was Professor of the Scandinavian Languages and Literatures at the University of Kiel; during the following seventeen years censor of the Royal theater and dramatic and literary critic. In the latter capacity he wrote several sympathetic and original criticisms of Shakspeare. His first collection of poems, *Billeder fra Jesu Liv* (Pictures from the Life of Jesus, 1840), is a successful attempt to reproduce Oriental local color. The drama, *Klintekongens Brud* (The Cliff-king's Bride, 1845), is almost wholly lyrical, but *Venusbjerget* and *Dante* (1852) show decided advance in dramatic power. His most popular work is the drama *Ambrosius* (1877), which displays remarkable technique. His translation of Dante (begun 1848), while characterized by great beauty and finish, is somewhat lacking in force and historical truth. Among his other works may be mentioned *Lyriske Digte og Romancer* (Lyrical Poems and Romances); *Dæmring* (Twilight, 1856); and *Efterladte Digte* (Posthumous Poems, 1889). D. May 20, 1888. D. K. DODGE.

Moldau, mōl'dow: a river of Bohemia. It rises in the Böhmerwald Mountains at an elevation of 3,750 feet, flows first in a southeastern, then in a northern direction, becomes navigable at Budweis, and joins the Elbe opposite Melnik after a course of 276 miles.

Moldavia: See ROUMANIA.

Molding: See MOULDING.

Molds: See MUCORACEÆ and WATER-MOULDS.

Mole [M. Eng. *molle*, appar. abbrev. of *molewerp*, *moldwerp* (: Germ. *maulwurf*, mole); O. Eng. *molde*, soil + *weorpan*, throw]: a name given to the various small inseetivorous mammals forming the sub-family *Talpinæ*, distinguished

by their adaptation to an underground life. The eyes are minute, the body cylindrical, the neck short, the feet broad, powerful, and more or less turned on edge. The fur is soft,

European mole (*Talpa europæa*).

Fore-foot of the mole.

Hind-foot.

thick, and silky in texture. The common European mole (*Talpa europæa*) constructs a dwelling consisting of a central nest, surrounded by two circular tunnels, an upper and a lower, connected by various passages, and from these the long burrows open out in different directions. The mole of the Eastern U. S., *Scalops aquaticus*, excavates long subterranean passages, the earth being thrown up at intervals, forming the well-known mole-hills. The star-nosed mole (*Condylura cristata*) is easily distinguished by the curious fleshy points surrounding the nose. The name mole is often applied to burrowing animals resembling the true moles in habits and general external appearance, such as the golden moles (*Chrysochloridæ*) of Africa, and the sand-mole or mole-rat (SPALAX, *q. v.*) of the *Muridæ*. See also TALPIDÆ.

F. A. LUCAS.

Molé, mō'lā', LOUIS MATHIEU: statesman; b. in Paris, Jan. 24, 1781; was educated in Switzerland and England; attended afterward the École Polytechnique of Paris; published in 1806 his *Essais de Morale et Politique*, which attracted the attention of Napoleon by their defense of monarchical principles; held different offices in the civil service during the empire; was made a count and peer of France, and was confirmed in the possession of these dignities by the Bourbons; became Minister of Marine in 1815, of Foreign Affairs in 1830, and Prime Minister from 1836 to 1839; retired from political life after the *coup d'état*, and died at Champlâtreux, Nov. 23, 1855.

Mole-cricket: a name given to the burrowing crickets, and primarily to those of the genus *Gryllotalpa*. In the U. S. they are most common in the South. They are more commonly found in wet ground, and some species are very destructive to crops.

Molecules: according to the commonly accepted theory of matter, the smallest particles of any definite substance that can exist in the free state. For example, water, the chemical compound, consists of the elements hydrogen and oxygen, which are combined chemically with each other. Now, the mass of water is believed to consist of extremely minute particles, each of which has the same composition as water. These particles are the molecules of water. If the molecule is decomposed, the constituents of the molecules are obtained, and these are hydrogen and oxygen. When water is converted into vapor these molecules are separated from one another, and move freely through the mass, the average velocity of the motion increasing with increasing temperature. See CHEMISTRY.

IRA REMSEN.

Mo'leschott, JACOB: physiologist; b. at Herzogenbusch, Holland, Aug. 9, 1822; studied medicine at Heidelberg; began to practice at Utrecht; lectured on physiology at Heidelberg from 1847 to 1854, but was considered to endanger religion and morals by his views of the absolute relation between the lowest material conditions and the highest spiritual manifestations of human life; received a professorship at Zurich in 1856; removed in 1861 to Turin (in 1879 was called to the same chair in Rome); in 1876 became an Italian senator. Wherever he was the physiological course became one of the most popular courses in the curriculum, and the influence of his teaching in rehabilitating the methods pursued in the Italian universities can not be overestimated. His principal works are *Physiologie des Stoffwechsels in Pflanzen und Thieren* (Erlangen, 1851); *Der Kreislauf des Lebens* (Mentz, 1852); *Lehre der Nahrungsmittel* (Erlangen, 1858); *Physiologie der Nahrungsmittel* (Giessen, 1859); *Physiologisches Skizzenbuch* (Giessen, 1861); *Lehre vom Leben* (Giessen, 1867). He was coeditor of the *Holländische Beiträge zu den anatomischen und physiologischen Wissenschaften* from 1846–48, and of the *Untersuchungen zur Naturlehre des Menschen und der Thiere* from 1856–70. D. at Rome, May 19, 1893.

S. T. ARMSTRONG.

Molesworth, GUILFORD LINDSAY, K.C.I.E.: civil engineer; brother of Rev. William Nassau Molesworth; b. at Millbrook, Hants, England, in 1828; was educated at the College of Civil Engineers, Putney; served an apprenticeship on the London and Northwestern Railway; perfected his studies in mechanical engineering under Sir William Fairbairn at Manchester; superintended the construction of the buildings and machinery of the royal arsenal at Woolwich in 1854–55; was for several years a consulting engineer in London; went to Ceylon in 1859; became chief engineer and director-general of the railways in that island, and in 1871 was appointed consulting engineer to the Government of India. His *Pocket-book of Engineering Formulæ* passed through six editions in a single year, and is recognized as a standard work in the profession. Among other publications are *State Railways in India* (1872) and *Imperialism in India* (1885).

Molesworth, Sir WILLIAM: statesman; b. at Camberwell, London, England, May 23, 1810; succeeded to the baronetcy in 1823; studied at the University of Cambridge, but was obliged to leave on account of having challenged a tutor to fight a duel; finished his education at Edinburgh University and in Germany; traveled through Europe; became in 1831 an enthusiastic advocate of reform measures; was elected to Parliament for East Cornwall Dec., 1832; was an intimate friend of Bentham and James Mill, of whose opinions he was a leading exponent in Parliament; founded *The London Review* in 1835, which he merged in *The Westminster Review* in 1836, and published at great expense a magnificent edition of the *Works of Thomas Hobbes* (16 vols., 1839–45), of which he presented copies to the leading libraries of Great Britain and Ireland, and left unfinished a *Life of Hobbes*, which remains unpublished. Sir William Molesworth was the first to call public attention to the horrors of the convict system then in vogue, and to the maladministration of the Colonial Office, and was largely instrumental in effecting a radical change in both these important branches of the administration. In 1853 he became first commissioner of public works in the cabinet of the Earl of Aberdeen, and in 1855 Secretary of State for the Colonies in Lord Palmerston's first cabinet. This appointment was hailed with great enthusiasm by the colonies, but before any considerable results could be derived from his policy Molesworth died in London, Oct. 22, 1855.

Molesworth, WILLIAM NASSAU: clergyman and historian; b. at Millbrook, near Southampton, England, Nov. 8, 1816; was educated at King's School, Canterbury, St. John's and Pembroke Colleges, Cambridge, where he was graduated in 1839; took orders in the Church of England; became incumbent of St. Andrew's, Manchester, in 1841, and vicar of St. Clement Spotland, Roehdale, in 1844. He published, besides several minor works, a *History of the Reform Bill of 1832* (1864); a *New System of Moral Philosophy* (1867); and a *History of England from the Year 1830* (3 vols., 1871–73). A later edition brings this valuable work to the year 1874. D. Dec. 19, 1890.

Revised by W. S. PERRY.

Molfet'ta: town; in the province of Bari delle Puglie, Southern Italy; in lat. 41° 13′ N., lon. 16° 39′ E.; on a little peninsula surrounded by the Adriatic except on the S. (see map of Italy, ref. 6–G). A commodious and secure harbor and its central position make this place one of the chief markets of the province, both for imports and exports, the latter consisting of grain, wine, almonds, olive oil, etc. There is also considerable industry here in the way of small manufactures. The origin of Molfetta is not well known, but probably it was founded about 300 A. D. Pop. about 30,000.

Molière, mō'li-ār': JEAN BAPTISTE POQUELIN: certainly the greatest dramatist, perhaps the greatest literary figure, of France, whose stage name, Molière, has completely supplanted his real one. He was baptized in Paris, Jan. 15, 1622, and it has been concluded that this was his birthday as well. Of the circumstances of his childhood and education we have but meager knowledge. As in the case of Shakspeare, with whose career that of Molière presents not a few parallels, what is positively known of his early years gives but a faint and fragmentary picture of his youth and training. That his parents, Jean Poquelin and Marie Cressé, were of the class of tradesmen, of comfortable but modest

circumstances, and that his father held the office of *valet-de-chambre* of the king, and obtained its continuance for his son; that Marie Cressé died in 1632, and that a step-mother came into the family the following year, but died three years later; that Jean Poquelin gave his son a good education, sending him to the College of Clermont and to the law school at Orleans, and looked forward to seeing him succeed to his own honorable trade and office; and that the son deliberately renounced this succession, chose the actor's profession, and at the age of twenty-one became a member of a troupe of players which he helped to form—these are the principal items of our positive knowledge of the youth of Molière. This scanty material has been overlaid with a rich embroidery of tradition and anecdote, to which criticism assigns various degrees of probability, but which can in no case have authority enough to be of any service in helping us to a knowledge of the discipline and development of his mind and talent. The same is true also for the following period of fifteen years, mainly spent in traveling in the provinces, during which he was obtaining the mastery of the instrument of language and of his other dramatic tools, and deepening and enriching that observation of life and that reflection on its facts that gave the materials on which those tools were to be exercised. The new troupe, which styled itself the *Illustre Théâtre*, had at its head the Béjart family, with which Molière connected himself later (1662) by marriage, and of which the most conspicuous member was Madeleine, a woman of beauty and brilliant talents, with the character of whose relations with Molière legend and conjecture have been unprofitably busy, but whose presence so near him in the intimate associations of the theatrical life must have had serious influence upon him. Compelled by a year of persistent failure to leave Paris, where it had made its trial of public favor in the then popular tragedy, the company returned fifteen years afterward (1658) with the fame of especial success in comedy. It was as purveyor of comic material for his troupe, of which he had meanwhile become manager, that Molière founded its prosperity, and at the same time prepared his own career as dramatic author. At first doubtless his work of composition was very slight, consisting merely in throwing into rough dramatic form whatever material came to hand, or adapting to the uses of his company dramatic works from foreign, particularly Italian, sources; but, however slight, it was sufficient to develop that alert, easy, and brilliant style that made even the two pieces which he brought back to Paris (*L'Étourdi*, *Le Dépit amoureux*) of such new and fresh charm that their success was immediate, and won for Molière the protection of the king's brother, and a permanent home in Paris for his players.

Molière, however, was not content with a comedy that redeemed by qualities of style the stereotyped characters and situations of the Italian fashion, and in 1659 he gave, as if to try both his own powers and the temper of the public, the *Précieuses ridicules*, a slight and rapid sketch, in one act and in prose, whose interest could not be sought in the very simple and transparent plot, but lay wholly in the satiric portraiture of features of contemporary society. In it was clearly foreshadowed his mature comedy of manners and character, in which he was to advance from the transient interest of passing fashions to the deeper and more permanent interest of the universal human passions; but in spite of the encouraging success of the *Précieuses ridicules*, he did not make this advance at once or rapidly. Besides a lingering weakness for tragedy, which led to the heroic comedy *Don Garcie de Navarre* (1661), a signal failure that rendered further experiment in that direction inexpedient, there were two serious impediments to the realization of his highest conceptions of comedy. The concern for financial success and the prosperity of his company, which as manager he was bound to feel, forbade him to be negligent of the public taste, and dictated those lighter and more extravagant farces that sacrifice the truth and interest of character to considerations of comic effect, and the royal favor enjoyed by Molière and his company since their return to Paris, which might have secured him a greater independence toward the public taste, was accompanied with no less serious restrictions of his complete artistic freedom; for as manager of the king's comedians he was frequently charged with the preparation of those semi-operatic comedies that were the delight of Louis XIV., and a constantly recurring feature of the great *fêtes* for which his reign is famous. Of the twenty-nine compositions written by Molière after he was finally established in Paris, no less than thirteen were produced directly in view of such festivities, and were intended by their great patron to be subordinate to the accompaniment of dance and music, for which they were hardly more than a pretext. It is not strange, therefore, that it was not till 1662 that Molière gave, in the *École des femmes*, an example of the mature development of his ideas. It is rather a striking mark of his genius and of the wealth of the materials with which observation had stored his mind that in the ten years that intervened before his early death (Apr. 17, 1673), in spite of all obstacles, and under the pressure of such various and absorbing tasks, he produced the series of great comedies that remain the glory of the French drama.

The form that comedy took in these mature and free exhibitions of his art, and of which we have glimpses also even in his farces and his pieces made to order in the striking vigor and truth in the drawing of their personages, is that of the serious comedy of character—serious, not because he ever renounced the use of his great comic gift, or sought to release himself from the comic dramatist's obligation to make his audience laugh, but because the subjects treated by him, the qualities of character and motives of conduct that he presents, and the human relations that he studies are of such profound and permanent concern. The preparation of woman for her *rôle* in society, the question of what that *rôle* really is (*L'École des femmes*, *Les Femmes savantes*); hypocrisy, the means that it uses and the evils that it works (*Le Tartuffe*, *Don Juan*); avarice as a mastering passion and its effects upon the normal human affections and instincts (*L'Avare*); selfishness and an easily sacrificed morality turning a sincere and honest heart to misanthropy (*Le Misanthrope*)—these are some of the more prominent themes of these serious comedies. These qualities of character are set forth, not in abstract types or personifications of a single passion, but in very lifelike, concrete individuals which a penetrating observation of life has endowed with great truth and vitality; and these motives of conduct and these human relations are exhibited in the careful grouping of these individuals and their action and reaction upon one another, which a sane reflection upon life has informed with great interest and value. The serious comedy of Molière hardly employs other means than these for its comic effect, which is none the less genuine and irresistible for being attained by such purely intellectual means. The intrigue is slight, and accessories of costume and scenery are dispensed with. A drawing-room with its ordinary furniture, and a company of men and women in their ordinary dress, furnished all the necessary material.

The following is a list of Molière's dramatic works, with the dates of their first production: *L'Étourdi*, 5 acts, verse (1653 or 1655); *Le Dépit amoureux*, 5 acts, verse (1656); *Les Précieuses ridicules*, 1 act, prose (1659); *Sganarelle, ou le Cocu imaginaire*, 1 act, verse (1660); *Don Garcie de Navarre*, 5 acts, verse (1661); *L'École des Maris*, 3 acts, verse (1661); *Les Fâcheux* (*comédie-ballet*), 3 acts, verse (1661); *L'École des femmes*, 5 acts, verse (1662); *La Critique de l'École des femmes*, 1 act, prose (1663); *L'Impromptu de Versailles*, 1 act, prose (1663); *Le Mariage forcé* (*comédie-ballet*), 1 act, prose (1664); *La Princesse d'Élide* (*comédie-ballet*), 5 acts, verse and prose; *Le Tartuffe*, 5 acts, verse (1664); *Don Juan*, 5 acts, prose (1665); *L'Amour médecin* (*comédie-ballet*), 3 acts, prose (1665); *Le Misanthrope*, 5 acts, verse (1666); *Le Médecin malgré lui*, 3 acts, prose (1666); *Mélicerte* (*comédie-ballet*), 2 acts (unfinished), verse (1666); *La Pastorale comique* (*comédie-ballet*), 1 act, verse (1667); *Le Sicilien* (*comédie-ballet*), 1 act, prose (1667); *Amphitryon*, 3 acts, verse (1668); *George Dandin* (*comédie-ballet*), 3 acts, prose (1668); *L'Avare*, 5 acts, prose (1668); *M. de Pourceaugnac* (*comédie-ballet*), 3 acts, prose (1669); *Les Amants magnifiques* (*comédie-ballet*), 5 acts, prose (1670); *Le Bourgeois gentilhomme* (*comédie-ballet*), 5 acts, prose (1670); *Psyché* (*tragédie-ballet*), 5 acts, verse (1671), Molière and Corneille joint authors; *Les Fourberies de Scapin*, 3 acts, prose (1671); *La Comtesse d'Escarbagnas* (*comédie-ballet*), 1 act, prose (1671); *Les Femmes savantes*, 5 acts, verse (1672); *Le Malade imaginaire*, 3 acts, prose (1673).

All previous editions of Molière's works are superseded for the student by that in the series *Les Grands Écrivains de la France*, edited by Eugène Despois and Paul Mesnard (10 vols., Paris, 1873–89). The tenth volume contains a life of Molière by Mesnard. A handy small edition, in two volumes, preceded by a notice by Sainte-Beuve, has been published. His works have several times been translated into English.

recently by Henri Van Laun (6 vols., London, 1875–77), and by C. H. Wall (3 vols., London, 1876–77). An excellent *Bibliographie Molièresque* has been prepared by Paul Lacroix (Paris, 1875). A. G. Canfield.

Molin, John Peter: sculptor; b. in Sweden, Mar. 17, 1814. In 1843 he went to Copenhagen to take lessons from Thorwaldsen, but the latter died six months later, and Molin was admitted into the studio of the medalist Christensen. He studied in Rome from 1845 to 1853, and on his return to Sweden he became a professor at the Art Academy in 1855. His group *The Wrestlers*, exhibited in London in 1862, secured him a European reputation. D. July 29, 1873. R. B. A.

Molina, mō-lee′năă, Juan Ignacio (in Italian, Giovanni Ignazio): Jesuit historian; b. in the province of Talca, Chili, June 23, 1737. He was educated by the Jesuits, and taught in their colleges, but did not join the order until after its expulsion from America (1767); he then went to Italy, where, in 1771, he was admitted to the society and took orders. After 1774 he resided at Bologna. He had already shown great talents, and was master of several languages; he now devoted himself to teaching, giving his leisure to the preparation of historical works on Chili. In 1776 he published anonymously *Compendio di storia del Chile*, and this was followed by *Saggio sulla storia naturale del Chile* (1782) and *Saggio della storia civile del Chile* (1787). The latter, especially, was very popular, and was translated into several languages, including English. He published various scientific papers, and the advanced doctrines which he taught led at one time to his temporary deposition from orders. A fortune which he inherited in 1815 was bequeathed to his native city to found a literary institute. Molina's works gave the first definite account of Chili, but he can hardly be called a profound historian. D. at Bologna, Sept. 12, 1829. H. H. Smith.

Molina, Luis: theologian; b. at Cuenca, in New Castile, Spain, in 1535; entered the order of the Jesuits in 1553; was Professor of Theology at the University of Evora, Portugal, for twenty years. D. in Madrid, Oct. 12, 1601. In 1588 he published his *Liberi Arbitrii cum Gratiæ Donis, Divina Præscientia, Providentia, Prædestinatione et Reprobatione Concordia*, which, under the form of a commentary on some parts of Thomas Aquinas's *Summa Theologiæ*, attempted to explain, on a new basis, the harmony between grace and free will. The Dominicans, of whom Aquinas is the chief glory, attacked the book and the Jesuits defended it. A heated controversy between the Thomists and Molinists ensued, the matter was referred to Rome, and Clement VIII., in 1597, appointed a commission, the celebrated Congregatio de Auxiliis, to examine it. The deliberations of this body lasted, with various interruptions, nine years, the only result being that the contestants were forbidden to denounce either Thomism or Molinism as heretical. Though discussion on the subject has been renewed at various times, no decision has been rendered by the Church.
Revised by John J. Keane.

Molina, Pedro: statesman; b. in Guatemala, in 1777; received an excellent education; became a physician, and was distinguished as a poet and a politician; was noted for the liberality of the political views which he inculcated in his writings; was one of the members of the first national executive in 1823; went as ambassador to Colombia 1825, and signed a treaty of alliance; represented Central America in the Congress of Panama 1826; was governor of Guatemala 1829, Secretary of State for Foreign Affairs 1832–33; was exiled by Carrera, and resided some years in Costa Rica; was deputy to the constitutional assembly 1848, and for many years president of the medical faculty and chief director of the University of Guatemala. D. about 1850.

Molina, Tirso, de: See Tellez, Gabriel.

Moline: city (incorporated in 1872); Rock Island co., Ill. (for location of county, see map of Illinois, ref. 3–C); on the Mississippi river, and the Burl. Route, the Chi., Mil. and St. P., and the Chi., Rock Is. and Pac. railways; opposite Rock Island, 2 miles E. of Davenport, Ia., 168 miles W. of Chicago. The three cities of Moline, Rock Island, and Davenport are connected by steam and street railways, ferries, and bridges, and all derive water-power for manufacturing from the river. The city is in a rich coal-region, and there are a number of productive mines in its vicinity. It has model water-works, gas and electric lights, 10 churches, 6 public-school buildings, 38 schools, public library (founded 1873), 2 national banks with combined capital of $250,000, 2 State banks with capital of $200,000, and 2 daily, 3 weekly, and 2 other periodicals. The industries include the manufacture of agricultural implements, malleable iron, steam-engines, carriages, buggies, and wagons, paper, lumber, cabinet and pipe organs, lead roofing, windmills, milling-machines, and furniture. Pop. (1880) 7,800; (1890) 11,995; (1900) 17,248. Editor of "Dispatch."

Molinet, mō′lĕĕ′nā′, Jean: chronicler and poet; the date of his birth is unknown. He was canon of Valenciennes, librarian of Marguerite of Austria, and historiographer of the house of Burgundy. D. at Valenciennes, 1507. He wrote a chronicle of Burgundy for the years 1474 to 1506, and a number of poems, *Le Temple de Mars*, *La Vigile des Morts*, *La Complainte de Constantinople*, etc. He turned the *Roman de la Rose* into prose, and gave a Christian interpretation to its allegory. His works are marked by an affectation of wit and by a pedantic Latinizing style which his example helped to accredit. A. G. Canfield.

Mol'inism: See Molina, Luis.

Moli'no del Rey [Span., king's mill]: a massive series of buildings half a mile N. of the castle of Chapultepec, near the city of Mexico. They were originally used as a flour-mill, afterward as a foundry of arms, and were occupied as a fortress by a portion of the Mexican army during the war between the U. S. and Mexico. On Sept. 8, 1847, the buildings were attacked and carried by storm by a division of the U. S. army led by Gen. Worth. The Mexicans were commanded by Leon and Perez. Each side had about 4,000 men, and the loss on both sides was heavy.
Revised by H. H. Smith.

Molinos, mō-lee′nōs, Miguel: mystic; b. near Saragossa, Spain, Dec. 21, 1627; studied at Pampeluna and Coimbra; settled, after being ordained priest, in Rome, where a great number of people chose him for their confessor; when afterward his papers were seized, they included about 20,000 letters from persons asking for his spiritual advice. In 1675 he published his *Guida Spirituale*, which attracted great attention and was translated into different languages. It teaches that true godliness consists in uninterrupted communion with God, established by contemplation, and was the foundation of the so-called Quietism which afterward found its most striking development in Madame Guyon. The Jesuits, however, found that this view endangered the doctrine of good actions. Pope Innocent XI. condemned the book in 1687; Molinos recanted, but was imprisoned for the rest of his life in a Dominican monastery at Rome, where he died Dec. 29, 1696. See Bigelow, *Molinos the Quietist* (New York, 1882).

Molise: See Campobasso.

Mollenhauer, Edward: violinist and composer; b. in Erfurt, Germany, Apr. 12, 1827: when nine years old made a concert tour as a violinist with his two elder brothers, Friedrich and Heinrich; studied under Ernst and Spohr; fled to England to avoid becoming a soldier, and went to the U. S. in 1853, settling in New York. He has played in many concerts as a violin soloist, and has taught many violin scholars. He has composed much for his instrument: three symphonies, some chamber music, songs and miscellaneous pieces, and three operas, *The Corsican Bride* (1861); *Breakers* (1881); and *The Mask Ball*. D. E. Hervey.

Möl'ler, Poul Martin; writer; b. in Denmark in 1794; studied theology, but became a private tutor and later teacher at a Latin school in Copenhagen; in 1818 took an active part in the literary struggle of that time as a supporter of Oehlenschläger; from 1819 to 1821 was chaplain on a China merchantman; from 1827 to 1831 was Professor of Philosophy at the University of Christiania; from 1831 to 1838 held the same position at the University of Copenhagen. Besides a number of songs, he published a translation of the first six books of the *Odyssey* (1825), the earliest in Danish, philosophical and critical articles, and an unfinished novel, *En dansk Students Æventyr* (The Adventures of a Danish Student). This last, his principal work, is one of the most characteristically national productions in Danish literature. It is full of rollicking fun, and shows deep insight into human character. D. 1838. See *P. M. Möllers efterladte Skrifter i et Udvalg ved Chr. Kinther* (Copenhagen, 1873). D. K. Dodge.

Mollus'ca [Mod. Lat., deriv. of Lat. *mollis*, soft]: that great division or branch (phylum) of the animal kingdom of which the cuttlefishes, squids, snails, slugs, clams, oysters,

etc., are familiar examples. The name is given in allusion to the soft character of the tissues, a point of no importance. That branch of zoölogy which treats of molluscs is sometimes termed malacology and sometimes conchology, but both terms are passing into disuse.

To make more clear the essential features of all molluscs we construct what we may term an ideal or schematic animal which will represent the conditions found in no one species, but rather a composite of all forms. By exaggeration of some parts and by modification or even suppression of others, this typical mollusc may be made to represent all known forms. Such a typical mollusc is bilaterally sym-

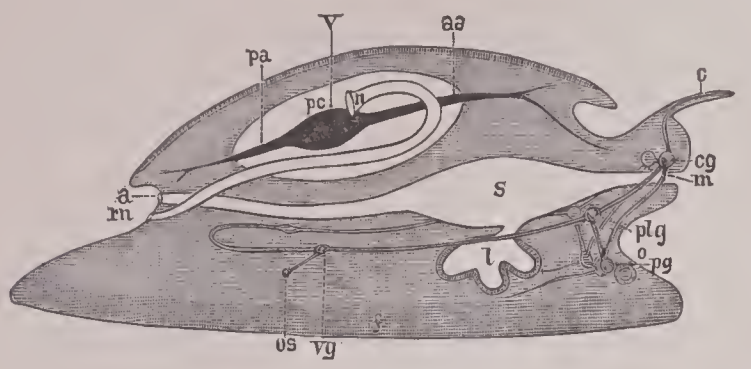


FIG. 1.—Diagrammatic longitudinal section of a mollusc: *a*, vent; *aa*, anterior artery; *c*, tentacle; *cg*, brain; *f*, foot; *l*, liver; *m*, mouth; *pg*, pedal ganglion; *plg*, pleural ganglion; *n*, nephridium; *o*, ear; *pa*, posterior artery; *pc*, pericardium; *os*, organ of smell; *rn*, right nephridial opening; *s*, stomach; *v*, ventricle of heart; *vg*, visceral ganglion.

metrical; its lower surface is developed into a strong muscular creeping-disk, the *foot*; its upper surface is thin, and in its center is a *shell-gland* which has the power of secreting the calcareous *shell* so characteristic of these animals. Around the shell-gland the wall of the body projects as a double fold in every direction, forming the *pallium* or *mantle*, and inclosing between it and the body and foot a *mantle-cavity*. At the anterior end of the body is the *head*, bearing a pair of sensory *tentacles*, and the nearly terminal mouth; the *vent* is in the median line at the posterior end of the body, and the alimentary canal with various convolutions connects the two. In the majority of forms the mouth is provided with jaws and a peculiar ribbon-like structure, armed with hooks or teeth, and variously known as the *radula*, *odontophore*, or *lingual ribbon*. This odontophore is a veritable file, and is used either to rasp the food into small particles or to drill holes through solid substances. The *stomach* is large, and is surrounded by a voluminous liver, while the *intestine* is variously wound and contorted in its course to the vent. The *heart* is dorsal; it consists of a median *ventricle* and a pair (right and left) of *auricles*, and pumps the blood received from the gills (hence arterial) through the arteries. There are no capillaries, the circulation being largely lacunar, i. e. through spaces without proper walls. Surrounding the heart is a *pericardium* or chamber which contains no blood and which is of especial interest, since it is the true body-cavity or *cœlom*, comparable with that of the annelids. This pericardium is connected with the external world by means of a pair of convoluted tubes (*organ of Bojanus*, *nephridia*) which function as kidneys. Their ducts empty into the posterior mantle-cavity, one on either side of the anus. The sexual glands (*gonads*) are also paired, and the sexual openings are near those of the excretory organs. The respiratory organs consist of a pair of

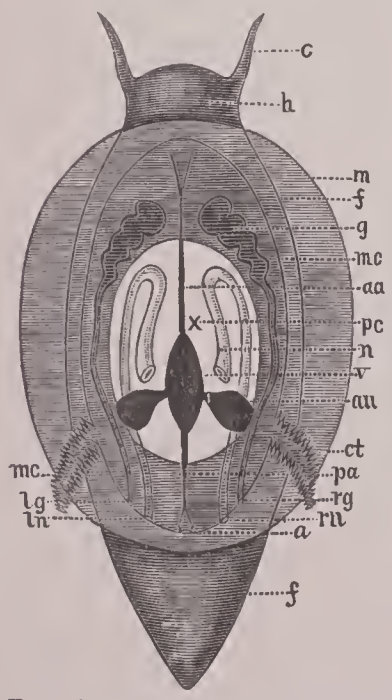

FIG. 2.—Diagram of a mollusc viewed as a transparent object from above: *au*, auricles of heart; *ct*, ctenidium (gill); *g*, reproductive organ; *h*, head; *lg*, left genital opening; *ln*, left nephridial opening; *m*, mantle; *mc*, inner boundary of mantle-cavity; *rg*, right genital opening. Other letters as before.

comb-like gills (*ctenidia*) in the posterior mantle-cavity, but these may disappear, their place being taken, functionally, by gills developed from other parts of the body or by other respiratory structures (lungs). The nervous system is complicated, and consists of several nerve-centers (*ganglia*) connected by nerve-cords (*commissures*). These paired ganglia are (1) the *cerebral*, above the mouth; (2) the *pleural*, on the sides near the head; (3) the *pedal*, in the foot; and (4) the *visceral*, on the sides of the body near the ctenidia.

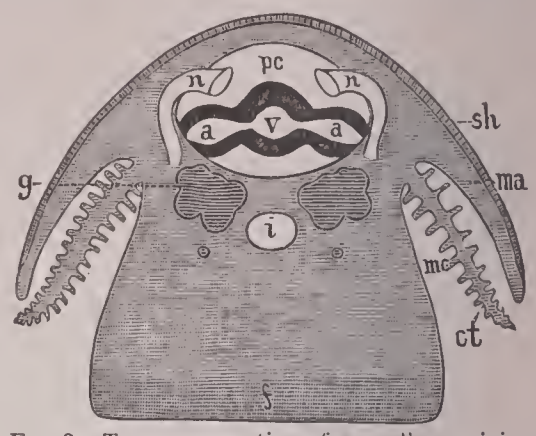

FIG. 3.—Tranverse section of a mollusc: *i*. intestine; *ma*, mantle; *sh*, shell. Other letters as before.

The typical molluscan larva is called a *veliger*, and presents many points of similarity to the larva (trochosphere) of an annelid, or to the larva of a turbellarian worm. It is characterized by the possession of a disk-shaped shell-gland with a delicate shell, a rudimentary foot, and a peculiar organ, the *velum*, consisting of a fold of skin above the mouth, armed with long vibratile cilia which serve as locomotor organs when the larva first escapes from the egg.

With this schematic mollusc as a starting-point, the structure of any of the 20,000 species may readily be understood. A few of the modifications presented by the various structures and organs may be considered here, the reader being referred to the various manuals of comparative anatomy for further details.

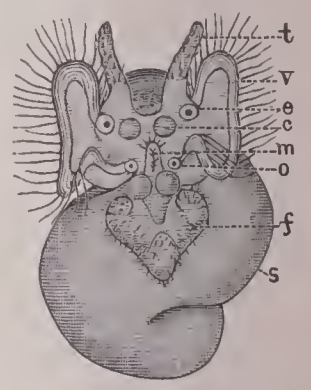

FIG. 4.—Veliger stage of *Vermetus* (after Lacaze-Duthiers): *c*, brain: *e*, eye; *f*, foot; *m*, mouth; *o*, ear; *s*, shell; *t*, tentacle; *v*, velum.

The Foot.—The primitive flat creeping-disk described above occurs in the chitons, in most Gasteropods, and in certain Lamellibranchs. It may at times be divided transversely so that three regions are recognizable, an anterior *propodium*, a middle *mesopodium*, and a posterior *metapodium*. Lateral outgrowths from the foot may also occur, *parapodia*, arising from the creeping surface, *epipodia* from its base. In most Lamellibranchs the foot is compressed, taking a tongue-like form or hatchet shape; in the Pteropods the parapodia are highly developed, and take the wing shape which gives the group its name. In the Cephalopoda two views obtain as to the foot. In one the siphon (see below) is regarded as the homologue of the foot of the Gasteropod; in the other the circle of arms around the mouth. In many molluscs the foot is provided with glands which in many Lamellibranchs secrete strong threads (*byssus*) which fasten the animal to some support.

The mantle is most primitive in the chitons and limpets, and from this condition modifications in various directions may be traced, more or less co-ordinated with the development of a *visceral sac*. This latter name is used to indicate that portion of the body which contains most of the viscera, and which may attain considerable size. It is least prominent in the Lamellibranchs, and here the mantle is developed chiefly as two lobes, one on either side, which envelop the whole body and foot. The lower edges of these mantle lobes may remain free or they may unite to a greater or less extent with openings for the protrusion of the foot and for the ingress and egress of water. These latter openings are always posterior, and the mantle may be prolonged into tubes (*siphons*) sometimes several times the length of the body. In the Cephalopods the visceral sac is greatly developed, and here the mantle is drawn out into a conical sac; in the Scaphopoda this type of modification reaches its extreme, and as the mantle is open at its dorsal end it is tubular in this group. In most Gasteropoda the visceral sac is also large, but it here undergoes a peculiar modification which needs mention. As it grows upward and backward

it topples to the one side or the other, and the result is an interference with the primitive symmetry characteristic of the typical mollusc. As a result the mantle-cavity of one side is more or less completely obliterated, the vent is forced to the opposite side, carrying with it sexual and excretory openings as well as the gills. In the extreme cases the vent is carried to the anterior end of the body, and one of the gills and one of the genital and nephridial ducts may persist, this being placed, by the twisting of the body, on the side opposite to that where it really belongs. The body may at the same time acquire a secondary symmetry, and all clews to the torsion are then to be traced only in the internal structures.

The shell is a characteristic structure, and as it is so easily preserved it is the best known part of the mollusc. It is formed primitively by the shell-gland, but the mantle may also participate in its secretion. It consists chiefly of carbonate and phosphate of lime plus a varying amount of a peculiar horny substance to which the name *conchiolin* has been given. From the method of its formation—secreted by the outer surface of the mantle and shell-gland—it follows that the newer layers of the shell are on its under or inner surface, and as the animal increases in size these newer layers project beyond the older ones, thus producing on the outer surface concentric striæ the *lines of growth*. The mantle is often ornamented with pigmented spots, and these reappear in the shell itself, giving it its peculiar markings, or there may be lobes on the margin of the mantle producing spines or ridges upon the shell. The shell layers are not all formed in the same way. In some the particles of lime have the shape of minute prisms, and in such cases the shells have a dull, earthy or porcelaneous appearance. In other forms the shell is marked with very fine lines which produce diffraction spectra, and such *nacreous* shells are prized for their irideseent or rainbow-like hues. The delicate play of color in pearls is due to the same cause.

The form of the shell varies greatly, but all forms may be reduced to the one type—a flattened cone—already mentioned, and in all but the chitons it is at first a single piece. In the Lamellibranchs this single shell breaks in the median line soon after hatching, and the resulting right and left halves form the two valves so familiar in the oysters and clams. In the case of some Gasteropods (limpets) the shell varies but little from its primitive condition, but in the others the bending of the visceral sac converts the elongate cone into a spiral, which is either right-handed or left-handed accordingly as the sac inclines to the one side or to the other. Most Gasteropod shells are right-handed, but left-handed (*sinistral*) shells occur sometimes as abnormalities in typically dextral species. In many Gasteropods the shell is more or less degenerate. In the slugs (*Limax*, etc.) it occurs only as an internal rudimentary plate, and in the naked molluscs (Nudibranchs) it is present only in the young. In the Cephalopods the shell is either external or internal, the latter being a secondary condition. In the nautilus it is divided internally by transverse partitions into a series of chambers, the purpose of which is not thoroughly understood. The internal shell in the Cephalopods may be illustrated by the "cuttle-bone" of the shops; but space will not allow a consideration of the relations of this to the *pen* of the squids and to the shell and *guard* of many fossil Cephalopods. The shell of the paper nautilus (*Argonauta*) is not a true shell, but rather an egg-protecting case.

In some Gasteropods the dorsal surface of the metapodium (see above) has the power of secreting limy matter, and thus is formed a horny or calcareous door or *operculum*

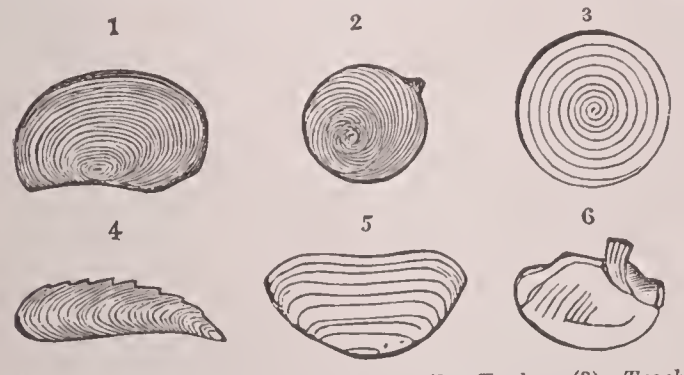

Fig. 5.—Opercula of (1) *Ampullaria*, (2) *Turbo*, (3) *Trochus*, (4) *Strombus*, (5) *Purpura*, (6) *Nerita*.

which closes the aperture of the true shell when the animal is retracted into it. From its method of formation this is clearly not the other valve of the univalve shell, comparable to the second valve of a bivalve shell, as was once held.

The various parts of the shell have received names, some of which may be defined here since they are important in the description of the various groups. In the Lamellibranchs (bivalves) the *hinge* is the line of meeting of the two valves or halves of the shell, and it is provided with an elastic *ligament*, the function of which is to open the valves when the *adductor muscles* which draw them together are relaxed. On the inner surface of the shell may be seen the impressions of these adductor muscles, one or two in number, as well as those produced by the *retractor muscles* of the foot. Along the margin is the *pallial line* caused by the attachment of the margin of the mantle, and in those forms with a well-developed siphon (see above) this line has a deep indentation (*pallial sinus*) behind, produced by the attachment of the muscles which retract these tubes. On the outer surface near the hinge is a prominence (*umbo*) around which, as a center, the lines of growth are arranged, and in most bivalves (except *Nucula*, etc.) this umbo points toward the anterior end. In the univalves the opening of the shell is the *aperture*, the axis of the spiral is the *columella*, the last whorl is the *body-whorl*, and the other whorls form the *spire*. The two edges of the aperture are the *lips*, and the place where they join the other whorls the *suture*. The spire is *posterior*, and both anterior and posterior margins of the aperture may be produced in grooves or *canals* named according to their position. The outer surface shows more or less clearly the lines of growth parallel to the outer lip, and in some species there are periods of rapid growth alternating with lines of rest. In these latter periods there is formed a thickened lip, which being left behind at the next time of growth forms a ridge or varix on the outer surface.

The odontophore occurs in all molluscs except the Lamellibranchiata and isolated individuals in other groups, and its presence or absence was formerly made a basis of division of the molluscs into two great groups. The odontophore consists of an elastic ribbon upon the floor of the throat, replaced by growth at its posterior end as rapidly as it wears away by use in front. It passes over a cartilaginous cushion, like a belt over a pulley, and is moved back and forth by appropriate muscles. On its upper surface are arranged, row after row, numbers of recurved hook-like siliceous teeth, the whole ribbon being not inaptly compared to a flexible file. The number and arrangement of these teeth vary in the different families and genera, and hence the characters presented by the ribbon have been seized upon as an aid in classification. In each transverse row there may be five different kinds of teeth; in the center a *rhachidian* tooth flanked on

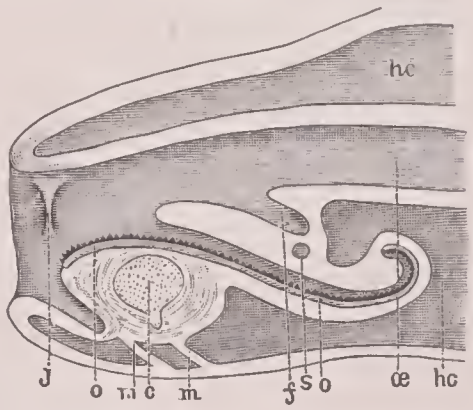

Fig. 6.—Diagram of molluscan mouth and odontophore (after Lang): *c*, tongue cartilage; *f*, fold of radula sheath; *hc*, cavity of head; *j*, jaw; *m*, muscle, *o*, odontophore; *œ*, œsophagus; *s*, opening of salivary gland.

Fig. 7.—Dentition of *Chitonellus*.

either side by one or several rows of somewhat similar *pleural* teeth, and outside of these a varying number of *uncini*. Sometimes the pleuræ may be suppressed, and in certain groups the rhachidian teeth may disappear. The number of teeth on the odontophore vary between very wide limits. Thus in *Eolis drummondi* the total is 30, in *Littorina litorea* 3,500, in *Helix pomatia* 21,000, and in *Helix ghiesbreghti* 39,596. A *dental formula* has been devised to represent diagrammatically the teeth in a transverse row. Thus in *Chitonellus* (see cut) the formula is 5 + 3 + 1 + 3 + 5, indicating that there are five uncini and three pleurals on either side and a single rhachidian in the middle,

while the formula for *Murex* is 1 + 0 + 1 + 0 + 1, the pleurals being absent.

The respiratory organs consist primitively of at least a pair of comb-like or feather-like gills, but the fact that in the chitons and in the Nautilus—the most primitive of the Cephalopods—there is more than one pair, points to the conclusion that this may have been the primitive condition. Each gill possesses two blood-vessels, an artery which brings venous blood from the body, while the vein carries it in the purified condition to the auricle of the heart. At the base of each gill is a peculiar sense-organ, regarded as an organ of smell. As this primitive type of gill may disappear, its functions being taken by other structures, the name *ctenidium* has been applied to it (Gr. κτείς, comb + εἶδος, form), to avoid confusion with other gill-like structures. The ctenidium has undergone least modification in the Lamellibranchs, Cephalopods, and lower Gasteropods. In the other Gasteropods occurs that twisting of the body whereby the gills change sides, and by which one of them may entirely disappear, and with its loss one of the auricles of the heart becomes obsolete. In others of the Gasteropods and in the tooth shells (Scaphopoda) the ctenidia may entirely disappear, their place being taken either by "adaptive gills" developed from almost any part of the body or by so-called lungs, as in our land snails or, lastly (Scaphoda), by the general body walls. The *lungs*, just referred to (see Pulmonata), are formed by a growth together of the mantle edge with the wall of the body, leaving but a small respiratory pore which communicates with the mantle cavity, now converted into the pulmonary sac. The inner upper surface of the sac is lined by a delicate membrane in which a rich network of blood-vessels occurs. The transfer of gases takes place here in the same way as in the human lung. Certain of the lung-bearing Gasteropods have become aquatic (*Lymnæidæ*), but these are forced to come occasionally to the surface and then to breathe like their terrestrial relatives. In the deep water of the Lake of Geneva, however, there occurs one of these Pulmonates (*Lymnæa abyssicola*) which fills its pulmonary sac with water, but the sac seems to have undergone no essential modifications.

Nervous System and Sense Organs.—The nervous system presents too many complications for description here, further than is hinted at in the account of our schematic mollusc. One feature, however, needs mention. In the twisting of the body as a result of the weight of the visceral sac, the commissures leading to the visceral ganglia may become included, the result being that the cords become crossed, and that visceral ganglion which morphologically belongs to the right side is carried to the left and *vice versa*. The organs of special sense deserving notice are the eyes and ears. The olfactory organ has already been mentioned. In most forms the eyes are borne on the head and present varying degrees of complexity. In all cases they are formed by an involution of the external skin, and in the Nautilus the interesting feature occurs of an image-forming eye without a lens, the structure being a reproduction of the "pin-hole camera," which is so familiar. In the Lamellibranchs, where a head is absent, the eyes, when present, occur in other parts. In some they are placed at the ends of the siphons, while in the scallops (Pecten) they are placed at regular intervals along the margin of the mantle, where they appear like veritable jewels. The ears, which are almost universally present, are epithelial sacs in close proximity to the pedal ganglia. The lining cells of these sacs (or *otocysts*) are connected with nerve-fibers, and the cavity is provided with (1 to 100 or more) hard bodies (*otoliths*), which, set in vibration by the sound-waves, hit the sense-cells and thus stimulate the nerves.

Class I. Amphineu'ra. Bilaterally symmetrical marine molluscs with two pairs of longitudinal nerves, untwisted, with ganglion-cells their whole length, and connected by numerous transverse cords.

Order I. Placoph'ora (or Polyplacoph'ora) Amphineura with an oval outline; above the body is protected by eight plates of shell overlapping like shingles. Below (except in *Chitonellus*) is a large creeping foot. In the mantle-cavity are numerous gills (*ctenidia*), and into it empty the paired reproductive and excretory ducts. The median heart is provided with two auricles; the head is not distinct, and cephalic tentacles are lacking. Eyes are usually said to be lacking, but in some species the shells are covered with sense organs (*æsthetes*), which Blumrich regards as tactile. Some of these, however, become modified into organs which, structurally at least, are eyes. A lingual-ribbon is present. The chitons (see Chiton) are comparatively few in number, and most species live in shallow water.

Order II. Solen'ogas'tres. Represented by a few worm-like molluscs (*Chætoderma*, *Neomenia*) from the deeper seas, in which a shell is lacking; the cuticle contains calcareous spicules, the mantle-cavity is reduced, and the foot is rudimentary or even entirely absent.

Class II. Gasterop'oda. Embraces the snails, slugs, etc. Asymmetrical molluscs with a distinct tentacle-bearing head, a large creeping-foot, the viscera contained in a large protruding dorsal visceral sac (which may be secondarily lost), which is usually covered by a univalve shell (generally spirally coiled) into which the whole body may be retracted for protection. A lingual ribbon is always present. The class is divided into three orders—Prosobranchia, Pulmonata, and Opisthobranchs—for the details of which reference should be made to the article Gasteropoda.

Class III. Scaphop'oda. Symmetrical marine molluscs in which the body is elongated in a dorso-ventral direction, and the mantle is converted into a tubular sac which secretes a slightly curved tubular shell open at either end. Ctenidia are lacking, and the strong foot forms an efficient digging organ. These forms (*Dentalium*, etc.), which receive their name, tooth-shells, from their resemblance to an elephant's tusk, have very little of popular interest.

Class IV. Lamellibranchiata. Symmetrical molluscs with the laterally compressed bodies inclosed in a bivalve shell, with a hinge above, the valves opening freely (except in a few sedentary forms) below. The valves are opened by an elastic hinge ligament, and are closed by means of adductor muscles which pass from one to the other. The mantle-cavity is large, and contains the usually broad lamellate gills, there being two on either side. Between the gills is the visceral mass, the foot extending from its lower surface. A distinct head is lacking, as are all of the cephalic organs—eyes, tentacles, radula, etc.—found in the other molluscs. Nephridia and sexual organs are paired, and the heart in most forms has two auricles. Some are dioecious, some hermaphrodite; all are aquatic, most living in the sea. Five orders are recognized: *Protobranchia*, *Filibranchia*, *Pseudolamellibranchia*, *Eulamellibranchia*, and *Septibranchia*. For details, see Lamellibranchiata.

Class V. Cephalopoda (*q. v.*). In these bilaterally symmetrical forms the body is usually elongated in the dorso-ventral direction, the mantle-cavity being large. The foot is divided into two portions. Of these the anterior becomes produced into a circle of arms or tentacles surrounding the mouth, while the rest is formed into the siphon, to be mentioned again below. The arms—eight, ten, or many in number—are provided with numerous sucking-cups, by means of which the animals are enabled to seize their prey. In many forms one of these arms, in the male, can be charged with packets of sperm, and then it is separated from the body and becomes attached to the female. The siphon is a tube on the lower surface of the body, produced by the union of the edges of the foot; into it empty the alimentary canal and the duct of the ink-gland, and it forms, besides, the most efficient organ of locomotion, the water which is taken into the mantle-cavity being forcibly expelled through this tube, the reaction carrying the animal swiftly through the water. The mouth is always provided with an odontophore, and it has, besides, a pair of horny jaws, shaped much like those of a parrot. The auricles and the ventricles of the heart are always separate, and the auricles may be either two or four in number, the number always agreeing with that of the gills. Another feature is the presence, in all the Dibranchiate forms, of an ink-bag which secretes a colored fluid which is discharged, making clouds in the water whenever the animal wishes to escape from its enemies. Many species have the power of changing the color of the body by means of curious expansible color-bearing cells (chromatophores) situated in the skin. In the rapidity and extent of these changes they far excel the famed chameleon. The nervous system is highly developed, and the central portion or brain is inclosed in a cartilaginous case recalling the vertebrate skull. The sense-organs, especially the eyes, are also highly developed. The eyes in the Nautilus are built upon the principle of the "pin-hole camera," but in the others a lens is present, and the whole closely simulates the visual organ of the vertebrates, although developed in an entirely different manner.

The Cephalopoda are divided into two orders based, among other things, upon the number of gills. In the Tetrabranchiata there are four gills, and in the single existing

genus, *Nautilus*, there is a coiled external shell, the interior of which is divided into chambers, in the outer one of which the animal lives. In geological times this order was much more numerous, Ammonites and Nautiloids being very abundant in the Palæozoic and Secondary rocks. In the Dibranchiata there is a single pair of gills, and the shell, when present, is rudimentary and internal. The Dibranchiates are subdivided into two groups, the Octopoda with eight arms and the Decapoda with ten. To the Octopoda belong the cuttlefish proper, and the cuttlebone, fed to birds, is the internal shell of these forms. In the case of the paper nautilus an external shell is built, but this occurs only in the female, and the shell, which is in reality but a case for the eggs, is formed, not by the mantle, but by a pair of expanded arms. In the Decapoda are grouped the squid and their allies, and of these the giant squid of Newfoundland deserve especial mention. Only recently have they been brought to the attention of naturalists. The largest one known measured 20 feet from the beak to the end of the body, while one of the arms was 35 feet in length. The smaller squid are caught in large numbers as bait for cod.

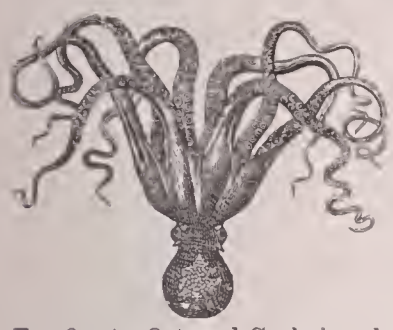

FIG. 8.—An Octopod Cephalopod: *Octopus tuberculatus* (about one-tenth its natural size).

The literature of the Mollusca, especially that descriptive of the shells, is enormous. In spite of its age, the best general work is Woodward's *Manual of the Mollusca* (3d ed. 1875). The best account of anatomy and embryology will be found in Lang's *Lehrbuch der vergleichenden Anatomie* (1892). Several authors have attempted monographs of all known species. Of these the most complete are the works of Kiener, Martini and Chemnitz, and Tryon. See PALEONTOLOGY. J. S. KINGSLEY.

Molluscoi'dea [Mod. Lat.; *mollus'ca*, mollusc + Gr. *εἶδος*, appearance, form, likeness]: a name applied by Henri Milne Edwards in 1844 to a group of animals containing the Brachiopods, Polyzoans, and Tunicates. These are now distributed in other classes, and the term is not now used in systematic zoölogy. See BRACHIOPODA, BRYOZOA, TUNICATA, and PALEONTOLOGY. F. A. L.

Mollymawk: the common or almost universal name among English-speaking sailors for the smaller albatrosses, *Diomedea brachyura*, and *D. melanophrys*. It is a modification of the German *mallemuck*, applied to the fulmar petrel (*Fulmarus glacialis*), which in turn came from the Dutch *mallemugge*, a name for small flies or midges which associate in swarms. F. A. L.

Mo'loch, or **Molech** [from Heb. *mōlekh*, deriv. of *melekh* (: Arab. *melik*), king], called also **Milcom** (1 Kings xi. 5) and **Malcham** (Zeph. i. 5): the fire-god of the Phœnicians (a modification or hypostasis of Baal, the sun-god), but spoken of in Scripture as more especially "the abomination of the Ammonites." That children were sacrificed to this deity is not to be questioned, although "passing through the fire to Molech" may not always mean so much. Solomon and other later Kings of Judah are mentioned as worshiping it, but the captivity seems to have effectually extirpated his cultus. Diodorus Siculus (xx., 14) describes a brazen image used among the Carthaginians in sacrificing children to Cronos or Saturn. Revised by S. M. JACKSON.

Molokai, mō-lō-kaa'ĕē: the middle island of the Hawaiian group, and one of the smallest. It is 35 miles long by 6 broad, contains about 175 sq. miles, and is thinly populated. It is flat in the center, but elevated at the ends; the western part is arid, the eastern wooded. There is a colony of lepers on the island, numbering about 700. On the island Oahu, to the W., is an asylum for the children of these lepers. Pop. Molokai and Lunai (1900), 2,504. M. W. H.

Molting: See MOULTING.

Molt'ke, HELMUTH CARL BERNHARD, von: field-marshal; b. Oct. 26, 1800, at Parchim, in Mecklenburg; was educated at the Military Academy of Copenhagen; entered the Prussian service in 1822, and was appointed a member of the staff in 1832. He devoted himself with great energy to the scientific part of his office, and published in 1835 a work on the Turko-Russian war of 1828–29. This war, as all questions relating to the Orient were of great interest to Prussia, led Moltke, who was thoroughly conversant with them, to make a journey to Turkey in 1835. The sultan, Mahmud, to whom he was introduced, and whose confidence he enjoyed, procured for him a furlough of several years, during which time he aided the sultan by his advice, both in the reorganization of the Turkish army and in the improvement of the fortifications of Silistria, Shoomla, Varna, Roostchuk, and the Dardanelles. Together with several other Prussian officers on furlough, he accompanied the Turkish army in the campaigns against the Kurds and against Mehemet Ali, Viceroy of Egypt. After the death of Sultan Mahmud he returned home, and published in 1841 *Letters on the Situation in Turkey in the Years 1835–39* (1841), and a map of Constantinople and the Bosphorus on the scale of 1 : 25,000. In 1846 he was appointed adjutant to Prince Henry of Prussia, who lived in Rome, and the fruit of his residence in this city was a map of its surroundings. After the death of the prince in 1847, he was attached to the governor-general on the Rhine, and became chief of a division of the staff in 1848, chief of the staff of the Fourth Army-corps from 1849 to 1855, adjutant to Prince Friedrich Wilhelm in 1856, and chief of the staff of the whole army in 1858. In this prominent position he made his name immortal as a general. Under his inspiriting leadership the staff became a most convenient and effective means of commanding the army, and in the subsequent wars his plans and dispositions resulted in an unbroken series of brilliant victories. For the achievement of such results the presence of the king was of vital importance. In 1866 and in 1870–71 the latter led as commander-in-chief, and gave absolute authority to Moltke's dispositions. On a minor field, in 1864 against Denmark, Prince Friedrich Karl having received the command in April, Moltke led the army for the first time in war, having drawn up beforehand the plan of the whole campaign. In 1866, in the war against Austria and her allies, he entered a larger theater, and showed his strategical talent in a most brilliant manner. In June, 1866, he was made a general of infantry, and after the short and astonishing campaign was finished the king gave him the highest Prussian order, that of the Black Eagle, and the Diet voted him a dotation. He was elected a deputy to the North German Diet in the next year. Anticipating the French attack, he planned a campaign against France immediately after the Austrian war. This plan was laid before the king in 1868, and followed out in 1870 as far as such a plan could be followed—that is, with respect to the organization of the army and the choice of the first point of attack. The French campaign of 1870–71 is probably one of the most brilliant that have ever been fought, and although its entire success can not be ascribed to Moltke, as many different agencies were at work, the larger share is nevertheless his due. Although possessed of the highest theoretical education, he was never caught by a theory, but surveyed with admirable freedom the changing incidents of war, and acted in accordance with them. With him the greatest audacity of plan was connected with a perfectly cool and sober calculation in the execution; and this was his greatness. On the day of the capitulation of Metz the king made him a count; on the conclusion of the armistice he gave him one of the five grand crosses of the Iron Cross, and on the day of the return of the troops to Berlin he made him a field-marshal. He also received a dotation of 300,000 thalers, and the freedom of many cities was presented to him. His ninetieth birthday was celebrated in Berlin with great magnificence. He was not very talkative, and as he was thoroughly conversant with several languages, people said of him, epigrammatically, that he was silent in seven languages. Among the works which he partly wrote, partly edited, are *The Italian Campaign of 1859* (1863); *The German Army* (1871); and *The Franco-German War* (1872). He was placed on the retired list of the army in 1888 and appointed president of national defense. D. in Berlin, Apr. 24, 1891. Revised by JAMES GRANT WILSON.

Moluc'cas, or **Spice Islands**: a large group of islands of the Malay Archipelago, lying between Celebes and New Guinea, between lats. 3° S. and 6° N., and between lons. 126° and 131° E. Total area about 42,000 sq. miles. They are all of volcanic origin, high, mountainous, and exceedingly fertile. The forests, which cover the mountains to their very tops, contain teak, ebony, sandal, iron, and satin wood, besides palms, breadfruit trees, and many varieties of the finest fruit-trees. Rice, sage, cotton, indigo, coffee, and sugar are grown; the nutmeg and the clove are indigenous to

all the islands, but the Dutch have confined the cultivation of the clove to Amboyna and the Uliassers, and that of the nutmeg to the Banda islands; on the other islands the trees of native growth have been rooted out. The original inhabitants were Malays; Arabs, Hindu, and Chinese have since immigrated and settled, and there are many mestizoes, descendants of Europeans—Portuguese, Spaniards, or Dutch—and natives. The northern division of the archipelago, comprising the islands of Ternate, Tidore, Batjan, Makian, Motir, and the Obi group, and forming the residency of Ternate, which contains about 100,000 inhabitants, is only indirectly under Dutch Government, while the southern division, comprising Amboyna, the Banda islands, and the Uliassers, and forming the two residencies of Amboyna and Banda, which together contain about 242,000 inhabitants, is governed directly as a province of the motherland. The northern division is inhabited largely by Mohammedan pirates; the southern by Christians in orderly communities. The Dutch have possessed these islands since the beginning of the seventeenth century. See AMBOYNA and BANDA ISLES.

Revised by M. W. HARRINGTON.

Mo'ly [= Lat. = Gr. *μῶλυ*]: a fabulous herb, a sovereign remedy for all diseases, which Mercury gave Ulysses as a counter-charm against Circe. The ancients identified it with a species of garlic. A wild Oriental garlic is now called *Allium moly*; it is a showy plant, cultivated under the name of golden garlic for ornament.

Molyb'denite: the natural sulphide, a mineral crystallizing in the hexagonal system, with eminent cleavage, and occurring commonly foliated or in highly flexible, inelastic scales. In its crystallization, hardness (1–1·5), lead-gray color, and metallic luster it much resembles graphite, but is distinguished from that mineral by its streak, which is lead gray, its specific gravity, 4·6, and by emitting sulphurous fumes before the blowpipe. It is met with in gneissoid, granitic, and other crystalline rocks. The natural dioxide, molybdic acid, occurs as *molybdite*, a yellow earthy mineral, and also combined in several minerals, as with lead in wulfenite.

Molybde'num [from Mod. Lat. *molybdæ'num*, from Lat. *molybdæ'na* = Gr. *μολύβδαινα*, galena or litharge, deriv. of *μόλυβδος*, lead]: an elementary metal, occurring in a well-known mineral which is so extremely similar to graphite or black lead that it was first discovered in 1778 by Scheele to yield the peculiar oxide known as *molybdic acid*. A few years later, in 1782, Hjelm isolated its metal. Molybdic acid occurs native, as *molybdite* or molybdic ocher, of which there are several American localities. Of the native sulphide, *molybdenite*, there are quite a number of localities in America. Its most important compound, practically, up to this time, is the compound of molybdic acid with ammonia, used in chemical analysis for the detection and determination of phosphoric acid.

Revised by IRA REMSEN.

Mombasa: an important town on a coral island near the east coast of Africa, in 4° 4′ S. lat., with one of the best harbors on that coast (see map of Africa, ref. 6–G). Founded by the Arabs after they began their occupation of the east coast in the eighth century, seized by the Portuguese in the sixteenth century, and from early in the seventeenth century the possession of the rulers of Muscat and Zanzibar, it was ceded (1891) in perpetuity to the Imperial British East Africa Company, and is the capital of their territory Ibea. It is comparatively healthful, its harbor has been greatly improved, many new houses have been built, and it is to be the coast terminus of the railway to Victoria Nyanza. Mombasa is the starting-point of many caravans to the interior. Pop. about 25,000.

C. C. ADAMS.

Moment: a term used in mechanics, with several significations. The moment of a force with regard to an axis is the product of the force by a certain function of its position with regard to the axis; it is the measure of the tendency of that force to cause rotation about the axis. If the axis and force are at right angles, the moment is simply the product of the force by its distance from the axis, and in that case the moment of the force may be said to be taken with regard to the point in which the perpendicular plane through the force meets the axis. If there be several forces acting in the same plane, the sum of their moments, with regard to an axis perpendicular to the plane, or a point in the plane, taken positively or negatively, according to the direction in which they cause rotation, is called the resultant moment. If this resultant moment be zero for all points in the plane the forces are in equilibrium, and conversely, if several forces in the same plane are in equilibrium the algebraic sum of their moments with regard to any point must vanish. (See STATICS.) If the forces be expressed in pounds and the distances in feet the moments are expressed in the compound unit called a pound-foot.

The *bending moment* at any section of a beam is the algebraic sum of the moments of all the forces on either side of that section. Thus in Fig. 1 the beam, whose depth is d

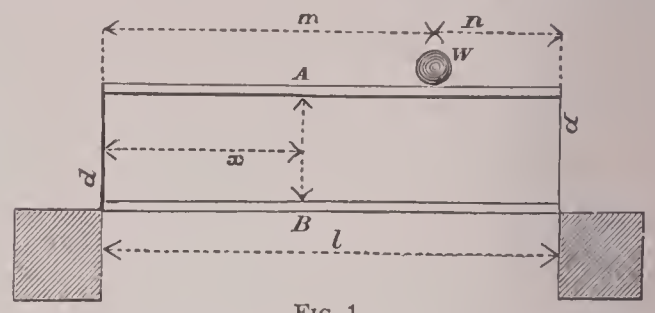

FIG. 1.

and length is l, is loaded with a single weight W, whose distance from the left and right supports are m and n respectively. The reaction of the left support, due to the weight W, then is $W\frac{n}{l}$, and the reaction of the right support is $W\frac{m}{l}$. The bending moment at the section AB distant x from the left support, is $W\frac{nx}{l}$. Accordingly, the bending moment for a section between the left support and the weight varies directly as x, it being zero at the support and becoming $W\frac{nm}{l}$ at the load. The greatest bending moment due to W will occur when it is at the middle of the span, or when $m = n = \frac{1}{2}l$, and this is the position which causes the greatest stress in the beam. (See FLEXURE.) If a load, W, be uniformly distributed over a beam, so that w is the load per linear unit, the bending moment at any section distant x from the support is

$$M = \tfrac{1}{2}wlx - \tfrac{1}{2}wx^2,$$

and the law of variation of the moments is that of a parabola. The maximum bending moment occurs at the middle of the span, or when $x = \frac{1}{2}l$, and its value is $\frac{1}{8}Wl^2$, which is only one-half of that due to the same load concentrated at the middle.

The *statical moment* of a plane surface is the sum of the products obtained by multiplying each element of the surface by its distance from an axis in that plane. If a be any elementary area and y its distance from an axis, the general expression for the statical moment is Σay. As one of the simplest special cases the rectangle in Fig. 2, whose breadth is b and depth d, may be considered, and with reference to an axis coinciding with the base the statical moment is $\frac{1}{2}bd^2$. This may be obtained by summing the expression Σay by the integral calculus, or more simply by multiplying the area of the surface by the distance of its center of gravity from the given axis. If the axis pass through the center of gravity of the surface the statical moment is zero.

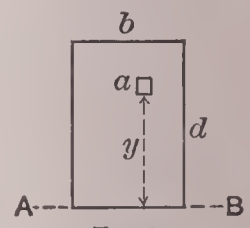

FIG. 2.

The *moment of inertia* of a plane surface is the sum of the products obtained by multiplying each element of the surface by the square of its distance from an axis in the same plane. Thus the general expression is Σay^2, and the value for any particular case is obtained by integration. For instance, the moment of inertia of the rectangle in Fig. 2, with respect to the axis AB, is

$$I = \int_0^d (bdy)y^2 = \tfrac{1}{3}bd^3.$$

The least moment of inertia with respect to an axis parallel to AB will be for an axis through the center of gravity of the given surface; for the rectangle this is $\frac{1}{12}bd^3$. The term moment of inertia when used without qualification generally means the value for an axis through the center of gravity of the figure; if this be called I the moment of inertia I' for any other parallel axis may be derived by the rule $I' = I + Ah^2$, where A is the area of the surface and h the distance between the two axes. The values of the least

moments of inertia for the cases of most importance are given in the article FLEXURE.

The polar moment of inertia of a plane surface is the product Σay^2, where y is estimated with respect to a point in the plane instead of with respect to a line. Its value can be found by a double integral in polar co-ordinates, or more simply by adding together the two moments of inertia taken with respect to two axes at right angles to each other and passing through the given point. Thus the polar moment of inertia of a rectangle with respect to its center is $\frac{1}{12}bd^3+\frac{1}{12}b^3d$. The polar moment is principally used in connection with the torsion of shafts.

In the computations arising in the design of structures and machinery, tables giving numerical values of the moments of inertia of angle-iron sections, I-beams, etc., are advantageous. These will be found in Trautwine's *Engineers' Pocket-book*, and extensive tabulations for the various sections of columns are given in Osborn's *Tables of Moments of Inertia* (New York, 1889). See also DYNAMICS and FORCE. MANSFIELD MERRIMAN.

Môniers, mō′mi-ā′ [= Fr., liter., mummers, maskers; cf. O. Fr. *momer*, mumm, mask one's self]: the cant name given in 1818 to a body of evangelical Protestants of Switzerland and the adjoining parts of France and Germany, whose distinguishing characteristic was the fervency of their religious exercises. The Môniers accused the national Church of Switzerland of apostasy from Calvinism, especially in denying the divinity of Christ. They were consequently subjected to repressive measures, and ultimately returned to the orthodox communion. The most distinguished of the Môniers was Rev. Cæsar Malan. See *Geschichte der Momiers* (2 parts, Basel, 1825).

Momm'sen, THEODOR: historian; b. at Garding, Schleswig, Germany, Nov. 30, 1817; studied law and philology at Kiel; traveled 1844–47 in France and Italy collating MSS. and inscriptions; was Professor of Roman Law at Leipzig in 1848, but was dismissed for political reasons; was called to Zurich in 1852, to Breslau in 1854, and to Berlin in 1858 as Professor of Ancient History. Mommsen is alike distinguished as a historian, jurist, epigraphist, numismatist, and philologist proper. Of the monumental *Corpus Inscriptionum Latinarum*, of which he is the originator and editor-in-chief, he himself published vol. i., iii., viii., ix., the preface to vol. i. being additionally noteworthy as one of the finest specimens of modern Latin prose. This work has illumined vast areas of previous darkness, and laid the foundation for the scientific study of Roman antiquities; his *Roman History* (vol. i.–iii., 8th ed., vol. v., 3d ed., on the Roman provinces; vol. iv. on imperial Rome is not to appear till after his death; transl. into English by W. P. Dickson) is one of the great masterpieces in the domain of historiography. Its style is of crystalline clearness, and in the famous chapters dealing with Roman literature or in his characterizations of individuals, for instance, it is brilliant. The originality of his inferences and historical combinations, based as they are upon an unprecedented mastery of all available sources of information, have elicited universal admiration even by those who attacked some of his views, notably his flagrantly unjust disparagement of Cicero. His *Römisches Münzwesen* (1850), *Römische Chronologie* (1859), and above all his *Römisches Staatsrecht* (3 vols., 3d ed. 1888), are the fundamental and standard works on these respective subjects. Equally celebrated are his edition of the *Digests*, *Solinus*, *Jordanes*, the *Monumentum Ancyranum*, his *Römische Forschungen*, 2 vols., *Zur Lebensgeschichte des jüngeren Plinius* (in *Hermes* iii., pp. 31–139), etc. A complete list of all his writings up to 1887 is given by C. Zangemeister, *Theodor Mommsen als Schriftsteller*, and takes up sixty closely printed pages. In 1880 part of his fine library was destroyed by fire, but was replenished by donations from foreign scholars.—TYCHO, brother of Theodor, b. at Garding, May 23, 1819; studied at Kiel, traveled in Italy and Greece, and taught in gymnasia in Eisenach, Oldenburg, and Frankfort. He is chiefly known as the editor of *Pindar* (1864); wrote *Parerga Pindarica* (1877); and is the author of a German translation of his favorite poet.—AUGUST, another brother, b. at Oldesloe, July 25, 1821; studied at Kiel; taught school in various German cities. He is an authority on Greek and Roman chronology. Cf. especially *Heortologie* (1864); *Chronologische Untersuchungen über das Kalenderwesen der Griechen* (1883). ALFRED GUDEMAN.

Momostenan'go: a town of Guatemala, department of Totonicapan; on the high plateau; about 12 miles N. N. W. of Totonicapan city and 60 miles W. N. W. of Guatemala (see map of Central America, ref. 3–D). It is an agricultural center of some importance. Pop. (1892) said to be nearly 17,000. H. H. S.

Momot'idæ [Mod. Lat., named from *Momo'tus*, the typical genus, from Eng. *momot*, from Amer. Ind. *motmot*, momot, Momotus]: a family of birds containing the motmots. The bill is rather long, somewhat decurved, depressed at the base, compressed forward, and with denticulated edges; the tarsi short and scutellated; the toes normal; the tail is graduated and produced toward the middle. The maxillopalatines and vomerine bones are of the "desmognath" type. The birds are most closely related to the todies (*Todidæ*) and more distantly to the *Coraciidæ*, *Meropidæ*, and *Alcedinidæ* or kingfishers. According to Murie (*Ibis*, 1872, pp. 383–412) there are four well-defined genera—viz., *Momotus*, *Barypthengus*, *Hylomanes*, and *Eumomotus*.

Revised by F. A. LUCAS.

Mompox, mōm-pōs′ (often written MOMPOS, or MOMPOZ): a town of the department of Bolivar, Colombia; on a swampy island, formed by the river Magdalena, which here divides into several channels; near lat. 9° 18′ N. (see map of South Ameriea, ref. 1–B). It was founded by Heredia in 1539 on the western bank of what was then the main river channel, and it was long the chief river-port of this region. In 1762 it was nearly destroyed by a flood, but was rebuilt. In 1868 the main river channel became changed to one of the other branches, and only small boats can now reach Mompox; in consequence, the place is falling to decay. Mompox has a college of some note. It was the scene of important combats during the war for independenee. Pop. about 10,000. H. H. S.

Mo'mus [= Lat. = Gr. *Μῶμος*, liter., blame, ridicule]: in Greek mythology, a son of Night, according to Hesiod, and the personification of mockery and censure. Aphrodite was the only being whom he found blameless, a fact which angered him so much that he burst.

Mon'achism [from Lat. *mo'nachus*, monk (whence Eng. *monk*) = Gr. *μοναχός*, monk, deriv. of *μόνος*, alone]: a life of religious retirement from the world, whether in solitude (the anchoretie or eremitic life) or in company with others (the cœnobitic life). Monachism is of very ancient origin, and has a history without as well as within the Christian Church.

I. PRE- AND EXTRA-CHRISTIAN MONACHISM.

Pre-Christian monachism had its most elaborate and striking development in India.

Hindu Monachism.—The beginnings of Hindu monachism are shrouded in mystery, but Buddha found it in existence as an important adjunct if not an essential feature of Brahmanism when he began his work in the fifth or sixth century before Christ, and doubtless it was already of long standing. According to the code of Manu, which, though of uncertain date, is the chief embodiment of nomistic Brahmanism, the lives of all twice-born men, or members of the three highest castes, Brahmans, Kshatriyas, and Vaisyas, are to consist of four stages or periods. They are to be first unmarried students, then married householders, then they are to leave their families and retire to the forest, where they are to live the life of anchorites, and finally they are to become and remain until death mendicants, absorbed entirely in religious contemplation. This rule was of course never carried out strictly by all, but Hindu monks, especially from the ranks of the Brahmans, were certainly numerous at an early day.

The austerities to which many of these monks subjected themselves were very severe. From the earliest times Brahmanism had made much of the doctrine of penance, and had taught that not only the voluntary relinquishment of the comforts and amenities of life, but also self-inflicted bodily torture, was efficacious for the acquirement of religious merit, and for the release of the soul from the bondage of transmigration and its absorption in deity. Where such a belief existed of course not only retirement from the world for the sake of religious meditation, but also ascetic practiees of the severest kind were bound to be widely adopted by such as were supposed to be in a position to benefit by them —that is, by the "twice-born." The forests and mountains during the centuries preceding the Christian era were filled with devotees, whose austerities equaled anything that can be found in history. They lived on roots and herbs; they drank water only; they exposed themselves unprotected to

all changes of the weather; they scourged and lacerated and mutilated themselves; they went almost naked, many of them entirely so. They became known to the Greeks in the time of Alexander, and were called by them gymnosophists, or "naked philosophers," and there can be little doubt that their influence was felt to a greater or less extent by many, not only among the Greeks, but also among the peoples of Western Asia, and possibly even among the Egyptians.

Gautama and Buddhistic Monachism.—The greatest figure in the history of Hindu monachism is Gautama, the founder of Buddhism. Out of the individualistic monasticism of Brahmanism he built a monastic order, and promoted the cœnobitic at the expense of the eremitic mode of life. His principal object was the formation of a monastic brotherhood, the members of which should be dominated by one idea and pledged to the propagation of one doctrine—that all life is misery and must be got rid of by a long process of discipline, which involves in this life the subjugation of the body and its passions by rigid asceticism, and by the undivided devotion of the soul to spiritual things. Such a monastic brotherhood or order, as Monier-Williams well says, "constituted in its earliest days the very essence, the very backbone, of Buddhism, without which it could never have been propagated nor even have held its own." Buddhism was in fact itself monasticism, for no one could become a truly enlightened disciple of Buddha, no one therefore could attain the blessedness of Nirvana, who had not lived for some time at least the life of a monk.

Buddhistic monachism differed from earlier Hindu monachism in still another and very important respect. In Brahmanism the monastic life was open only to the three upper castes, and in practice was confined chiefly to the Brahmans themselves; but Buddha threw his order open to all. Even the lowest might enter it and through it attain that blessedness which had hitherto been reserved for the favored few. Moreover, in spite of the stigma which attaches in India to unmarried women, Buddha even sanctioned female monachism and organized an order of nuns, thus making the highest blessedness possible of attainment to women as well as to men. Buddha's monastic order did not constitute a priest class, nor was the rite of initiation looked upon in any sense as an act of ordination conferring special grace upon the initiated. There was no hierarchical organization, and no central authority. No vow of obedience was taken, as in the monastic orders of Christendom, each monk being left to work out his own salvation in his own way, and expulsion from the brotherhood took place only in case of the gravest offenses, such as theft, murder, and indulgence in sexual intercourse. Nevertheless the monks were expected to govern themselves by certain well-defined rules. They were to eat only the simplest food, and to possess nothing except what they got by collecting alms from door to door. They were to eat only one meal a day, and were to abstain entirely from intoxicating drinks. They were to live during the dry season in the forests with no covering except the leaves of the trees; during the wet season they might dwell in caves, or in huts built in groups and forming regular monastic villages. Their clothing was to be of rags or strips of yellow cloth. Buddha disapproved of the nakedness of many of the Hindu monks, and insisted that his followers should always be fully clothed, though in the simplest and poorest possible manner. Moreover, he did not encourage the extreme austerities practiced by many, which resulted often in the entire breaking down of the physical constitution. He inculcated subjection but not destruction of the body.

Gautama's monastic order started with ten members, but grew very rapidly, until its adherents were numbered by hundreds of thousands. Buddhism was from the beginning a missionary religion, and the monks were the missionaries. They found their way gradually to China, Korea, Japan, Mongolia, Tibet, and many other Asiatic countries, and, though driven out of India, where they had become shamelessly corrupt, in the eighth and ninth centuries of our era, their numbers multiplied rapidly in other lands.

Monachism in China and in Persia.—Outside of India monachism seems never to have been widely prevalent in ancient Asia, except where Buddhism made its influence felt, though there are traces of ascetic tendencies of a mild character and of a predilection for a life of retirement in the teachings of Confucius and Mencius, the Chinese sages, and the monastic life apparently found a limited acceptance at an early day in Persia. The sharp dualism of the Persian religion would seem well calculated to promote the extremest kind of asceticism, and to lead to the general prevalence of monachism, but its effect was far less marked than might have been expected.

Among the Hebrews and Greeks.—Among the Hebrews the tendency toward an ascetic and monastic life appeared at an early day in the Nazarites and later in the Essenes, but the religious and ethical principles of the people at large were not favorable to its growth. Among the Greeks, foreign as all their native instincts were to anything of the kind, the ascetic and monastic tendency appeared in the Pythagoreans and in the Orphic brotherhood, and also, though in another form and on quite different grounds, in the Cynics.

Among the Egyptians.—In Egypt monachism found a home and enjoyed a striking development in the Alexandrian period in connection with the worship of Serapis. The Serapis temples, especially the famous one at Memphis, were made the abode of multitudes of monks, who came thither that they might dwell in seclusion from society and from their families and friends, in the hope of attaining that purity which was not to be gained in the midst of the engrossments of the world. Some rather striking similarities between the Serapis monachism and the Christian monachism of Egypt have been pointed out by Weingarten in his *Ursprung des Mönchthums* and in the *Zeitschrift für Kirchengeschichte* (1877, i.).

Among the Mohammedans.—The Mohammedans also, although the teachings of the Koran are not such as to promote or even to leave much room for monasticism, have had from an early day their dervishes or fakirs, many of them simply wandering monks, belonging to no sect or society, but others of them forming regularly organized monastic orders, and as such constituting the historic representatives of Sofism, or the spiritual and mystical side of Islam. There are to-day many such orders among the Mohammedans, and they are both influential and popular. Membership in some of them is compatible with marriage and home life and the pursuit of a regular trade or business; in other cases it involves temporary or permanent retirement from society and residence in regular monasteries; in still others absolute solitude, the strictest asceticism, and the most rigid and even revolting austerities.

BIBLIOGRAPHY.—Besides the general works upon the religions of India, China, Persia, Egypt, etc., see especially R. Spence Hardy's *Eastern Monachism* (1850); Monier-Williams's *Brahmanism and Hinduism* (1891) and *Buddhism* (1889); J. P. Brown's *Dervishes, or Oriental Spiritualism* (1868); Letronn's *Matériaux pour l'histoire du Christianisme en Égypte* (1832); and Boissier's *La religion romaine d'Auguste aux Antonines.*

II. Christian Monachism.

To such pre-Christian forms of monachism as have been described some scholars have sought to trace the origin of Christian monachism, regarding the latter as of foreign, not of native, growth. Weingarten, for example, puts the origin of Christian monachism into the Post-Constantinian period, and traces its rise especially to the influence of the Serapis monachism of Egypt, referred to above. It is true that Christian monachism in some sections may have felt to a greater or less degree the influence of one or another form of pagan monachism, but the causes to which it chiefly owed its rise are to be found not without but within the Christian Church. The tendency to the monastic mode of life, which has exhibited itself in so many peoples and under the influence of such various faiths, has proved itself largely independent of peculiarities in religious opinion, and is clearly due to a common human instinct. Though theoretically it would seem that only dualism furnishes a sufficient basis for it, it has shown itself in practice equally at home in pantheism (Brahmanism), atheism (Buddhism), and the strictest monotheism (Judaism and Mohammedanism). This being the case, the appearance of the tendency in the Christian Church need cause no surprise, and it is quite unnecessary to invoke the influence of pre-Christian forms in order to explain it; but there were peculiar reasons within the Church itself why monachism should find a congenial home on Christian soil, why it should there have the most remarkable and elaborate development it has anywhere enjoyed. Monachism is in fact a natural result of the ideal of the Christian life which prevailed in the Church almost from the beginning, and which had its roots in the teachings of Christ himself. Under the influence of their belief in the speedy return of Christ—a belief to which some warrant had been given by Christ himself in his eschatolog-

ical discourses—primitive Christians conceived of the Christian life as a heavenly, not an earthly, life. The present world was soon to pass away and the kingdom of heaven was soon to be revealed, and it was the duty of every believer to live as a pilgrim and stranger on the earth, to realize constantly his heavenly citizenship and destiny, to be separate from the world and superior to its interests and concerns, not because the world is evil, but because it is, at least in its present form, transient and unreal, and because it is soon to be replaced by new heavens and a new earth. It was inevitable that with this conception of the Christian life—a conception which has had a place in the Christian Church from the very beginning—the tendency should soon make itself felt to regard all that binds a man to this world—the ties of family, of friendship, of property, of citizenship—as hindrances to the highest spirituality, and hence to view them with suspicion and ultimately to repudiate them; but the conception of the Christian life which has been described led naturally to a peculiar emphasis upon individual purity and holiness as alone befitting the believer's heavenly calling, and this emphasis was greatly enhanced by the belief in the immediate and constant presence of the Holy Spirit, promised and sent by Christ, a belief which was universal and all-controlling in the primitive Church. Regarding their bodies as "temples of the Holy Ghost" in a most real and vivid sense, these primitive Christians must necessarily look upon fleshly sins with peculiar aversion. The result was that at an early day—even before the end of the first century—the ethical emphasis in Christian circles was transferred from active love for God and man, upon which Christ had laid chief stress, to abstinence from sin, especially from sin of a fleshly character. That asceticism should follow was inevitable. Another influence must also be recognized as contributing to the same general result. This was the growth of the conception of Christianity as a law which led naturally to the practice of penance, a practice which had begun to find a place within the Christian Church even before the middle of the second century. It was inevitable that as the belief in the necessity of penance rooted itself more and more firmly in the mind of the Church, Christians should seek to make amends for their breaches of the law by ascetic practices, by voluntary acts of self-sacrifice and mortification, just as the Hindus had done centuries before.

Early Asceticism.—Justin Martyr, writing about the middle of the second century, records that Christians were already beginning to abstain from flesh, wine, and sexual intercourse, and among various heretical sects of the same period, such as the Marcionites, Encratites, and some of the leading Gnostic schools, asceticism, often of a very severe kind, was made obligatory upon all. In the case of the Gnostics the ground of their ascetic practices is to be found in their dualism, but other sects, no less strenuous than they in their emphasis of asceticism—as, for instance, the Montanists—were not dualists in any sense, and only represented in an extreme form the same tendency which was making itself felt in the Church at large, and the growth of which has been described.

Anchoretic Life.—Out of this "asceticism in solution," as it has been called, this asceticism, practiced with ever-increasing zeal in the midst of society, grew naturally in course of time the earliest form of monachism proper, the anchoretic or eremitic life. It was soon found that the "separateness" from the interests and concerns of the world which the prevalent Christian ideal demanded of all Christians was not easy of realization in the midst of society, where those interests and concerns were constantly pressing themselves upon the attention of Christians as well as of others. It was natural that those who were in earnest in their desire to realize that ideal should flee from the distractions of society, and should endeavor in solitude to live the life of the Spirit, which they found it increasingly impossible to live to their satisfaction in the midst of the world. The necessity of flight from the world became increasingly pressing as the Church grew in numbers and influence, and in its effort to conquer and win the world became more and more secularized, more and more of a world-church. It was natural, too, that such flight from the world should be regarded by many not simply as a means of escape from its distractions, but also as the consistent realization of the Christian ideal which has been described—the ideal of world-renunciation. To renounce the world not simply in part, but wholly—to be not simply ascetics, but hermits—must be increasingly the desire of such as wished to make earnest work of the matter. Thus a double impulse—on the one hand to escape from temptation, on the other hand to give completer realization to the Christian ideal—the fruit on the one hand of a conscious sense of weakness, on the other hand of a conscious sense of strength—drove men into the desert; and thus was promoted the conception—itself as old as the second century—of a double standard of holiness, the one for the ordinary Christian, capable of realization in the midst of the world, and without the violation of the ties of family, the other for a select few, the spiritual aristocracy of the Church—capable of realization only in the desert, away from the haunts of men. With the general recognition by the Church at large of this double standard of holiness there was created a permanent place for Christian monachism, and its permanent influence and popularity were assured.

St. Anthony.—The earliest Christian hermit known to us is St. Anthony of Egypt (Jerome's account of Paul of Thebes, whom he calls *auctor vitæ monasticæ*, is without doubt purely legendary), whose life and personality are depicted in the pages of Athanasius's *Vita Antonii*, a work which is rather a romance than a sober biography, but which is doubtless based upon fact. The Athanasian authorship of the *Vita Antonii* has been denied by many scholars, with especial vehemence by Weingarten, but it is testified to by Gregory Nazianzen, Rufinus, and others, and can hardly be successfully impugned. (See especially Eichhorn's *Athanasii de vita ascetica testimonia*, 1886.) Born about the middle of the third century, Anthony was led in early life, under the influence of the Gospel story of the rich young man, to give all his property to the poor, and finally to retire to the desert in order to devote himself to unceasing communion with God and to the undivided contemplation of spiritual things. He lived in solitude until a great age a life of the most rigid asceticism. The fame of his holiness spread throughout Egypt, and his example was followed by many others, so that before his death, which took place about the middle of the fourth century, the deserts of Upper Egypt had become the home of a large multitude of Christian ascetics. At an early date, moreover, possibly even before the close of the third century, the eremitic life had found a home in Palestine, and it soon spread throughout Syria, and before the middle of the fourth century even beyond the confines of the empire toward the East. (Compare the sixth and eighteenth homilies of the Syrian Aphraates.)

Cœnobitic Life.—Originally living in the strictest solitude these anchorites gradually and quite naturally got into the habit of gathering about some especially famous and sainted hermit, in the hope of learning from him and of receiving in converse with him blessings greater than they could enjoy alone. Thus grew up λαῦραι, or villages of monks, each monk living in his own separate hut, but enjoying at will more or less intercourse and fellowship of worship with his companions. Such colonies grew rapidly by accession from the world-church, and were very numerous in Egypt, Syria, and Mesopotamia during the fourth century. The next step in the development came with the μοναστήριον, or common dwelling-house, which followed naturally when the advantages of association had made themselves felt. With the establishment of such houses the second or cœnobitic stage of monasticism proper was fairly launched, and monasticism in general speedily took on this form.

Pachomius and his Rule.—Such association within a common house made possible and at the same time necessitated some regulation of the life of the monks so associated. The first one, so far as we know, to draw up a definite set of rules for the government of the monastic life was Pachomius of the Thebaid, who built a monastery on the island of Tabennæ in the upper Nile before the middle of the fourth century. Pachomius also built a convent for his sister and her companions near his monastery, and thus became one of the earliest promoters, if not the founder, of female monachism. The historic significance of Pachomius does not lie, as is commonly supposed, in the fact that he was the founder of the cœnobitic life, for it certainly existed before he built his monastery (even before the end of the third century the Origenist Hieracas had gathered about himself at Leontopolis a band of disciples who led a common life of strict asceticism and joined with him in the pursuit of theological studies, as we learn from Epiphanius, *Haer.* 55, 67, 69), but in the fact that he formed rules for the government of that life, thus giving Christian monachism organization and law. His monastery was a large and important one, and the influence of his rule was not long in making itself felt in monastic circles everywhere. The form and details of Pacho-

mius's rule are no longer known, for the alleged longer and shorter recensions of it still extant are no longer considered authentic.

The Rule of Basil.—The next great figure in the history of Eastern monachism is Basil the Great, Bishop of Cæsarea in Cappadocia in the latter part of the fourth century. He was an ardent admirer of the monastic life, having himself indeed spent some years as a monk, and he did much when he became a bishop to promote its influence and at the same time to bring it under proper regulation. He approved rather of the cœnobitic than of the anchoretic life, and published a code of rules which gradually supplanted all earlier and local rules, and has remained substantially until the present day the monastic code of the Eastern Church. Basil's monastic rules are embodied in substance in his ascetic homilies, and two alleged recensions of them are still extant. Of these neither is the work of his own hand, though the shorter one is probably a fairly accurate reproduction of his original code. According to Basil's rule, a monk takes the three vows of chastity, poverty, and obedience, but the vows are not perpetual and irrevocable.

Since Basil's day monachism in the East, though always widespread and religiously influential, has remained practically stationary, and has had no such varied and interesting history as it has enjoyed in the Western Church. It has, moreover, never been so well and thoroughly organized, nor so great a social and political power in the East as in the West.

Western Monachism.—Knowledge of the new mode of life, which was already widespread in the East and which was gaining rapidly in favor among all classes of Christians, is said to have been first brought to Rome by Athanasius about 340 A. D. Whether the report be true or not, monachism, of which we have no traces in the West before this time, began to acquire a considerable hold in Italy and Southern Gaul before the end of the fourth century. Early in the fifth century John Cassian founded a monastery in Southern Gaul, and wrote two famous treatises (*Collationes Patrum* and *De institutis cœnobiorum*) which did much to spread among his countrymen a knowledge of Eastern monachism and to form the character of the monastic life of the entire West.

Contrast between Eastern and Western Monachism.—A marked difference between Eastern and Western monachism is apparent almost from the beginning, a difference due both to climate and to race constitution. Such exposure and such severe austerities as marked the lives of Eastern monks were impossible in the more rugged climate of the West (the West, for instance, boasts no "pillar saints" like Symeon Stylites of Syria, who, in the fifth century, won for himself fame by living thirty years on the top of a pillar); and a life of mere contemplation and of bodily inactivity could never find the same favor among Europeans as among Asiatics. The result was that Western monks have always satisfied themselves with a less extreme asceticism than their Eastern brethren, and in their restlessness and activity have always done more work and taken a more active part in the affairs of the world than they. The monastic ideal, to be sure, remained at least for a long time the same in the West as in the East, but a modified method of attaining that ideal was distinctly sanctioned by Cassian and adopted by the West at large.

Benedict of Nursia and the Benedictine Order.—The greatest figure in the history of early Western monasticism is Benedict of Nursia, who in 529 founded the famous monastery of Monte Casino, the parent monastery of the great Benedictine order. The historic significance of Benedict lies in the fact that he founded the first regular monastic order, and that he gave to his order, and through it to Western monachism in general, a definite rule which in time supplanted all others and gave permanent character to the monachism of the West.

Benedict's rule requires of all members of the order a threefold vow: *Stabilitas loci*, or permanent adherence to the order; *conversio morum*, involving poverty and chastity; and *obedientia*, not only to the rules of the order but also to one's superiors in the monastery. Labor is emphasized and made mandatory upon all. Asceticism is of course enjoined, but of a moderate, not a severe, type. Each monastery is to be thoroughly organized with an abbot at its head, elected by the unanimous vote of its inmates, but no federation of monasteries is proposed. The rule of Benedict speedily found favor in all parts of the West, and in the time of Charlemagne nearly all the monasteries of Western Europe were Benedictine.

Influence of Gregory the Great and of Cassiodorus.—Although Benedict made much of the element of labor, he did not propose any change in the prevalent monastic ideal, but Gregory the Great, himself a Benedictine monk, who became Bishop of Rome in 590, conceived the idea of employing monasticism as a great missionary agency for the spread of Christianity among the barbarians. Thenceforth the passive ideal of Eastern monachism was supplemented, and in many cases replaced, by the active missionary ideal, and the monks became the chief agents in the Christianization and civilization of barbarian Europe. Another important step was taken in the latter part of the sixth century by Cassiodorus, who made his own monastery of Vivarium a center of classical and theological learning, and thus gave to Western monachism an intellectual impulse which it never lost. Throughout the earlier Middle Ages the monasteries were the centers of learning, and the only theological seminaries the Western Church possessed. Even after the rise of the universities their teachers were for a long time taken from the ranks of the monks.

Rise of Clerical Monachism.—Originally monks were laymen, but for many and obvious reasons a transformation gradually took place, the result of which was that before the end of the ninth century nearly all monasteries were clerical establishments, and a regular monastic clergy was growing up alongside of the parish or secular clergy.

Change from Episcopal to Papal Jurisdiction.—During the next two centuries, moreover, the monasteries, which had hitherto been to a greater or less extent subject to the bishop in whose diocese they were situated, were gradually freed entirely from episcopal supervision and brought under the direct control of the pope, very much to the enhancement of the papal power.

Growing Corruption.—During the troublous Merovingian period the monasteries fell into a shameful state of corruption, many of them becoming practically the private property of this or that violent and avaricious prince or noble, and being transformed from religious institutions into fortresses and military camps, or still worse, into dens of vice, in the practice of which the monks themselves had their full share. In the latter part of the eighth century strenuous efforts were made by Benedict of Aniane to bring about a reformation, and his efforts were seconded by Charlemagne with some success.

The Clugniac Reformation.—The great reformation, however, came with the establishment in 910 by William of Aquitaine of the monastery of Clugny. This monastery was put under the immediate jurisdiction of the pope, the Benedictine rule was adopted and rigorously enforced, and the influence of the new foundation was speedily felt far and near. A number of other monasteries—newly founded or reorganized—soon united with Clugny to form a society known as the Congregation of Clugny, with the Clugniac abbot at its head as arch-abbot. This was the first instance of the federation of separate monasteries—a practice which later became quite common.

The aim of the Clugniac reformation was threefold: In the first place, the renovation and rejuvenation of monasticism—an aim which was successfully accomplished during the tenth century; in the second place, the extension of the monastic principle to the life of the secular clergy—an aim which was carried out by Gregory VII. when he forced celibacy upon the latter; and in the third place, the complete subjugation of the lay world to the reformed clergy—an aim which was realized in the papal supremacy of the twelfth and thirteenth centuries. Monasticism, which had been in the beginning a flight not only from the world, but also from the world-church, was brought by Gregory and his successors—consistent representatives of the Clugniac spirit—into the service of that church, and those who had renounced the world now came back into the world to subdue and control it. Monachism was thus given a new mission which it has never lost sight of.

Formation of New Orders.—In the latter part of the eleventh century, under the influence of the spirit which found voice at Clugny, began the formation of new monastic orders in great number, all of which put themselves at the service of the Church, and constituted an admirable and ever-growing standing army. Among them were the Cistercians, a reformed Benedictine order founded in 1098, and boasting as their greatest light St. Bernard of Clairvaux; the military orders, chief among which were the Knights of St. John (1118), the Knights Templar (1119), and the Teutonic Knights (1192); and finally the mendi-

cant orders—the Franciscans (1208) and the Dominicans (1215).

The Mendicant Orders.—The formation of the mendicant orders marks an epoch in the history of Western monachism hardly second to the foundation of Clugny. The chief impulse came from Francis Bernardone of Assisi. Fired with the desire of imitating the life of Christ, he adopted for himself, and later made the basis of his new monastic order, a threefold watchword—humility, love, and obedience—the first to be realized by a life of absolute poverty, corporate as well as individual; the second by a life of self-sacrificing devotion to the good of others; and the third by willing and complete submission to the Catholic Church. The Dominican order, founded about the same time by Dominic Guzman, with the especial aim of preaching the orthodox faith, early borrowed the mendicant principle of the Franciscans, and the members of the two orders, inspired by the gospel of St. Francis and fired with his zeal, became the great preachers and evangelists of Europe. These mendicant friars went everywhere as preachers and confessors, carrying the principles of St. Francis into the homes of the people, until there resulted a religious reformation of the entire Western Church, the effects of which were felt for a century and a half.

Decline of Monachism.—The thirteenth century was the golden age not of monachism alone, but of the Roman Catholic Church; but in the fourteenth century began a decline which affected all the monastic orders, the Mendicants included. Corruption took the place of purity, indolence of industry, selfishness of devotion to the good of others, and the church and monasticism gradually fell into disfavor and contempt, which the general skepticism attendant upon the great intellectual awakening of the dawning modern age served only to emphasize.

Monachism since the Reformation.—Protestantism, of course, was anti-monastic in its tendency, but the Protestant Reformation led to the formation of several new orders among the Catholics, chief of which were the Jesuits, founded by Ignatius Loyola in 1534, an order which subordinated everything, even personal holiness and growth in grace, to the advancement of the interests of the Roman Catholic Church, and thus departed as far as it was possible to depart from the early monastic ideal of world-renunciation.

The centuries since the Reformation, while they have seen the establishment of many new monastic orders, have been unfavorable to the growth of the monastic spirit and to the extension of monastic influence. This is especially true of the eighteenth century with its liberalizing and rationalizing tendencies. From the effects of that century, which culminated in the French Revolution, monachism has never recovered. With the exception of the Jesuits, the orders have little influence in Europe, and in some countries are not even allowed to exist, as, for instance, in Spain, Portugal, and Italy. In the U. S., on the other hand, a number of orders have found a home, and as many of them devote themselves wholly or chiefly to missionary and philanthropic work, they constitute an important agency in promoting the growth of the Roman Catholic Church.

Bibliography.—The literature upon the subject of Christian monachism is very extensive, and only a few works can be mentioned here. Weingarten, *Ursprung des Mönchthums* (1877); Harnack, *Das Mönchthum, seine Ideale und seine Geschichte* (3d ed. 1886); also *Die Pseudo-Clementischen Briefe de Virginitate und die Enstehung des Mönchthums* (S. B. der Berliner Akad., 1891, p. 361, *seq.*); Bornemann, *In investig. Monach., orig.*, etc. (1885); von Biedenfeld, *Ursprung und Gesch. sämmtlicher Mönchsorden im Orient und Occident* (3 vols., 1837); de Montalembert, *Les Moines d'occident depuis Saint-Bénoit jusqu'à St. Bernard* (Paris, 1860, *seq.*; translated into English, *The Monks of the West*, 2 vols., 1861). For literature upon special orders and monasteries, see special articles. A. C. McGiffert.

Monaci, mō-naa′chĕ, Ernesto: scholar; b. at Loriano, Italy, in 1844. He obtained his doctorate in 1872, and has since devoted himself to Romance philology, becoming one of the chief representatives of this science in Italy. In 1872 he founded with Stengel and Manzoni the *Rivista di filologia romanza*, which continued till 1876. In that year he was made Professor of Romance Philology in Rome. In 1878 he founded the *Giornale di filologia romanza*, which came to an end in 1884, and was followed by the series of studies called *Studj di filologia romanza*, still directed by him. Besides these useful labors, he has published numerous studies on subjects in the field of the Romance languages, texts, etc. Of these may be mentioned *Uffizj drammatici dei Disciplinati dell' Umbria* (in *Riv. di fil. rom.*, i., 235, and ii., 29); *Il Canzoniere portoghese della Biblioteca Vaticana* (Halle, 1875); *Il Canzoniere chigiano* (Bologna, 1878); *Crestomazia italiana dei primi secoli*, fasc. i. (1889). A. R. Marsh.

Monaco, mō-naa′kō: the smallest of the independent principalities of Europe; on the Mediterranean, nearly surrounded by the French department of Alpes-Maritimes; 9 miles E. of the city of Nice (see map of Italy, ref. 4–A). Area, 8 sq. miles. Up to 1861 it had an area of 72 sq. miles, and included Mentone and Roccabruna. It now consists of Monaco, the capital, Condamine, and Monte Carlo, the three towns having (1890) populations of 3,292, 6,218, and 3,794 respectively. Besides its sovereign prince, Albert (b. 1848), it has a governor-general and a council of state. There is a "guard of honor" and an army consisting of five officers and seventy men. There is a court of first instance and a juge de paix's court. Two judges from Paris, appointed by the prince, act as a court of appeal when necessary. The principality has its own coinage, which is current in all the states of the Latin Union, and its own postage-stamps. The revenue is derived from the gaming-tables and from the exportation of olive oil, oranges, citrons, and perfumes. The capital is situated on a rocky promontory on the port of Monaco, and is surrounded by ramparts. It is the see of a bishop, and contains among its public buildings a palace, a cathedral, and a museum. Condamine has manufactures of liqueurs and perfumes. At Monte Carlo is the Casino, a group of handsome buildings situated in a beautiful park, besides hotels and villas for the accommodation of visitors (about 400,000 annually) to the gambling-rooms in the Casino. For 500 years Monaco has belonged to the Grimaldis, a Genoese family. It was annexed to France in 1793; was restored to the Grimaldis by the Treaty of Paris (1814); was placed under the protection of Sardinia by the Treaty of Vienna (1815); and in 1860 came under the protection of France, which in 1861 bought from the Prince of Monaco Mentone and Roccabruna.

Mon'ad [from Lat. *mo'nas, monadis* = Gr. *μονάς, μονάδος*, unit, deriv. of *μόνος*, alone]: a philosophical term. It does not seem to have been used with any technical meaning by the ancients. It obtained such first in the writings of Giordano Bruno (1548–1600), who used it to designate the primal elements of all existence, spiritual as well as material. (See his *De Monade, Numero et Figura.*) The monads, which are minute spheres, contain the potency of all the forms of life. The soul is a monad, and God is the monad of monads. Probably it was the doctrine of Giordano Bruno that gave Leibnitz the fundamental thought of his *Monadology*. In that work Leibnitz lays down his doctrine of monads, which he elsewhere defines as "metaphysical atoms, destitute of parts and incapable of being produced or destroyed naturally" (i. e. without a creative or annihilating act of the primal monad or God). They all differ from each other, and are subject to continual automatic change, involving, of course, the existence of something that changes and something that remains—in other words, multitude in unity, which again involves appetite and perception. They are indeed "entelechies" (not in the Aristotelian sense) or potential souls, existing in a state of unconsciousness. They are created by God, the primitive Unity, who is the absolutely infinite and perfect Being, toward which they all tend, and which they all symbolize and more or less confusedly represent through their more or less numerous relations. Thus every created monad represents the entire universe. (See *Journal of Speculative Philosophy*, vol. i., pp. 132, *seq.*; cf. Coleridge, *Religious Musings*, "Believe thou, O my soul," etc.) The profundity of the *Monadology* has seldom been recognized. Kant propounded a doctrine of monads, which, however, he regarded as extended though simple. They exert attraction and repulsion through space, and are perfectly elastic. (Cf. Kant. *Monadologia Physica.*) He suggested, in his *Critique of Pure Reason* (*Amphibolie der Reflexionsbegriffe*) a doctrine somewhat similar, but approaching more nearly to that of Leibnitz. He holds that what to our external sense is objective may be, to its own internal sense, subjective—that the material is but the outside aspect of thought. Since then Hermann Lotze (*Medicinische Psychologie*) propounded a doctrine of spiritual monads or simple unextended beings, each of which is a modification of the absolute. (Cf. the *Song of the Norns*

in Jordan's *Nibelungen*.) There is no clear line of demarkation between monad and Atom (*q. v.*); but the former connotes rather the dynamic, the latter rather the material, side of the primitive elements. Thomas Davidson.

Monadnock: See Grand Monadnock.

Monads: a group of flagellate Infusoria (*q. v.*) embracing a number of minute forms occurring in stagnant water, a few being parasites in man and other animals.

Monagas, mō-naa'gäs, José Tadeo: general and politician; b. near Maturin, Venezuela, Oct. 28, 1784. He served with distinction under Bolivar 1813–21, attaining the rank of general of division in the latter year. Subsequently he lived in retirement until 1831, when, for a short time, he led a fruitless attempt to re-establish the fallen republic of Colombia. President Soublette gave him high military commands, and supported him as presidential candidate in 1846; the liberals, who were in opposition, claimed to have carried the elections, but congress adjudged it to Monagas, who was inaugurated Mar. 1, 1847. A revolt of the liberals which followed was suppressed, but Monagas, by his equivocal course, lost the support of his own party; in Jan., 1848, he dissolved congress by a *coup d'état*, and assumed dictatorial powers. Paez, who had declared against him, was defeated and imprisoned in 1850. He was succeeded in 1851 by his brother, and took command of the army. He was re-elected to the presidency for the term beginning 1855, but after the adoption of a new constitution in 1857 a revolution broke out, and he was forced to resign Mar. 15, 1858, and left the country. In 1868 he led the revolution which deposed Falcon, and was elected president by congress, but before he could assume office he died (near La Guayra, Nov. 18, 1868). H. H. Smith.

Mon'aghan: county of Ireland; in the province of Ulster. Area, 500 sq. miles. The surface is hilly, in the eastern part even mountainous. The principal range is that of Slievebeagh, which extends into Fermanagh, and, in its highest point, rises 1,254 feet above the level of the sea. The county was formerly densely wooded, but is now nearly bare of trees. The numerous small lakes and streams form a peculiar feature of the landscape. In the more level portions the soil is fertile, but on the hills it consists of a stiff clay difficult to handle. The main crops are oats, barley, flax, and potatoes. The only important manufacture is that of linens, and it has for several years been on the increase. Pop. (1891) 86,206. Principal town, Monaghan, named from a monastery very early founded there (see map of Ireland, ref. 6–H).

Mon'archy [from Lat. *monar'chia* = Gr. *μοναρχία*, deriv. of *μόναρχος*, monarch; *μόνος*, alone + *ἄρχειν*, rule]: government of a state by one chief only. Succession to the throne has generally been determined by heredity, but in some monarchies, as, for example, in the former kingdom of Poland, the elective principle has been recognized. Where the will of the monarch is supreme over all other authorities in the government there is an absolute monarchy. Such a government as that of Great Britain is called a limited monarchy, from the fact that the power of the crown is subjected to constitutional limitations, and is held in check by other authorities. Absolute monarchies, which as the world advances toward freedom are becoming rarer, are now found in perfection only in the East, where were the five great monarchies of the ancient world—namely, Chaldæa, Assyria, Media, Babylonia, and Persia. In Europe the rise of the absolute monarchy marks the transition from the mediæval to the modern age. The latter part of the fifteenth century saw England, France, and Spain under the dominion of absolute rulers, whose government was in general a great improvement on the petty tyranny of feudal magnates, but the revolution of 1688 in England and the changes on the Continent resulting from the French Revolution transformed the European absolute monarchies into the constitutional governments of the present. See Government. F. M. C.

Monasticism: See Monachism.

Monastir: chief town of vilayet of Monastir, European Turkey; important military post (see map of Turkey, ref. 4–B). It carries on large transit trade in wheat and skins; manufactures carpets and gold and silver ware. Pop. 50,000.

Monbod'do, James Burnet: lawyer and author; b. at Monboddo, Kincardineshire, Scotland, in 1714; educated at Aberdeen, Edinburgh, and Groningen; practiced as advocate in Scotland in 1767; became a judge, with the title of Lord Monboddo. His *Dissertation on Language* (6 vols., 1773–92) expresses his theory of the origin of the human race from the monkey, which he further elaborated in *Ancient Metaphysics* (6 vols., 1779–99). D. in Edinburgh, May 26, 1799.

Monck, Charles Stanley, G. C. M. G.: Fourth Viscount; statesman; b. at Templemore, Ireland, Oct. 10, 1819; educated at Trinity College, Dublin, and called to the bar in 1841; succeeded his father in 1849; entered the House of Commons 1852; was a lord of the Treasury 1855–57; was Governor-General of Canada 1861–68; received a seat as a baron in the House of Lords 1866; became in 1871 a commissioner of the Irish Church temporalities, and was land commissioner in 1882–84. D. Nov. 19, 1895. During his service in Canada the Dominion was established.

Moncreiff, mon-kreef', Sir Henry Wellwood, D. D.: clergyman and author; b. at Blackford, Perthshire, Scotland, Feb. 6, 1750, being eldest son of Rev. Sir William Monereiff; was educated at Glasgow and Edinburgh Universities; was ordained a minister of the Church of Scotland 1771; was for some time his father's successor as minister at Blackford; became pastor of St. Cuthbert's, Edinburgh, 1775, and moderator of the General Assembly 1785; was a popular preacher; "succeeded Dr. John Erskine in the chieftainship of the Whig party in the Kirk of Scotland"; took an active part in the ecclesiastical controversies of his time, and late in life assumed the name of Wellwood. D. in Edinburgh, June, 14, 1827. He was the author of *Discourses on the Evidence of the Jewish and Christian Revelations* (1815); *An Account of the Life and Writings of John Erskine, D. D.* (1818); of many pamphlets on ecclesiastical topics; and of several volumes of *Sermons*. His *Posthumous Sermons* (3 vols., 1829–31) were selected by Dr. Andrew Thomson, and edited, with an *Account of the Author's Life*, by his son, Sir James Wellwood Moncreiff (1776–1851), who became a judge of session and a lord justiciary, known by the courtesy title of Lord Moncreiff.

Moncton: town of Westmoreland co., New Brunswick; on the bend of the Petitcodiac river, a remarkable tidal stream flowing into the upper end of Shepody Bay, the western arm of the Bay of Fundy (see map of Quebec, ref. 5–I). It is a railway center, junction on the Intercolonial Railway, 89 miles N. E. of St. John and 186 miles N. W of Halifax, and terminus of the Moncton and Buctouche Railway, 32 miles long. It is a prosperous and rapidly growing place, having a sugar-refinery and cotton-factory, and surrounded by a flat and fertile farming region. The extreme range of tide in the Petitcodiac is 70 feet, and the bore passes up the river in a wall 4 to 6 feet high. The immense salt-meadows alternately covered and uncovered can be reclaimed, and are very rich in fertile soil. Pop. 8,765. M. W. H.

Monday [M. Eng. *moneday*, *monenday* < O. Eng. *mōnandæg*, liter., the day sacred to the moon; *mōna*, moon + *dæg*, day. Cf. Germ. *Montag*; *mond*, moon + *tag*, day]: the second day of the week.

Mondo'vi (anc. *Monsvi'ci*, *Monsrega'lis*, or *Vicodunum*): town in the province of Cuneo, Northern Italy; about 42 miles S. of Turin and about 1,600 feet above the sea-level (see map of Italy, ref. 3–B). It is surrounded by ancient walls. The episcopal palace is a very fine building, and the cathedral and other churches are of considerable interest. About 2 miles from Mondovi is the great sanctuary of the Madonna di Vico, adorned with interesting works of art. In 1796 occurred in this neighborhood the engagement known as the battle of Mondovi, in which Bonaparte defeated the Piedmontese army, and thus prepared the conquest of all Upper Italy. In 1799 the town was sacked by the French, and nearly destroyed. Pop. about 10,300.

Monera [Mod. Lat., from Gr. *μονήρης*, single, from *μόνος*, single]: a name given by Haeckel to a supposed group of Protozoa, which differed from all others in the lack of a nucleus, each individual being a living mass of undifferentiated protoplasm. Since the group was named various members have been found to possess a nucleus, and have consequently been referred to the Rhizopoda (*q. v.*). It is possible that in the forms that remain the absence of a nucleus is apparent rather than real, and the essential nuclear substance (*chromatin*, etc.) is scattered through the cell instead of being concentrated in one place. J. S. K.

Monet, mō'nā', Claude: landscape-painter; b. in Paris; contemporary. He is the chief of the modern impressionist landscape-painters in France, and his works are notable

for their luminosity, frank truth to nature in respect to light and air, and for original color schemes. His methods have been used by many imitators, most of whom fail to get more than the superficial qualities of his work in their own, but his influence has been beneficial in that it tends to draw attention to the supreme importance of light and atmosphere in landscape-painting. He paints many of his pictures near Giverny, a village of Normandy, where he has a studio and is surrounded by an enthusiastic group of followers. He does not exhibit at the Salon, but his works are often seen at various small exhibitions in Paris, and many of them are owned in the U. S. Four excellent ones are in the collection of William H. Fuller, New York.

WILLIAM A. COFFIN.

Monetary Standards: standards of *value*, i. e. exchange value, embodied in some form of money. Three such standards are now familiar to men's thought, gold alone, silver alone, and gold and silver used together, forming a bimetallic standard (not "double standard," a sad misnomer) and the basis for a system of bimetallism. In most or all countries having the sole gold standard silver is also used in some subordinate relation, either for full legal-tender money, as in the U. S., Germany, and France, or for subsidiary coins alone, as in Great Britain. Most countries having the silver standard employ more or less gold for trade with gold lands, buying and selling it as a commodity.

BIMETALLISM.—Bimetallic money is money constituted by admitting both gold and silver to free coinage, and making each an unlimited legal tender at a certain relation in value to the other. This system must be carefully distinguished from the mere use of full legal-tender silver along with gold (legal-tender tokens), as in the U. S., Germany, and France. That does not constitute bimetallism, because silver is not in those circumstances open to free coinage. A single nation may, of course, adopt bimetallism, but it is doubtful whether any nation by itself could now permanently maintain it. If bimetallic money is possible, i. e. if it is feasible to keep the two metals at a fixed value in relation to one another (see below), a bimetallic system of money must possess eminent superiority over any other system. 1. Bimetallic money guarantees to the value of the dollar, or other monetary unit, a *steadiness* attainable in no other system. The importance of this quality in money, preventing general prices from either rising or falling, is incalculable. Monometallists greatly underrate it, thinking too much of money as a mere means of effecting exchanges; whereas, in the present condition of the world's business, the vast bulk of time contracts and deferred payments renders paramount the character of money as a just *standard of value*, making general prices steadfast through periods of time. Fluctuations in the value of the money unit in any system will be slight, nearly in proportion to the whole volume of (unwrought) standard money metal contained in the system. Gold and silver freely coined together would make such volume not far from twice as vast as either could furnish alone. Even if the whole volume of money metal were the same in both cases, a bimetallic money unit would have a less variable value than a unit realized in a single metal, because fluctuations through extraordinary discoveries or losses, exportation, or new uses or disuses in the arts, are less likely to occur in both metals at the same time than in one alone. The vice of money with an unsteady value is manifest in gold countries, where, at present, owing to the progressive scarcity of gold available for monetary uses, a fall of prices is going on, to which no end is visible without an abandonment of the sole gold standard. The preciousness of gold, through military and other hoarding, will drive more and more nations to paper money, whose depreciation, acting as a premium on the exportation of products from these to gold countries, must depress in these latter the prices of international commodities, and to some extent all prices. As paper money, when it has displaced gold, almost inevitably works an increase in its own volume, leading to repeated elevations in prices, the process named bids fair to be endless. 2. A solid bimetallic monetary system would establish a common measure of value, a fixed par of exchange, not only between the different states uniting to sustain it, but between every pair of countries on earth. It would make the commercial world into the most perfect possible unity for purposes of trade. Such unity always existed till 1873, when silver was demonetized. Exchange processes between India and Great Britain, for instance, were then as simple and easy as they are now or ever were between any two separate sections of the earth. Between the money of London and that of Calcutta, in spite of the fact that one was gold and the other silver, there was practically a fixed par, as there is to-day between dollars and sovereigns, rates of exchange oscillating in the one direction or the other from this par as the balance of trade might swing, but never beyond the percentage required for the shipment of specie, and always in a way more or less calculable beforehand according to the season of the year. Merchants in one country could place orders for the other's products long beforehand. Contracts might be in gold money or in silver, in sterling or rupees, indifferently, for it could be foreseen almost to the penny how much a sum of either would mean in terms of the other at the date when they were to mature. After the demonetization of silver in 1873 all this was changed. The tie that had bound the two metals together at the relation in value of 15½ to 1 was gone. Nothing like fixity of par between East and West has since existed. The London trader can no longer with safety offer former or any silver prices for Indian products, since he can not tell a day or an hour beforehand what that sum of silver may soon equal in gold. Merchants in India are in like case if they wish British goods. This evil, which works against international *loaning* as well as against international *trade*, can never be remedied save by international bimetallism. The serious question is whether the two metals can be so united as to continue for, say, a century at the same value in terms of one another. Many respected writers still deny this possibility, but clearly they do not consider the whole case. All the members of the Royal British Gold and Silver Commission of 1886–88 (six of them then being gold monometallists, though one of these, L. H. Courtney, M. P., is now an ardent bimetallist) declare their belief that it is possible to bind the metals together in the way named. Jevons, Lexis, and Léon Say, among other eminent authorities not bimetallists, have expressed the same belief. A considerable list of eminent monetary writers could be given, who at first opposed bimetallism, but after examination embraced it. Moreover, bimetallism did actually work in France from 1803 to 1873, and that though conditions were far less favorable to it than they have ever been since, or ever could be under a careful international agreement. The argument for the feasibility of bimetallism is briefly as follows: 1. Were both gold and silver freely coined the monetary demand and supply of them would, in fixing the value of given quantities of them, have far more influence than the commodity supply and demand would have. 2. A legal-tender and debt-paying value ratio between a given quantity of gold and a given quantity of silver can be established by statute in any state and by treaty throughout any number of states. 3. Since men discharge their pecuniary obligations as easily as they can, the existence of such a legal value ratio would, if this ratio ever for any reason failed to match the commercial ratio, stimulate demand for the metal that was commercially the cheaper, lessening at the same time the demand for the dearer, and so tend to bring the bullion value ratio back to the legal value ratio. 4. If the field of the legal arrangement is large, so as to cover a third of the world's gold and silver, unless the legal value ratio determined upon is widely different from the ratio in quantity between the total stocks of the two, the stimulus of demand for the cheaper will overbear every tendency to part the parities named, and maintain the unit quantity of gold and the unit quantity of silver perpetually at the same value. This theory in no sense traverses the law of supply and demand. Bimetallist legislation is expected to bring the above result to pass, not in defiance of economic forces, but by setting free certain economic forces now latent and giving the proper direction to those already working.

LITERATURE.—*Reports* of Royal Gold and Silver Commission (1886–88); Nicholson, *Money and Monetary Problems*; Walker, *Money, Trade, and Industry*; H. H. Gibbs, *Colloquy on Currency*; Horton, *The Silver Pound*; Suess, *The Future of Silver* (Senate document); Andrews, *An Honest Dollar*; publications of British Bimetallic League.

E. BENJ. ANDREWS.

MONOMETALLISM is the use of only one metal as money of full legal tender, either gold or silver. In the seventeenth and eighteenth centuries most, if not all, civilized countries employed both gold and silver as money of full legal tender, intending to use them simultaneously, but really using them alternately. The use of two metals requires the establishment of a legal ratio between them, giving debtors the option of paying, for example, either 1 oz. of coined gold or

15½ oz. of coined silver for an equal sum, the mints of the country being open at all times to the coinage of either metal in unlimited amounts for private persons. Concurrent circulation of the two metals can continue only so long as the market ratio coincides with the legal ratio. When 1 oz. of gold, as in the example cited, comes to be worth a little more than 15½ oz. of silver, gold will be exported or withdrawn from general circulation. If the market ratio turns the other way, silver will be exported and gold will be retained. The monetary history of nations consists mainly of these changes and of the recoinages to which they led. There were twenty-six changes of the ratio in France between 1602 and 1773. Prior to the year 1871 the only countries that had the single gold standard were Great Britain and her colonies, Portugal, Turkey, Persia, Brazil, and the Argentine Republic. Those which had the single silver standard were Germany, Holland, the Scandinavian countries, Austria, Russia, Egypt, Mexico, Japan, India, China, Central America, Bolivia, Ecuador, and Peru. All the countries not named in either of these lists had the bimetallic system, or double standard, although some of them did not have any silver of full legal tender in actual circulation. The U. S. was in this category. The single gold standard was legally adopted by Great Britain in 1816, but it had been practically adopted in 1774, when an act was passed limiting the legal tender of silver coins to £25. Both silver and gold had been full legal tender up to this time, the ratio being a little less than 15¼ to 1. The legal and the market ratios did not coincide. There was a tendency to export silver, the new pieces of full weight being chosen for exportation and the old ones of light weight retained for home circulation. The reason for passing the act of 1774 was that the silver in circulation was so much worn that it was no longer worth its face value. This act limiting the legal tender of silver was in force with only a brief intermission more than forty years before the single gold standard was formally adopted. When the new German empire was formed one of the first questions that came before it was the disordered state of the currency, which consisted of seven different systems of legal-tender silver coins, besides a variety of gold coins, German and foreign, passing as commercial money, and also state notes and bank notes passing at varying rates of discount. The reasons offered to the Reichstag by the Minister of Finance for the adoption of the gold standard were that silver was too bulky and inconvenient for the needs of modern commerce, and that it had on this account created an artificial demand for bank notes and prevented any rational regulation of the banking system of Germany. Accordingly, in 1871 the Reichstag passed a law for the adoption of the gold standard, which was more effectually carried out in 1873. The Scandinavian countries immediately followed the example of Germany. In the meantime two officials of the U. S. Treasury, John Jay Knox and H. R. Linderman, had been charged by Secretary Boutwell to prepare a bill for revising and consolidating the coinage laws of the U. S. At this time the country had no gold or silver money in circulation, being still on the paper basis of the war period. Mr. Knox and Dr. Linderman, observing that gold had been the only metallic money of full legal tender in actual use since 1834, and that the silver dollar was worth as metal 2½ cents more than the gold dollar, omitted the silver dollar from the list of U. S. coins as an obsolete thing. In 1873 Congress passed the law, but it is not true that it was passed surreptitiously, or that the omission of the silver dollar from the list of coins was unnoticed. The effect of the measure was to make the U. S. monometallic in law as it had been in fact during a whole generation. The legal ratio in France was 15½ to 1. In 1873 the market ratio had risen to 15·75, in consequence of which there was an extraordinary flow of silver to the French mint, accompanied by an exportation of gold. A treaty had been formed in 1865 between France, Belgium, Switzerland, and Italy, by which their monetary systems had been assimilated. This association, called the Latin Union, is still in existence. The members were called together to take action in reference to the outflow of gold, and it was decided to stop it by restricting the coinage of silver to a fixed sum for each country. In 1876 it was stopped altogether in all those countries. In Holland the same policy was adopted for the same reason. Austria had an irredeemable paper currency, but she too became alarmed at the decline of silver. In 1879 the market ratio to gold had reached 18·30 to 1. The Austrian Government in that year ordered its mints to be closed to silver, and in this way checked the decline of its paper currency which was redeemable in silver. In 1892 Austria prepared to resume specie payments on the basis of the single gold standard. The arrangement is not yet (1894) fully completed, but will not be long delayed. Roumania changed her system from silver to gold about the same time. In 1893 British India took the first step to the introduction of the gold standard by closing her mints to silver. In 1894 the republic of Santo Domingo changed from silver to gold. The coinage of silver on private account in Russia has been stopped, although that country is still on a paper basis. The only silver monometallic countries of importance now are China and Mexico. There are no bimetallic countries, unless Japan may be called such, that country being actually on a paper basis. The advocates of the single gold standard contend that the monetary changes here enumerated have been the result of natural selection, being in this respect akin to all the other great improvements that have taken place in human affairs. The burden of proof to show the contrary is on those who would oppose a natural movement by artificial means. Three ineffectual attempts have been made to turn mankind back to bimetallism by international agreement. These were the two monetary conferences held at Paris in 1878 and 1881, and the one at Brussels in 1892. The only country in Europe that declared itself in favor of bimetallism in the Brussels conference was Holland. Bimetallists say that these changes in the monetary systems of nations have not been brought about naturally, but by the action of men, by the laws and decrees of governments. Of course, all changes which need to be expressed in laws and decrees are made by men and governments. Nobody contends that they grow on bushes, but the fact remains that they came to pass without outside compulsion. Germany, for example, was under no outside compulsion to change to the gold standand in 1871. She found it to her advantage to do so, and that is all that is meant by the word "naturally." The same may be said of all the other countries that have followed Germany's example. Germany did not compel France in any other sense than that of offering France a large amount of silver at the ratio which France had voluntarily chosen. This can hardly be called compulsion, but if it had been compulsion it is not easy to see what else could have been done if France preferred gold to silver. It is said that France held the two metals steady at the ratio of 15½ to 1 from 1803 to 1873. That is a mistake. The market ratio varied during that period between 15·40 and 16·25, with the result of driving gold and silver alternately out of circulation. If France had really held the ratio of the two metals steady for seventy years, of what consequence would that fact be if she failed on the seventy-first? Bimetallists say that gold monometallism has caused a fall of prices. If this were true a fall of prices is not necessarily harmful. It may be advantageous, and must be so if the money income of the larger part of mankind has increased or remained stationary during that period. As money wages have advanced materially in this country since 1873 this reasoning has no force. Space does not suffice to pursue all the arguments of the bimetallists. The main contention on the other side is that the gold standard has been adopted by governments because gold is universally acceptable to individuals, while silver is not; that money is an instrument of trade, and that no system is possible which neglects or runs counter to the preferences of traders; and that international bimetallism is impracticable.

The literature of this subject is vast, but is mostly found in government publications, such as the official reports of the three monetary conferences referred to, speeches in Congress, and public investigations. The pamphlet and magazine literature is very large. See Laughlin's *History of Bimetallism in the United States* (New York); Giffen's *Case against Bimetallism* (London); Bamberger's *Stichworte der Silberleute* (Berlin). HORACE WHITE.

Mon'ey [from O. Fr. *moneie* > Fr. *monnaie*: Ital. *moneta*: Span. *moneda* < Lat. *mone'ta*, mint, coin, money. See MINT]: a standard by which wealth is measured, and an instrument by which one kind of wealth can be exchanged for another. Money differs from currency; while currency is anything with which commodities can be bought and debts canceled, it does not always have an intrinsic value, but may be, as in the case of bank-bills or government notes, merely a voucher or representative of value, in which case it is not money. Money is that kind of currency which has an intrinsic value, and which thus, if not used as currency, would still be wealth.

Different Commodities Used as Money.—Any article of wealth—i. e. anything which has value—may be used as money. Tin was thus employed in ancient Syracuse and Britain, while to the same purpose we find iron in Sparta, cattle in Rome and Germany (*pecunia*, from *pecus*, cattle), a preparation of leather among the Carthaginians, platinum in Russia, lead in Burma, nails in Scotland, pieces of silk among the Chinese, cubes of pressed tea in Tartary, salt in Abyssinia, cowrie-shells on the coast of Africa. slaves among the Anglo-Saxons, tobacco in Virginia, codfish in Newfoundland, bullets and wampum in the early history of Massachusetts, logwood in Campeachy, sugar in the West Indies, soap in Mexico, etc.; but from the time of Abraham, when he paid (Gen. xxiii. 16) to the children of Heth 400 shekels of silver, "current money with the merchant"—the earliest historical record of a purchase with money—till now, gold and silver have been the money of the world with civilized and commercial people.

These metals possess some singular advantages which explain why they are used as money. They are intrinsically valuable, everybody in the civilized world desiring gold and silver, not simply as money, but for ornaments, for plate, and other uses, and no one being able to obtain them without labor. They have both the elements, therefore, of true value. Besides this, they wear out very slowly; they are very easily divisible and malleable, and can be readily alloyed and refined; they are largely distributed over the globe, and are yet of sufficient scarcity; they are of the same quality wherever found, and are subject to fewer fluctuations in value than any other commodity known. This last quality is a prime requisite in money. In exactly the degree in which the value of money were unstable would it cease to be a trustworthy standard of value, while in the same degree exchanges would be made difficult and contracts uncertain.

In order that money may be a standard of value as well as an instrument of exchange, its own value must be invariable—a condition to which gold and silver better conform than any other commodity, but in which any currency not convertible into these necessarily fails. When bank-notes or government notes become currency without a corresponding basis of money, nothing has ever been able to prevent their fluctuation in value and the consequent effect upon all other values. The temptation to increase these issues according to the fancied interest of the bank or the government is always likely to prove irresistible, in consequence of which the community employing them finds itself flooded with a currency upon which all values float with an unsteady motion, and any standard of value is out of the question. See COINAGE, CURRENCY, and MONETARY STANDARDS.

Monge, GASPARD: mathematician and physicist; b. at Beaune, France, May 10, 1746; studied at Lyon and Mézières, and, having made several important discoveries in the science of engineering, was called in 1783 to the chair of Hydrodynamics in the Paris Lyceum. During the Revolution he became Minister of Marine, but resigned that position soon after the execution of Louis XVI. and took charge of the manufactories for supplying the army with arms and gunpowder. Under the Directory he founded the École Polytechnique, but, after holding for a time the chair of Mathematics in that institution, was sent to Italy to take charge of the removal of the captured art treasures to France. While in Italy he formed a close friendship with Napoleon, whom he afterward accompanied to Egypt, assuming the direction of the Egyptian Institute. On his return to France he resumed his duties in the École Polytechnique; was chosen senator in 1805, and in the following year received the title of Count of Pelusium. After the second restoration he lost his positions, and died July 18, 1818. In addition to several important discoveries in physics, he invented the method of descriptive geometry and left valuable treatises on that subject: *Leçons de Géométrie Descriptive* and *Application de l'analyse à la Géométrie* (1795). He also wrote a *Traité élémentaire de Statique* (1788).

F. M. COLBY.

Monghir, or **Mungir**: a city of Bengal, India; chief place of a district of the same name, on the right bank of the Ganges; lat. 25° 22′ N., lon. 86° 30′ E.; terminus of a short branch railway connecting with the main line along the south bank of the Ganges (see map of N. India, ref. 7–H). The city consists of a rocky bluff, on which is a fort now occupied by administrative offices, and a lower part stretching along the Ganges for over 6 miles. It is a manufacturing city, and has long been celebrated for its manufacture of arms and objects in iron. The products of this industry are more recommended by their cheapness than their excellence, and the industry is in decadence. There are also factories of textiles, dyes, soaps, glassware, boxes, furniture, shoes, and idols. Much *ghi* or native butter is exported. The city was formerly a Mahommedan center, but the population is now mostly Hindu. Pop. 57,877.

M. W. H.

Mongo'lia: the land of the Mongols: a Chinese possession in Central Asia; bounded on the N. by Siberia, on the E. by Manchuria, S. by China proper, and on the W. by Chinese Turkestan; area, 1,288,000 sq. miles; population about 2,000,000. There is no natural boundary between Manchuria and Mongolia. A line of palisades (still shown on some maps) formerly marked the dividing-line, but it no longer exists.

A large portion of Mongolia is occupied by the great Desert of Gobi, a desolate and sterile tract of almost treeless country, extending N. E. and S. W. between the 90th and 120th meridians of E. lon., in some places exhibiting a considerable depression, and in some parts more than 200 miles in breadth. Generally this desert is a level land, and though, on the whole, at an average elevation of 2,600 feet above the sea, there are but few hills of any altitude. On the other hand, the Alashan country to the S. is mountainous and well wooded. On the western side of these hills the great river Hwang-ho runs for nearly 400 miles, and some peaks, beyond where the Hwang-ho forces its way eastward, are covered with perpetual snow, and are probably not less than 10,000 to 12,000 feet high. To the N. and N. W. chains of high mountains separate Mongolia from Siberia, the range of Altai being the most famous. This, which is the richest portion of Mongolia, is chiefly in the hands of the Buddhist monks, the high priest himself residing at URGA (*q. v.*). Though better watered than other parts of Mongolia, and the source of some considerable rivers, such as the Amur and the Orkhon (which flows into the Siberian lake Baikal), the intense winter cold renders the rearing of even the commonest and hardiest vegetables almost impossible.

There are three principal divisions of Mongolia: (1) *Inner Mongolia*, lying S. of the desert and N. of the Great Wall; (2) *Outer Mongolia*, between the desert and the Altai Mountains, and reaching from the inner Khingan to the T'ien Shan peh-lu; and (3) KOKONOR (*q. v.*), which is separated from the rest of Mongolia by the province of Kansuh. The inhabitants of Inner Mongolia are divided into 6 corps and 24 tribes, ranged under 49 koshun, or banners, each of which is commanded by a hereditary prince. The principal tribes are the Kortchin and the Ordos. The Tsakhars, who occupy the region immediately N. of the Great Wall, are governed by a tu-tung, who resides at Kalgan. Their pasture lands are now included in the extended boundaries of the province of Chihli, just as those occupied by the Tumets are included in Shansi. This portion of Inner Mongolia is being rapidly filled up by Chinese settlers. *Outer Mongolia* is divided into four circuits, or khanates (Tushetu, Tsetsen, Sainoin, and Jesaktu), the tribes belonging to one khanate being forbidden to migrate into another. These are politically under the rule of two Manchu residents at Urga. The four khanates constitute one aimak, or section, subdivided into 86 koshun, or banners. In the whole of Mongolia there are 33 aimaks and 172 banners.

Owing to the peculiar character of their country, the Mongols are now, as they have ever been, essentially nomadic. By far the largest number of the population dwell in tents, and their chief possessions are large herds of camels, horses, sheep, asses, and mules.

The Mongols are middle-sized, strong, and active; their skin of a dark-yellow hue; their faces broad, with flat noses and projecting ears. They have little beard, and generally shave off what they have except one tuft. They belong to the great group now often called Turanian, and are thus allied to the Chinese, Tibetans, and the Japanese, and more remotely to the Esquimaux, Samoyedes, Lapps, Turks, and Magyars; in other words, to nearly two-thirds of the whole human race. In ancient history we find their ancestors under the generic title of Scythians or Cimmerians, and the founders of the Median empire, whose cuneiform writings we are even now only partially able to decipher; in later times they appear as the terrible and devastating Huns, and still later as the scarcely less ferocious warriors of Genghis Khan and Timour.

As they are of the same stock as the present Manchu rulers of China, similar interests as well as relationship insure their chiefs many favors from the Chinese Government; thus, some are married to princesses of the imperial house, so as to attach them more closely to the reigning family, while, as a rule, the rich gifts they receive far exceed the nominal tribute exacted from them. Unlike other nomadic nations, they have an alphabet (derived from the Syrian Nestorians) and a literature—of little value, however, being chiefly translations from Chinese works, or stories more or less fabulous of their great national hero, Genghis Khan.

Except as wandering hordes, overwhelming each country in its turn, and rather by their vast numbers than by knowledge of war as an art, we hear little of the Mongols till the time of Genghis Khan. Not long after the Kalkhas, under their khan, Kublai, conquered all China, and held the chief power there for about a century; and though, as is usually the case with empires so formed, that of the Mongols was soon broken up into a number of separate dynasties, the great Timour widely extended the already vast frontiers of the Mongol empire. Lastly, in the year 1519, Baber, a lineal descendant of Timour, founded by conquest a monarchy in Hindustan, popularly called the "Mogul" dynasty, and celebrated for the famous Akbar, a contemporary of Queen Elizabeth of England. To the invasion of Western Asia by the Mongol tribes we owe the establishment of many dynasties which became notable in history, partly owing to their conflict with the Franks during the crusades, and partly to the great ability in matters of government which these wild tribes from Central Asia exhibited as soon as they found themselves settled in the fertile lands of the West. Among the dynasties which owe their origin to the Mongol conquests may be mentioned that of the Moguls of Persia and Syria (A. D. 1157–1355); the Karakoiunbu (Turkomans of the Black Sheep), A. D. 1357–1496; those of the White Sheep (A. D. 1406–1502): and, connected with these, the Kipchaks of the Crimea, and of the Kazan, with the Usbeks of Bokhara, Samarcand, and Balkh.

A considerable trade passes through Mongolia to China on the one side and Russia on the other, with frontier marts at Kiakhta in Siberia and Maimaichin in Mongolia. This trade is carried on wholly by barter, money being either forbidden or (at least) seldom used. The caravans perform their journeys between October and the end of winter, bringing furs, woolen stuffs, and leather from the West, and conveying thither teas, silks, cotton, rhubarb, and sugar-candy.

Besides Urga, Kalgan, and Maimaichin, already mentioned, the other chief centers of trade are at Kobdo, on a plateau of the same name in the Mongolian Altai, Uliasutai, some distance to the E. of Kobdo; Saicha and Kukukhto, on tributaries of the Hwang-ho, near the border of Shansi; Dolanor, or Lama-miao, 150 miles N. of Peking; Jehol, near the border of Manchuria; and Hada, 60 miles E. of Jehol. See Huc's *Travels in Tartary, Thibet, and China* (2 vols., 1852); Wolff's *Geschichte der Mongolen* (Breslau, 1872): Prjevalsky's *Mongolia, the Tangut Country and the Solitudes of Tibet* (trans. by E. Delmar Morgan, 2 vols., London, 1876); Howorth's *History of the Mongols* (3 vols., London, 1876–88); and Gilmour's *Among the Mongols* (London and New York, n. d.). Revised by R. Lilley.

Mongoos: See Mungoos.

Monier-Williams, Sir Monier: Sanskrit scholar and Indologist; b. at Bombay, India, in 1819; studied at King's College, London, and at the East India Company's College at Haileybury; became Boden Sanskrit scholar at Oxford 1843, and graduated 1844; Professor of Sanskrit at Haileybury 1844–58, and at Cheltenham College 1858–60; was chosen Boden Professor of Sanskrit at Oxford Dec., 1860; visited India 1875–76. Raised to the knighthood 1886. Author of a *Sanskrit Grammar* (1846; 4th ed. 1877); an *English-Sanskrit Dictionary* (1851); *Kálidása's Sákuntalá*, with translation (1853); text-books in Persian (1858) and Hindustani (1859); *Original Papers illustrating the History of the Application of the Roman Alphabet to the Languages of India* (1859); *Indian Epic Poetry* (1863); *A Sanskrit and English Dictionary* (1872); *Indian Wisdom* (1875); *Hinduism* (1877); *Modern India and the Indians* (1878); *Religious Thought and Life in India* (1883); *The Holy Bible and the Sacred Books of the East* (1887); *Buddhism in its connection with Brāhmanism and Hindūism and its contrast with Christianity* (1889). Monism: a philosophical term denoting a theory that holds one ultimate being in the universe. Dualism holds two ultimate principles, for example, mind and matter. Sir William Hamilton applies the term "monist" to the philosopher who "rejects the testimony of consciousness as to the ultimate duality of the subject and object in perception." The materialists may hold that the subject which thinks is material, like the object it perceives. The idealist may hold that the object it perceives is only a vision in the mind. The term "monism" has come into much use recently to indicate the doctrines of materialists like Haeckel, who holds "all matter to be ensouled or endowed with feeling and motion, or, better, the power of motion; on elementary attraction and repulsion is based every other psychical phenomenon, and consequently the highest developed soul-activity of man." W. T. Harris.

Monition: in the practice of the English ecclesiastical courts, the mildest form of ecclesiastical censure—simply an order admonishing the person complained of to do something specified in the instrument "under pain of the law and penalty thereof." Nevertheless, when duly and regularly served, disobedience to it entails the penalties of contempt of court. The other uses of the word are—(1) warning; (2) cautionary instructions or directions; (3) a formal letter or document issued from an archiepiscopal or episcopal court, ordering any person under the jurisdiction of the bishop to do, or to leave undone, some act or course of proceeding in which the bishop is interested.

Monitor [from Lat. *mo'nitor*, warner, deriv. of *mone're*, warn. So called because thought to give warning of the approach of a crocodile]: name of a genus of large Old World lizards, some of which approach the size of alligators. The typical species, the Nile monitor (*M. niloticus*) attains a length of 6 feet, half of this consisting of the slender tail. The animal is gray with dark blotches. It is believed by the natives to be hatched from crocodile's eggs, but in reality these form a portion of its food. The *M. dracæna* of India and *M. gouldii* of Australia are also well-known monitors. The great lizards of the South American family *Teiidæ* are often called monitors, and indeed closely resemble the true monitors. Revised by F. A. Lucas.

Monitor [from *Monitor*, the (proper) name given the first vessel of this type]: one of a special class of nearly submerged armored vessels, invented by John Ericsson (*q. v.*), the principal features of which are a revolving turret protecting guns of large caliber, and an overhang deck protecting the propeller and rudder. Plans for such a vessel were submitted by Ericsson to Napoleon III. in 1854, but were rejected, and the first vessel of the sort ever constructed was built under contract with the U. S., for use in blockading Southern ports in the civil war of 1861–65. It was named Monitor by Capt. Ericsson, was launched at Greenpoint, Long Island, on Jan. 30, 1862, and went to sea Mar. 6 in command

Ericsson's Monitor of 1861.

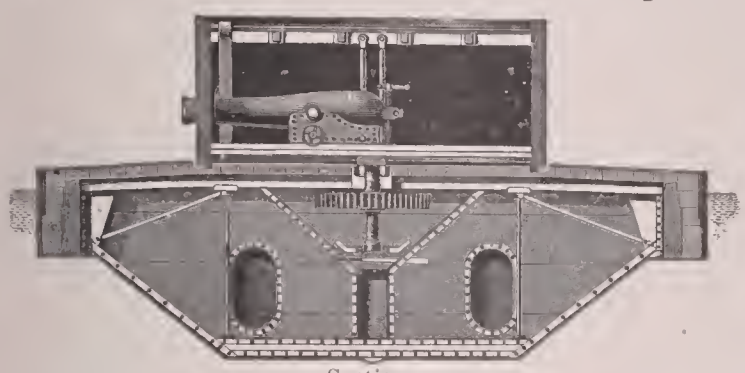
of Lieut. John L. Worden, U. S. navy, with a crew of forty-five men and twelve officers. The Monitor was an iron hull with wooden deck-beams and side projection, and of the following dimensions:

Extreme length	172 feet.
" breadth	41 " 6 in.
Depth of hold	11 " 4 "
Draught of water	10 " 6 "
Inside diameter of turret	20 "
Height of turret	9 "
Thickness "	.. 8 "
" of side-armor	.. 5 "
" " deck-plating	.. 1 in.
Diameter of propeller	9 "
" " steam-cylinders (two)	.. 36 in.
Length of stroke	2 " 2 "
Displacement	1,255 tons.

Armament, two 11-inch shell guns, each 15,668 lb.

The engravings represent a side elevation of the Monitor and turret, showing the position of the turret, pilot-house,

propeller, equipoise rudder, and anchor-well; also a transverse section. This vessel fought a memorable engagement with the Confederate ironclad Merrimack in the forenoon of Mar. 9, 1862, off Newport News, Va., neither being able to



Section.

destroy the other; but the Monitor was successful in protecting Union shipping, and the Merrimack was obliged to withdraw for repairs. There was no loss of life on either side. The Monitor foundered off Cape Hatteras Dec. 31, 1862.

During the civil war 54 monitors of various sizes were built, as follows: *Single turret*—10 of the Passaic class, 844 tons; 9 of the Canonicus class, 1,034 tons; 20 of the Casco class, 614 tons; and 5 for river service, 472 to 578 tons. *Double turret*—4 of the Winnebago class, 970 tons; 4 of the Miantonomoh class, 1,564 tons; and 2 seagoing monitors, Dictator and Puritan, of 3,000 tons, old measurement. Of these four were lost—the Weehawken by foundering at sea, the Patapsco, Milwaukee, and Tecumseh by explosions of torpedoes. In addition to the above there were begun four monitors of the Kalamazoo class, 3,200 tons, which the close of the war found upon the stocks unfinished. These with others, which by lapse of time had become no longer serviceable, were broken up later; a few were sold, and at present (1894) but eighteen remain on the list of vessels of the U. S. navy. Eight of these are of the Passaic and five of the Canonicus class, and all are laid up at some naval station. Of the remainder, four—Amphitrite (Tonawanda), Monadnock, Puritan, and Terror (Agamenticus)—are undergoing changes to meet the requirements of modern naval warfare; while one—Miantonomoh—has been completed and is in commission for service on the North Atlantic station,

Revised by C. Belknap.

Monitorial System: an educational system of importance in the history of pedagogy for the stir it made in the early part of the nineteenth century. The rival claims of Lancaster and Bell to the discovery of the system and the emulation developed between the two societies which they represented to carry out the principle did much to improve the English schools; still, neither really discovered the principle, since it had been advocated by Comenius 150 years before in the *Didactica Magna*. In Lancaster's own words, the distinct features of the plan are: First, that by his system of order and rewards, together with the division of the schools into classes and the assistance of monitors, one master is able to conduct a school of 1,000 children; second, that by printing a spelling-book or any other lessons for reading in large type, they may, when suspended with a nail against the wall, be read by a number of children, a method whereby one book will serve for a whole school; third, the introduction of slates and dictation, a method whereby 500 boys may spell and write the same word at the same instant of time; fourth, an entirely new method of instruction in arithmetic, whereby any child who can read may teach arithmetic with the utmost certainty; fifth, cheapness, three shillings a year for each child in a school of 300, and four shillings for a greater number. The system was founded on the assumption that a child who knows nothing of teaching, and scarcely more of the subject taught, can be a thorough instructor. The objections are too obvious to need relating. The last feature of the method as stated by Lancaster, namely, cheapness, was undoubtedly its main recommendation. See Sharpless, *English Education* (1892); *An Old Educational Reformer*, by J. M. D. Meiklejohn. See also articles Bell, Dr. Andrew; and Lancaster, Joseph. C. H. Thurber.

Monk, George: See Albemarle, Duke of.

Monkey [from dimin. of Ital. *monna*, Span. *mona*, O. Fr. *monne*, female ape, woman, crone, contraction of *madonna*, lady]: a name applied in a general way to any of the order *Primates* except man, but generally understood to mean one of the smaller, tailed species of *Anthropoidea* in distinction to the larger apes and baboons on the one hand, and lemurs on the other. See Hominidæ, Primates, Simiidæ, Howling Monkey, Entellus Monkey, etc.

F. A. Lucas.

Monk-seal: popular name of a large seal (*Monachus albiventer*) found in the Mediterranean, and southward in the Atlantic to the Canaries. It is of a dark-brown color, dirty yellowish white beneath, and attains a length of 5 to 6 feet. An allied species (*M. tropicalis*) occurs in the West Indies, and these two are peculiar as being the only earless seals (*Phocidæ*) found in warm latitudes. F. A. L.

Monkshood: the common name of the European aconite (*Aconitum napellus*), also called wolfsbane. This, the most important species of the genus, is a perennial herbaceous plant growing in the mountainous regions of Europe, and cultivated somewhat in gardens as an ornamental flower. The root is tapering or spindle-shaped, and is sometimes mistaken for horseradish. The stem is erect, simple, rising several feet. The leaves are dark green on the upper surface, shiny, and are deeply divided. The flowers, which are borne upon a handsome terminal raceme, are large, of a violet-blue color, and with the upper of the five petals developed into a hoodlike appendage. The fruit consists of three small pods. All parts of the aconite are highly poisonous, but the root and leaves only are used in medicine. Their virtues depend on an alkaloid, *aconitine*, which is one of the most virulent poisons known. Aconite produces sensory and motor paralysis, and especially affects the heart, directly lessening the force and frequency of its beats. In fatal dose it kills by cardiac and respiratory paralysis, the symptoms resembling those of death by hæmorrhage. A peculiar effect of aconite is a numbness and prickling, which in moderate dose is felt about the lips, throat, and tips of the fingers, but in larger dose extends up the arms and legs. Aconite is used for much the same purpose for which bleeding used to be employed—namely, to moderate the heart's action in the early stages of acute febrile complaints. It also seems to have a special power over inflammations of the tonsils and throat. From its poisonous properties it requires to be used with caution. Digitalis is the physiological antidote to it. Preparations of aconite are also very useful applied externally to relieve local pains. The application produces at the spot the peculiar tingling above referred to. Revised by H. A. Hare.

Monluc, mōn'lük', Blaise de Lasseran-Massencome, Seigneur de: soldier and author; b. near Condom, 1502 (?), of an old, noble family. In his youth he was a page in the household of Antoine de Lorraine, soon began a military career as archer under Bayard, and was almost continually under arms for fifty-five years. He had reached great distinction in the wars of Francis I. and Henry II., having been knighted in 1544, when the civil wars broke out, in which he defended the Catholic cause with ardor. In 1574 Henry III. gave him the marshal's staff. D. in 1577. His memoirs, entitled *Commentaires*, dictated in the last years of his life, are a simple, frank, and very vivid story of his career, and of great historical value. They have been published by de Ruble for the Société de l'Histoire de France (5 vols.)

A. G. Canfield.

Monmouth: city; capital of Warren co., Ill. (for location of county, see map of Illinois, ref. 4–C); on the Chi., Burl. and Q. and the Ia. Cent. railways; 26 miles E. of the Mississippi river. It is in an agricultural and bituminous coal region: is the seat of Monmouth College; has 2 libraries (Monmouth College and Warren County) with over 30,000 volumes, 3 national banks with combined capital of $250,000, and 6 newspapers; and has manufactories of agricultural implements, sewer-pipe, paving-brick, and carriages and road-carts. Pop. (1890) 5,936; (1900) 7,460.

Monmouth, Duke of: See the Appendix.

Monmouth, Battle of: See the Appendix.

Monmouth College: an institution in Monmouth, Ill.; founded Jan. 1, 1856. It is under the control of the United Presbyterian Church, and is pronounced in its Christian character, but in no sense sectarian. Its first class graduated in 1858. Its three presidents have been Dr. D. A. Wallace (1856–78), Dr. J. B. McMichael (1878–97), and Dr. Sam-

uel R. Lyons (1898–1901). In 1900 there were 20 professors and 300 students. The college buildings are situated in a beautiful campus of 10 acres. Four courses of studies are offered, leading to degrees A. B., B. S., and M. B. of four years each, and B. L. of three years. J. B. McMichael.

Monmouthshire: county of England; bounded S. by the estuary of the Severn and the Bristol Channel. Area, 534 sq. miles. Along the coast the land is low and level, but the northern and northwestern parts are elevated and hilly, the highest point, the Sugar Loaf, rising 1,856 feet. Wheat, oats, and barley are grown, coal, iron, and limestone abound, and mines are extensively worked. Pop. (1901) 230,792. The county formed part of Wales until 1535, and the Welsh language is still in general use. County town, Monmouth.

Monnier, mō′ni-ā′, Marc: scholar and writer; b. at Florence, Italy, of a French father and a Genevese mother, Dec. 7, 1829. After studying at Naples, Paris, Geneva, Heidelberg (1851–52), he finally settled in Naples, remaining from 1855 to 1864. Then he removed to Geneva, becoming correspondent for several Parisian journals, notably the *Journal des Débats*, and soon after Professor of Comparative Literature in the university. His lectures were remarkably successful, and hearers came from all over Europe to his courses. He died at Geneva, Apr. 18, 1885. His earlier published works were mainly pamphlets and books concerning Italy, for which he had the keenest sympathy. One of these, *L'Italie est-elle la terre des morts?* (1830), made a sensation in Europe. Later he began to publish on purely literary subjects, *Les aïeux de Figaro* (1868), a brilliant study in the history of the drama; *Genève et ses poètes du XVI^e siècle à nos jours* (1874); *Les contes populaires en Italie* (1880). In his last years he was at work on an extensive *Histoire de la littérature moderne*, to be made up from the lectures he had been giving for so many years. He succeeded in publishing, however, only two volumes, *La Renaissance, de Dante à Luther* (1884) and *La Réforme, de Luther à Shakspeare* (1885). Besides these more serious labors we have from his pen several interesting lighter productions—a romance, *Les amours permises* (1861); a series of short plays for marionettes, published in 1871 under the title *Théâtre de Marionnettes*; and several volumes of verse, *Lucioles* (1863); *Poésies* (1872); *La vie de Jésus*, in verse (1875); a translation of Goethe's *Faust* (1876); and *Récits et Monologues, vers* (1880). A. R. Marsh.

Monobromate of Camphor: a substance used as a drug; made by heating together in a sealed tube camphor and bromine. It occurs in colorless crystals or scales, and has a mild taste resembling camphor. It is almost entirely insoluble in water, but is freely soluble in ether, alcohol, and chloroform. It is supposed to possess the combined powers of the bromides and camphor, and is used as a nervous sedative. H. A. H.

Monocen'tridæ [Mod. Lat., deriv. of Gr. *μόνος*, single + *κέντρον*, spine]: name of a family of fishes of the order *Teleocephali* and sub-order *Acanthopteri*, represented by a single known species, *Monocentris japonicus*, which is an inhabitant of the Chinese and Japanese seas.

Monochord [from Lat. *monochor'don* = Gr. *μονόχορδον*, liter., a thing with a single string; *μόνος*, alone, single + *χορδή*, string]: an instrument chiefly used for the computation of musical intervals and the adjusting of their respective ratios with reference to the scale. It consists of a single string stretched over a board or box. At each end the string passes over a bridge, and is fastened to a strong peg or wrench-pin. Underneath the string there is usually placed a scale with numerous divisions and subdivisions, at any of which the string may be stopped by means of a movable or sliding bridge, which serves to divide the string into two parts from any desirable point. The string of the monochord should be of equal thickness throughout, and strong enough to bear a moderately high tension. For practical use, a string of sufficient length to give the sound of C C with clearness will be found most convenient. Such a string, if stopped exactly in the middle by the movable bridge, will sound on either side the octave of the C C—i. e. the sound of the *half* length of the string is an octave above that of its *whole* length. When stopped at one-third of its length, the sound is an octave and fifth above that of the open string: and one-fourth of its length produces the C of the second octave, or two octaves above C C. The ratios of all the intervals may be found by pursuing the same process of division.

Monochrome: See Camayeu.

Monocotyledons [from Gr. *μόνος*, single, and *κοτυληδών*, cotyledon]: a sub-class of higher flowering plants (Angiosperms), characterized by having their leaves, from the first, alternate (the lowermost, or first leaf, *cotyledon*, is thus single), the veins of the leaves mostly parallel, the parts of their flowers commonly in threes, and the woody bundles in their stems separate, and arranged with seeming irregularity. Exceptions to all of these characters occur, but there is such a general agreement that there is little difficulty in recognizing the plants which belong to this sub-class. Characteristic Monocotyledons are the lilies, orchids, palms, and grasses, many of which are among the most useful and best-known plants in the vegetable kingdom. Eight orders of Monocotyledons are pretty well defined, including from thirty to thirty-five families. There are now known about 20,000 species. See Dicotyledons, Plants, Fossil; and Vegetable Kingdom. Charles E. Bessey.

Monod, mō′nōd′, Frédéric Joël Jean Gérard: theologian; b. at Monnaz, Switzerland, May 17, 1794; was educated at Geneva; succeeded his father, Jean Monod (1765–1836), in the pastorate of the National Protestant Church of the Oratoire, Paris, but seceded in 1848, and became the leader of the Free Evangelical movement. D. in Paris, Dec. 30, 1863.—His brother, Adolphe, succeeded him in the pastorate at Paris in 1847, and was an able orator and author of the orthodox school. He was born at Copenhagen, Jan. 21, 1802; died in Paris, Apr. 6, 1856. He published *Lucile* (1841); *Saint-Paul* (1851); *La Femme* (1862); and several volumes of sermons. His *Life*, by one of his daughters, appeared in English translation (London, 1885).
Revised by S. M. Jackson.

Monodelphia: See Placentalia.

Monogram [from Lat. *monogram'ma*; Gr. *μόνος*, single (i. e. together in one) + *γράμμα*, letter, thing written, deriv. of *γράφειν*, write]: a character made up of all or the more important letters of a proper name. This is the strict sense of the word: a character made up of two or three initial letters; as, for instance, J. Q. A. for John Quincy Adams is not a monogram, but a Cipher (*q. v.*). Moreover, the character &c., or, as modified, &c., standing for *et cetera*, is not a monogram because not made up of a proper name. It will be seen, therefore, that real monograms are very uncommon. The great number of ciphers used by engravers, book-printers, etc., in the sixteenth and seventeenth centuries include hardly a half-dozen real monograms. A perfect one is seen in Mr. Philippe Burty's stamp (see cut), put upon the prints of his fine collection. The best known monogram is that of the word Christ in its Greek form, ΧΡΙΣΤΟΣ.

The letters Χ Ρ do not necessarily form a monogram, but when combined thus ☧ they form one which has been in use for centuries. See Labarum. R. Sturgis.

Mono Lake: a body of water in Central California, E. of the Sierra Nevada. It is without outlet, and is variable in area. In 1883 it was 13½ miles in diameter from E. to W. and 11 miles from N. to S., and had an area of 85·5 sq. miles, a mean depth of about 61 feet, and a maximum depth of 152 feet. Its elevation is 6,380 feet above the sea. The mountains along its southern border rise from 6,000 to 7,000 feet above its surface. The water contains 53·47 grammes of various salts to the liter, of which 18·5 are sodium chloride, 22·6 sodium carbonate and bicarbonate, and 11 sodium sulphate. The high percentage of sodium carbonate and bicarbonate, amounting to 42·25 per cent. of the total solids in solution, makes the brine of commercial value; by estimate the lake contains nearly 200,000,000 tons of these salts. The water is so intensely saline and alkaline that it is uninhabited by fishes, but it swarms with the larvæ of insects and with small crustaceans known as brine shrimps. The lake was formerly 680 feet deeper than it is now, as is shown by ancient beaches, and had an area of 316 sq. miles. Israel C. Russell.

Monomania: See Insanity.

Monometallism: See Monetary Standards.

Monongahela City: city (chartered as a city in 1873); Washington co., Pa. (for location of county, see map of Pennsylvania, ref. 5–A); on the Monongahela river, and the Penn. and the Pitts. and Lake Erie railways; 21 miles S. of Pittsburg. It is in a coal, petroleum, and natural-gas

region, and has the only manufactory of carborundum in the U. S. The city has electric lights, brick-paved streets, thorough sewerage, 2 private banks, and 2 daily and 2 weekly newspapers, and paper, flour, and planing mills, machine-shops, foundries, ship-yard and docks, and the usual industries connected with coal-mining. Pop. (1880) 2,904; (1890) 4,096; (1900) 5,173.

EDITOR OF "DAILY REPUBLICAN."

Monongahela River: a stream which rises in Randolph co., West Va., flows N. 300 miles in a tortuous course and joins the Allegheny to form the Ohio at Pittsburg, Pa. It is navigable by slackwater improvements 106 miles to Morgantown, W. Va., and 200 miles for keel-boats. It flows through a fertile and highly prosperous region abounding in coal, timber, and various minerals. The navigable Youghiogheny is its most important tributary.

Monoph'ysites [from Gr. *μονοφυσίτης*, monophysite; *μόνος*, single + *φύσις*, nature]: persons adhering to the doctrine of monophysitism. I. The Monophysites were an Oriental sect originating in the fifth century in the views of EUTYCHES (*q. v.*), concurring in the main with them, though with certain specific differences. They held that though Christ is *of* two natures, which became conjoined at the incarnation, he does not subsist *in* two natures. (See CHRISTOLOGY.) There is in this sense but *one nature* after the union, though that nature involves and embraces two parts. The human is not annihilated, but is virtually lost, or virtually, though not essentially, absorbed in the divine —"like a little honey mingled with the ocean." The Nestorians virtually argued there are two natures, therefore there must be two persons; the Monophysites, there is but one persons, therefore there can be but one nature—both arguing in this way from a true premise to a false conclusion.

II. The spirit of the Monophysites was that of their era, fierce and bloody. Only internal harmony was needed to make them very formidable; but a system which originated in extravagance and confusion of thought ran out of necessity into a number of sects. These multiplied rapidly after the extinction of the hopes of the Monophysites to maintain themselves as the orthodox and catholic Church of the East. The sects which arose were as follows: (1) The Acephaloi; (2) the Julianists; (3) the Severians; (4) the Julianists; (5) from the Severians sprang the Agnoetists; (6) the Tritheists; (7) the Damianists; (8) the Cononites; (9) the Niobites.

III. The most important councils associated with the history of the Monophysites are—(1) the Council of Constantinople (448–449); (2) the "Robber Synod" at Ephesus, which restored Eutyches (449); (3) the Council of Chalcedon, the fourth œcumenical (451). It decided that the two natures are united without fusion, without mutation, indivisibly and inseparably—one Christ *in* two natures. It is remarkable, however, that the common Greek text reads "*of* two natures," which is the precise form preferred by the Monophysites. (See Münscher, *Handbuch d. Dogmen. Gesch.*, iv., 101.) These results were accepted universally in the Western Church, and very generally in the East, but were rejected with great violence, as Nestorianizing, wherever the Monophysites were in force.

IV. The struggle was violent and protracted between the parties. (1) In *Palestine* the diphysite bishops were expelled, and Theodosius was made Patriarch of Jerusalem. (2) In *Egypt*, under the presbyter Ælurus and the deacon Mongus, the Monophysites separated themselves. (3) In *Antioch*, Peter the Fuller, from whom the Monophysites are sometimes called Fullonians, attempted to introduce into the Trisagion the formula, "Thou (God) wert crucified for us," which the enemies of the Monophysites insisted must mean that the divine nature was crucified if Christ had but one nature, and called them Theopaschites. (4) The Emperor Zeno (482) put forth the *Henoticon* (agreement), which was designed to harmonize the contending parties. It used general expressions, which ignored the exact points at issue, avoided equally the phrases "one nature" and "two natures," condemned both Eutyches and Nestorius, and made an allusion to the Council of Chalcedon which was far from respectful. It widened the breach and inflamed the animosity. (5) Pope Felix III. (483–492) pronounced against the *Henoticon* and excommunicated Acacius, the Patriarch of Constantinople (484). This led to a suspension of communion between the Western and Eastern Churches for thirty-four years. (6) The Emperor Anastasius I. (491–518) at the beginning of his reign held fast to the *Henoticon*, with an evident leaning to the Monophysites. (7) In addition to the doctrinal interests there was a struggle between Rome and Constantinople for supremacy. Rome and orthodoxy came forth triumphant. Justin I. (450–527), with Pope Hormisdas (514–523), effected the reunion of the Greek and Latin Churches (518), the *Henoticon* was set aside, the decisions of the Council of Chalcedon were established, the bishops deposed by the Monophysites were restored, the formula of faith demanded by the pope was acknowledged, Severus and his followers were condemned, the names of the obnoxious patriarchs of Constantinople were stricken from the DIPTYCH (*q. v.*), and the names of Leo the Great and of Euphemius and Macedonius, the patriarchs of Alexandria, were inserted in them (519). (8) The Monophysites were now branded as heretics both by the state and the dominant Church. A thousand of their bishops and other clergy were deposed, imprisoned, and outlawed. Prominent among these was Xenayas (Philoxenus, d. 522). (9) The strength of the Monophysites in Egypt was so great that they were able to find in it a refuge in the time of the terrible storm which had broken on them (Timotheus, Ælurus, Severus, Julian).

The sphere of the Monophysites was the East, where local and political jealousies intensified the disputes which arose with the Church of the West.

(1) Monophysitism was influential in Egypt, from Alexandria as a center. In that land it continues to this day. (See COPTIC CHURCH.) (2) In Syria, Mesopotamia, Asia Minor, Cyprus, and Palestine, under the Patriarch of Antioch, the Monophysites take their name from their organizer and restorer, the monk and presbyter Jacob Baradai, and are known as JACOBITES (*q. v.*).

The ARMENIAN CHURCH (*q. v.*) is nominally monophysite. The total number of the Monophysites is probably about 9,000,000. See Dorner's *History of the Doctrine of the Person of Christ* (1861–63). Revised by S. M. JACKSON.

Monop'olies [from Lat. *monopo'lium* = Gr. *μονοπώλιον*; *μόνος*, alone, sole + *πωλεῖν*, sell]: The possession by an individual or by a group of individuals of the exclusive right or the exclusive power to supply or to demand some special kind of goods or services is a monopoly. The word is often used to include special personal gifts, e. g. those of a great musician or artist, or possessions that from their nature are strictly limited in extent, as special tracts or pieces of land. (See RENT.) In its ordinary broad meaning, however, the word is applied only to a branch of business which, from whatever cause, is practically—not necessarily entirely or legally—controlled by one executive head.

From various points of view monopolies have been classed as natural and artificial, public and private, general and local, permanent and temporary, productive and trade monopolies, monopolies of purchase and of sale, etc. For the purposes of this article it is best to recognize (1) legal monopolies; (2) natural monopolies; (3) capitalistic monopolies, with various kinds under each. It will be noted, too, from the course of the discussion, that these titles are not necessarily exclusive, but that they rather serve only to emphasize important characteristics of origin or nature.

LEGAL MONOPOLIES.—(*a*) *State Monopolies.*—Simon Sterne calls attention to the fact that the greatest of state monopolies is that of government itself. We are apt to overlook the fact that the functions of the state are monopolistic, or else to think that these functions are clearly limited and peculiar in their nature. A brief consideration, however, shows us that the sphere of the state's monopolistic activity may be confined to the protection of the state from external attack and internal revolution, or it may be extended to include more and more of the duties usually left to private enterprise until we reach the socialistic state, in which the government, the one monopolist, controls all business.

With some differences, however, the practice of the great modern states is to monopolize only those lines of business that are of vital interest to the people, and in whose management the people must have confidence. For example, the education of children, the coinage of money, the care of highways, the postal service, the police service, are generally cared for by the states and are usually monopolies.

A chief purpose of many state monopolies, especially in early times, has been to procure revenue. Regular taxation, in the historical development of nations, is a late expedient for raising revenue, early states being compelled to rely upon income from state lands, mines, and claims and rights of various kinds. Ancient Greece and Rome furnish examples

of monopolies of salt and other mines, though corruption of the lessees sometimes made them unprofitable. The Middle Ages furnish numerous instances. The Emperor Frederick II. is said by Cibrario to have established in Naples early in the thirteenth century monopolies of iron, salt, copper, raw silk and wine, while salt was a state monopoly also in Venice, Pisa, and Zurich, and a century later in France; and in his account of the Italy of Dante's time he tells us of a monopoly of guardianships, from which large sums were obtained for permission to marry. The development of the monarchical system in the sixteenth and seventeenth centuries, with the mercantilistic doctrine of the same period, however, gave a great impulse to state activity and state interference in industry, and in this period state monopolies for revenue purposes especially flourished. In Spain, Italy, Germany, France, and elsewhere, such objects as coffee, powder, wheat, playing-cards, and alcohol were monopolized by the state. Colbert introduced the monopoly of tobacco into France in 1674, the business being farmed out. Austria introduced it in 1670.

At present we find state monopolies for fiscal purposes in many states: e. g. salt in Austria, Italy, Greece, Roumania, Servia, Turkey, and in part in India, while the production is so controlled in Prussia that an enormous tax can be collected from it; tobacco in Turkey, France, Italy, Austria-Hungary, and Spain; opium in Turkey and parts of India; watches and gunpowder in France; alcohol, since 1887, in Switzerland, in Russia until 1862. The purpose of the alcohol monopoly in Switzerland is also in part to reduce the consumption of alcohol and lessen alcoholism. The same purpose is aimed at in the Gothenburg system in Sweden, which is a monopoly of the sale of spirits farmed out to a private company. South Carolina in July, 1893, put into effect a law making the sale of alcoholic liquors a State monopoly. After some riots, brought about by the vigorous efforts of Gov. Tillman to enforce the law, the courts finally declared the law unconstitutional.

Quite opposed to these laws in spirit is the monopoly of the state lottery in Prussia, Saxony, Hamburg, Spain, Austria, and Italy, from which large sums are put into the state treasury by encouraging a popular vice.

Many of these monopolies, especially that of tobacco, have proved very satisfactory from the fiscal standpoint, while some authorities are of the opinion that whenever a common necessity like salt becomes a natural monopoly it ought for the safety of the public to be made a state monopoly.

(*b*) *Private monopolies granted by government* became very common in the sixteenth and seventeenth centuries. They had at times a fiscal aim, as they were often sold; but so many and so important kinds of business, including salt, leather, coal, soap, cards, beer, wine, etc., became thus monopolized, largely through gifts to courtiers in England in the reigns of Elizabeth and James I., that Parliament had to protest vigorously, and Sir Edward Coke, in 1602, in the famous case of *Darcy* vs. *Allin*, decided that while the king could grant a temporary monopoly, thus recognizing the value of patents, all grants in restraint of trade were illegal. In 1625 an act of Parliament limited this power to the granting of patent rights.

Monopolistic grants, however, to great commercial and colonizing companies from different states of that time may well be justified, e. g. such as were given to the East India Company, founded 1600; the Dutch East India Company 1602; Hudson Bay Company, 1670; John Law's Company of the West, 1717, afterward the Company of the Indies, 1719 (the Mississippi scheme); and many others. Though the last proved a gigantic speculative failure, and though even the first two did not prove so successful financially as had been hoped, yet the advantage of the monopoly of trade and government granted them seems clear. So large amounts of capital were needed to carry out the enterprises; the time that must elapse before any returns could be hoped for was so long; the risks, not merely of the business but also of capture of ships by hostile nations and by pirates, were so great; the necessity of dealing promptly and finally with semi-civilized, barbarous, and savage peoples was so imperative, that possibly no one could have been found willing to undertake the enterprises unless a monopoly of the trade and even of some of the prerogatives of government were granted in advance.

The abuse of power by the governments, as has been shown, led to a reaction against the monopolies, while the mercantilistic doctrines that had tended to foster them were greatly weakened in popular favor in the latter part of the eighteenth century, especially under the attacks of Turgot in France and Adam Smith in Great Britain. The era of free trade and *laissez faire* set in, and only since the rise of the socialistic movement has there been a vigorous effort made to strengthen and extend legal and especially state monopolies.

(*c*) A *patent right* given by the government of a state secures to the owner and his assigns the monopoly of the manufacture and sale of the patented article for a fixed term of years; in the U. S. seventeen years. The object is, of course, to stimulate invention, and no thinking person would deny either the right or the advisability of the state to secure to an inventor the fruits of his intellectual activity; but whether this justice to the inventor is best secured by a patent monopoly or not is doubtful. Some think that the desired end would be better gained by granting to the inventor a royalty on all the articles of his invention manufactured, while leaving free to any one on payment of this royalty the right of manufacture. Copyrights and trade-marks are of the same general nature and value as patent rights.

Natural monopolies have become in the most highly civilized states of greater significance, perhaps, than legal monopolies. Of these monopolies there are to be distinguished two chief classes, although the line between the two can not be sharply drawn: 1. The first includes those lines of business of which the output is closely limited by natural causes, with relatively speaking little reference to the amount of capital employed, as, for example, the mining of nickel, or the use of a water-power; or it might be the employment of the finest view-point near some natural wonder, as Niagara Falls. Wherever, from purely natural reasons, the possession and management of the business by one legal person excludes that of another, we have a natural monopoly of this first class. Generally speaking, these monopolies are relatively of little economic significance for the industrial world as a whole, though they may be of great local value, and have often been made state monopolies for revenue purposes. Were there but one or a few coal or iron mines in the world their owners would have a dangerous monopoly. As it is, it has been found that competition between the owners of different mines will generally prevent too gross exactions, although the anthracite coal mines in the U. S., acting in conjunction with railways, have at times proved oppressive. The private ownership of the land about Niagara Falls was oppressive to tourists, but it had little effect upon general economic conditions. It must be noted that these natural monopolies presuppose private ownership guaranteed by law. The natural monopoly of personal ability and of land ownership, properly classed here, may be passed with the mention of them.

2. The second class of the so-called natural monopolies includes all those lines of business that have been designated as "industries of increasing returns," i. e. industries that, when once firmly established, for an added amount of capital invested will give a product more than proportional to that on the first investment. The chief industries of this class are railways, the telegraph, telephone, tramways, gas and electric lighting works, water-works, etc., and are practically all modern. In Europe the railways are often state monopolies, the telegraph is uniformly so, and municipalities frequently own and manage the gas-works and sometimes the tramways. In the U. S. such enterprises are private generally, excepting water-works. After a railway has been once put into running order its carrying capacity can be doubled at an outlay of capital far less than the original one. Some of these industries are almost identical with the first class of natural monopolies, while others are more nearly like the capitalistic monopolies mentioned below. It is not practicable, even if it were profitable, for many competing tramway lines to be laid in the same street, owing to lack of space. The same principle holds regarding gas and water works. On the other hand, there is room enough in all country districts for many competing telegraph or telephone or even railway companies to do business if it were profitable. It is only the fact that such lines would not be profitable that prevents their construction. The nature of development of the business is the chief mark of distinction between these two classes.

Capitalistic monopolies is perhaps the best name for those industries that become monopolized simply through the business advantages that arise from the use of large capital. Only of late years has this kind of monopoly become prominent, and that chiefly in the U. S., but indica-

tions seem to point to its extension. The best-known examples of capitalistic monopoly in the U. S. are the Sugar-refineries Company (Sugar Trust), the Distillers and Cattle-feeders Company (Whisky Trust), and the Standard Oil Company, although the last mentioned, so far as it has had to do with the production or shipment of crude oil, either by railway or pipe-line, is in good part a natural monopoly also, and although, further, the Standard Oil Company achieved its power largely through the assistance of the railways, which are natural monopolies. The capitalistic monopolies can not always be sharply distinguished from the natural monoplies of the second class mentioned above; but, generally speaking, they are not to any noticeable extent industries of increasing returns, and the advantages that enable them to become monopolies are mostly of the nature of saving in cost of distribution of product or of management. For example, for a sugar-refinery to double its output would in many cases involve the outlay of nearly as much capital as did the original establishment, while for a street-railway to double its carrying capacity would probably involve only the purchase of extra cars and traction-power, the road-bed remaining the same. On the other hand, twenty sugar-refineries working in harmony under the same management could save in many ways, and be run for much less than if each refinery were managed independently.

A *trust*, as the word is applied to monopolies, is simply a form of business organization, usually of a capitalistic monopoly. As nearly all natural monopolies of the second class mentioned above and all capitalistic monopolies require the investment of vast capital, nearly all have been organized as corporations. The trust is a device to combine into one compact harmonious working whole any number of different corporations with differing interests.

As the writer of this article stated in *The Economic Journal* of Mar., 1892, "to accomplish this result it is necessary—(1) That the interests of the different corporations be made common. (2) That the management of the different corporations be made harmonious. (3) That no corporation or individual have it in his power to withdraw from or to break up the organization, as is done under pooling systems. In forming the trust to accomplish these ends: (1) The majority of the stockholders of each corporation interested (in the case of some of the trusts—as the Cotton-oil Trust and the Sugar Trust—*all* the stockholders) surrendered in trust their shares of stock to a board of trustees of nine or eleven men; i. e. they gave to this board an irrevocable power of attorney or proxy, by virtue of which this board held a majority of votes in each one of the corporations, and could therefore elect its officers and direct its policy. This naturally harmonized the actions of all, and, the trusteeship being irrevocable, no individual can make trouble. (2) To protect the stockholders and make their interests common, this board of trustees issues to the stockholders, in lieu of their surrendered stock, trust certificates. The profits of all the various corporations are put into one common fund by the trustees, and then divided among the holders of the trust certificates *pro rata*. The holder, therefore, of each certificate receives the same dividend, whether the corporation whose stock he surrenders pays a high or a low profit, or even is closed and makes no profit at all. It is readily seen that this arrangement makes it to the interest of each trust-certificate holder that those establishments be run that make the best profits, whether these include his own establishment or not, and that the poorer ones be shut down if they are not needed. The plan has been uniformly successful in attaining its ends. In practice it has generally been found advisable to leave the management of the individual corporations in the hands of their former officers, and they have exercised their power at discretion; but in every case the power of removal is of course in the hands of this board of trustees, so that their judgment will be followed, and any lack of success in management is sure to meet its penalty."

The trust may easily be put back into the corporation form by issuing to each trust-certificate holder a corresponding amount of capital stock, giving him an undivided interest in all establishments represented. This plan has been followed by some of the trusts under the pressure of hostile decisions by the courts.

THE CAUSES OF INDUSTRIAL AS DISTINCT FROM STATE MONOPOLY may be said to lie in the modern form of industrial organization itself, the form that was the outcome of the steam-engine, the power-loom, the railway, the telegraph, and the other great inventions of the age. Of course, in this whole discussion the ordinary economic motives on which demand for products depends, and in accordance with which demand fluctuates, are assumed. The necessity of doing business on a great scale has altered the nature of competition itself; and from excessive competition, where competition is possible at all, springs the great combination of interests that results in practical monopoly; and yet this competition manifests itself in different ways. It has already been noticed that in some natural monopolies, as street-railways, no competition is possible, because the nature of the business does not permit two companies to work in the same place. In the case of railways a would-be competitor may lay another track beside the original one, and enter into competition; but the principle of increasing returns that applies to such a business shows us that the increased work, if any, accomplished by the two railways might have been far more cheaply done by increasing the plant of the first one. If competition begins between the two railways, and each is able to do all or nearly all the business, rather than lose its traffic each can afford to carry freight at any price above the running cost, thus losing the interest in part or whole on the original investment. Experience shows that in the case of parallel railways competition often actually does continue, until both railways carry freight at losing rates, or combination is effected by means of a lease, or pool, or other device. Parallel railways are at times built for the mere purpose of forcing the original railway to purchase or lease them, in order to avoid the excessive competition.

The case of great manufacturing establishments, e. g. sugar-refineries, distilleries of alcohol, cotton-factories, which are not natural monopolies, and which are subject to the principle of increasing returns to no such extent as are railways, is nevertheless, as regards competition, not materially different. Although a new rival factory might perhaps be built nearly as cheaply as the original one could double its capacity, yet if two factories representing large investments of capital come into competition, it often happens that, rather than lose trade, or shut down, to the certain destruction of much of the capital, both companies will run, perhaps must run, when their gains are not enough to pay fair interest on the capital invested, in addition to the running expenses. The only remedy is combination, either tacit, with a common ceasing to cut prices, or formal, through a pool, or trust, or purchase. To be sure, competition may ruin the weaker establishment, leaving the fittest to survive; but where large capital is invested, and the competitors are fairly evenly matched, this result is not so easily reached as is a combination, nor in many cases is it economically desirable. In the early days of the civil war in the U. S. the Government, by raising the internal revenue tax on alcohol to 20 cents a gallon, then to 60 cents, then to $1.50, then to $2.00, with in each case a considerable interval of time intervening before the higher rate was imposed after it had been announced, so increased distillers' profits that a large number of new distilleries were built, far more than enough to supply the normal demand for alcohol. The result of the fierce competition that ensued was the ruin of some distillers, but nearly all the larger establishments survived, though there was relatively little or no profit in the business for most of them. To improve their condition they found it necessary to unite in a pool, to limit their production, and at times even to tax themselves to export alcohol at a loss in order to secure better prices on the home market. The tenacity of invested capital and the fierceness of the competition which finally led to the combination into the Whisky Trust, which, under various names and forms of organization, has been able to secure monopoly prices, are shown by the fact that at one time all the distillers in the pool, some eighty in number, agreed to run their distilleries at only 40 per cent. of their normal capacity for one year, and later, another year, at only 28 per cent. of this capacity; and also by the further fact that, after the formation of the trust, twelve of the best distilleries running to the full extent of their capacity produced as much alcohol as had the eighty distilleries before, and also paid good returns on the capital invested in them all. Similar facts, though perhaps not so striking, in the history of the salt, white-lead, cotton-oil, and cotton-bagging manufacture, as well as, in a less prominent way, the associations of lumber-dealers, millers, steel-manufacturers, etc., and the many local associations in all lines of business, a main feature of whose existence is the effort to keep up prices by hindering competition—all lead to the conclusion that, when business is done on a

large scale, so much is at risk that, with exceptions here and there, too fierce and yet neeessary competition is the force that drives competitors into combination more or less complete with the purpose of securing prices that are, in fact, monopoly prices, though they may not be high enough to yield great profits. To say that the combinations are made for the purpose of securing large capital in order to effect the saving made by more complete organization, is to state the same fact from another standpoint.

Some of the strongest combinations, notably the Standard Oil Company, have been aided in their growth to monopoly by the special freight rates granted them by the railways. In this way one company may have succeeded in crushing or absorbing its competitors instead of being forced to unite with them on equal terms; but in this ease as before the fierceness of competition springing from modern methods of production with large capital has produced the monopoly, whieh is powerful enough to prevent, within certain limits, effective competition.

The benefits of monopolies—if by that term we understand the great business organizations that, by virtue of their strength, are often enabled to put down smaller eompetitors almost at will, and that obtain prices higher than would be possible under a system of equal competition, although they may not be entirely without competition—are often great, both to the owners and to the community, though sometimes the benefits to the community may be more than offset by accompanying disadvantages:

1. When competition becomes fierce, there is frequently upon the market a supply of goods so great that it can not be sold at remunerative prices. Either the amount produced by each must be lessened, or some of the competing establishments must stop business entirely. In actual business it frequently happens that competitors agree to limit each his output to less than his producing capacity, of course at a waste of invested capital. If now all combine into one great institution with harmonious interests, a great saving will be effected by working the best plants at their full capacity, and stopping the others entirely, turning them to other purposes to the best advantage possible. The monopoly then saves to soeiety capital and labor that would otherwise be unprofitably employed; or, assuming that no combination is made, and many fail in business, the monopoly might have saved much of the capital thus lost by being forced out of business. 2. The saving in industrial energy obtained by putting all production in any one line under the management of the leading experts is almost inealculable. 3. A great organization with branches in various parts of the country saves much in transportation. Each customer is served from the establishment nearest him. In the case of bulky articles, such as salt, sugar, or oils, this saving is very large. 4. The saving in a large establishment from side products that in a small one must needs be wasted is great. The solicitor of the Standard Oil Company writes that in this way "the cost of manufacture of lubricating oils and wax in connection with the refining of petroleum has been reduced by improved methods and constant attention, and the price has been constantly reduced, averaging to-day (1889) 50 per cent. less than in 1878." 5. A cheapening of manufacture is often made in materials also from careful study by experts and from a complete organization, neither of which would be possible in a small establishment. According to the experience of the Standard Oil Company: "In 1872 barrels cost the trade $2.35 each. They are now manufactured at our own manufactories at a cost of $1.25 each. About 3,500,000 barrels are used per annum. This single item amounts to $4,000,000. In 1874 cans cost 30 cents each. They are now made by our manufactories for less than 15 cents. Thirty-six million cans are used each year, and this one item of saving amounts to $5,400,000 each year." The same cheapening process he shows in wooden cases, pumps, stills, tanks, and everything used in the business. Of course, many or all of these articles would have been cheapened within that time if made by others for the use of smaller establishments, and it is probable that the difference in the money standard was not fully taken into account. Still it holds true that this may well be a great source of saving to the community, made by the monopolies. 6. In addition to the advantages mentioned, the managers of the great monopolies claim a lowering of prices and a steadying of prices, both of which claims are commonly denied. It is charged also against them that their power enables them to force down unduly the prices of raw material and wages.

Their influence on prices may profitably be considered in detail. The fixing of prices by all who have goods to sell is for the purpose of making the highest possible profits, whether the business be a monopoly or be carried on under a system of free competition. Such a truism seems neeessary as a reply to the feeling often exhibited against monopolies. The feeling and purpose of a monopolist is the same as that of any other business man. Their circumstances differ. The monopolist puts his price as high as he can without thereby lessening the demand for his goods more than enough to counterbalance his high profit on each individual sale. He seeks the greatest net profit. So with the other; but in the case of the monopolist the subjective feeling of the purchaser alone limits the sale, and hence the price; in the case of the other it is this feeling working in harmony with the desires of competitors to make sales that fixes prices. If the article to be sold is a luxury that people can readily do without, or especially if it is an article for which another can be easily substituted, the monopoly price will probably not differ much from that which would be fixed by free competition. It may even, owing to prejudice against monopolies, be lower at times than that. If, however, the article in question is a necessary of life, the monopoly priee may be, and probably will be, fixed much higher. In the case too of most of the so-called natural and capitalistic monopolies of which we have spoken another element enters in fixing price. These monopolies are rather partial monopolies. Nearly all of them have some few competitors who can not enter seriously into rivalry so long as the prices are not very much higher than competitive prices would be, but who would become dangerous rivals if prices became too exorbitant. On the whole, we might conclude *a priori* that we should find prices somewhat, but not very much, higher than competitive prices, and experience establishes the conclusion. The monopoly might fix its price below the competitive price, but it will not.

In the case of the sugar monopoly, the price of refined sugar began to increase before the formation of the trust, but that of raw sugar kept pace with it. When the trust was formed, however, the difference between the prices of raw and refined sugars increased from about one cent per pound and even more occasionally, showing that the trust was getting a monopoly price and gaining from 1 cent a pound upward more than would have been possible under competition. The lessened cost of refining that must have been made by the trust from its better organization as well as its greater power both as a buyer and seller, doubtless made its profits even more than the figures show; but even this comparatively small monopolistic price worked in part its own defeat. After some two years it was enough to bring about adverse decisions by the courts, involving great expense and a reorganization. A hostile public opinion, and especially the high profits, called into the field new refineries, notably those of Claus Spreckles in Philadelphia, capable of offering effective competition. Prices were thus forced down, until the difference in priee between raw and refined sugars was but very little greater than before the trust was formed. The greater gains, if any, were practically all from savings under the better organization. In Mar., 1892, the chief competing refineries were absorbed by the company, so that since then it has had a more nearly complete monopoly. The effect was seen at onee by an increased profit of one-half cent a pound within a month, which soon became an increased profit of nearly, and at times quite, 1 cent a pound.

The history of the alcohol refining in the U. S. since 1881 leads to like conclusions. Whenever a pool was formed prices went up, and the difference between the price of a bushel of corn and that of the alcohol made from it increased. When a pool broke, prices and profits fell and remained low till there was a new organization. After the formation of the trust prices were cut for a time to force in competitors. Again during 1889 and part of 1890 prices were held low, because it was found that the higher profits were strengthening competitors and calling new ones into the field. Then more distillers joined the trust, and prices went up again. So with other similar organizations, such as the Lead Trust, Standard Oil Company, Cotton-oil Company, Linseed-oil Combination, etc. A careful statistical study shows that when prices do not go up, the downward tendency previously existing from new inventions and improved methods seems to be checked. Though the increased profits coming from the sources of saving mentioned above may satisfy some of the stockholders, yet it is generally not enough. A

monopoly might often lower prices and still make as good profits as under free competition. It generally does raise prices.

A monopoly has probably a tendency to steady prices, though this tendency is not always clearly manifested, the less frequent changes in prices being counterbalanced by the more than corresponding extent of the changes when they do come. See *Political Science Quarterly*, Sept., 1894, for statistics of prices.

Evils of Monopoly.—Besides the evils incidentally mentioned in connection with the consideration of the effects of monopolies on prices, the following may be noted: (*a*) The speculation in their stocks deprives the market of a class of securities in their nature especially well adapted for safe investment. (*b*) Having a practically certain market and sure profits, the monopolists tend to become less enterprising, inventive, careful in business methods than those under the spur of competition. The economic loss from this slothful spirit can not be computed, but it must be great, and the social effect must be baneful. (*c*) The organization of industrial society on the feudal plan, through the crushing of weak establishments or their absorption into the few large monopolies that control industry, must affect society profoundly; and unless the influence of subordinate position is counteracted in some way not now foreseen, the effect will be to weaken the independence and enterprising spirit of business men. (*d*) The possession of enormous capital and great interests at stake leads sometimes, perhaps often, to political corruption, buying of legislators, and courts.

Authorities.—*The Economic Journal*, June, 1891, has an excellent article by Prof. Bastable, summing up the state monopolies employed for revenue purposes; Stourm, *Les finances de l'Ancien Régime*; Cibrario, *Economia Politica del Medio Evo* (lib. iii., ch. vi.); de Parieu, *Traité des Impôts* (iv., p. 471 ff.); Adam Smith, *Wealth of Nations*; Report of House Committee of Congress on Manufactures, Fiftieth Congress, No. 4,165; New York Senate Report on Trusts, 1888; Report of Canadian Legislature on Trusts and Combinations, 1888; W. W. Cook, *Trusts, The Corporation Problem, Stock and Stockholders and Corporation Law* (ch. xxix.); Beach, *On Private Corporations* (ch. xli.). The last two authorities cited give an excellent bibliography of trusts. *The Economic Journal* (English), Mar., 1892; *Political Science Quarterly*, Mar., Sept., Dec., 1888, June, 1889, Sept., 1894; *Atlantic Monthly*, Mar., 1881; John M. Bonham, *Industrial Liberty*; S. C. T. Dodd, *Combinations, their Uses and Abuses.* Jeremiah W. Jenks.

Monopter'idæ [Mod. Lat. from *monop'terus*, the typical genus; Gr. *μόνος*, single + *πτερόν*, wing]: name of a family of the order of eels or Apodes, containing a peculiar species of fish (*Monopterus javanensis*), found in the East Indian and Chino-Japanese seas. It sometimes attains the length of 3 feet or more.

Mon'otheism [Gr. *μόνος*, alone, single, one + *θεός*, God]: the doctrine or belief that there exists but one God, as distinguished from polytheism, which teaches the existence of more than one divinity. Judaism, Christianity, and Mohammedanism are the principal monotheistic religions.

Monoth'elites [Gr. *μόνος*, single + *θέλειν*, wish, will; cf. *θέλημα*, the will]: adherents of monothelitism, the doctrine that there is but one Will in the person of Christ. (See Christology.) It is opposed to diothelitism, the doctrine that each nature of Christ possesses a distinct will, both in faculty and exercise.

I. Though monothelitism proceeded from the Catholic side, it is yet an offshoot of the monophysitic influence on the Church policy of the Byzantine court. The monophysite struggles of the fifth and sixth centuries had been the sources of uproar and of anarchy throughout the empire. These at last assumed such a shape as to threaten its unity and perpetuity. There seemed to be special ground for the fear that Egypt, where monophysitism ruled almost without restraint, would cut itself loose from the orthodox court in Byzantium and form a separate kingdom. The dangers of the hour were heightened by the prolonged war with the Persians (620–628). Heraclius (610–641) sought to avert the threatening evils by removing the terrible schism which still divided the Church. In his interview with Paul, the monophysite Patriarch of Armenia, the expression "the one energy of Christ" had been used, and the impression it made on both sides—it is disputed by which it was first used—suggested that it might be made the basis of a compromise between the Catholics and the Monophysites. With the Catholics, and in accordance with Chalcedon, the two natures were to be asserted, and yet with the doctrine of one theandric energy, one volition, implying one will, virtual provision would be made for the sort of unification for which the Monophysites contended. Protracted conferences followed with the monophysite patriarchs, Arcadius of Cyprus and Athanasius of Hierapolis, subsequently of Antioch, and with the orthodox patriarchs, Sergius of Constantinople and Cyrus, who was placed by the emperor in the see of Alexandria. These men, representing the great divided parties, were willing to concur in the doctrine propounded by the emperor as one which would preserve the truth, for which on each side the contest had been protracted. The first fruit of the compromise was that, under the energetic efforts of Cyrus, the Severians of Egypt were brought back to the orthodox Church (633). The Monophysites, who were not satisfied, were yet forced into compliance.

II. (1) Sophronius, a learned Palestinian monk, who at the time of the union was in Alexandria, maintained, especially against the seventh proposition of Cyrus, that the doctrine was in conflict with orthodoxy. When (634) he became Patriarch of Jerusalem he caused it to be condemned by a synod, on the ground that two natures involve two natural energies of will, two operations, two wills, and that in Christ the energy of each nature, of each will, operates under the coenergy of the other nature, the other will, undivided and unmingled. (2) On the appeal of Sergius, Pope Honorius I. (625–638) advised that the whole question should be dropped as involving fruitless speculation. Nevertheless he decided in favor of the monothelite view (633). (3) On this declaration the emperor felt himself authorized to put forth a new creed, under the title *Ecthesis pisteōs* (exposition of faith, 638). Probably it was written by Sergius. Its language is ambiguous; it forbids all controversy on the question; and while it confirms the doctrine of Chalcedon, it maintains that we are to "ascribe all the operations in Christ, the human as well as the divine, to the Word incarnate. . . . Every operation proceeded from the same incarnate Word, without division or confusion. . . . Christ's body, though animated with a rational soul, produced no motion whatever of itself." (4) Meanwhile Sophronius had been keeping up a correspondence with Rome, but an end was put to all the negotiations in that direction by the Mohammedan invasion of Palestine and Egypt (637–640). While these events cut off Sophronius from connection with the rest of the Christian world, his adherents, Stephen in the East and the abbot Maximus in the West, worked in his spirit. (5) Pyrrhus, the successor of Sergius in the see of Constantinople (639), approved of the Ecthesis, but was led by Maximus (645) to renounce it. An African general synod (646) without a dissenting voice condemned monothelitism. After the death of Honorius (638) Pope Severinus declared against the Ecthesis. Pope John IV. (640–642) condemned the Ecthesis, and urged Constantine III., the successor of Heraclius, to withdraw it (641). Pope Theodore I. (642–649), at the appeal of the African Church (646), made the same demand of the Emperor Constans II. (630–668), threatening that if it were refused he would excommunicate the Church of Constantinople. He constituted at the same time Stephen, Bishop of Dor in Palestine, apostolic vicar, with orders to depose all the monothelite bishops and clergy. Hemmed in in this way, the Byzantine court yielded; Constans withdrew the Ecthesis (648).

III. (1) In place of the Ecthesis, however, the emperor set forth the "Type of the Faith"—the *τύπος τῆς πίστεως*. The Type forbade anew all contention on the will or wills of Christ; men were to be satisfied with the decisions of the five general councils: matters were to be put back to the point at which they stood before the strife; and those who attempted to renew the discussion were to be visited with the severest penalties, ecclesiastical and civil. (2) Principle and party zeal, however, alike made it impossible at this stage to suppress the matter in this way. The reply of Pope Theodorus was excommunication and anathema against Paul, Patriarch of Constantinople, who was supposed to be the author of the Tupos. Pope Martin I. (649–655) pursued the warfare against the emperor with yet greater vigor. At the First Lateran Synod (649) diothelitism was established as the Church doctrine; the defenders of monothelitism in general, the Patriarch of Constantinople in particular, and the two imperial edicts were put under the anathema. The course of the pope was treated by the emperor as treasonable. He was seized (653) by Kalliopas,

imperial deputy, and taken to Constantinople a prisoner. His life was spared only on the intercession of the dying Patriarch Paul, but he was sent into exile, where he died of his sufferings, firm to the end. The abbot Maximus was appealed to by every form of persuasion to acknowledge the Tupos, but he could not be moved. Finally his right hand was cut off, his tongue torn out, and he was sent into exile, in which, at the age of eighty, he died (662). (3) Such savagery would have power for a little time, but for a little time only. Pope Adeodatus (677) excommunicated the Greek patriarchs; the Greek Church in return excommunicated the pope; and the Eastern and Western Churches were again sundered. The rapid growth of the Mohammedan power made the healing of this perilous breach of the most urgent importance. Constantine IV. Pogonatus (668–683) entered into negotiations which led to the convening of the sixth general council (680–681), the First Trullan. (See TRULLAN COUNCILS.) A doctrinal writing from the hands of Pope Agatho (680) formed the basis of the conclusions reached. The Monothelites saw that nothing but a miracle could save them. The miracle was attempted, but the dead body would not rise, and the doctrine of one will lay dead with it. The council anathematized all Monothelites. Pope Honorius had been anathematized in the letter of Agatho; the council anathematized him again. It was decided that there is in Christ two natural wills and two natural operations, unseparated, immutable, undivided, unmingled—"two natural wills, not in antagonism, but the human will following, not resisting, but rather subject to, his divine and almighty will." The Church of the West had stood firm for the faith, even at the price of the dishonor of her dead pope. The decrees of the council were confirmed at Rome, and by the Second Trullan Council (692), known as the Quinisextum. (4) The Emperor Philippicus (Bardanes) brought about a temporary triumph of the Monothelites at a council held at Constantinople (711), which reversed the decisions of the sixth general council, but at his downfall (713) monothelitism lost the little influence which had been left it, and vanishes out of history. A doctrine which for a century convulsed kingdoms, arrayed popes against emperors, and pope against pope, and council against council, had in a little while no representatives on earth, except the poor handful of Maronites, who gathered about a monastery on Lebanon, and who as a body survive that Byzantine kingdom to whose policy they owed their being, though they have long renounced the doctrine which sundered them from the great body of the Catholic Church.

Revised by S. M. JACKSON.

Monotocar'dia [Gr. *μόνος*, one + *καρδία*, heart]: a division or sub-order of the gasteropod MOLLUSCA (*q. v.*) frequently called Pectinibranchia. It comprises a large number of species, most of which are marine. These are all united by the fact that the heart has a single (left) auricle (whence the name), and a single feather-like (pectinate) gill is present. There is but a single renal organ, and usually the left anterior mantle-fold is greatly prolonged and more or less completely rolled into a tube (siphon) through which water is drawn for respiratory purposes, and which frequently leaves its impress on the shell as a groove-like outgrowth or canal from the anterior margin of the lip. The Monotocardia are subdivided by systematists upon characters chiefly derived from the lingual ribbon. (See MOLLUSCA.) These divisions are—

(1) Architænioglossa, in which the teeth in a transverse series on the lingual ribbon are arranged 3, 1, 1, 1, 3. This group is the most primitive of the Monotocardia, as is shown by the presence of a rudimentary right auricle and by certain peculiarities of the nervous system. It comprises, among other families, the cowries (*Cypræidæ*) of tropical seas, and the pond-snails (*Paludinidæ*) of fresh waters. In these the siphon is but slightly developed.
