BLANCHARD AND LEA,
in the Office of the Clerk of the District Court in and for the Eastern District of Pennsylvania.

PREFACE TO VOL. SECOND

OF THE AMERICAN EDITION.

THE appearance of the second volume of this work at a considerable period after the publication of the first, would seem to require some explanation other than has been given by the English editors.

As will be perceived from the Preface to the first volume, the author had undertaken a revision of the work so far as it had been printed in England, with especial reference to the American edition. This was performed with respect to three-fourths of the entire Treatise which had been issued, which therefore may be regarded as a fourth edition by him. The remainder has been printed simultaneously with the English edition, the sheets as they were produced being transmitted to the American publishers. A portion of the latter part had undergone the revision of the author himself, but, in consequence of his lamented decease, the residue has been issued under the auspices of the distinguished editors whose preface is appended. The present edition is therefore presented as the last revised work of Dr. Pereira, and the most complete that he published.

With reference to the additions made by the American editor to this second volume, it may be stated that they pertain to the prominent vegetable productions of this country, and to the directions of the United States Pharmacopœia, in connection with all the articles contained in the volume which are referred to by it. Throughout the two volumes now completed, the last revision of the U. S. Pharmacopœia has been referred to, and its directions followed. The illustrations have been materially increased over former editions, and where an opportunity presented of inserting in the American edition more finished representations of plants, it has been done from the abundant resources of the publishers. The additions of the American editor are simply inclosed in brackets [], while those of the English editors have ED. appended to them.

December 1, 1853.

PREFACE OF THE ENGLISH EDITORS.

THE Second Part of the Second Volume of the *Materia Medica* of the late Dr. Pereira now laid before the profession, brings to a completion the third edition of this valuable work.¹ In executing the difficult task of completing that which had been so ably commenced by the lamented author, the editors have endeavoured to act in accordance with his views, as embodied in a large collection of notes and memoranda which were entrusted to them for this purpose. They have, on their own responsibility, made such alterations and additions as the present state of science appeared, in their judgment, to render necessary; and the changes made in the preparations of the London and Dublin Pharmacopeias since the publication of the previous edition have been duly noticed.

At the time of his decease, the learned author had so far advanced with the present volume as to have completed the description of that important article of the *materia medica*, CINCHONA. The remainder of the volume has passed under the revision of the editors; and it may be proper to state that they have in no case interfered with the views or opinions of the author: but, when circumstances rendered it necessary, they have added, in brackets or in notes, such remarks as appeared to them requisite for the further elucidation of the subject. For some assistance in the performance of this duty, they feel bound to express their obligations to Mr. Jacob Bell and to Mr. Daniel Hanbury. Mr. Bell freely placed at their disposal the numerous papers contributed by the late Dr. Pereira to the pages of the *Pharmaceutical Journal*.

It will be perceived that the present edition of this standard scientific work has assumed an entirely new shape. The Mineral substances of the *materia medica* have been confined to the first, and the Organic substances to the second volume. Considerable additions have been made to both departments: but the Organic *Materia Medica* has been especially enlarged. The additions comprise four hundred pages of new matter; and the articles of *materia medica*, of which a complete medical and scientific history is given, amount to three hundred and sixty. Of the value of the matter thus contributed to the medical literature of the day the Editors feel themselves at liberty to speak, since the author is now no more, and they have

¹ The first part of Volume Second was published in London, before the decease of the author.

merely aided in carrying out his views in one small portion of this elaborate treatise. Their opinion is the expression of the opinion of the whole profession, both in this and foreign countries—namely, that in copiousness of details, in extent, variety, and accuracy of information, and in lucid explanation of difficult and recondite subjects, it surpasses all other works on *Materia Medica* hitherto published. The history of a drug, as it is given in these volumes, is not a dry description of its physical characters and its medicinal uses. Philology, Natural History, Botany, Chemistry, Physics, and the Microscope, are all brought forward to elucidate the subject; and the reader thus acquires a full scientific knowledge of each article of *materia medica* before he is introduced to a description of its effects on plants, animals, and man, or to the various theories of its operation, and the different uses to which it has been applied in ancient and modern times. In illustration of this statement, we refer to Article 232, on *CINCHONA*, the last which passed under the hand of the author. This article, when taken alone, displays an amount of scientific knowledge, a degree of industry in the collection of facts, and a judgment in selecting and describing them, which it is rare to meet with in one individual. In treating of the properties of the *Cinchona* alkaloids, it will be observed that even the abstruse subject of epipolization, or the internal dispersion of light, as a test for quina, has not escaped his notice. It was a peculiar feature in the writings of the author—one which is stamped upon every page of this treatise—that he was not satisfied until he had thoroughly exhausted the subject. His references to ancient and modern writers are constant and numerous; he goes to all sources which are capable of yielding information, and fairly acknowledges his obligations to those by whose learning, experience, or research, he profits. He has thus succeeded in transforming the substance of an unpretending course of lectures into a complete *Encyclopædia of Materia Medica*. We entertain no doubt that the present edition will be found to add to that high reputation which, while living, the author had acquired by his researches in this important branch of medical science.

II. ORGANIC BODIES.

I. Vegetabilia.—Vegetables.

I. Cryptogamia.—Cryptogams or Flowerless Plants.

Class I. Thallogenæ.—Thallogens.

ORDER I.—ALGÆ	50
<i>Sub-order I.—Confervacæ.</i>	51
1. Confervals of mineral waters	51
2. Confervals employed in medicine	52
3. Confervals developed in pharmaceutical liquids	53
4. Esculent confervals	53
1. Porphyra laciniata	54
2. Ulva latissima	54
<i>Sub-order II.—Phyceæ</i>	54
3. Fucus vesiculosus	55
<i>Æthiops vegetabilis</i>	56
<i>Sub-order III.—Floridææ</i>	56
4. Chondrus crispus	56
1. <i>Decoctum chondri</i>	59
2. <i>Gelatina chondri</i>	59
3. <i>Pasta cacao cum chondro</i>	59
5. Plocaria candida	60
1. <i>Decoctum plocariæ candidæ</i>	62
2. <i>Gelatina plocariæ candidæ</i>	62
6. Plocaria helminthocorton	62
ORDER II.—LICHENES	63
1. Lichenes esculenti et medicinales	64
7. Peltidea canina	64
8. Scyphophorus pyxidatus	64
9. Stieta pulmonaria	65
10. Gyrophora	65

	PAGE
11. Cladonia rangiferina	65
12. Cetraria islandica	66
<i>Decoctum cetrariæ</i>	69
13. Parmelia parietina	69
2. Lichenes tinctorii	69
14. Roccella tinctoria	72
1. <i>Lacmus</i>	75
1. <i>Tinctura lacmi</i>	77

EXPLANATION OF PLATE I.

This plate represents the appearance of starch grains when moistened with water, and viewed by a power capable of magnifying 250 diameters. In order that the reader may compare the sizes of the different grains, the micrometer lines are faintly indicated; each of the square spaces between the lines represents the $\frac{1}{10000}$ th part of a square inch.

1. *Wheat Starch*.—Most of the larger particles present their flattened faces to the observer. Three particles, seen edgewise, have a stronger lateral shading. (For a description of the grains, see p. 125.)

2. *Barley Starch*.—As wheat starch. (See p. 115.)

3. *Oat Starch*. (See p. 112.)

4. *Rye Starch*. (See p. 128.)

5. *Maize Starch*.—The upper portion represents isolated grains. The lower portion (*a*) represents a mass of grains, as seen in the outer or horny portion of the cells, the albumen with the cells *in situ*. (See p. 110.)

6. *Rice Starch*. (See p. 108.)

7. *Sago Meal*. (See p. 163.)

8. *Starch Grains of Pearl Sago*. (See p. 165.)

9. *Starch Grains of False Sago made from Potato Starch*.—One of the grains has escaped the action of the heating process to which they have been subjected; all the others have been ruptured. Chiefly taken from a specimen of Planche's "*Sagou de la Nouvelle Guinée*." (See pp. 166—7.)

EXPLANATION OF PLATE II.

10. *West India Arrow-root (Maranta Arundinacea)*. (See p. 224.)

11. *Portland Arrow-root (Arum)*. (See p. 387.)

12. *East India Arrow-root (Maranta Indica)*. (See p. 224.)

13. *Tous Les Mois (Canna Coccinea)*. (See p. 227.)

14. *Tapioca (Janipha Manihot)*. (See p. 381.)

15. *Do.* (See p. 381.)

16. *Starch of the Cycas Circinalis*. (See p. 283.)

17. *Potato Starch (Solanum Tuberosum)*. (See p. 501.)

18. *Tahiti Arrow-root (Tacca Oceanica)*. (See p. 221.)

19. *Starch of the Yam (Dioscorea Villosa)*. (See p. 260.)

20. *Starch of the Pea (Pisum)*.

21. *Starch of the Plantain (Musa Paradisiaca)*. (See p. 223.)

PLANTAE

ELEMENTS

OF

MATERIA MEDICA.

II. ORGANIC BODIES.

UNDER this division are included those vegetables and animals, with their educts and products, which are employed in medicine.

I adopt L. Gmelin's definition of an organic compound, and which I have already stated (see vol. i. p. 291, *foot note*).

For reasons which have been assigned in the Preface to the first volume, certain medicinal compounds, which consist of an organic acid and an inorganic base, have been referred to the first division of this work, which treats of inorganic bodies.

I. Vegetabilia.—Vegetables.

These may be conveniently arranged in four classes, as follows:—

- | | | | |
|---|---|---|------------------------|
| I. <i>Cryptogamia</i> ; acotyledonous, asexual, or flowerless | { | Stem and leaves undistinguishable | 1. <i>Thallogenæ</i> . |
| | | Stem and leaves distinguishable | 2. <i>Acrogenæ</i> . |
| II. <i>Phanerogamia</i> ; sexual, or flowering | { | Cotyledons solitary or alternate; wood of stem youngest in the centre | 3. <i>Endogenæ</i> . |
| | | Cotyledons opposite or verticillate; wood of stem youngest at the circumference | 4. <i>Exogenæ</i> . |

I. Cryptogamia, Linn.—Cryptogams or Flowerless Plants.

ACOTYLEDONES, *Jussieu*.—EXEMBRYONATÆ OF ARHIZÆ, *Richard*; AGAMÆ OR ATHEOGAMÆ, *Auctorum*; NEMÆ, *Fries*.

CHARACTERS—*Sexual organs*, and, consequently, *flowers* and *true seeds*, absent. Reproduction taking place either by *spores*, which are enclosed in cases called *thecæ*, or imbedded in the substance of the plants; or else by a mere dissolution of the utricles of cellular tissue. *Spores* destitute of embryo and cotyledons, germinating at no fixed point, but at any part of their surface.

Class I. Thallogenæ.—Thallogens.

ANANDRÆ, *Link*; ACOTYLEDONEÆ, *Agardh*; HOMONEMEÆ, *Fries*; CRYPTOPHYTA, *Link*; THALLOPHYTA, *Endlicher*; AMPHIGENÆ, *Ad. Brong.*

CHARACTERS.—*Substance of the plant* composed chiefly of cellular tissue, devoid of spiral vessels. *Cuticle* destitute of stomata, or breathing pores. *Stem* and *leaves* undistinguishable. No opposition of stem and root.

This class includes three orders:—

- | | |
|--|--|
| I. Thallogens nourished through their whole surface by the medium in which they vegetate | { Aquatic 1. <i>Algæ.</i> |
| | { Aërial 2. <i>Lichenes.</i> |
| II. Thallogens nourished through their thallus (spawn or mycelium) by juices derived from the matrix | 3. <i>Fungi.</i> |

ORDER I. ALGÆ, DC.—ALGALS.

ALGALES, *Lindley.*

CHARACTERS.—Cellular flowerless plants, nourished through their whole surface by the medium in which they vegetate; living in water or very damp places; propagated by zoospores, coloured spores, or tetraspores.

PROPERTIES.—None of the plants of this order are poisonous. Some of them are nutritious, emollient, and demulcent: these properties they owe to the presence of mucilage¹ (*carrageenin*), starch, sugar (*mannite*), and a little albumen. The peculiar *mucilage* of sea-weeds will be more fully noticed hereafter (see *Chondrus crispus*). It differs, says Dr. Stenhouse, from ordinary gum, for, when digested with nitric acid, it yields oxalic, but neither mucic nor saccharic acids.

Mannite is probably obtainable in greater or less quantity from most if not all sea-weeds. It was procured from eight out of nine species examined by Dr. Stenhouse.² He could not detect it in *Ulva latissima*. The following is a list of the Algæ which he examined, arranged in order, according to the quantity of mannite which they severally yielded:—

- | | |
|--|--|
| 1. <i>Laminaria saccharina</i> (12.15 per cent. of mannite). | 5. <i>Alaria esculenta</i> . |
| 2. <i>Halidrys siliquosa</i> (5 or 6 per cent.). | 6. <i>Rhodomenia palmata</i> (2 or 3 per cent.). |
| 3. <i>Laminaria digitata</i> . | 7. <i>Fucus vesiculosus</i> (1 to 2 per cent.). |
| 4. <i>Fucus serratus</i> . | 8. <i>Fucus nodosus</i> . |

Fig. 146.

Esulent Sea Weeds.

- | | | |
|--|----------------------------------|------------------------------|
| a. <i>Rhodomenia palmata</i> (or Dulse). | c. <i>Laminaria saccharina</i> . | e. <i>Alaria esculenta</i> . |
| b. <i>Rhodomenia ciliata</i> . | d. <i>Iridæa edulis</i> . | f. <i>Ulva latissima</i> . |

¹ *On the Mucilage of the Fuci, with Remarks on its Application to economical ends*, by Mr. S. Brown, Jr., in *Jameson's Edinb. New Phil. Journ.* vol. xxvi. p. 409, 1839.

² *Memoirs and Proceedings of the Chemical Society of London* for 1844.

On the first two of these plants, when dried, the mannite often forms crystalline incrustations, which by some have been erroneously supposed to be common salt. Dr. Stenhouse thinks that mannite might be more economically procured from sea-weeds than from manna.

The alterative and resolvent virtues ascribed to sea-weeds, and their presumed beneficial effects in scrofulous affections and glandular enlargements, are referable to the inorganic constituents; such as iodine, bromine, the phosphates, and the alkaline substances. The following table shows the composition and proportion of ash in certain sea-weeds:—

	Laminaria saccharina. North Sea.	Fucus serratus. North Sea.	Laminaria latifolia.	Furcellaria fastigiata.	Chondrus crispus.	Iridaea edulis.	Polysiphonia elongata.	Delesseria sanguinea.	Fucus digitatus. From the mouth of the Clyde.	Fucus nodosus. From the mouth of the Clyde.	Fucus serratus. From the mouth of the Clyde.	Approximate mean.
Potash	24.77	16.02	16.91	21.36	18.00	23.42	21.23	13.72	22.40	10.07	4.51	17.50

Phosphate of iron	0.75	0.64
Oxide of iron	0.62	0.29	0.34	0.24
Oxide of manganese	0.22
Sulphuric acid	10.60	18.35	13.63	32.63	42.86	25.19	28.66	40.42	13.26	26.69	21.06	24.76
Silica	0.58	0.40	0.69	2.83	12.38	1.56	1.20	0.43	1.82
	100 ¹	100 ¹	295.21	100 ²	100 ²	299.79	298.10	100 ²	100 ³	100	100 ³	99.98
Per centage of ash in weed dried at 212° F.	9.78	25.83	13.62	18.92	20.61	9.66	17.10	13.17	20.40	16.19	15.63	16.46

The presence of so large a proportion of potash and phosphoric acid in plants growing in sea-water, which contains so small a proportion of these ingredients, is very remarkable. There is reason, however, to believe that the quantity and constitution of the ash are liable to very considerable variation, depending on the locality, season, age of the plant, &c. A vermifuge property has been ascribed to some algae.

Laennec⁴ tried the influence of an artificial "marine atmosphere" (air impregnated with the vapour of fresh sea-weed) on consumptive patients, and was impressed with an idea of its efficacy; but experience has not confirmed his favourable opinion of its beneficial influence; moreover, the inhabitants of sea-coasts, like those of inland districts, are the subjects of phthisis.

Sub-order I. CONFERVACEÆ, *Endl.*—CONFERVALS.

CHARACTERS.—Vesicular, filamentary, or membranous algae, propagated by sporidia (endogenous cells, or a gelatinous substance which is ultimately formed into cells), which are produced at the expense of the endochrome of one or more cells, or sometimes by the copulation of distinct individuals, and discharged by the opening or absorption of the mother cell.

PROPERTIES.—These are similar to those of the Order, and which I have already noticed (see *ante*, p. 50).

1. Confervals of mineral waters.—Confervals are peculiarly abundant in both hot and cold sulphureous springs. *Calothrix nivea* (Fig. 147), the *Conferva nivea* of Dillwyn,⁵ has been found in the sulphur springs of Yorkshire, Durham, and Aix-la-Chapelle.⁶ The same, or an allied species, was found by Dr. Daubeny⁷ in the hot sulphur springs of Greoulx, in Provence. *Oscillaria labyrinthiformis*—the *Tremella thermalis* of some writers—is one of the most common species in the hot sulphur springs, and other thermal waters of Germany, France, and

⁷ *Op. citato.*

Italy. In the Karlsbad waters, *Sphærozyga Jacobi* (Fig. 148), and several species of *Oscillaria*, have been detected.¹ Humboldt found *Oscillaria calida* in the thermal waters of New Granada.

Fig. 147.

*Calothrix nivea*.

Fig. 148.

*Sphærozyga Jacobi*.

The organic substance found in mineral waters, and variously called *barégine* by Longchamp, *zoogen* by Gimbernat, *theiothermin* by Monheim, and *glairine* by Anglada, derives its origin from confervals. It is a glairy or mucus-like substance, which is said to communicate the flavour and odour of flesh-broth to the water in which it is contained. In the preparation of artificial sulphur baths, animal gelatine is sometimes used to represent the *barégine* (see *ante*, vol. i. p. 478).

The confervals, under the influence of light, decompose water, retain the hydrogen, and evolve the oxygen. Robiquet² obtained, from the Nérís water, gas containing 44 per cent. of oxygen, derived from the *Oscillatoria labyrinthiformis*; and he ascribed the medicinal qualities of these waters to the presence of this very oxygenated air. "Dr. Edwards," says Robiquet, "has shown that the air contained in water has a great influence over the life of batrachians, and it is probable that, in some cases, our organs may also be more or less influenced by it."

2. Confervals employed in medicine.—Yeast is referred to Algæ by Kützing,³ who calls it *Cryptococcus Fermentum*. It is more commonly, however, regarded as a fungus, and as such

Fig. 149.

will be noticed hereafter. (See *Fungi*.) With this doubtful exception, none of the Confervals are employed, at the present day, in medicine. *Nostoch commune*, or star-jelly, of which, formerly,

³ *Phycologia generalis*.

the most extraordinary superstitions were entertained,¹ and *Conferva rivularis*, or crow silk, recommended by Murray² for trial in asphyxia, asthma, and phthisis, on account of its evolving oxygen in solar light, have never been used in rational medicine.

3. Confervals developed in pharmaceutical and other liquids.—The vesicular and filamentous plants which grow in various chemical solutions,³ and to the naked eye appear like gelatinous or cottony masses, are considered by some botanists to be Algals. Kützing refers them to the genera *Cryptococcus*, *Ulvina*, *Hydrocrocis*, *Sirocrocis*, *Leptomitus*, and *Chamænema*.

(in a solution of emetic tartar).

But these minute plants are regarded by some eminent authorities as the spawn or mycelium of various moulds, or, in other words, as imperfect mucedinous fungi. "It is true," says the Rev. M. J. Berkeley, "that moulds will vegetate in fluids, but, as soon as they assume their normal form, there is a distinction between the immersed and free portion." If, however, they fructify under water, which, according to Kützing, they do, their algaecious nature is, I apprehend, proved.

4. Esulent Confervals.—Some few of the Confervals are cooked and brought to table under the name of *laver*; but the amount of nourishment which they contain is very small. They are species of *Porphyra* and *Ulva*.

¹ See the articles "*Nostoch*," in the *Dict. Univ. de Mat. Méd.* t. iv. p. 635, 1832; and "*Cælifolium*," in James's *Medicinal Dictionary*, vol. ii.

² *Appar. Medicaminum*, t. v. p. 550, 1790.—Pliny (*Hist. Nat.* lib. xxvii. cap. 45) says he knew a labourer who fell from the top of a tall tree, and thereby broke nearly every bone in his body, and who, being covered with a river conferva, kept moist by his own water, was cured in an incredibly short space of time. He adds, that the term *conferva* is derived from "*conferruminando*," in allusion to the supposed consolidating properties of this plant.

³ For some notices of these plants, the reader is referred to my paper *On the Microscopic Vegetations developed in Pharmaceutical Liquids*, in the *Pharmaceutical Journal*, vols. vii. and viii. 1848.

1. *Porphyra laciniata*, Agardh.—Lacinated Purple Laver.

Fig. 154.

*Porphyra laciniata*.

a. Small portion of the frond, showing the quaternate granules (magnified).

Porphyra umbilicalis, Kützing; *Ulva umbilicalis*, Eng. Bot.—The fronds are delicately membranaceous, deeply and irregularly cleft into several broad segments. Their colour is deepish purple, but, when not in a state of perfection, it tends to livid olive. "Under the microscope, the whole frond appears to be divided into squares, in the manner of a tessellated pavement, and within each square are four purple granules or spores, which constitute the fructification and the whole colouring matter of the frond" (see Fig. 154, a). Abundant on all our shores. This plant is pickled with salt, and sold in London as *laver*. The London shops are said to be supplied with it from the coast of Devonshire. When stewed, it is brought to the table and eaten with pepper, butter, or oil, and lemon juice or vinegar. Some persons stew it with leeks and onions. It is generally taken as a luxury; but it might be employed with advantage, by scrofulous subjects, as an alterative article of diet. In the absence of other vegetables, it might be valuable as an antiscorbutic to the crews of our whaling vessels cruising in high latitudes, where every marine rock at half-tide abundantly produces it.

2. *Ulva latissima*, Greville.—Broad Green Laver.

Ulva Lactuca var. *latissima* Lightf; *Green Stoke*; *Oyster Green*.—The fronds are bright herbaceous green, becoming tinged with brown in old age and decay. They are oblong or roundish, waved, and very tender (see Fig. 146, f). The granules are quaternate, and densely cover the whole frond. It is said to be used at table under the name of *green laver*, being cooked in the same way as the *Porphyra laciniata*, to which it is greatly inferior. It is rarely taken when the latter can be procured. I have never found it in the London shops.

Sub-order II. PHYCÆ, Endl.—SEA WRACKS.

FUCACEÆ, Lindl.; APLOSPORÆÆ, Decaisne.

CHARACTERS.—Cellular or tubular algals propagated by spores (endogenous cells), contained in superficial, often bladderly (*utricles*) cells, produced singly out of endochrome, consisting of a simple nucleus clothed by its proper cellular membrane (*epispore*), and discharged by the opening of a transparent mother cell (*perispore*).

PROPERTIES.—Similar to those of the order (see *ante*, p. 50). To this order several esculent species belong: such as *Limnaria digitata*, called by the English *sea-girdles*, by the Scotch *Tangle*; and *Alaria esculenta* (Fig. 146, e), termed *Badderlocks*, *Hen-ware*, or *Honey ware*. These, as well as several other species of this order, viz., *Laminaria saccharina* (Fig. 146, c), and *Halidrys siliquosa*, have been already referred to as containing mannite (see *ante*, p. 50).

The only species used for medicinal purposes which it will be necessary to notice is *Fucus Vesiculosus*.

¹ Harvey, *Phycologia Britannica*, vol. 1. pl. xcii. 1816.

3. FUCUS VESICULOSUS, Linn.—COMMON SEA WRACK.

Sex. Syst. Cryptogamia, Algæ.
(Herba cum fructu, *Offic.*)

HISTORY.—Theophrastus¹ mentions several species of Algæ (φῦκος). *Fucus vesiculosus* is sometimes termed *quercus marina*, *bladder fucus*, and *common sea-ware*, *kelp-ware*, and *black tang*.

BOTANY. **Gen. Char.**—*Fron*d linear, either flat, compressed, or cylindrical, dichotomous (rarely pinnated), coriaceous. *Air-vessels* [*vesiculæ*] when present innate, simple. *Receptacles* either terminal or lateral, filled with mucus, traversed by a network of jointed fibres, pierced by numerous pores, which communicate with immersed spherical *conceptacles*, containing *spores*, or *antheridia*, or both (*Harvey*).

Sp. Char.—*Fron*d plane, linear, dichotomous, entire at the margin. *Air-vessels* roundish-oval in pairs. *Receptacles* mostly elliptical, terminating the branches (*Greville*).

Very variable; but the varieties pass so insensibly into each other that it is difficult to define them strictly.

Hab.—Sea-shores. Very common everywhere.

PHYSICAL PROPERTIES.—Its substance is thickish, flexible, but very tough. Its colour is dark, olivaceous, glossy green, paler at the extremities, and becomes black by drying. Its odour is strong; its taste nauseous.

COMPOSITION.—It has been analyzed by Staekhouse,² by Gaultier de Claubry,³ by John,⁴ and by Fagerstrom.⁵ The following appear to be its constituents: *Cellulose*, *mucilage* (carrageenin), *mannite*, *odorous oil*, *colouring* and *bitter matters*, and various salts.

The following table shows the composition and proportion of ash of *Fucus vesiculosus* of different localities:—

	Mouth of the Clyde.	Mouth of the Mersey.	North Sea.	Denmark.	Greenland.	Mean.
Potash	15.23		17.68	9.03	17.86	11.96
Soda	11.16	15.10	5.78	7.78	21.43	12.25
Lime	8.15	16.77	4.71	21.65	3.31	10.92

Fucus vesiculosus.

- a. Upper part of a frond, with air vessels and receptacles.
b. Section of a receptacle.
c. Conceptacle.
d. Filaments and spores, of which the conceptacles are composed.
e. Filaments which issue from the pores on the surface of the frond.

CHEMICAL CHARACTERISTICS.—By treating the distilled water of *Fucus vesiculosus* with ether, a *semi-solid white oil* is extracted, which is the odorous principle. The aqueous decoction of this plant is neutral, and contains in solution mucilage (see carrageenin) and various salts. It yields, with chlorine and starch, faint traces only of iodine, sometimes none at all. But if alcohol be added, by which the mucilage and a part of the sulphates are thrown down, the alcoholic liquor evaporated, and the residue mixed with potash, then calcined, and afterwards treated with hydrochloric acid to disengage hydrosulphuric acid, we may sometimes detect iodine in the filtered liquor by the deep blue colour formed on the addition of starch and chlorine.¹

By combustion in the open air, this plant yields the ash called *kelp*; and by incineration in a covered crucible it gives a charcoal, termed *vegetable ethiops*.

PHYSIOLOGICAL EFFECTS.—During the winter, in some of the Scottish islands, horses, cattle, and sheep are fed on it.² Its local action is detergent, and, perhaps, discutient. Its remote effects are probably analogous to those caused by small doses of iodine, modified by the influence of salts of sodium and calcium.

USES.—Frictions of the plant, with its contained mucilage, were employed, with supposed advantage, by Dr. Russell,³ in glandular enlargements and other scrofulous tumours: the parts were afterwards washed with sea water. He also gave internally the expressed juice of the vesicles in glandular affections.⁴

ÆTHIOPS VEGETABILIS; Vegetable Ethiops.—This is prepared by incinerating *Fucus vesiculosus* in a covered crucible. It is composed of *charcoal* and various *salts* (see *supra*). When hydrochloric acid is added to it, traces of sulphuretted hydrogen are frequently evolved. By digesting the ethiops in water, and testing the solution with nitric acid and starch, I have sometimes failed to obtain the blue colour indicative of the presence of iodine. It has been exhibited in bronchocele and scrofulous maladies. Dr. Russell⁵ says it far exceeds burnt sponge in virtue. It has been employed also as a dentifrice. The dose of it is from ten grains to two drachms.

Sub-order III. FLORIDÆ, *Endl.*—ROSE-TANGLES.

CERAMIACEÆ, *Lindl.*; CHORISTOSPOREÆ, *Decaisne*.

CHARACTERS.—Cellular or tubular algals propagated by thecæ (*favella* vel *favellidia*, *coccidia* vel *keramidia*), composed of granules [spores?] contained within a cellular or gelatinous perisporangium; and by sphaerospores (or *tetraspores*), composed of four (or three) spores in a transparent perispor.

PROPERTIES.—Several species of this sub-order are esculent. They owe this property to the mucilage, starch, mannite, and perhaps a little albumen, which they contain. Besides the species presently to be described, *Iridæa edulis* (Fig. 146, *d*) and *Rhodomenia palmata* (Fig. 146, *a*), which is cried about the streets of Edinburgh under the name of *dulse*, may be mentioned as illustrative examples of esculent species.

4. CHONDRUS CRISPUS, *Grav.*—CARRAGEEN OR IRISH MOSS.

Sez. Syst. Cryptogamia, Algæ.
(Planta, *Offic.*)

SYNONYMES.—*Chondrus polymorphus*, Lamour; *Sphaerococcus crispus*, Agardh; *curled chondrus* (*chondrus*, from *χόνδρος*, *cartilage*).

HISTORY.—*Carrageen*, *Irish*, or *pearl moss*, was introduced into medicine by Mr. Todhunter, of Dublin.⁶

BOTANY. Gen. Char.—*Fronde* cartilaginous, nerveless, compressed or flat, flabelliform, dichotomously cleft: formed internally of three strata; the *inner*, of

¹ Guibourt, *Hist. des Drog.* 4me éd. ii 46.

³ *Op. cit.* p. 93.

⁶ *Reece's Monthly Gazette of Health*, Jan. 1831.

² Greville, *Algæ Brit.* xx.

⁴ *Op. cit.* p. 99.

densely-packed longitudinal fibres; the *medial*, of small roundish cells; the *outer*, of vertical, coloured, moniliform filaments. *Fructification*: 1, prominent *tubercles* (*nemathecia*) composed of radiating filaments, whose lower articulations are at length dissolved into *spores* (?); 2, *tetraspores* collected into sori, immersed in the substance of the frond (*Harvey*).

Sp. Char.—*Frond* stipitate, thickish, cartilaginous, flat or curled, segments wedge-shaped, very variable in breadth; apices truncate, submarginate, or eloven: axils obtuse; sori elliptical or oblong, concave on one side (*Harvey*). *Fron*ds from 2 or 3 to 10 or 12 inches long: their substance cartilaginous, in some varieties approaching to horny, flexible and tough; their *colour* deep, purple-brown, often tinged with purplish red, paler at the summit, becoming greenish, and at length white in decay.

This, says Dr. Greville, is the Proteus of marine Algæ. The varieties are innumerable, and pass into one another so insensibly that it is almost impossible to define them.

Mr. D. Turner¹ enumerates the following varieties:—

β. *virens*; frond submembranaceous, branches dilated upwards, flattish, extreme segments long and acuminate.

γ. *stellatus*; frond submembranaceous, branches dilated upwards, divided at their apices into very numerous clustered short laciniae.

δ. *equalis*; frond cartilaginous, thick, all the branches equal, linear, the extreme segments obtuse.

ε. *filiformis*; frond cartilaginous, subcylindrical, branches nearly linear, apices long and acuminate.

ζ. *patens*; fronds subcartilaginous, channelled on one side, dichotomous, angles of the dichotomies patent.

η. *lacerus*; frond cartilaginous, compressed, apices very narrow, elongated, branched.

θ. *sarniensis*; frond between coriaceous and cartilaginous, branches slightly channelled on one side, dilated upwards, apices rounded and emarginate.

ι. *planus*; frond subcoriaceous, flat, wide, branches linear, apices obtuse.

κ. *geniculatus*; frond cartilaginous, compressed, branches nearly linear, tubercles subglobose, black, frond bent, and often broken at the tubercles.

According to Ormancey,² carrageen is a zoophyte which he proposes to call *Antipathes polymorphus*. Unlike the fuci, he says, it has no canal, nerves, or roots; but, like the zoophytes, it has voluntary motion of tentacula, sensibility, and two distinct bodies, one secreted by the other, simulating a plant.

Hab.—On rocks and stones on the sea-coast; very common.—Perennial: spring.

PREPARATION.—For dietetical and medicinal uses, it is collected on the west coasts of Ireland (especially in Clare), likewise, according to Kohl,³ in Antrim; washed, bleached (by exposure to the sun), and dried.

In Ireland, it is sometimes employed by painters and plasterers as a substitute for size.

Fig. 156.

² *Journal de Pharmacie et de Chimie*, 3me sér. t. xii. p. 265, 1847.

³ *Ireland*, p. 247.

Along with *Chondrus crispus*, other allied species, especially *Ch. mamillosus*, are sometimes collected (see Fig. 158).

PHYSICAL PROPERTIES.—The carrageen or Irish moss of commerce (*muscus carragenicus*) consists of fronds, which are usually from two to three or four inches long, dry, crisp, mostly yellowish or dirty white, but intermixed with purplish red portions, inodorous, or nearly so, with a mucilaginous taste. The frond is formed internally of three strata; the inner, of densely-packed longitudinal fibres; the medial, of small roundish cells; the outer, of vertical, coloured, moniliform filaments.¹

<i>Feuchtwanger.</i>	
Jelly	Pectin [carrageenin] (a large portion).
	Starch.
	Oxalate of lime.
	Compounds of sulphur, chlorine, and bromine.
	No fungic, boletic, or lichenic acids.

In warm water, the dried commercial frond swells up, and, when boiled, almost entirely dissolves. If the swollen and partially-dissolved frond be examined by the microscope, it is seen to consist of very minute, somewhat fusiform cohering cells. A calcareous meshy crust (consisting of various species of *Fuflustra*) is frequently found on the frond.

Chondrus mamillosus is found in commercial carrageen. Some samples I found to be principally composed of this species.² The frond of this plant is more or less channelled; but the species is best distinguished by the fructification; in *Ch. crispus* the subhemispherical capsules are imbedded in the disk of the frond, producing a depression on the opposite side (see Fig. 156); in *Ch. mamillosus*, the spherical capsules are scattered over the disk of the frond, and are supported on little short stalks (Fig. 158).

COMPOSITION.—It has been analyzed by Herberger³ and by Feuchtwanger.⁴

Subsequently, iodine has been detected in it by Sarphati,⁵ and both iodine and bromine by Grosse.⁶ (For the composition of the ashes, see p. 51.)

CARRAGEENIN.—The mucilaginous constituent of carrageen moss is termed by some writers *vegetable jelly*, or *vegetable mucilage*, by others *pectin*. It appears to me to be a peculiar modification of mucilage, and I shall, therefore, call it *carrageenin*. It is soluble in boiling water, and its solution forms a precipitate with diacetate of lead and silicate of potash, and, if sufficiently concentrated, gelatinizes on cooling. Carrageenin is distinguished from ordinary gum by its aqueous solution not producing a precipitate on the addition of alcohol; from starch, by its not assuming a blue colour with tincture of iodine; from animal jelly, by tincture of nut-galls caus-

¹ *Phycologia Britannica*, vol. i. pl. lxiii. Lond. 1846.

⁴ *American Journal of Sciences and Arts*, xxvi.
⁵ *Commentatio de Iodio*, Lugd. Bat. 1835.
⁶ *Pharmaceutisches Central Blatt für* 1839, S. 159.

ing no precipitate;¹ from pectin, by acetate of lead not throwing down anything, as well as by no mucic acid being formed by the action of nitric acid.

According to Schmidt,² the cell-walls of carrageen do not essentially differ from the contents of the cells; for, when the plant is boiled in water, the whole swells up and forms a mucilage, which may be expressed through a linen cloth, leaving behind the *Flustræ* and small crustaceans with which this alga is covered. By digestion for a short time with dilute sulphuric acid in a water-bath, the whole plant is converted into sugar and gum.

The composition of carrageenin dried at 212° F., according to Schmidt, is represented by the formula $C^{12}H^{10}O^{10}$; so that it appears to be identical with starch and sugar. Mulder,³ however, represents it by the formula $C^{24}H^{19}O^{19}$.

CHEMICAL CHARACTERISTICS.—The presence of carrageenin in the decoction is demonstrated by the tests before enumerated. No iodine is recognizable by nitric acid and starch. Oxalate of ammonia detects lime (or calcium) in solution, while nitrate of silver points out the presence of chlorine. Guibourt⁴ could recognize neither sugar nor magnesia.

PHYSIOLOGICAL EFFECTS.—Carrageen moss is nutritive: its mucilaginous matter acts as an element of respiration (see *ante*, vol. i. p. 116), while its inorganic constituents (phosphate of lime, potash, salts, &c.) may also serve some useful purpose in the animal economy. It is generally regarded as being readily digestible.

Medicinally, it is emollient and demulcent (see *ante*, vol. i. pp. 207–8).

USES.—It is a popular remedy for pulmonary complaints (especially those of a phthisical character), chronic diarrhoea and dysentery, serofula, rickets, enlarged mesenteric glands, irritation of bladder and kidneys, &c. As a culinary article, it has been employed as a substitute for animal jelly, in the preparation of *blanc-mange*, jellies, white soup, &c. A thick mucilage of carrageen scented with some prepared spirit is sold as *bandoline*, *fixature*, or *clysphtique*, for stiffening the hair and keeping it in form.

ADMINISTRATION.—It is usually exhibited in the form of decoction or jelly. It has also been employed in combination with chocolate or cocoa.

1. DECOCTUM CHONDRI; Decoction of Carrageen or Irish Moss.—Macerate half an ounce of carrageen in cold or warm water, during ten minutes; then boil in three pints of water for a quarter of an hour. Strain through linen. When properly flavoured, it may be used as a *tisan* or common drink. By doubling the quantity of carrageen, a *mucilage* (*mucilago chondri*) is procured. Milk may be substituted for water when the decoction is required to be very nutritious. A preparation of this kind has been called *lac analepticum*. Sugar, lemon-juice, tincture of orange-peel, essence of lemon, or other aromatics, as cinnamon or nutmeg, may be employed as flavouring ingredients.

2. GELATINA CHONDRI; Carrageen Jelly.—This may be prepared by adding sugar to the strained decoction and boiling down until the liquid is sufficiently concentrated to gelatinize on cooling; or by employing a larger quantity of carrageen. If milk be substituted for water, *carrageen blanc-mange* is obtained. Sugar and other flavouring ingredients may be employed, as above mentioned.

3. PASTA CACAO CUM CHONDRO; Pasta Cacao cum Lichene Carragheno, Ph. Dan.; *Carrageen Cocoa*.—The Danish pharmacopœia gives the following directions for its preparation: Roasted and decorticated Cacao Seeds reduced to a very subtle mass in a warm iron mortar; Powdered White Sugar, of each ℥ij; Powdered Carrageen ℥iij. Mix, and form into quadrangular stieks. Clarus and Radius⁵ direct *carrageen*, or *white chocolate*, to be prepared as follows: Cocoa Paste ℥iv; Powdered Carrageen ℥vj; White Sugar ℥iv; Flour q. s. (℥vj). Mix.—These pastes are to be used like common cocoa or chocolate.

5. PLOCARIA CANDIDA, Nees.—CEYLON MOSS.

Sex. Syst. Cryptogamia, Algæ.

(Planta, Offic.)

SYNONYMES.—*Gracilaria lichenoides*, Greville; *Sphærococcus lichenoides*, Agardh; *Gigartina lichenoides*, Lamouroux; *Fucus lichenoides*, Turner; *Fucus amylaceus*, O'Shaughnessy; *Jaffna Moss*; *Edible Moss*.—According to Rumphius, it is called by the Malays *Sajor carang* and *Agar agar carang*; at Amboyna, it is termed *Aysana* and *Aytsana* (h. e. *arbuscula ramosa*), and *Rume yar waccar*; at Java, *Bulung*; at Macassar, *Dongi dongi*; and at other places, *Lottu lottu* and *Collocane*.

HISTORY.—It seems to have been long known and used in the East. It has been described by Rumphius,¹ Gmelin,² Turner,³ Nees,⁴ and Agardh.⁵ About the year 1837 it was introduced into England by Mr. Previté; and in the year 1840 public attention was drawn to its useful properties by Messrs. Sigmond and Farrer.⁶

BOTANY. Gen. Char.—*Fronde* composed of large oblong-cylindrical cells containing granular endochrome, those of the surface forming moniliform, densely-packed filaments. *Fructification* of two kinds: 1. hemispherical, pointed *coccidia*, containing a glomerule of oblong spores on a central placenta, within a pericarp of moniliform, densely crowded filaments; 2. oblong *tetraspores* imbedded in cells of the surface (*Endlicher*).

Fig. 159.

*Plocaria candida*.

- a. *Plocaria candida* (nat. size).
 d. Variety β . *edulis*.
 e. Part of frond with the coccidia (magnified).
 f. Section of coccidium.
 g. Spores.

Sp. Char.—*Fronde* cartilaginous, cylindrical, filiform, much and irregularly branched; branches smooth, spreading, acute, somewhat fastigiate. *Coccidia* sessile, scattered.

Rumphius mentions four kinds of *Alga coralloides*, which he distinguishes as the *prima*, *secunda*, *tertia*, and *quarta*; and he has figured three kinds. Nees figures two plants—one fertile, the other sterile. Turner notices two varieties: β *edulis* is a smaller variety, and has a remarkably flexuose frond, more thin and less branched than α : its colour is quite white.

Hab.—Ceylon, at Jaffnapatam; the islands of the Indian Archipelago.

COMMERCE.—It is exported to China by the islands of the Indian Archipelago. Mr. Crawford⁷ says that it forms a portion of the cargoes of all the junks; the price on the spot where it is collected seldom exceeding from 5s. 8d. to 7s. 6¼d. per cwt. The Chinese use it in the form of jelly with sugar, as a sweetmeat, and apply it in the arts as an excellent paste. The gummy matter which they employ for covering lanterns, varnishing paper, &c., is made chiefly, if not entirely, from it.

PHYSICAL PROPERTIES.—Ceylon moss is in whitish or yellowish-white ramifying filaments of several inches in length. At the base the largest fibres do not exceed in thickness a crowquill; the smallest fibres are about as thick as fine sewing thread. To the naked eye the filaments appear al-

⁷ *History of the Indian Archipelago*, vol. iii. p. 446, 1820.

most cylindrical and filiform; but, when examined by a microscope, they appear shrivelled and wrinkled. The branchings are sometimes dichotomous, at other times irregular. Dr. Farre states that in a bale opened at Mr. Battley's, about $\frac{1}{5}$ th appeared to bear fructification. The tubercles (*coccidia*) are inconspicuous when dry, but when moist, are readily seen. They are hemispherical, about the size of a poppy-seed, and contain, according to Rumphius, a mass of minute, oblong, dark red spores. The consistence of Ceylon moss is cartilaginous. Its flavour is that of sea-weed, with a feebly saline taste.

COMPOSITION.—This algal has been examined chemically, in 1834, by Dr. O'Shaughnessy;¹ in 1842, by Guibourt;² and in 1843, by Wonneberg and Kreyszig,³ by Bley,⁴ and by Riegel.⁵

Total	100				

1. MUCILAGINOUS MATTER (*Carrageenin?*); *Vegetable Jelly*; *Pectin*; *Soluble gelatine*.—The mucilaginous or gelatinizing principle of Ceylon moss appears to me to agree very closely, if indeed it be not identical, with carrageenin. It has not hitherto been analyzed.

2. STARCHY MATTER.—This resides chiefly in the cortical portion of the algal. But the internal cell-walls become deeply stained purplish brown on the addition of iodine, as if they were composed of a starchy substance (*starchy skeleton*).

CHEMICAL CHARACTERISTICS.—By moistening Ceylon moss with a weak solution of ioduretted iodide of potassium, the plant acquires a purplish-brown or red colour; the younger and more delicate fibres becoming almost black. The change of colour is most intense in the cortical portion, but the internal cell-walls also become stained. By digestion in warm water, the plant softens and swells up. By boiling it in water, and then compressing and rubbing it gently between two plates of glass, the larger spheroidal cells are readily separated from each other: they are stained purplish-brown by iodine. The aqueous decoction is mucilaginous, and when sufficiently concentrated, gelatinizes on cooling. Iodine colours it a dull or purplish brown, and gives an intense dark purplish colour to the undissolved residue of the plant. If the plant be immersed in diluted hydrochloric acid, slight effervescence occurs, owing to the escape of carbonic acid evolved by the action of the hydrochloric acid on carbonate of lime.

PHYSIOLOGICAL EFFECTS.—These are similar to those of *Chondrus crispus* (see *ante*, p. 59). Ceylon moss, therefore, may be denominated nutritive (chiefly as an element of respiration, see vol. i. p. 116), emollient, and demulcent. By the continued use of it at the table, the saline constituents of the plant would not be without some influence on the system.

USES.—In the form of decoction or jelly, it is employed as a light and readily digestible article of food for invalids and children. The residue of the decoction is not devoid of nutritive matter, and might be served and eaten like cabbage or leguminous substances; especially when the alterative influence of the saline constituents is desired. The decoction or jelly of Ceylon moss may be employed in irritation of

⁴ *Ibidem*, p. 409.
⁵ *Ibidem*.

the mucous surfaces, and in phthisis. It is not apt to occasion thirst, sickness, flatulence, heartburn, acidity, or diarrhœa.

ADMINISTRATION.—It may be administered in the form of decoction or jelly. Dr. O'Shaughnessy recommends that it should be steeped for a few hours in cold rain water, as the first step to its preparation: this removes a large portion of the sulphate of soda. It should then be dried by the sun's rays, and ground to a fine powder; for cutting or pounding, however diligently performed, still leaves the amylaceous matter so mechanically protected that the boiling may be prolonged for hours without extracting the starch. This grinding process, however, is seldom employed, the prepared plant being merely cut into very small pieces.

1. DECOCTUM PLOCARÆ CANDIDÆ; *Decoction of Ceylon Moss*.—This is prepared by boiling the prepared moss in water, milk, or whey. One drachm of the plant will give a mucilaginous quality to eight ounces of water. Milk, sugar, orange or lemon juice and peel, wine, cinnamon, or other aromatics, may be used to communicate flavour. This decoction may be taken *ad libitum*.

2. GELATINA PLOCARÆ CANDIDÆ; *Jelly of Ceylon Moss*.—Mr. Previté's directions for its preparation are the following: Boil half an ounce of the prepared moss in a quart of boiling water for twenty-five minutes, or until a spoonful of the liquid forms into a firm jelly within two or three minutes after it is removed from the boiler. Flavour with wine, a little cinnamon, lemon or orange juice and peel, and sweeten according to taste. Boil the whole for five minutes, and pass it two or three times through a jelly-bag or doubled muslin. Leave it undisturbed, and it will become a firm jelly in ten minutes. If it be required perfectly clear for table use, add the white of two eggs beaten up into a whip before the second boiling, and allow it to stand for a few minutes away from the fire, with some hot coals on the top of the boiler. When clear, pass it through the jelly-bag, and leave it to congeal. Should the jelly be required particularly firm, add an ounce of moss to the quart of water.

6. PLOCARIA HELMINTHOCORTON, *Endl.*—CORNICAN MOSS.

Sex. Syst. Cryptogamia Algæ.
(*Planta, Offic.*)

HISTORY.—This plant has been in use for several centuries among the natives of Corsica, as a remedy for intestinal worms. In 1756, Vaucher sent it to Paris.¹

BOTANY.—*Gen. Char.*—See *Plocaria candida*, p. 60.

Sp. Char.—*Fronde* cartilaginous, terete, tufted, entangled. *Stem* filiform, creeping; branches setaceous, somewhat dichotomous, marked indistinctly with transverse streaks.

Hab.—The Mediterranean Sea, on the shores of Corsica.

PHYSICAL PROPERTIES.—Under the name of Corsican moss, is sold in the shops a mixture of various marine vegetables and animals. The essential, though usually smaller, part of the mixture is the *Plocaria Helminthocorton*; the remainder consists of *Corallines*, *Sertularias*, and *Ceramiums*, to the number of twenty species.² Lamouroux states he found the remains of eighty species of marine plants.³ (See also T. C. Martius.)⁴

The structure of the frond of *Plocaria Helminthocorton* is "very peculiar, being exceedingly lax and cellular, with a consistence similar to that of the stems and leaf-stalks of some aquatic herbaceous phænogamous plants, and having the appearance of articulations which do not actually exist."⁵ The fructification is scarcely

¹ J. P. Schwendemann, in Schlegel's *Thesaurus Mat. Med.* t. iii. p. 181.

³ Fée, *Cours d'Hist. Nat.* i. 147.

⁴ Greville, *Algæ Brit.* p. 146.

⁵ *Grundriss d. Pharmakog.* 12.

ever seen. The plant has a reddish-gray colour externally, but is whitish internally. Its odour strong, marine, and disagreeable: its taste is saline.

COMPOSITION.—Bouvier¹ obtained from 100 parts of Corsican moss, *vegetable jelly* [mucilage? carrageenin?] 60.2; *vegetable fibre*, 11.0; *chloride of sodium*, 9.2; *sulphate of lime*, 11.2; *carbonate of lime*, 7.5; *iron*, *manganese*, *silica*, and *phosphate of lime*, 1.7. Straub² and Gaultier de Claubry³ have subsequently detected iodine, but the quantity is small.

CHEMICAL CHARACTERISTICS.—Corsican moss effervesces with acids, owing to the carbonate of lime which it contains. The brown watery infusion is deepened in colour by sesquichloride of iron, and lets fall some brown flocculi. Tincture of galls does not alter it. Nitric acid and starch give no indication of iodine.

PHYSIOLOGICAL EFFECTS.—Its effects are not very obvious. The vegetable jelly (mucilage) must render it somewhat nutritive; the iodine and saline matters alterative. Mr. Farr⁴ says that, after using the decoction for six or seven days, it acts as a diuretic and diaphoretic, and occasionally produces nausea and giddiness: after some time the stools become darker, present greenish specks, and are sometimes slimy.

USES.—It has been principally celebrated as an anthelmintic against the large round worm (*Ascaris lumbricoides*). Bremser⁵ ascribes its efficacy to chloride of sodium.

In 1822, Mr. Farr brought it forward as a remedy for cancer. He was led to try it from the circumstance of Napoleon Bonaparte having stated to Barry O'Meara that it was used in Corsica for dispersing tumours. Experience does not warrant us in ascribing any benefit to its employment in this disease.

ADMINISTRATION.—In *powder*, it is given in doses of a scruple to two drachms, mixed with honey or sugar; but the more usual mode of exhibiting it is in the form of *decoction*, prepared by boiling from four to six drachms of it in a pint of water; of this the dose is a wineglassful three times daily.

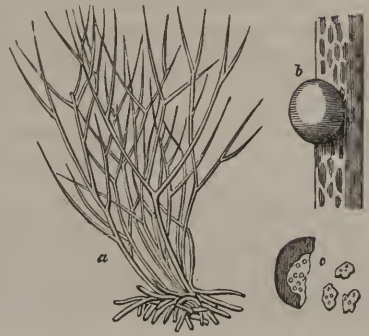

ORDER II. LICHENES, Juss.—LICHENS.

LICHENALES, Lind.

CHARACTERS.—*Perennial*, aerial thallogens, nourished through their whole surface by the medium in which they vegetate; always constituting a *thallus*, *crust*, or *frond* (*receptaculum universale*; *blastema*) formed of a cortical and a medullary layer, of which the former is simply cellular, the latter cellular and filamentous. *Apothecia* (*fructus*) consisting of a *receptacle* and a *proliferous layer* (*lamina prolifera*) composed of *spores* (*sporæ*) naked or enclosed in *spore-cases* (*asci*; *thecæ*), united to form a *nucleus* or disposed on a *disk* (*discus*).

PROPERTIES.—The tissue of lichens consists of *cellulose*. Many of them contain *amylaceous matters* (*lichenin* or *feculoid*, and *inulin*) and their congeners *gum* and *sugar*, which render them nutritive, emollient, and demulcent. *Bitter principles* (*cetraric acid*; *picrolichnin*) are sometimes found in lichens: these confer slight tonic properties. *Colouring matters* (*thallochlor*, *chrysophanic acid*, &c.) are frequently present. *Colorific principles* (*orellic*, *erythric*, *lecanoric*, and other acids), or principles which, under the combined influence of ammonia and oxygen, form colouring

⁵ *Sur les Vers Intestin.* 414.

matters (*orccine*, &c.), render some of the lichens valuable in the arts. Besides the before-mentioned bodies, several other *vegetable acids* (as the *tartaric*, *oxalic*, *tannic*, and *lichestearic*) are found in the lichens. The oxalic acid is found in combination with lime: one lichen (*Variolaria faginea*) contains 47 per cent. of calcareous oxalate. The *ashes* of the lichens constitute about 8 per cent. of the dried plants, and consist principally of the earths: the ashes of lichens growing on siliceous rocks contain more silica than those of lichens growing in other situations. It is deserving of especial notice that not a single poisonous lichen is known.

The lichens which I shall have to notice may be conveniently divided, according to their uses, into the esculent, the medicinal, and the tinctorial lichens.

1. LICHENES ESCULENTI ET MEDICINALES.—EDIBLE AND MEDICINAL LICHENS.

The only lichen employed medicinally by British practitioners is Iceland moss (*Cetraria islandica*). But several other lichens, whose medicinal qualities are in reality similar to, though much feebler than, Iceland moss are still kept in the London herb-shops, being occasionally employed as popular remedies. Those which I have met with are *Peltidea canina*, *Scyphophorus pyxidatus*, and *Sticta pulmonaria*. These, as well as *Gyrophora*, *Parmelia parietina*, and *Cladonia rangiferina*, require a short notice.

7. *Peltidea canina*, Ach.—Ash-coloured Ground Liverwort.

PELTIDEA CANINA, Ach. Syn. p. 239; *Lichen caninus*, Linn.; *Lichen cinereus terrestris*, Woodville, Med. Bot. vol. iv; *Ash-coloured ground liverwort*.

This species, and also *Peltidea rufescens*, Ach., are sold in the herb-shops as *Ground Liverwort*. It formerly was in repute as a preservative against the bite of a mad-dog,¹ and, mixed with half its weight of black pepper, it formed the *pulvis antilyssus* (ἀντί, against, and λύσσα, canine madness) of the London Pharmacopœia for 1721.

8. *Scyphophorus pyxidatus*, Hook.—Cup-Moss.

SCYPHOPHORUS PYXIDATUS, Hook, Engl. Fl. vi. p. 238; *Cenomyce pyxidata*, Ach. Syn.; *Cladonia pyxidata*, Schær. Lich. Helv. Spicil. p. 26; *Lichen Pyxidatus*, Linn.; *Muscus pyxidatus*, Dale, Pharm.; *Cup-moss*.—This species (frequently mixed with *S. fimbriatus*, Hook., and sometimes with *S. cocciferus*, Hook.) is the Cup-moss of the shops. It was recommended by Dr. Willis² as a remedy for hooping-cough.³ He gave it in drachm doses, in the form of powder, decoction, and syrup.

¹ *Phil. Trans.* vol. xx. p. 49; Mead, *A Mechan. Account of Poisons*, 5th ed. p. 165, Lond. 1756.

³ See, also, Dillenii, *Dissertatio de Lichene Pyxidato*, in Schlegel's *Thesaurus Materia Medicæ*, t. i. p. 307, Lipsiæ, 1793.

9. *Sticta pulmonaria*, Hook.—Tree Lungwort.

STICTA PULMONARIA, Hook, Engl. Fl.; *St. pulmonacea*, Ach. Syn. p. 233; *Lichen pulmonarius*, Linn.; *Muscus pulmonaria*, Dale, Pharm.; *Tree Lungwort*, *Oak-Lungs*.—This lichen has been analyzed by John,¹ who found it to contain *resinous chlorophylle*, 2; *bitter extractive*, 8; *lichen starch*, 7; *insoluble matters*, 80; *salts*, &c. 3. Its virtues are dependent on the bitter and amy-laceous matter, and are similar, but inferior, to those of Iceland moss. It has been esteemed as a pectoral in pulmonary affections; as an astringent in internal hemorrhages, and as a remedy for jaundice. It has been given in doses of a drachm, in the form of powder or decoction. In Siberia, where the plant seems to be more bitter than in this country, it is employed as a substitute for hops in brewing.²

10. *Gyrophora*.

Several species of *GYROPHORA* (as *G. proboscidea* β *arctica*, *G. hyperborea*, *G. Pennsylvanica*, and *G. Muhlenbergii*) are employed by the hunters of the Arctic regions of America as articles of food, under the name of *tripe de roche*. All four species were eaten by Captain Franklin and his companions in 1821, when suffering great privations in America; and to its use may their preservation be in part ascribed.³ But, not having the means of extracting the bitter principle, these lichens proved noxious to several of the party, producing severe bowel complaints.

Fig. 164.

*Tripe de Roche*.
(*Gyrophora*.)

11. *Cladonia rangiferina*, Hoffm.—Rein-Deer Moss.

CLADONIA RANGIFERINA, Hoffm.; *Cenomyce rangiferina*, Ach. Syn. p. 277; *Lichen rangiferinus*, Linn.; *Rein-deer Moss*.—This lichen has become celebrated on account of the beautiful description of it, and of its uses, given by Linnæus, in his *Flora Lapponica*, p. 332. It is this plant which, for the greatest part of the year, and especially during the winter season, is the support of the vast herds of rein-deer, wherein consists all the wealth of the Laplanders.

I have frequently bought this lichen, along with others, of the London herbalists, who, however, are unacquainted with its real name; but who sell various species of lichens, under the denomination of "mosses," for the use of bird stuffers, who decorate the inside of their cases with them.

12. CETRARIA ISLANDICA, Ach.—ICELAND MOSS.

Sex. Syst. Cryptogamia, Algæ.

(Planta, Offic.)

HISTORY.—The medicinal properties of this plant (usually termed *Lichen islandicus*) were probably first known to the natives of Iceland. According to Borrichius, the Danish apothecaries were acquainted with them in 1673. In 1683, Hiärne spoke favourably of its effects in hæmoptysis and phthisis.

BOTANY. Gen. Char.—*Thallus* foliaceous, cartilagino-membranaceous, ascending and spreading, lobed and lacinated, on each side smooth and naked. *Apothecia* orbicular, obliquely adnate with the margin of the thallus, the lower portion being free (not united with the thallus); the disk coloured, plano-concave, with a border formed of the thallus and inflexed (*Hooker*).

Sp. Char.—*Thallus* erect, tufted, olive brown, paler on one side, lacinated, channelled, and denticulate, the fertile lacinia very broad. *Apothecia* brown, appressed, flat, with an elevated border (*Hooker*).

Hab.—Dry mountainous districts of the new and old continents. Although met with in considerable abundance in Scotland, it is never gathered there as an article of commerce.

The word *cetraria* is derived from *cetra* or *caetra* (*χαίτρεα*, Hesych), an ancient shield made of leather, which the apothecia are supposed to resemble.

COLLECTION.—The lichen should be collected on dry and clear days, carefully deprived of all foreign matter by hand-picking, and dried in the sun.

PHYSICAL PROPERTIES.—The Iceland moss of commerce (*muscus islandicus*; *lichen islandicus*) is in general brownish or grayish white; the upper surface darker, towards the base sometimes marked with blood-red spots; the under surface paler, whitish, with white spots which have a chalky or mealy appearance, are lodged in little depressions of the thallus, and when submitted to microscopic examination appear warty, pearl-white masses. Apothecia are rather rare on the commercial lichen. When quite dry, the lichen is crisp, cartilaginous, and coriaceous. It is almost odourless, and has a bitter mucilaginous taste. Its powder (*farina*) is whitish gray.

COMMERCE.—It is imported in barrels and bags from Hamburgh and Gottenburgh, and is said to be the produce of Norway and Iceland. In 1836, 20,599 lbs. paid duty; in 1837, 12,845 lbs.; in 1838, 6179 lbs.; in 1839, 15,933 lbs.; and in 1840, 6462 lbs.

COMPOSITION.—It was analyzed by Berzelius¹ in 1808, who obtained the following products from 100 parts:—*green wax*, 1.6; *yellow extractive matter*, 7.0; *bitter matter*, 3.0; *uncrystallizable sugar*, 3.6; *gum*, 3.7; *starch*, 44.6; *starchy skeleton*, 36.2; *gallic acid*, trace; *bitartrate of potash*, *tartrate of lime*, and a little *phosphate of lime*, 1.9 (=101.6). In 1844–5 it was examined by Messrs. Schnedermann and Knop.²

The following figures represent the microscopic appearances of sections of the lichens.

Fig. 166.

*Cetraria islandica.*

a. The apothecia on the larger lobes of the thallus.

¹ *Ann. de Chim.* xc. 277.

Fig. 167.

Fig. 168.

Fig. 169.

Transverse section of the thallus.

Longitudinal section of the thallus.

Longitudinal section of the apothecium, with the thecae and the adherent filamentous layer.

Sections of Cetraria Islandica (highly magnified).

- a. External or cortical layer, which does not become blue by the addition of the tincture of iodine.
- b. Subcortical layer (*stratum gonimicum*), Wallroth; *stratum faculare*, Wallenberg), which becomes blue on the addition of tincture of iodine.
- c. Medullary layer, composed of felted filaments or tubes (*tela contexta*, Schleiden), and intermixed nucleated cells (*annuli*, Link).

1. **AMYLACEOUS MATTER**—*Cetraria islandica* contains at least two kinds of amylaceous matter, namely, one which is coloured blue by iodine (*lichen-starch*), and one which does not become blue with this agent (*inuline*).

Link¹ states that the amylaceous matter of *Cetraria* does not occur in a globular form. If by amylaceous matter is to be understood starch grains, which are rendered blue by iodine, my observations confirm his statement. Payen,² however, says he has seen the starch of Iceland moss in the form of little balls; but he has probably mistaken the cells for starch grains. When a thin section of the thallus has been soaked in cold water and then placed under the microscope, a general blue tint is communicated to the subcortical layer (see Figs. 167 and 168), on the addition of tincture of iodine: but none of the cells or granules become blue. A starchy non-granular matter, rendered blue by iodine, appears to reside in the intercellular tissue of the subcortical layer. My friend Mr. Henry Deane has traced this amylaceous matter to the surface of the apothecia, which appears to be deficient in the cortical non amylaceous layer. Moreover, iodine colours sections of the apothecia in stripes; rendering blue the starchy matter between the thecae and elongated cells (see Fig. 169).

I have sometimes seen the nucleated cells of the medullary layer (see Fig. 168) assume an amber colour when treated with iodine. Is this owing to the presence of inuline?

a. *Lichen-starch*. This becomes blue on the addition of iodine. According to Schnedermann and Knopp, hydrochloric acid converts it into a transparent jelly. Its formula, according to Mulder, is $C^{12}H^{10}O^{10}$.

Even after very prolonged boiling in water the tissue of Iceland moss still retains the property of being tinged blue by iodine: hence it has been called *amylaceous tissue, starchy skeleton*, &c. Mulder says, that when boiled sufficiently and acted on by solvents, the final residue of it is nothing but *cellulose*: it is improper, therefore, to call it amylaceous tissue.

β. *Inuline*. This, according to Payen and others, is a constituent of Iceland moss. It is tinged yellow by iodine. When insoluble in cold water its formula is probably $C^{12}H^{10}O^{10}$.

Mulder is of opinion that the chief part of lichen-starch must be composed of a starch which like inuline is turned yellow by iodine, and like common starch can be precipitated by basic acetate of lead.

2. **CETRARIC ACID; Cetrarin; bitter principle of Iceland moss**—This resides in the cortical portion of the thallus. It exists there for the most part in the state of free cetraric acid, and not as a cetrarate. In the pure state the acid occurs in the form of shining minute acicular crystals. It is intensely bitter, not volatile, and is infusible without decomposition. It is almost insoluble in water, which, however, acquires a bitter taste when boiled with the acid. It is

¹ *Icones selectæ Anatomico-Botanicae*, Fascic. iii. Berlin, 1841.

² *L'Institut de 1837*, p. 145.

soluble in boiling alcohol, but crystallizes in great part on cooling. It is slightly soluble in ether, and is quite insoluble in the fixed and volatile oils. Its formula is $C^{34}H^{16}O^{15}$. It is dissolved both by the caustic and carbonated alkalies, and is precipitated from its solution by acids. *Cetrarate of ammonia* ($2NH_3, C^{34}H^{16}O^{15}$) is a beautiful yellow salt, having a faint ammoniacal odour, and being soluble in water. By exposure to the air it gradually becomes brown. Schnedermann explains the production of the brown colour of Iceland moss by supposing that the cetraric acid of the thallus absorbs atmospheric ammonia, and the cetrarate of ammonia thus formed becomes brown by exposure to the air. The alkaline cetrarates yield a red colour (*cetrarate of iron*) with the salts of the peroxide of iron. Now as the ashes of Iceland moss contain iron, Schnedermann thinks it not improbable that the red spots which are sometimes found at the base of the lichen may be due to the presence of cetrarate of iron, produced by the action of cetrarate of ammonia (formed as above explained) on the ferruginous constituent. *Cetrarate of lead* ($2PbO, C^{34}H^{16}O^{15}$) forms a yellow flocculent precipitate.

3. **LICHESTEARIC ACID** (so called from *λεῖχιν*, *lichen*; and *στέαρ*, *fat*). When pure it is perfectly white, and consists of pearly crystalline plates. It is odourless, but has an acid taste. It is soluble in alcohol, ether, and the volatile and fatty oils, but is insoluble in water. At $248^{\circ}F$. it melts, and on cooling congeals into a crystalline mass. It cannot be volatilized without decomposition. Its formula is $C^{29}H^{25}O^6$. It is dissolved by alkalies, and is precipitated from its alkaline solution by acids. *Lichestearate of potash* is a white indistinctly crystalline powder; *Lichestearate of silver* ($AgO, C^{29}H^{24}O^5$) is grayish white; *Lichestearate of lead* ($PbO, C^{29}H^{24}O^5$) is white; *Lichestearate of baryta* is grayish white; *Lichestearate of ammonia* is crystallizable.

4. **FUMARIC ACID**; *Lichenic acid*.—This acid was discovered in Iceland moss by Pfaff.

5. A neutral substance, called provisionally "*the body C*," is mentioned by Schnedermann as being contained in tolerable quantity in the lichen. It is white, tasteless, insoluble in water, ether, oils, alkalies, and acids, and difficultly soluble in hot spirit.

CHLOROTHALLE; *Thallochlor*.—This is the green colouring matter. It is soluble in ether, alcohol, and petroleum. It has the properties of a weak acid, and is distinguished from chlorophylle by being little or not at all soluble in hydrochloric acid.

CHEMICAL CHARACTERISTICS.—Iceland moss swells up in cold water, to which it communicates some portion of bitterness, and a very little mucilage. If to the moistened thallus some tincture of iodine be added, the tissues become intensely blackish blue; but the white chalky or mealy-looking spots, before mentioned, are unaltered by iodine, and appear more brilliantly white, in consequence of the black ground on which they are placed.

By prolonged boiling in water, the lichen yields a mucilaginous decoction, which, when sufficiently concentrated, gelatinizes on cooling. A solution of iodine communicates a blue colour (*iodide of starch*) to the cold decoction.

When the decoction has been imperfectly prepared in consequence of being weak, and insufficiently boiled, it yields a dingy green colour with iodine. The green colour depends on the mixture of two coloured substances: one yellow, the other blue. "If," says Mulder, "a diluted decoction of Iceland moss, after being coloured with iodine, is allowed to settle for a while, the layer at the bottom is yellow, and that immediately above is blue."

The decoction yields, with the basic acetate of lead, a copious whitish precipitate (*amylate of lead*); and with a mixture of sulphate of copper and potash, a green precipitate (*cetrarate of copper*).¹

The sesquisalts of iron communicate a red colour (*cetrarate of iron*), both to the decoction and to an alcoholic tincture of Iceland moss (prepared by digesting \mathfrak{z} ij of the lichen in $f\mathfrak{z}$ vj of rectified spirit).

In strong hydrochloric acid the thallus swells up, owing to the gelatinization of the starch contained in the intercellular spaces.

PHYSIOLOGICAL EFFECTS. *a. On animals*.—In Carniola, pigs, horses, and oxen are fattened by it.²

β. On Man.—It is a mucilaginous or demulcent tonic, without any trace of astringency. If the bitter matter (*cetraric acid*) and extractive be removed, it is nutritive, emollient, and demulcent, like ordinary starch, over which it has no advantage. Captain Sir John Franklin and his companions tried it as an article of food, when suffering great privations in America, but its bitterness rendered it hardly eatable.³

¹ Herberger, *Journ. de Pharm.* xxii.

² *Narrative of a Journey to the Shores of the Polar Sea*, p. 414, 1823.

³ Murray, *App. Med.* v. 506.

USES.—Iceland moss is well adapted to those cases requiring a nutritious and easily-digested aliment, and a mild tonic not liable to disorder the stomach. It has been principally recommended in chronic affections of the pulmonary and digestive organs, particularly phthisis, chronic catarrh, dyspepsia, chronic diarrhoea, and dysentery; but its efficacy has been much exaggerated.

ADMINISTRATION.—It is best exhibited in the form of decoction. When employed as an alimentary substance merely, the bitter matter should be extracted before ebullition. This is effected by digesting the lichen in a cold weak alkaline solution (composed of water 300 parts, and carbonate of potash 1 part), and afterwards washing it with cold water.¹ But the subsequent washing will not remove the whole of the alkaline salt. Instead, therefore, of using an alkali, distilled water may be used to extract the bitter principle. The lichen should be heated once or twice in water up to about 180° F., by which the lichen will be deprived of most of its bitterness. It is then to be boiled in water or milk. When the decoction is sufficiently concentrated it gelatinizes on cooling. It may be flavoured with sugar, lemon peel, white wine, or aromatics, and then forms a very agreeable kind of diet.

DECOCTUM CETRARIE, L. [U. S.]; *Decoctum Lichenis Islandici*, D.; *Decoction of Iceland Moss*. (Iceland Moss ζv [ζj , D. (ζss , U. S.)]; Distilled Water [Water, U. S.] Ojss; boil down to a pint, and strain.) Dose, $\text{f}\zeta\text{j}$ to $\text{f}\zeta\text{iv}$ every four hours.

13. *Parmelia parietina*, Ach.—Common Yellow Wall Lichen.

PARMELIA PARIETINA, Ach.; *Lobaria parietina*, Hoffm.; *Lichen parietinus*, Linn.; *Common Yellow Wall Lichen*. Usually sold in the herb shops under the name of *common yellow wall moss*. χρυσο φύλλον, hodie in Zacyntho, Sibth. Thallus foliaceous, membranaceous, orbicular, bright-yellow: the lobes marginal, radiating, rounded, crenate, and crisped, granulated in the centre, beneath paler and fibrillose. Apothecia deep-orange, concave with an entire border (*Hooker*). This lichen has been the subject of repeated chemical investigation. According to Herberger,² it contains two beautiful colouring matters (parmelia-yellow and parmelia-red), several alimentary principles (gliadin, sugar, starch, and gum), and three medicinal substances (soft resin, bitter matter, and volatile oil); besides wax, stearine, chlorophylle, and woody fibre. Rochleder and Heldt³ give the name of *chrysophanic acid* (C¹⁰H⁸O³) to the golden yellow crystallizable colouring matter, which, more recently, Schlossberger and Doepping⁴ have found to be identical with the yellow colouring matter of rhubarb (*rheine, rheumine, rhabarbaric acid*). In 1815, this lichen was lauded by Dr. Sander⁵ as a valuable substitute for cinchona bark in intermittents. He also gave it with success in hemorrhages and fluxes. Haller had previously spoken favourably of it as a tonic in diarrhoea and dysentery; and Willemet had found it useful in contagious autumnal fluxes. Subsequent experience, however, has not confirmed the favourable reports made of its medicinal power. The dose of it in powder is from ʒj to ʒj . It may also be given in the form of decoction, tincture, and extract. Dr. R. D. Thomson⁶ has proposed it as a test for alkalies, which communicate to its yellow colouring matter (called by him *parietin*) a beautiful red tint.

2. LICHENES TINCTORII.—TINCTORIAL LICHENS.

1. NUMBER AND VARIETY.—A considerable number of lichens have been employed by man on account of the colouring matter which they yield him. Some of them (e. g., *Parmelia parietina* and *Evernia vulpina*) contain colouring principles (e. g., *chrysophanic* and *vulpinic acids*). Others (e. g., several species of *Rocella*, of *Lecanora*, of *Variolaria*, &c.) contain principles (e. g., *orsellic, erythric, lecanoric, and gyrophoric acids*) which are colourless while in the plant, but

¹ Dr. Davidson, in a paper *On the Removal of the bitter taste and lichenous odour of Iceland Moss* (Jameson's *Edinb. New Phil. Journ.* vol. xxviii. p. 260, 1840), recommends a solution of caustic potash for extracting the bitter taste of this lichen. A pound of carbonate of potash (rendered caustic by a pound of lime) is sufficient for 28 lbs. of the plant.

⁵ *Die Wandflechte, ein Arzneimittel, welches die peruv. Rinde nicht nur entbehrlich macht, sondern die auch ein gleichart. Heilkräften übertrifft*, Ato, Sondershausen, 1815.

⁶ *Lond. Ed. and Dub. Phil. Mag.* July, 1844.

which, under the influence of alkalies and atmospheric oxygen, yield colouring matters (e. g., *orceine*). Such principles I shall distinguish as *colorific*, or colour-making.

2. **COLOURS.**—Lichens furnish four principal colours, viz., brown, yellow, purple, and blue.

a. **Brown** colours are yielded by *Gyrophora pustulata* and *Sticta pulmonaria* (see *ante*, p. 65). The latter lichen, says Professor Guibourt,¹ produces on silk, by using, as mordants, bitartrate of potash and chloride of tin, a very fine and durable carmelite colour. For use in France, it is principally collected in the Vosges.

β. **Yellow** colours are yielded by *Parmelia parietina* (see *ante*, p. 69) and *Evernia vulpina*. The former lichen contains, as its yellow colouring principle *chrysophanic acid*; the latter, according to M. Bébert,² contains a yellow crystallizable acid called *vulpinic acid*.

γ and *δ.* **Purple and blue** colours are yielded by a considerable number of lichens. In this country, purple colours (*orchil* and *cudbear*) only are obtained from them; but in Holland a blue colour (*lünus*) is also prepared from these. And it appears that the same lichens yield either the one or the other colour according to the method of treatment.

The orchil makers of this country call the cylindrical and flat species of *Rocella* used in the manufacture of orchil and cudbear, *weeds* or *orchella weeds*, and distinguish them according to the countries yielding them (e. g., *Angola weed*, *Canary weed*, &c.); while the crustaceous and foliaceous lichens, employed for similar purposes, they term *mosses* (e. g., *tartareous moss*, *pustulatus moss*, *rock moss*, &c.). A similar distinction is made in French commerce; the term *herbe* being applied to what the English call a *weed*, while the name of *lichen* is given to what our dealers term a *moss*.

The following is a list of the principal lichens employed by British manufacturers of orchil and cudbear, with their commercial names:—

Orchella Weeds.		Mosses.	
Angola Orchella weed	(<i>R. fuciformis</i>).	Tartareous moss	(<i>Lecanora tartarea</i>).
Madagascar "	(<i>R. fuciformis</i>).	Pustulatus moss	(<i>Gyrophora pustulata</i>).
Mauritius "	"	Canary Rock moss	(<i>Parmelia perlata</i> ?) ³
Canary "	(<i>R. tinctoria</i>).	Corsica and Sardinia Rock moss.	
Cape de Verd "	(<i>R. tinctoria</i>).	Norway Rock moss.	
Azores "	(<i>R. tinctoria</i>).		
Madeira "	(<i>R. tinctoria</i> and <i>R. fuciformis</i>).		
South American (Lima), large and round	"		
"	(<i>R. tinctoria</i> ?)		
"	small and flat		
"	(<i>R. fuciformis</i>).		
Cape of Good Hope	" (<i>R. hypomecha</i>).		
Barbary (Mogadore)	" (<i>R. tinctoria</i>).		
Corsican and Sardinian	(<i>R. tinctoria</i>).		

Mr. Harman Visger, of Bristol, informs me that "every lichen but the best orchella weed is gone or going rapidly out of use; not from deterioration of their quality, for, being allowed to grow, they are finer than ever; but because the Angola-weed is so superior in quality, and so low-priced and abundant, that the product of a very few other lichens would pay the expense of manufacture."

In France, the *Variolaria dealbata*, De Cand., and *V. orcina* or *oreina*, Ach. (the *Parelle d'Auvergne*) are employed in the production of orchil. These two lichens constitute the *V. corollina*, Ach., which must be confounded neither with *Lecanora parella*, Ach., nor with *Isidium corallinum*, Ach.

3. **COLORIFIC PRINCIPLES.**—These in most, if not in all, cases are organic acids: e. g., *alpha orsellic*, *beta orsellic*, *erythric*, *lecanoric*, *gyrophoric*, *evernic*, *usnic*, &c. acids.

Under the united influence of water, atmospheric oxygen, and ammonia, these colorific principles yield coloured products, which, though probably not identical, pass under the general name of *orceine*.

The precise chemical changes which these colorific principles undergo when exposed to the joint action of water, air, and ammonia, are not definitely known. Some of these principles are not directly converted into coloured substances, but into intermediate colourless substances. Thus *lecanoric acid* becomes first *orcine* and then *orceine*. Liebig, adopting the formulæ which have been given for these three bodies respectively by Schunck, Will, and Dumas, has given the following explanation of the changes: *Lecanoric acid*, $C^{16}H^{8}O^8$, gives out two atoms of carbonic acid, C^2O^4 , and becomes anhydrous *orcine*, $C^{16}H^8O^4$, which, with three atoms of water, H^3O^3 , yields one atom of crystallized *orcine*, $C^{16}H^{11}O^7$; and one atom of crystallized *orcine*, $C^{16}H^{11}O^7$, with one atom of ammonia, NH^3 , and five atoms of oxygen, yield one atom of *orceine*, $C^{16}H^9NO^7$, and five atoms of water: but the accuracy of the formulæ has been called in question.

¹ *Hist. Nat. des Drog. simpl.* t. 2me p. 77, 4me éd. 1849.

² *Journ. de Pharm.* t. xvii. p. 696.

³ I have not met with the Canary Rock Moss in fructification, and cannot, therefore, positively state its botanical name. I found a similar lichen in commerce under the name of British Rock Moss. The thallus of both corresponds to that of *Parmelia perlata*, Ach.

4. TEST OF THE COLORIFIC PROPERTY OF LICHENS.—Hellot's test is maceration in a weak solution of ammonia (see *Roccella tinctoria*).

Another method is by testing an alcoholic tincture of the lichen with a solution of hypochlorite of lime. If the lichen possess any colorific power, a fugitive red colour is produced.

Dr. Stenhouse¹ proposes to estimate the quantity of colorific matter in lichens by means of a solution of hypochlorite of lime. Any convenient quantity of the lichen (say one hundred grains) may be cut into very small pieces, and then macerated with milk of lime till all the coloring principle is extracted. Three or four macerations are quite sufficient for this purpose, if the lichen has been sufficiently comminuted. The clear liquors should be filtered and mixed together. A solution of bleaching powder of known strength should then be poured into the lime solution from a graduated alkalimeter. The moment the bleaching liquor comes in contact with the lime solution of the lichen, a blood red colour is produced, which disappears in a minute or two, and the liquid has only a deep yellow colour. A new quantity of the bleaching liquid should then be poured into the lime solution, and the mixture carefully stirred. This operation should be repeated so long as the addition of the hypochlorite of lime causes the production of the red colour; for this shows that the lime solution still contains unoxidized colorific principle. Towards the end of the process, the bleaching solution should be added by only a few drops at a time, the mixture being carefully stirred between each addition. We have only to note how many measures of the bleaching liquor have been required to destroy the colouring matter in the solution, to determine the amount of the colorific principle it contained. The following are the results of trials with the same test liquors upon four varieties of lichen:—

	Measures.
Angola lichen required	200 = 1.00
American lichen	120 = 0.60
Cape lichen	035 = 0.17
<i>Lecanora tartarea</i> , from Germany near Giessen	025 = 0.12

The amount of colorific principle in a lichen may also be directly determined by extracting the lichen with milk of lime, by precipitating by means of acetic acid, collecting the precipitate on a weighed filter, drying it at the ordinary temperature, and then weighing it.

5. MODE OF EXTRACTING THE COLORIFIC PRINCIPLES FOR TRANSPORT.—Dr. Stenhouse suggests the following method: cut the lichens into small pieces, macerate them in wooden vats with milk of lime, and saturate the solution either with muriatic or acetic acid. The gelatinous precipitate is then to be collected on cloths, and dried by a gentle heat.

In this way almost the whole colorific matter can be easily extracted, and the dried extract transported at a small expense from the most distant inland localities, such as the Andes or Himalayas.

Dr. Stenhouse has kindly furnished me with the following table of the lichens, and their colorific principles and coloured products:—

LICHENS.		COLORIFIC PRINCIPLES.		COLOURING PRINCIPLES.		AUTHORITY.
Commercial names.	Locality.	Names.	Formulae.	Names.	Formulae.	
S. American Orchella-weed	Lima, &c.	Alpha Orsellic acid	$C^{20}H^{16}O^{13}+HIO$	Oreocine	$C^{16}H^{10}NO$	Stenhouse.
Cape Orchella-weed	Cape of G. Hope	Beta Orsellic acid	$C^{34}H^{18}O^{14}+HO$	Ditto	Ditto	Stenhouse.
Angola Orchella-weed	Angola, Africa	Erythric acid	$C^{20}H^{10}O^9+HO$	Ditto	Ditto	Stenhouse.
Perelle Moss (<i>Lecanora parvella</i>)	Switzerland	Lecanoric acid	$C^{18}H^8O^8$	Ditto	Ditto	Schunck.
Tartareous Moss (<i>L. tartarea</i>)	Norway	Gyrophoric acid	$C^{36}H^{18}O^{14}$	Ditto	Ditto	Stenhouse.
Pustulatus Moss (<i>Gyrophora pustulata</i>)	Norway	Ditto	Ditto	Ditto	Ditto	Stenhouse.
Ragged hoary Lichen (<i>Evernia prunastri</i>)	Scotland	Evernic acid	$C^{34}H^{15}O^{12}+HIO$	—	—	Stenhouse.
Usnea (<i>florida</i> , <i>plicata</i> , and <i>hirta</i> , &c.)	Germany	Usnic acid	$C^{38}H^{17}O^{14}$	—	—	Rochleder and Heldt.
Rein-deer Moss (<i>Cladonia rangiferina</i>)	—	Ditto	Ditto	—	—	Rochleder and Heldt.
Ramalina (<i>fastigiata</i>) [<i>calicaris</i>]	—	Ditto	Ditto	—	—	Rochleder and Heldt.

¹ Phil. Trans. for 1848.

14. ROCCELLA TINCTORIA, De Cand.—DYER'S ORCHELLA WEED.

Sex. Syst. Cryptogamia, Algæ.

HISTORY.—Theophrastus,¹ Dioscorides,² and Pliny,³ notice a plant which they respectively call *πόντιον φύκος*, *φύκος θαλάσσιον*, and *phycos thallassion*, i. e., *fucus marinus*. They state that it grew near the ground on the rocks of Crete, and was used for dyeing purple; and Dioscorides says that some persons imagine that the paint (*fucus*) used by women was this plant, but, he adds, it was a root bearing the same name.⁴

The *phycos thallassion* has been usually assumed to be *Roccella tinctoria*, and not, as the ancients state, a sea-weed.⁵ Bory de St. Vincent⁶ even thinks that the ancients made their celebrated purple dye, brought from the isles of Elishah,⁷ with the *R. tinctoria*, which he therefore calls *R. purpura-antiquorum*.

Early in the 14th century, the art of dyeing wool with *Roccella tinctoria* was made known at Florence by one of the descendants of a German nobleman named Ferro or Fredrigo. It is said that he accidentally discovered, in the Levant, the colour obtained by the action of urine on this plant, there called *respio* or *respo*, and in Spain *orciglia*; and that his family received the name of *Oricellarii*, altered to *Rucellai*, from this useful invention. From the latter term the generic name *Roccella* is supposed to be derived.⁸

BOTANY. **Gen. Char.**—*Thallus* coriaceo-cartilaginous, rounded or plane, branched or lacinated. *Apothecia* orbicular, adnate with the thallus; the disk coloured, plano-convex, with a border at length thickened and elevated, formed of the thallus, and covering a sublentiform, black, compact, pulverulent powder concealed within the substance of the thallus (*Hooker*).

Sp. Char.—*Thallus* suffruticose, rounded, branched, somewhat erect, grayish-brown, bearing powdery warts [*soredia*]. *Apothecia* flat, almost black and pruinose, with a scarcely prominent border (*Hooker*).

β. *R. tinctoria* β *hypomecha*, Ach.; *R. hypomecha*, Bory. *Thallus* terete, filiform, very long, simplish, subconjugate, prostrate, pendulous.—Cape of Good Hope; Mauritius.—2 to 5 inches long: the thallus geniculate where the apothecia are developed (*Bory*): the apothecia by age lose the thalloid margin and become convex, naked, smooth, and black (*Ach.*).

γ. *R. dichotoma*, Ach., has a terete ash-gray, brownish thallus, with longish dichotomous branches.

Hab.—Maritime rocks of the eastern Atlantic islands (the Madeira isles, the Azores, the Canaries, and the Cape de Verd isles); western coast of South America (on porphyry near Riobamba in Colombia, and on the sea-shore near Chancay in Peru—Humboldt);⁹ Bourbon; extreme south of England, Guernsey, Portland Island, and the Scilly Islands.

In commerce several other species, or varieties of the above species, are met with. The most important are the following:—

R. FUCIFORMIS, De Cand., *Ach. Syn.*, p. 244. *Hooker, Engl. Fl.*, vol. v. part 1, p. 222. Lichen fuciformis, *Linn.* Flat leaved orchiella weed.—*Thallus* flat, branched, nearly upright, grayish-white, bearing powdery warts. *Apothecia* pruinose, bordered (*Hooker*). Maritime rocks with *R. tinctoria*; Canaries; from Cherbourg to Mogadore; St. Malo; South of England.

R. fuciformis β *linearis*, Ach. Spain, Sumatra, the Dezertias (Madeira).

R. phycopsis, Ach., is also perhaps a variety of *R. fuciformis*. It is intermediate in character

⁸ *Synops. Plant. Equin.* i. 50.

⁹ Beckmann, *op. citato*.

between the latter and *R. tinctoria*. Its thallus is somewhat flattened (terete-compressed), and much branched; the divisions being somewhat fastigiate, rarely more than an inch long, and very farinaceous.

R. FLACCIDA, Bory. Branches somewhat cylindrical, filiform, very broad, pendulous, whitish. Mauritius.

R. MONTAGNEI, *Belanger, Voy. aux Indes Orient.* Pl. 13, Fig. 4 [no date]. *Thallus* coriaceous, flaccid, flat, entire and broad at the base, at length dichotomously (rarely trichotomously) lacinate, pale glaucous, sorediferous. *Apothecia* marginal, somewhat pedicellate, with a black convex pruinose disk, and persistent margin.—On the trunks of Mango trees (*Mangifera indica*) in India; especially at Pondicherry. This species, and *R. pygmaea*, D. R. and Mont., which grows in Algeria, are remarkable for growing on the trunks of trees; the others are found on maritime rocks.

COMMERCE.—All the species and varieties of *Rocella* found in commerce bear the general appellation of *Orchella weed*; but they are distinguished by the name of the country from which they are imported. The following is a list of the sorts which, within the last few years, have been found in the London market; those marked with the asterisk (*) I have myself examined, and possess samples of—

- | | | |
|-------------------------------|-------------------------------|-------------------------------------|
| *Angola <i>Orchella</i> weed. | *Canary <i>Orchella</i> weed. | *Lima (thick) <i>Orchella</i> weed. |
| Mauritius “ | Cape de Verde “ | *Lima (thin) “ |
| *Madagascar “ | *Western Island “ | Corsica and Sardinia “ |
| *Barbary (Mogadore) ditto. | *Madeira (Dezertas) ditto. | |
| *Cape of Good Hope ditto. | | |

In 1838, 567 ewts.; in 1839, 6494 ewts.; and in 1840, 4175 ewts. of *Orchella* weed paid duty.

PHYSICAL PROPERTIES.—Having fully described the botanical characters of the different species of *Rocella*, it will be unnecessary here to describe minutely the different commercial sorts.¹

The commercial kinds of *Orchella* weed may be conveniently arranged in three divisions, as follows:—

1. *Orchella* weeds having a cylindrical tapering thallus.—These consist usually of *Rocella tinctoria*, and perhaps *R. flaccida*, Bory. In one case (Cape of Good Hope orchella) the plant is *R. hypomecha*, a mere variety of *R. tinctoria*. Occasionally, flattened orchella weeds are found intermixed: these may be regarded as accidental.

¹ For figures of the microscopic structure of the *Rocella tinctoria*, the reader is referred to Link's *Icones Selectæ Anatomico-Botanicae*, Berl. 1811, 3tes Heft, Taf. vi.

a. *Canary Orchella Weed. Roccella tinctoria*.—Formerly the most esteemed sort of *Orchella*. Thallus filiform, seldom exceeding in thickness a pin, and in length an inch and a half. Colour from pale-yellowish gray to dark brown.

β. *Western Island Orchella Weed; St. Michael's Orchella Weed. Roccella tinctoria*.—Similar to the preceding; but less valuable as a dye-stuff.

γ. *Barbary Orchella Weed; Mogadore Orchella Weed. Roccella tinctoria*.—Somewhat smaller than the preceding sorts, and less valuable as a dye.

δ. *Lima thick Orchella Weed; South American thick Orchella Weed. Roccella tinctoria? R. flaccida*, Bory?—A very handsome lichen, brought from Lima and other parts of the west coast of South America. Distinguished from the other sorts by its large size; usually several, sometimes six or eight, inches long; its thickness from that of a crow-quill to that of a goose-quill. Thick tubercular excrescences are frequently found on it. It has a very leathery, sometimes a cartilaginous whitish appearance. Its quality as a dye is considered good, and superior to the preceding sorts.

ε. *Cape of Good Hope Orchella Weed. R. tinctoria β hypomecha*, Ach.—A large lichen, though rather smaller than the preceding. Remarkable for its white or gray-white appearance: many of the divisions of the thallus are geniculated. As a dye its quality is very bad.

2. *Orchella Weeds have a flat (plane) or compressed thallus*. These consist of *R. fuciformis*, and, perhaps, in some cases, of *R. Montagnei*.

ζ. *Angola Orchella Weed. R. fuciformis*.¹—Thallus very flat, seldom exceeding an inch and a half or two inches in length: in breadth (except at the fork or division) rarely more than one-sixth of an inch. Colour greenish or yellowish-gray. As a dye-stuff it is the most valuable of all the *Orchella* weeds.

η. *Madagascar Orchella Weed. R. fuciformis*.—Smaller, but in other respects similar to the preceding sort. Somewhat less valuable than the Angola sort.

θ. *Lima thin Orchella Weed. R. fuciformis?*—Somewhat more rounded or less flat than the preceding, which it in other respects very much resembles.

3. *Mixed Orchella Weeds, consisting of both flat and round Orchella Weeds*.

ι. *Madeira Orchella Weed. R. tinctoria* and *R. fuciformis β linearis*, Ach. Gathered on the Dezertas, near Madeira. The round and terete thalli resemble the Canary *Orchella*. The flattened thalli are thicker than those of the Angola sort.

COMPOSITION.—A qualitative analysis of *Roccella tinctoria* was made by Fr. Nees v. Esenbeck,² who found in it a *brown resin* (soluble in alcohol and ether, and becoming brownish red with ammonia), *wax*, *glutinous matter*, *insoluble starch*, *yellow extractive*, *yellowish-brown gummy matter*, *lichen-starch*, *tartrate* and *oxalate of lime*, and *chloride of sodium* from the adherent sea water.

The nature of the colorific principles of the *Orchella* weeds (*Roccella*) of commerce has been the subject of several analytical investigations; the most important of which are those of Heeren,³ in 1830; of Kane,⁴ in 1840; of Sehunck,⁵ in 1841, and also in 1846; of Rochleder and Heldt,⁶ in 1843; of Knop,⁷ in 1844; and of Stenhouse,⁸ in 1848.

Robiquet⁹ has thrown much light on the subject by his investigations into the nature of the colorific principle of *Variolaria dealbata*.

The only constituents of the *Orchella* weeds which will require separate notice are the colorific principles; and in describing these I shall follow Stenhouse.

1. **ALPHA-ORSELLIC ACID** (*Stenhouse*); *Colorific principle of Lima thick Orchella Weed (Roccella tinctoria)*.—Obtained by macerating the lichen in milk of lime, and then adding excess of hydrochloric acid to the filtered solution. A white gelatinous precipitate is obtained, which, when washed, dried, dissolved in warm alcohol, and the solution allowed to cool, yields stellate prismatic crystals of alpha-orcellic acid. It is nearly insoluble in cold water, but sparingly soluble in boiling water; pretty soluble in cold alcohol and ether, and readily so in boiling

¹ Dr. Scouler (in Dr. Stenhouse's paper on the Lichens in the *Phil. Trans.* for 1848, p. 72) has pronounced the Angola *Orchella Weed* to be *R. Montagnei* of Belanger. My own examination of it led me to believe that it was *R. fuciformis*. I therefore submitted samples of it to Sir W. Hooker and Mr. Bennett, of the British Museum, both of whom have declared it to be one of the numerous varieties of *R. fuciformis*.

alcohol. It reddens litmus, and forms crystallizable salts with the alkalies and earths. Its most characteristic reaction, by which its presence can be very readily detected, is the deep blood-red colour which it instantly strikes with a solution of hypochlorite of lime; the colour soon changes to yellow which gradually also disappears. A solution of orsellic acid in ammonia, on exposure to the air, soon assumes a bright-red colour, which gradually becomes darker and purple coloured. The rational formula for alpha-orsellic acid is $C^{32}H^{15}O^3 + HO$.

2. BETA-ORSELLIC ACID (*Stenhouse*); *Colorific principle of Cape of Good Hope Orchella Weed* (*Rocella hypomecha*).—Is intermediate in its properties between alpha-orsellic acid and erythric acid, but approaches the former more closely. It is crystallizable, and its solution yields a fugitive blood red colour with hypochlorite of lime. Its ammoniacal solution also becomes red in the air. The rational formula of the hydrated acid is $C^{34}H^{17}O^{14} + HO$.

3. ERYTHRIC ACID (*Schunck and Stenhouse*); *Colorific principle of Angola and Madagascar Orchella Weeds* (*Rocella fuciformis*).—By macerating the lichen in milk of lime, as before stated, Stenhouse obtained 12 per cent. of crude erythric acid. It is a feebler acid than alpha- and beta-orsellic acids; but it agrees with these acids in being crystallizable, and in yielding red-coloured compounds with ammonia, and also in its reaction with hypochlorite of lime. The formula of the hydrated acid is $C^{20}H^{10}O^9 + HO$.

CHEMICAL CHARACTERISTICS.—The aqueous decoction of Orchella weed forms a copious precipitate with diacetate of lead, and has its colour deepened by alkalies. Digested in a weak solution of ammonia, in a corked phial, at a heat not exceeding $130^{\circ} F.$, the plant yields a rich violet-red colour. This is *Hellot's test* for the discovery of a colorific property in lichens.¹ By adding a solution of hypochlorite of lime to an alcoholic tincture, or to an alkaline infusion of the lichen, a fugitive blood-red colour is produced.

PHYSIOLOGICAL EFFECTS.—Mucilaginous, emollient, and demulcent.

USES.—In the Mauritius it is employed in decoction to alleviate cough. In Europe it is only employed as a colorific agent.

1. LACMUS.—LITMUS.

SYNONYMES.—*Turnsole in cakes* (*tournesol en pains; tournesol en pierre*); *Dutch turnsole; lacca musica, musiva, vel musci; lacca cærulea*.

HISTORY.—The manufacture of litmus was probably discovered by the Dutch about the latter end of the seventeenth century.²

PREPARATION.—Litmus is obtained by the united influence of water, air, ammonia, and either potash or soda, on any of the tinctorial lichens capable of yielding orchil. If the potash or soda be omitted, the product is not litmus, but orchil.

The manufacture of litmus has been described by Ferber,³ by an anonymous writer,⁴ by Morelot,⁵ and by Amédée Gélis.⁶ From their accounts it appears that the lichen is macerated for several weeks, with occasional agitation in a mixture of urine, lime, and potashes, in a wooden trough under shelter. A kind of fermentation takes place, and the lichen becomes first reddish, and subsequently blue. When the pulp has acquired a proper blue colour, it is placed in proper moulds, and the cakes thus procured are subsequently dried.

The moulds are either of steel or brass, and consist of two parts: the lower one divided into rectangular cells, and the upper one supporting a series of metallic rods bearing small metallic disks, so arranged as to accurately fit the cells of the lower piece.

¹ Berthollet *On Dyeing*, by Ure, vol. ii. p. 184; also, *Proceedings of Comm. of Agricult. of Asiatic Society*, April 5th, 1837.

² Litmus is not mentioned by, and, therefore, was probably unknown to, Caspar Bauhin (*Pinax*, 1671), and to Dale (*Pharmacologia*, 3tia ed. 1737). The earliest authors in whose works I have found it mentioned are, Pomet (*History of Drugs*, Eng. ed. 1712), and Valentine (*Hist. Simpl.* 1716).

³ *Neue Beytrage zur Mineralgeschichte verschiedener Länder*, Bd. i. S. 378, Miatou, 1778. Ferber describes the process as practiced at Amsterdam. He says that the pulp is ground in a mill, and forced through a hair cloth, before it is placed in the moulds.

⁴ Nicholson's *Journal of Nat. Phil. Chem. and the Arts*, vol. ii. p. 311, 1799. The notice of litmus is a translation from an article in the *Journal du Commerce*. The lichen is said to be ground in a mill, and sifted through a brass wire sieve before maceration. The moulds are described as being $1\frac{1}{4}$ inches by 8-10ths of an inch.

⁵ *Mémoire sur le Lichen François, vulgò tournesol en pain*, in the *Mém. de la Soc. Méd. d'Emulation*, t. v. p. 281.

⁶ *Journ. de Pharm.* t. xxvii. p. 476, 1810.

The lower piece is immersed in the pulp with which they are filled, and the excess of pulp is then scraped off by means of a wooden spatula. The upper piece being then applied, the disks enter the cells, and force out the moulded cakes of litmus.

It appears from Gélis' experiments, that any of the lichens which serve for the production of orchil may be used in the preparation of litmus.¹

The urine serves for the production of carbonate of ammonia, and the lime employed abstracts the carbonic acid.

Fig. 174.

Moulds used in making Litmus.

a. The lower or cell-piece.

b. The upper piece.

The Dutch manufacturers add chalk or sulphate of lime, and some siliceous or argillaceous substance, to give body and weight to the litmus. Indigo is also introduced, doubtless for the purpose of increasing the blue colour of the cakes.

DESCRIPTION.—Litmus is imported from Holland, in the form of small, rectangular, light, and friable cakes of an indigo-blue colour. Examined by the microscope we find sporules, and portions of the epidermis and mesothallium of some species of lichen, moss leaves, sand, &c. The odour of the cakes is that of indigo and violets. The violet odour is acquired while the mixture is undergoing fermentation, and is com-

mon to all the tinctorial lichens. It has led some writers into the error of supposing that the litmus-makers use Florentine orris in the manufacture of litmus. The indigo odour depends on the presence of indigo in the litmus cakes.

COMPOSITION.—An accurate and complete analysis of litmus is yet a desideratum. In 1840, Dr. Kane² submitted it to examination, and obtained from it four colouring principles, to which he gave the names of *erythrolein*, *erythrolitmine*, *azolitmine*, and *spaniolitmine*. These, in their natural condition, are red, and the blue of litmus, he says, is produced by combination with a base. "There are, properly speaking," he adds, "only two characteristic colouring matters in litmus—the erythrolitmine and the azolitmine; for the erythrolein is coloured crimson purple only by alkalies, and the spaniolitmine occurs but very seldom. In the litmus of commerce these colouring substances are combined with *lime*, *potash*, and *ammonia*, and there is mixed up in the mass a considerable quantity of *chalk* and *sand*."

Gélis³ has published some interesting observations on litmus. He says that litmus owes its colour to *four different coloured products*, which he designates by the letters A, B, C, and D. The ash of litmus he found to contain *carbonate of potash*, *carbonate or sulphate of lime*, *alumina*, *silica*, *traces of oxide of iron*, *chlorine*, *sulphuric acid*, and *phosphoric acid*.

I shall provisionally call the proper colouring matter of litmus derived from the lichen, *lichen-blue*.

LICHEN-BLUE; *Litmus Blue*. By these terms I understand the peculiar blue colouring matter of litmus, which is soluble in water, and is reddened by acids. It is probably either some modification of *orceine*, or some allied principle. It may perhaps be a mixture or compound of several colouring principles.

It is soluble in both water and spirit, yielding a coloured solution, which, in the concentrated state, has a purple colour when viewed by transmitted light; but in the dilute state it is pure blue. Viewed by transmitted candle-light it has a reddish colour. An aqueous infusion of

¹ Ferber saw the *Rocella* lichen used at Amsterdam. Morelot stated that *Variolaria orcina* yielded it. Nees and Ebermaier (*Handb. d. Med. Pharm. Bot.* Bd. i. S. 49); and Thomson (*Org. Chemistry*, p. 241), on the other hand, say that *Lecanora tartarea* is employed.—An orchil-maker, under my care in the London Hospital, told me that he had been accustomed to make litmus of pipe clay, starch, soda, and orchil liquor; and he gave me some specimens of it thus prepared. Gélis prepared it with *Rocella tinctoria* (in the scutelliferous state), *Rocella fuciformis*, and the mixture of *Lecanora parella* & *pallidescens*, and *Isidium corallinum*, sold under the name of *Orseille d'Auvergne*; but the last-mentioned plants yielded a less fine product than the others.

² *Phil. Trans.* for 1840, p. 298.

³ *Journ. de Pharmacie*, t. xxvii. p. 483, 1840.

litmus neither reddens turmeric paper nor occasions a precipitate with a solution of chloride of calcium. It contains, therefore, no free alkali or alkaline carbonate.

It is reddened by acids; and also by many of the metallic salts—as corrosive sublimate, sulphate of copper, sulphate of iron, &c. The infusion of litmus, which has been reddened by acids, has its blue colour restored by alkalis, alkaline earths, the alkaline and earthy sulphurets, the alkaline carbonates, the soluble borates, the tribasic phosphate of soda, the alkaline cyanides, &c.

An infusion of litmus is decolorized by chlorine and by the alkaline hypochlorites. Certain deoxidizing agents also deprive it of colour; as sulphuretted hydrogen, hydrosulphuret of ammonia, sulphurous acid, the hyposulphites, nascent hydrogen (obtained by adding hydrochloric acid and zinc to an aqueous infusion of litmus), and the protosalts of iron. If an infusion of litmus be left in contact with sulphuretted hydrogen, in a well-stopped bottle, for a few days, the liquid is decolorized, but reacquires its colour by exposure to the air or oxygen gas.

CHARACTERISTICS.—The lichen-blue is an aqueous infusion of litmus, is distinguished from other vegetable blues by the action of acids and alkalies on it (see *supra*); for most vegetable blues and purples (as red cabbage juice, syrup of violets, &c.) are changed to green by alkalies, whereas, lichen-blue does not undergo this change.

If a lump of moistened litmus be laid on turmeric paper, the latter is reddened by it; but by the application of heat the redness disappears.

When litmus cakes are thrown into diluted hydrochloric acid, a copious effervescence ensues, and a solution of chloride of calcium is obtained.

If a cake of litmus be ignited in the outer cone of the flame of a candle, a whitish violet tint is communicated to the flame, indicative of the presence of potash.

If the ashes of litmus be thrown into diluted hydrochloric acid, violent effervescence takes place; a solution of chloride of calcium is obtained, and a quantity of siliceous sand remains undissolved.

IMPURITIES.—Inferior samples of litmus (including all those usually found in English commerce) contain indigo,¹ the presence of which in litmus cakes is proved by their odour; by the coppery lustre which they acquire when rubbed with the nail; by digesting them in oil of vitriol, by which a blue solution of sulphate of indigo is obtained; and by heating them in a watch glass or platinum capsule, by which indigo-vapour (characterized by its well-known odour and reddish violet colour) and crystals of indigo are obtained.

USES.—Litmus is employed as a test for acids and alkalies. The former communicate a red colour to blue litmus: the latter restore the blue colour of reddened litmus. (The action of various salts on litmus has been before stated.) If the litmus present be reddened by an unboiled, but not by a boiled, water, we may infer that the acid present is a volatile one; probably carbonic acid, or perhaps sulphuretted hydrogen. Reddened litmus may have its blue colour restored not only by alkalies, &c., as before mentioned, but also by carbonate of lime dissolved in water by a considerable excess of carbonic acid.

1. **TINCTURA LACMI**; *Tincture of Litmus*. (Litmus *one part*; Distilled Water *twenty-five parts*. M.)—Though called *tincture*, it is in reality an *infusion* of litmus. In order to preserve it, a portion (about $\frac{1}{10}$ th part) of spirit may be added to it. If required to be more concentrated, the proportion of litmus should be augmented. Some persons first bruise the litmus in a mortar, and then tie it up in a linen bag before steeping it in the water. By keeping in a closely-stopped bottle, its blue colour disappears, but is shortly restored on the admission of atmospheric air.

2. **CHARTA EXPLORATORIA CÆRULEA**; *Blue Test Paper*; *Blue Litmus Paper*.—This is prepared by dipping slips of paper in a strong and clear infusion of litmus; or by brushing the infusion over the paper.

Bibulous or unsized paper is usually preferred, on account of the facility with which it imbibes the liquid to be tested; and also because the alum which frequently enters into the composition of the size affects the colour of litmus. Professor

¹ See two papers by the author in the *Pharmaceutical Journal*, vol. ix. p. 12, 1849; and vol. x. p. 325, 1850.

Graham, however, recommends good letter paper; or, if the infusion is applied to one side only, thin and sized drawing paper. Faraday¹ recommends the infusion to be prepared from an ounce of litmus and half a pint of hot water. The Prussian Pharmacopœia of 1827 orders one part of litmus and four parts of water. Others employ one part of litmus and six parts of water.

In order to obtain *extremely delicate* test paper, the alkali in the litmus is to be almost neutralized by a minute portion of acid. To effect this, divide the filtered infusion of litmus into two parts; stir one portion with a glass rod which has been previously dipped into very dilute sulphuric acid, and repeat this until the liquid begins to look reddish: then add the other portion of liquid, and immerse the paper in the mixture.

Good litmus paper should be uniform in its colour, and neither very light nor very dark. When it has a purplish tint, it is a more delicate test for acids than when its colour is pure blue. When carefully dried, it may be preserved by wrapping it in stiff paper, and keeping it in well-stopped vessels in a dark cupboard or drawer.

Books of test papers, bound up like bankers' cheque-books, are sold in the shops, and are very convenient. They are about $1\frac{3}{4}$ inches long and $\frac{3}{8}$ ths of an inch wide. To preserve them they are kept in leathern cases.

Blue litmus paper is used to detect the presence of acids and of certain salts which react as acids.

§. **CHARTA EXPLORATORIA RUBEFACATA; Reddened Test Paper; Red Litmus Paper.** This is prepared with an infusion of litmus which has been slightly reddened by an acid. Blue litmus paper may be extemporaneously reddened by exposing it for a few seconds to the vapour of acetic acid; but for preserving, it is better to prepare the paper with litmus which has been reddened by a minute portion of dilute sulphuric acid: the acetic acid being objectionable, on account of its volatility.

Red litmus paper is employed as a test for alkalies and certain salts (see *supra*), which react as bases.

2. ORCHILLA.—ORCHIL-LIQUOR.

Two kinds of liquid or thin pulp called Orchil or Archil are met with: one termed *blue orchil*, the other *red orchil*. They are prepared as follows: *blue orchil* is procured by steeping the lichens before mentioned (see pp. 70 and 71) in an ammoniacal liquor in a covered wooden vessel. *Red orchil* is made with the same liquor in common earthen jars placed in a room heated by steam, and called a *stove*. In one manufactory which I inspected, the ammoniacal liquor was prepared by distillation from a mixture of lime, impure muriate or sulphate of ammonia obtained from gas-works, and water; but some makers still employ stale urine and lime. Both kinds of Orchil sold in the shops are liquids of a deep reddish purple colour and an ammoniacal smell. Red and blue orchils differ merely in the degree of their red tint.

According to Dr. Kane, Orchil consists of *orcein*, *erythroleic acid*, and *azorythrine*. To these must be added *ammonia*.

Orchil is employed merely as a colouring agent. It is used for dyeing, colouring, and staining. It is sometimes used as a test for acids.

3. CUDBEAR.

Cudbear is called by the Germans *Persio*.¹ The manufacture of this pigment was begun at Leith about the year 1777, by the late Mr. Macintosh of Glasgow, under the management of Dr. Cuthbert Gordon. From the latter gentleman's name the term *cudbear* (at first *Cuthbert*) originated.

¹ *Chemical Manipulation*.

² The word *persio* is probably derived from *persica*, on account of the resemblance of the colour of cudbear to that of a peach.

It is procured in the manner of Orchil, by the mutual action of some of the colorific lichens, air, and an ammoniacal liquor. *White Swedish* or *tartareous moss* (*Lecanora tartarea*) was formerly chiefly used in its manufacture. When the proper purplish red colour has been developed, the mixture is dried in the air and reduced to powder.

I have found in the shops two kinds of powder of cudbear, one called *red cudbear*, the other *blue cudbear*. Both are purplish red—but one is redder than the other. I have likewise met with *red* and *blue cudbear pastes*: but the term Orchil might with more propriety apply to these.

Cudbear is employed as a purple dye for woollen yarn; but the colour which it yields is fugitive. It is sometimes used for colouring pharmaceutical preparations; and it may be employed also as a test.

Cudbear paper is sometimes used as a test for acids and alkalies. "A paper prepared from an infusion of the best cudbear, without the addition of either alkali or acid, has a purple colour, and is affected by both acids and alkalies. It is convenient in alkalimetry, being already too red to be sensibly affected by carbonic acid, while it is distinctly reddened by the mineral acids."¹

Fig. 175.

*Lecanora tartarea*.

ORDER III. FUNGI, *Juss.*—FUNGALS.

FUNGACEÆ, *Lind.*

CHARACTERS—Plants consisting of a congeries of cells or filaments, or both variously combined, increasing in size in the more perfect species by addition to their inside, their outside undergoing no change after its first formation; chiefly growing upon decayed organic substances, or soil arising from their decomposition, frequently ephemeral, and variously coloured, never accompanied, as in Lichens, by reproductive germs of a vegetable green called gonidia; nourished by juices derived from the matrix. *Fructification* either spores attached externally, and often in definite numbers, to the cellular tissue, and frequently on peculiar cells called *sporophores* or *basidia*, which are in many cases surmounted by fine processes which immediately support the *spores*, and called *spicules* or *sterigmata*; or inclosed in membranous sacs or *asci*, and then termed *sporidia* (*Berkeley*, in *Lindley's Vegetable Kingdom*).

PROPERTIES.—Variable: we have esculent, medicinal, and poisonous species; and unfortunately there are no anatomical characters by which the poisonous are to be distinguished from the edible fungi.

They are remarkable for containing a very large proportion of water; and for their dry matter being rich in nitrogen and phosphates. Among their proximate constituents are several elementary principles (e. g. albumen, sugar, mannite, and mucilage), and some poisonous ones (*ergotin*, *tremellin*, and *amanitin*). The substance called *fungin*, formerly considered to be a nutritive principle, appears to agree with cellulose in its nature.

Sub-order I. GYMNOYCETES, *Endl.*

CONIOMYCETES, *Fries.*

CHARACTERS.—*Sporidia* naked (without any hymenium, peritheciun, asci, or sporidiferous flocci), produced beneath the epidermis of plants or within the matrix (*Fries*).

PROPERTIES.—No medicinal substances are obtained from this sub-order. The *yeast plant*, which *Turpin* refers to the genus *Torula* (from *torus*, a twisted cord), is more probably an imperfect mucedinous fungus, and as such will be noticed hereafter (see sub-order *Hyphomycetes*). The *ergot-mould*, called, by the late Mr. E. J. Quekett, *Ergotetia abortifaciens*, and referred to this sub-order, is considered by *Link* and some other authorities to be a species of *Oidium*, and as such will be noticed subsequently (see sub-order *Hyphomycetes*).

¹ *Graham, Elements of Chemistry*, p. 925.

Sub-order II. HYPHOMYCETES, *Fries.*

CHARACTERS.—*Flocci* sporidiferous, naked (*Fries*).

PROPERTIES.—To this sub order (which is closely allied to *Conservaceæ*, p. 51.) are referred the yeast plant, the ergot-mould, mother of vinegar, and some other plants interesting alike to the physician and pharmacist.

15. FERMENTUM CERVISIÆ.—BARM or YEAST.

(*Cerevisiæ Fermentum*, *L. D.*)

HISTORY.—Leaven and ferment have been known from the most remote periods. *Leaven* (or *sour dough*), called in Hebrew *seor*,¹ and *ferment*, termed in Hebrew *khametz*,² are both referred to in the Old Testament: the one applies to solids, the other to both solids and liquids. In the common version, however, both these Hebrew words are translated leaven.³ The Greeks appear to have used the term ζύμη in a general sense, to include both leaven and ferment. Dioscorides⁴ speaks of the medical properties of the *leaven of wheat* (ἄλευρων ζύμη), which Galen⁵ and Paulus⁶ simply call ζύμη. Pliny⁷ distinguishes *leaven* (*fermentum*) from *beer yeast* (*spuma cervisiæ*).

The history of the discovery of the vegetable nature of yeast is an interesting subject of inquiry. So long since as the year 1680, Leeuwenhoek⁸ described and figured the globules of beer-yeast. He was fully aware of its vegetable nature, but was ignorant of its power of vegetating or growing, and notwithstanding the high magnifying power which he used, he failed to detect the presence of the granules or nuelei in the interior of the yeast-cells.

In 1826, Desmazières⁹ published some observations on Persoon's genus *Mycoderma*, which he defined anew, and referred to Gaillon's class of infusory animals, called *Nemazozaria* (now placed among Algæ). He described a *Mycoderma vini*, *glutinis farinulæ*, *multi-juniperini*, *multi-cervisiæ*, and *cervisiæ*. The latter is frequently considered to be the yeast-plant; but Desmazières confounded two things which deserve to be considered entirely distinct, namely, the yeast-plant, properly so called (the *Torula Cerevisiæ* of Turpin), and a larger filamentous confervoid plant, to which more strictly the name of *Mycoderma Cerevisiæ* of Desmazières should be confined.

To Cagniard-Latour is due the credit of establishing the real nature of yeast. During the years 1835 and 1836, he communicated to the *Société Philomathique* some researches on ferments, which were published in the journal called *l'Institut* (Nos. 158, 159, 164, 165, 166, 167, 185, and 199); and on the 12th of June, 1837, he presented to the Academy of Sciences his *Mémoire sur le Fermentation Vineuse*, a notice of which appeared in the *Comptes Rendus* of that period. The report¹⁰ on this memoir, drawn up by Turpin, in the name of himself, Thenard, and Becquerel, was made to the Academy in July, 1838 (*Comptes Rendus*); and the memoir itself was printed in the 68th volume of the *Annales de Chimie et de Physique*, 1838.

About the same time, Schwann¹¹ was occupied in investigations on this sub-

¹ Hence the German *sauer* and English *sour*.

² The sour fermented mare's milk used by the Tartars appears to have derived its name, *koumiss*, from the Hebrew *khametz*.

³ In *Exodus*, xiii. 7, the terms *seor* and *khametz* occur together, and are evidently distinct. "Unleavened things (*matzah*) [ἄζυμα] shall be consumed during the seven days, and there shall not be seen with thee fermented things [ζυμωτόν], and there shall not be seen with thee leavened mass [ζύμη]."—(*Biblical Cyclopædia*, vol. ii. pp. 236-7.) The interpolated Greek words are from the Septuagint.

⁴ Lib. ii. cap. 107.

⁷ *Arcana Naturæ delecta*, p. 1, et seq. ed. nov. Lugd. Bat. 1722.

⁸ Desmazières's observations were first published at Lisle. They were afterwards reprinted in the *Annales des Sciences Naturelles*, t. x. p. 42, 1827.

⁹ A translation of this report appeared in Jameson's *Edinburgh New Philosophical Journal*, vol. xxv.

¹¹ Poggendorff's *Annalen der Physik*, Bd. xli. p. 184, 1837.

ject, but his observations were not published until 1837. He denied that the organized being found in fermenting liquids is one of the infusoria, as Desmazières had supposed, but asserted that it is undoubtedly a plant, and that it has great resemblance to many jointed fungi. Meyen, who examined it at Schwann's request, agreed as to its vegetable nature, and considered that the only doubt which could exist respecting it was, whether it was an algal or a fungus, but its deficiency in green pigment led him to regard it as a fungus. The filamentous fungus found in saccharine solutions which are undergoing fermentation, Schwann, therefore, proposed to call the *sugar-fungus* (Zuckerpilz). Meyen¹ adopts Schwann's proposal, and refers to three species of *Saccharomyces*, viz., *S. vini*, *S. cerevisiæ*, and *S. pomorum*.

In 1837, Kützing² described and figured the yeast-plant.

On the 20th of August, 1838, Turpin³ read to the Academy of Sciences at Paris, his valuable *Mémoire sur la Cause et les Effets de la Fermentation Alcoolique et Acteuse*.

The notion that yeast was an organized being, in fact a living plant, was at first strongly opposed by Berzelius and Liebig;⁴ but was soon adopted by the eminent chemist Mitscherlich.⁵

BOTANY.—The substance called yeast is a mass of microscopic cryptogams.

The organization and vitality of yeast are demonstrated by the *form* and *structure* of its particles, as determined by the microscope; by their *chemical composition*; by their *reproductive power*, as proved by the generation of yeast during the fermentation of beer; and lastly, by the *effects* of mechanical injuries,⁶ of heat and cold,⁷ and of chemical and other poisons.⁸

Kützing,⁹ who is a believer in the convertibility of some of the lower algals into species, or even genera, of a higher organization, is of opinion that yeast is an algal in its lowest, but a fungus in its highest, grade of development.

It is more probable, however, that this plant is a fungus in all stages of its existence; and that what we know as yeast is either a mass of sporidia or the separated joints of the spawn or mycelium of a fungus whose more perfect state is at present undetermined, but which is probably a mucedinous fungus, perhaps allied to *Penicillium*. In the present state of uncertainty, I have thought it preferable to designate

¹ *Report on the Progress of Vegetable Physiology during the year 1837*, translated by W. Francis, pp. 83-84, London, 1839.

² *Journal für praktische Chemie*, Bd. xi.

³ *Mémoire de l'Académie Royale des Sciences*, t. xvii. 1840.

⁴ In Liebig's *Annalen der Pharmacie*, vol. xxix. p. 100, 1839, a satirical paper (*The Mystery of Vinous Fermentation unfolded*) was published, representing yeast to be an infusory animal which fed on sugar, and evinced by the alimentary canal spirit of wine, by the urinary organs carbonic acid! In his *Chemistry in its Application to Agriculture and Physiology*, edited by Dr. Playfair, 2d edition, 1842, Liebig declares yeast to be a body in a state of decomposition, and states that the idea of its reproducing itself, as seeds reproduce seeds, cannot for a moment be entertained. But in the third edition of his *Animal Chemistry* (edited by Dr. Gregory, 1846) he does not attempt to deny the vegetable nature of yeast, though he thinks that investigation into the nature of this substance is not yet completed.

⁵ See the *Report of the Academy of Sciences at Berlin* for February 1843, quoted in the translation of Link's *Report on the Progress of the Physiological Botany*, published by the Ray Society, p. 425, 1846.

⁶ A very curious fact was mentioned to me by the importer of German and Dutch yeast, in Finch-lane, Cornhill, London: it is, that mechanical injury kills or destroys yeast. Foreign yeast is imported in bags, and of these great care is requisite in their removal from place to place. If they be allowed to fall violently on the ground, the yeast is spoiled. A bruise, as a blow given to the bag, also destroys it. The men who make up the dried yeast into quarter-pound and half-pound balls for sale, are obliged to handle it very dexterously, or they injure and destroy it. In fact, falls, bruises, or rough handling, kill it, and the yeast which has thus been mechanically injured may be readily distinguished from good, unaltered yeast. Its colour becomes darker, somewhat like the change which an apple or pear undergoes when it becomes rotten; and, from being crumbly or powdery, it becomes soft, glutinous, sticky to the fingers like flour-paste, and soon stinks. I have submitted some of this injured or dead yeast to microscopical examination, but have been unable to detect any difference in its appearance from healthy yeast. The effect of mechanical injuries is also noticed by several writers. Thus Liebig (*Chemistry in its application to Agriculture*, by Dr. Playfair, p. 286, 3d ed. 1842) remarks that simple pressure diminishes the power of yeast to excite vinous fermentation.

⁷ Boiling for a short period injures, and for a long period destroys, the power of yeast to excite fermentation (Berzelius). Cold interrupts fermentation, apparently by rendering the yeast-plant torpid.

⁸ The power of yeast to excite vinous fermentation is arrested or destroyed by alcohol, acids, alkalis, various salts (chloride of sodium, bichloride of mercury, nitrate of silver, &c.), volatile oils, excess of sugar, &c. (See Berzelius and Liebig; also, Quevenne, in the *Journ. de Pharmacie*, t. xxiv. p. 3334, 1838.)

⁹ The following are, according to Kützing, the generic and specific characters of the *Yeast-plant*, which he calls *Cryptococcus Fermentum*, and refers to *Mycophaceæ* (Pilztauze), a sub-order of Algæ.

CRYPTOCOCCUS.—Mucus hynline globules, collected in an intermedial mucous stratum.

C. Fermentum.—Submersed: globules elliptical, solid, in the centre 1- or 2-punctate.

nate it by its more classical name (*Fermentum Cerevisiæ*) than to adopt any of the following botanical names, which have been given to it: *Mycoderma Cerevisiæ*, Desmazières; *Torula Cerevisiæ*, Turpin; *Cryptococcus Fermentum*, Kützing; *Saccharomyces Vini et Cerevisiæ*, Schwann and Meyen. For while Myeoderma is a spurious genus (Fries and the Rev. M. J. Berkeley), the yeast-plant has been declared, by an eminent fungologist, to be certainly no *Torula*; and as Kützing's notion of its algeaceous nature is not admitted by botanists, his name of *Cryptococcus Fermentum* is scarcely admissible for it.

The Yeast-Plant.

i. Lateral branches composed of two joints.
l. An individual whose cell had evolved two branches.
The more or less small intermixed cells or granules are probably abortive.

When submitted to microscopic examination, yeast is found to consist of globose, or more or less ovoidal, ellipsoidal, or somewhat pyriform, transparent, nucleated cells, varying in size from $\frac{1}{7500}$ th to about $\frac{1}{2500}$ th of an English inch. The nucleus appears to me to consist of a mass of granules or nucleoli of unequal size: some of the larger ones are highly refractive, and probably contain oily or fatty matter. The nucleoli are called by Turpin, *globuline*.

Turpin spent a night in a brewery to examine the changes which the yeast under-

goes during the fermentation of beer. The fresh yeast had the appearance indicated in Fig. 176. In one hour after it had been added to the wort, he says that germination had commenced; the maternal cells had produced one or two buds or young cells (see Fig. 177). In three hours many of the cells were didymous, or double, the buds having attained the size of the maternal cells, and some of them had themselves begun to produce other buds or young cells (see Fig. 178). In eight hours the cells were arranged in rows, forming moniliform mucedinous plants, composed of several cells or joints, which varied somewhat in diameter and shape. Terminal, and in some cases lateral, buds or young cells were observed, showing that the plants were about to ramify. Some of the smaller rows were seen to explode and emit a fine powder, consisting of minuter globules (see Fig. 179). Turpin placed some yeast-cells in an aqueous solution of sugar, and in three days observed that jointed filaments, with lateral branches, were produced (see Fig. 180).

I have myself examined yeast at Messrs. Hanbury and Buxton's brewery at various stages of the fermentation of both porter and ale, from a few hours to many days. In the more advanced stages of fermentation, I observed the globules of yeast were frequently in strings, or rows, apparently forming moniliform often branched plants. But as the cells or joints were very readily separable, I could not satisfy myself that the adhesion was otherwise than mechanical, such as we see between the blood-disks when they arrange themselves in series like money-rolls, and such as we sometimes perceive even in inorganic amorphous precipitates. My experience agrees precisely with that of Schlossberger,¹ who states that he "never could perceive a budding or bursting of the yeast-cells, accompanied by a discharge of their contents, nor could I ever produce this by compression. These curious braehial and other adjustments of the cells of yeast to each other, appeared to me the work of chance." It is, however, proper to add, that the artificial rupture of the cells has been effected by Mitscherlich, who also confirms Turpin's observation of the budding of the yeast-cells (see p. 84).

ORIGIN.—It is well known that a pure solution of sugar will not undergo fermentation when exposed to the air, but a saccharine vegetable juice, which contains albuminous matter (as the juice of the grape), suffers spontaneous fermentation, and this process always begins with the formation of yeast-cells.

By some it is assumed that these arise from yeast-germs floating in the air, and which, meeting with a fit receptacle for their development in the vegetable juice, germinate and grow, and effect vinous fermentation. By others their production is ascribed to a *generatio primitiva*.

Turpin was of opinion that there are three sources or modes of production of the yeast-plant: 1st, the transformation of globuline into yeast-cells; 2dly, budding, or the separation of the joints of moniliform stems; 3dly, the escape of spores (*globulins seminulifères*) from the interior of the cells: Mitscherlich admits the two latter modes of growth.

The amylaceous particles contained in the cells of the albumen of barley (see Figs. 181, 182) are called by Turpin *globuline*. The transformation of these into yeast-cells is, according to the same authority, the primitive origin of beer yeast. Dr. Lindley²

Fig. 181.

Cell from the albumen of barley, containing starch grains, called by Turpin *globuline*.

Fig. 182.

Turpin's *globuline* of barley.

¹ *Pharmaceutical Journal*, vol. v. p. 131, 1845.

² *Introduction to Botany*, p. 113, 4th ed. 1848.

partly confirms Turpin, for he states that he has seen these smaller granules sprout during fermentation; and he adds, that they have at that time lost all their starch, for iodine produces no sensible effect upon their colour.

Turpin states that 35 lbs. of dried or pressed yeast produced during the brewing of 5700 litres [about 14 butts] of beer 247 lbs. of dried or pressed yeast: that is, an actual increase of 212 lbs. of new yeast.

In the deposit from the porter refrigerator of Messrs. Truman and Hanbury's brewery, I have observed the forms deposited in Fig. 183, *c*, *d*, *e*, and *f*. These constitute the plant called by Desmazières the *Mycoderma Cerveisæ*.

OCCURRENCE IN THE HUMAN BODY.—Yeast-cells have been found in the human body. Hannever detected them in the black coating of the tongue of a typhoid patient. They have also been discovered in the liquids of the œsophagus, stomach, and intestine. In some cases, probably, they may have been introduced by the beer drank by the patient; but, in other cases, their presence could not be accounted for in this way. As they are developed in the urine of diabetic patients, their occurrence in urine has been supposed to indicate the existence of sugar, but they have been found also in non-saccharine urine.¹

DESCRIPTION.—In commerce, three varieties of yeast are known and distinguished. These are, brewers' yeast, dried yeast, and patent yeast.

Fig. 183.

Mycoderma Cerveisæ.
Desmazières.

1. *Brewers' yeast.*—In breweries, two kinds of yeast may be distinguished, namely, *upper* or *top yeast*, and *lower* or *bottom yeast*. These have been described by Mitscherlich.²

Top yeast consists of large cells, at the extremities of which small ones are developed. It appears, therefore, to be produced by buds. In Berlin, the most beautiful top yeast is obtained at a temperature of 77° F.

Bottom yeast consists of cells of various sizes, without any small globules attached to the large ones. It appears to be produced by the growth of small isolated granules (spores?), which Mitscherlich thinks have escaped from the yeast-cells which have burst and disburthened themselves of their contents. Bottom yeast is multiplied at a lower temperature than top yeast: Mitscherlich says, that the bottom ferment of Bavarian beer is produced at a temperature which must not exceed 48° F. nor go below 32° F. The bottom yeast sold at breweries is generally impure.

Brewers and bakers distinguish yeast according to the quality of the beer from which it is obtained. *Ale yeast* is the best and strongest; and is used for bread-making. *Porter yeast* is objected to by bakers, but is used in distilleries.

Small-beer yeast is said to be weak, but rapid in

its effects, and is sometimes used in making rolls.

2. *Dried yeast.*—Under this name is sold a granular or pasty mass of yeast-cells, which have been separated from mechanically admixed solids, as well as from the supernatant fermented liquid, probably by filtration through linen cloths and subsidence. That which is sold in London is imported from Holland, Belgium, and Germany, and is commonly called *German yeast*. It comes over in hempen bags,

¹ *Des Végétaux qui croissent aux l'Homme et sur les Animaux*, par M. Ch. Robin, Paris, 1847.

² Poggend. Ann. lix.; also, *Chem. Gazette*, vol. i. p. 568, 1843.

each holding half a hundred weight. If transported in casks it is apt to burst them, unless they are strongly iron-bound, by the quantity of carbonic acid which it evolves.

3. *Patent yeast*.—This might with more propriety be called *artificial yeast*. It is a watery liquid, containing yeast-cells, and which has usually been prepared purposely by the fermentation of an infusion of malt and hops. The hops probably contribute to prevent the liquid becoming rapidly sour. Turpin thinks that their oil may act as a stimulant in the development of the yeast-plant. I am informed by a baker that he prepares patent yeast for bread-making by mashing half a peck of ground malt with six gallons of water at 170° F.; then boiling the wort with half a pound of hops; and to the cooled liquid adding some brewers' yeast. In 24 hours the patent yeast is fit for use.¹ It rapidly turns sour in warm weather; and I am informed that bread made with it does not keep so well as that prepared with other kinds of yeast. It is in general use among bakers, especially those who use an inferior kind of flour.

Mr. Fownes² describes the following mode by which he prepared some artificial yeast: "A small handful of ordinary wheat-flour was made into a thick paste with cold water, covered with paper, and left for seven days on the mantle-shelf of a room where a fire was kept all day, being occasionally stirred. At the end of that period three quarts of malt were washed with about two gallons of water, the infusion boiled with some hops, and when sufficiently cooled, the ferment added. The results of the experiment were a quantity of beer (not very strong, it is true, but quite free from any unpleasant taste), and at least a pint of thick barm, which proved perfectly good for making bread."

COMPOSITION.—Yeast has been analyzed by Marcet,³ by Dumas,⁴ by Mitscherlich,⁵ by Mulder,⁶ and by Schlossberger.⁷

It consists of two parts, the *cell-walls*, composed of a kind of *cellulose*, and the *contents of the cells*, composed of a *proteine substance*, and probably *fat*, or *oil*.

1. **CELL-WALLS**.—By digesting yeast in a weak solution of potash, the contents of the cells are removed, and the membranous matter composing the cell-walls is left. In its composition it approximates to *cellulose* or *starch*.

	Atoms.	Eq. Wt.	Per Cent.	Mulder.	Schlossberger.	
					With chromate of lead.	With oxide of copper and chromate of potash.
Carbon	12	72	44.44	45.00	45.45	45.09
Hydrogen	10	10	6.17	6.11	6.87	6.60
Oxygen	10	80	49.38	48.88	47.68	48.31
Cellulose of yeast	1	162	99.99	100.00	100.00	100.00

2. **CONTENTS OF THE CELLS**.—According to both Mulder and Schlossberger, yeast-cells contain a substance allied to the *proteine* bodies.

	Mulder.	Schlossberger.	
Carbon	43.35	55.53	55.53
Hydrogen	6.56	7.50	7.50
Nitrogen	12.68	14.01	13.75
Oxygen	37.41	22.96	23.22
	100.00	100.00	100.00

Besides traces of *phosphorus* and *sulphur*.

Mulder regards the contents of the cells as being the *hydrated oxide of proteine*, $C^{40}H^{31}N^5O^{26} = C^{40}H^{31}N^5O^{12} + O^8 + 6HO$.

¹ Various receipts for making yeast are given in Webster's *Encyclopædia of Domestic Economy*, p. 760.
² *Pharmaceutical Journal*, vol. ii. p. 403, 1842.
³ Quoted by L. Gmelin, *Handb. d. Chem.* Bd. ii. S. 1100.
⁴ *Traité de Chimie appliquée aux Arts*, t. vi. p. 316, 1843.
⁵ *Lehrbuch d. Chemie*, 4 Aufl. S. 370 (quoted by Schlossberger).
⁶ *The Chemistry of Vegetable and Animal Physiology*, translated by Dr. Fromberg, p. 48; also, *Pharm. Central Blatt für 1844*, S. 891.
⁷ *Ann. d. Chem. u. Pharm.* Bd. li. S. 193, 1844; also, *Pharm. Journal*, vol. v. p. 42, 1846.

It is probable that, besides a proteine body, the cells contain a *fatty, or oily substance*. Schlossberger states that he extracted a yellow oil from yeast by means of ether.

3. **ASHES.**—According to Schlossberger, the ashes of upper yeast amounted to 2.5; of lower yeast, to 3.5 per cent.

PHYSIOLOGICAL EFFECTS.—The effects of yeast on the animal economy are, if at all, not very obvious. The constituent of the cell-walls is insoluble, and therefore inert. The contents of the cells may, perhaps, be slightly nutritive. To the evolved carbonic acid have been ascribed the topical antiseptic effects of yeast.

The tonic and laxative effects ascribed to beer yeast, are probably referable to the fermented malt liquor in which the yeast-cells are usually contained and exhibited (see *Wort*).

USES.—Yeast is employed both for medicinal and chemical purposes.

As a medicine, yeast has been used both internally and externally. Internally, it has been administered as a tonic and antiseptic in typhoid fevers. Dr. Stoker states, that it usually acts as a mild laxative, improves the condition of the alvine evacuations, and is more effectual in removing petechiæ and black tongue than any other remedy. It is admissible where cinchona and wine cannot be employed, on account of the inflammatory symptoms. The dose of it is two tablespoonfuls every third hour, with an equal quantity of camphor mixture. Enemata of yeast and assafœtida are said, by the same writer, to be efficacious against typhoid tympany.

Externally, it has been used in the form of poultice. (See *Cataplasma Fermenti*.)

Yeast is an important agent in panification and brewing. In some cases of dyspepsia, unfermented bread appears to agree better with the stomach than fermented bread, which is supposed to derive an injurious quality from the yeast used in its preparation.

Yeast is sometimes added to liquids to excite the vinous fermentation, and thereby to detect the presence of saccharine matter.

L. Gmelin² employed this test to detect sugar in the animal fluids after the ingestion of amyloceous food. Dr. Christison³ found it so delicate, that he could detect with it one part of sugar in 1000 parts of healthy urine of the sp. gr. 1.030. Messrs. Richard Phillips, Graham, and George Phillips,⁴ used it to detect the presence of saccharine matter in tobacco adulterated with this substance. (For the mode of using this test, see *Saccharum*.)

1. **CATAPLASMA FERMENTI, L.**; *Cataplasma Fermenti Cerevisiæ*; *Yeast Poultice*.—(Yeast, Water heated to 100° F., of each f̄3v; Flour ℥j. Mix the yeast with the water, and add the flour, stirring so that a poultice may be made. Place it before the fire until it swells up.)—It is applied, when cold, to fetid and sloughing sores as an antiseptic and stimulant: it destroys the fetor, often checks the sloughing, and assists the separation of the dead part. It should be renewed twice or thrice a day. I have frequently heard patients complain of the great pain it causes. The carbonic acid is supposed to be the active ingredient.

The following poultices are analogous in their nature and effects:—

2. **CATAPLASMA FÆCULÆ CEREVISIÆ**, Guy's Hospital Ph.; *Poultice of the grounds of beer*.—(Grounds of beer; Oatmeal; as much of each as may be required to make a poultice.)—It is applied cold twice or thrice a day, in the same cases as the preceding preparation, to which its effects are analogous.

This poultice was formerly called⁵ the *discutient cataplasm* or *cataplasma discutiens*, and was applied to disperse tumours.

3. **CATAPLASMA BYNES**, Guy's Hospital Ph.; *Malt-meal and Yeast Poultice*; *Malt Poultice*.—(Malt-meal and Beer yeast; as much of each as may be required to make a poultice.)—This poultice is to be applied warm.

16. OIDIUM ABORTIFACIENS.—THE ERGOT-MOULD.

HISTORY.—Phillipar,¹ in 1837, recognized the joints or sporidia of this fungus on ergot. Phœbus,² in 1838, detected and figured these bodies, but did not consider them to be of a fungie nature. Mr. John Smith,³ of the Kew Garden, in November, 1838, recognized them on various ergotized grasses. He considered them to be the joints of a minute articulated fungus, from whose action ergot resulted. In December, 1838, the late Mr. E. J. Quekett⁴ gave an extended account of this fungus, in a paper read before the Linnean Society. Mr. Quekett named the plant *Ergotætia abortans* (*Ergotætia*, from *Ergot*, and *αἰτία*, *origin*; *abortans*, in allusion to its destroying the germinating power of the grain of grasses, and also to the medicinal powers of ergot). Subsequently, at my suggestion, he substituted the word *abortifaciens* for *abortans*.

Mr. Quekett at first⁵ considered this fungus to belong to the sub-order *Hyphomycetes*, tribe *Mucedines*; but after his paper had been read at the Linnean Society, and was returned to him for correction, he was led to suppose that the fungus belonged to the sub-order *Coniomycetes*, tribe *Sporidesmiei*, because its sporidia were produced beneath the epidermis of the grain. Both Link⁶ and the Rev. M. J. Berkeley consider the ergot-mould to be a mucedinous fungus belonging to the genus *Oidium* (so called from *ὄν*, *an egg*, and *ἴδος*, *resemblance*), and I have, therefore, called it, at the suggestion of the last-named eminent fungologist, *Oidium abortifaciens*. Corda⁷ has recently referred it to the genus *Hymenula*, of the sub-order *Hymenophycetes*, and names it *Hymenula Clavus*.

BOTANY. Gen. Char.—Microscopic. Threads white or brightly coloured, simple or irregularly branched, moniliform above, and breaking up into more or less elliptical spores. (Berkeley in Lindl. *Med. and Econ. Bot.*, p. 14, 1844.)

⁴ *Ibid.*, p. 453. An abridgment of this paper was published in the *Lond. Med. Gaz.* vol. xxiii. p. 606, Jan. 19, 1839.

⁵ See the *Lond. Med. Gaz.* Jan. 19, 1839.

⁶ *Report on the Progress of Physiological Botany in 1841*, published by the Ray Society, p. 91.

⁷ *Beitrag zur Kenntniss der Brandarten der Cerealien und des Mutterkorns*, in the *Oekonomische Neuigkeiten und Verhandlungen*, No. 83, 1846: a periodical publication. I am indebted to the Rev. M. J. Berkeley for the loan of Corda's paper. A copy of Corda's figures, illustrating the structure of the ergot of rye, and of the microscopic appearance of the fungus, will be given hereafter (see *Secale Cornutum*).

Sp. Char.—Threads white, irregularly branched; spores abundant, elliptic, containing two nuclei (Berkeley).

Mr. Quekett's description of the ergot-mould (called by him *Ergotretia abortifaciens*) is as follows: Sporidia elliptical, moniliform, finally separating, transparent, sometimes slightly contracted about their middle, usually containing one, two, or three, but occasionally as many as ten or twelve well-defined greenish granules. They are, on the average, about 1-4000th of an inch long, and 1-6000th of an inch broad. When placed on glass and moistened with water, they readily germinate or produce other plants, though in various ways, as sometimes by emitting tubes (B), by the development of buds (c), and by the formation of septa across their interior (E, F, G, H).

Hab.—Floral envelopes, and ovaria of grasses: Europe, America.

By the growth of these fungi upon or within the ovarium of grasses, a diseased condition of the ovarium, involving the whole of the embryo, and sometimes partially or wholly the albumen, is produced. This disease, called the *ergot* or *spur*, will be described hereafter (see *Secale Cornutum*). Mr. Quekett¹ has shown that the sporidia of this fungus are capable of infecting healthy grains of corn, and of ergotizing them.

PROPERTIES.—The chemical properties and physiological effects of this fungus are at present quite unknown. We have yet to learn whether the peculiar properties of ergotized grasses depend on the fungi, or on the morbid products of the ovarium.

Sub-order III. GASTEROMYCETES, *Endl.*

CHARACTERS—*Sporidia* free within a closed receptacle (*peridium*) collected together in the centre, or immersed and concrete, intermixed with *flocci*, or contained in proper receptacles (*sporangia*).

17. *Elaphomyces granulatus*, *Fries.*—**Granulated Elaphomyces.**

Lycoperdon cervinum, Linn.; *Cervi Boletus*, I. Bauh.; *Elaphomyces officinalis*, Nees; *Tuber cervinum*, Nees; *Boletus cervinus*; *Hart's Truffles*; *Deer Balls*. Sold at Covent Garden Market, as *Lycoperdon nuts*. (*Elaphomyces*, from *ἐλαφός*, a stag; and *μύκης*, a fungus.) Rounded or oblong, from half an inch to two inches in diameter, brown, papillose verrucose, hard. Peridium internally white. Sporidia abundant, globular, black.—Indigenous. Grows underground.

A very complete analysis has been made by Biltz.² The sporidia consisted of a disagreeable odorous volatile substance, soft resin, 0.325; hard resin, 0.052; red colouring matter, uncrystallizable sugar, with fungic ozmazome, 2.708; gum, 2.083; inulin, 8.333; soluble albumen, a trace; fungin, red colouring and albuminous matter, soluble in potash; free vegetable acid, vegetable salts of ammonia, potash, and lime, sulphate and phosphate of lime, chloride of sodium, silica, manganese, and iron. The ashes amount to 1.25. The peridium deprived of its warty coat consisted of yellow rancid, soft fat, 0.33; fungic ozmazome, with crystalline sugar, 12.000; gum, 10.40; albumen, fungin, gummy and albuminous matter, soluble in potash; free vegetable acid, vegetable salts of ammonia and lime, phosphate and sulphate of lime. The ashes amount to 1.1. The warty coat contains yellow, bitter fat, colouring matter, soluble in water and alkalies, but not in alcohol or ether; bitter and other substances, but neither sugar nor inulin. The capillitium contains sugar, but no inulin.

Though still retained in some of the best modern works on medical botany published on the continent, this subterranean fungus is no longer used in medicine, at least in England. As, however, I have met with it in the stock of a London herbalist, I presume at no very long period since it must have been in use. "It was formerly used by apothecaries for the preparation of the bal-

Fig. 185.

Elaphomyces granulatus.

- a. The fruit with the mycelium (nat. size).
 b. Vertical section of ditto.
 c. Sporidia, with flocci of the capillitium (magnified).

² *Trommsdorff's Neues Journ. d. Pharm.* Bd. xi.

samus apoplecticus; and great power was ascribed to it in promoting parturition and the secretion of milk. Even now the country people in some places esteem it as an aphrodisiac, and prepare from it a spirituous tincture."¹ Parkinson² says the dose of it is one drachm and a half in powder, taken with sweet wine, or with such other things as provoke venery.

18. *Lycoperdon giganteum*, Batsch.—Giant Puffball.

LYCOPERDON BOVISTA (GIGANTEUM), Fries; *Bovista gigantea*, Nees.—Sold in the London herb shops as the *Common Puffball*, or simply as *Puffball*.—They are the *Fusseballs* of Parkinson.—In somewhat globular or obconical masses of variable size, sometimes one or two feet in diameter, and usually of a more or less yellow colour. *Peridium* very brittle, bursting in areolæ, evanescent, at length broadly open. *Capillitium* rare, evanescent together with the olive dingy-brown *sporidia*. This species, as well as *Lycoperdon cælatum* of Bulliard, has been used in medicine under the name of *bovista*, *fungus chirurgorum*, and *crepitus lupi*. The spongy capillitium with the sporidia has been employed for staunching blood: thus it has been used as a plug in epistaxis, hemorrhage from the teeth, rectum, &c. The spongy base is employed as tinder. The fumes of this fungus, when burnt, are said to possess a narcotic quality, and have been employed to stupefy bees.

19. *Tuber cibarium*, Sibth.—Common Truffle.

LYCOPERDON TUBER, Linn.; *Tubera*, Tourn.; *Tubera sincera*, Pliny, lib. xix. cap. 11. Dr. Sibthorp (*Floræ Gr. Prodr.* ii. 352) considers it to be the *Ἰδύον* of Diosc. lib. ii. cap. 175: its modern Greek name being *ἰδύον ἢ ἰκύνος*: but Fries, while he admits, on the authority of Sprengel, that it is the *Ἰδύον* of Theophrastus (*Hist. Pl.* lib. i. cap. 9), says it is certainly not the *Ἰδύον* of Dioscorides.³

The truffle of the markets occurs in rough, rounded nodules, varying in size from a filbert to the fist, cracked into small subpyramidal warts. Internally, it is marbled or veined. The white portions are filamentous, and are regarded by the Rev. M. J. Berkeley as constituting a sort of mycelium to the darker portions, which he calls the veins: the latter are cellular, and contain many subovate, shortly pedicellated *sporangia*, at first filled with a granular mass, which is ultimately collected into one or two globular, yellowish echinulate *sporidia*.

Fig. 186.

A truffle (natural size) from which a slice has been cut to expose the internal structure.

Tuber cibarium.

A section of a truffle (magnified).

- a a. Cells.
- b b c. Pedicellated peridiola or sporangia containing sporidia.
- d. A sporidium (or spore) more highly magnified.

In France, three varieties of truffle are known:⁴ the *truffle de Perigord* with black flesh; the *truffle de Bourgogne* with white flesh; and a third sort with violet flesh. The first is the most esteemed, on account of its odour and tenderness.

This fungus grows several inches below the surface of the ground in several parts of England. Covent Garden market is chiefly supplied from the downs of Wiltshire, Hampshire, and Kent. Its odour is peculiar and penetrating, by which its presence is detected. In this country it is usually hunted by dogs trained for the purpose: in Italy, by pigs.

Riègel⁵ analyzed the dried Perigord truffles, and found them to consist of a *brown fat oil* (olein) with traces of *volatile oil*, an *acrid resin*, *osmazome*, *mushroom sugar*, *nitrogenous matter* insoluble

¹ Gleditsch, quoted by Nees v. Esenbeck and Ebermaier, *Handb. d. med. pharm. Botanik*, Bd. i. S. 28, 1832.

in alcohol, *fungic acid*, *boletic acid*, *phosphoric acid*, *potash*, *ammonia*, *vegetable mucus*, *vegetable albumen*, *pectine*, and *fungine* (fungic skeleton).

Truffles are a highly esteemed luxury at the table, being used as a seasoning or flavoring ingredient for ragouts, sauces, stuffings, &c. They are considered to possess aphrodisiac properties; and an Italian physician essayed to prove that births were more numerous in those years which correspond to the more abundant production of truffles!

Sub-order IV. PYRENOAMYCETES.

CHARACTERS.—*Perithecium* indurated, at first closed up, then perforated by a pore or irregular laceration, inclosing a softer nucleus. *Sporidia* immersed in mucus, or inclosed in *asci*, which are attached by their base.

20. *Sphæria Sinensis*, Berk.

Hia Tsao Tom Tchom, Reaumur, Mém. de l'Acad. des Sc. 1726, p. 302, tab 16; *Hia Tsao Tong Tchong*, Du Halde, Descr. Géogr. et Hist. de la Chine, vol. iii. p. 490, 1770; *Totsu Kaso*, Thunberg, Travels in Europe, Asia, &c. between 1770 and 1779, vol. iii. p. 68; *Hiastatomtchom*, Rees's Cyclop.; *Tong Chong Ha Cho*, Reeves; *Summer-Plant-Winter Worm*, Pereira, Pharm. Journ. vol. ii. p. 590, 1843; *Hea Tsaou Taong Chung*, Westwood, Ann. of Nat. Hist. vol. viii. p. 217; *Sphæria Sinensis*, Rev. M. J. Berkeley, in Hooker's Lond. Journ. of Botany, vol. ii. p. 207, 1843.

This remarkable production is a highly esteemed article of the Chinese Materia Medica. It consists of a caterpillar or larva of a lepidopterous insect (probably a species of *Agrotis*), from whose neck projects the fungus, called by the Rev. M. J. Berkeley, *Sphæria Sinensis*.

SPHÆRIA, Fries. *Perithecia* rounded entire, furnished at the apex with a minute orifice. *Asci* converging, at length dissolving.

S Sinensis, Berkeley. Brown; stem cylindrical, somewhat thicker downwards; head cylindrical, confluent with the stem, pointletted.

Fig. 187.

Fig. 188.

Sphæria Sinensis.

Fig. 187, Isolated individual.

Fig. 188, Bundle.

(Natural size.)

Du Halde says that it is produced in Thibet, and also on the frontiers of the province of Se-tchuen, which borders on Thibet, or Laza. It is brought to Canton in bundles tied up in silk (see Fig. 188): each bundle containing about one dozen individuals.

Each individual (see Fig. 187) is about three inches long, half being the caterpillar; the other half projecting from the back of the neck is the club-shaped fungus, attached by slender filaments, which spread over the surface of the larva. The substance of the caterpillar is replaced by a mass of fine branched threads, mixed with globules of oil. In none of the specimens examined by Mr. Berkeley were the perithecia developed.

In China, it is reputed as a strengthening and renovating substance, and is supposed to possess properties similar to those ascribed to ginseng. It is recommended in cases where the powers of the system have been reduced by over-exertion or sickness. But on account of its scarcity it is only used in the palace of the Emperor.

The mode of employing it is curious. The belly of a duck is to be stuffed with five drachms of this fungus, and the animal roasted by a slow fire. The virtue of the fungus is supposed to pass into the flesh of the animal, which is to be eaten twice daily for eight or ten days!

Sub-order V. HYMENOMYCETES.

CHARACTERS.—Spores generally quaternate on distinct sporophores (*basidia*). *Hymenium*, naked.

21. *Exidia Auricula Judæ*, Fries.—Jew's Ear.

Tremella Auricula Judæ, Linn.; *Peziza Auricula*, Linn. This fungus grows on living trees, especially the elder; whence its name *fungus sambuci*, vel *sambucinus*. It is still professed to be kept in the London herb-shops; but in its place, I find that *Polyporus versicolor*, Fries, is usually sold for it. Dr. Martiny¹ states that other species—namely, *Polyporus adustus*, Fries, *Polyporus zonatus*, Fries (especially when this is strongly dried and half charred), and *Dadalea unicolor*, Fries, are substituted for the genuine plant. All these adulterations or substitutions may be readily detected by immersing the dried fungus in water: the genuine *Exidia Auricula Judæ* softens and swells up so as to resume its natural gelatinous condition, whereas the others do not soften in water. It was formerly in repute as a topical astringent and discutient; and was employed in the form of decoction or infusion (made with water, rose-water, vinegar, or milk), and cataplasm made with milk and water. It has been used in sore-throat, sore-eyes, and deafness.² On account of its absorbing and retaining liquids, it has been soaked in collyria and applied to the eyes, as a substitute for sponge.

22. *Morchella esculenta*, Linn.—Common Morell.

Phallus esculentus, Linn; *Helvella esculenta*, Sowerby; *Fungus faginosus*, Lobel., Gerarde, Parkinson; *Merulius*, J. Bauh. Hist. Pl.

This fungus is sold at the Italian warehouses, and at Covent Garden Market, in the dried and shrivelled state; and though a native of this country, is usually imported from the Continent. In the fresh state it is from 2 to 5 inches high, and hollow (see Fig. 189). The stem is white, from 1 to 3 inches long, $\frac{1}{2}$ to 1 inch in diameter. The pileus, which is confluent with the stem, varies in size from that of a pigeon's egg to that of a swan's egg; is deeply pitted or formed in irregular areolæ, divided by anastomosing ribs, and varies in colour from a pale yellowish brown to olivaceous and smoke gray. The *hymenium* covers the whole pileus. The *thece* usually contain five globular spores.

The Morell is a highly-esteemed luxury at table. It usually enters into ragouts or other dishes; but is sometimes cooked by itself, being either stewed, or stuffed and dressed between thin slices of bacon. Though considered to possess nutritive qualities, it is employed at the table as a flavouring ingredient. Virey³ enumerates it among aphrodisiacs.

23. *Polyporus officinalis*, Fries.—Larch Agaric.

SYNONYMES.—*Boletus Laricis*, Jacq., Misc. ii. p. 164; Ph. Boruss. *Boletus purgans*, Pers. Syn. p. 531. *Boletus officinalis*, Villars Delph. p. 1041. *Polyporus Laricis*, Roques.

HISTORY.—This fungus was used by the ancients. It is described by Dioscorides¹ under the name of Ἀγαρικόν. In the modern Greek Pharmacopœia, it is termed Ἀγαρικόν τὸ λευκόν, its Turkish name being Κατράν μανταρί.

BOTANY. Gen. Char.—*Hymenium* concrete, with the substance of the pileus, consisting of subrotund pores with their simple dissepiments. (*Berkeley*.)

Sp. Char.—*Pileus* corky-fleshy, unguulate, zoned, smooth. Pores yellowish (*Fries*).

Hab.—South of Europe and Asia, on the Larch.

COMMERCE.—The best agaric is brought from Asia and Carinthia. A small and inferior kind is collected in Dauphinè. I was informed by the late Mr. Butler, of Covent Garden Market, that the London shops were supplied from Germany.

¹ *Encyklop. d. Naturalien u. Rohrwarenk*, Bd. i. S. 911, 1843.

² For further details respecting it, consult Alston's *Lect. on the Mat. Medica*, vol. i. p. 351, 1770; and Murray, *App. Medicaminum*, vol. v. p. 533.

³ *Bull. de Pharm.* t. v. p. 201, 1813.

⁴ Lib. iii. cap. 1.

Levant Agaric (an inferior sort of which is known at Marseilles by the name of *cucumule*) is exported from Smyrna. The Russian larch agaric, exported from Archangel, is the product of *Larix sibirica*.¹

2. A section of ditto.
3. Thecæ and sporules magnified.

*Polyporus officinalis*.

(Represented as growing on the stem of a tree.)

COLLECTION.—It is collected in the months of August and September, decorticated, dried, and bleached in the sun. Martiny states that it is beaten with wooden hammers to make it soft. But that which I have found in English commerce has neither been decorticated nor beaten.

DESCRIPTION.—This fungus is still kept in the herb-shops, being sold under the name of *agaric*, *white agaric* (*agaricus albus*), or *larch* or *female agaric* (*fungus laricis*). It occurs in masses, varying in size from that of the fist to that of a child's head. The most usual shape which I have found is that of a horse's hoof, or of half a cone (divided by a plane passing through both the apex and the base).² Externally, it is yellowish or reddish gray; internally, it is white. It has a very feeble odour, and a bitter acrid taste. It is liable to be attacked by a beetle, the *Anobium festivum*, Panz.

COMPOSITION.—It has been analyzed by Bouillon-La-Grange;³ by Bucholz;⁴ by Braconnot,⁵ and by Bley.⁶

The constituents, according to Bley, are *resin*, 33.1; *extractive*, 2; *gum and bitter extractive*, 8.3; *vegetable albumen*, 0.7; *wax*, 0.2; *fungic acids*, 0.13; *boletic acid*, 0.06; *tartaric and phosphoric acids*, 1.354; *potash*, 0.329; *lime*, 0.16; *ammonia and sulphur*, traces. The following substances were obtained by the action of caustic potash and hydrochloric acid: *coagulated albumen*, 0.4; *artificial gum*, 15.5;

¹ Martius, in Buehner's *Repertorium*, N. S. Bd. xli. S. 92, 1846.

² The specimen from which Fig. 190 was taken was kindly lent me by the Rev. M. J. Berkeley. I have had it represented as growing on the stem of a tree.

³ *Ann. de Chimie*, t. li. p. 76, 1808; also, Thomson's *Chemistry of Organic Bodies—Vegetables*, p. 939, 1838.

⁴ Berlin, *Jahrbuch für* 1808, p. 111.

⁵ *Bull. de Pharm.* t. iv. p. 304, 1812.

⁶ Trommsdorff's *N. Journ.* 3d. xxv. S. 119, 1832; Martiny, *Encyklop. d. Natur.* S. 909.

artificial resin, soluble in ether, 9.5; residual *fibre* called *fungine* (cellulose), 15; *moisture*, 11, and *loss*, 2.367 = 100.000.

The active principle of agaric has been usually said to reside in the resin; but Martius¹ states that it is a peculiar substance, which he proposes to call *laricin*. This is a white amorphous powder, possessing a bitter taste, soluble in alcohol and oil of turpentine, and forming with boiling water a paste. It has been analyzed by Dr. Will, who found that its formula was $C^{14}H^{12}O^4$.

The *resin* of agaric possesses purgative qualities, and was formerly employed for the adulteration of jalap resin.² It probably contains laricin.

EFFECTS.—Larch agaric is an acrid substance. Its dust irritates the eyes, and causes sneezing, cough, and nausea. When swallowed in the dose of a drachm or two, this fungus excites nausea, vomiting, griping, and purging, and is said to check sweating.

USES.—It has been employed internally as an emetic, cathartic, discutient, and to check colliquative sweating: externally, as an astringent. De Haen reported favourably of it as an anti-sudorific in phthisis, and Barbut confirms his statements. Favourable reports of it were also made by Toel, Nenmann, Kopp, Burdach, Andral, and others. Subsequently, however, Andral has expressed an opinion that little benefit is to be derived from it.

ADMINISTRATION.—The dose of it is from ℥ss to ℥j as a purgative; and from grs. iij to grs. viij, taken before going to sleep, to check sweating.³

24. Polyporus igniarius, Fries.—Hard Amadou Polyporus.

Boletus igniarius, Linn.—An indigenous fungus found on willow, cherry, plum, and other trees, and commonly known by the names of *Agaric of the Oak* (*Agaricus seu Fungus Quercus*; *Agaricus Quernus*), or *Surgeon's Agaric* (*Agaricus Chirurgorum*); *Spunk*; *Touchwood*. Formerly used in surgery as a mechanical styptic, and still retained in some foreign pharmacopœias (e.g. *Pharm. Castrensis Ruthenica*, 1840). It is prepared by decorticating it, cutting it into thin slices, and beating it with a mallet until it has become sufficiently soft. Its action in restraining hemorrhages is mechanical, like lint.⁴ In some places, both it and the following species are employed in the preparation of Amadou or tinder.

25. Polyporus fomentarius, Fries.—Real Amadou.

Boletus fomentarius, Linn.—Another indigenous fungus, found on the oak, birch, and other trees. Its uses are similar to the preceding, and it might, with more propriety, be called *Agaric of the Oak*, or *Surgeon's Agaric*. The substance sold in the shops as *Amadou*, or *German tinder*, is prepared from this, as well as the preceding species, by cutting the fungus in slices, beating it, and then soaking it in a solution of nitre, and afterwards drying it. When impregnated with gunpowder it is called *black amadou*. Amadou, or German tinder, has been recommended by Mr. Wetherfield⁵ as an elastic medium for applying support and pressure, and as a defence to tender and delicate parts; as in the form of a graduated compress, in umbilical hernia of newborn infants, and as a compress over fistulous ulcers of the groin. It does not lose its elasticity, like lint.

26. Agaricus campestris, Linn.—Mushroom.

Agaricus edulis, Roques.—Fries⁶ considers this species to be the *μύκης ἐδάδιμος* of Dioscorides (lib. i. cap. 109); and the *Fungi qui rubent callo* of Pliny (*Hist. Nat.* lib. xxii. cap. 47). *Μαντράπι hodiè* Gr. Sibth.

AGARICUS, Linn. *Hymenium* consisting of plates radiating from a common centre, with shorter ones in the interstices, composed of a double closely connected membrane, more or less distinct from the pileus. *Veil* various or absent.—Named from *Agaria*, a region of Sarmatia (Berkeley).

¹ Buchner's *Repertorium*, Bd. xli. S. 93, 1846.

² Jacquin, *Diss. de Agarico Offic.*, Vind. 1778 (Richter's *Arzneimittellehre*, Bd. ii. S. 275).

⁵ *Lond. Med. Gaz.* Nov. 26, 1841, p. 337.

Systema Mycologicum, vol. i. p. 281, 1821.

A. campestris, Linn.; pileus fleshy, dry, subsquamose or silky, gills pink free ventricose, at length brown, stem stuffed, furnished with a ring white (*Berkeley*).

Pileus or caps 2-5 inches broad, at first convex, then plano-convex, white or light brown, silky or clothed with reddish brown adpressed fibrillæ collected into little fascicles; epidermis easily peeled off, projecting beyond the gills, and often curled back, fleshy; flesh firm, thick, white, more or less stained with reddish brown, especially when bruised. Gills very unequal, at first of a beautiful pink, free, obtuse, and sometimes forked behind, broad in the middle; at length dark, mottled with brownish purple; the edge white, and minutely denticulate. Spores minute, elliptical, purplish brown immediately supported on spicules (*sterigmata*) which surmount the sporophores (*basidia*). Root consisting of branched fibres (*mycelia*). When quite young, there is a fine silky universal veil (*Berkeley*, with additions).

Fig. 191.

Section of one of the gills of *A. campestris*.

a a a. Sporophores surmounted by spicules bearing spores. Link¹ terms these bodies small tubes with stalked granules (*antheridia*).

b b b. Small tubes with transverse septa. According to Link they become spores.

c c. The central vesicular tissue.

fibres (*mycelia*), which form the so-called root of the mushroom, and upon which, at short intervals, are many very small round buds (the infant state of the plant). This spawn is collected and saved by gardeners, and at the commencement of autumn is planted on beds of dung, and covered with straw: in about two months the mushrooms come up, and rapidly increase. Mixed with dung, and made up into rectangular cakes, it forms what are called *spawn cakes* or *spawn-bricks*. These are sold at Covent Garden Market, and are planted in beds.

Mushrooms are also propagated without spawn. The principal ingredient employed in preparing the compost used for this purpose is horse-droppings.² "The artificial production of this species without the aid of spawn," says the Rev. M. J. Berkeley,³ "has been frequently brought

Fig. 192.

² See Loudon's *Encyclopædia of Gardening*.

³ *English Flora*, vol. v. part ii. p. 107.

forward as an argument for the equivocal generation of fungi. But when it is considered how many millions of these sporules must be devoured together with the herbage by the animal, whose dung is a principal material in the compost, much of the force of this argument vanishes."

The young mushroom is gathered while the margin of the pileus is connected with the stalk by the veil, and at this period it is commonly called the *button mushroom* (Fig. 192, A a). The mature mushrooms are collected and sold as *full grown* or *flap mushrooms* (Fig. 192, B). Dr. Badham¹ mentions a very large variety commonly called by peasants the *ox-mushroom*.

The mushroom was analyzed by Vauquelin,² who found in it a *brown red fat*, a *spermaceti-like fat*, *mushroom sugar*, *peculiar animal matter*, *ozmazome*, *albumen*, *fungine* [cellulose], *acetate of potash*, and *other salts*.

This species is esculent, and in general wholesome; but it is employed at table for its savory, rather than for its nutritive qualities. At times it proves indigestible and unwholesome; occasionally, perhaps, from some peculiarity in the quality of the mushroom, or from the mode of cooking it; but frequently from idiosyncrasy on the part of the sufferer. The particular circumstances, however, which render it unwholesome, are very obscure. Its use should be avoided by dyspeptics, by persons liable to pruriginous, exanthematous, and scaly diseases of the skin, and by those who have a highly susceptible nervous system.

The juice of the mushroom, flavoured with salt and aromatics, constitutes the sauce called *ketchup* (a word said to be derived from the Japanese *kil-jap*), which, though in common use at table, rarely produces any unpleasant effects when used in small quantities.

AGARICUS GEORGII, Withering.—This species, called *St. George's Mushroom*, because it grows up about St. George's day (April 23d), is said by the Rev. Mr. Berkeley to be frequently sold in London under the name of *White Caps*. But I have inquired for it by this name among the dealers in Covent Garden Market, but cannot meet with any one acquainted with it (Fig. 192, C).

It is larger than the common mushroom (*A. campestris*), which it resembles in shape. When bruised it soon turns yellow, and by this character may be readily distinguished from the common mushroom, which turns pink when cut. Its smell is strong and unpleasant. It contains but little juice, and that of a yellow colour, and is, therefore, not adapted for making ketchup.

Though not poisonous, it is less wholesome than the preceding species, and is usually rejected by housekeepers. It is very tough, and difficult of digestion.

27. *Agaricus oreades*, Bolton.—Champignon.

Agaricus oreades, Withering, Brit. Pl., vol. iv.; *A. pratensis*, J. Sowerby, Eng. Fungi; J. Sowerby, Jun. The Mushroom and Champignon illustrated; *A. Pseudo Mousseron*, Bulliard; *Fairy Ring Agaric*; *Scotch Bonnets*.—This indigenous plant occurs in pastures, and is one of several fungi which grow in circles forming what have been termed *Fairy-rings*. It is commonly sold in the shops for use at table, and is liable to be mistaken for several other species of *Agaricus*, viz.: *A. dealbatus*, *dryophilus*, *semiglobatus*, and *feniseeii*. Of these, *A. dealbatus* is the only one which, like the true champignon, forms "fairy-rings."

Fig. 193.

Agarici.³

a b. *A. oreades*.
c d e. *A. dealbatus*.

f g h. *A. dryophilus*.
i k. *A. semiglobatus*.

l m. *A. feniseeii*.

¹ *Treatise on Esculent Funguses*, p. 85, 1847.

² *Ann. de Chimie*, lxxxv. 5, 1813.

³ In the above cut, the figures marked a and b are from Mr. J. Sowerby, Jr.'s "*Mushroom and Champignon Illustrated*;" the others, from Mrs. Hussey's *Illustrations of British Mycology*, part xiii. pl. xxxix. 1818.

The fungus varies in colour from a pale to a deep buff or nankeen colour. The stem is 1 or 2 inches high, and 2 or 3 lines thick, round, solid, often slightly twisted, readily splitting longitudinally into silky fibres, and is of the same colour as the gills. The pileus or cap is from $\frac{1}{2}$ to 1 inch in diameter, irregularly round, convex, most elevated in the centre, tough and coriaceous. The gills free, distant, waved at the edges, often lacerated, paler than the pileus. "If the pileus be cut through (Fig 193, *b*) the gills will not be found to separate from it, but the fleshy part runs down the middle of each gill, which is covered by the continuation of the same buff-coloured coat that lines the under surface of the pileus between the gills—a structure widely different from the poisonous one [*Ag. semi globatus*]."¹ Taste and odour agreeable.

A. DEALBATUS, Sowerby (Fig. 193, *c d e*) is distinguished from the champignon by the margin of the pileus being at first rolled inwards, by its very fine dingy whitish gills, by its becoming gray-brown in zones when soaked in water, and by its disagreeable odour. This species, according to Mrs. Hussey, resembles the champignon more than any other; and like it also grows in fairy-rings.

A. SEMI-GLOBATUS, Batsch. (Fig. 193, *i k*); the *A. virosus* of Sowerby is distinguished from the champignon by its dark-coloured gills, its hollow stem, and shining glutinous pileus. When young, this species has an annulus or ring, but this commonly disappears when the plant has attained its full size.

A. FÆNISÆII, Persoon (Fig. 193, *l m*), is distinguished from the champignon by its dark-coloured gills, its hollow stem, and its umber-purple spores.

A. DRYOPHILUS, Bulliard (Fig. 193, *f g h*), is distinguished from the champignon by its fine close gills, its hollow stem, and its reddened swollen base.

Like the *Agaricus campestris*, or mushroom, the *A. oreades*, or Champignon, is used at table on account of its savory qualities, and not for its nutritive power, which is probably very slight.

28. Fungi venenati.—Poisonous Fungi; Toadstools.

Many fungi are poisonous, and a still larger number frequently prove indigestible and unwholesome. The same species which may be taken with impunity by one individual will excite in another various inconveniences, such as nausea, vomiting, griping, diarrhœa, &c. Dyspepsia, and a highly susceptible condition of the nervous system, such as that called the hysterical constitution, dispose to those ill effects, which, in other cases, are ascribed to idiosyncrasy of constitution.

It must be obvious from these remarks that there can be no absolute anatomical characters by which the unwholesome can be distinguished from the wholesome species; the effects greatly depending on the constitution of the eater, or on some other insufficiently determined circumstances. An illustrative fact of the truth of this statement has been adduced in the case of a French officer and his wife, who died in consequence of breakfasting off some poisonous

Agaricus, which were nevertheless eaten by other persons in the house with impunity. These, and other circumstances, have led to a general distrust of all fungi, except the cultivated ones; and so strongly was the late accomplished botanist, Professor L. C. Richard, impressed with this feeling, that, though no one was better acquainted with the distinctions of Fungi than he was, yet he would never eat any except such as had been raised in gardens in mushroom beds.

Of the genus *Agaricus*, all those species which belong to the subgenus *Amanita* are either actually poisonous or highly suspicious. The characters of this subgenus are thus laid down by the Rev. M. J. Berkeley:—

AMANITA (a name given to some esculent Fungus by Galen). *Veil* double: one universal, covering the whole plant in a young state, distinct from the epidermis, at length burst by the protrusion of the pileus, part remaining at the base of the stem, part either falling off, or forming warts on the pileus; the other partial, at first covering the gills, and afterwards forming a reflected subsistent ring on the top of the stipes. *Stem* puffed, at length hollow, squamoso fibrillose, thickened at the base. *Pileus* with the disk fleshy, the margin thin, campanulate, then plane; viscid, when saturated with moisture. *Gills* attenuated behind, free, broader in front, ventricose, close, but little unequal; when full-grown, denticulated.

One of the most remarkable species of this subgenus is the *AGARICUS MUSCARIUS*, Linn. (*Amanita muscaria*, Greville), the remarkable effects and uses of which have been already noticed (see *ante*, vol. i. p. 152).

Fig. 194.

Agaricus muscarius.

¹ Sowerby, Jr., *The Mushroom and Champignon Illustrated*.

The Russians, who eat no less than sixteen species of agaricus,¹ never employ any belonging to the subgenus *Amanita*.²

Besides the species of the subgenus Amanita, many other Agarici are poisonous or suspicious.

The symptoms produced by poisonous fungi are those indicating gastro-intestinal irritation (nausea, vomiting, purging and abdominal pain), and a disordered condition of the nervous system (delirium, stupor, blindness, convulsions, muscular debility, paralysis, and drowsiness). In some cases, the power of the vascular system is remarkably depressed, the pulse being small and feeble, the extremities cold, and the body covered with a cold sweat. At one time, local irritation only; at another, narcotism alone is produced.³

In some cases the active principle of poisonous fungi seems to be a *volatile acrid principle*; in other instances it is a brown, uncrystallizable solid, called by Letellier *amanitin*.

No specific antidote is known. The first object, therefore, is to expel the poison from the stomach and bowels. The subsequent treatment will depend on the nature of the symptoms which manifest themselves, and must be conducted on general principles.⁴

Class II. Acrogenæ, Ad. Brogniart.—Acrogens

PSEUDOCOTYLEDONÆ, *Agardh*; HETERONEMÆ, *Fries*; ACROBRYA, *Mohl*, *Endlicher*.

CHARACTERS.—*Substance of the plant* composed of cellular tissue chiefly, and, in the higher forms, of vessels. *Cuticle* bearing stomata or breathing pores. *Stem and leaves* distinguishable. *Opposition of stem and root*. *Stem* growing at the point only

This class includes a number of Orders, of which two only (*viz. Lycopodiaceæ* and *Filices*) need be here noticed as yielding anything useful in medicine.

ORDER IV. FILICES, *Juss.*—FERNS.

FILICALES, *Lindley*.

CHARACTER.—Herbaceous plants with a perennial *rhizome*, more rarely having an erect arborescent trunk [when they are called tree ferns, *filices arboreæ*; Fig. 195]; *trunk* coated, of a prosenchymatous structure, with the entire cylinder of woody fasciculi divided into two concentric parts, the one narrow, placed between the bark and the wood; the other larger, central, medullary, sending fasciculi of vessels towards the petioles, and communicating with the exterior by means of chinks in the woody cylinder. *Leaves* [*frondes*] scattered upon the rhizome or rosacco-fasciculate on the apex of the caudex, with circinate vernation, annual or perennial, the base of the petioles persistent, growing to the caudex; simple or pinnate, entire or pinnatifid, [equal-] veined (the veins composed of elongated cells), frequently having cuticular stomata. *Sporangia* [*theceæ*], placed on the veins of the back or margin of the leaves, collected in little naked heaps [*sort*], or covered with a membranous scale [*indusium*], or transmuted margin of the leaf, pedicellate [with the stalk (*seta*), passing round them in the form of an elastic ring (*annulus*)], or sessile, unilocular, indefinitely deliquescent. *Spores* [*sporules*] numerous, free, globose, or angular, in germination at first

Fig. 195.

Cyathea glauca (a tree fern).

¹ For some remarks on the Fungi used as food by the Russians, see Lyall's *Character of the Russians, and a detached History of Moscow*, p. 556, Lond. 1823.

² Dr. Lefevre. *Lond. Med. Gaz.* xxiii. 414.

³ For illustrations of the effects of particular species, consult Phœbus, *Deutschl. kryptog. Giftgewächse*, 1838; and Letellier, *Journ. de Pharm.* Août. 1837.

⁴ For further information respecting poisonous fungi, consult Christison's *Treatise on Poisons*.

elongated in every direction, throwing out radicles downwards, and the cauliculus upward (Endlicher).

PROPERTIES.—The leaves are mucilaginous, and frequently slightly astringent and aromatic. The rhizomes contain starch, saccharine matter and gum, usually tannic and gallic acids, with more or less bitter matter, and sometimes both fixed and volatile oils, resin. They are considered to possess astringent and tonic properties, and in some cases act as vermifuges.

From the tuberous rhizomes of fern is obtained, in some of the Polynesian islands, as well as in some other parts of the world, a farinaceous or ligneous matter, which is employed by the natives as a nutritive substance. The rhizomes are cooked by baking or roasting. In general, however, they are only resorted to in times of scarcity, when other and more palatable food cannot be obtained.¹

Several ferns have been used in medicine. Those which I shall particularly notice are *Nephrodium Filix mas*, still retained in the British pharmacopœias, and used as a vermifuge, and *Adiantum* or *Maidenhair*, a syrup of which, or a substitute for it, is still found in the shops under the name of *capillaire*.

Ruiz² has written a memoir on three fern roots sent from Peru, in South America, to Spain, under the name of *Calaguala* (more correctly *Ccallahuala*, from *ccallua*, a batten or trowel, and *hualas*, a boy, i. e. a boy's batten). The first, or the genuine *Calaguala*, or *Ccallahuala*, or slender *Calaguala*, is the rhizome of *Polypodium Calaguala*, Ruiz; the second, called thick *Calaguala*, *Puntu-puntu*, and sometimes *Deer's tongue* (*Lengua de Ciervo*), is the rhizome of *Polypodium crassifolium*, Linn.; and the third, termed middling *Calaguala*, the little cord (*Coroncillo*), or *Huacsaro*, is the rhizome of *Acrostichum Huacsaro*, Ruiz. The first is the species which should be used in medicine: as, however, it is unknown in English commerce, I need not describe it. Professor Guibouri³ has figured three sorts of the rhizome, but states that, judging from Ruiz's description, he has not seen the true *Calaguala*. He once found the *Maltese fungus* (*Cynomorium coccineum*) in some *Calaguala* which he received from Marseilles. *Calaguala* has been analyzed by Vauquelin⁴. This rhizome is regarded in Peru as possessing deobstruent, sudorific, diuretic, anti-venereal, and febrifuge virtues; and it is frequently used to thin the blood, to promote perspiration, and to mitigate rheumatic and venereal pains. It is commonly administered in the form of decoction, prepared by boiling one ounce of the fresh root in six pints of water to three pints. This decoction is taken *ad libitum* as a kind of diet drink.

29. NEPHRODIUM FILIX MAS, Richard.—MALE SHIELD FERN.

Sex. Syst. Cryptogamia, Filices.
(Rhizoma.)

SYNONYMES.—*Polypodium Filix mas*, Linn.; *Aspidium Filix mas*, Swartz.

HISTORY.—Fern-root was employed by the ancients in medicine. Theophrastus⁵

¹ Ellis, *Polynesian Researches*, vol. i. p. 363; Bennet, *Narrative of a Whaling Voyage*, vol. ii. p. 394, 1840.—Dieffenbach (*Travels in New Zealand*, vol. ii. 1843) says that the "korau or mamako, the pulposus stem of a tree-fern (*Cyathea medullaris*) is an excellent vegetable;" and, he adds, "it is prepared by being cooked a whole night in a native oven."

² *Memoria sobre la legitima Calaguala y otras dos raices que con el mismo nombre nos vienen de la America Meridional*, Madrid, 1805. A translation of Ruiz's Memoir is contained in Lambert's *Illustration of the Genus Cinchona*, p. 93, 1821.

³ *Hist. Nat. des Drogues simpl.* t. ii. p. 87, 4me. ed. 1849.

⁴ *Hist. Plant.* lib. ix. cap. xx. and xxii.

⁵ *Ann. Chimie*, t. lv. p. 22.

notices two kinds of fern; the male, which he calls *πτέρις*, and the female, termed *δηλωπτέρις*. Dioscorides¹ also mentions these two ferns, and states that the *πτέρις* is by some persons called *βλάκνον*, by others *πολύρριζον*. Pliny² notices both ferns, and says the *pteris* is supposed to be the male fern (*filiX mas*).

BOTANY. Gen. Char.—*Sori* roundish, scattered. *Inclusium* orbicularreniform, fixed by the sinus.

Sp. Char.—*Fronde* bipinnate, pinnules oblong, obtuse serrated, their stalk and midrib chaffy. *Sori* near the central nerve (*Hooker*).

The rhizome is large, tufted, and scaly. The leaves grow in a circle to a height of 3 or 4 feet.

Hab.—It is an indigenous plant, frequent in woods and in shady banks. It is a native of other parts of Europe, of Asia, of the North of Africa, and of the United States of America.

DESCRIPTION.—The subterraneous stem (*rhizoma*; *caudex*; *fern root*, *radix filicis*, offic.) lies obliquely in the ground. It varies in length and breadth, according to its age. For medical purposes it should be from three to six or more inches long, and from half an inch to an inch or more broad.

It is almost completely enveloped by the thickened bases of the footstalks of the fallen leaves. These bases (*phyllopodia*) are arranged closely around the rhizome in an oblique direction, overlapping each other. They are one or two inches long, from three to five lines thick, curved, angular, brown, surrounded near their origin from the rhizome by two or more shining, reddish yellow, thin, silky scales (*ramenta*). The radicle fibres (root, properly so called) arise from the rhizome between these footstalks.

The *fern root* of the shops consists of fragments of the dried thickened bases of the footstalks (*phyllopodia*), to which small portions of the rhizome are found adhering, and of the root fibres.

Internally, the rhizome and footstalks are, in the recent state, fleshy, of a light yellowish-green colour; but in the dried state, yellowish or reddish-white. Iodine colours the fresh rhizome bluish black, indicating the presence of starch; particles of which may be recognized by the microscope. In a transverse section of the

¹ Liv. iv. cap. clxxxvi. and clxxxvii. Sibthorp (*Prodr. Fl. Græcæ*, vol. ii. p. 274) puts a query whether *Aspidium aculeatum*, Willd. be not the *πτέρις* of Dioscorides? But in the *Pharmacopœia Græca* of 1837, *πτέρις* is given as the modern Greek name of *Aspidium Filix mas*.

² *Hist. Nat. lib. xxvii. cap. lv.*

rhizome, we observe five or six, or more, bundles of woody fibres and scalariform ducts. These bundles are arranged in a circle, are of a reddish-white colour in the recent rhizome, but yellow in the dried one.

The dried root has a feeble, earthy, somewhat disagreeable odour. Its taste is at first sweetish, then bitter astringent, and subsequently nauseous, like rancid fat.

COLLECTION.—The rhizome should be collected in the month of July, August, or September. The black portions, fibres, and scales, are to be removed, and the sound parts carefully dried and reduced to powder: this is of a yellowish colour, and is to be preserved in well-stoppered bottles. Both the whole rhizome and powder deteriorate by keeping.

Fern buds (*gemmæ filicis maris*) which are sometimes employed in medicine, are to be collected in the spring.

COMPOSITION.—Fern rhizome was analyzed in 1805 by Vauquelin,¹ in 1821 by Gebhard,² in 1824 by Morin,³ in 1826 by Wackenroder,⁴ and by Geiger.⁵ Subjoined are the results of the analyses of Geiger and Morin:—

Geiger.	Morin.	
Green fat oil	6.9	Volatile oil.
— resin	4.1	Fixed oil (stearin and olein).
Uncrystallizable sugar }	22.9	Tannin.
Easily oxidizable tannin }	22.9	Gallic and acetic acids.
Gum and salts, with sugar and tannin	0.8	Uncrystallizable sugar.
Ligneous fibre and starch	56.3	Starch.
	100.0	Gelatinous matter, insoluble in water and alcohol.
		Ligneous fibre.
		Ashes (carbonate, sulphate, and hydrochlorate of potash, carbonate and phosphate of lime, alumina, silica, and oxide of iron).

The anthelmintic property of the rhizome resides in the oil (*oleum filicis maris*). Luck⁶ obtained from the granular sediment which forms in oil of fern, tabular *rhombic plates*, whose formula was $C^{59}H^{38}O^{20}$ (probably it should be $C^{60}H^{36}O^{20}$), a *brown substance* soluble in alcohol and alkaline liquids, and whose formula was $C^{105}H^{54}NO^{45}$, and a *gray body*, insoluble in all solvents, except caustic alkalies, and whose formula was $C^{24}H^{12}NO^3$.

Batsch⁷ found a peculiar acid (*acidum filicicum*) and an alkali (*filicina*) in the rhizome.

Fern buds contain, according to Peschier,⁸ a *volatile oil*, *brown resin*, *fat oil*, *solid fatty matter*, *green-colouring principle*, a *reddish-brown principle*, and *extractive*.

CHARACTERISTICS.—The presence of tannic acid in the aqueous decoction of fern rhizome is shown by the sesquisalts of iron producing a dark green colour (*tannate of iron*), and by a solution of gelatin causing a yellowish precipitate (*tannate of gelatin*). No indication of the presence of a vegetable alkali in the decoction can be obtained by tincture of nutgalls. If the rhizome be digested in alcohol, and afterwards boiled in water, the decoction when cold forms, with a solution of iodine, a dingy blue precipitate (*iodide of starch*).

PHYSIOLOGICAL EFFECTS.—These are not very obvious; but they are probably similar to those caused by other astringents. Large doses excite nausea and vomiting.

USES.—It is only employed as an anthelmintic. Theophrastus, Dioscorides, Pliny, and Galen, used it as such. The attention of modern practitioners has been directed to it principally from the circumstance of its being one of the remedies employed by Madame Nouffer, the widow of a Swiss surgeon, who sold her secret method of expelling tape-worm to Louis XVI. for 18,000 francs.⁹ At the present time fern rhizome is but seldom employed in this country, partly because the efficacy of Madame Nouffer's treatment is referred to the drastics used, and partly because

⁶ Quoted by Soubeiran, Nouv. Traité de Pharm. t. ii. p. 159, 2nde Ed.

⁷ Trait. contre le Tania, &c. 1776, quoted by Bremser, Sur les Vers Intest.

⁸ Diss. inaug. in Pfaff's Syst. d. Mat. Med. 7er Bd. 219.

⁹ De Anthelm. regni Vegetab.

other agents (especially oil of turpentine) have been found more effectual. "It is an excellent remedy," says Bremser,¹ "against *Bothriocephalus latus* [the tape-worm of the Swiss], but not against *Tænia Solium* [the tape-worm of this country]; for though it evacuates some pieces of the latter, it does not all of it."

ADMINISTRATION.—It may be administered in the form of powder, of oil or ethereal extract, or of aqueous decoction. The dose of the recently prepared powder is from one to three drachms. Madame Nouffer's *specific* was two or three drachms of the powder taken in from four to six ounces of water in the morning fasting, and two hours afterwards a *purgative bolus*, composed of calomel ten grains, scammony ten grains, and gamboge six or seven grains. The bolus was exhibited to expel the worm which the fern rhizome was supposed to have destroyed.

The *Ethereal Tincture of Male Fern Buds* (prepared by digesting 1 part of the buds in 8 parts of ether) has been used with success by Dr. Peschier (brother of the chemist of that name), and by Dr. Fosbroke² as a vermifuge.

OLEUM FILICIS MARIS; *Oil of Male Fern*.—The impure oil of fern (called *oilum filicis Peschieri*, *extractum filicis æthereum*, seu *balsamum filicis*), recommended by Peschier,³ is an ethereal extract, and is composed, according to its proposer, of a *fatty matter*, *resin*, *volatile oil*, *colouring matter*, *extractive*, *chloride of potassium*, and *acetic acid*. A pound of the rhizome yielded Soubeiran⁴ an ounce and a half of thick black oil, having the odour of fern. It may also be prepared from the buds as above stated. The dose is from half a drachm to a drachm, in the form of electuary, emulsion, or pills: an hour afterwards, an ounce or an ounce and a half of castor oil should be exhibited. Numerous testimonies of its efficacy have been published.⁵ I have tried it in several cases of tape-worm, but without success. By substituting alcohol for ether, twelve or thirteen drachms of oil can be obtained from 2½ lbs. of the rhizome.⁶

30. Adiantum, Linn.—Maidenhair.

HISTORY.—The term *Maidenhair* or *Capillary* (*Capillaris*, Apuleius; *Capillaire*, Fr.) has been applied to several species of fern which have been used in medicine. Dioscorides (lib. iv. cap. 136 and 137) and Pliny (lib. xxii. cap. 30) notice two kinds, one termed *Adianton*, *Polytrichon*, or *Callitrichon* (ἀδίαντον, πολύτριχον, καλλιτριχόν), the other called *Trichomanes* (τριχομανές). The former is supposed by Sibthorp¹ to be the *Adiantum Capillus Veneris*, Linn., or *True Maidenhair*, the latter the *Asplenium Trichomanes*, Linn. *Common Maidenhair Spleenwort* of modern botanists. In later times, other ferns have been also employed under the name of *Maidenhair*; especially *Asplenium Adiantum nigrum*, Linn. or *Black Maidenhair Spleenwort*; *Asplenium Ruta muraria*, Linn. *Wall-rue* or *White Maidenhair*, formerly called *Salvia Vita*; *Ceterach officinarum*, DC., or *Rough Spleenwort*; and *Scolopendrium vulgare*, Smith, or *Common Hart's-tongue*. To these must be added, *Adiantum pedatum*, Linn. or *Canadian Maidenhair*, and *Adiantum trapeziforme*, Linn. or *Mexican Maidenhair*.

The only species which it will be necessary here to notice are, *Adiantum Capillus Veneris* and *A. pedatum*.

BOTANY. Gen. Char.—*Sporangia* placed on the distinct points of the veins in a linear or point-like receptacle, arranged in marginal sori. *Indusia* continuous with the edge of the frond, united to the receptacle, opening inward (*Endlicher*).

1. *A. Capillus Veneris*, Linn.; Frond bipinnate, pinnules thin, membranaceous, obovate-cuneate inciso-sublobate, segments of the fertile pinnules terminated by a linear oblong sorus, sterile ones serrated (*Hooker*).—Indigenous. Perennial. May—September.

2. *A. pedatum*, Linn. Frond pedate, divisions pinnate, pinnae halved, oblong lunate, incised at the upper edge, the sterile segments toothed; sori linear; petiole smooth.—North America.

DESCRIPTION.—The official part of *Maidenhair* is the frond, or rather the whole plant without the root.

The herb of *True Maidenhair* (*herba capillorum veneris*) is sold at herb-shops in the dried state. When rubbed, it has a feeble odour, and its taste is sweetish and bitterish.

The herb of *Canadian Maidenhair* (*herba capillorum veneris canadensis* vel *adanthi pedati*) is more aromatic than the preceding.

¹ *Op. cit.* p. 422.

² *Journ. génér. de Med.* 1825, p. 375.

³ Dierbach, *Neuesten Entd. in d. Mat. Med.* Band 1, 1837.

⁴ *Journ. de Chim. Méd.* t. v. 2nde Sér. p. 68.

⁵ *Lancet* for 1834-35, vol. ii. p. 597.

⁶ *Nouv. Traité de Pharm.* ii. 161, 2nde éd.

⁷ *Prodr. Fl. Græcæ*, vol. ii.

COMPOSITION.—No analysis has been made of these species of *Adiantum*. The most important constituents appear to be *tannic* or *gallic acid*, *bitter extractive*, and a *volatile oil*.

EFFECTS AND USES.—None of the sorts of Maiden-hairs appear to be endowed with any active powers; though a great variety of imaginary properties have been ascribed to them. They are mucilaginous, bitterish, somewhat astringent, and aromatic substances; and in modern times have been used as pectorals in chronic catarrhs. The Canadian Maiden-hair (*Adiantum pedatum*, Linn.) is the most esteemed sort, on account of its stronger and more agreeably aromatic qualities.

A *Syrup of Maiden-hair* (*Syrupus Adianthi*; *Syrupus Capilli Veneris*; *Sirup de Capillaire*), prepared by adding sugar and orange-flower water to an infusion of Maiden-hair, has long been popular. Both Baumé and the French Codex direct it to be prepared with the Canadian Maiden-hair. When diluted with water, it forms a very refreshing beverage. But as the Maiden-hair serves no essential purpose in this drink, it is usually omitted, and the syrup sold in the shops under the name of *capillaire* is nothing but clarified syrup flavoured with orange-flower water. The Prussian and Hamburg Pharmacopœias authorize this substitution by giving formulæ for a *syrupus florum aurantii* to be used in “*loco syrupi capillorum veneris*.”

ORDER V. LYCOPODIACEÆ, DC.—CLUB-MOSSES.

CHARACTERS.—Herbaceous or shrubby vascular terrestrial *plants*. *Stem* terete, branched, leafy. *Leaves* inserted spirally on the stem, imbricated, simple, sessile or decurrent, never articulated. *Spore-cases* (*sporocarpia*; *thecæ*; *sporangia*) axillary, mostly uniform, sometimes, on the same individuals biform; some bivalved, containing a farinaceous powder, composed of polygonal smooth or papillose-spinulose granules (*sporules*; *pollen*?) ; others 3-4-cocccous, 3-4-valved, containing a few (usually 3 or 4) somewhat globular corpuscles (*spores*? *gemmæ* or *buds*?) marked at the vertex with a three-legged raphe.

PROPERTIES.—These are but little known.

An acrid principle resides in several species. Both *Lycopodium clavatum* and *L. Selago* act as emetics. The latter species, called *muscus catharticus* seu *erectus*, and supposed to be the *Selago*¹ of the Druids, has also been employed as a cathartic emmenagogue, and to produce abortion. In large doses it operates as a narcotico-acrid poison. A decoction of it is sometimes employed by the peasants of Sweden, and other places, as a lotion to destroy pediculi on the skin of horses, cows, pigs, &c.² Dr. Buchner³ has recorded some cases of accidental poisoning by it, in which it caused staggering and sickness. *Lycopodium catharticum*, Hooker (*L. rubrum*, Chamisso) is also a violent purgative. Some species, e. g. *Lycopodium Phlegmaria*, Linn., and *Selaginella convoluta*, Spring (*L. hygrometricum*, Mart.) are reputed aphrodisiacs.

31. *Lycopodium clavatum*, Linn.—Common Club-Moss.

(Herba; Sporulæ.)

HISTORY.—The earliest writers by whom the medicinal qualities of this plant are distinctly referred to, are the herbalists (Brunfels, Tragus, Cordus, &c.) of the 16th century.

BOTANY. **Gen. Char.**—*Spore-cases* unilocular, uniform or biform; the *fariniferous* ones subreniform, and bivalved; the *globuliferous* ones somewhat globose, 3-4-lobed, 3-4-valved. (*Endlicher, Gen. Pl.*)

Sp. Char.—*Stem* ereeping; branches ascending; *leaves* linear-lanceolate, nerveless, terminating at the point in a bristle; *spikes* in pairs, stalked, cylindrical; *bracts* ovate, acuminate, premorse, toothed (*Endl. Med. Pflanzen*).

Roots of several strong scattered fibres. *Stems* procumbent, trailing, branching, leafy, several feet in length. *Leaves* crowded, curved upwards, linear-lanceolate, flat, ribless, smooth, deep green, partly serrated, tipped with a capillary point; those of the branches erect; the upper ones loosely dispersed. *Spikes* terminal, usually in pairs, rarely one, or three, densely beset with shortened, dilated, ovate, entire, long-pointed *leaves* or *scales*, in whose bosoms the small, sulphur-coloured *capsules* [*thecæ*] are situated (*Smith*).

Hab.—Mountainous heaths and moors all over Europe. Indigenous. Perennial. July, August.

¹ Pliny, *Hist. Nat.* lib. xxiv. cap. 65.

² *Repert. für d. Pharmacie*, Bd. xiv. s. 311, 1823.

³ Murray, *App. Medicam.* vol. v. p. 493.

Fig. 198.

*Lycopodium clavatum.*

a. Scale of a spike with a capsule (magnified).

DESCRIPTION.—1. *Sporulæ Lycopodii.* The powder sold in the shops under the name of *lycopodium* (*pulvis, farina, pollen, seu semina lycopodii*), *witch-meal*, or *vegetable sulphur* (*sulphur vegetabile*), consists of granules, usually regarded as sporules, but by some considered to be grains of pollen. In both their physical and chemical properties they resemble the latter. They are gathered towards the end of the summer, and are separated from the capsules, &c., by sifting.

Lycopodium is a very fine, odourless, tasteless, and very mobile powder, of a pale-yellow colour. It adheres to the fingers, but exhibits a repulsive force for water, and hence is with difficulty mixed with it. If strewed on this liquid it floats, and the hand may be dipped to the bottom without being moistened. If shaken up with water a portion of it sinks, but the greater part floats. With spirit of wine it is readily miscible. It is tinged brown by iodine. When thrown into the flame of a candle it burns with great rapidity, producing an instantaneous flash of yellowish-white light.

When moistened by spirit of wine, or, still better, by oil of vitriol, and examined by the microscope, the granules are found to have the shape of tetrahedrons, with a convex base; or they may be described as spheroids, on a portion of whose surface there are three faces, or planes, uniting to form a three-sided pyramid. The faces appear to have been produced by the mutual pressure of the granules on each other, while in the spore-cases. The external membrane forms reticulated elevations, with intervening depressions or pits, giving a cellular appearance to the surface of the granules. The three-legged mark, at the union of the three planes, appears to be formed by a cleft in the membrane.

Fig. 199.

Sporules of Lycopodium clavatum
(highly magnified).

2. *Herba Lycopodii* (*Herba musci clavati terrestris*). This is odourless; at first sweetish, and then bitterish. Digested in water it yields a yellowish infusion, whose colour is deepened by sesquichloride of iron.

COMPOSITION.—*Lycopodium* sporules have been analyzed by Buchholz¹ and by Cadet.² The former chemist obtained the following results: *Fat oil*, 6.0; *sugar*, 3.0; *mucilaginous extract*, 1.5; and *pollenin*, 89.5. The substance called pollenin is, however, a complex organized body, and cannot be regarded as a proximate principle. By the action of caustic potash on *lycopodium*, Muspratt³ has shown that acetic acid is obtained.

The herb has not been analyzed. It appears to contain some acrid principle.

ADULTERATION.—As met with in the London shops, I have never found *lycopodium* (the sporules) adulterated.

The sporules of other species of *Lycopodium* are said to be sometimes substituted for those of *L. clavatum*: the microscope alone can detect the difference.

The pollen of some plants, as of *Typha latifolia*, and of some coniferous plants, is said to be sometimes substituted for the *lycopodium* sporules. The microscope readily distinguishes the substitution. The shape, the size, the character of the surface, and the cohesion or isolation of the grains, must be attended to in distinguishing them. The pollen of coniferous plants is also sometimes recognizable by its terebinthinate odour when rubbed in the hand: that of *Typha latifolia* is not so inflammable as genuine *lycopodium* meal.

Starch, talc, gypsum, chalk, boxwood powder, &c. &c., have been reported as adulterating substances. By throwing the suspected *lycopodium* on water, the mineral substances present would readily fall to the bottom, and might be detected by their appropriate chemical tests. Iodine and the microscope will detect starch. Boxwood powder has been separated from *lycopodium* by a fine sieve, which let the genuine sporules through, but retained the wooden particles.

Once I have seen *lycopodium* infected by a fungus, the matted mycelium of which had a slate colour, and a membranous or papery appearance.

EFFECTS.—1. *Of the sporules*.—Applied externally, *lycopodium* acts as an absorbent and desiccant. Taken internally, it is reputed to possess demulcent, sedative, and diuretic properties; but these qualities are of doubtful existence.

2. *Of the herb*.—The herb appears to be endowed with some active properties. It acts as an emetic and cathartic, and is reputed to possess diuretic and emmenagogue qualities.

USES.—1. *Of the sporules*.—*Lycopodium* is used both medicinally and pharmaceutically, as well as in the arts.

It is applied as a dusting powder to excoriated surfaces, especially the intertrigo of infants, and to parts affected with erysipelas, herpetic ulceration, eczema, &c. It is sometimes used in the form of ointment. In Poland, it is popularly employed as an external application in *plica polonica*. As an internal remedy, its powers are very doubtful. It has, however, been used by Wedelius and others,⁴ and, in later times, by Hufeland, Jawandt, Rademacher, and Busser,⁵ in the retention of urine, and flatulent colic of infants; and in calculous complaints, hemorrhoids, gout, &c., of adults.

In pharmacy, it is used for enveloping pills and boluses. It serves both to isolate the pills and cover their taste.

But its principal use is at theatres, where it is employed for filling flash-boxes, and for producing artificial lightning. It is also used in pyrotechny. Gray says that females employed in delicate works use it to keep their hands free from sweat.

2. *Of the herb*.—This is rarely employed. It has been celebrated in the treatment of *plica polonica*, and, in consequence, has been called *plicaria*. It was employed in the form of decoction, both externally, as lotion and liniment, and

¹ Berlin. Jahrb. für d. Pharm. 1807, S. liv.; also L. Gmelin's Handb. d. Chem.

² Bull. de Pharm. t. iii. p. 31, 1811.

⁴ Murray, App. Med. vol. v.

³ Pharmaceutisches Central-Blatt für 1844, S. 904.

⁵ Hufeland's Journal, Bd. ii. iv. and xxxvi.

internally.¹ More recently it has been recommended by Dr. Rodewald² in retention of urine, from gravel, or pus [!], in atony of the muscular coat of the bladder, in weakness and relaxation of the inner membrane of the bladder, and as a diuretic. He states that he has used it for many years with great success.

ADMINISTRATION.—The *sporules* are administered internally in doses of from ten grains to a scruple, in the form of a mixture, or emulsion, made with syrup, mucilage, or yolk of egg. Externally, they are sometimes used in the form of ointment, composed of one drachm of lycopodium to an ounce of lard. The *herb* is administered in the form of decoction or infusion. Two up-heaped tablespoonfuls, with a pint of water, are to be boiled to one-half; and of this decoction a teacupful may be taken every ten minutes, or at longer intervals. In a more dilute state it may be drunk as a tea.

II. Phanerogamia, *Auct.*—Phanerogams or Flowering Plants.

COTYLEDONÆ, *Juss.*—EMBRYONATÆ, *Rich.*—VASCULARES, *De Cand.*

CHARACTERS.—Substance of the plant composed of cellular tissue, woody fibre, ducts, and spiral vessels. *Leaves* usually present; *cuticle* with stomata. *Flowers* with perceptible stamens and pistils. *Seeds* with an embryo enclosed within a spermoderm, furnished with one or more cotyledons.

Class III. Endogenæ, *DC.*—Endogens.

MONOCOTYLEDONES, *Juss.*

CHARACTERS.—*Trunk* usually cylindrical, when a terminal bud only is developed, becoming conical and branched when several develop: consisting of cellular tissue, among which the vascular tissue is mixed in bundles, usually without any distinction of bark, wood, and pith, and destitute of medullary rays; increasing in diameter by the addition of new matter to the centre. *Leaves* frequently sheathing at the base, and not readily separating from the stem by an articulation, mostly alternate, generally parallel-veined, rarely netted. *Flowers* usually having a ternary division; the calyx and corolla either distinct or undistinguishable in colour and size, or absent. *Embryo* with but one cotyledon; if with two, then the accessory one is imperfect, and alternate with the other; *radicle* usually enclosed within the substance of this embryo, through which it bursts when germinating (*Lindley*, chiefly).

This class includes two subclasses: 1. *Glumacæ*, or glumaceous endogens. 2. *Petaloidæ*, or endogens, whose floral envelopes, if present, are whorled.

Sub-class I. *Glumacæ*, *Endl.*

CHARACTERS.—*Flowers* disposed in spikelets, and enclosed within imbricated bracts. *Ovary* free, unilocular, containing one erect ovule. *Fruit* a caryopsis. *Embryo* at the base of farinaceous albumen.

This class includes two orders: 1. *Graminæ*, or glumaceous endogens with round stems, leaves having split sheaths, and embryo lying on the outside of the albumen. 2. *Cyperacæ*, or glumaceous endogens with angular stems, leaves with entire sheaths, and embryo included within the albumen.

¹ Vicat, *Mémoire sur la Plaque Polonoise* (Murray, *App. Med.*).

² No. 16, *Allenberger medicinische Zeitung*, 1833. (Quoted by Dierbach, *die neueste Entd. in d. Mat. Med.* Bd. i. S. 56, 1837.)

ORDER VI. GRAMINEÆ, R. Brown.—GRASSES.

GRAMINA, Juss.—GRAMINACEÆ, Lind.

CHARACTERS.—Flowers usually hermaphrodite, sometimes monœcious or polygamous; consisting of imbricated bracts, of which the most exterior are called *glumes*, the interior immediately enclosing the stamens *paleæ*, and the innermost at the base of the ovary *scales*. *Glumes* usually 2, alternate; sometimes single; most commonly unequal. *Paleæ* two, alternate; the lower or exterior simple; the upper or interior composed of 2, united by their contiguous margins, and usually with 2 keels, together forming a kind of dislocated calyx. *Scales* 2 or 3, sometimes wanting; if 2, collateral, alternate with the *paleæ*, and next the lower of them, either distinct or united. *Stamens* hypogynous, 1, 2, 3, 4, 6, or more, 1 of which, alternates with the 2 hypogynous scales, and is, therefore, next the lower *paleæ*; *anthers* versatile. *Ovary* simple: *styles* 2 or 3, very rarely combined into 1; *stigmas* feathery and hairy; *ovule* ascending by a broad base, anatropal. *Pericarp* usually undistinguishable from the seed, membranous. *Albumen* farinaceous; *embryo* lying on one side of the albumen at the base, lenticular, with a broad cotyledon and a developed plumule; and occasionally, but very rarely, with a second cotyledon on the outside of the plumule, and alternate with the usual cotyledon.—Evergreen herbs. *Rhizoma* fibrous or bulbous. *Stems* cylindrical, usually fistular, closed at the joints, covered with a coat of silex, sometimes solid. *Leaves* narrow and undivided, alternate, with a split sheath, and a membranous expansion (*ligula*) at the junction of stalk and blade. *Flowers* in little spikes, called *locustæ*, arranged in a spiked, racemed, or paniced manner (*Lindley*).

PROPERTIES.—Considered with reference to their ultimate or mineral constituents, the grasses are remarkable for the large proportion of *silica*, *potash*, and *phosphoric acid*, and for the small proportion of *chlorine* which they contain. The silica predominates in the leaves and stem, the phosphoric acid in the seeds. The following table¹ represents the mean composition of the ashes of the most important cereal grains.

MEAN PER CENTAGE COMPOSITION OF THE ASH OF THE FOLLOWING CEREAL GRAINS:—

	Wheat.	Barley (with the husk).	Oat.	Rye.	Indian corn.	Rice.

¹ Drawn up from the calculated means contained in Johnston's *Lectures on Agricultural Chemistry and Geology*, 2d edit. 1847.

² *Précis de Chimie Industrielle*, p. 394, Paris, 1849.

³ The proportions of azotized substances have been deduced from the elementary analysis by multiplying by 6.5 the weight of azote obtained.

Of the proximate or organic constituents of grasses, *starch* and *sugar* are found in large proportion, the former in the seed, the latter in the stem. These constituents, with *proteinaceous matter* (gluten, albumen), to which may be added *gum*, confer on corn its valuable nutritive properties. (For the per centage proportion of starch and proteinaceous matter in corn, see *ante*, p. 106, and vol. i. p. 119.)

Fragrant volatile oils are obtained from herbaceous parts of some grasses. Several of these are employed in perfumery and in medicine (see the genus *Andropogon*).

The grasses are remarkable for their deficiency of pectin, as well as of pectic, tartaric, citric, and other vegetable acids commonly found in plants.

Considered with regard to their dietetical uses, the grasses are most important and valuable to man. They contain nitrogenized principles fitted for the production of the essential constituents of the blood and of the organized tissues, and also non-nitrogenized principles for the production of fatty matters, lactic acid, and, by combustion, of heat. The following table gives a general view of the uses which several constituents of grains of corn serve in the animal economy:—

	<i>Corn.</i>	<i>Blood.</i>	<i>Organs.</i>	<i>Excreta.</i>
1. Complex nitrogenized substances.	{ Gluten } { Albumen }	{ Fibrine } { Albumen } { Hæmatin }	{ Fibrine, albumen, hæmatin, gelatine, chondrine, kreatin, kreatinin, inosinic acid. }	{ Urea, uric acid, hippuric acid, kreatin, kreatinin, horny matter (in hair, nails, and epidermis). }
2. Complex non-nitrogenized substances.	{ Starch } { Sugar } { Gum }	{ Fat } { Sugar } { Lactic acid }	{ Fat } { Sugar } { Lactic acid }	{ Carbonic acid. } { Water. } { (Caloric.) }
3. Mineral substances.	{ Potsh, soda, lime, magnesia, iron, phosphoric acid, sulphur (in gluten, &c.), (fluor?), chlorine, silica. }	{ Potsh, soda, lime, magnesia, iron, phosphoric acid, sulphur (in fibrine, albumen, &c.), (fluor?), chlorine, silica? }	{ Potsh, soda, lime, magnesia, iron, phosphoric acid, sulphur (in fibrine, albumen, gelatine, &c.), fluor, chlorine, silica. }	{ Potsh, soda, lime, magnesia, iron, phosphoric acid, sulphur, sulphuric acid, chlorine, fluorine, silica. }
4. Water	Water =	Water =	Water =	Water

Almost every species of grass is wholesome. Some supposed exceptions to this statement have been already noticed (see vol. i. pp. 134 and 135). Of these, the best established is *Lolium temulentum*, which will be presently noticed. In a state of disease, corn sometimes acquires most important and valuable medicinal properties. (See *Ergot*.)

TRIBE I. ORYZEÆ, *Endl.*

32. *Oryza sativa*, *Linn.*—Common Rice.

Sex. Syst. Hexandria, Digynia.
(Semina.)

SYNONYMES.—*Ὠρυζον*, Theophr. *Hist. Plant*, lib. iv. cap. 5; *Ὠρυζα*, Dioscor., lib. ii. cap. 117; Galen, *de simpl. facult.*, lib. viii. cap. xv. 16; *Oryza*, Pliny, *Hist. Nat.*, lib. xviii. cap. 13.

BOTANY.—*Stems* numerous, 2 to 8 or 10 feet long. *Leaves* long and slender. *Panicle* diffuse thin, bowing when the seed is weighty. *Spikelet* hermaphrodite, 1-flowered; *glumes* 2, small; *paleæ* 2; *scales* 2, smooth; *stamens* 6; *ovary* sessile; *styles* 2; *stigma* feathery. *Caryopsis* compressed, enclosed by the paleæ.—Originally a native of Asia. Extensively cultivated in India, China, the Indian Archipelago, and most other Eastern countries; in the West Indies, Central America, and the United States; and in some of the Southern countries of Europe. Forty or fifty varieties¹ are known to and cultivated by the Indian farmers; of these some are awned—others are awnless. The kinds most esteemed in this country are the *Carolina* and *Patna rice*. *Patna rice* is imported in bags holding 1½ cwt. each. It has usually been mixed with lime, to prevent the attacks of insects. The grain, whilst enclosed in the paleæ or husk, is called *paddy* (*padi* or *paddie*) by the Malays, *bras* when deprived of the husk, and *nasi* after it has been boiled.

COMPOSITION.—Rice has been analyzed by Vauquelin,² by Braconnot,³ by Vogel,⁴ and by d'Arcet and Payen⁵ (see *ante*, p. 106). The composition of Carolina and Piedmont rice is, according to Braconnot, as follows:—

¹ Roxburgh, *Flora Indica*, vol. ii. p. 200, 1822.

² *Mém. du Muséum d'Hist. Nat.* t. iii. p. 229, 1817.

Gum	0.71	0.10
Phosphate of lime	0.40	0.40
Water	5.00	7.00
Acetic acid, phosphate of potash, chloride of potassium, and vegetable salts of potash and lime.	traces	traces
	100.00	100.00

The inorganic constituents of rice have been before stated (see *ante*, p. 106).

1. *Rice starch* is manufactured, under Mr. Orlando Jones's patent, as follows: Patna rice is first freed from stones, dust, &c., by a process analogous to winnowing, and is then digested whole in a solution of caustic soda containing 200 grains of soda to the gallon. The solution being poured off, the grain, which has thus been deprived of part of its gluten, is ground in a mill, and the ground rice mixed with a solution of the same strength, so as to form a mixture having the consistence of thick cream. More lye is then added, and the mixture stirred up for a few hours, and then left to deposit: a heavy matter, called *fibre* (heavy starch), deposits, while the starch (lighter starch) remains suspended. The liquor is then run off into shallow vessels, where the starch deposits: the alkaline solution of gluten is then drawn off, and the starch repeatedly washed with water and then allowed to deposit. The starch mass is now obtained of the consistence of clay. It is then usually mixed with blue colouring matter (sinalt), to fit it for the use of the laundress, and removed to draining-boxes, which are lined with cloth. These consist each of two cells, whose size is 3 feet long, 6 inches deep, and 6 inches broad. Here the starch forms a lump or mass of the shape and size of the cell, and is afterwards cut into 6 cubical blocks, which are placed on chalk-stones to drain, and are then partially dried in a stove, to produce what is called *crusting*. The crust is scraped off, the block wrapped in paper and returned to the stove to dry, when it splits into the columnar masses commonly known as the *races* of the starch. If, instead of crusting the lumps, the starch were slowly dried, decomposition is apt to take place; and, if rapidly dried, the races are apt to be small and needle like. 100 lbs. of Patna rice, as it occurs in the market, yield from 80 to 85 lbs. of *good marketable starch*, 7.5 lbs. of *fibre*, the remainder being *gluten*, *gruff* or *bran*, and a small quantity of light starch, carried off in suspension in the alkaline liquor.

Vogel states that, from dried rice, he obtained 96 per cent. of starch.

When examined by the microscope, the granules are observed to be polygonal, and very minute; their average diameter being about $\frac{1}{52634}$ part of an inch.¹ They are the smallest granules of all the commercial starches. According to Vauquelin, rice starch begins to dissolve in water at from 122° to 132° F.

Two kinds of rice starch are found in the shops: one, prepared under Orlando Jones's patent; the other, called *Mechlin glaze starch*, manufactured by Mottram, Rehè & Co.

2. *Proteine matters*.—Rice contains a much smaller proportion of the so-called *gluten* than wheat does. According to Horsford² and Payen (see *ante*, p. 106, and vol. i. p. 119), the quantity is about 7 per cent.

The substance which the rice starch-makers term *gluten* is analogous to what Mulder calls *proteine*, being obtained by carefully neutralizing the alkaline solution in which rice has been digested with an acid, by which a precipitate forms, which, when separated from the supernatant liquor, has a creamy consistence, an agreeable smell, and a bland taste, like pap. By

¹ The following are measurements of the particles of rice starch made by my friend Mr. Jackson:—

	Inches.
1.	.00027
2.	.00021
3.	.0002
4.	.00017
5.	.0001

5).00095

.00019 = $\frac{1}{5263}$

Most of the particles are angular; but the measurements were taken on those which most nearly approached the globular form.

² *Ann. Chem. u. Pharm.* Bd. xlviii. 1846.

evaporation, it forms a dark-coloured hard mass. If kept for some time in the moist state, it undergoes decomposition, and evolves an odour somewhat like sour yeast. Mixed with eggs, I have employed it, in the form of a baked pudding, in diabetes.

3. *Fatty matters*.—The quantity of fatty matter contained in rice is smaller than in other varieties of corn. The outer part of the grain appears to contain more than the inner part.

EFFECTS—Rice, though nutritious, is less so than wheat: this is proved by chemical analysis, which shows the much smaller proportion of glutinous or nitrogenous matter found in the former than in the latter grain (see *ante*, p. 106, and vol. i. p. 119). "Rice," says Boussingault,¹ "is held up as a most nutritive food; but though I have lived long in countries which produce it, I am far from considering it as a substantial nourishment. I have always seen it, in ordinary use, replace bread; and when it has not been associated with meat, it has been employed with milk."

The solid or dry part of rice does not materially differ from the solid or dry part of potatoes in the proportion of starch and gluten which it contains; and, therefore, as far as regards these two principles, the nutritive values of anhydrous rice and anhydrous potatoes are about equal. But, in some Union poor-houses, the substitution of an equal weight of boiled rice for potatoes was followed in a few months by scurvy.²

Rice, when swallowed in the raw state, swells up in the alimentary canal, and acts injuriously by the mechanical distension it gives rise to. Mr. Hovell³ has reported a case in which great pain, peritoneal inflammation, and death, arose from the ingestion of a tumblerful of raw rice.

"Rice," says Marsden,⁴ "is the grand material of food, on which a hundred million of the inhabitants of the earth subsist, and although chiefly confined by nature to the regions included between, and bordering on the tropics, its cultivation is probably more extensive than that of wheat, which the Europeans are wont to consider as the universal staff of life."

Rice is less laxative than the other cereal grains. Indeed, it is generally believed to possess a binding or constipating quality; and, in consequence, is frequently prescribed by medical men as a light, digestible, uninjurious article of food in diarrhœa and dysentery.

Various ill effects, such as disordered vision, &c., have been ascribed to its use;⁵ but, as I believe, unjustly so. Neither does there appear to me to be any real foundation for the assertions of Dr. Tytler,⁶ that malignant cholera (which he calls the *morbus oryzeus*, or *rice disease*) is induced by it.

USES.—Rice is employed as a nutriment in a variety of forms; e. g. *boiled rice*, *rice milk*, *rice pudding*, *rice cakes*, &c. In China, *rice vermicelli* is prepared from it. This is sold in flat bundles (of about 5 inches long, and 1½ inch broad), composed of a folded thread or filament made of rice paste. Medicinally, rice is employed as a demulcent, somewhat binding, nutritive substance in diarrhœa, &c. *Gardiner's alimentary preparation* is very finely ground rice meal.

TRIBE II. PHALARIDÆÆ.

33. *Zea Mays*, Linn.—Indian Corn; Maize.

Sex. Syst. Monœcia, Triandria.

(Semina.)

HISTORY.—*Frumentum Indicum Mays dictum*, Casp. Bauhin, Pinax; *Frumentum* vel *Triticum Turcicum*; *Turkish Corn* or *Wheat*.—The first undoubted notice of this plant occurs in the works of Tragus,⁷ who died in 1554; though by some writers it is thought to be referred to both in the Bible⁸ and in the works of Greek and Roman authors.⁹

BOTANY.—*Stem* 2 to 10 feet high. *Leaves* broad, flat, entire with a short ligula. *Flowers* monœcious; *males* terminal, racemose; *females* axillary, densely spiked. *Stamens* 3. *Ovary* sessile ovate. *Style* 1, long, capillary. *Stigma* ciliated. *Caryopsides* roundish or reniform, ar-

¹ *Ann. Chim. et Phys.* lxxvii. p. 413.

² *Provincial Medical and Surgical Journal*, June, 1847. Dr. Garrod (*Monthly Journal of Medical Science*, January, 1848) calculates that, prior to the substitution, the usual weekly food of the men in the Credition Union contained 186 grains, and of the women 181 grains of potash; but, after the substitution, the weekly amount of potash taken by the men was about 51 grains, and by the women 46 grains, or a reduction of more than two-thirds: and he ascribes the occurrence of scurvy after the use of rice to the inferior proportion of potash which this grain contains in comparison with potatoes. We ought, however, also to take into consideration the fact that rice is deficient in certain vegetable acids found in the potato (see *ante*, p. 107).

⁶ *Lancet*, 1833-34, vol. i.

⁷ *De Stirpium Historia*, p. 651, 1532. (Sprengel, *Hist. Rei Herb.* t. i. p. 320, 1807.)

⁸ *Genesis*, ch. xii. ver. 5; *Leviticus*, ch. ii. ver. 14, ch. xxiii. ver. 14; *Matthew*, ch. xii. ver. 1, &c. See Cobbett's *Treatise on Cobbett's Corn*, ch. ii. 13, 1823.

⁹ Both Theophrastus (*Hist. Plant.* lib. viii. cap. iv.) and Pliny (lib. xviii. cap. xiii.) mention a Bac-trian corn of remarkably large size. Theophrastus says the grains were as large as olive stones; and Pliny states that they were as large as the ears of our corn. Fraas (*Synopsis Plant. Floræ Class.* p. 312, 1845) suggests that the *β:ζ:ραπος* of Strabo (lib. xv.) may be our maize.

ranged on a large cylindrical receptacle or rachis, popularly called the *cobb*—An annual plant, indigenous in tropical America, but cultivated in various parts of the world.

The ordinary colour of the ripe grains or caryopsides is yellow; but they are frequently met with white, partly-coloured, red, purple, or even black.

Maize meal is sold in the shops under the name of *polenta*.

COMPOSITION.—Maize has been analyzed by Dr. Gorham,¹ by Bizio,² and more recently by Payen, whose analysis may be considered to have superseded his predecessors (see *ante*, p. 106).

Fig. 201.

Zea Mays.

a. Male flowers.

b, b, b, b. Female flowers. (The styles which project beyond the enveloping sheaths form a kind of tassel, popularly called the *silks*.)

1. *Maize starch* is not at present an article of commerce,³ though a patent⁴ has been taken out for its manufacture by fermentation as well as by the action of caustic and carbonated alkalies. The quantity of starch contained in dried maize is, in round numbers, about 67 per cent. (see *ante*, p. 106, and vol. i. p. 119).

When examined by the microscope, the particles of maize starch are seen to be more or less rounded or ovoid, with a very distinct either circular or slit hilum; but with no visible rings or laminae. Their shape is mostly somewhat irregular and knobby; some mullar-shaped. Owing to their mutual compression, many of the particles are angular or polyhedral: this is especially the case with those contained in the outer or horny portion of the albumen; while those found in the interior or farinaceous portion are more rounded. Occasionally, particles are seen with a projection like a stalk. The particles of maize starch are mostly of the medium size⁵ (.0005 to .0007 of an inch). By polarized light they show very distinct crosses.

2. *Proteine matters*—The quantity of *gluten* and other azotized constituents in maize is smaller than in wheat. Horsford⁶ obtained 13.65 per cent. from maize meal, and 14.66 per cent. from maize grains. But Payen (see *ante*, p. 106,) found only 12.5 per cent. Partly in consequence of this smaller proportion of gluten, and partly from some difference in the quality of this substance,⁷ maize is less adapted for making bread than wheat.

3. *Fatty matters*.—Of all the cereal grains, maize appears to be richest in *fatty matter*. MM. Dumas and Payen procured 9 per cent. of yellow oil from maize;⁸ but Liebig⁹ was able to obtain only 4.25 per cent. This oil consists, according to Fresenius, of carbon 79.68, hydrogen 11.53, and oxygen

8.79. More recently, Payen¹⁰ has given 8.80 per cent. as the proportion of oil found in maize.

EFFECTS.—Maize agrees generally with the other cereal grains in its nutritive properties (see *ante*, p. 107). It is remarkable for its fattening quality, and which probably depends on the larger amount of fatty matter contained in it than in other cereal grains. In those unaccustomed to its use, it is considered apt to excite or keep up a tendency to diarrhœa.

USES.—It is exclusively employed as an article of food.

¹ *Quarterly Journal of Science*, vol. xi. p. 206, 1821.

TRIBE III. AVENACEÆ.

34. AVENA SATIVA, Linn.—THE COMMON OAT.

Sex. Syst. Triandria, Digynia.
(Semen tunicis nudatum, L.—The seeds, E. D.)

HISTORY.—The oat is not mentioned in the Old Testament; but it is noticed by the ancient Greek¹ and Roman² writers, the former of whom called it βρόμος, the latter *avena*.

BOTANY. Gen. Char.—*Spikelets* three, many-flowered; flowers remote; the upper one withered. *Glumes* two, thin, membranous, awnless. *Paleæ* two, herbaceous; the lower one awned on the back, above the base, at the point almost bicuspidate; the upper one bicarinate, awnless; awn twisted. *Stamina* three. *Ovarium* somewhat pyriform, hairy at the point. *Stigmata* two, sessile, distant, villosoplumose; with simple hairs. *Scales* two, smooth, usually two-cleft, large. *Caryopsis* long, slightly terete, internally marked by a longitudinal furrow, hairy at the point, covered by the paleæ, adherent to the upper one (?) (*Kunth*).

Sp. Char.—*Panicle* equal. *Spikelets* two-flowered. *Florets* smaller than the calyx, naked at the base, alternately awned. *Root* fibrous, annual (*Kunth*).

Hab.—Cultivated in Europe.

A considerable number of varieties³ of this species are cultivated; these may be arranged under the two heads of *white oats* and the *red, dun, or black oats*.

The *white oats* have the paleæ of a whitish or straw colour. To this division belong the *potato oat*, the *Georgian oat*, the *Poland oat*, and the *Friesland or Dutch oat*.

The *red, dun, or black oats*, are so called on account of their colour.

Besides the *Avena sativa*, several other species of *Avena* are cultivated as oats. The following are the chief:—

Avena orientalis, Kunth.—*Tartarian, Hungarian, or one-seeded oat*. Cultivated in Europe.

Avena brevis, Kunth.—*Short oat*. Germany, Austria, and Hungary. Cultivated in France and Spain.

Avena nuda, Kunth.—*Naked oat*. Cultivated in Europe.

DESCRIPTION.—Oats (*caryopsides vel semina avenæ cruda*) are too well known to need description. As found in commerce, they are usually enclosed in the paleæ or husk. When deprived of their integuments, they are called *groats* (*semina integumentis nudata*, L.; *avena excorticata seu grutum*): these, when crushed, are denominated *Emden groats*. *Oatmeal* (*farina ex seminibus*, D.) is prepared by grinding the grains. It is not so white as wheaten flour, and has a somewhat bitterish taste.

COMPOSITION.—Oats have been analyzed by Vogel,⁴ by Payen,⁵ and, more re-

Fig. 202.

Avena.

- a. The white oat.
b. Siberian or Tartarian oat.

¹ Hippocrates *De victus ratione*, lib. ii. sect. iv. p. 356, ed. Fæs.; Theophrastus, *Hist. Plant.* lib. viii. cap. 9; Dioscorides, lib. ii. cap. 116, and lib. iv. cap. 140; Galen, *De Alim. Facult.* lib. i. cap. 14, p. 322, tom. vi.—Fraas (*Synops. Plant. Floræ Classicæ*, p. 303, 1845) considers that the term βρόμος includes both *Avena sativa* and *A. fatua*, Linn.

² Pliny, *Hist. Nat.* lib. xviii. cap. 44.

³ For an account of the different sorts of cultivated oats, see *The Agriculturist's Manual*, by Peter Lawson and Son, 1836; and *Supplement*, 1842. Also, Loudon's *Encyclopædia of Agriculture*.

⁴ Quoted by L. Gmelin, *Handb. d. Chemie*, Bd. ii. S. 1345.

⁵ *Précis de Chimie Industr.* 1849.

cently, by Messrs. Norton and Fromberg; and oatmeal by Dr. Christison.¹ The results of Payen's analysis have been already stated (see *ante*, p. 106).

Four varieties of Scotch oats were analyzed by Messrs. Norton and Fromberg² with the following results:—

	HOPETON OATS.			POTATO OATS.
	Northumberland.	Ayrshire.	Ayrshire.	Northumberland.
Starch	65.24	61.80	61.79	65.60
Sugar	4.51	2.58	2.09	0.80
Gum	2.10	2.41	2.12	2.28
Oil	5.44	6.97	6.41	7.38
Proteine compounds { Avenin	15.76	16.26	17.72	16.29
{ Albumen	0.46	1.29	1.76	2.17
{ Glutin	2.47	1.46	1.33	1.45
{ Epidermis	1.13	2.39	2.84	2.28
Alkaline salts and loss	2.84	1.84	0.94	1.75
	100.00 N.	100.00 F.	100.00 F.	100.00 N.

Oats consist of from 22 to 28 per cent. of *husks*; and of from 72 to 78 per cent. of grain.

The composition of the husk of the oat, according to Professor Norton, is as follows:—

	HOPETON OAT.	POTATO OAT.
Oil	1.50	0.92
Sugar and gum	0.47	0.75
Gluten and coagulated albumen	1.88	1.88
Cellulose	89.68	89.46
Saline matter (ash)	6.47	6.99
	100.00	100.00

The husk of the oat, therefore, though nutritive, is less so than the bran of wheat.

1. **OAT STARCH**, when examined by the microscope, is perceived to consist of small particles, whose normal shape is round; but which is modified by the mutual compression of the particles—some being mullar-shaped, from the mutual pressure of two particles—some being rounded at one end and dihedral at the other, from the mutual pressure of three particles—and others being polyhedric or many-angled, from the mutual pressure of many particles. The hilum is tolerably distinct in the rounded granules, but rings or laminæ are not visible. The great bulk of the granules are of the medium size³ and polyhedral, frequently presenting a pentagonal outline. Unlike most other starches, little or no variation is observed in their appearance when they are viewed by polarized light; no crosses are visible.

2. **AVENIN**—This is a proteine compound analogous to casein or curd of milk, and on it much of the nutritive value of oats depends. If oatmeal be washed on a sieve, and the milky liquid which runs through be left till the starch is deposited, then heated to 200° F. to coagulate the albumen, and to it, when cooled, acetic acid added, a white powder falls, which is *avenin*.

CHEMICAL CHARACTERISTICS.—Iodine forms, when added to the cold decoction of oats, the blue iodide of starch. Oatmeal, when mixed with water, does not form a dough as wheaten flour does; but by washing it with water on a sieve, the whole of the meal, with the exception of the coarse parts, will be washed through.

PHYSIOLOGICAL EFFECTS.—Oatmeal is an important and valuable article of food. With the exception of maize or Indian corn, it is richer in oily or fatty matter than any other of the cultivated cereal grains; and its proportion of protein compounds exceeds that of the finest English wheaten flour. So that both with respect to its heat- and fat-making, and its flesh- and blood-making principles, it holds a high rank.

A diet of unfermented oat-bread is apt to occasion dyspepsia in those unaccustomed to its use; and it was formerly suspected of producing or aggravating chronic

¹ *Dispensatory*

² Johnston's *Lect. on Agricult. Chemistry*, p. 886, 2d. edit. 1847.

³ The following measurements of six (including large and small) grains of oat starch were made by Mr. George Jackson:—

1.0010 of an English inch.	4.0003 of an English inch.
2.0006 " "	5.0002 " "
3.0004 " "	6.0001 " "

skin diseases, but without just grounds. Oatmeal porridge, taken at breakfast, sometimes relieves habitual constipation.

Intestinal concretions, composed of phosphate of lime, agglutinating animal matter, and the small, stiff, silky bristles seen at one end of the inner integument of the oat, are sometimes formed in those who habitually employ oats as food: forty-one specimens, collected by Dr. Monro secundus, are still in the Anatomical Museum of the University of Edinburgh. These formations are now comparatively rare, probably because the oats are more perfectly deprived of their investing membranes before being ground (Christison).

USES.—The oat is employed dietetically and medicinally.

As a dietetical agent, it is employed in the form of *oat-cake* or *unfermented oat-bread*, *oatmeal porridge* or *stir-about*, and *gruel*. The latter is sometimes given to infants as a substitute for the mother's milk. When there is a tendency to diarrhœa, either in adults or infants, it is advisable to substitute wheatmeal for oatmeal.

In medicine we employ *gruel*, prepared from groats or oatmeal, as a mild, nutritious, and, in most cases, easily-digested article of food in fevers and inflammatory affections. It is also in general use after parturition; and is the basis of *caudle*. In poisoning by acrid substances, it is employed as an emollient and demulcent. It is given, after the use of purgatives, to render them more efficient and less injurious. It is frequently used, either alone or in conjunction with other agents, as a clyster. *Oatmeal* is used for making poultices.

Oats are also employed by distillers for the production of spirit (see *Alcohol*).

DECOCTUM AVENÆ; Oatmeal Gruel; Water Gruel.—This is usually prepared by boiling oatmeal or groats in water for about half an hour, and then straining. Dr. Cullen¹ directs it to be prepared by boiling an ounce of oatmeal with three quarts of water to a quart, constantly stirring; strain, and when cold decant the clear liquid from the sediment. Sugar, acids, or aromatics may be employed for flavouring.

TRIBE IV. HORDEACEÆ.

35. *Lolium temulentum*, Linn.—Bearded Darnel.

Sex. Syst. Triandria, Digynia.
(Semina.)

SYNONYMS.—*Αἴζα*, Dios. lib. ii. cap. 122; Galen, de simpl. med. fac. lib. vi. § 10, and de aliment. facult. lib. i. cap. 37; Paulus Æg. lib. vii. sect. iii.; *Lolium*, Pliny, Hist. Nat. lib. xxii. cap. 79; *Lolium infelix*, Virgil, Georg. i. 153.

HISTORY.—This grass was used medicinally by the ancient Greeks and Romans, though it is somewhat remarkable that it is mentioned neither by Hippocrates nor Celsus.

BOTANY. Gen. Char.—*Spikes* many-flowered, distichous, sessile, contrary to the rachis. *Flowers* beardless at the base. *Glumes* 2, nearly equal, herbaceous, lanceolate, channelled, awnless; the lower or inner ones very often deficient in the lateral spikelets. *Paleæ* 2, herbaceous; the lower concave, awnless, or awned below the point; the upper bicarinate. *Stamens* 3. *Ovary* smooth; *styles* 2, very short, inserted below the point; *stigmas* feathery, with long, simple, finely-toothed, transparent hairs; *scales* 2, fleshy, smooth, acute, entire or two-lobed. *Caryopsis* smooth, adhering to the upper paleæ (Kunth).

Sp. Char.—*Spikelets* about 6-flowered, equalling or shorter than the glume. *Outer palea* as long as its awn.—*Root* without barren shoots. *Stem* erect, 2 feet high, smooth and shining below, rough upwards. *Ligule* short. *Inner glume* usually present, often bifid.

Lolium temulentum, *β. arvense*, (Babington, Brit. Bot.) is a variety of the above. It is usually smaller and smoother; its spikelets 4- or 5-flowered; its awns either absent or at most short, lax, and weak.

Europe (indigenous), Japan, New Holland, Chili, Monte Video.—Annual.—Fl. July.

DESCRIPTION.—The grain (*caryopsis*) enclosed in the husk is ovato-oblong, on one side flattened and furrowed—on the other convex, grayish brown; odourless, with a sweetish-bitterish, not disagreeable, taste. It yields a darkish meal or farina (called *ærina* by Pliny).²

¹ *Treatise of the Materia Medica*, p. 280.

² *Hist. Nat. lib. xxii. cap. 58.*

Fig. 203.

Lolium temulentum, or Bearded
Darnel.

COMPOSITION.—In 1827, Bizio¹ examined darnel, and discovered in the seeds two peculiar substances, which he called respectively *glajulico* and *lalico*; the latter he stated possessed a narcotic power similar to that of opium. In 1837, Muratori² analyzed darnel seeds, and ascribed their poisonous properties to a peculiar acid. In 1834, Bley³ examined them, and obtained the following substances: Traces of volatile oil, *dilroprophyll* 7.5, soft resin 3.5, bitter extractive with chlorides and sulphates 6.0, gum with chloride of calcium 6.0, sugar 0.7, albumen 0.65, extractive with malate of lime 1.55, gum with sulphate and muriate of potash 2.5, gum with malate of potash 3.0, starch 29.9, artificial gum and coagulated albumen 2.9, gluten 0.8, vegetable fibre 11.0, moisture 20.0 [loss 0.4?]. Bley concluded that the poisonous principle of darnel was extractable from the seeds by water. Subsequently,⁴ he procured from the watery extract of darnel seeds a peculiar substance, which he called *loliin*. 1000 grains of the seeds yielded him 294 grains of starch.

Loliin is a foliated or pulverulent dirty white substance, soluble in hot and cold water, and in hot alcohol. Its aqueous solution reddened litmus paper feebly. A tenth of a grain of *loliin* caused an acrid sensation in the throat, followed by an affection of the head and weakness of the whole body, which effects continued only for a short time.

CHEMICAL CHARACTERISTICS.—According to Ruspini,⁵ the presence of grains of *Lolium temulentum* in wheat-flour may be detected by digesting the suspected farina in rectified spirit. If the *Lolium* be present, the spirit immediately acquires a characteristic green tint, which gradually deepens; and the taste of the tincture is astringent, and so disagreeable that it may even excite vomiting. By evaporation it yields a green resin. But I have not succeeded in obtaining these results. By digesting bruised and coarsely powdered grains of *Lolium temulentum* in rectified spirit, the liquid had acquired in forty-eight hours a pale yellow colour and scarcely any flavour, and yielded, by spontaneous evaporation, a minute portion of yellowish residue with a saline taste.

PHYSIOLOGICAL EFFECTS. *a. On Animals.*—The effects of bearded darnel on animals have been examined by Seeger, Burghard, Mariotti, and Hertwig; and the general results establish the poisonous action of the seeds of this grass. Vomiting was a general effect; followed by tremblings, convulsions, insensibility, and augmentation of urine and sweat.⁶

b. On Man.—The ill effects of the seeds of bearded darnel on man were known to the ancient Greeks and Romans. The symptoms which they produce are twofold: those indicating gastro-intestinal irritation—such as vomiting and colic; and those which arise from disorder of the cerebro-spinal system—such as headache, giddiness, languor, ringing in the ears, confusion of sight, dilated pupil, delirium, heaviness, somnolency, trembling, convulsions, and paralysis. These seeds, therefore, appear to be acro-narcotic poisons. According to Seeger, one of the most certain signs of poisoning by them is trembling of the whole body. Both Burghard and Schober (quoted by Wibmer) mention death as having resulted from their use. In Cordier's cases their ill effects were directly ascertained by experiments made upon himself; but in most other cases they were the results of accidental poisoning. In general, they have arisen from the intermixture of bearded darnel seeds with other cereal grains.⁷ In a prison at Cologne, sixty per-

⁷ See Christison *On Poisons*; and Wibmer, *op. supra cit.*

sons suffered from the use of a bread-meal containing a drachm and a half of *lolium temulentum*, in six ounces of meal.¹

Regarded in a medicinal point of view, bearded darnel appears to possess sedative and anodyne properties. Fantoni² and Giacomini consider it to be a direct hyposthenic (see vol. i. p. 134) depressing the cerebral circulation and acting like aconite.

USES.—Darnel has been recently employed in headache, in rheumatic meningitis, and in sciatica. Fantoni used it with success in the case of a widow who, at the climacteric period, was affected with giddiness, headache, and epistaxis, which had resisted various other remedies. In a case of violent rheumatic meningitis, very great benefit was obtained by its use.

ADMINISTRATION.—The dose of powdered darnel is one or two grains every four or six hours in the form of powder or pill. It may also be employed in the form either of decoction or of extract. The extract is given to the extent of half a grain or a grain in the day.

ANTIDOTES.—No specific chemical antidote is known. In the event, therefore, of a case of poisoning by darnel, our principal reliance must be on the use of evacuants and dynamical antidotes (see vol. i. p. 145). After the removal of the poison from the stomach and bowels, stimulants (such as ammonia, coffee, &c.) may be administered to relieve the depression.

36. HORDEUM DISTICHON, *Linn.*—TWO-ROWED OR LONG-EARED BARLEY.

Sex. Syst. Triandria, Digynia.

(*Semen tunicis nudatum, L.*—Decorticated Seeds, *E. D.*)

HISTORY.—Pliny,³ on the authority of Menander, says barley (*hordeum*) was a most ancient aliment of mankind. It was cultivated in Egypt nearly 1500 years before Christ.⁴ Hippocrates mentions three kinds of *αρειδή* or barley; namely, barley simply so called,⁵ three-month barley,⁶ and Achilles barley.⁷ These probably were *H. vulgare*, *H. distichon*, *H. hexastichon*.

BOTANY. **Gen. Char.**—*Spikelets* three together, the lateral ones usually withered, two-flowered, with an upper flower reduced to a subulate rudiment. *Glumes* two, lanceolate-linear, with subulate awns, flattish, unequal sided, at right angles [*contrariæ*], with the paleæ almost unilateral, turned inwards [*anticæ*], herbaceous, rigid. *Paleæ* two, herbaceous; the inferior one (turned inwards) concave, ending in an awn; the superior one (turned outward) contiguous to the rachis, bicarinate. *Stamina* three. *Ovarium* hairy at the apex. *Stigmata* two, sessile, somewhat terminal, feathery. *Scales* two, entire or augmented by a lateral lobe, usually hairy or ciliated. *Caryopsis* hairy at the point, oblong, with a longitudinal furrow internally, adherent to the paleæ, rarely free (*Kunth*).

Sp. Char.—The lateral *florets* male, awnless; the hermaphrodite ones distichous, close pressed to the stem, awned (*Kunth*).

β. With naked seeds; *H. nudum*; *Naked two-rowed Barley*.—The grains of this variety separate from the paleæ or chaff-like wheat.

Hab.—A native of Tartary, cultivated in this country.

Several sorts of this species are in cultivation: such as the *common two-rowed* or *English barley*, the *Chevalier barley*, the *Annat barley*, *Dunlop barley*, *golden* or *Italian barley*, and *black two rowed barley* (*Hordeum distichon nigrum*).

Besides *H. distichon*, several other species of *Hordeum* are in cultivation—namely, *H. vulgare*, or *Spring Barley*; *H. hexastichon*, or *Six-rowed Barley*; and *H. Zeocitron*, *Sprat* or *Battledore Barley*.

DESCRIPTION.—The grains (*caryopsides* vel *semina hordei cruda*) are too well known to need description. As found in commerce, they are usually enclosed in the paleæ or husk. Deprived of their husk by a mill, they form *Scotch, hulled*, or *pot barley* (*hordeum mundatum*). When all the integuments of the grains are removed, and the seeds are rounded and polished, they constitute *pearl barley* (*hor-*

deum perlatum). The farina (*farina hordei*) obtained by grinding pearl barley to powder is called *patent barley*.

Fig. 204.

Hordeum or *Barley*.

a, *H. vulgare*. b, *H. hexastichon*. c, *H. distichon*. d, *H. Zeocitron*.

Three qualities of barley are distinguished in the market: the hard and flinty, fit for making pot barley; a softer kind, called malting barley, which is next in value; and feeding barley, which is adapted for neither of the uses of the two other kinds.

COMPOSITION.—According to Einhof,¹ barley has the following composition:—

<i>The Ripe Seeds.</i>		<i>Barley-meal.</i>	
Meal	70.05	Starch	67.13
Husk	18.75	Fibrous matter (gluten, starch, and lignin)	7.29
Moisture	11.20	Gum	4.62
	100.00	Sugar	5.21
		Gluten	3.52
		Albumen	1.15
		Phosphate of lime with albumen	0.24
		Moisture	9.37
		Loss	1.42
			100.00

Payen's analysis of barley has been already given (see *ante*, p. 106), as also the proportion of starch and proteine constituents according to Krockner and Horsford (see vol. i. p. 116). Mr. Johnston² gives the following as the average composition of fine barley-meal: *Starch* 68; *gluten, albumen, &c.* 14; *fatty matter* 2; *saline matter* or *ash* 2; *water* 14=100.

1. **PROTEINE COMPOUNDS.**—The proportion of proteine matter in barley is much less than that in wheat, and its quality is very different. If barley dough be washed with water, nearly the whole is washed away, the husk alone excepted: it contains, therefore, little or no gluten properly so called. The milky liquid deposits starchy matter and an insoluble proteine matter (insoluble cascade?), while the clear liquid holds in solution a small quantity of albumen (coagulable by heat), and of caseine (precipitable by acetic acid). If the starchy deposit be digested with water containing ammonia, a solution of the proteine compound is obtained, from which a voluminous precipitate (caseine?) is thrown down by acetic acid. (Johnston.)

2. **STARCH.**—Barley starch, like wheat starch, consists principally of large and small grains, with but few of intermediate size: but the diameter of the largest grains is somewhat larger than that of the corresponding grains of wheat starch.³ The shape of the larger grains is irregularly circular, or elliptical, or obscurely triangular, flattened or lenticular, the flattened surfaces being undulated or uneven: the smaller grains are globular, ellipsoidal, rarely angular or mullar-

¹ L. Gmelin's *Handb. d. Chemie*, ii. 1344.

² *Lect. on Agricultural Chemistry*, p. 881, 2d edit. 1847.

³ The following measurements of seven (including the largest and smallest) grains of barley starch were made by Mr. George Jackson:—

1.	0.0011 of an English inch.	5.	0.0005 of an English inch.
2.	0.0010 " "	6.	0.0002 " "
3.	0.0009 " "	7.	0.0001 " "
4.	0.0008 " "		

shaped. The hilum is scarcely, if at all, perceptible on the larger grains, and the rings are very faintly indicated: in these respects the grains of barley starch differ remarkably from those of rye starch. On the smaller grains, a hilum, or what appears to be such, is frequently perceptible. By polarized light the cross is less distinctly seen than in rye starch. Barley starch offers more resistance to the action of boiling water than some other starches; and the insoluble residue, after the prolonged ebullition of it in water, constitutes what Proust¹ called *hordeine*.

3. **FATTY OR OILY MATTER.**—Fourcroy and Vauquelin² detected a yellow, acrid, saponifiable, butyraceous oil, in barley.

CHEMICAL CHARACTERISTICS.—Iodine forms the blue iodide of starch, when added to the cold decoction of barley. Decoction of whole barley has an acrid bitter taste, which it derives from the husk.

PHYSIOLOGICAL EFFECTS.—Barley is a valuable nutritive. Considered in relation to wheat, it offers several peculiarities. In the first place it contains much less proteine matter; in other words, less of the flesh-and-blood-making principles; though Count Rumford³ considered barley-meal in soup three or four times as nutritious as wheat-flour. Secondly, its starch offers more resistance to the action of the gastric juice, in consequence of its more difficult solubility in water. Thirdly, its husk is slightly acrid; and, therefore, this should be removed from barley intended for dietetical purposes, as in Scotch and pearl barley. Fourthly, barley-meal is more laxative than wheat-meal.

USES.—Barley is employed both dietetically and medicinally; as well also in the brewery and distillery.

Barley-meal is sometimes added to three times its weight of wheat-meal to form infant's food; the addition of the barley-meal being intended to obviate the constipating effects of wheat-meal.

Scotch and *pearl barley* are employed to thicken soups, and to yield barley water. It is frequently used in the dietaries of pauper establishments; but when bowel complaints prevail, some other cereal grain (wheat, for example) should be substituted for it.

1. **DECOCTUM HORDEI**, L. D. [U. S.]; *Aqua hordeata*; *Barley Water*.—(Barley [pearl barley] ꝑ̄iiss [ꝑ̄iiss, D.]; Water Oivss [Oiss, D. (Barley ꝑ̄ij; Water Oivss, U. S.)].)—First wash away, with water, any foreign matters adhering to the barley seeds; then, half a pint of the water being poured on them, boil the seeds a little while. This water being thrown away, pour the remainder of the water, first made hot, on them, and boil down to two pints, and strain, L.—This is a valuable demulcent and emollient drink for the invalid in febrile cases and inflammatory disorders, especially of the chest and urinary organs. It is sometimes given to children as a slight laxative. It is usually flavoured with sugar, and frequently with some slices of lemon. It is a constituent of the *Enema Aloes*, L., *Enema Terebinthinæ*, L., and *Decoction Hordei compositum*, L.

The **MUCILAGO HORDEI**, Ph. D., is prepared with Ground Pearl Barley ꝑ̄ss; Water f ꝑ̄xvj.

2. **DECOCTUM HORDEI COMPOSITUM**, L.; *Mistura Hordei*, E.; *Decoction Pectorale*; *Compound Decoction of Barley*; *Pectoral Decoction*.—(Decoction of Barley Oij; Figs, sliced, ꝑ̄iiss; Liquorice [root] sliced and bruised ꝑ̄v; Raisins [stoned] ꝑ̄iiss [and Distilled Water Oj, L.]. Boil down to two pints, and strain.—The process of the *Edinburgh Pharmacopœia* is essentially the same.)—This decoction is emollient, demulcent, and slightly aperient. It is employed in the same cases as the simple decoction.

3. **BYNE** (βύνη); *Brasium*; *Maltum*; *Malt*.—This is barley which has been made to germinate by moisture and warmth, and afterwards dried, by which the vitality of the seed is destroyed.—By this process part of the proteine matter of the barley is converted into *diastase*. This, although it does not constitute more than about

¹ *Ann. Chim. Phys.* v. 339.

² *Essay on Feeding the Poor*, 1500.

³ *Ann. de Mus. d'Hist. Nat.* No. xxxvii. p. 8.

$\frac{1}{50}$ th of the malt, serves to effect the conversion of about 40 per cent. of the starch of the seed into *grape-sugar*, or *gum* (dextrine). The grain loses by the operation of malting about 8 per cent. of its weight, and gains about $\frac{1}{11}$ th or $\frac{1}{12}$ th in bulk. This loss arises in part from the separation of the radicles in the form of malt-dust or eummins. The colour of the malt varies with the temperature at which it is dried. If the temperature does not exceed 100° F., the result is *pale malt*; if it be above this and does not exceed 180°, the result is *amber malt*. These varieties of malt yield fermentable infusions. *Brown* or *blown malt* dried at 260° F. is used to communicate flavour; while *roasted*, *burned*, or *high-dried malt*, which has been scorched, is employed for colouring porter.

The *infusion of malt* (*infusum bynes*), commonly called *sweet-wort*, contains saccharine matter, starch, glutinous matter, and mucilage. It is nutritious and laxative, and has been used as an antiscorbutic and tonic. Macbride¹ recommended it in scurvy;² but it is apt to increase the diarrhœa. As a tonic it has been used in serofulous affections, purulent discharges, as from the kidneys, lungs, &c., and in pulmonary consumption.³ The *decoction* (*decoctum bynes*) is prepared by boiling three ounces of malt in a quart of water. This quantity may be taken daily.

4. **CERVISIA;**⁴ *Ale and Beer*.—By the fermentation of an infusion of malt and hops are obtained ale and beer. These liquids consist of *alcohol*, *sugar*, *mucilage*, an *extractive and bitter principle*, *fatty matter*, *aroma* (*volatile oil?*), *glutinous matter*, *lactic and carbonic acids*, *salts*, and *water*. Common beer contains about 1 per cent., strong ale or beer about 4 per cent., best brown stout 6 per cent., and the strongest ale about 8 per cent. of spirit of sp. gr. 0.825. The ashes of beer consist of potash, soda, lime, chlorine, sulphuric acid, phosphoric acid, and silica.⁵

Beer is a thirst-quenching, refreshing, exhilarating, intoxicating, and slightly nutritious beverage.⁶

a. *Ale*⁷ is prepared with pale malt. It is, therefore, lighter coloured; and, when made with an equal weight of malt, is richer in alcohol, sugar, and gum, than porter or stout. *Pale* or *bitter ale*, brewed for the India market, has been carefully fermented so as to be devoid of saccharine matter, and contains an extra quantity of the active principles of hops. It is frequently used as a restorative beverage for invalids and convalescents.

β. *Porter* (the stronger kinds of which are called *stout*) owes its dark colour to high-dried or charred malt. When fresh or new, it is said to be *mild*; and, when old and acid, is called *hard*. An extract of *coeculus indicus*, called *black extract* or *hard multum*, is occasionally used by dishonest dealers to augment its intoxicating quality. For medicinal purposes *bottled porter* (*cervisia lupenaria*) is usually preferred to draught porter. It is used as a restorative in the latter stages of fever, and to support the powers of the system after surgical operations, severe accidents, &c.

¹ *Hist. Account of a new Method of Treating Scurvy*, 1767.

² See also a paper by Dr. Badenoeh, *Med. Obs. and Inq.* vol. v. p. 61.

³ Rush, *Med. Observ. and Inq.* iv. 367.

⁴ Pliny (*Hist. Nat.* lib. xxii. cap. 82, ed. Valp.), in noticing the drinks prepared from corn, says that "*Zythum* is made in Egypt, *celia* and *certa* in Spain, and *cervisia*, and many more sorts, in Gaul." For *cervisia*, some writers use the term *cerevisia*. *Zythum* (ζυθος) was a kind of beer obtained by fermentation from barley. (See Herodotus, lib. ii. cap. 77.) As *cervisia* was made from unmaltd barley, its colour would be pale, and it would, therefore, in this respect, agree with our ale. But the ale and beer of the present day differ from the ancient *cervisia* in being flavoured with hops, and hence the phrase *cervisia lupulata*, which is sometimes applied to them.

⁵ Dickson, *Phil. Mag. and Journal of Science*, vol. xxxiii. p. 311, 1818.

⁶ For further details respecting the nutritive and dietetical properties of beer, see the author's *Treatise on Diet*, p. 415, et seq.

⁷ *Ale*, in Saxon *eale* or *ealo* (probably from the word *celia*, before mentioned), is sometimes Latinized, *ala* or *alla*.

37. TRITICUM VULGARE, Kunth.—COMMON WHEAT.

Sex. Syst. Triandria, Digynia.

(Farina; farina seminis: Amylum; seminis, fœcula, L.: Amylum; secula of the seeds, E.: The seeds, from which are prepared flour and starch, D.)

HISTORY.—In the earlier ages wheat was an esteemed article of food,¹ and is frequently spoken of by Hippocrates,² who calls it *πυρός*, and mentions three kinds of it: wheat, simply so called, three-month wheat, and Sitanian wheat. Pliny³ describes several kinds of *triticum*.

BOTANY. Gen. Char.—*Spikelets* three or many flowered: the fructiferous rachis generally articulated, flowers distichous. *Glumes* two, nearly opposite, almost equal, awnless or awned: the upper one beakate; the keels more or less aculeato-ciliate. *Stamina* three. *Ovarium* pyriform, hairy at the apex. *Stigmata* two, terminal, sessile, feathery; with long, simple, finely-toothed hairs. *Scales* two, generally entire and ciliated. *Caryopsis* externally convex, internally concave, and marked by a deep furrow, distinct, or adhering to the palcæ (Kunth).

Sp. Char.—*Spike* four-cornered, imbricated; with a tough rachis. *Spikelets* generally four-flowered. *Glumes* ventricose, ovate, truncate, mucronate, compressed below the apex, round, and convex at the back, with a prominent nerve. *Flowers* awned or awnless. *Grains* loose (Kunth).

a. æstivum,⁴ Kunth; *T. æstivum*, Linn. D.; *Spring* or *Summer Wheat*.—Annual; glumes awned.—This variety includes a great many sorts known to farmers by different names, and which may be arranged in two divisions—viz., the *white bearded* and the *red bearded*.

β. hybernum,⁴ Kunth; *T. hybernum*, Linn.; *T. compactum*, Host.; *T. velutinum*, Schuebl.; *T. erinaceum*, Hort. Hal.; *Winter Wheat*.—Biennial; glumes almost awnless. This variety also includes many sorts, which may be arranged in two divisions—viz., the *white beardless* and the *red beardless*.—Talavera wheat is a white beardless winter wheat. Mr. Hard, miller, of Dartford, tells me that "this kind (Talavera wheat) is far superior to any description of wheat, either foreign or English; and the great advantage it possesses consists in its strength, colour, and sweetness. The reason of there being so small a quantity at market, arises from the fact of its being so

Fig. 205.

Triticum.—Wheat.

a. *T. vulgare*, α . *æstivum*.
b. *T. vulgare*, β . *hybernum*.
c. *T. turgidum* (compositum).
d. *T. turgidum*.

f. *T. Spelta*.
g. *T. monococcum*.

¹ Levit. ii.

² Hist. Nat. xviii. 12.

³ The distinction of wheats into *summer* and *winter* wheats, or into those sown in the spring and those sown in the autumn, has been objected to on the ground that under the name of *T. hybernum* are included several of the earlier sorts of spring wheat, and under *T. æstivum*, are included several wheats which require as long a time to arrive at maturity as the common winter sorts.

⁴ De victùs rat. lib. iii. p. 374, ed. Fœsii.

unprofitable to the farmer, scarcely producing one crop in three, which I greatly regret, as it is the most valuable grain we have; and, technically speaking, if the flour is properly manufactured, 8 oz. will absorb as much liquor as 11 oz. of that used by the baker."

Hab.—It is a native of the country of the Baseskirs, and is cultivated in Europe.

Besides *T. vulgare*, other species of *Triticum* are cultivated. The following are the chief:—*T. TURGIDUM*, Kunth; *Turgid Wheat*. Some of the sorts of this species have smooth ears; others downy, woolly, or velvety ears.—This species includes the *T. turgidum*, Linn. and *T. compositum*, Linn.

T. DURUM, Kunth; *Hard or Horny Wheat*.

T. POLONICUM, Kunth; *Polish Wheat*.

T. SPELTA, Kunth; *Spelt Wheat*.

T. MONOCOCCUM, Kunth; *One-grained Wheat*.

DESCRIPTION.—Wheat-grains (*caryopsides tritici*; *semina tritici*), as brought to market, are completely devoid of their paleæ (*chaff* or *husk*).

The number of parts into which millers separate wheat varies in different localities. According to Mr. Hard, miller, of Dartford, in Kent, the products obtained by grinding one quarter or eight bushels of wheat are as follows:—

PRODUCE OF ONE QUARTER OF WHEAT WEIGHING 504 lbs.

Flour	392 lbs.
Biscuit or fine middlings	10
Toppings or specks	8
Best pollard, Turkey pollard, or twenty-penny	15
Fine pollard	18
Bran and coarse pollard	50
Loss sustained by evaporation, and waste in grinding, dressing, &c.	11

504 lbs.

Wheat-grains vary in size, smoothness, transparency, and hardness, and in the thickness of their integuments; and, consequently, the relative proportions of bran (and pollard) and flour which they yield vary. The integument readily separates in soft-grained wheat, but with difficulty in the hard-grained: the former, therefore, yields more bran and less flour; while the latter produces flour of a lower quality, because it is intermixed with some of the ground integuments.

Semolina, *Soujee*, and *Manna Croup*¹ are granular preparations of wheat, deprived of bran.

I am indebted to Mr. Hard for the following notice (as well as for samples) of the products obtained in grinding wheat:—

"The wheat having been ground in the usual way, should be allowed to remain in the meal for some time before dressing, which removes the heat caused by the process, and enables the miller to obtain more flour, and the baker a better quality, than if dressed immediately it is ground.

"The process of dressing is by a wire cylinder containing a certain number of sheets of different texture or fineness, which cylinder contains eight hair-brushes attached to a spindle passed through the centre of the cylinder, and laid out so as to gently touch the wire: this cylinder is fed by a shoe with the meal; then the flour and offal, after passing through the wire in this way, are divided by wood partitions fixed close to the outside of the cylinder. The produce of wheat-meal dressed through the wire machine consists of—1st, *Flour*; 2d, *White Stuff*, or *Boxings*, or *Sharps*; 3d, *Fine Pollard*; 4th, *Coarse Pollard*, or *Horse Pollard*; 5th, *Bran*. The second product (*i. e.* the *White Stuff*) is then submitted to another dressing through a fine cloth machine, and produces—1st, *Fine Middlings*, for *biscuits*; 2d, *Toppings or Specks*; 3d, *Dustings*; 4th, *Best Pollard*, *Turkey Middlings* or *Coarse Middlings*.

COMPOSITION.—1. *Wheat-flour* has been analyzed by Vogel,² by Proust,³ by Henry,⁴ and by Vauquelin.⁵ The following are the results obtained by Vauquelin.

¹ The term *Manna Croup* is probably derived from *Manna-Grout*, the name of a nutritious food prepared from the grain of *Glyceria fluitans*. (See Curtis, *Fl. Lond.* vol. i. p. 7; also, Tooke's *View of the Russian Empire*, vol. iii. p. 168. 2d edit. 1800.)

Wheat flour . .	100.49	98.73	98.56	100.44	100.02	100.0	97.9	100.20

Payen's analysis of wheat has been already given (see *ante*, p. 106); as also the proportions of water, proteine matters, and starch, according to the investigations of Horsford and Kroecker (see vol. i. p. 116); and the composition of the ash of wheat (see *ante*, p. 106).

Mr. Johnston¹ found that in 20 samples of English flour the proportion of water varied from 15 to 17 per cent.

The proportion of the organic constituents of wheat is liable to considerable variation, according to soil, climate, variety of seed, mode of culture, time of cutting, and quality of manure.

2. The composition of *bran*, like that of wheat-flour, is subject to great variation; but the following is given by Mr. Johnston as the average:—

COMPOSITION OF BRAN.

Water	13.1
Albumen (coagulated)	19.3
Oil	4.7
Husk and a little starch	55.6
Saline matter (ash)	7.3

Bran 100.0

1. STARCH.—As wheat-starch is an article of the *materia medica*, it will be noticed among the official preparations (see *ante*, p. 124).

2. PROTEINE MATTERS.—The quantity of proteine matters in wheat has been already stated (see vol. i. p. 116, and vol. ii. p. 123). Wheat contains at least four different proteine compounds, namely, *albumen*, *vegetable fibrine*, *gluten*, and *caseine*. They have an analogous composition, and contain each about 16 per cent. of nitrogen.

If wheaten-dough be washed on a sieve by a stream of water, a milky liquid passes through, and a tenacious elastic mass is left behind called *crude gluten*, or sometimes *Beccaria's gluten*. The milky liquid holds in solution gum, sugar, and albumen; and in suspension starch: the crude gluten contains vegetable fibrine, gluten, caseine or mucine, and oil. According to Saussure² crude gluten has the following composition:—

Gluten	20
Vegetable fibrine	72
Mucine (caseine?)	4
Oil	3.7
Starch (accidental)	a small quantity

Crude gluten 99.7

a. *Vegetable Albumen*.—Obtained by allowing the milky liquid above mentioned to deposit its starch, and then heating the supernatant liquor nearly to boiling: flakes of coagulated albumen are formed. Its composition was found by Dr. Benee Jones³ to be carbon 55.01, hydrogen 7.23, nitrogen 15.92, oxygen, sulphur, and phosphorus 21.84.

β. *Glutin*; *Gliadine* (from γλα, glue); *Pure Gluten*.—Obtained by boiling crude gluten in alcohol, which extracts gluten, caseine or mucine, and oil. By cooling, the caseine is deposited. The supernatant liquid is then evaporated to dryness, and the adhesive mass thus obtained digested with ether to extract the oil: the residue is gluten. Its composition has been before noticed (see vol. i. p. 112).

γ. *Vegetable Fibrine*; *Zymome* (from ζύμη, ferment).—This is the part of crude gluten which is insoluble in alcohol. Mulder considers it to be coagulated albumen; Liebig as vegetable fibrine. Johnston, on the other hand, thinks it different from both albumen and fibrine, and,

¹ *Lectures on Agricultural Chemistry*, 2d edit. p. 867.

² *Bibliothèque universelle, Sciences et Arts*, t. liii. p. 260, 1833.

³ *Liebig's Animal Chemistry*.

therefore, calls it simply gluten. When obtained as above described it much resembles the fibre of lean beef. Dr. Bence Jones ascertained its composition to be carbon 55.22, hydrogen 7.42, nitrogen 15.98, oxygen, &c., 21.38.

3. *Caseine*.—After the albumen has been separated by heat from the aqueous liquid before alluded to, the addition of acetic acid causes the separation of what is supposed to be caseine. The white flocculent substance, which deposits on cooling from the alcoholic liquor in which crude gluten has been boiled, and which has been called *micine*, somewhat resembles caseine.

3. OIL.—Obtained by digesting wheat flour in ether. The quantity procured varies from $1\frac{1}{2}$ to 3 per cent. As bran yields about twice as much as fine flour, it follows that the oil exists in greater proportion in the outer than in the inner part of the grain. The oil resembles the fatty oils or butter in its properties. By washing wheat-dough, part of the oil is washed out, and part remains in the crude gluten.

4. WATER.—According to Johnstone, English flour contains, on an average, from 15 to 17 per cent. of water.

5. MINERAL CONSTITUENTS.—The composition of the ashes of wheat has been already stated (see *ante*, p. 106). The most important of these constituents are the alkaline and earthy phosphates.

CHEMICAL CHARACTERISTICS.—The cold decoction of wheat-flour forms, with tincture of iodine, the blue iodide of starch. Nitric acid gives wheat-flour a fine orange-yellow colour. Recently-prepared tincture of guaiacum forms a blue colour with good wheat-flour.

DISEASES OF WHEAT.¹—Five diseases of wheat are produced by the attacks of parasitic fungi; namely, 1st, *bunt*, *smut-balls*, or *pepper-brand*, produced by *Uredo Caries*, De Candolle; 2dly, *smut*, *dust-brand*, or *burnt-ear*, produced by *Uredo segetum*; 3dly, *rust*, *red-rag*, *red-robin*, or *red-gum*, caused, as Professor Henslow has shown, by the young state of *Puccinia graminis*, which was formerly supposed to form two distinct fungi, to which the names of *Uredo Rubigo* and *U. linearis* had been given; 4thly, *mildew*, produced by the *Puccinia graminis* in a more advanced period of its growth; and 5thly, *ergot*, caused by the *Oidium abortifaciens* (see *ante*, p. 87).

Two diseases of wheat are produced by parasitic animalcules; namely, first, the *ear-cockle*, *purples*, or *peppercorn*, caused by a microscopic, eel-shaped animalcule, called *Vibrio Tritici*; and, secondly, the *wheat-midge*, an abortion of the grain caused by a minute two-winged fly called *Cecidomyia Tritici*.

Corn affected with any of these diseases is of course deteriorated in value; but we have still to learn what are the precise effects on the animal economy of grain thus infected. The *bunt* imparts to flour its disgusting odour, and makes it less fit for bread; but flour thus tainted is used in the manufacture of ginger-bread. *Smut* does not give any unpleasant odour to corn, which, when infected with it, is frequently used for feeding fowls, apparently without producing any ill effects. I have ascertained that *ergot of wheat* is as powerful in its action on the uterus as *ergot of rye*. It has been suggested that some remarkable cases of spontaneous gangrene which occurred at Wattisham, in Suffolk, in 1762, may possibly have arisen from the presence of *ergot* in the corn used by the persons affected; but of this there is no evidence.

DETERIORATION; ADULTERATION.—By exposure to a damp air, wheat-flour absorbs moisture, and, after some time, acquires a musty odour, and becomes mouldy; the gluten being the first to suffer change. In this state it may be readily conceived that wheat-flour would prove injurious to health.

Wheat-flour is subject to adulteration with various vegetable and mineral substances.

Among vegetable substances used for the purpose of adulterating wheat-flour, the following have been named: potato starch, the meal of other cereal grains (*viz.*, of maize, rice, barley, and rye), of buckwheat, and of certain leguminous seeds (*viz.*, of beans, peas, and vetch).

In the detection of these adulterations, the microscope lends important assistance.

¹ For an excellent account of the diseases of wheat, see the Rev. Professor Henslow's *Report* on this subject, in the *Journal of the Royal Agricultural Society of England*, 1811, vol. ii. part 1.

It enables us to judge of the size and shape, the markings on, and the isolation and agglomeration of, the starch grains, and thereby to distinguish the starch grains of one meal from those of another.

In some cases, the microscopic examination of suspected flour is aided by the use of a solution of potash. Thus it enables us readily to detect the presence of either potato starch or the meal of leguminous seeds. If a solution containing about $1\frac{3}{4}$ per cent. of potash¹ be added to a mixture of potato-starch and wheat-starch (or wheat-flour), the granules of potato-starch swell up, and acquire three or four times their original volume, while those of wheat-starch are scarcely affected by it. A solution of potash, containing about 12 per cent. of potash, dissolves all the varieties of starch, but not cellulose; hence, if to wheat-flour, intermixed with the meal of some leguminous seed, this solution be added, the starch grains dissolve, and the hexagonal tissue of the adulterating leguminous seed is rendered very-obvious.²

Occasionally, polarized light may be used to aid the microscope in detecting adulterations of wheat-flour. Thus, unlike wheat-starch, the starch of the oat produces no effect on polarized light, and presents no crosses when viewed by it.

In the detection of the meal of the leguminous seeds, the odour and flavour of the suspected flour, and its chemical characters, aid in detecting the fraud. If the suspected flour be digested with twice its volume of cold water, the infusion filtered and a few drops of acetic acid added to it, a precipitate of legumine (a kind of caseine) is produced, if the meal of a leguminous seed be present;³ but wheat-flour, treated in the same way, yields a slight precipitate (of caseine), and, therefore, this test must not be relied on. Donny has pointed out a mode of detecting the meal of two leguminous seeds, viz., the vetch (*Vicia sativa*), and beans (*Faba vulgaris*, common tick bean): it consists in exposing the suspected flour to the successive action of the vapours of nitric acid and ammonia: wheat-flour, when thus treated, becomes yellow; but the meals of the leguminous seeds just referred to become red, and hence, wheat-flour adulterated with either of them becomes more or less spotted with red, according to the proportion of the leguminous meal present.

The mineral substances which have been used to adulterate wheat-flour are chiefly chalk and sulphate of lime (plaster of Paris). White clay and bone-ashes are also said to have been used. Sulphate of copper and alum are sometimes added to bad wheat-flour to improve its quality and render it more fitted for making bread. These different adulterations may be readily detected. Their quantity and nature may be judged of by incinerating the suspected flour, weighing the ash (which in genuine flour amounts to about 1 or $1\frac{1}{4}$ per cent.), and determining its nature. Flour mixed with chalk effervesces on the addition of hydrochloric acid, and yields a calcareous solution detectable by a solution of oxalate of ammonia (see vol. i. p. 568). Flour mixed with sulphate of lime, when digested in water, yields a solution which answers to the tests both for lime (see vol. i. p. 568) and for sulphuric acid (see vol. i. p. 368). Pure wheat-flour is almost completely soluble in a strong solution of potash containing about 12 per cent. of alkali; but mineral substances used for the purpose of adulteration remain undissolved.

PHYSIOLOGICAL EFFECTS.—The nutritive qualities of wheat are similar to those of the cereal grains generally, and which have been already noticed (see *ante*, p. 107).

As it exceeds other kinds of corn in the proportion of proteine matters which it contains, so it surpasses them in its flesh- and blood-making qualities. But, as it contains less starch and fatty matters than some other cereal grains, it is probably inferior to the latter as a fattening agent.

¹ I find that a mixture of 1 measure of *liquor potassæ*, Ph. L., and 2 or 3 measures of distilled water, readily distinguishes potato-starch from wheat-starch.

² Donny, *Ann. de Chim. et de Phys.* 3me Sér. t. xxi. p. 5, 1847; and *Journ. de Pharm. et de Chim.* 3me Sér. t. xiii. p. 139, 1845. Also, Mareska, *Journ. de Pharm. et de Chim.* 3me Sér. t. xii. p. 98, 1847; also, *Pharmaceutical Journal*, vol. vii. p. 394, 1848.

³ *Journ. de Pharm. et de Chim.* 3me Sér. t. xi. p. 322, 1817; also, *Pharmaceutical Journal*, vol. vii. p. 84, 1817.

The different parts of the grain differ in composition, and, therefore, in nutritive value. The external sub-epidermoid part contains a larger proportion of oil, of salts (chiefly phosphates), and albuminous and caseine matter than the more internal and farinaceous portion; and it is, therefore, probable that the finest flour, which has been freed as much as possible from all traces of bran, is actually somewhat less nutritive than the coarser flour.

Wheat-flour, especially when baked, is rather constipating than purgative. In this it differs from both barley-meal and oat-meal. Infants who are fed on baked flour frequently suffer with constipation; and to relieve this it is sometimes found necessary to substitute a portion of barley-meal for an equivalent weight of wheat-flour.

Wheat-flour yields the finest, whitest, lightest, and most digestible kind of bread. It owes its superiority in these respects to the large quantity of tenacious gluten which it contains.

Undressed wheat-flour appears to act, by the bran which it contains, as a mechanical stimulant to the bowels; and hence brown bread is resorted to for the purpose of counteracting habitual constipation.

USES.—Wheat-flour is employed in medicine both as a therapeutical and a pharmaceutical agent.

It is used with great advantage as a dusting powder in burns and scalds. It cools the part, excludes the air, and absorbs the discharge, with which it forms a crust which effectually protects the subjacent part. When the crust has become detached by the accumulation of purulent matter beneath, a poultice may be applied, and, after the removal of the crust, the exposed surface may be again dusted over with flour.

A mixture of flour and water is used as a chemical antidote in poisoning by the salts of mercury, copper, zinc, silver, and tin, and by iodine (see vol. i. p. 203).

Flour is a constituent of some poultices, as the *yeast-poultice* (see *ante*, p. 86), and the *mustard-poultice*.

It is used in pharmacy for enveloping pills.

1. *AMYLUM TRITICI*; *Amylum*; *Wheat-Starch*.—This starch was known to Pliny,⁴ who says the discovery of it was first made in Chios, and that it received its name *amylum* (*ἄμυλον*; from *a*, negative, and *μύλος*, a mill) because it was not prepared by grinding in a mill.

There are various modes of preparing it, but the method followed in this country is a mechanico-chemical one, the starch being separated from the other ingredients of wheat, partly by mechanical agency, and partly by chemical means. The cellulose or woody fibre of the grain is separated by mechanical means; the gum, sugar, albumen, and soluble salts, are dissolved out by cold water; and the gluten is got rid of partly by allowing it to undergo decomposition, and partly by solution in the acetic acid which is developed by fermentation.

A mixture of coarsely-grained wheat is steeped in water in a vat for one or two weeks (according to the state of the weather), by which acetous fermentation is established. The acid liquor (called *sour water*, or simply *sours*) is drawn off, and the impure starch washed on sieves to separate the bran. What passes through is received in shallow vessels termed *frames*. Here the starch is deposited. The sour liquor is again drawn off, and the *slimes* removed from the surface of the starch, which is to be again washed, strained, and allowed to deposit. The liquid which is drawn off is called *green water*. If the operation of washing be again resorted to, the part washed off is called *white water* instead of slimes, the liquid itself being still termed *green water*. When, by these processes, the starch has become sufficiently pure, it is *boxed*; that is, it is placed in wooden boxes perforated with holes and lined with canvas, where it drains. It is then cut in square lumps, placed on chalk stones or bricks, to absorb the moisture, and dried in a stove. By this pro-

⁴ *Hist. Nat. lib. xviii. cap. 17, ed. Valp.*

cess the blocks are *crusted* (see *ante*, p. 108). The blocks are then scraped, papered, labelled, stamped, and returned to the stove. Here they split into columnar masses (like grain, tin, or basaltic columns), commonly called the *race*.

In commerce, there are two kinds of wheat-starch—one *white*, the other *blue*.

1. *White wheat-starch* is the sort which should be employed for dietetical or medicinal purposes. What is sold under the names of *French starch* and *patent white starch* is of this kind.

2. *Blue wheat-starch* is used by the laundress for stiffening linen. It owes its colour to finely-powdered smalt or indigo, which has been introduced into it before the boxing process. The *Poland* and *glaze starches* of the shops are of this kind. They are not adapted for medicinal purposes.

When examined by the microscope, wheat-starch is perceived to consist principally of large and small grains, with but few of intermediate size.¹ The smaller particles appear to be spheroidal or nearly so. The large ones are rounded, and flattened or lenticular. When at rest, they appear to be globular; but, by making them roll over in water, they are seen to be flattened, compressed, or lenticular; one of the flattened faces being sometimes a little more convex than the other. Viewed edgewise, the particles are strongly shaded. In the middle, or nearly so, of the flattened surface is the rounded, elongated, or slit hilum. This is surrounded by concentric rings, which extend frequently to the edge of the grains. When heated, the particles crack at the edges.

When heated in a tray in an oven to 300° F., wheat-starch acquires a buff colour, and is converted into dextrine or *British gum*.

Boiled in water, wheat-starch yields a *mucilage*, which, when sufficiently concentrated, forms, on cooling, a *jelly* (*hydrate of starch*). The consistence of this jelly is due to the mutual adhesion of the swollen hydrated integuments of the starch grains. When submitted to prolonged ebullition in a large quantity of water, the granule almost entirely dissolves, and the decoction, on cooling, does not gelatinize. With iodine the decoction, when cold, forms the blue iodide of starch, the colour of which is destroyed by alkalis and by heat.

The composition of wheat-starch is C¹²H¹⁰O¹⁰.

Wheat-starch is not employed alone as food. As found in commerce, its taste is somewhat disagreeable.

Starch powder is used as a dusting powder to absorb acrid secretions and to prevent excoriation. Its decoction is used as an emollient and demulcent clyster in inflammatory conditions of the large intestines, and as a vehicle for the formation of other more active enemata. Starch is an antidote for poisoning by iodine, and is sometimes given in combination with this substance to prevent its local action (see vol. i. p. 405). It enters into the composition of the *Pulvis Tragacanthæ compositus*, Ph. L.

2. **DECOCTUM AMYLI, L.**; *Mucilago Amyli*, E. D.; *Decoction or Mucilage of Starch*.—(Starch ʒiv; Water Oj [Oss, D.]) Rub the starch with the water gradually added, then boil for a short time.)—It is sometimes used alone as an enema in dysentery, irritation of the rectum, &c. It is a constituent of the *Enema Opii*, L.

3. **FURFURES TRITICI; Bran.**—Decoction or infusion of bran is sometimes employed as an emollient foot-bath. It is also taken internally as a demulcent in catarrhal affections. Its continued use causes a relaxed condition of bowels. Bran poultice

¹ The following measurements of the starch grains of different sizes of common and spelt wheat were made by Mr. George Jackson:—

<i>Common Wheat.</i>		<i>Spelt Wheat.</i>	
1.0009 of an English inch.	1.0012 of an English inch.
2.0006 " "	2.0010 " "
3.0004 " "	3.0005 " "
4.0003 " "	4.0003 " "
5.0002 " "	5.0001 " "
6.0001 " "		

tices are applied warm in abdominal inflammation, spasms, &c. *Bran bread* is used in diabetes (see p. 127, foot-note).

4. *FARINA TRITICI TOSTA*; *Baked Flour*.—Wheat-flour lightly baked, so as to acquire a pale buff tint, is an excellent food for infants, invalids, and convalescents. Unlike the more amylaceous substances (such as arrow-root, tapioca, sago, &c.), it contains flesh- and blood-making as well as fat-making ingredients. Moreover, it has no tendency to relax the bowels; on the contrary, I think it is somewhat constipating. Hence, therefore, it may be used with advantage where there is a tendency to diarrhœa. When employed as an infant's food, it may be sometimes desirable to mix it with a fourth of its weight of prepared barley-meal, to obviate its constipating effects. It is prepared by boiling it in milk or milk and water, and is taken as a kind of pottage or gruel.

Hard's Farinaceous Food is a fine wheat-flour, which has been subjected to some heating process. It is an excellent preparation.

5. *TURUNDÆ ITALICÆ*; *Macaroni*, *Vermicelli*, and *Italian or Cagliari Paste* (in the form of stars, lentils, &c.).—These are pastes made with the finest and most glutinous wheat. By the artificial addition of wheat-gluten to the ordinary wheat, products may be obtained which rival the finest Italian pastes.¹ The *granulated gluten* (*gluten granulé*) of MM. Véron frères is a paste made in this way. These various preparations are agreeable and most nourishing foods. Boiled in beef-tea, or similar fluids, they may be taken with great advantage by invalids and convalescents.

6. *PANIS TRITICEUS, L.*; *Wheaten Bread*.—This is of two kinds, fermented or leavened, and unfermented or unleavened.

a. *Panis fermentatus*; *Fermented or Leavened Bread*.—The ingredients used in its manufacture are wheat-flour, salt, water, and yeast. In making the ordinary loaf-bread of London, the baker always employs a portion of potatoes; not for adulteration, but to assist fermentation, and to render the bread lighter. Patent yeast (see *ante*, p. 85) is generally employed by him on the score of economy. The yeast excites the fermentation of the sugar, which it converts into alcohol and carbonic acid: the former is dissipated in the oven, and the latter, distending the dough, causes it to *rise*, and gives the vesicular character to bread. During the process, a portion of starch is converted into soluble gum (dextrine) and a small portion of sugar.

The following table represents the comparative composition of the flour and bread of wheat, according to Vogel:—²

<i>Flour.</i>		<i>Starch.</i>	
Starch	68.0	Starch	53.5
Sugar	2.3	Sugar	3.6
Gum	2.5	Starch-gum	18.0
Moist gluten	24.3	Gluten, with some starch	20.75
Albumen	1.5	Carbonic acid, and the muriates of lime and magnesia
	98.6		95.85

Flour in baking takes up a considerable quantity of water, the absolute amount of which, however, depends on several circumstances. Home-made bread baked in separate tins contains about 44 per cent. of water, whereas the flour from which it is made contains only about 16 per cent. Ordinary bakers' bread, baked in united loaves, contains as much as 50 or 51 per cent. of water. Various additions made to wheat-flour enable it to take up more water. Common salt does this: in the language of the baker it gives stiffness or strength to the dough. Alum (used by bakers under the name of "*stuff*") has a similar effect: it also augments the whiteness and fineness of bread, and renders it less liable to crumble. It, therefore,

¹ Payen, *Précis de Chimie Industr.* p. 307, 1849.

² Quoted by Gmelin, *Handb. d. Chem.* Bd. ii. S. 1311 and 1343; also, *Journ. de Pharm.* t. iii. p. 211, 1817.

enables the baker to use an inferior flour with less chance of detection. Sulphate of copper (in the proportion of one grain to two pounds of flour) has a like effect, and has been used in some parts of Belgium to adulterate bread. It is said to enable the latter to take up 6 per cent. more water without appearing moister.¹

The general dietetical properties of bread resemble those of wheat-flour (see *ante*, p. 124). In diabetes, its use is objectionable on account of its augmenting the saccharine condition of the urine.² In some forms of dyspepsia, fermented bread disagrees with the patient; and, in such, benefit is occasionally obtained by the substitution of unfermented bread. The use of *brown bread* as a preventive of habitual costiveness has already been referred to (see *ante*, p. 124). It, however, frequently fails to produce the desired effect.

Fermented bread is employed both in medicine and pharmacy. *Crumb of bread* (*mica panis*) is sometimes used in the formation of pills; but is objectionable for this purpose, on account of the pills thus made becoming excessively hard by keeping. Furthermore, in some cases, the constituents of bread decompose the active ingredients of the pills. Thus, the chloride of sodium of bread decomposes nitrate of silver. Crumb of bread is most valuable for the preparation of poultices. The *bread-and-water-poultice* is prepared by covering some bread in a basin with hot water: after it has stood for ten minutes, pour off the excess of water, and spread the bread about one-third of an inch thick on soft linen, and apply to the affected part. Sometimes lint dipped in oil is applied beneath the poultice.³ Decoction of poppy, or Goulard's water, may be substituted for common water. This is a valuable application to phlegmonous inflammation. A *bread-and-milk-poultice*, to which lard is sometimes added, is also used to promote suppuration; but it should be frequently renewed, on account of its tendency to undergo decomposition. Both poultices are used in the treatment of irritable ulcers.

β. *Panis sine fermento*; *Panis azymus*; *Unfermented Bread*.—Of this there are two kinds; one compact and heavy, the other light and elastic.

Of the *heavy and compact* kind of unfermented bread we have an example in the common sea-biscuit or ship-bread (*panis nauticus*), which, on account of its hardness and compactness, must be more slowly permeated and acted on by the gastric juice than the ordinary light and porous fermented bread. These biscuits are frequently adulterated with chalk. Some dyspeptics prefer the lighter kinds of biscuits (*panis biscoctus*) to fermented bread. *Biscuit powder* is frequently used for infants' food.

The *light and porous* kinds of unfermented bread owe their lightness and porosity to some volatile or gaseous body developed in the dough by either heat or chemical action. In the preparation of certain kinds of biscuits, solid sesquicarbonate of ammonia is used to produce lightness. The heat of the oven volatilizes the salt, the vapour of which distends the dough. Carbonic acid (developed by the action of an acid on an alkaline carbonate) is, however, the agent generally employed to give porosity to unfermented bread. The *patent unfermented bread* is a preparation of this kind. The following receipt yields an excellent product: Take of

¹ For further details respecting the chemistry of fermented bread, the reader is referred to Dumas, *Traité de Chimie appliquée aux Arts*, t. vi. 1843; Johnston's *Lectures on Agricultural Chemistry*, 2d edit. 1847; and Payen, *Précis de Chimie Industrielle*, 1849.

² Bouchardat (*Comptes Rendus*, Nov. 1841, p. 912) suggested the use of a *gluten-bread*, in diabetes, as a substitute for the ordinary wheaten-bread, but in practice it has not been found available. When quite devoid of starch, it can be masticated only with extreme difficulty, and, in fact, is not edible.—*Bran-bread* is, perhaps, the best kind of bread for diabetic patients. Dr. Prout (*Stomach and Renal Diseases*, 5th edit. p. 44, 1848) has published a receipt for a bread of this kind devised by his patient, the late Rev. J. Rigg. The following formula yields the best product which I have seen, and has proved highly useful in one case of diabetes: Take coarse *wheat-bran*, wash it thoroughly with water on a sieve, until the water passes through clear; then dry it in an oven, and grind to a fine powder by a mill (the mill which was found to answer was made by White, in Holborn). Then take 7 eggs, 1 pint of milk, $\frac{1}{2}$ lb. of butter, a few carraways or some ginger, and make into a paste with a sufficiency of the bran-flour. Divide the mass into seven equal parts, and bake each separately, in a saucer, by rather a quick oven; the time required for baking is usually about 20 minutes.—Dr. Percy (*Chemical Gazette*, March 15, 1849) has published a receipt for a bread for diabetic patients made of the ligneous matter of potatoes (see the article *Solanum tuberosum*).

³ Abernethy, *Lancet*, vol. v. 1821, p. 135.

Flour ℥j; Bicarbonate of Soda 40 grains; Cold Water half a pint, or as much as may be sufficient; Muriatic Acid of the shops 50 drops; Powdered White Sugar a teaspoonful. Intimately mix the bicarbonate of soda and sugar with the flour, in a large basin, by means of a wooden spoon. Then gradually add the water with which the acid has been previously mixed, stirring constantly, so as to form an intimate mixture very speedily. Divide into two loaves, and immediately put them into a quick oven.—If any soda should escape the action of the acid, it causes one or more yellow spots, which, however, are more unsightly than detrimental. The sugar may be omitted if thought desirable. This kind of bread is well adapted for the use of invalids and dyspeptics. With the latter it sometimes agrees when ordinary fermented bread disagrees. It is superior to biscuits in lightness and porosity. It is a very convenient kind of bread for persons on ship-board and in other places where yeast cannot be procured.

38. SECALE CEREALE, Linn.—COMMON RYE.

Sex. Syst. Triandria, Digynia.
(Semina, Offic.)

HISTORY.—Rye is mentioned in the English version of the Old Testament;² but, in the opinion of Sprengel,³ spelt wheat is meant. The same writer also states that Theophrastus⁴ is the earliest author who notices the *Secale cereale*; but the word *τῖψη*, used by Theophrastus, is thought by Fraas⁵ to refer to *Triticum monococcum*, and not to rye. Galen⁶ mentions rye under the name of *βρίσα*, the term by which, as well as by *σικαλι*, rye is known in modern Greece.⁷ Pliny⁸ speaks of *secale* or rye.

BOTANY. Gen. Char.—*Spikelets* two-flowered. *Florets* sessile, distichous, with the linear rudiment of a third terminal one. *Glumes* two, herbaceous, keeled, nearly opposite, awnless or awned. *Paleæ* two, herbaceous; the lower one awned at the point, keeled, unequal sided, broadest and thickest on the outer side; the upper shorter and bicarinate. *Stamina* three. *Ovarium* pyriform, hairy. *Stigmata* two, nearly sessile, terminal, feathery, with long, simple, finely-toothed hairs. *Scales* two, entire, ciliate. *Caryopsis* hairy at the point, loose (Kunth).

Sp. Char.—*Glumes* and *awns* scabrous (Kunth).

Hab.—The Caucasian-Caspian desert. Cultivated in Europe; but little in England; frequently on the Continent.

DESCRIPTION.—Rye grains (*caryopsides* vel *semina secalis* vel *frumenti*), in external appearance, more resemble wheat than other cereal grains; but they are

¹ The above formula yields a bread of excellent quality, as I can vouch from having repeatedly employed it. Various other formulæ have been published, many of which doubtless also yield excellent products. The following are given in a little pamphlet entitled *Instructions for making Unfermented Bread*, by a Physician, 15th edit. 1848:—

TO MAKE WHITE OR FLOUR BREAD.

Take of Flour, dressed or household	3 lbs. avoirdupois.
Bicarbonate of soda, in powder	9 drachms, apothecaries' weight.
Hydrochloric (muriatic) acid	11½ fluidrachms.
Water	about 25 fluidounces.

TO MAKE BROWN OR MEAL BREAD.

Take of Wheat meal (that is, wheat well ground, as it comes from the mill, retaining the whole of the bran)	3 lbs. avoirdupois.
Bicarbonate of soda, in powder	10 drachms, apothecaries' weight.
Hydrochloric (muriatic) acid	12½ fluidrachms.
Water	about 25 fluidounces.

In the shops are sold powders under various names (such as *Borwick's Original German Baking Powder for making Bread without Yeast*; and *Edwards's Egg Powder*) to enable persons to prepare a light bread without yeast, or even light puddings without eggs. They are usually mixtures of *tartaric acid* and *carbonate of soda*, with some farinaceous substance (*wheat flour* and *potato starch*); to which is sometimes added a small portion of *alum*. They are very useful and convenient preparations; and, for employment on board ship, and in various other situations, will be found very valuable.

smaller and darker externally. Internally they are white and farinaceous; externally brownish. Like wheat, as found in commerce, they are devoid of their husk or paleæ.

In order that the changes which rye undergoes when it becomes ergotized may be better understood, Corda¹ has given the following description of the microscopic characters of healthy rye grains: "When we submit a thin transverse section of a healthy grain of rye to microscopic examination, we perceive that the seed-coat (Fig. 207, *a*) consists of three layers of thick-walled cells, beneath which we find the second, properly the third, seed-coat (207, *b*), composed of a single layer of thick-walled cells, having scarcely any cavity. Next follows a layer of cells containing gluten (207, *c*); and afterwards the cellular tissue of the albumen (207, *d*). This consists of large roundish hexagonal cells, which contain grains of starch (Fig. 208). The starch-grains (Fig. 209) are roundish or ellipsoidal, and about the 0.000150 of the Paris line in length."

² L. Gmelin, *Handb. d. Chem.* Bd. ii. S. 1343.

³ Quoted by Johnston, *Lectures on Agricultural Chemistry*.

⁴ *Journ. f. pr. Chem.* Bd. xxxi. S. 195.

The composition of the ashes of rye is stated at p. 106.

1. **PROTEINE COMPOUNDS.** *Fibrine, Glutin, and Albumen.*—The so-called gluten of rye differs from wheat-gluten. It is not cohesive, and is soluble in water and alcohol; but after it has been dissolved in alcohol it is insoluble in water. It agrees in its properties with the gluten of wheat (see vol. i. p. 116, and *ante*, p. 106). Heldt¹ considers it to be identical in composition with the other proteine compounds of rye analyzed by Dr. Benze Jones and Scheerer.

2. **STARCH.** The starch of rye, like that of wheat, consists principally of large and small grains, with but few of intermediate size; the larger ones being, on the whole, somewhat larger than the corresponding ones of wheat.² The shape of the larger grains is circular, flat, or lenticular; of the smaller ones globular (chiefly), ellipsoidal or ovoidal, rarely angular or mullar-shaped. On the flattened surface of the larger grains is seen the central, rarely circular, usually slit, or 3-, 4-, or even 5- radiate hilum, sometimes surrounded by very faint concentric rings and delicate radiating lines. By polarized light the grains show a central cross.

CHEMICAL CHARACTERISTICS.—A cold decoction of rye forms with iodine the blue iodide of starch. By washing rye-dough with water, nearly the whole becomes diffused through the liquid, little more than husk or bran remaining behind. The milky liquid deposits on standing starch grains, and the decanted portion yields on evaporation the so-called gluten; from which, sugar is extracted by water, and oil by ether: the residue (*glutin*) is soluble in alcohol.

PHYSIOLOGICAL EFFECTS.—In its nutritive qualities rye resembles wheat, especially in the fitness of its flour for making bread; but it contains less proteine matter and more sugar.

USES.—Rye is employed dietetically and medicinally; and also in the distillery and brewery.

Rye-bread (in Germany called *Schwartzbrod* or *black bread*) is in common use among the inhabitants of the northern parts of Europe, but in this country is rarely employed. It is said to be more laxative (especially to those unaccustomed to its use) than wheat-bread; and hence is sometimes taken to counteract habitual constipation. The *roasted seeds* (*semina secalis tosta*) have been employed as a substitute for coffee. On the continent *rye-flour* and *rye-bran* are applied to the same medicinal uses that wheat-flour and wheat-bran are applied in England. Rye pottage (*pulmentum vel jusculum secalinum*) is said to be a useful article of diet in consumptive cases.³

39. SECALE CORNUTUM.—SPURRED RYE OR ERGOT.

ERGOTA.—*Secale cereale semen purgo parasitico corruptum?* *L.* The ergot, a peculiar excrescence supposed to be produced by a parasitical fungus, *D.*

SYNONYMES.—*Clavi siliginis*, Lonicerus; *Secalis mater*, Thalius; *Secale luxurians*, Bauhin, Pinax, lib. i. sect. iv. p. 23; *Grana secalis degenerati*, Brunner; *Secale cornutum*, Baldinger; *Clavus secalis* vel *secalinus*; *Secale maternum*, *turgidum* vel *temulentum*; *Ergota*, Ph. Lond. et Ed.; *Spur*; *Spurred* or *horned Rye*; *Ergot of Rye*; *Cockspur Rye*; *Cockspur*.

HISTORY.—No undoubted reference to ergot is found in the writings of the ancients. The disease produced by it is supposed to be referred to in the following passage: "1089. A pestilent year, especially in the western parts of Lorraine, where many persons became putrid, in consequence of their inward parts being consumed by St. Anthony's fire. Their limbs were rotten, and became black like coal. They either perished miserably, or, deprived of their putrid hands and feet, were reserved for a more miserable life. Moreover, many cripples were afflicted with contraction of the sinews [*nervorum contractio*]."⁴

¹ *Ann. d. Chem. u. Pharm.* Bd. xlv. S. 193, 1843.

² The following measurements of eight (including the largest and smallest) grains of rye starch were made by Mr. George Jackson:—

1.	0.0016 of an English inch.	5.	0.0005 of an English inch.
2.	0.0015 " "	6.	0.0003 " "
3.	0.0013 " "	7.	0.0002 " "
4.	0.0010 " "	8.	0.0001 " "

³ Pearson, *Pract. Synop. of the Mat. Alim.* 91.

⁴ Extract from the works of Siebert, in the *Recueil des Histor. des Gauls et de la France*, tom. xiii. p. 259. A passage somewhat similar to the above, with the addition of the following, "the bread which

The first botanical writer who notices ergot¹ is Lonicerus.² It seems to have been employed by women to promote labour pains long before its powers were known to the profession. Camerarius,³ in 1683,⁴ mentions that it was a popular remedy in Germany for accelerating parturition. In Italy and France, also, it appears to have been long in use.⁵

BOTANY.—The nature and formation of ergot are subjects on which botanists have been much divided in opinion.

1. Some regard ergot as a fungus growing between the glumes of grasses in the place of the ovary.—Oto von Münchhausen,⁶ Schrank,⁷ De Candolle,⁸ Fries,⁹ Wiggers,¹⁰ and formerly Berkeley,¹¹ adopted this opinion, and described ergot as a fungus under the name of *Spermoedia Clavus*,¹² Fries (*Clavaria Clavus*, Münch.; *Sclerotium Clavus*, De Cand.). Fries and Berkeley, however, evidently entertained some doubts respecting its nature; for the first suggests that the genus *Spermoedia* consists of "*semina graminum morbosa*," and the second says, "it appears to be only a diseased state of the grain, and has scarcely sufficient claim to be admitted among fungi as a distinct genus." The latest writer who has adopted this view is Guibourt,¹³ who concludes that ergot is not an ovary or altered grain, but a fungus which, after the destruction of the ovary, is grafted in its place on the peduncle.

Against this opinion may be urged the circumstance noticed by Tessier,¹⁴ that a part only of the grain may be ergotized. Moreover, the scales of the base of the ergot, the frequent remains of the stigma on its top, and the articulation of it to the receptacle, prove that it is not an independent fungus, but an altered grain.¹⁵

2. Some regard ergot as a diseased condition of the ovary or seed.—The arguments adduced against the last opinion are in favour of the present one. Though a considerable number of writers have taken this view of the nature of ergot, there has been great discordance among them as to the causes which produced the disease.

α. Some have supposed that ordinary morbid causes (such as moisture combined with warmth) were sufficient to give rise to this diseased condition of the grain. Tessier¹⁶ and Willdenow¹⁷ appear to have been of this opinion.

β. Some have ascribed the disease to the attack of insects or other animals. Tillet, Fontana, Réad, and Field,¹⁸ supported this view, which, I may add, has subsequently been satisfactorily disproved.

γ. Some, dissatisfied with the previously assigned causes of the disease, have been content with declaring ergot to be a disease, but without specifying the circumstances which induce it. Mr. Bauer,¹⁹ who closely watched the development of ergot during eight years (1805–13), and has made some beautiful drawings of it in different stages, arrived at this conclusion; as also Phœbus.²⁰

δ. Others have referred the production of the disease to the presence of a parasitic fungus. This opinion, which appears to me to be the correct one, and which must not be confounded with that entertained by De Candolle and others (vide *supra*), has been adopted and supported by Lévillé in 1826,²¹ by Dutrochet,²² by Mr. John Smith,²³ and by the late Mr. Edwin Quekett;²⁴ and more recently by Fée²⁵ and by Corda.²⁶ But though the writers just mentioned agree in

was eaten at this period was remarkable for its deep violet colour,"¹⁷ is quoted by Bayle (*Biblioth. Thérap.* tom. iii. p. 374) from Mézerai, *Abrégé Chronologique*. But I cannot find the passage in the first and best edition of Mezeray's *Abrégé Chron.* 3 vols. 4to. 1668; or in his *Histoire de France*; or in his *Mémoires Hist. et Critiques*. Whether or not it be in the second and less perfect edition of Mezeray's *Abrégé Chronologique*, I am unable to decide, not having seen this work.

¹ The etymology of the word *ergot* is very doubtful. Whiter (*Etymologicon Universale*, ii. 594) thinks that it is derived from *arguo*, and is attached to such terms as *urgeo*. It was anciently written *ergot*.

²⁴ *Ibid.*

considering ergot to be a disease of the ovary or seed, caused by a parasitic fungus, considerable difference exists among them as to the real nature of the parasite.¹

The statements of Lévillé,² Phillipar,² Smith, and Quekett, leave, I think, but little doubt that ergot is a disease of the grain caused by the presence of a parasitical fungus. This view is supported by the observations of Wiggers, that the white dust (*sporidia*, Quek.) found on the surface of ergot will produce the disease in any plant (grass?) if sprinkled in the soil at its roots. Mr. Quekett (see *ante*, p. 87) infected grains of corn by immersing them in water in which the sporidia of the *Oidium abortifaciens* were contained. The plants which were produced by the germination of the grains were all ergotized.

Mr. Quekett, who most carefully examined the development of ergot, says that the first appearance of the ergot is observed by the young grain and its appendages becoming covered with a white coating composed of multitudes of sporidia (Fig. 184 A, p. 87) mixed with minute cobweb-like filaments (*Oidium abortifaciens*, Fig. 184, H I, p. 87). This coating extends over all the other parts of the grain, cements the anthers and stigmas together, and gives the whole a mildewed appearance. When the grain is immersed in water, the sporidia fall to the bottom of the liquid. A sweet fluid—at first limpid, afterwards viscid—is found in the affected flower at this stage; and, when examined by the microscope, is found to contain the sporidia just referred to (Phillipar, Smith, Quekett). Phillipar says this fluid oozes from the floral centre; and Mr. Quekett, who at first thought that it had an external origin, was subsequently convinced that it escaped from the ergot or the parts around it.

If we examine the ergot when about half-grown (Fig. 210), we find it just beginning to show itself above the paleæ, and presenting a purplish-black colour. By

Fig. 210.

Ergot of Rye.

 B. Front view of a section of the above infected grain, cut at letter *a*: magnified sixteen times in diameter.
 C. Ditto, cut at letter *b*: magnified sixteen times in diameter.
 D. Side view of an unripe but advanced ergotized grain, at the upper part of which is the tuberculated portion, having a vermiform appearance, and constituting the fungus (*Sphacelia Segetum*) of Lévillé.
 E. Longitudinal section of the grain.
 F. A full-grown ergot, within its floret, magnified twice its diameter.

¹ I have given an abstract of M. Fée's opinion in the *Pharmaceutical Journal*, vol. v. p. 262.
² *Traité Organogr. et Phys.-Agr. sur la Carie, le Charbon, l'Ergot, &c.* Svo. Versailles, 1837.

this time it has lost in part its white coating, and the production of sporidia and filaments has nearly ceased. At the upper portion of the grain, the coating now presents a vermiform appearance, which Lévillé¹ describes as constituting cerebri-form undulations. These are beautifully depicted in Mr. Bauer's drawings (Fig. 210, A D E). Lévillé regards this terminal tubercle of the grain as a parasitical fungus, which he calls the *Sphacelia Segetum*. But these undulations are merely masses of sporidia; for if a little be scraped off with a knife, then moistened, and examined by the microscope, we find nothing but myriads of sporidia. The ergot now increases in a very rapid manner.

Corda has confirmed the observations of Messrs. Smith and Quekett; but, as I have already stated (see *ante*, p. 87), he considers the fungus to be a new species of *Hymenula* (of the sub-order *Hymenophycetes*), to which he has given the name of *H. clavus*.

To the agriculturist, an important subject of inquiry is the predisposing causes of ergot. Very little of a satisfactory nature has, however, been ascertained on this point. One fact, indeed, seems to have been fully established—viz. that moisture, which was formerly thought to be the fertile source of the spur, has little, if anything, to do with it.² Moreover, the disease is not peculiar to rye. Many other grasses (Phœbus has enumerated 31 species) are subject to it. In the summer of 1838, I found the following grasses, growing in Greenwich marshes, ergotized: *Lolium perenne*, *Dactylis glomerata*, *Alopecurus pratensis*, *Festuca pratensis*, *Triticum repens*, *Arundo phragmites*, *Hordeum murinum*, and *H. pratense*. Professor Henslow found it in wheat which had been sent to the miller.³ I am indebted to him also for fine specimens of ergot on *Ammodendron arundinacea*. But the disease is not confined to the *Graminæ*: the *Cyperacæ* are also subject to it, and perhaps, likewise, *Palmacæ*.⁴

COMMERCE.—Ergot is imported from Germany, France, and America. The late

Fig. 211.

A full grown ear of rye, strongly infected with ergot (natural size).

¹ Quoted by Richard, *Elém. d'Hist. Nat.* i. 332.

² Phillipar, *op. cit.* 126; also, Bauer, MSS.

³ Report on the Diseases of Wheat, p. 20, from the *Journal of the Royal Agricultural Society of England*.

⁴ Phœbus, *op. cit.* 105.

Mr. Butler, of Covent Garden Market, told me that about $1\frac{1}{2}$ tons were imported in the year 1839.

DESCRIPTION.—When we examine a number of ears of ergotized rye, we find that the number of grains in each spike which have become ergotized varies considerably: there may be one only, or the spike may be covered with them.¹ Usually, the number is from three to ten.

The mature ergot (Fig. 211) projects considerably beyond the paleæ. It has a violet-black colour, and presents scarcely any filaments and sporidia.

The spurred rye, or ergot (*ergota*) of commerce, consists of grains which vary in length from a few lines to an inch, or even an inch and a half, and whose breadth is from half a line to four lines. Their form is cylindrical or obscurely triangular, with obtuse angles, tapering at the extremities (fusiform), curved like the spur of a cock, unequally furrowed on two sides, often irregularly cracked and fissured. The odour of a single grain is not detectable, but of a large quantity is fishy, peculiar, and nauseous. The taste is not very marked, but is disagreeable, and very slightly acrid. The grains are externally purplish-brown or black, more or less covered by a bloom, moderately brittle, the fractured surface being tolerably smooth, and whitish or purplish-white. Their sp. gr. is somewhat greater than that of water, though, when thrown into this liquid, they usually float at first, owing to the adherent air. The lower part of the grain is sometimes heavier than the upper.

When examined by the microscope, we find that the ergot consists of three distinct parts:—

1. The *internal part* or *body* of the ergot: this is composed of the hexagonal or rounded cellular tissue. The cells have the shape and regularity of the normal cells of the albumen, but they are considerably smaller (Corda says they are only $\frac{1}{3}$ th of the size), and contain, instead of starch, from one to three globules of oil, which are lighter than water and soluble in ether (Fig. 212, *d*, and 214). If the structure of ergot be examined after the grains have been dried and re-moistened, the tissue presents a very irregular appearance.
2. The *violet* or *blackish* coat of the ergot: this consists of a layer of longitudinally elongated delicate cells (see Fig. 212, *c*).
3. The *bloom*, which to a greater or less extent, covers the violet coat of the ergot: it resembles the bloom of plums, and may be readily wiped off. According to the late Mr. Quekett, it consists of the sporidia of the *Oidium*

 Fig. 213. Spores of the fungus very highly magnified.
 Fig. 214. Body of the receptacle, with the cells containing oil.

¹ Phillipar, *op. cit.* p. 96.

abortifaciens (Fig. 184, A). But Corda describes it as consisting of two parts: a layer of cylindrical, undivided cells (*sporophores* or *basidia*, Fig. 212, *b*), supporting the spores (Fig. 212, *a*, and Fig. 213).

In considering the metamorphosis which the normal rye grains have undergone by becoming ergotized, it appears that the seed coats and gluten cells (Fig. 206, *a b c*, p. 129) have been replaced by a layer of dark cells (Fig. 212, *c*); that the large cells of the albumen (Fig. 207, *d*, and Fig. 208, p. 129) have been replaced by the small cells of the ergot (Figs. 212 *d*, and 214); that the starch grains of the cells of the albumen (Fig. 208, and Fig. 209) have been replaced by drops of oil in the cells of the ergot (Fig. 212, *d*, and Fig. 214); and that the little body at the top of the ergot (Fig. 210, *F a*), which Phœbus calls the *Mützchen*, is the remains of the hairy crown of the grain, of the stigmata, and of the withered elevated pericarp.

Thus the entire organization of the grains is changed, and at the same time their effects on the animal body are altered; for while sound rye is edible, nutritive, and healthy, ergotized rye is unwholesome and poisonous, producing raphania and abortion.

DETERIORATION.—The ergot of rye is fed on by a little acarus, which is about one-fourth of the size of a cheese-mite. This animal destroys the interior of the ergot, and leaves the grain as a mere shell. It produces much powdery excrementitious matter (Quekett). In four months 7½ ounces of this fecal matter of the acarus were formed in seven pounds of ergot. I have some ergot which has been kept for eleven years in a stoppered glass vessel without being attacked by the acarus, and it has all the characteristics of good ergot. It is advisable, however, not to use ergot which has been kept for more than two years.

COMPOSITION.—Ergot was analyzed, in 1816, by Vauquelin;¹ in 1817, by Pettenkofer;² in 1826, by Winkler;³ in 1829, by Maas;⁴ in 1831, by Wiggers;⁵ and more recently by Chevallier.⁶ The results obtained by Chevallier were analogous to those of Wiggers.

Vauquelin's Analysis.

Pale yellow matter, soluble in alcohol, and tasting like fish-oil.
 White bland oil, very abundant.
 Violet colouring matter, insoluble in alcohol, soluble in water.
 A fixed acid (phosphoric?).
 Vegeto-animal or nitrogenous matter, prone to putrefaction, and yielding ammonia and oil by distillation.
 Free ammonia, disengaged at 212° F.

Wiggers's Analysis.

<i>Ergotin</i>	1.25
Peculiar fixed oil	35.00
White crystallizable fat	1.05
Cerin	0.76
Fungin	46.19
Vegetable osmazome	7.76
Peculiar saccharine matter	1.55
Gummy extractive, with red colouring matter	2.33
Albumen	1.46
Superphosphate of potash	4.42
Phosphate of lime, with trace of iron	0.29
Silica	0.14
Ergot	102.20

1. **ERGOTIN** was procured by digesting ergot with ether, to remove the fatty matter, and then in boiling alcohol. The alcoholic solution was evaporated, and the extract treated by water. The ergotin remained undissolved. It was brownish-red, with an acrid bitter taste, and, when warmed, had a peculiar but unpleasant odour. It was soluble in alcohol, but insoluble in water or ether. It is probable, therefore, that it is a resinoid colouring matter. It proved fatal to a hen. Nine grains of it were equal to an ounce and a half of ergot. It appears, then, that though a poisonous principle, it is probably not the agent which acts on the uterus, for the latter is soluble in water, whereas ergotin is not. It is possible, however, that it may be rendered soluble in water by combination with some other body.

2. **OIL OF ERGOT.**—As this is now used in medicine, its properties will be described hereafter (see p. 143).

There are no good grounds for suspecting the existence of either hydrocyanic acid or phosphate of morphia in ergot, as supposed by Pettenkofer.

CHEMICAL CHARACTERISTICS.—Ergot is inflammable, burning with a clear yellowish white flame. The aqueous infusion or decoction of ergot is red, and possesses acid properties. Both acetate and diacetate of lead cause precipitates in a decoction of ergot. Iodine gives no indication of the presence of starch. Nitrate of silver causes a copious precipitate soluble in ammonia, but insoluble in nitric acid. Tincture of nutgalls also produces a precipitate, (*tannate of ergotin?*) Alkalies heighten the red colour of the decoction.

PHYSIOLOGICAL EFFECTS.—Great discrepancy is to be found in the accounts published respecting the influence of spurred rye on man and animals. While the majority of experimenters or practical observers concur in assigning to it energetic powers, others have declared it harmless.

a. On Vegetables.—Schübler and Zeller have tried its effects on plants, and I infer from their statements that they found it poisonous.¹

β. On Animals.—Accidental observation and direct experiment concur in showing that in most instances spurred rye acts as a poison to the animal economy. But as Phœbus correctly observes, we cannot call it a *violent* poison, since drachms and even ounces are required to destroy small animals (*e. g.* rabbits and pigeons).

It has proved poisonous to flies, leeches, birds (geese, ducks, pigeons, common fowls, &c.), and mammals, (dogs, cats, pigs, sheep, rabbits, &c.) Birds and mammals refuse to take it, even mixed with other kinds of food. Diez² gives the following as the symptoms produced by it in dogs who are compelled to swallow it: "Great aversion to it, discharge of saliva and mucus from the mouth, vomiting, dilatation of the pupil, quickened respiration and circulation, frequent moanings, trembling of the body, continual running round, staggering gait, semi-paralysis of the extremities, especially the hinder ones, sometimes diarrhœa; sometimes hot anus, increased formation of gas in the alimentary canal; faintness and sleepiness, with great thirst, but diminished appetite. Death followed under gradually increasing feebleness, without being preceded by convulsions. To the less constant symptoms belong inflammation of the conjunctiva, and the peculiar appearance of turning round in a circle from right to left." Similar observations as to its injurious operation have been made by Robert.³ In some cases abscess and gangrene of various parts of the body, with dropping off of the toes, and convulsions, have been noticed. A strong decoction injected into the vein of a dog caused general feebleness, paralysis of the posterior extremities, vomiting, and death.⁴

But there are not wanting cases apparently showing that spurred rye has no injurious action on animals. The most remarkable and striking are those related by Block.⁵ In 1811, twenty sheep ate together nine pounds of it daily for four weeks without any ill effects. In another instance, twenty sheep consumed thirteen pounds and a half daily, for two months, without injury. Thirty cows took together twenty-seven pounds daily, for three months, with impunity; and two fat cows took, in addition, nine pounds of ergot daily, with no other obvious effect than that their milk gave a bad caseous cream, which did not yield good butter. These statements furnish another proof to the toxicologist that the ruminants suffer less from vegetable poisons than other animals.

Another interesting topic of inquiry is the action of ergot on the gravid uterus of mammals. Chapman⁶ says "it never fails, in a short time, to occasion abortion." We have the testimony of Percy and Laurent, that a decoction injected into the veins of a cow caused the animal to calve speedily; and in one out of three experiments, Mr. Combes has stated, the ergot caused the abortion of a bitch.⁷ Diez² found that it caused uterine contractions in dogs, rabbits, and sows. Large doses given to bitches induced an inflammatory condition of the uterus, and destroyed both mother and her young. However, in opposition to these statements, we have

⁸ Phœbus, p. 106.

the evidence of Chatard, Warner, Villeneuve, and others, who failed in producing abortion with it.¹

I am indebted to the late Mr. Youatt, formerly Veterinary Surgeon to the Zoological Society, for the following note respecting the effects of ergot on animals:—

“I have, for the last six or seven years, been in the habit of administering the ergot of rye to quadrupeds in cases of difficult or protracted parturition, in order to stimulate the uterus to renewed or increased action. In the *monogastric*, if I may venture to use the term, I have never known it fail of producing considerable effect, even when the uterus has been previously exhausted by continued and violent efforts. In the *ruminant*, with its compound stomach or stomachs, I have witnessed many a case of its successful exhibition. I have had recourse to it in the cow, the sheep, and the deer, both foreign and domestic. Parturition has not always been accomplished, from false presentations or other causes, but the uterus has in every case responded—it has been roused to a greater or less degree of renewed action. On the other hand, there are cases recorded by veterinary practitioners, in which it has been given in very large quantities without producing the slightest effect. I have always attributed this to a certain degree of forgetfulness of the construction of the stomachs of ruminants. If the medicine, as is too often the case, is poured hastily down, and from a large vessel, it breaks through the floor of the œsophagean canal and falls into the rumen, and there it remains perfectly inert. But if it is suffered to trickle down the œsophagean canal, although a portion of it may still enter the rumen, the greater part will flow on through the œsophagean canal and the manyplies into the fourth or villous stomach, and produce the desired effect.”

γ. *On Man*.—These may be noticed under two heads: 1, effects of single doses; 2, effects of its continued use as an article of food.

1. *In single or few doses*.—Hertwig,² Lorinser,³ Jörg,⁴ and Diez,⁵ who have endeavoured to ascertain the effects of ergot by experiment, agree in stating that, in doses of from half a drachm to two drachms, nausea, inclination to vomit, dryness of the throat, great thirst, aversion to food, uneasiness or actual pain in the abdomen, occasionally alvine evacuations, weight and pain in the head, giddiness, in some cases stupor and dilatation of pupils, have resulted from its use. It deserves, however, to be noticed, that these effects have not been observed by some experimenters.⁶

The effects produced by the use of single or a few doses of ergot may be conveniently arranged under four heads.

a. *Effects on the uterine system*. (*Uterine contractions*.)—The action of spurred rye on the uterus, when labour has actually commenced, is usually observed in from ten to twenty minutes after the medicine has been taken, and is manifested by an increase in the violence, the continuance, and the frequency of the pains, which usually never cease until the child is born; nay, they often continue for some minutes after, and promote the speedy separation of the placenta and the firm contraction of the uterus in a globular form. The contractions and pains caused by ergot are distinguished from those of natural labour by their continuance; scarcely any interval can be perceived between them, but a sensation is experienced of one continued forcible effort. If, from any mechanical impediment (as distortion), the uterus cannot get rid of its contents, the violence of its contraction may cause its rupture, as in the cases alluded to by Dr. Merriman,⁷ Mr. Armstrong,⁸ and Mr. Coward.⁹

Ergot sometimes fails to excite uterine contractions. The causes of failure are, for the most part, conjectural. The quality of the ergot, peculiarities on the part

⁹ *Gebrauch inn. Reizm. z. Beförd. d. Geburt.* 1833.

of the mother, and death of the fœtus, have been assigned as such. The two first will be readily admitted; but why the remedy should be altogether inert "where the fœtus has been for some time dead, and putrefaction to any extent taken place,"¹ cannot be readily explained. Its occasional failure has been urged by the late Dr. Hamilton² as an argument in favour of his notion that ergot acts "in no other way than by influencing the imagination." But, on the same ground, the sialagogue power of mercury might be denied. Dr. Hamilton's erroneous estimate of the powers of ergot is referable to a want of experience of its use; for he admits that he has only had two opportunities in practice of making a fair trial of it.

There is usually much less hemorrhage after delivery, when ergot has been employed, than where it has not been exhibited. The lochial discharges are also said to be less; but this is certainly not constantly the case. Moreover, it has been asserted "that the menstrual discharge has not recurred after the use of the ergot in certain cases of protracted parturition."³ But the inference intended to be conveyed here, viz., that ergot caused the non-recurrence, is not correct; at least, I am acquainted with several cases in which this effect did not follow the employment of spurred rye, and I know of none in which it did.

Ergot has been charged with causing the death of the child; but the charge has been repelled by some experienced practitioners as being devoid of the least foundation. "The ergot," says Dr. Hosack,⁴ "has been called, in some of the books, from its effects in hastening labour, the *pulvis ad partum*; as it regards the child, it may, with almost equal truth, be denominated the *pulvis ad mortem*; for I believe its operation, when sufficient to expel the child, in cases where nature is alone unequal to the task, is to produce so violent a contraction of the womb, and consequent convulsion and compression of the uterine vessels as very much to impede, if not totally to interrupt, the circulation between the mother and child." However, Dr. Chapman⁵ strongly denies this charge, and tells us that in 200 cases which occurred in the practice of himself and Drs. Dewees and James, the ergot was used without doing harm in any respect; and, he adds, "no one here believes in the alleged deleterious influence of the article on the fœtus." It is not improbable, however, where the impediment to labour is very great, that the violent action of the uterus may be attended with the result stated by Dr. Hosack. Dr. F. H. Ramsbotham⁶ has suggested that the poisonous influence of ergot may be extended from the mother to the fœtus, as in the case of opium. He also states⁷ that of 36 cases in which he induced premature labour by puncturing the membranes, 21 children were born alive; while, in 26 cases of premature labour induced by ergot only, 12 children only were born alive. This fact strongly favours the notion of the deleterious influence of the ergot on the fœtus.

Given to excite abortion, or premature labour, ergot has sometimes failed to produce the desired effect. Hence, many experienced accoucheurs have concluded that, for this medicine to have any effect on the uterus, it was necessary that the process of labour should have actually commenced.⁸ But, while we admit that it sometimes fails, we have abundant evidence to prove that it frequently succeeds; and most practitioners, I think, are now satisfied that in a large number of cases it has the power of originating the process of accouchement. Cases illustrating its power in this respect are referred to by Bayle;⁹ and others are mentioned by Waller,¹⁰ Holmes,¹¹ Ramsbotham,¹² Müller,¹³ and others.

The action of ergot on the unimpregnated uterus is manifested by painful contractions, frequently denominated "bearing-down pains," and by the obvious

influence which it exercises over various morbid conditions of this viscus; more particularly by its checking uterine hemorrhage, and expelling polypous masses. Tenderness of the uterus, and even actual metritis, are said to have been induced by it.¹

β. *Effects on the Cerebro-Spinal System. (Narcotism).*—Weight and pain in the head, giddiness, delirium, dilatation of pupil, and stupor, are the principal symptoms which indicate the action of ergot of rye on the brain. Dr. Maunsell² has published five cases (viz., two which occurred to Dr. Churchill, one to Dr. Johnson, and two to Dr. Cusack), in which delirium or stupor resulted from the use of ergot (in half-drachm and two-drachm doses), and was accompanied by great depression of pulse.³ Trousseau and Pidoux⁴ found that under the repeated use of ergot, dilatation of pupil was the most common symptom of cerebral disorder. It began to be obvious in from twelve to twenty-four hours after the commencement of the use of the medicine, and sometimes continued for several days after its cessation. The cerebral disorder is frequently preceded by the uterine contractions, and usually remains for some time after these have subsided.

Effects of ergot on the Circulatory System.—I have known increased frequency and fulness of pulse, copious perspiration, and flushed countenance, follow the use of ergot during parturition. But in most instances the opposite effect has been induced; the patient has experienced great faintness, the pulse has been greatly diminished in both frequency and fulness, and the face has become pale or livid. In one case, mentioned by Dr. Cusack,⁵ the pulse was reduced from 120 to 90. Dr. Maunsell has referred to four other cases. These effects on the circulatory system were accompanied with cerebral disorder, of which they were probably consequences. Similar observations, as to the power of ergot to diminish the frequency of the pulse, have been noticed by others.⁶

δ. *Other effects of ergot.*—Nausca and vomiting are not uncommon consequences of the exhibition of ergot when the stomach is in an irritable condition. Various other symptoms have been ascribed to the use of ergot; such as weariness of the limbs and itching of the skin.⁷

2. *Effects produced by the continued use of ergot as an article of food (Ergotism, Fr.; Raphania, Linn., Vog., Cull., Good; Convulsio raphania, and Eclampsia typhodes, Sauv.; Morbus spasmodicus, Rothm.; Morbus convulsivus, malignus, epidemicus, cerealis, &c., Alt.; Kriebelkrankheit, or the creeping sickness, Germ.).*—Different parts of the continent, e. g. France (especially in the district of Sologne), Silesia, Prussia, Bohemia, Saxony, Denmark, Switzerland, and Sweden, have been, at various periods, visited with a dangerous epidemic (known by the names above mentioned), which affected, at the same time, whole districts of country, attacking persons of both sexes and of all ages.⁸ So long back as 1597 (Tissot), the use of ergotized rye was thought to be the cause of it. Various circumstances have appeared to prove the correctness of this opinion,⁹ which has been further confirmed by the effects of ergot on animals, as well as by the occurrence of a disease similar to, if not identical with, ergotism, in consequence of the use of damaged wheat.¹⁰ Yet several intelligent writers have not acquiesced in this view; and the circumstances mentioned by Trousseau,¹¹ and by Dr. Hamilton,¹² are certainly calculated to throw some doubts over the usually received opinion.

Ergotism assumes two types; the one of which has been denominated the *convulsive*, the other the *gangrenous ergotism*. Whether these arise from different conditions of the ergot, or from peculiarities on the part of the patient, or from the

different quantity of the ergot taken, we are hardly prepared now to say. In *convulsive ergotism*, the symptoms are weariness, giddiness, contraction of the muscles of the extremities, formication, dimness of sight, loss of sensibility, voracious appetite, yellow countenance, and convulsions, followed by death. In the *gangrenous ergotism* there is also experienced formication; that is, a feeling as if insects were creeping over the skin, voracious appetite, coldness and insensibility of the extremities, followed by gangrene.¹

Uses.—To Dr. Stearns, of the United States, is due the credit of introducing ergot of rye to the notice of the profession as an agent specifically exciting uterine contractions.² In 1814, a paper was published by Mr. Prescott,³ on the effects of it in exciting labour-pains, and in uterine hemorrhage. It was not employed in England until 1824. The following are the principal uses of it:—

1. *To increase the expulsive efforts of the womb in protracted or lingering labours.*—When the delay of delivery is ascribable solely to the feeble contractions of the uterus, ergot is admissible, provided, first, that there be a proper conformation of the pelvis and soft parts; secondly, that the os uteri, vagina, and os externum, be dilated, or readily dilatable, and lubricated with a sufficient secretion; and, lastly, that the child be presenting naturally, or so that it shall form no great mechanical impediment to delivery. A natural position of the head is not an absolute essential for the use of ergot, since this medicine is admissible in some cases of breech presentation.⁴ The circumstances which especially contraindicate or preclude the use of this medicine are those which create an unusual resistance to the passage of the child: such are, disproportion between the size of the head and of the pelvis, great rigidity of the soft parts, and extraneous growths. Moreover, “earliness of the stage” of labour is laid down by Dr. Bigelow⁵ as a circumstance contraindicating the use of ergot. The proper period for its exhibition is when the head of the child has passed the brim of the pelvis. Some practitioners assert that a dilated or lax condition of the os uteri is not an essential requisite for the exhibition of ergot. It has been contended that one of the valuable properties of this medicine is to cause the dilatation of the uterine orifice; and cases are not wanting to confirm these statements.⁶

2. *To hasten delivery when the life of the patient is endangered by some alarming symptom.*—Thus, in serious hemorrhages occurring during labour, after the rupture of the membranes, and where the placenta is not situated over the os uteri, the ergot is especially indicated.⁷ It has also been employed to accelerate delivery in puerperal convulsions. Five successful cases of its use are recorded by Bayle,⁸ on the authority of Waterhouse, Mitchell, Roche, Brinkle, and Godquin. But the narcotic operation of ergot presents a serious objection to its use in cerebral affections.

3. *To provoke the expulsion of the placenta when its retention depends on a want of contraction of the uterus.*—In such cases, ergot has often proved of great advantage.⁹ When the hemorrhage is excessive, the ergot must not be regarded as a substitute for manual extraction, since, during the time required for its operation, the patient may die from loss of blood.¹⁰ In retention of the placenta from spasmodic or irregular contraction of the uterus, as well as from morbid adhesion, ergot is improper or useless.¹¹

4. *To provoke the expulsion of sanguineous clots, hydatids, and polypi from the*

¹ Christison, *Treatise on Poisons*; Orfila, *Toxicol. Gén.*; *Phil. Trans.* 1762; Henslow's *Report on the Diseases of Wheat*, in the *Journal of the Royal Agricultural Society of England*, vol. ii. 1841.

⁶ Bayle, *op. cit.* p. 539.

⁷ Dr. Blundell, *Lancet* for 1827-28, vol. i. p. 805; Dr. F. H. Ramsbotham, *Lond. Med. Gaz.* vol. xvi. pp. 86 and 692.

⁸ *Bibl. Thérap.* lii. 448 and 548.

⁹ Dr. Blundell, *Lancet*, 1827-28, vol. ii. 259; Bayle (*Bibl. Thérap.* vol. iii. 541) has recorded nine cases from Balarini, Bordol, Davjes, Duchâteau, and Morgan; and many others will be found in the medical journals.

¹⁰ Dr. F. H. Ramsbotham, *Lond. Med. Gaz.* xiv. 738.

¹¹ Dr. Jackson, *Lond. Med. Gaz.* iv. 105.

uterus.—Coagula of blood collected within the womb after delivery may sometimes require the use of ergot to excite the uterus to expel them, as in the case mentioned by Mackenzie.¹ Ergot is also valuable in promoting the expulsion of those remarkable formations called uterine hydatids,² and which are distinguished from the accephalocysts of other parts of the body by their not possessing an independent life, so that when separated from their pedicles they die.³ A successful case of the use of ergot in this affection has been published by Dr. Macgill.⁴ In uterine polypus, ergot has been exhibited with the view of hastening the descent of the tumour from the uterus into the vagina, so as to render it readily accessible for mechanical extirpation;⁵ for it is well known that, until this is effected, the patient is continually subject to hemorrhage, which in some cases proves fatal. In some instances, ergot has caused the expulsion of a polypus.⁶

5. *To restrain uterine hemorrhage, whether puerperal or non-puerperal*.—Ergot checks hemorrhage from the womb, principally, if not solely, by exciting contraction of the muscular fibres of this viscus, by which its blood-vessels are compressed and emptied, and their orifices closed. The experience of physicians and surgeons in all parts of the civilized world has fully and incontestably established the efficacy of ergot as a remedy for uterine hemorrhage.⁷ Maisonneuve and Trousseau⁸ have shown that the beneficial influence of ergot is exerted equally in the unimpregnated as in the impregnated state; proving, therefore, that the contrary statement of Prescott and Villeneuve is incorrect. Even in a case of cancer of the uterus, they have found it check the sanguineous discharge. In females subject to profuse uterine hemorrhages after delivery, ergot may be administered as a preventive, just before the birth of the child.⁹ Even in placenta presentations, a dose or two of ergot may be administered previously to the delivery being undertaken.¹⁰ To restrain excessive discharge of the lochia or catamenia, this remedy is sometimes most beneficial.

6. *To provoke abortion, and to promote it when this process has commenced and is accompanied with hemorrhage*.—Under certain circumstances, the practitioner finds it expedient to produce abortion: as in serious hemorrhage during pregnancy, and in deformed pelvis which do not admit the passage of a full-grown fœtus. In such cases, the ergot may be employed with great advantage.¹¹ When abortion has already commenced, ergot may be employed to quicken the process and check hemorrhage.

7. *In leucorrhœa and gonorrhœa*.—Ergot was first given in leucorrhœa by Dr. M. Hall;¹² and was subsequently employed by Dr. Spajrani¹³ with success; and in eight cases by Dr. Bazzoni,¹⁴ seven of these were cured by it. Dr. Negri¹⁵ published seven successful cases of its use. Its efficacy has been confirmed by many other practitioners. Dr. Negri also used it with apparent benefit in gonorrhœa, in both the male and female. He concludes that “secale cornutum has a peculiar action on the mucous membranes; but, if exhibited when there is a state of acute inflammation, their morbid secretions may be considerably increased; on the contrary, when a more chronic form of inflammation does exist, the secale cornutum may have a beneficial influence in arresting their preternatural discharge.”

8. *In hemorrhages generally*.—The power possessed by ergot of exciting uterine contractions, readily explains the efficacy of this agent in restraining sanguineous discharges from the womb; but it has also been used to check hemorrhage from other organs. In these cases it can only act as a sedative to the circulation, in a

similar way to foxglove. A considerable number of cases have been published in proof of its power of checking hemorrhage from other organs (as the nose, gums, chest, stomach, and rectum).¹ But, having found it unsuccessful in my own practice, seeing that in the hands of others it has also failed,² and knowing how difficult it is to ascertain the influence of remedies on hemorrhages, I think further evidence is required to prove the anti-hemorrhagic powers of ergot.

9. *In amenorrhœa*.—Some few cases have been published tending to show that ergot possesses emmenagogue properties.³ It appears to me to be more calculated to cause than to relieve amenorrhœa.

10. *In other diseases*.—Ergot has been employed in various other diseases with apparent success; viz., intermittent fever,⁴ paraplegia,⁵ &c.

ADMINISTRATION.—Ergot is usually given in the form either of powder or infusion. The decoction, less frequently the tincture, and still more rarely the extract, are also used. Latterly, the ethereal oily extract and oil have been used.

1. **PULVIS ERGOTÆ**; *Pulvis Secalis Cornuti*; *Powdered Ergot*.—This powder is only to be prepared when required for use. The dose of it, for a woman in labour, is twenty grains, to be repeated at intervals of half an hour for three times; for other occasions (as leucorrhœa, hemorrhages, &c.), five to ten or fifteen grains three times a day: its use should not be continued for any great length of time. It may be taken mixed with powdered sugar. It has had the various names of *pulvis parturiciens* (more correctly *parturificiens*), *pulvis ad partum*, *pulvis partem accclerans*, *obstetrical powder*, &c.

2. **INFUSUM ERGOTÆ, D.**; *Infusum Secalis Cornuti*; *Infusion of Ergot*.—Ergot, in coarse powder, ℥ij; Boiling Water f℥ix. Infuse for one hour, in a covered vessel, and strain. The product should measure about eight ounces. The dose for a woman in labour is f℥ij, to be repeated at intervals of half an hour or an hour. Sugar, aromatics (as nutmeg or cinnamon), or a little wine or brandy, may be added to flavour it.

3. **TINCTURA ERGOTÆ, D.**; *Tinctura Secalis Cornuti*; *Tincture of Ergot*.—(Ergot, in coarse powder, ℥viii; Proof Spirit Oij. Macerate for fourteen days, strain, express, and filter, *D*).—Five fluidrachms of this tincture contain one drachm of ergot. Dose ℥j to ℥iij.

Various other formulæ have been published,⁶ some made with rectified, others with proof, spirit. In most of them the proportion of ergot is smaller than in the Dublin formula. One formula⁷ orders of Ergot, bruised, f℥j; Boiling Water f℥ij. Infuse for twenty-four hours, and add Rectified Spirit f℥iss. Digest for ten days. Half a drachm of this tincture is said to be equivalent to ten grains of the powder. One or two spoonfuls of a tincture of ergot (prepared by digesting ℥ss of ergot in ℥iv of rectified spirit), mixed with water, has been recommended as an injection into the uterus in difficult labour. It is to be introduced between the head of the child and the neck of the uterus.⁸

4. **TINCTURA ERGOTÆ ÆTHEREA, L.**; *Tinctura Secalis Cornuti Ætherea*; *Ethereal Tincture of Ergot*.—(Ergot, bruised, ℥xv; Ether Oij. Macerate for seven days; then express and strain, *L*).—Half a fluidounce of this tincture contains a drachm and a half of ergot. The dose is a teaspoonful. The objection to this preparation is that it is not miscible with water.

The *ethereal solution of ergot*, used by Dr. Lever⁹ to promote uterine contraction, is essentially a solution of the oil of ergot. It was prepared by digesting ℥iv of

⁹ *Lancet*, 1827-28, vol. ii. p. 435.

powdered ergot in f̄iv of ether during seven days. The tincture was submitted to spontaneous evaporation, and the residue dissolved in f̄ij of ether. The dose of this solution is from ℥xv to ℥xxx on a lump of sugar.

[5. VINUM ERGOTÆ, U. S.; *Wine of Ergot*.—Take of Ergot, bruised, two ounces; White Wine a pint. Macerate for fourteen days, with occasional agitation; then express and filter through paper. This preparation is used as a substitute for the tincture. Dose, f̄ij, or f̄ij.]

6. OLEUM ERGOTÆ; *Oil of Ergot*.—The liquid sold in the shops under the name of *pure oil of ergot* is obtained by submitting the ethereal tincture of ergot to evaporation by a very gentle heat. Its colour is reddish brown. Mr. Wright¹ states that this depends on the age of the ergot, and that when obtained from recent specimens it is not unfrequently entirely free from colour. Its taste is oily and slightly acrid. It is lighter than water, and is soluble in alcohol and in solutions of the caustic alkalis. It is probably a mixture of several proximate principles. I made a guinea-pig swallow a fluidrachm of it: the only obvious effect was copious and frequent diuresis. Two fluidrachms diffused through water and injected into the jugular vein of a dog, caused trembling of the muscles, paralysis of the hind, and great weakness of the fore legs, which lasted for more than two days. The respiration and action of the heart were exceedingly rapid. The saliva streamed copiously from the mouth. The pupil was strongly dilated before the experiment, and no obvious change in it was induced by the oil. Mr. Wright found the oil very energetic. A drachm, he states, injected into the jugular vein caused dilatation of the pupil, feeble, slow, and intermittent action of the heart, deep and interrupted respiration, general paralysis, insensibility to punctures, and death in two hours and forty minutes.

According to evidence adduced by Mr. Wright, the oil possesses the same influence over the uterus as that of the crude drug; that is, it occasions powerful uterine contractions. To produce this effect, it should be given in doses of from 20 to 50 drops in any convenient vehicle, as cold water, warm tea, or weak spirit and water.

7. EXTRACTUM ERGOTÆ; *Extractum Secalis Cornuti*; *Bonjean's Ergotine*.—This is prepared by exhausting ergot of rye by means of water, and evaporating the liquors to the consistence of syrup. To this extract is to be added a considerable excess of alcohol, by which all the gummy matters and salts insoluble in alcohol are precipitated. The supernatant liquid is to be decanted and reduced in a water bath to the consistence of a soft extract. From 100 parts of ergot, from 14 to 16 parts of extract, called, by Bonjean, *ergotine*, are obtained. This extract is soft, reddish-brown, and homogeneous; has an odour of roast meat, and a slightly piquant bitter taste. It may be employed medicinally in substance, made into pills, or dissolved in water. The dose of it is from five to ten grains. The aqueous solution of it is red, limpid, and transparent.

ANTIDOTE.—The proper treatment to be adopted in a case of poisoning by an overdose of ergot has not been accurately determined. The first object would be, of course, to evacuate the poison from the alimentary canal by the use of emetics or purgatives. As chlorine decomposes ergotin, Phœbus recommends the employment of chlorine water. In the absence of this, nitro-hydrochloric acid (properly diluted) might be exhibited. The subsequent treatment should be conducted on general principles.

TRIBE V. ANDROPOGONEÆ, *Kunth*.40. SACCHARUM OFFICINARUM, *Linn.*—THE SUGAR CANE.*Sex. Syst.* Triandria, Digynia.

(Saccharum; caulis succus præparatus purificatus crystallinus. Sacchari Fæx; succus præparatus impurus, *L.*—Saccharum commune; Sacchari Fæx; Saccharum purum, *E.*—Saccharum purificatum; Refined Sugar; White Sugar.—Theriaca; Treacle; Molasses; or the concentrated uncrystallized juice, *D.*)

HISTORY.—The manufacture of sugar is said by Humboldt to be of the highest antiquity in China. Cane-sugar was known to the ancient Greeks and Romans, and was considered by them to be a kind of honey. Possibly, Herodotus¹ refers to it when he says that the Zygantes make honey in addition to that which they get from bees. Theophrastus² calls it *mel in arundinibus*; Dioscorides³ terms it *σάκχαρον*; Pliny⁴ *saccharum*. Humboldt⁵ adopts too hastily, I think, the opinion of Salmasius, that the latter writers meant the siliceous product of the Bamboo, viz., *Tabasheer*; for, in the first place, as they arrange it with honey, it was probably sweet, which tabasheer is not; secondly, the Sanscrit name for sugar is *Sarkura*;⁶ thirdly, a passage in Lucan⁷ seems distinctly to refer to the sugar-cane: "Quique bibunt tenera dulces ab arundine succos." Surely no one will pretend that the bamboo is a "tenera arundo?"⁸

BOTANY. **Gen. Char.**—*Spikelets* all fertile, in pairs; the one sessile, the other stalked; articulated at the base, two-flowered; the lower floret neuter, with one palea; the upper hermaphrodite, with two paleæ. *Glumes* two, membranous. *Paleæ* transparent, awnless; those of the hermaphrodite flower minute, unequal. *Stamens* three. *Ovary* smooth. *Styles* two, long; *stigmas* feathered, with simple toothletted hairs. *Scales* two, obscurely two or three-lobed at the point, distinct. *Caryopsis* smooth (?), loose (?) (*Kunth*).

Sp. Char.—*Panicle* effuse. *Flowers* triandrous. *Glumes* obscurely one-nerved, with very long hairs on the back (*Kunth*).

The *stem* is solid, from six to twelve feet high. *Leaves* flat. *Panicle* terminal, from one to three feet long, of gray colour, from the long soft hair that surrounds the flower. *Paleæ* rose-coloured.

Kunth admits four varieties:—

a. commune, the common yellow cane, called by the Bengalees *Poori*, and, by the West Indians, the *Creole Cane* or *Native Cane*, from its having been the one originally introduced into the New World.

β. purpureum, the purple cane, called by the Bengalees *Kajooli*, and which is said to yield juice one-eighth richer than the yellow cane.

γ. giganteum, the giant cane, a large light-coloured cane, called by the Bengalees *Kullooa*. It grows in a low swampy soil, where the other two will not succeed. Its juice is weaker than that of the yellow cane, but the plant grows to a much larger size; and it is, therefore, much cultivated in India.

δ. tahitense, the *Tahiti cane*, commonly called the *Otaheite cane*.

Hab.—It is cultivated in both Indies. Its native country is uncertain.

Two other species of *Saccharum* are cultivated for the sugar they produce:—

S. VIOLACEUM, Tussac, Antill. i. 160—*Kunth*, *Agrostogr.* i. 474; *Violet Sugar-cane*. (By some authors considered to be identical with *Tahiti sugar cane* above mentioned.)—Cultivated in both Indies.

S. SINENSE, Roxb., *Fl. Ind.*; *China Sugar-cane*.—Cultivated in China, where sugar is made from it.

² *Lib. ii. cap. civ.*

³ *Journal of Science and Arts*, vol. v. p. 15.

² *De Melle.*

⁴ *Hist. Nat.* lib. xii. cap. xvii.

⁶ *Royle's Essay*, p. 83.—In his more recent work, called *Cosmos*, Humboldt (*Sabine's transl.* vol. ii. pp. 109 and xxvi.) states that the Sanscrit name for sugar is the source of the Greek and Semitic names for it.

⁷ *Lib. iii. v. 237.*

⁸ References to passages in other ancient authors will be found in the notes to Valpy's edit. of *Pliny's Hist. Nat.* vol. iv. 2193; see, also, Moseley's *Treatise on Sugar*, Lond. 1799.

COMPOSITION OF THE SUGAR-CANE.—Avequin¹ analyzed the Tahiti and ribbon varieties of the fresh sugar-cane of Louisiana, and Dupuy² analyzed the fresh sugar-cane at Guadaloupe. Peligot,³ by combining the composition of cane-juice with that of the dried canes sent him from Martinique, has also deduced the composition of the fresh cane. More recently, Casaseca⁴ analyzed the sugar-cane of Cuba.

	Dupuy.	Peligot.	Avequin.	
			Tahiti Cane.	Ribbon Cane.
Sugar	17.8	18.0	14.280	13.392
Cellulose	9.8	9.9	8.867	9.071
Mucilaginous, resinous, fatty, and albuminous matter	—	—	0.415	0.441
Salts	0.4	— { Salts, silica, and oxide of iron }	0.358	0.368
Water	72.0	72.1	76.080	76.729
Fresh sugar-cane	100.0	100.0	100.000	100.001

The dried sugar-cane was analyzed by O. Hervy.⁵

The composition of *sugar cane ash* is an important consideration for the sugar-planter, as it enables him to deduce the most appropriate manure for promoting the growth of the cane.⁶

The sugar-cane, especially the violet variety, is coated by a glaucous powder of a peculiar kind of wax, which has been called *cerosine* or *sugar-cane wax*.⁷ This is fusible at 180° F., and dissolves in boiling alcohol: the alcoholic solution, even when it contains but a small quantity of cerosine, gelatinizes or solidifies on cooling like an alcoholic solution of soap. The composition of this wax is C⁴⁸H⁵⁰O² (Dumas).

EXTRACTION OF CANE-JUICE.—Cane-juice is generally extracted from the stems by means of the *sugar mill*. The canes, when ripe, are cut close to the ground, stripped of their leaves, and carried in bundles to the mill-house, where they are twice subjected to pressure between iron rollers, placed either vertically or horizontally. The residue of the canes which have been thus crushed and deprived of their juice is called *megass*.

Other methods of extracting the cane-juice have been suggested. The *hydraulic press* has been introduced into Jamaica and St. Vincent's. By *Michiel's patent* it is proposed to macerate thin slices of the cane in a mixture of lime and water, so as to coagulate the albuminous matters but to extract the sugar. It has also been proposed to extract the sugar in Europe from the canes imported in the dried state.⁸

PROPERTIES OF CANE-JUICE.—Cane-juice is pale yellowish-gray, and has an agreeable sweet taste and a faint fragrant odour. As it flows from the mill it is frothy, and, owing to the suspension in it of finely-divided matter, is turbid or opalescent. Its sp. gr. ranges from 1.067 to 1.106: Mr. Fownes⁹ found it to be from 1.070 to 1.090. By boiling, its turbidity is commonly a little increased, and sometimes a few small flocks are separated from it. Both nitric acid and corrosive sublimate occasion, after a time, a very slight precipitate. A large addition of alcohol throws down flocks resembling gum or dextrine. A few drops of sulphate of copper, and an excess of caustic potash, occasion, on heating, a very abundant red precipitate of suboxide of copper, indicative of the presence of glucose or grape-sugar.

According to Mr. Fownes, the juice contains the following substances: *Cane-sugar* in great quantity, a notable amount of *glucose* or *grape-sugar*, *gum* or *dextrine*, *phosphates of lime and magnesia*, some *other salt of lime and magnesia*, *sulphates* and *chlorides*, *potash* and *soda*, and, lastly, a *peculiar azotized matter* belonging to the albuminous family, forming an insoluble compound with lime,

⁵ *Journ. de Pharm.* t. xxvi. p. 569, 1840.

⁶ For analyses of the ash of the entire sugar-cane, as well as of the crushed and pressed cane (*megass*), see Johnston's *Lectures on Agricultural Chemistry*, pp. 393 and 628, 2d edit. 1817. The same author also gives the formula for a special manure for the sugar-cane, deduced from the analyses of the ash (*op. cit.* p. 614).

⁷ *Journ. de Pharm.* t. xxvi. p. 738, 1840.

⁸ For further details, see Dr. Evans's *Sugar-Planter's Manual*, 1847.

⁹ *Pharmaceutical Journal*, vol. viii. p. 15, 1848.

not coagulable by heat or acids, and readily putrefiable. Of ordinary *vegetable albumen* there are but indistinct traces, and of caseine or legumine none. Avequin found a portion of *cerosine* or sugar-cane wax in cane-juice. It is detached from the canes in the mill.

Cane-juice has been analyzed by Proust,¹ by Avequin,² by Peligot,³ by Plagne,⁴ and by Casaseca.⁵ The following are their more important results:—

	Avequin.	Peligot.	Plagne.	Casaseca.
Sugar	15.784	20.90	20.8000	20.94
Various organic matters	0.140	0.23	0.8317	0.12
Salts	0.236	0.17	small quantities	0.14
Water	83.840	78.70	78.3325	78.80
Cane-juice	100.000	100.00	99.9642	100.00

It appears, therefore, from these analyses, that cane-juice contains about 20 per cent. of saccharine matter. Or, assuming that the juice has an average sp. gr. of 1.073, the quantity will be 18 per cent. Moreover, according to both Peligot and Casaseca, the whole of the saccharine matter is crystallizable, or true cane-sugar; the uncrystallizable sugar, or molasses, which is obtained by evaporation from the juice, being the product of alterations effected in the crystallizable sugar by the operation: but Mr. Fownes observed that this statement must be received with some reservation.

Of late years, *concentrated West Indian cane-juice* has been imported. It contains nearly half its weight of granular sugar, besides a variable amount of molasses.

CLARIFICATION OF CANE-JUICE.—The clarification or defecation of cane-juice is effected, usually in large copper vessels of the capacity of 300 or 400 gallons, by the combined use of heat and lime: the latter is technically called “the *temper*.” The heat serves to coagulate any vegetable albumen which may be present. The lime neutralizes the free acid and combines with the peculiar albuminous or proteine body mentioned by Mr. Fownes, and forms a coagulum, the separation of which is promoted by the heat. Part of it rises to the top as a scum, and the remainder subsides as a thick muddy deposit.

Various other substances⁶ have been tried as a substitute for lime with more or less success. Diacetate of lead has been employed for this purpose, but its use has been discontinued on account of a great number of persons having suffered the ill effects of this metal from partaking of sugar prepared with it.

CONCENTRATION OF THE CANE-JUICE.—The clarified juice should be filtered prior to evaporation. This, however, is not usually practised. It is generally drawn off from the clarifier into a copper *boiler*, where it is evaporated and skimmed. It is then passed successively through a series of boilers, the last of which is called the *teache*. When it has acquired a proper tenacity and granular aspect, it is emptied or “skipped” first into a copper cooler and afterwards into a wooden vessel, where it is allowed to crystallize or *grain*. The concrete sugar is then placed in casks (usually sugar hogsheads) perforated with holes in the bottom, each of which is partially closed by the stalk of a plantain leaf. Here the sugar is allowed to drain for three or four weeks. It is then packed in hogsheads and sent to this country under the name of *muscovado* or *raw sugar*.

The drainings, or uncrystallized portion of sugar, constitute *molasses*. This is received in an open cistern beneath.

The feculencies separated in the clarifying vessel, and the skimmings of the evaporating coppers, are employed in the manufacture of *rum*.

PROPERTIES OF RAW SUGAR.—Raw sugar is a mixture of crystallizable and uncrystallizable sugar, contaminated by various organic and mineral substances. Its mineral constituents are, according to Avequin, silica, phosphate and subphos-

⁵ *Ibid.*, p. 218, 1840.

⁶ See Dr. Evans's *Sugar-Planter's Manual*.

phate of lime, carbonate of lime, sulphate of potash, chloride of potassium, and the acetates of potash and lime.

The raw sugar of the shops reddens litmus, and is not completely soluble in alcohol. Its aqueous solution yields precipitates with the diacetate of lead, oxalic acid, and caustic ammonia; and is frequently darkened by the addition of the sesquichloride of iron. By keeping, *strong* raw sugar becomes *weak*—that is, soft, clammy, and gummy. This change the late Mr. Daniell¹ ascribed to the action of the lime.

SUGAR REFINING.—The following is a sketch of the process as usually practised in London: Raw sugar is dissolved in water by the aid of steam (this process is called giving the sugar a *blow-up*). The liquid is then heated with bullock's blood² (technically called *spice*), and filtered through canvas bags (called *Schröder's bags*). The clear liquor is allowed to percolate slowly through a bed of coarse-grained animal charcoal placed on a woollen cloth, supported on a false bottom of basket-work, and contained in a large wooden vessel. The depth of the bed of charcoal varies in different refining-houses. I have seen it three feet deep; but I am told that some refiners employ a bed twenty feet in depth. The filtered liquor, which is nearly colourless, is conveyed to a copper vessel (Howard's *vacuum-pan*), where it is boiled by the aid of steam, under diminished atmospheric pressure, at a temperature of about 170° F.

Fig. 215.

View of two Vacuum Pans and their subsidiary Apparatus.

a a. Charging measures, supplied by pipes, which descend from *c c*, the liquor cisterns. *d d*, are the vacuum spheroidal pans, the lower half of each being supplied with a jacket, as a case for the steam. At the sides of the neck of each pan are a barometer and thermometer. Below the neck, and just above the horizontal line *b b*, is the handle of the proof-stick, which appears like a stop-cock. When the syrup is sufficiently concentrated, it is discharged into the heater, *e e*.

The consistence of the liquid is examined from time to time by taking out a sample by the *proof-stick*, which is so constructed as not to admit air.

When the requisite degree of concentration has been attained, a valve is opened in the bottom of the vacuum pan, and the syrup allowed to escape into a copper vessel (*heater*), enveloped by a jacket, so as to enable it to be heated by steam. The syrup is then transferred to conical moulds (made of earthenware or iron), whose orifices are closed by a paper plug, and the next morning, when solidified, these moulds are carried to the *curing-floor*, when the stoppers are withdrawn and

¹ *Quarterly Journal of Science*, vi. 33.

² At one time hydrate of alumina, under the name of *finings*, was used in addition to blood.

the moulds placed in pots, in order to allow the *green syrups* to drain off: these are made into an inferior sort of refined sugar (*brown lumps*). The loaves are then either *clayed* or *sugared*, generally the latter.

*Claying*¹ (which is now almost entirely out of use) consists in pouring clay and water on the base of the sugar loaf: the water slowly percolating through the sugar, a portion of which it dissolves, carries with it the colouring matter and other impurities. *Sugaring* is effected by substituting a saturated solution of pure sugar (called *liquor*) for the clay and water; it washes out the colouring matter, but does not dissolve the pure sugar. The loaves are afterwards dried in a stove, and put in blue paper for sale.²

The following may be regarded as an approximation to the produce of 112 lbs. of raw sugar by the above process:—

Refined sugar	79 lbs.
Bastard	17
Treacle	16 (12 lbs. solid matter.)
Water	4
	112
Raw sugar	112

The animal charcoal used in sugar refining is changed every week, and of course is a more powerful decolorizer when fresh than when it has been used several times. It follows, therefore, that the quality of the refined sugar obtained varies with the day of the week—that is, with the age of the charcoal. At the commencement of the week, when the charcoal is fresh, the finest white *loaves* of sugar are made; about the middle of the week *titlers* and *lumps* are obtained; and, at the end of the week, *bastards*.

In the process of sugar refining, various salts have been proposed to be used as defecators; such as the trisacetate of lead,³ acetate of lead,⁴ bisulphite of lime,⁵ sulphate of tin,⁶ &c. The salts of lead are probably the most effective agents, but, on account of their poisonous properties, are dangerous to the public health.⁷

PROPERTIES.—Common or cane-sugar is the sweetest of all kinds of sugar. When pure, it is white and odourless. It is very soluble in water, both hot and cold (see *Syrupus*, vol. i. p. 153); is soluble in rectified spirit, but not in ether. Its watery solution, aided by heat, decomposes some of the metallic salts (as those of copper, mercury, gold, and silver); but several of them (as the diacetate of copper and nitrate of silver) require nearly a boiling temperature to change them. A dilute watery solution of common sugar, with a little yeast, undergoes the vinous fermentation. Sugar promotes the solubility of lime in water, and forms both a soluble and an insoluble compound with oxide of lead.

Cane-sugar is capable of existing either in the crystallized or amorphous state. In this respect it resembles sulphur (see vol. i. p. 355).

1. *Crystallized Cane-sugar.*—To this division are referred sugar-candy and the ordinary loaf and lump sugar of the shops. By the slow cooling of a saturated aqueous solution of sugar, we obtain the large and fine crystals which constitute the commercial *sugar-candy* (*saccharum candum*), and of which three kinds are kept in the shops; namely, *white candy*, prepared from pure sugar; *brown candy*, prepared from brown sugar; and *pink* or *rose candy*, prepared from sugar artificially coloured (probably by cochineal).

The crystals of sugar are doubly oblique prisms, and, therefore, have two axes of double refraction⁸ (see vol. i. p. 187). Their sp. gr. is 1.6065.

Common crystallized sugar is permanent in the air and phosphorescent in the

¹ "Claying sugar, as they report here, was first found out in Brazil: a hen, having her feet dirty, going over a pot of sugar by accident, it was found under her tread to be whiter than elsewhere."—Sloane's *Jamaica*, vol. i. p. 61.

⁷ See *Pharmaceutical Journal*, vol. x.

⁸ Sugar-candy makes an interesting polariscope object. It is usually cut so as to show one only of its two systems of rings.

dark when struck or rubbed. When heated, it melts and soon becomes coloured. By this process, its tendency to crystallize is diminished or destroyed.

The commercial varieties of common crystallized cane-sugar are of two kinds—*white* or *brown*. The first is refined sugar.

1. **PURIFIED OR REFINED SUGAR** (*Saccharum*, L.; *Saccharum purum*, F.; *Succus concretus purificatus*, D.; *Saccharum purificatum*) is met with in the shops in conical loaves (*loaf sugar*) or truncated cones, called lumps (*lump sugar*), of various sizes and degrees of purity. Small lumps are called *titlers*. The finest refined sugar (*saccharum albiſſimum*) is perfectly white, and is termed *double refined*; the inferior kind (*saccharum album*) has a slightly yellowish tint, and is called *single refined*. Both varieties are compact, porous, friable, and made up of small crystalline grains.

2. **BROWN SUGAR** (*Saccharum commune*, E.; *Saccharum fuscum*; *Succus concretus non purificatus*, D.) occurs in commerce in the form of a coarse powder composed of shining crystalline grains. It is more or less damp and sticky, and has a peculiar smell and a very sweet taste. Its colour is brownish-yellow, but varying considerably in intensity. *Muscovado*, or *raw sugar*, has the deepest colour, and is intermixed with lumps. *Bastard* is a finer kind, prepared from molasses and the green syrups. The *Demerara crystal sugar* is the finest: its colour is pale yellow, and its crystals are larger and more brilliant than the preceding varieties.

2. **Amorphous Cane-sugar**.—When syrup or a strong solution of crystallized cane-sugar is rapidly boiled down, and then poured out on a marble or metallic plate, it congeals in an amorphous, vitreous, more or less coloured mass, usually called *boiled sugar*, of which *barley-sugar* (*saccharum hordeatum*), *acidulated drops*, and *hard-bake*, are familiar examples. During the preparation of barley-sugar and acidulated drops, the confectioners usually add a small quantity of cream of tartar to the melted sugar, in order to destroy its tendency to crystallize. Vinegar and tartaric acid are mentioned by some writers as being used for this purpose.

If when the melted sugar has partially solidified, but while it is yet soft, it be hung on a hook and rapidly and repeatedly drawn out, it becomes opaque and white. This *pulled sugar* was formerly termed *sugar penides* (*saccharum penidium*).

When crystallized cane-sugar is subjected to a temperature of about 356° F., it melts; and, at a higher temperature, begins to give off water and to suffer decomposition. If the heat be gradually augmented, it becomes brown, evolves a remarkable odour, loses its sweet taste and acquires a bitter one. In this condition it is called *caramel* (from *καίω*, *I burn*, and *μέλι*, *honey*), or *burnt sugar* (*saccharum tostum*). It enjoys acid properties, and is composed, according to Peligot,¹ of C²⁴H¹⁸O¹⁸.

Molasses and Treacle.—These are viscid, dark brown, dense liquids, composed of amorphous or uncrystallizable sugar, crystallizable sugar, gum, extractive, various salts, and water. They are frequently confounded, but in trade are considered distinct.

1. **MOLASSES** (more correctly *Melasses*, from *mel*, honey, because it is soft and sweet like honey) is the drainings from raw or muscovado sugar. *West India molasses* is occasionally imported for refining. It yields brown sugar, or *bastard*, and *treacle*.

2. **TREACLE** (*Theriaca*, D.; *Fax Sacchari*, L. E.) is the viscid, dark brown, uncrystallizable syrup which drains from refined sugar in the sugar moulds. It is thicker than West Indian molasses, and has a somewhat different flavour. Its sp. gr. is generally 1.4; and it contains, according to Dr. Ure, on an average, 75 per cent. of solid matter. Payen says that it may be regarded as a saturated solution of crystallizable sugar, of which it contains from 40 to 50 per cent. of its weight. It is employed in the manufacture of gingerbread, and, by poor people, as a substitute for sugar. It is also sometimes used to yield, by fermentation, an alcoholic liquor—either to be drank as a kind of beer, or to yield, by distillation, spirit. It is sold under the names of "*mélasse de la Cochinchine*" and "*prepared melasse*," to be taken with lentilmeal (sold as *erva-lenta* or *revulenta arabica*), as a remedy for habitual constipation.

CHEMICAL CHARACTERISTICS.—As a species of sugar,² cane-sugar is known by its susceptibility of undergoing the vinous fermentation; that is, of suffering a peculiar decomposition into alcohol and carbonic acid. For this purpose it is dissolved

¹ Peligot, *Ann. Chim. et de Phys.* lxxvii. p. 175.

² Mannite, glycyrrhizin, glycerine, and some other sweet substances, which were formerly called sugars, are, by modern chemists, excluded from the list of sugars, properly so called, because they are incapable of undergoing the vinous fermentation.

in water, and to the solution a small portion of yeast (dry yeast is to be preferred) is added, and the mixture exposed to a temperature of about 70° F. Effervescence soon takes place, carbonic acid is evolved, and a vinous or alcoholic liquor is produced. In this process the cane-sugar combines with water, and becomes grape-sugar, $C^{12}H^{12}O^{12}$, which, by fermentation, is resolved into four atoms of carbonic acid, $4CO^2$, and two atoms of alcohol, $2C^2H^6O^2$.

The quantitative determination of sugar is effected by ascertaining the amount of carbonic acid evolved during fermentation. 171 grains of sugar-candy furnish 88 grains, or about 186.4 cubic inches of carbonic acid gas. At mean temperature and pressure, 100 cubic inches, or 47.2 grains, of carbonic acid gas are given out by 91.7 grains of sugar-candy. In round numbers, we may say that one cubic inch or half a grain of carbonic acid gas is equal to one grain of sugar-candy.¹

Cane-sugar is distinguished from other kinds of sugar by the following characters:—Its crystallizability in prismatic crystals, its very sweet taste, its ready solubility in water, its solution being charred and letting fall a brown or black powder when heated with a few drops of oil of vitriol, but being unchanged when treated in the same way with caustic potash—and by the difficulty with which it reduces the blue hydrated oxide of copper to the orange suboxide.

Fig. 216.

Plan of the Apparatus for showing the circular polarization of liquids.

(In this figure, *g* indicates a lens which is used to produce well-defined images.)

Grape-sugar reduces the hydrated oxide of copper to the suboxide with great facility. The test is applied thus: Add to the saccharine solution a small quantity of a solution of caustic potash, and then a few drops of a weak solution of sulphate of copper; taking care that the alkali is in excess. Then apply heat: if grape-sugar be present, an ochre-yellow or red precipitate of suboxide of copper is formed before ebullition takes place. Uncrystallizable sugar, as well as sugar of milk, also readily reduces the oxide; but this effect does not take place with crystallizable cane sugar; or rather, a higher temperature or a longer action of the ingredients is required to produce the effect. This is called *Trommer's test*.

A solution of crystallizable cane-sugar is distinguished from solutions of some other kinds of saccharine matters by possessing the property of *right-handed* circular polarization.

If a ray of common light (Fig. 216, *a*) be polarized by reflection at an angle of 56°.45 from the surface of glass² (*b*), the plane polarized ray (*c*), which is thus obtained, transmitted through a pure solution of crystallizable cane-sugar (*d*), and the emergent ray (*e*) ana-

Fig. 217.

lyzed by a double refracting rhomb of calcareous spar (*f*), two coloured images are perceived (Figs. 216 and 217); one (*o*) caused by ordinary refraction, the other

¹ Full directions for the quantitative determination of sugar by fermentation are given by Dr. Miller, in the article *Organic Analysis* of the *Cyclopædia of Anatomy and Physiology*, vol. iii. p. 799.

² The plane polarization of the ray may be effected by a Nicol's prism instead of a glass-mirror. The use of a silvered glass-mirror is objectionable, on account of its producing elliptical polarization.

(*x*) by extraordinary refraction. The colours of the images are complementary; that is, when one image is red, yellow, or blue—the other is green, violet, or orange. By rotating the analyzer (the rhomb of calcareous spar), the colours change: if the rotation be right-handed (that is, as we turn a screw or corkscrew to make it enter), the sequence of the colours is red, orange, yellow, green, blue, indigo, and violet.

SEQUENCE OF COLOURS FOR A SOLUTION OF CRYSTALLIZABLE CANE-SUGAR, AS OBTAINED BY THE RIGHT-HANDED ROTATION OF THE ANALYZER.

Ordinary Image.	Extraordinary Image.
Red	Green.
Orange	Blue.
Yellow	{ Indigo.
	{ Violet.
Green	Red.
Blue	Orange.
Indigo }	Yellow.
Violet }	
Red	Green.

In one complete revolution of the analyzer, each of the colours of the spectrum occurs twice for each image.¹

COMPOSITION.—The following is the ultimate composition of sugar:—

Atoms. Eq. Wt. Per Cent.	Atoms. Eq. Wt. Per Cent.
Carbon 12 . . . 72 . . . 47.05	Anhydrous sugar . . 1 . . . 153 . . . 89.47
Hydrogen 9 . . . 9 . . . 5.9	Water 2 . . . 18 . . . 10.53
Oxygen 9 . . . 72 . . . 47.05	
Anhydrous sugar ² . . 1 . . . 153 . . . 100.00	Crystallized sugar . . 1 . . . 171 . . . 100.00

ADULTERATION; PURITY.—The purity of genuine sugar is readily judged of by its physical or sensible qualities. The impurities may also be detected by chemical means, but it is rarely necessary to resort to these. A solution of pure sugar is colourless, and yields no precipitate with oxalic acid, diacetate of lead, or caustic ammonia. Pure sugar is completely soluble in rectified spirit.

Brown sugar of commerce contains crystallizable and uncrystallizable sugar, woody tissue of the sugar-cane, vegetable albumen, siliceous particles, sporules and filaments of fungi; and, in most samples, a peculiar species of mite (*Acarus*), which has been called the *sugar mite*³ (*acarus sacchari*). In most cases the animal is dead, but frequently it is met with in the living state. Starch or flour is also said to be found in brown sugar.

Various adulterations have been practised on sugar. The most important of these is the intermixture of *starch sugar*. A few years ago I inspected an extensive manufactory of sugar from potato-starch at Stratford, in Essex: the sugar obtained was sold for the adulteration of brown sugar, and the molasses produced was consumed in an oxalic acid manufactory. Brown cane-sugar adulterated with starch sugar is less sweet, less readily soluble in water, and less crystalline and sparkling than pure brown cane-sugar. Moreover, potato-sugar always contains sulphate of lime, the detection of which (see the tests for sulphuric acid and lime, pp. 368 and 562) in a suspected sample of sugar is, therefore, of some value. It has been proposed to detect the presence of potato-sugar by Trommer's test (see *ante*, p. 150) and by caustic potash. But though Trommer's test readily detects starch-sugar in a solution of white cane-sugar, the detection is not so easily effected by it in a solution of brown cane-sugar, because the uncrystallizable cane-sugar, or treacle, which

¹ The nature of the present work does not admit of a further elucidation of circular polarization, which I have here introduced as an aid in the qualitative determination of a saccharine solution. Biot has applied it to the quantitative determination of sugar. To his various papers contained in the *Mémoires de l'Académie des Sciences*, and especially to his *Instructions Pratiques sur l'Observation et la Mesure des Propriétés Optiques appellées rotatoires*, Paris, 1845, the reader is referred for further information. See, also, the article *Saccharimétrie Optique*, in Pelouze and Fremy's *Cours de Chimie Générale*, t. iii. p. 337, 1850.—A popular sketch of the subject will be found in my *Lectures on Polarized Light*, published by Messrs. Longman and Co.—A very admirable report on this and other methods of effecting the qualitative and quantitative analysis of sugars, syrups, and molasses, by Professor R. S. McCulloch, is contained in a *Letter from the Secretary of the [United States] Treasury to the United States Senate*, read Feb. 21, 1845.

² Peligot, *Ann. de Chim. et de Phys.* lxxvii. p. 124.

³ *Pharmaceutical Journal*, vol. x. pp. 343 and 396, Jan. and Feb. 1851; *Lancet* for Jan. 18 and 25, 1851.

is present readily reduces the blue hydrate of copper to the orange suboxide—acting thus like starch-sugar. Chevallier¹ proposes to detect starch-sugar in cane-sugar by means of caustic potash: Boil the suspected sugar in a ley of caustic potash: if no starch-sugar be present, the liquor remains colourless; but, on the contrary, it becomes brown if starch-sugar be present. But this test, like the last one, is better adapted for detecting starch-sugar in white cane-sugar than in the ordinary brown cane-sugar of the shops.²

Farinaceous substances and dextrine may be detected by boiling the suspected sugar in water and testing the decoction, when cold, with iodine, which causes a blue colour with starch and a purplish colour with dextrine.

Gum is distinguished from sugar by its insolubility in rectified spirit.

Various other substances have, it is said, been used for the adulteration of sugar; as finely-powdered marble, chalk or whiting, sand, bone-dust, and common salt. With the exception of salt, all the substances here mentioned are insoluble in water, and by this character, therefore, may be readily separated from sugar. Common salt may be detected in a solution of the suspected sugar by the ordinary tests for that substance (see vol. i. p. 537).

PHYSIOLOGICAL EFFECTS.—Sugar, considered as an article of food, is an alimentary principle which belongs to the class of “elements of respiration,” (see vol. i. p. 117.) It contributes to the formation of fat and of lactic acid, and by its oxidation furnishes heat. It has recently been detected in the tissue of the liver, but in no other organ.³

It disagrees with some dyspeptics, and is reputed to have a tendency to cause flatulency and preternatural acidity (by the formation of lactic acid?) of the *primæ viæ*.

Treacle, and therefore raw sugar, check the tendency to constipation.

USES.—Sugar is used dietetically, medicinally, and pharmaceutically. *Medicinally*, it is but little employed. In the form of lozenges, sugar-candy, &c., it is slowly dissolved in the mouth to allay tickling cough. As a chemical antidote, it has been recommended in poisoning by the salts of copper, mercury, silver, gold, and lead.⁴ But any advantage procured by its use in these cases is referable to its demulcent and emollient properties, and not to its chemical influence. The same remark may be made with respect to the benefit said to have been obtained by the use of the juice of the sugar-cane in poisoning by arsenious acid.⁵ Powdered white sugar is sometimes sprinkled over ulcers, to remove spongy granulations, denominated proud flesh. The same remedy has also been employed for the removal of specks on the cornea.

In *pharmacy*, the uses of sugar are much more extensive. It serves to preserve, to give flavour, bulk, form, colour, cohesiveness, and consistence; to subdivide and to suspend oily substances in aqueous liquids. To fulfil one or more of these objects, it is a constituent of *syrups*, *elæosacchara*, *conserves*, *electuaries*, *confections*, *lozenges*, some *pills* and *powders*, &c. For making pills, treacle serves to give cohesiveness, to preserve the pill-mass soft, prevent mouldiness, and in some cases to check chemical changes. As an antiseptic, it is used for the preservation of various medicinal organic substances. It acts in at least two ways—by excluding air and by absorbing moisture (see vol. i. p. 205); and perhaps, also, in some other way—as when it promotes the solidification of pectine. Sugar is also useful in preserving some inorganic compounds: thus it checks, though it does not absolutely prevent, the higher oxidation of some of the protosalts of iron; hence its

¹ *Journ. de Chim. Méd.* t. viii. 2de Sér. p. 472, 1842.

² On a trial for the recovery of excise duties on potato-sugar, it was stated that this sugar possessed only three-fifths of the sweetening properties of genuine cane-sugar, and that it was mixed with whiting, bone-dust, &c. previous to its being offered for sale. (*Pharm. Journ.* vol. i. p. 603, 1842.)

³ *Comptes rendus*, xxvii. p. 514; *Chemical Gazette*, March 1, 1849.

⁴ Vogel and Buchner, in *Schweigger's Journ.* xiii. 162; xiv. 224.

⁵ Chisholm, *Quarterly Journal of Science*, x. 193.

use in the *ferri carbonas saccharatum* (see vol. i. p. 724), and *syrupus ferri iodidi* (see vol. i. p. 744).

It is employed in the manufacture of oxalic acid; and it is sometimes used in distilleries to yield, by fermentation, alcohol. The Edinburgh College directs it to be used in the rectification of sulphuric acid (see vol. i. p. 359).

As a test, it is sometimes used in the laboratory in conjunction with oil of vitriol, to detect the cholic acid of bile.

1. SYRUPUS, L. [U. S.]; *Syrupus simplex*, E. D.; *Syrup*; *Simple Syrup*.—(Sugar lbij [lbv, D. (lbiss, U. S.)]; Water Oj [Oij, D. (Oj, U. S.)]. Dissolve the sugar in the water by a gentle heat.)—By keeping for several months, syrup undergoes some molecular changes, by which its power of producing right-handed circular polarization is considerably diminished.

The proportion of water and sugar used by the London College is, by weight, water 1 part, sugar 1.9748 parts; by the Edinburgh College, water 1 part, sugar 2.1942 parts—or, very nearly, water 1 part, sugar $2\frac{1}{2}$ parts; and, by the Dublin College, water 1 part, sugar 2 parts.

In order to yield a clear and bright syrup, distilled water and well-refined sugar should be employed. Ordinary spring water becomes turbid by boiling, owing to the precipitation of carbonate of lime.¹

The sp. gr. of boiling syrup should be 1.264 (equal to 30° of Beaume's areometer). When it has cooled down to 60° F., its sp. gr. should be 1.321 (equal to 35° of Beaume's areometer). The Dublin College states the sp. gr. of simple syrup to be 1.330.

Syrup is used in medicine to give flavour, cohesiveness, and consistence.

2. LIQUOR SACCHARI TOSTI; *Caramel*; *Burnt Sugar*.—This is a useful, innocuous colouring agent. It is prepared by melting half a pound of brown sugar in an iron pot, and applying heat until the liquid acquires a deep brown colour; then adding a gallon of boiling water.

41. *Andropogon muricatus*, Retz.—*Vittie-Vayr*, or *Cuscus*.

Sex. Syst. Triandria, Digynia.

(Radix.)

Virana, *Asiat. Res.* iv. 306; *A. squarrosus*, Linn., *Suppl.* 433; *Phalaris zizanoides*, Linn., *Syst. Veg.* v. 104; *Anatherum muricatum*, Beauv., *Agrost.* 128, t. xxii f. 10; *Vetiveria odorata*, Virey, *Journ. de Pharm.* xiii. 499; *Bena* (Bengalee), Roxburgh, *Fl. Ind.* i. 265; *Vittie-Vayr* (Tamool), Ainslie, *Mat. Indica*, ii. 470; *Woetiwear* (Tamool), Roxb., *op. supra cit.*—Coromandel, Bengal: very common on every part of the coast.—Its root, called *cuscus*, or *khus-khus* (*radix vetiveriæ*), is imported from Bombay: it is long, fibrous, brownish or yellowish-white; has a fragrant aromatic odour,² and a feeble bitterish, aromatic taste. Iodine colours it bluish-black. In 1809, Vauquelin³ analyzed it under the name of *schœnanthus*. It was analyzed in 1828 by Henry,⁴ and in 1831 by Geiger;⁵ the latter found *volatile oil*, *resin*, *bitter extractive*, *starch*, traces of *hydrochloric* and *calcareous salts* and *woody fibre*. Cap⁶ submitted the root to distillation with water, and obtained two volatile oils: one limpid, amber coloured, and lighter than water; another, in larger quantity, which was heavier than water, opaque, and adhered to the bottom of the receiver. The dried roots, when slightly moistened, emit a pleasant kind of fragrance, and are employed in India for making *vissaries* (large fans) and door- and window-screens (composed of a frame-work of bamboo covered by cuscus root). During the hot winds, the outsides of these screens are kept watered by natives, and the air that passes through is thereby rendered both cool and fragrant. Cuscus root is imported into England for perfumery purposes. It serves to make scented baskets, and is put into drawers to guard linen and woollen goods from the attacks of insects. This root has also been employed in medicine. It acts as a gentle

¹ See some observations by Mr. Savory, on the preparation of syrup, in the *Pharmaceutical Journal*, vol. ii. p. 452, 1843.

² The odour is said by Martius (*Buchner's Repertorium*, Bd. xxxix. S. 230, 1831) to be between that of galbanum and of violet-root, and to approach that of serpentary; while Geiger considers it to be between that of eulamus and of yellow water iris-root, and similar to myrrh.

³ *Ann. du Muséum*, xiv. 28; and *Ann. de Chimie*, lxxii. 302.

⁴ *Journ. de Pharm.* tom. xiv. p. 57, 1828.

⁵ Quoted by Goebel, *Pharm. Waarenkunde*, Bd. ii. S. 265.

⁶ *Journ. de Pharm.* t. xix. p. 45, 1833.

excitant and diaphoretic. In India, an infusion of it is used as a diaphoretic and gentle stimulant in febrile cases. The warm infusion has been employed as an antispasmodic, diaphoretic, diuretic, and emmenagogue. An ointment of the root has also been applied to destroy pediculi on the heads of children.¹ In 1831, it was used in Paris as a preservative against the cholera: it was worn by the ladies; bundles of it were hung up in the rooms; and fumigations were prepared with it.² In Hamburg, it was used by Dr. Buchheister³ and others in cholera. A weak infusion has been used by Foy⁴ in rheumatism and gout. It may be employed in the form of powder, infusion, tincture, or volatile oil. The dose of the powder (*pulvis veliveriæ*) is about a scruple in the form of pills. A weak infusion or tea is prepared with one or two drachms of the root and two pints of water; this may be drunk *ad libitum*. A strong infusion, prepared with one ounce of the root to half a pint of water, may be administered in doses of a tablespoonful. A tincture (*tinctura veliveriæ*), made with one ounce of the root and half a pint of proof spirit, is given in doses of a teaspoonful.

42. *Andropogon Iwarancusa*, Roxburgh.

Sex. Syst. Triandria, Digynia.
(Radix.)

Ibharankusha, *Iwarankusha*, *Kurankusha*, Beng. and Hind.; *Iwarancussa*, *Asiat. Res.* iv. 109; *Teruncus*, Blane, *Phil. Trans.* vol. lxxx. p. 286, 1790; Sir G. Blane considered that it might be the *Nardus Indica*, or *Spikenard*, of the ancients: Mr. Hatchett⁵ supposed it to be the source of the *grass oil of Nemaur*, an opinion which Dr. Royle⁶ has declared to be incorrect.—This fragrant grass, which has a bitter, warm, pungent taste, is a native of the skirts of the northern mountains of India; between the river Rapti and the northern mountains, and about Hurdwar. It comes remarkably near *A. Schenanthus* both in habit and taste. It is employed by the natives in fevers, whether continued or intermittent. They infuse about a drachm of it in half a pint of hot water, with a small quantity of pepper, and give this for a dose thrice daily. The virtues almost entirely reside in the larger parts of the roots, marked with annular cicatrices.

43. *Andropogon Calamus aromaticus*, Royle.

Sex. Syst. Triandria, Digynia.
(Oleum volatile.)

According to Dr. Royle,⁷ the *grass-oil of Nemaur* is obtained from a new species of *Andropogon*, to which he has given the name of *A. Calamus aromaticus*. He says that it is "found in Central India, extends north as far as Delhi, and south to between Godavery and Nagpore, where, according to Dr. Malcolmson, it is called *spear-grass*: it may be the *A. Martini* of Roxburgh, as, I believe, it is also thought to be by Dr. Wight, though it has been named *A. Nardoides* by Nees von Esenbeck." Dr. Royle examined Mr. Hatchett's specimens of the grass, obtained from Mr. Swinton, as the source of the *grass-oil*, and found them to be identical with his *A. Calamus aromaticus*, though Mr. Hatchett's figure of the plant (copied from: the *Phil. Trans.* vol. lxxx.) actually represents another species, viz., *A. Iwarancusa*. Dr. Wallich⁸ examined a specimen of the plant from which the *grass-oil* is obtained, and declared it to be either *A. Iwarancusa*, or, perhaps, *A. Martini*, Roxburgh.

Dr. Royle⁹ considers this species to be the *sweet calamus*¹⁰ and *sweet cane*¹¹ of Scripture—the *κάλαμος ἀρωματικός* of the ancient Greeks.¹²

GRASS-OIL OF NEMAUR; *Roosa-ke-tel*, Hind.; *Oleum graminis Indici*.—This oil is imported from India under the name of *grass-oil* or *ginger-grass oil*.¹³

In 1845, I obtained from a merchant in London a sample of essential oil which agreed in its sensible qualities with the *grass-oil of Nemaur* given me by Dr. Royle. With it I received the following notice: "A sample of three canisters of essential oil imported from Bombay, under the name of *ginger-grass oil*, and, according to the importer, used by the natives against rheu-

¹² *Dioscorides*, lib. i. cap. 17.

¹³ Ainslie (*Mat. Indica*, vol. ii. p. 401) applies the names of *ginger-grass*, *spice-grass*, *false spikenard*, *sukkunaro-piloo* (Tampool), to the *Andropogon Nardus* (?) of Dr. Rottler, which he says is common in the Cautalun hills and in the Tinnevely district; but he puts a query whether it may not be the fragrant grass described by Mr. Maxwell in the *Transactions of the Medical Society of Calcutta*, vol. i. p. 367, 1825.

matism, and by them called *rosa oil*. The grass grows, according to the same authority, fifty or sixty miles from Bombay in the jungle, and is there called *rosa grass*. It smells, as you will perceive, of ginger and turpentine."

Grass-oil of Nemaur is commonly known to the perfumers by the name of *oil of geranium*. I have been informed that it is sometimes called *oil of rose geranium*. It is occasionally sold by druggists as *oil of spikenard*.

Under the name of "*Ol. Palm, ros.*" [sic.] a volatile oil has been sent from a merchant in Constantinople to his correspondent in London, as an oil used for reducing (that is, adulterating) otto of roses; and, in the accompanying letter, it was stated that if genuine otto be mixed with from 20 to 30 per cent. of this oil, it would be still equal to the finest commercial otto. By the dealers in London this oil was called *oil of geranium*.¹ It is almost colourless, and is clearer, brighter, and more fragrant and roseate than ordinary grass-oil; but its odour is, I think, essentially that of the latter. Is it rectified grass-oil? It is remarkable that Dioscorides (lib. i. cap. xvi.) states that *σχινοσ* (a native of Arabia) has the odour of the rose.

Grass-oil of Nemaur is, according to Mr. Forsyth,² procured at the foot of the Vindhya range of hills in the vicinity of Jaum Ghat, and thirty miles further west, near Nalcha.

It is obtained by distillation. When the plant begins to flower, it is cut and bound in small bundles or maniples, 250 or 300 of which are introduced into a wrought-iron boiler fitted over an earthen fireplace. Water being added, ebullition is promoted. The oil, with water, distils over into two large copper receivers immersed in cold water. The process occupies about six hours. After the product has stood for some time, the oil is skimmed off the surface by a small shallow spoon.

Commercial grass-oil of Nemaur is of a light straw colour, and has a fragrant aromatic roseate odour, with taste which is not very dissimilar to that of oil of lemons. It floats on water. Dr. Stenhouse³ found that it is usually a mixture of a pure volatile oil (C⁴H⁸), and of about half its bulk of a fluid resin, the latter probably being the product of the oxidation of the oil.

In India, the grass-oil is frequently adulterated; usually, according to Mr. Forsyth, with the *ol. sesami*. As this is a fixed oil, the sophistication is readily detected by dropping the suspected grass-oil into rectified spirit: if pure, it dissolves, but if it be mixed with a fixed oil, the spirit becomes milky.

Grass-oil is chiefly employed in perfumery; but it is also employed in medicine. Its medicinal properties are similar to those of other aromatic fragrant volatile oils, and are those of a stimulant and diaphoretic. It is highly esteemed in India for the cure of the more chronic forms of rheumatism. It is applied as a liniment. A couple of drachms of it are rubbed into the affected part in the heat of the sun, or before the fire, twice daily. It causes a sense of warmth and pricking which lasts for two hours or longer. It is also employed to excite diaphoresis in slight catarrhal affections; and for this purpose it is rubbed into the soles of the feet and wrists.

44. *Andropogon Schœnanthus*, Linn.

Sex. Syst. Triandria, Digynia.

I suspect that under this name three species of *Andropogon* have been confounded.

1. Rumphius's *Schœnanthum Amboinicum*, called by the natives of Amboyna *Siree*. Its odour is that of a mixture of roses and fresh-mown hay. As Linnæus, in the later editions of his *Systema Plantarum*, cites Rumphius's figure,⁴ we may take this species as the genuine *Andropogon Schœnanthus* of Linnæus.⁵ It has been recently very fully described by the late celebrated Professor Th. F. L. Nees von Esenbeck.⁶ Rumphius proposes to call it *Schœnanthum Indicum sterile*, to distinguish it from the Arabian plant.

2. The *Arabian Schœnanthus* is said by Hasselquist⁷ to grow plentifully in the deserts of both the Arabias, and to be gathered near Limbo, a port of Arabia Petræa, and exported to Egypt. The Arabians call it *Heisi Meccavi* and *Idhir Mecchi*. It is said that in the deserts between Syria and Egypt there is no grass but this which camels eat: hence it has received the name of *fanum* vel *stramen camelorum*, or *camel's hay* or *straw*. It was formerly in the London Pharma-

¹ Recluz (*Journ. de Pharm.* t. xiii. p. 529, 1827) obtained from *Pelargonium odoratissimum*, var. *odore rosato* (Persoon), a concrete volatile oil, which he calls *volatile oil of geranium with the odour of the roses* (*huile volatile du Géranium à odeur de roses*). It must not be confounded with the so-called oil of geranium alluded to in the text.

² *Transactions of the Medical and Physical Society of Calcutta*, vol. iii. p. 213, Calcutta, 1827.

³ *Memoirs and Proceedings of the Chemical Society of London*, vol. ii. p. 123, 1845.

⁴ *Herbarium Amboinense*, pars v. lib. viii. cap. 24, page 181, tab. lxxii. Fig. 2.

⁵ In the *Linnean Herbarium*, there is a single specimen of *A. Schœnanthus*, but without any statement indicating its place of growth.

⁶ Geiger's *Pharmacie*, 2te Aufl. von Th. F. L. Nees von Esenbeck, J. H. Dierbach, und Cl. Marquart, Bd. ii. 1te Hälfte, S. 115, 1839.

⁷ *Voyages and Travels in the Levant in the years 1719, 50, 51, 52*, Lond. 1766.—It is remarkable that Forskål, in his *Flora Arabico-Yemen*, does not mention, in his list of odorous plants (p. xcv.), a single odorous grass as growing in Arabia Felix.

copœia, and was called *schœnanthus*, *squinanthus*, vel *juncus odoratus*; its vernacular name being *squinanch* or *sweet-smelling rush*. The herbs (stem, leaves, and sometimes the flowers) were brought from Turkey and Arabia, tied up in bundles about a foot long. The stem, which resembled a barley straw, was filled with a pith like those of our common rushes; the flowers were of a carnation colour, striped with light purple.¹

It was considered to possess stimulant and diaphoretic properties, and was commended in hiccup, vomiting, flatulent colic, and female obstructions; but was little used, except in the *mithridatum* and *theriaca*. It was administered to the extent of one or two drachms in the form of infusion or tea.

It is not improbable that this plant may be the *σχόινος εὐοσμῶς* of Hippocrates,² the *σχόινος* of Dioscorides,³ for the last-mentioned writer states that the most esteemed sort grew in that part of Arabia called Nahatæa, which agrees with the statement of Hasselquist.

3. The *Andropogon citratum*, De Cand.—As this is undoubtedly the source of the oil of lemon-grass of the shops, it deserves a separate notice.

45. *Andropogon citratum*, De Cand.—Lemon-Grass.

Although all the Anglo-Indian botanists, whose works I have consulted, consider the *Lemon-grass* of India to be identical with the *Andropogon Schœnanthus* of Linnæus, yet various circumstances have long since led me to suspect that they are in error. Its citron or lemon odour is so very strong and remarkable, that any one familiar with the plant, or its volatile oil, could not overlook or mistake it. Yet not one of the authorities quoted by Linnæus, nor any of the pharmacologists of the last century who were familiar with the Linnæan plant, mention it. Rumphius,⁴ whose figure of the plant is referred to by Linnæus, says the odour of the Amboyna plant is similar to that of roses mixed with that of new-mown hay. Dale⁵ describes the odour of *Schœnanthus* as being sweet and very fragrant, and Lewis⁶ simply says it is agreeable.

The first botanical writer who notices the peculiar citron odour of lemon-grass is De Candolle,⁷ who states that under the name of *Andropogon citratum* there was frequently met with in botanical gardens a grass which had very much the habit of *A. Schœnanthus*, but was larger, did not require a hot-house, and was most distinctly characterized by the citron-odour of the bruised leaves. The late eminent botanist professor Th. Fr. L. Nees von Esenbeck⁸ pointed out some botanical characters which distinguish the two plants. Thus he states that the leaves of *A. citratum*, De Cand. are much broader, *flat*, of a strong bluish-green colour, and both above and at the margin are very rough when drawn backwards through the fingers; whereas, the leaves of *A. Schœnanthus* are narrow (half a line in breadth), *completely keeled*, like those of the sedges, bluish-green, and somewhat sharp at the margin when drawn backwards through the fingers. Moreover, the hairs of the rachis of the spikelets of the *A. citratum* are much shorter than those of *A. Schœnanthus*.

Lemon-grass is a native of the continent of India and of Ceylon. It was introduced into the West Indies towards the latter part of the last, or beginning of the present century.⁹

The peculiar characteristic of this species of *Andropogon* is its odour, which, when the grass is fresh, is very distinctly citron-like; or rather, especially when the plant is dry, resembles that of balm—the *Melissa officinalis*, Linn., called by the French *Citronnelle*.

The lemon-grass yields, by distillation, an essential oil, which is imported from Ceylon, Bombay, Cochin (Malabar coast), and Madras, under the names of *lemon-grass oil* or *citronnelle oil*. It is yellow, and has a fragrant, citron-like odour. It is much used in perfumery under the name of *oil of verbena*. It is frequently adulterated with a fixed oil, and when thus sophisticated it forms a milky liquid, when dropped into rectified spirit; whereas, the pure oil dissolves and yields a transparent solution.

The lemon-grass is employed in the form of infusion, in both the East and West Indies, as a mild diaphoretic in slight colds. The fresh leaves are sometimes used as a substitute for tea, and the white succulent centre of the leaf-bearing stems serves to give an agreeable flavour to curries. In Martinique, it is reputed poisonous, or at least as capable of producing abortion both in animals and the human species.¹⁰

ORDER VII. CYPERACEÆ, *R. Brown.*—SEDGES.

CHARACTERS.—The plants in this order closely resemble grasses (see *ante*, p. 106), from which they are distinguished by their *embryo* being inclosed within the base of the albumen; by their *leaf-sheaths* being whole or entire, not slit; and by their *stems* being solid, angular, and without joints or diaphragms.

PROPERTIES.—These plants are remarkable for their deficiency of those organic principles which render the grasses so valuable and important to man (see *ante*, p. 107). The so-called roots (rhizomes) of several species of *Cyperus* (e. g. *longus*, *rotundus*, and *esculentus*) were formerly employed in medicine. They are mild aromatics, stomachics, and diaphoretics. The roasted roots of *C. esculentus* have been used as a substitute for coffee. The rhizomes of *Carex arenaria* have been employed as a substitute for sarsaparilla, under the name of *bastard* or *German sarsaparilla* (*radix sarsaparillæ germanicæ* vel *radix graminis major*).

Sub-class II. *Petaloidæ* vel *Floridæ*.

CHARACTERS.—Floral envelopes, if present, whorled.

This sub-class includes all the remaining orders of endogens, which may be arranged in two subdivisions.

SUBDIVISION I.

Floral envelopes absent; or, if present, imperfect, squamiform, sometimes more or less glumaceous.

ORDER VIII. AROIDEÆ, *Endl.*

ARACEÆ and ORONTIACEÆ, *Lindl.*

CHARACTERS.—*Flowers* generally unisexual, rarely hermaphrodite, arranged upon a *spadix*, in the axil of a *spathe*. *Perianth* either none, or, in the hermaphrodite flowers, rudimentary and scaly. *Stamens* numerous, or definite and opposite to the segments of the perianth: *anthers* opening outwards. *Ovaries* free, 1-, 3-, or many-celled. *Fruit* succulent or dry, indehiscent. *Seeds* usually with fleshy or mealy albumen, rarely with none. Usually herbaceous plants with either subterranean tubers (cormi) or a creeping rhizome.

PROPERTIES.—The fresh plants of this order are frequently remarkable for acidity, which especially resides in the tubers and rhizomes, and often renders them violent poisons. This is especially remarkable in *Dieffenbachia Seguina*, or the Dumb Cane, a native of the West India Islands, two drachms of whose juice have been known to prove fatal in two hours. The acrid principle (which, perhaps, may be a sulphurated volatile oil) is in many cases readily dissipated or decomposed and rendered inert by cooking. Even drying seems to injure or destroy it. As it is soluble in water, washing removes it from the starch.

The useful qualities of the order depend on *starch* and *aromatic volatile oil*: on the former depend the esculent properties of some species, and on the latter the medicinal properties of some.

Colocasia esculenta (also called *Caladium esculentum* or *Arum esculentum*) is used in some parts of the world as food. Its large, fleshy, and farinaceous tubers are called *yams* in Madeira, from whence they were sent me by Mr. Nobrega. I find that when boiled they form a very agreeable substitute for potatoes.

Colocasia Antiquorum is cultivated in Egypt and other parts of the world for the nutritious matter yielded by the tubers.

Sub-order I. ARACEÆ, *Endl.*

Flowers naked, unisexual.

46. *Arum maculatum*, *Linn.*—Cuckow-pint.

Sex. Syst. Monœcia, Polyandria.

(Tuber.)

ARUM VULGARE, Lam.; *Common Cuckow-pint; Wake Robin; Lords and Ladies.*—A well-known, indigenous, acrid, and poisonous plant, which, by drying or by the aid of heat, loses its acidity. From the underground tubers is manufactured, in the island of Portland, a starch called *Portland*

arrow-root or *Portland sago* (*ſæcula ari*; *farina ari*). It is procured by cleansing the roots (tubers), pounding them in a stone mortar with water, and then straining. The starch subsides from the strained liquor, and, the supernatant water being poured off, is collected and dried.¹ Care is requisite in the pounding of the roots on account of their acidity.

From a peck of the roots about a pound of starch is procured.

Portland arrow-root is a white amylaceous powder. Examined by the microscope, its particles are found to be exceedingly small,² circular, mullar-shaped, or polyhedral. The angular appearance of some of them arises from compression. The hilum is circular, and apparently lies in a small depression. It cracks in a linear or stellate manner. The dietetical uses of this starch are similar to those of other starches, as of the West Indian arrow-root. It makes very agreeable puddings.

The roasted tubers are esculent.

The fresh plant is an acrid poison; causing burning and swelling of the throat, vomiting, colic, diarrhœa, and convulsions. By drying, the activity of the plant is in a great measure destroyed. Medicinally, the tubers were formerly used as diuretics in dropsies, and as expectorants in chronic catarrhs.³

47. *Arisæm atrorubens*, Blume.—Dragon-Root.

Sex. Syst. Monœcia, Polyandria.
(Tuber.)

ARISÆMA ATRORUBENS, Blume, Rumphia, i. 97; *Arum triphyllum*, Linn.; *Dragon-root*; *Indian Turnip*; *Wake Robin*.—A native of the United States of America. Its properties agree closely with *Arum maculatum*, and, like the latter, it yields a pure white fecula. The tuber is used in the United States as a stimulant to the secretions in chronic bronchial affections, rheumatism, &c., in doses of from ten grains to a scruple. The powder, made into a paste with honey, has been beneficially applied to the mouth and throat of children in aphthæ.

Sub-order II. CALLACEÆ, Endl.

Perfect stamens associated with ovaries in hermaphrodite florets.

48. *ACORUS CALAMUS*, Linn.—COMMON SWEET FLAG.

Sex. Syst. Hexandria, Monogynia.
(Rhizoma, L.—Rhizome, E.)

HISTORY.—This is probably the *ἀκρον* of Dioscorides.⁴ Dr. Royle says that in Persian works *akoron* is given as its Greek appellation. It must not be confounded with the *χάλαμος ἀρωματικός* of Dioscorides, which, according to Dr. Royle,⁵ is *Andropogon Calamus aromaticus*, Royle (see *ante*, p. 154).

BOTANY. *Gen. Char.*—*Flowers* arranged upon a *spadix*. *Spathe* replaced by a two-edged leaf-blade. *Perianth* of 6 pieces or scales, inferior, persistent. *Stamens* 6, filiform. *Stigma* sessile. *Ovaries* 2-3-celled. *Berries* 1-celled, 1-3-seeded. *Seeds* albuminous.

Sp. Char.—*Spathe*, a continuation of the 2-edged *scape*, rising much above the *spadix*.

Rhizome thick, rather spongy, with many long roots, aromatic, like every part of the herbage, but much more powerfully so. *Leaves* erect, two or three feet

¹ Mrs. Gibbs, *Transactions of the Society of Arts*, vol. xv. p. 238, 1797.

² The following measurements of five particles were made by Mr. Jackson:—

1.	0.0004	of an English inch.
2.	0.0003	“ “
3.	0.00022	“ “
4.	0.00013	“ “
5.	0.0001	“ “

5)0.00115

Average 0.00023

The average size, therefore, is the $\frac{1}{4338}$ th of the inch in diameter.

³ See Murray, *App. Med.* vol. v. p. 44, 1790; and Alston's *Lectures on the Materia Medica*, vol. i. p. 387.

⁴ Lib. i. cap. 2.

⁵ *Essay on the Antiq. of Hindoo Med.* p. 33.

high, bright green, near an inch broad. *Stalk* like the leaves, except being thicker below the *spadix*, and not quite so tall. *Spadix* about a foot above the root, a little spreading, two or three inches long, tapering, covered with a mass of very numerous, thick-set, pale green *flowers*, which have no scent, except when bruised. A very narrow wavy membrane may be observed at the base of the *spadix*, which perhaps ought to be taken into the generic character as a *spathe* (*Smith*).—Perennial: flowers in June.

Hab.—It is a native of this country, growing in watery places about the banks of rivers, and is very plentiful in the rivers of Norfolk, whence the London market was formerly supplied. It grows, also, in other countries of Europe, in Asia, and in the United States.

DESCRIPTION.—The dried underground stem (*rhizoma*, L.; *radix acori veri seu radix calami aromatici*, Offic.) occurs in the shops in flattened pieces four or five or more inches long, and about as broad as the thumb; jointed, somewhat curved, of a spongy or corky texture internally; of a yellowish brown or fawn colour externally, and buffy, with a slight roseate hue, internally. Their fracture is short: their upper surface is marked transversely with the vestiges of the leaves which were attached to it; the lower surface has numerous dark points, surrounded by small light-coloured elevated circles, from which the roots arise. Their taste is warm and bitter; their odour is aromatic. In Germany, the rhizome is usually peeled before drying it (*rhizoma decorticata*); but the operation is unnecessary and wasteful. In this state, the rhizome is grayish-white and easily pulverizable.

The rhizome should be gathered in spring or late in the autumn, and dried quickly. It is usually gathered on the banks of the Thames about May for the London market.

The fresh rhizome is employed for distillation. The pieces are sometimes fourteen or fifteen inches long, and one inch wide.

The rhizome of the Yellow Water Iris (*Iris Pseudo-acorus*) is said to be sometimes substituted for that of the true *Acorus*.

COMPOSITION.—The fresh rhizome was analyzed by Trommsdorff,¹ who obtained the following results: *Volatile oil*, 0.1; *soft resin*, 2.3; *extractive, with a little chloride of potassium*, 3.3; *gum, with some phosphate of potash*, 5.5; *starchy matter* (like inulin), 1.6; *woody fibre*, 21.5; and *water*, 65.7. Meissner found traces of copper in the ashes.

The active constituents are the oil, the resin, and the extractive.

OIL OF THE COMMON SWEET FLAG (*oleum acori calami*, called, in the shops, *oleum calami aromatici*) is obtained by distilling the fresh rhizome with water. Its odour is similar to, though less agreeable than, that of the rhizome. Its colour is yellow. It is bought by snuffmakers, so that it is used, I presume, for scenting snuff. It is also employed in the preparation of *aromatic vinegar*.

CHEMICAL CHARACTERISTICS.—Iodine blackens the rhizome (especially when it has been boiled), thereby indicating the presence of starch. The cold decoction of the rhizome forms, with a solution of iodine, the blue *iodide of starch*. Acetate and diacetate of lead, and protonitrate of mercury, cause precipitates with the decoction. These precipitates consist principally of metallic oxides or subsalts, and the substance called extractive. Nitrate of silver produces a precipitate (*chloride of silver*), which is insoluble in nitric acid, but soluble in ammonia. The decoction reddens litmus.

PHYSIOLOGICAL EFFECTS.—It is an aromatic stimulant and mild tonic. Vogt² arranges it with the *excitantia volatilia*, and regards it as approaching angelica root on the one hand, and cascarilla and angustura barks on the other.

USES.—It is rarely employed by medical practitioners, though it might be frequently substituted, with good effect, for the more costly oriental aromatics. It is a useful adjunct to other stimulants and tonics. It has been employed in continued

¹ Guelin, *Handb. d. Chem.* ii. 1339.

² *Lehrb. d. Pharmakodyn.* i. 454, 2te Aufl.

asthenic fevers accompanied with much prostration of strength and greatly weakened digestive power. For the cure of ague, the dried root powdered is used by the country people in Norfolk.¹ It is well adapted for dyspeptic eases accompanied with, or dependent on, an atonic condition of the digestive organs, and is especially serviceable in gouty subjects. It has also been used as a local agent, viz., in the formation of aromatic baths, poultices, and gargles, as an application to foul-conditioned ulcers, &c. It is employed, I am informed, by some rectifiers to flavour gin.

ADMINISTRATION.—In *powder*, the rhizome may be given in doses of from a scruple to a drachm. The *infusion* is, perhaps, the most eligible preparation; it is made by digesting ʒj of the rhizome in ʒxij of boiling water; the dose is two or three tablespoonfuls. The *decoction* is an objectionable preparation, as the oil of the rhizome is dissipated by boiling. The *tincture* (Ph. Bor.) is procured by digesting ʒij of the rhizome in ʒxij of spirit (sp. gr. 0.900); the dose is a teaspoonful.

SUBDIVISION II.

Flowers with a proper, often corolline perianth, usually hermaphrodite.

1. Leaves with parallel veins, either proceeding from the base to the apex (*straight-veined*), or curved and proceeding from the midrib to the margin (*curved-veined*).

† Flowers sessile on a branched scaly spadix, usually unisexual.

ORDER IX. PALMÆ, Juss.—THE PALM TRIBE.

PALMACEÆ, Lindl.

CHARACTERS.—*Flowers* hermaphrodite, or frequently polygamous. *Perianth* six-parted, in two series, persistent; the three outer segments often smaller, the inner sometimes deeply connate. *Stamens* inserted into the base of the perianth, usually definite in number, opposite the segments of the perianth, to which they are equal in number, seldom three; sometimes, in a few polygamous genera, indefinite in number. *Ovary* one, three-celled, or deeply three-lobed; the lobes or cells one-seeded, with an erect ovule, rarely one-seeded. *Fruit* baccate or drupaceous, with fibrous flesh. *Albumen* cartilaginous, and either ruminate or furnished with a central or ventral cavity; *embryo* lodged in a particular cavity of the albumen, usually at a distance from the hilum, dorsal, and indicated by a little nipple, taper or pulley-shaped; *plumule* included, scarcely visible; the cotyledonous extremity becoming thickened in germination, and either filling up a pre-existing cavity, or one formed by the liquefaction of the albumen in the centre.—*Trunk* arborescent, simple, occasionally shrubby and branched, rough, with the dilated half-sheathing bases of the leaves or their scars. *Leaves* clustered, terminal, very large, pinnate, or flabelliform, plaited in vernation. *Spadix* terminal, often branched, enclosed in a one or many-valved spathe. *Flowers* small, with bractlets. *Fruit* occasionally very large. (*R. Brown*, 1810.)

PROPERTIES.—Palms, considered in a dietetical and medicinal point of view, are of the highest importance to the inhabitants of tropical regions. Their *stems* yield starch (sago) sugar, and wax; their *terminal leaf buds* are boiled and eaten as a kind of cabbage; their *fruits* yield oil, sugar, and resins; and their *seeds* form articles of food, and yield, by pressure, fixed oil.

In the abundance of *sugar* and *starch* which the palms yield, this family resembles the grasses. But they are distinguished from the latter in containing, in some cases, a large quantity of fixed oil. To these three principles are chiefly due the nutritive qualities of palms. But these substances being non-nitrogenized, are merely fat-making and heat-yielding, and without the addition of *proteine compounds* (found in the seeds, and probably in other edible parts of palms), would be insufficient to support life.

Palm sugar, in the crude state, is called *jaggary*. By fermentation, it yields *toddy* or *palm wine*, from which, by distillation, an ardent spirit (*arraek* or *rack*) is obtained. *Date sugar*, and also other kinds of palm sugar, are imported into England, and are used by grocers for mixing; but, being deficient in what in trade is called "strength," they do not pay for refining.²

Wax, *astringent matter* (tannin), and *resinous principles*, are useful products obtained from palms, but they are of less frequent occurrence than the substances before mentioned. Still less frequently met with are *acid* principles.

The ashes obtained by the combustion of palm leaves yield *potash*.

¹ Sir J. E. Smith, *Engl. Flora*, ii. 158.

² *Pharmaceutical Journal*, vol. v. p. 61, 1845.

1. PALMÆ FARINIFERÆ.—SAGO PALMS.

The farinaceous substance called *sago* is obtained from the stems of several palms. Those of the genera *Sagus* and *Saguerus* are the most important, and will be separately noticed.

The trunk of old trees of *Caryota urens*, called, by Robinson,¹ the *Sago palm of Assam*, yields a sago which both Roxburgh² and Robinson consider to be very little if at all inferior to the sago of the Malay countries. From *Phœnix farinifera*, which grows in the Coromandel coast, is likewise obtained a sago, but which is less nutritious and palatable than the common sago.³ *Corypha umbraeulifera*, or the Talipat palm, yields sago in Ceylon; which would appear from the statement of Bennett⁴ to be of inferior quality.

Japan Sago is said to be obtained from several species of *Cycas*. None of this, however, reaches England. (See order CYCADÆÆ.)

49. SAGUS, Gærtner.

Sex. Syst. Monœcia, Hexandria.

Metroxylon, Rottb.

Gen. Char.—*Flowers* hermaphrodite or polygamo-monœcious on the same spadix. *Spadix* much branched, sheathed by many incomplete spathes. *Amenta* terete. *Braet* squamiform: *bractlets* very densely villose-bearded, connate like a cupule. *Calyx* 3-cleft. *Corolla* 3-partite. *Stamens* 6: filaments subulate, connate at the base; *anthers* affixed by the back. *Ovary* subtrilocular: *stigmata* 3, connate in a pyramid. Berry coated by reversed scales, 1-seeded. *Albumen* ruminated or uniform. *Embryo* dorsal. (*Blume*, Rumphia.)

1. SAGUS LÆVIS, Rumph. i. 76, tab. 86 and 126–127 (nomine S. Rumphii); Blume, Rumphia, vol. ii. p. 147; Jack, in Comp. Bot. Mag. i. 266; *Sagus inermis*, Roxb. Fl. Ind. iii. 623; *Metroxylon læve*, Mart. Gen. et Sp. Plant. p. 215, 2; Kunth, Enum. Plant. iii. 214, 2. *Metroxylon Sagus*, Rottb. *Rambia* or *Rambija* of the Malays. The *Unarmed Sago-Palm*.

Stem tallish. Petioles, rachides, and spathes, unarmed. Fruit somewhat globose, and depressed on both sides. (*Blume*, in Rumphia, p. 147.)

Islands of the Indian Archipelago, Sumatra and Borneo, and the islands between them, growing spontaneously in low swampy lands.

A large quantity of granular sago is prepared from this species⁵ in Sumatra especially, the peninsula of Malacca, and in Borneo. It is chiefly exported to Europe, Bengal, and China. The farina which is brought from Siak, on the northern coast of Sumatra, although inferior in whiteness to that of Borneo, is much sought after on account of its being less friable. It commonly fetches twice the price of the latter.⁶

The quantity of sago yielded by this palm is prodigious: Crawford⁷ says 500 or 600 lbs. is not an unusual produce for one tree: and Blume mentions 600 to 800 lbs. as the quantity obtained from a single tree when mature.

2. SAGUS GENUINA, Rumph. (ex parte); Blume, Rumphia, vol. ii. p. 150; *Sagus Rumphii*, Roxb. Fl. Ind. iii. p. 623 (excl. synonym.); *Sagus spinosus*, Roxb. *ibid.*; *Metroxylon Rumphii*, Mart. Gen. et Sp. Palm. p. 214, tab. 102 and 159.

Stem of middling height. Petioles, rachides, and spathes prickly; the prickles scattered or confluent. Fruit somewhat globose, depressed on both sides. (*Blume*.)

¹ *A Descriptive Account of Assam*, p. 56, Calcutta, 1841.

² *Flora Indica*, vol. iii. p. 626.

³ *Ceylon, and its Capabilities*, p. 95, Lond. 1843.

⁴ Roxburgh (*Flora Indica*, vol. iii. p. 623) says that from the pith of this tree "the granulated sago which we meet with in Europe is made."

⁵ Blume, *Rumphia*, vol. ii. p. 148.

⁶ *History of the Indian Archipelago*, vol. i. p. 393.

Islands of the Indian Archipelago. Abounds in the Malacca islands, especially where the nutmeg and clove grow naturally.

"This, the Malay Sago Palm, is the tree the pith of which is the staff of life to the inhabitants of the Moluccas." (Roxburgh.)

The stature of this tree seldom exceeds thirty feet. Before maturity, and previous to the formation of the fruit, the stem consists of a thin hard wall, about two inches thick, and of an enormous volume of tissue (commonly termed the *medulla* or *pith*), from which the farina, called sago, is obtained. As the fruit forms, the farinaceous medulla disappears; and when the tree attains full maturity, the stem is no more than a hollow shell. The utmost age of the tree does not exceed thirty years.¹

50. SAGUERUS SACCHARIFER, Blume.—THE GOMUTO PALM.

Sex. Syst. Monœcia, Polyandria.

SYNONYMES.—*Palma Indica vinaria secunda*, *Saguerus*, sive *Gomutus Gomuto*, Rumph. Amb. i. p. 57, t. 13; *Anau*, Marsden, Hist. Sum. p. 88, 3d ed.; *Saguerus Rumphii*, Roxb. Fl. Ind. iii. 626; *Arenga saccharifera*, Mart. Gen. et Sp. Palm. p. 191, tab. 108.

BOTANY. **Gen. Char.**—*Flowers* monœcious by abortion, on separate spadices, sessile, the female ones between two males. *Spadices* simply branched. *Spathes* many incomplete. *Calyx* 3-cleft, with imbricated leaflets. *Corolla* 3-petalous, with valvate æstivation. **MALES:** *Stamina* indefinite: *filaments* filiform: *anthers* linear, cuspidate. **FEMALES:** *Ovary* trilocular, with the *Ovule* affixed at the bottom of the internal angle. *Stigmata* 3, acute, connivent. *Berry* 3- or, by abortion, 2-seeded. *Albumen* uniform. *Embryo* dorsal. (Blume.)

Sp. Char.—*Petioles* unarmed. *Segments* of the fronds linear-lanceolate, at the base 1- or sub-2-auriculate, beneath whitish. *Branches* of the spadices elongated, fastigate, pendulous. *Berry* turbinate-globose. (Blume.)—From 20 to 25 feet high: readily distinguished by its rude and wild aspect.

Hab.—Very common in the islands of the Indian Archipelago, the Moluccas, and the Philippines.

A saccharine juice called *nēra* or *toddy* is obtained in large quantities by wounding the spadices and receiving the liquor in earthenware pots or bamboos closely fastened beneath.² This juice yields by boiling a coarse dark kind of sugar (*jaggary*), and by fermentation an intoxicating beverage. Wine which is used by the Chinese residing in the Indian islands in the preparation of Batavian arrack.³ When the trees are exhausted by the incessant draining of their juices, sago of good quality is obtained from the trunk—as much as 150 to 200 lbs. weight from a single tree.⁴

The flesh of the fruit is acrid, and affords a juice which when applied to the skin occasions great pain and inflammation. The inhabitants of the Moluccas were in the practice of using in their wars, in the defence of posts, a liquor afforded by the maceration of the fruit, which the Dutch denominated *hell water* (*aqua infernalis*).⁵

SAGO.

(Sago; *Saguslævis*, Rumph., et alia fortasse Palmarum species. *Caudicis Fœcula*, L.)

HISTORY.—Sago does not appear to have been known to the Greeks, Romans, or Arabians. The preparation of sago-meal and sago-bread, as carried on at Fanfur

¹ Crawford, *History of the Indian Archipelago*, vol. i. p. 384.

² Marsden's *History of Sumatra*, p. 88, 3d edit. 1811.

³ Crawford's *History of the Indian Archipelago*, vol. i. p. 399, 1820.

⁴ Blume, *Rumphia*, vol. ii. p. 126.

⁵ Crawford, *op. cit.*

(Kampar, in Sumatra?), was first described by Marco Polo¹ in the 13th century. Sago-bread was described and figured by Clusius.²

Granulated sago was not known until a later period. It is said³ to have been introduced into England in 1729, into France in 1740, and into Germany in 1744. Rumphius⁴ states that in Borneo grains of the size of a coriander seed are made from the farina of the *Saguerus* (*Saguerus saccharifer*, Blume).

The word *sagu* (also written by some of the earlier authors *zagu* and *saga*⁵) is the Malay name both for the palm and its farina:⁶ it is also used in Java to signify the bread made from the farina.⁷

COMMERCE.—Sago is brought to England from Singapore in bags, &c. The quantity on which duty was paid in 1840 was 26,895 cwts.

Newbold⁸ gives the following as the quantities imported into Singapore in 1836:—

	Bundles.
Sago from Sumatra	157750
“ West Side Peninsula	140
“ Borneo, 1308 piculs	140560
“ North Islands, 140 piculs	15251
Total imported	313701

The quantity exported from Singapore in the same year was 28,764 piculs.

MANUFACTURE. a. *Of Raw Sago-Meal*.—The manufacture of sago-meal varies somewhat in different localities. In the Moluccas, it is procured as follows: When the tree is sufficiently mature, it is cut down near the root, and the trunk subdivided into portions of six or seven feet long, each of which is split into two parts. From these the medullary matter is extracted, and with an instrument of bamboo or hard wood is reduced to powder, like sawdust. To separate the farina from the accompanying bran and filaments, it is mixed with water, and the mixture then strained by a sieve. The strained liquor deposits the farina, which, after two or more edulcorations, is fit for use. This is *raw sago-meal*.⁹

b. *Of Sago-Bread*.—In the Moluccas, sago-cakes are made by throwing the dry meal into heated earthenware moulds: a hard cake is formed in a few minutes, so that one heating of the mould serves to bake several series of cakes.¹⁰

c. *Of Granulated Sago*.—To prepare this the meal is mixed with water and made into a paste, which is then granulated. Forrest says that in New Guinea granulated sago is made by mixing the sago-meal with water and passing the paste through a sieve into a very shallow iron pot held over a fire, by which it is made to assume a globular form; so that, he adds, our grain sago is half baked and will keep long. This, according to Blume, is the process which is followed by the Chinese colony in Singapore; the meal being first repeatedly worked and dried. Blume adds that, during the heating process, the grains are constantly turned, and that, though quite white at the commencement, they become hard and somewhat pellucid during the process.

One kind of pearl sago of the shops has been obviously subjected to some heating process: this is the *Tapioka sago* of Guibourt; but the application of heat must have been most carefully regulated, for charred sago is unknown to commerce. Some of the granulated sago of the

⁷ Sir F. Drake, in Hakluyt's *Principal Navigations, Voyages, &c.* vol. iii. p. 742.

⁸ *Political and Statistical Account of the British Settlements in the Straits of Malacca*, vol. i. p. 304, Lond. 1839.

⁹ Crawford, *op. supra cit.* vol. i. p. 390. Mr. Crisp (*Asiat. Researches*, vol. vi. 1799) has described the mode of preparing sago-meal in the Pogy Islands, lying off Sumatra. See, also, Forrest's *Voyage to New Guinea*, 2d edit. 1780, pp. 39-41, for the method of preparing it by the Papuans.

¹⁰ Forrest (*op. supra cit.*) has figured a mould, which he calls the *Papua oven*.

shops presents no evidence of having been heated; and it has, therefore, been supposed that its granulation must have been effected by a mill.

DESCRIPTION OF SAGO.—Sago occurs in commerce in two states—pulverulent and granulated.

1. **Pulverulent Sago; Sago Meal; Sago Flour (Farina Sagi).**—This is imported in the form of a fine amylaceous powder. It is whitish, with a buffy or reddish tint. Its odour is faint, but somewhat unpleasant and musty. Viewed by a powerful pocket-lens, it presents a glistening granular appearance. Examined by the microscope, it is found to consist of irregularly elliptical or oval, more or less ovate, usually isolated particles,¹ which are often somewhat narrowed or tapered at one extremity. Owing to their mutual pressure, many of them appear as if truncated, either by a single plane perpendicular to the axis of the particle, in which they are more or less mullar-shaped—or by two inclined planes, giving the particles a dihedral extremity. Some of them resemble in form a cautehouse bottle cut off at the neck. From their strong lateral shading they are obviously convex. Many of the particles are more or less broken. Most of them have an irregular or tuberculated surface, as if eroded. The hilum, when perfect, is circular; but it cracks in the form of a single slit, or of a cross, or in a stellate manner. The surface of the particles presents the appearance of a series of concentric rings or annular lines, which, however, are much less distinct than in potato starch. These lines are indicative of the concentric layers of which each particle is composed. When examined by the polarizing microscope, the particles show a black cross, the centre of which is the hilum.

I have met with sago-meal in commerce under different names. Once, I received a sample from Cockermonth, in Cumberland, where it was sold as "*Food for the People.*" A sample of a fine white and carefully-prepared sago-meal was given me under the name of *arrow-root*. I shall distinguish it as *refined sago-meal*.

The following information respecting the mode of refining sago-meal was furnished me by a starch manufacturer: "By sifting and washing, the best sago-meal loses about one-fifth of its weight in the form of earthy matter and woody fibre. The meal thus sifted and washed is then bleached by means of chloride of lime and sulphuric acid. The bleached meal is afterwards washed in successive waters until a perfectly pure product is obtained. In this state it serves as a food for infants and invalids. Coloured by turmeric, and flavoured by the essential oils of cassia and bitter almonds, it forms a *custard powder*. Without the colouring matter, it serves as a *blanc-mange powder*."

2. **Granulated Sago; Grain Sago (Sagus granulosa); Grana Sagi.**—The grains are more or less rounded masses of variable size and colour. Examined by a microscope with a low object-glass (say of 2- or 3-inch focus), they are seen to be masses of glistening particles. There are two kinds of granulated sago—brown sago, and pearl sago.

a. **Common or Brown Sago (Sagus fusca); Sagou gris des Moluques, Planche and Guibourt.**—This is the only kind of sago which was known in English commerce prior to the introduction of pearl sago.

¹ The following measurements, in parts of an English inch, of the particles of starch of sago-meal, brown sago, and pearl sago, were made for me by Mr. George Jackson:—

PARTICLES.	SAGO-MEAL.		BROWN SAGO.		PEARL SAGO.	
	Long diam.	Short diam.	Long diam.	Short diam.	Long diam.	Short diam.
1.	0.0022	0.0016	0.0026	0.00155	0.0031	0.0019
2.	0.00195	0.00135	0.0020	0.0014	0.0022	0.0015
3.	0.0017	0.0013	0.0017	0.0015	0.0021	0.0014
4.	0.0014	0.0014	0.0017	0.0012	0.0018	0.0013
5.	0.0013	0.00095	0.0013	0.0010	0.0018	0.0012
6.	0.0012	0.00095	0.0009	0.0006	0.0017	0.0012
7.	0.0005	0.0008	0.0008	0.0008	0.0012	0.0008
8.	0.00075	0.0006	0.0008	0.00075

It occurs in somewhat irregularly-rounded or globular masses or grains, which are whitish on one side, and grayish-brown on the other. The ordinary brown sago of the shops consists of grains which are usually about the size of the grains of pearl barley. This may be termed the *smaller* or *ordinary brown sago*. It is the *sagou gris des Moluques* of both Planche and Guibourt. But there is another variety, the globular masses of which are larger, sometimes as large as gray peas. To distinguish it from the smaller sort just mentioned, I shall call it *large brown sago*. I received it first from Dr. Douglas Maclagan, of Edinburgh, and subsequently from Professor Guibourt, who terms it *gros sagou gris des Moluques*. The smaller masses of it are about equal in size to the larger masses of the former sort of brown sago. Except in the size of the grains or masses, the two sorts are identical.

Examined by the microscope, the grains of brown sago are found to consist of particles like those of sago-meal, but somewhat more broken and less regular in their shape. Some of them present the appearance of containing in their interior a smaller particle, or rather, perhaps, an air-cavity, which, when examined by polarized light, forms the centre of the black cross. Intermixed with the starch particles is a yellowish-brown substance, which gives colour to the sago.

β. *Pearl Sago (Sagou perlata)*.—The manufacture of this kind of sago is comparatively recent. Crawford,¹ who wrote in 1820, says: "Within the last few years the Chinese of Malacca have invented a process by which they refine sago so as to give it a fine pearly lustre. . . . A small quantity of it, exposed for sale in the London market in 1818, sold for about thrice the price of ordinary [that is, brown] sago." The sago used by the Chinese at Malacca in the manufacture of pearl sago is, according to Newbold,² brought from Sumatra. Pearl sago is also prepared at Singapore.³

Pearl sago occurs in pearl-like grains, which vary in size from that of poppy seeds to that of white mustard seeds, or even somewhat larger than these. The shape of the larger grains is more or less globular, that of the smaller ones being often much less regular. The surface of the larger grains is smooth, even, and regular; that of the small grains often rough, uneven, and somewhat tuberculated. Occasionally, two or three of the smaller grains adhere together. Some samples are white, some brownish yellow, pink, or roseate. The coloured grains are not of uniform tint over the whole of their surface; often being on one side white, on the other coloured. By the aid of a solution of chloride of lime, the coloured kinds can be bleached and rendered perfectly white (*bleached pearl sago*).

When submitted to microscopic examination, pearl sago is found to consist of the same kind of starch particles as sago-meal, but all more or less ruptured, and presenting indistinct traces of rings. These peculiarities are doubtless produced by the process of granulation.

αα. *White Pearl Sago*.—Grains smaller than white mustard seeds; opaque and white on one side, pearly on the other. The filtered cold aqueous infusion does not strike a blue colour with tincture of iodine. The whiteness of this kind of pearl sago has probably been produced by bleaching.

ββ. *Coloured pearl sago*.—Grains of different size. Those of some sorts are not larger than poppy seeds (*small coloured pearl sago*), while those of other sorts are nearly as large, or even somewhat larger, than white mustard seeds (*large coloured pearl sago*). The colour varies in intensity, and slightly in shade also; but the prevailing tint is that of bran, or sometimes pinkish brownish yellow. Some sorts are as pale as ground, unsifted wheat-flour (*pale-coloured pearl sago*); others are nearly as deep-coloured as bran itself. Some of the larger sorts have a grayish or brownish colour (*grayish* or *brownish pearl sago*); but, like all kinds of coloured

¹ *History of the Indian Archipelago*, vol. iii. p. 349, 1820.

² *Political and Statistical Account of the British Settlements in the Straits of Malacca*, vol. i. pp. 243-4, 1839.

³ Blume, *Rumphia*, vol. ii. p. 148.

sago, the tint is not uniform on different parts of the same grain, being deep on one side and pale on the other.

The filtered cold aqueous infusion of some sorts does not strike a blue colour with tincture of iodine. This kind corresponds to the *Sagou rosé des Moluques* of Planche and Guibourt.

The filtered cold aqueous infusion of other sorts yields a blue colour on the addition of tincture of iodine, showing that a higher temperature has been employed in the preparation of it than of other sorts. This corresponds to the *Sagou-tapioka* or *Tapioca-sago* of Guibourt. When examined by the microscope, the particles are found to be more ruptured and torn—an obvious effect of heat on them. This sort of pearl sago is often not distinguishable by its external appearance from that of the *Sagou rosé des Moluques* of Planche and Guibourt.

Under the name of *damaged pearl sago*, I have received a sample of coloured pearl sago, some of the particles of which are yellow (from sulphur-yellow to orange coloured). When bleached by means of chloride of lime, it becomes quite white (*bleached pearl sago*).

FACTITIOUS SAGO.—This is prepared in both Germany and in France (at Gentilly, near Paris) with potato-starch. It occurs both white and coloured.

I have two kinds of *white factitious sago*—one small-grained, the grains of which are scarcely so large as white mustard seeds; the other large-grained, the grains of which are intermediate in size between white mustard seeds and coriander seeds. The first, I met with in English commerce; for the other, I am indebted to Professor Guibourt.

I have also two kinds of *coloured factitious sago*, both large-grained—one red,¹ the other brownish,² and somewhat resembling brownish pearl sago. For both of these I am indebted to Professor Guibourt.

The white and the red sorts are remarkable for being spherical and smooth.

The microscope can alone distinguish factitious sago from the real sort. The difference in the size, the shape, and other characters, between the particles of sago-starch and the unaltered particles of potato-starch, readily distinguish the one from the other. (See also *Potato-starch*.)

But many of the starch particles of potato sago are ruptured by the influences to which they have been subjected during the preparation of the sago. They have become swollen, ruptured in the direction of their long axis, and, by drying, have shrivelled, leaving a long, linear, sometimes curved or even-branched line with incurved or involuted edges, indicating the situation of the rupture.

I have received from Professor Guibourt samples of "*Sagou des Maldives* de Planche, donné par lui," and "*Sagou de la Nouvelle Guinée* de Planche,³ donné par lui," and find them to be factitious sagos made from potato-starch. The grains of New Guinea sago are undistinguishable externally, and, by the microscopic examination of their starch particles, form red-coloured "*Sagou de féculé de pomme de terre*," also sent me by Professor Guibourt. Both are bright red on one side and whitish on the other. Most of their starch grains are ruptured and shrivelled as above described. The Maldivé Sago is paler coloured, and some of its starch particles are little or not at all altered; others are ruptured and shrivelled.

COMPOSITION.—Sago has not been analyzed. The pure starch, of which it essentially consists, doubtless has the same composition as other amylaceous substances, viz., C¹²H¹⁰O¹⁰. Sago-meal is contaminated with various impurities (see *ante*, p. 164). Granulated sago contains some colouring matter, particles of which may readily be detected by the microscope.

CHEMICAL CHARACTERISTICS.—Sago possesses the general characters of an amylaceous substance.

Sago-meal is insoluble in cold water; but, by boiling in water, it almost entirely

¹ This is, perhaps, the kind mentioned by Planche (*Journ. de Pharm.* t. xxiii. p. 305, 1837) as being "falsified sago coloured by cochineal."

² This, perhaps, is the brown sort of German sago made from potato-starch, and said, by Dierbach (*Synopsis Materia Medica*, Abt. 1. S. 27, 1841), to be coloured by burnt sugar.

³ *Journ. d. Pharm.* tom. xxiii. p. 155, 1837.

dissolves, and yields a tolerably clear solution. The decoction, when cold, strikes a blue colour with tincture of iodine.

Granulated sago swells up in cold water, but does not completely dissolve by boiling, a more or less considerable amount of insoluble matter remaining behind. The remarkable difference in the action of boiling water on sago-meal, and on different kinds of granulated sago, leads me to suspect that some substance of difficult solubility in water is used in the preparation of the paste for making granulated sago. The filtered cold aqueous infusion of some sorts of pearl sago (*Sagou-tapioka* of Guibourt) strikes a blue colour with tincture of iodine. The cold infusion of brown sago is rendered milky by nitrate of silver, diacetate of lead, and protonitrate of mercury; but the cold infusions of pulverulent and of pearl sago are scarcely affected by these tests.

PHYSIOLOGICAL EFFECTS.—It is nutritive and easy of digestion, and is an important article of food in some parts of the East. "The Malay sago palm," says Dr. Roxburgh, "is the tree, the pith of which is the staff of life to the inhabitants of the Moluccas." It is probable that this pith contains some nitrogenized nutritive substance in addition to the amylaceous matter.

USES.—Sago puddings are occasionally brought to table. But the principal use of sago is to yield a light, nutritious, easily-digestible, and non-irritating article of food for the invalid in febrile and inflammatory cases. For this purpose it should be boiled in water (in some cases milk is preferred), the solution strained, and flavoured with sugar and spices, or even with a little white wine, when the use of this is not contraindicated.

2. PALMÆ OLEIFERÆ.—OIL PALMS.

Oil is obtained from the fruit of some, and from the seeds of many palms. Two oils obtained from palms are found in commerce: they are palm oil and cocoa-nut oil; the one obtained from a species of *Elæis*, the other from a *Cocos*.

51. *Elæis*, Jacquin.—The Guinea Oil Palms.

Sex. Syst. Diœcia, Hexandria.

(*Fructus oleum*.)

Palm oil is obtained from two species of *Elæis*, both natives of Guinea, and to both of which the name of Guinea Oil Palm is equally applicable. The oil resides in the fleshy portion of the fruit, which, in this respect, resembles the olive.

1. *ELÆIS GUINEENSIS*, Jacquin; *The True Guinea Oil Palm*; *The Palm Oil-Tree*; Sloane's Jamaica, vol. ii. p. 113, 1725; *Avoira*, Aubl., Pl. de la Guiane, 1775.—A native of Guinea; cultivated in tropical America. The drupes are about the size of pigeons' eggs, ovate, somewhat angular, deep orange yellow, collected in heads. They have a thin epicarp, a fibrous, oily, yellow sarcocarp, which covers and closely adheres to the hard stony putamen or endocarp, within which is the seed.

From the sarcocarp is procured *palm oil* (*oleum palmæ*). This is obtained by boiling the pulp in water, by which the oil separates and floats on the surface.

2. *ELÆIS MELANOCOCCA*, Gartner.—The drupes are somewhat smaller than those of the preceding species. Some time since I received from Mr. Warrington a bunch of them, which had been recently brought from Guinea as the fruit from which palm oil is obtained. The flesh of the fruit is oily, and has the well-known odour and colour of palm oil. Gartner¹ thought that it might be only a variety of *E. guineensis*; but Von Martius,² who has fully described it, regards it as a distinct species.

At the ordinary temperatures of this country, it is solid, and might, therefore, with more propriety be termed *palm butter*. It is said that, when quite fresh, it fuses at 81° F.; but that, by keeping, its fusing point rises. Steinhous³ found that very old palm oil required a temperature of 98½° F. to fuse it.

Palm oil has a rich orange yellow colour, a sweetish taste, and an agreeable odour resembling

¹ *De Fructibus et Semin. Plant.* vol. i. p. 18, 1801.

² *Ann. d. Chemie u. Pharm.* Bd. xxxvi. S. 50.

³ *Palmæ Brasil.* p. 62, tab. 54-56.

that of the rhizome of the Florentine orris. It is soluble in boiling alcohol and in ether. By exposure to solar light it becomes white.

Palm oil requires to be bleached for various uses in the arts, and there are several agents which are used for decolorizing it—viz., chlorine, oxygen, powerful acids (sulphuric, nitric, or chromic acid), and the combined influence of air, heat, and light.¹

Palm oil consists of *oleine*, *palmitine*, and *colouring matter*. As found in commerce, it usually contains also *free fatty acids* (oleic and palmitic) and *free glycerine*, and, therefore, may be said to be rancid. The cause of the separation of these acids from the glycerine has not been satisfactorily explained. The quantity of them increases with the age of the oil, and, according to Pelouze and Boudet,² varies from 33 to 80 per cent. of the entire oil. In proportion as the quantity increases, the fusing point of the oil rises. The glycerine which is set free gradually becomes converted into *sebacic acid*, which is also found in old palm oil. These various changes seem to be effected by a kind of fermentation, to the commencement of which, according to Guibourt,³ the presence of atmospheric air is necessary.

Palmitine is a white solid fat, which is resolved, by saponification and by the fermentation just alluded to, into *palmitic acid* ($C^{32}H^{31}O^3+HO$), considered by Dumas to be identical with ethalic acid—and *glycerine* (oxide of glycerule).

The Africans use palm oil as a kind of butter. It is now rarely employed in medicine. By the public it is occasionally used by way of friction in bruises, sprains, &c. It is a constituent of the common black bougie. Its ordinary use in this country is in the manufacture of soap and candles. It readily becomes rancid.

The seeds of both species of Elæis are nutritive. They yield by pressure a fixed oil (*palm-seed oil*; *oleum palmæ seminis*), which is solid at ordinary temperature. It is devoid of the orange-yellow colour and orris odour of palm oil. It is said to be used in Africa as a kind of butter. It is rarely brought to Europe, but a few years since I obtained from Africa a specimen of it, with a sample of the seeds from which it was procured.

52. *Cocos nucifera*, Linn.—The Cocoa-Nut Tree.

Sex. Syst. Monœcia, Hexandria.
(Semina.)

Tenga, Rheede, Hort. Malab. i. t. 1, 2, 3, 4; *Calappa*, Rumph., Herb. Amb. i. t. 1, 2.—A native of tropical countries, but does not thrive except near the coast. It is one of the most important and valuable palms. Five varieties of it are indigenous to Ceylon.⁴ Its stem yields *porcupine wood*. A powerful oil is extracted from the bark, which is used by the Cingalese in the form of ointment in cutaneous diseases. By incision into the spathe at the top of the leaves, *sweet toddy* is obtained, which, by fermentation, yields *palm wine*, from which *arrack* is procured by distillation. The fruit, the *cocoa-nut in the shell* of the shops, is a drupe, the fibrous portion of which yields *coir*, which is used for making ropes, mats, &c.; and is also employed, as a substitute for horse-hair, for stuffing mattresses. Within the *cocoa-nut* is the nucleus or kernel (in the dried state called *copra* in commerce), consisting of the albumen (the edible portion), within which is the unsolidified liquor amnii (called *cocoa-nut milk*) and the embryo, which is lodged in a small cavity at the base of the albumen. The albumen and cocoa-nut milk have been analyzed by Brandes,⁵ Buchner,⁶ and Bizio.⁷ According to the latter authority, 100 parts of cocoa-nut milk contain—water, 95; crystallizable glycine (identical with oricine and granatine), 3.825; zymome, 0.75; and mucilage, 0.25 [loss, 0.175]. In 100 parts of the albumen, he found—71.488 of oil; 7.665 of zymome; 3.588 of mucilage; 1.595 of crystallizable glycine; 0.325 of yellow colouring matter; and 14.950 of woody fibre [loss, 0.392]. There are two modes, practised at Malabar and Ceylon, of obtaining *cocoa-nut oil* or *oleum cocoa-nut butter*: the one is by pressure, the other by boiling the bruised nut and skimming off the oil as it forms on the surface. It is a white solid, having a peculiar odour, like that of the flowers of furze (*Ulex europæus*), and a mild taste. It fuses at a little above 70° F., readily becomes rancid, and dissolves easily in alcohol. It consists of a solid fat called *cocin* or *cocinine* (a combination of glycerine and cocinic or coco-stearic acid, $C^{27}H^{26}O^3+2HO$), and of a liquid fat or oleine, which has not been much examined. Cocoa-nut oil is used in the manufacture of candles and soap.⁸ It serves particularly for the manufacture of marine soap, which forms a lather with sea-water. Cocoa-nut oil has been used for medicinal purposes. Loureiro considered it, when fresh, not inferior to olive oil. On the continent of India, as well as in Ceylon, it is used as a pomatum for promoting, preserving, and softening the hair. Mr. Bennett thinks that if it were perfumed, and used for this purpose by Europeans, it would soon display its virtues to such advantage as

⁸ Knapp's *Chemical Technology*, vol. i. p. 465, 1848.

to ensure its general use. But the great drawback to its medicinal employment in pomatums and unguents is its odour, and the facility with which it becomes rancid.

3. PALMÆ CERIFERÆ.—WAX-BEARING PALMS.

The only palm wax which has been brought to Europe as an article of commerce is the produce of the following palm:—

CORYPHA CERIFERA, Mart., Gen. et Sp. Palm. tab. 49 and 50; *Caranaiba*, and *Ananuchi cariri*, Piso et Maregrave, pp. 62 and 130, 1648; *Carnauba*, Brande, Phil. Trans. 1811, and Virey, Journ. de Pharm. t. xx. p. 112, 1834.—Grows on the shores of the Rio Franceseo, in the Brazils.¹ In the axillæ of the leaves, waxy scales are secreted, which are collected and melted by the Indians. The wax thus obtained is imported into this country from Rio Janeiro under the names of *Carnauba Wax*, *Brazilian Wax*, or *Palm Wax*. It was submitted to chemical examination by Mr. Brande, and has subsequently been analyzed by Lewy, who found it to consist of $C^{36}H^{36}O_2$. The fusing point of this wax is $180^{\circ} F$. It is, therefore, less fusible than bees' wax, whose melting point is about $150^{\circ} F$. Being a genuine wax, it is applicable to some of the purposes for which common bees' wax is now employed.

4. PALMÆ RESINIFERÆ.—RESIN-BEARING PALMS.

The only resinous substance used in medicine and the arts, and which is obtained from the palms, is Dragon's blood, the produce of *Calamus Draco*.

53. *Calamus Draco*, Willd.—The Dragon's Blood Calamus.

Sex. Syst. Diœcia, Hexandria.

(Resina; Sanguis Draconis.)

Palma Juncus Draco, Rumph., Herb. Amb. pars v. p. 114, t. lviii. Fig. 1.—A native of the islands of the Indian Archipelago. The berry, which is round, pointed, and about the size of a cherry, yields a resinous substance called in commerce *dragon's blood* (*sanguis draconis*)—a term which is also applied to a product of the *Dracæna Draco* (vide LILIACEÆ), and likewise to a substance obtained from the *Pterocarpus Draco* (vide LEGUMINOSÆ). Lieut. Wellstead says that, in Socotra, Dragon's blood exudes spontaneously from the stem of a tree.² The following are the kinds of it which I have met with:—

1. *Dragon's blood in the reed*; *Dragon's blood in sticks*; *Sanguis Draconis in baculis*.—This occurs in dark reddish-brown sticks of from twelve to eighteen inches long, and from a quarter to half an inch in diameter, enveloped with the leaf of the Talipot palm (*Corypha umbraculifera*), and bound round with slender slips of cane (probably the stem of *Calamus pteræus*). It is supposed to be obtained from a species of *Calamus*, perhaps *C. Draco*.

2. *Dragon's blood in oval masses*; *Dragon's blood in drops*; *Sanguis Draconis in lachrymis*, Martius.—This occurs in reddish-brown lumps of the size and shape of an olive, enveloped with the leaf of *Corypha umbraculifera* or *Corypha Licuala*, which thus connects them together in a row, like the beads of a necklace. This kind is rare in English commerce. It is obtained, according to Rumphius, by rubbing or shaking the fruit of *Calamus Draco* in a bag. A resinous exudation is by this means separated, and is afterwards softened by heat, and made up in these masses.

3. *Dragon's blood in powder*.—This is a reddish powder, of very fine quality, imported from the East Indies. It is probably the dust obtained from the fruit of the *C. Draco*, in the way just described.

4. *Dragon's blood in the tear*; *Sanguis Draconis in granis*, Martius.—It occurs in irregular pieces, some as large as the fist. T. W. C. Martius³ says pieces of the fruit of the *Calamus Rotang* are frequently found intermixed.

5. *Lump Dragon's blood*; *Sanguis Draconis in massis*.—This is of inferior quality. It occurs in large masses, which, when broken, present a heterogeneous appearance.

Other varieties of Dragon's blood are described, but I have never met with them. Guibourt mentions a *dragon's blood in cakes*, and a *false dragon's blood in oval masses*.

Dragon's blood is composed of *red resin* (called *draconin*) 90.7, *fixed oil* 2.0, *benzoic acid* 3.0, *oxalate of lime* 1.6, *phosphate of lime* 3.7.⁴ According to Johnstone,⁵ the resin of *lump dragon's blood* has the formula $C^{40}H^{21}O^9$; that of *reed dragon's blood* $C^{40}H^{20}O^9$.

¹ The stems of this palm are sold at Haynes's timber-yard, Long Lane, Smithfield, London, under the name of *Palm Wood*.

² *Athenæum*, May 16, 1835; also, *Journal of Royal Geographical Society*.

³ *Pharmakognosie*.

⁴ Herberger, *Journ. de Pharm.* xvii. 225.

⁵ *Phil. Trans.* for 1840, p. 384.

It is inert, or nearly so, but was formerly reputed an astringent. It is a constituent of some tooth-powders and tinctures, but is never prescribed by medical practitioners. Its principal consumption is for colouring spirit and turpentine varnishes.

5. PALMÆ TANNINIFERÆ.—TANNIN-BEARING PALMS.

The only palm which yields any officinal astringent substance is the *Areca Catechu*.

54. ARECA CATECHU, *Linn.*—CATECHU PALM.

Sex. Syst. Monœcia, Hexandria.

(Semen.—Extract of the kernels, *E.*—Carbo seminis, *Offic.*)

HISTORY.—*Areca* nuts are not mentioned in the writings of the ancient Greeks and Romans. Avicenna speaks of them under the name of *Fufel*.¹

BOTANY. **Gen. Char.**—1. MALE: *Calyx* three-parted. *Corolla* three-petalled. 2. FEMALE: *Calyx* three-leaved. *Corolla* three-petalled; *nectary* six-toothed. *Ovarium* superior, one-celled, one-seeded; attachment inferior. *Drupe* coriaceous. *Seed* single, ruminant. *Embryo* in the base of the albumen. (*Roxburgh.*)

Sp. Char.—*Trunk* straight and slender, from forty to fifty feet high. *Frons* pinnate; *leaflets* compound, linear, opposite, premorse. *Spathæ* erect, ramous. *Male flowers* hexandrous. *Seed* of a roundish conic form, and obtuse. (*Roxburgh.*)

Hab.—Cultivated in all the warmer parts of Asia.

1. DESCRIPTION AND USES OF THE SEEDS.—The fruit of the *Catechu* palm is about the size and shape of a small egg, yellowish, and smooth. Within the fibrous pericarp is the seed (*areca nut*; *betel nut*; *pinang*). This is about the size of a nutmeg, roundish conical, flattened at the base, hard, horny, inodorous, externally reddish brown, internally brown with whitish veins. The principal part of the seed is the ruminant albumen, at the base of which is the embryo.²

The varieties of this fruit are numerous: of these, some have been figured by Blume,³ viz., *Pinang Putie* (*Areca alba*), *Pinang Susu* (*Areca lactea*), *Pinang Betul* (*Areca propria*), and *Pinang Pict*.

According to Morin,⁴ *areca* nuts (seeds) are composed of *tannin* (principally), *gallie acid*, *glutin*, *red insoluble matter*, *fixed oil*, *gum*, *oxalate of lime*, *liquin*, &c.

With lime and the leaves of *Piper Betel*, these nuts form the celebrated masticatory of the East, called *betel*. They are usually cut into four equal parts; one of which is rolled up with a little lime in the leaf of the *Piper Betel*, and the whole chewed. The mixture acts as a sialagogue, and tinges the saliva red. The Indians have an idea that by this means the teeth are fastened, the gums cleansed, and the mouth cooled. Peron⁵ was convinced that he preserved his health, during a long and difficult voyage, by the habitual use of the *betel*, while his companions, who did not use it, died mostly of dysentery. In this country, *areca-nut charcoal* is used as a tooth powder. I know of no particular value it can have over ordinary charcoal, except, perhaps, that derived from its greater hardness.

2. ARECA-NUT CATECHU.—In the southern parts of India, and probably in Ceylon, an extract called *catechu* is procured from *areca* nuts.⁶ The mode of preparing it has been described by Herbert de Jäger⁷ and Dr. Heyne.⁸ The last-

¹ Lib. ii. tract. ii. cap. 262, p. 306, Venet. 1564.

² Roxburgh's *Plants of Coromandel*, pl. 75; *Flora Indica*, vol. iii. p. 615.

³ *Rumphia*, vol. ii. p. 68, tab. 102, 1536.

⁴ *Voyage aux Terres Australes*.

⁴ *Journ. de Pharm.* viii. 449.

⁶ Ainslie (*Mat. Indica*, vol. i. p. 65) notices two preparations of *areca* nuts, which, he says, have been confounded with the true or real *catechu* (*i. e.* *catechu* of the *Acacia Catechu*). One of these he calls *cuttacambo* (in Tamool), the other *cashcuttie* (in Tamool); and he adds that both are brought to India from Pegu. It is probable, however, from his description, that by *cuttacambo* he means *gambir* (an extract of *Naucelea Gambir*), and by *cashcuttie*, *Pegu cutch* (an extract of *Acacia Catechu*).—Blume (*Rumphia*, vol. ii. p. 67) denies that an extract called *catechu* is procured from *areca* nuts; and says that the error has arisen from the circumstance that old and dry *areca* nuts, broken in small pieces, are macerated in rose-water in which *catechu* has been dissolved.

⁷ *Miscellanea curiosa*, Dec. ii. Ann. iii. p. 10, Norimb. 1685.

⁸ Dr. Heyne, *Tracts, Historical and Statistical, on India*.

mentioned author states that it is largely procured in Mysore, about Sirah, in the following manner: "Areca nuts are taken as they come from the tree, and boiled for some hours in an iron vessel. They are then taken out, and the remaining water is inspissated by continued boiling. This process furnishes *Kassu*, or most astringent terra japonica, which is black, and mixed with paddy husks and other impurities. After the nuts are dried, they are put into a fresh quantity of water, boiled again, and this water being inspissated, like the former, yields the best or dearest kind of catechu, called *Coury*. It is yellowish brown, has an earthy fracture, and is free from the admixture of foreign bodies."

None of the extracts brought from India under the denomination of catechu are distinguished by any name by which they can be referred to the areca nut. It is probable, however, that some of them which come over in the form of *round and flat cakes*, and also *in balls*, and which are more or less covered with paddy husks (glumes of rice), are obtained from this seed. A decoction of some of these kinds of catechu yields, when cold, a blue colour on the addition of iodine, indicating the presence of starch. The presence of fatty matter in them is considered by Professor Guibourt¹ to be a proof that the areca nut has been employed in their production.

I think it probable that the *Colombo* or *Ceylon catechu* of commerce, in the form of round flat cakes, covered by paddy husks, is the *Kassu* of Heyne; and Professor Guibourt is of opinion that the *dull reddish catechu in balls* partially covered by paddy husks is the *Coury* of Heyne. (For further details, the reader is referred to the article *Acacia Catechu*, where a general notice will be given of all the commercial sorts of catechu.)

†† Flowers with a true perianth free from the ovary (*superior ovary*), usually hermaphrodite.

ORDER X. MELANTHACEÆ, R. Brown.

CHARACTERS.—*Perianth* inferior, petaloid, in six pieces, or, in consequence of the cohesion of the claws, tubular; the pieces generally involute in æstivation. *Stamens* six; *anthers* mostly turned outwards. *Ovary* three-celled; many seeded; *style* trifid or three-parted; *stigma* undivided. *Capsule* generally divisible into three pieces; sometimes with a loculicidal deliensecence. *Seeds* with a membranous testa; *albumen* dense, fleshy. (R. Brown.)

PROPERTIES.—Several violently poisonous alkaloids (*veratria*, *colchicina*, *sabadillina*, and *jerivina*) are peculiar to this order. They exist in combination with organic acids. These bases, as well perhaps as resins, are the active principles of the order. The Melanthaceæ are acrids (emetics, purgatives, diuretics, and errhines) and sedatives (see vol. i. p. 258). When acting as poisons, they are called narcotico-acrids (see vol. i. p. 234).

55. COLCHICUM AUTUMNALE, Linn.—COMMON MEADOW SAFFRON.

Sez. Syst. Hexandria, Trigynia.

(Herbæ agrestis cornus recens et exsiccatæ: semen, L.—Cornus et semina, E.—The cornus and seeds, D.)

HISTORY.—Dioscorides² speaks of *Colchicum* (κολχικόν), and states that it grows abundantly in Messenia and at Colehis (from which latter place it received its name). Dr. Sibthorp³ found three species of Colchicum in Greece—viz. *C. autumnale*, *C. montanum*, and *C. variegatum*; and of these he considers the first to be the Colchicum of Dioscorides. In this opinion he is to a certain extent confirmed by the editors of the *Pharmacopœa Græca* (1837), who apply the modern Greek name of κολχικόν to *C. autumnale*. But there is reason to doubt the accuracy of this opinion: for this species is only found in Greece, on this side of the Sperchius, at an elevation of at least 3500 to 4000 feet—at Parnassus, and Thymphrastus; whereas

¹ *Journ. de Pharm. et de Chimie*, 3me Sér. t. xi. p. 303, 1847.

² *Prodr. Fl. Græcæ*, i. 250.

³ *Lib. iv. cap. 61.*

C. variegatum, which Fraas¹ thinks is the *κολχικόν* of Dioscorides, is common, and occurs on the Xirobuni,² at an elevation of only 1000 to 2000 feet, at Hymettus, Messapius, and Helicon.

For the introduction of colchicum into modern practice we are chiefly indebted to Störk,³ in 1763; but partly, also, to the opinion that it is the active principle of a celebrated French remedy (*eau médicinale*) for gout.

BOTANY. **Gen. Char.**—*Perianth* single, tubular, very long, rising from a spathe; limb campanulate, six-partite, petaloid. [*Stamens* six, inserted into the throat of the tube. *Ovarium* three-celled. *Styles* three, filiform, long. *Stigmas* somewhat clavate.] *Capsule* three-celled; cells united at the base (*Hooker*, with some additions).

Sp. Char.—*Leaves* plane, broadly lanceolate, erect (*Hooker*).

Root fibrous. *Cormus* (improperly called *root* or *bulb*) ovate, fleshy, large, covered with a loose brown membrane. The *leaves* are produced in the spring along with the fruit, and disappear before the flower appears. *Flowers* several, lilac or pale purple, arising from the cormus by a long, narrow white tube.⁴ *Fruit* oblong, elliptical, composed of three cells, which may be regarded as distinct follicles, with intermediate fissures. *Seeds* small, spherical, with a rough brown testa and large fleshy strophiole; internally they are white, and consist of a minute embryo lodged in a horny elastic albumen. The flowers appear in September, and the fruit the following spring or summer.

There is a variety, β with late flowers (*floribus serotinis*), growing near Devizes, in Wiltshire, which flowers in the spring.

Florists cultivate several sorts; such as the *white*, the *striped-flowered*, the *striped-leaved*, the *broad-leaved*, the *many-flowered*, and the *double-flowered*.

Hab.—Moist rich meadows in many parts of England and in various countries of Europe.

The plant is propagated by seeds, by a single mature cormus, or by several immature or infant cormi.

COLLECTION OF THE CORMI.—The cormus is biennial. It first appears about the end of June or beginning of July: it flowers in the autumn, and produces its leaves in the spring, and its seed in the June of the following year. It then begins to shrivel, becomes leathery, and finally disappears in the succeeding spring or summer.

The activity of the cormus varies at different seasons of the year. It is usually considered to be greatest when the cormus is about a year old—that is, about the month of July, between the withering of the leaves and the sprouting forth of the flower of the young cormus. At this period the cormus is fully developed, and has not exhausted itself by the production of the young one. But many of the cormi brought to market have already pushed forth their flowers, which are broken off so as to prevent the

³ *Libellus quo demonstratur Colchici Autumnalis Radicem non solum tuto posse exhiberi hominibus, sed et ejus usu interno curari quandoque morbos difficillimos, qui aliis Remediis non cedunt*, Svo. Vindob. 1763.

⁴ Miller says that, in Warwickshire, the flowers are called *naked ladies*, because, they appear without leaves.

circumstance from being observed. "I have seen many cwts.," says Dr. Lindley,¹ "sent to town in this state, which nevertheless found a ready sale, and at the best price."

It is to be dug up in the month of July, or before the autumnal bud shoots up.—*Ph. Lond.*

Dr. Christison² has expressed some doubts as to the propriety of collecting the cormi in July; for though they are plump, firmest, and abound most in starch at this period, yet he has found the shrivelled cormi in the succeeding April to be equally if not more bitter; and he quotes the analyses of Stoltze to show that, while the October cormus yields 2 per cent., the March cormus yields 6 per cent., of bitter extract. But there is an error in the quotation which vitiates the inference intended to be drawn from it. Stoltze found that the October cormus contained 2.17 per cent. of bitter extractive, and that the March cormus contained 5.91 of sweet extractive matter combined with some bitter extractive; and he concludes that the October cormus is much more active, and contains more bitter extractive, than the spring cormus.

The seeds should be gathered when fully ripe. The London market is principally supplied from Gloucestershire, but partly, also, from Hampshire and Oxfordshire.

DESCRIPTION.—The cormus, commonly called the bulb or root (*radix colchici*, Offic.), when gathered at the proper season, is about the size of a chestnut, and somewhat resembles in external appearance the bulb of the common tulip (*Tulipa Gesneriana*); which, as well as other liliaceous bulbs, are distinguished from the cormus of colchicum by being composed of laminæ or scales, whereas the cormus of colchicum is solid.³ It is rounded on one side—flattened on the other, where is perceived the fibrous germ of a new cormus, which, if allowed to grow, shoots up and bears the flower, while the old cormus wastes. It is covered by two coats—an inner reddish-yellow one, and an external brown one. Internally, the cormus is white, fleshy, solid; contains a milky juice, is very feculent, and has an acrid bitter taste.

DESICCATION.—The slices are to be quickly dried, in a dark airy place, with a heat not exceeding 170° F.⁴

Having removed the outer coats, cut the cormus transversely in thin slices, and dry by a heat which is to be at first gentle, and afterwards slowly raised to 150°.—*Ph. Lond.*

The late Dr. A. T. Thomson⁵ recommended the slices to be dried upon clean white paper without artificial heat; but the time required for this is an objection to it in practice. The dried slices (*radix siccata*, Offic.) should be about the eighth or tenth of an inch thick, rounded, oval, with one notch only on one part of their circumference (not fiddle-shaped), inodorous, of a grayish-white colour and an amylaceous appearance.

The seeds (*semina*) are about the size of those of black mustard, odourless, and have a bitter acrid taste. Their colour is brown, varying from pale to dark or blackish. They somewhat resemble several of the cruciferous seeds (black mustard, turnip, and rape), but are larger than these; moreover, the latter being more oily are more readily crushed. I have known colchicum seeds mistaken for grains of paradise.

COMPOSITION.—The colchicum cormus was analyzed in 1810 by Melander, and Moretti;⁶ in 1818 and 1819, by Stoltze;⁷ and in 1820 by Pelletier and Caventou.⁸

¹ *Flora Medica*, p. 589.

² *Dispensatory*, 2d edit. p. 353.

³ Some years ago, a load of tulip bulbs was delivered at Apothecaries' Hall, London, for colchicum cormi. The late Mr. Anderson, gardener to the Apothecaries' Botanic Garden at Chelsea, for many years cultivated some of these tulips, in commemoration, I suppose, of the attempted fraud.

The seeds have been submitted to chemical examination, in 1832, by L. A. Buchner, Jun.,¹ who found in them *fixed oil, free acid, bitter extractive* (impure colchicina), and *resin*.

1. **COLCHICINA**; *Colchicia*; *Colchicene*.—The existence of this principle in colchicum seeds was announced by Geiger and Hesse.² They prepared it by digesting the seeds in boiling alcohol: this dissolved a supersalt, which was precipitated by magnesia, and the precipitate treated with boiling alcohol. By evaporation, colchicina was deposited. The following are said to be its *properties*: It is a crystallizable alkaline substance, without odour, but having a bitter taste. Its hydrate is feebly alkaline, but neutralizes acids, and forms crystallizable salts having a bitter taste. It is soluble in water, and the solution precipitates the solution of chloride of platinum. Nitric acid colours colchicina deep violet, which passes into indigo blue, and quickly becomes first green and then yellow. Concentrated sulphuric acid colours it yellowish brown.

Colchicina is said to be distinguished from veratria by the following characteristics: 1st, it is soluble in water, whereas veratria is not; 2dly, it is crystallizable, whereas pure veratria is not; 3dly, it does not possess the acidity of veratria; and it differs from the latter in this, that, when applied to the nose, it does not excite sneezing, whereas the least portion of [impure] veratria occasions a most convulsive sneezing.

Colchicina is a powerful poison. One-tenth of a grain, dissolved in weak spirit, killed a young cat in about twelve hours. The symptoms were salivation, diarrhœa, vomiting, a staggering gait, cries, convulsions, and death. The stomach and intestines were violently inflamed, and had extravasated blood throughout the whole course.

2. **STARCH**.—The starch grains of the cormus of colchicum are moderately uniform in size: though normally rounded, they present more or less flattened faces, produced by their mutual compression in the cells of the plant, by which they have acquired a polygonal appearance. Many are mullar-shaped, some are dihedral at one end, others trihedral; owing to the mutual pressure of two, three, or four particles. The hilum is usually stellate.

CHEMICAL CHARACTERISTICS. *a. Of the Cormi*.—The decoction of the fresh cormi, when cold, forms, with a solution of iodine, a deep blue precipitate (*iodide of starch*); with sesquichloride of iron, a faint bluish tint (*gallate of iron*); with diacetate of lead, or protonitrate of mercury, a copious white precipitate; with nitrate of silver, a precipitate which is at first white, but becomes in a few minutes black; with tincture of nutgalls, a very slight, dirty-looking precipitate, which is somewhat diminished by the effect of heat [Pelletier and Caventou³ regard this precipitate as a mixture of the *tannates of starch* and *inulin*⁴ (and of veratrin?)]; and with a solution of gelatine, a slight haziness. Fresh-prepared tincture of guaiacum, with a few drops of acetic acid, produces a cerulean blue colour with the fresh cormus, indicating the presence of gluten.

β. Of the Seeds.—The decoction of the seeds, when cold, yields, with oxalate of ammonia, a white precipitate (*oxalate of lime*); with diacetate of lead, a copious white precipitate; and, with nitrate of silver, a precipitate. If the decoction be concentrated, and poured into alcohol, a gelatiniform precipitate is produced.

PHYSIOLOGICAL EFFECTS. *a. On Vegetables*.—Not yet determined.

β. On Animals.—Colchicum is a poison to animals. It acts as a local irritant,

¹ *Repert. für die Pharm.* Bd. xliiii. S. 376, 1832.

² *Journ. de Chim.* x. 465.

³ *Journ. de Pharm.* vi. 365.

⁴ The precipitate produced in an amylaceous decoction by infusion of nutgalls, disappears when the liquor is gradually heated to 122° F.: but if inulin be present, it does not disappear until the liquor has reached the boiling point.

reduces the force of the circulation, and causes inflammation of the alimentary canal. Animals, for the most part, refuse to feed on it. It has, however, been eaten by deer and cattle, and proved poisonous to them.¹ It is said to prove injurious at spring-time only.² Moreover, we are told that when dry it may be eaten in hay with impunity. Störck³ and Kratochwill⁴ gave it to dogs, on whom it acted as an acrid poison, and caused death. Sir E. Home⁵ injected 160 drops of a vinous infusion of colchicum into the jugular vein of a dog: all power of motion was instantly lost, the breathing became slow, the pulse hardly to be felt. In ten minutes it was 84, in twenty minutes 60, in an hour 115, with the respiration so quick as scarcely to be counted. In two hours the pulse was 150, and very weak. The animal was purged, vomited, and very languid: he died in five hours. On dissection, the internal coat of the stomach was found inflamed, in a greater or less degree, universally. From this experiment it appears that the action of colchicum on the alimentary canal is of a specific kind.

In opposition to the above statements, it deserves notice that Orfila⁶ has frequently given to dogs, in the month of June, two or three cormi without perceiving any sensible effects; from which he infers that climate and season of the year have great influence on their deleterious properties.

It has been said that horses eat colchicum with impunity; but it is probable that this statement is erroneous. Withering⁷ states, on the authority of Mr. Woodward, that, "in a pasture in which were several horses, and eaten down nearly bare, the grass was closely cropped, even under the leaves, but not a leaf bitten."

Some further information on the effects of colchicum on dogs will be found in Sir C. Seudamore's *Treatise on Gout and Rheumatism*, 3d edit. p. 477, 1819.

γ. *On Man.*—Colchicum is acrid and sedative. Taken internally, in small and repeated doses, it promotes the action of the secreting organs, especially the intestinal mucous membrane. The kidneys, the skin, and the liver, are less certainly and obviously affected by it. Salivation has been ascribed to it by Dr. Aldridge.⁸ The most constant effects observed from the use of larger doses are nausea, vomiting, and purging. Reduction of the frequency of the pulse is a common, though not an invariable effect. Mr. Haden⁹ was, I believe, the first to direct attention to the advantages to be taken of this effect in the treatment of inflammatory diseases. In some experiments made on healthy individuals by Dr. Lewins,¹⁰ debility, a feeling of illness, and headache, were experienced. This feeling of debility is not, however, to be referred to the evacuations produced; for, as Dr. Barlow¹¹ has observed, the number of motions is sometimes considerable without any proportionate depression of strength ensuing. "I have known," says Dr. B., "even twenty stools occasioned by a single dose of colchicum, the patient not complaining of the least debility." The action of colchicum on the secretory apparatus is not confined to that of the alimentary canal: after the use of three or four full doses of this medicine, copious sweating is often produced, especially when the skin is kept warm. On other occasions, the kidneys are powerfully acted on. In one case, mentioned by Dr. Lewins, seventy drops of *Vinum Colchici* caused the discharge of upwards of a pint of bile by vomiting. Violent salivation resulted, in a case recorded in an American journal.¹² Chelius, of Heidelberg,¹³ asserts that, in gout and rheumatism, colchicum occasions a striking increase in the quantity of uric acid contained in the urine: in one case it was nearly doubled in the space of twelve days. But this effect is by no means constant, as Dr. Graves¹⁴ has pointed out. Indeed, it some-

times happens, in acute rheumatism, when the urine is loaded with uric acid or the urates, that under the use of colchicum the quantity of these matters in the urine is diminished; so that it would seem rather to prevent the formation of uric acid in the system than to provoke its elimination.

In excessive or poisonous doses colchicum acts as a powerful poison. In a case related by Mr. Fereday,¹ where two ounces of the wine of the seeds of colchicum were swallowed, the symptoms were acute pain in the bowels, coming on in about an hour and a half after taking it, vomiting, acute tenesmus, small, slow, and feeble pulse, cold feet, and weakness of limbs. The nausea, vomiting, and pain in the stomach continued with undiminished violence, the pulse became also imperceptible and intermitting, the urine was suppressed, the respiration hurried, purging of copious liquid stools came on, and loss of sight for a minute or two after getting out of bed. The patient died forty-seven hours after swallowing the poison. On a *post-mortem* examination, the skin of most parts of the body was found to be covered with a purple efflorescence: no inflammation was observed in the alimentary canal; two red patches were found, one in the stomach, and the other in the jejunum. These were produced by the effusion of a small quantity of blood, in the one case, between the muscular and mucous coats; in the other, between the peritoneal and muscular coats. Ecchymosed spots were observed on the surface of the lungs, of the heart, and of the diaphragm. More recently, a case of poisoning by a decoction of the seeds has been recorded;² as, also, by the leaves of this plant.

In Mr. Fereday's case, the only indications of an affection of the nervous system were weakness of the limbs, the temporary loss of sight, and the slowness and feebleness of the pulse.

It is deserving of notice that, in this case, also in another related by Chevallier,³ likewise in a third mentioned by Mr. Dillon,⁴ and in Mr. Haden's case,⁵ no convulsions were observed; and, in the first three cases, no insensibility. In the last case, however, Mr. Haden mentions that at "ten P. M. she fell into an apoplectic kind of sleep, which terminated in death before morning." It is remarkable that convulsions are ascribed to veratria by Magendie, and to colchicina by Geiger and Hesse. In one case of fatal poisoning from an ounce and a half of the tincture of colchicum,⁶ delirium occurred.

It is a popular notion that colchicum acts as an emmenagogue; and hence it is sometimes used to produce abortion. Several poisonous cases of its use for this purpose have occurred.

Some persons appear to be peculiarly susceptible of the influence of colchicum. In Mr. Haden's case, Zijss of tincture of colchicum caused death in a female whose mother was also exceedingly susceptible of the action of colchicum in even very small doses. In a case related by Mr. Mann,⁷ Zijss of the wine of colchicum in divided doses caused death on the fourth day.

The above account of the effects of colchicum applies both to the *cormi*, the *seeds*, and the *leaves*. The *flowers* are likewise poisonous, and a fatal case from their use is mentioned by Dr. Christison.⁸ They have been recommended for medicinal use.

USES.—The following are the principal diseases in which the Meadow Saffron has been employed:—

1. *In Gout*.—The circumstances which of late years have led to the extensive employment of colchicum in gout are the following: About seventy years ago, M. Husson, a military officer in the service of the king of France, discovered, as he informs us, a plant possessed of extraordinary virtues in the cure of various diseases. From this plant he prepared a remedy called *Eau Médicinale*, which acquired great celebrity for abating the pain and cutting short the paroxysm of

gout.¹ Various attempts were made to discover the nature of its active principle. In 1782, MM. Cadet and Parmentier declared that it contained no metallic or mineral substance, and that it was a vinous infusion of some bitter plant or plants. Alyon² asserted that it was prepared with Gratiola; Mr. Moore³ that it was a vinous infusion of white hellebore with laudanum; Mr. Want⁴ that it was a vinous infusion of colchicum. Although most writers have adopted Mr. Want's opinion, we should bear in mind that the proofs hitherto offered of its correctness, viz., analogy of effect, cannot be admitted to be conclusive, as is well shown by the fact that they have been advanced in favour of the identity of other medicines with the *Eau Médicinale*.

The power of colchicum to alleviate a paroxysm of gout is admitted by all; but considerable difference of opinion exists as to the extent of this power, and the propriety of employing it. Sir Everard Home,⁵ from observation of its effects on his own person, regarded it as a specific in gout, and from experiments on animals concluded that its beneficial effects in this malady are produced through the circulation.

Dr. Paris⁶ observes: "As a *specific* in gout its efficacy has been fully ascertained; it allays pain, and cuts short the paroxysm. It has also a decided action upon the arterial system, which it would appear to control through the medium of the nerves." But if by the word *specific* is meant a medicine infallibly, and on all patients, producing given salutary effects, and acting by some unknown power on the disease, without being directed by indications,⁷ undoubtedly colchicum is no specific for gout.

That colchicum alleviates a paroxysm of gout, I have before mentioned; but that alleviation is palliative, not curative. It has no tendency to prevent a speedy recurrence of the attack; nay, according to Sir Charles Scudamore,⁸ it renders the disposition to the disease much stronger in the system. Furthermore, by repetition its power over gouty paroxysms becomes diminished.

The *modus medendi* of colchicum in gout is an interesting, though not very satisfactory part of our inquiry. I have already stated that some regard this remedy as a specific; that is, as operating by some unknown influence. Others, however, and with more propriety, refer its therapeutical uses to its known physiological effects. "Colchicum," says Dr. Barlow,⁹ "purges, abates pain, and lowers the pulse. These effects are accounted for by assigning to it a cathartic and sedative operation; and it is this combination, perhaps, to which its peculiar virtues are to be ascribed." The fact that a combination of a drastic and a narcotic (as claterium and opium, mentioned by Dr. Sutton,¹⁰ and white hellebore and laudanum, recommended by Mr. Moore)¹¹ has been found to give, in several cases of gout, marked and speedy relief, seems to me to confirm Dr. Barlow's opinion. The idea entertained by Chelius, and adopted by Dr. G. Hume Weatherhead,¹² that colchicum relieves gout by augmenting the quantity of uric acid in the urine, is not supported by fact, as I have already mentioned. Whether it acts by preventing the formation of uric acid in the system, I am not prepared to say.

In acute gout occurring in plethoric habits, blood-letting should precede the use of colchicum. This medicine should then be exhibited in full doses, so as to produce a copious evacuation by the bowels, and then the quantity must be considerably diminished. Though purging is not essential to the therapeutical influence of colchicum, it is admitted by most that, in a large number of cases at least, it promotes the alleviation of the symptoms. Hence, many practitioners recommend its com-

bination with saline purgatives, as the sulphate of magnesia. Sir Charles Scudamore has experienced "the most remarkable success from a draught composed of *Magnesie* gr. xv ad xx; *Magnes. Sulphat.* ʒj ad ʒij; *Aceti Colchici* ʒj ad ʒij; with any distilled water the most agreeable, and sweetened with any pleasant syrup, or with 15 or 20 grains of Extract. Glycyrrhiz."

2. *In rheumatism.*—The analogy existing between gout and rheumatism has led to the trial of the same remedies in both diseases. But its therapeutical powers in the latter disease are much less marked than in the former. Rheumatism may affect the fibrous tissues of the joints, the synovial membrance, the muscles or their aponeurotic coverings, the periosteum, or the neurilemma, constituting thus five forms of the disease, which may be denominated respectively the *fibrous* or *ligamentous*; the *synovial*, *arthritic*, or *capsular*; the *muscular*; the *periosteal*; and the *neuralgic* forms of rheumatism.¹ Of these, colchicum is said to produce its best effects in the synovial form. It is remarkable, however, that in all the severe cases of this variety of rheumatism which have fallen under my notice, the disease has proceeded unchecked, or was scarcely relieved by the use of colchicum. In one instance, that of my much-lamented friend, the late Dr. Cummin (whose case is noticed by Dr. Macleod, in the *Lond. Med. Gaz.* xxi. 358), the disease proved fatal by metastasis to the brain. In another melancholy, but not fatal case, the gentleman lost the sight of both his eyes, and has both knee-joints rendered stiff. In neither of these cases was colchicum of the slightest avail.

Of the mode of administering colchicum in "rheumatic gout," recommended by Mr. Wigan,² I have no experience. He gives eight grains of the powder in some mild diluent every hour until active vomiting, profuse purging, or abundant perspiration take place; or, at least, till the stomach can bear no more. The usual quantity is eight or ten doses; but, while some take fourteen, others can bear only five. Though the pain ceases, the more active effects of the colchicum do not take place for some hours after the last dose. Thus administered, Mr. Wigan declares colchicum "the most easily managed, the most universally applicable, the safest, and the most certain specific in the whole compass of our opulent Pharmacopœia." But its use in these large doses requires to be carefully watched.

3. *In dropsy.*—Colchicum was used in dropsy with success by Störck.³ It has been employed in dropsical cases with the twofold view of purging and promoting the action of the kidneys. Given in combination with saline purgatives, I have found it beneficial in some cases of anasarca of old persons.

4. *In inflammatory diseases generally.*—Colchicum was recommended as a sedative in inflammatory diseases in general by the late Mr. C. T. Haden.⁴ He used it as an auxiliary to blood-letting, for the purpose of controlling arterial action; and gave it in the form of powder, in doses of six or seven grains, three or four times daily, in combination with purgatives, in inflammatory affections of the lungs and their membranes, and of the breasts and nipples. In chronic bronchitis it has also been found useful by Dr. Hastings.⁵

5. *In fevers.*—The late Mr. Haden,⁶ and more recently Dr. Lewin,⁷ have spoken favourably of the use of colchicum in fever. In my opinion, it is only admissible in those forms of the disease requiring an active antiphlogistic treatment. In such it may be useful as an auxiliary to blood-letting and cathartics.

6. *In various other diseases.*—For expelling tape-worm, colchicum has been found efficacious by Chisholm and Baumbach. In some chronic affections of the nervous system, as chorea, hypochondriasis, hysteria, &c., Mr. Raven⁸ employed it with advantage. In humoral asthma, and other chronic bronchial affections, I have

⁸ *Op. cit.*

found it of great service, especially when these complaints were accompanied with anasarcaous swellings.

ADMINISTRATION.—The corni and seeds of meadow saffron have been employed in substance, in a liquid form, and in the state of extract.

1. PULVIS CORNI COLCHICI.—Dose, from two to eight or nine grains. To preserve it, Mr. Wigan recommends it to be kept mixed with sugar.

2. PULVIS SEMINUM COLCHICI.—Dose the same as that of the cornus. The seeds are to be preferred to the corni, as being more uniform in their properties.

3. TINCTURA [SEMINUM] COLCHICI, L. Ed.; *Tinctura Seminum Colchici*, D. [*Tinctura Colchici Seminis*, U. S.].—(Meadow Saffron seeds, bruised [ground finely in a coffee-mill, *Ed.*], ℥v; Proof Spirit Oij. Macerate for seven [fourteen, *D.*] days, and strain, *L.* “Percolation is much more convenient and speedy than digestion,” *E.*—[Colchicum seed, bruised, four ounces; diluted alcohol two pints. Macerate for fourteen days, express and filter through paper, or moisten the powder with the diluted alcohol, allow to stand for twenty-four hours, and then displace, *U. S.*].—Dr. Williams¹ objected to this preparation as being “turbid, unpalatable, and disposed to precipitation.” The same writer² also asserts that the active property of the seeds resides in their husk or cortical part, and, therefore, protests against bruising them. But were his assertion correct (and it is most improbable that the embryo is devoid of activity), bruising them cannot destroy or injure their activity. The average dose is from ℥ss to ℥j. I have repeatedly given ℥ij at a dose without any violent effect. Dr. Barlow, who prefers this to the other preparations of colchicum, advises that in gout a drachm, a drachm and a half, or two drachms of the tincture should be given at night, and repeated the following morning. If this quantity fail to purge briskly, a third dose may be administered the ensuing night. Externally, the tincture has been employed as a liniment to relieve rheumatic, gouty, venereal, and other pains.³

4. TINCTURA [SEMINUM] COLCHICI COMPOSITA, L.; *Spiritus Colchici ammoniatus*, L. 1824.—(Meadow Saffron seeds, bruised, ℥v; Aromatic Spirit of Ammonia Oij. Macerate for seven days, then express and strain.) Dose ℥xx to ℥j. —This preparation was recommended by Dr. Williams as being “of greater value when acidity or flatulence prevails than the *Vin. sem. Colchici*, and better adapted to the palates of those who object to the flavour of white wine.” It is seldom employed. Mr. Brande⁴ says doubts are entertained as to the propriety of employing ammonia in it.

5. VINUM SEMINUM COLCHICI [*Vinum Colchici Seminis*, U. S.].—No formula for this exists in any of the British pharmacopœias. The following is Dr. Williams’s formula: Meadow Saffron seeds, dried, ℥ij; Sherry Wine Oj (*wine measure*). Macerate for eight or ten [fourteen] days, occasionally agitating, then filter. The average dose is ℥ss to ℥j. I have given it to the extent of ℥ij. Dr. Williams says it may be gradually increased to ℥ijj.

[This formula has been adopted by the *U. S. Pharmacopœia*, which directs double the proportion of each of the ingredients, and directs maceration for fourteen days.]

6. VINUM [CORNI] COLCHICI, L. E. [*Vinum Colchici Radicis*, U. S.].—(Meadow Saffron cornus, dried and sliced, ℥vij; Sherry Wine Oij. Macerate for seven days [express strongly the residuum, *E.*], and strain) [The directions of the *U. S. Pharm.* are: Take of Colchicum Root one pound; White Wine two pints. Macerate for fourteen days, with occasional agitation, and filter; or by displacement.] Average dose ℥ss to ℥j. —Sir E. Home⁵ thought that the second and subsequent deposits

⁴ *Dict. of Mat. Med.* 1839.

⁵ *Phil. Trans.* 1837.

which take place from this wine contain the principle which acts on the stomach and bowels, while that which cures the gout is retained in permanent solution. But Sir C. Scudamore¹ found the sediment to be inert.

7. ACETUM [CORMI] COLCHICI, L. E. D. [U. S.].—(Meadow Saffron cormus, dried [and bruised, *D.*], ꝑiiiiss [ꝑj, *D.*]; Dilute Acetic Acid Oj [Acetic Acid of commerce (sp. gr. 1044) fꝑiv; Distilled Water ꝑxij, *D.*]; [Proof Spirit fꝑiiss, *L.*]. Macerate the colchicum in the acid [diluted with the water, *D.*], in a covered vessel, for three [seven, *D.*] days; then express, set aside for the feces to subside, and strain. [To the strained liquor, add the spirit, *L.*]—The *Edinburgh College* directs colchicum-bulb, fresh and sliced, ꝑj; Distilled Vinegar fꝑxvj; Proof Spirit fꝑj.)—The London and Dublin Colleges, in their Pharmacopœias for 1850, have very properly substituted the *dried* for the *fresh* cormus ordered in the preceding Pharmacopœia, on account of the impossibility of procuring the fresh at all seasons of the year. [The *U. S. Pharm.* orders of Colchicum Root, bruised, two ounces; Diluted Acetic Acid two pints. Macerate the root with the diluted acetic acid, in a close glass vessel, for seven days; then express the liquor and set it by, that the dregs may subside; lastly, pour off the clear liquor.]—In practice, one part of the dried cormus may be considered equal to three parts of the fresh: for Mr. Battley² says the cormus loses about 67 per cent. of its weight in drying; and Mr. Bainbrigge³ obtained 2 lbs. 15 oz. of dried slices from 8 lbs. of fresh cormi. The proof spirit used in preparing the acetum is for the purpose of checking decomposition. By the action of the acetic acid on the colchicina of the cormus, an acetate of this alkaloid is obtained. Sir C. Scudamore⁴ regards an acetic preparation of colchicum as milder than the wine or tincture made with the same relative weights of cormi and liquids, though it is a most efficient preparation in gout. He advises, as I have before mentioned, that it should be given in combination with magnesia, by which its acid menstruum is destroyed (acetate of magnesia being formed), and the active principle of the colchicum left in the most favourable state for administration. The average dose is from fꝑss to fꝑij.

8. EXTRACTUM [CORMI] COLCHICI ACETICUM, L. E. D. [U. S.].—(Fresh Meadow Saffron cormus, ℥bj; Acetic [pyroligneous, *Ed.*] Acid fꝑiij. Bruise the cormus gradually sprinkled with the acetic acid, then press out the juice, and evaporate it in an earthen vessel which is not glazed with lead [over the vapour-bath, *Ed.*] to a proper consistence. The *Dublin College* orders of Colchicum Root, dried, ꝑiv; Dilute Acetic Acid fꝑviiij. Digest the root in the acid for fourteen days, then filter, and evaporate, by means of a water-bath, to the consistence of a soft extract. [Take of Colchicum Root, in coarse powder, a pound; Acetic Acid four fluid-ounces; Water a sufficient quantity. To the acetic acid add a pint of water, and mix the resulting liquid with the colchicum root. Transfer the mixture to a percolator, and pour water gradually upon it until the liquid passes with little or no taste. Lastly, evaporate the liquid in a porcelain vessel to the proper consistence, *U. S.*]—This compound contains the acetate of colchicina. It is a very favourite remedy in the treatment of gout and rheumatism, and was introduced into practice by Sir C. Scudamore. Dr. Paris⁵ observes that he has “found it useful in promoting healthy discharges of bile.” He occasionally combines it with blue pill, calomel, or potassio-tartrate of antimony. The dose is from gr. j to gr. iij twice or thrice a day.

9. EXTRACTUM COLCHICI [CORMI], L.—(Fresh Meadow Saffron cormus ℥bj. Bruise the cormus, sprinkled with a little water, in a stone mortar; then press out the juice, and evaporate it, unstrained, to a proper consistence.)—This is a favourite

preparation with Dr. Hue, of St. Bartholomew's Hospital, in the early stage of acute rheumatism. The dose is gr. j every four hours.

10. SUCCUS COLCHICI; Preserved Juice of Colchicum.—I am informed that in one experiment from one cwt. of very fine cormi gathered at the end of August, and well bruised and pressed, four imperial gallons and f ʒxij of a light fawn-coloured juice were obtained. This juice becomes darker coloured by exposure to the air. After standing forty-eight hours the spirit is added to it. A large quantity of feculent deposit is formed, and the liquor acquires a paler tint. The deposit by boiling yields a coagulum. Exposure to light appears to render it somewhat paler. The smallest dose of succus colchici is five minims.

ANTIDOTE.—See VERATRUM ALBUM.

56. Hermodactylus, Auct.—Hermodactyl.

HISTORY.—Among the later Greek and the Arabian physicians, a medicine called hermodactyl (*ἡρμωδάκτυλος*, from *ἕρμης*, Mercury or Hermes; and *δάκτυλος*, a finger) was in great repute as a remedy for arthritic diseases. It was first mentioned by Alexander of Tralles,¹ who flourished A. D. 560. Paulus Aegineta,² who lived A. D. 650, Avicenna,³ Serapion,⁴ and Mesue,⁵ also speak of it. It is deserving of especial notice, that, under the name of *Surugen* or Hermodactyl, Serapion comprehends the *καλχηκόν* and *εφήμερον* of Dioscorides, and the *ἡρμωδάκτυλος* of Paulus. By some of the old writers, hermodactyl was called *anima articulorum*, or the soul of the joints.

NATURAL HISTORY.—The cormi brought from Oriental countries in modern times under the name of hermodactyls, answer to the descriptions given of the ancient substance bearing this name. I am, therefore, induced to believe them to be identical with the latter. Their resemblance to the cormi of *Colchicum autumnale* leads me to reject the notion of Matthioli, at one time entertained by Linnæus,⁶ and adopted by Martius⁷ and Fraas,⁸ that they are produced by *Iris tuberosa*. That they are the underground stems of some species of colchicum can scarcely, I think, be doubted by any one who carefully examines them. Notwithstanding the statements of Mr. Wain⁹ and of Sir H. Halford,¹⁰ I cannot admit the assumption that hermodactyls are the cormi of *Colchicum autumnale*, though this is the only species of *Colchicum* admitted into the new Greek Pharmacopœia. Though resembling the latter in several circumstances, they possess certain distinctive peculiarities. Some of the most eminent pharmacologists of Europe (e.g. Guibourt, Gœbel, Geiger, Geoffroy, &c.) also regard them as distinct. The *Colchicum illyricum*, mentioned in many works as yielding hermodactyl, is unknown to modern botanists. The cormus of *Colchicum byzantinum* is too large to be confounded with hermodactyl. *Colchicum variegatum* has been supposed by several botanists and pharmacologists to be the source of hermodactyl, but further evidence is required to establish the opinion. This plant is a native of Sicily, Crete, Greece, and Portugal. Dr. Sibthorp¹¹ found it on Helicon, Parnassus, and other mountains of Greece. It is not improbable, I think, that *Colchicum bulbocodiodes* may yield hermodactyl, which Dale¹² tells us is brought from Syria. Dr. Lindley informs me that this species was found by Colonel Chesney near the Euphrates, where it was very common, flowering in March. The cormi were not brought over. *Iris tuberosa* was not found there. Forskål¹³ found *Colchicum montanum* (which Sprengel, in his *Syst. Veg.*, regards as identical with *C. bulbocodiodes*) at Kurma, in Arabia.

DESCRIPTION.—Mesue says that hermodactyl is either long, like the finger, or round. Of the round, he adds, there are three kinds—the white, the red, and the black; the white being the best. C. Bauhin¹⁴ considered that the black and red hermodactyl of Mesue and Serapion are *C. autumnale*, or, as he terms it, "*Colchicum commune*;" but the white hermodactyl he regarded as a distinct kind, which he calls "*Colchicum radice siccata alba*." Through the kindness of my friend Professor Royle, I have had the examination of two kinds of hermodactyl, procured by him in the bazaars of Northern India, brought, he thinks, from Surat or Bombay, and probably imported there from the Red Sea.

1. Tasteless Hermodactyl; Sorinjan sheeran (i. e. sweet sorinjan), Royle; *Hermodactylus*, Auct. nostræ a tatis.—In their general form these cormi resemble those of *Colchicum autumnale*. They are flattened, cordate, hollowed out or grooved on one side, convex on the other. At

¹⁴ *Pinax*, p. 67, 1671.

their lower part (forming the base of the heart) is a mark or disk for the insertion of the root fibres. Their size varies: the specimens I have examined were from $\frac{3}{4}$ to $1\frac{1}{2}$ inches in length or height, 1 to $1\frac{1}{2}$ inches in breadth, and about $\frac{1}{2}$ an inch in depth. They have been deprived of their coats, are externally dirty yellow or brownish, internally white, easily broken, farinaceous, opaque, odourless, tasteless, or nearly so, and worm-eaten. They agree precisely with hermodactyls furnished me by Professor Guibourt. They are readily distinguished from the corni of *Colchicum autumnale* by the following characters, which are correctly stated by Geoffroy:¹ They are not rugose, are white internally, are moderately hard, easily broken, and form a whitish powder; whereas the dried corni of *Colehium autumnale* are rugose, softer, and have a reddish or grayish tint both internally and externally.

2. *Bitter Hermodactyl*; *Sorinjan tulkh* (i. e. bitter sorinjan), Royle. ? *Bulbs* [corni] of another *Colchicum*.² ?? *Hermodactylus rubens et niger* (Aveenna and Mesue).—The corni of this variety are distinguished from the preceding by their bitter taste, their smaller size, and by having externally a striped or reticulated appearance. Their colour for the most part is darker; in some specimens it is blackish. One cornus is ovate-cordate; 1 inch in height or length, $\frac{3}{4}$ of an inch broad, and about $\frac{1}{4}$ of an inch thick, grooved or hollowed on one side, convex on the other; of a brownish-yellow colour, semi-transparent, has a horny appearance, and is marked by longitudinal stripes, indicating a laminated structure. A second is opaque, amylaceous, reticulated externally, white internally, less flattened, and of a remarkable shape, the concave or hollow side of the cornus being continued half an inch below the mark for the attachment of the root fibres. The other corni are of the size and shape of a large orange pip, but flattened or grooved on one side; some of them are worm-eaten, and one is blackish-brown externally.

COMPOSITION.—Lecanu³ analyzed hermodactyls (the tasteless variety), and obtained the following results: *Starch* (forming the principal constituent of the hermodactyl), *fatty matter*, *yellow colouring matter*, *gum*, *supermalates of lime and potash*, and *chloride of potassium*.

Is the absence of veratria or colchieina to be ascribed to the corni having undergone decomposition by keeping? No inulin was detected.

CHEMICAL CHARACTERISTICS.—Both the tasteless and bitter hermodactyls are blackened by tincture of iodine, showing the presence of starch. A cold decoction of the bitter variety produced an intense blue precipitate (*iodide of starch*) with a solution of iodine. Tincture of galls, and solutions of protonitrate of mercury, and of diaacetate of lead, caused a cloudiness in the cold decoction.

EFFECTS AND USES.—No modern experiments have been made to determine the activity of hermodactyl. The tasteless variety is probably inert, or nearly so; but the bitter variety, I suspect, possesses some activity. Is its operation analogous to that of the cornus of *Colchicum autumnale*?

Speaking of the treatment of gout and arthritis, Paulus says: "Some, in the paroxysms of all arthritic diseases, have recourse to purging with hermodactylus; but it is to be remarked that the hermodactylus is bad for the stomach, producing nausea and anorexia, and ought, therefore, to be used only in the case of those who are pressed by urgent business, for it removes rheumatism speedily, and after two days at most, so that they are enabled to resume their accustomed employment."⁴

57. VERATRUM ALBUM, Linn.—WHITE HELLEBORE.

Sex. Syst. Polygamia, Monœcia.
(Rhizoma, L.—Rhizoma, E.)

HISTORY.—This is, I think, the *ἐλλέβορος λευκός* of Dioscorides (lib. iv. cap. 150), and probably, therefore, of other ancient writers, as Hippocrates and Theophrastus. On this point, however, considerable difference of opinion has existed. Schulze,⁵ while he acknowledges the great similitude between *Veratrum album*, Linn. and the white hellebore of Dioscorides, is of opinion that the true hellebore (both white and black) of Theophrastus is wholly lost. And Dr. Sibthorp,⁶ who found both *V. album* and *V. nigrum* in Greece,⁷ regards *Digitalis ferruginea* as the white hellebore of Dioscorides—an opinion from which Sir J. Smith, the editor of the *Prodromus*, expresses his dissent.⁸ The term *veratrum* is said by Lemery to be derived

¹ *Trait. de Mat. Méd.* t. ii. p. 79.

² *Journ. de Pharm.* xi. 350.

³ Adams's *Translation*, vol. i. p. 660, Sydenham Society's edition.

⁴ *Diss. inaug. sist. Toxicol. Veterum*, Halæ. 1788.

⁵ Goebel, *Pharm. Waarenk.* p. 271

⁶ *Prod. Fl. Græcæ*, i. 439.

⁷ Neither Fraas, nor any other botanists, whose collections in Greece he examined, found either of the above-mentioned species of veratrum.

⁸ For some interesting information respecting the ancient hellebore, consult Dierbach, *Arzneimittel. d. Hippocrates*, p. 107.

from *vere atrum* (*truly black*), in reference to the colour of the rhizome; but this etymology is improbable.

BOTANY.—**Gen. Char.**—*Flowers* polygamous. *Perianth* six-parted; segments broad, concave, imbricating, nearly equal, striated, not excavated at the base. *Stamens* six, equal, inserted into the base of the segments; *filaments* subulate; *anthers* reniform, with confluent cells. *Ovary* with three divaricating *stigmas*. *Capsule* three-horned, separating into three many-seeded follicles. *Seeds* compressed, winged at the apex. (*Lindley*.)

Sp. Char.—*Panicle* decompound. *Bracts* equalling the flowers. *Pedicels* pubescent. *Segments of the perianth* somewhat erect and obtuse, serrulate. *Leaves* ovate-oblong, plaited. (*Sprengel*.)

Root composed of numerous fleshy brownish-white fibres, arising from a perennial, cylindrical, fleshy, subterraneous stem or *rhizome*, which is brown externally, brownish-white internally, and is placed obliquely in the earth. *Stem* one to four feet high. The plant flowers from June to August.

Two varieties (by some considered distinct species) are included here:—

a. *albiflorum* (*V. album*, Bernh.) with decompound raceme and white flowers.

β. *viridiflorum* (*V. Lobelianum*, Bernh.) with compound raceme and greenish flowers.

Hab.—Mountainous regions of Europe. Abounds in the Alps and Pyrenees.

DESCRIPTION.—The *rhizome* or *cornus* (*radix veratri*, offic., *radix hellebori albi*) is single-, double-, or many-headed, having the form of a cylinder, or, more frequently, of a truncated cone. It is from two to four inches long, and about one inch in diameter, rough, wrinkled, grayish, or blackish-brown externally, whitish internally. Portions of the root fibres are usually attached to it, as well as some soft, fine hair-like fibres. At the upper extremity of the rhizome we frequently observe the cut edges of numerous concentric, woody, or membranous scales: they are portions of the dried leaf-sheaths. When cut transversely, the rhizome presents a large central portion (frequently called *medulla*), which varies in its qualities; being woody, farinaceous, or spongy, in different specimens. This is separated by a brown fine undulating line from a thick woody ring, in which the root fibres take their origin. On the outside of this is a narrow but compact brown epidermoid coat. The odour of the dried rhizome is feeble; the taste is at first bitter, then acid. By keeping, the rhizome is apt to become mouldy.

The rhizome of *Veratrum viride* is used in the United States as a substitute for that of *Veratrum album* (see p. 186).

COMPOSITION.—White hellebore rhizome was analyzed in 1820 by MM. Pelletier and Caventou,¹ who obtained the following results: *Fatty matter* (composed of *olein*, *stearin*, and a *volatile* [cevadie?] *acid*), *supergallate of veratria*, *yellow colouring matter*, *starch*, *ligneous matter*, and *gum*. The ashes contained much *phosphate* and *carbonate of lime*, *carbonate of potash*, and some traces of *silica* and *sulphate of lime*, but no chlorides. They could not obtain the volatile [cevadie?] acid in a crystalline form.

1. VERATRIA. (See p. 190).

2. JERVIN (so called from *Jerva*, the Spanish name for a poison obtained from the root of white hellebore);² *Barytin*.—A white crystalline, fusible, and inflammable substance, discovered

Fig. 219.

Veratrum album, Linn. var. *albiflorum*.

¹ Journ. de Pharm. vol. vi. p. 363.

² Bauhin's Pinax, p. 156.

by Simon.¹ It is soluble in alcohol, but not in water. With acetic and phosphoric acids it yields readily soluble salts; but, on the contrary, with sulphuric, nitric, and hydrochloric acids, it forms difficultly soluble compounds.² On account of its resembling baryta in being precipitable from its solution in acetic acid by sulphuric acid, it was called at first *barytin*. Its composition, according to Will, is $C^{60}H^{45}N^{20}O^5$.

CHEMICAL CHARACTERISTICS.—A decoction of the rhizome undergoes, on the addition of a solution of gelatin, no change, showing the absence of tannic acid; but with the sesquichloride of iron, it becomes olive green (*gallate? of iron*). With tincture of galls, it became slightly turbid (*tannates of veratria and starch*). With acetate and diacetate of lead, and protonitrate of mercury, it formed copious precipitates. Oil of vitriol reddens the concentrated decoction, owing to its action on the veratria. The rhizome left after the decoction had been prepared from it, becomes, on the addition of a solution of iodine, black (*iodide of starch*).

PHYSIOLOGICAL EFFECTS. *a. On Vegetables.*—Not ascertained.

b. On Animals generally.—"The best account of its effects is contained in a thesis by Dr. Schabel, published at Tübingen, in 1817. Collecting together the experiments previously made by Wepfer, Courten, Viborg, and Orfila, and adding a number of excellent experiments of his own, he infers that it is poisonous to animals of all classes—horses, dogs, cats, rabbits, jackdaws, starlings, frogs, snails, and flies; that it acts in whatever way it is introduced into the system—by the stomach, windpipe, nostrils, pleural membrane of the chest, on external wounds, or the veins; that it produces in every instance symptoms of irritation in the alimentary canal, and injury of the nervous system; and that it is very active, three grains of the extract applied to the nostrils of a cat having killed it in sixteen hours."³

γ. On Man.—Its local action is that of a powerful acrid. Applied to the Schneiderian membrane, it excites violent sneezing. Epistaxis even is said to have been induced by it. Its operation, when swallowed or placed in contact with the skin, is also that of an energetic irritant.

Its remote action is on the secretory apparatus, the stomach and intestines, and the nervous system. In *small and repeated doses*, it promotes secretion from the mucous surfaces, the salivary glands, the kidneys, and the uterus, and increases the cutaneous exhalation.⁴ In *larger doses*, it causes vomiting, purging, pain in the abdomen, tenesmus, and occasionally bloody evacuations, and great prostration of strength. In some instances, a few grains even have had these effects. Schabel says there is no substance which so certainly and promptly provokes vomiting; and Horn⁵ employed it as a sure emetic. In addition to the local action which it exercises, when swallowed, on the stomach and intestines, it possesses a specific power of influencing these viscera: for Etmüller⁶ has seen violent vomiting result from the application of the rhizome to the abdomen; and Schröder⁷ observed the same occurrence where the rhizome was used as a suppository. In *excessive doses*, it operates as a narcotico-acrid poison, producing gastro-intestinal inflammation and an affection of the nervous system. The symptoms are violent vomiting and purging (sometimes of blood), tenesmus, burning sensation of the mouth, throat, œsophagus, stomach, and intestines, constriction of the throat, with a sense of strangulation, griping pain in the bowels, small, and, in some cases, almost imperceptible pulse, faintness, cold sweats, tremblings, giddiness, blindness, dilated pupils, loss of voice, convulsions, and insensibility, terminating in death. A cutaneous eruption has, in some instances, followed the use of white hellebore.

I am indebted to Dr. Wm. Rayner, of Stockport, for notes of three cases of poisoning by infusion of white hellebore. The symptoms resembled those just mentioned, except that there was no purging. All three cases rapidly recovered.

⁵ Orfila, *Toxicol. Gén.*

⁶ *Grœding Sämml. med. Schrift.* Th. 1, S. 179.

⁷ *Opera omnia*, tom. ii. pt. ii. p. 144.

Hutchinson¹ remarked that, when death did not occur, palpitation and intermitting pulse, besides dyspeptic and nervous symptoms, remained for some time.

These effects were not observed in Dr. Rayner's cases.

In its action on the system, *Veratrum album* is more closely related to celandine and meadow saffron than to any other medicinal agents. It is more acrid and less stupefying than *Helleborus niger*, with which it has been so frequently compared both by ancients and moderns. Orfila² ascertained, by experiment on animals, that it is more active as a poison than the last-mentioned substance. It exercises no known chemical influence over the tissues by which it is distinguished from the mineral irritants, as baryta and emetic tartar, with which Schabel compared it.

USES.—It is but rarely employed, principally on account of the alleged uncertainty of its operation. But, from the few trials which I have made with it, I suspect this uncertainty is much exaggerated, and is principally referable to the varying lengths of time which the rhizome has been kept after its removal from the earth, for, like colchicum, it deteriorates by keeping. The following are the principal cases in which it has been employed:—

1. *In affections of the nervous system*, as melancholia, mania, and epilepsy.³ As an emetic, purgative, and promoter of the secretions generally, we can easily understand that it may prove occasionally beneficial.

2. *In chronic skin diseases*, as herpes, Dr. C. Smyth⁴ gave the tincture internally with benefit. As external applications, the decoction and ointment are used in scabies (hence the Germans call the rhizome *Kratzwurzel*, i. e. *itch-root*), tinea capitis, &c.; but their use is not quite free from danger.

3. *In gout*, it was given in combination with opium, by Mr. Moore,⁵ as a substitute for, or in imitation of, the *Eau Médicinale*. The dose, in a paroxysm of gout, was from forty minims to two drachms of a mixture composed of three parts of *Vin. Veratri albi* and one part of liquid laudanum.

4. *In amaurosis and chronic affections of the brain* occurring in torpid habits, it is employed as an errhine or sternutatory (hence its German name, *Nieswurzel*, i. e. *sneeze-root*). It is usually diluted with some mild powder. The German snuff called *Schneeberger* is said to contain it.

5. *To destroy pediculi*, the decoction is used as a wash.

6. *As an emetic*, it was employed by Horn.

ADMINISTRATION.—The following are the principal modes of exhibition:—

1. **PULVIS VERATRI**; *White Hellebore Powder*.—The dose of this at the commencement should not exceed one or two grains. This quantity will sometimes occasion nausea and vomiting; but Greding found that in some cases eight grains, and, in a few instances, a scruple of the bark of the rhizome in powder were required to excite vomiting. As an errhine, not more than two or three grains, mixed with eight or ten of some mild powder (as starch, liquorice, Florentine orris, or lavender) should be employed at one time. It is a constituent of the *Unguentum Sulphuris compositum* (see vol. i. p. 360).

2. **VINUM VERATRI, L.**; *Tinctura Veratri albi*; *Tincture of White Hellebore*.—(White Hellebore, sliced, ℥vii; Sherry Wine Oij. Macerate for seven days, and strain.)—As a substitute for colchicum in gout and rheumatism, the dose is ten minims twice or thrice daily. This quantity is to be gradually increased. A full dose acts as an emetic and cathartic.

3. **DECOCTUM VERATRI, Ph. L. 1836**; *Decoction of White Hellebore*.—(White Hellebore, bruised, ℥x; Distilled Water Oij; Rectified Spirit fʒiij. Boil the hellebore in the water down to a pint, and when it is cooled, add the spirit.)—This preparation is only used as an external application in skin diseases (scabies, lepra,

¹ Schwartz's *Pharm. Tab.* 2te Ausg.

² Greding, *Sammil. mediz. Schriften*. T. 1, S. 179.

³ *Two Letters to Dr. Jones*, 1811.

⁴ *Toxicol. Gén.*

⁵ *Med. Communications*, vol. i. p. 207.

tinea capitis, &c.), and to destroy pediculi. When the skin is very irritable, the decoction will sometimes require dilution. If the surface to which it is applied be denuded, absorption of the veratria may occur, and constitutional symptoms be thereby induced; hence it is a dangerous application, especially to children.

4. UNGUENTUM VERATRI, Ph. L. 1836 [*Unguentum Veratri albi*, U. S.]; *Ointment of White Hellebore*.—(White Hellebore, powdered, ℥ij; Lard ℥viiij; Oil of Lemons ℥xx. Mix.)—This ointment is used in the treatment of the itch as a substitute for the disagreeable, though far more effective, sulphur ointment. Like the decoction, there is danger of the absorption of the active principle of the rhizome when the ointment is applied to raw surfaces; it is, therefore, an unfit remedy for children.

ANTIDOTES.—Astringent solutions have been recommended; and in one case, which fell under my notice, infusion of nutgalls seemed to give relief. The supposed benefit has been referred to the union of tannic acid with veratria, by which the solubility and activity of the latter are diminished; but Schabel¹ found that three drachms of a tincture of white hellebore, given with infusion of galls, to a cat, proved fatal in twenty minutes. Hahnemann recommends coffee, both as a drink and in elystr. Demulcent liquids, and, in some cases, opiates, may be useful. The other parts of the treatment must be conducted on general principles. Stimulants will be usually required on account of the failure of the heart's action.

58. *Veratrum viride*, Willd.—American Hellebore.

Sex. Syst. Polygamia, Monœcia.
(Rhizoma)

[THE VERATRUM VIRIDE, U. S. (*Secondary List*), is known in the United States as *American Hellebore*, *Swamp Hellebore*, *Indian Poke*, and *Itch Weed*. It has a perennial, thick, fleshy root, unicated at top, the lower part solid and sending off numerous white or light-yellow radicles. The stem is annual, from two to three feet high, pubescent. Leaves at base six inches to a foot long, broad, oval, nerved, acuminate, of a deep green colour, and pubescent; those on the stem narrower, and, at the summit, bractæiform. Flowers in panicles, terminal, and of a greenish-yellow tint. The calyx is wanting; petals six, stamens six, pistil a rudiment (*Willdenow*). Germs three, when not rudimentary, on the lower portion of the panicle.

The plant is found in many parts of the United States, from Canada to Carolina, inhabiting damp places in the neighbourhood of streams and meadows. It appears early in March.

The whole plant has an acrid and burning taste; the root only is officinal. This, when dried, consists of a somewhat unicated top, with a thick hard base, and numerous radicles attached to it. The odour, disagreeable in the recent state, is lost by drying. The taste is at first sweetish, then bitter, followed by an acrid burning sensation in the mouth, which lasts for some hours after it has been chewed. When powdered, it acts as a sternutatory. For the composition of this root, we are indebted to Mr. Henry Worthington (*American Journal of Pharmacy*, vol. x. p. 97), who found it to contain gum, starch, sugar, bitter extractive, fixed oily matter, colouring matter, gallic acid, an ALKALOID SUBSTANCE identical with veratria, lignin, and salts of lime, and potassa. With regard to the alkaloid substance, he describes it as "nearly insoluble in water, more soluble in ether, and entirely soluble in absolute alcohol. When exposed to flame, it first melts, then swells up, and burns without residue. It produces a burning acrid sensation in the mouth, which lasts for several hours. It acts powerfully as a sternutatory, producing violent sneezing, which lasts for half an hour after it has been applied to the nose." "In its chemical relations, the analogy is carried out by not being changed to a red colour by the action of nitric acid, and from its forming salts with the acids, none of which are crystallizable but the sulphate, tartrate, and oxalate."

That the framers of the United States Pharmacopœia have done well in the introduction of this article, is shown by the testimony in its favour as a potent medicine. Dr. Osgood (*Am. Journ. of Pharm.*, vol. vii. p. 202), and Dr. Ware (*Bigelow's Med. Bot.* vol. ii. pp. 127, 132), have each instituted a course of experiments to test its remedial powers. The first found it an emetic; and the second met with a case where this effect on the stomach was produced by the application of the ointment to an ulcer on the leg. Mr. Worthington submitted himself to the test of its powers. He took the fourth of a grain of the *Alcoholic Extract*, which caused an acrid burning sensation in the mouth, and communicated to the throat and fauces a sense of dryness and heat, which finally reached the stomach. In the course of about an hour, this dryness an

¹ Quoted in Brandt and Ratzburg's *Giftgewächse*, Abt. 1, S. 25.

burning sensation in the throat and stomach became intense, and a disposition to hiccough was excited, which soon commenced, gradually increasing in frequency until it reached fifteen or twenty times per minute. This was attended with some sickness and retching until vomiting took place. This was violent, and seemed to come on about every ten or fifteen minutes for the space of an hour. During this time, dizziness and tremor were created, which passed off with the effect of the dose. With the hiccough there was a copious secretion of saliva and discharge of mucus from the stomach and nose. During the action of this dose, the pulse was weakened so as to be scarcely perceptible, and reduced from sixty-eight to fifty-two pulsations per minute. (*Op. cit.*)

The experiment just detailed was repeated three times, and in neither was there a disposition to catharsis. The effects are those of an acro-narcotic, and not one of the least potent of this class of remedies. The uses and mode of administration are similar to those of the White Hellebore. In gout and rheumatism, the medical gentlemen before mentioned speak in its favour. A knowledge of it is stated to be possessed by the North American Indians.—[J. C.]

59. *Veratrum Sabadilla*, Retz.

Sex. Syst. Polygamia, Monœcia.
(Semina.)

A native of Mexico and the Antilles. Its leaves are radical, oval-oblong, obtuse, ribbed. Its stem is almost leafless. The panicle is nearly simple. The flowers have short pedicels, and are nodding.

Its fruit and seeds are said to be brought from the Antilles, under the name of *cebadilla* (*semina sabadillæ caribææ*), but I have never met with them.

60. ASAGRÆA OFFICINALIS, Lind.—SPIKE-FLOWERED ASAGRÆA.

Sex. Syst. Hexandria, Trigynia.

(Alkali semine comparatum, L.—Sabadilla; Fruit of *Veratrum Sabadilla*¹ of *Helonias officinalis*, and probably of other Melanthaceæ, E.)

SYNONYMES.—*Veratrum officinale*, *Schlecht*; *Helonias officinalis*, *Don*.

HISTORY.—This plant was described by Schlechtendahl,² afterwards by Mr. Don,³ and subsequently by Dr. Lindley.⁴ The seeds were known to Monardes in 1573. They were called *sabadilla*, or *cevadilla*, or, more properly, *cebadilla* (from the Spanish *cebada*, *barley*), on account of the supposed resemblance of the inflorescence of the plant to that of *hordeum*.

BOTANY. *Gen. Char.*—*Flowers* polygamous, racemose, naked. *Perianth* six-partite; *segments* linear, veinless, almost equal, with a nectariferous excavation at the base, equal to the stamens. *Stamens* alternately shorter; *anthers* cordate, as if unilocular, after dehiscence shield-shaped. *Ovaries* three, quite simple, attenuated into an obscure stigma. *Follicles* three, acuminate, papery; *seeds* semitar-shaped, corrugated, winged. *Bulbous herbs*, with grass-like leaves, and small, pale, densely-racemed flowers. (*Lindley*.)

Sp. Char.—The only species known.

Leaves linear, acuminate, subearinate, roughish at the margin, four feet long, and three lines broad. *Scape* round, about six feet high. *Raceme*, a foot and a half long, very dense, very straight, spiciform. *Flowers* white, with a bractea at the base. *Anthers* yellow.

Hab.—Eastern side of the Mexican Andes, near Baranca de Tioselo (*Schiede*). Neighbourhood of Vera Cruz (*Hartweg*).

DESCRIPTION.—The *cebadilla*, *cevadilla*, or *sabadilla* of the shops (*sabadilla*; *semina sabadillæ mexicanæ*), comes from Vera Cruz and Mexico. It consists of the follicles (some containing seeds, others empty), loose seeds, stalks,

Fig. 220.

Asagræa officinalis.

a. Fruit-bearing stem.
b. Root, bulb, and leaves.

¹ See p. 185.

² *Linnea*, vi. 45.

⁴ *Bot. Reg.* Junc. 1839.

and abortive flowers of the *Asagraea officinalis*, and perhaps of *Veratrum Sabadilla* also.

The follicles, commonly termed capsules, rarely exceed, or even equal, half an inch in length, and are about one line or a line and a half in diameter. They are ovate-oblong, acuminate. Their colour is pale yellowish-brown, or reddish-gray. The coat of each is thin, dry, and of a papery consistence. Each fruit is composed of three follicles mutually adherent towards the base, open at the superior and internal part. The receptacle, fruitstalk, and the remains of the dried and withered calyx, are usually present in the cebadilla of the shops. Seldom more than one or two, though sometimes three, seeds are found in each follicle.

The seeds are two or three lines long, scimitar-shaped, pointed, blackish-brown, shiny, wrinkled or corrugated, slightly winged. Internally, they are whitish or horny. Embryo straight, next the hilum, lodged in fleshy albumen. They have little odour, but a bitter, acrid, persistent taste.

COMPOSITION.—Two analyses of cebadilla have been made about the same time (1819); one by Meissner;¹ and a second by Pelletier and Caventou.² The following are the results:—

MEISSNER'S ANALYSIS.		PELLETIER AND CAVENTOU'S ANALYSIS.	
Fatty matter (<i>olein</i> and <i>stearin</i>)	24.63	Fatty matter composed of	{ Olein. Stearin. Cevadic acid.
Wax (<i>myricin</i>)	0.10		
Sabadillin (<i>veratria</i>)	0.58		
Resin (soluble in ether)	1.45	Wax.	
Hard resin (insoluble in ether)	8.45	Supergallate of <i>veratria</i> .	
Bitter extractive with the acid which is united } to the sabadillin	5.97	Yellow colouring matter.	
Sweet extractive	0.65	Starch.	
Extractive separable by alkalis	21.14	Lignin.	
Gum	4.90	Gum.	
Vegetable jelly (<i>phyteumacolla</i>) with chloride of potassium and vegetable salts of potash	1.11	Ashes composed of	{ Carbonate of potash. " lime. Phosphate lime. Chloride potassium. Silica.
Oxalate of lime combined with bassorin	1.06		
Lignin	20.56		
Water	6.40		
Cebadilla	100.00	Cebadilla.	

The ashes contained oxide of copper.

1. CEVADIC OR SABADILLIC ACID.—This is a crystalline, fusible, volatile, fatty acid, having an odour analogous to butyric acid. It is soluble in water, alcohol, and ether. It is obtained by the saponification of the oil of *cebadilla* (fatty matter). Cevadate of ammonia causes a white precipitate with the persalts of iron. The composition of this acid is unknown.

Oil of cebadilla given me by Mr. Morson is green, lighter than water, and has a faint, somewhat rancid taste.

2. VERATRIC ACID, of Merck.³—This is a crystalline, fusible, volatile acid, soluble in alcohol, slightly so in water, but insoluble in ether. According to Schroetter, it consists of $C^{15}H^{9}O_7 + aq$.

3. RESINS.—The two resins found by Meissner, but overlooked by Pelletier and Caventou, are probably endowed with activity.

Concrbe obtained from cebadilla seeds, *sabadillina*, *helonin* or resin of *veratria*, and gum resin of *sabadillina*.

a. *Sabadillina* is a white crystalline solid, possessing alkaline properties, being soluble in boiling water and in alcohol, but not in ether. In the fused state it consists of $C^{20}H^{15}NO_3$. It forms with acids crystallizable salts. It is said, by Simon,⁴ to be merely a compound of resinate of soda and resinote of *veratria*. Dr. Turnbull found it inferior in activity to *veratria*.

β. *Helonin* or resin of *veratria* (*veratrin*, Couerbe; *pseudo-veratria*) is a brown solid, fusible at 365°. Insoluble in ether (by which it is distinguished from *veratria*), and in water. It combines with acids; but neither saturates them, nor forms with them any crystallizable salts. It consists of $C^{14}H^9NO_3$. Its action on the animal economy has not been determined.

γ. Gum-resin of *sabadillina* (*resinogomme*, Couerbe; *monohydrate of sabadillina*, Alter.) is a reddish solid, soluble in water and alcohol, but slightly so in ether. It saturates acids, but does not form crystalline compounds with them. Alkalies throw it down from its saline combinations. It consists of $C^{20}H^{14}NO_6$. Hence it differs from anhydrous *sabadillina* in containing an atom more water. Furthermore, it is distinguished from this alkali in not being crystallizable.

4. VERATRIA.—(See p. 190.)

¹ Schweigger's Journ. f. Chem. xxxi. 167.

² Pharmaceutisches Central-Blatt für 1839, S. 235.

³ Journ. de Pharm. vi. 353.

⁴ Berl. Jahrb. Bd. xxxix. S. 393.

CHEMICAL CHARACTERISTICS.—The brownish-coloured decoction of ceadilla reddens litmus, owing to the presence of free acid. Sesquichloride of iron deepens the colour of the decoction, and causes an olive brown precipitate. Alkalies deepen, whilst acids diminish, the colour of the decoction (by their action on the yellow colouring matter, *Pelletier*). Acetate and diacetate of lead, protonitrate of mercury, and sulphate of copper, form precipitates in the decoction. Oxalate of ammonia renders it turbid (*oxalate of lime*). Nitrate of silver forms a coloured precipitate, which is, for the most part, soluble in nitric acid: the insoluble portion is *chloride of silver*. Solutions of iodine and tincture of nutgalls have no obvious effect. Oil of vitriol reddens the decoction owing to its action on the veratria.

PHYSIOLOGICAL EFFECTS. *a. On Vegetables.*—Not ascertained.

β. On Animals.—Are similar to those of *Veratrum album*. Ceadilla has proved poisonous to dogs and cats.¹ A pinch of it produced violent spasms in cats; half a drachm caused vomiting and convulsions in dogs. It is a poison to insects. Thus bugs die from it in convulsions: hence its use as a bug poison!² Its efficacy in destroying pediculi has long been known.

γ. On Man.—The action is probably similar to, though more acrid than, white hellebore. The effects of *small and repeated doses* have not been satisfactorily ascertained. *Large and poisonous doses* cause burning and pain in the throat and stomach, nausea, vomiting, purging, prostration of strength, convulsions, delirium, and sometimes a cutaneous eruption. Even the external application of the powder has caused dangerous effects. Plenck tells us of a young man who was rendered temporarily insane by the application of powder of ceadilla to the head. Lentin says an infant, whose nurse had sprinkled the powder in its hair, died in convulsions.³

Rubbed on the skin, the tincture causes a stinging sensation similar to that produced by veratria. After its use for some days, a slight eruption appears on the skin. Rubbed over the cardiac region, it in some instances reduces the frequency and force of the pulse in a marked degree. The alcoholic extract has nearly the same effects, when taken internally, as veratria. It also induces sensations of heat and tingling on the surface of the skin, and sometimes acts as a diuretic.⁴

USES.—Ceadilla has been employed internally, as an *anthelmintic*, in both thread-worms and tape-worms.⁵ Dr. Turnbull⁶ has given the extract with benefit in painful rheumatic and neuralgic affections. Though it is applicable in all the maladies for the relief of which veratria has been recommended, it is rarely administered by the mouth.

Externally the powder of the seeds has been used to destroy pediculi; hence the Germans called the seeds *Läusesaamen*, or *lice-seeds*. But it cannot be applied with safety to children, and especially when the skin is broken. I have already referred to the dangerous consequences of its employment. The tincture has been used as a rubefacient in chronic rheumatism, and, rubbed over the heart, in some cases of nervous palpitation.⁷ It may, in fact, be employed as a cheap though efficient substitute for the tincture of veratria.

But the principal use of the seeds, for which indeed they have been introduced into the Pharmacopœia, is for yielding veratria.

ADMINISTRATION.—The following are the preparations of ceadilla which have been employed in medicine.

1. PULVIS SABADILLÆ; *Pulvis contra pediculos; Poudre de Capucin; Powder of Ceadilla.*—The dose for an adult is from two to six grains; gradually increased. In one case of tape-worm, half a drachm was taken daily for fourteen days.⁸

⁵ Schmucker's *Verm. chirurg. Schrift.* Bd. ii. S. 271.

⁶ Turnbull, *op. cit.*

⁷ *Op. cit.* p. 7.

⁸ Seeliger, in *Schmucker, op. cit.* vol. ii. p. 271.

2. **TINCTURA SABADILLE**; *Saturated Tincture of Cebadilla*, Turnbull.—(Cebadilla seeds, freed from their capsules and bruised, *any quantity*; Rectified Spirit, *as much as will cover them*. Digest for ten days.)—Used as a rubefacient liniment in chronic rheumatism and paralysis. It is rubbed over the heart in nervous palpitation.

3. **EXTRACTUM ALCOHOLICUM SABADILLE**; *Alcoholic Extract of Cebadilla*.—Evaporate the saturated tincture, with a very gentle heat, to a proper consistence. Dose, 1-6th of a grain, gradually increased. It is given, in the form of pill, in rheumatic and neuralgic cases.

4. **VERATRIA**, L. E. [U.S.]; *Veratrin*; *Veratrina*, Thomson; *Sabadillin*, Meissner.—This vegetable alkaloid was discovered about the same time (1819), by Meissner in Germany, and by Pelletier and Caventou in France. Couerbe¹ probably was the first who obtained it pure.

The process of the Edinburgh Pharmacopœia is as follows:—

“Take any convenient quantity of Cevadilla: pour boiling water over it in a covered vessel, and let it macerate for 24 hours; remove the Cevadilla, squeeze it, and dry it thoroughly with a gentle heat. Beat it now in a mortar, and separate the seeds from the capsules by brisk agitation in a deep narrow vessel. Grind the seeds in a coffee-mill, and form them into a thick paste with rectified spirit. Pack this firmly in a percolator, and pass rectified spirit through it till the spirit ceases to be coloured. Concentrate the spirituous solutions, by distillations, so long as no deposit forms, and pour the residuum, while hot, into twelve times its volume of cold water. Filter through calico, and wash the residuum on the filter so long as the washings precipitate with ammonia. Unite the filtered liquid with the washings, and add an excess of ammonia. Collect the precipitate on a filter, wash it slightly with cold water, and dry it, first by imbibition with filtering paper, and then in the vapour bath. A small additional quantity may be got by concentrating the filtered ammoniacal fluid, and allowing it to cool.

“Veratria thus obtained is not pure, but sufficiently so for medicinal use. From this coloured substance it may be obtained white, though at considerable loss, by solution in very weak muriatic acid, decolorization with animal charcoal, and re-precipitation with ammonia.”

Cebadilla yields, to rectified spirit, veratria in combination with a vegetable acid. Ammonia unites with the vegetable acid, and sets free the alkaloid.

By Couerbe's process, a drachm of commercial veratria may, it is said, be procured from one pound of cebadilla.

Commercial veratria was said by Couerbe to be composed of *pure veratria*, *sabadillina*, *resin of veratria* (veratrin, Couerbe), and *gum-resin of veratria* (resinogomme, Couerbe). These are separated from each other by the successive action of water, ether, and alcohol, as shown by the following table:—

<i>Commercial Veratria</i>	{	yields to boiling water . .	1. <i>Sabadillina</i> , which crystallizes on cooling.
		insoluble in boiling water	2. <i>Resin of Veratria</i> , left in the cold solution. 3. <i>Veratria</i> , soluble in ether. 4. <i>Gum-resin of veratria</i> , insoluble in ether, but soluble in alcohol.

The nature of sabadillina has been already pointed out (p. 188).

PROPERTIES.—*Commercial veratria* is pulverulent, odourless, and grayish or brownish white. All the samples I have tasted were bitter and acrid, and produced a feeling of numbness and tingling when applied to the tongue. But *pure veratria* is an almost white, friable solid, having the aspect of a resin: it is uncrystallizable, odourless, has a very acrid taste, without any mixture of bitterness. It is fusible at 240° F. It is sparingly soluble in ether, readily so in alcohol, scarcely so in cold water. It possesses alkaline properties: thus, it restores the blue colour of reddened litmus, and saturates acids. Its salts crystallize with difficulty: indeed, the *sulphate* and *hydrochlorate* alone have been obtained in the state of crystals; the other salts have a gummy aspect. Both the hydrochlorate and sulphate are soluble in water.

Characteristics.—Veratria is known by the following characters: Its alkalinity, its combustibility, its uncrystallizability, the difficult crystallizability of its salts, its solidity at ordinary temperatures, its ready solubility in alcohol, its being almost

¹ *Ann. de Chim. et de Phys.* t. 52, p. 368.

insoluble in water, and by the intense red colour which it assumes when mixed with oil of vitriol. Pure veratria is readily soluble in ether; not so, impure or commercial veratria. Nitric acid renders commercial veratria reddish, and forms a yellow solution with it (see *Morphia and Narcotina*). A solution of veratria in dilute acetic acid produces a whitish precipitate (*tannate of veratria*) with tincture of nutgalls, a white one (*hydrated veratria*) with ammonia, and an intense red colour with oil of vitriol. Carbazotic acid does not occasion a precipitate unless the solution be concentrated. To these chemical peculiarities must be added those characteristics derived from its physiological effects: A minute portion of veratria causes violent sneezing, and a small quantity of a solution of four grains of veratria in a fluidrachm of rectified spirit, rubbed on the wrist or forehead, produces, within three or four minutes, heat and tingling. Pure veratria is less apt to occasion sneezing, by handling, than the impure or commercial sort.

The *London College* (1851) gives the following characters of veratria: Dissolves but slightly in water, more soluble in ether, but most in alcohol. It has no smell, but violently irritates the nostrils, and has a bitter taste. It is to be cautiously administered.

[The following characteristics are given by the *U. S. Pharm.* Pulverulent, grayish-white, inodorous, but very irritant to the nostrils, and of an acrid bitter taste, causing a sensation of tingling with numbness in the tongue. It is very slightly soluble in water, but readily and wholly dissolved by alcohol. It has an alkaline reaction, and is entirely dissipated by a red heat. With nitric acid it forms a yellow solution, and, when in contact with concentrated sulphuric acid, becomes intensely red.]

COMPOSITION.—The following is the composition of pure veratria, according to Courbe:—

	Atoms.	Eq. Wt.	Per Cent.	Courbe.
Carbon	34	204	70.83	70.786
Hydrogen	22	22	7.64	7.636
Nitrogen	1	14	4.86	5.210
Oxygen	6	48	16.67	16.363
Veratria	1	288	100.00	100.000

PHYSIOLOGICAL EFFECTS. *α. On Animals.*—Magendie¹ has shown that the local action of veratria is that of an irritant. Placed in the nostrils of a dog, the acetate of veratria provoked violent and continued sneezing. When introduced into the intestinal canal, it caused inflammation. Applied to parts whence absorption goes on actively (as the pleura and tunica vaginalis), it occasions tetanus, and death in a few minutes. Foreke² gave moderate and gradually increased doses ($\frac{1}{8}$ to $\frac{1}{4}$ of a grain) of veratria for twenty days. It caused vomiting, and occasionally foaming at the mouth. The stools continued hard. Dr. Bardsley³ observed vomiting and giddiness (reeling) produced in animals to whom he gave veratria.

β. On Man.—Applied to the nose, a minute quantity excites excessive sneezing. Rubbed on the skin in the form of ointment, it causes a sensation of heat and tingling (called by Dr. Turnbull *electro-stimulation*). This effect is not confined to the part and its immediate neighbourhood where the application has been made; for somewhat similar sensations are occasionally experienced in distant parts.

Taken internally, in *small or medicinal doses*, veratria excites a feeling of warmth in the stomach and bowels, which extends to the chest and extremities. Tingling and various anomalous sensations (as of a current of hot or cold air or water passing over the skin) are perceived in various parts of the body. Nausea and vomiting are occasionally excited by a full dose. On the secretions and exhalations its action is not very uniform. It frequently produces perspiration, and not unfrequently diuresis. Foreke⁴ mentions increased secretion of saliva and of tears produced without the contact of the veratria either with the conjunctiva or mouth. The bowels are for the most part confined, so that purgatives are not unfrequently required during the use of it. Yet in some cases veratria has caused copious bilious evacuations. In

¹ *Formulaire*, p. 162, 8me edit.
² *Hosp. Facts and Observ.* 1829.

³ *Untersuch. über d. Veratrin*, 1837.
⁴ *Op. cit.* p. 22.

some instances it has promoted, in others diminished, the appetite. Foreke mentions that a pustular eruption is sometimes induced by it. Dr. Bardsley generally found the pulse become slower and depressed after the use of veratria.

I am not acquainted with any cases of poisoning in the human subject by *excessive doses* of veratria. Vomiting and convulsions would probably be induced.

USES.—Veratria is employed externally or internally: sometimes in both ways at the same time. It has been tried in the following cases:—

a. In neuralgia, it has been used by Dr. Turnbull, Dr. Ebers of Breslau,¹ and Dr. Foreke. It is applied in the form of ointment, containing from twenty to forty grains of veratria to an ounce of lard. The frictions are to be continued until the heat and tingling caused by the veratria have acquired a considerable degree of intensity. Though, according to my own experience, it fails to give relief in a large majority of cases, yet in some few its effects are highly beneficial, and in none is it injurious. As a remedy for neuralgia, it is, however, far inferior to *Aconitum* and its alkali *Aconitina*.

β. In some nervous diseases (Neuroses, *Cull.*)—Veratria has been extensively used in this class of diseases, but for the most part empirically. If it possess any therapeutical power, “a more extended experience is required to establish its claim to our regard.”² Among the maladies against which it has been used (in some instances internally, but mostly externally) are—nervous palpitation, paralysis, hooping-cough, epilepsy, hysteria, hypochondriasis, &c.³

γ. In rheumatism and gout.—Dr. Bardsley gave it internally in rheumatism, but with no remarkable results. Externally it has been employed in the form of ointment by Sir C. Scudamore and Dr. Turnbull. It should not be applied while the inflammation is of an active kind. It would appear to be best adapted for the neuralgic forms of rheumatism.

δ. In dropsy.—Dr. Bardsley administered it internally in dropsy, but says it possesses “no particular claims to the attention of the profession.” Ebers employed veratria endermically, and also in the form of ointment, epidermically. It acted as a diuretic, and gave relief.⁴

ADMINISTRATION.—The ordinary veratria of the shops is administered in doses of one-sixth of a grain, three times a day. On account of its acridity it should not be given in solution, but in the form of pills.

a. Pilulæ Veratriæ; Veratria Pills; Turnbull.—Veratria gr. j; Extract of Hyoscyamus; Liquorice powder, aa. gr. xij. Let 12 pills be made, of which one may be taken every three hours.

β. Tinctura Veratriæ; Veratria Embrocation; Turnbull.—Veratria ℥j.; Rectified Spirit ℥ij. Dissolve. This embrocation is sometimes used as a substitute for the ointment. Magendie (*Formulaire*) directs a tincture of veratria to be prepared by dissolving four grains of the alkali in an ounce of alcohol. Of this from 10 to 25 drops are taken, in a cup of broth, as a substitute for the tincture of colchicum.

γ. Unguentum Veratriæ; Veratria Ointment; Turnbull.—Veratria ℥ss.; Olive Oil ℥j; Prepared Lard ℥j. M.

δ. Sales Veratriæ.—The sulphate and tartrate of veratria (prepared by saturating veratria with sulphuric or tartaric acid) are sometimes used instead of the uncombined alkali. The dose and mode of administration are the same as for the latter.

ANTIDOTE.—*Vide VERATRUM ALBUM.*

ORDER XI. LILIACEÆ, *Lindl.*—LILYWORTS.

CHARACTERS.—*Calyx* and *corolla* both alike, coloured, regular, occasionally cohering in a tube. *Stamens* six, inserted into the sepals and petals; *anthers* opening inwards. *Ovary* superior, three-celled, many seeded; *style* one; *stigma* simple or three-lobed. *Fruit* succulent, or dry and capsular, three celled. *Seeds* packed one upon another in one or two rows; *embryo* with the

¹ Dierbach, *Neuest. Entd. in d. Mat. Med.* 1837.

² Paris, *Appendix* to the 8th edit. of the *Pharmacologia*.

³ See the treatises of Turnbull and Forcke, before referred to.

⁴ See Forcke, *op. supra cit.*

same direction as the seed, in the axis of fleshy *albumen*, or uncertain in direction and position, occasionally very minute. *Herbaceous* plants, shrubs, or trees, with bulbs, or tubers, or rhizomes, or fibrous roots. *Leaves* narrow, with parallel veins, membranous, not articulated with the stem; either sessile or with a narrow leafy petiole.

PROPERTIES.—Not uniform. Mucilage, resinous matters, acrid volatile oils, and acrid extractive substances, are the organic principles to which the medicinal qualities of this order are chiefly referable. Their relative proportions, however, vary considerably in different species.

The fleshy bulbs are usually more or less acrid. Those of the genus *Allium* owe their acridity to a volatile oil (*sulphuret of allyle*) whose composition is C^6H^5S (see vol. i. p. 253). Bundles of acicular crystals or *raphides*, usually considered to be phosphate, but by Schleiden declared to be oxalate, of lime are found in some of the cells of these bulbs.

61. ALOË, Linn.—ALOE.

Sez. Syst. Hexandria, Monogynia.

(Succus proprius spissatus foliorum ex variis Aloëis speciebus.

HISTORY.—Neither aloe plants nor the inspissated juice of their leaves are mentioned by Hippocrates or Theophrastus; but both are described by Dioscorides¹ and Pliny.²

BOTANY. Gen. Char.—*Perianth* tubular, six-cleft, fleshy, nectariferous at the base, the sepals of the same form as the petals, and closely imbricating them. *Stamens* hypogynous, as long as the perianth, or even longer. *Capsule* membranous, searious, three-corned, three-celled, three-valved, with a loculicidal dehiscence. *Seeds* numerous, in two rows, roundish or angular. (*Lindley*).—Succulent plants.

Species.—The following species furnish the greater part of the substance called in the shops *aloes*:—

1. ALOË VULGARIS, Lam. L. D.; *Aloë perfoliata* π, *vera* Linn.; *A. bardadensis*, Miller, Haworth; 'Αλόη, Dioscor. Sibth.—*Stem* woody, simple, cylindrical, short. *Leaves* fleshy, amplexicaul, first spreading, then ascending, lanceolate, glaucous, green, flat above, convex below, armed with hard, distant, reddish spines, perpendicular to the margin; a little mottled with darker colour; the parenchyma slightly coloured brown, and very distinct from the tough leathery cuticle. *Scape* axillary, glaucous reddish, branched. *Spike* cylindrical-ovate. *Flowers* at first erect, then spreading, afterwards pendulous, yellow, not larger than the stamens. (*Lindley*).—East Indies, Barbary, Spain, Italy, Sicily, Malta, Greece, West Indies.

Specimens of this species are frequently brought to London from the West Indies by sailors, a tarred cloth being closely tied around the truncated stem to prevent the escape of the juices of the plant. If suspended by a cord from the ceiling of a room, they continue to live for a considerable time, and throw out fresh leaves. I have had one in my possession for nearly two years, and it is still living and growing.

This species yields *Barbados aloes* (*Aloe Barbadosensis*, Ph. Lond.).—The brownish-yellow, bitter, resinous juice which, by inspissation, forms aloes, is contained in parallel greenish vessels beneath the epidermis of the leaves.

2. A. ARYSSINICA, Lam. is by some writers considered to be a variety of *A. vulgaris*. By Kunth it is regarded as a distinct species. Its flowers are greenish yellow. It is a larger and more resinous species than the preceding, and was brought from Africa by Bruce. It may, perhaps, yield a portion of the aloes of commerce. It contains a very bitter juice, which becomes brown in the air.

3. ALOË SOCOTRINA, Lam. De Cand.—*Stem* woody, straight, one and a half feet high or more, naked below, where it is strongly marked with the scars of leaves. *Leaves* amplexicaul, ascending, ensiform, green, curved inwards at the point, convex below, rather concave above, marked with numerous small white marginal serratures, the parenchyma abounding in a bright brownish-yellow juice. *Raceme* cylindrical, unbranched. *Flowers* scarlet at the base, pale in the middle, green at the point. *Stamens* unequal, three of them longer than the flowers. (*Lindley*).—Socotra; also, according to Nees von Esenbeck, Cape of Good Hope.

¹ Lib. iii. cap. xxv.

² Hist. Nat. lib. xxvii. cap. v.

Fig. 221.

*Aloë socotrina.*

Lieut. Wellstead¹ says that the hills on the west side of Socotra are covered for an extent of miles with aloe plants; and he observes that it is not likely, at any future period, that the whole quantity will be collected which might be required.

It is said to yield *socotrine* (and *real hepatic*?) aloes.—Under the epidermis of the leaves are parallel greenish vessels containing the bitter resinous juice, as in the last-mentioned species. By drying, the leaves of *A. socotrina* (like those of *A. purpurascens*, but unlike those of *A. vulgaris*) acquire a purplish-red colour, which commences first in the parallel vessels, and is probably produced by the oxidation of the resinous juice contained in these vessels.

4. *A. PURPURASCENS*, Haworth.—This species has dark red flowers and glaucous leaves, which become purplish-red when drying. It has the same localities as the last-mentioned species. Its juice is very bitter and resinous, and becomes blood-red in the air.

5. *ALOE SPICATA*, Thunb. D.—*Stem* three to four feet high, as thick as a man's arm. *Leaves* thick, fleshy, broad at the base, gradually narrowing to the point, channelled, full two feet long, distantly toothed, with a few white spots; their parenchyma almost colourless. *Spike* a foot long, very compact, with the flowers campanulate and horizontal. The three petals broader, ovate, obtuse, white, with a triple green line, the sepals narrower, less concave. *Stamens* much longer than the perianth. The flowers are filled with a purplish honey. (*Lindley*.)—This species is a native of the interior of the Cape of Good Hope, and contributes to yield *Cape Aloes*. Thunberg² states that it yields the best hepatic aloes, (“succus Aloës hepaticus purus et optimus.”)

6. *ALOE FEROX*, Lam.—*Stem* very lofty. *Leaves* perfoliate, thick, juicy, sword-shaped, deflexed, glaucous, prickly throughout, but bearing larger and sharper spines along the margins. *Flowers* racemose, crowded. *Stamens* double as long as the corolla. L. Pappe, *Fl. Capensis Med. Prodr.*—A native of Swellendam, Cape of Good Hope. Yields the best Cape aloes.

7. *ALOE AFRICANA*, Miller.—Yields Cape aloes almost equally good with *A. ferox*, but not so bitter, nor so powerful a drastic.

8. *ALOE PLICATILIS*, Miller.—Inhabits the mountainous range near the Paarl, Drakenstein, and Fransehe Hoek, at the Cape of Good Hope. It yields the aloes commonly used by the colonists, which is milder than the preceding, and much resembles Barbados aloes.

OTHER SPECIES.—It is probable that several other species contribute to the supply of the aloes of commerce. I have received four species from Mr. Dunsterville, of Algoa Bay, who writes that from all of them, as well as from other species, the so-called Cape aloes is obtained. Thunberg³ states that *A. perfoliata* yields a large quantity of aloes at the Cape, and he also says⁴ that *A. linguiformis*, Linn. yields the best and purest sort. Dr. Christison⁵ suggests that *A. Comelini* of Willdenow may yield some. He was informed, by Mr. John Lyell, that at Swellenden and George (South Africa), aloes is obtained from *A. spicata*, *A. Africana* of Haworth, and varieties of these crossed with *A. ferox*. The last-mentioned species is now cultivated in Barbados, according to Schomburgk.⁶

In Arabia, Forskål⁷ found *A. officinalis* (*A. rubescens* of De Candolle?), whose juice had the odour of the officinal socotrine aloes. Its flowers were red.

In India, there is also a species with reddish flowers, which Dr. Royle⁸ has called *A. Indica*. This, if known to Roxburgh, was probably included by him in *A. perfoliata*.

Nees von Esenbeck mentions the following species as being rich in a bitter resinous juice: *A. humilis*, Lam.; *A. Ferra*, De Cand.; *A. ferox*, Lam.; and *A. subferox*, Spreng. He also found that the following were feebly bitter, but in different degrees: *A. glauca*, Mill.; *A. paniculata*, Jacq.; *A. saponaria*, Haw.; *A. cæsia*, S. D.; *A. plicatilis*, Mill.; *A. arborescens*, Mill.; and *A. frutescens*, S. D. He says that *A. glauca*, Mill. was also slightly bitter, but that the juice became

dark brown in the air, which shows that this colouring matter is a peculiar principle originally different from the bitter matter.

PREPARATION.—The finest kind of aloes is obtained by evaporating the juice which flows spontaneously from the transversely-cut leaves. This juice is lodged in vessels running longitudinally beneath the epidermis. The exudation of it is promoted by gravity, by dipping the leaves in hot water, and by making fresh sections of the leaves. But if pressure be employed, the proper aloetic juice becomes mixed with the mucilaginous liquid of the leaves, and thus an inferior kind of aloes is obtained. A still commoner variety is procured by boiling the leaves, from which the juice has been previously allowed to escape, in water.

a. Of Socotrine Aloes.—In the Island of Socotra the leaves are plucked at any period, and by any one who chooses to take the trouble; and after being placed in a skin, the juice is allowed to exude from them.¹ The following mode of preparing socotrine aloes, as related by Hermann, was communicated to Ray by Dr. Palmer:² “When the leaves which have been pulled from the roots are gently compressed by the hand or an instrument, the juice drops from them into a receiving vessel; and being allowed to stand during a night deposits the grosser parts. The next day it is transferred to another vessel, in which it is exposed to the sun that it may harden and become dry, when it acquires a brownish-yellow colour.”

β. Of Barbados Aloes.—In Barbados, the aloes is best procured in the month of March. It is obtained as follows: “Every slave hath by him three or four portable tubs. The leaves being cut near the roots, are thrown into these with their broken ends downwards; and as the leaves are full of large longitudinal veins or vessels, they yield an easy passage to the juice (which is of a greenish-yellow colour) to drip out. This being boiled for about five hours in a copper or kettle, the watery particles evaporate, and the remainder comes to a consistency and thickening as sugar doth when sufficiently boiled. The way to know when it is enough boiled is, to dip a stick in the liquor, and observe whether the aloes sticking to it, when cold, breaks short: if it doth, then it is boiled to perfection, and fit to be poured into gourds or calabashes, or other vessels, for use.”³

Dr. Wright⁴ says, that in Jamaica, the leaves contained in hand-baskets or nets are boiled in water, and the strained liquor evaporated to a proper consistence, and then poured into gourds or calabashes. Dr. Patriek Browne,⁵ on the other hand, states that the sun-dried juice is called *socotrine aloes*; but the common aloes, he adds, is obtained by squeezing out the juice by the hand, adding water to it, and boiling down to a proper consistence.

γ. Of Cape Aloes.—The method of preparing aloes followed at the Cape of Good Hope has been described by Thunberg,⁶ Lieut. Moody,⁷ and others.⁸

Mr. George Dunsterville, surgeon of Algoa Bay, and formerly one of my pupils, has furnished me with the following information respecting the manufacture of Cape aloes: “A shallow pit is dug, in which is spread a bullock’s hide or sheep’s skin. The leaves of the aloes plants in the immediate vicinity of this pit are stripped off, and piled up on the skin, to variable heights. These are left for a few days. The juice exudes from the leaves, and is received by the skin beneath. The Hottentot then collects in a bucket or other convenient article the produce of many heaps, which is then put in an iron pot capable of holding 18 or 20 gallons. Fire is applied to effect evaporation, during which the contents of the pot are constantly stirred to prevent burning. The cooled liquor is then poured into wooden cases of about three feet square by one foot deep, or into goat or sheep skins, and is thus fitted for the

¹ Welstead, *op. citato*.

² Dale, *Pharmacologia*.
³ Hughes, *Natural History of Barbados*, p. 154, 1750. This account is further confirmed by that of Mr. Millington, *Lond. Med. Journ.* vol. viii. p. 423. But Dr. Christison states, the Barbados aloes of the present day is the extract of a decoction.

⁸ *Four Months in Cape Colony*, in Chambers’s *Miscellany of Useful and Entertaining Tracts*, vol. xx. No. 173, Edinb. 1817; also, Mr. John Lyell in Christison’s *Dispensatory*, 2d ed.

market. In the colony, aloes realizes about 2½d. to 3½d. per lb." Mr. Dunsterville also informs me that the Hottentots and Dutch boors employ indiscriminately different species of Aloë in the preparation of Cape aloes. He adds, that "the Cape aloes, which is usually prized the highest in the English market, is that made at the Missionary Institution of Bethelsdorp (a small village about nine miles from Algoa Bay, and chiefly inhabited by Hottentots and their missionary teachers). Hence it is called *Bethelsdorp Aloes*. Its superiority arises, not from the employment of any particular species of Aloë, for all species are indiscriminately used; but from the greater care and attention paid to what is technically called 'the cooking of the aloes,' that is, to the evaporation, and to the absence of all adulterating substances (fragments of lime-stone, sand, earth, &c.) often introduced by manufacturers."

DESCRIPTION AND VARIETIES.—I am acquainted with seven commercial varieties of aloes; namely, *Socotrine*, *Hepatic*, *Barbados*, *Cape*, *Mocha*, *Caballine*, and *Indian*. To these must be added *Curacao Aloes*.

The terms socotrine, hepatic, and caballine, have been used to indicate rather the quality and purity, than the origin, of aloes. Thus Thunberg¹ says, "Pro diversa puritate potius, quam quidem sua origine, triplicem imprimis Aloës speciem in Pharmacopolis nostris introductam invenimus, scilicet *socotrinam*, *hepaticam*, et *caballinam*." And Jussieu² states that he saw all three varieties prepared at Morvedro, in Spain, from the Aloë vulgaris.

The term *Aloë lucida*, or *clear aloes*, has been applied by Schröder,³ Geoffroy,⁴ Fée,⁵ and others, to a clear or transparent aloes supposed to be formed by the concretion of the juice on the leaves after they have been incised. It is probable that by this term are meant the clearest and most transparent pieces of socotrine aloes. I have never met with, in English commerce, any aloes by this name: and a similar remark has been made by Alston.⁶

1. **Socotrine Aloes** (*Aloë socotrina*, L.; *Aloë socotorina* and *Aloë Indica*, E.).⁷ A few years ago this kind of aloes was brought by way of Smyrna, and hence was frequently termed *Turkey aloes*. But since the expiration of the charter of the East India Company, it is usually brought by way of Bombay. It is the kind sold at Apothecaries' Hall, London, and at other places under the name of *extract of spiked aloes* (*extractum aloës spicatum*), although there is no evidence of its being obtained from Aloë spicata. The London College (1851) states it to be the juice of the cut-off leaves, dried in the air, of an uncertain species of aloes. It comes over in skins⁸ contained in casks (holding from 11 to 15 ewt. each), kegs, and chests. Its consistence and colour are subject to considerable variation. The exterior portion of each skinful is usually hard, but the internal portion is frequently soft or even semi-liquid.

The hardened portions vary in colour in different parts of the same mass; sometimes they are garnet red, at other times much paler, and when quite dry are golden red, and yield a golden yellow powder. By exposure to the air the colour is deepened. The fracture of fine selected pieces is smooth, glassy, and conchoidal; but socotrine aloes of excellent quality often breaks with a roughish fracture. The finest kind of socotrine which I have met with had the semi-transparent red colour observed when we break a fine tear of myrrh. Thin films of pure and hardened socotrine aloes are usually translucent or nearly transparent. The fragments, which have a ruby colour, are called *aloe socotrina vera*. The odour of fresh broken pieces (especially when breathed on) is very fragrant, and is much stronger in recent and soft specimens. The same agreeable odour is obtained by heating the aloes on a point of a knife in a candle. By distillation with water, we obtain a liquid having the same odour, but free from any bitter taste. When fresh, socotrine aloes pos-

¹ *Dissertatio Botanico-Medica de Aloë*, 1785.

² *Elements of Chemistry*, by M. J. A. Chaptal, vol. iii. p. 86, 1791.

³ *The Complete Chymical Dispensatory*, p. 500, 1669.

⁴ *Tractatus de Materia Medica*, t. ii. p. 649, 1741.

⁵ *Cours d'Hist. Nat. Pharm.* t. i. p. 327, 1828.

⁶ *Lectures on the Materia Medica*, vol. ii. p. 422, 1770.

⁷ I have received from Dr. D. MacLagan, Lecturer on Materia Medica in Edinburgh, two specimens of aloes; one marked "True Socotrine Aloes, garnet red in their fragments;" the other "Aloes given to me as True Socotrine, rough fracture nearly garnet red in thin fragments. Included under Aloë indica, Ed. Pharm." Both kinds are Socotrine aloes.

⁸ I am informed that they are the skins of the Gazelle.

sesses considerable acidity, and the late Mr. Hennell informed me that, in the preparation of the compound extract of coloeynth, he had frequently observed the fatty acid of the soap set free by the acid of the socotrine aloes. I have been shown a sample of what was declared to be socotrine aloes, which was soft or semi-liquid, and had a bright or palm-oil yellow colour, and a very fragrant odour.

When a package of socotrine aloes arrives at a druggist warehouse, it is usually garbled or sorted. The finest, clear, and hard pieces are separated for sale. The soft portions are placed upon slabs or in shallow tin trays, or other vessels, and exposed to a very gentle heat to harden them (*hardened socotrine aloes*), and at the same time to preserve the favourite colour of this kind of aloes. Mr. Whipple, who has had great experience in these matters, informs me that "the loss would be frightful, if, after selecting or separating the clean aloes, the skins were not washed and the aloes obtained by subsequent evaporation."

It is brittle, bitter, reddish brown, with an aromatic odour; fresh thin films of it are translucent. *Ph. Lond.*

"In thin pieces, translucent, and garnet red; almost entirely soluble in spirit of the strength of sherry. *Very rare.*" *P. Ed.*

But socotrine aloes as imported is not "*in thin pieces*;" this character being given to it in the garbling process, or by drying the soft portions in thin layers as above mentioned. *Translucency* and a *garnet red* colour are qualities not possessed by many fine specimens of socotrine aloes. The *alcoholic strength of sherry* is subject to variation, and, therefore, the statement of the College as to the solubility of socotrine aloes is not very definite. Lastly, as to socotrine aloes being *very rare*, I may observe that the late Mr. Hennell, of Apothecaries' Hall, informed me (Dec. 21, 1841), that he would be happy to take an order for 500 lbs. of it.

The impure and dirty pieces of socotrine aloes are sometimes melted and strained (*strained socotrine aloes*), by which the colour and odour are impaired, and the other qualities somewhat altered.

Socotrine aloes has long been regarded as the best kind of aloes, though its commercial value is now below that of Barbados aloes. It is, I suspect, inferior in activity.

Socotrine aloes is mentioned by Avicenna and Mesue, both of whom regarded it as the best kind. By Fée,¹ and some other continental writers, it is confounded with Cape aloes.

The aloes prepared in the Island of Socotra is probably procured from *Aloë socotrina*; and perhaps also *A. purpurascens*. In 1833, the quantity exported from this island was 83 skins, or 2 tons. But a much larger quantity might be procured if required.² Two samples (one of which I have in my museum) brought direct from the Island of Socotra, by a friend of Professor Royle, are largely intermixed with foreign substances, as sand, skins, &c.

Sir Whitelaw Ainslie³ says, that the greater part of the extract now sold under the name of socotrine aloes is prepared in the kingdom of Melinda; and I am informed by an eminent drug merchant that both socotrine and hepatic aloes have been imported into London directly from Zanzibar.

2. Genuine Hepatic Aloes; Liver-coloured Socotrine Aloes (*Aloë hepatica*, L. D.; *Aloë Indica*, E.).⁴—This sort of aloes usually comes to London from Bombay (hence it is sometimes called *Bombay* or *East India Aloes*) in skins, contained in casks holding from 200 to 300 pounds,⁵ or in kegs. The London College (1851) declares it to be the "inspissated juice of the leaf?" of "an uncertain species of aloë." Its odour is very much the same as that of the socotrine kind, or perhaps it is a little

¹ *Cours d'Hist. Nat. Pharm.* t. i. p. 325.

² Wellstead, *Journ. Geograph. Soc.* vol. v.

³ *Materia Indica*, vol. i. p. 9.

⁴ I suspect hepatic aloes is included by the Edinburgh College under "*Aloë indica*." For, in preparing Decoction of Aloes, the College orders Socotrine or Hepatic Aloes, though the term hepatic does not occur in the list of *Materia Medica*.

⁵ Mr. Whipple informs me that it is "received in packages varying from 56 lbs. to 12 cwt. casks, most commonly in firkins. Lately, it has come over in boxes lined with tin, and holding about 56 lbs. All of these, except the last, contain the skin packages."

less fragrant. It is distinguished from the latter by its opacity and its liver colour. It might, therefore, be called *opaque liver-coloured socotrine aloes*. It appears to me to bear very much the same relation to the transparent or real socotrine aloes that the opaque yellow rosin bears to the dark transparent or fiddler's rosin. It is sometimes imported in a soft or liquid state, and in this condition I know not how to distinguish it from liquid socotrine aloes. The similarity of the odour of socotrine and hepatic aloes leads to the suspicion that they are obtained from the same plants; and which is further confirmed by the two being sometimes brought over intermixed, the socotrine occasionally forming a vein in a cask of hepatic aloes. Some samples of hepatic aloes, when digested in rectified spirit of wine, yield a tincture, at the bottom of which there remains undissolved a yellowish granular powder (in appearance something like lycopodium), which is insoluble in water, alcohol, ether, and dilute sulphuric acid, but is readily soluble in a solution of caustic potash, forming a red-coloured liquid.

The place of produce of this species is probably the same as that of the so-called socotrine aloes.

Opake, liver coloured, bitter, with an unpleasant odour. *Ph. Lond.*

3. Barbados Aloes; *Aloes in gourds* (*Aloë barbadensis*, Ph. L. and Ed.)—This is the kind denominated by most continental writers (as Geiger, Theod. Martius, Pfaff, Fée, and others), *hepatic aloes* (*aloë hepatica*), but its colour is not constantly that of the liver. It is imported from Barbados or Jamaica usually in gourds (*Lagenaria vulgaris*), weighing about 60 to 70 pounds, or even more than this; and sometimes in cases or boxes holding 56 lbs. each. The hole in the gourd-shell is partially closed by a piece of gourd let in and covered by a portion of coarse cloth, which is nailed down over the aperture.

The finest Barbados aloes is the inspissated juice, which I have heard called by an inhabitant of the island *cold drawn Barbados aloes*, to distinguish it from the extract of the decoction, which is of inferior quality.

Barbados aloes varies in colour from a dark brown or black (*brown or black Barbados aloes*) to a reddish-brown or liver colour (*liver-coloured or hepatic Barbados aloes*): even in the same gourd a difference of colour is occasionally observed. The fracture also varies, sometimes being dull, at other times glossy, or even resinous. Its unpleasant odour (which is much increased by breathing on it) will always distinguish it from the foregoing kinds. Its powder is of a dull olive-yellow colour. This kind of aloes is obtained chiefly, if not exclusively, from the *Aloë vulgaris*.¹

The London College (1851) declares it to be the "inspissated juice of the cut-off leaves of *Aloe vulgaris*."

Opake, not glistening, liver-coloured, becoming blackish, with a bitter nauseous taste, and very unpleasant odour.—*Ph. Lond.*

The quantity of aloes annually exported from Barbados is stated by Sir R. H. Schomburgk (op. cit. pp. 149, 150, and 160) to be as follows:—

1740	}	average annually	327 gourds.
to			
1748			
1792			515 gourds.
1841			1361 gourds.
1842			2956 gourds, 1 case, 1 package.
1843			4227 gourds, 8 puncheons, 27 boxes.
1844			2371 gourds, 2173 packages, and 78 boxes.
1845			1955 packages.

4. Cape Aloes (*Aloë capensis*; *A. lucida* of Geiger).—This kind is imported, as its name indicates, from the Cape of Good Hope. It is brought over in chests and skins, the latter being preferred, as the aloes contained therein are usually purer

¹ Dr Maycock (*Flora Barbadosensis*, 1830) notices no other species of *Aloë* indigenous, naturalized, or cultivated in Barbados. But Dr. Christison observes that, though at one time Barbados aloes was made only from *A. vulgaris*, he is assured by various pupils from that island that, while this species is commonly used, others are likewise employed. Sir R. H. Schomburgk (*History of Barbados*, p. 590, 1847) mentions *A. ferox*, Lam. or Great Hedge-hog Aloe, as having been introduced from the Cape of Good Hope. Kunth (*Enum. Plant.*) says, but I know not on what authority, that *A. socotrina* is cultivated at Barbados.

and more glossy. It has a shining resinous appearance, is of a deep brown colour, with a greenish tint, and has a glossy or resinous fracture; its edges, or thin laminæ, viewed by transmitted light, have a yellowish red or ruby colour; its odour is stronger and more disagreeable than the Barbados aloes; its powder is greenish yellow. Some of the commoner kinds of Cape aloes have a rough fracture. The finest kind of Cape aloes is called *Bethelsdorp aloes* (see *ante*, p. 196).

Occasionally it has been imported of a reddish-brown colour, like that of the liver, and opake (*liver-coloured* or *hepatic Cape aloes*). Some years since an experienced dealer bartered 3 lbs. of Cape aloes for 1 lb. of what he thought to be the genuine hepatic aloes, but which turned out to be a fine sort of Cape aloes. I presume this is the kind which Professor Guibourt,¹ to whom I sent a specimen of it, formerly termed *false hepatic aloes*; and which more recently² he calls *opake Cape aloes*. Its odour, when breathed on, instantly detects it.

I have received four species of *Aloë* plants from Mr. Dunsterville, of Algoa Bay, and the four extracts which he was informed were obtained respectively from the species sent. Two of the plants were dead and rotten; and the others were unknown to the late Mr. Anderson, of the Chelsea Gardens. The four extracts are as follows:—

a. *Ordinary Cape Aloes*.—Dark, glossy, very resinous, with a strong disagreeable odour, and greenish tint.

β. *Socotrine Cape Aloes*.—This, in colour, resembled socotrine aloes; but it was more glossy, brittle, and transparent. Its odour, though disagreeable, was less so than the first kind.

γ. *Hepatic Cape Aloes*.—This is an intermixture of an opake liver-coloured extract (*hepatic Cape aloes*) with a dark, glossy, transparent extract.

δ. This very much resembled the preceding, and might equally claim for its opake portion the name of *hepatic Cape aloes*.

Cape aloes is procured from *Aloë spicata* and other species (see *ante*, p. 194).

5. **Fetid, Horse, or Caballine Aloes** (*Aloë caballina*).—I have never met with any particular kind of aloes under this name in English commerce; Barbados aloes being used in England for horses. From Prof. Guibourt I have received two substances, which he denominates *Aloës Caballin*.

a. One is *impure* or *foot Cape aloes*.

β. The other is in black opake masses, intermixed with straws, pieces of bark, sand, charcoal, and other impurities. Its fracture is uniform. It is difficult to pulverize, adheres to the pestle, gives a greenish powder, has a very little odour, and yields a dark brown decoction. It is probably an extract prepared by boiling the leaves in water.

Guibourt says Caballine aloes is procured either in the countries which furnish ordinary aloes, or in Spain³ or Senegal.

6. **Mocha Aloes** (*Aloë de Mochâ*).—Under this name, I found in a drug warehouse, where it had lain for many years, an impure kind of aloes, in large irregular masses, opake, and black externally, intermixed with sand, strings, &c. In its brittleness, odour, and the pale colour of its decoction, it resembles Cape aloes. The interior of the mass is not uniform: in some places it is dark and opake, somewhat like Barbados aloes; in other places it resembles socotrine aloes, and here and there we find portions having the transparency and resinous appearance of Cape aloes. Recently, this kind of aloes has been imported under the name of Mocha aloes from Muscat, in chests containing nearly 2 *cut*. each.⁴ Dr. Christison thinks it is East Indian aloes of low quality. It is described by Guibourt under the name of *blackish* or *fetid aloes* (*aloës noirâtre et fétide*).

7. **Indian Aloes** (*Aloë indica*; not the *Aloe indica* of the Edinburgh Pharmacopœia).—Dr. O'Shaughnessy⁵ mentions two kinds of Indian aloes: *Kurachee* aloes, nearly black, opake, and soluble in water to the extent of 52 per cent.; and *Deccan* aloes, deep brown, and soluble to the extent of 98 per cent.

¹ *Hist. des Drog. simpl.* 3me édit. t. ii. p. 418.

² *Ibid.* 4me édit. p. 168.

³ Formerly the inhabitants of Morvedro, in Valencia, cultivated the aloe plant (*A. vulgaris*), and obtained from it three kinds of aloes, called respectively socotrine, hepatic, and caballine (Jussieu in *Chaptal's Elements of Chemistry*, vol. iii. p. 86); but Laborde (*View of Spain*, vol. i. p. 302, 1809) says the cultivation is now neglected.

⁴ Mr. Whipple tells me that, in dissolving and straining Mocha aloes, he has never found less than 25 per cent. of impurities (sand, stones, &c.).

⁵ *Bengal Dispensatory*.

Through the kindness of Professor Royle, I have examined four kinds of aloes brought from the interior of India:—

- a. *Aloes from Northern India*.—Is dull, black, and brittle, and has little odour. It came from the northern parts of India, where it is common in the bazaars (*Bazaar aloes*). It is probably the kind which Ainslie¹ says resembles Barbados aloes, and is brought to India from Yemen, in Arabia. Is this the produce of *Aloe officinalis*, Forskål?
- β. *Guzerat Aloes*.—Is dark, more gummy in its appearance and feel, more difficult to fracture.
- γ. *Salem Aloes*.—In blackish masses. It was brought from Salem. It is distinguished from all the preceding by the numerous large air cavities observed in its interior. Its odour is analogous to that of socotrine aloes. Its price is marked one anna and nine pice [about two-pence halfpenny] a pound.
- δ. *Trichinopoli Aloes*.—Resembles Cape aloes in its brittleness, odour, and colour, but is more opake. Its price is marked at two annas [about three pence] a pound.

These aloes are the produce, in part at least, of *Aloë indica*;² a species with reddish flowers, common in dry situations in the northwestern provinces of India, and which, if known to Roxburgh, was included by him in the *A. perfoliata*, Linn., and perhaps also of *A. vulgaris*, or the plant mentioned by Rheede.³

8. *Curacoa Aloes*.—This species of aloes is not known in the London market, but a notice of it has been published by Mr. A. Fabr.⁴ It is the produce of the Dutch West India Island, Curacoa; but as even in Holland it cannot be regularly obtained, it is probable that its production is scanty.

It is most like Cape aloes, but does not possess the greenish colour which is sometimes perceived in the latter; its appearance is more dull; and its colour is often that of the liver. From hepatic aloes it differs by its saffron-like odour. It is probably the produce of *A. vulgaris*.

Powdered Aloes.—In January, 1846, the lecture assistant of the Pharmaceutical Society carefully powdered selected samples of five kinds of aloes in the Society's museum. The colour of the various powders were as follows:—

Powders.

- No. 1. Cape aloes . . . Lightest colour. Tint, pale yellow.
 “ 2. Hepatic aloes . . . Nearly alike. Deeper coloured than No. 1. No. 2 had a reddish, No. 3 a greenish
 “ 3. Barbados aloes } tint.
 “ 4. Socotrine aloes { Both darker than the three preceding sorts. That of No. 4 had
 “ 5. Mocha aloes . . . Darkest colour { the tint of, but was less deep than, roasted chicory powder;
 that of No. 5 was olive or greenish. In twelve months, No. 4 had become coherent and darkest of all.

Strained Aloes; Aloë colata.—In order to deprive aloes of the various foreign matters with which they are frequently mixed, the wholesale druggist purifies the extract by melting and straining it. The fusion is effected in a metallic vessel heated by steam or hot water, a hair or wire sieve being used for straining the liquor. By this process the aloes suffers a physical, and probably also a chemical change. It becomes darker coloured, harder, and somewhat less odorous. It is probable that the deepened colour is produced by the action of atmospheric oxygen.

COMPOSITION.—Aloes has been analyzed by Trommsdorff,⁵ by Bouillon-Lagrange and Vogel,⁶ by Braconnot,⁷ and by Winkler.⁸

1. **ALOESIN**, Pfaff (*Saponaceous Matter; Extractive; Bitter Principle of Aloes or Aloe bitter; Aloin*).—This is the principal constituent of aloes. It is contained in the cold infusion of aloes, and also in a decoction which has cooled: it may be obtained from either by evaporation. Thus procured, it is a brown and bitter mass, readily soluble in water, but difficultly so in spirit of wine. In pure alcohol or ether it is said to be insoluble, or nearly so. Besides *carbon, hydrogen, and oxygen*, it contains *nitrogen*, for it yields ammonia by destructive distillation, and furnishes carbazotic acid when treated by nitric acid. Aloesin is probably a mixture or compound of various proximate principles. Obtained as above, Braconnot says it contains some of the *puce-coloured principle*, which may be removed by oxide of lead.

2. **ALOE RESIN**.—The substance which deposits from a decoction of aloes as it cools is usually denominated resin. Braconnot says it is a mixture of aloesin and *puce-coloured principle*; while Berzelius regards it as *apothème* combined with unaltered extract. It is transparent, brown, fusible, soluble in alcohol, ether, and alkaline solutions. The *puce coloured principle* of Braconnot is an odourless and tasteless powder, combustible, but not fusible; and is prepared by digesting aloes with water and oxide of lead: a compound of the puce principle and the oxide is procured, which is to be washed and decomposed by weak nitric acid: the oxide is dissolved, and the puce principle left. From Braconnot's observations, this principle seems to be rather oxidized extractive (*apothème, Berz.*) than resin.

3. **VEGETABLE ALBUMEN**.—This term is applied to a substance insoluble in both water and alcohol.

4. **ALOESIC ACID**.—This is the acid which Trommsdorff supposed to be *gallic acid*. A solution of aloes reddens litmus, darkens ferruginous solutions, but does not precipitate gelatin: hence Trommsdorff assumed the presence of gallic acid. But while gallic acid causes a blue colour with the persalts of iron, infusion of aloes produces an olive brown one. Furthermore, if excess of diacetate of lead be added to this infusion, and sulphuretted hydrogen be passed through the filtered liquor, to throw down the excess of lead, the boiled and strained liquor possesses the property of becoming olive brown on the addition of sesquichloride of iron. Hence it appears to me that the acid is a peculiar one, and I have accordingly termed it *aloesic acid*. It must not be confounded with an acid obtained by the action of nitric acid on aloes, and which has been termed *aloetic acid*.

Meissner has given the name of *Aloine* to a supposed alkali in aloes. Its solution was brown, and acted as an alkali on reddened litmus paper. With sulphuric acid, aloine formed a crystalline salt.

Winkler² regards aloes as a neutral vegetable salt, composed of two peculiar basic substances (viz., a non-bitter resin, and a bitter substance) and an acid, viz., a colouring, non-bitter matter.

Fabroni³ obtained a fine violet colour from the recent juice of the Aloë, which has been proposed as a dye for silk. It is formed by the action of the oxygen of the air on the juice.

Messrs. T. and H. Smith⁴ have obtained a yellow crystalline substance from aloes, to which they have given the name of *aloine*. Its composition is stated by Dr. Stenhouse to be $C^{34}H^{12}O_3$. In doses of one or two grains it operates as a purgative.

CHEMICAL CHARACTERISTICS.—Aloes is almost completely soluble in boiling water. When the decoction of aloes cools, the substance called *resin* is deposited. The clear cold solution (*aloesin*) reddens litmus, strikes a deep olive-brown tint (*aloesate of iron*) with sesquichloride of iron, is deepened in colour by alkalis, but is unchanged with gelatine. Diacetate of lead forms a copious yellow precipitate with it.

The alcoholic tincture of aloes does not become turbid when mixed with water. When the ethereal tincture is poured in water, the ether evaporates, and leaves a film of resin.

The bitter principle of aloes (*aloesin*) is distinguished from that of rhubarb by its not striking a green colour with the salts of iron, and by its insolubility in ether.

The differential chemical characters of the various kinds of aloes are not constant. The following, however, are the results of some experiments:—

a. Cape aloes, when good, usually completely dissolves in boiling water, leaving no residuum of vegetable albumen, &c. The decoction is clear, usually paler than that of the other kinds, and deposits much of the so-called resin in cooling.

β. Barbados aloes sometimes leaves an insoluble residuum (vegetable albumen, &c.) when boiled in water. The decoction, when cold, is dark and usually turbid: generally, it is darker than that of the other sorts, yet I have found it the palest. I have also observed that the

¹ Pfaff's *Mat. Med.* vol. vii. p. 171.

² *Ann. de Chim.* xxv. 301.

³ Schwartz, *Pharm. Tabell.* p. 294, 2te Ausg.

⁴ *Chemical Gazette*, March 15, 1851.

decoction on cooling becomes turbid, and lets fall a yellow powder like that which I have seen in decoction of hepatic aloes.

γ. *Socotrine aloes* yields a decoction which, when cold, is dark and nearly clear.

δ. *Hepatic aloes* yields a decoction which, on cooling, frequently deposits a yellow powder.

Products of the decomposition of aloes by nitric acid.—When aloes is heated with nitric acid, nitrous fumes are evolved, and the principles of which aloes consist are oxidized. The residuum has an intensely bitter taste, and is termed *artificial aloes bitter* (*künstliches Aloe bitter*.) It is a mixture of several principles.

The products of the action of nitric acid on aloes have occupied the attention of several distinguished chemists; but the results of their experiments, though highly interesting, are not uniform. Braconnot¹ and Chevreul² examined the reaction. The former applied the term *aloetic acid* to the residual solid, which Liebig³ subsequently declared to be a mixture of *nitric* or *nitrous acid*, *carbazotic acid*, and a *peculiar, non-acid, resinous, red matter*. Boutin⁴ has more recently examined the reaction of nitric acid on aloes, and he states the products to be *polychromatic acid* (the aloetic acid of Braconnot) composed, according to Pelouze, of $C^{15}H^{22}N^2O^{13}$, *oxalic acid*, *carbazotic acid*, and *cyanile*. Schunk⁵ states that, by the action of nitric acid on aloes, he obtained four peculiar acids, viz., *aloetic acid*, *aloëresinic acid*, *chrysammic acid*, $C^{15}HN^2O^{12}+HO$, and *chrysolepic acid*, $C^{12}H^2N^3O^{13}+HO$.

Mulder⁶ has recently examined the products of the reaction of nitric acid on aloes. *Anhydrous chrysammic acid*, he says, consists of $C^{14}HN^2O^{11}$. The so-called *chrysolepic acid* he considers to be identical with nitropic acid (*i. e.* carbazotic acid). He found the composition of the foliaceous crystals of this acid to be $C^{12}H^3N^3O^{14}$.

PHYSIOLOGICAL EFFECTS. α. *On Vegetables.*—Not ascertained.

β. *On Animals.*—Aloes is the ordinary purgative for solipedes (the horse, the ass, the zebra, &c.), as it is both safe and sure. In horses, previously prepared by two or three bran-mashes to soften the dung, the dose is from five to seven drachms.⁷ It acts slowly, requiring from eighteen to forty-eight hours for its operation.⁸ Mr. Youatt informs me that aloes is a valuable purgative for the dog, in doses of from one to three drachms, and with the addition of from one to three grains of calomel. Barbados aloes is preferred by veterinarians, as being more effective than Cape aloes, in the ratio of about seven to five. Aloes proves purgative to oxen, sheep, and pigs, but, as in the other cases, it operates slowly.⁹ Moiroud¹⁰ injected into the veins of a horse four drachms of aloes dissolved in water with a little alcohol, and the next day an ounce more, without any other effect than the evacuation of a large quantity of urine. The dung, however, was enveloped by a thin pellicle formed by altered intestinal mucus. This was collected and analyzed subsequent to the death of the animal (which followed three days after the injection): it offered scarcely any traces of the constituents of the bile.

γ. *On Man.*—Taken internally in small doses aloes acts as a tonic to the alimentary canal, assisting the digestive process, strengthening the muscular fibres, and promoting the secretions, especially that of the liver, which organ it is thought specifically to influence. In large doses it acts as a purgative. There are, however, some peculiarities attending its cathartic operation deserving of notice. In the first place, these effects are not so speedily produced as by some other purgatives; for eight, twelve, and sometimes twenty-four hours elapse before they are produced. Secondly, aloes acts especially on the large intestines, and a full dose is in some persons apt to produce heat and irritation about the rectum, and tenesmus; and, in those troubled with hemorrhoids, it is said not unfrequently to increase; or even to bring on, the sanguineous discharge. Fallopius¹¹ tells us, that of one hundred persons who used aloes as a purgative, ninety were affected with the hemorrhoidal flux, which ceased when the use of aloes was omitted. But though this statement has been often quoted as an objection to the use of aloes, it is of little importance, as there is no evidence that the disease was brought on by aloes. The uterus, in

common with all the pelvic viscera, is stimulated by aloes. A determination of blood towards these organs, and a fulness of the blood-vessels (especially of the veins), are produced, and thus uterine irritation and menorrhagia are apt to be increased by aloes, while in amenorrhœa and chlorosis it may occasionally act as an emmenagogue. Dr. Wedekind¹ says that small doses of aloes often occasion erection, and increase the sexual feelings.

The purgative effects of aloes do not arise merely from their local action on the alimentary canal, since this effect is sometimes produced when the medicine has been neither swallowed nor given by the rectum. Thus Monro *primus*² tells us, that the tincture of aloes applied to a caries of the bone produced purging; and it is said³ that an aloetic pill used as a stimulant to an issue had a similar effect; lastly, applied to a blistered surface it has the same operation. So that the purgative action of aloes appears to be of a specific kind.

According to Dr. Wedekind,⁴ the operation of aloes depends on the increased secretion of bile, which is produced by the specific action of this medicine on the liver. He founds this opinion on the results of various experiments. Thus, he says, that if aloes be added to purgatives (a laxative infusion and sulphate of soda), whose operation is speedy, its effects do not take place for some hours after those caused by the other purgatives; and he also asserts that the evacuations in the second purging differ from those of the first both in appearance and smell. Moreover, he found that, as long as the stools were white or gray in ieterus, the aloes did not purge even when exhibited in large doses; but the purgative effect supervened immediately after the fecal matter began to contain bile, proving that the presence of bile in the intestinal canal is a necessary condition of the purgative effect of aloes. But in Moiroud's experiment, above quoted, no effect seemed to be produced on the hepatic secretion.

In all probability, the increased secretion of bile, the irritation about the rectum, the disposition to hemorrhoids, and the vascular excitement of the sexual organs, all of which are said to be produced by aloes, are the effects of a stimulant action exerted by this medicine over the venous system of the abdomen, and especially of the pelvis.

Dr. Greenhow⁵ ascribes a diuretic effect to aloes, and his statement is corroborated by Moiroud's experiment.

Socotrine aloes is said not to be so apt to occasion hemorrhoids as the Barbados kind. Some years since, Dr. Clutterbuck instituted numerous experiments at the General Dispensary, Aldersgate Street, which I witnessed, to determine the effects of the different kinds of aloes, but scarcely any difference in their operation on the human subject was perceptible. However, it is probable that Cape aloes is less powerful in its action on man, as it is on the horse, than the Barbados kind. But the difference is the less obvious in the human subject, on account of the comparative smallness of the dose required to produce the purgative effect.

As a purgative, aloes holds an intermediate rank between rhubarb and senna. Vogt⁶ places it between jalap and rhubarb. From rhubarb it is distinguished by its more stimulant influence over the large intestines and the pelvic organs: from senna by its feebler action as a purgative, by its slow operation, and by its tonic influence when given in small doses. It irritates less powerfully than either jalap or scammony: further, its influence over the blood-vessels of the pelvic viscera is greater than these.

USE.—The uses of aloes may be readily inferred from the remarks already made. It is evidently not adapted for those cases in which a speedy effect is required; and it is, therefore, useless to add it to purgatives to quicken their operation. It is well fitted for cases of costiveness where there is a scanty secretion of bile, and for

⁶ *Pharmakodynamik*, Bd. ii. S. 334, 2te Aufl.

torpid conditions of the large intestines, especially when attended with deficient uterine action. Some of the ill effects ascribed to the use of aloes are probably imaginary, and others are much exaggerated.¹ It is, however, advisable to avoid the use of this purgative in inflammatory conditions and organic diseases of the liver, in biliary calculi, in mechanical impediments to the passage of the blood through the branches of the portal veins, in hemorrhage from any of the pelvic organs (as the uterus and rectum), in irritation of the rectum, prostate gland, or bladder, in pregnancy, &c. For we have many other equally efficient purgatives, to the use of which, in these cases, no ill consequences have been ascribed. While, therefore, I concur with Dr. Fothergill² in advising that the exhibition of aloes should be avoided when the menses are about to cease, I am not prepared to admit that "the piles, strangury, immoderate discharges of the menses, racking pains in the loins, representing labour pains, and other similar complaints," are frequently induced by this medicine. On the contrary, I suspect this catalogue of the evils of aloetic purges to be much overcharged. "Aloetic medicines," says Dr. Denman,³ "are forbidden during pregnancy, lest they should do mischief by their supposed deobstruent qualities; but they are cheap, and conveniently given in the form of pills, and I have not observed any bad effects from them." The emaciation, stricture of the rectum, and enteritis, referred by Dr. Greenhow⁴ to the long-continued use of aloetic medicines, ought, doubtless, to be ascribed to other causes.

The following are some of the cases in which the use of aloes has been advised:—

1. *In loss of appetite and dyspepsia*, depending on a debilitated condition of the digestive organs, accompanied by costiveness, but unattended with any signs of local irritation, aloes may be given in small doses as a stomachic.

2. *In habitual costiveness*, depending on deficiency of bile, or on a sluggish condition of the large intestines—particularly in hypochondriacal or studious persons, or in those whose habits or occupations are sedentary—aloes, given in sufficient doses to purge, will be found a very useful medicine. A torpid state of the colon, with large fecal accumulation, is not unusual in females.⁵ In such, the use of aloes is often attended with much benefit.

3. *To excite the menstrual discharge*, aloes is frequently employed. It has been supposed that, by determining an afflux of blood to the pelvic organs, aloes would stimulate the uterine vessels, and thus relieve deficient menstruation connected with atonic conditions of the uterus. But it often fails: indeed, Dr. Cullen⁶ says that it rarely succeeds.

4. *To reproduce the hemorrhoidal discharge*, aloes has been frequently employed in large doses. Serious affections of the head, or of other parts, have sometimes disappeared on the occurrence of the hemorrhoidal flux; and, therefore, in persons who have been subject to this discharge, but in whom it has stopped, it is advisable to attempt its re-establishment, with the view of relieving other more serious disorders.

5. *To promote the secretion of bile* where a deficiency of this fluid does not arise from hepatic inflammation; as in some forms of jaundice which are unconnected with biliary calculi, inflammation, mechanical obstruction of the ducts, &c.

6. *In cerebral affections*.—The compound decoction of aloes is a most valuable stimulating purgative for elderly persons in whom a tendency to apoplexy exists, especially in cold and phlegmatic habits. It will frequently be necessary to conjoin other cathartics, as the infusion of senna.

7. *As an anthelmintic*, a decoction of aloes, used as an enema, has been efficacious in the small thread-worm (*Ascaris vermicularis*).

ADMINISTRATION.—On account of its nauseous taste, aloes is frequently given in the form of pill (*pilulæ aloeticæ*, offic.). One or two grains seldom fail to pro-

⁶ Treat. of the Mat. Med.

duce one stool, which seems to be merely an evacuation of what may be supposed to have been present for the time in the great intestines (Cullen). The ordinary dose is five grains; but ten, fifteen, or even twenty grains are sometimes given.

1. *PILULA ALOËS COMPOSITA*, L. D.; *Pilulæ Aloës*, E.; *Compound Pills of Aloes*.—(Socotrine Aloes [Hepatic, D.], powdered, $\bar{3}$ j; Extract of Gentian $\bar{3}$ ss; Oil of Caraway \mathfrak{m} xl. [\bar{f} $\bar{3}$ ss, D.]); Treacle, as much as may be sufficient [$\bar{3}$ ss, D.] L.; beat them together until incorporated. The *Edinburgh College* orders of Socotrine Aloes and Castile Soap *equal parts*; Conserve of Red Roses a sufficiency; beat them into a proper pill mass. This pill may be also correctly made with the finer qualities of East Indian Aloes, as the Socotrine variety is very scarce; and many, not without reason, prefer the stronger Barbados Aloes, E.)—This pill is a valuable purgative in habitual costiveness. Dose, five to fifteen grains.

2. *PILULA ALOËS CUM MYRRHÂ*, L. D.; *Pilulæ Aloës et Myrrhæ*, E. [U. S.]; *Pilulæ Rufi*, offic.; *Pills of Aloes and Myrrh*; *Rufus's Pills*.—(Socotrine or Hepatic Aloes $\bar{3}$ ss [*four parts*, E.]; Saffron $\bar{3}$ ij [*one part*, E.]; Myrrh $\bar{3}$ ij [*two parts*, E.]; Soft Soap $\bar{3}$ ij; Treacle [Conserve of Red Roses, E.], as much as may be sufficient. Rub the aloes and the myrrh separately to powder; then beat the whole together until incorporated [Aloes $\bar{3}$ ij; Myrrh $\bar{3}$ j; Saffron $\bar{3}$ ss; Syrup q. s. M. To be divided into 480 pills, U. S.].—Used as a purgative in chlorosis and amenorrhœa. Dose, ten to twenty grains.

3. *PILULA ALOËS CUM SAPONE*, L.; *Pilula Aloës diluta*; *Pills of Aloes and Soap*.—(Extract of Barbados Aloes powdered, Soft Soap, Extract of Liquorice, *equal parts*; Treacle as much as may be sufficient. Beat the aloes with the soap; then, having added the others, beat the whole together until incorporated.)—Dose, grs. v to grs. x.

4. *PILULÆ ALOËS ET ASSAFËTIDÆ*, E. [U. S.]; *Pills of Aloes and Assafetida*.—(Aloes [Socotrine or East Indian], Assafetida, and Castile Soap, *equal parts*. Beat them, with Conserve of Red Roses, into a proper pill mass.)—Used in dyspepsia attended with flatulence and costiveness. Dose, ten to twenty grains.

5. *PILULÆ ALOËS ET FERRI*, E.; *Pills of Aloes and Iron*.—(Sulphate of Iron *three parts*; Barbados Aloes *two parts*; Aromatic Powder *six parts*; Conserve of Red Roses *eight parts*. Pulverize the aloes and sulphate of iron separately; mix the whole ingredients, and beat them into a proper mass, which is to be divided into five-grain pills.)—A valuable emmenagogue in atonic amenorrhœa and chlorosis. Dose, one to three pills.

6. *PULVIS ALOËS COMPOSITUS*, L.; *Compound Powder of Aloes*.—(Socotrine or Hepatic Aloes $\bar{3}$ iss; Guaiacum Resin $\bar{3}$ j; Compound Powder of Cinnamon $\bar{3}$ ss. Rub the aloes and the guaiacum resin, separately, to powder; then mix them with the compound powder of cinnamon.)—Purgative and sudorific. Seldom used. Dose, ten to twenty grains.

7. *PULVIS ALOËS CUM CANELLÂ* [U. S.]; *Iliera Picra*, offic.; *Powder of Aloes and Canella*.—(Hepatic Aloes \bar{h} j; Canella bark $\bar{3}$ ij. Powder them separately, and then mix.)—A popular emmenagogue. Dose, five to fifteen grains.

8. *DECOCTUM ALOËS COMPOSITUM*, L. D.; *Decoctum Aloës*, E.; *Compound Decoction of Aloes*.—(Extract of Liquorice $\bar{3}$ vij [$\bar{3}$ ss, E. D.]; Carbonate of Potash $\bar{3}$ j [$\bar{3}$ ij, E. D.]; Extract of Socotrine Aloes [Hepatic, D., or Socotrine, E.] powdered, Myrrh powdered, Saffron, of each $\bar{3}$ iss [$\bar{3}$ j, E. D.]; Compound Tincture of Cardamom \bar{f} $\bar{3}$ vij [\bar{f} $\bar{3}$ iv, E., as much as is sufficient, D.]; Distilled Water Oiss [\bar{f} $\bar{3}$ xvj, E., \bar{f} $\bar{3}$ xiv, D.]. Boil down the liquorice, carbonate of potash, aloes, myrrh, and saffron, with the water, to a pint [\bar{f} $\bar{3}$ xij, E.], and strain; then add the compound tincture of cardamom [as much as will make sixteen fluidounces, D.].—A most valuable preparation. A mild cathartic, tonic, antacid, and emmenagogue. Used

in the before-mentioned cases in doses of $f\bar{3}ss$ to $f\bar{3}ii$. Acids, acidulous salts, and most metallic salts, are incompatible with it. If it be desirable to conjoin chalybeates with it, either the *Potassæ Ferrico-Tartras* (see vol. i. p. 752) or the *Ammoniacæ Ferrico-Citras* (see vol. i. p. 749) may be added to the cold decoction without undergoing decomposition. The quality of the aloes used, the length of time the decoction is boiled, and the purity of the extract of liquorice, affect the transparency or turbidity of this decoction, which is never so bright as tincture of aloes.¹

9. **EXTRACTUM ALOËS, L.**; *Extractum Aloës Purificatum*; *Purified Extract of Aloes*.—(Socotrine Aloes $\bar{3}xv$; Boiling Water Cong. j. Macerate for three days with a gentle heat; afterwards strain and set by, that the dregs may subside. Pour off the clear liquor, and evaporate it to a proper consistence.)—It is intended to deprive the aloes of the substance called resin, on which its irritating and griping qualities have been supposed to depend. Dose, five to fifteen grains.

β. **EXTRACTUM ALOËS BARBADENSIS, L.**; *Extract of Barbados Aloes*.—This is prepared in the same way as the *Extractum Aloës, L.*

γ. **EXTRACTUM ALOËS HEPATICÆ**; *Extractum Aloës Aquosum, D.*; *Extract of Hepatic Aloes*; *Watery Extract of Aloes*.—Hepatic Aloes, in coarse powder, $\bar{3}iv$; Water Oij. Boil the aloes until it is dissolved; when the solution is cold, and the dregs have subsided, pour off the clear liquid, and evaporate it to a proper consistence, *D.*

The effects, uses, and doses of these two preparations are the same as those of *Extractum Aloës*.

10. **TINCTURA ALOËS, L. E. [U. S.]**; *Tincture of Aloes*.—(Socotrine or Hepatic Aloes, coarsely powdered, $\bar{3}j$; Extract of Liquorice $\bar{3}iij$; Distilled Water Oiss [Oj and $f\bar{3}viij$, *E.*]; Rectified Spirit Oss [$f\bar{3}xij$, *E.*]. Macerate for seven [with occasional agitation, *E.*] days, and strain. This tincture cannot without difficulty and delay be prepared by percolation, *E.*)—Purgative and stomachic. Dose, $\bar{3}ij$ to $\bar{3}j$.

11. **TINCTURA ALOËS COMPOSITA, L.**; *Tinctura Aloës et Myrrhæ, E. [U. S.]*; *Elixir Proprietatis* of Paracelsus, *Compound Tincture of Aloes*.—(Socotrine or Hepatic Aloes, coarsely powdered, $\bar{3}iv$ [$\bar{3}iij$, *U. S.*]; Saffron $\bar{3}ij$ [$\bar{3}i$, *U. S.*]; Tincture of Myrrh Oij. Macerate for seven days, and strain, *L.* This tincture cannot be well prepared by percolation, *E.*)—Purgative, stomachic, emmenagogue. Used in cold, sluggish habits. Dose, $\bar{3}ss$ to $\bar{3}j$.

12. **VINUM ALOËS, L. E. [U. S.]**; *Tinctura Sacra*; *Wine of Aloes*.—(Socotrine or Hepatic Aloes, rubbed to powder, $\bar{3}ij$; Canella, powdered, $\bar{3}iv$; Sherry Wine Oij. Macerate for seven days, frequently shaking, and strain. The *Edinburgh College* uses Aloes [Socotrine or East Indian] $\bar{3}iss$; Cardamom seeds ground, Ginger in coarse powder, of each $\bar{3}iss$; Sherry Oij. Digest for seven days, and strain through linen or calico [Aloes, in powder, $\bar{3}i$; Cardamom bruised, Ginger bruised, of each a drachm; White Wine a pint. Macerate for fourteen days, with occasional agitation, and filter through paper, *U. S.*].—Wine of aloes is purgative in doses of $f\bar{3}ss$ to $f\bar{3}ij$; stomachic in doses of $f\bar{3}j$ to $f\bar{3}ij$.

Aloes is a constituent of several other preparations (as *Pilula Colocynthis composita, L. D.*; *Pilula Colocynthis, E.*; *Pilula Rhei compositæ, L. E.*; *Pilula Cambogiæ, E.*; *Pilula Cambogiæ compositæ, L.*; *Tinctura Rhei et Aloës, E.*), which will be described hereafter.

¹ *Pharmaceutical Journal*, vol. i. p. 182, 1841.

62. URGINEA SCILLA, *Steinheil*.—THE SEA ONION, OR OFFICIAL SQUILL.

Sex. Syst. Hexandria, Monogynia.
(*Bulbus recens*, L.—*Bulb*, E. D.)

SYNONYMES.—*Squilla maritima*, Steinheil;¹ *Scilla maritima*, Linn.; *Cepa marina*, Lobel.

HISTORY.—The Egyptians worshipped a bulbous plant called by Lucian Κρόμμυον, and which Pauw² asserts to be the squill, and further suggests that it was the red variety (? *Squilla Pancration* var. *a Bulbo rufo*, Steinheil); but by others it has been thought to be the onion (see *Allium Cepa*). Pythagoras³ is said to have written a volume on the medicinal properties of squill, and to have invented the *acetum scillæ*. Hippocrates employed squill (σκίλλα) internally,⁴ externally,⁵ and as a pessary.⁶ Pliny⁷ says there are two medicinal sorts of squills—one, which he calls the *male*, with white leaves; the other, or *female*, with black leaves: the former probably is white, the latter red squills.

BOTANY. **Gen. Char.**—*Sepals* three, coloured, spreading. *Petals* very like them, and scarcely broader. *Stamens* six, shorter than the perianth; *filaments* smooth, somewhat dilated at the base, acuminate, entire. *Ovary* three-parted, glandular and melliferous at the apex; *style* smooth, simple; *stigma* obscurely three-lobed, papillose. *Capsule* rounded, three-cornered, three-celled. *Seeds* numerous, in two rows, flattened with a membranous testa. (*Steinheil*.)

Sp. Char.—*Leaves* very large, subsequently spreading. *Braets* long. *Flowers* white; flower-bud somewhat acute. *Anthers* yellow. *Ovarium* thick, yellowish. *Bulb* very large. (*Steinheil*.)

Bulb roundish-ovate, half above ground. The *leaves* appear after the flowers: they are broad, lanceolate, twelve to eighteen inches long. *Scape* about two feet high, terminated by a dense long raceme.

Hab.—Shores of the Mediterranean, viz.: Spain, France, Sicily, Africa, &c. Navarino has long been celebrated for its squills. In its native soil the plant flowers about August.

SQUILLA PANCRATION, Steinh. (Παγκράτιον, Dioscorides) is said by Steinheil to yield a small bulb of a reddish colour, found in commerce under the name of squill.

DESCRIPTION.—The fresh bulb (*bulbus recens*, L.; *radix recens*, offic.) is pyriform, of the size of the fist to that of a child's head, and is composed of thick, fleshy, smooth, shiny scales, attenuated at their edges, closely applied over each other, and attached to a conical disk (a rudimentary stem) which projects inferiorly, and gives origin to the root fibres, the remains of which are to be frequently found in the bulbs of commerce. The outer scales are usually dry, thin, coloured, membranous, or papery. By cracking the inner or fleshy scales, numerous spiral vessels may be drawn out. On submitting the cuticle of the scales to a microscopic examination, numerous acicular crystals (*raphides*) are perceived in cells, which are distinguished from the surrounding angular cells by being larger and elliptical. The *pulvis scillæ*, offic., contains nine or ten per cent. of these crystals.

Two kinds of squills, both abounding in an acrid juice, and having a very bitter taste, are met with in commerce; viz., the *white* (*scilla alba*, *mascula*, vel *hispa-*

¹ In 1831, Steinheil (*Ann. Sc. Nat.* t. i. p. 321, 2^{de} Sér.) proposed the name *Urginea* for the genus to which squill (*Urginea Scilla*, Steinh.) belongs. Some objections having been raised to it, and no systematic writer having then adopted it, Steinheil, in 1836 (*op. cit.* t. vi. p. 272), proposed to substitute the name of *Squilla* (σκίλλα) for *Urginea*; but subsequently some writers have adopted the term *Urginea* as the generic name.

⁷ *De Nat. Mul.*

nica), and the red (*scilla rubra, femina, vel italica*),¹ both of which are so called from the colour of the scales. The white is preferred in England.

In the London Pharmacopœia (1851) the fresh bulbs are directed to be dried like colehium.

Dried squill (*radix scillæ siccata, offic.*) is, however, for the most part imported, in consequence of the duty being no higher for this than for the recent bulb. It occurs in white or yellowish-white, slightly diaphanous pieces, which, when dry, are brittle, but when moist are readily flexible. As their affinity for moisture is great, they should be preserved in well-stoppered bottles, or in a very dry place.

Squill is imported from Malta, and other countries of the Mediterranean. Also from Petersburg and Copenhagen.²

COMPOSITION.—The more recent analyses of squill are those of Vogel, in 1812,³ and of Tilloy, in 1826.⁴ Buchner,⁵ in 1811, examined the juice of the fresh bulb.

Vogel's Analysis of Squills, dried at 212° F.	Tilloy's Analysis of dried and fresh Squills.	Buchner's Analysis of fresh Squill bulb juice.
Scillitin with some sugar . . . 35	Acrid bitter resinous extractive (<i>Scillitin</i>)	Peculiar bitter extractive . . . 9.4
Tannin 24	Uncrystallizable sugar	Mucilage 3.09

Woody fibre, and some ci- trate (and perhaps tartrate) } 30	Fatty matter	Phosphate of lime 0.31
of lime }	Piquant, very fugaceous matter.	Fibrous matter 3.38
Acrid volatile matter		Water 79.01
Loss 5		Astringent acid traces
		Loss 4.40
Squill bulb 100	Squill bulb	Squill juice 100.60

1. ACRID, VOLATILE? MATTER.—It is well known that squill, in the recent state, is very acrid, and, when applied to the skin, causes irritation, inflammation, and even vesication. By drying, the greater part of this acidity is got rid of; and hence the acrid principle is usually described as being of a volatile nature, and, in confirmation of its volatility, Athanasius⁶ states that two ounces of water distilled from fresh squills caused the death of a dog in six hours. However, by others, its volatility is denied; and Vogel says, that six ounces of water distilled from fresh squills had no effect on dogs. Buchner⁷ states, that besides the bitter scillitin, squill contains, according to his experiments, another principle, which is combined with phosphate of lime, and which is capable of exciting itching and inflammation. This acrid matter may be easily decomposed, but is not volatile, as is generally supposed.

2. SCILLITIN (*Scillitite*, Thomson).—The substance to which Vogel gave the name of Scillitin is a whitish transparent deliquescent substance, which, when dry, has a resinous fracture, and may be easily rubbed to powder. Its taste is bitter, and subsequently sweetish. It readily dissolves in water, spirit of wine, and acetic acid. The substance sold in the shops under the name of Scillitin is a thick treacle-like liquid. Landerer⁸ obtained crystals of Scillitin. He says they possessed alkaline properties. Lebordais,⁹ on the other hand, says it is neutral and incrySTALLIZABLE. It obviously requires further examination.

3. RAPHIDES (*Phosphate of lime? Oxalate of lime?*).—The acicular crystals found in the cuticle of the scales of the bulb, as before mentioned, probably consist of phosphate of lime, or, according to Schleiden, of oxalate of lime. These, perhaps, are the needle-like crystals obtained by Vogel by evaporating the juice of the bulb, and which he regarded as citrate of lime. According to the late Mr. E. Quekett they constitute about 10 per cent. of powdered squills.

CHEMICAL CHARACTERISTICS.—An aqueous decoction of squills is pale, and very bitter. Sesquichloride of iron communicates an intense purplish blue colour (*gallate of iron*) to it. (This test I have not found to succeed uniformly. The decoction of some specimens of squills scarcely becomes altered by the salts of iron.) Gelatin has scarcely any effect on it. Nitrate of silver forms a white precipitate (*chloride of silver*) soluble in ammonia, but insoluble in nitric acid. Oxalate of ammonia renders the decoction turbid, and after some time causes a white precipitate (*oxalate of lime*). Diacetate of lead and proto-nitrate of mercury form pre-

¹ Is the red kind the *Squilla Pancratium* var. *a Bulbo Rufo*, Steinheil?

² *Trade List*, Sept. 11, and Nov. 20, 1835. Sir James Wylie (*Pharm. Castren. Ruthenica*, p. 335, ed. 4to, 1840) gives North Russia as one of the habitats of this plant.

precipitates in the decoction. Tincture of nutgalls has little or no effect on it; it sometimes occasions a cloudiness. Starch is not recognizable in it by iodine. Alkalies heighten the colour of the decoction.

An infusion of squills in water acidulated with hydrochloric acid yields a white precipitate with oxalate of ammonia (*oxalate of lime*); and with caustic ammonia sometimes a precipitate (*phosphate of lime*), at others scarcely a cloud.

PHYSIOLOGICAL EFFECTS. *a. On Vegetables.*—Not ascertained.

β. On Animals.—An ounce of powdered squills acts as a diuretic on horses and other large animals; the same effect is produced on smaller animals by half a drachm.¹ When the dose is large, squill acts as a poison. It first causes local irritation; then its active principle becomes absorbed, affects the nervous system, and thereby quickens the respiration, causes convulsions, and death.² Hillefeld³ mentions paralysis produced in a rabbit by nineteen grains of powdered squill. Emmert and Hoering⁴ state that the squill juice introduced into the abdominal cavity became absorbed.

γ. On Man.—Squill is an acrid. *In small doses* it acts as a stimulant to the excretory organs. Thus it promotes secretion from the mucous membranes (especially the bronchial and gastro-intestinal) and the kidneys. Its most marked effect is that of a diuretic. Its expectorant effects are less obvious and constant. Sometimes, when it fails to act on the kidneys, it increases cutaneous exhalation. Its influence on secreting organs is probably to be referred to the local stimulus communicated to their vessels by the active principle of squill in its passage out of the system, for Emmert and Hoering⁵ have shown that the juice is absorbed, so that squills may be regarded as an acrid even for these remote parts. When it proves diuretic in dropsies, it usually promotes the absorption of the effused fluid—an effect which is, I think, indirect, and a consequence of the diuresis. But Sundelin⁶ observes of squill, that it promotes the secretion of urine less by its local irritation of the kidneys, than by its general excitement of the absorbent apparatus.

By the continued use of squill, in gradually increased doses, it disturbs the functions of digestion and assimilation.

In full medicinal doses, squill excites nausea and vomiting. Purging, also, is not unfrequently produced. When squill proves emetic or purgative, its diuretic operation is much less obvious—a circumstance which Cullen⁷ refers to the squill being prevented reaching the blood-vessels and kidneys. Home,⁸ however, alleges that the diuretic effects are not to be expected unless there be some operation on the stomach. But the operation on the stomach may be, as Cullen suggests, a mere test of the activity of the squills. However, that the effect of squill, in strong doses, is not confined to the alimentary canal, is proved by the fact, that when the vomiting and purging were present, the pulse has been observed to be reduced in frequency, often to forty beats per minute (Home).

In excessive doses, squill acts as a narcotico-acrid poison, and causes vomiting, purging, griping pain, strangury, bloody urine, convulsions, inflammation, and gangrene of the stomach and intestines.⁹ Twenty-four grains of the powder have proved fatal.¹⁰

Considered with reference to its diuretic effect, squill is comparable with foxglove. But it exceeds the latter in its stimulant influence over the urinary organs. On the other hand, foxglove is characterized by its powerfully sedative effect on the vascular system; for though squill has, in some instances, reduced the frequency of the pulse, this effect is by no means common. Squill, says Vogt,¹¹ preponderates in its action on the inferior or vegetative [organic] life; foxglove, on the other hand, in its action on the higher or animal life.

USES.—The principal uses of squill are those of an emetic, diuretic, and expectorant.

1. *As a diuretic in dropsies.*—It is applicable to those cases of dropsy requiring the use of stimulating or acrid diuretics, and is improper in inflammatory cases. It is an unfit remedy for dropsy complicated with granular kidney or vesical irritation; but when these conditions are not present, it is adapted for torpid leucophlegmatic subjects. Hence, it is more serviceable in anasarca than in either ascites or hydrothorax. It should be given so as to excite a slight degree of nausea (not vomiting), as recommended by Van Swieten.¹ By this means its absorption is promoted. The acetate or bitartrate of potash may be conjoined. Calomel is usually regarded as a good adjunct for promoting the diuretic influence of squill. When it does not purge it is beneficial, but its tendency to affect the bowels is an objection to its use.

2. *As an expectorant in chronic pulmonary affections* admitting of the use of a substance stimulating the capillary vessels of the bronchial membrane. Thus, in chronic catarrh, humid asthma, and winter cough, it is often employed with considerable benefit. It is of course improper in all acute cases accompanied with inflammation or febrile disorder. In old persons it is often combined with the *tinctura camphoræ composita*, and with good effect. The oxymel or syrup of squill may be given to relieve troublesome chronic coughs in children.

3. *As an emetic*, it is occasionally used in affections of the organs of respiration requiring or admitting of the use of vomits. Thus, the oxymel is given, with the view of creating sickness and promoting expectoration, to children affected with hooping-cough; and sometimes, though with less propriety, in mild cases of croup. The great objection to its use is the uncertainty of its operation: in one case it will hardly excite nausea, in another it causes violent vomiting. Furthermore, it is of course highly objectionable as an emetic for delicate children with irritable stomachs, on account of its acrid properties, and the irritation it is capable, in these cases, of setting up.

ADMINISTRATION.—The following are the preparations of squills usually employed:—

1. PULVIS SCILLÆ; *Powder of Squill.*—The bulb loses about four-fifths of its weight by drying; so that six grains of the dry powder are equal to half a drachm when fresh. Powdered squill readily attracts water from the atmosphere, and becomes soft and mouldy; hence the necessity of preserving it in stoppered bottles and in a dry place. I have seen it become hard and massive like diachylon plaster. It is usually administered in the form of pill. The dose of the powder, as an emetic, is from six to fifteen grains; ten grains being the average. As an expectorant or diuretic we should commence with one grain, and gradually increase the dose until slight nausea is excited.

2. PILULA SCILLÆ COMPOSITÆ, L.; *Pilulæ Scillæ Compositæ*, D. [U. S.]; *Pilulæ Scillæ*, E.; *Compound Squill Pill.*—(Squill, fresh dried and powdered, ℥j [℥iiss, D.]; Ginger powdered, Ammoniacum powdered, of each ℥ij; Soft Soap ℥iij [Castile Soap ℥ij, D.] [Syrup, U. S.]; Treacle as much as may be sufficient [by weight ℥ss, D.]. Mix the powders together; then beat them with the other ingredients until they are incorporated. The *Edinburgh College* takes of powdered Squill *five parts*; powdered Ammoniac, Ginger, and Spanish Soap, of each *four parts*; Conserve of Red Roses *two parts*; and forms them into five-grain pills.)—Expectorant and diuretic. Principally used in chronic bronchial affections. Dose, from five to twenty grains. It readily spoils by keeping.

3. TINCTURA SCILLÆ, L. D. E. [U. S.]; *Tincture of Squills.*—(Squill, fresh dried [in coarse powder, E.], ℥v; Proof Spirit Oij; macerate for seven [fourteen, D.] days, and strain, L. “Prepare this tincture by percolation, as directed for

¹ *Commentary upon Boerhaave's Aphorisms*, vol. xii. p. 435.

tincture of cinchona, but without packing the pulp firmly in the percolator. It may likewise be obtained by the process of digestion from the sliced bulb." *E.*) [The *U. S. Pharm.* directs of Squill four ounces; diluted Alcohol two pints; macerate for fourteen days, compress and filter through paper; or, this tincture may also be prepared by thoroughly moistening the Squill in powder, with diluted Alcohol, allowing it to stand for twenty-four hours, then transferring to an apparatus for displacement, and gradually pouring upon it diluted Alcohol, until two pints of the filtered liquor are obtained.]—Expectorant and diuretic. Used in chronic bronchial affections. Dose, ℞x to fʒss.

4. ACETUM SCILLÆ, L. D. E. [U. S.]; *Vinegar of Squills*.—(Squill, fresh dried and powdered, ʒijss [ʒij, *D.*]; Dilute Acetic Acid Oj [Acetic Acid of commerce (sp. gr. 1.044), fʒiv; Distilled Water ʒxij, *D.*]; [Proof Spirit fʒiss, *L.*]. The ingredients and relative proportions used by the Edinburgh College are the same as those of the London College, except that distilled vinegar is employed. Macerate the squill with the vinegar, with a gentle heat, in a covered vessel, for three [seven, *D. Ed.*] days; afterwards press out [the liquor] and set it aside, that the dregs may subside; lastly, add the spirit to the clear liquor. [The *U. S. Pharm.* directs, of Squill, bruised, four ounces; Dilute Acetic Acid two pints; Alcohol a fluidounce. The process is the same as that of the Dublin College; or it may be made by displacement.]—Expectorant and diuretic. Used in chronic pulmonary affections and dropsies, under the regulations before described. Dose, ʒss to ʒiiss, in some aromatic water.

5. OXYMEL SCILLÆ, L. [U. S.]; *Syrupus Scillæ*, E.; *Oxymel of Squills*; *Syrup of Squills*.—(Honey ℔v; Vinegar of Squill Oijss. Boil down the vinegar, with a slow fire, to twelve fluidounces, and mix the honey, made hot, *L.*—Vinegar of Squills Oij; Pure Sugar ℔vij. Dissolve the sugar in the vinegar of squills with the aid of a gentle heat and agitation, *E.*) [Vinegar of Squill Oij; Clarified Honey Ojss. Mix them, and evaporate, by means of a water-bath, to the proper consistence. The specific gravity should be 1.32, *U. S.*]—Used as an expectorant in chronic catarrhs and asthma, in doses of fʒj or fʒij. As an emetic, it is sometimes given to children affected with hooping-cough or croup, in doses of a teaspoonful repeated every quarter of an hour until vomiting occurs.

[6. SYRUPUS SCILLÆ, U. S.; *Syrup of Squills*.—This is directed to be prepared of Vinegar of Squills a pint; Sugar two pounds. Add the sugar to the vinegar of squill, and proceed in the manner directed for syrup. This preparation is used in place of the preceding as an emetic and expectorant. In affections of the lungs, where squill is beneficial, it may be employed as an ingredient of cough mixtures, variously compounded. As a common remedy for children in cases of cough or cold, it is with safety directed and commonly used. The dose is fʒss to ʒj or ʒij.

7. SYRUPUS SCILLÆ COMPOSITUS, U. S.; *Compound Syrup of Squill*; *Hive Syrup*.—Take of Squill bruised, Senega bruised, each four ounces; Tartrate of Antimony and Potassa forty-eight grains; Water four pints; Sugar three pounds and a half. Pour the water upon the squill and senega, and having boiled to one-half, strain, and add the sugar; then evaporate to three pints, and, while the syrup is still hot, dissolve in it the tartrate of antimony and potassa. Another mode of preparation is, to take of Squill in coarse powder, Senega in coarse powder, each four ounces; Tartrate of Antimony and Potassa forty-eight grains; Alcohol half a pint; Water a sufficient quantity; Sugar three pounds and a half. Mix the alcohol with two pints and a half of water, and macerate the squill and senega in the mixture for twenty-four hours. Put the whole in an apparatus for displacement, and add as much water as may be necessary to make the filtered liquor amount to three pints. Boil the liquor for a few minutes, evaporate to one-half, and strain; then add the sugar, and evaporate until the resulting syrup measures three pints. Lastly, dissolve the tartrate of antimony and potassa in the syrup, while it is still hot.

This preparation is a modification of that made according to the formula given

by Dr. J. R. Coxe, and which goes by the name of *Coxe's Hive Syrup*. In the former editions of the Pharmacopœia, the formula of Dr. Coxe was adopted; and as honey was substituted for sugar, it had the officinal name of *Mel Scillæ compositum*. The formula above cited authorizes the substitution of sugar for honey, as it is less liable, when prepared as directed, to undergo fermentation—a great desideratum in hot weather. There is no difference between the proportions of the ingredients, so that an equal strength of the two preparations is obtained by both. The latter was introduced in accordance with the recommendation of the Committee of Revision of the Philadelphia College of Pharmacy.

This preparation combines the advantages of squill, senega, and tartarized antimony, and is an exceedingly active preparation. In sufficient doses, it operates upon the stomach, producing free vomiting and expectoration. It is used at the commencement of croup, hooping-cough, and catarrhal affections in children, with the view to its evacuant impression. In the inflammatory stages, as an expectorant and nauseant, it may also be employed with advantage, in reduced doses. The dose is from gtt. x to fʒi, according to the age of the child, repeated every ten or fifteen minutes until it pukes. As an expectorant for adults, the dose is gtt. xx to gtt. xxx.]

ANTIDOTE.—No antidote is known. The first object, therefore, in a case of poisoning, is to evacuate the stomach; the second, to allay the inflammatory symptoms which may supervene.

63. ALLIUM SATIVUM, Linn.—COMMON OR CULTIVATED GARLIC.

Sex. Syst. Hexandria, Monogynia.

(Bulb, E.)

HISTORY.—This plant was well known to the ancients. The Greeks called it *σκόροδον*;¹ the Romans *Allium*.² It was used by Hippocrates.³

BOTANY. Gen. Char.—*Flowers* umbellate, with a membranous *spathe*. *Perianth* six-parted, permanent, equal. *Stamens* inserted into the base of the perianth; *filaments* either all alike, or every other one tricuspidate, with the *anther* on the middle point. *Style* subulate, *stigma* simple. *Capsule* usually obtusely three-cornered or three-lobed, depressed, three-celled, bursting into three valves through the dissepiments, and containing two or one black angular seed in each cell. (Lindley.)

Sp. Char.—*Bulb* surrounded by smaller ones. *Leaves* linear, entire. *Umbel* bulbiferous, globose. *Spathe* ovate, rounded. *Segments of the perianth* ovate, obtuse. *Pistil* and *stamens* exsert.⁴ *Stem* about two feet high. *Flowers* whitish.

Hab.—?South of Europe. ?Egypt. ?Persia. Cultivated in kitchen gardens. It flowers in July.

DESCRIPTION.—The *bulb* (*bulbus allii*) is composed of *cloves* (*spicæ vel nuclei allii*), each furnished with its proper envelopes. Its odour is strong, irritating, and characteristic; its taste is acrid.

COMPOSITION.—Cadet⁵ analyzed garlic. He found the constituents to be *acrid volatile oil*, *extractive* (a little), *gum*, *woody fibre*, *albumen*, and *water*. The ashes contained alkaline and earthy salts. Bouillon-Lagrange has detected, besides these, *sulphur*, *starch*, and *saccharine matter*.⁶

OIL OF GARLIC (*Oleum Allii*) is a sulphuret of allyle, $\text{AllS}=\text{C}^6\text{H}^5\text{S}$ (see vol. i. p. 253). According to Wertheim,⁷ oxide of allyle, $\text{AllO}=\text{C}^6\text{H}^5\text{O}$, also exists in the crude oil. Oil of garlic has a very acrid taste, a strong smell, and a yellow colour. It is heavier than water, and is soluble in alcohol. As it contains sulphur it produces, in burning, sulphurous acid. According to Cadet, 20 lbs. of garlic yielded only six drachms of essential oil; Wertheim obtained between

¹ Theophrastus, *Hist. Plant.* lib. vii. cap. iv.; Dioscorides, lib. ii. cap. 132.

² Pliny, *Hist. Nat.* lib. xix. cap. 31, ed. Valp.

³ De Candolle, *Bot. Gall.*

⁴ *Journ. de Pharm.* t. ii. p. 358.

⁵ *De victus ratione in acutis*, p. 404, ed. Fœslii.

⁶ Gmelin, *Handb. d. Chem.* ii. 1336.

⁷ *Ann. d. Chem. u. Pharm.* Bd. li. S. 289, 1814; *Pharmaceutical Journal*, vol. iv. p. 325, 1845.

three and four ounces from 1 cwt. of garlic. It strikes a black colour when rubbed with oxide of iron. It is a powerful irritant, and when applied to the skin causes irritation. The Hindoos, according to Dr. Ainslie,¹ prepare a stimulating expressed oil from garlic, which they give internally in ague, and use externally in palsy and rheumatism.

PHYSIOLOGICAL EFFECTS.—Garlic is a local irritant. When swallowed, it operates as a tonic and stimulant to the stomach. Its volatile oil becomes absorbed, quickens the circulation, occasions thirst, and is thrown out of the system by the different excretories, the activity of which it promotes, and to whose excretions it communicates its well-known odour. Large doses occasion nausea, vomiting, and purging. Puihn² says the expressed juice has proved fatal.

USES.—Employed by the cook as a flavouring ingredient in various made-dishes, sauces, &c. Rarely used by the medical practitioner. Internally, it has been exhibited as a stimulant and stomachic in enfeebled digestion; as an expectorant in old chronic catarrhs; as a diuretic in atonic dropsies; and as an anthelmintic. Externally, it has been employed as a resolvent in indolent tumours; as a local irritant or rubefacient applied to the feet to cause revulsion from the head or chest; as an antispasmodic liniment (composed of oil and garlic juice) in infantile convulsions; as a remedy for some cases of deafness, a clove or a few drops of the juice being introduced into the ear.

ADMINISTRATION.—A clove may be swallowed either entire, or, more conveniently, cut into small pieces. The dose of the fresh bulbs is one or two drachms. The expressed juice mixed with sugar, the infusion of garlic, and a syrup, are sometimes employed.

[**SYRUPUS ALLII.**—Take of fresh Garlic, sliced, six ounces; diluted Acetic Acid a pint; Sugar two pounds. Macerate the garlic in the diluted acetic acid in a glass vessel for four days, then express the liquor, and set it by that the dregs may subside. Add the sugar to the clear liquor, and proceed in the manner directed for syrup.

This formula was adopted upon the recommendation of Mr. Daniel B. Smith, of Philadelphia, who demonstrated the futility of the old method of preparing syrup of garlic, of which formula (*Journal of Philadelphia College of Pharmacy*, No. 1, p. 50) it is a modification. Dose, ʒi.]

64. ALLIUM CEPA, Linn.—THE ONION.

Sex. Syst. Hexandria, Monogynia.
(Bulbus.)

HISTORY.—The onion was known and used in the most ancient times. By Fraas³ it is considered to be the *κρόμμυον* (see *ante*, p. 207) of Theophrastus⁴ and Dioscorides.⁵ The *σπράμιον* of Theophrastus was a variety of onion. By Pliny⁶ the onion is called *cepa*. It was employed in medicine by Hippocrates. An onion taken from the hand of an Egyptian mummy perhaps 2000 years old has been made to grow.⁷

BOTANY. *Gen. Char.*—Vide *Allium sativum*.

Sp. Char.—*Stem* fistulose, ventricose beneath; longer than the terete, fistulose leaves. *Umbel* capsuliferous, globose. *Segments of perianth* linear-elliptic, obtuse; shorter than the stamens and pistil.⁸ *Biennial*. *Flowers* whitish. *July*.

Loudon⁹ enumerates eighteen varieties deserving of culture.

Hab.—Egypt. Cultivated in kitchen gardens.

Besides *A. sativum* and *A. Cepa*, various other species of *Allium* are also cultivated for culinary purposes; ns, *A. Porrum*, the Leek; *A. ascalonicum*, the Shallot; *A. Schenoprasum*, the Chive; and *A. Scorodoprasum* or Rocambole. Their virtues are analogous to those of the onion and garlic.

² *Synops. Plant. Fl. Class.* p. 291, 1845.

³ *Lib.* ii. cap. 181.

⁴ Müller's *Physiol.* by Baly, vol. i. p. 29.

⁵ *Encyclopædia of Gardening*.

⁶ Quoted by Wibmer, *Die Wirk. d. Arzneim.*

⁷ *Hist. Plant.* lib. vii. cap. 4.

⁸ *Hist. Nat.* lib. xix. cap. 32, ed. Valp.

⁹ *Botanicon Gallicum*.

DESCRIPTION.—The bulb (*bulbus*) is tunicated. When cut, it evolves an acrid principle, having a well-known odour, and a powerful action on the eyes, causing a flow of tears. Its taste is sweet and acrid. *Onion juice* is colourless, but by exposure to the air it becomes reddish.

COMPOSITION.—According to Fourcroy and Vauquelin,¹ the onion contains an *acrid volatile oil, uncrystallizable sugar, gum, woody fibre, albumen, acetic and phosphoric acids, phosphate and citrate of lime, and water.*

OIL OF ONIONS (*Oleum cepæ*) contains sulphur, and is probably similar in composition to oil of garlic, $\text{AllS}=\text{C}^6\text{H}^5\text{S}$. It is acrid, piquant, and colourless.

PHYSIOLOGICAL EFFECTS.—Analogous to those of garlic, but milder. The oil becomes absorbed, and communicates the well-known onion odour to the breath. By boiling onions the volatile oil is dissipated, and the bulb is deprived of its irritating qualities, and becomes a mild esculent substance.

USES.—Extensively used as an article of food and as a condiment. It is very rarely employed in medicine, but is adapted to the same cases as garlic. Raw onions are occasionally taken as an expectorant, with advantage, by elderly persons affected with winter cough.

ADMINISTRATION.—A roasted onion is sometimes employed as an emollient poultice to suppurating tumours, or to the ear to relieve ear-ache. The expressed juice has been given to children, mixed with sugar, as an expectorant.

65. *Asparagus officinalis*, Linn.—Common Asparagus.

Sex. Syst. Hexandria, Monogynia.

(Turiones et Radix.)

A well-known indigenous culinary vegetable, which is extensively cultivated in gardens for its young succulent shoots (*turiones asparagi*), which, when boiled, form a much admired article of food. These, as well as the root (*radix asparagi*), have been used in medicine.

The shoots have been chemically examined by Robiquet,² who found in their juice *asparagin, mannite, peculiar aqueous extractive, green acrid oleo-resinous matter, wax, gluten, albumen, colouring matter, and salts of potash and lime.*

Dulong³ analyzed the root, and found in it *albumen, gum, a peculiar matter* (precipitable by basic acetate of lead and protonitrate of mercury), *resin, saccharine matter* (reddened by oil of vitriol), and *salts of potash and lime.* He detected neither asparagin nor mannite.

Asparagin (also called *asparamid, althain, and agédoil*) crystallizes in right rhombic prisms,⁴ whose formula is $\text{C}_8\text{H}^8\text{N}^2\text{O}^6+2\text{HO}$. When heated to 248° F., they lose 12 per cent. of water. They have a cooling, somewhat nauseous taste, are slightly soluble in cold water, more so in boiling water, but are insoluble in alcohol and ether. By the action of acids and alkalis aided by heat asparagin is resolved into *aspartic acid, C}^8\text{H}^5\text{NO}_6, and ammonia, NH^3 . Asparagin is found in the urine of those who have swallowed it (see *ante*, p. 279).*

The young shoots act as diuretics, and communicate a peculiar fetid odour⁵ to the urine. This is produced neither by the asparagin nor by the volatile matter contained in the distilled water of the shoots, but by something which resides in the aqueous extract.⁶ Formerly, an emmenagogue and aphrodisiac property was ascribed to asparagus.

The medicinal properties of the root are similar to those of the shoots. Like the latter, it communicates an unpleasant odour to the urine. It formed one of the *five greater aperient roots* (*radices quinque aperientes majores*) which were formerly used in visceral diseases. The other four were butcher's broom (*Ruscus aculeatus*), celery or snallage (*Apium graveolens*), parsley (*Petroselinum sativum*), and fennel (*Feniculum officinale*).

Though no longer contained in our Pharmacopœia, asparagus is still occasionally used as a popular remedy, chiefly as a diuretic in dropsies, and as a lithic.⁷ For these purposes the shoots are boiled and used at table; or the root, which is considered superior to the shoots, is taken in the form of an infusion or decoction (prepared by boiling an ounce of the root in a quart of water), which may be taken as a common drink.

⁵ Murray (*App. Med.* vol. v. p. 184, 1790) thinks the odour not dissimilar to that of *Geranium robertianum*.

⁶ Plisson et Henry fils, in *Journ. de Pharm.* xvi. 725, 1830.

⁷ For some experiments on the solvent power of asparagus-juice for urinary calculi, see Lobb's *Treatise on Dissolvents of the Stone*, 1739.

66. *Polygonatum vulgare*, Desf.—Solomon's Seal.

Sex. Syst. Hexandria, Monogynia.
(Rhizoma.)

Convallaria Polygonatum, Linn.—A well-known indigenous plant, whose rhizome (*radix polygonati*), though long banished from the Pharmacopœia, is still kept in the herb shops, and sold as *Solomon's Seal* (*Sigillum Salomonis*). I suspect that the rhizome of *P. multiflorum* is also sold under the same name. When neither species is to be obtained, bryony root is commonly substituted.

Solomon's seal is a white, fleshy, odourless rhizome, having a sweetish, mucilaginous, very slightly bitterish, acrid taste. Iodine applied to the fresh cut surface of the rhizome gathered in September does not darken it. In these properties, the rhizomes of both the above-mentioned species of *Polygonatum* agree. Walz¹ examined chemically the herb, stem, and root of *P. multiflorum*. He found in them asparagin, uncrystallized sugar, starch, gum, gluten, peculiar nitrogenous matter, acrid resin, pectin, malic, citric, hydrochloric, and phosphoric acids, potash, magnesia, lime, and alumina.

Solomon's seal is a popular application to bruised parts (the eye, for example), to remove the marks. For this purpose it is scraped and applied to the parts. Gerarde² says it "taketh away in one night, or two at most, any bruse, blacke or blew spots gotten by falls or women's wilfulness, in stumbling upon their hastie husbands' fists."

67. *Dracæna Draco*, Linn.

Sex. Syst. Hexandria, Monogynia.

This tree, which has the habit of a palm, is a native of the Canary Islands. Its stem yields by incision a red juice, which concretes and forms a red resin resembling *dragon's blood* (see *ante*, p. 169), which appears to have been collected by the Spaniards when they took possession of those islands. Hence this species has usually passed for one of the sources of dragon's blood. But none of the commercial article is obtained from it. Indeed, Guibourt³ states that, at the present time, it is impossible to obtain the smallest quantity of it at the Canary Islands.

One of the *Dracæna*-trees growing at Orotava has long been celebrated for its great size and age; and next to the Baobab trees (*Adansonia digitata*), it is regarded as one of the oldest inhabitants of the earth.⁴

68. *Xanthorrhæa*, Smith.

Sex. Syst. Hexandria, Monogynia.
(Resina.)

The *Xanthorrhæas* or *Grass-Trees* of Australia differ considerably in habit from the other Liliacæ. Their stems are usually shrubby and resiniferous; their leaves long, narrow, grass-like, and in tufts; and their flowers small, white, and densely crowded on long cylindrical spikes like those of bulrushes (*Typha*). Mr. Brown⁵ has described seven species, viz., *X. arborea*, *australis*, *hastile*, *media*, *minor*, *bracteata*, and *pumilio*. The first two are arborescent, the third and fourth have short stems, and the last three are stemless.

Two resins, both the produce of this genus, have been imported into this country—one yellow, the other red.

1. The yellow resin of *Xanthorrhæa*, known by the various names of *yellow resin of New Holland* (*resina lutea novi Belgii*), *Botany Bay resin*, and *acaroid resin or gum* (*resina vel gummi acaroides*), was first noticed by Governor Phillips,⁶ in 1789.

It is obtained from the trunk of one or more species⁷ of *Xanthorrhæa* by spontaneous exudation.⁸ It occurs in more or less rounded tears; in flattened pieces, bearing on one side an in-

¹ *Jahrb. f. pr. Pharm.* vi. 15; vii. 17. (Wittstein's *Vollstand. etym. chem. Handwörterbuch*, Bd. i. S. 360, 1847.)

² *Herball*, 1633.

³ *Hist. Nat. des Drogues*, 4ème édit. t. ii. p. 145.

⁴ Humboldt, *Tabl. de la Nature*.—See, also, *Ann. des. Scien. Nat.* t. xiv. p. 137.

⁵ *Prodromus Floræ Novæ Hollandiæ*, 1810. One of the arborescent species (probably *X. arborea*) is called *black boy* (Drummond, in Hooker's *Journal of Botany*, vol. ii. p. 344, 1840).

⁶ *Voyage to Botany Bay*, 1789.

⁷ Smith (Rees's *Cyclop.* vol. xxxix. art. *Xanthorrhæa*) refers it to *X. hastile* and some other species (see, also, Bennett's *Wanderings in New South Wales*, &c. 1834). On the other hand, L. Gmelin (*Handb. d. Chem.* ii. 618), on the authority of Sieber, and Méral and De Lens (*Dict. Mat. Méd.* vi. 970, 1834); on the verbal authority of Mr. R. Brown, refer it to *X. arborea*.

⁸ White, *Journal of a Voyage to New South Wales*, in 1787, p. 235, 1790.

pression of the stems to which they were attached, and intermixed with portions of wood, stalks, earth, &c.; and in masses of variable size and irregular shape, having, when fractured, a speckled or granitic character. The pure resin is reddish-yellow. Its fresh fractured surface resembles that of gamboge; its powder is greenish-yellow. When heated, it emits a vapour having a fragrant odour like that of Tolu or storax. It has been repeatedly subjected to chemical examination; viz., by Lichtenstein,¹ Schrader,² Laugier,³ Widmann,⁴ Trommsdorff,⁵ and more recently by Stenhouse.⁶ It consists essentially of resin, cinnamic acid, a small quantity of benzoic acid, and a trace of volatile oil. Some samples contain a small quantity of bassorine. Heated with peroxide of manganese and oil of vitriol, it evolves the odour of the oil of bitter almonds. Its alcoholic solution yields, on the addition of water, a yellow precipitate soluble in caustic potash. By the action of nitric acid it yields so large a portion of carbazotic acid that it is likely to prove the best source of that acid. As it sometimes resembles Tolu and storax in composition, so it probably resembles them also in its medicinal properties. Mr. Kite⁷ employed it in several diseases. He says it neither vomits, purges, nor binds the belly; nor does it act materially as a diuretic or diaphoretic. More recently, Dr. Fish⁸ has employed it in the form of tincture with opium in *fluxus hepaticus*, and the colliquative diarrhœa of phthisis. On account of its resemblance in composition to the balsams, it deserves a trial in chronic catarrhs. A tincture of New Holland resin is prepared by digesting the resin in rectified spirit: Kite used equal parts of resin and spirit; Fish, 2 ounces of resin to ℥j of spirit. The dose of the tincture is ʒj or ʒij in milk or mucilaginous mixture.—It might be used as a substitute for, or mixed with other substances in the preparation of fumigating pastiles.

2. The red resin of *Xanthorrhœa* is sometimes imported under the name of *black-boy gum*. In colour it somewhat resembles dragon's blood, or Botany Bay kino (*Eucalyptus resinifera*); but many of the pieces, like some of those of the yellow resin of *Xanthorrhœa*, are marked by the impression of the trunk to which they have adhered. When heated, it evolves a fragrant balsamic odour; and, with the exception of the intermixed and adherent ligneous matters, is completely soluble in rectified spirit. The source of this resin would appear to be *X. Hastile*, for Viquet (quoted by Nees Von Esenbeck⁹) says that this species yields a red resin which resembles dragon's blood.

†† Flowers with a true perianth adherent to the ovary (*inferior ovary*), usually hermaphrodite.

ORDER XII. IRIDACEÆ, Lindl.—IRIDS, OR CORN-FLAGS.

IRIDEÆ, Juss.

CHARACTERS.—*Calyx* and *corolla* superior, confounded, their divisions partially cohering, or entirely separate, sometimes irregular, the three petals being occasionally very short. *Stamens* 3, arising from the base of the sepals; *filaments* distinct or connate; *anthers* bursting externally lengthwise, fixed by their base, 2-celled. *Ovary* 3-celled, cells many-seeded; *style* 1; *stigmas* 3, often petaloid, sometimes 2-lipped. *Capsule* 3-celled, 3-valved, with a loculicidal dehiscence. *Seeds* attached to the inner angle of the cell, sometimes to a central column, becoming loose; *albumen* horny, or densely fleshy; *embryo* enclosed within it.—*Herbaceous* plants, or very seldom *under-shrubs*, usually smooth; the hairs, if any, simple. *Roots* tuberous or fibrous. *Leaves* equitant, and distichous in most genera. *Inflorescence* terminal, in spikes, corymbs, or panicles, or crowded, sometimes radical. *Bracts* spatheaceous, the partial ones often scarious; the *sepals* occasionally rather herbaceous (*Lindley*).

PROPERTIES.—The underground stems and roots usually abound in fecula and mucilage; but these nutritive substances are generally combined with an acrid principle, which excludes their employment as articles of food. However, *Morœa edulis*, *M. sisyrinchium*, *Gladiolus edulis*, and a species of *Tigridia*, have been used as esculent substances. The rhizomes of several species of *Iris* (as *I. Pseudo-acorus*, *I. germanica*, *I. sibirica*, and *I. versicolor*) are remarkable, especially in the fresh state, for their acridity, in consequence of which some of them have been used as purgatives, sialagogues, or errhines, or for issue-peas. The rhizomes of some species (as *I. florentina* and *I. germanica*) have an agreeable smell. The colour and the odour of saffron are to be regarded as part of the petaloid qualities of the stigmata of *Crocus*. The effects of this medicine on the nervous system are regarded by De Candolle¹⁰ as similar to those of [certain odorous] flowers.

69. CROCUS SATIVUS, *Allioni*.—THE SAFFRON CROCUS.

Sex. Syst. Triandria, Monogynia.
(Stigma, L.—Stigmata, E. D.)

HISTORY.—Saffron is mentioned in the Old Testament.¹ Homer² speaks of the *crocus* (κρόκος). Hippocrates³ employed saffron in uterine and other maladies. The word *saffron* (*za'faran*) is probably of Persian origin.

BOTANY. **Gen. Char.**—*Perianth* [coloured], with a slender tube twice as long as the limb; limb 6-partite, equal, erect. [*Stamens* 3, inserted into the tube; *anthers* sagittate.] *Stigmata* 3, thick, convoluted, generally crested. *Capsule* under ground, elevated by a short peduncle from the root, which peduncle elongates after the decay of the flowers, and the capsules appear above ground. (*Hooker*, with some additions.)

Sp. Char.—*Stigma* protruded, drooping, in 3 deep linear divisions. (*Hooker*.) *Cormus* roundish; its brownish coats reticulated, separating superiorly into distinct parallel fibres. *Leaves* linear, with a white central stripe, and surrounded at their base with long membranous sheaths. *Flowers* light purple, shorter than the leaves, with a two-valved membranous spathe. *Anthers* pale yellow. *Stigmata* deep orange-coloured.

Hab.—A native of Asia Minor. Now naturalized in England, France, and some other European countries. It is a doubtful native of the eastern parts of Europe. It is said to have been introduced into Spain by the Arabs.⁴ It flowers in September and October.

PREPARATION.—The flowers are gathered in the morning, and the stigmata, with a portion of the style, plucked out for use, the rest of the flower being thrown away. The stigmata are then dried on paper, either by means of portable kilns over which a hair-cloth is stretched,⁵ or in a room by the sun.⁶ When dried between paper under the pressure of a thick board and weights, the saffron is formed into cakes now no longer to be met with.

DESCRIPTION.—The only saffron now found in the shops is that called *hay saffron*. The article sold as *cake saffron* is in reality not saffron.

Hay saffron (*crocus in feno*) consists of the stigmata with part of the style, which have been very carefully dried. They are from an inch to an inch and a half long, thin, brownish-red; the upper portion (stigma) is expanded, notched at the extremity; the lower portion, which constitutes part of the style (called by Th. Martius⁷ *Föminelle*), is narrow, capillary, yellowish. The odour is penetrating, aromatic, and, of large quantities, narcotic. The taste is bitter, somewhat aromatic. When chewed, saffron tinges the mouth and the saliva yellow.

It consists of triparted red filaments having an orange colour; the segments dilated at the apex. Moistened with water and rubbed on paper, it produces an intense orange-coloured stain. —*Ph. Lond.*

I find by careful examination that one grain of good commercial saffron contains the stigmata and styles of nine flowers; hence 4,320 flowers are required to yield one ounce of saffron.

a. *English saffron* (*crocus anglicus*) is no longer found in commerce.

β. *Spanish saffron* (*crocus hispanicus*) constitutes the best saffron of the shops. It is imported from Gibraltar (principally), Cadiz, Denia, Santander, and Malaga. From the concurrent accounts of pharmacologists it would appear that formerly Spanish saffron was spoiled by being dipped in oil to preserve it. But the saffron now imported from Spain has not been subjected to this treatment. Occasionally Spanish, as well as any other kind of saffron, is oiled by the dealers to give it an appearance of freshness.

γ. *French saffron* (*crocus gallicus*) is usually considered in commerce to be of second quality.

⁵ *Iliad*, xiv. 346.

⁶ Dillon, *Travels through Spain*.

⁷ *Pharmakognosie*, 1832.

It is the produce of Gatinais (*Gatinais saffron*) and Orléanais, which comprehend part of the departments of Seine-et-Marne and Eure-et-Loire, and the whole of the department of Loiret. The saffron of Angoulême is intermixed with the pale styles, and is the worst.¹ French saffron is shipped for England at Calais, Boulogne, and Havre.

Besides the preceding, several other varieties of saffron are mentioned by pharmacologists, but they are not distinguished in English commerce, and I am unacquainted with them. Such are *Austrian*, *Bavarian*, *Oriental*, and the *Sicilian saffron* (*C. austriacus*, *bavaricus*, *orientalis*, and *siciliensis*) mentioned by Murray,² Geiger,³ and others. The saffron of Lower Austria is said to be the best and most costly in Europe, but the produce is scarcely sufficient for the home consumption; and, therefore, saffron is imported into Austria. Austrian saffron is chiefly produced at Ravelsbach, Meissau, Eggendorf, Kirchbeg, and Wagram.⁴

From the Customs report⁵ it appears that saffron is occasionally imported into England from Hamburg, Antwerp, Genoa, Naples, and Bombay. But I am ignorant of its place of growth and quality. According to Gussone,⁶ *Crocus odoratus* yields Sicilian saffron. Dioscorides considered the saffron of Corycus (a mountain of Cilicia, in Asia Minor, now called *Curco*) to be the best, and that of Lyeia and Olympus to be of second quality; while Cyrenaic saffron, as well as that from Centuripinum (*Centorbe*) in Sicily, he declares to be the worst.

Cake saffron (*crocus in placenta*) was formerly prepared by compressing hay saffron. But the cakes now met with in the inferior shops are composed of Safflower (*Carthamus tinctorius*) and gum-water, made into a paste, and rolled out on a tin plate with a rolling-pin into oval cakes of 11 inches long, 10 inches broad, and about one-tenth of an inch thick. These are dried on brown paper in a stove. They are shining, and of a brownish-red colour. I can detect neither saffron nor marigolds (*Calendula officinalis*) in them. Their price is considerably less than that of good hay saffron. I am informed by a maker of cake saffron that there is only another person besides himself by whom this substance is made in London.

ADULTERATION.—To increase the weight of saffron, it is said to be sometimes intermixed with *sand* or *grains of lead*. To detect these, it is sufficient to scatter the saffron loosely over a sheet of white paper, when the sand or grains of lead fall out.

To give saffron flexibility and an appearance of freshness, as well as to augment its weight, it is sometimes damped or oiled. To detect either *water* or *oil*, a small portion of saffron should be subjected to pressure between folds of white blotting paper; if this become either moistened or greased, the adulteration is obvious.

Another adulteration practised on saffron is intermixing it with the petals of some plant; usually of *safflower* (*Carthamus tinctorius*), which is sometimes called *bastard saffron*. The safflower readily escapes the eye of a superficial observer. If rubbed with the moistened finger on paper, it produces a slightly yellow mark only, whereas genuine saffron causes a very intense orange-yellow stain. The fraud may also be detected by carefully examining the suspected portion by a magnifying glass. The fraud is the more easily detected if the suspected saffron be previously macerated in hot water. Genuine saffron consists of a filiform style, divided at one extremity into three long, convoluted, deep orange stigmata, which are a little dilated upwards and notched at the extremity. Safflower, on the other hand, is composed of florets, each consisting of a monopetalous, tubular, 5-toothed red corolla, inclosing 5 syngenesious stamina and a style. Moreover, the corolla is devoid of the softness and flexibility of the stigmata of saffron; but is, on the contrary, dry and brittle.

Other florets, or strips of petals, artificially dyed to give them colour, and greased with oil to render them supple, have been employed to adulterate saffron. Guibourt mentions the *marigold* (*Calendula officinalis*), *arnica*, and *soapwort* (*Saponaria*), as having been used for this purpose. By attention to the above-mentioned characters of saffron, the fraud may be readily detected. The dilated extremities of the stigmata of saffron are broader than the style: whereas the extremities of the divisions of a strip of a petal will usually be found narrower than the body of the strip.

⁴ Lindley, *Flora Medica*.

⁵ *Handb. der Pharm.*

⁶ *Trade List* for 1837-8-9

⁷ *Lib. i. cap. xxv.*

Genuine saffron, from which the colouring matter has been extracted, is sometimes found in commerce.¹ The sample which I have seen had the essential characters of the stigmata of saffron, but wanted the softness and flexibility of good saffron, and was somewhat darker coloured. It did not present the pale yellow filaments (styles) of ordinary saffron, and imparted no colour to spirit of wine.

Fibres of smoked beef are said to have been used for adulterating saffron.

COMMERCE.—The quantity of saffron on which duty (of 1s. *per lb.*) is paid is about 5,000 lbs. *per annum*. The places from which it is imported have been already mentioned. It is brought over in cases, barrels, and boxes.

COMPOSITION.—Saffron was analyzed, in 1811, by Vogel and Bouillon-Lagrange,² and in 1818 by Aschoff.³

	Vogel and Bouillon-Lagrange.	Aschoff.
Volatile oil	7.5	1.4
Wax	0.5	4.0
Polychroïte	65.0	52.0
Gum	6.5	10.4
Soluble albumen	0.5	—
Woody fibre	10.0	19.0
Water	10.0	10.0
Balsamic matter, soluble in ether and alcohol	—	2.0
Saffron	100.0	98.8

1. VOLATILE OIL OF SAFFRON. (*Oleum Croci*).—Obtained by distilling saffron with water. It is yellow, heavier than water, has a burning, acrid, somewhat bitter taste, and is slightly soluble in water. By keeping, it becomes white, solid, and lighter than water. On it depend probably the medicinal properties of saffron.

2. COLOURING MATTER: *Polychroïte* (so called from *πολύς*, many, and *χρῶς*, colour, in consequence of its being susceptible of numerous changes of colour).—By digesting the aqueous extract of saffron in alcohol, and evaporating the tincture to dryness, a substance is obtained which Bouillon-Lagrange and Vogel called *polychroïte*, but which Henry⁴ has separated into volatile oil and a bitter red substance (*polychroïte properly so called*). Pure polychroïte is pulverulent, bitter, scarlet-red, odourless, slightly soluble in cold water, much more so in hot water, readily soluble in alcohol and oils (both fixed and volatile), slightly soluble in ether. Sulphuric acid turns it blue, then lilac. Nitric acid makes it green, but the colour is very fugitive. The hypochlorites destroy the yellow colour of a solution of polychroïte.

CHEMICAL CHARACTERISTICS.—An aqueous infusion of saffron gives no indication of starch on the addition of a solution of iodine. The hypochlorites bleach it. Sulphuric and nitric acids act on it as on polychroïte above mentioned. Acetate of lead causes no precipitate. By evaporation, the infusion yields an extract from which alcohol removes the colouring matter and leaves a gummy substance.

PHYSIOLOGICAL EFFECTS.—Formerly, saffron was considered to be cordial, aromatic, narcotic, and emmenagogue. Some⁵ have accused it of causing laughing delirium; others⁶ have ascribed to its use great mental dejection; and several⁷ have declared that they have seen immoderate uterine hemorrhage produced by it, which, in the case referred to by Riverius, is said to have terminated fatally. But modern experience has proved that most of these statements are erroneous. Alexander⁸ swallowed four scruples of saffron without perceiving any obvious effects therefrom; and Wibmer⁹ took a drachm without observing the slightest effect.

By the long-continued use of saffron, the colouring particles become absorbed, and tinge the secretions, especially the urine and perspiration. In some instances, the *fœtus in utero* has been stained by it.¹⁰ The failure of Alexander to detect the yellow tinge in his secretions arose probably from the short time he had been using this medicine. Mr. Gibson¹¹ gave a considerable quantity of saffron to a pigeon, which thereby had its feces tinged, yet no perceptible alteration was produced in its bones.

¹⁰ *Experim. Essays*, p. 88, 1768.

¹¹ Wibmer, *op. cit.*

Headache, prostration of strength, apoplexy, and even death, have been ascribed to the inhalation of the vapour arising from large quantities of saffron; and perhaps correctly so, for it is well known that the odours of other plants (as the rose, the pink, &c.) act on some individuals as narcotic poisons.²

USES.—Saffron is employed, especially on the Continent, as a flavouring and colouring ingredient in various culinary preparations, articles of confectionery, liqueurs, &c. It was used by the ancients as a perfume as well as a seasoning agent.³

In the modern practice of medicine, it is used chiefly as a colouring ingredient. It is a popular remedy for assisting the eruption of exanthematous diseases; on the same principle, I suppose, that bird-fanciers give it to birds when moulting. It was at one time esteemed as an antispasmodic in asthma, hysteria, and cramp of the stomach; and was formerly used as an emmenagogue, and to promote uterine contractions and the lochial discharge. Lastly, it has been employed as a stimulant to the nervous system in hypochondriasis.

ADMINISTRATION.—It may be given in doses of from ten grains to a drachm, in the form of powder or pill. It is popularly used in the form of infusion or tea.

1. SYRUPUS CROCI, L. E. D.; *Syrup of Saffron*.—(Saffron [chopped fine, D.] ʒv [ʒx, E., ʒss, D.]; Boiling Distilled Water Oj; Sugar lbij [or as much as may be sufficient; Rectified Spirit, fʒijss or as much as may be sufficient, L.]. Macerate the saffron in the water for twelve hours, in a vessel lightly covered, then strain the liquor and add the sugar to it. To the syrup, when cold, add the spirit.)—It is employed principally for its colour.

2. TINCTURA CROCI, E. D.; *Tincture of Saffron*.—(Saffron, chopped fine, ʒij; Proof Spirit Oij [Oj, D.]. Macerate for fourteen days, strain, express, and filter, D.—This tincture is to be prepared like tincture of cinchona, either by percolation or by digestion, the former method being the more convenient and expeditious, E.)—Used as a colouring liquid. It is also employed as a stimulant and emmenagogue in doses of from fʒj to fʒij.

As a colouring and flavouring ingredient, saffron is a constituent of several other preparations.

70. *Iris florentina*, Linn.—Florentine Orris.

Sez. Syst. Triandria, Monogynia.
(Rhizoma.)

The orris root (*radix iridis florentina*) of the shops consists of the rhizomes of three species of *Iris*; namely, *I. florentina*, *I. pallida*, and *I. germanica*.⁴ They acquire their well-known violet odour while drying. They are brought to us in the decorated state, in casks, from Leghorn and Trieste.

Orris root consists, according to Vogel,⁵ of volatile oil, acrid resin, astringent extractive, gum, starch, and ligneous matter. Raspail⁶ detected in it crystals, which he considered to be those of oxalate of lime. The starch of orris root⁷ consists of elliptical-shaped particles, which form interesting objects for the polarizing microscope. Some of them consist of two mullar-shaped particles applied base to base. Most of them are cracked at the hilum, and even at their edges.

⁴ See the Reports of Borellus, Tralles, Forster, and others, quoted by Wibmer and Murray, *op. cit.*

⁵ Orfila, *Toxicol. Gén.*

⁶ Beckmann, *History of Inventions and Discoveries*, vol. i. p. 278.

⁷ According to Savi, orris root is collected in Italy indiscriminately from the three species named in the text. (F. G. Hayne, *Getreue Darst. u. Beschreib. der in d. Arzneykunde gebraucht. Gewächse*, Bd. xi. 1530.)

⁸ *Journ. de Pharm.* i. 431.

⁹ The following measurements, in parts of an English inch, of particles of starch of orris root, were made for me by Mr. George Jackson:—

Particles.	Length.	Breadth.	Particles.	Length.	Breadth.
1	0.0011	0.0010	5	0.0004	0.0004
2	0.0012	0.0006	6	0.0003	0.0002
3*	0.0009	0.0006	7	0.0002	0.0002
4	0.0006	0.0004			

The most prevalent-sized particle is marked thus *.

Schleiden¹ describes the starch particles of *Iris florentina* and kindred species as being perfectly hollow, and apparently cup-shaped.

Orris root is an acrid substance, and in full doses causes vomiting and purging. It is principally used on account of its violet odour. Thus *hair* and *tooth powders*, *perfumed oils*, &c., are frequently scented with it. Issue peas (*pois d'iris*) have been made of it. During teething, infants are sometimes permitted to rub their gums with, and bite, the rhizome; but the practice is objectionable, since it is not unfrequently attended with irritation of the mouth, and disorder of the stomach and bowels. Furthermore, the danger of the rhizome getting into the œsophagus or trachea is not to be overlooked. One fatal case of this kind is recorded.² Powdered orris root is sometimes used as an erbine.

A *tincture of orris root* (*tinctura iridis florentinæ*), prepared by digesting one part of powdered orris root in eight parts of rectified spirit, is used as a scent, and is frequently sold as *essence of violets*, or *eau de violettes*.

ORDER XIII. TACCACEÆ, Lindley.

CHARACTERS.—A small and imperfectly known order of endogenous plants, with tuberous roots, leaves with curved parallel veins, hermaphrodite regular flowers, a petaloid tubular, 6-parted perianth, 6 stamens, a 1-celled inferior ovary, and seeds with fleshy albumen.

PROPERTIES.—The tuberous roots are bitter and acrid, but by cultivation become larger and milder. They yield a large quantity of nutritive farina.

71. Tacca, Forster.

Sex. Syst. Hexandria, Monogynia.

(Radix; Farina.)

This genus contains two species, which deserve a short notice.

1. *TACCA PINNATIFIDA*, Roxb. Fl. Ind. ii. 172.—A native of the Moluccas and Malay countries. The tuberous roots are intensely bitter when raw, but yield a large quantity of beautifully white starch, used for puddings, cakes, and other articles of confectionery. The tubers "are the *tacca youy* of some navigators; they form an article of diet in China and Cochin China, as also in Travancore," where, according to Dr. Ainslie, they attain a large size, and are eaten by the natives, with some acid, to subdue their acrimony.³

2. *TACCA OCEANICA*, Nuttall, Amer. Journ. of Pharm. vol. ix. p. 306.—A native of Tahiti, and other islands of the South Sea. Until Mr. Nuttall pointed out its peculiarities, it was supposed to be identical with *T. pinnatifida*. Ellis⁴ says that the "*pia*, or arrow-root, *chaitea tacca*" grows on the high sandy banks near the sea, or on the sides of the lower mountains.

The tuberous roots yield a highly nutritious fecula. At Tahiti (Otaheite), this fecula is procured by washing the tubers, scraping off their outer skin, and then reducing them to a pulp by friction on a kind of rasp made by winding coarse twine (formed of the cocoa-nut fibre) regularly round a board.⁵ The pulp is washed with sea-water through a sieve, made of the fibrous web which protects the young frond of the cocoa-nut palm. The strained liquor is received in a wooden trough, in which the fecula is deposited; and the supernatant liquor being poured off, the sediment is formed into balls, which are dried in the sun for 12 or 24 hours, then broken and reduced to powder, which is spread out in the sun to dry.⁶

Tacca starch, or *Tahiti arrow-root*, sometimes called *Otaheite salep*,⁷ is imported into London, and sold as "Arrow-root, prepared by the native converts at the Missionary stations in the South Sea Islands." It is a white amylaceous powder, with a slightly musty odour. Examined by the microscope, I find it to consist of particles⁸ which appear circular, mullar-shaped, or polyhedral. Some of the mullar-shaped particles are slightly narrowed at the base. Moreover, the base of the mullar, instead of being flat, appears to me to be hollowed out. The hilum is

¹ *Principles of Scientific Botany*, pp. 15-16, translated by Ed. Lankester, M. D., 1849.

² Kraus, *Heilmittellehre*, S. 541.

³ Royle, *Illustrations of the Botany of the Himalayan Mountains*, p. 378.

⁴ *Polynesian Researches*, vol. i. p. 361, 1829.

⁵ Ellis states that the rind of the root is scraped off by a courie shell, and the root then grated on a piece of coral.

⁶ Matthews, *Gardener's Magazine*, vol. viii. p. 585, Lond. 1832.

⁷ Rees's *Cyclopædia*, art. *Tacca pinnatifida*.

⁸ The following measurements, in parts of an English inch, of the particles of *Tacca starch*, were made for me by Mr. George Jackson:—

Particles.	Length.	Breadth.	Particles.	Length.	Breadth.
1	0.0012	0.0009	4	0.0006	0.0005
2	0.0011	0.0009	5	0.0004	0.0004
3*	0.0008	0.0007	6	0.0003	0.0003

The most prevalent-sized particle is marked thus *.

small and circular; it cracks in a linear or stellate manner. The rings are few and not very distinct.

This fecula is used as a substitute for the West Indian Arrow-root, to which it would probably be equal if it were prepared with equal care. Its composition, like that of other starches, is presumed to be $C^{12}H^{10}O^{10}$.

ORDER XIV. AMARYLLIDACEÆ, Lindley.—AMARYLLIDS.

NONE of the plants of this order are employed in England as articles of the *Materia Medica*. Yet many of them act powerfully on the system, and one of them (*Hæmanthus toxicarius*) is said to be used by the Hottentots to poison their arrow-heads. The prevailing property of the order is acidity, which is possessed principally by the bulbs, several of which (as those of *Panacium maritimum* and *Hæmanthus coccineus*) seem to be endowed with properties very similar to those of squill. The leaves and flowers of *Narcissus Pseudo-Narcissus* or *Daffodil* are enumerated among the simples of the French *Codex*. In doses of 20 or 30 grains they sometimes cause vomiting. They have been employed in spasmodic affections (as whooping-cough), in diarrhœa, and in agues.¹ Several other species of *Narcissus*, as *N. Tazetta* and *N. odorus*, also possess emetic properties.² *Narcissus Tazetta*, the *Italian* or *Polyanthus Narcissus*, is supposed by Dr. Sibthorp to be the *Narcissus* of the poets. The root and succulent leaves of the *Agave Americana* or *American aloe*, a native of Tropical America, yield a saccharine juice which lathers like soap, and when fresh is said to be laxative, diuretic, and emmenagogue. By fermentation it yields an acid liquor. The ligneous fibres of the leaves and roots are used as a thread (*pita thread*).

ORDER XV. MUSACEÆ, Agardh.

CHARACTERS.—Leaves with veins curved, and proceeding from the midrib to the margin (*curved veined*). *Perianth* 6-parted, adherent, petaloid, irregular; *Stamens* normally 6, by abortion usually 5; *Anthers* 2-celled. *Ovary* inferior, 3-celled. *Fruit* 3-celled. *Seed* albuminous.

PROPERTIES.—An important order of endogens, whose fruits (bananas and plantains) form a valuable article of food in some tropical regions.

72. *Musa sapientum*, Linn.—Plantain; Banana.

Sex. Syst. Pentandria, Monogynia.³

(Fructûs; Amylum.)

Plantains (*Musa paradisiaca*, Linn.) and Bananas (*Musa sapientum*, Linn.) are probably only varieties of the same species. The former have a stem wholly green, and persistent male flowers; the latter have a spotted stem, deciduous male flowers, and shorter and rounder fruit. Numerous varieties of each are cultivated in the tropical parts of Asia, Africa, and America; the wild parent is found at Chittagong, and other parts of tropical Asia. The fruit is a berry, and in the unripe state abounds in starch; but during maturation this disappears, being converted into a mucilaginous substance and this into sugar, so that in the ripe fruit not an atom of starch can be detected.⁴

Boussingault⁵ analyzed the ripe fruit of *Musa paradisiaca*, and found in it *sugar, gum, malic, gallic, and pectic acids, albumen, and lignin*.

Plantains and bananas form important and valuable articles of food to the inhabitants of many tropical regions. "But for plantains," says Dr. Wright,⁶ "Jamaica would scarcely be habitable, as no species of provision could supply their place. Even flour, or bread itself, would be less agreeable and less able to support the laborious negro, so as to enable him to do his business, or to keep in health."

Humboldt⁷ calculates that, as 33 lbs. of wheat and 99 lbs. of potatoes require the same space as that in which 4,000 lbs. of bananas are grown, the produce of bananas is consequently to that of wheat as 133.1, and to that of potatoes as 44.1.

Dr. Shier,⁸ in an interesting report on the starch-producing plants of British Guiana, has given

¹ Mérat and De Lens, *Dict. de Mat. Méd.* t. iv.

² De Candolle, *Essai sur les Propriétés Méd.*

³ I have followed Roxburgh (*Fl. Indica*, vol. i.) in referring this genus to Pentandria, Monogynia. In Reichard's edition of Linnæus's *Systema Plantarum* (1780), it is placed in Polygamia, Monogynia; and in Loudon's *Encyclopædia of Plants*, it is referred to Hexandria, Monogynia.

⁸ Report on the Starch-producing Plants of the Colony of British Guiana, Demerara, 1847; also, *Pharmaceutical Journal*, vol. vii. p. 193, 1847.

us some interesting details respecting the plantain. He states that "a new plantain walk in this colony will yield 450 bunches of 50 lbs. each, of which, as nearly as possible, 50 per cent. will be core, containing 17 per cent. of starch, thus producing 17 cwt. of starch per acre." I am indebted to this gentleman for specimens of the *sliced plantain core dried*, *plantain meal*, and *plantain starch*, prepared in April 1847.

Fig. 222.

The Plantain.

Fig. 223.

The Banana.

a. Sliced Plantain core.—The sample sent to me by Dr. Shier was prepared in April, 1847. It was obtained by stripping off the husk of the plantain, slicing the core, and drying it in the sun. The dried slices, as I have received them, are segments of circles from $\frac{1}{2}$ to $\frac{3}{4}$ of an inch in diameter, and $\frac{1}{8}$ to $\frac{1}{4}$ of an inch in thickness. Their prevailing tint is whitish, like that of dried slices of colchicum corni, but marbled with reddish veins. Their odour is fragrant, and somewhat similar to that of orris root. Their taste is farinaceous.

β. Plantain meal; Conquin-tay.—Obtained by powdering and sifting the thoroughly dried sliced plantain core. It is known among the creoles of the colony by the name of *Conquin-tay*. It is a whitish meal, speckled with minute dark-reddish spots. Its odour is fragrant, and similar to that of orris root (Dr. Shier says it resembles fresh hay or tea). Its taste is bland, like that of common wheat flour. When examined by the microscope, it is seen to consist chiefly of starch grains. According to Dr. Shier's statement, plantain meal contains about 68 per cent. of starch. 100.0 parts of plantain meal yielded Dr. Shier 0.88 parts of nitrogen. If this number be multiplied by 6.5 (see *ante*, p. 106, foot-note), we have 5.72 as the per centage amount of proteinaceous matter (albumen, gluten, &c.) contained in plantain meal.

It is obvious, therefore, that plantain meal must be greatly superior to the pure starches, inasmuch as it contains blood- and flesh-making principles which the latter are devoid of. Dr. Shier states that it is easy of digestion, and that it is largely employed in British Guiana as the food of infants, children, and invalids; but it will not serve for the manufacture of maccaroni, as this, when made from it, falls to powder when put into hot water. The same authority tells us that the plantain yields about 20 or 25 per cent. of meal.

γ. Plantain starch.—This is obtained from the plantain by rasping and washing; but owing to the flesh-coloured tissue in which the starch is imbedded being somewhat denser than the latter, it settles below the starch, and it is somewhat difficult to separate completely the finer parts of it from the starch; hence the latter is not perfectly white. The plantain yields about 17 per cent. of starch. Examined by the microscope, I find the starch grains¹ to be flat, transparent disks, like those of the starch of Zingiberacæ; hence they have but little lateral shading, and when superimposed the contour of the lower grains can be seen through the upper ones. Their shape is more or less elliptical and ovate, the extremity at which the so-called nucleus or hilum is placed being narrower than the opposite one. When viewed edgewise, their shape appears to be linear, and the lateral shading is stronger.

¹ The following measurements, in parts of an English inch, of the particles of plantain starch (prepared by Dr. Shier, of Demerara) were kindly made for me by Mr. George Jackson:—

Particles.	Length.	Breadth.	Particles.	Length.	Breadth.
1	0.0020	0.0013	5*	0.0013	0.0008
2	0.0018	0.0009	6	0.0009	0.0006
3	0.0016	0.0010	7	0.0007	0.0005
4*	0.0014	0.0007	8	0.0005	0.0003

The most prevalent-sized particles are marked thus *.

The lines or segments of rings seen on the flat surfaces of the grains do not extend to the edges of the grain, nor do they surround the hilum. When examined by the polarizing microscope, these grains present the well-known crosses. In its chemical, dietetical, and medicinal properties, the starch of the plantains agrees with those of other starches.

ORDER XVI. MARANTACEÆ, *Lindl.*

CANNACEÆ, *Agardh.*

CHARACTERS.—*Calyx* superior, of 3 sepals, short. *Corolla* tubular, irregular, with the segments in 2 whorls; the outer 3-parted, nearly equal, the inner very irregular; one of the lateral segments usually coloured, and formed differently from the rest; sometimes by abortion fewer than 3. *Stamens* 3, petaloid, distinct, of which one of the lateral and the intermediate one are either inactive or abortive, and the other lateral one fertile. *Filament* petaloid, either entire or 2-lobed, one of the lobes bearing the anther on its edge. *Anther* 1-celled, opening longitudinally. *Pollen* round (papillose in *Canna coccinea*, smooth in *Calathea zebrina*). *Ovary* 1-3-celled; *ovules* solitary and erect, or numerous and attached to the axis of each shell; *style* petaloid or swollen; *stigma* either the mere denuded apex of the style, or hollow, hooded, and incurved. *Fruit* capsular, as in Scitamineæ. *Seeds* round, without aril; *albumen* hard, somewhat starchy; *embryo* straight, naked, its *radicle* lying against the hilum. *Herbaceous* tropical plants, destitute of aroma. *Rhizome* often tuberous, and abounding in starch. *Stem* often branching. (*Lindley*.)

PROPERTIES.—The rhizomes frequently abound in starch.

73. MARANTA ARUNDINACEA, *Linn.*—THE WEST INDIAN ARROW-ROOT.

Sex. Syst. Monandria, Monogynia.

(*Tuberis fœcula.* *Ph. Lond.*—*Fœcula* of the tubers; Arrow-root. *Ed., D.*)

HISTORY.—This plant was brought from the island of Dominica, by Colonel James Walker, to Barbados, and there planted. From thence it was sent to Jamaica. That gentleman observed that the native Indians used the root against the poison of their arrows, by mashing and applying it to the poisoned wounds.¹

The valuable properties of the starch made from the root are mentioned by Hughes,² in 1751, and the mode of procuring it described by Browne,³ in 1789.

BOTANY. *Gen. Char.*—*Corolla* unequal, one of the inner segments in the form of a lip. *Stamens* petaloid, with half an anther on its edge. *Style* hooded, adhering to the edge of a sterile filament. *Ovary* 3-celled, smooth; *ovules* solitary. *Fruit* even, dry, 1-seeded.—Caulescent plants with fleshy *rhizomata* or *tubers*. *Stems* branched, often dichotomous. *Inflorescence* terminal, paniced, jointed, with glumaceous, deciduous *bracts*. (*Lindley*.)

Sp. Char.—*Culm* branched, herbaceous. *Leaves* ovate, lanceolate, somewhat hairy underneath. *Peduncles* 2-flowered (*Willdenow*).

Rhizome white, articulated, tuberous, placed horizontally in the earth, and giving origin to several tuberous jointed stoles (*stolones tuberosi*), similar to itself, but covered with scales. Those stoles are often more than a foot long, and curved, so that the points rise out of the earth and become new plants (*Nees and Ebermaier*). *Stem* two or three feet high. *Leaves* alternate, with long, leafy, hairy sheaths. *Flowers* white and small.

The *Maranta indica*, Tussac,⁴ E., is characterized by its leaves being smooth on both sides, and by its seeds; those of *M. arundinacea* being violet. But, after a careful examination, Wickström declares that Tussac's plant is identical with the *M. arundinacea*, Linn.⁵

Hab.—West Indies. It is cultivated both in the West and East Indies, Ceylon, Sierra Leone, &c.

COMPOSITION OF THE ROOT.—According to P. C. Benzon,⁶ the root of the *Maranta*

¹ Sloane's *Jamaica*, vol. i. p. 254.

² *The Natural History of Barbados*, p. 221, 1750.

³ *The Civil and Natural History of Jamaica*, p. 112, 1789.

⁴ *Journ. Bot.* iii. 41.

⁵ *Nees v. Esenb. and Eberm. Handb. d. Med. pharm. Bot.*

⁶ *Buchner's Repertorium für die Pharmacie*, Bd. xvi. S. 255, 1823.

has the following composition: *volatile oil*, 0.07; *gummy extract*, 0.50; *starch*, 26.00; *woody fibre*, 6.00; *albumen*, 1.58; *muriate of lime*, 0.25; and *water*, 65.600.

The per centage quantity of starch obtained from the root has been thus stated by other authorities: 7.81 (Dr. J. Clark),¹ 12.5 (De Candolle),² 21.43 (Dr. Shier³ from roots scarcely ripe).

EXTRACTION OF THE FECULA.—The starch, or fecula, is extracted from the roots (tubers) when these are about ten or twelve months old. The process is entirely a mechanical one, and is performed either by hand or by machine.

In Jamaica, it is procured as follows: The tubers are dug up, well washed in water, and then beaten in large, deep, wooden mortars to a pulp. This is thrown into a large tub of clean water. The whole is then well stirred, and the fibrous part wrung out by the hands and thrown away. The milky liquor being passed through a hair-sieve, or coarse cloth, is suffered to settle, and the clear water is drained off. At the bottom of the vessel is a white mass, which is again mixed with clean water and drained; lastly, the mass is dried on sheets in the sun, and is pure starch.⁴

In Bermuda⁵ the roots are first deprived of their paper-like scales, and then rasped by a kind of wheel-rasp (something like Fig. 224, p. 228), and the fecula well washed through sieves and carefully dried.

Upon the Hopewell estate, in the Island St. Vincent,⁶ the carefully-skinned tubers are washed, then ground in a mill, and the pulp washed in tinned-copper cylindrical washing-machines. The fecula is subsequently dried in drying houses. In order to obtain the fecula free from impurity pure water must be used, and great care and attention paid in every step of the process. The skinning or peeling of the tubers must be performed with great nicety, as the cuticle contains a resinous matter, which imparts colour and a disagreeable flavour to the starch. German silver palettes are used for skinning the deposited fecula, and shovels of the same metal for packing the dried fecula. The drying is effected in pans covered by white gauze to exclude dust and insects.

COMMERCE.—Arrow-root is brought, in tin cases and in barrels and boxes, from the West India Islands (Jamaica, Barbados, Antigua, St. Vincent, Dominica, Bermuda, St. Kitt's, Grenada, Demerara, and Berbice), Calcutta, and Sierra Leone.

The packages of West-Indian arrow-root sent to this country are lined with paper attached with arrow-root paste. When sent to this country in the hold of the ship, their contents are easily tainted by noisome effluvia.

Arrow-root is usually distinguished by the name of the island or place producing it; as *Bermuda arrow-root*, *St. Vincent's arrow-root*, *Jamaica arrow-root*, *African or Sierra-Leone arrow-root*, &c. Bermuda arrow-root is the most esteemed variety. In 1845, about 400,000 lbs. were manufactured, of which more than three-fourths came to England. Dr. Ure says that the St. Vincent's arrow-root prepared on the Hopewell estate vies with the Bermuda sort.

In commerce, the term *arrow-root* is frequently used generically to indicate a starch or fecula. The following are illustrations of its use in this way:—

Portland Arrow-root is obtained from *Arum maculatum* (see *ante*, p. 158).

East India Arrow-root is the fecula procured from *Curcuma angustifolia*, and will be described hereafter. But the West Indian plant (*Maranta arundinacea*) is also cultivated in the East Indies, and the fecula obtained therefrom is exported from thence, and might with equal propriety be called *East India arrow-root*.

Brazilian Arrow-root is the fecula of *Jatropha Manihot*, and will be noticed hereafter (vide **EUPHORBIACEÆ**).

Tahiti Arrow-root is the fecula of *Tacca oceanica*, and has already been noticed (see *ante*, p. 221).

⁵ Cogswell, in *Cornack's Monthly Journal of Medical Science*, vol. v. p. 789, 1845.

⁶ *Recent Improvements in Arts and Manufactures*, by A. Ure, M. D., 1844.

PROPERTIES.—The starch or fecula (*amylum vel fœcula marantæ*), called in the shops *West Indian arrow-root*, or simply *arrow-root*, is white, odourless, and tasteless. It is in the form either of a light opake white powder, or of small pulverulent masses. When passed between the fingers, it feels firm, and, when rubbed, produces a slight crackling noise. When viewed by a good pocket lens, it is seen to consist of glistening particles. When examined by a microscope, these are seen to be convex, more or less elliptical, and moderately uniform in size.¹ The shape is more or less irregular, but often oblong, or usually somewhat ovate-oblong, frequently obscurely triangular, or oyster-shaped, or mussel-shaped.² After having been digested for a short time in water, one, or rarely two, mammillary processes are, in some samples, seen projecting from the surface of some of the particles. In some specimens, these processes have appeared like short spines. The rings are very distinct, though fine. The nucleus, central cavity, or hilum is usually very distinct, generally towards one end of the particle normally circular, but frequently cracked in a linear or stellate manner. When viewed by the polarizing microscope, the particles show very distinct crosses: the junction of the arms of the cross indicates the position of the hilum.

COMPOSITION OF THE STARCH.—Arrow-root has been analyzed by Dr. Prout³ and by Payen,⁴ who obtained the following results:—

PROUT.				PAYEN.		
	Air dried.	Dried between 200° and 212° for 20 hours.	Dried at 212° for 6 hours longer.		Portion most easily dis-aggregated, dried at 212° F.	Amidon intact purified by alcohol & water, and dried at 38° F.
Carbon	36.4	42.8	44.4	Carbon	44.3	44.33
Water	63.6	57.2	55.6	Hydrogen	6.2	6.25
				Oxygen	49.5	49.42
Arrow-root	100.0	100.0	100.0	Arrow-root	100.0	100.00

The formula which agrees with Prout's third analysis is $C^{12}H^{10}O^{10}$.

Dr. Prout regards arrow-root as a low variety of starch analogous to the low sugar of honey; while wheat-starch he considers to be the most perfect form of starch, analogous to sugar-candy.

SUBSTITUTIONS, IMPURITIES, AND ADULTERATIONS.—The presence of accidental impurities (such as insects, dust, &c.) may be readily detected by alterations in the colour, odour, and flavour of the arrow-root.

Other cheaper feculas are sometimes substituted for the genuine arrow-root; especially sago-meal, potato-starch, and tapioca-starch or Brazilian arrow-root.

The fraud is readily detected by the microscope.⁵ When squeezed in the hand, the sago-meal crackles like arrow-root; but when submitted to microscopic examination, the truncated extremity of many of the particles giving them either a mullar shape or dihedral summit, the irregular or tuberculated surface, and the size of the particles, readily served to distinguish it from arrow-root.

¹ The following measurements, in parts of an English inch, of the particles of West India arrow-root, were kindly made for me by Mr. George Jackson:—

Particles.	Length.	Breadth.	Particles.	Length.	Breadth.
1	0.0020	0.0013	4	0.0008	0.0005
2	0.0012	0.0009	5	0.0006	0.0004
3*	0.0010	0.0008	6	0.0005	0.0003

The most prevalent-sized particle is distinguished thus*.

² Schleiden (*Principles of Scientific Botany*) describes the granules as being compound, without evident central cavity, and always exhibiting the smooth connecting surfaces; but this description does not apply to commercial West Indian arrow-root.—Raspail has depicted the grains of the fecula of *Convolvulus Batatas* for arrow-root (see Payen, *Ann. Sci. Nat. 2de Sér. t. x. Botanique*, p. 18, 1838).

³ *Phil. Trans.* 1827.

⁴ *Ann. des Sci. Nat. 2de Sér. Botanique*, 1838, pp. 183-184.

⁵ *Lancet*, Feb. 1, 1851.

Potato-starch is sometimes sold for West Indian arrow-root. I have met with it in commerce under the name of English arrow-root. It is devoid of the dull or dead white appearance presented by West India arrow-root. The naked eye, or still better a pocket lens, readily distinguishes its large glistening particles from those of genuine arrow-root. The microscope instantly detects the difference. The particles of potato-starch are larger than those of arrow-root, and have coarser and more distinct rings. Moreover, the shape of the particles serves to distinguish them (see *Potato-starch*). Lampadius¹ observed that potato-starch evolves a peculiar odour when boiled with water and sulphuric acid, and that arrow-root does not evolve this odour when treated in a similar way. Arrow-root, moreover, "is destitute of that fetid, unwholesome oil, extractible by alcohol from potato-starch."² Mixed with one and a half, or twice its weight, of concentrated hydrochloric acid, arrow-root yields an opaque paste, whereas that produced by potato-starch is transparent. Arrow-root takes a longer time than potato-starch to become viscid when mixed with equal parts of acid and water.³

Other kind of feculas, which are said to have been substituted (on account of their cheapness) for the genuine arrow-root, such as East India arrow-root or Curcuma starch (see *Curcuma angustifolia*), and Brazilian arrow-root or tapioca-starch (see *Jatropha Manihot*), are readily distinguishable by the microscope.

PHYSIOLOGICAL EFFECTS.—By the Indians of South America, and even by some Europeans, the roots (tubers) have been supposed to possess alexipharmic properties⁴ But their chief if not their only real value is that of yielding the starch called *arrow-root*, which is a much esteemed non-nitrogenized alimentary principle, which, like some other agents of this kind (see vol. i. p. 116), are useful in the animal economy for the production of fatty and saccharine matters, lactic acid, and heat. Arrow-root is one of the most palatable and digestible of the starches.

USES.—The roots (tubers) have been used by the South American Indians to counteract the effects of wounds inflicted by poisoned arrows. Very recently⁵ the expressed juice of the root has been lauded as an antidote to poisons taken into the stomach, and to the bites and stings of venomous insects and reptiles.

The starch or *arrow-root* is employed at the table as an article of food, in the forms of puddings. It forms an agreeable, non-irritating diet for invalids or infants. In irritation of the alimentary canal, of the pulmonary organs, or of the urinary apparatus, it is especially valuable as a nutritive, emollient, and demulcent.

ADMINISTRATION.—To invalids and infants arrow-root (the starch) is exhibited when boiled in water or milk and flavoured. Milk disagrees with some patients, and in such is of course to be avoided. The addition of sugar improves the flavour and increases the nutritive qualities. Spices, lemon juice, or wine may be employed according to circumstances.

74. *Canna edulis*, Ker.—Tous-les-Mois?

Sex. Syst. Monandria, Monogynia.

(Canna. Fecula of the root of an imperfectly determined species of *Canna*. *Tous-les-Mois*, E.—The root is supposed to furnish the fecula called *Tous-les-Mois*, D.)

The starch or fecula called *Tous les-Mois* was introduced to the notice of the British public by the late Mr. Olpherts⁶ of St. Kitts, about 1836. It was at first stated to be the produce of *C. coccinea*; but as this species, like *C. indica*, has fibrous, and not tuberous roots, it is tolerably clear that this cannot be the source of the starch in question.

There is good reason for believing that *C. edulis* of Ker is a native of the West Indies, and that it is the species which yields *tous les-mois*. Descourtiz⁷ and Lunan⁸ speak of a species of

⁷ *Fl. Méd. des Antilles*, p. 3, tab. 210.

⁸ *Hortus Jamaicensis*, vol. ii. p. 417.

Canna with fleshy tubercous roots, which grows in the West Indies, and which they call *C. indica*. But the character of the roots just mentioned shows that the West Indian plant is not *C. indica*, Linn. Ruiz and Pavon¹ speak of a South American plant which they term *Canna indica* of Linnæus, whose fleshy tubers are eaten by the Peruvians, who call the plant *Achira*. They considered it to be the *C. Indica* of Linn. But when their herbarium came into Mr. Lambert's possession, he raised plants from the seeds of the original specimens, and found the species to be a new one, which he named *C. edulis*.²

Mr. Lambert afterwards received seeds, from Dr. Gillies of Mendoza, of a *Canna* known in South America as "*Achira*." This has been described and figured³ as a new species under the name of *C. Achiras* (more properly *C. Achira*); but it is not improbable that it may prove to be identical with *C. edulis*.

C. glauca is also said to yield a valuable starch.⁴

My friend Mr. Wordsworth, assistant-surgeon to the London Hospital, and who resided some time at St. Kitts, tells me that he cultivated the *Tous-les-Mois* in his garden. Its height was about 4 feet; and its tubers three or four times the size of the fist. In order to extract the fecula, the tubers are rasped by means of a circular or wheel-rasp⁶ worked by a treddle. The tuber is held against the edge of the rasp, at the point marked *a* in the accompanying figure. The starch is obtained from this pulp by the ordinary methods of washing, straining, decantation of the supernatant liquor, and desiccation of the deposited starch.

Fig. 224.

Wheel-rasp used for rasping the tubers of the *Tous-les-Mois* plant.

The quantity of starch procured from the roots of the *tous-les-mois* plant has not been satisfactorily ascertained. Ricord Madianna⁶ obtained from a pound of the root two ounces of a starch of fine quality: this is equal to 12.5 per cent. It is probable, however, that

on the large scale the product would be much greater.

Tous-les-mois starch is imported from St. Kitts. To the naked eye it greatly resembles potato-starch. On account of the large size of its particles, it has a satiny or glistening appearance, and is devoid of that dead white or opaque appearance presented by the West Indian arrow-root. Examined by a pocket lens, the sparkling and glistening appearance of its particles is very obvious. When submitted to examination by means of the compound microscope, its particles are seen to be very large⁷ (in this respect exceeding those of all other starches), somewhat egg-shaped, to have a very distinct nucleus, central cavity, or hilum, and concentric rings indicative of their laminated structure. Strictly speaking, their shape is oval or oblong; but generally more or less ovate. The circular hilum is usually placed at the narrow extremity; very rarely it is double; once I have seen it treble. The rings are numerous, regular, close, but somewhat unequally so. The hilum and the body of the particle are frequently cracked.

Potato-starch is the only amylaceous substance which can be confounded with *tous-les-mois*. The two starches may be distinguished by a careful attention to their relative sizes and shapes, to the appearance of their rings, the position of the hilum, and the action of polarized light on them.

First, the particles of potato-starch are on the average smaller than those of *tous-les-mois*, and are subject to greater irregularity of size (both as regards different sorts of potatoes and the different particles of the same potato).

Secondly, the larger particles of potato-starch are more irregular in shape than those of *tous-les-mois*; the latter are more constantly rounded or oblong or ovate-oblong; the former are oval, often approximating in shape to an oyster-shell, a mussel-shell, or a triangle with rounded corners, and being frequently gibbous or tumid at different parts of their surface.

Thirdly, the rings seen on particles of *tous-les-mois* are fine, regular, uniform, concentric, and

¹ *Flora Peruviana*.

² *Ibid.* tab. 1358.

³ *Piso (Hist. Nat. Brasiliae, p. 53, 1648)* represents a somewhat similar machine as being used in the preparation of cassava or tapioca starch.

⁶ *Journ. de Pharmacie, t. xvi. p. 306, 1830.*

⁷ The following measurements, in parts of an English inch, of the particles of "*tous-les-mois*," were made for me by Mr. George Jackson:—

² *Botanical Register, tab. 7.*

⁴ *Bennett, Ceylon and its Capabilities, p. 127, 1843.*

Particles.	Length.	Breadth.	Particles.	Length.	Breadth.
1	0.0042	0.0035	4*	0.0032	0.0020
2	0.0037	0.0026	5*	0.0025	0.0017
3*	0.0031	0.0027	6	0.0013	0.0010

The most prevalent-sized particles are those marked thus *.

crowded; those of potato-starch are coarser, irregular, often excentric, irregularly drawn out, distorted, or more and unequally distant from each other. In potato-starch a greater number of complete rings is visible, and we can trace the lines around the hilum, even in the case of many of the larger rings; but in *tous-les-mois* this can be done with a very few of the smaller rings only.

Fourthly, in both the hilum is situated nearer to the end of the particle; but in potato-starch this character is less obvious, the hilum frequently being less distant from the centre of the particle than in the case of *tous-les-mois*.

Lastly, when viewed by polarized light the cross is less frequently regular in potato-starch than in *tous-les-mois*; in the former, the arms are often distorted.

Tous-les-mois of commerce contains about 16.74 per cent. of hygroscopic water. It is very soluble in boiling water; and, according to Dr. Shier's experiments, yields a jelly, which is considerably more tenacious than the jelly of any other starch; but which, in clearness or translucency, is inferior to that of arrow-root, and of some other substances.

The composition of *tous-les-mois* starch is assumed to be the same as that of other starches, viz., $C^{12}H^{10}O^{10}$.

In its dictetical qualities *tous-les-mois* resembles other starches (see vol. i. p. 116). It yields very agreeable articles of food for invalids and others, and appears to be very readily digested.

ORDER XVII. ZINGIBERACEÆ, Lindl.—GINGERWORTS.

DRYMYRHIZÆ, Vent.—SCITAMINEÆ, R. Brown.

CHARACTERS.—*Calyx* superior, tubular, 3-lobed, short. *Corolla* tubular, irregular, with 6 segments in 2 whorls; the *outer* 3-parted, nearly equal, or with the odd segment sometimes differently shaped; the *inner* (sterile stamens) 3-parted, with the intermediate segment (*labellum*) larger than the rest, and often 3 lobed, the lateral segments sometimes nearly abortive. *Stamens* 3, distinct, of which the 2 lateral are abortive, and the intermediate one fertile; this placed opposite the *labellum*, and arising from the base of the intermediate segment of the *outer* series of the *corolla*. *Filament* not petaloid, often extended beyond the anther in the shape of a lobed or entire appendage. *Anther* 2-celled, opening longitudinally, its lobes often embracing the upper part of the style. *Pollen* globose, smooth. *Ovary* 3-celled, sometimes imperfectly so; *ovules* several, attached to a placenta in the axis; *style* filiform; *stigma* dilated, hollow. *Fruit* usually capsular, 3-celled, many seeded [sometimes by abortion 1-celled]; occasionally berried (the dissepiments generally central, proceeding from the axis of the valves, at last usually separate from the latter, and of a different texture, *R. Br.*). *Seeds* roundish or angular, with or without an aril (*albumen* floury, its substance radiating, and deficient near the hilum, *R. Br.*); *embryo* enclosed within a peculiar membrane (*vitellus*, *R. Br. Prodr. membrane of the amnios*, *ibid.* in King's Voyage, 21), with which it does not cohere.—Aromatic, tropical, *herbaceous* plants. *Rhizome* creeping, often jointed. *Stem* formed of the cohering base of the leaves, never branching. *Leaves* simple, sheathing their *lamina*, often separated from the sheath by a taper neck, and having a single midrib, from which very numerous, simple, crowded veins diverge at an acute angle. *Inflorescence* either a dense spike, or a raceme, or a sort of panicle, terminal or radical. *Flowers* arising from among spathaceous membranous bracts, in which they usually lie in pairs. (*Lindley*.)

PROPERTIES—The rhizomes contain a volatile oil and resin, which confer on them aromatic or acro-aromatic qualities. Many of them abound in starch, the particles of which (like those of plantain starch, see *ante*, p. 223) are flattened disks. This is sometimes extracted and used as food. Some of them are remarkable for the yellow colouring matter which they yield.

The seeds also contain volatile oil and resin; and possess aromatic or acro-aromatic qualities.

75. ZINGIBER OFFICINALE, Roscoe.—THE NARROW-LEAVED GINGER.

Amomum Zingiber, Linn. D.
Sex. Syst. Monandria, Monogynia.
(*Rhizoma*, L. E.—*Radix*, D.)

HISTORY.—Dioscorides¹ and Pliny² speak of ginger: the former calls it ζιγγίβερις; the latter *zingiberi* and *zimgeri*.

BOTANY. **Gen. Char.**—*Corolla* with the outer limb 3-parted, inner 1-lipped. *Filament* lengthened beyond the anther into a simple incurved beak. *Capsule* 3-celled, 3-valved. *Seeds* numerous, arillate.—*Rhizocarpial* plants. *Rhizomes* tu-

¹ Lib. ii. cap. 190.

² *Hist. Nat.* lib. xii. cap. 14, ed. Vulp.

berous, articulated, creeping. *Stems* annual, enclosed in the sheaths of distichous leaves. *Leaves* membranous. *Spikes* cone-shaped, radical or rarely terminal, solitary, consisting of 1-flowered imbricated bracts (Blume¹).

Sp. Char.—*Leaves* sub-sessile, linear-lanceolate, smooth. *Spikes* elevated, oblong. *Bracts* acute. *Lip* 3-lobed. (Roxburgh.)

Rhizome biennial. *Stems* erect and oblique, and invested by the smooth sheaths of the leaves; generally three or four feet high, and annual. *Leaf-sheaths* smooth, crowned with a bifid ligula. *Scapes* solitary, six to twelve inches high. *Spikes* the size of a man's thumb. *Lip* dark purple. *Ovary* oval, with numerous *ovules*; *style* filiform; *stigma* funnel-shaped, eiliate. *Capsule* roundish, unilocular. *Seeds* numerous; mostly abortive.²

Hab.—Cultivated in the tropical regions of Asia and America, and at Sierra Leone. Native soil doubtful, probably Asia.

PREPARATION.—*Green ginger* is sometimes imported from Jamaica. It consists of soft and juicy rhizomes with buds; and appears to have undergone but little preparation beyond picking and washing.

The young shoots put forth every spring by the perennial rhizome are used in the manufacture of the delicious *preserved ginger* (*conditum zingiberis*). These shoots are carefully picked, washed, scalded, scraped, peeled, and then preserved in jars with syrup. (Dr. P. Browne.)

The finest preserved ginger is imported from Jamaica usually in jars. Barbados preserved ginger is seldom brought over. The China preserved ginger is stringy. It is sometimes imported in the dried state.

The dried rhizomes, called in the shops *ginger* (*radix zingiberis*), are prepared when the stalks are wholly withered, and the rhizomes are about a year old. In Jamaica, this happens in January or February. The rhizomes are dug up and separately picked, washed, and scraped; and afterwards dried in the sun and open air. (Dr. P. Browne.) The product is the uncoated ginger of the shops, formerly called *white ginger* (*zingiber album*).

The coated ginger of the shops has obviously not undergone this careful preparation. In Barbados, the rhizomes are dug up, scraped clean, and sun-dried.³ The *black ginger* (*zingiber nigrum*), formerly prepared in Jamaica, is obtained by pickling and cleaning the rhizomes, scalding them gradually in boiling water, and afterwards sun-drying them.⁴

DESCRIPTION.—The *rhizome*, called in commerce *ginger root* or simply *ginger* (*radix zingiberis*), occurs in flattish, jointed, branched, or lobed, palmate pieces, called *races* or *hands*, which rarely exceed four inches in length.

Barbados ginger, the old sorts brought from Malabar and Bengal, and African ginger, are covered by a dry, shrivelled epidermis commonly called the "coat;" hence these sorts are usually said to be *coated* or *unscraped*; whereas the ginger of Jamaica, and the new sorts which of late years have been brought from Malabar and Bengal, have been deprived of their epidermis, and are, therefore, said to be *uncoated* or *scraped*. The external colour varies in the different sorts from pale or bright yellow to dark or brown: the palest sort is the fine Jamaica ginger; the darkest being the Bengal old sort; and the other sorts being intermediate. Ginger breaks moderately short, but the fractured surface presents numerous projecting pointed fibres, imbedded in a mealy or farinaceous tissue. A transverse section of the larger and more perfect pieces shows an outer, horny, resinous-looking zone, surrounding a farinaceous centre, which has a speckled appearance from the cut extremities of the fibres and ducts. The internal varies like the external colour; the best ginger is that which cuts pale but bright. The consistence of ginger, as

¹ *Enumeratio Plantarum Javae.*

² Roxburgh, *op. cit.*; and Dr. P. Browne, *History of Jamaica.*

³ Hughes, *Nat. Hist. of Barbados*, p. 233, 1750.

⁴ Dr. P. Browne, *op. cit.*—According to Dr. Wright (*Lond. Med. Journ.* vol. viii.; also, *Memoir of the late Dr. Wright*, p. 185, 1828), two sorts of ginger are cultivated in Jamaica, viz., the white and the black; the latter has the more numerous and the larger roots.

ascertained by cutting, varies from soft to hard, or, as it is termed in trade, "flinty;" the soft being preferred. The taste of ginger is aromatic, hot, and biting; the odour of a fresh broken piece is peculiar and pungent, though aromatic.

VARIETIES.—Seven kinds of ginger, distinguished partly by their place of growth, and partly by their quality, are known in English commerce. Of these, two are from the West Indies, four from the East Indies, and one from Africa.

A. **West Indian Gingers.**—This division includes Jamaica and Barbados gingers.

1. *Jamaica ginger.*—Imported in barrels holding 1 cwt. each. It is an uncoated, pale sort, and when of fine quality occurs in large, bold, fleshy races, which cut soft, bright, and pale coloured. Inferior samples are small in the race, darker coloured, more or less flinty, and shrivelled.

2. *Barbados ginger.*—Imported in bags of about 60 or 70 lbs. It is a coated sort, in short, flat races, which are darker coloured than Jamaica ginger, and are covered with corrugated epidermis.

B. **East Indian Gingers.**—This division includes two sorts from Malabar and two from Bengal, all of which are more liable to be wormy than either the West Indian or African sorts.

a. **Malabar Gingers.**

3. *Coated Malabar Ginger; Unscraped Malabar Ginger; Old sort of Malabar Ginger; Common Malabar Ginger; Bombay Ginger.*—Imported from Bombay in bags or packets. It is a coated, dark, small sort.

4. *Uncoated Malabar Ginger; New sort of Malabar Ginger; Tellicherry Ginger; Calicut Ginger; Cochin Ginger.*—A pale, uncoated sort, imported in chests, casks, or bags, sometimes from Tellicherry, but usually from Calicut or Cochin. It resembles Jamaica ginger both in external appearance and flavour; but has externally more of a brownish or reddish tint. It first appeared in English commerce about 1841.

β. **Bengal Gingers.**

5. *Coated Bengal Ginger; Common Bengal Ginger; Old sort of Bengal Ginger.*—Imported in bags. It is a coated or unscraped dark sort, which cuts flinty and brownish, but is plumper and less wormy than common Malabar ginger.

6. *Uncoated Bengal Ginger; Scraped Bengal Ginger; New sort of Bengal Ginger; Calicut sort of Bengal Ginger.*—Imported in chests of about 1½ cwt. It is an uncoated sort, darker than Jamaica ginger. It is not so large as the uncoated Malabar sort, and is harder and darker.

C. **African Ginger.**—Only one kind of African ginger is known, viz., that from Sierra Leone.

7. *Sierra Leone Ginger; African Ginger.*—Imported in casks or bags. It is a coated sort; the races being generally larger, less flat, and less plump than those of the Barbados sort, which in other respects they resemble.

Chinese Ginger.—The Chinese ginger described by Bassermann¹ is unknown in English commerce; the only ginger imported into England from China being *preserved ginger*.

ASSORTMENT.—The uncoated gingers, namely, the Jamaica, uncoated Malabar, and uncoated Bengal, are assorted for commercial purposes, according to their qualities, somewhat thus—

- | | | |
|-----------------------------------|--|---|
| 1. Bold, soft, and bright ginger. | | 3. Flinty and dark. |
| 2. Smaller, but soft and bright. | | 4. Shrivelled, and only fit for grinding. |

The Barbados, African, and coated Malabar and Bengal gingers are usually sold unassorted.

The following are the quantities of ginger on which duty was paid for six years:—

¹ *Pharmaceutisches Central-Blatt* f2r 1835.

	British West Indies.	East Indies.	Total.
	cwts.	cwts.	cwts.
In 1835	6,496	867 =	7,363
1836	4,426	1,912 =	6,338
1837	9,157	3,520 =	12,677
1838	9,305	1,911 =	11,216
1839	6,357	818 =	7,175
1840	7,528	1,635 =	9,063

WASHED GINGER; BLEACHED GINGER.—Ginger is sometimes washed in water, and then dried, by wholesale dealers, prior to its being offered for sale to the retailers.

Some of the darker sorts are bleached by washing them in a solution of chloride of lime, and sometimes by exposing them to the fumes of burning sulphur. By this treatment the ginger acquires a chalky-white character, and is then often termed *white-washed* ginger.

Ginger is said¹ to be sometimes washed in whiting and water (or white-washed) under the pretence of preserving it from insects.

ADULTERATION.—Powdered ginger is said to be sometimes admixed with flour and other amylaceous substances. The microscope would readily detect the adulteration, except in the case of East Indian arrow-root (*Curcuma angustifolia*), the particles of which are similar in appearance to those of ginger.

COMPOSITION.—Ginger was analyzed in 1817 by Bucholz,² and in 1823 by Morin.³

<i>Bucholz's Analysis.</i>		<i>Morin's Analysis.</i>	
Pale yellow volatile oil	1.56	Volatile oil.	
Aromatic, acrid, soft resin	3.60	Acrid soft resin.	
Extractive, soluble in alcohol	0.65	Resin insoluble in ether and oils.	
Acidulous and acrid extractive, insoluble in alcohol	10.50	Gum.	
Gum	12.05	Starch.	
Starch (analogous to bassorin)	19.75	Woody fibre.	
Apothème, extracted by potash (ulmin?)	26.00	Vegeto-animal matter.	
Bassorin	8.30	Osmazome.	
Woody fibre	8.00	Acetic acid, acetate of potash, and sulphur.	
Water	11.90	The ashes contained carbonate and sulphate of potash, chloride of potassium, phosphate of lime, alumina, silica, and oxides of iron and manganese.	
White Ginger	102.31	Ginger.	

1. VOLATILE OIL OF GINGER.—Is pale yellow, very fluid, lighter than water, odour that of ginger, taste at first mild, afterwards acrid and hot.

2. SOFT RESIN.—Obtained by digesting the alcoholic extract of ginger first in water, then in ether, and evaporating the ethereal tincture. The residual resin is yellowish-brown, soft, combustible, has an aromatic odour, and a burning aromatic taste. Is readily soluble in alcohol, ether, oil of turpentine, and hot almond oil.

3. STARCH.—Ginger starch consists of thin flat disks, which resemble those of East Indian arrow-root (see *Curcuma angustifolia*) and plantain starch (see *ante*, p. 223).

PHYSIOLOGICAL EFFECTS.—Ginger is one of the aromatic stimulants (see vol. i. p. 253) which possess considerable pungency or acidity. Its dust applied to the mucous membrane of the nostrils acts as an irritant, and provokes sneezing. The rhizome chewed is a powerful sialagogue. The powder mixed with hot water, and applied to the skin, causes a sensation of intense heat and tingling, and slight redness. When taken into the stomach, ginger operates as a stimulant; first, to the alimentary canal; secondly, to the body generally; but especially to the organs of respiration. Like some other spices (the peppers, for instance), it acts as an excitant to the genital organs. Furthermore, it has been said to increase the energy of the cerebral functions. It is less acrid than pepper.

USES.—Its principal consumption is as a *condiment*. Its powers in this way are considerable, while its flavour is by no means disagreeable, and its acidity scarcely sufficient to enable it, when taken with food, to irritate or inflame.

As a *stomachic* and *internal stimulant*, it serves several important purposes. In

¹ Brande, *Dict. of Mat. Med.*

² *Journ. de Pharm.* ix. 253.

³ *Gmelin's Handb. d. Chem.*

enfeebled and relaxed habits, especially of old and gouty individuals, it promotes digestion, and relieves flatulency and spasm of the stomach and bowels. It checks or prevents nausea and griping, which are apt to be produced by some drastic purgatives. It covers the nauseous flavour of many medicines, and communicates cordial and carminative qualities to tonic and other agents. As a *sialagogue*, it is sometimes chewed to relieve toothache, relaxed uvula, and paralytic affections of the tongue. As a *counter-irritant*, I have frequently known a *ginger plaster* (prepared by mixing together powdered ginger and warm water, and spreading the paste on paper or cloth) relieve violent headache when applied to the forehead.

ADMINISTRATION.—*Powdered ginger* may be administered, in doses of from ten grains to a scruple or more, in the form of a pill. Made into a paste with hot water, it may be applied as a *plaster*, as already mentioned.

Preserved ginger (*conditum zingiberis*), though commonly used as a sweetmeat, may be taken with advantage as a medicine to stimulate the stomach. *Ginger lozenges*, *ginger pearls* (commonly termed *ginger seeds*), and *ginger pipe* are useful articles of confectionery, which are frequently of benefit in dyspepsia accompanied with flatulence.

1. **TINCTURA ZINGIBERIS**, L. E. D. [U. S.]; *Tincture of Ginger*.—(Ginger, sliced [in coarse powder, *E. D.*], ℥ijss [℥vij, *D.* (U. S.)]; Rectified Spirit Oij. Macerate for seven [fourteen, *D.*] days, and strain, *L. D.* “Proceed by percolation or digestion, as directed for tincture of cinchona,” *E.*)—A very valuable carminative. It is commonly employed as an adjunct to tonic, stimulant, and purgative mixtures. Its dose is fʒj to fʒij. The tincture, made with proof spirit, becomes turbid by keeping, in consequence of the mucilage it contains.

Essence of ginger is prepared as a tincture, except that the quantity of rhizome should be increased. Some preparers of it concentrate the tincture by distilling off part of the alcohol.

2. **SYRUPUS ZINGIBERIS**, L. E. D. [U. S.]; *Syrup of Ginger*.—(Ginger, sliced, ℥ijss; Boiling Distilled Water Oj; Sugar ℔ijss, or as much as may be sufficient [Rectified Spirit as much as may be sufficient, *L.*] Macerate the ginger in the water for four hours, and strain; then add the sugar, and dissolve it.—The *Dublin College* directs it to be prepared with Tincture of Ginger fʒj, and Simple Syrup fʒvij. Mix with agitation.)—Used for flavouring. It is scarcely strong enough to be of much value. An extemporaneous syrup may be prepared by adding the tincture of ginger to common syrup. The *Syrupus Zingiberis* of the United States Pharmacopœia is made by adding fʒij of tincture of ginger (prepared with ℥vij of ginger, and Oij, *wine measure*, of alcohol) to a gallon of syrup, and evaporating the alcohol by a water-bath.

3. **INFUSUM ZINGIBERIS**; *Infusion of Ginger*; *Ginger Tea*.—This is a very useful domestic remedy, and is prepared by digesting from ℥ij to ℥iv of Ginger in fʒvj of Boiling Water, for two hours. When flavoured, it is employed as a carminative in flatulence, &c., in doses of one or two tablespoonfuls.

4. **CEREVISIA ZINGIBERIS**; *Ginger Beer*; *Ginger Pop*.—For the following excellent formula for the preparation of this popular and agreeable beverage, I am indebted to Mr. Pollock, of Fenchurch Street: “Take of White Sugar ℔xx; Lemon (or Lime) juice fʒxvij; Honey ℔j; Ginger, bruised, ℥xxij; Water cong. xvij. Boil the ginger in three gallons of water for half an hour; then add the sugar, the juice, and the honey, with the remainder of the water, and strain through a cloth. When cold, add the white of one egg and fʒss of essence of lemon; after standing four days, bottle. The bottles are to be laid on their sides in a cellar, and the beer is ready for use in about three weeks. If a little yeast be used, the beer is ready in a day or two; but in this case it does not keep well.” This yields a very superior beverage, and one which will keep for many months. Lemon-juice may be pur-

chased for sixpence a pint in Botolph Lane, Thames Street. A formula for the preparation of *Ginger Beer Powders* has already been given (see vol. i. p. 523).

76. *Zingiber Cassumunar*, Roxburgh.

Sex. Syst. Monandria, Monogynia.
(Radix.)

The root of this plant is "perennial, tuberous, furnished with long, white, fleshy fibres, and jointed like ginger, but much larger; when fresh, of a deep yellow; possessing a strong, not very agreeable, camphoraceous smell, and warm, spicy, bitterish taste," (Roxburgh.) Sir Joseph Banks and Dr. Comb (to whom specimens of it were given) thought that it was the true *cassumunar* of the shops.¹ But the great resemblance of *cassumunar* root to round *zedoary* leads me to think that it is obtained from a species of *Curcuma*.

About the year 1672, Dr. Pechey received from his brother, factor to the East India Company, a root which was called *cassumunar* (variously spelt *casmunar*, *casumunar*, &c.), *rysagone* (or *risagon*), and *bengale* (or *bengalle*).² These names were probably fictitious, and were merely given to conceal the secret of its nature.

This root is still found in the warehouses of some London druggists, who call it *cassumunar root* (*radix cassumunar*), and consider it to be identical with *zerumbet root* (see *Curcuma Zedoaria*). It appears to me to be the *turmeric-coloured zedoary* of Ainslie, the *zedoaria radice lutea* of Breynius,³ the *tommon besaar* or *tommon lawac* of Rumphius.⁴ It occurs in segments (halves or quarters) of an ovate tuber (which in the dried state must have been about the size of a pigeon's egg), the external surface of which is marked with circular rings and the bases of the root fibres, and is of a dirty turmeric-yellow colour. Internally it is reddish-brown, and has some resemblance, in its colour and pellucidity, to a fresh-fractured surface of Socotrine aloes. Its flavour is warm and aromatic; its odour is somewhat like that of turmeric. It has not been analyzed. Its effects must be similar to those of *zedoary* and ginger. It was at one time used in convulsive and other cerebral diseases,⁵ but has fallen into disuse.

77. *CURCUMA LONGA*, Linn.—THE LONG-ROOTED TURMERIC.

Sex. Syst. Monandria, Monogynia.
(Rhizoma, L. E.—Radix, D)

HISTORY.—Turmeric is probably the *κύπερος ινδικός* (*Cyperus indicus*) of Dioscorides.⁶ Both he and Pliny⁷ state that this Indian *Cyperus* has the form of ginger, and that, when chewed, it colours the saliva yellow like saffron. The word *curcuma* is derived from *kurkum*, the Persian name for saffron.⁸

BOTANY. **Gen. Char.**—Tube of the *corolla* gradually enlarged upwards; limb 2-lipped, each 3-parted. *Filament* broad. *Anther* incumbent, with 2 spurs at the base. *Style* capillary. *Capsule* 3-celled. *Seeds* numerous, arillate.—Stemless plants, with palmate tuberous roots. *Leaves* with sheathing petioles, bifarious, herbaceous. *Scape* simple, lateral or central. *Spike* simple, erect, comose, somewhat imbricated at the base with braets or saccate spathes. *Flowers* dull yellow, 3 to 5 together, surrounded by braeteolæ.⁹

Sp. Char.—*Bulbs* small, and with the numerous, long, *palmate tubers*, inwardly of a deep, orange yellow. *Leaves* long-petioled, broad-lanceolate, of a uniform green (Roxburgh).

Hab.—Much cultivated about Calcutta, and in all parts of Bengal, also in China and Cochin-China. One acre yields about 2000 lbs. of the fresh root.

DESCRIPTION.—The *tubers*, called in the shops *turmeric* (*radix curcumæ*, seu *terra merita*), are of two kinds: one *round* (*curcuma rotunda*), the other *long* (*cur-*

⁹ Blume, *op. cit.*

cuma longa), but both produced on the same plant. The first are round, oval, or ovate, about two inches long, and one inch in diameter, pointed at one end, and marked externally with numerous annular wrinkles. The second are cylindrical, not exceeding the thickness of the little finger; two or three inches long, somewhat contorted, tuberculated. Both kinds are yellowish externally, internally more or less orange-yellow passing into reddish-brown. The fractured surface has a waxy appearance. The odour is aromatic, somewhat analogous to ginger, but peculiar; the taste is aromatic. When chewed, it tinges the saliva yellow. Its powder is orange-yellow. The tubers are frequently worm-eaten.

If a thin slice of turmeric root be examined by the compound microscope, it is seen to consist chiefly of rounded or oblong, yellow, readily separable cells or vesicles, which appear to be filled with a minutely granular matter, and to be contained in an hexagonal cellular tissue. Intermixed with these cells are observed globules of a viscid, oleaginous, orange-coloured liquid. By boiling the slices in rectified spirit, the oleaginous liquid is dissolved, and the cells are deprived of their yellow colour. The colourless cells appear still to be filled with a granular matter. On the addition of iodine, the cells, but not the hexagonal tissue in which they are contained, acquire a dark blue colour, showing their amylaceous nature.

VARIETIES.—Five varieties of turmeric are known in the English market, namely, China, Bengal, Madras, Malabar or Bombay, and Java turmeric. These are readily distinguishable from each other by their external appearance; but if they were sorted according to their resemblance, the China and Java turmeric would be placed in one group, the Madras and Malabar in a second group, and the Bengal in a third.

1. *China Turmeric*.—This sort consists of smooth, plump, round, and long tubers (*curcuma rotunda et longa*, Figs. 225 and 226) of a greenish-yellow hue externally. They yield a bright powder, and on that account are much preferred for medicinal purposes. Hence they fetch a higher price than any other sorts of turmeric. Probably if much of it were brought to market, it would not fetch more than the Bengal sort.

Fig. 225.

*China round Turmeric.*

Fig. 226.

*China long Turmeric.*

Fig. 227.

*Bengal Turmeric.*

2. *Bengal Turmeric*.—This sort consists of thin or narrow long tubers (*curcuma longa*, Fig. 227) which are moderately smooth externally, and of a grayish dull yellow colour. They break with a deep reddish fracture. Although, from the dull appearance of its narrow tubers, it is not a very inviting sort to the inexperienced

eye, yet it fetches a higher price than the Madras sort, on account of its being a much stronger dye.

3. *Madras Turmeric*.—This is the most showy of all the kinds of turmeric. It consists principally of large long tubers (*curcuma longa*, Fig. 228), but mixed with transverse segments of round tubers (*c. rotunda*, Fig. 229). Externally, the tubers are marked by longitudinal wrinkles, the surface of which is rubbed and bright yellow; internally, the colour is that of a fresh-fractured surface of gamboge.

Fig. 228.

Madras long Turmeric.

Fig. 229.

Madras round Turmeric.

Fig. 230.

Malabar Turmeric.

4. *Malabar Turmeric*; *Bombay Turmeric*.—This sort is not constantly found in the market. It consists principally of long tubers (*c. longa*, Fig. 230); the round tubers (*c. rotunda*) being few and of very inferior quality. This sort of turmeric is smaller and more shrivelled than the Madras sort, but otherwise somewhat resembles it.

Fig. 231.

Java Turmeric.

Fig. 232.

Batavian Turmeric.

5. *Java Turmeric*.—Not frequently found in the English market. In a general way, it may be said to resemble the China sort. It consists of both round and long tubers (*c. rotunda et longa*, Fig. 231), but chiefly the latter. They have a greenish-yellow hue.

Under the name of *bulbs of Batavian turmeric*, I have received a sample of round tubers (Fig. 232) said to be from Java. Dr. Th. Martius notices this sort as having been brought for many years from Batavia, and adds that it contains much colouring matter, and is probably the produce of *Curcuma viridiflora*.

COMPOSITION.—Two analyses of turmeric have been made; one by John,¹ and a second by MM. Vogel and Pelletier.²

¹ Gmelin's *Handb. d. Chem.*

² *Journ. de Pharm.* i. 289.

John's Analysis.		Vogel and Pelletier's Analysis.	
Yellow volatile oil	1	Acrid volatile oil.	
Curcumin	10 to 11	Curcumin.	
Yellow extractive	11 to 12	Brown colouring matter.	
Gum	14	Gum (a little).	
Woody fibre	57	Starch.	
Water and loss	7 to 5	Woody fibre.	
		Chloride of Calcium.	
<hr/>		<hr/>	
Turmeric	100	Turmeric.	

CURCUMIN. *Yellow Colouring Matter.*—Is obtained, mixed with some volatile oil and chloride of calcium, by digesting the alcoholic extract of turmeric in ether, and evaporating the ethereal tincture to dryness. In the mass, *curcumin* is brownish-yellow, but when powdered it becomes full yellow. It is tasteless, odourless, almost insoluble in water, but readily soluble in alcohol and ether. These properties show that it is of a resinous nature. The alkalis colour it reddish-brown, and readily dissolve it. The alcoholic solution, evaporated with boracic acid, becomes red. Hydrochloric acid, also, reddens it. The alcoholic solution of curcumin produces coloured precipitates with several salts, as acetate of lead and nitrate of silver.

CHEMICAL CHARACTERISTICS.—The alkalis change an infusion of turmeric, or turmeric paper, to reddish-brown. A similar alteration of colour occurs when turmeric paper is exposed to the vapour of hydrochloric acid gas, or is touched with oil of vitriol. If, to tincture of turmeric, boracic acid be added, and the mixture be evaporated to dryness, an orange-red residue is obtained, whereas, without the acid, the residue is yellow. By this test the yellow colouring matter of turmeric can be distinguished from that of rhubarb (see *Rheum*). Sulphate of copper causes a yellowish precipitate with an infusion of turmeric. A similar effect is produced by sesquichloride of iron.

PHYSIOLOGICAL EFFECTS.—Are those of a mild aromatic stimulant (see vol. i. p. 253). The colouring matter becomes absorbed, and communicates a yellow tinge to the urine.¹ According to Mr. Gibson,² the colouring matter of turmeric is somewhat changed by the digestive organs; for the stools of animals fed with this root were green, whilst both logwood and madder exhibited their respective hues after passing through the intestines.

USES.—Employed as a condiment, colouring ingredient, and test. It is a constituent of the well-known *curry powder* and *curry paste*, and of many other articles of Indian cookery. Formerly, it had some reputation in hepatic and other visceral diseases, and especially in jaundice.

As a test, it is used to detect the presence of free alkalis, which change its yellow colour to a reddish-brown.

But alkaline earths and the alkaline carbonates, borates, and sulphurets, as well as boracic and hydrochloric acids, change the colour of turmeric from yellow to brown. Though not a very delicate test, it is often a very useful one.

1. TINCTURA CURCUMÆ; Tincture of Turmeric.—Prepared by digesting one part of bruised Turmeric in six parts of Proof Spirit. Employed for the preparation of turmeric paper. Diluted with water, it yields a slightly turbid yellow liquid, which is sometimes used in the class-room as a test for alkalis, &c.

2. CHARTA CURCUMÆ; Charta exploratoria flava; Turmeric Paper.—Prepared with white, bibulous, or unsized paper, which is to be brushed over with, or soaked in, tincture of turmeric, and dried in the air, the access of alkaline and acid fumes being prevented. Mr. Faraday³ directs it to be prepared with a *decoction of turmeric* (prepared by boiling one ounce of the coarsely-powdered turmeric in ten or twelve ounces of water, straining through a cloth, and allowing the fluid to settle for a minute or two). Turmeric paper is employed as a test for alkalis, &c., which render it reddish or brownish.

³ *Chemical Manipulation*.

78. CURCUMA ANGUSTIFOLIA, Roxburgh.—THE NARROW-LEAVED TURMERIC.

Sex. Syst. Monandria, Monogynia.

(*Fæcula tuberis.* East Indian Arrow-root, *Offic.*)

HISTORY.—This plant was found by H. T. Colebrook, Esq., in the forests extending from the banks of the Sona to Nagpore, and was by him introduced into the Botanic garden at Calcutta.¹

BOTANY. *Gen. Char.*—Vide *Curcuma longa*.

Sp. Char.—*Bulb* oblong, with pale, oblong, pendulous *tubers* only. *Leaves* stalked, narrow lanceolate. *Flowers* longer than the bracts.

Hab.—East Indies; from the banks of the Sona to Nagpore (Roxburgh). Also in abundance on the Malabar coast (Ainslie).

EXTRACTION OF THE FEcula.—From the tubers of several species of *Curcuma* is obtained, in the East Indies, a fecula called *tikor*.

According to Dr. Roxburgh,² the biennial roots of the genus *Curcuma* consist of what he calls *bulbs*, *tubers*, and *fibres*. The *bulbs* are formed during the first year, and support the aerial parts of the plants; hence they may be termed *phyllophorous receptacles*. From these bulbs issue the *palmate tubers*, and chiefly the *fibres* or genuine roots; the latter issuing from the lower part of the bulbs. Some of the fibres end in a single oblong, pearl-coloured, solid *tuber*. From these tubers, and from no other parts, the natives of various parts of India obtain starch.

At Bhagulpore this is procured from *C. leucorrhiza*. “The root is dug up, and rubbed on a stone, or beat in a mortar, and afterwards rubbed in water with the hand, and strained through a cloth; the fecula having subsided, the water is poured off, and the *Tikor* (fecula) dried for use.”³

At Travancore, and also, according to Bennett,⁴ at Bombay, from the *C. angustifolia*. “So much of it has been made of late years on the Malabar coast, where the plant grows in abundance, that it has become a considerable object in trade, and is much prized in England.”⁵

C. rubescens is another species which also yields the fecula called *tikor*.

DESCRIPTION.—*Curcuma starch* (*amylum curcuma*) or *tikor* is imported from the East Indies under the name of *East India arrow-root*. But as this name is also applied to the starch of *Maranta arundinacea*, cultivated in the East Indies, I have thought it advisable to distinguish it by the name of “*Curcuma starch*.”

Two kinds of *Curcuma starch* are imported from Calcutta; one white, the other buff-coloured.

a. *White tikor*, or *curcuma starch*, or *white East Indian arrow-root*, is a fine white powder, readily distinguishable, both by the eye and the touch, from West Indian arrow-root. To the eye it somewhat resembles a finely-powdered salt (as bicarbonate of soda or Rochelle salt). When pinched or pressed by the fingers, it wants the firmness so characteristic of West Indian arrow-root, and it does not crepitate to the same extent when rubbed between the fingers.

Examined by the microscope, the particles of this starch are found to be transparent flattened disks of about the $\frac{1}{33\frac{1}{3}}$ of an inch in thickness.⁶ Their shape is ovate, or oblong-ovate, with a very short neck or nipple-like projection at one extremity, where is situated the part called the hilum. The largest are about $\frac{1}{37\frac{1}{8}}$ of an inch in length, and $\frac{1}{77\frac{1}{8}}$ of an inch in breadth.⁷

¹ Roxburgh, *Fl. Indica*, vol. i. p. 31.

² Roxburgh, *Asiatic Researches*, vol. xi. p. 218; also, *Fl. Indica*, vol. i. p. 21.

³ Roxburgh, *Fl. Indica*, vol. i. p. 30.

⁴ *Ceylon and its Capabilities*, p. 151.

⁵ Ainslie, *Mat. Indica*, vol. i. p. 19, 1826.

⁶ The particles of plantain-starch, like those of curcuma-starch, are flat disks (see *ante*, p. 223).

⁷ The following measurements, in parts of an English inch, of the particles of East India arrow-root, were made for me by Mr. George Jackson:—

On account of their flatness they have but little lateral shading, except when viewed edgewise. The hilum or nucleus is placed at the narrow extremity—is circular, very small, and not very distinct. The rings (or rather portions of rings) are seen both on the flat surface and on the edges; they are numerous, close, and very fine.

β. *Buff-coloured tikor, or curcuma starch; pale buff-coloured East Indian arrow-root.*—In the form of powder, or of pulverulent masses, which are dirty or buffy white. Paddy husks, woody fibre, and various impurities, are intermixed.

To the microscope both kinds present the same appearance, from which it is probable that they are obtained from the same plant, but with unequal degrees of care. The particles of East Indian arrow-root are very unequal in size, but on the average are larger than those of West Indian arrow-root.

COMPOSITION.—Not ascertained, but doubtless analogous to that of other starches, viz. $C^{12}H^{10}O^{10}$.

EFFECTS AND USES.—Analogous to those of the West Indian starch. Its commercial value, however, is much below that of the latter. At Travancore, it forms a large portion of the diet of the inhabitants (Roxburgh).

79. Curcuma Zedoaria, Roxburgh.—Round Zedoary.

Sez. Syst. Monandria, Monogynia.
(Tubera.)

Dr. Roxburgh gave some of the dried roots of this plant to Sir Joseph Banks, who ascertained that they agreed well with the *zedoaria rotunda* of the shops.¹

1. ZEDOARIA ROTUNDA.—The *zedoary root (radix zedouræ)* now found in the shops of English druggists is the *round zedoary (zedoaria rotunda)* of pharmacological writers. It occurs in segments (halves, quarters, or flat sections) of a roundish or ovate tuber. The external portion of the tuber is marked by the remains, membranes, and fibres, and is of a pale brownish-gray or whitish appearance. When cut, it presents a yellowish marbled appearance, not very dissimilar to the cut surface of rhubarb. It has a warm, aromatic, bitter taste, and an aromatic odour. It has been analyzed by Bucholz² and by Morin.³ Its constituents, according to the latter chemist, are—*volatile oil, resin, gum, starch, woody fibre, vegeto-animal matter (?), osmazome (?), free acetic acid, acetate of potash, sulphur, and in the ashes carbonate and sulphate of potash, chloride of potassium, phosphate of lime, alumina, silica, oxides of iron and manganese.* It possesses aromatic and tonic properties. It is less heating than ginger and galangal, and is more analogous to turmeric.

2. ZEDOARIA LONGA.—The root called *long zedoary (zedoaria longa)* is no longer found in the shops of English druggists. It is in pieces scarcely so long and wide as the little finger. Its chemical and medicinal properties resemble those of round zedoary. It is, perhaps, the *zerumbet root (radix zerumbet)*, for a piece of which I am indebted to Dr. Royle. It is very similar in shape to a curved or arched piece of long turmeric. Its colour is yellowish-gray.

The plant which yields long zedoary has not been satisfactorily ascertained; but it is probably the *Curcuma Zerumbet* of Roxburgh, who states that the *zerumbet* or *kuchoor* of the native druggists of Calcutta are the roots of this species of *Curcuma*, and that they are principally obtained from Chittagong. He also adds, that he sent the sliced and dried bulbous and palmate tuberous roots to Sir J. Banks, who ascertained that they were the real *zedoaria* of our *Materia Medica*, and that the root of *C. Zedoaria* was the *zedoaria rotunda* of the shops.

3. ZEDOARIA LUTEA.—The *turmeric coloured zedoary* of Ainslie,⁴ the *yellow zedoary (zedoaire jaune)* of Guibourt, is probably the *cassumunar root (radix cassumunar)* of English druggists (see *ante*, p. 234).

Particles.	Length.	Breadth.	Thickness.

80. AMOMUM CARDAMOMUM, Linn.—THE CLUSTER OR ROUND CARDAMOM.

Sex. Syst. Monandria, Monogynia.
(Semina.)

HISTORY.—The fruit of this plant is the *ἀμωμον* of Dioscorides,¹ the *Amomi ura* of Pliny.²

BOTANY. Gen. Char.—*Inner limb of the corolla* one-lipped. *Filament* dilated beyond the anther, with an entire or lobed crest. *Capsule* often berried, 3-celled, 3-valved. *Seeds* numerous, arillate.—*Herbaceous perennials*, with articulated creeping rhizomes. *Leaves* in 2 rows, membranous, with their sheaths split. *Inflorescence* spiked, loosely imbricated, radical (Blume).³

Sp. Char.—*Leaves* with short petioles, lanceolate. *Spikes* half immersed in the earth, loosely imbricated with villous, lanceolate, acute, 1-flowered bracts. *Lip*, with the interior margin, 3-lobed. *Crest* 3-lobed (Roxburgh).

Hab.—Sumatra, Java, and other islands eastward to the Bay of Bengal.

DESCRIPTION.—The fruit of this plant is the *round cardamom* (*cardamomum rotundum*) of the shops. It varies in size from that of a black currant to that of a cherry. It is roundish or roundish-ovate, with three convex rounded sides or lobes, more or less striated longitudinally, yellowish or brownish-white, sometimes with a red tint, and when examined by a pocket lens shows the remains of hairs, the greater part of which have probably been rubbed off. The seeds are brown, angular, cuneiform, shrivelled, with an aromatic, camphoraceous flavour. The fruits in their native clusters or spikes (constituting the *Amomum racemosum*) are rarely met with; a fine sample is in the Sloanian collection of the British Museum.

Fig. 233.

Round Cardamom.

COMPOSITION.—It has not been analyzed. Its constituents are probably analogous to those of the Malabar cardamom (*Elettaria Cardamomum*).

EFFECTS AND USES.—Similar to those of the Malabar cardamom. Round cardamoms are rarely employed in this country. They are officinal in the French Codex, and are principally consumed in the southern parts of Europe. The seeds are directed to be used by the Dublin Pharmacopœia, but I presume those of the *Elettaria Cardamomum* are intended.

81. AMOMUM GRANUM PARADISI, Afzelius; et A. MELEGUETA, Roscoe.

Sex. Syst. Monandria, Monogynia.
(Semina.)

HISTORY.—The term "*Malagueta*⁴ pepper" has been applied to the fruit or seeds of several zingiberaceous plants,⁵ as well as to the pimento or allspice.⁶ It is usually considered to be synonymous with the terms "*grains of paradise*," and "*Guinea grains*."

¹ Lib. i. cap. xiv.

² Hist. Nat. lib. xii. cap. xxviii. ed. Valp.

³ Op. cit.

⁴ This word is variously spelt Malagueta, Malaguetta, Melegueta, Mellegetta, Meligetta, &c. Several etymologies of it have been given: some say the seeds have been so called in consequence of their resemblance to Turkey millet, termed by the Italians *melica* or *melega*. Savary says the term is derived from *mala gente*, the designation applied by the Portuguese to the people of the coast yielding the seeds. Another derivation (suggested to me by Mr. R. Thomson, of the London Institution) is *Melli* (also written *Melle* and *Mall*), a kingdom of Nigritia; and *gitti* (or *gitter*), a Portuguese name for pepper. Barbot says the Portuguese word malagueta is from the native name for the pepper, *emanégéta*.

⁵ See a paper on "*Grains of Paradise*," by the author, in the *Pharmaceutical Journal*, vol. ii. p. 413, 1843.

⁶ See Ortega, *Historia natural de la Malagueta, ó Pimienta de Tavasco*, Madrid, 1780.

Malagueta pepper is said to have been known in Italy before the discovery of the Guinea coast by the Portuguese in the 15th century. It was brought by the Moors, who used to cross the great region of Madingha and the deserts of Lybia, and carry it to Mundi Barca (or Monte da Barca), a port in the Mediterranean. The Italians, not knowing the place of its birth, as it is so precious a spice, called it *grana paradisi*.¹

BOTANY.—The botanical history of these seeds is still involved in some obscurity. Two plants, one called by Afzelius and Smith *Amomum Granum Paradisi*, the other termed by Roscoe *A. Melegueta*, have been said to produce them. But some doubt exists whether these be identical or distinct species. In 1847, in a paper² on Roscoe's *A. Melegueta*, I mentioned that there were slight differences in the appearance of the seeds of the two plants. Since then, I have ascertained that there are two sorts of grains of paradise in the market, and that these are brought from different parts of the African coast, are readily distinguished from each other in trade, and are of unequal commercial value: one of these is identical with the seeds of *A. Granum Paradisi* of Afzelius and Smith, the other with those of *A. Melegueta* of Roscoe.

1. *A. GRANUM PARADISI*, Afzelius, Remed. Guineens. x. n. 1; Nocs, Offic. Pflanzen (fig.); *A. Grana-Paradisi*, Smith, Rees's Cyclopæd. vol. xxiii. art. Mellegetta, and vol. xxxix. suppl. art. Amomum.—Guinea coast, about Sierra Leone.

Rhizome perennial, woody, creeping horizontally. *Stems* erect, simple, slender, three feet high, leafy, but destitute of flowers. *Leaves* numerous, crowded, two-ranked, alternate, a span long and an inch broad, lanceolate, or slightly ovate, with a long taper point, entire, smooth, single-ribbed, striated with innumerable oblique veins. Their flavour is slightly aromatic, after having been dried 20 years. *Foot-stalks* sheathing, linear, very long, smooth, striated. *Flower-stalks* radical, solitary, an inch or two in length, ascending, clothed with numerous, close, sheathing bracts, all abrupt, ribbed, somewhat hairy and fringed; the lower ones very short; the upper gradually much larger. Of the parts of the flower nothing could be made out in Sir J. Smith's specimens.

[According to Afzelius, the flowers are large and white, and formed like those of *A. excusum*, Sims.] *Capsule* an inch and a half long, half an inch in diameter, oblong, bluntly triangular, scarcely ovate, beaked, of a dark reddish brown, ribbed, coriaceous, rough, with minute deciduous bristly hairs. When broken, it is very powerfully aromatic, even after being kept 20 years, with a peculiar pepper-like flavour, rather too strong to be agreeable. *Seeds* numerous, enveloped in membranes formed of the dried pulp, roundish or somewhat angular, of a shining golden brown, minutely rough or granulated, extremely hot and acrid (Smith).

2. *A. MELEGUETA*, Roscoe, Monandrian Plants, 1828; Pereira, Pharm. Journ., vol. vi. p. 412, 1847.—Cultivated at Demerara: probably from Africa.

Stem erect, six feet high. *Leaves* two-ranked, subsessile, narrow-lanceolate. *Scape* radical, covered at the base with about seven imbricated, ovate, concave, pointed, and somewhat cuspidate bracts. *Calyx* cylindrical, of one leaf, green, spotted with red. *Flowers* cylindrical, expanding in a double border; outer border in three sections, the middle section largest, ovate, the two others linear and opposite; inner lip very large, broad-ovate, crenate, pale yellow at the base, crimson at the margin. *Filament* strong, erect, clavate, terminating in three lobes, middle lobe erect and bifid, the other two pointed and recurved; a pair of hornlets on the filament, near the base of the lip. *Anthor* in two lobes, seated in front of the filament, a little below the apex, bright yellow. *Style* erect, tubular, expanding into a dilated stigma or cup, supported at the base

¹ De Barros, quoted in the *Encyclop. Metropol.* art. Guinea.

² *Pharmaceutical Journal*, vol. vi. p. 412, 1847.

by two linear *processes*, about an inch in length, and one-eighth of an inch in breadth, by much the largest specimen of this part observable in any scitamineous plant.

Fig. 235.

Leaves and Flower of *Amomum Melegueta*, Roscoe.

a. Stem and leaves.
b. Entire flower and floral bracts.
c. Exterior limb of corolla.

d. Interior limb of corolla or lip.
e. Filament, anther, stigma, style, and ovary.
f. Style and barren anthers (germinal processes).

Capsule cylindrical, coriaceous, six inches long, yellow, spotted with orange, supported at the base by the large ovate, concave, cuspidate bracts, and containing a columella or receptacle about four inches long, covered with seeds beautifully arranged, arilled, and imbedded in a tomentose substance. Seeds angular, light brown, with a highly aromatic and grateful flavour (Roscoe).

DESCRIPTION. *a.* **Of the dried fruits.**—I have met with two kinds of dried fruits whose seeds bear the name of grains of paradise or Guinea grains.

1. *Grains of Paradise Fruit* (Fig. 240).—These are oval or oval-oblong capsules, somewhat reddish-brown, and wrinkled longitudinally. Their length (exclusive of stalk and beak) rarely exceeds $1\frac{1}{2}$ inches; and their diameter is about $\frac{1}{2}$ an inch. The seeds agree with the grains of paradise brought from Cape Palmas and Sierra Leone. I am indebted to Dr. Daniell for specimens gathered from the high lands on the right of the River Congo. Some of them are strung on a cord; the usual form in which they are sold in Africa.—These fruits appear to me to agree with the Grain of Paradise *Amomum* described by Afzelius and Smith.

Fig. 236.

Fig. 236. Entire fruit preserved wet.
Fig. 237. Transverse section of ditto.

Fig. 238. Entire fruit dried.
Fig. 239. Seeds of ditto.

2. *Malagueta Pepper Fruit* (Fig. 241).—These fruits are larger than the preceding, and more ovate. Exclusive of beak and stalk they are two inches long, and one inch in diameter. They are ovate or ovate-oblong, coriaceous, wrinkled as if

Fig. 240.

*Capsule of Grain of Paradise.*

(From Dr. Burgess's collection in the College of Physicians.)

Fig. 241.

*Malagueta Pepper Fruit.*

(From a specimen in the Sloanian collection of the British Museum, where it is labelled "Melegetta—a pod from Guinea.")

shrivelled, yellowish-brown. The seeds are identical with those sold in the shops as grains of paradise or Guinea grains. From the large size of this fruit, I suspect it may be the produce of Roscoe's *A. Melegueta*.

β. *Of the seeds.*—The seeds, called in the shops *grains of paradise* (*grana paradisi*) or *Guinea grains* (*grana guineensia*), are roundish or ovate, frequently bluntly angular, and somewhat cuneiform; shining golden brown; minutely rough, from small warts and wrinkles; internally white. Their taste is aromatic, and vehemently hot or peppery: when crushed and rubbed between the fingers, their odour is feebly aromatic. Their greatest diameter rarely exceeds $1\frac{1}{4}$ line. The acrid taste resides in the seed coats.

Two sorts are distinguished by the importers:—

1. *Guinea grains from Acra.*—These are somewhat larger, plumper, and more warty than the ordinary sort. On the umbilicus of the seeds there is a short, conical, projecting tuft of pale-coloured fibres. This sort fetches a somewhat higher price than the next sort. The seeds agree precisely in appearance with those obtained from Roscoe's *A. Melegueta*.

2. *Guinea grains from Cape Palmas and Sierra Leone.*—Smaller and smoother than the preceding. They are devoid of the projecting fibrous tuft on the umbilicus. Being somewhat cheaper than the foregoing sort, they form the ordinary grains of paradise of the shops. They are perhaps the produce of Afzelius and Smith's *A. Granum Paradisi*.

COMMERCE.—Grains of paradise are imported in casks, barrels, and puncheons, from the coast of Guinea. The quantities on which duty was paid during six years are as follows (*Trade List*):—

In 1835 14,603 lbs.	In 1837 17,134 lbs.	In 1839 19,036 lbs.
1836 16,231	1838 16,199	1840 9,916

"Extract or preparation of Guinea grains" was formerly imported.¹

The heavy duty formerly imposed on grains of paradise was intended to act as a prohibition of their use.²

COMPOSITION.—Grains of paradise were analyzed in 1811 by Willert,³ who obtained the following results: Volatile oil 0.52, acrid resin 3.40, extractive 1.27, tragacanthin and woody fibre 82.8 [? water and loss 12.01].

1. The VOLATILE OIL has a light yellow colour, a camphoraceous smell, and a hot penetrating taste.

2. The RESIN is brown, soft, odourless, and has an acrid burning taste.

PHYSIOLOGICAL EFFECTS.—Analogous to those of pepper. A very erroneous notion prevails that these seeds are highly injurious.⁴

USES.—Rarely employed as an aromatic. Esteemed in Africa as the most wholesome of spices, and generally used by the natives to season their food.⁵

Its principal consumption is in veterinary medicine, and to give an artificial strength to spirits, wine, beer, and vinegar.

By 56 Geo. III. c. 58, no brewer or dealer in beer shall have in his possession or use grains of paradise, under a penalty of £200 for each offence: and no druggist shall sell it to a brewer, under a penalty of £500 for each offence.

82. *Amomum maximum*, Roxburgh.—The Great-winged Amomum.

(Fructus: Java Cardamom, offic.)

HISTORY.—This plant was first described by Roxburgh.⁶

BOTANY. Gen. Char.—Vide *Amomum Cardamomum*.

Sp. Char.—Leaves stalked, lanceolate, villous underneath. Spikes oval, even with the earth. Bracts lanceolate. Lip elliptical. Corolla of one semilunar lobe. Capsules round, 9-winged. (Roxburgh.)

The capsule is "almost globular, size of a gooseberry, 3-celled, 3-valved, ornamented with nine [seven to thirteen, Blume] firm, short, ragged (when old and dry), membranaceous wings. The seeds possess a warm, pungent, aromatic taste, not unlike that of cardamoms, but by no means so grateful." (Roxburgh.) The *Nepal cardamom*, described by Dr. Hamilton,⁷ appears to be identical with the Java cardamom. Dr. Hamilton says, the plant yielding it "is a species of *Amomum*, as that genus is defined by Dr. Roxburgh, and differs very much from the cardamom of Malabar."

Hab.—The Malay Islands (Roxburgh); Java (Blume). Cultivated in the mountainous parts of Nepal, where it is propagated by cuttings of the root [rhizome]; the plants yield in three years, and afterwards give an annual crop (Hamilton).

DESCRIPTION.—The fruit of this plant is known in commerce by various names; such as greater Java cardamoms (*cardamomi majores javanenses*, Th. Martius; Java cardamoms, offic.; *Nepal cardamoms, desi elachi* [i. e. country cardamoms] of Hindustan, Hamilton; the *hura elachee* [i. e. great cardamoms] of Saharunpore—the *Bengal cardamoms* of the Calcutta market, Royle; *cardamome ailé de Java* and *cardamome fausse maniguette*, Guibourt) are oval or oval-oblong, frequently somewhat ovate, three-valved, from eight to fifteen lines long, and from four to eight lines broad, usually flattened on one side, convex on the other, occasionally curved, sometimes imperfectly three-lobed, and resembling in their form the pericarp of the cocoa-nut (Fig. 242). Their colour is dirty grayish-brown. They have a

⁵ Trommsdorff's *Journ.* xx. St. 2, 1811.

⁶ Fourth Report of the African Institution.

⁷ *An Account of the Kingdom of Nepal*, ed. 1819.

course, fibrous, aged appearance, are strongly ribbed, and when soaked in hot water (Fig. 243) become most globular, and present from nine to thirteen ragged, membranous wings, which occupy the upper half or three-fourths of the capsule, and are scarcely perceptible in the dried state of the pericarp. By the possession of wings, these cardamoms are distinguished from all others of commerce, and hence might be called the *winged cardamoms*. Occasionally the foot-stalk is attached, with, now and then, portions of brown, membranous, imbricated scales, as long as the fruit. At the opposite or winged extremity of the capsule are frequently the fibrous remains of the calyx. Seeds (Fig. 244) somewhat larger than grains of paradise, dull, dirty brown, with a shallow groove on one side, internally white; taste and odour feebly aromatic. One hundred parts of the fruit consist, according to Th. Martius,¹ of seventy parts seeds, and thirty parts pericarpial coats. They are imported from Calcutta in bags.

COMPOSITION.—Analogous probably to that of the Malabar cardamom, except in the quantity of volatile oil which it yields; for Martius procured only four scruples of it from a pound of the fruit. The oil obtained was white and thickish.

EFFECTS AND USES.—Java cardamoms are not used here. They are of inferior quality, and when brought to this country are usually sold in bond for continental use. In 1839, a quantity of them was sold at seven-pence *per lb.*

83. *Amomum Korarima*.—The Korarima Cardamom.

The fruit of this plant is the *cardamomum majus* of Valerius Cordus,² of Matthioli,³ Geoffroy,⁴ Smith,⁵ and Geiger.⁶ In Dr. Burgess's Collection of *Materia Medica* at the College of Physicians, there are several fine specimens marked "*Cardamomum maximum Matthioli*." (Fig. 245.)

Under the name of *Korarima*, or *Gurâgîe spice*, I have received specimens of the same fruit, which had been brought from Abyssinia by Major Harris's embassy, by Dr. Beke, and by Mr. Charles Johnston⁷ (Fig. 246).

In former editions of this work, I followed Sir J. E. Smith,⁸ in considering this fruit to be identical with the *Amomum Madagascariense* of Lamarck,⁹ and the *A. angustifolium* of Sonnerat.¹⁰ As there is some reason to doubt the propriety of this proceeding, I have considered it advisable to designate the plant provisionally the "*Amomum Korarima*;" the word *Korarima* (pronounced in English *Korahrêma*), being the Galla name for the fruit which in Arabic is called *Kheil* or *Khil*.

The capsule is ovate, pointed, flattened on one side, striated, with a broad circular umbilicus or scar at the bottom, around which is an elevated, notched, and corrugated margin. Some authors, who have mistaken the base of the capsule for its summit, have compared the shape to that of a fig.

Some of the fruits which I received from Abyssinia had been perforated and strung upon a cord (Fig. 246), probably for the purpose of hanging them to dry. Dr. Beke thinks that the pierced or perforated fruits are those which have been gathered before they were perfectly ripe.

The seeds (Fig. 247) are rather larger than grains of paradise, roundish or somewhat angular, abrupt at the base, olive-brown, with an aromatic flavour analogous to that of the Malabar cardamom, but totally devoid of the vehemently hot acrid taste of the grains of paradise.

The *Korarima* is brought to the market of Bâso, in southern Abyssinia, from Tùmhe, (known among the native merchants as the "*country of the Korarima*,") somewhere about 9° N. lat. and 35° E. long. It is carried to Massowáh, the port of northern Abyssinia on the Red Sea,

¹⁰ *Voyage aux Indes*, t. ii. p. 242.

and exported from thence to India. Dr. Rüppell was informed that the annual export is of the value of one thousand dollars (about £200 sterling). Although it is not impossible that the same fruit may grow in Madagascar, yet it is highly improbable that the Korarima of Abyssinia is the produce of Madagascar.¹

At Báso, Dr. Beke purchased it at the rate of forty for one penny sterling.

The seeds are aromatic, and possess properties similar to, but more feeble than, those of the Malabar cardamom. In Abyssinia, they are used as a condiment and in medicine.

84. *Amomum citratum*.

Cardamomum majus.—In Dr. Burgess's collection at the College of Physicians is a capsule (in a bad state of preservation) marked "*Cardamomum majus*." It has a fibrous tuft at one extremity, and is much split at the other. The seeds are angular, oblong, larger than those of Malabar cardamoms, shining brownish-yellow, and have a large concave depression (hilum) at one extremity. They have a warm aromatic flavour, somewhat analogous to that of the oil of lemon-grass. When crushed, they evolve the odour of this oil. Hence I have given them the specific name "*citratum*," as by this character they are readily distinguished from all other seeds of this order with which I am acquainted.

I have found the same fruits in the Sloanian collection of the British Museum. They are tied together in bunches. One sample is unnamed; another is marked in the catalogue "12057. *Grana Paradisi*."

I have met with the same fruits in a collection at Apothecaries' Hall; and I am indebted to Mr. Warrington for the specimens from which Fig. 248 was taken. The capsules are tied together in bunches, as shown in the accompanying figure.

Fig. 248.

Amomum citratum.

Fruits tied together in a bunch—seeds.

85. *Amomum Clusii*, *Smith*.—Clusius's Cardamom.

Fructus, xiv., Clusius, *Exotic. lib. ii. cap. xv. pp. 37 and 38*; *Grana paradysi sive Mellegetæ affinis fructus*, Bauhin, *Pinax*, p. 413; *Amomum Clusii*, or *Long-seeded Amomum*, Smith, *Rees's Cyclop.* vol. xxxix., *Addenda*.—Capsule ovate, pointed, slightly triangular, cartilaginous, striated, smooth, yellowish [reddish, *Smith*] brown. The seeds have scarcely any flavour, are oblong or ovate, inclining to cylindrical, dark-brown, highly polished, as if varnished; with a pale yellowish brown, corrugated, and notched margin surrounding the scar.

On comparing my specimen (Fig. 249), which was given to me by a druggist, with the one marked *A. Clusii*, in Sir J. E. Smith's collection of fruits in the possession of the Linnæan Society, I find the seeds of the latter are somewhat longer, and rather more cylindrical; in other respects, the two specimens agree.

I have subsequently received, from Dr. T. W. C. Martius, specimens of a fruit marked "*Cardamomum maximum von Amomum Clusii?*" The capsules are somewhat plumper, but in other respects they agree with the preceding. I gave one of them to Professor Guibourt, who has published a figure of it.²

I have received from Dr. Daniell specimens of an *Amomum* which greatly resembles, if it be not identical with, *A. Clusii*. The capsules (Figs. 250 and 251), however, are narrower and more tapering than the latter. The seeds (Fig. 252) are obovate, highly polished, smooth, and

¹ Dr. Beke, *Pharmaceutical Journal*, vol. vi. p. 511.

² *Hist. Nat. des Drog.* 4ème édit. t. ii. p. 220, fig. 120, 1849.

dark brown. Are these capsules the produce of *A. Afzelii*? Dr. Daniell¹ says they grow in the thickets at Attahpah, on the gold and slave coasts, and plentifully on the outskirts of Clarence and Fernando Po, where they are known under the name of "bastard Melligetta." The seeds

Fruits and Seeds of an *Amomum* from the
Western Coast of Africa.

are contained in a soft acidulous pulp of a pleasant flavour, which the natives use in lengthened expeditions to allay thirst, and also as an adjunct to allay the irritative effects of cathartic and other medicines.

86. *Amomum macrospermum*, Smith.—Large-seeded Guinea *Amomum*.

(Semina.)

Zingiber Meleguetta, Gaertner de Fructib, vol. i. p. 34, pl. xii. fig. 1; *Fructus Cajeputi*, Trew, *Commercium Litterarium*, ann. 1737, Norimbergæ, p. 129, tab. 1, figs. 7–11; also *Herb. Blackwellianum emend. et auctum*, vol. iii. cent. vi. tab. 584, figs. 9–13, Norimb. 1773.—Native of Sierra Leone.

The capsule (*fructus cajeputi*, Trew; *cardamomum bandaense*, T. W. C. Martius; *grand cardamome de Gaertner*, Guibourt; *mabooboo* of the natives of Sierra Leone),² is ovate, pointed, somewhat striated, about two inches long, and six lines broad, with a corrugated beak.

¹ *Sketches of the Medical Topography of the Gulf of Guinea*, pp. 111 and 112, 1849.

² Sir J. E. Smith (*Rees's Cyclop. Suppl.*) states, on the authority of Afzelius, that the African name is "Mabooboo." But Nyberg (*Remedia Guineensia*, Upsal, 1813) says that the name "Mabubu" is applied to a species which he calls *Amomum latifolium*, whose seeds, in size, shape, and colour, agree with grape seeds.

The seeds (*semina cajuputi*, Trew) are ovate, or nearly globular, or somewhat oblong, variously angular, scarcely larger than grains of paradise, smooth, polished, greenish-gray, or lead coloured, with a strong umbilicated scar at their base, with a whitish or pale-yellow margin; flavour slightly aromatic. Smith says that Gaertner's figure represents them scarcely half large enough. This statement, however, does not apply to the seeds of my specimens.

The seeds yield, by distillation, a volatile oil. Cartheuser¹ obtained from half a pound of them a drachm and a half of a pale-yellowish, aromatic, camphoraceous oil, resembling, but less fragrant and penetrating than, cajuput oil. Trew erroneously supposed that these seeds were the source of the cajuput oil of commerce, and hence have arisen the erroneous denominations of "*fructus et semina cajuputi*," applied to the fruit and seeds of this species.

The seeds are aromatic, but are much inferior to those of the Malabar cardamom.

I have received from Dr. Daniell specimens of the fruit of this or some closely allied species growing at Gambia and Cape St. Mary. One of the specimens consists of a stalk five inches long, supporting two capsules, and clothed with bracts. The seeds are angular, and lead-coloured. Dr. Daniell tells me that the natives of Africa suck the acidulous pulp of the fruit.

Fig. 253.

Amomum macrospermum.

87. *Amomum globosum*, Loureiro?

(Semina.)

Mé tlé, Cochinch.; *Tsão keu*, Chin. Loureiro, Fl. Cochinch.—Mountains of Cochinchina and China.

I am indebted to Professor Guibourt for the loan of this fruit, which he calls the *round China cardamom* (*cardamome rond de la Chine*), and from which the accompanying figure was taken.

: *Capsule* thin, round, or oval. *Seeds* in globular masses, marked, on the surface opposed to the pericarp, by a linear depression or groove.

I have observed specimens in the Sloanian collection of the British Museum, and also in a collection of Chinese medicines at the College of Physicians.

This fruit may perhaps be the produce of Loureiro's *Amomum globosum*, the seeds of which he says are slightly calefacient and stomachic. They are frequently employed by medical practitioners in China and Cochinchina, and are useful in restraining abdominal pain, sickness, and diarrhœa.

On comparing Professor Guibourt's specimen with the fruit of *Alpinia nutans* (sec p. 250) in Dr. Wallich's collection, in the possession of the Linnean Society, the two are scarcely distinguishable externally. The seeds, however, are quite dissimilar.

88. *Amomum villosum*, Loureiro?

(Semina.)

Sa ngon, Cochinch.; *Sõ Xâ mí*, Chin., Loureiro.—Mountains of Cochinchina.

I am indebted to Professor Guibourt for specimens of a fruit which he calls the *hairy, China cardamom* (*cardamome poilu de la Chine*), and which, in the collection of the Muséum d'Histoire Naturelle, is termed (by mistake?) *tsao keou*.

¹ *Dissert. nonnullæ select. Physico-Chem. ac Medicæ*, Francof. 1775.

² Professor Guibourt (*Hist. Nat. des. Drog.* 4ème édit. p. 218, fig. 119) has figured one of the specimens given to me by Dr. Martius; but he has erroneously stated that the figure was from a specimen in the Sloanian collection of the British Museum.

Capsules ovate, oblong, obtusely triangular. *Seeds* have no linear depression or groove as those of the preceding variety, and by the absence of this they may be readily distinguished from it; coherent in masses, which are 3-lobed, not quite globular. In my specimens, the pericarp is rugous, as if eroded; but, when examined by a magnifier, it is seen to be covered by asperities and the remains of fine downy hairs. The flavour of the seeds is aromatic and terebinthinate, but not powerful.

Fig. 257. Fruit.

Fig. 258. Globular mass of seeds.

Fig. 259.

Black Cardamom
(Guibourt).

M. Guibourt thinks this fruit may perhaps be the produce of *Amonum villosum* of Loureiro, the oriental names of which, however, are very different to that on the specimen in the Paris Museum. Loureiro states that the seeds of *A. villosum* are sub-calefacient and stonachic, and are exported from the provinces of Qui-nhon and Phy-yen, in Cochin China (where they grow spontaneously), to China, where they are largely used in medicine.

BLACK CARDAMOM, Guibourt.—I am indebted to M. Guibourt for a fruit which he calls the *black cardamom of Gaertner* (*cardamome noir de Gaertner*), or the fruit of *Zingiber nigrum*, Gaertner. The capsule is larger than the short Malabar cardamoms, acuminate at its two extremities, and formed, as it were, of two obtusely-triangular pyramids joined base to base. The pericarp ash-brown, aromatic, but less so than the seeds. *Seeds* annular, brown, slightly aromatic, but devoid of the terebinthinate flavour.

Gaertner states that his plant is the *Alughas* of the Ceylonese. But the black cardamom of Guibourt is certainly not Roxburgh's *Alpinia Allughas*.

89. *Alpinia Galanga*, Linn.; *A. chinensis*, Roscoe (?); and *A. nutans*, Roscoe.

Sex. Syst. Monandria, Monogynia.
(Rhizoma.)

Two kinds of *galangal root* (*radix galangæ*), a *lesser* and a *greater*, have long been known in medicine: to these Guibourt has added a third, which he calls *light galangal*. These three sorts are the produce of different parts of the East, and probably of different species of *Alpinia*.

1. *Radix galangæ majoris*; *greater* or *Java galangal root*.—This is the root of the *Alpinia Galanga*, Linn. It is a coarser and larger root, with a feebler and somewhat different odour from that of the lesser galangal root. Although it occasionally comes to Europe, I cannot learn that it finds any use here.

2. *Radix galangæ minoris*; *lesser* or *Chinese galangal root*.—This is the root of a plant growing in China, according to Guibourt,¹ the *Alpinia chinensis*, Roscoe (*Hellenia chinensis*, Willd.). It may perhaps be *Alpinia alba*, which Kœnig calls *galanga alba*. It is brought to England from China either directly or by way of Singapore. It is the only sort usually kept by English druggists. It occurs in pieces which are as thick as the finger, seldom exceeding three inches in length, cylindrical or somewhat tuberous, often forked, sometimes slightly striated longitudinally, and marked with whitish circular rings. Externally its colour is dull reddish-brown; internally pale, reddish-white. Its odour is agreeably aromatic; its taste peppery and aromatic. It has been analyzed by Bucholz² and by Morin.³ The former obtained *volatile oil* 0.5, *acid soft resin* 4.9, *extractive* 9.7, *gum* 8.2, *bassorin* 41.5, *woody fibre* 21.6, *water* 12.3, *loss* 1.3. It is a warm and agreeable aromatic, and is sometimes administered in the form of infusion in dyspepsia. Its effects, uses, and doses are analogous to those of ginger. It is, however, rarely employed in England—its principal consumption being on the continent.

3. *Radix galangæ levis*; *galanga leger*, Guibourt; *light galangal root*.—This variety, according to M. Guibourt, is characterized by its great lightness; its weight being not more than a third of that of the previous sort. Its epidermis is smooth and shining. It is, perhaps, the root of *Alpinia nutans* (Roscoe), which Dr. Roxburgh⁴ states is odorous, and is sometimes brought to England for galanga major.

90. *Alpinia alba*, Roscoe.

(Semina.)

Hellenia alba, Willd.; *Heritiera alba*, Retz.; *Linguas vulgare*, Kœnig; *Amomum medium*, Loureiro, Fl. Cochinch. — The latter gives *Tsão quo* as the Cochinchina name, and *Thao qua* as the Chinese name of the plant.

Specimens of this fruit are in the Muséum d'Histoire Naturelle of Paris, where they are labelled *tsao-quo*. For my specimens, I am indebted to Professor Guibourt, who calls the fruit the *ovoid China cardamom* (*cardamome ovoïde de la Chine*).

The dried fruit is about the size and shape of a large nutmeg; it is ovoid, from ten to fourteen lines long, and from six to eight lines broad, rather rigid, striated longitudinally, yellowish-brown with a reddish tint [scarlet when recent, Kœnig]. Seeds numerous, very large, pyramidal, brown externally, flavour and odour terebinthinate; albumen white, embryo yellow.

Grows in the province of Yu-nan. The seeds are aromatic, and are used by the natives as a condiment. They are said to be useful in intermittents. Kœnig terms the plant *galanga alba*, and says it is much used among the Malays.

Sez. Syst. Monandria, Monogynia.

(Semen, L.—The fruit; Cardamoms, Ed.—The seeds, D.)

HISTORY.—A medicine, called Cardamom (*καρδάμμων*), is mentioned by Hippocrates,¹ Theophrastus,² and Dioscorides,³ the first of whom employed it in medicine. But it is now scarcely possible to determine what substance they referred to, as their notices of it are brief and imperfect; though I believe it to have been one of the fruits which we call cardamoms. Pliny⁴ speaks of four kinds of cardamoms, but it is almost impossible to ascertain with any certainty what species he refers to.

BOTANY. **Gen. Char.**—The same as that of *Amomum*, but the *tube of the corolla* filiform, and the *anther* naked (Blume).

Sp. Char.—*Leaves* lanceolate, acuminate, pubescent above, silky beneath. *Spikes* lax. *Scape* elongated, horizontal. *Lip* indistinctly three-lobed (Blume).

Rhizome with numerous fleshy fibres. *Stems* perennial, erect, smooth, jointed, enveloped in the spongy sheaths of the leaves; from six to nine feet high. *Leaves* subsessile on their sheaths, entire; length from one to two feet. *Sheaths* slightly villous, with a roundish ligula rising above the mouth. *Scapes* several (three or four) from the base of the stems, flexuose, jointed, branched, one to two feet long. *Branches* or *racemes* alternate, one from each joint of the scape, suberect, two or three inches long. *Bracts* solitary, oblong, smooth, membranaceous, striated, sheathing, one at each joint of the scape. *Flowers* alternate, short-stalked, solitary at each joint of the racemes, opening in succession as the racemes lengthen. *Calyx* funnel-shaped, three-toothed at the mouth, about three-quarters of an inch long, finely striated, permanent. *Tube of corolla* slender, as long as the calyx; limb double, exterior of three oblong, concave, nearly equal, pale greenish-white divisions; inner lip obovate, much larger than the exterior divisions, somewhat curled at the margin, with the apex slightly three-lobed, marked chiefly in the centre with purple violet stripes. *Filament* short, erect; *anther* double emarginate. *Ovary* oval, smooth; *style* slender, *stigma* funnel-shaped. *Capsule* oval, somewhat three-sided,

¹ Pages 265, 572, 603, 651, ed. Fœs.

² Lib. i. cap. 5.

³ *Hist. Plant.* lib. xi. cap. vii.

⁴ *Hist. Nat.* lib. xii. cap. xxix. ed. Valp.

size of a small nutmeg [!], three-celled, three-valved. *Seeds* many, angular (Roxburgh).

Hab.—Mountainous part of the coast of Malabar.

PRODUCTION.—Cardamoms are produced naturally or by cultivation. Between Travancore and Madura they grow without cultivation,¹ and also at certain places in the hills which form the lower part of the Ghaûts in Cadutinada and other northern districts of Malayata.² The cardamoms of the Wynaad, which are esteemed the best, are cultivated: the spots chosen for the cardamom farms are called *Ela-Kandy*, and are either level or gently sloping surfaces on the highest range of the Ghaûts after passing the first declivity from their base.³ “Before the commencement of the periodical rains, in June, the cultivators of the cardamom ascend the coldest and most shady sides of a woody mountain; a tree of uncommon size and weight is then sought after, the adjacent spot is cleared of weeds, and the tree felled close at its root. The earth, shaken and loosened by the force of the fallen tree, shoots forth young cardamom plants in about a month’s time.”⁴

The quantity of cardamoms brought for sale at Malabar is about 120, or, according to another account, only 100 candies, from the following places:⁵—

	Candies of 640 lbs.	Candies of 640 lbs.
Coorg	40	30
Wynaad	57	65
Tamarachery	20	3
Cadutinada or Cartinaad	3	2
	120	100

The cardamoms of the Wynaad are shorter, fuller of seed, and whiter, than those of Malabar, and sell for 100 rupees a candy more. Those of Coorg have fewer fine grains, but they have also fewer black or light ones. The cardamoms of Sersi (western part of Soonda) are inferior to those of Coorg.⁶

DESCRIPTION.—The fruit of the *Elettaria Cardamomum* constitutes the *small, officinal Malabar cardamom* (cardamoms, Ed.; *cardamomum minus*, Clusius, Matthioli, Bontius, Geoffroy, Dale, Geiger, Th. Martius, and Guibourt; *cardamomum malabarensis*). It is an ovate oblong, obtusely triangular capsule, from three to ten lines long, rarely exceeding three lines in breadth; coriaceous, ribbed, grayish or brownish yellow. It contains many angular blackish or reddish-brown rugose seeds (*cardamomum*, L.; *cardamomum excorticatum*, Offic.), which are white internally, have a pleasant aromatic odour, and a warm, aromatic, agreeable taste.⁷ 100 parts of the fruit yield 74 parts of seeds and 26 parts of pericarpial coats.⁸

Three varieties of Malabar cardamoms are distinguished in commerce; viz. *shorts*, *short-longs*, and *long-longs*. The two latter differ from each other in size merely.

a. SHORTS. *Malabar cardamoms, properly so called; Petit cardamome* (Guibourt); ? *Wynaad cardamom* (Hamilton); *Prima species Elettari planè rotunda et albicans* (Rheede).⁹—From three to six lines long, and from two to three lines broad; more coarsely ribbed, and of a browner colour, than the other varieties. This is the most esteemed variety.

β. SHORT-LONGS. *Secunda species Elettari oblongior sed vilior* (Rheede).—Differs from the third variety in being somewhat shorter and less acuminate.

γ. LONG-LONGS. *Moyen cardamome* (Guib.): *Tertia species Elettari vilissima et planè acuminata* (Rheede).—From seven lines to an inch long, and from two to three lines broad:

elongated, somewhat acuminate. This, as well as the last variety, is paler and more finely ribbed than var. *a. shorts*. The seeds also are frequently paler (in some cases resembling those of the Ceylon cardamom) and more shrivelled.

The three sorts are brought from Bombay in chests. The shorts are usually the dearest, and fetch from 3d. to 6d. per lb. more than the longs. The long-longs are seldom brought over. From Madras, only long cardamoms (usually short-longs, rarely long-longs) are brought: they are generally packed in bags, and are lighter by weight than the Bombay sort, and usually fetch 3d. per lb. less than the latter.

COMPOSITION.—The small cardamom was analyzed by Trommsdorff in 1834.¹ He obtained the following results: *Essential oil* 4.6, *fixed oil* 10.4, *a salt of potash (malate?)* combined with a *colouring matter* 2.5, *fecula* 3.0, *nitrogenous mucilage* with *phosphate of lime* 1.8, *yellow colouring matter* 0.4, and *woody fibre* 77.3.

1. VOLATILE OR ESSENTIAL OIL OF CARDAMOM.—Is obtained from the seeds by distilling them with water. 50 lbs. of good short Malabar cardamoms yielded, at one operation, about ℥viss of oil for every lb. of fruit.² It is colourless, has an agreeable odour, and a strong, aromatic, burning taste. Its sp. gr. is 0.943. It is very soluble in alcohol, ether, oils (both fixed and volatile), and acetic acid. It is insoluble in potash-ley. By keeping, it becomes yellow, viscid, and loses its peculiar taste and smell. It then detonates with iodine, and takes fire when placed in contact with concentrated nitric acid. On this oil depend the odour, flavour, and aromatic qualities of the seeds. Its composition is analogous to that of oil of turpentine, being C¹⁰H⁸.

2. FIXED OIL OF CARDAMOM.—Is insoluble in alcohol, ether, and the oils, both fixed and volatile. Nitric acid, assisted by heat, reddens it. It has some analogy to castor oil.

3. STARCH.—Schleiden says that in these seeds he has discovered amorphous paste-like starch in the cells.

PHYSIOLOGICAL EFFECTS.—The effects of cardamoms are those of a very agreeable and grateful aromatic, devoid of all acridity.

USES.—Cardamoms are employed partly on account of their flavour, and partly for their cordial and stimulant properties. They are rarely administered alone, but generally either as adjuvants or correctives of other medicines, especially of stimulants, tonics, and purgatives.

ADMINISTRATION.—Though cardamoms enter into a considerable number of pharmaceutical compounds, only two preparations derive their names from these seeds. They are the following:—

1. TINCTURA CARDAMOMI, E. [U. S.]; *Tincture of Cardamoms*.—(Cardamom seeds, bruised, ℥ivss [℥iv, U. S.]; Proof Spirit Oij [Diluted Alcohol, U. S.]. Macerate for seven days [fourteen, U. S.], and strain. “This tincture may be better prepared by the process of percolation in the same way with the tincture of capsicum, the seeds being first ground in a coffee-mill,” *E.*)—This compound is agreeably aromatic. It is used as an adjunct to cordial, tonic, and purgative mixtures. Dose ℥j to ℥ij.

2. TINCTURA CARDAMOMI COMPOSITA, L. E. D. [U. S.]; *Compound Tincture of Cardamoms*.—(Cardamom seeds bruised, Caraway seeds bruised, of each ℥iiss [℥ss, D.]; Cochineal, powdered, ℥ijss [℥ij, D., ℥j, E.]; Cinnamon, bruised, ℥v [℥j, D.]; Raisins [stoned] ℥v [E.]; Proof Spirit Oij [Oij, D.]. Macerate for seven [fourteen, D.] days, and filter. “This tincture may also be prepared by the method of percolation, if the solid materials be first beat together, moistened with a little spirit, and left thus for twelve hours before being put into the percolator,” *Ed.* The *Dublin College* omits the cochineal and raisins. [Take of Cardamom, bruised, six drachms; Caraway, bruised, two drachms; Cinnamon, bruised, five drachms; Raisins, deprived of their seeds, five ounces; Cochineal, bruised, a drachm; Diluted Alcohol two pints and a half. Macerate for fourteen days, express, and filter through paper, U. S.]—This tincture is used for the same purposes and in the same doses as the former preparation, over which it has the advantage of a more agreeable flavour. Moreover, its colour often renders it useful in prescribing.

² *Private information.*

92. ELETTARIA MAJOR, *Smith*.—THE GREATER OR CEYLON ELETTARIA.

Alpinia Granum Paradisi, *Moon*.
(Fructus; Ceylon Cardamom, *offic.*)

HISTORY.—The fruit of this plant was known to Clusius,¹ who has noticed and figured it under the name of the *Cardamomum majus vulgare*.²

BOTANY.—The flower has not yet been described, but the other parts of the plant are so similar to the corresponding parts of *Elettaria Cardamomum*, that I have felt no difficulty in referring this plant to the genus *Elettaria*. Sir James Edward Smith,³ who was acquainted with the fruit only, observes, “we are persuaded they must belong to the same genus as the Malabar Cardamom.”

Gen. Char.—See *Elettaria Cardamomum*, p. 1142.

Sp. Char.—*Capsule* lanceolate oblong, acutely triangular, with flat sides. *Calyx* three-lobed (Smith).

Rhizome with numerous fibres. *Stem* erect, smooth, enveloped by leaf sheaths. *Leaves* sessile on their sheaths, silky beneath, acuminate; the shorter ones lanceolate, the larger ones oblong-lanceolate; breadth 2 to 3 inches, length not exceeding 15½ inches. *Sheaths* about half the length of the leaves, with a roundish ligula. *Scape* from the upper part of the rhizome, flexuose, jointed, 9 inches long, branched; the branches alternate, one from each joint of the scape, sub-erect, half an inch long, supporting two or three pedicels of about 3-10ths of an inch. *Bracts* solitary, sheathing at each joint of the scape, withered; partial ones, solitary, ovate, acute. *Flowers* not present. *Capsules* one or two on each branch of the scape, with the permanent calyx attached to them; their characters are described in the text.

Fig. 264.

Elettaria major.

The plant from which the above description has been drawn formed part of a collection made for me in Ceylon, by my much lamented friend and pupil, the late Mr. Frederick Saner, Assistant-Surgeon in Her Majesty's 61st regiment. He received it from Mr. Lear, Acting Superintendent of the Royal Botanic Gardens in Ceylon, whose letter, describing it as "*Alpinia* [*Amomum*] *Granum paradisi*," I have in my possession. I presume, therefore, that it is the plant which Mr. Moon,⁴ the former Superintendent of the Gardens, has described under the same name. The following facts favour this conclusion:—

1. Mr. Moon states that its Singalese name is *Ensal*, a term which both Hermann⁵ and Burmann⁶ gave as the native name for cardamon.

2. Mr. Moon states that it is cultivated at Candy. If the real grain of paradise plant were cultivated in Ceylon, it would be somewhat remarkable that its seeds are never exported. Now, I have carefully

examined the list of exports from that island for several years, but the word grain of paradise never once occurs; and all the seeds imported into England under that name, I find, by the Custom-House returns, come from the western coast of Africa. On the other hand, the Ceylon cardamom comes, as its name indicates, from that island.

It is probable, I think, that the plant which yields the grains of paradise of European commerce does not grow in the East; and that writers who have stated otherwise have confounded it with the plant yielding Ceylon cardamom. But the term "grains of paradise" is so truly

¹ *Exoticorum*, lib. i. pp. 166 and 187.

² For further details respecting the history of this cardamom, the reader is referred to a paper by the author, in the *Pharmaceutical Journal*, vol. ii. p. 384, 1842.

³ Rees's *Cyclopædia*, vol. xxxix. art. *Elettaria*.

⁵ *Musaum Zeylanicum*, p. 66, Ed. 2nda, Lugd. Bat. 1726.

⁶ *Thesaurus Zeylanicus*, p. 54, Amstelæd. 1737.

oriental in its character, that I suspect it was first applied to Ceylon cardamoms—a supposition rendered probable by the much more agreeable flavour of the latter seeds, as well as by the observation of Dale,¹ that grains of paradise were often substituted for the Ceylon cardamom.²

Hab.—Cultivated at Candy.

COMMERCE.—Bertolacci³ says that the Ceylon cardamom is collected chiefly in the Candian territory, and that he was informed it is not indigenous, but was introduced by the Dutch. The quantity exported from 1806 to 1813 inclusive varied from 4½ to 18 candies annually. Percival⁴ states that cardamoms grow in the south-east part of Ceylon, particularly in the neighbourhood of Matura. I am informed that occasionally Ceylon cardamoms come from Quillon.

DESCRIPTION.—The *Ceylon cardamom*, or, as it is sometimes termed in English commerce, the *wild cardamom* (*cardamomum zeylanicum*; *cardamomum medium*, Matth. and Geoffr.; *cardamomum majus*, Bont. and Dale; *cardamomum majus vulgare*, Clusius; *cardamomum majus officinarum*, C. Bauhin; *cardamomum longum*, Th. Martius and Geiger; *grande cardamome*, Guib.), is a lanceolate-oblong capsule, acutely triangular, more or less curved with flat and ribbed sides, about an inch and a half long and one-third of an inch broad. At one extremity we frequently find the long, cylindrical, permanent, three-lobed calyx; at the other, the fruit-stalk, which is sometimes branched. The pericarp is coriaceous, tough, brownish or yellowish ash-coloured, three-celled. The seeds are angular, rugged, have a yellowish-red tinge, a fragrant and aromatic but peculiar odour, and a spicy flavour. The long diameter of the vitellus is parallel to that of the embryo. Th. Martius⁵ says that 100 parts of these fruits yield 71 parts of seeds, and 29 parts of pericarpial coats.

COMPOSITION, EFFECTS, AND USES.—Ceylon cardamoms have not been analyzed. Their constituents, as well as their effects and uses, are doubtless analogous to those of the Malabar cardamom. Their commercial value is about one-third that of the latter. They are chiefly used on the Continent.

ORDER XVIII. ORCHIDEÆ, R. Brown.—ORCHIDS.

ORCHIDES, Jussieu.—ORCHIDACEÆ, Lindley.

CHARACTERS.—*Flowers* irregular, gynandrous. *Perianth* adherent (superior), coloured, or rarely herbaceous; its parts arranged in 2 rows. *Column* consisting of the stamens and style consolidated into a central body. *Stamens* 3, the central only being perfect, except in *Cypripedium*, where the central is abortive and the two lateral perfect; *pollen* powdery, or cohering in waxy masses. *Ovary* adherent (inferior), 1-celled, composed of 6 carpels, of which 3 have parietal placentæ; *stigmas* usually confluent in a mucous disk. *Capsule* membranous or coriaceous, rarely fleshy. *Seeds* innumerable, without albumen; *embryo* solid. *Roots* fasciculated and fibrous, sometimes with fleshy tubercles. *Leaves* never lobed; their veins usually parallel, very rarely somewhat reticulated. *Stem* sometimes swollen and jointed, forming *pseudo-bulbs*.

PROPERTIES.—See *Salep* and *Vanilla*.

¹ *Pharmacologia*, p. 252, 3tia ed. Lond. 1737.

² It would appear, however, that the term Grain of Paradise is also applied, in Ceylon, to *Alpinia Allughas*. (See Burmann's *Thesaurus*, p. 54; and Sir J. E. Smith, in Rees's *Cyclopædia*, vol. xxxix. art. *Alpinia*.)

³ *Agricultural, Commercial, and Financial Interests of Ceylon*, p. 157, 1817.

⁴ *Account of Ceylon*, 1805.

⁵ *Pharmakognosie*.

93. *Orchis*, Linn.

Sez. Syst. Gynandria, Monandria.
(Radix; Salep.)

The term *salep*¹ (*radix salep*) is applied to the prepared tubercles of several orchideous plants.

1. ORIENTAL SALEP.—This is usually imported from the Levant, and is said to be the produce of Turkey, Natolia, and Persia. It consists of small ovoid tubercles, frequently strung on a cord. In 1825-6, salep of the value of 35,000 francs was imported into France from Persia.² Salep is the produce, probably, of different species of *Orchis*. Fraas³ states that the σαλίπ or σαλίπι of Greece is collected from *O. Morio*, and also from *O. mascula*, *coriophora*, and *undulatifolia*. Dr. Royle thinks that the salep of Cashmere is obtained from a species of *Eulophia*. Caventou⁴ states that the constituents of salep are gum (which does not become coloured by iodine), much bassorin, a little starch, common salt, and phosphate of lime. Others, however, have found an abundance of starch in salep;⁵ and it is probable, therefore, that the quantity varies at different seasons, and is most abundant before the tubercle is exhausted by the nutrition of the stem.⁶

2. INDIGENOUS SALEP.—That prepared from *Orchis mascula* is most valued; but the roots of some of the palmated sorts, as *Orchis latifolia*, are found to answer almost equally well. Geoffroy,⁷ Retzius,⁸ and Moul⁹ have each pointed out the method of preparing it. The latter directs the roots to be washed and the brown skin removed by a brush or by dipping the root in hot water and rubbing it with a coarse linen cloth. The roots are then put on a tin plate and placed in an oven heated to the usual degree for six or ten minutes, in which time they will have lost their milky whiteness and acquired a transparency like horn. They are then removed and allowed to dry and harden in the air.

The fresh roots of the orchis contain a peculiar odorous principle (which is almost entirely dissipated by drying), starch, mucilaginous matter, a small quantity of bitter extractive, ligneous matter, salts, and water.

Salep possesses the dietetical properties of the starchy and mucilaginous substances (see *ante*, vol. i. p. 117). Its medicinal properties are those of an emollient and demulcent. It was formerly in repute as an aphrodisiac and restorative, and as a preventive of miscarriage,¹⁰ but it has no claim to these powers. The notion of its aphrodisiac properties seems to have been founded on the doctrine of signatures.

Indigenous salep was recommended by Dr. Thomas Percival¹¹ as a wholesome article of food; and in a medicinal point of view as a restorative, emollient, and demulcent.

Mucilage of salep (*mucilago radices salep*; *decoctum salep*) is prepared, according to the Hamburg Codex, with 5 grains of powdered salep and ʒj of distilled water. Dissolve by boiling and constantly stirring, and strain.

94. *Vanilla*, Swartz.

Sez. Syst. Gynandria, Monandria.
(Fructus.)

HISTORY.—Vanilla (so-called from *vainilla* or *baynilla*, the diminutive of *vaina* or *bayna*, a sheath or pod) is said¹² to have been brought to the Continent, as a perfume, about the year 1510. It could not, however, have obtained much attention; for Clusius,¹³ who received it from England in 1602, confesses that he had not seen it before; and he calls it *lobus oblongus aromaticus*. Hernandez¹⁴ describes the vanilla plant under the name of *tlizochitl* or *aracus aromaticus*. The pods were afterwards denominated *benzanelles* quasi *benzionelles*, on account of their benzoin-like odour.¹⁵

BOTANY. Gen. Char.—Fruit a long pulpy pod, with round seeds not inclosed in a loose membrane. (Lindley.)

¹ The term *saloop* is sometimes applied to sassafras tea.

¹⁵ Mentzelius, *Index Nomin. Plant.* Berol. 1652.

Species.—Although, until recently, most authors have ascribed the vanilla of commerce to the *V. aromatica* of Swartz; yet the assertion rested upon no certain or known fact, but chiefly upon the belief that *V. planifolia* bore no odoriferous fruit.¹ Morren,² however, by artificial impregnation, obtained fruit from the *V. planifolia*, which, in fragrance and other qualities, vied with the best vanilla of commerce; and it is probable, therefore, that this species yields part at least of the best or Mexican vanilla.

But Schiede³ states that there are four forms of Vanilla in Mexico, which he calls respectively *V. sativa*, *V. sylvestris*, *V. pompona*, and *V. inodora*;⁴ the first two of which he thinks have been confounded under the name of *V. planifolia*. He did not, however, see the flowers of any of these species; and, therefore, it is impossible to characterize them. He likewise mentions a *baynilla de mono* or *monkey vanilla*, which he did not examine; and also a *baynilla mestiza* or *hybrid vanilla*, a fruit intermediate between that of *V. sativa* and *V. sylvestris*.

But although the best vanilla comes from Mexico, there are other sorts which are the produce of other parts of tropical America, and which are certainly not the produce of *V. planifolia*; I shall, therefore, also notice such other species as probably contribute some of the vanilla of commerce.

1. *V. PLANIFOLIA*, Andrews, Bot. Rep. t. 538.—Fruit very long, cylindrical, and very fragrant.—West Indies (Aiton), Mexico (?), and Guatemala (?).—Probably yields the best Mexican Vanilla.—Schiede's *V. sativa* and *V. sylvestris* are perhaps referable to this species:—

a. *V. sativa*, Schiede; *Baynilla mansa* or *cultivated vanilla* of the Mexicans. Leaves oblong, succulent, the floral ones very small; fruits without furrows.—Grows wild; and is also cultivated in Papantla, Misantla, Nautla, and Colipa.—Yields the finest sort of Vanilla. This, probably, is the *La Corriente* or Current Vanilla of Desvaux.⁵

β. *V. sylvestris*, Schiede; *Baynilla cimarrona* or *wild vanilla* of the Mexicans. Leaves oblong-lanceolate, succulent, the floral ones very small; fruits with two furrows.—Grows in Papantla, Nautla, and Colipa.—Its fruit is collected in Papantla, and mixed with that of the preceding sort.—According to the information furnished to Desvaux, this form is the same species as the preceding; but, growing wild in the woods, and deprived of the solar rays, it yields a smaller fruit.

2. *V. AROMATICA*, Swartz, in Act. Upsal. vi. 66.—Fruit cylindrical, very long.—South America: Brazil.—Said by Martius to yield the *true vanilla* (*vera siliqua vanillæ*).

3. *V. GUIANENSIS*, Splitberger, Ann. Scien. Nat., 2de Sér. t. xv. Bot. p. 279, 1841.—Fruit fragrant, 6-8 inches long, three-edged, straight or somewhat falcate; sides 11-15 lines broad, one somewhat convex, two flattish, angles obtuse.—Surinam. Probably yields *La Guayra vanilla*, and the *large vanilla* (*vanille grosse*) of Guiana.

4. *V. PALMARUM*, Lindley, Gen. and Sp. of Orchid. Plants, p. 437; Splitberger, Ann. Scien. Nat., 2de Sér. t. xv. p. 283.—Fruit fleshy, 2 inches long and $\frac{1}{2}$ an inch diameter, cylindrical, or slightly three-faced, obtuse at the extremities, bivalved.—Bahia. Yields a vanilla inferior in fragrance to the preceding.

5. *V. POMPONA*, Schiede; *Baynilla pompona* or *large vanilla* of the Mexicans.—Fruit with two furrows, rich in volatile oil, with an agreeable odour, yet will not dry, but always remains soft, and cannot be transmitted to Europe as an article of commerce. Humboldt⁶ says that it has scarcely any sale on account of its odour. Desvaux observes that it is certainly the vanilla called by some authors *bova* (*vanilla bouffie, tumid* or *swollen vanilla*), and which is found in French commerce under the name of *vanillon*.

CURING.—The preparation or curing of vanilla varies probably in different places. At Misantla the fruits are sun-dried, and afterwards sweated in blankets; or, when the weather is unfavourable, they are dried by artificial heat.⁷ In some places they are dipped in boiling water, then suspended in the sun to dry, and afterwards oiled.⁸ These different processes have for their object not merely the preservation of the fruits, but the development and preservation of their odour, which is supposed to be effected by a kind of fermentation; for in the fresh state, Aublet says, they have no aroma. The seat of the odour has been variously stated to be in the seeds, the pulp, and the fruit coats: probably all these parts possess it in different degrees.

¹ Plumier, who published a figure of *V. aromatica*, expressly states in his MS., published by Geoffroy (*Tract. de Mat. Méd.* t. ii. p. 363. 1741), that his plant differs from the Mexican species in being inodorous.

² *Annals of Natural History*, vol. iii. p. 1, 1839.

³ Schlechtendal's *Linnaea*, Bd. iv. S. 573, Oct. 1829; also, *Pharmaceutisches Central Blatt für 1830*, S. 46.

⁴ *V. inodora*, the *baynilla de puero* or *hog vanilla* of the Mexicans, is, Schiede states, a distinct species, but, being deficient in volatile oil, is not used. Desvaux says that in drying it gives out a disagreeable odour, and from this has obtained the name of "hog" vanilla.

⁵ *Ann. Sciences Nat.* 3me Ser. Botanique, t. vi. p. 119, 1846.—Desvaux says there are two varieties of *La Corriente*; one of which is well filled with seeds and pulp, and has a fine skin—this is the most esteemed; the other, or *Cuéruda* (leathery), has a thick skin, and, though inferior, is *legitimate* in commerce: it is the *Lec*, *Leg*, or *Leg* of some parts of South America.

⁶ *Political Essay on the Kingdom of New Spain*, translated by J. Black, vol. iii. p. 26, 1822.

⁷ Desvaux, *op. supra cit.*

⁸ Aublet, *Hist. des Plantes de la Guiane Française*, t. ii. 1775.

DESCRIPTION.—The dried fragrant fruits of several species of vanilla constitute the *vanilla* or *vanilloes* of the shops (*fructus vel capsula vanilla*; *siliquæ vanigliæ vel banigliæ*).

Four sorts are known in the English market; viz., the Mexican or Vera Cruz, the Honduras, the La Guayra, and the Brazilian or Bahia. A fifth sort I have received by private hand.

1. *Mexican or Vera Cruz Vanilla*.—Imported from Vera Cruz, tied in bundles of 50 pods, weighing, when of good quality, about $9\frac{1}{2}$ or 10 oz. The heavier the bundle, the better the quality and the greater the value per lb. The bundles come packed in tin cases, each holding 60 bundles. I have met with two varieties:—

a. *Finest Mexican Vanilla*.—This consists of pods which are 7 or 8 inches long, $\frac{1}{3}$ of an inch wide, tapering at the extremities, and curved at the base. They are longitudinally wrinkled, soft, clammy, and dark brown. Their odour is very fragrant, resembling, but being more delicious than, that of balsam of Peru. By keeping they become coated with brilliant acicular crystals, and are then called *crystallized vanilla*.

β. *Second Mexican Vanilla*.—The pods of this sort are shorter (being about 5 inches long), narrower, drier, paler, and less odorous than the preceding, with only a few isolated or no crystals on them. In other respects this sort agrees with the preceding.

Desvaux states that in Mexico five legitimate sorts of vanilla are distinguished; viz., the *primera* (the *grande fina* of Humboldt), or the finest; *chica-fina* (the *mancuerna* of Humboldt), or small fine; *sacate*, or middlings; *resacate*, or middling middlings; and *basura*, or the sweepings.

The *puerca* and *pompona* are not considered to be legitimate sorts.

Bourbon Vanilla, according to Bouchardat,¹ differs from Mexican vanilla only in being somewhat smaller, redder, less brown, drier, and less unctuous.

2. *Honduras Vanilla*.—Imported from Honduras. Its value is from 2s. to 4s. per lb. The fruits are cylindrical, or slightly flattened, $3\frac{1}{2}$ or four inches long, $\frac{1}{3}$ l or $\frac{2}{3}$ ths of an inch in diameter, longitudinally wrinkled, brown, and dry. Their odour is vanilla-like, but feeble, and not of that fragrant kind which characterizes the best vanilla.

3. *La Guayra Vanilla*.—Imported from La Guayra, in Venezuela, in various packages (mostly tins in cases). It is an inferior sort, chiefly used by perfumers, and fetches from 2s. to 4s. per lb.

The fruits are large flattened, or somewhat plano-convex, or obscurely triangulated pods, from 5 to 7 inches long, $\frac{1}{2}$ to $\frac{2}{3}$ of an inch wide, somewhat narrowed at the extremities, a little twisted or curled, longitudinally wrinkled, here and there presenting a somewhat blistered appearance, brown, with a peculiar (sweetish fruity) vanilla odour. On the flattened side, at each edge, is a more or less distinct welt-like suture.

In the Museum of the Pharmaceutical Society are two pods, probably of the same sort, received from Mr. Stutchbery, of Demerara. They are, however, $7\frac{1}{2}$ inches long, more distinctly triangular, blackish externally, and appear as if oiled. They were sent along with a pod of what I believe to be *V. guianensis*, preserved wet.

La Guayra Vanilla is probably the produce of *V. guianensis* of Splitberger. It is perhaps the *large vanilla* (*vanille grosse*) of Aublet; and is said by Dr. T. W. C. Martius to be sometimes met with under the name of *vanillon*.

4. *Brazilian or Bahia Vanilla*.—This consists of pods of about $7\frac{1}{2}$ inches long and $\frac{2}{3}$ of an inch wide. The samples which I have seen have been divided longitudinally, and strictly speaking, therefore, are half pods. This sort is blackish, and damp and sticky to the touch, somewhat as if it had been covered with treacle or some glutinous substance. By digestion in spirit it is deprived of its glutinous coating. It is sometimes brought over quite wet. By some persons it is said to have been preserved in sugar, and that to this substance it owes its dampness. Its odour is not equal to that of the best vanilla.

This sort of vanilla corresponds with the fruit neither of *V. aromatica* of Swartz, nor of *V. palmarum*, Lindley—the only two species of vanilla which, according to Martius, are found in the Brazils. Is it *V. pompona* of Schiede?

5. *Panama Vanilla*.—I have received a single pod only of this. It is flat, $3\frac{1}{2}$ inches long, nearly $\frac{2}{3}$ of an inch wide, dark brown, and fragrant.

GOODNESS.—The best vanilla is dark shining brown, plump, heavy, pliant, and soft, and has a fine fragrant smell. The crystallized variety is preferred.

Shrivelled, dull, dry, pale or yellowish brown, faintly smelling, or musty or mouldy pods are bad.

Sometimes dry shrivelled pods are freshened up with balsam of Peru, or are rolled in benzoic acid to give them a crystallized appearance.

COMPOSITION.—The crystallized vanilla was analyzed by Bucholz,² who obtained the following results: Odorous brownish-yellow fixed oil, 10.8; soft resin, scarcely soluble in ether, 2.3; bitter extractive with some acetate of potash, 16.8; acidulous, bitterish, astringent extractive, 9.0; sweet extractive, 1.2; saccharine matter with benzoic acid, 6.1; gum, 11.2; starchy matter,

¹ *Journ. de Pharm.* 3e Sér. t. xvi. p. 274, 1849.

² *Buchner's Repertorium*, Bd. ii. S. 253, 1828.

2.8; woody fibre, 20.0; oxidized extractive dissolved by potash, 7.1; gum extracted by potash, 5.9; benzoic acid, 1.1; water and loss, 5.7.—The ashes of the insoluble fibre consisted of the carbonates of soda, potash, lime and magnesia, sulphate of lime, sulphates, chlorides, alumina, oxide of iron, and oxide of copper.

The nature of the *odorous principle*¹ of vanilla has not been satisfactorily made out. It probably resembles that of the balsam of Peru and belongs to the einnamon series. By distillation with water, alcohol, or ether, vanilla yields no volatile oil; the liquid obtained by distillation with water being nearly inodorous. It is said that when the fruit is mature it yields from two to six drops of a liquid which has an exquisite odour, and bears the name of *balsam of vanilla*—none of which, however, reaches Europe, though it is stated to be used in Peru.

The *soft needle like crystals* which incrust the finest kind of vanilla are usually regarded as either benzoic or cinnamic acid. They are slightly soluble in hot water, and the solution, according to my experiments, reddens litmus. Bley,² who examined them, denies that their solution reddens litmus, and considers them to be a peculiar solid volatile oil. They require to be farther examined.

PHYSIOLOGICAL EFFECTS.—Vanilla is an aromatic stimulant. Its effects probably resemble those of balsam of Peru. It is considered to have an exhilarating effect on the mental functions, to prevent sleep, to increase the energy of the muscular system, and to act as an aphrodisiac.³

USES.—As a medicinal agent it is not employed in England. On the continent it has been used in hysteria, melancholia, impotency, asthenic fevers, rheumatism, &c.

Its principal use in this country is to flavour chocolate and various articles of confectionery (ices, creams, &c.), liqueurs, &c. It is also employed in perfumery.

ADMINISTRATION.—It is exhibited in the form of powder or tincture.

1. *Pulvis Vanilla; Powder of Vanilla.*—Vanilla is powdered by the intervention of sugar. The pods being cut in small pieces are pounded in an iron mortar with sugar, then sifted, the residue powdered with more sugar, and so on. The powders are then to be mixed. The quantity of sugar required varies according to the state of dryness or succulency of the pods; but in general four parts of sugar are required for one part of vanilla. This powder is used for aromatizing various culinary and medicinal preparations. It may be administered medicinally in doses of a drachm; equal to about twelve grains of the pure vanilla.

2. *Tinctura Vanilla; Tincture of Vanilla; Essence of Vanilla.*—This is prepared by digesting one part of good Mexican vanilla in six parts of rectified spirit. When inferior sorts of vanilla are used, the proportion of this substance is increased.—Vogler⁴ states that a tincture of balsam of Peru is sometimes substituted for that of vanilla.

2. Leaves with netted (reticulated) veins. *Dictyogens; Retosæ.* Lindley.

† Flowers unisexual, with the perianth adherent to the ovary (*inferior ovary*).

ORDER XIX. DIOSCOREACEÆ, Lindl.—YAMS.

Dioscoreæ, R. Brown.

CHARACTERS.—Twining endogenous plants with reticulated leaves, unisexual regular flowers, a 6-parted superior perianth, 6 stamens, a 3 celled inferior ovary with 1- or 2-seeded cells, and capsular or berried fruit.

PROPERTIES.—See *Dioscorea* and *Tamus*.

95. *Dioscorea, Linn.*—The Yam.

Sez. Syst. Diœcia, Hexandria.

(Tuber.)

In tropical countries (East and West Indies, Africa, Polynesia) the tuberous roots of many species of *Dioscorea* or *Yam*⁵ are used as food. Of seventeen species described by Roxburgh,⁶ eleven are stated to be employed for food. The four following are cultivated in India, and are esteemed in the order in which they are enumerated: *D. globosa*, *D. alata*, *D. purpurea*, and *D. rubella*. Roxburgh also says that *D. atropurpurea* is extensively cultivated at Malacca, Pegu,

¹ An odour more or less allied to that of vanilla, and therefore called the *vanilla odour*, is common to many vegetable substances (see Virey, *Journ. de Pharm.* t. vi. p. 591; also, Mérat and De Leas, *Dict. Mat. Méd.* t. vi. p. 843, and Suppl. p. 727.)

² *Pharmaceutisches Central Blatt für* 1831, p. 579.

³ Sundelin, *Heilmittellehre*, ii. 203, 3te Aufl.

⁴ *Pharmaceutisches Central Blatt für* 1848, S. 448.

⁵ The term *yam* is frequently, but erroneously, applied to the tubers of *Tacca* and *Arum* (see ante, p. 157).

⁶ *Fl. Indica*, vol. iii. p. 797.

and the eastern islands; and that *D. fasciculata* is cultivated to a considerable extent in the vicinity of Calcutta, not only for food, but to make starch of the roots. In the West Indies several species are used as food; the chief are *D. aculeata*, *D. alata*, *D. bulbifera*, and *D. sativa*. The tuberous roots sold in the London shops as West India yams are said to be those of *D. alata*.

Yams are large fleshy roots, sometimes weighing from thirty to forty pounds each. Some of them are highly acrid in the fresh state, but become agreeable articles of food when cooked, owing to the dissipation or decomposition of the acrid principle.

The fresh root of *Dioscorea sativa*, from the West Indies, was analyzed by Süersen,¹ who obtained the following results: resin, 0.05; uncrystallizable sugar, 0.26; mucilage, 2.94; starch, 22.66; ligneous fibre, 6.51; nitrogenized matter, quantity undetermined; and water, 67.58. The fresh roots yield 0.52 of ashes, containing carbonate of lime and silica.

The following are the per centage quantities of *yam-starch* obtained by Dr. Sheir² from the fresh roots of the several species of *Dioscorea* :—

Per Centage of Starch.		Per Centage of Starch.	
Common yam (<i>D. sativa</i>)	24.47	Buck yam (<i>D. triphylla</i>)	16.07
Barbados yam (<i>D. ——— ?</i>)	18.75	Another sample	15.63
Guinea yam (<i>D. aculeata</i>)	17.03	A third	14.83 (From a dark-coloured variety.)

I am indebted to Dr. Sheir for specimens of the starches of three species: viz., *D. sativa*, *D. aculeata*, and *D. triphylla*. They were prepared in the Colonial Laboratory at Demerara. They are beautifully white, inodorous, and tasteless. Examined by the microscope, the particles of the three starches present a general similarity of character. They are large, somewhat compressed, elliptical or ovate, or somewhat obtusely triangular. They may be compared in shape to the seed of the common scarlet runner bean (*Phaseolus multiflorus*), and are surrounded by rings, which, when viewed on the middle of the flat side of the particle, appear to be but slightly curved. In the latter character they approximate to curcuma starch. Some of the particles present one or two slight nipple-like projections analogous to those of maranta starch. In polarized light, they present the usual crosses observed with most other starches. Their size³ is about $\frac{1}{500}$ th of an inch in length, and about $\frac{1}{700}$ th of an inch in breadth.

Yams are roasted and boiled, and eaten like potatoes. "They are dressed in various forms, being boiled in soups or broths, &c., made into pudding, or roasted in the fire."⁴ Some of them, however, are violently acrid, causing vomiting and diarrhœa, even after being carefully cooked. This is said to be the case with *D. triphylla* and *dæmona*. Yet Dr. Wright and Dr. Sheir declare that the roots of *D. triphylla* are nearly equal to potatoes.

96. *Tamus communis*, Linn.—Common Black Bryony.

Sex. Syst. Diœcia, Hexandria.
(Radix.)

**Ἀμπελος μέλαινα*, Dioscor. lib. iv. cap. 185?; *Chironia*, *Gynæcanthe* aut *Apronia*, Pliny, lib. xxiii. cap. 17, ed Valp.?; *Bryonia nigra*, Gerard, 871.—Indigenous. The root (*radix bryoniæ nigræ*) is large and fleshy, black externally, white internally. When fresh, it possesses some acidity. No analysis of it has been made. Taken internally, it acts as a diuretic, and has been esteemed as a lithic (see vol. i. p. 283). It is kept in the herb shops, and sold, like Solomon's seal (see ante, p. 215), as a topical application for removing bruise marks. In France, it is called the *herbe aux femmes battues*, or the *herb for bruised women*.

¹ Quoted by L. Gmelin, *Handb. d. Chemie*, Bd. ii. S. 1334.

² *Report on the Starch-producing Plants of the Colony of British Guiana*, by John Sheir, LL.D. Demerara, 1847.—Dr. James Clark (*Medical Facts and Observations*, vol. vii. 1797) obtained from 4 lbs. of the roots of *D. triphylla* 5 oz. 2 dr. of starch, and from the same quantity of the roots of *D. bulbifera* 8 oz. of starch.

³ The following measurements, in parts of an English inch, of the particles of yam starch, were made for me by Mr. George Jackson :—

Particles.	Guinea Yam.		Common Yam.		Buck Yam.	
	Length.	Breadth.	Length.	Breadth.	Length.	Breadth.
1	0.0025 . . .	0.0020	0.0019 . . .	0.0012	0.0030 . . .	0.0015 . . .
2	0.0018 . . .	0.0014	*0.0019 . . .	0.0009	*0.0022 . . .	0.0014 . . .
3	*0.0015 . . .	0.0011	*0.0016 . . .	0.0010	*0.0017 . . .	0.0010 . . .

7	0.0013 . . .	0.0005				

The most prevalent-sized particles are those marked thus *.

⁴ Dr. Wright, *Medicinal Plants growing in Jamaica*, in the *Memoir of his life*, p. 208, 1828.

†† Flowers with the perianth free from the ovary (*superior ovary*).

ORDER XX. SMILACEÆ, *Lindl.*—SARSAPARILLAS.

CHARACTER.—*Flowers* biennial or polygamous. *Calyx* and *corolla* both alike, free, 6-parted. *Stamens* 6, inserted into the perianth near the base; seldom hypogynous. *Ovary* 3-celled, the cells 1 or many-seeded; *style* usually trifid; *stigmas* 3. *Fruit* a roundish berry. *Albumen* between fleshy and cartilaginous; *embryo* usually distant from the hilum.—*Herbaceous* plants or *under shrubs*, with a tendency to climb. *Stems* scarcely woody. *Leaves* reticulated. (*Lindley*.)

PROPERTIES. See *Smilax*.—The *Ripogonum parviflorum*¹ of R. Brown, a native of New Zealand, where it is called *kareao*, is said to possess virtues similar to those of sarsaparilla, and may be termed the *New Zealand sarsaparilla*. The stems yield 12 per cent. of extract, which is bitter, and contains starch-gum and traces of astringent matter.²

97. SMILAX, *Linn.*, several Species of, yielding Sarsaparilla.

Sex. Syst. Diœcia, Hexandria.

(*Sarsa Jamaicensis*; *Smilax officinalis*, *Kunth?* *Radix, L.*—*Smilax officinalis*. Jamaica sarsaparilla. The root, *D.*)

HISTORY.—The root of sarsaparilla was brought into Europe from the West Indies, about the year 1530, with the character of being a medicine singularly efficacious in the cure of lues venerea.³ *Monardes*⁴ says that, when the Spaniards first saw it, they called it *çarça-parilla*, on account of its resemblance to the *çarça-parilla* of Europe (*Smilax aspera*). The Spanish term *zarzaparilla* (from *zarza*, a Bramble; and *parilla*, a vine) signifies a thorny vine.

BOTANY. **Gen. Char.**—*Diœcious*. *Perianth* 6-parted, nearly equal, spreading. **MALE FLOWERS:** *stamens* 6; *anthers* erect. **FEMALE FLOWERS:** *perianth* permanent; *ovary* 3-celled, the cells 1-seeded; *style* very short; *stigmas* 3. *Berry* 1- to 3-seeded. *Seeds* roundish; *albumen* cartilaginous; *embryo* remote from the hilum. (*R. Brown, Prodrom. p. 293.*)

Species.—Considerable uncertainty prevails as to the botanical origin of the various sorts of sarsaparilla of commerce. From four species of *Smilax*, a great part, at least, of this drug is obtained.

1. *S. OFFICINALIS*, HBK.—*Stem* twining, shrubby, prickly, quadrangular, smooth; the young shoots are unarmed, and almost round. *Leaves* ovate-oblong, acute, cordate, netted, 5- to 7-nerved, coriaceous, smooth, a foot long, and 4-5 inches broad; the young ones are narrow, oblong, acuminate, and 3-nerved. *Petioles* smooth, an inch long, bearing 2 tendrils above the base. *Flowers* and *fruit* unknown.—Grows in New Granada, on the banks of the Magdalena, near Bajorque. It is called *zarzaparilla* by the natives, who transmit large quantities of it to Carthage and Mompo; whence it is shipped for Jamaica and Spain (*Humboldt*).⁵ According to *Pohl*, it is collected near the river Abaité, in the western part of the province of Minas Geraes (*Martius*).

This species probably yields the sarsaparilla exported from Colombia (*Savanilla*, *Santa Marta*, *Caracas* and its port *La Guayra*, *St. Margarita* and its port *Porta Arenas*), and Guatemala (*Costa Rica*).

2. *S. MEDICA*, *Schlechtendal*, in *Linnaea*, vi. 47.—*Stem* angular, armed at the joints with straight prickles, with a few hooked ones in the intervals. *Leaves* shortly acuminate, smooth, 5- to 7-nerved; inferior ones cordate, auriculate-hastate; upper ones cordate-ovate. *Peduncle* axillary, smooth, about an inch long. *Inflorescence*

¹ Allan Cunningham, in *Hooker's Companion to the Botanical Magazine*, vol. ii.

² See a paper, by the author, in the *Pharmaceutical Journal*, vol. v. p. 73.

³ *Pearson, Observations on the Effects of various Articles of the Materia Medica in the Cure of Lues Venerea*, 1800.

⁴ *Clusii Exotic. lib. x. cap. xxii. p. 317.*

⁵ *Nov. Gen. et Spec. i. p. 215.*

an 8- to 12-flowered umbel. *Fruit* red, size of a small cherry; contains 1—3 red-dish-brown *seeds*. *Embryo* cylindrical, lodged in horny albumen (T. F. L. Nees).¹

Schiede² says, that of the numerous species of *Smilax* which grow on the eastern slope of the Mexican Andes, this is the only species which is collected in the villages of Papantla, Tuspan, Nautla, Misantla, &c., and carried to Vera Cruz, from whence it is sent into European commerce under the name of *zarsaparilla*. We may, therefore, safely state that Mexican sarsaparilla (Vera Cruz and Tampico) is the produce of this species.

3. *S. PAPYRACEA*, Poiret; *S. syphilitica*, Mart. (non Humb.) Reise, iii. 1280; *Sipó ém* of the natives.—*Stem* 4-cornered or plane-angular, polished, prickly. *Leaves* somewhat membranous, oval-oblong, obtuse at both ends, or usually pointletted at the apex, quite entire, unarmed, 5-ribbed, with 3 more prominent ribs. *Cirrhii* inserted beneath the middle of the petiole.—Province of Rio Negro, in marshy spots on the Japura, near Porto dos Miranhos (Martius); near Ega (Poeppig); and near Borba, in the province of Rio Negro (Riedel).—Yields Brazilian (also called Maranham, Para, or Lisbon) sarsaparilla.

The “Rio Negro Sarsa” of Dr. Hancock³ is perhaps the produce of this species.

The preceding are the species of *Smilax*, from which probably the greater part, if not all, of the sarsaparilla of commerce is obtained. Other species, however, which have been mentioned in connection with this drug, require to be noticed.

4. *S. SARSAPARILLA*, Linn.—It is common in the hedges and swamps of the United States of America; but, notwithstanding its name, it does not yield any of the sarsaparilla of commerce: and there is no evidence that it ever did yield any. Dr. Wood⁴ remarks that its root would certainly have been dug up and brought into the market, had it been found to possess the same properties with the imported medicine.

5. *S. SYPHILITICA*, HBK.—Humboldt and Bonpland discovered it in New Granada, on the river Cassiquiare, between Mandavala and San Francisco Solano.⁵ In the former edition of this work, I stated, on the authority of Martius⁶, that this species yielded Brazilian sarsaparilla. But this botanist has subsequently⁷ ascertained that he had mistaken *S. papyracea* for this species.

Poeppig⁸ states that *S. syphilitica*, HBK., is collected at Maynas (in Colombia), and forms the *sarsa fina* which is mixed with *sarsa gruésa* (*S. cordato-ovata*, Pers.) and sent to Para.

6. *S. CORDATO-OVATO*, Persoon.—Cayenne; Maynas. Yields *sarsa gruésa* (see *supra*).

7. *S. PURHAMPTI*, Ruiz, Memoria sobre las virtudes, &c. &c., Purhainpy, p. 65.—Peru. Yields one of the best sorts of sarsaparilla, which Ruiz calls *China peruviana*. Lindley⁹ thinks this may be the same species as *S. officinalis*.

8. *S. OBLIQUATA*, Poiret.—Peru. Guibourt¹⁰ ascribes to this species the *Peruvian sarsaparilla* of commerce, but I know not on what authority.

GENERAL DESCRIPTION.—The *sarsaparilla* or *sarza* (more properly *zárza*) of commerce (*radix sarsaparilla* vel *sarzæ*) consists essentially of the roots of the before-mentioned, and perhaps also of other species of *Smilax*. In some sorts of sarsaparilla the roots are attached to a portion of the *rhizome*.

a. The *rhizome* or *rootstock* (*rhizoma*), called by druggists the *chump*, is a tuberous subterranean stem, which in the living plant is placed horizontally or obliquely in the earth. It grows throwing out aerial stems and roots at the more pointed extremity, and gradually dies off at the thicker and older end. One or more *aerial stems* are frequently found attached to the rhizome of the shops: these are rounded or square, with *nodes* and usually with *aculei* or prickles. If a transverse section be made of either the rhizome or aerial stem, no distinction of bark, wood, and pith is perceptible.

β. The roots (*radices*) are called by Schleiden¹¹ *adventitious* (*r. adventitiæ*): they are usually several feet long, and of variable thickness; on the average about that

of a writing quill. The thin shrivelled roots are more or less wrinkled or furrowed longitudinally, and in trade are usually said to be *lean*; while the thick, plump, swollen ones are described as being *gouty*. The latter usually abound in starch, and are said to be *mealy*. Frequently, especially in some sorts of sarsaparilla, the roots are said to be *bearded*; that is, they give off, more or less abundantly, fibres, which are themselves often divided into fibrils.

The colour of the roots varies, being more or less red or brown, frequently with a grayish tint. The washed or unwashed condition, the greater or less care taken of them in drying, the time of year when they were collected, the colour and nature of the soil in which they grew, as well as the species or sort of plant from which they are obtained, and many other circumstances, doubtless modify the colour. The taste of the root is mucilaginous, and slightly acid. The acidity is only perceived after chewing the root for a few minutes. The odour is somewhat earthy.

By a transverse section the roots are seen to consist of a cortex or rind, and a ligneous cord or medullium inclosing the pith, somewhat in the manner of an exogenous stem.

The *cortex* or *rind* consists 1st, of the *cuticle* or *epidermis*, composed of compact cells; 2dly, of the *outer cortical layers*, composed of coloured (from golden yellow to deep orange-red), elongated, thick, flattened cells (some of which are porous), which form a *subcuticular tissue* (*epiphylæum* or *periderm*?) ; and, 3dly, of the *inner cortical layers*, consisting of shorter, thinner, cylindrical, often porous cells with large intercellular spaces. In some sorts of sarsaparilla most of these cells abound in starch, while a few contain bundles of acicular crystals (oxalate of lime?) called *raphides*. The mealy cortex is frequently colourless, but sometimes has a roseate tint.

The *ligneous cord* or *medullium* consists of 1st, a *cellular layer* (*liber*?), called by Schleiden the *Kernscheide* or *nucleus-sheath*, whose cells are empty, thick, and strongly coloured (like those of the outer cortical layers); 2dly, a *woody zone*, called by Schleiden the *Gefässbündelkreis* or *vascular-bundle-circle*, usually of a pale yellowish colour, and composed of woody tissue, vessels,¹ and cambial cells; and, 3dly, *medulla* or *pith*, generally colourless, composed of cylindrical cells (like those of the inner cortical layers) which often abound in starch. Sometimes an isolated vessel, or a small group of vessels surrounded by a thin layer of ligneous cells, is seen in the pith.

|---|---|

¹ The apertures in the woody zone, seen with the naked eye in a transverse section of the root, are those of large vessels. Occasionally we perceive an isolated bundle of vessels whose interior is filled up with a yellowish-red colouring matter.

The chief anatomical characters, which vary in the different species of sarsaparilla, are the relative breadths of the cortical, ligneous, and medullary layers, the characters of the cells of the nucleus sheath, and the number of layers composing the subcuticular tissue. Schleiden pretends that he can, by these characters, distinguish the South American, Central American, and Mexican sarsaparillas from each other. The following is the way in which he applies them: *South American sarsaparillas*, he says, have, almost without an exception, a mealy cortex and a vascular-bundle-circle whose breadth, from the nucleus sheath to the pith, is one-fourth, or at most one-third, the diameter of the pith. They have, therefore, a large white pith. The *Central American* and *Mexican sarsaparillas* have, on the other hand, a vascular-bundle-circle whose breadth is commonly equal to, and sometimes exceeds, the diameter of the pith. Sometimes, but rarely, the pith is half as thick again as the vascular-bundle-circle. The Central American and Mexican sarsaparillas are, according to Schleiden, readily distinguished from each other by the nucleus sheath, whose cells, in the *Central American* sorts, are either quadrangular or somewhat elongated transversely (tangentially), and are nearly equally thick on all sides (Fig. 268); whereas in the *Mexican* sort these cells are elongated in the direction from within outwards (radially), and have walls which are thicker on the inner than on the outer side (Fig. 269).

Magnified Views of the Cells composing the Nucleus Sheath (according to Schleiden).

a, a, a, a, The cells of the sheath. |

b, A portion of the woody zone.

The Central American and Mexican sorts are less strikingly distinguished, according to Schleiden, by the external cortex (subcuticular tissue), which, in the Central American, consists of only one, rarely two, layers of very thick cells, and altogether has fewer cellular layers; while the Mexican has from 2 to 4 layers of very thick cells, and altogether sometimes 6 or 7 layers.

COMMERCIAL SORTS.—Several sorts of sarsaparilla are met with in commerce, and are well known to our dealers; but I find that, with some exceptions, there is a great want of precision in the names applied to some of the varieties. The terms *Jamaica*, *Lima*, *Honduras*, and *Lisbon* or *Brazilian*, are, by English dealers, applied to sorts which are well known to them either by the characters of the roots or the mode of packing. There is another kind, called by English druggists *gouty* or *Vera Cruz* sarsaparilla, which appears to me to be identical with that called by Continental and American writers *Caraccas sarsaparilla*, under which name I shall describe it.

a. **Geographical Classification.**—Sarsaparilla is exclusively the produce of America, and grows in the southern part of North America and the northern part of South America. The exact limits are not known.

1. *Mexican sarsaparilla.*—This is the produce of *Smilax medica*, and is the growth of Papantla, Tuspan, Nautla, Misantla, &c. It is usually shipped at Vera Cruz, and is, therefore, usually known in commerce by the name of *Vera Cruz sarsaparilla*. From Tampico, another Mexican port, a similar sort of sarsaparilla is also exported, which is known in Europe as *Tampico sarsaparilla*. According to Monardes, the first sarsaparilla which came to Europe was brought from New

Spain (Mexico). He describes it as being whiter, somewhat yellowish, and smaller than the Honduras sort.

2. *Central American sarsaparilla*.—Guatemala produces sarsaparilla, which is sometimes exported to Jamaica; but it is not distinguished in European commerce as the produce of Guatemala. *Honduras sarsaparilla* is a well-known and distinct sort in the London market. Monardes says it was the second kind known in Europe. He describes it as darker and thicker than the Mexican sort; and says that it was more esteemed. *Costa Rica sarsaparilla* is usually sold as *Lima sarsaparilla*, with which it agrees in quality. Much sarsaparilla is collected on the Mosquito coast by the Seeo Indians, who sell it to the Sambos. The latter carry it in their doreys to Truxillo, where they barter it for goods.¹ I have been informed that sarsaparilla, the produce of the Mosquito Shore of St. Juan de Nicaragua, is sometimes sent to England by way of Jamaica.

3. *Colombian sarsaparilla*.—Since 1831, Colombia has been divided into three independent states, viz., New Granada, Venezuela, and Ecuador, from all of which sarsaparilla is exported to Europe, either directly or indirectly, by way of Jamaica or New York.

a. *New Granada*.—According to Humboldt and Bonpland, sarsaparilla (*Smilax officinalis*) is collected on the banks of the Magdalena, and transmitted to Cartagena and Mompox, whence it is shipped for Jamaica and Spain. Occasionally sarsaparilla is imported into England from Santa Marta and Savanilla.

β. *Venezuela*.—From La Guayra (the sea port of the Caraccas) is shipped to the United States of America and Europe *Caraccas sarsaparilla*. Sarsaparilla is sometimes imported into England from Porta Arenas.

γ. *Ecuador*.—Occasionally sarsaparilla is imported into London from Guayaquil; but whether it is the produce of Maynas or of Central America I know not.

4. *Brazilian sarsaparilla*.—This is a well-known sort, and is imported from Para; and according to Martius is the produce of *Smilax papyracea*. Poeppig, however, says that two sorts of sarsaparilla, *sarsa fina* and *sarsa gruésa*, are collected in Maynas and transmitted to Peru: the first is the produce of *Smilax sphyllitica*, the second of *S. cordato-ovata*.

5. *Peruvian sarsaparilla*.—Sarsaparilla is sometimes imported from Lima; but whether it is the produce of Peru or of Maynas, or of Central America, I know not. Under the name of *Lima sarsaparilla* is sold, not only the sarsaparilla from Lima, but also that from Costa Rica. It is probable that no sarsaparilla grows on the western declivity of the Andes, and that the sarsaparilla exported from Lima is either the produce of Maynas or has been carried to Lima from some other ports on the Pacific.

A considerable quantity of sarsaparilla is imported into London from Jamaica (*Jamaica sarsaparilla*), from Valparaiso, and from New York; and formerly also from Lisbon (*Brazilian sarsaparilla*). But it is not the produce of these places.

β. **Qualitative Classification**.—The various commercial sorts of sarsaparilla differ from each other in the anatomical and other characters of the roots, in the manner in which they are folded and packed, and in the absence or presence and character of the attached rhizomes and stalks.

I have already given a sketch of Schleiden's anatomical arrangement of the commercial sorts of sarsaparilla roots. I shall not adopt it, because I do not consider it accurate or easily applied. His classification would associate Costa Rica sarsaparilla with that of Honduras, and the Lima with the Caraccas and Brazilian sorts.

I shall arrange the sarsaparillas of commerce in two divisions: the first including those commonly termed mealy; the second, those which are not mealy.

¹ Young, *Narrative of a Residence on the Mosquito Shore during the Years 1839, 1840, and 1841*, Lond. 1842.

Div. 1. *Mealy Sarsaparillas.*

(Sarsaparillæ farinosæ seu amylicæ.)

These are characterized by the mealy character of the inner cortical layers, which are white or pale-colored. The meal or starch is sometimes so abundant, that a shower of it, in the form of white dust, falls when we fracture the roots. The thickest mealy coat which I have measured was barely $\frac{1}{10}$ th of an inch in thickness. Compared with the diameter of the medullium or ligneous cord, the thickness of the mealy coat is sometimes nearly equal to it, but usually does not exceed $\frac{3}{4}$ d or $\frac{1}{2}$ of it. The thick mealy roots have a swollen appearance, and are technically called *gouty* by the dealers: the cortex, being brittle, is frequently cracked transversely in rings, and readily falls off. The colour of the mealy coat varies from white to yellowish or pinkish.

Fig. 270.

Magnified view of a section of mealy (Honduras) sarsaparilla.

- a. Cuticle or epidermis.
 b. Outer cortical layers.
 c. Mealy coat, or inner cortical layers.
 d. Cellular sheath.
 e. Woody zone.
 f. Medulla or pith.

The medulla or pith is frequently very amylicæous.

If a drop of oil of vitriol be applied to a transverse section of the root of mealy sarsaparilla, the mealy coat is but little altered in colour; while the woody zone becomes dark purplish or almost black. Sometimes the pith also acquires a darkish tint.

A decoction of mealy sarsaparilla, when cold, becomes dark blue on the addition of tincture of iodine.

The aqueous extract of mealy sarsaparilla, when rubbed down with distilled water in a mortar, does not completely dissolve, but yields a turbid liquid, which becomes blue on the addition of iodine.

This division includes three commercial sorts of sarsaparilla; namely, the *Brazilian*, the *Honduras*, and a third kind, which by English dealers is commonly called *gouty* or *Vera Cruz* sort, but which, by Continental and American writers, is usually denominated *Caraccas*.

They may be subdivided thus:—

- A. Pith 2- to 4-times the breadth of the woody layer; cells of the nucleus sheath elongated radially.
- a. Pale, folded, often swollen (or *gouty*) roots with the rhizomes or stems attached 1. *Caraccas*.
 - β. Reddish-brown, unfolded roots with rhizomes or stems attached, packed in rolls or cylindrical bundles 2. *Brazilian*.
- B. Pith 1- to $1\frac{1}{2}$ times the breadth of the woody layer; cells of the nucleus sheath square or elongated tangentially 3. *Honduras*.

1. **CARACCAS SARSAPARILLA** (*Radix Sarsaparillæ de Caraccas*).—This is the *gouty* or *Vera Cruz sarsaparilla* of most English dealers. It would appear to come to this country by various routes. One sample, which I have received, came, as I was informed by Mr. Price (of the firm of Price and Gifford, drug brokers), from the Pacific side of South America by way of Valparaiso. Mr. Luckombe, of the firm of Hodgkinson and Co., informs me that some of this sort of sarsaparilla has come by way of New Orleans. Dr. Wood¹ states that it is imported in large quantities into the United States from La Guayra (the port of the Caraccas). He says it comes in oblong packages of about one hundred pounds, surrounded with broad strips of hide, which are connected laterally with thongs of the same material, and leaves much of the root exposed. The roots, he adds, are separately, closely, and carefully packed, and are often very amylicæous internally.

¹ *United States Dispensatory.*

I have a bundle (Fig. 271) of this sarsaparilla (called by English druggists *gouty* or *Vera Cruz sarsaparilla*) which was imported into Liverpool from Valparaiso. It weighs $5\frac{1}{2}$ lbs. It is flattened, about $2\frac{1}{2}$ feet long, scarcely 1 foot broad at its widest parts, and is 3 or 4 inches thick. At each extremity are two rhizomes, with

Fig. 271.

Bundle of Caraccas Sarsaparilla.

portions of rounded or obscurely square stems bearing a few small prickles. The roots are pale yellowish or reddish-gray, and are very amylaceous. The cells of the nucleus sheath are elongated radially, and their walls are thicker on the inner side (Fig. 269).

This sort is probably the produce of *Smilax officinalis* and *S. syphilitica*, HBK.

Guibourt's *Maracaibo sarsaparilla* is perhaps only a variety of Caraccas sarsaparilla.

2. BRAZILIAN SARSAPARILLA; *Lisbon, Portugal, or Rio Negro Sarsaparilla* (*Radix Sarsaparillæ braziliensis, seu lisbonensis; S. de Maranon; S. de Para; S. insipida*).—Prior to the introduction of the Jamaica sort of sarsaparilla into the London market, the Lisbon sort commanded the highest price.¹ This is usually imported from Para and Maranham. It is brought over unfolded, tied in rolls or cylindrical bundles (*sarsaparilla longa*) of from three to five feet long, and about a foot in diameter.

In the museum of the Pharmaceutical Society is a roll (Fig. 272) weighing $14\frac{1}{4}$ lbs.: its length is 3 feet 1 inch, and its diameter 7 inches.

Fig. 272.

A Roll of Brazilian Sarsaparilla.

It is free from the rhizome or chump. But, as it is not easy to get at the interior of the rolls, this sort of sarsaparilla is more liable to false packing than any other sort. It has fewer longitudinal wrinkles than the Jamaica kind, fewer radicles, especially at one end; has a reddish-brown colour, and abounds in amylaceous matter, both in the cortex and pith. Its decoction is much paler coloured than the Jamaica variety.

This sort of sarsaparilla is collected on the branches of the Amazon: according to Poeppig, at Huallaga, Intay, Jurua, Rio de los Euanos; according to Martius, at Ucayala, Ica, Jupura, and Rio Negro.

¹ Pope, *Med.-Chir. Trans.* vol. xii. p. 344, 1823.

Martius¹ says that the Indians gather it all the year round, according to the state of the weather and of the rivers. After being dried over a fire, the roots are tied up in bundles with a flexible stem called *Timbotitica*; and to prevent them being worm-eaten, they are preserved in the gables of the houses, where they are exposed to smoke.

The same writer² also states that this sarsaparilla is the produce of *Smilax papyracea* and *S. officinalis*. Poeppig tells us that there are two sorts of sarsaparilla which the dealers mix together; these are *sarsa fina*, a thin, lean sort, less active, but also less liable to be worm-eaten—and *sarsa gruésa*, a thicker, more active sort, but more liable to be attacked by insects: the first, he says, is the produce of *S. sypilitica*, the second of *S. cordato-ovata*. Schleiden suggests that *S. Purhampuy* of Ruiz may perhaps yield some Brazilian sarsaparilla.

3. HONDURAS SARSAPARILLA; *Mealy Sarsaparilla* (*Radix Sarsaparilla de Honduras*; *S. acris* vel *gutturalis*).—It is imported from Belize, and other parts of the Bay of Honduras. It comes in large and smaller bundles, two or three feet long, folded lengthwise (in a kind of hank), and secured in a compact form by a few transverse circular turns. A large bundle (Fig. 273) in the museum of the Pharmaceutical Society is 2½ feet long, from 10 to 12 inches in diameter, and weighs about 17 lbs. A smaller bundle (Fig. 274) is 2 feet 2 inches long, 3½ inches in diameter, and weighs about 2 lbs.

Fig 273.

Fig. 274.

Figs. 273 and 274. Large and Smaller Bundles of Honduras Sarsaparilla.

The bundles are packed in bales, weighing from 80 to 110 lbs. or more, and imperfectly covered by skins. In the interior of the bundles are found roots of inferior quality, rhizomes with adherent stems, stones, clumps of wood, &c. The roots are furnished with a few rootlets. The general colour of the roots is dirty grayish or reddish brown. The cortex is very mealy, and the medullium or central cord is thinner than in the Jamaica sort. The cells of the nucleus sheath are square, or are elongated tangentially, and are equally thick on all four sides (see Fig. 268).

The taste of the root is amylaceous, and ultimately somewhat acrid. Its decoction becomes intensely blue by the addition of a solution of iodine. Its powder is fawn-coloured, and, when rubbed with water and tincture of iodine, becomes intensely bluish black. From five pounds of the root of fine quality about one pound of extract may be produced (Hennell). A sample, examined by Mr. Battle, yielded six and a half ounces of extract from three pounds of root, which is

¹ *Reise*, Bd. iii. S. 1280.² *Systema Mat. Med. Brasil.*

about ten and a half ounces from five pounds: 874 grains of the cortical portions of the root yielded 230 grains of extract (Battley). In one operation, in the laboratory of a friend of mine, 170 lbs. of root yielded 45 lbs. of extract. According to Mr. Pope, the cortex yields twice as much extract as the medullium.

Nothing whatever is known respecting the botanical origin of this sort of sarsaparilla.

Div. 2. *Non-mealy Sarsaparilla.*

(*Sarsaparilla non-farinosa vel non-amylacea.*)

The sarsaparillas of this division are characterized by a deeply coloured (red or brown) usually non-mealy cortex. The cortex is red and much thinner than in the mealy sorts. Although by the microscope starch grains can be detected in the inner cortical layers, yet their number is comparatively small, and is quite insufficient to give the mealiness which characterizes the sarsaparilla of the first division. The diameter of the medullium or ligneous cord is much greater than in the mealy sarsaparillas, and is frequently six or more times greater than the thickness of the cortex. The roots have never that swollen appearance called by dealers gouty, and which is frequently observed in the mealy sorts.

Starch grains are usually recognizable in the pith by the microscope.

If a drop of oil of vitriol be applied to a transverse section of the root of the non-mealy sarsaparillas, both cortex and wood acquire a dark red or purplish tint.

A decoction of non-mealy sarsaparilla, when cold, does not yield a blue colour when a solution of iodine is added to it.

This division includes the sorts known in commerce by the names of *Jamaica* and *Lima* sarsaparillas, as well as a sort which I have received as a *lean Vera Cruz* sarsaparilla.

They differ from the Caraccas, Brazilian, and Honduras sarsaparillas, in having a red or brown usually non-mealy cortex. In the relative thickness of the pith and woody layer they agree with the Honduras sarsaparilla; but they differ from it in having the cells somewhat elongated radially, in this respect approaching the Caraccas and Brazilian sorts.

I have been unable to detect any anatomical difference between the roots of the Jamaica, the so-called Lima, and the lean Vera Cruz sorts. The Jamaica and Lima sorts are, I believe, not essentially different from each other. Both are probably the produce of Central America. They differ in colour somewhat, in the mode of packing, and in the route by which they reach England. What I have received as lean Vera Cruz sarsaparilla, might pass for a lean, thin, pale-coloured Lima sort whose roots are unfolded.

4. JAMAICA SARSAPARILLA, offic.; *Red-bearded Sarsaparilla* (*Radix Sarsaparilla jamaicensis vel rubra*).—This

sort first appeared in the London market about 1819 or 1820.¹ The roots are folded and made up in bundles (*sarsaparilla rotunda*) of about a foot or half a yard long, and four or five or more inches broad. These bundles are neither trimmed nor closely packed.

The bundle from which Fig. 276 was taken, was about 17 inches long,

Fig. 275.

- f. Medulla or pith.

Fig. 276.

Bundle of Jamaica Sarsaparilla.

¹ Pope, *Med.-Chir. Trans.* vol. xii. p. 344, 1823.

from 5 to 7 inches wide, and 3 inches thick; its weight was $21\frac{1}{2}$ oz. In the museum of the Pharmaceutical Society are some plaits of Jamaica sarsaparilla. One of these (Fig. 277) weighs $5\frac{1}{2}$ ounces, and is $4\frac{1}{2}$ feet long, and $1\frac{3}{4}$ inches wide.

Fig. 277.

A Plait of Jamaica Sarsaparilla.

The bundles of Jamaica sarsaparilla are packed in circular bales of from 60 to 80 lbs. each. The roots of this sort are long, slender, furnished with numerous small fibrous rootlets (called the *beard*). Its cortex is brownish, but with an orange-red tint, which distinguishes it from other kinds of *red* sarsaparilla. The cortex is reddish, and when examined by the microscope is found to contain some starch globules. The medullium has frequently a reddish tint. When chewed, Jamaica sarsaparilla tinges the saliva. Its taste is not remarkably mucilaginous, but slightly bitter, and after a few minutes slightly acrimonious. Its decoction is deepened in colour by a solution of iodine, but no blue is perceptible. Its powder is pale reddish-brown, and when rubbed with water and tincture of iodine becomes blue, but less intensely so than the powder of the Honduras variety. It yields a larger quantity of extract than the other varieties; its extract is perfectly soluble in cold water. From three pounds of average quality about one pound of extract may be obtained (Hennell, also Battley); but from the same quantity of root of very fine quality, nearly one pound and a quarter of extract may be procured (Hennell). 874 grains of the cortical portion of the root yielded 484 grains of extract (Battley). According to Mr. Pope, the cortex yields five times as much as the medullium.

The following are the characters of Jamaica sarsaparilla according to the London Pharmacopœia (1851):—

Reddish, copiously covered with rootlets, with a non-mealy bark.

Jamaica sarsaparilla is not the produce of the island whose name it bears, but, as I have been informed by wholesale dealers, of the Mosquito shore on the eastern coast of Honduras and of St. Juan, from whence it is brought to England by way of Jamaica; and occasionally it is said to be brought from Guatemala.

I am indebted to Mr. G. R. Porter, of the Board of Trade, for the following official account of the sources of Jamaica sarsaparilla:—

Account of the Quantities of Sarsaparilla Imported into Jamaica in each year from 1840 to 1845, distinguishing the Countries from which Imported.

	1840.	1841.	1842.	1843.	1844.	1845.
	<i>lbs.</i>	<i>lbs.</i>	<i>lbs.</i>	<i>lbs.</i>	<i>lbs.</i>	<i>lbs.</i>
Guatemala	11,326	—	—	11,176	—	—
Colombia	75,309	11,778	31,442	48,527	143,730	166,148
United States	—	125	80	208	1,210	1,512
Total	86,635	11,903	31,522	59,911	144,940	167,660

The Quantities of Sarsaparilla Exported from Jamaica to Great Britain was—

In 1840	157,868 <i>lbs.</i>	In 1843	27,271 <i>lbs.</i>
1841	19,214	1844	125,733
1842	17,208	1845	175,278

This accords with Humboldt's statement before mentioned (see *ante*, p. 265) that sarsaparilla is exported from Colombia (he says from Carthagena and Mompox) into Jamaica.

But, although this table may be relied on for showing the countries from which sarsaparilla is imported into Jamaica, it does not establish the place of growth.

It is probable that Jamaica sarsaparilla is the produce of *Smilax officinalis*.

In the collection of *Materia Medica* at Apothecaries' Hall, London, is a sample of sarsaparilla said to have been grown in Jamaica; but it does not resemble the Jamaica sarsaparilla of commerce. Its colour is pale cinnamon brown. Internally it is mealy.

5. LIMA SARSAPARILLA (*Radix Sarsaparillæ de Lima*).—This name is, of course, strictly applicable to sarsaparilla brought from Lima only, from whence, in fact, the first parcels came. But of late years sarsaparilla of the same quality has been brought from various other places; and the dealers, to distinguish it from other kinds, have called it the *Lima sort*; and gradually the term Lima sarsaparilla has been applied, rather to indicate the quality than the place of shipment. The true Lima sort is brought round Cape Horn; whereas much of the so-called Lima sort is the produce of Costa Rica, and is brought from the Caribbean Sea. I know of one importation of 99,000 lbs. from Costa Rica. The Lima sort is also brought from Guajaquil and Valparaiso.

Although some druggists prefer good parcels of Costa Rica to Lima sarsaparilla, still the general run of the Lima parcels comes nearer to Jamaica than the Costa Rica sort. On the whole, however, it is difficult to say whether any dealer can with certainty distinguish the Lima and Costa Rica sorts.

I am informed that the Costa Rica sort sometimes comes from St. Marta, Savanilla, and Caraccas; though that from Costa Rica is usually of a better description.

Lima (including Costa Rica) sarsaparilla is imported folded in bundles or hanks of about 2 or 3 feet long, and 6 or 9 inches in diameter, with the attached rhizome (chump) contained in the interior of the bundle. The bundle, of which a cut (Fig. 278) is subjoined, came *via* Jamaica: it weighed 2 lbs. 13 oz.; was 2 feet long, and 6 inches in diameter.

Fig. 278.

Bundle of Lima Sarsaparilla.

The bundles are usually packed in bales of from 60 to 80 lbs. each.

In quality, Lima sarsaparilla closely resembles the Jamaica sort; but it yields a smaller quantity of extract. Its colour is brown or grayish-brown. Occasionally a few roots are found in a bale of good Lima sarsaparilla, which, as well as their rhizome and stem, are light clay-coloured. The stems are square and prickly: the prickles are few and small, except in the clay-coloured variety.

Lima sarsaparilla is probably the produce of *Smilax officinalis*.

Occasionally a knobby root or rhizome, like the *radix Chinæ*, with a round stem, and long, smooth, wiry, brown root-fibres, is found in a bale of Lima sarsaparilla. A transverse section of the stem presents, to the naked eye, a structure somewhat similar to that of the common cane. I have received the same root (under the name of *Salsepareille-Squine de Macaraïbo*) from Professor Guibourt, who found it in Caraccas sarsaparilla.

6. VERA CRUZ SARSAPARILLA (*Radix Sarsaparillæ de Vera Cruce*).—Much confusion exists about the sarsaparilla called the Vera Cruz sort; this name being usually applied to the gouty Caraccas sort before described. The sort which I received some years ago under the name of "lean Vera Cruz sarsaparilla," I was

informed came from Vera Cruz; but it is now seldom met with. It is the sort which Mr. Pope¹ described as “lean, dark, and fibrous.” The bundle (Fig. 279) is 2 feet long, and, at the widest part, 7 inches broad: the weight is 7 ounces. The roots are unfolded (*sarsaparilla longa*), and have the *chump* attached at one end.

Fig. 279.

Bundle of Vera Cruz Sarsaparilla.

They are thin, tough, of a grayish-brown colour, with a shrivelled, thin, non-mealy cortex. They give off very few rootlets. This sort yields a deep-coloured decoction, which is unchanged by a solution of iodine.

Vera Cruz sarsaparilla is the produce of *Smilax medica*.

Tampico sarsaparilla is probably identical with the Vera Cruz sort.

THERAPEUTICAL VALUE AND QUALITY.—The relative therapeutical values of the different sorts of sarsaparilla are not easily determined. There are only two ways by which we can attempt to arrive at them—one chemical, the other clinical or empirical. But while, on the one hand, we have neither comparative analyses of the various commercial sorts of this root, nor an accurate knowledge of its active principle; so, on the other, we have no clinical observations of the relative effects of the different sorts, and great difficulty exists in the way of making them, on account of the immediate and obvious effects of this root being very slight. To this absence of actual precise information must be ascribed the different relative values assigned to the various sorts in different countries.

In the southern parts of Europe, where sarsaparilla has been the longest in use, the *thickest* and most *mealy* roots, irrespective of the country producing them, are preferred. It is, however, quite certain that starch is not the active principle of the root, but is regarded as being contemporaneous with it. I believe this opinion to be erroneous; for, 1stly, the mealy sarsaparillas give, to the test of oil of vitriol, slighter indications of the presence of smilacin than the non-mealy sorts; 2dly, the mealy sorts are the least acrid to the taste; and, 3dly, the largest quantity of extract is obtained from a non-mealy sort, viz., that brought *via* Jamaica.

In England the non-mealy sarsaparillas are almost universally, and, as I believe, properly preferred; and of these the Jamaica sort is most esteemed, and next to this, that called the Lima.

The *colour* of the root is not to be absolutely depended on, but roots having a deep orange-red tint are preferred. *Taste*, perhaps, is the best criterion: the more acrid and nauseous the taste, the better is the quality of the root. This test has been much insisted on by Dr. Hancock.² The *quantity of extract* yielded by a given weight of the root has been much insisted on by Mr. Battley and Mr. Pope as a test of goodness; both these writers have asserted the superiority of Jamaica sarsaparilla, because it yields a larger quantity of extract. But though a sarsaparilla which yields very little extract cannot be regarded as good, yet it does not follow, especially in the absence of comparative trials, that a sarsaparilla which yields the most abundant extract is necessarily the best, since the quantity may arise from the presence of mucilage and other inert matters. The *beard* is another criterion of goodness: the greater the quantity of root-fibres (technically called *beard*), the better the sarsaparilla.

³ *Ibid.* xx. 682, 1831.

⁴ By epidermis, I presume the author means both epidermis properly so called and the outer cortical layers.

⁵ By cortical pith (*Rindemark*), the author obviously means the inner cortical layers.

1. **ESSENTIAL OIL OF SARSAPARILLA.**—Sarsaparilla contains a small quantity of volatile oil.

The following experiments were made by a friend, a manufacturing chemist, who gave me the products for examination. 140 lbs of Jamaica sarsaparilla were distilled, by steam heat, at twice, with 220 gallons of water. 50 gallons of a milky liquid were obtained, which were again submitted to distillation until 20 gallons had passed over. 20 lbs. of common salt were added to the distilled product, and heat being applied, 3 gallons were drawn over. The liquor was milky, held in solution carbonate of ammonia, and contained a few drops of a volatile oil, which was heavier than water, was soluble in rectified spirit, and had the odour and acid taste of sarsaparilla. 100 lbs. of Jamaica sarsaparilla were distilled with 100 gallons of water. The distilled liquor was acid, and formed a white precipitate with solutions of acetate of lead. It was re-distilled: the liquor that first passed over was not ammoniacal, but towards the end of the process became so.

2. **SMILACIN.**—Discovered in 1824 by Palotta,¹ who termed it *pariglin*. Folchi, about the same time, also procured it, and gave it the name of *smilacin*. Thubent, in 1831, called it *salseparin*. In 1833, Batka announced that the active principle of this root was an acid, which he termed *parallinic acid*. Lastly, in 1834, Poggiale² showed the identity of these different substances.

It is procured by decolorizing a concentrated hot alcoholic tincture of sarsaparilla by animal charcoal. The tincture deposits, on cooling, impure smilacin, which may be purified by repeated solution and crystallization. Soubeiran³ has proposed a more economical process.

It resides both in the cortical portion and in the woody zone.

Smilacin is a white, crystallizable, odourless, and, in the anhydrous state, almost tasteless substance; very slightly soluble in cold water, more so in boiling water, and depositing from the latter by cooling. Its solution has the bitter acrid taste of sarsaparilla, and froths on agitation. It is soluble in alcohol, ether, and oils. It does not combine with acids to form salts. Strong sulphuric acid colours it red, then violet, and, lastly, yellow. It dissolves in cold and pure hydrochloric acid: the solution becomes red and afterwards gelatinous when heated. It is soluble in strong nitric acid: if the solution be heated, nitrous gas escapes; and, by evaporation, a solid residuum is obtained, which is soluble in boiling water, from which it precipitates in white flocks as the liquid cools.

Smilacin is closely allied to, if it be not identical with, saponin. Now, as the latter is readily converted into an acid (*esculic acid*), so probably is the former: hence, perhaps, the parallinic acid of Batka may not be absolutely identical with smilacin, but bear the same relation to it that esculic acid does to saponin.

Smilacin has the following composition:—

	Poggiale. (Mean of 12 analyses.)	Henry.	Petersen.
Carbon	62.53	63.84	62.80
Hydrogen	8.67	9.76	9.14
Oxygen	28.80	27.40	28.06
Anhydrous smilacin	100.00	100.00	[Parillina] 100.00

Poggiale gives the following formula for its atomic constitution, $C^9H^7\frac{1}{2}O^3$; while O. Henry⁴ assumes $C^9H^8O^3$, and Petersen⁵ $C^9H^8O^3$. As no definite compound of smilacin has been obtained, these formulæ are of little value. Thubeuf says that hydrated [crystallized] smilacin contains 8.56 water.

Cullerier⁶ gave it to nine syphilitic patients. In doses of six grains, the stomach readily supported it; but nine grains caused weight at the stomach and nausea. It appeared to relieve the patients' symptoms, and, in one case, seemed to effect a cure. According to Palotta, pariglin, in doses of from two to thirteen grains, acts as a debilitant, reducing the circulation, sometimes producing constriction of the œsophagus, and exciting nausea and diaphoresis. He thinks it might be useful in chronic rheumatism, skin diseases, &c.

3. **STARCH.**—This is found in both the cortical and medullary cells. It is most abundant in the Caraccas, Brazilian, and Honduras sarsaparillas, to which it gives their mealy character. According to Schleiden, it exists in two forms—as grains and as paste.

The *starch-grains* are arranged in groups of 2, 3, 4, or 6; their shapes being modified by their mutual compression: the prevailing form being that of a mullar. Their average length is about $\frac{1}{2000}$ th of an inch.⁷ The nucleus (central cavity or hilum) is scarcely perceptible by ordinary light (Schleiden says that the grains are without evident central cavity); but by the

of the grains of starch of sarsaparilla, were

aid of polarized light its position may be determined, as it is at the junction of the arms of the cross. In some grains it can be detected by common light. Towards the circumference of some of the grains a series of faint parallel curved lines are observed.

Starch paste, or amorphous starch, is found in some of the cortical cells. It is more abundant in Vera Cruz sarsaparilla, which is sun-dried, than in the Brazilian sort, which has been dried by exposure to the smoke of fires; hence, probably, its formation depends on the season, and not on the action of heat on the grain starch. Iodine colours it blue. This so-called starch-paste, or amorphous state, is, perhaps, only imperfectly formed and closely aggregated starch grains.

4. **RESIN AND EXTRACTIVE.**—These principles require further examination. On them probably depends a part, at least, of the medicinal properties of sarsaparilla.

CHEMICAL CHARACTERISTICS.—A decoction of sarsaparilla froths greatly when shaken. It scarcely, if at all, reddens litmus. Diacetate of lead and protonitrate of mercury cause precipitates. Alkalies deepen the colour of the decoction.

If a strong decoction be added to oil of vitriol, a red colour is produced (owing to the action of the acid on the smilacin?).

Decoctions of mealy sarsaparilla become dark blue (*iodide of starch*) on the addition of a solution of iodine. Decoctions of non-mealy sorts are usually somewhat darkened by iodine, but the effect frequently disappears after a few minutes.

If a solution of a persalt of iron be added to the decoction, more or less darkening is usually produced. The greatest effect is produced with decoctions of either Jamaica or Lima sarsaparilla: with those of the Honduras and Brazilian sorts the effect is much feebler. In some cases a flocculent precipitate slowly subsides.¹

If oil of vitriol be applied to a section of sarsaparilla, a greater or less portion of the woody surface (the woody zone, and, in the case of Jamaica and Lima sarsaparilla, the cortex also) becomes dark red, and then violet (owing to the action of the acid on the smilacin?). The same colour is also produced by the action of the acid on a fresh cut surface of the rhizome (*chump*).

If a strong decoction of mealy sarsaparilla be poured into alcohol, a copious precipitate (*starch*) is produced.

PHYSIOLOGICAL EFFECTS. *a. On Vegetables.*—Not ascertained.

β. On Animals.—Not ascertained.

γ. On Man.—Imperfectly determined; no experiments having been made to ascertain its physiological effects.

To the taste, sarsaparilla is slightly acrid, and somewhat nauseous. Diaphoresis is by far the most common effect of its internal use. When the skin is kept cool, diuresis is not unusual. But in estimating the diaphoretic or diuretic power of sarsaparilla, we must take into consideration the amount of liquid in which the medicine is usually taken, and the other medicines which are frequently conjoined with it: for, in many instances, the diaphoresis or diuresis is referable rather to these than to sarsaparilla.

In several cases I have given the powder of this root in very large doses, in order to ascertain its effects. Nausea, vomiting, and temporary loss of appetite, were alone observed.

Dr. Hancock² says, that on one patient, an African, an infusion of four ounces of Rio Negro sarsa acted as a narcotic, producing nausea, great prostration of strength, torpor, and unwillingness to move. The pulse was scarcely altered, unless

5	0.0002

The bulk of this specimen consisted of particles of the size of those distinguished by an asterisk.

One of the hemispherical or mullar-shaped particles measured 0.0007 by 0.0005.

A compound grain, consisting of three grains, was found to be 0.0005 in diameter.

¹ See, also, Marquart's comparative examinations of several kinds of sarsaparilla, in the *Pharmaceutical Journal*, vol. iii. p. 126, 1813.

² *Trans. Med.-Bot. Soc.* 1829.

it were a little retarded. Though the effects here stated agree, to a certain extent, with those ascribed to smilacin, they cannot be regarded as the ordinary effects of this root.

In some conditions of system, especially those of a cachectic kind, sarsaparilla acts as a powerful and valuable alterative tonic. Its continued use is often attended with improvement of appetite and digestion, augmentation of strength, increase of flesh, the production of a more healthy tone of mind, and the palliation, or, in some cases, complete disappearance, of various morbid symptoms—as eruptions, ulcerations, pains of a rheumatic character, &c. Sarsaparilla differs in several respects from the bitter vegetable tonics. Though it is not devoid of, yet it does not, as they do, abound in a bitter principle. It is not adapted for the cure of intermittents, or of simple debility. But its best effects are seen in those depraved conditions of system, which the public, and even some medical men, ascribe to the presence of a morbid poison, or to a deranged condition of the fluids. Hence it is frequently denominated a *purifier of the blood*. Those who do not adopt the pathological notion here referred to, call it an *alterative*.

Those varieties of sarsaparilla which abound in starch (as the *Curaccas* and *Honduras* sorts) possess demulcent and nutritive properties.

USES.—By many practitioners sarsaparilla is considered to possess no remedial properties; by others it is regarded as a medicine of great efficacy. Considering that more than 100,000 lbs. of it are annually consumed in this country, the number of those who entertain the latter opinion cannot be small. It has been justly remarked by Mr. Lawrence,¹ that physicians have no confidence in it, and surgeons a great deal. I think that this fact is readily explained by the circumstance that physicians are much less frequently called in to prescribe for those forms of disease in the treatment of which surgeons have found sarsaparilla so efficacious.

Many practitioners have doubted or denied its remedial activity on what, it must be admitted, are very plausible grounds; viz., that the root possesses very little taste and no smell; that, by the ordinary mode of using it, it produces very slight, if any, obvious effects on the animal economy; and that it has failed in their hands to relieve or cure diseases in which others have asserted they found it effectual. They are, therefore, disposed to refer any improvement of a patient's health, under the long-continued use of sarsaparilla, either to natural changes in the constitution, or to the influence of the remedial means with which the sarsaparilla was conjoined. But I would observe, that hitherto no experiments have been made to ascertain what effects the long-continued employment of sarsaparilla may give rise to in the system of a healthy man; and we are not warranted in assuming that none would result, because none are observable from the employment of a few doses. Moreover, it is to be remembered that some of our most powerful poisons prove the most efficacious remedies when given in such small doses that they excite no other obvious effect on the system than the removal of morbid symptoms. Witness the beneficial influence of the minute doses of arsenious acid in lepra. Furthermore, no one has ascribed to sarsaparilla the power of a specific, and its warmest advocates admit its occasional failure. But so often has it been found, that various diseases, which had resisted all other tried remedial means, and were gradually increasing, became stationary, and afterwards subsided, under the use of sarsaparilla, that a large majority of British surgeons, including the most eminent of the present day, have been compelled to admit its therapeutic power.

As no obvious relationship exists between its known physiological effects and its apparent therapeutic agency, an argument has been raised against its medicinal activity, on the ground that we cannot explain its *modus medendi*; but, for the same reason, we might refuse to admit the power of *cinchona* to cure ague. Mr.

¹ *Lectures on Surgery*, in the *Lond. Med. Gaz.* vol. v. p. 770.

Lawrence¹ justly observes that, although we cannot point out the manner in which a remedy “operates, we are not, on that account, to withhold our confidence in its power. It is enough for us, in medical science, to know that certain effects take place. In point of fact, we are in many cases unable to distinguish the *modus operandi* of medicines—the manner in which their influence is produced.” The most plausible explanation of the agency of alterative medicines is that offered by Müller,² and which I have before had occasion to notice (see vol. i. p. 137). It assumes that these remedies cause changes in the composition of the nutritive fluids (the chyle and blood), and thereby produce slight chemical alterations in organs morbidly changed in composition, by which already existing affinities are annulled, new ones induced, and the vital principle enabled to effect the further restoration and cure. This hypothesis may be used to explain the remedial influence of sarsaparilla.

Sarsaparilla has been found especially serviceable in the following maladies:—

1. *In inveterate venereal disease.*—It is beneficial principally when the malady is of long continuance, and the constitution is enfeebled and emaciated, either by the repeated attacks of the disease, or by the use of mercury. In such cases it is, as Sir William Fordyce³ correctly observed, “the great restorer of appetite, flesh, colour, strength, and vigour.” When the disease resists, or is aggravated by, the use of mercury, sarsaparilla evinces its most salutary powers. It is given to relieve venereal pains of a rheumatic character; to remove venereal eruptions; to promote the healing of ulcers of the throat; and to assist in the cure when the bones are affected. In recent chancre, or bubo, it is of little use; nor does it appear to possess the least power of preventing secondary symptoms. We cannot ascribe to it “the same anti-syphilitic properties—that is, the same power of arresting or curing the venereal disease—that experience warrants us in attributing to mercury.”⁴ Sarsaparilla is sometimes given alone, but more frequently with other remedies: as with stimulating diaphoretics (mezercon, sassafras, and guaiacum), or with mercurials in small or alterative doses, or with acids (especially the nitric), or with alkaline substances (as potash or lime), or with iodine or with the bitter tonics. It is difficult to lay down concise rules to guide us in the selection of these adjuncts. In venereal pains and eruptions, sudorifics, the copious use of warm diluents and warm clothing, are especially applicable, and should be conjoined with sarsaparilla. In serofulous constitutions, with enlarged glands, it will be for the most part advisable to avoid the use of mercury. In such I have seen the alkalies most serviceable. When extreme debility is present, the bitter tonics and nitric acid are often added to sarsaparilla with benefit. When the periosteum is affected, iodide of potassium should be conjoined.

2. *In chronic rheumatism* sarsaparilla is often advantageously conjoined with powerful sudorifics and anodynes (as opium or hyoseyamus), especially when any suspicion exists as to the venereal origin of the disease.

3. *In obstinate skin diseases* benefit is frequently obtained by the use of sarsaparilla. Its employment is not confined to cutaneous affections of one particular elementary form, since it is given with good effect in papular, vesicular, pustular, and tubercular skin diseases, of a chronic kind, when they occur in enfeebled and emaciated constitutions. Though, in these cases, its value principally depends on its tonic and alterative effects, its diaphoretic operation is to be encouraged by the use of diluents, warm clothing, &c.

4. *In cachectic conditions of the system generally*, sarsaparilla may be given, often with the best effects, and never with any ill consequences, save that of producing slight nausea. Indeed, one of the great advantages of sarsaparilla over many other alteratives and tonics, is, that although it may fail in doing good, it never does any

¹ *Op. cit.* p. 769.

² *Medical Observations and Inquiries*, vol. i. p. 169.

harm beyond that of now and then causing slight disorder of stomach. In chronic abscesses, attended with profuse discharge, diseases of the bones, obstinate ulcers, chronic pulmonary affections accompanied with great wasting of the body, enlarged glands, and various other maladies connected with a depraved state of the system, sarsaparilla is often a very useful medicine.

ADMINISTRATION.—Sarsaparilla is administered in substance, and in the form of infusion, decoction, extract, and syrup.

1. PULVIS SARSÆ; *Powdered Sarsaparilla*.—The ordinary dose of this is from half a drachm to one or two drachms. Half an ounce frequently nauseates, and in some cases gives rise to vomiting. Powder of Jamaica sarsaparilla is to be preferred to that of other varieties. It is redder than that of the Honduras kind, and produces a much less intense blue colour when rubbed with water and tincture of iodine. I have been informed that some druggists employ, in the preparation of the powder, the roots from which the extract has been prepared. This fraud may be detected by the powder being almost devoid of taste, macerating it in water, and carefully comparing the infusion with one prepared from an unadulterated sample. The microscope might sometimes be carefully employed to detect adulterations of powdered sarsaparilla. The presence of foreign starch grains would indicate the presence of some other vegetable in the suspected powder.

[2. INFUSUM SARSAPARILLÆ [U. S.].—Take Sarsaparilla, bruised, an ounce; Boiling Water a pint. Digest it for two hours in a covered vessel or strain, or by displacement.]

3. DECOCTUM SARSÆ, L. E.; *Decoction Sarsaparillæ*, D.; *Decoction of Sarsaparilla*.—(Sarsa, sliced [in chips, E.], ḡv [ḡij , D.]; Boiling Water Oiv [Ojss, D.]. Boil down to two pints, and strain. [“The product should measure a little more than a pint,” D.])—An objection has been taken to this, as well as to all preparations of sarsaparilla made by boiling, that the heat employed volatilizes or decomposes the active principle of the root. “An infusion of sarsaparilla,” says Soubeiran,¹ “which is odorous and sapid, loses both its odour and taste by boiling for a few minutes: these changes speak but little in favour of the decoction. On the other hand, it is known that the fibrous parts of vegetables always give less soluble matters to water, when treated by decoction; and if it be added that sarsaparilla is completely exhausted by hot water, I cannot see what advantages the decoction can possess over preparations made by other methods.” Without denying the injurious effects of long boiling, and, therefore, the superiority of preparations made without it, I cannot admit that either the decoction or extract of sarsaparilla is inert. No objection, however, exists to the substitution of an *infusion* for a decoction. But it is advisable to employ a somewhat larger quantity of the root, and to have it crushed before macerating it. The proportions of root and water, in the above preparation, are such that one ounce of the decoction contains the extractive of one drachm only of the root. Hence the extract or syrup is usually conjoined.

Mr. Jacob Bell² objects to taking out the roots after maceration, in order to bruise them, on the ground that by this process the wood may absorb a larger portion of the virtues of the bark in return for the inert starch which it gives out.

An infusion or decoction of Jamaica sarsaparilla usually produces little or no blue colour with tincture of iodine; whereas the corresponding preparations of Honduras sarsaparilla (the kind usually met with, cut in small split lengths, in the shops) becomes bluish black on the addition of a solution of iodine. The dose of *Decoction Sarsæ* is fḡiv to fḡvii three or four times daily.

4. DECOCTUM SARSÆ COMPOSITUM, L. E.; *Decoction Sarsaparillæ Compositum*, D. [U. S.]; *Compound Decoction of Sarsaparilla*.—(Decoction of Sarsaparilla, boiling hot, Oiv; Sassafras sliced and bruised, Guaiaecum-wood shavings, Liquorice-root bruised, of each ḡx ; Mezercon [bark of the root], ḡij [ḡss , E.]. Boil for a

¹ *Nouv. Traité de Pharm.* t. ii. p. 168.

² *Pharmaceutical Journal*, vol. i. p. 55, 1841.

quarter of an hour and strain.—The *Dublin College* orders of Sarsaparilla Root, sliced, ℥ij; Sassafras Root in chips, Guaiacum wood turnings, Liquorice Root bruised, of each ℥ij; Mezereon root-bark ℥j; Boiling Water Oiss. Digest for one hour, then boil for ten minutes, cool and strain. The product should measure a little more than a pint.—[The *U. S. Pharm.* orders of Sarsaparilla, sliced and bruised, six ounces; Bark of Sassafras root sliced, Guaiacum wood rasped, Liquorice root bruised, each an ounce; Mezereon, sliced, three drachms; Water, four pints. Boil for a quarter of an hour, and strain.]—This preparation is an imitation of the celebrated *Lisbon Diet Drink*. The objections made to the use of ebullition in preparing the simple decoction apply equally to the present preparation. The additions are for the most part valueless. The guaiacum-wood is useless, water not being able to dissolve the resin. The volatile oil contained in the sassafras-wood is in part dissipated by the boiling. The mezereum, an active agent, is used in such small quantity that it can confer but little medicinal power. Moreover, these acids are apt to disorder the stomach. The liquorice is employed merely to communicate flavour. An improvement in the present formula would be to omit the guaiacum, to increase the quantity of sarsaparilla and mezereum, to substitute maceration for decoction, and to add oil of sassafras. The dose of the officinal preparation is from f̄℥iv to f̄℥vj three or four times a day. The syrup or extract is usually conjoined with it. During its use the skin should be kept warm.

A *Liquor Sarsæ compositus concentratus* is usually kept in the shops for the extemporaneous preparation of the compound decoction of Sarsaparilla.

5. SYRUPUS SARSÆ, L. E.; *Syrupus Sarsaparillæ*; *Syrup of Sarsaparilla*.—(Sarsa ℔ijss; Distilled Water Cong. ij; Sugar ℥xij; Rectified Spirit f̄℥ij. Boil the sarsa, in two gallons of the water, down to one gallon; pour off the liquor, and strain it while hot. Again boil the sarsa in the remaining water down to one-half. Evaporate the mixed liquors to two pints, and dissolve the sugar in them. Lastly, when cold, add the Spirit, L.—The *Edinburgh College* orders of Sarsa, in chips, ℥xv; Boiling Water Cong. j; Pure Sugar ℥xxv.)—Simonin¹ has successfully prepared the syrup by the percolation method.

This I conceive to be a very unnecessary preparation; for, as the late Dr. A. T. Thomson² justly observes, “it can be much better and more easily supplied by rubbing up a few grains of the extract with some simple syrup.” It is, however, frequently prescribed as an adjunct to the decoction. Prepared with Jamaica sarsaparilla, it is not liable to ferment, and its flavour is somewhat agreeable, being very analogous to that of West India molasses. Mr. Brande³ says that, to be an effective form of sarsaparilla, it ought to be of such strength that one ounce is equal to a pint of the simple decoction. Of this, f̄℥ss or f̄℥vj may be taken two or three times a day, diluted with about two parts of water. A few drops of solution of potassa sometimes prevent its disagreement with the stomach.

The *Syrup of Sarsaparilla* of the United States Pharmacopœia is intended to represent the famous French *Sirope de Cuisinier*. It is prepared with proof spirit, which extracts the acrid principle of the root without taking up the inert fecula; and the tincture being evaporated, to get rid of the alcohol, is made into syrup. By this means the long-continued boiling is avoided. As the editors of the *United States Dispensatory* speak most confidently of the remedial value of this preparation, I subjoin the formula for its preparation, taken from the American Pharmacopœia:—

Compound Syrup of Sarsaparilla [*Syrupus Sarsaparillæ Compositus*], U. S.—“Sarsaparilla, bruised, ℔ij; Guaiacum wood, rasped, ℥ij; Red Roses, Senna, Liquorice-root, bruised, each ℥ij; Oil of Sassafras, Oil of Anise, each ℥v; Oil of Partridge-berry [*Gaultheria procumbens*, an astringent aromatic] ℥ij; Sugar ℔vij; Diluted Alcohol Ox [*wine measure*]. Macerate the sarsaparilla, guaiacum wood, roses, senna, and liquorice root, in the diluted alcohol for fourteen days; then express and filter through paper. Evaporate the tincture, by means of a water-bath, to four pints

¹ *Journ. de Pharm.* xx. 110.

² *London Dispensatory*, 9th edit.

³ *Dict. of Mat. Med.*

and a-half; then add the sugar, and dissolve it so as to form a syrup. With this, when cold, mix the oils, previously triturated, with a small quantity of syrup." The dose is ℥ $\bar{3}$ ss (equivalent to somewhat less than ʒj of the root), taken three or four times a day.

A *Syrupus Sarsæ compositus* is usually kept in the shops.

6. **EXTRACTUM SARSÆ LIQUIDUM**, L.; *Extractum Sarsæ fluidum*, E.; *Extractum Sarsaparillæ fluidum*, D. [U. S.]; *Fluid Extract of Sarsaparilla*, Offic.—(Sarsa ℥iijss; Distilled Water Cong. v; Rectified Spirit ℥ $\bar{3}$ ij, L.—Sarsa, in chips, ℥ij; Boiling Water Ovj, E.—Sarsaparilla ℥ij; Boiling Water Ovij; Rectified Spirit as much as is sufficient, D.—Boil the sarsa in three gallons of water down to twelve pints; pour off the liquor, and strain while hot. Again boil the sarsa in the remaining water to half, and strain. Evaporate the mixed liquors to ℥ $\bar{3}$ xviiij, and when the extract has become cold add the spirit to it, L.—“Digest the root for two hours in four pints of the water; take it out, bruise it, replace it in the water, and boil for two hours; filter and squeeze out the liquid; boil the residuum in the remaining two pints of water, and filter and squeeze out this liquor also; evaporate the united liquors to the consistence of thin syrup; add, when the product is cool, as much rectified spirit as will make in all sixteen fluidounces; filter. This fluid extract may be aromatized at will with various volatile oils or warm aromatics,” E. The U. S. Pharm. orders of Sarsaparilla, sliced and bruised, sixteen ounces; Liquorice root bruised, Root of Sassafras bruised, each two ounces; Mezereon, sliced, six drachms; Sugar, twelve ounces; Diluted Alcohol, eight pints. Macerate all of the ingredients together, excepting the sugar, for fourteen days; then express and filter. Evaporate the liquid, by means of a water-bath, to twelve fluidounces; add the sugar to it while still hot; and remove it from the bath as soon as the sugar is dissolved.]

In this country, Jamaica sarsaparilla is preferred for the preparation of the extract; and next to this the Lima sort. If Honduras, or any other mealy sarsaparilla be employed, the product contains a large quantity of starch-gum. Extract of Jamaica sarsaparilla, when rubbed on white paper or porcelain, exhibits a reddish tint not observable in the extract of the Honduras kind. The flavour and odour are characters which assist in distinguishing well-prepared extract. Rubbed up with water, it is almost completely soluble, and the solution, which should be clear, by standing scarcely deposits anything. The dilute solution should not remain blue on the addition of a solution of iodine. But extract prepared from a mealy sarsaparilla does not completely dissolve in water, and yields a turbid liquor, which becomes dark blue on the addition of a solution of iodine.

In England the fibrils or *beard* of Jamaica sarsaparilla are preferred to both root and rhizome (*chump*). They contain less starch and woody fibre than the latter, and they yield a greater proportion of extract.

The quantity of extract obtained from Jamaica sarsaparilla has already been alluded to (see *ante*, p. 270). The following table is from the papers of Thu-beuf:—¹

6 lbs. of Sarsaparilla	<i>yielded of Extract.</i>
Roots cleaned and deprived of rhizome	Red Jamaica sarsaparilla ʒxxj, ʒij.
	Red sarsaparilla of the Coast [Costa Rica ?] ʒxxj, ʒij.
	Vera Cruz sarsaparilla ʒxvij, ʒvij.
	Caraccas sarsaparilla ʒxv, ʒiiij.
	Honduras sarsaparilla ʒxiv,
Rhizome cut thin and bruised	Lisbon ʒxiiij, ʒiss.
	ʒix, ʒiiijss.

Extract made by the evaporation of an infusion prepared by the displacement process is devoid of starch, and is consequently richer in the active principles. By the avoidance of ebullition, the destruction or dissipation of volatile matters is less likely to be effected.

¹ *Journ. de Pharmacie*, t. xiv. p. 701; and t. xviii. p. 157.

In effecting the evaporation of the decoction or infusion, steam heat should be employed; and the temperature of the liquid should not be allowed to exceed 212° F.

When the concentrated decoction (especially of the Honduras kind) is allowed to cool, as at night, a kind of fermentation is readily set, and gas is copiously evolved.

Extract of sarsaparilla, when it has been kept for some time, frequently becomes covered by cubical crystals of chloride of potassium.

It deserves notice that though smilacin is said to be soluble in boiling alcohol and ether, yet I find that the extract of Jamaica sarsaparilla yields but little to these liquids.

Extract of sarsaparilla is declared by many writers to be an inert and useless preparation; but the assertions are, for the most part, founded rather on theoretical than practical considerations. I have extensively used it, and believe that, when properly prepared from Jamaica or Lima sarsaparilla, it is a most valuable and efficient remedy; and the enormous quantity of it which is consumed by the profession generally (including some of the most eminent of its members), is a proof that many others entertain a similar opinion of it. It is given in doses of from half a drachm to two or three drachms three or four times a day. It should be rubbed down with water, and flavoured by the tincture of orange-peel, or by some volatile oil (as the oil of cloves, allspice, lemon, or cinnamon). Alkalies render its flavour somewhat disagreeable, though they frequently increase greatly its remedial powers.

7. **EXTRACTUM SARSÆ COMPOSITUM;** *Compound Extract of Sarsaparilla.*—Not in any Pharmacopœia, though kept in the shops. It is made by mixing, with extract of sarsaparilla, an extract prepared by evaporating a decoction of mezereon bark, liquorice root, and guaiacum shavings, to which a small quantity of oil of sassafras has been added. This preparation is employed as a convenient substitute for the compound decoction of sarsaparilla. The dose of it, and the mode of exhibition, are the same as of the simple extract. Three-quarters of an ounce of the compound extract are equal to a pint of the compound decoction.

98. Smilax China, Linn.

(Radix.)

SMILAX CHINA, Kaempf. Amœn. Exot., p. 783; Loureiro, Fl. Cochinchinensis, p. 622.—A native of Japan, China, and Cochin China.—The *China root* of the shops (*radix Chinae orientalis seu verae vel ponderosæ*) is said to be the produce of this species. But, according to Roxburgh,¹ the roots of *S. glabra* and *S. lanceifolia*, which are used in the East in medicine, are not to be distinguished by the eye from the roots of *S. China*, brought from China.

China root is imported into England, usually in baskets, from Calcutta and Singapore. Dr. O'Shaughnessy² states that it is largely imported into Calcutta from the eastward. It is said to be the produce of the province of Onansi, in China. It occurs in large, ligneous, knotty pieces, of from three to eight inches long, and an inch or two thick. Externally it has a grayish-brown colour, and internally a light flesh or yellowish-white colour. It is inodorous, and has a slightly astringent taste.

It has been analyzed by Reinsch,³ who found it to consist of wax 0.3, balsamic resin 0.4, crystalline matter (smilacin) 2.8, with sugar, tannic acid, salts, and resinous colouring matter (quantity not stated), tannic acid with salts, reddish gummy colouring matter, and smilacin 4.8, starch-gum, vegetable gluten, and salts 2.6, starch 23.5 with salts, starch with tannic acid 34.0, woody fibre 20.0, and water 12.0 (=100.4).

It was introduced into Europe, in 1535, as an infallible remedy for the venereal disease, and obtained great celebrity in consequence of the benefit which the Emperor Charles the Fifth is said to have derived from it in gout. Its effects are not very obvious, but it is said to be diaphoretic. It tinges the sweat. It has been used in the same maladies as sarsaparilla, viz., venereal diseases, rheumatism, gout, obstinate skin diseases, &c. It is given in the form of decoction.

¹ *Fl. Indica*, vol. iii. p. 792.

² *Buchner's Repertorium*, 2ter Reihe, Bd. xxxii. S. 145, 1843.

³ *Bengal Dispensatory*.

SPURIOUS CHINA ROOTS.—Several smilaceous roots, the produce of the New World, but resembling the oriental China root, have been described under the name of *American* or *occidental China root* (*radix Chinæ Americanae* vel *occidentalis*). Their origin is by no means well ascertained, though they are usually said to be the produce of *Smilax Pseudo China*, Linn. Hernandez¹ notices three sorts: one which he calls *Olcacatzan* or Mexican China root; a second termed *Phaco*; and a third called *Cozohmecatl*.

One or more sorts of *occidental China root* are frequently found in the middle of the bundles of Lima and some other kinds of sarsaparilla (see *ante*, p. 271).

Brazilian China root, known by the various names of *Juapecanga*, *Inhapecanga*, *Jupicanga*, *Jupicanga*, and *Raiz de China branca* vel *rubra*, is obtained from several species of *Smilax*: viz., *S. Japicanga*, Grisebach; *S. syringoides*, Grisebach (*Jupicanga*, Piso, Med. Braz. i. 99); *S. Brasilensis*, Grisebach (*S. glauca*, Martius, Reise, i. 283); and *S. syphilitica*, Humboldt. It has not been analyzed. Its uses resemble those of oriental China root.²

99. *Smilax aspera*, Linn.

(Radix.)

Σμῖλαξ τραχηῖα, Dioscorides, lib. iv. cap. 144. *Smilax*, Pliny, lib. xvi. cap. 63.—A native of the South of Europe. Its roots constitute *Italian sarsaparilla* (*Sarsaparilla italica*). They have not been analyzed. Their effects, uses, and mode of administration resemble those of the ordinary sarsaparilla brought from America.³

The roots of *Hemidesmus indicus*, or Indian sarsaparilla, are frequently sold in London under the name of *Smilax aspera*. They will be noticed hereafter.

Class IV. Exogenæ, DC.—Exogens.

DICOTYLEDONES, Jussieu.

CHARACTERS.—*Trunk*, consisting of bark, wood, and pith, placed one within the other, the pith being innermost. *Bark*, composed of strata (the younger and inner being called *endophlæum* or *liber*), each usually increasing by the deposit of new matter on its inner side. *Wood*, consisting of ligneous strata, traversed by *medullary rays*, and increasing by the deposit of new woody matter on its outer side (*exogenous growth*); the older and inner strata are called *duramen*, or *heart wood*; the younger and outer strata are termed *alburnum*, or *sap wood*. *Leaves* usually articulated with the stems; their veins commonly branching and anastomosing (*netted, reticulated*). *Flowers*, if with a distinct calyx, often having a quinary, sometimes a quaternary, rarely a ternary arrangement. *Embryo* with two or more cotyledons (*dicotyledonous*); if two, they are opposite; if more than two (*polycotyledonous*), they are verticillate, radicle naked, i. e. elongating, without penetrating any external case (*exorrhizous*).

This class includes two sub-classes: 1. *Gymnospermæ*, or naked-seeded exogens; 2. *Angiospermæ*, or covered-seeded exogens.

Sub-class I. *Gymnospermæ*.—*Gymnosperms*.

GYMNOGENS, Lindl.

CHARACTERS.—*Ovules* naked, in an open carpellary leaf or perovious disk, fertilized by direct application of the pollen to the foramen (*micropyle*) without the intervention of stigma, style, and ovary. *Ligneous tissue* porous at the sides, the pores being apparently surrounded each by one or two circles.

This sub-class includes two orders: 1. *Cycadææ*, or Cycads; 2. *Pinacææ*, or Conifers.

¹ *Rerum Med. Nov. Hispan. Thesaurus*, pp. 212-213, Romæ, 1651.

² For a figure and description of Brazilian China root, see Goebel and Kunze's *Pharmaceutische Waarenkunde*, Bd. ii. S. 129, Taf. xviii. Fig. 2.

³ For further details respecting the medicinal properties of *Smilax aspera*, see Mérat and De Lens, *Dict. Univ. de Mat. Méd.* t. vi. p. 374, 1831; and Dierbach's *Neuest. Entdeck. in d. Mat. Méd.* Bd. iii. Abt. ii. S. 1088. 1847.

ORDER XXI. CYCADACEÆ, *Lindl.*—CYCADS.

CYCADEÆ, *Richard and R. Brown.*

CHARACTERS.—Gymnosperms with a simple continuous stem, parallel-veined pinnate leaves, and scales of the cone antheriferous.

PROPERTIES.—Mucilage and starch are the useful products of this order. They are found in the stems and seeds (see *Cycas* and *Zamia*). The seeds of *Dion edule* yield a starch which is used in Mexico as arrow-root. (*Lindley.*)

100. *Cycas*, *Linn.*

Sex. Syst. Diœcia, Polyandria.

No product of this genus is employed in Europe, either as medicine or food. From the stems of *C. circinalis* and *C. revoluta* a starch is obtained, of which a kind of sago is said to be made in the East. I have prepared starch from both of these species, and find that its microscopic characters are entirely different from those of the sago starch of European commerce. The starch of *C. circinalis* consists of grains united in masses of from 2 to 6: the single grains are rendered more or less irregular or polygonal by their mutual compression, but hemispherical and muller-shaped particles predominate. Their size¹ varies, but is on the average smaller than that of the starch grains of genuine sago. The so-called hilum frequently appears split and surrounded by rings. In polarized light the grains show a distinct cross.—The starch of *C. revoluta*, of which *Japan sago* is said to be made, resembles that of the preceding species. None of it comes to England. The Dublin Pharmacopœia, 1850, states that sago is the farina of the interior of the trunk of *Cycas circinalis*, and also of other species of *Cycas*, and various *Palmacœ*. The facts, however, are as I have stated them.—A clear mucilage, which concretes into a gum like tragacanth, exudes from fresh-wounded parts of several species of *Cycas*.²

101. *Zamia*, *Linn.*

Sex. Syst. Diœcia, Polyandria.

In the Bahamas, and some other of the West India Islands, a starch is obtained from the trunk of some species of this genus, which is employed as an excellent sort of arrow-root. None of it, to my knowledge, comes to Europe as an article of commerce. In the Museum of Economic Botany, at the Botanic Garden, Kew, there is a specimen of a starch, sent from Jamaica by Mr. Purdie, and stated to be "A nutritious powder made from the trunk of *Zamia integrifolia*, and sold in the West India Markets." In external appearance it resembles West Indian Arrow-root (*Maranta arundinacea*): but when examined by the microscope it is found to consist of rather large-sized grains,³ some of which are spheroidal; but most of them are the

¹ The following measurements, in parts of an English inch, of the starch of *C. circinalis*, were made for me by Mr. George Jackson:—

Single Grains.	Compound Grains.
0.0015	0.0015 by 0.0003
0.0013	0.0013 by 0.0010

Those particles of which one diameter only is given had a circular outline, and were probably muller-shaped grains seen endwise.

² Roxburgh, *Fl. Indica*, vol. iii. p. 749.

³ The following measurements of 12 grains were made for me by Mr. George Jackson:—

MEASUREMENTS OF STARCH FROM ZAMIA INTEGRIFOLIA.

Parts of an English Inch.	Parts of an English Inch.
1. 0.0022 × 0.0021	7. 0.0011 × 0.0009
2. 0.0022 × 0.0018	8. 0.0013 × 0.0010
3. 0.0020 × 0.0019	9. 0.0009 × 0.0007
4. 0.0018 × 0.0016	10. 0.0007 × 0.0006
5. 0.0017 × 0.0014	11. 0.0004 × 0.0004
6. 0.0014 × 0.0013	12. 0.0003 × 0.0003

separated parts of compound grains, and, therefore, are variously shaped, owing to their mutual compression; some being hemispheres, others muller-shaped grains, &c. The nucleus and rings are scarcely discernible. Most of the grains present a superficial protuberant scar (like the hilum of some seeds), the situation of which is remote from the nucleus (as ascertained by polarized light).

[*Zamia Media*.—This is an intermediate species between *Z. integrifolia* and *Z. angustifolia*. It differs from the former in having more numerous, longer, and narrower leaflets, which are perfectly entire, or nearly destitute of the serratures at the apex. The footstalk is hairy at base, and the female cone is obtuse, not pointed. Specimens have been brought to me from Florida by Dr. Godon, of the U. S. Navy, which agree with those, from the same locality, in the Herbarium of the Academy of Natural Sciences.

The root of this plant is a large spheroidal or somewhat tapering coated tuber, rough and dark-coloured externally, fleshy, internally white and succulent, and, when incised, pouring forth a fluid of gummy consistence, which hardens in small tears at the point of exit. This root is called *coonti root* in Florida by the Indians and white settlers, and the farina prepared from it is also called *coonti*. As a nutriment, it is found in the shops of the northern cities of the United States, under the name of *Florida arrow root*. When carefully prepared, it has a mealy appearance and feel, is of a pure white colour, and somewhat of a lustrous appearance; it is apt to be lumpy. The mode of preparation is the same as that of Bermuda arrow root. The form of the granule is that of the "half, fourth, or third of a solid sphere." Some of the granules are completely muller-shaped, in fact the form is exactly that given by Raspail for the granule of the *Maranta Arundinacea*, which is invariably round.

Florida arrow-root is employed for the same purposes and in the same manner as the other species of farina in use.—J. C.]

ORDER XXII. PINACEÆ, Lindley.—CONIFERS.

CHARACTERS.—*Flowers* monœcious or diœcious, naked. *Males* monandrous or monadelphous; each floret consisting of a single *stamen*, or of a few united, collected in a deciduous amentum; about a common rachis; *anthers* 2-lobed or many-lobed, bursting longitudinally; often terminated by a crest, which is an unconverted portion of the scale out of which each stamen is formed. *Females* in cones. *Ovary* spread open, and having the appearance of a flat scale destitute of style or stigma, and arising from the axil of a membranous bract. *Ovule* naked; in pairs or several, on the face of the ovary, inverted, and consisting of one or two membranes, open at the apex, together with a nucleus. *Fruit* consisting of a cone formed of the scale-shaped ovaries, become enlarged and indurated, and occasionally of the bracts also, which are sometimes obliterated, and sometimes extend beyond the scales in the form of a lobed appendage. *Seed* with a hard crustaceous integument. *Embryo* in the midst of fleshy, oily albumen, with 2 or many opposite *cotyledons*; the *radicle* next the apex of the seed, and having an organic connection with the albumen.—*Trees* or *shrubs*, with a branched trunk abounding in resin. *Wood* with a ligneous tissue marked with circular disks. *Leaves* linear, acerose or lanceolate, entire at the margins; sometimes fasciated in consequence of the non-development of the branch to which they belong; when fasciated, the primordial leaf to which they are then axillary is membranous, and enwraps them like a sheath. (Lindley.)

PROPERTIES.—Every part of coniferous plants contains an oleo-resinous juice, which, by distillation, is resolved into volatile oil and resin. The medicinal properties of this juice have been before noticed (see vol. i. pp. 254–256).

Sub-order I. ABIETEÆ.

Ovules inverted; pollen oval, curved.

102. PINUS, DC.—THE PINE.

Sex. Syst. Monœcia, Monadelphia.
(Oleo-resinæ.)

BOTANY. **Gen. Char.**—*Flowers* monœcious. **MALES**:—*catkins* racemose, compact and terminal; squamose; the *scales* stamiferous at the apex. *Stamens* 2; the *anthers* 1-celled. **FEMALES**: *catkins* or *cones* simple, imbricated with acuminate scales. *Ovaries* 2. *Stigmas* glandular. Scales of the *cone* oblong, club-shaped, woody; umbilicato-angular at the apex. *Seeds* [nuts, DC.] in pairs, covered with

a sharp-pointed membrane. *Cotyledons* digitato-partite. *Leaves* 2 or many, in the same sheath (DC. and Dubuy, *Bot. Gall.*).—Hardy, evergreen trees.

Species.—1. *PINUS SYLVESTRIS*, Linn.; *Wild Pine* or *Scotch Fir*.—*Leaves* in pairs, rigid. *Cones* ovato-conical, acute; young ones stalked, recurved, as long as the leaves; generally in pairs. Crest of the *anthers* very small. *Embryo* 5-lobed (*Bot. Gall.*).—Highlands of Scotland, Denmark, Norway, and other northern countries of Europe. Flowers in May and June. A tall, straight, hardy, long-lived tree, determinately-branched. Its *wood* is the red or yellow deal. It yields *common turpentine*, *tar*, and *pitch*.

2. *PINUS PINASTER*, Aiton, Lambert; *P. maritima*, DC.; *the Pinaster* or *Cluster Pine*.—*Leaves* twin, very long, rigid, pungent, furnished at the base with a reflexed scale. *Cones* oblong-conical, obtuse, very smooth, bright, shorter than the leaves. *Scales* bristly (*Bot. Gall.*).—Southern maritime parts of Europe. Very abundant in the neighbourhood of Bordeaux, and between this city and Bayonne. It is a much larger tree than the Scotch Fir. Flowers in May. It yields *Bordeaux turpentine*, *galipot*, *tar*, and *pitch*.

3. *PINUS PALUSTRIS*, Lambert; *the Swamp Pine*. *Leaves* 3, very long. *Cones* subeylindrical, armed with sharp prickles. *Stipules* pinnatifid, ragged, persistent (Lambert).—A very large tree, growing in dry sandy soils, from the southern parts of Virginia to the Gulf of Mexico. "Its mean elevation is 60 or 70 feet, and the diameter of its trunk about 15 or 18 inches for two-thirds of this height. The *leaves* are about a foot in length, of a brilliant green colour, and united in bunches at the ends of the branches. The names by which the tree is known in the Southern States are *long-leaved pine*, *yellow pine*, and *pitch pine*; but the first is the most appropriate, as the last two are applied also to other species. This tree furnishes by far the greater proportion of *turpentine*, *tar*, &c., consumed in the United States, or sent from this to other countries."¹

4. *PINUS TÆDA*, Lambert; *the Frankincense Pine*.—Abundant in Virginia. Yields *common turpentine*, but of a less fluid quality than that which flows from the preceding species.

5. *PINUS PINEA*, Lambert, DC.; *the Stone Pine*.—Grows in the south of Europe and northern part of Africa. Yields the cones called, in the shops, *pignoli pines*, the seeds of which, termed *pine nuts* ($\pi\alpha\tau\upsilon\delta\epsilon\varsigma$, Diosc.; *pityda*, Pliny; *nuclei pineæ pignoli*) are used as a dessert.

6. *PINUS PUMILIO*, Lambert; *the Mugho* or *Mountain Pine*.—A native of the mountains of the south of Europe. An oleo-resin, called *Hungarian balsam* (*Balsanum Hungaricum*), exudes spontaneously from the extremities of the branches, and from other parts of the tree. By distillation of the young branches with water, there is obtained in Hungary an essential oil, called *Krummholzöl*, or *oleum templinum*.

7. *PINUS CEMBRA*, Lambert, DC.; *the Siberian Stone Pine*.—The seeds, like those of *Pinus Pinca*, are eaten. By distillation the young shoots yield *Carpathian balsam* (*balsamum carpathicum*; *b. Libani*).

103. ABIES, DC.—THE FIR.

Sez. Syst. Monœcia, Monadelphia.
(Oleo-resinæ.)

BOTANY. Gen. Char.—*Flowers* monœcious. **MALES:** *catkins* solitary, not racemose; the *scales* stamiferous at the apex. *Stamens* two; the *anthers* 1-celled. **FEMALES:** *catkins* simple. *Ovaries* 2. *Stigmas* glandular. *Scales* of the *cone* imbricated; thin at the apex, rounded (neither thickened, angular, nor umbilicated on the back). *Cotyledons* digitato-partite. *Leaves* solitary in each sheath (*Bot. Gall.*).

¹ United States Dispensatory.

Species.—1. *ABIES EXCELSA*, DC.; *A. communis*, Hort.; *Pinus Abies*, Linn.; *the Norway Spruce Fir*.—*Leaves* tetragonal. *Cones* cylindrical; the scales rhomboid, flattened, jagged, and bent backwards at the margin (*Bot. Gall.*)—A native of Germany, Russia, Norway, and other parts of Europe; also of the northern parts of Asia. Commonly cultivated in England. Flowers in May and June. A very lofty tree, growing sometimes to the height of 150 feet. It yields by spontaneous exudation *common frankincense* (*abietis resina*; thus, L. D.), from which is prepared *Burgundy pitch*, D. (*pix burgundica*, L. E., *pix abietina*).

The leaf-buds (*gemmæ seu turiones abietis*) of this species of *Abies*, as well as of the *Silver Fir* (*Abies Picea*), are used on the continent, in the form of decoction or beer; or, with the woods of guaiacum and sassafras, and juniper berries, in the form of tincture (*tinctura pini composita*, Ph. Bor.). They are employed in scorbutic, rheumatic, and gouty complaints.

2. *ABIES BALSAMEA*, Lindley; *Pinus balsamea*, Linn., Lambert; *the Canadian balsam Fir*; *Balm of Gilead Fir*.—*Leaves* solitary, flat, emarginate, subpetiolate, suberect above. Scales of the flowering *cone* acuminate, reflexed.—An elegant tree, seldom rising more than 40 feet. Inhabits Canada, Nova Scotia, Maine, Virginia, and Carolina. Yields *Canadian balsam* (*Terebinthina canadensis*, L.; *Balsamum canadense*, E. D.).

3. *ABIES CANADENSIS*, Lindley;¹ *Pinus canadensis*, Linn., Lambert; *the Hemlock Spruce Fir*.—Said to yield an oleo-resin analogous to Canada balsam.

4. *ABIES PICEA*, Lindley; *Abies pectinata*, DC.; *Pinus Picea*, Linnæus; *the Silver Fir*.—Mountains of Siberia, Germany, and Switzerland. Yields *Strasbourg turpentine*.

5. *ABIES NIGRA*, Michaux; *Pinus nigra*, Lambert; *the Black Spruce Fir*.—The concentrated aqueous decoction of the young branches is *essence of spruce*, used in the preparation of *spruce beer*.²

Essence of spruce (*essentia abietis*) is prepared by boiling the young tops of some coniferous plant (in America, those of *Abies nigra*, or *black spruce*, are used) in water, and concentrating the decoction by evaporation. "It is a thick liquid, having the colour and consistence of molasses, with a bitterish, acidulous, astringent taste."³ It is used in the preparation of spruce beer.

Spruce beer (*cerevisia abietis*) is thus prepared: "Take of *Essence of Spruce half a pint*; *Pimento* (bruised), *Ginger* (bruised), *Hops*, of each *four ounces*; *Water three gallons*. Boil for five or ten minutes; then strain, and add, of *Warm Water eleven gallons*; *Yeast a pint*; *Molasses six pints*. Mix, and allow the mixture to ferment for twenty hours."⁴ It is sometimes taken as an agreeable and wholesome drink in summer. It is diuretic and anti scorbutic, and is, in consequence, employed in long sea-voyages as a preventive of scurvy.

104. LARIX EUROPEÆA, DC.—THE COMMON LARCH.

Sex. Syst. Monœcia, Monadelphia.
(*Terebinthina Veneta*, L. D.)

BOTANY. **Gen. Char.**—*Flowers* monœcious. *Character* as in *Abies*; but the *cotyledons* are simple, and never lobed. *Cones* lateral. *Leaves*, when first expanding, in tufted fascicles, becoming somewhat solitary by the elongation of the new branch (*Bot. Gall.*).

Sp. Char.—*Leaves* fascieled, deciduous. *Cones* ovate-oblong. Edges of *scales* reflexed, lacerated. *Braets* panduriform (Lambert).

Hab.—Alps of Italy, Switzerland, Germany, Siberia, &c. Cultivated in woods.

PRODUCTS.—This species yields *larch* or *Venice turpentine*. When the larch forests of Russia take fire, a gum issues forth from the medullary part of the trunks, during combustion, which is called *Orenburgh gum* (*gummi orenburgense*). A saccharine matter exudes from the larch, about June, which is called *manna of the larch*, or *manna de Briançon*. Lastly, a fungus, called *Polyporus officinalis* (see *ante*, p. 92), is nourished on this tree.

⁴ *Ibid.*

MEDICINAL SUBSTANCES OBTAINED FROM THE PRECEDING CONIFEROUS PLANTS.

The term *turpentine* (*terebinthina*) is ordinarily applied to a liquid or soft solid oleo-resinous juice of certain coniferous plants, as well as of the *Pistachia Terebinthus*, a plant of the order *Terebinthaceæ*, Juss. Indeed, this last-mentioned plant, *Pistachia Terebinthus*, is probably the true *Terebinthus* of the ancients (Τερμίνθος, Theoph. and Dioscorides). When submitted to distillation, these juices are resolved into *volatile oil* and *resin*. The roots, and other hard parts of coniferous trees, yield, by a kind of *distillatio per descensum*, the thick liquid called *tar*, from which *pitch* is procured. Hence it will be convenient to speak of the coniferous terebinthines under four heads: 1st, the *oleo-resinous juices*; 2dly, the *volatile oil* obtained therefrom by distillation; 3dly, the *resinous residuum*; 4thly, *tar* and *pitch*.

1. Oleo-Resinæ Terebinthinæ.—Terebinthinate Oleo-Resins.

At first these oleo-resins are liquid, but by age and exposure to the air they become, more or less speedily in the different varieties, solid, partly by the volatilization, and partly by the resinification of the volatile oil. They have a certain general similarity in taste and odour. They soften and become very fluid by heat, readily take fire in the air, and burn with a white flame, and, if the supply of air be limited, with the copious deposition of finely-divided carbon (*lamp black*). They are almost completely soluble in alcohol and ether; and yield, by distillation, a volatile oil and a resinous residuum. It must not be inferred that the identical volatile oil and resin into which these oleo-resins are resolved by distillation pre-exist in the juices which yield them; for in some cases it is certain they do not, but are products, not educts, as I have elsewhere¹ shown. Thus balsam of Canada possesses the property of *right-handed* circular polarization; and, by distillation, yields a volatile oil and a residual resin, both of which enjoy the power of *left-handed* circular polarization. It is obvious, therefore, that during distillation some molecular change must have been effected in the proximate principles of the balsam. American turpentine, on the other hand, possesses the power of *left-handed* circular polarization; but, by distillation, yields a volatile oil (oil of turpentine of English commerce) which produces *right-handed* polarization.

Water acquires a terebinthinate flavour when digested with them; and by the aid of the yolk or the white of an egg, or, still better, by that of vegetable mucilage, forms an emulsion with them.

1. COMMON TURPENTINE (*Terebinthina vulgaris*).—Under this name we find oleo-resins brought from various parts of the world, obtained from different species of *Pinus*, and, though agreeing in the main in their properties, possessing certain distinctive characters. At the present time, the London market is almost exclusively supplied from the United States of America, a small quantity only being occasionally imported from Bordeaux.

a. *American or White Turpentine, Terebinthina Americana*, L. (the *Térébenthine de Boston* of the French) "is procured chiefly from the *Pinus palustris*, partly, also, from the *Pinus Tæda*, and perhaps some other species inhabiting the Southern States. In former times, large quantities were collected in New England; but the turpentine trees of that section of the Union are said to be nearly exhausted; and our commerce is almost exclusively supplied from North Carolina and the south-easterly parts of Virginia."²

The method of procuring this turpentine is as follows: A hollow is cut in the tree, a few inches from the ground, and the bark removed for the space of about

¹ *Pharmaceutical Journal*, vol. v. p. 67, 1845.

² *United States Dispensatory*.

18 inches above it. The turpentine runs into these excavations from about March to October; more rapidly, of course, during the warmer months. It is transferred from these hollows into casks¹

It is imported from New York in casks; those from North Carolina holding 2 cwts., while those from South Carolina contain 2½ cwts. It is yellowish-white, with an aromatic odour, and a warm, pungent, bitterish taste. It is translucent or opaque. Its consistence varies, being semifluid, or, in cold weather, that of a soft solid. It contains various impurities (leaves, twigs, chips, &c.). That got from the first tappings is the best, and is called *virgin turpentine*. Recent American turpentine is said² to yield 17 per cent. of essential oil.

This sort of turpentine possesses the property of left-handed circular polarization; but it yields by distillation a volatile oil having right-handed polarization.

American turpentine is melted and strained, and in this state it is sometimes called *refined turpentine*.

Old and concrete American turpentine is sometimes sold for *frankincense* (*thus vel abietis resina*).

Bordeaux Turpentine is obtained by making incisions in the *Pinus Pinaster*, Lambert (*P. maritima*, DC.), and collecting the turpentine in hollows at the foot of the tree. Every month these hollows are emptied, and the oleo-resin conveyed in pails to a reservoir. In this state it is called *soft gum* (*gomme molle*). It is purified either by heating it in large boilers, and filtering through straw (*térébenthine galipot*), or by exposing it in a barrel, the bottom of which is perforated by holes, to the sun; the liquid which drains through is called *térébenthine au soleil*. The last method yields the best product, since less volatile oil is dissipated by it.³ The turpentine which flows during the winter is called *galipot* in Provence, *barras* in Guienne. It is in the form of semi-opaque, solid, dry crusts of a yellowish-white colour, a terebinthinate odour, and a bitter taste.⁴

Bordeaux turpentine is whitish, thickish, and turbid. It has a disagreeable odour, and an acrid, bitter, nauseous taste. On standing, it separates into two parts: one thinner, yellow, and almost transparent; another thicker, whitish, and of the consistence of thick honey, having a granular consistence. Bordeaux turpentine readily becomes hard and dry by exposure to the air. It possesses the property of left-handed circular polarization; and yields by distillation an oil which also has left-handed polarization. It enjoys, with balsam of copaiva, the property of solidifying with magnesia, and in this respect is distinguished from Strasburgh turpentine.

Common turpentine has been analyzed by MM. Moringlane, Duponchel, and Bonastre,⁵ and by Unverdorben.⁶ The last-mentioned chemist found it to consist of *two volatile oils* (*oil of turpentine*), *pinic acid*, a little *sylic acid*, a trace of an *indifferent resin* not soluble in oil of petroleum, and a small quantity of *bitter extractive*. The quantity of volatile oil varies from 5 to 25 per cent. of the weight of the turpentine. Laurent has discovered in Bordeaux turpentine a resinous acid, *pimarinic acid*, isomeric with pinic acid.

2. **LARCH OR VENICE TURPENTINE** (*Terebinthina veneta*; *Terebinthina laricea*). Obtained from *Larix Europæa*, DC., by boring the trunks of the trees, and adapting to each hole a wooden gutter, which conveys the juice into a tub or trough, from which it is afterwards withdrawn for filtration.⁷

Through the kindness of Professor Guibourt I have received an authentic sample of larch turpentine. It was collected in the wood of the Bishop of Maurienne, in Savoy, by order of the bishop, and at the urgent solicitation of M. Bonjean, pharmacien, naturalist of Chambéry. The same kind of turpentine, collected in Swit-

¹ Michaux, *N. Am. Sylv.* iii.; Way, *Trans. of the Society of Arts*, vol. xxviii. p. 89; Duhamel, *Traité des Arbres*, t. ii. p. 146, Paris. 1755.

⁶ *Journ. de Pharm.* t. viii. p. 329.

⁷ Duhamel, *Traité des Arbres*, t. i. p. 335.

zerland (*Swiss turpentine*)¹ is sold in Paris as *Strasbourg turpentine* (*Térébente de Strasbourg*),² and was formerly called *Venice turpentine*. It is a thick and consistent fluid, flowing with difficulty, is sometimes transparent, but more frequently cloudy, has a yellow or greenish-yellow tint, an odour which is peculiar, not very agreeable, weaker than that of either Strasbourg or common turpentine, but less disagreeable than the latter, and an acrid, very bitter taste. It has little or no tendency to concreate by keeping—a property known to Pliny,³ and which distinguishes it from common turpentine.

A factitious substance (*terebinthina veneta factitia*) is sold by London druggists for Venice turpentine. It is prepared by melting together oil of turpentine and black rosin. A similar preparation is found in the shops of the United States of America,⁴ and is probably identical with that imported from America under the name of Venice turpentine.⁵

Berzelius and Unverdorben⁶ have submitted Venice turpentine to examination, and with the following results:—

Berzelius's Analysis.

1. Oil of turpentine, probably composed of two oils.
2. Resin insoluble in cold oil of petroleum.
3. Resin soluble in cold oil of petroleum.

Unverdorben's Analysis.

1. Volatile oil, which readily distils.
2. Volatile oil, which distils less readily, and has a tendency to resinify.
3. Succinic acid (small quantity).
4. Much pinic acid.
5. A little sylvic acid.
6. Indifferent resin, insoluble in oil of petroleum.
7. Bitter extractive.

Old Venice Turpentine.

Fresh Venice Turpentine.

Larch resin yields, according to Berzelius,⁷ from 18 to 25 per cent. (according to Guibourt only 15 to 24 per cent.) of volatile oil which possesses the power of left-handed circular polarization. Its odour is citron-like, and on this account the oil might be substituted for essence of lemons in the preparation of *scouring drops*. Its sp. gr. is 0.863.

3. STRASBURG TURPENTINE (*Terebinthina argentoratensis*; *Térébenthine au citron, ou Térébenthine d'Alsace*, Guib.)—This is obtained from *Abies Picea*. The peasantry, in the vicinity of the Alps, collect it by puncturing the vesicles adhering to the bark with sharp-pointed hooks, and receiving the juice in a bottle. It is afterwards filtered through a rude kind of bark funnel.⁸

Strasbourg turpentine is very fluid, transparent, of a yellowish colour, has a very agreeable odour of citron, and a taste moderately acrid and bitter. It consists, according to Caillot,⁹ of volatile oil 33.5, resin insoluble in alcohol 6.20, *abietin* (a crystallizable resin) 10.85, *abietic acid* (? pinic and sylvic acids) 46.39, *extractive* and *succinic acid* 0.85, *loss* (principally volatile oil) 2.21.

4. CANADIAN TURPENTINE, or *Canada Balsam* (*Terebinthina canadensis*; *Balsanum canadense*), is obtained from *Abies balsamea* in Canada and the State of Maine. Between the bark and the wood of the trunks and branches of these trees are vesicles containing this oleo-resin, which exudes when they are broken, and is received in a bottle. It is imported in casks containing each about one cwt. When fresh it has the consistence of thin honey, but by age gradually solidifies: it is yellow, transparent, very tenacious, of a peculiar and agreeable terebinthinate odour, and of a slightly bitter, somewhat acrid, taste. Like Bordeaux turpentine, it solidifies when mixed with a sixth of its weight of calcined magnesia. It is imperfectly soluble in alcohol.

Canada balsam has been analyzed by Bonastre,¹⁰ who obtained the following

¹ Guib. MSS.² *Hist. Nat. lib. xvi. cnp. 19. ed. Valp.*³ Dr. Maton, in Lambert's *Description of the Genus Pinus*; and Dr. A. T. Thomson, *London Dispensatory*.⁴ Berzelius, *Traité de Chim. t. v. p. 477*; and Gmelin, *Hand. d. Chim.*⁵ Berzelius, *op. cit.*⁶ Duhamel, *Traité des Arbres*, t. i. p. 9.⁷ *Journ. de Pharm. viii. 337.*⁸ *Idem. Hist. des Drog. 3me éd. t. ii. p. 577.*⁹ *United States Dispensatory.*¹⁰ *Journ. de Pharm. xvi. p. 436.*

results: *volatile oil* 18.6, *resin* easily soluble in alcohol 40.0, *subresin* difficultly soluble 33.4, *fibrous caoutchouc*, like subresin, 4.0, *acetic acid* traces, *bitter extractive* and *salts* 4.0.

Balsam of Canada possesses the property of right-handed circular polarization; but both the oil and resin, into which it is resolved by distillation, have left-handed polarization.¹

Canada balsam is used by varnish-makers, by opticians as a cement, and by microscopists as a medium for mounting objects in.

The great value of Canada balsam for optical purposes depends on its transparency and its refractive power, which is nearly equal to that of glass. When used to connect the pieces of an achromatic lens, it prevents the loss of light by reflexion, and excludes moisture and other foreign bodies from the space between the surfaces of the glasses. In Nicol's prisms (single image prisms of Iceland spar), it serves the important purpose of transmitting the ordinary ray and of interrupting the passage of the extraordinary one; its index of refraction being intermediate between that of Iceland spar for the ordinary ray and that of the same substance for the extraordinary ray. The following table of indices of refraction serves to illustrate the preceding statements:—

<i>Indices of Refraction.</i>		<i>Indices of Refraction.</i>	
Canada balsam	1.528 to 1.549	Flint glass	1.576 to 1.642
Plate glass	1.500 to 1.550	Iceland spar, ordinary ray	1.651
Crown glass	1.525 to 1.544	Iceland spar, extraordinary ray	1.483

5. COMMON FRANKINCENSE (*Abietis resina*; *Thus*).—This is the spontaneous exudation of *Abies excelsa*. I am indebted for an authentic sample of this oleo-resin to Mr. Daniel Hanbury, who collected it, in the autumn of 1849, from the *A. excelsa*, in Switzerland. It is a soft solid, glistening in places, as if covered with a film of water. Its colour is not uniform: it is whitish, yellowish, pinkish, or pale violet red, and dark in different portions. The pinkish or violet red or peach-blossom hue seems to have been produced by exposure of the resin to the air and light, and in this circumstance resembles the peach-blossom red colour which assafetida acquires under similar circumstances. It is probable, however, that this tint is not permanent. Its odour is not disagreeable, but is somewhat like that of Strasburg turpentine. Guibourt says it is analogous to that of castoreum. The taste is balsamic, and without any bitterness.

When melted in water, and strained through a coarse cloth, it forms *Burgundy pitch* (*pix abietina* vel *burgundica*; *poix jaune* ou *blanche*). An authentic sample, prepared by Mr. D. Hanbury from *thus* collected by himself, is of an opake whitish-yellow colour, somewhat resembling emplastrum plumbi.

The substance sold as common frankincense in the London shops is usually concrete American turpentine; and most of the so-called Burgundy pitch found in commerce is a fictitious article.

Common frankincense or thus has been analyzed by Caillot,² who obtained the following results: *volatile oil* 32.00, *resin* insoluble in alcohol 7.40, *abietin* (a crystallizable resin) 11.47, *abietic acid* (? pinic and sylvic acids) 45.37, *extractive* and *succinic acid* 1.22, *loss* (principally volatile oil) 2.54.

PHYSIOLOGICAL EFFECTS.—The effects of terbinthinic substances have been before noticed (see vol. i. p. 254). Locally they operate as irritants. Applied to the skin they cause rubefaction, and sometimes a vesicular eruption. Swallowed they give rise to a sensation of warmth at the stomach, in large doses occasion sickness, and promote the peristaltic movement of the intestines. After their absorption they operate on the general system as stimulants, and excite the vascular system, especially of the abdominal and pelvic viscera. Their influence is principally directed to the secreting organs, more especially to the mucous membranes and the urinary apparatus. They act as diuretics, and communicate a violet odour to the urine. This odour depends on a portion of the oil having undergone a slight change in its nature during its passage through the system. Part of the oil, however, is thrown

¹ See a paper by the author, in the *Pharmaceutical Journal*, vol. v. p. 67, 1845.

² *Journ. de Pharm.* t. xvi. p. 436.

off unchanged; for Moiroud¹ has observed that, at the same time that the turpentes cause a violet odour, they flow in part with the urine. "I have verified," says he, "this double phenomenon on many horses, to whom turpentine has been given, for some days, in the enormous dose of ten or twelve ounces." But the kidneys are not the only parts engaged in getting rid of the absorbed turpentine. All the secreting organs, but more especially the bronchial surfaces and the skin, are occupied in the same way. By these the oil is exhaled apparently unchanged, or at least with its usual odour. During the circulation of the terebinthinate particles in the system, they exercise a local influence over the capillaries and secerning vessels, in the vital activity of which they effect a change. In certain morbid conditions, this change is of a most salutary nature. In catarrhal affections of the mucous membranes the secerning vessels become constricted under the use of terebinthines, and the discharge is, in consequence, checked.

The most important, because by far the most active, constituent of the terebinthinate oleo-resins is volatile oil. Hence their effects are almost identical with those of the latter, and will be noticed hereafter (see p. 1193). Some slight differences, however, are to be noticed. They are less rapidly absorbed, are more permanent in their operation, confine their influence principally to the apparatus of organic life, not affecting, at least to the same extent, the brain, and act less powerfully on the cutaneous system.

We have few data on which to rely in judging of the comparative influence of the different terebinthines; but as their most active constituent is volatile oil, we may fairly infer that those which possess the greatest liquidity, and which, in consequence, contain the largest quantity of oil, are the most powerful preparations. *Venice* and *Strasburg turpentes* stand in this respect pre-eminent. *Canada balsam* is valuable on account of its purity and agreeable flavour. In activity, purity, and flavour, *common turpentine* holds the lowest rank.

USES.—The terebinthinate oleo-resins are, with some exceptions, applicable for the same purposes as the volatile oil. The following are the principal cases in which they are employed:—

1. *In mucous discharges from the urino-genital organs*; as gonorrhœa, gleet, leucorrhœa, and chronic cystirrhœa.
2. *In chronic catarrh, both mucous and pituitous*, occurring in old persons of a lax fibre and lymphatic temperament.
3. *In chronic mucous diarrhœa, especially when accompanied with ulceration of the mucous follicles.*
4. *In colic and other cases of obstinate constipation*, Cullen² found a turpentine emulsion used as a clyster "one of the most certain laxatives."
5. *In chronic rheumatism*, especially sciatica and lumbago, the turpentes are occasionally used.
6. *As detergents and digestives* they have been sometimes applied to indolent and ill-conditioned ulcers.

ADMINISTRATION.—The dose of the terebinthinate oleo-resins is from a scruple to a drachm. They are given in the form of *pill*, *emulsion*, or *electuary*. To communicate to the softer kinds a consistence fit for making pills, liquorice powder may be added to them. Bordeaux turpentine and balsam of Canada, mixed with about one twenty-eighth part of their own weight of calcined magnesia, solidify in about twelve hours; the acid resins combine with the magnesia, and form solid resinates, which absorb the volatile oil. A turpentine emulsion is made with the yolk of egg, or mucilage of gum Arabic, sugar, and some aromatic water. To form an electuary the turpentine is mixed with sugar or honey. An emulsion, containing from half an ounce to an ounce of turpentine, may be used as a clyster, in obstinate constipation, ascarides, &c.

¹ *Pharmacol.-Vétérin* p. 312.

² *Treat. of the Mat. Med.*

The terebinthinate oleo-resins yield several officinal substances, and enter into several preparations:—

1. *TEREBINTHINA VULGARIS* yields *Oleum Terebinthinæ* and *Resina*; and enters into the composition of *Emplastrum Galbani*, L., and *Unguentum Elemi*, L.
2. *TEREBINTHINA VENETA* is a constituent of *Emplastrum Cantharidis compositum*, E., and *Unguentum Infusi Cantharidis*, E.
3. *ABIETIS RESINA*; THUS. yields *Pix Burgundica*, L. E. D.; and enters into the composition of *Emplastrum Galbani*, L., *Emplastrum Opii*, L., *Emplastrum Picis*, L., *Emplastrum Calcificiens*, D., *Emplastrum Ferri*, L. D., and *Emplastrum Cumini*, L.

2. *Oleum Terebinthinæ*, E. D.—Oil of Turpentine.

This essential oil is frequently, though erroneously, called *spirits* or *essence of turpentine*.

PREPARATION.—It is obtained by submitting to distillation a mixture of American turpentine (which has been melted and strained) and water in due proportions, in the ordinary copper still, with a naked fire. The distilled product is found to consist of oil of turpentine swimming on water; the residue in the still is resin. If no water be employed, a much higher temperature is required to effect the distillation, and danger is thereby incurred of causing empyreuma. Mr. Flockton, a large distiller of turpentine in this metropolis, informs me that the average quantity of oil yielded by American turpentine is from 14 to 16 per cent. He also tells me that Bordeaux turpentine yields an oil having a more disagreeable odour, and a resin of inferior quality.

To deprive it of all traces of resinous and acid matters, oil of turpentine should be redistilled from a solution of potash, and this is actually done, as Mr. Flockton informs me. The British Colleges, however, direct it to be purified by distillation with water only.

The directions of the Edinburgh College for the preparation of Rectified Oil of Turpentine (*Oleum Terebinthinæ purificatum*, E.), are as follows:—

Take of Oil of Turpentine Oj; Water Oiv. Distil as long as oil comes over with the water.

The London College gives no directions for the rectification of the oil; but places the rectified oil (*oleum e terebintho destillatum, rectificatum*, L.).

PROPERTIES.—Pure oil of turpentine is a colourless, limpid, very inflammable fluid. It has a peculiar, and, to most persons, disagreeable odour, and a hot taste. When pure, it is neutral to test paper. Its sp. gr. is 0.86 at about 70° F. It boils at about 314° F.; the density of its vapour is 4.76 (Dumas). It is very slightly soluble in hydrated alcohol; but 100 parts of alcohol, of sp. gr. 0.840, dissolve 13 or 14 parts of it, and absolute alcohol takes up a still larger proportion. The oil is also soluble in ether. Exposed to the air, it absorbs oxygen, becomes yellowish, and somewhat denser, owing to the formation of resin (*pinic* and *sylic acids*). This resinification is accompanied with the production of a small quantity of formic acid.

Oil of turpentine enjoys the power of rotating the ray of plane-polarized light; but the direction of rotation is different in the English and French oils—in the former being right-handed, in the latter left-handed.

Plan of the apparatus for showing the circular polarization of oil of turpentine.

- a. A ray of common or unpolarized light.
- b. A glass reflector, placed at an angle of $56^{\circ}.45'$, for effecting the plane-polarization of the light.
- c. The reflected plane-polarized ray.
- d. The oil of turpentine, which effects the double refraction and rotation of the plane-polarized light.
- e. The emergent circularly polarized light.
- f. The analyzer (a double refracting rhomb of calcareous spar), which produces two-coloured images: one caused by ordinary refraction, and called the *ordinary image* (o); the other by extraordinary refraction, and termed the *extraordinary image* (x).
- g. A lens employed to produce well-defined images.

Fig. 280.

Fig. 281.

Ordinary and extraordinary images.

ordinary, the other (x) the extraordinary image. The colours of these images are complementary to each other. By rotating the analyzer (f) on its axis, the extraordinary image (x) revolves around the ordinary image (o); each image undergoing a succession of changes of colour; the sequence of colours being different for the English and French oils of turpentine.

SEQUENCE OF COLOURS FOR OIL OF TURPENTINE AS OBTAINED BY THE RIGHT-HANDED ROTATION OF THE ANALYZER.

<i>English Oil of Turpentine.</i> (Obtained from American turpentine, the produce of <i>Pinus palustris</i> and <i>P. tæda</i> .)		<i>French Oil of Turpentine.</i> (Obtained from Bordeaux turpentine, the produce of <i>Pinus Pinaster</i> .)	
<i>Ordinary Image.</i>	<i>Extraordinary Image.</i>	<i>Ordinary Image.</i>	<i>Extraordinary Image.</i>

Blue	Red.	Green	{ Violet.
Indigo }	Orange.	Yellow	{ Indigo.
Violet }	Yellow.	Orange	Blue.
Red	Green.	Red	Green.

Moreover, the degree of rotatory power is not uniform.

English oil of turpentine (obtained by distillation with water from American turpentine) is remarkable for its comparatively feeble odour. A sample of oil whose sp. gr. was 0.863, had a molecular power of right-handed rotation of 18.5 to 18.7.

French oil of turpentine (obtained by distillation from Bordeaux turpentine) enjoys the power of left-handed rotation; the intensity of which, however, is subject to some variation, as the following table shows:—

	<i>Sp. Gr.</i>	<i>Left-handed Rotatory Power.</i>
Unrectified oil	0.8506	28.83
First product of the rectification with water	0.8736	31.657
Latter product of the rectification with water	0.889	22.327
Oil rectified without water	0.873	32.23
Oil rectified without water preserved 10 years with potash	0.87	33.95

It is obvious, therefore, that the molecular constitution of oil of turpentine is not constant.

Bouchardat found that the unrectified oil was an imperfect solvent of caoutchouc; and the oil rectified without water a better one. But the same oil distilled from bricks was pyrogenous, had a slight lemon-yellow colour, a sp. gr. of 0.8422, a rotatory power of only $8^{\circ}.68$, and a much increased power of dissolving caoutchouc.

Rectified oil of turpentine is sold in the shops under the name of *camphene*, for burning in lamps. When it has become resinified by exposure to the air, it is unfit for the purposes of illumination, and requires to be rectified from carbonate of potash, or some similarly active substance, to deprive it of resin.

The *sweet oil of turpentine* or *sweet spirits of turpentine*—sold in the shops for “painting without smell”—does not appear to differ from the rectified oil of turpentine of English commerce.

The common or unrectified oil of turpentine, sold in the shops under the name of *turps*, contains resin, and is, in consequence, denser and more viscid than camphene. Its sp. gr. varies from 0.87 to 0.884.

Oil of turpentine is composed of

	Atoms.	Eq. Wt.	Per Cent.
Carbon	20	120	88.23
Hydrogen	16	16	11.76
Oil of Turpentine	1	136	99.99

Hydrates of oil of turpentine.—Four hydrates of oil of turpentine are known. When the commercial oil is exposed to an intense cold, crystals either of the binhydrate $C^{20}H^{16}, 2HO$, or of the hexahydrate $C^{20}H^{16}, 6HO$, are deposited. The latter forms large prismatic crystals, which, at a temperature of about $217\frac{1}{2}^{\circ} F.$, became converted into the quadhydrate $C^{20}H^{16}, 4HO$. The monohydrate, $C^{20}H^{16}, HO$, is a liquid which List calls *terpinol*.

Hydrochlorate of oil of turpentine; Artificial Camphor.—When hydrochloric acid is passed into oil of turpentine, surrounded by ice, two compounds are obtained—one solid, called *solid* or *Kind's artificial camphor*; the other fluid, and termed *liquid artificial camphor*, *terebene*, or *terebylene*.

Solid artificial camphor, $C^{20}H^{16}, HCl$, is white, transparent, lighter than water, and has a camphoraceous taste. It is neutral to test paper, fuses at a temperature above the boiling point of water, and is volatilizable usually with the evolution of hydrochloric acid. It burns in the air with a greenish sooty flame; and when the flame is blown out, evolves a vapour which has a terebinthinate odour. Distilled with lime, it yields chloride of calcium, water, and a volatile oil called *camphylene*, which is isomeric with oil of turpentine, but has no rotatory power in relation to polarized light.

The quantity of solid artificial camphor yielded by oil of turpentine depends on the sort of oil employed. From Thenard's experiments, it would appear that French oil of turpentine yields the largest produce.

Artificial camphor does not produce the lesion of the nervous system which is caused by ordinary camphor. Orfila found that half an ounce of it, dissolved in olive oil, and given to a dog, caused merely a few small ulcers in the mucous membrane of the stomach.

CHARACTERISTICS OF OIL OF TURPENTINE.—As a volatile oil, it is recognized by its combustibility, its burning with a very sooty flame, its almost insolubility in water, its solubility in alcohol and in ether, its volatility, and its evaporating without leaving any greasy stain on paper.

It is sometimes used to adulterate other more costly volatile oils; and it may then be detected by one or more of the following characters: 1st, its remarkable odour; 2dly, its rotatory power in relation to polarized light; 3dly, its being only very slightly soluble in diluted spirit; 4thly, its ready admixture with, and solubility in, the fixed oils; 5thly, its not being able to dissolve, in the cold, santaline (the colouring principle of the wood of *Pterocarpus santalinus*), whereas some of the other

volatile oils (as oil of lavender) do dissolve it; 6thly, by the violent action of both chlorine and iodine on it.

PHYSIOLOGICAL EFFECTS. *a. On Vegetables.*—Plants exposed to the vapour of this oil are rapidly destroyed.¹

β. On Animals.—On both vertebrated and invertebrated animals it operates as a poison. Injected into the veins of horses and dogs it excites pneumonia.² Two drachms thrown into the veins of a horse caused trembling, reeling, falling, inclination to pass urine and stools, and frequent micturition. Inflammatory fever, with cough, continued to the 8th day; then putrid fever appeared. On the 9th day death took place. The body presented all the signs of putrid fever and pneumonia (Hertwich). Schubarth³ found that two drachms of the rectified oil, given to a dog, caused tetanus, failure of the pulse and breathing, and death in three minutes. The skin of the horse is very sensible to the influence of oil of turpentine, which produces acute pain. "It is a remarkable circumstance," says Moiroud,⁴ "that this pain is not accompanied with any considerable hyperæmia. It is quickly produced, but is of short duration." Oil of turpentine is sometimes employed by veterinarians as a blister, but it is inferior to cantharides, and, if frequently applied, is apt to blemish (*i. e.*, to cause the hair of the part to fall off). In doses of three ounces it is a most valuable antispasmodic in the colic of horses.⁵ In small doses it acts as a diuretic. Tiedemann and Gmelin⁶ detected oil of turpentine in the chyle of a dog and a horse, to whom this agent had been given.

γ. On Man.—In small doses (as six or eight drops to ℥ʒj) it creates a sensation of warmth in the stomach and bowels, becomes absorbed, circulates with the blood, and in this way affects the capillary vessels, and is thrown out of the system by the different excretories, on the secerning vessels of which it acts in its passage through them. The exhalations of the skin and bronchial membranes acquire a marked terebinthinate odour, while the urine obtains the smell of violets. By its influence on the renal vessels it proves diuretic. By the same kind of local influence on the cutaneous vessels it proves sudorific. It appears to have a constringing effect on the capillary vessels of the mucous membranes, for, under its use, catarrhal affections of, and hemorrhages from, these parts are frequently checked, and often are completely stopped. Its continued use sometimes brings on irritation of the urinary organs, or when this state pre-existed, it is often aggravated by the use of turpentine.

In a medium dose (℥ʒj or ℥ʒij) its effects are not constant. Dr. Ed. Percival⁷ saw two drachms given without any unpleasant effect being produced either on the digestive or urinary organs; they acted as an agreeable stomachic, and promoted the catamenia. Mr. Stedman,⁸ on the other hand, has seen this dose produce strangury, bloody urine, suppression of this secretion, fever, thirst, and vomiting. These two cases, however, may be regarded as the opposite extremes; and, in general, we may expect, from a medium dose, a feeling of heat in the stomach and bowels, accelerated peristaltic motion, increased frequency of pulse, diaphoresis, diuresis, and sometimes irritation of the urinary organs. Occasionally it provokes the catamenia.

In a large or maximum dose (℥ʒiv to ℥ʒij) its effects are not constant. It usually causes a sensation of abdominal heat, sometimes nauseates, and in general operates as a tolerably active purgative, without causing any unpleasant effects. I have administered from one to two fluidounces in a considerable number of cases of tape-worm, and have rarely seen any ill consequences therefrom. "It has been given," says Dr. Duncan,⁹ "even to the extent of four ounces in one dose, without any perceptible bad effects, and scarcely more inconvenience than would follow from an equal quantity of gin." Cases are reported, however, in which it has failed to

produce purging, and in such it has acted most violently on the system, accelerating the pulse, depressing the muscular power, and giving rise to a disordered state of the intellectual functions, which several persons have compared to intoxication. A remarkable and well-detailed instance of this occurred in the person of Dr. Copland,¹ who refers the disorder of the cerebral functions, in his case, to diminished circulation of blood in the brain; while the gastric heat, &c., he ascribes to increased vascular activity in the abdominal region. The oil passed off most rapidly by the skin and lungs (principally by the latter), and the air of the apartment became strongly impregnated with its effluvia. In some cases it causes sleepiness. Purkinje² experienced this effect from one drachm of the oil. Dr. Duncan has sometimes seen it produce "a kind of trance, lasting twenty-four hours, without, however, any subsequent bad effect." The same writer adds, "the largest dose I have known given has been three ounces, and without injury." A scarlet eruption is mentioned by Wibmer as being produced in one case by an ounce of the oil.

USES.—The following are the principal uses of the oil of turpentine:—

1. *As an anthelmintic.*—It is the most effectual remedy for *tape-worm* we possess. It both causes the death of, and expels the parasite from the body. To adults it should be given in doses of an ounce at least. I have frequently administered an ounce and a half, and sometimes two ounces. Occasionally, as in Dr. Copland's case, it fails to purge, but becoming absorbed, operates most severely on the system, causing disorder of the cerebral functions. It is said to be more apt to act thus in persons of a full and plethoric habit. To prevent these ill consequences, an oleaginous purgative should be either conjoined with it, or given at an interval of four or five hours after it. An excellent and safe method of employing it is to combine it with a castor-oil emulsion. *Chaber's empyreumatic oil* (described at vol. i. p. 263) used by Bremser³ against *tape-worm*, consists principally of oil of turpentine. A very effectual remedy for the *small thread-worm* (*Ascaris vermicularis*) is the turpentine enema.

2. *In blennorrhœa.*—Oil of turpentine sometimes checks or stops profuse chronic discharges from the mucous membranes. It appears to effect this by a topical influence over the capillary and seerning vessels, in its passage through them out of the system. In many cases, it would appear to confine its operation to the production of an increase of tonicity in the vessels which pour out mucus; but in other instances, especially in blennorrhœa of the urinary apparatus, it seems to set up a new kind of irritation in the affected membrane, which supersedes the previously existing disease. Hence its use is not admissible in acute or recent affections of these tissues. In gonorrhœa and gleet I have frequently employed it as a substitute for balsam of copaiba with success. In leucorrhœa it has occasionally proved serviceable. In catarrhus vesicæ or cystirrhœa, it now and then acts beneficially; but it requires to be used in small doses and with great caution. In chronic pulmonary catarrh, either mucous or pituitous, it is said to have been employed with advantage. In chronic diarrhœa and dysentery it has proved advantageous: in these cases it has a direct local action on the affected part, besides exerting its influence over this in common with other mucous membranes after its absorption.

3. *In hemorrhages.*—In sanguineous exhalations, called hemorrhages, from the mucous surfaces, oil of turpentine may, under some circumstances, act efficaciously. On the same principle that it checks excessive secretion of mucus in catarrhal conditions of these tissues, so we can readily conceive it may stop the exhalation of blood. But it is only admissible in cases of a passive or atonic character, in the absence of plethora and a phlogistic diathesis.⁴ In purpura hæmorrhagica it has been recommended as a purgative, by Dr. Whitlock Nichol,⁵ Dr. Magee,⁶ and others.

⁵ Quoted by Wibmer, *Wirk. d. Arzn.*

⁶ *Ibid.* vol. xxiv. p. 307.

I have seen it act injuriously in this disease, while blood-letting has seemed to relieve.

4. *In puerperal fever.*—The use of the oil of turpentine as a specific in this disease was introduced by Dr. Brennan, of Dublin;¹ and strong testimonies were subsequently borne to its efficacy by several highly respectable practitioners.² Dr. Brennan gave one or two tablespoonfuls of the oil, every three or four hours, in cold water, sweetened; and applied flannel soaked in the oil to the abdomen. But the apparent improbability of a stimulant like turpentine curing an inflammatory disease, has prevented many practitioners placing any faith in it, or even giving it a trial. In other instances, the unconquerable aversion which patients have manifested to it, has precluded its repetition. Lastly, it has failed, in the hands of some of our most accurate observers, to produce the good effects which Dr. Brennan and others have ascribed to it, and in some instances has appeared to aggravate the malady. These reasons have been conclusive against its employment, at least in the way advised by Dr. Brennan. But there are two valuable uses which may be made of turpentine, in puerperal fever: it may be given in the form of clyster, to relieve a tympanic condition of the intestines, and for this purpose no remedy perhaps is superior to it; secondly, flannel soaked in the hot oil may be applied to the abdomen, to cause rubefaction, as a substitute for a blister, to the employment of which several objections exist.

5. *In ordinary fever.*—As a powerful stimulant in some forms of low fever, oil of turpentine has been well spoken of by Dr. Holst,³ Dr. Chapman,⁴ Dr. Douglas,⁵ and more recently by Dr. Wood.⁶ When the skin is dry, the bowels flatulent, and ulceration of the mucous membrane suspected, it often proves most serviceable.

6. *In rheumatism.*—In chronic rheumatism, oil of turpentine has long been celebrated. Its beneficial influence depends on its stimulant and diaphoretic operation, and is more likely to be evinced in old and debilitated persons. I have found medium doses occasionally succeed when small ones have failed. But for the most part I have not met with that success with it in chronic rheumatism, to induce me to place much confidence in it. In the form of liniment it has often proved serviceable.

7. *In sciatica and other neuralgic affections.*—Oil of turpentine was proposed as a remedy for sciatica by Drs. Pitcairn and G. Cheyne. Its efficacy was subsequently confirmed by Dr. Hone.⁷ More recently it has been extensively employed, and with great success, in France, in sciatica as well as in various other neuralgias.⁸ But it has proved more successful in those which affect the lower extremities. My own experience does not lead me to speak very favourably of it. In a disease the pathology of which is so imperfectly understood as is that of neuralgia, it is vain to attempt any explanation of the *methodus medendi* of an occasional remedy for it. I have known oil of turpentine now and then act most beneficially in sciatica, without giving rise to any remarkable evacuation by the bowels, skin, or kidneys, so that the relief could not be ascribed to a cathartic, a diaphoretic, or a diuretic operation.

8. *In suppression of urine.*—I have seen oil of turpentine succeed in reproducing the urinary secretions when other powerful diuretics had failed.

9. *In infantile diabetes.*—Dr. Dewees⁹ has cured three cases of diabetes [?] in infants under fifteen months old “by keeping the bowels freely open, and putting a quantity of spirits of turpentine upon the clothes of the children, so as to keep them in a terebinthinate atmosphere.”

10. *In nephritic diseases.*—In some diseases of the kidneys, as ulceration, the use of oil of turpentine has been much extolled. It has proved successful in renal hydatids.¹⁰

¹⁰ Bayle, *op. cit.*

11. *In dropsy*.—Oil of turpentine has occasionally proved serviceable in the chronic forms of this disease.¹ Its efficacy depends, in part, on its derivative operation as a stimulating diuretic; and in part, as I conceive, on its powerful influence over the capillary and secreting vessels, by which it exercises a direct power of checking effusion. It is inadmissible, or is contraindicated, in dropsies accompanied with arterial excitement, or with irritation of the stomach or the urinary organs. When the effusion depends on obstruction to the return of venous blood, caused by the pressure of enlarged or indurated viscera, tumours, &c., turpentine can be of no avail. But in the atonic forms of dropsy, especially in leucophlegmatic subjects, attended with deficient secretion of the skin and kidneys, this oil is calculated to be of benefit. Dr. Copland² has used it in the stage of turgescence, or invasion of acute hydrocephalus, as a drastic and derivative.

12. *In spasmodic diseases*.—Oil of turpentine has been employed successfully in the treatment of epilepsy, by Drs. Latham, Young, Ed. Percival, Lithgow, Copland, and Pritchard.³ No benefit can be expected from this or any other medicine, when the disease depends on organic lesion within the osseous envelops of the nervous centres. But when the disease is what Dr. Marshall Hall terms *centripetal* or *eccentric* (as the convulsion of infants frequently is), that is, takes its origin in parts distant from the cerebro-spinal axis, which becomes affected only through the incident or excitor nerves, we can easily understand that benefit may be obtained by the use of agents like this, which, while it stimulates the abdominal viscera, operates as a cathartic and anthelmintic, and produces a derivative action on the head. A more extended experience of its use in chorea, hysteria, and tetanus, is requisite to enable us to speak with confidence of its efficacy in these diseases, though a few successful cases have been published.⁴

13. *In inflammation of the eye*.—Mr. Guthrie⁵ has employed oil of turpentine in inflammation of the iris and choroid coat, on the plan recommended by Mr. Hugh Carmichael.⁶ In some cases, especially those of an arthritic nature, it succeeded admirably, in others it was of little or no service. It was given in doses of a drachm three times a day.

14. *In tympanites*.—To relieve flatulent distension of the stomach and bowels, and the colic thereby induced, both in infants and adults, oil of turpentine is a most valuable remedy. It should be given in full doses, so as to act as a purgative; or when, from any circumstance, it cannot be exhibited by the mouth, it may be employed in the form of elyster. Dr. Ramsbotham⁷ speaks in the highest terms of the efficacy of the oil of turpentine in the acute tympanites of the puerperal state, and thinks that most of the cases of the so-called puerperal fever, which yielded to this oil, were in fact cases of acute tympanites; and in this opinion he is supported by Dr. Marshall Hall.

15. *In obstinate constipation*.—Dr. Kinglake,⁸ in a case of obstinate constipation, with a tympanic condition of the intestines, found oil of turpentine a successful cathartic, after the ordinary means of treating these cases had been assiduously tried in vain. Dr. Paris⁹ also speaks highly of it in obstinate constipation depending on affections of the brain.

16. *To assist the passage of biliary calculi*.—A mixture of three parts sulphuric ether and two parts oil of turpentine has been recommended as a solvent for biliary calculi.¹⁰ But there is no foundation for the supposition that the relief which may be obtained by the use of this mixture in icterus, and during the passage of a biliary calculus, depends on the dissolution of the latter.

17. *As an external remedy.*—Oil of turpentine is employed externally, as a *rube-facient*, in numerous diseases, on the principle of counter-irritation, before explained (vol. i. p. 170). Thus in the form of liniment, it is used, either hot or cold, in chronic rheumatism, sprains, sore throat, neuralgic affections of the extremities, &c. In the form of fomentation the hot oil is applied to produce redness of the skin in puerperal peritonitis, as I have already mentioned. As a powerful local *stimulant*, it was recommended by Dr. Kentish¹ as an application to burns and scalds, his object being to restore the part gradually, not suddenly, to its natural state, as in the treatment of a case of frost-bite. The practice is most successful when the local injury is accompanied with great constitutional depression. I can bear testimony to its efficacy in such cases, having employed it in several most severe and dangerous burns with the happiest results. In that form of gangrene which is not preceded by inflammation, and is called *dry* or *chronic*, oil of turpentine may occasionally prove serviceable, especially when the disease affects the toes and feet of old people. There are many other topical uses to which it has been applied; but as they are for the most part obsolete, at least in this country, I omit any further mention of them. They are fully noticed in the works of Voigtels² and Richter.³ Oil of turpentine is the principal ingredient in *Whitehead's Essence of Mustard*, which contains also camphor and a portion of the spirits of rosemary. *St. John Lony's liniment* consisted of oil of turpentine and acetic acid, held in suspension by yolk of egg.⁴

ADMINISTRATION.—When given as a diuretic, and to affect the capillary and secreting vessels (in catarrhal affections of the mucous membranes, dropsy, suppression of urine, hemorrhage, &c.) the dose is from six or eight minims to fʒj; as a general stimulant (in chronic rheumatism, chorea, &c.) or to produce a change in the condition of the intestinal coats (in chronic dysentery), from fʒj to ʒij; as an anthelmintic (in tape-worm) or as a revulsive (in apoplexy, in epilepsy previous to an expected paroxysm, &c.), from fʒss to fʒij. It may be taken floating on some aromatic water, to which some hot aromatic tincture, as *tinctura capsici*, has been added; or it may be diffused through water by the aid of mucilage or an emulsion; or it may be made into a linetus with honey or some aromatic syrup.

1. ENEMA TEREBINTHINÆ, L. E. D.; *Clyster of Turpentine*.—(Oil of Turpentine fʒj; the Yolk of one Egg; Decoction of Barley fʒʒix. Rub the oil with the yolk, and add the decoction, *L.*—The *Edinburgh College* substitutes plain Water for Barley Water.—The *Dublin College* orders of Oil of Turpentine fʒj; Mucilage of Barley fʒxvj.)—Used as an anthelmintic in ascariides; as an antispasmodic and purgative in colic, obstinate constipation, and tympanites. Dr. Montgomery⁵ says, “it is much used in cases of peritoneal inflammation.”

2. LINIMENTUM TEREBINTHINÆ, L. D.; *Linimentum Terebinthinatum*, E.; *Turpentine Liniment*.—(Soft Soap ʒij; Camphor ʒj; Oil of Turpentine fʒxvj. “Shake them together until they are mixed,” *L.*—Resinous Ointment ʒiv; Oil of Turpentine fʒv; Camphor ʒss. Melt the ointment, and gradually mix with it the camphor and oil till a uniform liniment be obtained,” *E.*—Ointment of White Resin ʒviiij; Oil of Turpentine fʒv, *D.*)—Introduced by Dr. Kentish⁶ as a dressing for burns and scalds. The parts being first bathed with warm oil of turpentine, alcohol, or camphorated spirit, are to be covered with pledgets of lint thickly spread with this liniment. When the peculiar inflammation, excited by the fire, has subsided, milder applications are then to be resorted to. This liniment may also be used in any other cases requiring the employment of a more stimulant application than the ordinary soap liniment.

3. Resinæ Terebinthinæ.—Terebinthinate Resins.

1. *Resina*, L. E. D. [U. S.].—*Rosin*, or *Common Resin*.

(Quod restat Terebinthinæ postquam oleum destillatum est, L.)

PREPARATION.—This is the residue of the process for obtaining oil of turpentine. It is run, while liquid, into metallic receivers coated with whiting to prevent adhesion, and from these is ladled into wooden moulds or casks. When the distillation is not carried too far, the product contains a little water, and is termed *yellow rosin* (*resina flava*). A more continued heat expels the water and produces *transparent rosin*; and if the process be pushed as far as it can be without producing a complete alteration of properties, the residue acquires a deep colour, and is termed *brown* or *black rosin*, or *colophony* (*resina nigra seu colophonium*). If melted rosin be run into cold water contained in shallow tanks, and a supply of cold water be kept up until the rosin has solidified, a pale yellow product is obtained, called *Flockton's patent rosin*.

PROPERTIES.—Rosin is compact, solid, brittle, almost odourless and tasteless, with a smooth, shining fracture, becomes electric by friction, is fusible at a moderate heat, decomposable at a higher temperature, and burning in the air with a yellow smoky flame. It is insoluble in water, but soluble in alcohol, ether, and the volatile oils. With wax and the fixed oils it unites by fusion; with the caustic alkalies it unites to form a *resinous soap* (the *alkaline resinate*s, principally the *pinates*). Heated with concentrated sulphuric or nitric acid mutual decomposition takes place.

By distillation, rosin yields *rosin oil* and *tar*. *Rosin oil* is a mixture of four carburets of hydrogen: *retinaphte*, $C^{14}H^8$; *retinyle*, $C^{10}H^{12}$; *retinole*, $C^{32}H^{16}$; and *metanaphthaline*, $C^{20}H^8$. The rosin oil which distils over at from $226\frac{1}{2}^{\circ}$ F. to 302° F. is a mixture of retinaphte and retinyle. It is sometimes used in the arts as a substitute for oil of turpentine. The part which boils at about 464° F. is retinole; it enters into the composition of some printing inks. Mixed with lime, it forms a sort of grease for wheels, machinery, &c. Rosin oil has been used in the preparation of *rosin gas*.¹

Yellow rosin is opaque and yellow, or yellowish-white. Its opacity is owing to water, with which it is incorporated. By continued fusion this is got rid of, and the rosin then becomes transparent (*transparent rosin*). *Brown rosin*, or *colophony*, is more or less brown and transparent.

COMPOSITION.—Rosin is a compound or mixture of *pinic acid* (principally), *colophononic acid* (variable in quantity), *sylic acid* (a small quantity), and traces of an *indifferent resin*.²

Pinic and sylic acids are isomeric: according to Laurent, their equivalent is expressed by the formula $C^{30}H^{20}O^3, HO$; and their salts by the formula $MO, C^{30}H^{20}O^3$.

1. **PINIC ACID.**—It is soluble in cold alcohol of sp. gr. 0.883. The solution forms a precipitate (*pinate of copper*) on the addition of an alcoholic solution of acetate of copper. *Pinate of magnesia* dissolves with difficulty in water.

2. **COLOPHONIC ACID (Colophonic Acid).**—Formed by the action of heat on pinic acid, and therefore the quantity of it contained in rosin varies according to the heat employed. Rosin owes its brown colour to it. It is distinguished from pinic acid by its greater affinity for salifiable bases, and its slight solubility in alcohol.³

3. **SYLVIC ACID.**—Is distinguished from pinic acid by its insolubility in cold alcohol of sp. gr. 0.883.

4. **INDIFFERENT RESIN.**—Is soluble in cold alcohol, oil of petroleum, and oil of turpentine. It forms with magnesia a compound readily soluble in water.

PHYSIOLOGICAL EFFECTS.—Not being used internally, its effects when swallowed are scarcely known. It is probable, however, that they are of the same kind as those of common turpentine, though very considerably slighter. In the horse it

¹ Pelouze and Fremy, *Cours de Chimie générale*, t. iii. p. 543, 1850.² Unverdorben, in Gmelin, *Hand. d. Chem.* ii. 520.³ Berzelius, *Traité de Chim.* t. v. p. 489.

acts as a useful diuretic, in doses of five or six drachms.¹ Its local influence is mild. "It may be considered," says Dr. Maton,² "as possessing astringency without pungency."

USE.—Powdered rosin has been applied to wounds to check hemorrhage, and is occasionally used for this purpose in veterinary practice. But the principal value of rosin is in the formation of plasters and ointments, to which it communicates great adhesiveness and some slightly stimulant properties.

1. CERATUM RESINÆ, L. [U. S.]; *Unguentum Resinosum*, E.; *Unguentum Resinæ*, D.; *Yellow Basilicon* or *Basilicon Ointment*, offic.—(Resin, Wax, of each ℥xv; Olive Oil Oj. Melt the resin and the wax together with a slow fire; then add the oil, and press the cerate, while hot, through a linen cloth, L.—The *Edinburgh College* orders of Resin ℥v; Axunge ℥viiij; Bees' Wax ℥ij. Melt them together with a gentle heat, and then stir the mixture briskly while it cools and concretes. [The *U. S. Pharm.* directs the same.]—The *Dublin College* orders of Resin, in coarse powder, ℔ss; Yellow Wax ℥iv; Prepared Lime ℔j.)—A mildly stimulant, digestive, and detergent application to ulcers which follow burns, or which are of a foul and indolent character, and to blistered surfaces to promote a discharge.

2. EMPLASTRUM RESINÆ, L. D. [U. S.]; *Emplastrum Resinosum*, E.—Has been already described at vol. i. p. 715.

2. *Pix Burgundica*, L. E. D.—*Burgundy Pitch*.

(*Resina impura e terebinthinâ præparata*, L.)

PREPARATION.—True Burgundy pitch is prepared by melting common frankincense (*Abietes resina*; *Thus*) in hot water, and straining through a coarse cloth. By this process part of the volatile oil and the impurities are got rid of. The substance sold as Burgundy pitch in the shops is rarely prepared in this way, but is fictitious. Its principal constituent is rosin, rendered opake by the incorporation of water, and coloured by palm oil. One maker of it informed me that he prepared it from old and concrete American turpentine.

I have a sample of genuine Burgundy pitch prepared by Mr. D. Hanbury from *Thus* collected by himself in Switzerland (see *ante*, p. 290). In colour it somewhat resembles *emplastrum plumbi*. Its odour resembles the Burgundy pitch imported from Hamburg, and which, when strained, constitutes the best commercial Burgundy pitch.

Hamburg pitch is of a dark colour, and contains many impurities. It would appear to be melted but unstrained *Thus*. It yields, when re-melted and strained, a Burgundy pitch which is darker coloured, but which otherwise agrees with the genuine sample prepared by Mr. Hanbury.

PROPERTIES.—Genuine Burgundy pitch is hard, brittle when cold, but readily taking the form of the vessel in which it is kept. It softens by the heat of the hand, and strongly adheres to the skin. Its colour is yellowish-white; its odour is not disagreeable; its taste slightly bitter. Fictitious Burgundy pitch is usually of a fuller yellow colour than the genuine, and has a somewhat less agreeable odour.

COMPOSITION.—Consists of *resin* principally and a small quantity of *volatile oil*.

PHYSIOLOGICAL EFFECTS.—Its effects are similar to those of the other terebinthinate resins. In activity it holds an intermediate station between common turpentine and rosin; being considerably less active than the first, and somewhat more so than the last of these substances. Its local action is that of a mild irritant. In some persons it excites a troublesome vesiculo-pustular inflammation.³

USES.—It is employed as an external agent only, spread on leather, forming the well-known *Burgundy pitch plaster* (*emplastrum picis burgundicæ*), which is applied to the chest in chronic pulmonary complaints, to the loins in lumbago, to the joints in chronic articular affections, and to other parts to relieve local pains of a rheumatic character. It acts as a counter-irritant or revulsive.

³ Lambert's *Pinus*

EMPLASTRUM PICIS, L. E.; *Plaster of Pitch*.—(Burgundy Pitch ℔ij; Frankincense [Thus] ℔j; Resin, Wax, of each ℥iv; Expressed Oil of Nutmeg ℥j; Olive Oil, Water, of each f℥ij. Add the oils and water to the pitch, resin, and wax, melted together. Lastly, mix them all, and boil down to a proper consistence, *L.*—The formula of the *Edinburgh College* is as follows: Burgundy Pitch ℔jss, Resin and Bees' Wax, of each ℥ij; Oil of Mace ℥ss; Olive Oil f℥j; Water f℥j. Liquefy the pitch, resin, and wax, with a gentle heat; add to the other articles; mix them well together, and boil till the mixture acquires a proper consistence.)—Stimulant and rubefacient; used in the same cases as the simple Burgundy pitch.

[4. *Pix Canadensis, U. S.*

Canada Pitch; Hemlock Pitch; the prepared concrete juice of the Abies Canadensis, Mich.—As a substitute for Burgundy Pitch, this article is employed in the United States, over which it has the advantage of being in a state of purity. It is the product of the

ABIES CANADENSIS, or *Hemlock Spruce*, a large tree, attaining a height of seventy or eighty feet, with a circumference of six or nine feet. The leaves are six or eight lines long, very narrow, flat, and downy at the time of their expansion. The cones are a little longer than the leaves, oval, pendulous, and situated at the extremity of the branches.

This species of *Abies* is solely a native of North America, and belongs to the coldest regions of the continent, beginning to appear about Hudson's Bay. In the vicinity of Lake St. John and near Quebec, the forests are filled with it, and it is found in all the Northern States. It prefers high situations, and those the most humid and gloomy.

The wood of this tree is of little value; the bark contains a large amount of tannin, and is used in the tanneries where the oak is scarce.

Hemlock resin does not flow from the bark by incision, but is invariably the result of spontaneous exudation from knots or excrescences, the heat of the sun bringing it to the surface; and it is always obtained from old trees or those approaching decay. The proportion of trees from which any resin can be procured is not more than one in a hundred. Mr. Ellis (*Journ. of Pharm.*, vol. ii. p. 20) informs us that the mode of obtaining it is as follows: "Trees are selected upon whose bark the resin is incrustated, which are easily designated by a streak of a dark brown colour on one side of the tree, from near the top to the bottom. These are cut down, and the bark, upon which the resin has hardened, stripped off and thrown into a kettle containing water, with weights placed upon it to prevent its floating. By boiling the water, the resin is melted and rises to the surface, is skimmed off, and thrown into cold water. It is then put into a coarse linen bag and submitted to a second ebullition, treating it as in the former instance, which deprives it of many of its impurities."

The quantity from good-sized trees is from six to ten pounds, the average from four to five. The colour of it as it exudes is nearly white; it hardens immediately, and changes to yellow, brown, and sometimes nearly black. Hemlock resin is in masses, very brittle. It is a resin in combination with a small quantity of volatile oil. It is heavier than water, sp. gr. 1.034. The odour is peculiar, and unlike turpentine. To purify it, it should be melted and strained. From its adhesiveness and stimulating properties, it affords a plaster which is equal to that made with Burgundy Pitch, if not superior. It may be employed for the same purposes.]

5. *Pix liquida and Pix solida.*—Tar and Pitch.

1. *Pix Liquida.*—Vegetable Tar.

(Bitumen liquidum e ligno igne præparatum, *L.*—*Pix liquida, L. E. D.*)

HISTORY.—This is the *πίττα* of Theophrastus,¹ the *πίσσα ὑγρά* (*liquid pitch*), or *κῶρος* of Dioscorides,² and the *pix liquida* of Pliny.³

PREPARATION.—Two kinds of *tar* are known in commerce; namely, *coal tar* and *wood tar*. They are obtained in the destructive distillation—the first of coal, the second of wood.

Of wood tar there are two sorts: one procured in the northern parts of Europe and in America, from the waste of fir timber, and known in commerce as *Stockholm tar*, *Archangel tar*, *American tar*, &c.; the other obtained as a secondary product in the manufacture of pyroligneous acid and gunpowder charcoal. The former is the kind used in medicine. That which is procured from *Pinus sylvestris*, in the northern parts of Europe, is considered to be much superior to American tar.

The process now followed seems to be identical with that practised by the Macedonians, as described by Theophrastus. It is a kind of *distillatio per descensum* of

Fig. 282.

Preparation of Tar.

the roots and other woody parts of old pines. As now carried on in Bothnia, it is thus described by Dr. Clarke:¹ "The situation most favourable to the process is in a forest near to a marsh or bog, because the roots of the fir, from which tar is principally extracted, are always most productive in such places. A conical cavity is then made in the ground (generally in the side of a bank or sloping hill); and the roots of the fir, together with logs and billets of the same, being neatly trussed in a stack of the same conical shape, are let into this cavity. The whole is then covered with turf, to prevent the volatile parts from being dissipated, which, by means of a heavy wooden mallet and wooden stamper, worked separately by two men, is beaten down, and rendered as firm as possible about the wood. The stack of billets is then kindled, and a slow combustion of the fir takes place, without flame, as in working charcoal. During this combustion the tar exudes, and a cast-iron pan being at the bottom of the funnel, with a spout which projects through the side of the bank, barrels are placed beneath this spout to collect the fluid as it comes away. As fast as the barrels are filled, they are bunged, and ready for immediate exportation."

Wood-tar is also obtained as a secondary product, in the manufacture of acetic acid, by the dry distillation of wood.

¹ *Hist. Plant.* lib. ix. cap. ii. and iii.² *Hist. Nat.* lib. xxiv. cap. 24, ed. Valp.³ *Travels in Scandinavia*, part iii. p. 251; see also Duhamel, *Traité des Arbres*.⁴ Lib. i. cap. xciv.

COMMERCE.—Wood-tar is imported into this country chiefly from the northern parts of Europe (Russia, Sweden, Norway, Denmark, and North Germany)—partly from the United States of America. It usually comes in barrels, each holding 31½ gallons; twelve barrels constituting a *last*. Tar is also produced in this country.

PROPERTIES.—It is a dark brown, viscid, semi-liquid substance, which preserves during a long period its softness. It is soluble in alcohol, ether, and the oils both fixed and volatile. Submitted to distillation, it yields an aqueous acid liquor (*pyroligneous acid*), and a volatile oily matter (*oil of tar*); the residue in the still is *pitch*.

COMPOSITION.—Wood-tar is a very complex substance. It consists principally of *pyretine* (pyrogenous or empyreumatic resin), *pyroliene* (pyrogenous oil), *acetic acid*, and *water*.—Reichenbach has obtained from it *creasote*, *paraffin*, *cupion*, *picamar*, *kapnomor*, *pittacal*, and *cedriret*.—*Pyren* and *chrysen* have likewise been found in it.

The tar obtained from coniferous woods contains also *colophony* and *oil of turpentine*.

PHYSIOLOGICAL EFFECTS.—The effects of tar are analogous to those of turpentine, but modified by the presence of acetic acid and the pyrogenous products. Locally it acts as a stimulant; and when applied to chronic skin diseases and indolent ulcers, it frequently induces a salutary change in the action of the capillary and seerning vessels, evinced by the improved quality of the secretions, and the rapid healing of the sores. In such cases, it is termed detergent, digestive, or cicatrisant. Swallowed, it acts as a local irritant and stimulant, becomes absorbed, and stimulates the secreting organs, especially the kidneys, on which it operates as a diuretic. Slight¹ states that a sailor swallowed a considerable quantity of liquid tar, which caused vomiting, great lassitude, and violent pain in bowels and kidneys. The urine was red, and, as well as the other evacuations, had the odour of tar. The head and the pulse were unaffected. The *vapour of tar*, inhaled, acts as a stimulant and irritant to the bronchial membrane, the secretion of which it promotes.

USES.—Tar is rarely employed *internally*. It has, however, been administered in chronic bronchial affections, and in obstinate skin diseases.

The *inhalation of tar vapour* was recommended by Sir Alex. Crichton² in phthisis; but at best it proves only a palliative, and it frequently, perhaps generally, fails to act even thus, and in some cases occasions a temporary increase of cough and irritation.³ In chronic laryngeal and bronchial affections it has more chance of doing good.⁴ Sir A. Crichton's directions for using it in phthisis are as follows: The tar employed should be that used in the cordage of ships; to every pound of which half an ounce of carbonate of potash must be added, in order to neutralize the pyroligneous acid generally found mixed with the tar, the presence of which will necessarily excite coughing. The tar thus prepared is to be placed in a suitable vessel over a lamp, and to be kept slowly boiling in the chamber during the night as well as the day. The vessel, however, ought to be cleansed and replenished every twenty-four hours, otherwise the residuum may be burned and decomposed—a circumstance which will occasion increased cough and oppression on the chest.

Applied *externally*, tar is used in various forms of obstinate skin diseases, especially those which affect the scalp, lepra, &c.

ADMINISTRATION.—Internally, tar is administered either in substance, in the form of pills, made up with wheat flour, or of electuary, with sugar; or in the form of tar water. In substance, it may be taken to the extent of several drachms daily.

1. *AQUA PICIS LIQUIDÆ*; *Tar Water*.—(Tar Oij; Water Cong. j [*wine measure*]. Mix, stirring with a stick for a quarter of an hour; then, as soon as the tar subsides, strain the liquor, and keep it in well-stoppered jars.)—Tar water has the colour of

² *Practical Observations on the Treatment and Cure of several varieties of Pulmonary Consumption and on the Effects of the Vapour of boiling Tar in that Disease*, 1823.

³ Dr. Forbes, Translation of Laennec's *Treatise on Diseases of the Chest*, p. 365.

⁴ Trousseau and Pidoux, *Traité de Thérap.* t. i. p. 459.

Madeira wine, and a sharp empyreumatic taste. It reddens litmus, but does not effervesce on the addition of a solution of carbonate of potash, though its colour becomes deepened. With a solution of bicarbonate of potash a very slight effervescence takes place. By persulphate of iron, tar water is rendered very dark, or even blackish. The volatile oil contained in tar water is partly held in solution by acetic acid, which, as is well known, dissolves creasote. It consists of water holding in solution acetic acid, and pyrogenous oil and resin. Notwithstanding the high eulogies passed on it by Bishop Berkeley,¹ tar water is now rarely employed. It is occasionally administered in chronic catarrhal and nephritic complaints, to the extent of one or two pints daily. As a wash in chronic skin diseases, especially those affecting the scalps of children, I have frequently seen it used, and sometimes with apparent benefit.

2. **UNGUENTUM PICIS LIQUIDÆ**, L. E. D. [U. S.]; *Tar Ointment*.—(Tar, Mutton Suet, of each ℥j. Melt them together, and press through a linen cloth. The *Edinburgh College* takes of Tar ℥v, and Beeswax ℥ij; melt the wax with a gentle heat, add the tar, and stir the mixture briskly, while it concretes on cooling. The *Dublin College* orders of Tar Oss; Yellow Wax ℥iv.)—Its principal use is as an application to ringworm of the scalp and scalled head, in which it sometimes succeeds, but more frequently fails to cure. It is now and then applied to foul ulcers.

3. **OLEUM PICIS LIQUIDÆ**; *Oleum Pini rubrum*; *Oil of Tar*.—This is obtained by distillation from tar. It is a reddish, limpid fluid, having the odour of tar. It is a mixture of various volatile constituents of tar. By redistillation it may be rendered colourless, and then becomes very similar to oil of turpentine. It is occasionally used as an application to ringworm of the scalp and scalled head. Swallowed in a large dose it has proved fatal.²

2. *Pix nigra*.—*Black Pitch*.

(Pix, L.; Bitumen aridum e Pice liquida præparata; Pix arida.)

HISTORY.—This is the *πίσσα ξηρά* (*dry pitch*) of Dioscorides,³ which, he says, some call *παλίμπισσα* (*pitch re-boiled*).

PREPARATION.—The residuum in the still after the distillation of wood-tar is *pitch* (*pix nigra*, L.)

PROPERTIES.—At ordinary temperatures it is a black solid, having a brilliant fracture. It softens at 99° F. and melts in boiling water. It dissolves in alcohol, and in solutions of the alkalies and of the alkaline carbonates.

COMPOSITION.—Pitch is composed of *pyrogenous resin* and *colophony*.

PHYSIOLOGICAL EFFECTS.—Made into pills with flour or any farinaceous substance, pitch may be taken to a great extent, not only without injury, but with advantage to the general health. It affords one of the most effectual means of controlling the languid circulation, and the inert and arid condition of the skin.⁴ As a local remedy it possesses great adhesiveness, and when applied to wounds and ulcers acts as a stimulant and digestive.

USES.—Bateman⁵ speaks favourably of the internal use of pitch in *ichthyosis*. It has been employed also in other obstinate skin diseases. But the principal use of pitch is in the form of ointment, as an application to cutaneous affections of the scalp.

ADMINISTRATION.—Dose from grs. x to ℥j, made into pills with flour. The unpleasant pitchy flavour of the pills is materially diminished by keeping them for some time.

UNGUENTUM PICIS, L.; *Unguentum Picis nigri*; *Unguentum Basilicum nigrum* vel *Tetrapharmacum*.—(Black Pitch, Wax, Resin, of each ℥xj; Olive Oil Oj.

⁵ *Op. cit.*

Melt them together, and press through a linen cloth.)—Stimulant and digestive; used in the obstinate cutaneous eruptions of the scalp.¹

Sub-order II. CUPRESSEÆ.

Ovules erect; pollen spheroidal.

105. JUNIPERUS COMMUNIS, Linn.—COMMON JUNIPER.

Sex. Syst. Diœcia, Monadelphia.

(Fructus; et Oleum e fructu destillatum, L.—Cacumina; Fructus; Olcum, E.—Cacumina; Baccæ, D.)
[Juniperus. The fruit of Juniperus Communis, U. S.]

HISTORY.—The tree which in our translation of the Bible² is called the *juniper*, is supposed to have been a leguminous plant, either broom or furse (*genista* vel *ulex*).

Juniperus communis is a native of Greece, and must, therefore, have been known to the ancient Greeks. Sibthorp³ thinks that it may perhaps be the ἀρκευθος μύρα of Dioscorides,⁴ a name which Fraas⁵ considers to have been applied to *Juniperus oxycedrus*. The last-mentioned authority is of opinion that the κέδρος μύρα of Dioscorides⁶ is our juniper. The fruit mentioned in the Hippocratic writings under the name of ἀρκευθίς, and which was used in some disorders of females, was the produce of a species of *Juniperus*; perhaps of the *J. phœnicia*, which is very common in Greece and the islands of the Archipelago, and whose fruit is yellowish, but has the size, form, and powers of that of the common juniper.

BOTANY. Gen. Char.—*Diœcious*, rarely *monœcious*. **MALES:** *Catkins* ovate; the *scales* verticillate, peltato-pedicellate. *Anthers* 4 to 8, unilocular. **FEMALES:** *Catkins* globose; the 3 concave scales united. *Stigma* gaping. *Galbulus* composed of the united and fleshy scales, and containing 3 triquetrous osseous *seeds*.

Sp. Char.—*Leaves* 3 in each whorl, spreading, linear-subulate, keeled, mucronate, longer than the *galbulus*.

Fig. 283.

Female flower and fruit of *Juniperus communis*.

- a. Female amentum (magnified).
b. Ditto at a later stage of evolution (magnified).
c. Two ovaries; the third having been removed to expose the ovules.
d. Fruit approaching maturity.
e. Ripe galbulus, seen from the vertex.
f. Ditto, seen from the base.

A bushy *shrub*. *Leaves* evergreen, numerous, with a broad, flat, shallow channel above, the keel beneath with a slender furrow, pungent, glaucous on the upper side, dark green beneath. *Flowers* axillary, sessile, small; the *males* discharging a copious cloud of yellow pollen: *females* green, on scaly stalks. *Fruit* commonly called a *berry*, but is in reality that kind of cone called by botanists a *galbulus*, which has fleshy coalescent carpella, whose heads are much enlarged. It requires two seasons to arrive at maturity. The *galbulus* is black tinged with blue, and is scarcely more than half the length of the leaves.

Loudon⁷ mentions no less than seven varieties; but some of these are probably distinct species.

Juniperus nana (Smith), Dwarf Alpine Juniper, has a procumbent stem; imbricate, incurved, linear-lanceolate leaves; and fruit nearly as long as the leaves.—Indigenous On mountains.

¹ Vide *Unguentum Picis liquidæ*.

² *Prod. Fl. Græcæ*.

³ *Synopsis Plant. Fl. Classicæ*, p. 259, 1845.

⁴ *Arboretum*, vol. iv. p. 2489.

⁵ *Job*, xxx. 4; *1 Kings*, xix. 4.

⁶ *Lib. i. cap. 103*.

⁷ *Ibid.* 105.

Hab.—North of Europe. Indigenous, growing on hills and healthy downs, especially where the soil is chalky. It flowers in May.

DESCRIPTION.—In this country the *fruit* and *tops*, and on the continent, the *wood*, are officinal.

Juniper berries (*baccæ juniperi*), as the dried fruit of the shops is commonly termed, are about the size of a pea, of a blackish-purple colour, covered by a glaucous bloom. They are marked superiorly with a triradiate groove, indicating the adhesion of the succulent carpella; inferiorly with the bracteal scales, which assume a stellate form (see Fig. 283, *c* and *f*). They contain three seeds. Their taste is sweetish, with a terebinthinate flavour; their odour is agreeable and balsamic.

Juniper tops (*cacumina seu summitates juniperi*) have a bitter terebinthinate flavour and a balsamic odour.

Juniper wood (*lignum juniperi*) is obtained either from the stem or root; it evolves a balsamic odour in burning, and, by distillation with water, yields volatile oil. On old stems there is sometimes found a resinous substance (*resina juniperi*; *sandaraca germanica*).

SANDARACH OF JUNIPER RESIN.—The resin called *sandarach* (*sandaraca*), or *gum juniper* (*gummi juniperi*), is imported from Mogadore. It is the produce of *Callitris quadrivalvis*, Vent. (*Thuja articulata*, Desf.). Though sold by chemists and apothecaries, it is not employed in medicine. It is used in the manufacture of varnishes. Its powder is *pounce*.

COMMERCE.—Juniper berries are imported in bags and barrels from Rotterdam, Hamburgh, Leghorn, Trieste, and other European ports. In 1838, duty was paid on 5896 cwts.

COMPOSITION.—Juniper berries were analyzed in 1822 by Trommsdorff,¹ and in 1831 by Nicolet.² Trommsdorff obtained *volatile oil* 1.0, *wax* 4.0, *resin* 10.0, a *peculiar species of sugar with acetate and malate of lime* 33.8, *gum with salts of potash and lime* 7.0, *lignin* 35.0, *water* 12.9 (=103.7, *excess* 3.7).

1. **OIL OF JUNIPER** (see below).

2. **RESIN.**—Is green, according to Trommsdorff. Nicolet obtained it in the crystallized state, and found it to consist of C⁵H²O⁴.

3. **WAX.**—Is brittle. Consists, according to Nicolet, of C¹³H²⁴O⁴.

4. **SUGAR**—Is crystallizable, and analogous to grape sugar, according to Trommsdorff. But Nicolet describes it as being like molasses.

PHYSIOLOGICAL EFFECTS.—Juniper berries and tops are analogous in their operation to the terebinthinate substances. Three ounces of the berries act on the larger herbivorous animals as a diuretic.³ On man, also, these fruits operate on the urinary organs, promoting the secretion of urine, to which they communicate a violet odour.⁴ In large doses they occasion irritation of the bladder and heat in the urinary passages. Piso⁵ says their continued use causes bloody urine. They promote sweat, relieve flatulency, and provoke the catamenia. Their activity is principally dependent on the volatile oil which they contain, and which, according to Mr. Alexander's experiments,⁶ is, in doses of four drops, the most powerful of all the diuretics.⁷

USES.—Juniper berries or oil are but little used in medicine. They may be employed, either alone or as adjuncts to other diuretic medicines, in *dropsical disorders* indicating the employment of renal stimuli. Van Swieten⁸ speaks favourably of their use in mild cases of ascites and anasarca. In some affections of the *urino-genital apparatus* juniper may be employed with advantage. Thus in mucous discharges (as gonorrhœa, gleet, leucorrhœa, and cystirrhœa) it may be used under the same regulations that govern the employment of copaiba and the terebinthimates. Hecker⁹ praised it in the first stage of gonorrhœa.

Juniper has been advised in some other diseases, but I do not think it necessary to enumerate them.¹⁰

⁹ *Experimental Essays*, p. 149, 1763.

¹⁰ *Commentaries*, English edit. 12mo. vol. xii. p. 431.

ADMINISTRATION.—The dose of the *berries* is one or two drachms, triturated with sugar. The *infusion* (prepared with an ounce of the berries and a pint of boiling water) is a more convenient mode of exhibition; the dose is ℥̄iv every four hours.

1. **OLEUM JUNIPERI**, E. D. [U. S.]; *Oleum Juniperi* (*Anglicum*), L.; *Oil of Juniper*; *English Oil of Juniper*.—Is obtained by submitting the fruit, tops, or wood, to distillation with water. The full-grown green fruit yields more than the ripe fruit, for, in the act of ripening, a portion of the oil becomes converted into resin. It is limpid, transparent, nearly colourless, and lighter than water, and causes the left-handed rotation of polarized light—in this respect agreeing with French oil of turpentine. It has the odour of the fruit and an aromatic balsamic taste. It dissolves with difficulty in alcohol. According to Blanchet, it consists of two isomeric oils, carburets of hydrogen, C²⁰H¹⁶: one colourless, and more volatile: a second coloured, and less volatile. Both, when agitated with a solution of salt, form crystalline hydrates. The more volatile oil almost entirely constitutes the oil obtained from the ripe fruit. It is soluble in alcohol and in hydrochloric acid, with which it forms a liquid artificial camphor. Its density is 0.839.

The oil is, perhaps, the best form for exhibiting juniper. The dose is two to six drops, either in the form of pill or diffused through water by the aid of sugar and mueilage.

OLEUM EMPYREUMATICUM JUNIPERI.—By the dry distillation of the wood of *Juniperus Oxycedrus* there is obtained, in France, a tarry oil called *huile de cade* (*oleum cadinum*). It is a brownish, inflammable liquid, having a strong empyreumatic and resinous odour, and an acrid caustic taste. It is employed in veterinary medicine; to cure ulcers in horses, and, formerly, to cure the itch in sheep. Oil of tar, which is often substituted for it, is considered to be inferior. It has also been used in the human subject, both externally and internally; in obstinate skin diseases, worms, toothache, &c. Dose, a few drops.

2. **SPIRITUS JUNIPERI COMPOSITUS**, L. E.; *Compound Spirit of Juniper*.—(Oil of Juniper ℥̄iiss; Oil of Caraway, Oil of Fennel, of each ℥̄xij [℥̄x, U. S.]; Proof Spirit, Cong. j. Dissolve, L.—Juniper Berries, bruised, ℥̄ij; Fennel bruised, and Caraway bruised, of each ℥̄iiss; Proof Spirit Oviij; Water Oij. Macerate the fruits in the spirit for two days, add the water, and distil off seven pints, E.)—This preparation, when sweetened, may be regarded as an officinal substitute for *genuine Hollands* and *English gin*, both of which compounds are flavoured with juniper. It is used as an adjunct to diuretic mixtures. The dose is ℥̄ij to ℥̄iv.

106. JUNIPERUS SABINA, Linn.—COMMON SAVIN.

Sex. Syst. Diœcia, Monadelphia.

(Cacumen recens et exsiccatum. Oleum e cacumine destillatum, L.—Tops, E.)
[Sabina, U. S.]

HISTORY.—This is the βράβυ of Dioscorides,¹ the *sabina* of Pliny.² Each of these writers notices both the cypress-leaved and the tamarisk-leaved varieties of savin.

BOTANY. Gen. Char.—Vide *Juniperus communis*.

Sp. Char.—*Leaves* ovate, convex, densely imbricated, erect, decurrent, opposite; the oppositions pyxidate (*Bot. Gall.*).

A small bushy shrub. Branches closely invested by the very small glandular leaves. Gallulus round, purple, somewhat smaller than that of *Juniperus communis*.

London³ mentions five varieties. Of these the most interesting are the two following:—
α. *J. S. cupressifolia*, Aiton.—The Cypress-leaved Savin. La Sabine mâle. Leaves acute more spreading, three lines long.

β *J. S. tamariscifolia*, Aiton.—The Tamarisk-leaved or berry-bearing Savin. La Sabine femelle. Leaves shorter, almost appressed and obtuse.

¹ Lib. i. cap. 104.

² *Arboretum*, vol. iv. p. 2499.

³ *Hist. Nat.* lib. xxiv. cap. 61, ed. Vslp.

Another variety, *J. S. foliis variegatis*, has variegated leaves. A fourth, *J. S. prostrata*, is a low trailing plant. The fifth, *J. S. alpina*, is procumbent, and more slender than the fourth.

Hab.—Midland and southern parts of Europe, Asiatic Russia. Cultivated in gardens in this country. Flowers in April.

JUNIPERUS VIRGINIANA, Linn., the *Red Cedar* (the wood of which is used for black-lead pencils) is used in the United States as a substitute for savin.

DESCRIPTION.—The officinal parts of the plant are the *tops* (*cacumina, summitates*), which consist of the young branches with their attached leaves. They have, in the fresh state (*cacumina recentia*), a strong, peculiar, heavy odour, especially when rubbed; and a nauseous, resinous, bitter taste. The dried tops (*cacumina exciccata*) are yellowish green, and less odorous than the fresh ones.

COMPOSITION.—Some experiments on the composition of savin were made by Berlisky.¹ In 1837, an analysis of this plant was made by a young chemist of the name of Gardes.² The constituents are *volatile oil, resin, gallic acid, chlorophylle, extractive, lignin, and calcareous salts.*

OIL OF SAVIN (see p. 311).

CHEMICAL CHARACTERISTICS.—An aqueous infusion of savin is yellowish, has the odour and bitter taste of the herb, and forms a soluble green compound (*gallate? of iron*) on the addition of sesquichloride of iron, but is unchanged by a solution of gelatin. Oxalate of ammonia causes, in the infusion, a white precipitate (*oxalate of lime*). Alcohol acquires a green colour when digested with the tops: on the addition of water to the alcoholic tincture some *resin* is separated. By distillation with water, both the fresh and dried tops (but especially the first) yield *volatile oil*.

DETECTION.—Savin is sometimes employed for criminal purposes, and, therefore, occasionally becomes the subject of medico-legal inquiries. Powdered savin in the stomach and bowels might, on account of its green colour, be mistaken for bile; but, when mixed with distilled water, it entirely subsides; and, provided no bile be intermixed, the supernatant liquor will be devoid of a green colour. The powder, when dry, may be detected to be that of savin by the peculiar odour of this herb. The odorous principle (volatile oil) might, if the quantity of powder be sufficient, be separated by submitting this to distillation with water. Moreover, savin powder yields a green colour to alcohol, and its aqueous infusion strikes a green colour with the tincture of the sesquichloride of iron. If the powder be coarse, the microscope may give us important aid in detecting savin. A careful examination of the woody fibres will detect their circular pores (Fig. 284, A B), characteristic of the Gymnosperms (see *ante*, p. 282); and by the shape of the apex of the leaves (when these can be obtained), savin (Fig. 284, C D) may be detected from another poisonous gymnospermous plant (Fig. 284, E), namely, the Yew (*Taxus baccata*).³

C D. Magnified extremity of the leaf of Savin, showing the subulate linear leaves.

E. Magnified extremity of the leaf of Yew (*Taxus baccata*), showing the linear acute leaves.

¹ Trommsdorff's *Journ.* viii. 1, 94.

² *Journ. de Chim. Méd.* t. iii. p. 331, 2de Sér.

³ See an interesting report of a case of poisoning by savin, in which the above characters were successfully made use of to detect the poison, by Dr. A. Taylor and Mr. Charles Johnson, in the *Lond. Med. Gaz.* for Aug. 8, 1815, p. 616.

PHYSIOLOGICAL EFFECTS. *a. On Animals.*—Savin acts on animals as an acrid poison. Orfila¹ applied two drachms of the powder to an incised wound in the leg of a dog; inflammation and infiltration of the limb took place, and death occurred in about thirty-six hours. Four drachms introduced into the stomach of a dog, and the œsophagus tied, caused death in thirteen hours; the stomach was bright red, and the rectum a little inflamed. Orfila infers that its effects depend principally on its absorption and its action on the nervous system, the rectum, and the stomach. A drachm of *oil of savin* was given by Hillefield² to a cat. It caused a flow of saliva, anxiety, frequent discharge of urine, dulness, trembling, and, in an hour and a quarter, bloody urine. The animal having been strangled, the bladder was found contracted, with some coagulated blood contained in its cavity.

β. On Man.—Oil of savin, the active principle of the herb, is a powerful local irritant. When applied to the skin, it acts as a rubefacient and vesicant. On wounds and ulcers its operation is that of an acrid (not chemical) caustic. Swallowed in large doses, it occasions vomiting, purging, and other symptoms of gastro-intestinal inflammation. In its operation on the system generally, it is powerfully stimulant. "Savin," says Sundelin,³ "operates not merely as irritants generally do, as a stimulant to the arterial system, but it also eminently heightens the vitality of the venous system, the circulation in which it quickens. It next powerfully stimulates the absorbing vessels and glands, the serous, the fibrous, and the mucous membranes, and the skin. It operates as a specific excitant and irritant on the kidneys, and yet more obviously on the uterus. The increased secretion of bile and the augmented volume of the liver, both of which conditions have sometimes been observed after the copious and long-continued use of savin, appear to be connected with its action on the venous system." Mohrenheim⁴ mentions the case of a woman, 30 years of age, who swallowed an infusion of savin to occasion abortion. Violent and incessant vomiting was induced. After some days she experienced excruciating pains, which were followed by abortion, dreadful hemorrhage from the uterus, and death. On examination, the gall-bladder was found ruptured, the bile effused in the abdomen, and the intestines inflamed. The popular notion of its tendency to cause abortion leads, on many occasions, to the improper use of savin; and the above is not a solitary instance of the fatal consequences thereof. A fatal case of its use as an emmenagogue is recorded by Dr. Dewees.⁵ That it may frequently fail to provoke premature labour is shown by the case, related by Fodéré,⁶ of a woman who, in order to produce abortion, took every morning, for twenty days, one hundred drops of this oil, and yet went her full time and brought forth a living child. It ought to be well known that, in those cases in which it may succeed in causing miscarriage, it can only do so at the risk of the woman's life. Vogt⁷ says that it has a tendency to induce an apoplectic state in the fœtus. The emmenagogue power of savin is fully established. Perhaps the observations of Home⁸ are the most satisfactory of any on this subject, confirmed as they are by the reports of many other accurate observers.

USES.—Savin is not much used internally; but, in cases of amenorrhœa and chlorosis depending on or accompanied by a torpid condition or deficient action of the uterine vessels, it may be given as a powerful uterine stimulant. In such cases it proves a most efficient remedy. According to my own observation, it is the most certain and powerful emmenagogue of the whole materia medica. My experience of it, therefore, confirms the statements of Home.⁹ Though I have employed it in numerous cases, I never saw any ill effects result from its administration. Of course its use is contraindicated where irritation of the uterus, or indeed of any of the pelvic viscera, exists.

⁴ *Murray, App. Med.* vol. i. p. 59.

⁶ *Méd. Lég.*

⁸ *Clinical Experiments*, p. 419.

⁹ *Ibid.*

In chronic rheumatism, with a languid circulation in the extreme vessels, Chapman¹ speaks in very high terms of it. It has been used as an anthelmintic.

As a topical agent, savin is frequently employed, mostly in the form of the cerate, to make *perpetual blisters*. Equal parts of savin and verdigris, in powder, form one of the most efficacious applications for the removal of venereal warts. The powder, an infusion, or the expressed juice of the plant, is occasionally applied to warts, to old and indolent ulcers, and in cases of psora and tinea.

ADMINISTRATION.—By drying, savin loses part of its volatile oil, and hence the powder is not the best preparation of it. It is, however, sometimes given in doses of from five to fifteen grains. A *decoction* and *extract* are also objectionable preparations, on account of the heat employed in making them. An *infusion* may be prepared by digesting ℥j of the fresh herb in ℥viii of boiling water: the dose is one or two tablespoonfuls. The *oil* is by far the most convenient and certain preparation of savin, and is the only one which I employ. A *conserve* of the fresh leaves is sometimes used.

1. OLEUM SABINÆ, B. D. [U. S.]; *Oil of Savin*.—This is obtained by submitting the fresh tops to distillation with water. It is a limpid, almost colourless liquid, having the unpleasant odour of the plant, and a bitter acrid taste. Its sp. gr. is 0.915. Its composition is analogous to that of oil of turpentine, being C²⁰H¹⁶. It agrees with English oil of turpentine in its power of effecting the right-handed rotation of plane polarized light. Winckler² states that he dissolved one ounce of savin oil in the same quantity of concentrated sulphuric acid, and then distilled it from milk of lime (to remove the sulphurous acid), and obtained two drachms of an oil which was undistinguished from the volatile oil of thyme. The dose of oil of savin, as an emmenagogue, is from two to six drops, diffused in a mucilaginous or oleaginous mixture.

2. UNGUENTUM SABINÆ, L. D.; *Savin Ointment*, E. [U. S.]; *Ceratum Sabinæ*.—(Fresh Savin, bruised, ℥ss; White Wax ℥iij; Lard ℥j. Mix the savin in the lard and wax melted together, then press through a linen cloth. The *Edinburgh College* orders of Fresh Savin *two parts*; Beeswax *one part*; Axunge *four parts*. Melt the wax and axunge together, add the savin and boil them together till the leaves are friable; then strain. The *Dublin College* orders Savin Tops, dried and in fine powder, ℥j; Ointment of White Wax ℥vij. Mix the powder intimately with the ointment by trituration. [The *U. S. Pharm.* directs Savin, in powder, ℥ij; Resin Cerate ℥j. Mix the savin with the cerate previously melted.]—The boiling is considered objectionable on account of the loss of a portion of the oil. The colour of this cerate should be fine green, and its odour that of the plant; the former property depends on chlorophylle, and the latter on the oil of savin. Savin cerate is used as a dressing to blistered surfaces, to produce what is termed a *perpetual blister*. It is preferred to the ceratum cantharidis as being less acrid, and not liable to cause strangury. It is sometimes applied to seton tapes, to increase the discharge from stragons.

ANTIDOTES.—In a case of poisoning by savin herb or its oil, the first indication is to remove the poison from the stomach and bowels. Opiates and demulcent drinks should then be given. The warm bath may be advantageously employed. Bloodletting should be resorted to if the inflammatory symptoms indicate, and the condition of the system permit it.

ORDER XXIII. TAXACEÆ, Lindl.—TAXADS.

TAXINÆ, Endl.

CHARACTERS.—Naked seeded exogens, with repeatedly branched, continuous *stems*, simple *leaves* often fork-veined, solitary female *flowers*, 2-celled *anthers* opening longitudinally, membrane

¹ *Elem. of Therap.*

² *Buchner's Repertorium*, 2ter Reihe, Bd. xlii. S. 330, 1846.

next the nucleus of the *ovule* inclosed, *seed* usually supported or surrounded by a succulent imperfect cap-shaped pericarp, *embryo* straightened, dicotyledonous, and *albumen* fleshy.

PROPERTIES.—The *Taxacæ* agree with the *Pinacæ* in the resinous quality of their juices, but abound more in bitter astringent, and some of them in narcotico-acrid principles.

107. *Taxus baccata*, Linn.—Common Yew.

Sex. Syst. Diœcia, Monadelphia.

(*Folia et semina*.)

Σμῖδαξ, by some called Σύμαλος, by the Romans termed τῆξος, Dioscorides, lib. iv. cap. 80.—*Taxus*, Pliny, lib. xvi. cap. 20 et 33; and lib. xxiv. cap. 72.—A tree often attaining a considerable bulk. Leaves scattered, nearly sessile, 2-ranked, crowded, linear, acute, entire, very slightly revolute, about 1 inch long, dark green, smooth and shining above, paler with a prominent midrib beneath, terminating in a small harmless point. Flowers axillary sessile. Fruit drooping, consisting of a succulent, sweet, internally glutinous, scarlet cup, inclosing an oval, brown, nut-form seed, unconnected with the fleshy part.—In 1828, Peretti¹ analyzed yew (the *leaves*?), and obtained a bitter volatile oil, a bitter non-crystallizable substance, a yellow colouring matter, resin, tannin, gallic acid, chlorophylle, mucilage, sugar, and malate of lime. In 1818, Chevallier and Lassaigne² examined the pulpy cup of the *fruit*, and found in it a non-crystallizable fermentable sugar, gum, malic and phosphoric acids, and a carmine-red fatty matter. In 1843, Martini³ analyzed the seeds, and obtained from them a volatile oil having a terebinthinate odour, fixed oil, a green very bitter resin, sugar, albumen (in small quantity), sulphate of lime, and vegetable fibre.

The poisonous properties of yew were known to the ancient Greeks and Romans, and have been fully established by modern experience, although some few writers have expressed doubts concerning them. Percival⁴ states that three children were poisoned by the fresh leaves. Dr. Mollan⁵ has mentioned the case of a lunatic who died in 14 hours after taking yew-leaves: the symptoms were giddiness, sudden prostration of strength, vomiting, coldness of the surface, spasms, and irregular action of the heart. Mr. Hurt⁶ has reported an interesting case of a child, three years and a half old, who died in less than four hours after eating the fruit: the symptoms were vomiting, convulsions, purple lips, and dilated pupil. Considered both in a toxicological and therapeutical point of view, the yew appears to hold an intermediate position between savin and foxglove. To savin it is allied by its botanical affinities and chemical composition, but also by its acrid, evacuant, diuretic, and emmenagogue properties. But, on the other hand, its relation to the neurotics, especially to sedatives (see vol. i., p. 258), is marked by the giddiness, irregular and depressed action of the heart, convulsions, and insensibility which it produces. It is said that, when used for medicinal purposes, it is unlike digitalis, in not being apt to accumulate in the system. As a poison it belongs to the class of acro-narcotics; as a medicine it is used as a sedative, antispasmodic, emmenagogue, lithic, and resolvent. As a sedative it has been proposed by Rempinelli and Martin to be used as a substitute for, and under the same indications as, digitalis. As an emmenagogue it has been given in cases similar to those for which savin is sometimes administered. Dr. A. Taylor⁷ says that "infusion of yew-leaves, which is popularly called yew-tree tea, is sometimes used for the purpose of procuring abortion by ignorant midwives." As a lithic it has been employed in calculous complaints; as an antispasmodic in epilepsy and convulsions; as a resolvent in hepatic and gouty complaints. In pulmonary and vesical catarrh it has likewise been used. The *powder* of the leaves or seeds is given in doses of from half a grain to two or three grains. The *extract of the leaves* (*extractum taxi*, Cod. Hamb.) prepared by evaporating the expressed juice of the leaves, is administered in doses of one or two grains, and gradually increased. The *alcoholic and ethereal extract* of the seeds is employed in doses of from $\frac{1}{8}$ th or $\frac{1}{3}$ d of a grain. In cases of poisoning by yew, the first indication is to expel the poison from the stomach by the means already pointed out (see vol. i. p. 201). The sedative and narcotic effects are to be counteracted by stimulants such as ammonia (see the treatment for poisoning by foxglove).

Sub-class II. *Angiospermæ*.—*Angiosperms*.

EXOGENS, Lindl.

CHARACTERS—*Ovules* inclosed in an ovary, and fertilized by the application of the pollen to the stigma.

⁷ *On Poisons*, p. 790.

In accordance with the classification followed by De Candolle, the natural orders of this subclass will be arranged in the four following subdivisions: 1st, *Monochlamydeæ*; 2dly, *Corollifloræ*; 3dly, *Calycifloræ*; and 4thly, *Thalamifloræ*.

SUBDIVISION I. MONOCHLAMYDEÆ, *De Cand.*APETALÆ, *Endlicher.*

Flowers frequently unisexual. Perianth absent, rudimentary or simple, calycine or coloured, free or connate with the ovary.

ORDER XXIV. LIQUIDAMBARACEÆ, *Richard.*—
LIQUIDAMBARS.BALSAMIFLORÆ, *Blume, Endl.*—ALTINGIACEÆ et olim BALSAMACEÆ, *Lindley.*

CHARACTERS.—Tall trees, with amentaceous unisexual flowers; a 2 celled, 2-lobed, many-seeded capsule; and winged seeds, with the embryo inverted in fleshy albumen.

PROPERTIES.—Balsamic, fragrant.

108. Liquidambar, *Linn.*ALTINGIA, *Noronha.*

As this is the only genus of the order, its characters are necessarily those of the latter. It consists of a very small number of species, of which none probably are officinal. But, as their balsamic products have been confounded with storax and balsam of Peru (two officinal substances), a short notice of them is requisite.

1. *L. STYRACIFLUA*, *Linn*; *Sweet Gum*; *White Gum*.—A native of the United States and Mexico, attaining, in the southern districts, an immense size. In Louisiana and Mexico there is obtained, by making incisions into the stem, a fluid balsamic juice called *liquidambar* or *copalm balsam*. In this fluid state it constitutes the *liquid liquidambar*, or *oil of liquidambar* of Guibourt. It is transparent, amber-yellow, has the consistence of a thick oil, a balsamic odour, and an aromatic, acrid, bitter taste. By time it concretes, and becomes darker coloured. The soft solid called by Guibourt *soft* or *white liquidambar*, is perhaps a mixture of the opaque deposit of the fluid balsam, and of the latter rendered concrete by keeping. It is a soft, almost opaque solid, very similar in appearance to concrete turpentine. Its odour is similar to, though weaker than, the liquid balsam. Its taste is balsamic and sweetish. Bonastre¹ analyzed a very fluid sample, recently received from America, and found it to consist of—*volatile oil*, 7.0, *semi-concrete matter*, 11.1; *benzoic acid*, 1.0; *crystalline matter soluble in water and alcohol*, 5.3; *yellow colouring matter*, 2.05; *oleo-resin*, 49.0; *styracin*, 24.0; loss, 0.55. The volatile oil consists, according to Henry, of C¹⁰H⁷. Styracin is a fusible, crystalline substance, soluble in boiling alcohol, and composed, according to Henry, of C¹¹H⁵O². The proportion of benzoic [cinamic?] acid is increased by time. Mr. Hodgson² obtained from a sample which he examined 4.2 per cent.

Liquidambar has been confounded with both *white balsam of Peru* and *liquid storax*. The liquidambar which I have received from M. Guibourt is quite different from a genuine sample of the *white balsam of Peru* received by me from Guatemala, and it is equally different from the liquid storax of the shops. And Dr. Wood³ observes that some of the genuine juice of *liquidambar styraciflua* brought from New Orleans, which he examined, had an odour entirely distinct from that of liquid storax.

A thick, dark-coloured, opaque, impure substance is obtained from the young branches of this species by boiling them in water and skimming off the fluid balsam which rises to the surface. This also has been confounded with liquid storax, but none of it comes to this country.

The effects and uses of liquidambar are similar to those of storax and other balsamic substances. The dose of it is from ten to twenty grains.

2. *L. ALTINGIA*, *Blume*; *Altingia excelsa*, *Noronha*.—A native of Java, where it is called *Ras sama-lu* (*Rasamalla* or *Rosa-mallas*, *Auct.*) It yields a fragrant balsam, which by some writers has been regarded as the liquid storax of the shops. But the latter substance comes to England by way of Trieste, and, according to Landerer,⁴ is the produce of *Styrax officinale*, and as such I shall describe it hereafter (see *Styrax officinale*).⁵ Petiver says that the *Rosa-mallas* grows in Cobross, an island at the upper end of the Red Sea, near Cadess, which is three days'

¹ *Journ. de Pharm.* t. xvii. p. 338, 1831.² *Journal of the Philadelphia College of Pharmacy*, vi. 190.³ *Pharmaceutisches Central-Blatt für 1840*, p. 11.⁴ *United States Dispensatory*.⁵ *Phil. Trans.* vol. xxvi. p. 44.

journey from Suez. Its bark is removed annually, and boiled in salt water until it comes to a consistence like birdlime; it is then separated, put in barrels (each holding 420 lbs.), and sent to Mocha, by way of Judda. The Arabs and Turks call it *Cotter Mija*.

Dr. Marquart¹ analyzed some of the genuine resin of *L. Altingia*, and, by distillation with carbonate of soda, obtained a volatile oil resembling styrol, and a substance resembling styracin, but which had a different composition.

3. *L. ORIENTALE*, Miller; *L. imberbe*, Aiton; *Platanus orientalis*, Pocock.—This tree grows in Cyprus, where it is called *Xylon Effendi* (the wood of our Lord). By incisions made in the bark, it yields a kind of white turpentine, and a very fragrant oil. Dr. Lindley thinks it is probable that the liquid storax of the shops is collected from this tree; but I do not agree with him in this opinion.

ORDER XXV. SALICACEÆ, Lindl.—WILLOWWORTS.

SALICINÆ, Richard.

CHARACTERS.—*Flowers* unisexual, amentaceous. *Stamens* distinct or monadelphous; *anthers* 2-celled. *Ovary* superior, 1-celled; *ovules* numerous, erect, at the base of the cell, or adhering to the lower part of the sides; *style* 1 or 0, *stigmas* 2 or 4. *Fruit* coriaceous, 1-celled, 2-valved, many-seeded. *Seeds* either adhering to the lower part of the axis of each valve, or to the base of the cell; comose; *albumen* 0; *embryo* erect; *radicle* inferior.—*Trees or shrubs*. *Leaves* alternate, simple, with deliquescent primary veins, and frequently with glands; *stipules* deciduous or persistent (Lindley).

PROPERTIES.—The barks of the species of this order are astringent and tonic; the astringency being due to tannic acid, the tonic property to salicine or some other bitter principle. An oleo-resinous or balsamic substance, of a stimulant nature, is secreted by the buds of some of the species.

109. SALIX, Linn.—WILLOW.

Sex. Syst. Diœcia, Diandria.

(Cortex e speciebus salicis diversis; cortex salicis, *offic.*)

HISTORY.—Dioscorides² speaks of the astringent qualities of the *ιτέα*, or willow (*Salix alba*?), which was employed in medicine by the ancients. For a long series of years it fell into disuse, but was again brought into notice in 1763, by the Rev. Mr. Stone,³ who published a paper on the efficacy of the bark of *Salix alba*, as a remedy for agues. The broad-leaved willow bark (*Salix Caprea*) was subsequently introduced into practice by Mr. James,⁴ whose observations on its efficacy were afterwards confirmed by Mr. White⁵ and Mr. G. Wilkinson.⁶

BOTANY. Gen. Char.—*Flowers* diœcious, or rarely monœcious, amentaceous; *scales* imbricated; a *gland* surrounding the stamens or ovary. **MALES:** *Stamens* 2 to 5, usually 2, sometimes the 2 united into 1, and then the anther is 4-celled. **FEMALES:** *Seeds* comose; the *radicle* inferior (*Bot. Gall.*).

Species.—Sir J. E. Smith⁷ mentions sixty-four indigenous species of *Salix*; but pharmacological and botanical writers are not agreed as to which species possesses the most medicinal power. The best practical rule to follow is this: Select those whose barks possess great bitterness, combined with astringency. The following are those which are in the greatest repute:—

1. *SALIX RUSSELLIANA*, Smith; the *Bedford Willow*.—*Leaves* lanceolate, tapering at each end, serrated throughout, very smooth. *Footstalks* glandular or leafy. *Germen* tapering, stalked, longer than the scales. *Style* as long as the stigmas (Smith).—A *tree*. In marshy woods, wet meadows, &c., in various parts of Britain. Flowers in April and May. Its bark abounds in tannic acid. On account of its astringency, Sir J. E. Smith regards it as the most valuable officinal

¹ *Jahrb. für prakt. Pharmacie*, Bd. v. p. 486 (quoted by Dierbach, in the *Ergänzungsheft* to Geiger's *Handb. d. Pharm.* 2te Aufl. 1843).

⁶ *Experiments and Observ. on the Cortex Salicis Latifoliae*, 8vo Newcastle-upon-Tyne [1803].

⁷ *Engl. Flora*, iv.

species; and he observes, that if it has occasionally disappointed medical practitioners, they probably chanced in such cases to give the *S. fragilis*.

2. *SALIX ALBA*, Linn.; *the Common White Willow*.—Leaves elliptic-lanceolate, pointed, serrated, silky on both sides; the lowest serratures glandular. *Stamens* hairy. *Germen* smooth, almost sessile. *Stigmas* deeply cloven. *Scales* rounded (Smith).—A tall tree. River-sides, moist woods, &c., in various parts of Britain. Flowers in May. Its bark, called *cortex salignum*, or *cortex amylicanum* of some writers, is astringent, but less so than that of the preceding species.

3. *SALIX CAPREA*, Linn.; *Salix latifolia rotunda*, Bauhin; *Great Round-leaved Willow*.—Stem erect. Leaves roundish-ovate, pointed, serrated, waved; pale and downy beneath. *Stipules* somewhat crescent-shaped. *Catkins* oval. *Germen* stalked, ovate, silky. *Stigmas* nearly sessile, undivided. *Capsules* swelling (Smith).—A tree. Indigenous, very common; growing in woods and hedges. Flowers in April. Its bark is the *broad-leaved willow bark* (*cortex salicis latifoliae*) recommended by James, White, and Wilkinson (see ante, p. 314).

4. *SALIX FRAGILIS*, Linn.; *the Crack Willow*.—Leaves ovate-lanceolate, pointed, serrated throughout, very smooth. *Footstalks* glandular. *Germen* ovate, abrupt, nearly sessile, smooth. *Scales* oblong, about equal to the stamens and pistils. *Stigmas* cloven, longer than the style (Smith).—A tree. Indigenous; about the banks of rivers. Flowers in April and May.

5. *SALIX PENTANDRA*, Linn.; *Sweet Bay-Leaved Willow*.—This species is official in the Prussian Pharmacopœia, and is preferred by Nees von Eesenbeck to all other species. Its bark is the *cortex salicis laurææ* of some pharmacologists.

6. *SALIX PURPUREA*, Linn.; *Bitter Purple Willow*.—This species deserves notice on account of the intense bitterness of its bark.

DESCRIPTION.—Willow bark (*cortex salicis*) varies, in its appearance and qualities, according to the species and the age of the tree from which it is procured. In the dried state it is usually quilled and odourless. It should have a bitter and astringent taste.

COMPOSITION.—The bark of *Salix alba* was analyzed by MM. Pelletier and Caventou,¹ who obtained the following results: *Bitter yellow colouring matter*, *green fatty matter* similar to that found in cinchona, *tannin*, *resinous extract*, *gum*, *wax*, *woody fibre*, and a *magnesian salt* containing an organic acid.

These celebrated chemists failed to isolate *salicine*, which must have been contained in their bitter yellow colouring matter, either mixed or combined with some other matter. Their resinous extract is probably identical with what Braconnot calls *corticin*.

1. *TANNIC ACID*.—This is the astringent principle of willow bark. Sir H. Davy² gives the following as the quantities of tannin [impure tannic acid] in the bark of two willows:—

	480 lbs. of bark.	lbs. of tannin.
Leicestershire Willow [<i>Salix Russelliana</i>] large size		33
Common willow [<i>Salix</i> ?] large		11

2. *SALICINE*.—See p. 316.

CHEMICAL CHARACTERISTICS.—A decoction of the bark, made with distilled water, is coloured dark green (*tannate of iron*) by sesquichloride of iron; but, made with spring water, dark purple. Solution of gelatin produces a precipitate (*tannate of gelatin*) in the decoction, but tincture of nutgalls causes no turbidness. A strong decoction of willow bark, containing much salicine, is reddened by concentrated sulphuric acid.

PHYSIOLOGICAL EFFECTS.—Willow bark possesses both bitterness and astringency. It belongs, therefore, to the *astringent bitters*, whose effects have been already noticed (see vol. i., p. 244). It is less apt to disturb the stomach than cinchona, but its tonic and febrifuge powers are less than the latter. Vogt³ ascribes to it balsamic properties.

¹ *Journ. de Pharm.* t. vii. p. 123.

² *Pharmakodynamik*, Bd. i. S. 658.

³ *Elements of Agricultural Chemistry*, 4th edit. p. 83.

USES.—It has been employed as an indigenous substitute for cinchona. The indications for its use, therefore, are the same as those for the latter. It is given in intermittents, dyspeptic complaints accompanied with, or dependent on, a debilitated condition of the digestive organs, passive hemorrhages, chronic mucous discharges, in the stage of convalescence after fever, and as an anthelmintic. As a local astringent, the powder or infusion is sometimes employed, but there are many more efficient remedies of this kind.

ADMINISTRATION.—The dose of the *powder* is ʒss to ʒj. The *infusion* or *decoction* (prepared with ʒj of the bark and Oj of water) may be given in doses of from fʒj to fʒij.

SALICINUM; Salicine.—Obtained in a more or less impure state by Brugnatelli, Fontana,¹ in 1825, and Buchner² in 1828, and in a pure state by Leroux³ in 1829. Has been found in about fourteen species of *Salix* and eight species of *Populus*.⁴ It has been detected in the bark, leaves, and flowers. Herberger obtained 250 grains, Merck 251 grains, from 16 ounces of the bark and young twigs of *Salix Helix*; Erdmann, however, procured, by another process, 300 grains from the bark of *Salix pentandra*.⁵ Merck's process for obtaining it, as stated by Liebig,⁶ is as follows:—

“Dried or fresh willow bark is cut small, and exhausted by repeated boiling with water. The decoctions are concentrated, and while boiling treated with litharge till the liquor appears nearly colourless. The dissolved oxide of lead is removed, first by sulphuric acid, afterwards by sulphuret of barium, and, after the separation of sulphuret of lead, evaporated, when salicine crystallizes; and is purified by repeated solution and crystallization (Merck). From willow bark, which is fresh and rich in salicine, it may be obtained by cautious evaporation of the cold aqueous infusion (Merck). The oxide of lead removes from the solution gum, tannin, and extractive matter, which would impede the crystallization of the salicine. It also combines with the salicine, forming a kind of salt which is decomposed by the sulphuric acid and sulphuret of barium. If the latter be carefully added, neither sulphuric acid nor baryta remain in the solution; and the sulphuret of lead, which separates, acts as a decolorizing agent.”

Salicine crystallizes in silky needles and laminæ. It is white, very bitter, inodorous, neutral to vegetable colours, fusible at 230° F., and combustible at a higher temperature. It rotates to the left a ray of plane polarized light. It is much more soluble in boiling than in cold water, 100 parts of which dissolve only 5.6 parts of salicine. It is also soluble in alcohol, but not so in ether or the volatile oils. It is not precipitated by any agent. Oil of vitriol colours it blood-red.⁷ By this test the presence of salicine is detected in its solutions, and in decoctions of willow and poplar barks. Chromic acid (or a mixture of bichromate of potash and sulphuric acid) converts salicine (C²⁶H¹⁸O¹⁴) into hydruret of salicyle (also called salicylous acid), C¹⁴H⁵O³,H (oil of meadow-sweet) carbonic acid and formic acid. Hence this acid may be employed as a test for salicine. For this purpose 3 parts of salicine, 3 of bichromate of potash, and 24 of water, are to be dissolved in water, and to the solution 4½ parts of oil of vitriol diluted with 12 parts of water are to be added. On the application of heat, the well-known odour of the flowers of meadow-sweet (*Spiræa ulmaria*) is evolved. If diluted hydrochloric or sulphuric acid be boiled with a solution of salicine, the fluid becomes suddenly turbid, and deposits a precipitate of saliretine, glucose being at the same time formed.

⁴ Herberger. *Pharmaceutisches Central-Blatt für 1838*, S. 848.

⁵ *Ibid.* S. 852.

⁶ Turner's *Chemistry*, 7th edit. p. 816.

⁷ Phloridzin, veratria, pipérin, oil of bitter almonds, &c. are also coloured red by oil of vitriol.

By the prolonged action of heat, saligenine loses the elements of water (2HO) and becomes saliretine (C¹⁴H⁶O²).

Salicine has been repeatedly subjected to analysis.

	Atoms.	Eq. Wt.	Per Ct.	Piria. ¹			
				I.	II.	III.	IV.
Carbon	26	156	54.54	54.87	54.24	54.73	54.48
Hydrogen	18	18	6.29	6.36	6.39	6.43	6.31
Oxygen	14	112	39.17	38.77	39.37	38.84	39.21
Salicine	1	286	100.00	100.00	100.00	100.00	100.00

Salicine possesses tonic properties analogous to disulphate of quina, than which it is less liable to irritate the stomach. In its passage through the system salicine undergoes oxidation, and is converted into hydruret of salicylic acid, which is found in the urine. Its presence is detected by a persalt of iron, which strikes an intense violet colour with urine containing it.² It is employed in dyspepsia, intermittents, and other diseases for which cinchona and disulphate of quina are usually exhibited. In the event of the latter becoming scarce, salicine would prove an exceedingly valuable substitute. The dose of it is from 10 to 30 grains. It may be given in powder mixed with sugar or dissolved in some aromatic water.³ Its quickest action in intermittents is said to be obtained when it is given in powder.⁴

ORDER XXVI. CUPULIFERÆ, Richard.

CORYLACEÆ, Mirbel.

CHARACTERS.—*Flowers* unisexual: males amentaceous; females aggregate or amentaceous. *Males*: Stamens 5 to 20, inserted into the base of the scales, or of a membranous valvate calyx, generally distinct. *Females*: Ovaries crowned by the rudiments of an adherent (superior) calyx, seated within a coriaceous involucre (*cupule*) of various figure, and with several cells and several ovules, the greater part of which are abortive; *ovules* twin or solitary, pendulous or peltate: *stigmas* several, subsessile, distinct. *Fruit* a bony or coriaceous, 1-celled nut, more or less inclosed in the involucre. *Seeds* solitary, 1, 2, or 3: *embryo* large, with plano-convex, fleshy cotyledons, and a minute superior radicle.—*Trees* or *shrubs*. *Leaves* with stipules, alternate, simple, often with veins proceeding straight from the midrib to the margin (Lindley).

PROPERTIES.—The prevailing quality of this order is astringency, owing to the presence of tannic acid.

Besides the species presently to be described, the following may be here briefly referred to: *Quercus tinctoria*, or the *Black Oak*, is a native of America. Its bark, called *quercitron*, is used by dyers. In the United States it is employed medicinally, but it is said to be disposed to irritate the bowels.—The large capsules or acorn cups of *Quercus Ægilops* are imported from the Levant, under the name of *Vebonia*. They are astringent, and are employed by dyers.—A saccharine substance exudes from the leaves of *Quercus mannifera* in Kurdistan.⁵

110. QUERCUS PEDUNCULATA, Willd.—THE COMMON BRITISH OAK.

Quercus Robur, Linn.

Sex. Syst. Monœcia, Polyandria.

(Cortex, L.—The Bark, E. D.)

HISTORY.—The oaks (*Quercus* of botanists) were held sacred by the Greeks, Romans, Gauls, and Britons. They are mentioned in the Old Testament.⁶ Both Dioscorides and Galen were acquainted with their astringent qualities. “Every part of the oak” (δρῦς; *Q. sessiliflora* and *pedunculata* according to Fraas, but

according to Sibthorp (*Q. Ægilops*), says Dioscorides,¹ “but especially the liber, possesses an astringent property.”

BOTANY. Gen. Char. Monœcious. **MALE FLOWERS:** *Catkins* lax and pendulous. *Perianth* lacerated. *Stamens* 5 to 10. **FEMALE FLOWERS:** *Involucre* scaly; the *scales* numerous, imbricated; combined with a coriaceous, hemispherical cup. *Perianth* 6-lobed, adnate to the ovary. *Ovary* 3-celled; 2 of the cells abortive. *Stigmas* 3. *Nut* 1-celled, 1-seeded, surrounded at the base by the cupule (*acorn-cup*). (*Bot. Gall.*)

Fig. 284*.

a. Male catkins. b. Magnified male flower. c. Female flower with the stigmas magnified. d. Acorn in embryo. e. Sections of young acorn. f. Cotyledon with the radicle.

Sp. Char.—*Leaves* deciduous, shortly-stalked, oblong-ovate, deeply sinuate; their sinuses rather acute, lobes obtuse. *Fruits* 2 or 3 upon a long peduncle (*Hooker*).

A large and handsome *tree*, remarkable for its longevity. *Twigs* round, smooth, grayish-brown. *Leaves* bright green, furnished with a single midrib sending off veins into the lobes. *Male flowers* yellowish; *females* greenish, tinged with brown.

The long peduncles which support the female catkins have given the name of *pedunculata* or *long-stalked* to this species of *Quercus* or *Oak*.

Hab.—Indigenous, growing in woods and hedges. Flowers in April. It is found in most European countries.

BARKING.—In the spring, the barks of trees contain more astringent matter, and are more readily separated from the wood. The usual time for barking the oak is from the beginning of May to the middle of July. The barkers make a longitudinal incision with a mallet furnished with a sharp edge, and a circular incision by means of a barking-bill. The bark is then removed by the peeling-irons, the separation being promoted, when necessary, by beating the bark with the square end of the mallet. It is then carefully dried in the air, by setting it on what are called lofts or ranges, and is afterwards stacked.²

DESCRIPTION.—Oak bark (*cortex quercus*) consists of pieces of from one to two feet long, which vary in their appearance according to the age of the stem or branch

¹ Lib. i. cap. 142.

² Loudon's *Encyclopædia of Agriculture*, 3d edit. pp. 656-9.

from which they have been taken. The bark of young stems is thin, moderately smooth, covered externally with a silvery or ash-gray cuticle, and is frequently beset with lichens. Internally it is, in the fresh state, whitish; but, when dried, brownish, red, fibrous. The bark of old stems is thick, very rough externally, cracked, and wrinkled, and is usually of inferior quality.

COMPOSITION.—According to Braconnot,¹ oak bark contains—*tannic acid, tannates of lime, magnesia, potash, &c., gallic acid, uncrystallizable sugar, pectin, and lignin.*

The quantity of TANNIN [impure tannic acid] obtained by Davy² from oak bark, is as follows:—

480 lbs. of	Tannin afforded.
Entire bark of middle-sized oak, cut in spring	29 lbs.
“ coppice oak	32
“ oak, cut in autumn	21
White interior cortical layers of oak bark	72

Biggins³ obtained 30 parts of tannin from the bark of an oak felled in winter, while the same weight of the bark of an oak felled in spring yielded him 108 parts.

CHEMICAL CHARACTERISTICS.—Decoction of oak bark reddens litmus, and becomes dark blue or purple (*tannate of iron*) on the addition of sesquichloride of iron. A solution of gelatin causes a precipitate (*tannate of gelatin*) with it. It is somewhat remarkable, however, that a solution of emetic tartar causes no precipitate with the decoction. [If alcohol be added to the decoction, concentrated to the consistence of a syrup, it causes the precipitation of *pectin*. A decoction, rendered alkaline by a fixed alkali, deposits a gelatinous matter (*pectic acid*) on the addition of acetic acid. *Braconnot.*]

PHYSIOLOGICAL EFFECTS.—The effects of oak bark are similar to those of other vegetable astringents containing tannic acid, and have been already described (see vol. i., p. 201).

USES.—The principal value of oak bark in medicine arises from its astringent property. Thus we employ a decoction of it as a gargle in relaxed conditions of the uvula, and in chronic inflammatory affections of the throat;⁴ as a wash in flabby, ill-conditioned, or bleeding ulcers; as an injection in leucorrhœa, in piles, or in prolapsus of the uterus or rectum; as an internal astringent in old diarrhoeas, in the last stage of dysentery, in alvine hemorrhages, &c. Poultices made of powdered oak bark have been applied with benefit to mortified parts.⁵ Mr. Lizars⁶ states that he has obtained “wonderful success” in the cure of reducible herniæ by bathing the groin (the hernia having been previously reduced) three or four times daily with a warm inspissated decoction of oak bark, and then applying a truss. The practice, however, is not a new one.⁷

The inhalation of finely-powdered oak bark is said to have proved very beneficial in supposed cases of pulmonary consumption.⁸ I have already noticed (see vol. i., p. 175) the inspiration of impalpable powders of other astringents as a remedy for phthisis. Connected with this, the popular opinion of the exemption of operative tanners from phthisis pulmonalis deserves to be mentioned. Dr. Dods,⁹ who has paid some attention to this subject, concludes, that the popular notion is correct; and he ascribes the exemption to “the inhalation of that peculiar aroma, or volatile matter, which is constantly arising from tan-pits during the process of tanning with bark.” Hitherto, however, no sufficient evidence has been advanced to prove that tanners are exempt from the disease.

As a tonic, oak bark has been employed in medicine, but it is much inferior to the cinchona. Baths made of a decoction of this substance have been used by Dr. Eberle in the intermittents of very young children with benefit; and Dr. Fletcher,

⁹ *Lond. Med. Gaz.* vol. iii. p. 479.

of Virginia, has recommended the same remedy in *tabes mesenterica*.¹ The decoction, powder, and extract, have been taken internally in intermittents, but they are very apt to irritate the stomach. Dr. Cullen² says, that both by itself, and joined with chamomile flowers, he has prevented the paroxysms of intermittents.

ADMINISTRATION.—Dose of the *powder* from half a drachm to one or two drachms.

DECOCTUM QUERCÛS, L. E. D.; *Decoction of Oak Bark*.—(Oak Bark, bruised, $\bar{3}\pi$ [$\bar{3}$ iss, *D.*]; Water [Distilled, *L.*] Oij [*Oiss.*, *D.*]. Boil down to a pint and strain.)—Used as a local astringent for various purposes, in the form of gargle, injection, or lotion. Administered in doses of $f\bar{3}ii$ to $f\bar{3}vi$. Sometimes employed as a bath, especially for children.

III. QUERCUS INFECTORIA, Olivier.—THE GALL, OR DYER'S OAK.

Sex. Syst. Monœcia, Polyandria.

(Galla; Tumor ramuli a Cynipe; Gallæ tinctoriæ'excitatus, *L.*—Gallæ; Excrecences, *E.*—Galls, the excrecences formed by *Diplolepis Gallæ tinctorium*, *D.*)

HISTORY.—Hippocrates employed the nutgall ($\pi\eta\kappa\iota\varsigma$) as an astringent, both internally and externally.³ Dioscorides⁴ describes it as the fruit of the oak; and the same error is found in the works of comparatively recent writers, as of Pomet.⁵

BOTANY. *Gen. Char.*—Vide *Quercus pedunculata*.

Sp. Char.—*Leaves* ovate-oblong, sinuate-dentate, very smooth, deciduous. *Fruit* sessile, very long.⁶

Small tree or shrub, from four to six feet high. *Stem* crooked. *Leaves* on short petioles, with a few short mucronate teeth on each side. *Acorn* two or three times as long as the cupules.

Hab.—Asia Minor, from the Bosphorus to Syria, and from the Archipelago to the frontiers of Persia.

FORMATION OF GALLS.—The term *gall* (*galla*) is applied to an excrescence or

Fig. 285.

Chinese Galls, or Woo-pei-tsze.

tumour formed on any part of a vegetable, in consequence of the puncture of an insect.

¹ Eberle, *op. cit.* vol. i. pp. 267-5.

⁴ *Mat. Med.* vol. i. p. 45.

⁵ *Lib i cap.* 146.

⁶ Olivier, *Voy. dans l'Empire Ottom.* t. ii. p. 64.

In general, the insects which give rise to galls are the gall-flies, constituting the genus *Cynips*, and forming the tribe *Gallicolæ* (*Diphlolepariæ*, Lat.) of the order *Hymenoptera*. But sometimes they are plant-lice, or *Aphidii* of the order *Hemiptera*. Thus the very astringent *Chinese galls* called *Woo pei-tze* (Fig. 285), of which I have elsewhere¹ given a description, are produced, as the late Mr. Doubleday² has shown, by an Aphidian.

The gall-flies (*Cynips*) are those by whose puncture the officinal galls are produced, and to which, therefore, our attention must be principally directed. The females of these insects are supplied with an ovipositor, called by Latreille the *borer* (*terebra*), channelled with lateral teeth.—By means of this instrument they are enabled to perforate the foliaceous or cortical parts of plants for the purpose of depositing their eggs, along with an acrid liquor, in the wound thus made. The irritation thereby produced gives rise to an influx of the juices of the plant to the wounded part, and an excrescence is formed, which is termed a *gall* (*galla*). Here the insect usually undergoes its transformations: the egg produces the larva (or maggot), which feeds on the juices of the plant, and is changed into the pupa. This afterwards becomes the perfect insect (*imago*), and, perforating the gall, produces a small, round hole, through which it escapes from its prison-house.

The external form and appearance of galls are very constant when formed by the same insect, on the same part of the same plant; but the galls of different species of vegetables, and of different parts of the same plants, as well as those of the same vegetable species, produced by a different insect, vary considerably. There is reason for believing that the form and appearance of the gall is determined more by the insect than by the plant; for we sometimes have on the same oak two kinds of galls, of very dissimilar appearance, produced by different insects.

OAK GALLS.—Most, if not all plants, but especially the oaks, are liable to the production of galls. The *oak galls* vary considerably in size, shape, texture, and other properties, according to the species and part of the oak in which they grow, and the insect by whose puncture they are produced. From their fancied resemblance to nuts, apples, currants, &c., they have been respectively called, *nut-galls*, *apple-galls*, *currant-galls*, *grape-galls*, *cherry-galls*, *artichoke-galls*.³

The largest species of British oak-galls is the *oak-apple* or *oak sponge*, produced by *Cynips Quercus terminalis*. They are astringent, like nutgalls.

The small round *currant-galls* are produced by *C. Q. pedunculæ*. They are scattered over the rachis of the amelum, giving it the appearance of a bunch of currants.

The *artichoke-gall* or *oak-strobile* is a beautiful foliose gall, produced by *C. Q. gemmæ*.

Galls of various species are produced on oak-leaves. One of the larger sorts is red and succulent, and has been called the *cherry gall*. A smaller one is called by Reaumur the *currant-gall*. Mr. Westwood states that the large ones (as large as a boy's marble) are formed by *C. Q. foliæ*.

The large *Mecra* or *Fussorah galls*,⁴ sometimes called *Dead-sea apples*, *mad-apples* (*mala insana*), or *apples of Sodom* (*poma sodomitica*), are produced on the *Quercus infectoria* by a species of *Cynips* which Mr. Westwood calls *C. insana*.

A very irregular, deeply-furrowed, angular gall is formed on the capsule of the *Quercus pedunculata* by the *Cynips Quercus calycis*. This is the *acorn gall*. It is sometimes used in Germany by dyers as a substitute for nutgalls under the name of *Knoppeln* or *Knobben*. These galls appear to me to be identical with some which I have received from M. Guibourt under the name of *gallon de Hongrie* ou *du Picnont*. The acorn, with its capsule, is usually attached to it. A very similar shaped gall, attached by its middle to a young branch, is frequently found intermixed: this M. Guibourt calls the *horned gall* (*galle corniculée*).

NUTGALLS.—The *nutgalls* (*gallæ officinarum*) of commerce are produced by the *Cynips gallæ tinctoriæ* on the *Quercus infectoria*. Ollivier⁵ says that this insect lives on this species of *Quercus* only.

On the sides and at the ends of the branches and shoots of this tree, the female

¹ *Pharmaceutical Journal*, vol. iii. p. 384, 1814.

² *Ibid.* vol. vii. p. 310, 1818.

³ For further details respecting galls, the reader is referred to Reaumur's article on this subject, in his *Mémoires pour servir à l'Histoire des Insectes*, 4to. vol. iii. 1737. Also to Westwood's *Introduction to the Modern Classification of Insects*, 2 vols. 8vo. 1838-40.

⁴ See a notice of this gall, by the author, in the *Pharmaceutical Journal*, vol. viii. p. 423.

⁵ *Op. cit.*

makes a puncture and deposits her egg. An excrescence is soon formed, within which the larva is developed, which is changed first into the pupa and then into

Fig. 286.

Mecca or Bussorah Galls.

a. Branch, bearing a gall.

b. Section of a gall.

the imago. As soon as the perfect insect is produced, it eats its way out. If we examine those galls from which the animal has escaped, we observe externally a circular hole, of about a line in diameter, leading to a canal of from $2\frac{1}{2}$ to $3\frac{1}{2}$ lines long, which passes to the centre of the gall. But in those galls in which the insect has not put off its pupa state, we find neither an external hole nor an internal canal. In the imperforated gall, the part sometimes called "the kernel" is the cocoon of the insect in the pupa state (Kirby and Spence). Guibourt¹ states that in the immediate envelop of the central cavity of the gall he detected starch grains, and, in the exterior covering, chlorophyll and volatile oil. Guibourt has also observed, around the spherical amylaceous mass, cells serving for the respiration of the insect.

Bluish black, heavy, not yet perforated. *Ph. L.*

Those galls from which the insect has escaped are commonly larger, lighter coloured, and less astringent: they are termed *white galls*.

The nutgalls of different countries vary in their size, shape, weight, and quality of surface.

1. *Levant Nutgalls (Gallæ Levanticæ)*.—These are the ordinary nutgalls of the shops. They are in general about the size of a nut, somewhat round, tuberculated or warty; whence they were formerly called spiny or prickly galls (*galles à l'épine, gallæ spinosæ*), to distinguish them from the smooth French and other galls. They are imported from Syria and Turkey. The most esteemed *Syrian galls (gallæ syricæ)* are the produce of Mosul on the Tigris: these are the *Mosul galls (gallæ mossulicæ)*. The *Aleppo galls (gallæ haleppenses)* usually pass for Mosul galls. *Tripoli galls (gallæ tripolitanæ)* come from Tripoli (also called Taraplus or Tara-

¹ *Hist. Nat. des Drogues simples*, 4me édit. t. ii. 1849.

bulus, whence the corrupt name of "Tarablous galls"), and are inferior to the Aleppo galls. The *Turkey galls* (*gallæ turcicæ*) usually come from Constantinople or Smyrna. *Smyrna galls* (*gallæ smyrnenses*) are not so heavy, are lighter coloured, and contain a larger admixture of white galls than those brought from Aleppo. The galls brought from Bombay (*East India galls*) are probably the produce of Persia or neighbouring parts.¹

In commerce, three kinds of Levant galls are distinguished, viz., *black* or *blue*, *green*, and *white*; but there is no essential distinction between the first two.

α. *Black or blue nutgalls* (*gallæ nigræ seu cæruleæ*); *green nutgalls* (*gallæ virides*).—These are gathered before the insect has escaped, and are called by the natives *yerli*. They vary from the size of a pea to that of a hazel-nut, and have a grayish colour. The smallest have a blackish-blue tint, and are distinguished by the name of *black* or *blue galls*; while the larger and greener varieties are called *green galls*. Externally they are frequently tuberculated, but the surface of the tubercles and of the intervening spaces is usually smooth. Their texture is compact, but fragile. They have no odour, but a styptic and powerfully astringent taste.

β. *White galls* (*gallæ albæ*).—These are for the most part gathered after the insect has escaped, and hence they are perforated with a circular hole. They are larger, lighter coloured (being yellowish or whitish), less compact, less heavy, and less astringent. They are of inferior value.

γ. The *marmorine nutgalls* (*galles marmorines*, Guibourt) of the French writers are a sort of Levant gall about the size of the black or blue galls, but without tubercles or warts. The surface, however, is dull and roughish, something like orange berries. Their shape is round, with sometimes a little elongation where the peduncle is attached.

δ. *Small Aleppo nutgalls*.—Occasionally there is imported from Aleppo a small sort of nutgall, called the *coriander gall*.

Somewhat larger than these is another sort of small Aleppo gall, called the *small crowned Aleppo galls* (*gallæ haleppenses coronatæ*). They are about the size of a pea, or a little larger, and crowned superiorly by a circle of points or tubercles like the fruit of the myrtle or Eugenia. Although very small, they are often perforated by a large hole, so that they must have attained their maximum size; and, therefore, are a distinct sort from the usual Aleppo kind.

Somewhat larger than these, and having a speckled surface, is a sort which I have received under the name of *Turkish diamonds*.

2. *European Nutgalls*.—Various sorts of nutgalls are produced in Europe. The *Istria nutgalls* are intermediate in size between the usual Levant galls and the small Aleppo sort. They are somewhat turbinate or pear-shaped, wrinkled, and usually have a short peduncle. The *Mored nutgalls* are about the size of the preceding. *French nutgalls* are spherical, very light, usually very smooth or even polished, but sometimes very slightly wrinkled. *Hungarian, Italian, Bohemian, &c. nutgalls* are but little known in England.

COMPOSITION.—Nutgalls were analyzed by Sir H. Davy,² who obtained the following results:—

Matter soluble in water = 37; viz.	{ Tannin	26.0
	{ Gallic acid, with a little extractive	6.2
	{ Mucilage and matters rendered insoluble by evaporation	2.4
	{ Carbonate of lime and saline matter	2.4
Matter insoluble in water (<i>lignin</i>)		63.0
Good Aleppo nutgalls		100.0

Pelouze³ found in 100 parts of nutgalls the following constituents: *tannic acid* 40.0, *gallic acid* 3.5, *ellagic acid* and *insoluble matter* 50, *extractive colouring matter* 6.5 = 100.0.

¹ *Mat. Indica*, vol. i. p. 145.

² *Ann. de Chimie et de Physique*, t. liv. p. 337.

³ *Phil. Trans.* for 1830.

1. TANNIC ACID (see p. 325).

2. GALLIC ACID (see p. 326).

3. ELLAGIC OR BEZOARDIC ACID (*Acidum Ellagicum* vel *Bezoardicum*), $C^{14}H^{10}O_7, 3HO$.—Discovered by Braconnot, who called it *ellagic acid*, from the French word *galle* spelt backwards. It is probably produced by the slow decomposition of the tannin contained in the nutgall. It is a yellowish gray insipid powder, scarcely soluble in cold water, a little more so in alcohol, but insoluble in ether. Like the tannic and gallic acids it forms a bluish black precipitate with the persalts of iron. Hot nitric acid, according to Braconnot, gives it a blood-red colour. The acid has recently acquired additional interest in consequence of the discovery by Mr. Thomas Taylor¹ (subsequently confirmed by Merklein and Wöhler²) that the *Oriental Bezoar* is an ellagic acid calculus formed in the intestines of animals (usually a species of wild goat, termed by the Persians *Pasen*), which feed on vegetable substances containing tannin, from which the ellagic acid is produced. Ellagic acid, therefore, must be regarded as identical with *bezoarine* (*Bezoarstoff* of John).

CHEMICAL CHARACTERISTICS.—Infusion of nutgalls reddens litmus paper, forms an inky compound (*tanno-gallate of iron*) on the addition of a sesquisalt of iron, and a yellowish white precipitate (*tannate of gelatin*) with a solution of gelatin. If a piece of skin, depilated by lime, be immersed in the infusion, and agitated with it from time to time, all the tannic acid is absorbed, the filtered liquor striking a blue colour (*gallate of iron*) with the sesquisalts of iron, but giving no precipitate with a solution of gelatin. Infusion of galls forms precipitates (*metallic tannates* or *tanno-gallates*) in many metallic solutions; it also produces a precipitate (*a tannate*) in aqueous solutions of the vegetable alkaloids.

PHYSIOLOGICAL EFFECTS.—As nutgalls contain a larger portion of tannic acid than any other known vegetable production, they possess in the highest degree the properties of an astringent (see vol. i. pp. 200 and 243).

USES.—The following are the principal uses of nutgalls:—

1. *As a tonic in intermittents.*—Notwithstanding Poupart's favourable report of the use of galls in these cases, they scarcely deserve notice, as we have in arsenic, cinchona, and sulphate of quinia, much more effective and certain febrifuges.

2. *As an astringent in hemorrhages*, especially passive alvine hemorrhages.

3. *In chronic mucous discharges*, as old diarrhoeas.

4. *As a chemical antidote* (see vol. i., p. 198).—Nutgalls may be given in poisoning by ipecacuanha, emetina, the organic alkalies generally, and those vegetable productions whose activity depends on an organic alkali; as opium, white hellebore, colchicum, nux vomica, &c. Their efficacy arises from the tannic acid, which combines with the vegetable alkali to form a tannate possessing less activity than the other salts of these bases; perhaps because of its slight solubility. Nutgalls

¹ *Lond. and Edinb. Philosoph. Magazine* for May 1844, and also for January 1846; and *Catalogue of the Museum of the Royal College of Surgeons*, published in July 1845.

² *Ann. der Chem. u. Pharm.* Bd. lv. S. 129, 1845.

³ Brande's *Manual of Chemistry*, 1818.

⁴ Discrepancies arise from the strength of the solutions as well as from their acid or basic characters, so that neutral solutions should as far as possible be used.

are recommended as an antidote in cases of poisoning by emetic tartar, but I very much doubt their efficacy (see vol. i. p. 670).

5. *As a topical astringent.*—Nutgalls are applicable in any cases requiring the topical use of a powerful vegetable astringent. Thus, in the form of gargle, in relaxation of the uvula; as an injection, in gleet and leucorrhœa; as a wash, in flabby ulcers, with profuse discharge; *prolapsus ani seu vaginæ*; in the form of ointment, in piles, &c.

ADMINISTRATION.—The dose of the *powder* is from ten to twenty grains. Nutgalls are also used in the form of *infusion* and *tincture*.

Roasted nutgalls (*gallæ torrefactæ*) are used in the manufacture of copying-ink (see p. 329).

Besides the following officinal formulæ for the use of galls, others have been published by Mouchon.¹

1. **INFUSUM GALLÆ**; *Infusion of Galls.*—Prepared by digesting ℥iv of coarsely powdered nutgalls in f℥vj of boiling water.—Employed as a chemical antidote and as a reagent or test (see *ante*, p. 324). The dose is from f℥ss to f℥ij; or, in cases of poisoning by the vegetable alkalies, f℥iv.

2. **TINCTURA GALLÆ**, L. D. [U. S.]; *Tinctura Gallarum*, E.; *Tincture of Galls.*—(Galls, bruised, ℥v; Proof Spirit Oij. Macerate for seven [fourteen, *D.*] days, and filter. [Galls, bruised, ℥iv; Diluted Alcohol Oij. Macerate for fourteen days, and filter, *U. S.*] “This tincture may be prepared either by digestion or percolation, as directed for tincture of capsicum,” *E.*)—A powerful astringent. Dose from f℥ss to f℥ij. Diluted with water, it forms a very useful and convenient astringent gargle and wash. Its principal use is as a chemical test, especially for the persalts of iron, gelatin, and the vegetable alkaloids. After it has been kept for some time its tannic acid becomes converted into gallie acid, and it then ceases to occasion precipitates in solutions of gelatin and of the vegetable alkaloids.

3. **UNGUENTUM GALLÆ**, D. [U. S.]; *Ointment of Galls.*—(Galls, in very fine powder, ℥j; Ointment of White Wax ℥vij. Mix them.)—[Galls, in powder, ℥j; Lard ℥vij. Mix them, *U. S.*]—Astringent. Mixed with zinc ointment it is applied to piles after the inflammatory stage is passed. The above is Dr. Cullen’s formula; but Mr. B. Bell² recommends an ointment composed of equal parts of powdered galls and hog’s lard or butter, in external hemorrhoidal swellings. [A smoother ointment, and one which leaves no gritty, rough deposit on irritable surfaces, is prepared by adding ℥j of Aqueous Extract of Galls to ℥j of Simple Ointment.—*ED.*]

4. **UNGUENTUM GALLÆ COMPOSITUM**, L.; *Unguentum Gallæ et Opii*, E.; *Compound Ointment of Galls.*—(Galls, in fine powder, ℥vj; Opium, powdered, ℥ss; Lard ℥vj. Mix.—The *Edinburgh College* orders of Galls, in fine powder, ℥ij; Opium, in powder, ℥j; Axunge ℥j.)—An excellent astringent application to *blind piles* (*i. e.* piles without hemorrhage) and *prolapsus ani*. The opium diminishes the pain which the galls might otherwise occasion, where the hemorrhoidal tumours are very sensible. From ℥ss to ℥i of camphor is frequently added to this ointment.

5. **ACIDUM TANNICUM**, L. D. [U. S.]; *Acidum Quercitanicum*; *Tannic Acid*: in the impure state called *Tannin*, the *Tanning Principle*, or *Materia Scytodaphica* (σχυτοδερφικός, belonging to curriers).—Extracted from nutgalls by ether in the percolation or displacement apparatus.³ The ether employed is that of commerce (which contains about 10 per cent. of water). The tannic acid at first dissolves in the ether, but is afterwards precipitated, in the form of a thick syrup, by the water contained in the ether. The syrupy layer is to be repeatedly washed with pure ether, and afterwards evaporated *in vacuo*, or at a temperature not exceeding 212° F. The residue is almost pure tannic acid.

¹ *Gaz. des Hôp. Civ. et Milit.* 13 Avril, 1837.

² Pelouze, *Ann. de Chim. et de Physique*, t. liv.

³ *Syst. of Surgery.*

Galls, in tolerably fine powder, \bar{z} vij: Sulphuric Ether Oij; Distilled Water \bar{z} v. Incorporate the water and ether by agitation, and pour the resulting solution, in successive portions upon the galls, previously introduced into a glass or porcelain percolator. The liquid which accumulates in the lower bottle will consist of two distinct strata, the heavier of which is to be separated and evaporated to dryness, finally applying an oven heat, which, however, should not exceed 212° . From the lighter liquid the ether may be removed by distilling it by means of a water-bath, and with the aid of a Liebig's condenser.—D.

Tannic acid is a spongy, brilliant, light, odourless white, or commonly yellowish, solid. It dissolves in water, alcohol, and ether; but less so in ether than in alcohol. In the solid state it is unalterable in the air; but, dissolved in water, it absorbs oxygen, and is transformed into carbonic acid, which escapes, and gallic acid, which remains in solution: hence it should be dissolved only at the time we are about to use it.

The following are the characteristics of this substance: It has an intensely astringent taste, and produces, with a solution of gelatin, a white precipitate (*tannate of gelatin*); with a solution of a sesquisalt of iron, a deep blue compound (*tannate of iron*: see vol. i. p. 711); and with solutions of the vegetable alkalies, white precipitates (*tannates*) slightly soluble in water, but very soluble in acetic acid. The mineral acids also cause precipitates with concentrated solutions of tannic acid, as do the alkalies and their carbonates. Gelatinous alumina rapidly absorbs tannic acid from its solution, and forms an insoluble compound with it.

Almost colourless; its solution in water is strongly astringent; with a solution of isinglass it produces a white precipitate. In other respects it agrees with the characters assigned to gallic acid. *Ph. Lond.*

Tannic acid is composed of $C^{14}H^5O^{12} = C^{14}H^5O^9, 3HO$; consequently its equivalent or atomic weight is 212. Its symbol is $\overline{Tan}, 3HO$; or $\overline{Qt}, 3HO$.

Tannic acid is employed in medicine, in chemistry, and in the arts.

Considered as a medicine, tannic acid is a powerful agent of the astringent class. As a *topical* remedy it is probably the most powerful of all vegetable astringents or styptics. Its chemical action on fibrine, albumen, and gelatin explains this. It is the active principle of a very large proportion of vegetable astringents (see vol. i., pp. 200 and 243). Given to a dog in doses of from $7\frac{1}{2}$ grains to about 93 grains, it did not affect the health of the animal: it caused constipation, but its appetite remained the same. The urine gradually became darker coloured and opaque, and was found to contain both gallic and pyrogallic acids and humus-like substances. The tannic acid had become converted into these bodies in its passage through the animal system.¹ The gallic acid was detected by the blackish blue precipitate produced by the persalts of iron, and by no precipitate being produced with gelatin. Pyrogallic acid was detected by the bluish black precipitate produced by the protosalts of iron. On the human subject tannic acid also operates as a constipating agent when given in a sufficient dose and frequently repeated. Cavarra² states that $2\frac{1}{2}$ grains taken three days successively produced this effect on himself. The *remote* effects of tannic acid are not so obvious, but they appear to be astringent, though in a much feebler degree. As the tannic acid becomes changed into gallic acid in its passage through the system, it is probably the latter agent which operates on remote parts as an astringent when tannic acid is administered. If this opinion be correct, tannic acid would act, as Dr. Garrod³ has suggested, less powerfully as a remote astringent than an equal weight of gallic acid. But, as a topical astringent, tannic is far more powerful than gallic acid; because its chemical reaction on albumen, gelatin, and fibrine is more energetic.

Tannic acid is used as an astringent chiefly in hemorrhages and profuse secretions; and also to constrict relaxed fibres. In hemorrhages, it has been used both topically, as a styptic (in bleeding gums, piles, and uterine hemorrhage), and remotely, as an astringent (in hemorrhage from the lungs, stomach, bowels, kidneys,

¹ Wöhler and Frerichs, *Chemical Gazette*, vol. vi. p. 231, 1848.

² Cavarra, *Lond. Med. Gaz.* vol. xx. p. 171, 1837.

³ *Lancet*, Dec. 30, 1848.

and uterus). In chronic fluxes it has likewise been employed both as a topical and a remote remedy: topically in gonorrhœa, gleet, leucorrhœa, and ophthalmia; remotely in pulmonary catarrh, diarrhœa, dysentery, leucorrhœa, gonorrhœa, and cystirrhœa. To restrain the phthical sweating it has been recommended by Charvet and others, and Giadorow¹ states that, given in combination with opium, he cured (?) two cases of diabetes by it. To constringe fibres, it is applied to spongy gums and prolapsed bowel. As an application to sores, it has been employed by Ricord in chancres, and by Mr. Druitt² in sore nipples. Dr. Scott Alison³ has recently recommended its use in various other cases: as a tonic or peptic in dyspepsia; as an "histogenetic" to promote the genesis and improve the quality of the blood, in rickets, &c.; as a nervine in nervous debility and languor; and to arrest or retard the growth of heterologous formations (tubercle, malignant disease, &c.). It has likewise been given as an antidote to check excessive vomiting from ipecacuanha or emetina.—Tannic acid may be administered in doses of from 3 to 10 or more grains, in powder, pill, or solution. When we employ it as a remote agent, the pill-form seems to be the most appropriate mode of exhibition.—As a lotion or injection, it may be used in the form of aqueous solution containing from 4 to 6 or more grains in the fluidounce. It has also been employed in the form of ointment composed of ℥ij of the acid dissolved in f℥ij of distilled water and mixed with ℥ij of lard.

In chemistry, tannic acid is employed as a reagent or test. Its solution should be fresh made when used.

In the arts it serves various useful purposes. It is the active principle of the tanning substances. In the manufacture of white wines it is used to coagulate the substance called *glaiadine*, which is apt to excite the viscous fermentation in these wines.

6. ACIDUM GALLICUM, L. D. [U.S.]; *Gallic Acid*.—It is usually prepared by exposing for a long time an infusion of nutgalls to the air; removing now and then a mouldy skin which forms on the surface of the liquid. A sediment of impure gallic acid is obtained, which requires to be purified by solution in boiling water, decolorized by animal charcoal, and crystallized.

In this process the tannic acid of the nutgalls absorbs atmospheric oxygen, and is converted into gallic acid, carbonic acid, and water.

This process is favoured by the presence of a nitrogenized matter which acts as a ferment; and the decomposition is termed the *gallic fermentation*. The mouldy skin which forms on the surface is called *mycoderma*, and resembles mother of vinegar (see *ante*, p. 85).

Galls, in coarse powder, lb. j; Distilled Water, as much as may be necessary. Having placed the galls in a porcelain dish, pour on as much water as will convert them into a thick paste, and keep them in this moistened condition for six weeks, at a temperature of between 60° and 70°, adding water from time to time, so as to supply what is lost by evaporation. Let the residue be boiled for twenty minutes, with forty-five ounces of water, and then placed on a calico filter. The filtered solution, on cooling, will afford a copious precipitate. Let this be drained on a calico filter, then subjected to strong expression, after having been first enveloped in blotting paper, and again dissolved in ten ounces of boiling water. When, upon ceasing to apply heat, the solution has cooled down to 80°, pour it off from the crystals which have formed, and, having washed these with three ounces of ice-cold water, dry them—first in blotting paper, and finally by a steam or water heat.

By boiling the undissolved portion of the galls with forty-five additional ounces of water, filtering into a capsule containing the liquor decanted from the crystals formed in the preceding process, evaporating down to the bulk of ten ounces, and cooling to 80°, an additional quantity of the crystallized acid will be obtained.

¹ *Annali universali, di Medicina*, quoted by Dr. Dunglison, in his *New Remedies*, 5th edit. 1846.

² *Provincial Med. Journal*, Oct. 9, 1844.

³ *London Journal of Medicine*, 1850.

Or: Galls lb. j; Oil of Vitriol of commerce ℥xxvj; Water Ov. ℥xiv. Steep the galls for twenty-four hours in one pint of the water, then transfer them to a glass or porcelain percolator, and pour on a pint and a half of the water in successive portions. Dilute five ounces of the oil of vitriol with an equal bulk of water, and, when the mixture has cooled, add it to the infusion obtained by percolation, stirring well, so as to bring them into perfect contact. Let the viscid precipitate which forms be separated by a filter, and to the solution which passes through, add five ounces more of the oil of vitriol, which will yield an additional precipitate. This being added to that previously obtained, let both be enveloped in calico, and subjected to powerful pressure. Dissolve the residue in the rest of the oil of vitriol, this latter being first diluted with what remains of the water; boil the solution for twenty minutes, then allow it to cool, and set it by for a week. Let the deposit which has formed at the end of this period be pressed, dried, and then dissolved in three times its weight of boiling water, clearing the solution, if necessary, by filtration, and, when it has cooled down to 80°, decant the liquid from the crystalline sediment which has formed, and wash the latter with three ounces of ice-cold water. Finally, let it be transferred to blotting paper, and, when deprived by this of adhering liquid, let it be dried perfectly, at a temperature not exceeding 212°.

The gallic acid obtained by either of the preceding processes may be rendered nearly white by dissolving it in twenty times its weight of boiling distilled water, and causing the solution to traverse a stratum of prepared animal charcoal spread upon a calico filter. When the liquid passes through colourless, it should be evaporated to one-sixth of its volume, and then suffered to cool, in order to the separation of the crystallized acid.—D.

Pure gallic acid is a colourless, crystallizable acid, with an acidulous and styptic taste. It is soluble in water, alcohol, and slightly so in ether. It produces a deep blue colour with the salts of the sesquioxide of iron, in which circumstance it agrees with tannic acid, but it differs from the latter acid in not precipitating gelatin or the salts of the alkaloids. To detect gallic acid mixed with tannic acid, the latter is to be previously removed from its solution by immersing in it a piece of skin depilated by lime. The tannic acid is absorbed. The gallic acid may then be detected by the salts of the sesquioxide of iron.

Colourless; destroyed by fire. Soluble both in water and in rectified spirit. It strikes a bluish black colour with solutions of the sesquioxide of iron; but produces no precipitate with a solution of isinglass. *Ph. Lond.*

It does not occasion any precipitate with the salts of the protoxide of iron. By this it is distinguished from pyrogallic acid.

Gallic acid consists of $C^7H^3O^5$; hence its equivalent or atomic weight is 85. When heated to 410° or 420° F., it gives out carbonic acid, and is resolved into *pyrogallic acid* ($C^6H^3O^3$). If this acid is heated to 480° F., it gives out water and becomes *metagallic acid* ($C^{12}H^3O^3$).

Gallic acid is employed in medicine as an astringent; but as a topical agent it is greatly inferior to tannic acid. Unlike the latter acid it causes precipitates neither in gelatinous nor in albuminous solutions: and a piece of skin does not absorb gallic acid from its aqueous solution, as it does tannic acid from its solution. Its chemical action on the constituents of the animal tissues is thus much weaker than that of tannic acid. No obvious effects result from the introduction of a few grains into the stomach. Twenty-four grains have produced a sweetish taste and a slight feeling of internal heat; but no other effect¹. It has been administered in doses of from fifteen to thirty grains against the *Tænia Solium*, but without any benefit. For the reasons already stated (see *ante*, p. 326) it is probable that, in equal doses, it is more powerful, as a remote astringent, than tannic acid. Dr. Todd² says that in all cases of hemorrhage, whether hæmoptysis, hæmatemesis, hæmaturia, or any other form dependent on hemorrhagic tendency, he considers it to be the best styptic we possess. The dose of it is from three to ten grains or more three or four times a day. It may be used in the same forms as tannic acid (see *ante*, p. 326).

7. ACIDUM PYROGALLICUM; *Pyrogallic Acid*.—At a temperature of from 410° to 420° F., gallic acid is converted into pyrogallic acid and carbonic acid.

¹ Chevallier, *Dict. des Drogues*, t. i. p. 93, Paris, 1827.

² *London Medical Gazette*, N. S. vol. viii. p. 101, January 19, 1849.

Pyrogallic acid is a crystallizable volatile acid. It is more soluble in water than gallic acid. It produces a very intense blue colour with the salts of the protoxide of iron, and by exposure to the air it absorbs oxygen, and is converted into a dark brown substance, which is insoluble in water and alcohol.

Pyrogallic acid, in an impure form, is employed in the preparation of a hair dye and of copying ink. By the dry distillation of galls, it is obtained partly in the form of a sublimate, partly in the fluid form. The sublimate and fluid are to be dissolved in distilled water, the solution decolorized by animal charcoal, concentrated by evaporation, and then mixed with spirit of wine and some agreeable volatile oil. The resulting compound is a *hair-dye*, which stains the hair dark brown; and the tint is not removed by sweat or moisture. It must be cautiously applied, as it stains the hands.¹ Roasted nutgalls are used in the manufacture of copying ink on account of the dark colour which the pyrogallic acid produces with the sulphate of the protoxide of iron.

[*Quercus tinctoria*, Bartram.—Black or Dyer's Oak.

Sex. Syst. Monœcia, Polyandria.

Gen. Char.—See *ante*, p. 318.

Sp. Char.—The *leaves* are obovate or oblong, sinuate, lobed, pubescent beneath. *Male flowers* in slender, long, filiform aments. *Cup* turbinate. *Acorn* small, ovoid, flattened at top.

This is one of the largest forest-trees of the United States, attaining, in favourable situations, the height of ninety or one hundred feet, with spreading branches, and a rough, dark-coloured bark.

The bark when separated is thick and rugged, full of fissures, and black externally; internally, it is fibrous and of a red colour increased by drying. It breaks with a rough fracture. That obtained from the young shoots and smaller branches is smoother externally, and the inner fibres are finer. The odour is strong, and the taste is bitter and styptic, tinging the saliva yellow when chewed. The cellular integument contains a yellowish-brown colouring principle. The interior layer when separated constitutes *Quercitron Bark*, used for the purpose of dyeing; it is shipped to Europe.

In consequence of the colour imparted to leather, it is not as much used for tanning. As it soils the clothes an objection is urged against it in medicine.

The medical properties and uses are the same as those enumerated under *Q. pedunculata*.

Quercus alba, Linn.—White Oak.

Sex. Syst.—Monœcia, Polyandria.

Gen. Char.—See *ante*, p. 318.

Sp. Char.—*Leaves* obovate, oblong; obliquely divided into obtuse lobes; *segments*, oblong entire; *cup* hemispherical, tuberculated; *acorn* ovoid, oblong; *fruit* in pairs.

This tree is less elevated than the *Q. tinctoria*. It forms, however, a larger and more regularly-expanded head, with numerous horizontal branches. The trunk and branches have a whitish hue, hence the name *White Oak*. The leaves are of a silvery appearance, with a hoary under surface. The young leaves are covered with a fine silky down.

The bark is rough externally, of a light colour; the effete epidermis being arranged in flat layers. On drying, the internal layer becomes brown. It breaks with a stringy fracture. The odour is decided and tan-like; taste astringent and bitter. This bark is used in tanning. For medicinal purposes it is preferred to the black oak.

DECOCTUM QUERCUS ALBÆ, U. S.; *Decoction of White Oak Bark.*—(Take of White Oak Bark, bruised, an ounce: Water a pint and a half. Boil down to a pint and strain.)—Used as the *Decoction Quercus*, p. 320.]

112. *Quercus Suber*, Linn.—The Cork-Tree.

Sex. Syst. Monœcia, Polyandria.
(Cortex.)

φελλός, Theophrast., *Hist. Plant. lib. iii. cap. 16;* *Suber*, Rliny, *Hist. Nat. lib. xvi. cap. 13*, and *lib. xxiv. cap. 8.*—This species of *Quercus* has a cracked fungous bark, and ovate-oblong, bluish, coriaceous, entire or sharply serrated leaves, which are downy beneath. It is a native of northern parts of Africa and of the southern parts of Europe, especially of Spain, Portugal, and France. It grows to the height of twenty or thirty feet. According to Mohl,¹ the bark of a young branch of *Quercus Suber* consists of four distinct parts: 1st, an exterior layer or *epidermis*; 2dly, colourless cellular tissue, the *epiphylæum* of Link, the *phylæum* (φλοιός, the bark of trees) or *peridermis* of Mohl, the *suberosus envelop* of some writers; 3dly, green parenchyma, the *mesophylæum* of Link, the *herbaceous or cellular integument* of others; 4thly, a fibrous layer called *endophylæum* or *liber*. Of these four layers, two (namely the 2d and 4th) are useful in pharmacy and medicine.

Fig. 286.*

1. **SUBER; Cork; Cortex exterior Quercus Suberis; Exterior Bark of the Cork-Tree.**—The substance known in commerce as *cork* is the *epiphylæum* or *suberosus envelop*, above mentioned. When the branches are from three to five years old, the *epidermis* cracks by distension, and the second layer enlarges on the inner side by the deposition of new layers. These constitute *cork*.² It falls naturally every eight or nine years, but for commercial purposes is usually removed one or two years before

this period. That season of the year is selected when the bark adheres the most firmly to the wood, in order that the cork may be raised without endangering the separation of the liber from the alburnum. By this precaution, the trees are not at all injured by the corking process; nay, they are said to be more healthy and vigorous than when the cork is allowed to accumulate on their stems. The trees yield these crops from the age of fifteen to one hundred and fifty years.

To remove the cork, an incision is made from the top to the bottom of the tree, and a transverse circular incision at each extremity; the cork is then stripped off. To flatten it, a number of layers are piled up in a pit of water, and loaded with weights to keep them down. Subsequently they are dried, and in that state exported. Our supply is principally derived from Spain and Portugal. To close the transverse pores, cork is charred.

The physical properties of cork are too well known to need description. Its leading character is elasticity. In this respect it is similar to the wood of *Anona palustris*, called *cork wood*, and which is used in Jamaica by the country people, instead of corks, to stop up their jugs and calabashes.³ When thin slices of cork are examined by the microscope, they present a cellular appearance, the cells being four-cornered and tabular.

The most important chemical examinations of cork are those of Chevreul⁴ and Doepping.⁵ According to Chevreul, cork contains traces of a *volatile oil*, *wax* (cerin), *soft resin*, *red and yellow colouring principles*, *tannin*, a *nitrogenous brown substance*, *gallic acid*, *acetic acid*, *calcareous salts*, and *suberin*.

The substance to which the name of *suberin* has been given is the body which remains after cork has been successively treated with alcohol, ether, water, and diluted hydrochloric acid. In its form and physical characters it differs but little from ordinary cork. According to Doepping, it cannot be obtained pure, but always contains *cork cellulose* ($C^{24}H^{50}O^{20}$), some *cork wax* ($C^{25}H^{50}O^3$), and a small quantity of a *nitrogenous body*. He found it to consist of carbon 67.5, hydrogen 8.7, nitrogen 2.3, and oxygen 21.12. When cork is treated with nitric acid, the

¹ *Lond. and Edinb. Phil. Mag.* vol. xii. p. 53, 1835.

² See also Dutrochet, *Comptes Rendus*, t. iv. p. 48, Paris, 1838.

³ *The Civil and Natural History of Jamaica*, by P. Brown, M. D. p. 256, Lond. 1759.

⁴ *Ann. Chimie*, t. xvi. p. 155.

⁵ *Annalen d. Chem. u. Pharm.* Bd. xlv. S. 286, 1813; also *The Chemical Gazette*, July 1, 1843.

suberin yields suberic acid ($C^8H^6O^3$), which imparts a peculiar character to cork, and to all barks containing cork.¹

The uses of cork for making floats for fishermen's nets, anchor-buoys, stoppers to vessels (*obtumenta cadorum*), and women's winter shoes, are mentioned by Pliny. On account of the astringent matter which it contains, cork is an improper substance for closing vessels containing chalybeate liquids (especially such as are intended for analysis), as the iron is in part absorbed by the cork.

Cork was formerly employed in medicine. Reduced to powder, it was applied as a styptic: hung about the necks of nurses, it was thought to possess the power of stopping the secretion of milk; lastly, burnt cork, mixed with sugar of lead and lard, has been used as an application to piles.

2. CORTEX ALCORNOCÆ EUROPÆÆ; *European Alcornoque*² Bark; *Cork-Tree Bark*.—The bark of the cork oak, which I received from Spain under the name of *alcornoque bark*, bears considerable resemblance to oak bark, and was probably obtained from the younger branches of the cork-tree. It is ash-gray externally, and wrinkled or grooved internally. The bark imported from Italy, Spain, and Barbary, under the name of *cork tree bark*, and which is used by tanners, appears to be the inner bark of older stems. It consists apparently of the third and fourth layers above mentioned. It is in fibrous or stringy pieces, externally rusty red, internally deeply grooved or furrowed. It has very little odour, and an astringent taste. For tanning purposes the Italian bark is considered inferior to the Spanish and Barbary barks. In its medicinal properties, European alcornoque bark resembles oak bark. It owes its astringency to tannic acid. Its powder, in the dose of a drachm, has been used in hemorrhages and diarrhœa.³

3. CORTEX ALCORNOCÆ AMERICANÆ; *American Alcornoque Bark*.—This is the genuine alcornoque bark of French and German pharmacologists. The Spanish colonists have applied the name of alcornoque bark to one or more American barks which possess some real or fancied resemblance to the alcornoque bark of their mother-country. Humboldt⁴ says that the *Bowdichia virgiloides* (HBK.) is called by the inhabitants of the districts where it grows, in South America, the alcornoque. In another place,⁵ he states that the same name is given to a *Malpighia* (*Byrsonima*) on account of the suberous bark of the trunk. Nees von Esenbeck⁶ considered *Byrsonima crassifolia* (*Malpighia crassifolia*, Auct.) to be the source of the American alcornoque bark. The bark which comes from South America, and is considered to be genuine alcornoque bark, occurs in large, flat, occasionally arched pieces, having some resemblance to coarse, flat Cinchona bark. The epidermis is usually wanting. Externally the bark is reddish, or dark cinnamon brown; internally it is pale. The taste is slightly bitter. It has been repeatedly subjected to analysis. Biltz⁷ gives as the constituents—*peculiar crystalline matter* (al-kornin), 1.15; *matter soluble in alcohol, not in ether* (oxydized tannin?), 1.67; *tannin* with a lime salt, 14.27; *gummy extractive with starch, a nitrogenous substance, and a supersalt of lime*, 33.74; *woody fibre and loss*, 47.71; *ashes of the woody fibre*, 1.46=100.0.

American alcornoque bark possesses astringent properties. It was introduced into European practice, in 1811, as a remedy for phthisis, but, after a short trial, it soon fell into disuse; and there are no grounds for supposing that it has any curative powers whatever in this disease.—Dose, in powder, ℥j to ʒj. It may also be used in the form of infusion or decoction (prepared with ʒss of bark and ℥ʒ viij of water), in doses of ℥ʒj or ℥ʒij. The dose of the extract is from gr. x. to ʒj.⁸

ORDER XXVII. ULMACEÆ, *Mirbel.*—ELMWORTS.

CHARACTERS.—Flowers hermaphrodite or by abortion unisexual, in loose clusters, never in catkins. *Calyx* membranous, imbricated, campanulate, inferior, irregular. *Petals* 0. *Stamens* definite; inserted into the base of the calyx; erect in æstivation. *Ovary* superior, 1- or 2-celled; *ovules* solitary; pendulous; *stigmas* 2, distinct. *Fruit* 1- or 2-celled, indehiscent, membranous, or drupaceous. *Seed* solitary, pendulous; *albumen* none, or in very small quantity; *embryo* straight or curved, with foliaceous cotyledons; *radicle* superior.—*Trees or shrubs*, with rough, alternate, deciduous leaves, and stipules.

PROPERTIES.—The plants of this order bear some analogy to those of Cupuliferæ, in their chemical and medicinal properties. Their bark contains tannic acid; combined, however, with mucilaginous and bitter matters. Hence it is reputed astringent and tonic.

¹ Mulder, *The Chemistry of Vegetable and Animal Physiology*, p. 478, 1849.

² *Alcornoque* is the Spanish name for the cork-oak. It is of Arabic origin, being derived from *dorque*, signifying "denuded or badly clothed," adding the article *al*, changing *d* into *c*, and introducing the syllable *no* into the middle of the word. (*Diccionario de la Lengua Castellana, compuesto por la Real Academia Espanola*, 1726-39.)

⁸ For further details respecting alcornoque bark, the reader is referred to a paper by the author in the *Pharmaceutical Journal*, vol. vi. p. 362, 1817.

Dr. M'Dowall, of Virginia, has proposed the bark of *Ulmus fulva* for bougies, tents, catheters, &c.¹

113. ULMUS CAMPESTRIS, Linn.—THE COMMON SMALL-LEAVED ELM.

Sex. Syst. Pentandria, Digynia.

(Cortex interior, L.)

HISTORY.—Dioscorides² speaks of the astringent property of the bark of the elm (*πτελέια*), as does also Pliny.³

BOTANY. Gen. Char.—*Flowers* hermaphrodite. *Calyx* campanulate, 4- to 5-toothed, coloured, persistent. *Stamens* 3 to 6. *Ovary* compressed. *Stigmas* 2. *Fruit* (a samara) suborbicular, with a broad membranous margin (*Bot. Gall.*).

Sp. Char.—*Leaves* doubly serrated, rough. *Flowers* nearly sessile, 4-cleft. *Fruit* oblong, deeply cloven, naked (Sir J. E. Smith).

A large tree, with rugged bark. By the latter character it is readily distinguished from *Ulmus glabra*, which has a smooth, dark, lead-coloured bark.

Hab.—Southern parts of England. Flowers in March or April.

DESCRIPTION.—The officinal part of the elm is the inner cortical portion, or *liber*. To obtain it, the bark should be separated from the tree in spring; and, after the epidermis and a portion of the external cortex have been removed, the *liber* should be quickly dried.

As met with in the shops, the *inner elm bark* (*cortex ulmi*) consists of thin tough pieces, which are inodorous, and have a brownish-yellow colour, and a mucilaginous, bitter, very slightly astringent taste.

COMPOSITION.—According to Rink,⁴ 100 parts of elm bark contain—*resin* 0.63, *gum* and *mucus* 20.3, *impure gallic acid* (tannin?) 6.5, *oxalate of lime* 6.3 (?), *chloride of sodium* (?) 4.6.

1. TANNIC ACID.—Davy⁵ states that 480 grs. of elm bark yielded 13 grs. of tannin.

2. ULMIC ACID; *Ulmia*.—On many trees, especially the elm, there is not unfrequently observed a substance which was supposed to be a morbid production. When dried, it consists of a mucilaginous matter, and carbonate or acetate of potash. By the combined agency of the air and the carbonate, the organic matter is altered in its properties, and is converted into a brown substance, which combines with the potash. This brown matter has been termed *ulmia*, or *ulmic acid*. It may be formed, artificially, by a variety of processes; as by heating a mixture of wood and potash, by the action of sulphuric acid on vegetable matters, and by other methods.

CHEMICAL CHARACTERISTICS.—Infusion of elm bark becomes green (*tannate of iron*) on the addition of a salt of the sesquioxide of iron, and forms a precipitate (*tannate of gelatin*) with a solution of gelatin.

PHYSIOLOGICAL EFFECTS.—The effects of elm bark are those of a mild astringent tonic, containing a considerable quantity of mucilage, which gives it a demulcent property. Hence, in the classification of Richter,⁶ it is arranged as a *mucilaginous astringent*. The decoction, taken in full doses, accelerates the pulse and acts as a diaphoretic and diuretic.

USES.—Lysons⁷ recommended the decoction of this bark in cutaneous eruptions, and Dr. Lettsom⁸ found it successful in ichthyosis. It has now fallen almost into disuse. It has been employed as a cheap substitute for sarsaparilla.⁹

ADMINISTRATION.—Used only in the form of decoction.

DECOCTUM ULMI, L.; *Decoction of Elm Bark*.—(Fresh Elm Bark, bruised, ʒijss; Distilled Water Oij. Boil down to a pint, and strain.)—Formerly given in skin diseases; now fallen into disuse. Dose, fʒiv to fʒvj three or four times a day.

[ULMUS FULVA, Mich.—SLIPPERY ELM.

(Slippery Elm Bark, U. S.)

Sp. Char.—*Leaves* very scabrous above, rather unequal, and somewhat cordate at base. *Buds* clothed with a fulvous tomentum. *Flowers* in dense sub-sessile fascicles. *Samara* orbicular, naked on the margin. (*Beck. Bot.*)

This tree is sometimes called also Red Elm. It is from 20 to 40 feet high, with rugate branches. The leaves are from 4 to 6 inches long, and 2 or 3 inches broad, lanceolate oval, or obovate oblong, conspicuously acuminate, doubly serrate, the upper surface scabrous, beneath tomentose pubescent, especially along the nerves and midrib, petioles about one-third of an inch long, pubescent. *Stipules* pilose. *Flowers* on short pedicels, numerous, in dense lateral clusters. *Calyx* about 7 cleft; segments obtuse, clothed and ciliate, with a reddish tawny pubescence. *Stamens* often 7, much exerted; anthers dark-purple. *Styles* granular pubescent, purple. *Samara* orbicular, about half an inch in diameter, radiately veined, pubescent in the centre, on a slender pedicel as long as the calyx; margin smooth, cleft at apex between the styles; segments acuminate by the pubescent adnate styles, and so incurved and over-lapped as to give the margin the appearance of being entire at apex. (*Darlington.*)

This plant is common in the United States, growing in low grounds and along fences.

The inner bark is fibrous, and is removed from the trunk and large branches of the tree in long pieces. It is found in the shops in this form or ground into powder. It is bland and demulcent, and is used as a substitute for flaxseed and other demulcent articles. From the powder can be made an excellent poultice by mixing with the requisite quantity of hot water.

INFUSUM ULMI, U. S.; *Infusion of Slippery Elm Bark.*—Made by macerating an ounce of Slippery Elm Bark in a pint of boiling water. Used for the ordinary purposes of a demulcent solution.

ORDER XXVIII. URTICACÆ, *Endl.*—NETTLEWORTS.URTICÆ, *Jussieu.*

CHARACTERS.—*Flowers* herbaceous, inconspicuous, polygamous. *Calyx* membranous, lobed, persistent. *Stamens* definite, distinct, inserted in the base of the calyx, and opposite its lobes. *Ovary* superior, simple. *Ovule* solitary, erect. *Fruit* a simple, indehiscent nut, naked or surrounded by the persistent calyx. *Embryo* straight, with fleshy albumen; cotyledons flat; radicle superior.—*Trees, shrubs, or herbs.* *Leaves* frequently covered with asperities or stinging hairs. *Stipules* mostly persistent, rarely deciduous or absent.

PROPERTIES.—The order is now very circumscribed; and contains but few properties interesting to the physician. The most remarkable property of the order is the acridity (sometimes very extreme) of the liquid contained in the epidermoid gland at the base of the stinging hair. *Endlicher*¹ says that it is bicarbonate of ammonia; but this is an obvious error, as ammonia, in any known form, is incompetent to produce the violent effect ascribed to some of the East Indian Urticacæ.

Urtication, or flagellation by a bunch of nettles (*Urtica dioica*), is an old method of treating palsy².

114. *Parietaria officinalis*, *Lin.*—Common Wall-Pellitory.*Sex. Syst.* Tetrandria, Monogynia.

(II. rba.)

This is a common indigenous plant, which was formerly in great repute as a diuretic and lithonriptic. By some practitioners it is still highly esteemed. It is used in calculous and other urinary affections, and also in dropsies. The *expressed juice* may be taken in doses of one or two fluidounces. Or the *decortion* (prepared by boiling ℥j of the herb in a pint of water) may be substituted. The *extract* has also been used. On account of a nitrate which the plant contains, the extract is said to have taken fire in making it.³

¹ *Enchiridion Botanicum.*² *Withering, Arrangement of British Plants*, 7th edit. vol. ii. p. 237.³ *Celsus*, lib. iii. cap. 27.

ORDER XXIX. CANNABINACEÆ, *Lindl.*—HEMPWORTS.CANNABINEÆ, *Endl.*

CHARACTERS—*Flowers* diœcious. **MALES:** in racemes or panicles. *Calyx* herbaceous, singly, imbricated. *Stamens* 5, opposite the sepals; *filaments* filiform; *anthers* terminal, 2-celled, opening longitudinally. **FEMALES:** in spikes or cones. *Sepal* 1, enwrapping the ovary. *Ovary* free, 1-celled. *Ovule* solitary, pendulous. *Stigmas* 2, subulate. *Fruit* 1-celled, indehiscent. *Embryo* without albumen, hooked, or spirally coiled, radicle superior, lying against the back of the cotyledon.

PROPERTIES.—There are only two species in this family, and each of these will be separately noticed. One of these (*Cannabis sativa*) is remarkable for the tenacity of its fibre, and the narcotic intoxicating quality of its juices: the other (*Humulus Lupulus*), for its bitter principle, and its fragrant oil, whose vapor is soporific.

115. CANNABIS SATIVA.—COMMON HEMP.

Sex. Syst. Diœcia, Pentandria.

(Herba et Resina. The Extract, D.)

HISTORY.—This plant was well known to the ancient Greeks and Romans, but they do not appear to have been acquainted with its narcotic properties. Dioscorides¹ merely mentions that the expressed juice of the seeds of *κάνναβις* allays earache, and the same statement is made by Galen.² Herodotus³ mentions it, and states that the Scythians cultivated it and made themselves garments of it. He also adds that they threw the seeds on red-hot stones, and used the perfumed vapour thereby obtained as a bath, which excited from them cries of exultation. This I presume refers to the intoxicating properties of its smoke. The hemp may have been, as Dr. Royle⁴ suggests, the “assuager of grief” or the *nepenthes* (*νῆπι-θίς*) of which Homer⁵ speaks as having been given by Helen to Telemachus in the house of Menelaus. Helen is stated to have received the plant from a woman of Egyptian Thebes. It is known in India, as the “increaser of pleasure,” the “exciter of desire,” the “cement of friendship,” the “causer of a reeling gait,” the “laughter mover,” &c.⁶

Pliny⁷ mentions it under the name of *Cannabis*.

BOTANY. Gen. Char.—*Flowers* diœcious. **MALES:** *Flowers* racemose. *Calyx* 5-parted, imbricated. *Stamens* 5. **FEMALES:** *Flowers* in spikes. *Calyx* (bract?) 1-leaved, acuminate, rolled round the ovary. *Ovary* roundish. *Style* short. *Stigmas* 2, filiform, pubescent. *Fruit* 1-celled, 2-valved.

Sp. Char.—The only species.

Annual. Stem 3 to 5 or 6 feet high, erect, branched, angular. Leaves on long weak petioles, digitate, serrated, roughish. Stipules subulate. Flowers in clusters, axillary. The whole plant has a clammy feel.

CANNABIS SATIVA, VAR. INDICA; Indian Hemp.—The plant which grows in India, and has been described by some botanists⁸ under the name of *Cannabis indica* or *Indian Hemp*,⁹ does not appear to possess any specific differences from the common hemp. Roxburgh¹⁰ and most other distinguished botanists have accordingly considered it identical with the *Cannabis sativa* of

¹ Lib. iii. cap. 165. The *κάνναβις ἀγρία* of this author (lib. iii. cap. 166) is the *Althœa canabina* of modern botanists.

⁷ *Hist. Nat.* lib. xix. cap. 56; and lib. xx. cap. 97.

⁸ Rumphius, *Herbarium Amboinense*, vol. v. t. 77.

⁹ In the United States of America, the denomination of *Indian hemp* is applied, both in the Pharmacopœia and Dispensatory, to the *Apocynum cannabinum*; and it has been imported and sold in London for the real Indian hemp (*Cannabis sativa*, var. *Indica*), according to the statement of Dr. Fred. J. Farre (*Lond. Med. Gaz.* May 5, 1843, p. 209).

¹⁰ *Flora Indica*, vol. iii. p. 772.

Linnaeus and Willdenow. *C. indica* branches from the ground up to within two feet of the top; whereas common hemp grows three or four feet before it branches. The fruit also of *C. indica* is smaller and rounder. I have carefully compared *C. indica* (both that grown in the Chelsea Garden and that contained in Dr. Wallich's Herbarium in the possession of the Linnean Society) with the *C. sativa* in Linnaeus's collection, and I cannot discover any essential distinction between them. The male plant appears to me to be in every respect the same.¹ In the female plants, the flowers of *C. indica* were more crowded than those of common hemp.

Hab.—Persia, Caucæus, hills in the north of India. Cultivated in various other countries.

DESCRIPTION.—The parts employed in Asia for the purposes of intoxication, and in Europe for medicine, are the herb (leaves) and the resin.

1. *Herba Cannabis sativæ*.—This is used in India in two forms; one called *gunjah*, the other *bang*. The *hashish* of the Arabs differs somewhat from *gunjah*.

a. *Gunjah*.—This is the dried hemp plant which has flowered, and from which the resin has not been removed. It is sold in the Calcutta bazaars, for smoking chiefly, in bundles of about two feet long and three inches in diameter, each containing twenty-four plants. That which I have received from Dr. O'Shaughnessy, and also found in commerce, consists of cylindrical or fusiform masses (about the size and shape of the fingers) of a grayish or greenish-brown colour, and composed of stems, leaves, and petioles pressed together. It has a faint odour and feeble bitterish taste. In commerce it is known by the name of *quaza* or *quazah*.

β. *Bang*, *Subjee*, or *Sülhee*.—This consists of the larger leaves and capsules without the stalks. I have not met with this in commerce.

γ. *Hâshîsh* or *Hashish*.—This, according to Steeze,² consists of the tops and tender parts of the plant collected after inflorescence.

2. *Resina Cannabis sativæ*.—The concreted resinous exudation from the leaves, slender stems, and flowers, is called *Churrus*. The mode of collecting it is somewhat analogous to that adopted in Crete for the collection of ladanum. In "Central India and the Saugor territory, and in Nipal, Churrus is collected during the hot season in the following singular manner: Men clad in leathern dresses run through the hemp fields, brushing through the plant with all possible violence; the soft resin adheres to the leather, and is subsequently scraped off and kneaded into balls, which sell from five to six rupees the seer. A still finer kind—the *Momeca* or *waxen Churrus*—is collected by the hand in Nipal, and sells for nearly double the price of the ordinary kind. In Nipal, Dr. M'Kinnon informs me, the leathern attire is dispensed with, and the resin is gathered on the skin of the naked coolies. In Persia, it is stated by Mirza Abdul Razes that the Churrus is prepared by pressing the resinous plant on coarse cloths, and then scraping it from these and melting it in a pot with a little warm water. He considers the Churrus of Herat as the best and most powerful of all the varieties of the drug."³ I have a specimen of spurious Churrus.

Churrus, such as I have received it from Dr. O'Shaughnessy, is in masses having the shape and size of a hen's egg, or of a small lemon, and formed by the adhesion of superimposed elongated pieces. It has a dull grayish-brown colour, and not much odour. It consists of resinous and various foreign matters (fragments of flowers, leaves, seeds, &c.)

3. *Fructus Cannabis sativæ*.—The fruits, called usually *hempseed* (*semen can-*

Fig. 287.

*Cannabis sativa.*

¹ This agrees with a remark in the *Hortus Cliffortianus*: "Quod mas in Horto Malabarico exhibitus nostru sit planta nullum dubium detur; femina autem pirum recedit foliis ternatis, tamen et ejusmodi plantas in sole inero apud nos observamus non infrequenter."

² *Pharmaceutical Journal*, vol. v. p. 83, 1815.

³ O'Shaughnessy, *op. supra cit.* p. 6.

nabis), are small, ash-coloured, shining, nut-like or seed-like bodies. They are demulcent and oleaginous, but not narcotic. They are employed for feeding cage-birds. They are said by Burnett¹ to possess the singular property of changing the colour of the plumage of bullfinches and goldfinches from red and yellow to black, if the birds are fed on the seeds for too long a time or in too large a quantity (?).

COMPOSITION.—The leaves of common hemp have been submitted to analysis by Tscheppe,² by Schlesinger,³ and by Bohlig.⁴ The results of the two former of these are as follows:—

TSCHEEPE.		SCHLESINGER.	
Chlorophylle.	} Green fecula.	Bitter matter	1.95
Gluten.		Chlorophylle soluble in ether	4.75
Phosphate of Lime.		Chlorophylle soluble in alcohol	9.375
Brown extractive.		Green resinous extractive	5.0
Sweetish bitter extractive.		Colouring matter	10.15
Brown gum.		Gummy extract	19.15
Lignin.		Malate of lime with extractive	6.775
Soluble albumen.		Extractive	6.875
Salts of ammonia, potash, lime, and magnesia.		Vegetable albumen	8.0
Alumina.		Lime, magnesia, and iron	9.5
Silica.		Lignin	12.0
		Loss	6.875
Leaves of <i>Cannabis sativa</i> .		Leaves dried at 200° F	100.000

Bohlig found a great agreement between the constituents of common hemp and those of the stinging nettle (*Urtica dioica*).

Dr. Kane⁵ has made an ultimate analysis of the leaves and herb of hemp as well as of their ashes; but the results have no medical interest.

Hempseeds have been analyzed by Bueholz,⁶ who obtained—fixed oil 19.1, resin 1.6, sugar with extractive 1.6, gummy extract 9.0, soluble albumen 24.7, woody fibre 5.0, husk 38.3, loss 0.7=100.0.

1. VOLATILE OIL OF HEMP.—This has hitherto been procured in such small quantities that its properties are but imperfectly known. When the dried plant is distilled with a large quantity of water, traces of the oil pass over, and the distilled liquor has the odour of the plant.

2. CANNABIN; Resin of Hemp.—This appears to be the active principle of hemp. It is a soft, neutral resin, soluble in alcohol and in ether, and separable, by the addition of water, from its alcoholic solution, in the form of a white precipitate. It has a warm, bitterish, acrid, somewhat balsamic taste, and a fragrant odour, especially when heated. Messrs. T. and H. Smith⁷ say that it very much resembles jalap resin or jalapine, except in remaining soft even after continued drying, and in its odour and taste.

3. FIXED OIL OF HEMPSEED; Hempseed Oil; *Oleum Cannabis*.—This is a drying oil obtained in Russia, by expression, from hempseeds, which yield about 25 per cent. of it. At first it is greenish-yellow, subsequently yellow. It has an acrid odour, but a mild taste. Its sp. gr. is 0.9276 at 52°. It dissolves readily in boiling alcohol, in 30 parts of cold alcohol. At -17° F. it freezes. It is used in the preparation of a soft soap, in paint, and in lamps for the purpose of illumination; but it is apt to clog the wick by the formation of a viscid adherent varnish. When boiled it makes a good varnish.

PHYSIOLOGICAL EFFECTS.—A general statement of the effects of Indian hemp has already been made (see *ante*, p. 236). Its action as a neurotic is essentially that of a cerebro-spinal (see *ante*, p. 235). It operates as a *phrenic*: in moderate doses producing exhilaration, inebriation with phantasms, and more or less confusion of intellect, followed by sleep; in large doses causing stupor. Hence it may be called an exhilarant, inebriant, phantasmatic, hypnotic or soporific, and stupefacient or narcotic.

On Orientals, the inebriation or delirium produced by it is usually of an agreeable or cheerful character, exciting the individual to laugh, dance, and sing, and to commit various extravagancies—acting as an aphrodisiac, and augmenting the appetite for food. In some, it occasions a kind of reverie. It renders others excitable and quarrelsome, and disposes to acts of violence.⁸

⁴ Quoted by L. Gmelin, *Handb. de Chemie*.

⁵ It has been stated that the men who attempted the assassination of Lord Cornwallis in India were

⁶ Gmelin, *Hand. de Chemie*, Bd. ii. S. 1324.

⁷ *Ibid.* S. 519.

⁸ *Pharmaceutical Journal*, vol. vi. p. 127, 1846.

⁸ It has been stated that the men who attempted the assassination of Lord Cornwallis in India were intoxicated by Indian hemp (Thornton, *History of the British Empire in India*, vol. ii. p. 486, 1848.)

The singular form of insanity said to be brought on by it has already (see vol. i. p. 237) been noticed.

It acts as an *anæsthetic* (see vol. i. p. 238). It relieves pain, and is, therefore, employed as an *anodyne* or *paregoric*. Moreover, Mr. Donovan¹ found that under its influence his sense of touch and feeling gradually became obtuse, until at length he lost all feeling unless he pinched himself severely; and Dr. Christison² states he felt a pleasant numbness of his limbs after its use.

Its influence as a *cinetic* (see vol. i. p. 240) or agent affecting the action of the muscles, is remarkable. It relieves spasm, and is, therefore, frequently used as an *antispasmodic*. On Orientals large doses produce a cataleptic condition (in which the muscles are moderately contracted, but flexible and pliant, and the limbs retain any position or attitude in which they may be placed).

The following illustrative cases are taken from Dr. O'Shaughnessy's paper on Indian hemp:—

At two P. M. a grain of the resin of hemp was given to a rheumatic patient. At four P. M. he was very talkative, sang, called loudly for an extra supply of food, and declared himself in perfect health. At six P. M. he was asleep. At eight P. M. he was found insensible, but breathing with perfect regularity, his pulse and skin natural, and the pupils freely contractile on the approach of light. Happening by chance to lift up the patient's arm, the "professional reader will judge of my astonishment," observes Dr. O'Shaughnessy, "when I found that it remained in the posture in which I placed it. It required but a very brief examination of the limbs to find that the patient had by the influence of this narcotic been thrown into that strange and most extraordinary of all nervous conditions, into that state which so few have seen, and the existence of which so many still discredit—the genuine *cataplexy* of the nosologist. We raised him to a sitting posture, and placed his arms and limbs in every imaginable attitude. A waxen figure could not be more pliant or more stationary in each position, no matter how contrary to the natural influence of gravity on the part. To all impressions he was meanwhile almost insensible." He continued in this state till one A. M., when consciousness and voluntary motion quickly returned.

Another patient who had taken the same dose fell asleep, but was aroused by the noise in the ward. He seemed vastly amused at the strange aspects of the statue-like attitudes in which the first patient had been placed. "On a sudden he uttered a loud peal of laughter, and exclaimed that four spirits were springing with his bed into the air. In vain we attempted to pacify him; his laughter became momentarily more and more uncontrollable. We now observed that the limbs were rather rigid, and in a few minutes more his arms and legs could be bent, and would remain in any desired position. He was moved to a separate room, where he soon became tranquil, his limbs in less than an hour gained their natural condition, and in two hours he expressed himself perfectly well and excessively hungry."

On Europeans I have never heard of a cataleptic state being produced by this drug. In a case of tetanus under my care in the London Hospital, and which was carefully watched by Dr. O'Shaughnessy and myself, the resinous extract of Indian Hemp was given in increasing doses up to twenty grains. It caused stupor and cessation of spasms; but no perfect cataleptic state. The only tendency to this condition which was observed was when the arm of the patient was lifted and then cautiously let go: it fell slowly and gradually, not quickly, as it would have done under ordinary conditions: the patient was at this time quite insensible.

By internal use it acts as a *mydriatic* (see vol. i. p. 246), causing preternatural dilatation of the pupil. But Dr. Lawrie³ states that when applied around the eye it does not cause dilatation of the pupil.

Indian hemp does not appear much to affect the secretions. It neither excites nausea nor lessens the appetite. It neither causes dryness of the tongue nor constipation of the bowels. It does not appear to check or otherwise affect the bronchial secretions. I am disposed to think that it is somewhat sudorific. Drs. Ballard and Garrod⁴ state that in large doses it communicates an odour to the urine like that evolved when the tincture is mixed with water, and in part like that of the Tonquin bean.

Compared with opium, Indian hemp differs in its operation on the system in several remarkable circumstances: as by its inebriating, phantasmatic, and aphrodisiac effects; by its causing catalepsy and dilatation of pupil; and by its not

¹ *Dublin Journal of Medical Science*, Jan. 1845.

⁴ *Elements of Materia Medica*.

³ *Dispensatory*

causing nausea, loss of appetite, dry tongue, constipation, or diminution of the secretions.

Dr. Hooke, in his account of Indian hemp (Bangué) read to the Royal Society, Dec. 18, 1689, notices the various odd tricks shown by persons while in the ecstasy caused by this plant; and adds that, when this condition subsides, the patient finds himself mightily refreshed and exceedingly hungry.

The general effects of Indian hemp on man, as stated by Dr. O'Shaughnessy, from his own observations, are alleviation of pain (mostly), remarkable increase of appetite, unequivocal apirodisia, and great mental cheerfulness. Its more violent effects were delirium of a peculiar kind, and a cataleptic state.

Its effects on animals were analogous: he gave ten grains of Nipalese Churrus dissolved in spirit to a middling-sized dog: "In half an hour he became stupid and sleepy, dozing at intervals, starting up, wagging his tail as if extremely contented; he ate some food greedily, on being called to he staggered to and fro, and his face assumed a look of utter and helpless drunkenness. These symptoms lasted about two hours, and then gradually passed away; in six hours he was perfectly well and lively."

It would appear that Indian hemp acts more powerfully in India than in Europe. My experiments (detailed in the 2d edition of this work, pp. 1097-8) fully bear out this statement. Dr. O'Shaughnessy, when in England, satisfied himself of the difference of the effect of Indian hemp in this country and in Bengal; and he observes,¹ that while in India he had seen marked effects from half a grain of the extract, or even less, and had been accustomed to consider one grain and a half a large dose, in England he had given ten or twelve or more grains to produce the desired effect.

USES.—Indian hemp is chiefly employed as a medicine, for its hypnotic, anodyne, and antispasmodic properties; occasionally, also, for its mental influence (*i. e.* as a phrenic and nervine). Compared with opium, it is less certain than the latter agent; over which, however, it has several advantages. Thus it does not constipate the bowels, lessen the appetite or create nausea, produce dryness of the tongue, or check the pulmonary secretion, as opium is well known to do. Moreover, in some patients in whom opium causes headache, and various distressing feelings, Indian hemp occasionally acts without any of these inconveniences; but I have heard others object to its continuance on the ground of its very unpleasant effects.

As a *hypnotic*, I have used it with advantage in spirit-drinkers, and have succeeded in one or two cases in producing sleep with it where large doses of morphia had failed. In some hysterical patients, and in cases of chorea, I have occasionally employed it to induce sleep, where the use of opium was from some cause objectionable. Dr. Clendinning² speaks favourably of its soporific influence in pulmonary affections and low fever. It has the great advantage over opium of neither repressing the secretions nor lessening the appetite for food.

As an *anodyne*, it is, I think, in general, decidedly inferior to opium; but there are occasions where its use is to be preferred to the latter agent. In acute and subacute rheumatism, in gout, and in neuralgia, it frequently alleviates the pain.

As an *antispasmodic*, it has been employed in tetanus, hydrophobia, malignant cholera, chorea, and infantile convulsions. In the cases of tetanus (both traumatic and idiopathic) and of hydrophobia which I have seen treated with it, it completely failed to give permanent relief. In one case of traumatic tetanus, it alleviated the pain and spasms, but the patient notwithstanding died. In a case under the care of Professor Miller,³ it was given, and the patient recovered. It has failed, however, in the hands of Mr. Potter⁴ and others. And in a case of idiopathic tetanus in Guy's Hospital, under the care of Dr. Babington,⁵ it proved useless. In chorea, I have found it serviceable, sometimes as an antispasmodic, at others as a hypnotic; and the same may be said of its use in hysteria.

As a *phrenic* or medicinal agent affecting the mental functions, Indian hemp has also been employed. Dr. Clendinning speaks favourably of its use as a nervine stimulant, in removing languor and anxiety, and raising the pulse and spirits; and

Dr. Conolly thinks that it may be useful in some chronic forms of mania.¹ Dr. Sutherland has not obtained any good effect from it.²

ADMINISTRATION.—In England, Indian hemp is usually administered in the form of resinous or alcoholic extract and of tincture.

1. *EXTRACTUM CANNABIS INDICÆ ALCOHOLICUM*; *Resinous or Alcoholic Extract of Indian Hemp*.—This is the preparation usually sold in the shops under the name of *resin of Indian hemp* or *cannabin* (see *ante*, p. 336). Dr. O'Shaughnessy directs it to be prepared by boiling the rich adhesive tops of the dried gunjah in rectified spirits until all the resin is dissolved. "The tincture thus obtained is evaporated to dryness in a vessel placed over a pot of boiling water. The extract softens at a gentle heat, and can be made into pills without any addition." Mr. Robertson,³ of Calcutta, prepared it by a kind of percolation process; the vapour of alcohol being transmitted through the dry herb. At first a thin tarry matter containing much resin, latterly a brown liquor containing little resin but much extractive passed over. At this point, water was substituted for the spirit in the still, and as much as possible of the spirit retained by the plant thus expelled from it. Part of the alcohol was removed from the fluid by distillation; but the rest was dissipated by evaporation at a temperature not exceeding 150° F. From 1 cwt. of the plant about 8 lbs. of extract were obtained at one operation, which was so slowly conducted as in all its stages to last a fortnight.

The following is the process given by the Messrs. Smith, of Edinburgh,⁴ for the preparation of this extract: Digest bruised gunjah in successive quantities of warm water till the expressed water comes away colourless; and again for two days, at a moderate heat, in a solution of carbonate of soda, in the proportion of one part of the salt to two of gunjah. Colouring matter, chlorophylle, and inert concrete oil being thus removed, express and wash the residuum, dry it, and exhaust it by percolation with rectified spirit. Agitate with the tincture, milk of lime containing an ounce of lime for every pound of gunjah, and, after filtration, throw down the excess of lime by a little sulphuric acid. Agitate with the filtered liquor a little animal charcoal, which is afterwards to be removed by filtration. Distil off most of the spirit, add to the residual tincture twice its weight of water in a porcelain basin, and let the remaining spirit evaporate gradually. Lastly, wash the resin with fresh water till it comes away neither acid nor bitter, and dry the resin in thin layers. This resin contains the peculiar taste and odour of the gunjah. A temperature of 180° F. acting for eight hours on thin layers of it exposed to the air does not impair its activity. 100 lbs. of dry gunjah yield about 6 or 7 lbs. of this extract.

The *Dublin College* directs the *Extractum Cannabis Indicæ purificatum* to be prepared as follows:—

Take of Extract of Indian Hemp of Commerce $\overline{3}$ j; Rectified Spirit \overline{f} iv. Dissolve the extract in the spirit, and when the dregs have subsided, decant the clear liquid, and evaporate, by means of a water-bath, to the consistence of a soft extract.

The dose of the alcoholic extract of Indian hemp is usually from gr. j to grs. v. I have usually found one grain of the extract kept in the London shops to act as a narcotic. The Messrs. Smith state that two-thirds of a grain of the pure resin produced on themselves and others powerful narcotic effects. In a case of tetanus under my care in the London Hospital, the dose of the extract (supplied by Dr. O'Shaughnessy, who watched the case with me) was gradually increased to grs. xx. It may

⁴ *Ibid.* p. 171, 1846

be administered in the form of pill; or better by diffusion through an emulsion (prepared by rubbing the extract with olive oil, in a warm mortar, and gradually adding mucilage, and afterwards water), or by solution in rectified spirit, and dropping the tincture into water immediately before its administration.

2. **TINCTURA CANNABIS INDICÆ, D.;** *Tincture of Indian Hemp.*—(Purified Extract of Indian Hemp $\bar{3}$ ss; Rectified Spirit Oss. Dissolve the extract in the spirit, D.)—These are the proportions directed to be used by Dr. O'Shaughnessy; but, probably by a typographical error, he has ordered *proof* spirit instead of rectified spirit. Dose from η x to $f\bar{3}j$. Dr. O'Shaughnessy gives in tetanus $\bar{3}j$ every half hour, until the paroxysms cease, or catalepsy is induced; in cholera, ten drops every half hour. It may be administered in an emulsion or mucilaginous mixture, or in water sweetened with sugar. It should be swallowed soon after it has been added to the aqueous liquid, as the resin precipitates, and is apt to adhere to the side of the vessel.

OTHER PREPARATIONS OF INDIAN HEMP.—By the Asiatics, Egyptians, and others who employ Indian hemp for the purposes of intoxication, various preparations of this drug are in use. In some of these the plant itself is employed, either rubbed up with water and made into a draught or formed into an electuary. But a favourite mode of using it is to extract the active principle by some fatty matter (generally butter or oil), by which an oleaginous solution or fatty extract is obtained. For this purpose the hemp is boiled in butter or oil, with a little water, usually until the water is boiled away. It is said that the fatty extract thus obtained will preserve its intoxicating powers for years. It is usually mixed up with other ingredients, and taken in the form of an electuary, confection, or paste. The *majoon* used at Calcutta,¹ the *mpouchari* employed at Cairo,² and the *dawamesc* of the Arabs,³ are preparations of this kind. Lastly, hemp is also used for smoking in pipes.

ANTIDOTES.—In a case of poisoning by Indian hemp the treatment should be the same as that for poisoning by opium (which see).

116. HUMULUS LUPULUS, Linn.—THE COMMON HOP.

Sex. Syst. Diœcia, Pentandria.

(Amentum, L.—Catkin, E.—The dried strobiles. Lupulina; the yellow powder separated from the strobiles by rubbing and sifting, D.)

HISTORY.—This plant is probably the *Lupus salictarius* of Pliny.⁴ Its culture was introduced into this country from Flanders, in the reign of Henry VIII.⁵

BOTANY. Gen. Char.—*Diœcious.* MALES:—*Calyx* 5-partite. *Stamens* 5. FEMALES:—*Strobiles* consisting of large, persistent, concave scales [bracts], having a single flower in the axilla of each. *Ovary* 1. *Styles* 2. *Seed* 1, with an arillus. *Embryo* spirally contorted (*Bot. Gall.*).

Sp. Char.—The only species.

Perennial. *Stems* annual, long, weak, and climbing, scabrous. *Leaves* petiolate, 3- to 5-lobed, serrated, veiny, rough. *Flowers* greenish yellow.

Hab.—Thickets and hedges in many parts of Europe. Indigenous [?]. Flowers in July.

CULTIVATION.—The female plant is cultivated in several counties in England, especially Kent, Sussex, Surrey, Worcestershire, and Herefordshire. The third year after planting it generally comes into full bearing. *Stacking* or *setting the poles* is performed in April or May. The *gathering* or *picking* takes place in September. The cones are dried in kilns, and are then packed in hempen sacks, called *bags* or *pockets*. This operation is called *bagging*.⁶

DESCRIPTION.—The aggregate fruits of the *Humulus Lupulus* are strobiles or catkins (*strobili* seu *amenta lupuli*), in commerce termed *hops*. They consist of scales, nuts, and lupulinic glands or grains. The *scales* are the enlarged and persistent bracts, which enclose the nuts: they are ovate, membranous, and at their

base glandular. The *nuts* (achenia) are small, hard, nearly globular, and covered with aromatic, superficial, globose glands. The *lupulinic glands* or *grains* (commonly termed *yellow powder* or *lupulin*) are the most important parts of the strobiles. By thrashing, rubbing, and sifting, Dr. Ives¹ procured 14 ounces from six pounds of hops; and he therefore concluded that dry hops would yield about a sixth part of their weight of these grains. They are usually intermixed with sand. They are rounded, of a cellular texture, golden yellow, and somewhat transparent. They are sessile, or nearly so. The common centre, around which the cells are arranged, has been called the *hilum*. By drying they lose

their spherical form. Placed in water they give out an immense number of minute globules. Under other circumstances they become ruptured, and allow an inner envelop to escape. According to Turpin,² they consist of *two vesicles*, one enclosing the other. The inner one contains *globules, an aromatic oil, and a gas*. He also states that, in the bubbles of the disengaged gas, an immense number of crystals are formed.

COMPOSITION.—Payen, Chevallier, and Pelletan³ analyzed the scales and lupulinic grains. Dr. Ives⁴ also examined the latter.

⁴ *Journal of Science*, vol. xi. p. 205.

1. **VOLATILE OIL OF HOPS.**—Resides in the lupulinic grains. Obtained by submitting these, or hops which contain them, to distillation with water. Its colour is yellowish, its odour that of hops, its taste acrid. It is soluble in water, but still more so in alcohol and ether. Its sp. gr. is 0.910. By keeping, it becomes resinified. It is said to act on the system as a narcotic. The water which comes over, in distillation, with the oil, contains acetate of ammonia, and blackens silver: from which circumstance the presence of sulphur is inferred.

2. **BITTER PRINCIPLE OF HOPS; Lupulite.**—It is procured by treating the aqueous extract of the lupulinic grains, united with a little lime, with alcohol. The alcoholic tincture is to be evaporated to dryness, the residue treated with water, and the solution evaporated. The residue, when washed with ether, is lupulite. It is uncrystallizable, yellowish white, very bitter, soluble in 20 parts of water, very soluble in alcohol, and slightly so in ether. The aqueous solution froths by agitation; it forms no precipitate with either tincture of nutgalls or acetate of lead. Lupulite contains no nitrogen. It is devoid of the narcotic property of the oil. In small doses it is said to have caused loss of appetite and diminished digestive power; but a repetition of the experiment is very desirable.

3. **TANNIC ACID; Tannin.**—In the manufacture of beer, this principle serves to precipitate the nitrogenized or albuminous matter of the barley, and, therefore, for clarification.

4. **RESIN.**—Is of a golden yellow colour, and becomes orange-yellow by exposure to the air. It is soluble in both alcohol and ether. It appears to be the oil changed into resin, partly by oxidization.

CHEMICAL CHARACTERISTICS.—A decoction of hops reddens litmus, owing to the presence of free acid. Sesquichloride of iron strikes an olive green colour (*tannate of iron*). A solution of gelatin renders the filtered decoction turbid (*tannate of gelatin*). Chloride of barium occasions with it a white precipitate (*sulphate of baryta*). Oxalate of ammonia also causes a white precipitate (*oxalate of lime*).

PHYSIOLOGICAL EFFECTS.—The odorous emanations (vapour of the volatile oil) of hops possess narcotic properties. Hence a pillow of these cones promotes sleep, as I have several times witnessed. Moreover, we are told that stupor has occasionally been induced in persons who have remained for a considerable time in hop warehouses.

The lupulinic grains are aromatic and tonic. They appear also to possess soothing, tranquillizing, and, in a slight degree, sedative and soporific properties. But the existence of any narcotic quality has been strongly denied by Dr. Bigsby,¹ Magendie,² and others. "I have tried, at different times," says Magendie, "both the lupuline [lupulinic grains] in substance, and its different preparations, on animals, but I have never observed that it is a narcotic, although this property is one which is most strikingly displayed in experiments on animals." Dr. Maton³ found that it allayed pain, produced sleep, and reduced the frequency of the pulse from 96 to 60 in twenty-four hours.

Both infusion and tincture of hops are mild but agreeable aromatic tonics. They sometimes prove diuretic, or, when the skin is kept warm, sudorific. Their sedative, soporific, and anodyne properties are very uncertain.

USES.—A pillow of hops (*cervicale seu pulvinus, pulvinar lupuli*) is occasionally employed in mania, and other cases in which inquietude and restlessness prevail, and in which the use of opium is considered objectionable. In hop countries it is a popular remedy for want of sleep. The benefit said to have been obtained from it by George III., for whom it was prescribed by Dr. Willis, in 1787, brought it into more general use.

Hops are given internally to relieve restlessness consequent upon exhaustion and fatigue, and to induce sleep in the watchfulness of mania and of other maladies; to calm nervous irritation; and to relieve pain in gout, arthritic rheumatism, and after accouchement. Though they sometimes produce the desired effect, they frequently fail to give relief. Dr. Maton used it, with good effect, as an anodyne in rheumatism.

As a tonic, it is applicable in dyspepsia, cachectic conditions of the system, or any other maladies characterized by debility.

Hops have been applied, topically, in the form of fomentation or poultice, as a

¹ *Lond. Med. Rep.* vol. iv. p. 287.

² *Observations on Humulus Lupulus*, by A. F. Craque, 2d edit.

³ *Formulaire.*

resolvent or discutient, in painful swellings and tumours. Freake employed an ointment, composed of lard and the powder of the hop, as an anodyne application to cancerous sores.¹

But the principal consumption of hops is in the manufacture of beer and ale, to which they communicate a pleasant, bitter, and aromatic flavour, and tonic properties; while, by their chemical influence, they check the acetous fermentation. Part of the soporific quality of beer and ale is usually ascribed to the hops used in the manufacture of these beverages.

ADMINISTRATION.—The best preparation of hops, for internal use, is the yellow powder (*lupulinic grains* or *lupulin*). The *infusion* and *tincture* are less eligible modes of exhibition. The *extract* is still more objectionable. *Well-hopped-beer* is a convenient mode of administering hops, when fermented liquors are not contra-indicated (see *ante*, p. 118).

1. INFUSUM LUPULI, L.; *Infusion of Hops*.—(Hops ʒvj; Boiling Distilled Water Oj [Hops ʒss; Boiling Water Oj, U. S.]. Macerate for four [two, U. S.] hours in a vessel lightly covered, and strain.)—Dose, fʒj to fʒij.

2. TINCTURA LUPULI, L. [U. S.]; *Tinctura Humuli*; *Tincture of Hops*.—(Hops ʒvj [ʒv, U. S.]; Proof Spirit Oij. Macerate for seven days, and strain.)—Dose, fʒss to fʒij.

3. EXTRACTUM LUPULI, L. E.; *Extractum Humuli*, D.; *Extract of Hops*.—(Hops lbjss [lbj, E.]; Boiling Distilled Water Cong. ij [Cong. j, E.]. Macerate for twenty-four hours, then boil down to a gallon [Oiv, E.], and strain the liquor while hot; lastly, evaporate [in the vapour bath, E.] to a proper consistence. The directions of the Dublin College are nearly the same as those of the Edinburgh College.)—Dose, grs. v to ʒj. Whatever virtue this preparation possesses is owing to the bitter principle or lupulite.

4. LUPULINA; *Yellow Powder*; *Lupulinic Grains* or *Glands*.—(Separated from the strobiles by rubbing and sifting.)—Dose, grs. vj to grs. xij, taken in the form of powder or pills.

5. TINCTURA LUPULINÆ, D.; *Tinctura Lupuli*, E.—(Lupulin ʒv; Rectified Spirit Oij. Macerate for fourteen days, strain, express, and filter, D.—Take any convenient quantity of Hops, recently dried; separate by friction and sifting the yellowish-brown powder attached to the scales. Then take of this powder ʒv [ʒiv, U. S.]; and of Rectified Spirit Oij; and prepare the tincture by percolation or digestion, as directed for tincture of capsicum. *Ph. Ed.*)—Dose, ʒss to ʒij.

ORDER XXX. MORACEÆ.

MORACEÆ, *Endlicher*.

CHARACTERS.—*Flowers* unisexual. MALES:—*Calyx* 0, or 3—4-parted. *Stamens* 3—4, inserted into the base of the calyx and opposite its segments. FEMALES:—*Calyx* 0, or 4—5-parted. *Ovary* 1-celled, rarely 2-celled. *Ovules* solitary, pendulous, or amphitropal, with the foramen uppermost. *Fruit* small nuts or utracles, 1-seeded, inclosed within the succulent receptacle, or collected in a fleshy head formed by the consolidated succulent calyx. *Seed* solitary, with a thin brittle testa; embryo lying in fleshy albumen, hooked, with the radicle long, superior, folded down towards the cotyledons.—*Trees* or *shrubs*, with a milky juice. *Leaves* furnished with stipules.

PROPERTIES.—Various. The milky juice of some species is bland and potable; of others acrid and poisonous. In India, *Ficus elastica* yields caoutchouc. *Maclura tinctoria* furnishes the dyewood called *Fustic*, whose colouring principle is termed *morine*.

¹ *Op. cit.* p. 13; see also *Annals of Medicine*, vol. ii. p. 403.

117. MORUS NIGRA, Linn.—THE COMMON MULBERRY.

Sex. Syst. Monœcia, Tetrandria.

(Fructus Succus, L.)

HISTORY.—The mulberry (*μωρέα*) is mentioned by Hippocrates¹—"Mora calefaciunt et humectant ac alvo secedunt," says the Father of Physic. Dioscorides² also speaks of the mulberry.

BOTANY.—Gen. Char.—Monœcious. *Catkins* unisexual. *Calyx* 4-lobed; the lobes concave. *Stamens* 4, alternate with the segments of the calyx. *Ovary* free. *Stigmas* 2. *Seeds* 1-2, covered by the pulpy calyx (*Bot. Gall.*).

Sp. Char.—*Leaves* cordate, ovate, lobed, or unequally dentate; rough and thickish. *Fruit* dark purple (*Bot. Gall.*).

Fig. 291.

*Morus Nigra.*

A small tree, with rugged bark. *Flowers* greenish. "*Fruit*, consisting of the female flowers, become fleshy and grown together, inclosing a dry membranous pericarp." (Lindley.)

Hab.—Native of Persia and China. Cultivated for its fruit. Flowers in May.

DESCRIPTION.—The fruit is usually called a berry (*baea mori nigrae*), but is, in fact, that kind called by botanists a *sorosis*. Its odour is peculiar and agreeable; its taste is peculiar, pleasant, acidulous, and sweet. The juice is dark violet red.

COMPOSITION.—The fruit has not been analyzed. Its principal constituents are—violet-red colouring matter, tartaric acid, sugar, and woody fibre. The root has been analyzed by Wackenroder.³

PHYSIOLOGICAL EFFECTS.—Mulberries are alimentary in a slight degree; they allay thirst, diminish febrile heat, and, in large quantities, prove laxative.

USE.—They are employed as an agreeable aliment, and are well adapted to check preternatural heat and relieve thirst in fevers, but are objectionable when a tendency to diarrhoea exists. They owe their retention in the Pharmacopœia to their colour and flavour.

SYRUPUS MORI, L.; *Syrup of Mulberry*.—(Juice of Mulberries, strained, Oj; Sugar lbijss; Rectified Spirit fʒijss. Dissolve the sugar in the mulberry juice with a gentle heat, and set aside for twenty-four hours; then remove the scum, and pour off the clear liquor from the dregs if there are any. Lastly, add the spirit.)—Used as a colouring and flavouring substance. Its acidity prevents its being used with alkalies, earths, or their carbonates.

118. FICUS CARICA, Linn.—THE COMMON FIG.

Sex. Syst. Polygamia, Triœcia, Linn.—Polygamia, Diœcia, Willd.—Diœcia, Triandria, Pers.

(Fructus præparatus, L.—Fici: the dried fruit, E. D.)

HISTORY.—In the Old Testament we are informed that Hezekiah (who lived 600 years before Christ) used figs as a topical application to a boil.⁴ The fig-

¹ *De victus ratione*, lib. ii. p. 360, ed. Fœs.² *Gmelin's Handb. d. Chem.* ii. 1321.³ *Lib. i. cap. 150.*⁴ *Isaiah*, xxxviii. 21.

tree is the $\sigma\alpha\lambda\tilde{\eta}$ of Dioscorides,¹ the *Ficus* of Pliny.²

BOTANY. **Gen. Char.**—Monœcious. *Flowers* numerous, pedicellated, inclosed within a fleshy receptacle, which is umbilicated, and nearly closed at the apex, hollow within. *Calyx* 3—5-lobed : lobes acuminate. *Male-flowers* near the umbilicus. *Stamens* 3—5. *Ovary* free (Desf.) ; semi-adnate (Gaertn.). *Style* 1. *Stigmas* 2. *Drupe* or *utricle* 1-seeded, sunk into the pulpy receptacle. *Coat* of the nut fragile, crustaceous (*Bot. Gall.*).

Sp. Char.—*Leaves* cordate, palmate ; scabrous above, pubescent beneath (*Bot. Gall.*).—A small *tree*. *Flowers* in June. *Receptacle* green. At the base of each receptacle are two or three bractéal scales.

Hab.—Native of Asia and South of Europe.

DESCRIPTION.—Figs (*fici* seu *caricæ*) constitute that kind of collective fruit called, by Mirbel, a *syconus*. They consist of fleshy, hollow, pyriform receptacles, within which are numerous, small, seed-like bodies (*achenia*, Lindley ; *utricles*, Auctor). In the unripe state they contain an acrid and bitter juice, but which, when they are ripe, is replaced by sugar. Ripe figs are dried in the sun or in ovens, and are afterwards packed in drums and baskets, in which they are imported. As met with in the shops, they are more or less compressed, are covered with a whitish, saccharine efflorescence, have a brownish or yellowish colour, and are somewhat translucent. They have a peculiar and agreeable odour, and contain a sweet, viscid pulp, in which are the achenia. *Turkey* or *Smyrna figs* are the largest, most juicy, and sweetest ; hence they are sometimes termed *fat figs* (*caricæ pingues*) : they are distinguished into *pulled* and *flat*. Of 20,406 *cwts.* of figs, imported in 1830, no less than 18,801 came from Turkey (*Parliam. Return*).

COMPOSITION.—Bley³ analyzed Smyrna figs, and obtained the following results : *Sugar of figs* 62.5, *fatty matter* 0.9, *extractive with chloride of calcium* 0.4, *gum with phosphoric acid* 5.2, *woody fibre and seeds* [achenia] 15.0, and *water* 16.0 = 100.0.

PHYSIOLOGICAL EFFECTS.—Figs are nutritive, emollient, demulcent, and laxative. In the fresh state they are both agreeable and wholesome : when dried, as we receive them, they readily disorder the stomach and bowels, and occasion flatulence, griping, and mild diarrhœa.

USES.—In those countries where they are plentiful, figs are used as food. Here they are chiefly employed as a dessert. Internally they are given in the form of demulcent decoctions (as the *Decoctum Hordei compositum*, L. D.) in pulmonary and nephritic affections. As laxatives they are sometimes taken with the food to relieve habitual constipation, and enter into the composition of *Confectio Sennæ*, L. (*Electuarium Sennæ*, E.). Roasted or boiled, and split open, they are employed as suppurative cataplasms in gum-boil, &c.

119. DORSTENIA CONTRAJERVA, Linn.; and D. BRASILIENSIS, Lam.

Sex. Syst. Tetrandria, Monogynia.
(Radix.)

HISTORY.—The earliest notice of this plant is that by Monardes,¹ who states that the word *contrayerva* is the Indo-Spanish term for alexipharmic or counterpoison. In 1581, Clusius² received from Sir Francis Drake a root, which he called, after the donor, *drakena radix*, and which has been supposed, to be *contrayerva* root.

BOTANY. Gen. Char.—Monœcious. *Flowers* arranged upon a fleshy receptacle, usually flat and expanded, and extremely variable in form: *males* on the surface of the receptacle, 2-lobed, fleshy, diandrous; *females* immersed in the receptacle, also 2-lobed in most species. *Ovary* 1—2-celled, with a single suspended ovule in each cell. *Style* 1. *Stigma* 2-lobed. *Achenia* lenticular, imbedded in the fleshy receptacle, from which they are projected with elasticity when ripe.—Dwarf *herbaceous* plants with scaly rhizomata (Lindley).

Fig. 293.

Dorstenia Contrajerva.

A. Entire receptacle.
B. Section of ditto: a. Female flowers; b. Male ditto.
C. Male flower in its superficial hollow.

(Lindley). A native of New Spain, Mexico, Peru, Tobago, St. Vincent's (Willd.). The root of this is not met with in commerce.

2. *D. brasiliensis*, Lam.—A native of Jamaica, Brazil, and Trinidad. This yields the *contrayerva* root usually met with in the shops.

DESCRIPTION.—The *contrayerva* root (*radix contrajervæ*) usually found in the shops, is imported from the Brazils. It consists of an ovoid or oblong rootstock, terminating inferiorly in one or several long, tapering, more or less curved root-fibres. From the sides of the rootstock also arise numerous slender fibres. Externally the colour is yellowish-brown. The odour of the root is peculiar, but aromatic. The taste is warm, bitterish, slightly acrid.

I have also found another kind of *contrayerva* root in the shops. The root-stalk is smaller, cylindrical, blackish-brown, with fewer fibres. The receptacle and leaves are attached; the latter are reniform. Is this the *drakena radix* of Clusius?

COMPOSITION.—The root has not been analyzed. It contains, according to Geiger,³ *volatile oil*, *bitter extractive*, and *starch*. To which may be added *resin*, *free acid*, and *woody fibre*.

PHYSIOLOGICAL EFFECTS.—Stimulant, tonic, and diaphoretic. Its operation is very analogous to that of serpentary root, between which and the rhizome of the sweet flag it deserves to be arranged. The root of the *Dorstenia brasiliensis* often proves emetic.⁴

¹ Clusius, *Exoticorum*, lib. x. p. 311.

² *Hand. d. Pharm.*

³ *Ibid.* p. 83.

⁴ De Candolle, *Essai sur les Propriétés Méd.*

USES.—Obsolete, or nearly so. It has been employed in fevers of a low type, and in other diseases requiring a mild, stimulant, and diaphoretic treatment.

ADMINISTRATION.—The dose of the root in powder is ʒj or ʒss. The infusion (prepared by digesting from ʒiv in fʒvj of boiling water) may be given in doses of fʒj or fʒij. The *pulvis contrajervæ compositus* (composed of powdered contrajerva root ʒv, and prepared shells ʒjss) is no longer official.

ORDER XXXI. ARTOCARPACEÆ, Lindley.

ARTOCARPEÆ, R. Brown; Endl.

CHARACTERS.—Flowers unisexual, in dense heads. MALES:—Calyx 0, or consisting of 2—4 sepals. Stamens opposite the sepals. FEMALES:—Flowers arranged over a fleshy receptacle. Calyx tubular, with a 2—4-cleft or entire limb. Ovary free, 1-celled. Ovules suspended. Fruit surrounded by a dry or fleshy receptacle, or composed of consolidated fleshy calyxes, within which lies a multitude of nuts. Seeds erect, parietal or pendulous. Embryo more or less albuminous, straight, with the radicle directed towards the vertex of the ovary.—Trees or shrubs, with a milky juice. Leaves alternate. Stipules large, convolute.

PROPERTIES.—The milky juice is variable in quality: in some species being poisonous, in some edible, in others neither. It usually, if not invariably, contains enouchouc.—The *Artocarpus incisa*, or Bread fruit tree, and the *A. integrifolia* or Jak fruit, deserve notice on account of their important alimentary uses. *Artocarpus incisa* is a native of the islands of the Pacific and of the Moluccas. Its fruit is to the inhabitants of Polynesia what corn is to the people of the other parts of the world. *Artocarpus integrifolia* is cultivated throughout southern India, and all the warmer parts of Asia. Its fruit forms a very considerable article of food in Ceylon.¹

120. *Antiaris toxicaria*, Leschinault.—Antsjar or Upas.

This is the celebrated *Antsjar* or *Upas* poison tree of Java, rendered notorious principally in consequence of certain gross falsehoods concerning it, about the year 1780, by a person of the name of Foersch, said to have been a surgeon in the service of the Dutch East India Company. Malefactors, says this person, when they receive sentence of death, are offered the chance of life, if they will go to the Upas-tree for a box of poison; and although every precaution is taken to avoid the injurious influence of the emanations of the tree, yet of 700 criminals who went to collect the poison, scarcely two out of twenty returned. Foersch further adds, that for fifteen or eighteen miles around this tree no living animal of any kind has ever been discovered.² Dr. Horsfield³ and M. Leschinault⁴ have shown that the above statements are for the most part fabulous. From their observations it appears that the true poison tree of Java is the *Antiaris toxicaria*⁵ (Fig. 295). It is one of the largest forest trees of Java, being from 60 to 100 feet high. The milky juice is collected by incision, and is then inspissated by boiling along with the juice of arum, galanga, onions, &c. The poison, when brought to this country, is found to be a thick fluid of a grayish-brown or fawn-colour, and an unpleasant odour. It consists, according to Pelletier and Caventou,⁶ of a peculiar elastic resin, slightly soluble gummy matter analogous to bassorin, and a bitter matter, soluble in water. This bitter matter is composed of a colouring matter absorbable by charcoal, an undetermined acid, and antiarin, the active principle of the plant, and which is precipitable by tincture of galls. More recently, Mulder⁷ has submitted this juice to analysis, and found it to consist of vegetable albumen 16.14, gum 12.34, antiar-resin 20.93, myricin 7.02, antiarin 3.56, sugar 6.31, and extractive 33.70. The antiar-resin was composed of C¹⁶H¹²O. Antiarin consisted of C¹⁴H¹⁰O⁵. Sir B. Brodie⁸ says, the poison renders the heart insensible to the stimulus of the blood. Magendie and Delile⁹ found that, besides acting on the brain and spinal marrow, it proved emetic. According to Andral, it causes convulsions, with alternations of relaxation.

ORDER XXXII. PIPERACEÆ, *Richard*.—PEPPERWORTS.

CHARACTERS.—*Flowers* naked, hermaphrodite, with a bract on the outside. *Stamens* 2 or more, arranged on one side, or all round the ovary; to which they adhere more or less; *anthers* 1—2-celled, with or without a fleshy connective; *pollen* roundish, smooth. *Ovary* superior, simple, 1-celled, containing a single erect, orthotropical *ovule*; *stigma* sessile, simple, rather oblique. *Fruit* superior, somewhat fleshy, indehiscent, 1-celled, 1-seeded. *Seed* erect, with the embryo lying in a fleshy sac, placed at the apex of the seed on the outside of the albumen.—*Shrubs* or *herbaceous plants*. *Stems* articulated. *Leaves* opposite, verticillate, or alternate, in consequence of the abortion of one of the pair of leaves. *Stipules* 0, or in pairs, or single and opposite the leaf. *Flowers* usually sessile, sometimes pedicellate, in spikes which are either terminal or axillary; or opposite the leaves (*Lindley*).

PROPERTIES.—Fruits remarkable for their hot taste, and acrid and stimulant properties. These qualities they owe to the presence of an acrid oil and resin.

121. PIPER NIGRUM, *Linn.*—THE BLACK PEPPER.

Sex. Syst. Diandria, Trigynia.

(Fructus immaturus, *L.*—Dried unripe berries, *E. D.*)

HISTORY.—The ancient Greeks were acquainted with pepper (πέπερι), their knowledge of which must have been derived, directly or indirectly, from the Hindoos. Hippocrates¹ employed it in several diseases. Pliny² notices its uses as a condiment,

¹ *De morb. mul. &c.*

² *Hist. Nat. lib. xii. cap. 14, ed. Valp.*

and expresses his astonishment that it should have come into general use, since it has neither flavour nor appearance to recommend it.

BOTANY. **Gen. Char.**—*Spadix* covered with flowers on all sides. *Flowers* hermaphrodite, rarely dioecious, each supported by a scale. *Stamina* 2 or more. *Ovarium* with 1 solitary erect *ovule*. *Stigma* punctiform, obtuse, or split. *Berry* 1-seeded. *Embryo* dicotyledonous [monocotyledonous, *Blume*], inverted (*Blume*).¹

Sp. Char.—*Stem* shrubby, radicant, climbing, terete. *Leaves* ovate or elliptical, acuminate, occasionally somewhat oblique, subcordate, 5—7-nerved, coriaceous, smooth, recurved at the margin, glauco-greenish beneath. *Spadices* shortly pedunculated, pendulous. *Fruits* distinct (*Blume*).²

Stem 8—12 feet long, jointed, dichotomous. *Fruit* at first green, then red, afterwards black.

According to Dr. Roxburgh,³ *Piper triicum* is cultivated, and yields excellent pepper.

Hab.—Cultivated in various parts of India and its islands (Roxburgh), also in the West Indies.

PREPARATION.—When any of the berries on a spadix change from green to red, the whole are considered fit for gathering; for, if they are allowed to become fully ripe, they are somewhat less aerid, and, moreover, easily drop off. When collected, they are spread out and dried in the sun, and the stalks separated by hand-rubbing. They are afterwards winnowed.⁴ The dried and shrivelled berries constitute *black pepper* (*piper nigrum*).

White pepper (*piper album*) is prepared from the best and soundest grains, taken at their most perfect stage of maturity. These being soaked in water, swell and burst their tegument, which is afterwards carefully separated by drying in the sun, hand-rubbing, and winnowing.⁵

COMMERCE.—The pepper countries extend from about the longitude of 90° to that of 115° E., beyond which no pepper is to be found; and they reach from 5° S. latitude to about 12° N., where it again ceases. The following estimate of the production of pepper is drawn up by Mr. Crawford.⁶

PRODUCTION OF PEPPER.

Sumatra (west coast)	20,000,000 lbs.
Sumatra (east coast)	8,000,000
Islands in the Straits of Malacca	3,600,000
Malay peninsula	3,733,333
Borneo	2,666,667
Siam	8,000,000
Malabar	4,000,000
Total	50,000,000

DESCRIPTION.—*Black pepper* (*piper nigrum*) is round, covered externally with a brownish-black corrugated layer (the remains of the succulent portion of the berry), which may be readily removed by softening it in water. Internally we have a hard, whitish, spherical, smooth seed, which is horny externally, but farinaceous internally. The taste of both nucleus and covering is aerid and hot. Amongst wholesale dealers three sorts are distinguished:—

1. *Malabar pepper.*—This is the most valuable: it is *brownish-black*, free from stalks, and nearly free from dust.

2. *Penang pepper.*—This is *brownish-black*, larger, smoother, free from stalks, but very dusty. It is sometimes used in England to manufacture white pepper.

⁴ *Op. cit.*

⁵ *Marsden*, *History of Sumatra*, 3d edit. p. 137.

⁶ *M'Culloch*, *Dict. of Commerce*.

Fig. 295.

Piper nigrum.

3. *Sumatra pepper*.—This is the cheapest sort. It is *black*, mixed with stalks, and contains much dust. (Under the name of Sumatra pepper, some dealers include the Penang or brownish-black sort, and the black Sumatra sort.)

The heavier the pepper is, the more it is esteemed in the market. The heaviest of all, being hard and smooth, is called *shot pepper*, which is either Malabar or Sumatra sort; the Penang sort never yielding this kind of pepper.

Most dealers sift their black pepper before offering it for sale, and use the dust (called P. D.) for pickling or grinding.

Fulton's decorticated pepper is black pepper deprived of its husk by mechanical trituration.

Bleached pepper or *English bleached pepper* is Penang pepper bleached by chlorine. In this state it ought perhaps to be classed among the white peppers.

White pepper (*piper album*) is the fruit deprived of the external fleshy portion of the pericarp. The grains are larger than those of black pepper, spherical, whitish, and smooth, horny externally; internally they are farinaceous or hollow in the centre. They are less acid and pungent than black pepper. In commerce three sorts are distinguished:—

1. *Tellicherry pepper*, which is of two kinds. *Large* or *fine Tellicherry pepper* is larger and whiter than any other description of white pepper, and fetches a higher price. *Small* or *coriander-like pepper* is shrivelled.

2. *Common white pepper* comes from Penang by Singapore. It is round and not shrivelled. Its value depends on its size and whiteness.

3. *English bleached white pepper*.—When the two preceding sorts are scarce, brown Penang pepper is bleached. The yellowest and largest grains are chosen for this purpose, for neither an expensive nor small sort would pay.

COMPOSITION.—In 1819, Oersted discovered *piperin* in pepper. In 1821, black pepper was analyzed by Pelletier.¹ In 1822, white pepper was analyzed by Lucä.²

BLACK PEPPER (*Pelletier*).

Acrid soft resin.
Volatile oil.
Piperin.
Extractive.
Gum.
Bassorin.
Starch.
Malic acid.
Tartaric acid.
Potash, calcareous and magnesian salts.
Woody fibre.

WHITE PEPPER (*Lucä*).

Acrid resin	16.60
Volatile oil	1.61
Extractive, gum, and salts	12.50
Starch	18.50
Albumen	2.50
Woody fibre	29.60
Water and loss	19.29

Black pepper.

White pepper 100.00

Dr. Ure³ obtained from 100 parts of white peppercorns, a trace of volatile oil, 8½ grains of a pungent resin containing a small fraction of piperin, about 60 grains of starch with a little gum, and nearly 30 grains of matter (lignin) insoluble in hot or cold water.

Lucä found no *piperin* in white pepper, but Poutet⁴ subsequently detected it. Probably, therefore, in Lucä's analysis the piperin was contained in the resin.

1. **RESIN OF PEPPER** (*resina piperis*).—This is a very acrid substance, soluble in alcohol and ether, but not so in volatile oils. It possesses in high perfection the acrid properties of pepper. Dissolved in ether, it was employed by Dr. Lucas in intermittents, and in two out of three cases with success.⁵ In the museum of the Pharmaceutical Society there are two kinds of pepper resin: one called the "green resin," the other the "red resin."

2. **VOLATILE OIL OF PEPPER** (*oleum piperis*).—When pure, this is colourless; it has the odour and taste of pepper. Its sp. gr. is 0.9932 (Lucä). Its composition is C¹⁰H⁸. It absorbs hydrochloric acid in large quantity, but does not form a crystalline compound with it. According to Meli,⁶ it possesses the same febrifuge properties as piperin, perhaps because it retains some of the latter principle. It has been used in some forms of dyspepsia depending on general debility.

⁴ Schwartze, *Pharm. Tabellen*.

⁵ *Journ. de Pharm.* t. vii.

⁶ Dierbach, *op. cit.*

3. PIPERIN.—This substance was discovered by Oersted in 1819, but was more accurately examined by Pelletier in 1821. It exists in black, white, and long pepper, and also in cubebs.

It is a crystalline substance, the crystals being rhombic prisms, with inclined bases. It fuses at 212° F., is insoluble in cold water, and is only very slightly soluble in boiling water. Its best solvent is alcohol: the solution throws down piperin when water is added to it. Ether dissolves it, but not so readily as alcohol. Acetic acid likewise is a solvent for it.

Piperin, when pure, is white; but, as met with in commerce, it is usually straw-yellow. It is tasteless and inodorous. It was at first supposed to be an alkali; but Pelletier has shown that it possesses no analogy with vegetable alkalies, and that it is related to the resins. With strong sulphuric acid it forms a blood-red liquid. Nitric acid colours it first greenish-yellow, then orange, and afterwards red. The action of hydrochloric acid is similar.

Its formula, according to Regnault, is $C^{14}H^{10}NO^6$.

Piperin has been recommended and employed by Meli and several other physicians¹ as a febrifuge in intermittent fevers. It is said to be more certain and speedy, and also milder in its action, than the cinchona alkalies. Moreover, we are told that it might be procured at a cheaper rate than sulphate of quina. Its dose is about six or eight grains in powder or pills. Sixty grains have been taken in twenty-four hours, without causing any injurious effects. Meli considers two or three scruples sufficient to cure an intermittent. Magendie² proposes it in blennorrhagia, instead of cubebs.

4. STARCH.—Both black and white peppercorns contain abundance of very minute starch grains.

ADULTERATION.—Sago is said to have been used to adulterate ground white pepper. The microscope would readily detect the fraud; the starch grains of sago being very much larger than those of pepper, from which they also differ in shape. The following are the adulterations recently discovered³ in pepper by the microscope: wheat-flour, linseed meal, pea-flour, mustard-seed, and starch grains.

PHYSIOLOGICAL EFFECTS.—Pepper is one of the acrid species whose general effects have been already noticed (see vol. i. p. 252). Its great acidity is recognized when we apply it to the tongue. On the skin it acts as a rubefacient and vesicant.⁴ Swallowed, it stimulates the stomach, creates a sensation of warmth in this viscus, and, when used in small doses, assists the digestive functions, but if given in large quantities induces an inflammatory condition. Thirty white peppercorns, taken for a stomach complaint, induced violent burning pain, thirst, and accelerated pulse, which continued for three days, until the fruits were evacuated.⁵ Wendt, Lange, and Jager⁶ have also reported cases in which inflammatory symptoms supervened after the use of pepper. On the vascular and seerning systems pepper acts as a stimulant. It accelerates the frequency of the pulse, promotes diaphoresis, and acts as an excitant to the mucous surfaces. On one of my patients (a lady) the copious use of pepper induced burning heat of skin, and a few spots of *Urticaria evanida* usually on the face. "I have seen," says Van Swieten,⁷ "a most ardent and dangerous fever raised in a person who had swallowed a great quantity of beaten pepper." It has long been regarded as a stimulant for the urino-genital apparatus. The opinion is supported by the well-known influence of the peppers over certain morbid conditions of these organs. Moreover, the beneficial effect of pepper in some affections of the rectum leads us to suspect that this viscus is also influenced by these fruits.

USES.—It is employed as a condiment, partly for its flavour, partly for its stimulant influence over the stomach, by which it assists digestion. As a gastric stimulant it is a useful addition to difficultly-digestible foods, as fatty and mucilaginous matters, especially in persons subject to stomach complaints from a torpid or atonic condition of this viscus. Infused in ardent spirit it is a popular remedy for preventing the return of the paroxysms of intermittent fevers, given shortly before the expected attack. The practice is not recent, for Celsus⁸ advises warm water with pepper to relieve the cold fit. The febrifuge power of this spice has been fully proved, in numerous cases, by L. Frank,⁹ Meli,¹⁰ Riedmüller (Dierbach), and others;

¹⁰ *Ibid.* t. xiii. p. 121.

though Schmitz¹ denies it. Barbier² says that, in some instances, where large doses were exhibited, death occurred in consequence of the aggravation of a pre-existent gastritis. It has been employed in gonorrhœa as a substitute for eubebs. In relaxed uvula, paralysis of the tongue, and other affections of the mouth or throat requiring the use of a powerful aërid, pepper may be employed as a masticatory. In the form of ointment it is used as an application to tinea capitis. Mixed with mustard, it is employed to increase the acridity of sinapisms.

ADMINISTRATION.—The dose of black pepper (either of corns or powder) is from five to fifteen grains; the powder may be given in the form of pills.

1. CONFECTIO PIPERIS, L.; *Confectio Piperis Nigri*, D.; *Electuarium Piperis*, E.; *Confection of Black Pepper*.—(Black Pepper, Elecampane-root [Liquorice-root in powder, E.], of each ℥ij; Fennel ℥iij; Honey, White Sugar, of each ℥ij. Rub the dry ingredients together to a very fine powder, L. E.—Black Pepper in fine powder, Liquorice Root in powder, of each ℥ss; Refined Sugar ℥j; Oil of Fennel ℥ss; Clarified Honey, *by weight*, ℥ij, D. The London College keeps this in a covered vessel, and directs the Honey to be added when the Confection is to be used. But the *Edinburgh* and *Dublin Colleges* order the Honey to be added immediately after the ingredients have been mixed.)—This preparation is intended to be a substitute for a quack medicine, called "*Ward's Paste*," which has obtained some celebrity as a remedy for fistulæ, piles, and ulcers about the rectum. Its efficacy doubtless depends on the gentle stimulus it gives to the affected parts. Sir B. Brodie³ observes that severe cases of piles are sometimes cured by it; and he thinks that it acts on them topically, the greater part of the paste passing into the colon, becoming blended with the feces, and in this way coming into contact with the piles, on which it operates as a local application, much as *vinum opii* acts on the vessels of the conjunctiva in chronic ophthalmia. In confirmation of this view, he mentions the case of a patient attended by Sir Everard Home, who was cured by the introduction of the paste into the rectum. Confection of black pepper is adapted for weak and leucophlegmatic habits, and is objectionable where much irritation or inflammation is present. The dose of it is from one to two or three drachms twice or thrice a day. "It is of no use," says Sir B. Brodie, "to take this remedy for a week, a fortnight, or a month; it must be persevered in for two, three, or four months." As it is apt to accumulate in and distend the colon, gentle aperients should be exhibited occasionally during the time the patient is taking the confection.

2. UNGUENTUM PIPERIS NIGRI; *Ointment of Black Pepper*.—(Prepared Hog's Lard ℥ij; Black Pepper, reduced to powder, ℥iv. Make an ointment.)—Formerly in vogue for the cure of tinea capitis.

[3. EXTRACTUM PIPERIS FLUIDUM, U. S.; *Fluid Extract of Black Pepper*.—Take of Black Pepper a pound; Ether a sufficient quantity. Put the powder into a percolator, and pour ether gradually upon it until two pints of filtered liquor are obtained. From this distil off, by means of a water-bath, at a gentle heat, a pint and a half of ether, and expose the residue, in a shallow vessel, until the whole of the ether has evaporated and the deposit of piperin and crystals has ceased. Lastly, separate the piperin by expression through a cloth and keep the liquid portion.

This preparation is of semifluid consistence, of a dark colour, and possessed strongly of the odour and taste of black pepper. It may be used where the article is usually employed. Dose, gtt. xx—f℥ss.]

³ *Lectures in Lond. Med. Gaz.* vol. xv. p. 716.

122. CHAVICA¹ ROXBURGHII, *Miquel*.²—COMMON LONG PEPPER.

Sez. Syst. Diandria, Trigynia.

(Fructus immaturus, *L.*—Dried Spikes, *E.*)

SYNONYMES.—*Piper longum*, Linn. in part; figure, in Nees' Plant. Medic. tab. 23.

HISTORY.—Long pepper (*πέπερι μακρόν*) is mentioned both by Dioscorides³ and Galen.⁴

BOTANY. *Gen. Char.*—Woody. *Spikes* solitary, opposite to the leaves. *Flowers* sessile, dioecious. *Bracts* with short stalks, nearly quadrangular, peltate. *Style* very short or 0. *Berries* sessile, united with the permanent bracts and the thickened rachis of the spike. *Seeds* oblong or almost lenticular, with a crustaceous finely scrobiculate testa and a mealy albumen.

Sp. Char—Rather hairy; lower leaves roundish ovate, 7-nerved; female spikes cylindrical, about as long as their stalk.

Hab.—India. Found wild among bushes on the banks of watercourses, up towards the Circar Mountains. It flowers and bears fruit during the wet and cold seasons (Roxburgh). It is cultivated in Bengal, and in the valleys amongst the Circar Mountains. The roots and thickest parts of the stems, when cut into small pieces and dried, form a considerable article of commerce all over India under the name of *Pippula moola*.

DESCRIPTION.—When fully grown, but yet unripe, the spadices are gathered and dried by exposure to the sun. They are then packed in bags for sale.

As met with in commerce, *long pepper* (*piper longum*) is grayish brown, cylindrical, an inch or more in length, having a mild aromatic odour but a violent pungent taste.

The long pepper imported from our possessions in India is the produce of *Chavica Roxburghii*, Mig. But that which is brought to Europe from the Dutch colonies is the produce of *Chavica officinarum*, Miq.

COMPOSITION.—This pepper was analyzed by Dulong in 1825.⁵ The following are the substances he obtained from it: *Acrid fatty matter* (resin?), *volatile oil*, *piperin*, *nitrogenous extractive*, *gum*, *bassorin*, *starch*, *malates* and *other salts*.

The VOLATILE OIL OF LONG PEPPER is colourless, and has a disagreeable odour and an acrid taste.

PHYSIOLOGICAL EFFECTS AND USES.—The effects of long pepper are analogous to those of black pepper. Cullen⁶ and Bergius⁷ consider it less powerful; but most other pharmacologists are agreed on its being more acrid. Medicinally it may be employed in similar cases. It is used principally for culinary purposes. It is a constituent of several pharmacopœial preparations.

123. Chavica Betle, *Miquel*.—Betle Pepper.

PIPER BETLE, *Linnaeus*.—The leaf of this plant (as well as of *Chavica Siriboa*, Miq.) is extensively used by the Malays and other nations of the East, who consider it a necessary of life. The mode of taking it in Sumatra consists simply in spreading on the *sirih* (the leaf of the Chavica Betle) a small quantity of *chunam* (quick-lime prepared from calcined shells), and folding it up with a slice of *pinang* or Areca nut (see *ante*, p. 170). From the mastication there proceeds a juice which tinges the saliva of a bright red, and which the leaf and nut, without the lime, will not yield. This hue being communicated to the mouth and lips, is esteemed ornamental, and an agreeable flavour is imparted to the breath. The juice is usually, but not

¹ Chavica is the Sanscrit name for plants of this kind.

⁷ *Mat. Med.* vol. ii. p. 209.

always, swallowed. To persons who are not habituated to this composition it causes giddiness, astringes and excoriates the mouth and fauces, and deadens for a time the faculty of taste. Individuals, when toothless, have the ingredients previously reduced to a paste, that they may dissolve without further effort.¹

124. CUBEBA OFFICINALIS, Miq.—THE CUBEBA PEPPER.

Sex. Syst. Diandria, Trigynia.

(Fructus immaturus, *L.*—Fruit, *E.*—The berries, *D.*)
[Cubeba; Cubebs, *U. S.*]

SYNONYME.—*Piper Cubeba*, Linn. fil. Blume. *Ph. L.*

HISTORY.—It is somewhat doubtful when cubebs were first employed in medicine, and by whom they were first noticed. I am inclined to believe, however, that they are mentioned in the Hippocratic writings² under the name of *μυρτίδαρον*; for 1stly, the remedy termed *μυρτίδαρον* is distinguished from pepper (*πέπερι*), and is said to be a round Indian fruit which the Persians call pepper. 2dly, the modern Greek name for cubebs is *μυρτίδαρον*.³

The word cubebs is derived from the Arabic name for these fruits, which first occurs in the writings of Serapion,⁴ Rhazes, and Avicenna. From the same source Aeturius⁵ derived the name *κομβέβας*, by which he has designated cubebs.

Cubebs were in use in England more than 500 years ago, for in 1305 Edward I. granted to the corporation of London the power of levying a toll of one farthing a pound on this article in its passage over London Bridge.⁶

BOTANY. *Gen. Char.*—Woody. *Spikes* solitary, opposite the leaves. *Flowers* diœcious. *Ovary* sessile. *Stigmas* 3—5, sessile. *Berries*, by the contracted basis, apparently stalked (pseudo-pedicellate). *Seed* roundish, with leathery or horny testa and mealy albumen. (Condensed from Miquel).

Sp. Char.—*Leaves* smooth; the lower ones unequal, somewhat cordate at the base, ovate, acute; the upper ones more oblong-ovate, with rounded base and smaller; those of the male plant 5-nerved, of the female plant 5—9-nerved. *Fruit* globose, shorter than their stalks.—A climbing shrub.

Hab.—Grows wild in Bantam, the western part of Java; also on some of the neighbouring islands.—Cultivated in the lower parts of Java.

The above is, according to Miquel, the mother-plant of the genuine cubebs. But a neighbouring species—*Cubeba canina*, Miquel—yields a fruit which, according to Blume, also forms part of the cubebs of commerce. This plant grows on the Sunda and Molucca islands. The fruits and seeds of the two species are thus distinguished.

C. OFFICINALIS, Miq.

Berries far more numerous, crowded, almost globose, scarcely acuminate; when dry, rugous, blackish brown, having a very acrid, aroniac, almost bitter taste

Seed-coat (spermoderm), grayish brown, traversed by about eight longitudinal nerves, oblong-globular.

Fruit-Stalks (formed of the thin lower portion of the berry) longer than the berries.

C. CANINA, Miq.

Fewer, more remote, ovate; when dry, remarkably beaked (rostrate), black, smaller, scarcely rugous, having a weaker, almost anise-like taste.

Reddish, almost shining, lined (*striolata*) longitudinally, spherical.

Nearly of the same length as the berries.

DESCRIPTION.—The dried unripe fruit of this plant constitutes the *cubebs* (*cubebæ* vel *piper caudatum*) of the shops.

In appearance, cubebs resemble black pepper, except that they are lighter coloured,

¹ Marsden, *Hist. of Sumatra*, 3d edit. p. 281.

² *De Morbis Mulierum*, lib. ii. p. 672, ed. Fæsius.—The term *μυρτίδαρον* was also used to signify a myrtle-like plant, and likewise a rough excrescence growing on the *μυρτίδαρον* (*Ruscus aculeatus*). See Dioscorides, lib. i. cap. 156.

³ *Pharmacopœia Græca*, Athenis, 1837.

⁴ In his account of cubebs, Serapion has translated what Dioscorides has said of *μυρτίδαρον* (*Ruscus aculeatus*) and added everything which Galen has stated respecting *κάρπύσιον*. But Galen expressly states that *κάρπύσιον* resembles *εἶδος* (the root of *Valeriana Dioscorides*); and it is improbable, therefore, that cubebs and carpesium should be identical.

⁵ C. Bauhini *Pinax*.—No Greek edition of Aeturius has been published, and I am, therefore, obliged to quote his writings at second-hand. In my copy of the Latin translation (*De Medicamentorum compositione*, J. Ruellio interprete, p. 69 b, 1546), the phrase runs thus—“*carpesii* (cubebe barbari vocant).”

⁶ *Liber Niger Scaccarii*, vol. i. p. *479; also *The Chronicles of London Bridge*, p. 155.

and are each furnished with a stalk two or three inches long, and from which circumference they have received their name *caudatum* ("fructus pedicellatus," Ph. Lond.). The cortical portion of cubebs (that which constituted the fleshy portion of the fruit) appears to have been thinner and less succulent than in black pepper. Within it is a hard spherical seed, which is whitish and oily. The taste of cubebs is acrid, peppery, and camphoraceous; the odour is peculiar and aromatic.

COMPOSITION.—Three analyses of cubebs have been made: one by Trommsdorff, in 1811;¹ a second by Vauquelin, in 1820;² and a third by Monheim, in 1835.³

Vauquelin.

1. Volatile oil, nearly solid.
2. Resin, like that of copaiva.
3. Another coloured resin.
4. A coloured gummy matter.
5. Extractive.
6. Saline matter.

Monheim.

1. Green volatile oil	2.5
2. Yellow volatile oil	1.0
3. Cubebin	4.5
4. Balsamic resin	1.5
5. Wax	3.0
6. Chloride of sodium	1.0
7. Extractive	6.0
8. Lignin	65.0
Loss	15.5

Cubebs.

Cubebs 100.0

1. ESSENTIAL OIL OF CUBEBS.—(See p. 356.)

2. RESIN OF CUBEBS—Vauquelin has described two resins of cubebs: one is green, liquid, acrid, and analogous, both in odour and taste, to balsam of copaiva; the other is brown, solid, acrid, and insoluble in ether.

3. CUBEBIN (*Piperin*).—From cubebs is obtained a principle to which the term *cubebin* has been applied. It is very analogous to, if not identical with piperin. Cassola, a Neapolitan chemist,⁴ says, it is distinguished from the latter principle by the fine crimson colour which it produces with sulphuric acid, and which remains unaltered for twenty or twenty-four hours; moreover, cubebin is not crystallizable.

Monheim,⁵ however, declares cubebin to be identical with piperin, and that it is combined with a soft acrid resin. In this state it is soluble in ether, alcohol, the fixed oils, and acetic acid; but it is insoluble in oil of turpentine and dilute sulphuric acid. It fuses at 68° F.

Dr. Görres⁶ gave cubebin, in both acute and chronic gonorrhœa, to the extent of one drachm, four times daily. But he premised the use of phosphoric acid.

4. EXTRACTIVE MATTER OF CUBEBS.—Vauquelin says, the extractive matter of cubebs is analogous to that found in leguminous plants. It is precipitable by galls, but not by acetate of lead.

PHYSIOLOGICAL EFFECTS.—Cubebs belong to the acrid species already (see *ante*, p. 221) noticed. Their sensible operation is very analogous to that of black pepper. Taken in moderate doses, they stimulate the stomach, augment the appetite, and promote the digestive process. In larger quantities, or taken when the stomach is in an irritated or inflammatory condition, they cause nausea, vomiting, burning pain, griping, and even purging. These are their local effects. The constitutional ones are those resulting from the operation of an excitant—namely, increased frequency and fulness of pulse, thirst, and augmented heat. It probably stimulates all the mucous surfaces, but unequally so. In some instances cubebs give rise to an eruption on the skin like urticaria. Not unfrequently they cause headache; and occasionally disorder of the cerebro-spinal functions, manifested by convulsive movements or partial paralysis, as in a case related by Mr. Broughton.⁷

Cubebs appear to exercise a specific influence over the urinogenital apparatus. Thus they frequently act as diuretics, and at the same time deepen the colour of, and communicate a peculiar aromatic odour to the urine. Their stimulant operation on the bladder is well illustrated by a case related by Sir Benjamin Brodie.⁸ A gentleman, labouring under chronic inflammation of the bladder, took fifteen grains of cubebs, every eight hours, with much relief. Being anxious to expedite his cure, he, of his own accord, increased the dose to a drachm. This was followed by an aggravation of the symptoms: the irritation of the bladder was much in-

⁷ Dierbach, *Neuesten Entd. in d. Mat. Med.* S. 253, 1837.

⁸ *Ibid.* vol. i. p. 300.

creased, the mucus was secreted in much larger quantity than before, and ultimately the patient died—"his death being, I will not say occasioned," adds Sir Benjamin, "but certainly very much hastened, by his imprudence in overdosing himself with cubebs."

Three drachms of cubebs caused in Pül¹ nausea, acid eructations, heat at the pit of the stomach, headache, uneasiness, and fever.

USES.—The principal use of cubebs is in the treatment of *gonorrhœa*. They should be given in as large a dose as the stomach can bear, in the early part of the disease; for experience has fully proved that, in proportion to the length of time gonorrhœa has existed, the less amenable is it to the influence of cubebs. In some instances an immediate stop is put to the progress of the malady. In others the violent symptoms only are palliated; while in many (according to my experience in most) cases no obvious influence over the disease is manifested. The presence of active inflammation of the urethra does not positively preclude the use of cubebs, though I have more than once seen them aggravate the symptoms. Mr. Jeffreys² thinks the greatest success is met with in the more inflammatory forms of the disease. Cubebs have been charged with inducing swelled testicle; but I have not observed this affection to be more frequent after the use of cubebs than when they were not employed. Mr. Broughton³ gave them to fifty patients, and in forty-five they proved successful. Of these only two had swelled testicle. The explanation of the *methodus medendi* is unsatisfactory. Sir A. Cooper⁴ thinks that cubebs produce a specific inflammation of their own on the urethra, which has the effect of superseding the gonorrhœal inflammation. The occasional occurrence of a cutaneous eruption from the use of cubebs deserves especial attention, as I have known it create a suspicion of secondary symptoms.

Cubebs have been recommended in gleet and leucorrhœa.⁵ In abscess of the prostate gland, twenty or thirty grains of cubebs, taken three times a day, have in many cases appeared to do good.⁶ They seemed to give a gentle stimulus to the parts, and to influence the disease much in the same way that Ward's Paste operates on abscesses and fistulæ, and ulcers of the rectum. In cystorrhœa also they have occasionally proved serviceable in small doses.⁷ In piles, likewise, they are given with advantage.⁸

The efficacy of cubebs in mucous discharges is not confined to the urinogenital mucous membrane. In catarrhal affections of the membrane lining the aerian passages, it proves exceedingly useful, especially when the secretion is copious and the system relaxed.

Formerly cubebs were employed as gastric stimulants and carminatives in dyspepsia, arising from an atonic condition of the stomach. They have also been used in rheumatism. The Indians macerate them in wine, and take them to excite the sexual feelings.

ADMINISTRATION.—Cubebs, in the form of *powder*, are given in doses varying from ten grains to three drachms. In affections of the bladder and prostate gland the dose is from ten grains to thirty grains. In gonorrhœa, on the other hand, they should be administered in large doses. Mr. Crawford⁹ says, that in Malay countries they are given in doses of three drachms, six or eight times during the day.

1. OLEUM CUBEBÆ, E.; *Volatile Oil of Cubebs*. (Prepared by grinding the fruit, and distilling with water.)—By distillation, cubebs yield about 10.5 per cent. of a transparent, slightly-coloured (when pure, colourless) volatile oil, which is lighter than water (sp. gr. 0.929), and has the cubeb odour, and a hot, aromatic, bitter taste. Its formula is C¹⁰H⁸.

⁵ Dr. Orr, *Ed. Med. Journ.* vol. xviii. p. 318.

⁶ Sir B. Brodie, *Lond. Med. Gaz.* vol. i. p. 396.

⁷ *Ibid.* p. 300.

⁸ *Ibid.* xv. 747.

⁹ *History of the Indian Archipelago*, vol. i. p. 465.

By keeping, it sometimes deposits crystals (*cubeb stearoptene* or *cubeb camphor*), the primary form of which is the rhombic octohedron.¹ They form a hydrate whose composition is $C^{10}H^8,11O$. Their odour is that of cubebs; their taste, at first, that of cubebs and camphor, afterwards cooling. They are fusible at $133^{\circ} F.$, soluble in alcohol, ether, and oils, but are insoluble in water. Oil of cubebs is an excellent and a most convenient substitute for the powder. The dose of it, at the commencement of its use, is ten or twelve drops. This quantity is to be gradually increased as long as the stomach will bear it. In some instances, I have given it to the extent of a fluidrachm for a dose. It may be taken suspended in water by means of mucilage, or dropped on sugar; or in the form of *gelatinous capsules of cubebs*, a combination of oil of cubebs and oil of copaiva forms a very useful medicine in some cases of gonorrhœa.

2. **EXTRACTUM OLEO-RESINOSUM CUBEBE;** *Oleo-resinous Extract of Cubebs.*—Dublane directs this to be prepared by adding the oil to the resinous extract of cubebs, which is prepared by digesting the cake, left after the distillation of the oil, in alcohol, and distilling off the spirit.² The process of Mr. Procter, Jun.,³ appears to be a better one. It consists in exhausting cubebs by ether in the displacement apparatus, and submitting the ethereal tincture to distillation in a water bath. The residual *ethereal extract of cubebs* has a dark olive brown colour, and contains all the volatile oil, cubebin, and resin (the active principles of the fruit) as well as most of the waxy matter, but none of the extractive. 1 lb. avoirdupois of cubebs yields 2 oz. of ethereal extract. One drachm of it, therefore, is equal to one ounce of cubebs. It may be administered in the form of emulsion, pills, or capsules. Dose from grs. v to ʒss.

3. **EXTRACTUM CUBEBE FLUIDUM, U. S.;** *Fluid Extract of Cubebs.*—Take of Cubebs a pound; Ether a sufficient quantity. Put the cubebs into a percolator, and having packed it carefully, pour ether gradually upon it until two pints of filtered liquor are obtained, then distil off, by means of a water-bath at a gentle heat, a pint and a half of the ether, and expose the residue, in a shallow vessel, until the whole of the ether has evaporated. The above are the directions in full adopted by the *U. S. Pharm.* from Mr. Procter. The dose is as above stated.]

4. **TINCTURA CUBEBE, L. [U. S.];** *Tinctura Piperis Cubebæ, D.;* *Tincture of Cubebs.*—(Cubebs, powdered, 1ʒj [ʒ̄v, *D.* (ʒ̄iv, *U. S.*)]; Proof [Rectified, *D.*] Spirit Oij [Diluted Alcohol Oij, *U. S.*]. Macerate for seven [fourteen, *D. (U. S.)*] days, then express and strain.—Dr. Montgomery⁴ says, “I have found this tincture cure gonorrhœa, both speedily and satisfactorily.” The dose of it is one or two drachms three times a day.

Some druggists keep a more concentrated tincture.

125. *Artanthe elongata, Miquel.*—*Matico-plant.*

Sex. Syst. Diandria, Monogynia.

(Herba; folia.—The Leaves, *D.*)

Piper angustifolium, Ruiz and Pavon, Fl. Peruv.; *Piper elongatum*, Vahl; *Stephensia elongata*, Kunth; *Moho Moho* id est *Nodus Nodus*, vernacul. name.—This plant has long been in use among the natives of Peru in venereal diseases; and having been employed on some occasion by a soldier as a mechanical agent to staunch blood, it got the name of the *Soldier's herb*, and, in 1839, was introduced into this country as an internal or chemical styptic. The term *matico* (*materô* or *matica*) is not exclusively applied to the leaves of this plant; but to those of others also. Dr. Laidley has given to the Museum of the Pharmaceutical Society some leaves of the *Eupatorium glutinosum*, Kunth. They are marked *Matico*, and are said to be excellent in powder for staunching blood and healing wounds. In appearance and texture they closely resemble the leaves of *Artanthe elongata*; and would, I doubt not, be equally valuable as mechanical styptics.

Artanthe elongata is a shrub of about 12 feet high, with jointed stem and branches. Its leaves are harsh, short-stalked, oblong lanceolate, acuminate: pubescent beneath, tessellated or rough on the upper side on account of the sunken veins. The spikes are solitary, cylindrical,

² *Journ. de Pharm.* t. xiv. p. 40.

³ *Pharmaceutical Journal*, vol. vi. p. 319, 1846.

⁴ *Observations on the Dubl. Pharm.* p. 439, Lond.

and opposite the leaves; the bracts lanceolate; and the flowers hermaphrodite.—It grows at Huanuco, Cuchero, Panao, Chaclea and Muna in Peru; and flowers from July to September.

Matico (*herba matico* vel *maticæ*) is imported in scrons, and consists of the dried leaves, stalks, and spikes (some unripe, others ripe), and more or less compressed into a lump. The colour of the dried plant is greenish; and the leaves, which are from 2 to 8 inches long, in structure somewhat resemble those of sage, and are easily reducible to powder. The plant has an aromatic odour somewhat similar to that of cubeb.

Matico has been analyzed by Dr. J. F. Hodges,¹ who found the following substances in it:—an aromatic volatile oil, a bitter principle (masticine), a soft dark green resin, a brown colouring matter, a yellow colouring matter, chlorophylle, gum and nitrate of potash, salts, and lignin.—The oil of matico has a light green colour, and when recent, the consistence of good castor oil, but becomes thick and crystalline on keeping. The bitter principle called masticine, is soluble in alcohol and water, but not in ether.

Infusion of matico yields a dark greenish colouring and precipitate with the sesquichloride of iron;² but undergoes no change on the addition of gelatin, emetic tartar, or perchloride of mercury. It, therefore, contains little or no tannin. Acetate of lead and infusion of nutgalls each occasion copious coloured precipitates.

Matico is an aromatic bitter stimulant, which agrees with cubeb and the pepper in the character of its effects. Its active principles are volatile oil, resin, and the bitter principle.

Matico may be used (like lint, felt, cobweb, &c.) as a topical application for staunching blood, or from slight cuts and other wounds, leech-bites, the nose, gums, &c. It acts mechanically as a styptic by the structure of its leaf, which divides the blood and promotes its coagulation.

As an internal remedy it is applicable as a substitute for cubeb, in discharges from the mucous surfaces, as leucorrhœa, gonorrhœa, &c. It might, perhaps, be useful in affections of the rectum, in similar cases to those in which the confection of pepper has been serviceable. The Indians use the infusion as an aphrodisiac.³

Matico has been greatly lauded⁴ as an internal styptic or astringent in internal hemorrhages (from the lungs, stomach, bowels, and uterus). But the botanical, chemical, and sensible qualities of matico are opposed to the idea of its astringent properties; and with regard to the supposed therapeutic evidence, it may be observed that from the often temporary character and uncertain duration of internal hemorrhages generally, it is very difficult to determine the therapeutic influence of the agents called astringents, and to distinguish *post hoc* from *propter hoc* phenomena. If matico have any styptic power, it is derived not from tannic or gallic acids, but from the volatile oil which the plant contains; and in that case the oils of pepper, cubeb, or turpentine, would be much more energetic and preferable.

[Dr. Ruschenberger, who became acquainted with it during a visit to Peru in 1834, and introduced it into the United States, has used it locally in chronic ophthalmia with advantage. With regard to its anti-hemorrhagic power, the latter gentleman informs me that he applied it to arrest hemorrhage after an operation on the side of the neck below the angle of the jaw, in which there was considerable bleeding and difficulty in taking up the divided vessels, owing to induration of the part from chronic inflammation; and the application was successful. The same arrest of the discharge of blood followed its use in hæmatemesis.]

Matico is administered in the form of powder, infusion, and tincture. The dose of the powder is from ℥ss to ℥ij.

1. **Infusum Matico, D.**; *Infusion of Matico*.—(Matico Leaves, cut small, ℥ss; Boiling Water Oss. Infuse for one hour, in a covered vessel, and strain. The product should measure about eight ounces. D.)—Dose from ℥ʒj to ℥ʒij.

2. **Tinctura Matico, D.**; *Tincture of Matico*.—(Matico Leaves, in coarse powder, ℥vij; Proof Spirit Oij. Macerate for fourteen days, strain, express, and filter, D.)—Dose from ℥ʒj to ℥ʒij.

ORDER XXXIII. EUPHORBIACEÆ, *Juss.*—SPURGEWORTS.

EUPHORBIÆ, *Juss.*

CHARACTERS.—*Flowers* unisexual. *Calyx* free (inferior), with various glandular or scaly internal appendages; sometimes wanting. *Corolla* usually absent, sometimes polypetalous or monopetalous. *Stamens* definite or indefinite, distinct or monadelphous; *anthers* 2-celled. *Ovary* free (superior). *Ovules* solitary or twin, suspended from the inner angle of the cell. *Fruit* generally trilocous, consisting of 3 carpels splitting and separating with elasticity from their common axis, occasionally fleshy and indehiscent. *Seeds* solitary or twin, suspended often with an aril; embryo enclosed in fleshy albumen; cotyledons flat; radicle superior.—*Trees, shrubs, or herbs*, often abounding in a milky juice. *Leaves* opposite or alternate, simple, rarely compound, often with stipules. *Flowers* axillary or terminal, sometimes inclosed within an involucre re-

¹ *Memoirs and Proceedings of the Chemical Society*, vol. ii. p. 123, 1841.

² Peppermint and other labiate plants yield infusions which produce a dark green colour with the sesquichloride of iron.

³ Martius, *Pharmaceutical Journal*, vol. ii. p. 660, 1843.

⁴ See Jeffrey's *Remarks on Matico*, 1813.

sembling a calyx. Some of the Euphorbiaceæ are succulent or fleshy, and have a considerable resemblance to Cactaceæ; from which they may in general be distinguished by the presence of an acrid milky juice.

PROPERTIES.—Mostly acrids; operating, toxicologically, as acrid, narcotic-acrid, or acro-narcotic poisons; and medicinally, as rubefaciens, suppurants, emetics, diuretics, and cathartics. The acrid or poisonous principle or principles reside in the roots, stems, leaves and seeds. It is a constituent of the acrid milky juice found in many of the species. "M. Berthollet has recorded a remarkable instance of the harmless quality of the sap in the interior of a plant, whose bark is filled with a milky proper juice of a poisonous nature. He described the natives of Teneriffe as being in the habit of removing the bark from the *Euphorbia canariensis*, and then sucking the inner portion of the stem in order to quench their thirst, this part containing a considerable quantity of limpid and non-elaborated sap."¹ In some cases an acrid principle (see vol. i. p. 206) is found in the embryo, but not in the albumen of the seed. Thus Aulet² states that the kernels of *Omphalea diandra* are edible if the embryo be extracted; but if this be left in, they prove cathartic. In some cases, however, as those of *Croton* and *Ricinus*, the albumen also possesses acrid and poisonous properties. The chemical nature of the acrid principle or principles has not been determined. In some cases it appears to be volatile, in others fixed. If it be true that persons have been poisoned by sleeping under the Mauchineel tree (*Hippomane Mancinella*), this species must give out a poisonous vapour. In some cases, however, resin appears to be the active principle; as in the officinal substance called gum euphorbium.

The expressed oils of the seeds of several of the Euphorbiaceæ (as *Croton*, *Ricinus*, *Jatropha*, *Euphorbia*, and *Anda*) are purgative; in some cases violently so. They probably owe this to some active principle dissolved in the fixed oil; for the residual oil cake acts as a drastic purgative, in some cases more so than the expressed oil. Soubeiran³ thinks that some of the euphorbiaceous seeds owe their purgative qualities to resin. The fixed oil of some of the seeds is remarkable for its more ready miscibility with, or solubility in, alcohol, than most other fixed oils.

Some euphorbiaceous plants are devoid of acridity, or possess it in a very slight degree only. Some of these are aromatic, resiniferous, and tonic. Von Buch⁴ says, the branches of *Euphorbia balsamifera* contain a mild sweet juice, which is eaten by the inhabitants of the Canary Isles. The aromatic tonic bark of the *Croton Eleutheria* is another exception to the very general acridity of these plants.

Some of the roots are harmless and nutritious. Others of neighbouring species abound in nutritive starch (c. g., *tapioca-starch*), which resides in a poisonous juice.

TRIBE. EUPHORBIEÆ, Bartling.

Ovules solitary. *Seeds* albuminous. *Flowers* monœcious, apetalous; male and females mixed in a cup-shaped involucre.

126. EUPHORBIA CANARIENSIS, Linn.—THE CANARY EUPHORBIA.

Sex. Syst. Dodecandria, Trigynia, Linn.—Monœcia, Monandria, Smith.

(Euphorbium; gummy-resina, L. D.—Concrete resinous juice, E.)

HISTORY.—The plant which yields the saline waxy-resin called in the shops *gum euphorbium*, is said both by Dioscorides⁵ (who calls it *εὐφώρβιον*) and Pliny⁶ to have been first discovered in the time of Juba, king of Mauritania; that is, about, or a few years before, the commencement of the Christian era. Pliny says that Juba called it after his physician, Euphorbus; and that he wrote a volume concerning it, which was extant in Pliny's time. Saluasius, however, states that this word occurs in the writings of Meleager the poet, who lived some time before Juba. But in the passage in question the commonly received reading in the present day is not *εὐφώρβης*, but *ἐκ φώρβης*.⁷

BOTANY. **Gen. Char**—*Flowers* collected in monœcious heads, surrounded by an involucre consisting of 1 leaf with 5 divisions, which have externally 5 glands alternating with them. *Males* naked, monandrous, articulated with their pedicel, surrounding the female, which is in the centre. *Females* naked, solitary. *Ovarium* stalked. *Stigmata* 3, forked. *Fruit* hanging out of the involucre, consisting of

⁵ Lib. iii. cap. 96.

⁶ *Hist. Nat. lib. xxv. cap. 38*, ed. Valp. Pliny calls the plant *euphorbia*, and the resin *euphorbium* (lib. xxvi. cap. 31).

⁷ Dr. Greenhill, *Dict. of Greek and Roman Biography*, art. *Euphorbus*, vol. ii. p. 97.

3 cells, bursting at the back with elasticity, and each containing 1 suspended seed (Lindley).

Sp. Char.—Branches channelled, with 4, rarely 5, angles, armed with double, straight, spreading, dark, shining spines.

These specific characters apply to the branches found mixed with the euphorbium of commerce. They agree with the description and figure of *Tithymalus aizoides* sen *Euphorbia canariensis* of Plukenet.¹ This agrees with the statement of Miller,² who states that by looking over some euphorbium in a shop, he “found several spines amongst it, which exactly agreed with those of that plant.” I feel very little hesitation, therefore, in referring the euphorbium of English commerce to *E. canariensis*; and the species still retained by the Dublin College.

From the *E. canariensis* of Willdenow and of some other botanists, this plant is distinguished by its straight spines; but on examining the *E. canariensis* at the Kew Garden, I find as many of the spines straight as uncinatæ. The diameter of the stems, however, and even of the young shoots, is greater than that of stems found in the euphorbium of commerce. The species which most closely agrees with the latter in the sizes of the stems, the number of angles, and the number and directions of the spines, is *Euphorbia tetragona*. This species has mostly square stems; though some of the larger stems are somewhat channelled. The dried stems found in the euphorbium of commerce, however, appear to be uniformly channelled. The *E. officinarum* (adopted by the London College) has many angles: the *Dergmuse* of Jackson³ has many scolloped angles. *Euphorbia antiquorum* has been said to yield euphorbium, but the statement is denied by both Hamilton⁴ and Royle.⁵

Hab.—The Canary Islands; Africa, in the neighbourhood of Mogadore?

EXTRACTION.—Euphorbium is thus procured: The inhabitants of the lower regions of the Atlas range make incisions in the branches of the plant, and from these a milky juice exudes, which is so acrid that it excoriates the fingers when applied to them. This exuded juice hardens by the heat of the sun, and forms a whitish-yellow solid, which drops off in the month of September, and forms the euphorbium of commerce. “The plants,” says Mr. Jackson,⁶ “produce abundantly once only in four years; but this fourth year’s produce is more than all Europe can consume.” The people who collect it, he adds, are obliged “to tie a cloth over their mouth and nostrils to prevent the small dusty particles from annoying them, as they produce incessant sneezing.” The acrid resinous juice resides in the outer or cortical portion of the stem (see *ante*, p. 359).

PROPERTIES.—Euphorbium consists of irregular yellowish, slightly friable tears, usually pierced with one or two holes, united at the base, and in which we find the remains of a double aculeus. These tears are almost odourless; but their dust, applied to the olfactory membrane, acts as a powerful sternutatory. Their taste is at first slight, afterwards acrid and burning.

When heated, euphorbium melts, swells up imperfectly, evolves an odour somewhat like that of benzoic acid vapour, takes fire, and burns with a pale flame. Alcohol, ether, and oil of turpentine are its best solvents; water dissolves only a small portion of it.

COMPOSITION.—Euphorbium has been the subject of several analyses—namely, in 1800, by Laudet;⁷ in 1809, by Braconnot;⁸ in 1818, by Pelletier⁹ and by Mühlmann;¹⁰ in 1819, by Brandes;¹¹ and more recently by Drs. Buchner and Herberger.¹²

RESIN is the active ingredient of euphorbium. It coincides in many of its properties with ordinary resins; thus, it is reddish-brown, hard, brittle, fusible, soluble in alcohol, ether, and oil of turpentine, and somewhat less so in oil of almonds. Its leading and characteristic property is intense acidity. It differs from some resins in being slightly soluble only in alkalies. It is a compound of two resinous substances.

a. One resinous substance is soluble in cold alcohol. Its formula, according to Mr. Johnston,¹ is $C^{40}H^{31}O^6$.

β. The other resinous substance is insoluble in cold alcohol. The mean of Rose's analyses² of it gives as the composition of this resin, carbon 81.58, hydrogen 11.35, and oxygen 7.07.

PHYSIOLOGICAL EFFECTS. a. *On Animals generally.*—Euphorbium acts on horses and dogs as a powerful acrid substance, irritating and inflaming parts with which it is placed in contact, and affecting the nervous system. When swallowed in large quantities, it causes gastro-enteritis (two ounces are sufficient to kill a horse); when applied to the skin, it acts as a rubefacient and epispastic. Farriers sometimes employ it, as a substitute for cantharides, for blistering horses, but cautious and well-informed veterinarians are opposed to its use.

β. *On Man.*—The leading effect of euphorbium on man is that of a most violent acrid, but under certain circumstances a narcotic operation has been observed. When *euphorbium dust is inhaled, and also applied to the face*, as in grinding this drug, it causes sneezing, redness, and swelling of the face, and great irritation about the eyes and nose. To prevent as much as possible these effects, various contrivances are adopted by different drug-grinders; some employ masks with glass eyes, others apply wet sponge to the nose and face, while some cover the face with crape. The pain and irritation, I am informed, are sometimes very great. Individuals who have been exposed for some time to the influence of this dust, suffer with headache, giddiness, and ultimately become delirious. All the workmen of whom I have inquired (and they comprise those of three large firms, including the one alluded to by Dr. Christison) agree that these are the effects of euphorbium. An old labourer assured me that this substance produced in him a feeling of intoxication; and I was informed at one drug-mill of an Irish labourer who was made temporarily insane by it, and who, during the fit, insisted on saying his prayers at the tail of the mill-horse.

Insensibility and convulsions have been produced by euphorbium. The only instance I am acquainted with is the following: A man was engaged at a mill where euphorbium was being ground, and remained in the room longer than was considered prudent. Suddenly he darted from the mill-room, and ran with great velocity down two pairs of stairs. On arriving at the ground-floor or yard he became insensible, and fell. Within five minutes I saw him: he was lying on his back, insensible and convulsed; his face was red and swollen, his pulse frequent and full, and his skin very hot. I bled him, and within half an hour he became quite sensible, but complained of great headache. He had no recollection of his flight down stairs, which seems to have been performed in a fit of delirium.

When *powdered euphorbium is applied to the skin*, it causes itching, pain, and inflammation, succeeded by vesication.

When *swallowed*, it causes vomiting and purging, and, in large doses, gastro-enteritis, with irregular hurried pulse and cold perspirations.

USES.—Notwithstanding that it is still retained in the Pharmacopœia, it is rarely employed in medicine. It was formerly used as an *emetic* and *drastic purgative* in dropsies, but the violence and danger of its operation have led to its disuse. Sometimes it is employed as an *errhine* in chronic affections of the eyes, ears, or brain; but its local action is so violent that we can only apply it when largely diluted with some mild powder, as starch or flour.

Mixed with turpentine or Burgundy pitch (or rosin), it is employed in the form of plaster, as a *rubefacient*, in chronic affections of the joints. As a *vesicant*, it is rarely employed. As a *caustic*, either the powder or alcoholic tincture (*Tinctura Euphorbii*, Cod. Hamb., prepared by digesting euphorbium ʒj, in rectified spirit ℥ij) is sometimes employed in carious ulcers.

¹ *Phil. Trans.* 1810, p. 365.

² Poggendorff's *Annalen*, xxxiii. 52.

ANTIDOTE.—In a case of poisoning by euphorbium, emollient and demulcent drinks, elysters (of mucilaginous, amylaceous, or oleaginous liquids), and opium, should be exhibited, and blood-letting and warm baths employed. In fact, as we have no chemical antidote, our object is to involve the poison in demulcents, to diminish the sensibility of the living part by opium, and to obviate the inflammation by blood-letting and the warm bath. If the circulation fail, ammonia and brandy will be required.

127. *Euphorbia Lathyris*, Linn.—Caper Spurge.

(Semina.)

This is an indigenous or naturalized biennial plant, which is cultivated in gardens. *Sem* solitary, erect, 2 or 3 feet high, purplish, round, smooth, like every other part. *Leaves* numerous, spreading in 4 rows, opposite, sessile, oblong, acute, entire, of a dark glaucous green; their base heartshaped: the lower ones gradually diminishing. *Umbel* solitary, terminal large, or 4 repeatedly forked branches. *Braets* heartshaped, entire, tapering to a point. *Flowers* sessile in each fork, solitary, variegated with yellow and dark purple. *Nectaries* rounded with blunt horns. *Capsules* large, smooth (Smith)—The seeds (*sem. euphorbiæ lathyris*; *sem. cataputiæ minoris*; *grana regii minoris*) are about the size of peppercorns. They yielded Soubeiran¹ a yellow fixed oil, stearine, a brown arid oil, a crystalline matter, a brown resin, an extractive colouring matter, and vegetable albumen. The yellow fixed oil is purgative, but it owes this property to matters which it holds in solution. The brown arid oil is the active principle: it has a disagreeable odour, approaching that of croton oil, and readily dissolves in alcohol and ether. Oil of caper spurge (*oleum euphorbiæ lathyris*) may be obtained by expression, by alcohol, or by ether. The expressed oil, unlike that of croton oil, is insoluble in alcohol. It is less active than the oil prepared by alcohol (as 3 is to 2). Both the milky juice of the plant and the seeds are acrid, and violently purgative. In a case of poisoning by the seeds, narcotic symptoms also were present.² The oil may be employed as an indigenous substitute for croton oil. The dose of it is from three to ten drops.³ The capsules are pickled and used as a substitute for capers, which they resemble in size, appearance, and pungency. When recent, they are certainly acrid and poisonous; and it is probable, therefore, that the pickling process lessens or destroys their virulence; but the free use of the pickled fruits is dangerous.

128. *Euphorbia Ipecacuanha*, Linn.—Ipecacuanha Spurge.

(Radix.)

This plant (also called *American Ipecacuanha*) is a native of the United States of America. The dried root (*radix euphorbiæ ipecacuanhæ*; vel *rad. ipecacuanhæ spurie alba*) is cylindrical, grayish yellow, inodorous, and has a sweetish, not unpleasant taste. According to Dr. Bigelow, it contains caoutchouc, resin, gum, and probably starch. Its active principle is perhaps resin. This root is "an energetic, tolerably certain emetic, rather milder than *E. corollata*, but, like that, disposed to act upon the bowels, and liable, if given in over doses, to produce excessive nausea and vomiting, general prostration, and a alarming hypercatharsis. It is, therefore, wholly unfit to supersede ipecacuanha."⁴ The dose of the powdered root is from ten to fifteen grains. In small doses it is diaphoretic.

TRIBE. CROTONEÆ, Blume.

Ovule solitary. *Flowers* usually having petals, in clusters, spikes, racemes, or panicles.

129. CROTON TIGLIUM, Lam.—THE PURGING CROTON.

Croton Jamalgota, Hamilton.

Sex. Syst. Monœcia, Monadelphia.

⁶ *De Simplicibus*, cccxlviii.

d'Acosta, in 1578,¹ who terms them *pini nuclei molucani*. When Commeline wrote, they were known in the shops by the name of *cataputia minor*, although they were sold by itinerants as *grana dilla* or *grana tilli*. They were much employed by medical men in the 17th century, and were known by various names, but principally by that of *grana tiglia*. They, however, went out of use, probably in consequence of the violence and uncertainty of their operation. Their re-employment in modern practice is owing partly to the notices of them by Dr. White and Mr. Marshall, in the first edition of Dr. Ainslie's work;² but principally to the introduction of the oil, in 1820, by Dr. Conwell.³

BOTANY. Gen. Char.—Flowers monœcious, or very rarely diœcious. *Calyx* 5-parted. **MALES:** *petals* 5; *stamens* 10 or more, distinct. **FEMALES:** *petals* 0; *styles* 3, divided into two or more partitions. *Capsule* tricocous [with one seed in each cell] (Adr. de Jussieu).

Sp. Char.—Arboreous. *Leaves* oblong-ovate, acuminate, 3—5-nerved, slightly serrate, smooth. *Stamina* 15, distinct. Each cell of the fruit filled by the seed.

A middle-sized tree, from 15 to 20 feet high. *Bark* smooth, ash-coloured. *Leaves* thin and membranous, sometimes cordate, and with two flat round glands at their base; when young, covered on both surfaces, but especially the lower one with minute stellate hairs. At the base of the leaves are two flat round glands. *Raceme* terminal, erect, simple. *Petals* of male flower white.

Hab.—Continent of India, islands forming the Indian Archipelago, and Ceylon.

The **CROTON PAVANA**⁴ is said also to yield tiglium or croton seeds. It is distinguished from *C. Tiglium* by having only ten stamina, and by the seeds being much smaller than the cells in which they are placed. *C. Pavana* is a native of Ava, north-eastern parts of Bengal? Amboyna?? Dr. Hamilton thinks it is the *Granum Moluccum* of Rumphius.

DESCRIPTION.—*Croton seeds* (*semina tiglii seu semina crotonis, grana tiglii, purging nuts* of some authors) in size and shape are very similar to castor seeds. Viewed laterally, their shape is oval or oval-oblong; seen from either extremity, they have a rounded or imperfectly quadrangular form. Their length does not exceed 6 lines, their thickness is 2½ to 3 lines, their breadth 3 or 4 lines. Sometimes the surface of the seeds is yellowish, owing to the presence of an investing lamina (epidermis?). The testa is dark brown or blackish, and is marked with the ramifications of the raphé. The endocarp, or internal seed-coat, is thin, brittle, and of a light colour. It encloses a yellowish oily albumen, which envelops the embryo, whose cotyledons are foliaceous or membranous. The seeds are without odour; their taste is at first mild and oleaginous, afterwards acrid and burning. When heated, they evolve an acrid vapour. The proportion of shell and kernel in 100 parts by weight of the seeds is thus stated by two authorities:—

	Nimmo.	Caventou.
Shell or seed-coats	36	33.3
Kernel or nucleus	64	66.6
	100	99.9

COMPOSITION.—Croton seeds were analyzed in 1818 by MM. Pelletier and Caventou,⁵ in 1822 by Dr. Nimmo,⁶ and in 1823 by Brandes.⁷ The following are their results:—

¹ Clusius, *Eroticor.* p. 292.
² See his *Récherch. sur les Propr. Méd. et l'Emploi en Méd. de l'Huile de Croton Tiglium*, 1824.—For further historical details, consult Prof. II. H. Wilson's paper in the *Transactions of the Med. and Phys. Society of Calcutta*, vol. i. p. 249.
³ Hamilton, *Trans. Linn. Soc.* vol. xiv. 257.
⁴ *Journ. de Pharm.* t. iv. p. 289, 1818; and t. xi. p. 10, 1825. In the first paper, croton seeds were, by mistake, said to be the seeds of *Jatropha Curcas*. Caventou corrected this statement in the second paper. In the *Journ. de Pharm. et de Chim.* for March 1830, M. Guilbourt states that he has recently ascertained that the seeds of *J. Curcas* are sold by respectable dealers in Paris for croton seeds. It is stated by Mr. Frost (*Lond. Medic. Reposit.* vol. xvii. p. 461, 1822; and vol. xviii. p. 474, 1822) that in England, the former seeds have been mistaken for the latter.
⁵ *Quarterly Journal of Science*, vol. xiii. p. 62, 1822. Soubeiran (*Journ. de Pharm.* t. xv. p. 514, 1829) states, though I know not on what authority, that the oil which Dr. Nimmo analyzed under the name of croton oil, was extracted from the *Jatropha*.

1. **VOLATILE OIL OF CROTON SEEDS.**—This is but imperfectly known, traces only of it having been obtained. Brandes regards it as extremely acrid, and thinks that by the united agencies of air and water it is converted into crotonic acid; for the distilled water of the seeds becomes more acid by keeping.

2. **FIXED OIL OF CROTON SEEDS.**—This also is but imperfectly known. It must not be confounded with croton oil of the shops, which is a mixture of this and other constituents of the seeds. Fixed oil of croton seeds is, probably, a combination of crotonic and other fatty acids with glycerine.

3. **CROTONIC ACID.** (*Jatrophic Acid*).—Discovered by Pelletier and Caventou. Though this acid exists in the free state in the seed, yet an additional quantity of it is obtained when the oil is saponified. For this purpose the oil is saponified by potash, the resulting soap decomposed by tartaric acid, and the watery fluid, from the surface of which the separated common fatty acids have been removed, is to be submitted to distillation. In this way is obtained an aqueous solution of a solid, very volatile, fatty acid, which congeals at 23° F., and, when heated a few degrees above 32° F., is converted into vapour, having a strong nauseous odour, and which irritates the eyes and nose, and has an acrid taste.

At first Pelletier and Caventou regarded this acid as the active principle of the oil; but Caventou subsequently expressed doubts on the subject, and stated that fresh experiments induced him to think that the irritating and volatile principle of the oil, and which so strongly irritated the nose and eyes, is not of an acid nature. My colleague, Mr. Redwood, informs me that he has ascertained that crotonic acid and the crotonates are inert, or nearly so; and in experiments with crotonic acid prepared by him support his statements.

Crotonic acid unites with bases forming a class of salts called *crotonates*, which are inodorous. The *crotonate of ammonia* precipitates the salts of lead, copper, and silver, white; and the sulphate of iron, yellow. *Crotonate of potash* is crystalline, and dissolves, with difficulty, in alcohol. *Crotonate of barytes* is soluble in water; but *crotonate of magnesia* is very slightly soluble only in this liquid.

4. **CROTONIN.**—The crystallizable substance which Brandes thought to be a peculiar alkaloid, and which he called *crotonia*, and which appeared to be identical with the *tiglin* of Adr. de Jussieu, has been found by Weppen¹ to be (as formerly suggested by Soubeiran²) a magnesian sap with an alkaline reaction.

5. **RESIN.**—Is brown and soft; and has a disagreeable odour, on account, doubtless, of the oil which it retains. It is soluble in alcohol, but insoluble in ether and in water. The alkalies dissolve it by separating a whitish matter. It contributes to the purgative properties of croton oil.

PHYSIOLOGICAL EFFECTS. 1. **Of the Seeds.** a. *On Animals generally.*—Croton seeds are powerful local irritants or acrids, causing inflammation in those living parts with which they are placed in contact. Orfila³ found that three drachms being introduced into the stomach of a dog, and the œsophagus tied to prevent vomiting, caused death in three hours; and on examination of the body, the alimentary canal was found to be in a state of inflammation. In another experiment, a drachm caused death under the same circumstances. A drachm, also, applied to the cellular tissue of the thigh, was equally fatal. A dose of from twenty to thirty grains of the powder of the kernel given to the horse causes, in six or eight hours, profuse watery stools, and is recommended by some veterinarians as a purgative; but the uncertainty of its operation, and the griping and debility which it occasions, are objections to its use.⁴ Lansberg⁵ found that twenty of the seeds killed a horse, by causing gastro-enteritis. The pulse was frequent, small, and soft.

β. *On Man.*—In the human subject a grain of croton seed will frequently pro-

¹ *Ann. d. Chem. u. Pharm.* Bd. lxx. S. 254, 1849; also *Chemical Gazette*, vol. vii. p. 355, 1849.

³ *Toxicol. Gén.*

⁴ Youatt, *The Horse*, in *Library of Useful Knowledge*. ⁵ Wibmer, *Arzneim. u. Gifte*, Bd. ii. S. 222.

duce full purgation. Mr. Marshall¹ says that this quantity, made into two pills, is about equal in power to half a drachm of jalap, or to six grains of calomel. The operation, he adds, is attended with much rumbling of the bowels; the stools are invariably watery and copious. Dr. White recommends the seeds to be torrefied, and deprived of their seed-coats, before employing them.² Dr. Wallich informed me that the labourers in the Caleutta Botanic Garden were in the habit of taking one of these seeds as a purgative, but that on one occasion this dose proved fatal.

The seed-coats, the embryo, and the albumen, have each in their turn been declared to be the seat of the acrid principle; I believe the remarks which I shall have to make with respect to the seat of the acidity of castor-oil seeds, will apply equally well to that of croton seeds.

The following is a case of poisoning by the inhalation of the dust of the seeds:—

Thomas Young, aged 31, a labourer in the East India warehouses, was brought into the London Hospital on the 8th of December, 1841, labouring under symptoms of poisoning by the inhalation of the dust of croton seeds. He had been occupied about eight hours in emptying packages of these seeds, by which he was exposed to their dust. The first ill effects observed were loss of appetite, then a burning sensation in the nose and mouth, tightness at his chest, and copious lachrymation, followed by epigastric pain. Feeling himself getting worse, he left the warehouse, but became very giddy, and fell down insensible. Medical assistance was procured, an emetic was administered, stimulants were exhibited, and he was wrapped in warm blankets. When he became sensible, he complained of his mouth being parched, and that his throat was swelling. He was then removed to the hospital. On his admission he appeared in a state of collapse, complained of burning pain at the stomach, in the throat, and in the head, and of swelling and numbness of his tongue. The epigastrium felt hot and tense, the pupils were dilated, the breathing short and hurried, the countenance distressed, pulse 85, surface cold. He stated that his tongue felt too large for his mouth, and appeared to be without feeling, and he had bitten it two or three times to ascertain whether there was any sensation in it. On examination, however, no change could be observed in the size or appearance of the tongue or parts about the mouth. Hot brandy and water were given to him, and he was put into the hot bath with evident relief. He continued in the hospital for several days, during which time he continued to improve, but still complained of epigastric pain. It deserves notice that his bowels were not acted on, and on the day following his admission several doses of castor-oil were given to him.

It would be interesting to know whether the seeds of *Croton Pavana* are equally active with those of *Croton Tiglium*; and, also, whether the seeds of both species are found in commerce.

2. *Of the Oil.* *a. On Animals generally.*—On vertebrated animals (horses, dogs, rabbits, and birds), it acts as a powerful local irritant or acrid. When taken internally, in moderate doses, it operates as a drastic purgative; in large doses, as an acrid poison, causing gastro-enteritis. Moiroud³ says, that from twenty to thirty drops of the oil are, for the horse, equal to two drops for a man; and that twelve drops injected into the veins cause alvine evacuations in a few minutes. Thirty drops administered in the same manner, have caused, according to this veterinarian, violent intestinal inflammation and speedy death. A much less quantity (three or four drops) has, according to Hertwich,⁴ terminated fatally when thrown into the veins. After death the large intestines have been found to be more inflamed than the small ones. Flies, which had eaten some sugar moistened with the oil of croton, died in three or four hours—the wings being paralyzed or immovable before death.

β. On Man.—*Rubbed on the skin* it causes rubefaction and a pustular or vesicular eruption, with sometimes an erysipelatous swelling of the surrounding parts. When rubbed into the abdomen, it sometimes, but not invariably, purges. Rayer⁵ mentions a case in which thirty-two drops rubbed upon the abdomen produced purging, large vesicles, swelling, and redness of the face, with small, prominent, white, crowded vesicles on the cheeks, lips, chin, and nose. *Applied to the eye*, it gives rise to violent burning pain, and inflammation of the eye and face. In one

¹ Ainslie, *Mat. Indica*, vol. i. p. 104.

² *Pharm. Vétér.* p. 272.

³ *Treatise on Diseases of the Skin*, by Dr. Willis, p. 367.

⁴ *Ibid.*

⁵ *Wibmer, Arzneim. u. Gifte*, Bd. ii. S. 218.

ease it produced giddiness.¹ Ebeling obtained relief by the application of a solution of carbonate of potash. *Swallowed in small doses*, as of one or two drops, it usually causes an acrid burning taste in the mouth and throat, and acts as a drastic purgative, giving rise to watery stools, and frequently increasing urinary secretion. Its operation is very speedy. Frequently it causes evacuations in half an hour: yet it is somewhat uncertain. Sometimes six, eight, or even ten drops may be given at a dose without affecting the bowels. In moderate doses it is less disposed to cause vomiting or purging than some other cathartics of equal power. Mr. Hiff,² however, observes that it produces nausea and griping more frequently than has been supposed.

The following is a case of poisoning by an *excessive dose* of croton oil: A young man, aged 25, affected with severe typhoid fever, swallowed by mistake two and a half drachms of croton oil. At the end of three-quarters of an hour the skin was cold and covered with cold sweats, the pulse and action of the heart scarcely perceptible, respiration difficult; the points of the toes and fingers, the parts around the eyes and the lips, blue, as in malignant cholera; abdomen sensible to the touch; but no vomiting. In an hour and a half there were excessive and involuntary alvine evacuations, sensation of burning in the œsophagus, acute sensibility of the abdomen, skin colder, respiration and circulation difficult, the cyanosis extended over the whole body, the skin became insensible; and death occurred, with some of the symptoms of asphyxia, four hours after the poison was swallowed. No lesion was found in the gastric membrane. The intestines presented ulcerations such as are characteristic of typhus fever.³

In comparing croton oil with other violently acrid purgatives, we find it distinguished by its speedy operation, the great depression of the vascular system as well as the general feeling of debility which it produces, and by the uncertainty of its operation.

USES.—The value of croton oil as an internal remedial agent depends principally on two circumstances—first, its powerful and speedy action as a drastic cathartic, by which it is adapted for obviating constipation, or for operating on the bowels as a counter-irritant; and secondly, on the smallness of the dose, which in practice presents many advantages. These circumstances render it peculiarly applicable in cases requiring powerful and speedy catharsis, and in which the patient cannot swallow, or does so with extreme difficulty, as in *trismus*, *coma*, and *some affections of the throat*; or where he will not swallow, as in *mania*. In all such cases the oil may be dropped on the tongue. In *obstinate constipation*, whether from the poison of lead or from other causes, it has sometimes succeeded where other powerful cathartics had been tried in vain. It is especially serviceable where the stomach is irritable, and rejects more voluminous purgatives; and it is of course objectionable in all inflammatory conditions of the digestive tube. In stercoraceous vomiting, with other constitutional symptoms of hernia, but without local evidence of displacement, and where the stomach rejected the ordinary senna draught, I have known oil of croton prove most effectual. In *torpid conditions of the intestinal canal*, in *tendency to apoplexy*, in *dropsy* unconnected with inflammation, in *paralysis*—in a word, in any cases in which a powerful and speedy intestinal irritant is required, either for the purpose of evacuating the canal merely, or for acting as a revulsive or counter-irritant, and thereby relieving distant parts, croton oil is a very useful, and, on many occasions, most valuable cathartic. In employing it, two cautions are necessary: it must be avoided, or at least used with great caution, in extreme debility; and it is improper in inflammatory affections of the digestive organs. The great drawback to its use is its uncertainty. In one case it acts with extreme violence, in another it scarcely produces any effect. In the *diseases of children*, where a powerful purgative is required, croton oil has been administered, on account of the minuteness of the dose and the facility of its exhibition. In hydrocephalus, and other head

¹ Dierbach, *Neuesten Entd. in d. Mat. Med.* 1837, p. 201.

² *Lond. Med. Rep.* vol. xvii.

³ *Journ. de Chim. Méd.* 2nde sér. t. v. p. 509.

affections of children, I have several times used it where other cathartics have failed, or where extreme difficulty was experienced in inducing the patients to swallow the more ordinary remedies of this class. In some of these it has disappointed me. In the case of a child of four years of age, affected with incipient hydrocephalus, I gave six doses, of one drop each, of the oil without any effect. In *uterine obstructions* (chlorosis and amenorrhœa) it has occasionally proved serviceable. In *tape-worm* it has been recommended, but I have no experience of its efficacy.

Rubbed on the skin, croton oil has been employed to produce rubefaction and a pustular eruption, and thereby to relieve diseases of internal organs, on the principle of counter-irritation, before explained¹ (see vol. i. p. 170). *Inflammation of the mucous membrane lining the air-passages, peripneumonia, glandular swellings, rheumatism, gout, and neuralgia*, are some of the diseases against which it has been applied in this way; and doubtless frequently with benefit. It is sometimes used in the undiluted form, but more commonly with twice or thrice its volume of olive oil, oil of turpentine, soap liniment, alcohol, ether, or some other convenient vehicle. But, in all the cases just enumerated, it has never appeared to me to present any advantage over many other counter-irritants in common use—as emetic tartar; while the chance of causing purging is, in some cases, an objection to its use, and its greater cost sometimes precludes its employment on a large scale in pauper establishments. Frictions with it on the abdomen have been used to promote alvine evacuations, but it frequently fails to produce the desired effect. To promote the absorption of the oil in these cases, it should be dissolved in ether or alcohol, and the frictions are to be assiduously made.

ADMINISTRATION.—*Croton seeds* are rarely or never used in this country. Their farina may, however, be given in doses of a grain or two.

CROTONIS OLEUM, E.; Tiglii Oleum, L.; Oleum Tiglii, U.S.; Croton Oil.—This is the expressed oil of the seeds. It is imported from the East Indies, principally from Madras and Ceylon, but in part from Bombay. I have been informed by an oil-presser at Calcutta that it is prepared like castor oil, except that it is strained instead of being boiled. In shelling the seeds, the women often suffer severely with swelling of the face, &c. Croton oil is also expressed in England. The operation is usually effected by a Bramah's press in a room heated to about 75° F. The men engaged in the process are usually much affected by it; they suffer redness of the face, irritation of the eyes and air-passages, and purging. The following are the results obtained at two operations: the weights are avoirdupois:—

	Seeds.			Oil obtained.
	cwts.	qrs.	lbs.	lbs.
Croton Seeds	2	0	17.	51
Ditto	5	3	10.	150
Total	7	3	27.	201

This gives a per centage produce of about 22.46. The colour of the oil thus obtained, when viewed by transmitted light, was that of dark sherry. No use is made of the cake.

In France, the croton cake is subjected to the action of alcohol, and the oil thus obtained mixed with the previously expressed oil. Guibourt² obtained by expression 41.6 per cent. of oil from the kernels of the seeds, and subsequently 10.4 per cent. by the action of alcohol: making together 52 per cent. Calculating the shells at one-third the weight of the entire seeds, this product would be equal to nearly 35 per cent. for the entire seeds.

Genuine croton oil varies in colour from very pale yellow (like that of Canada balsam) to dark reddish-brown (like the deepest-coloured sherry). Its consistence is unctuous, and increases with age. It has an unpleasant but marked odour and

¹ *Bamb iger, De olei crotonis externe adhibiti efficacia, Berol. 1833.*

² *Journ. de Pharm. et de Chim. 3d ser. t. xvii. p. 183, 1850.*

an acrid taste, and leaves behind an acrid sensation in the fauces. It reddens litmus, and is soluble in ether and in the fixed and volatile oils.

The following are the characteristics of the goodness of the oil according to the Edinburgh College:—

When agitated with its own volume of pure alcohol and gently heated, it separates on standing, without having undergone any apparent diminution.

This statement is not correct, according to my observations. Pure croton oil expressed in London dissolves in alcohol (sp. gr. 0.796) without requiring to be "gently heated." The oil imported from the East Indies does, however, require to be heated with the alcohol to effect its solution. In the second place, separation does not take place, at ordinary temperatures, in the case of a mixture of English croton oil and alcohol. But by a low temperature, separation takes place on standing, but in that case the volume of oil is found to be slightly augmented. East India croton oil mixed with alcohol separates by repose: the volume of the oil, however, is increased and that of the alcohol proportionately lessened.

In one experiment, 8 vols. of E. I. croton oil were mixed with 8 vols. of alcohol, sp. gr. 0.796, and gently heated. In two days separation had taken place: the oil now measured $8\frac{1}{4}$ vols., and the alcohol $7\frac{1}{4}$ vols. In a second experiment, 7 vols. of another E. I. croton oil were mixed with 7 vols. of alcohol: in four days separation had taken place: the oil measured $7\frac{1}{4}$ vols., and the alcohol $6\frac{3}{4}$ vols.

According to Dr. MacLagan, only 96 per cent. of the oil separates. It is obvious, therefore, that commercial croton oils, believed to be genuine, are not uniform in their relation to alcohol.

According to Mr. Twining,¹ there are two kinds of croton oil met with in commerce. One is dark yellow and thickish, the other is straw-coloured. The first is the most energetic. These oils, he thinks, may perhaps be obtained from different plants; the one from Croton Tiglium, the other from Croton Pavana.

The croton oils found in the London market are of two kinds; one exotic, imported from India and Ceylon—the other expressed in London. These differ both in their appearance and relation to alcohol.

a. OLEUM CROTONIS EXOTICUM; Foreign or East Indian Croton Oil; Pale Croton Oil.—This is imported from Ceylon and the continent of India. It is paler than London expressed oil. Some samples are very transparent and pale yellow, like Canada balsam. Others (the more usual sort) are of a pale amber colour. If equal volumes of East India oil and alcohol (sp. gr. 0.796) be shaken together, an opaque milky mixture is obtained: but, if the heat of a spirit-lamp be applied, the mixture becomes transparent and uniform. By standing, however, for twenty-four hours, it separates into two strata: the lower one consisting of the oil which has taken up a small quantity of alcohol, and has, in consequence, become somewhat augmented in bulk, and the upper one, the alcohol, which has suffered a corresponding diminution in volume (see above).

β. OLEUM CROTONIS ANGLICUM; English Croton Oil; Dark Croton Oil.—The oil expressed from croton seeds in London is darker coloured than that usually imported from India. By transmitted light it is of a reddish-brown colour, like that of the deepest sherry, almost approaching to chestnut brown. By reflected light it has a greenish tinge. The dark colour of the oil may perhaps depend on some change which the seeds have suffered by keeping. After the oil has stood for a few months it is found to have deposited some white fat (margarine?). If equal volumes of alcohol (sp. gr. 0.796) and this oil be shaken together at ordinary temperatures, they form a uniform transparent mixture, and no separation takes place on standing for many weeks, unless the mixture be exposed to a low temperature. This fact, which was mentioned to me by Mr. Redwood, he has verified with various samples of croton oil expressed respectively by himself, by Mr. Morson, by Messrs. Herrings, and by Messrs. May and Co. I have verified it with a sample expressed by Messrs. Herrings. Exposure* to artificial cold (as a freezing mixture) or to the atmosphere during a very cold night will cause a separation: the oil is then found to have slightly increased in bulk, and the alcohol to have suffered a corresponding diminution of volume.

On what, it may be asked, does this difference in the properties of the East Indian and English croton oils depend? Does it arise from some difference in the mode of preparation? Or is the East Indian oil contaminated with jatropa oil?

Dr. Christison observes, that croton oil "is not easily adulterated with the com-

¹ Dierbach, *op. cit.*

mon fixed oils, with the exception of castor-oil, because this is the only common oil which possesses sufficient thickness to impart due unctuousity. Castor-oil may be detected by the test mentioned in the Edinburgh Pharmacopœia. Absolute alcohol shaken with the adulterated oil will dissolve out the impurity, and thus lessen its volume; but no visible diminution is produced on pure croton oil. Five per cent. of castor-oil may be thus detected; but the application of heat, as recommended by the College, is unnecessary." It is obvious, however, that this test is not applicable to English croton oil adulterated with castor-oil, both of which oils are soluble in the cold in alcohol.

If any fraud be practised in respect to croton oil, the adulterating ingredient is, I suspect, jatropha oil, which is less soluble in alcohol than croton oil.

Croton oil is exhibited in doses of one, two, or three drops. In some instances it is simply placed on the tongue—as in coma, tetanus, mania, &c.; or it may be taken in a teaspoonful of syrup. These methods of administering it are objectionable, on account of the acrid taste produced. The usual mode of employing it is in the form of pill, made with conserve of roses or bread-crumbs. Some have employed it in the form of emulsion, flavoured with some carminative oil or balsamic substance; but the burning of the mouth and throat to which it gives rise is an objection to its use.

α. *Tinctura Crotonis*; *Tincture of Croton*.—This is prepared by digesting the seeds, or dissolving the oil in rectified spirit. Soubeiran's formula is one drop of croton oil, and half a drachm of rectified spirit.

β. *Sapo Crotonis*; *Croton Soap*.—This is prepared with two parts of croton oil and one part of soap-boiler's lye. It is, in fact, a crotonate of soda. A croton soap is sold by Mr. Morson, of Southampton Row, Russell Square. It may be used as a purgative, in doses of from one to three grains. It has been said that the alkali diminishes the acrimonious property of the oil without affecting its cathartic powers—a statement, however, which is highly improbable.

2. **LINIMENTUM CROTONIS, D.**; *Croton Liniment*.—(Croton Oil $f\frac{3}{5}$; Oil of Turpentine $f\frac{3}{7}$. Mix them with agitation, *D.*)—A croton liniment is frequently prepared by mixing one part of croton oil with four or five parts of olive oil. Rubbed repeatedly on the skin, it occasions redness and a pustular eruption. It is used as a counter-irritant.

ANTIDOTES.—In a case of poisoning by the seeds or oil, the first object is to remove the oil from the stomach. Mild, demulcent, and emollient drinks are then to be given. Alkaline substances have been recommended as chemical antidotes, but their efficacy is not proved. Full doses of opium will be requisite to check the diarrhœa. To relieve a failing circulation, ammonia and brandy may be given, and the warm bath employed.

130. CROTON ELEUTERIA, Swartz.—THE SEA-SIDE BALSAM OR SWEET-WOOD.

Sex. Syst. Monœcia, Monadelphia.

(Cortex, *L.*—Cascarilla. Bark probably of *Croton Eleuteria*, and possibly of other species of the same genus, *E.*—The bark, *D.*)

HISTORY.—Great confusion has existed with regard both to Cascarilla or Eleuteria bark and the plant yielding it.

The bark is said to have been first noticed by Vincent-Garcias Salat,¹ a Spaniard, in 1692. In the following year, Stisser,² a German professor, gave a more extended notice of it, and states that he had some of it given him by a person of distinction,

¹ *Unica quæstionculla in quâ examinatur pulvis de quarango vulgò cascarilla in curatione tertiana*, in Ato. Valentia, 1692. (Duvai, *Journ. de Pharm. et de Chimie*, 3me sér. t. viii. p. 91, 1845: see also Alibert, *Nouv. Elém. de Thérap.* t. i. p. 74, 5me édit. 1826.)

² *Acta laboratorii chymici*, specimen ii. Helmstadâ, 1693 (quoted by Geoffroy). Stisser was the author of a letter to the Fellows of the Royal Society, entitled *De machinis fumiductoriis*, and published at Hamburg, in 1686.

at that time just returned from England, who told him that it was then the custom in England to mix it with tobacco, in order to render it more agreeable for smoking.

By Dale¹ and some other pharmacologists, it was thought to be *cortex thuris*, or frankincense bark, and by Geoffroy² and others to be a species of cinchona bark. Its name *cascarilla* (the diminutive of *cascara*, the Spanish name for the rind or bark of trees) is also a Spanish name for Peruvian bark.

In 1754, Catesby³ noticed and figured a plant, which, he said, grew plentifully on most of the Bahama Islands, and yielded Cascarilla bark, or, as he called it, "*The Ilatheria bark, La Chacrilla.*" This plant is generally supposed to be the *Croton Cascarilla*, Linn. (*C. lineare*, Jacq.); and several reasons led me, at one time,⁴ to think that it might be the source of the cascarilla bark of the shops—an opinion also entertained by Dr. Wood;⁵ but Dr. Lindley⁶ adduced several reasons for believing that the *Croton Elcuteria* was the true species, as Drs. Wright and Woodville had already asserted; and the subsequent receipt, by Dr. Lindley, of specimens of the plant, from the Hon. J. C. Lees, Chief Judge in the Bahamas, has fully confirmed the accuracy of Dr. Lindley's opinion.⁷ "The plant," says Mr. Lees, "is scarcely known here by the name of Cascarilla, but is commonly called Sweet Wood Bark, and often Eleuthera Bark, because it is chiefly gathered on the island of Eleuthera. It is the only bark receiving the name of Cascarilla exported from the Bahamas, where the tree grows in abundance."

The *Croton Cascarilla*, Don, L. (*C. Pseudo China*, Schiede), yields Copalchi (not Cascarilla) bark.

BOTANY. Gen. Char.—See *Croton Tiglium*.

Sp. Char.—A small tree; leaves ovate, obtuse, entire, beneath silvery and densely downy; racemes axillary and terminal, compound; flowers subsessile, monœcious (Lindley).

Branches and twigs angular, somewhat compressed. *Leaves* stalked, alternate, with a short but obtuse point. *Flowers* monœcious, subsessile. **MALES:** *petals* whitish; *stamens* 10—12. *Ovary* roundish; *styles* 3, bifid; *stigmas* obtuse. *Capsules* roundish, minutely warted, not much bigger than a pea, with three furrows, 3 cells, and 6 valves.⁸

Hab.—The Bahama Islands, Jamaica.

DESCRIPTION.—*Eleutheria* or *cascarilla bark* (*cortex cleuteriæ* seu *cascarillæ, chaquerille* vel *schacharilla*) is in the form of fragments, or quills, of about one or two, more rarely three or four, inches long; the fragments being thin, and usually curved both longitudinally and transversely, the quills varying in size from that of a writing pen to that of the little finger. The bark is compact, hard, moderately heavy, and has a short resinous fracture, not fibrous or splintery, as in cinchona bark. Some of the pieces are partially or wholly covered with a whitish rugous epidermis, cracked both longitudinally and transversely. If a longitudinal section of the bark be examined by the microscope, cells are observed filled with an orange-red matter (oleo-resin?). The cortical layers are of a dull brown colour. The taste of this bark is warm, spicy, and bitter; its odour is peculiar, but agreeable. When burned, it evolves a pleasant odour (which has been compared by Pfaff to that of vanilla or amber when heated), on which account it is a constituent of *fumigating pastiles*.

Fée⁹ has enumerated no less than forty-three species of lichens found on this bark. With one exception (*Parmelia perlata*, which I have never seen on cascarilla), every one of these lichens has an adherent, crustaceous, amorphous thallus.

¹ *Pharmacologia*, 3tia ed. p. 316, 1737. Many of the synonymes for this bark given in Dale's work are erroneous.

² *Treat. on Foreign Vegetables*, by R. Thicknesse, M. D. (chiefly taken from Geoffroy), Lond. 1749.

⁴ See *Lond. Med. Gaz.* vol. xx. p. 4-9.

⁵ *Fl. Med.* p. 179.

⁶ *United States Dispensatory*.

⁷ Specimens of the stems and bark accompanied the specimens of the plant. The former were kindly presented to me by Dr. Lindley.

⁸ Swartz, *Fl. Ind. occ.*

⁹ *Essai sur Cryptogames*, 1824.

A very common species is *Lecidea Arthonioides*, Féc; the thallus of which is very white, and the apothecia minute, round, and black.

COMMERCE.—It is imported from Nassau, in New Providence (one of the Bahama Islands).

COMPOSITION.—Cascarilla bark was analyzed by Trommsdorff,¹ who obtained from it the following substances: Volatile oil 1.6, bitter resin 15.1, gum and bitter matter with trace of chloride of potassium 18.7, woody fibre, 65.6. Meissner² detected in the ashes of the bark the oxide of copper. Brandes³ has announced the existence of a peculiar alkaline substance (*cascarillina*).

1. VOLATILE OIL OF CASCARILLA (*Oleum Cascarilla*).—It possesses the odour and taste of the bark. Its sp. gr. is 0.938. Its colour is variable, sometimes being greenish, at others yellow or blue. It consists of two oils, one boiling at 344°, and which contains no oxygen (its formula probably being C¹⁰H⁸); the other less volatile and oxygenated. Nitric acid converts it into a yellow, pleasant smelling resin. By distillation with water the bark yields about 1-120th of its weight of this oil.

2. RESIN.—Separated from the alcoholic tincture of the cascarilla by the addition of water. It is reddish brown; has a balsamic, slightly bitter, not astringent taste; and, when thrown on hot coals, evolves an agreeable odour.

3. EXTRACTIVE.—Has a bitter, but not balsamic taste. Its watery solution reddens litmus, and is unchanged by either ferruginous solutions or tincture of nutgalls.

CHEMICAL CHARACTERISTICS.—The sesquichloride of iron deepens the colour of the infusion of cascarilla. The tincture of nutgalls causes turbidness, and at the end of twenty-four hours a very slight precipitate. A very concentrated alcoholic tincture deposits some resin on the addition of water.

PHYSIOLOGICAL EFFECTS.—Cascarilla bark belongs to the *aromatic bitters*, before noticed (see *ante*, p. 244): that is, it produces the combined effect of an aromatic and of a moderately powerful tonic; but it does not possess any astringency. Some pharmacologists place it with aromatics, others with tonics. Cullen,⁴ though at one time uncertain as to which of these classes it belonged, ultimately classed it with the tonics. Krauss⁵ states that moderate doses give rise, in very susceptible, especially in sanguine subjects, to narcotic effects; but though I have frequently employed it, I never observed an effect of this kind. Mixed with tobacco, and used for smoking, it is said to cause giddiness and intoxication.⁶

USES.—Cascarilla has been employed as a substitute for cinchona; and although it is inferior to the latter in tonic and febrifuge qualities, its aromatic quality frequently enables it to sit easily on the stomach, without causing either vomiting or purging, which, in irritable affections of the alimentary canal, cinchona is apt to produce. In this country it is principally employed in those forms of dyspepsia requiring an aromatic stimulant and tonic. It is also used in cases of debility generally; and in chronic bronchial affections, to check excessive secretion of mucus. In Germany, where it is a favourite remedy, it is used in many other cases; such as low nervous fevers, intermittents, the latter stages of diarrhoea, and dysentery.

ADMINISTRATION.—The *powder* may be given in doses of from ten grains to half a drachm; but it is a less agreeable form than the infusion.

1. INFUSUM CASCARILLÆ, L. E. D.; *Infusion of Cascarilla*.—(Cascarilla Bark, bruised, ʒij [ʒj, D.]; Boiling [distilled, L.] Water Oj [Oss, D.]. Macerate for two [one, D.] hours in a vessel lightly covered, and strain [through linen or calico, E.]. The product should measure about eight ounces, D.)—A light and aromatic bitter tonic. It is a good vehicle for acids and alkalies. The tincture of cascarilla is usually joined with it. Dose, from fʒj to fʒij.

2. TINCTURA CASCARILLÆ, L. E. D.; *Tincture of Cascarilla*.—(Cascarilla Bark, bruised [in moderately fine powder, E.], ʒv; Proof Spirit Oij. Macerate for seven [fourteen, D.] days, then express and filter, L. “Proceed by percolation or diges-

⁶ *United States Dispensatory*.

tion, as afterwards directed for tincture of cinchona," *E.*)—Generally employed as an adjunct to tonic and stomachic infusions. Dose, from ʒj to ʒij.

131. Croton Pseudo-China, *Schlectendal*.—Copalche Bush.

(Cortex Copalche vel Copalchi.)

CROTON PSEUDO-CHINA, *Schlectendal*, Berlin, *Jahrb. f. d. Pharmacie*, 1829, p. 1 (with a figure); *Linnaea*, Bd. v. S. 84, 1830; and Bd. vi. S. 359, 1831.—*Croton Cascarilla*, Don, *Ed. New Phil. Journ.* vol. xvi. p. 368.

This species of *Croton* was discovered by Schiede (*Linnaea*, Bd. iv. S. 211, and 579, 1829) between Plan del Rio and Puente in Mexico. A small variety (*C. Pseudo-China* var. *minor*) was found between Laguna Verde and Actopan. Both plants yield a bark very similar to that of cascarilla, and which is called in the apothecaries' shops of Jalapa *quina blanca* or *copalche*.

According to v. Bergen and v. Santen four serons of this bark were imported in 1817 into Hamburg from Cuba under the name of *cascarilla de Trinidad*. In 1827, more than 30,000 lbs. of it came along with cinchona bark from Peru to Hamburg, by way of Liverpool. Of this, 32 serons were shipped at Payta and 300 serons at Guayaquil. It was said to be a *cinchona* called *copalchi* (*quina dit copalchi*). The Prussian Minister, v. Altenstein, received it from Mexico under the name of *copalche*.¹ In 1825, Mercadieu² published an analysis of it; and stated that it was known in Mexico as *copalchi* or *cortex amarus*. He showed a sample of it to Humboldt, who suggested that it might be the produce of *Croton suberosum*, HBK.

I have met with two sorts of copalche bark in English commerce:—

1. *Quilled Copalche*.—Under the name of a *new kind of cinchona bark* I received copalche bark in the form of small thin quills, which in shape, size, and general appearance, resemble that kind of cinchona bark called by druggists "ash cinchona." In flavour, it closely resembles cascarilla bark; and in burning evolves a similar odour. It is the kind figured by Göbel and Kunze, and is doubtless the sort which the late Mr. Don mistook for genuine cascarilla bark. It might with propriety be called *Mexican cascarilla*. From genuine or Bahama cascarilla it is distinguished by the length of the quills, their colour, and the absence of transverse cracks.

2. *Corky Copalche Bark*.—Under the name of *copalche* or *chiquique bark*, I have received a bark in coarser larger quills and twisted pieces covered with a very thick and much cracked corky coat. Its taste is very bitter. In burning, it evolves an aromatic odour. Is this the produce of *Croton suberosum*? Dr. Stark³ states that he received it from Chili under the name of *nutri*; and that at Santa Cruz it is known as *chiquique*.

Copalche bark has been analyzed both by Mercadieu and Brandes. According to the latter chemist, 100 parts of the bark yield a *yellow bitter extractive with malates* 13.3, *brown tasteless extractive* obtained by potash 3.3, *acid aromatic soft resin* 6.3, *green resin* 1.0, *semi-resin* 8.3, *fat with green resin* 1.1, *wax with malate of lime* 0.7, *glutinous nitrogenous matter* 33.3, *albumen* 8.7, *malate of lime* 3.3, *oxalate of lime* 4.1, *phosphate of lime* 1.4, *sulphates and muriates* 0.7, *ligneous fibre* 18.0, *loss in water and volatile oil* 6.2.

The medicinal properties of copalche resemble those of cascarilla bark. In Mexico it is used as a substitute for cinchona in the treatment of intermittents. It may be exhibited in powder, infusion, decoction, tincture, or spirituous extract, in the same doses as cascarilla. Dr. Stark says the infusion or decoction is best made by half an ounce of bark to a pint of water: the dose being a tablespoonful or small wineglassful. The tincture he prepares with an ounce of bark to one pint of proof spirit; the dose being one or two teaspoonfuls.

132. RICINUS COMMUNIS, *Linn.*—THE CASTOR-OIL PLANT, OR PALMA CHRISTI.

Sex. Syst. Monœcia, Monadelphia.

(*Oleum e semine calore aut vi comparatum, L.*—Expressed oil of the seeds, *E.*—The seeds from which the oil is expressed; *Oleum ricini, D.* [*U. S.*])

HISTORY.—The castor-oil plant was known in the most ancient times. Caillaud found the seeds of it in some Egyptian sarcophagi, supposed to have been at least 4000 years old.⁴ Whether this is, as some persons imagine,⁵ the plant called *kikayon* in the Bible,⁶ and which, in our translation, is termed the *gourd*, I cannot pretend to decide. The pious fathers, Jerome and Augustin, differed so much in

¹ Martiny, *Encyclop. d. med.-pharm. Naturalien- und Rohwaarenkunde*, Bd. i. 1813; also, Göbel and Kunze, *Pharmaceut. Waarenkunde*.

⁶ *Jonah*, iv. 6.

their opinions as to what was the particular plant meant in the passage just referred to, that from words we are told, they proceeded to blows!¹

The ancient Greeks were acquainted with the *ricinus*, for both Herodotus² and Hippocrates³ mention it; the latter employed the root in medicine. Dioscorides⁴ calls it the *ξιχι* or *χροτων*. It was termed *χροτων* by the Greeks, and *ricinus* by the Romans,⁵ on account of the resemblance of its seeds to a little insect bearing these names, which infest dogs and other animals, and whose common name in English is the *tick*.

BOTANY. **Gen. Char.** — *Flowers* monœcious. *Calyx* 3—5-parted, valvate. *Petals* 0. *Filaments* numerous, unequally polyadelphous; cells of the *anther* distinct, below the apex of the filament. *Style* short; *stigmas* 3, deeply bipartite, oblong, coloured, feathery; *ovary* globose, 3-celled, with an ovule in each cell. *Fruit* generally prickly, capsular, 3-coecous, with 1 seed in each cell.—*Trees, shrubs, or herbaceous* plants, sometimes becoming arborescent. *Leaves* alternate, palmate, petlate, with glands at the apex of the petiole. *Flowers* in terminal panicles, the lower male, the upper female; all articulated with their peduncles, and sometimes augmented by bi-glandular braets (Lindley, from Endlicher).

Sp. Char.—*Stem* herbaceous, pruinose. *Leaves* peltato-palmate, in 7 lobes; the lobes ovate acuminate, serrated. *Flowers* in long glaucous racemes. *Stigmas* 3, bifid at the apex. *Capsule* covered with spines.

The *stems* of plants growing in this country are round, greenish or reddish-brown, and blue pruinose, and branched. *Leaves* on long round petioles, 8- or 10-lobed. A large scutelliform gland on the petiole, near its junction with the lamina. *Filaments* capillary, branched. *Stigmas* reddish. *Capsules* supported on stalks, which are somewhat longer than the capsules themselves.

Hab.—India. When cultivated in Great Britain, *Ricinus communis* is an annual, seldom exceeding three or four feet high; but in other parts of the world it is said to be perennial, arborescent, and to attain a height of fifteen or twenty feet. Dr. Roxburgh⁶ says that in India several varieties are cultivated, "some of them growing to the size of a pretty large tree, and of many years' duration." Clusius⁷ saw it in Spain with a branch-

ed trunk as thick as a man's body, and of the height of three men. Belon¹ also tells us that in Crete it endures for many years, and requires the use of ladders to mount it. Ray² found it in Sicily as large as our common alder trees, woody, and long-lived; but it has been a question with botanists whether these arborescent and other kinds are mere varieties of, or distinct species from, the ordinary *Ricinus communis*.

The following (varieties or distinct species) are enumerated by Nees and Ebermaier³ as common in gardens, and as distinguished principally by the colour and pruinose condition of the stem—characters which, however uncertain in other cases, appear here to be constant.

1. *RICINUS AFRICANUS* (Willd.).—Stem not pruinose, green, or on one side reddish. The fruit-racemes abbreviated, the fruit-stalk longer than the capsule. Seeds attenuated on one side, marbled gray and yellowish-brown. [Arborescent. Cultivated in Bengal.]

2. *RICINUS MACROPHYLLUS* (H. Berol.).—Nearly allied to the foregoing: stem quite green, not pruinose. Fruit-racemes elongated, fruit-stalk shorter than the fruit.

3. *RICINUS LEUCOCARPUS* (H. Berol.).—Stem pale green, white pruinose. Fruit-stalk as long as the fruit. The unripe fruit and prickles almost quite white.

4. *RICINUS LIVIDUS* (Willd.).—Stem, petiole, midrib purple red, not pruinose. Nearly allied to *R. africanus*, and, like this, more woody and perennial. [Arborescent. Cultivated in Bengal (Hamilton).]

5. *RICINUS VIRIDIS* (Willd.).—Stem pale green, blue pruinose, by which it is distinguished from *R. macrophyllus*. Seed somewhat smaller, more oval, marked with white and fine brown. [Herbaceous. Cultivated in Bengal (Hamilton).]

DESCRIPTION.—*Castor seeds (semina ricini seu sem. cataputiae majoris)* are oval, somewhat compressed, about four lines long, three lines broad, and a line and a half thick; externally they are pale gray, but marbled with yellowish-brown spots and stripes. The seed-coats consist, according to Bischoff,⁵ of a smooth external coat (*epidermis seminalis*). 2dly, a difform, hard *testa*, consisting of two layers—an external thick and dark brown one, and an internal one, thinner and paler. 3dly, a *cuticula nuclei* or *membrana interna*. The fleshy tumid *cicatricula stomatis* (also termed *strophiola*) is very evident at the upper end of the seed; beneath it is a small *hilum*, from which passes downwards the longitudinal *raphé*.⁶ The *chalaza* is colourless.⁷ The *nucleus* of the seed consists of oily *albumen* and an *embryo*, whose cotyledons are membranous or foliaceous.

COMPOSITION.—The only analysis of these seeds, as yet published, is that of Geiger.⁸ The following are his results:—

a. Seed coats	{ Tasteless resin and extractive 1.91	} 23.62
	{ Brown gum 1.91	
	{ Ligneous fibre 20.00	
	{ Fatty oil 46.19	
b. Nucleus of the seeds	{ Gum 2.40	} 69.09
	{ Casein (albumen) 0.50

Loss (moisture)		7.09
	Castor seeds	100.00

1. VOLATILE ACRID PRINCIPLE (? *ricinoleic acid*).—This principle is not mentioned by Geiger, and its existence has been doubted or denied by others. But the following as well as other facts establish, in my opinion, its presence: First, Guibourt⁹ experienced a peculiar feeling of dryness of the eyes and throat, in consequence of having been exposed to the vapour arising from a vessel in which bruised castor seeds and water were boiling. Secondly, Planche obtained a permanent odorous principle by distilling a mixture of water and castor-oil. Bussy and Lecanu¹⁰ ascribe the occasional acidity of the oil to the production of fatty acids, by the action of the air on it.

2. FIXED OIL.—(See *Oleum Ricini*.)

3. ACRID RESIN?—Castor seed appear to contain a fixed acrid principle, probably of a resinous nature, as suggested by Soubeiran.¹¹ The acrid principle (whatever its nature may be) appears to reside in both the *albumen* and *embryo* of the seeds. Jussieu¹² and some others have asserted that it resided exclusively in the embryo; while Boutron-Charlard and Henry, jun.¹³ declared the albumen to be the exclusive seat of it. But any unprejudiced person may soon

satisfy himself, by tasting separately the embryo and albumen, that both parts possess acidity. Dierbach¹ states that in fresh seeds the innermost seed-coat contains the acrid principle. If this be correct, it is most remarkable that the same coat, when dry, contains none.

Callond² found that castor cake (the residual cake left after the expression of the oil from the seeds), after having been deprived of all its principles soluble in alcohol, still contains an acrid principle, and excites vomiting when given in doses of about $7\frac{1}{2}$ grains.

PHYSIOLOGICAL EFFECTS.—Castor seeds possess considerable acidity. Bergius³ states that a man masticated a single seed at bedtime: the following morning he was attacked with violent vomiting and purging, which continued the whole day. Lanzoni also states that the life of a woman was endangered by eating three grains of the seeds.⁴ More recently, a girl, 18 years of age, was killed by eating "about twenty" seeds: the cause of death was gastro-enteritis.⁵

OLEUM RICINI, L. E. D.; Castor-Oil.—This may be obtained from the seeds by expression, by decoction, or by the agency of alcohol. The chief part, if not the whole of the oil consumed in England, whether imported or extracted in England, is procured by expression.

Soubiran⁶ considers all processes in which heat is employed as objectionable, as a quantity of fatty acids is produced which renders the oil acrid. In America, on the contrary, heat is considered useful by expelling a volatile acrid principle.⁷ It cannot be doubted but that too high a temperature develops acrid matter. In England, the oil is expressed, either by Bramah's hydraulic press or by the common screw-press, in a room artificially heated. It is purified by rest, decantation, and filtration. It is bleached by exposure to light on the tops of houses.

In Calcutta, it is prepared as follows: The fruit is shelled by women; the seeds are crushed between rollers, then placed in hempen cloths, and pressed in the ordinary screw or hydraulic press. The oil thus procured is afterwards heated with water in a tin boiler until the water boils, by which the mucilage or albumen is separated as a scum. The oil is then strained through flannel and put into canisters. The castor seeds are distinguished according to the country yielding them. Two principal kinds are known, the large and the small nut; the latter yields the most oil.⁸ The best East Indian castor-oil is sold in London as cold drawn.

In the Southern provinces of India, according to Ainslie,⁹ castor-oil is obtained by decoction.

Much of the American castor-oil is prepared by mere expression, rest, and decantation; but the following are the outlines of the process usually employed in the United States by those who prepare it on the large scale. The seeds, cleansed from the dust and fragments of the capsules, are placed in a shallow iron reservoir, where they are submitted to a gentle heat insufficient to scorch or decompose them, and not greater than can be readily borne by the hand. The object of this step is to render the oil sufficiently liquid for easy expression. The seeds are then introduced into a powerful screw-press, and submitted to pressure, by which a whitish oily liquid is obtained, which is boiled with a considerable quantity of water in clean iron boilers, and the impurities skimmed off as they rise to the surface. The water dissolves the mucilage and starch, and the heat coagulates the albumen, which forms a whitish layer between the oil and water. The clear oil is now removed, and boiled with a minute portion of water until aqueous vapour ceases to arise, and till a small portion of the liquid taken out in a phial preserves a perfect transparency when it cools. The effect of this operation is to clarify the oil, and to render it less irritating by driving off the volatile acrid matter. But much care is requisite not to push the heat too far, lest the oil acquire a brownish hue, and an acrid peppery taste similar to the West India medicine. One basket of the seeds yields five or six quarts, or about twenty-five per cent., of the best oil.¹⁰

In the West Indies the oil is obtained by decoction; but none of it comes to this country in the way of commerce. In Jamaica, the bruised seeds are boiled with water in an iron pot, and the liquid kept constantly stirred. The oil, which separates, swims on the top, mixed with a white froth, and is skimmed off. The skimmings are heated in a small iron pot, and strained through a cloth. When cold, it is put in jars or bottles for use.¹¹ The object of the second heating is to dissipate the volatile acrid principle; but if the process be not suspended immediately after the water is driven off, the oil acquires a reddish-brown colour, an acrid flavour and irritating qualities. It is said that the seeds are sometimes roasted to increase the product. By this process also the oil is coloured and rendered acrid.

In Armenia, the oil is obtained by decoction; in Russia, by expression.¹²

On the continent of Europe, castor-oil is sometimes obtained by the agency of alcohol. The process is more expensive, and the product is inferior.

The *oleum ricini alcoholicum*, in use in Italy, is apparently an alcoholic extract, composed of 72 per cent. of oil and 28 per cent. of alcohol and water. The dose is from half an ounce to an ounce.¹

Properties.—Castor-oil is a viscid oil, usually of a pale yellow colour, with a slightly nauseous odour and a mild taste. It is lighter than water, its sp. gr. being, according to Saussure, 0.969 at 55° F. When cooled down to about 0°, it congeals into a transparent yellow mass. By exposure to the air it becomes rancid, thick, and ultimately congeals, without becoming opaque; and hence it is called a *drying oil*. When heated to a little more than 500° F. it begins to decompose.

Solubility.—Castor-oil is remarkable for its ready solubility in alcohol. Strictly speaking, castor-oil and alcohol exercise a mutual solvent action on each other. When they are shaken together, an homogeneous transparent mixture is obtained. Rectified spirit of wine² may be substituted frequently with a similar result; but with some samples of genuine oil the mixture does not become clear until heat is applied; and moreover by standing a separation takes place into two strata, an upper spirituous one holding oil in solution, and an inferior oleaginous one containing spirit. In one experiment, 65 vols. of oil and 65 vols. of rectified spirit were mixed, and by shaking a transparent uniform mixture was obtained: after several weeks a separation had taken place: the upper stratum measured 12 vols., the lower one 118 vols. Of three samples of genuine oil, one English, a second West Indian, and the third East Indian, I find the English to be the most, and the East Indian the least soluble in rectified spirit.—I find that castor-oil enables other fixed oils (olive, nut, lard, and other oils) to dissolve in alcohol. Thus, if one vol. of olive oil, 2 vols. of castor-oil, and 2 vols. of rectified spirit be mixed and heated, a transparent homogeneous solution is obtained.—Ether readily dissolves castor-oil.

Varieties.—In the London market there are chiefly three sorts of castor-oil; namely, the oil expressed in London from imported seeds, East Indian oil, and the American. West Indian and Australian oils are rarely to be met with.

1. *English Castor-Oil.*—By this is meant castor-oil drawn in England from imported seeds. It differs somewhat from the imported oil. I am informed that it never bleaches so completely by exposure to light as the East Indian oil. This is usually ascribed to the seeds having suffered some change before they are pressed. But something is probably due to the mode of preparation: in England the oil is not heated in boiling water, as it is in Calcutta.

2. *East Indian Castor-Oil* is the principal kind employed in this country. It is imported from Bombay and Calcutta. It is an oil of exceedingly good quality (both with respect to colour and taste), and is obtained at a very low price. It is procured from *Ricinus communis* and *R. lividus*. I am informed that occasionally it solidifies by keeping.

3. *American or United States Castor-Oil* is, for the most part, imported from New York. All the samples which I have examined have been of very fine quality, and, in my opinion, had a less unpleasant flavour than the East Indian variety. Our druggists object to it, on the ground of its depositing a white substance (*margaritine*) in cold weather—a circumstance which has led some persons to imagine it had been mixed with some other fixed oil (lard oleine?).

4. *West Indian Castor-Oil.*—For an authentic specimen of this oil I am indebted to Mr. Spencer, of Lamb's Conduit Street, who received it some years since from the wife of the Governor of the Island of Tobago, on whose estate it was procured. Its colour is that of golden brown sherry.

5. *Australian Castor-Oil.*—Of this I have seen but one sample, which was dark coloured.

Commerce.—Castor-oil is imported in casks, barrels, hogsheads, and dippers. The latter are made, as I am informed, of gelatin (prepared by boiling the cuttings of skin) moulded in earthen moulds. In this country the oil is purified by decantation and filtration, and is bleached by exposure to solar light on the tops of houses.

Composition.—The following is the *ultimate* composition of castor-oil, according to the analyses of Saussure and Ure:—

	<i>Saussure.</i>	<i>Ure.</i>
Carbon	74.178	74 00
Hydrogen	11.034	10.29
Oxygen	14.788	15.71
Castor-oil	100.000	100.00

¹ *Pharmaceutical Journal*, vol. vii. p. 354, 1848.

² According to Stoltze, benzoic acid augments the solubility of castor-oil in spirit containing 75 per cent. of alcohol; that is, in spirit whose sp. gr. is 0.860. Camphor has a similar influence.

The *proximate* principles have not been accurately determined. From Bussy and Lecanu's¹ researches we may infer that castor-oil contains three fats, each composed of oxide of glyceryle and a fatty acid. But according to the more recent investigations of Saalmuller,² there can be but two fats in this oil. In addition to these fats there is probably a small proportion of an acrid resin. The following table, therefore, represents the

PRESUMED COMPOSITION OF CASTOR-OIL.

- Ricinoleine.
- Margaritine.
- Acrid resin?

1. *Ricinoleine*.—This has not been isolated. It is the constituent of castor-oil which by saponification yields oxide of glyceryle and a liquid acid, the *ricinoleic acid*, $C^{35}H^{35}O^5$. Bussy and Lecanu regard this acid as a mixture of two acids, which they term *ricinic* and *elaïodic* acids.

2. *Margaritine*; or *Ricino-stearine*.—This is a solid, white crystalline fat which separates from castor-oil in cold weather. By saponification it yields oxide of glyceryle and a solid crystallizable fatty acid called *margaritic acid*, which in its melting point ($165^{\circ} F$) and composition exhibits a great resemblance to stearic acid, $C^{60}H^{60}O^7$. But with a margaritic acid obtained from another sample of castor-oil, he found the composition to approach more to that of palmitic acid, $C^{32}H^{32}O^4$.

According to Lecanu and Bussy, margaritic acid constitutes only 0.002 of the products of saponification of castor-oil: it follows, therefore, that the proportion of margaritine in the oil must be small. But it is probable that the quantity is variable, and that the differences observed in the action of alcohol in the different specimens of castor-oil depend on variations in the relative proportions of the margaritine and ricinoleine.

3. *Acrid Resin?*—Some years since, Soubeiran³ obtained from castor-oil by a complicated process what he supposed to be a soft resinous oil, but which was evidently a complex product. To this he in part ascribed the purgative qualities of castor-oil.

Products of decomposition.—By saponification and distillation castor-oil yields certain peculiar products by which it is characterized.

PRODUCTS OF SAPONIFICATION.

100 Parts of Castor-Oil yielded:

1. Fatty acids (viz. <i>ricinic</i> , <i>elaïodic</i> , and <i>margaritic acids</i>)	91
2. Glycerine	8

2. Solid residuum	63.0
3. Loss (inflammable gas)	3.5

Castor-oil 100.00

1. α -Nanthal.—Described by Bussy and Lecanu as *volatile oil*; but more recently by Bussy⁴ as α -nanthol. It is a colourless limpid aromatic liquid, whose formula is $C^{14}H^{14}O^2$. It is scarcely soluble in water, but dissolves in alcohol and ether. It rapidly oxidizes in the air, and becomes α -nanthyllic acid ($C^{13}H^{13}O^3,HO$). It combines with water, forming a crystalline hydrate, $C^{14}H^{14}O^2,HO$. By the action of nitric acid it yields at a low temperature an isomeric compound called *met α -nanthal*; and at a high temperature, besides α -nanthyllic and other volatile fatty acids, a volatile oil resembling oil of cassia.

2. *Solid residuum of distillation*.—Pale, yellow, elastic, spongy, having the consistence of soft new bread, gelatiniform, odourless, tasteless, combustible, solid. It is insoluble in alcohol, ether, and the oils (both fixed and volatile).

By the action of hyponitric acid on castor-oil Boudet obtained a solid odorous fat called *palmine*, which, by saponification, yielded palmic acid, $C^{34}H^{32}O^5,HO$, and glycerine; and by the action of nitric acid on castor-oil, Mr. Tilley⁵ obtained α -nanthyllic acid.

Adulteration.—Two kinds of frauds have been practised with regard to castor-oil.

One consists in the admixture of a small quantity of croton oil to it, with the view of increasing its activity. This mixture is introduced into gelatine capsules, and sold as *concentrated castor-oil*. This fraud is a very dangerous one. I have

¹ *Journ. de Pharm.* t. xiii. p. 57, 1827.

² *Annal. d. Chem. u. Pharm.* Bd. lxiv. S. 108, 1848; also *The Chem. Gaz.* vol. vi. p. 74, 1848.

⁴ *Ibid.* 3me sér. t. viii. p. 321, 1845; also, *Chemical Gazette*, vol. iii. p. 381, 1845.

⁵ *Memoirs of the Chemical Society*, vol. i. p. 1, 1843.

heard of several cases in which very violent and dangerous effects were produced by these capsules on pregnant females.

The other fraud consists in the adulteration of the castor-oil with some bland viscid cheaper oil. I have been informed that the oleine of lard, called *lard oil*, has been used for this purpose, but I have not been enabled to procure evidence of it. This kind of fraud is said to be detected by alcohol, which dissolves the genuine castor-oil, but not the admixed oil; and accordingly, in the Edinburgh Pharmacopœia, the test of the purity of the oil is that "it is entirely dissolved by its own volume of alcohol." Unfortunately, however, for this test, castor-oil may be adulterated with 33 per cent. of another fixed oil, and yet be soluble in its own volume of alcohol.

PHYSIOLOGICAL EFFECTS.—*a.* *On Animals generally* castor-oil acts as a laxative or mild purgative. Large animals, as the horse, require a pint or more for a dose; smaller ones need only a few ounces.¹ Mr. Youatt, however, declares this oil to be both uncertain and dangerous in the horse.²

β. *On Man.*—*Injected into the veins* castor-oil gripes and purges, and causes a nauseous oily taste in the mouth:³ hence it would appear to have a specific influence over the mucous lining of the alimentary canal. *Swallowed* to the extent of one or two ounces, it usually acts as a mild but tolerably certain purgative or laxative, without producing any uneasiness in the bowels. "It has this particular advantage," says Dr. Cullen,⁴ "that it operates sooner after its exhibition than any other purgative I know of, as it commonly operates in two or three hours. It seldom gives any griping, and its operation is generally moderate—to one, two, or three stools only." It not unfrequently occasions nausea, or even vomiting, especially if somewhat rancid; in many cases, I believe, rather from its disgusting flavour than from any positively emetic qualities.

It has been stated by continental writers that castor-oil is most unequal in its action, at one time operating with considerable violence, at another with great mildness; but I have never found it so, nor is it usually considered to be so in this country. I can, however, readily believe that a difference in the mode of its preparation, especially with reference to the heat employed, may materially affect its purgative property.

When castor-oil has been taken by the mouth, it may be frequently recognized in the alvine evacuations; but it presents itself under various forms, "sometimes resembling caseous flakes, or a soap-like scum, floating on the more fluid part of the dejection: occasionally it had been arranged in a form not unlike bunches of grapes, or more nearly of hydatids of a white colour; more generally, however, it is found mixed up with the fæces as a kind of emulsion, and in some few instances it has been discharged under the form of solid tallow-like masses."⁵ Mr. Brande⁶ says in one case it was discharged from the bowels in the form of indurated nodules, which were at first regarded as biliary concretions. A remarkable case is mentioned by Dr. Ward, of a woman on whom this oil does not act as a purgative, but exudes from every part of her body.⁷

Uses.—Castor-oil is used to evacuate the contents of the bowels in all cases where we are particularly desirous of avoiding the production of abdominal irritation (especially of the bowels and the urino-genital organs). The principal, or I might say the only objection to its use in these cases, is its nauseous taste. The following are the leading cases in which we employ it:—

1. *In inflammatory affections of the alimentary canal*, as enteritis, peritonitis, and dysentery, a mild but certain purgative is oftentimes indicated. No substance, I believe, answers the indication better, and few so well, as castor-oil.

2. *In obstructions and spasmodic affections of the bowels*, as intussusception, ileus, and colic, especially lead colic, this oil is the most effectual evacuant we can employ.

⁵ *Lond. Med. Gaz.* vol. x. p. 377.

⁶ *Mat. Med.*

⁷ *Dict. of Mat. Med.*

3. *After surgical operations about the pelvis or abdomen* (for example, lithotomy, and the operation for strangulated hernia), as well as after *parturition*, it is the best and safest purgative.

4. *In inflammatory or spasmodic diseases of the urino-genital organs*, inflammation of the kidneys or bladder, calculous affections, gonorrhœa, stricture, &c., castor-oil is a most valuable purgative.

5. *In affections of the rectum*, especially piles, prolapsus, and stricture, no better evacuant can be employed.

6. *As an anthelmintic* for tape-worms, castor-oil was first employed by Odier. Arneemann, however, has shown that it possesses no peculiar or specific vermifuge properties.

7. *As a purgative for children*, it has been used on account of its mildness, but its unpleasant taste is a strong objection to its use.

8. *In habitual costiveness*, also, it has been recommended. Dr. Cullen observed that, if castor-oil be frequently repeated, the dose might be gradually diminished; so that persons who, in the first instance, required half an ounce or more, afterwards needed only two drachms.

Administration.—The dose of castor-oil for children is one or two teaspoonfuls; for adults, from one to two or three tablespoonfuls. To cover its unpleasant flavour, some take it floating on spirit (especially gin), but which is frequently contra-indicated; others on coffee, or on peppermint or some other aromatic water; or it may be made into an emulsion by the aid of the yolk of egg or mucilage of tragacanth.

133. *Curcas Purgans*, *Adanson*; and *C. multifidus*, *Endlicher*.— Physic Nuts.

(Semina.)

The seeds of both these species of *Curcus* are met with under the name of *physic nuts*; and as their effects and uses are similar, I include them under a common head.

Gen. Char.—*Flowers* monœcious. *Calyx* very short, 5-parted. **MALES:** *Corolla* globose-campanulate, 5-cleft. *Stamens* 10, united at the base, the 5 exterior alternating with the same number of conoid glands; filaments filiform; anthers turned inwards, 2-celled. **FEMALES:** *Corolla* much larger than the calyx, convolute; consisting of 5 petals. *Ovary* on a 5-lobed disk, 3-celled, with 1 ovule in each cell. *Styles* 3, filiform, distinct. *Stigmas* thick, 2-lobed. *Capsule* 3-coccos, with 1 seed in each cell.—*Tropical shrubs* of America. *Leaves* alternate, petioled, angulate-5-lobed, quite entire, truncated at the base, reticulate-7-nerved, quite smooth. *Corymbs* with long peduncles; the males terminal; the females axillary (Endlicher).

Species.—1. *CURCAS PURGANS*, Adanson; *Jatropha Curcas*, Linn.; *English Physic Nut*, Wright; *Physic-nut tree*, Hughes; Browne; *Angular-leaved Physic Nut*, Miller; *Pinheiro de purga*, *Pinhão paraguay*, Mart., Syst. Mat. Med. Brasil.—Leaves long-stalked, broadly cordate, angular, roundish; panicles terminal or axillary, in cymes.—West Indies; Brazils; Coast of Coromandel; Ceylon.

The fruit is a tricoccos capsule about the size and shape of a walnut.

The seeds (*semina curcudis*), sometimes called *American* or *English physic nuts*, or simply *physic nuts* (*nucis cathartice americanae*), *Barbados seeds* or *nuts* (*nucis barbadenses*), *semina ricini majoris* or *gros pignon d'Inde*, have the shape of castor seeds, but are somewhat rough to the touch, and black, but marked with numerous minute cracks. The kernels are covered with a fine white pellicle (*cuticula nuclei*). The seeds have been analyzed by Cadet de Gassicourt¹ and by Soubeiran.² The latter chemist found in them a *fixed oil*, a *peculiar fixed acrid resin*, *saccharine matter*, *gum*, a small quantity of *fatty acid*, *glutine* (emulsin?), a *free acid* (malic?), and some *salts*.

The expressed oil, commonly called *jatropha oil* (*oleum jatrophae curcudis vel oleum infernale*), was imported a few years ago under the name of *oil of wild castor seeds*. It is sometimes expressed in England. As commonly met with, it has a yellowish colour, with a feeble odour, and during the cold weather deposits a white solid fat (margarine or stearine). When fresh and pure it is described as being odourless, colourless, and quite limpid. 1000 parts of the seeds yielded Guibourt 656 parts of kernels, from which he obtained 265 parts of a colourless very fluid oil, which in the cold deposited a considerable quantity of stearine. *Jatropha* oil differs from castor and croton oils in its slight solubility in alcohol; but mixture with castor-oil

¹ *Journ. de Pharm.* t. x. p. 176, 1824.

² *Ibid.* t. xv. p. 503, 1829.

augments its solubility. According to Mr. Quekett,¹ it is well adapted for burning in lamps, for which purpose it is employed in India.

Jatropha seeds and oil resemble the seeds and oil of croton in the character of their effects. Mr. Bennett² swallowed four seeds, and experienced a very unpleasant sensation in the stomach and bowels, with nausea, which, after an interval of nearly two hours, terminated in vomiting: their purgative effects followed soon afterwards, and were mild; the sickness had then passed away, but the burning sensation continued for some time longer. The kernels of five seeds caused in a labourer vomiting, purging, perspiration, debility, giddiness, and delirium. Four hours after taking the poison he walked to the London Hospital: the pupils were natural, the countenance pale, the hands cold, and the pulse 140. An opiate and a mild cordial were given to him, and he soon recovered.³ Jatropha oil is occasionally used as a drastic purgative. It is less powerful than croton oil. Dr. Christison states that twelve or fifteen drops of it are about equal to one ounce of castor-oil. The residual cake from which the oil has been expressed is very active. The last-mentioned authority found that a few grains of it caused violent vomiting and purging. The juice of the plant⁴ has been successfully applied externally as a remedy for piles. Dr. McWilliam⁵ says, that a decoction of the leaves is used by the natives of the Cape Verde Islands to excite a secretion of milk in women who have borne a child, and who are not past child bearing.

2. *CURCAS MULTIFIDUS*, Endlicher, Enchir. Botan.; *Jatropha multifida*, Linn.; *Adenorhopium multifidum*, Pohl; *French Physic Nut*; *Spanish Physic Nut*.—Leaves large, stalked, palmate or digitate, many-lobed, smooth; lobes pinnatifid, cuneate.—West Indies; Brazils.—The capsule is yellowish, about the size of a walnut, obtusely 3-cornered, somewhat tapering above, 3 celled; each cell containing 1 seed. The seeds, called *French physic nuts* (*semina curcadis multifidi*; *noces purgantes*; *avellana purgatrice*; *ben magnum*), are about the size of those of a common nut, rounded externally, with two flattened surfaces separated by an ovule internally. The seed coat is marbled and smooth: the kernel is white.—The composition of these seeds is, according to Soubeiran,⁶ similar to that of the seeds of the *Curcas purgans*.—The expressed oil (*oleum curcadis multifidi*; *oleum pinhoen*), as well as the seeds, are drastic cathartics. In their operation they resemble the preceding oil and seeds. Death is said to have been produced by them.⁷

3. The seeds of the *JATROPHA GOSSYPIFOLIA*, Linn.; *Bastard French Physic Nut*, *Belly-ache*, or *Wild Cassada*, have also been used as purgatives in dropsies.⁸

134. *Anda brasiliensis*, Raddi.

(Semina.)

Anda, Piso, I. 72; II. 148; *Anda brasiliensis*, Raddi, Quarante piante, &c. 1821; *Anda Gomesii*, Ad. Jussieu, De Euphorb. Generib. 1824; *Anda-agu*, *Indayagu*, *Purga de Gentio*; *Coco de Purga*, *Purga dos Paulistas*, *Fruita d'Arara*, Brazil.—Brazil.—The fruit is about the size of an orange, with 2 large and 2 smaller angles. It contains two roundish nut-like seeds (*semina anda brasiliensis*) about the size of small chestnuts. By pressure they yield a fixed oil (*oleum anda brasiliensis*; *oil of anda-agu*). Both seeds and oil are purgative. One seed, according to Von Martius,⁹ is a dose for a man. The expressed oil is clear and pale yellowish. Like jatropha oil, it is not very soluble in alcohol; but its solubility is increased by the addition of castor-oil. Mr. Ure¹⁰ found that in doses of 20 drops it operated moderately as a purgative.

135. *MANIHOT UTILISSIMA*, Pohl.¹¹—BITTER CASSAVA.

disk, free, the alternate ones shorter: *filaments* filiform; *anthers* turned inwards, 2-celled. *Ovary* placed on the fleshy disk, 3-celled, with 1 ovule in each cell. *Style* short. *Stigmas* 3, many-lobed, the lobes consolidated into a conical sinuated-sulcated mass. *Capsule* 3-coecous; the cocci 2-valved and 1-seeded (Endlicher).

Sp. Char.—*Leaves* with very long petioles, deeply 7-parted, palmate; the segments lanceolate, acuminate, attenuated at the base, quite entire, the outer ones smaller, unequal, diverging, straggling. *Root* whitish-yellow (Pohl).

Root large, thick, tuberous, fleshy; containing an acid, milky, highly poisonous juice. *Flowers* axillary, racemose.¹

Hab.—Native of the Brazils; where, as well as in other parts of South America, it is cultivated.

MANIHOT APII, Pohl.—*Sweet Cassava*, Bancroft, Nat. Hist. of Guiana, 1769.—This is usually regarded as a variety of the above; but Pohl considers it to be a distinct species; characterized by the leaves which are 5-parted, and by the root, which is reddish, and contains a milky non-poisonous juice. It is cultivated in the Brazils, and in Spanish America.

MANIHOT JANIPHA, Pohl; *Jatropha Janipha*, Linn.; *Janipha Loefflingii*, HBK.—This species is said to yield the *sweet or white cassava* of the West Indies. Dr. Hamilton² says it so closely resembles the *Janipha Manihot*, Linn. (*Manihot utilissima*, Pohl), that an experienced eye can hardly distinguish it with certainty. Is not the sweet cassava of the West Indies the *Manihot Apii* of Pohl? Like the latter, it is devoid of poisonous properties.

DESCRIPTION.—1. *Bitter cassava root* is a large tuberous root³ which abounds in a poisonous milky juice. It is difficult to distinguish by its appearance from the sweet cassava root; but it is devoid of the tough, fibrous, or woody filaments found in the heart of the sweet cassava root; and it does not become soft, like the latter root, by boiling or roasting. The rasped root mixed with water, boiled, and then fermented, yields a spirituous liquor called *cassiri*.⁴ *Cassava meal* is obtained by subjecting the grated root to pressure to express the juice, and then drying and pounding the residual cake. Of this meal *cassava bread* is made. The expressed juice by repose deposits the farina called *cassava starch*, of which *tapioca* is made. A sauce called *casareep* or *cassireepe*, is made from the juice.⁵

2. *Sweet cassava root* resembles the bitter cassava root in external appearance; but, unlike the latter, it is not poisonous. It has a bundle of tough, fibrous, or woody filaments at the heart, running longitudinally through the root. By boiling or roasting it becomes soft, and is used at table.

A few pounds of *dried sweet cassava root* have recently been sent to England from Jamaica on speculation, to ascertain whether it was likely to prove a profitable article of commerce. It consisted of transverse and longitudinal segments, which were beautifully white, had a very faint agreeable odour, and were mucilaginous or farinaceous to the taste. The circular disks were from one to two or more inches in diameter, and had in the centre the ligneous cord above alluded to. Some of the pieces were worm-eaten: a few were slightly scorched or burnt, apparently by over-heating in the drying process.

Cassava meal and *bread*, *cassava starch*, and *tapioca*, are prepared from the sweet as well as from the bitter cassava root.

COMPOSITION.—The bitter cassava root has been analyzed by MM. O. Henry and Boutron-Chalard,⁶ who inferred that it contained *free hydrocyanic acid*, *starch*, a small quantity of *sugar*, an *organic salt of magnesia*, a *bitter principle*, a *crystallizable fatty matter*, an *azotized matter* (vegetable osmazome), *phosphate of lime*, and *woody fibre*.

¹ Hooker, *Bot. Mag.* t. 3071.

² Hamilton, *Pharmaceutical Journal*, vol. v. p. 27, 1845.

³ A figure of the root is given in the *Journ. de Pharm.* t. xxii. 1836.

⁴ Dr. Hamilton, *Pharmaceutical Journal*, vol. v. p. 29, 1849.

⁵ *Casareep* is the concentrated juice of the roots of the bitter cassava flavoured by aromatics. During the evaporation, the poisonous principle of the juice is either dissipated or destroyed. *Casareep* is used to flavour soups and other dishes; and is the basis of the West Indian dish *pepper-pot*. It is a powerful antiseptic (Shier, *Report on the Starch-producing Plants of the Colony of British Guiana*, Demerara, 1847; Hamilton, *Pharmaceutical Journal*, vol. v. p. 30, 1845).—In French Guiana, the term *cabion* or *cabion* is applied to a similar condiment (Henry and Boutron-Chalard, *Journ. de Pharm.* t. xxii. p. 123). The unexpressed juice flavoured with capsicum pods is used in the Brazils as a sauce, under the name of *Tucupi* or *Tucupi* (Martius, *Syst. Mat. Med. Veg. Brasil*, p. 94).

⁶ *Journ. de Pharm.* t. xxii. p. 118, 1836.

1. **HYDROCYANIC ACID.**—According to O. Henry and Boutron-Chalard, the active principle of the root is hydrocyanic acid. Their statement is confirmed by Dr. Christison, who examined some well-preserved juice from Demerara.

2. **VOLATILE ACRID PRINCIPLE?**—The vomiting and purging, and other abdominal symptoms ascribed to bitter cassava, would lead us to suspect that, like other euphorbiaceous plants, it contains an acrid principle.

PHYSIOLOGICAL EFFECTS.—The fresh roots as well as the expressed juice are virulent poisons, destroying life in a very short period of time. O. Henry and Boutron-Chalard described the effects on guinea-pigs as resembling those caused by hydrocyanic acid; but death did not occur until from forty to fifty-five minutes after the use of the poison. Ricord Madianna¹ has killed dogs in ten minutes with a poison obtained from this root. The symptoms described by Barham² are pain and swelling of the abdomen, vomiting and purging, dimness of sight, syncope, rapid diminution of the powers of life, and death in a few hours. Half a pint of the juice has produced death in an hour.³

USES.—Dr. Wright⁴ says that the scrapings of the fresh root are successfully applied to ill-disposed ulcers; and Dr. Hamilton⁵ speaks of the instantaneous relief which he experienced on himself from the application of a cataplasm of the rasped roots, with all their juices unexpressed, to the spot where a nest of chigres (*Pulex penetrans*) had been dislodged. The root is used to catch birds, which, by eating it, lose the power of flying.⁶ It yields cassava meal and cassava starch.

1. **FARINA MANDIOCÆ; Cassava or Cassava Meal; Farinha de Pao**, or simply *Farinha*; *Farine de Manioc*.—This is obtained by washing and scraping the roots, then rasping or grating them, and subjecting the pulp to pressure, by which the poisonous juice is expressed. The residual compressed pulp is then dried over a fire, being stirred during the whole time. In this way is obtained *cassava meal*.⁷

Cassava meal is a mixture of *cassava starch*, *vegetable fibre*, and *proteine* or *albuminous matters*. Dr. Shier⁸ found that in the sliced and dry roots the percentage of nitrogen is 0.78, but in the cassava meal (the juice expressed) only 0.36. If these numbers be multiplied by 6.5 (see foot-note at p. 106), the percentage quantity of protein or albuminous matters in the dried root will be 5.0, and in cassava meal 2.34.

I have received from Dr. Shier two kinds of cassava meal; one called cassava meal, the other termed cassava flour. I shall distinguish them as coarse and fine meal.

a. **Coarse Cassava Meal; Cassava Meal**, Shier; *Couaque* or *Couac*, Guibourt.—This is meal which in coarseness is about equal to sawdust or small dried crumbs of bread. I have found a similar preparation in English commerce under the name of "*Tapioca Flour from Bahia*."

Coarse cassava meal has a slight yellowish or brownish tint, varying in different samples.

β. **Fine Cassava Meal; Cassava Flour**, Shier; *Farine de Manioc*, Guibourt.—This is a finer and whiter meal than the preceding. In fineness it resembles wheat flour.

Cassava bread or *cassava cakes* are made by baking the compressed cassava pulp on a hot plate, in the manner muffins and crumpets are baked in England.

Cassava meal and cassava bread are important and valuable articles of food to the inhabitants of tropical America. The flavour of cassava cakes reminds me of Scotch oatcakes.

2. **AMYLUM MANDIOCÆ; Mandioca or Cassava Starch; Tapioca**.—The juice which is expressed from the rasped root deposits on standing an amyllum or starch (*cassava starch*), of which *tapioca* is made.

¹ Quoted by Sloane, *Jamaica*, vol. ii. p. 363.

² *Journ. de Pharm.* t. xvi. p. 310, 1830.

³ Martius, in Wibmer, *Arzneim. u. Gifte*, Bd. iii. S. 273.

⁴ *Hortus Americanus*, p. 31, 1791.

⁵ *Med. Plants of Jamaica*.

⁶ *Pharmaceutical Journal*, vol. v. p. 28, 1848.

⁷ The details of the process for making cassava meal vary somewhat in different localities. According to Piso (*De Medicina Brasil.* lib. iv. p. 53), the roots are grated by a handmill somewhat similar to that used in the preparation of Tons-les-Mois (see *ante*, p. 228, Fig. 224). Edwards (*Voyage up the River Amazon*, p. 21, Lond. 1847) says they are grated upon stones, and the pulp compressed in a slender bag of rattan six feet in length.

⁸ *Report*, p. 15.

a. **Cassava Starch; Tapioca Meal; Brazilian Arrow-root; Moussache or Cippa.**—The fecula or starch deposited from the expressed juice of the cassava root, after being washed and dried in the air without heat, constitutes the *tapioca meal* or *Brazilian arrow-root* of commerce. It is usually imported into this country from Rio Janciro. For some years past it has been imported into France from Martinique, and is sold as arrow-root (Guibourt). It is white and pulverulent, and resembles in external appearance genuine arrow-root (maranta starch). When examined by the microscope, however, it is readily distinguished.

Cassava starch, when examined by the microscope, is found to consist of small single grains,¹ which, in the living plant, were united in groups or compound grains, each composed of 2, 3, or 4 grains. Most of the grains are mullar-shaped, and, therefore, have been united in groups of two each: when seen endwise, they appear circular or globular. Some of them are truncated egg-shaped grains, with one or two facets at the truncation. The nucleus, central cavity, or hilum, is circular, surrounded with rings, and bursts in a stellate manner.

These statements apply equally to *bitter cassava starch* and *sweet cassava starch* sent to me from Demerara by Dr. Shier, as well as to starch obtained by myself from sweet cassava root received from Jamaica.

Cassava starch has not been analyzed; but there can be no doubt but that its composition is similar to that of other starches, and that its formula is $C^{12}H^{10}O^{10}$. Its effects and uses are also like those of other starches (see *ante*, p. 119).

β. **Tapioca.**—This is imported from Bahia and Rio Janeiro. It is cassava meal, which while moist or damp has been heated, for the purpose of drying it, on hot plates. By this treatment the starch grains swell, many of them burst, and the whole agglomerate in small irregular masses or lumps. In consequence of the change thus effected in the starch grains, tapioca is partially soluble in cold water; and the filtered cold infusion strikes a blue colour with tincture of iodine. The drying to which it has been subjected renders it difficult of solution. In boiling water it swells up, and forms a transparent viscous jelly-like mass. Submitted to prolonged ebullition in a large quantity of water, it leaves an insoluble residue, which precipitates. This, when diluted with water and coloured by iodine, appears to consist of mucous flocks.

Made into puddings, tapioca is employed as a dietetical substance. Boiled in water or milk, and flavoured with sugar, spices, or wine, according to circumstances, it is used as an agreeable, nutritious, light, easily digestible article of food for the sick and convalescent. It is devoid of all irritating and stimulating properties.

136. *Crozophora tinctoria*, Necker.—Turnsole.

(Succus.)²

Heliotropium tricoccum, Pliny, lib. xxii. cap. 29; *Croton tinctorium*, Linn.—South of France: Mediterranean coast. Cultivated since 1833 in the neighbourhood of Grand Gallargus, in the department of Gard, in France. The expressed juice is green: but, under the combined influence of the air and ammonia, it becomes purplish. Coarse sacking stained purple by this juice is termed *turnsole rags* (*tournesol en drapeaux*), or *bezetta² carulea*. These rags are exclusively employed by the Dutch; but for what purpose is not well known, though it has been supposed for colouring cheese, confectionery, liqueurs, &c.³

¹ The following are the measurements, in parts of an English inch, of ten grains of cassava starch. They were made by Mr. George Jneksou:—

Lengths. Breadths.		Lengths. Breadths.	
1	0.0012 × 0.0012	6	0.0005 × 0.0004
2	0.0008 × 0.0008	7	0.0004 × 0.0004
3	0.0008 × 0.0007	8	0.0003 × 0.0003
4	0.0007 × 0.0006	9	0.00025 × 0.0002.5
5	0.0005 × 0.0004	10	0.0002 × 0.0002

² *Bezetta*, the diminutive of the Spanish word *bézo*, a lip, a term originally applied to pigments used to color the lips.

³ See an interesting notice of Turnsole by Mr. D. Hanbury, jun. in the *Pharmaceutical Journal*, vol. ix. p. 308, 1850.

ORDER XXXIV. ARISTOLOCHIACEÆ, *Lindley*.— BIRTHWORTS.

ARISTOLOCHIÆÆ, *Jussieu*; ASARINÆ, *Bartling*.

CHARACTERS.—*Flowers* hermaphrodite, axillary, solitary. *Calyx* adherent (superior), tubular, monosepalous, with the segments valvate or induplicate in æstivation, sometimes regular, sometimes very unequal. *Stamens* 6 to 12, epigynous, distinct, or adhering to the style and stigmas. *Ovary* inferior, 6-celled, very rarely 3—4-celled; *ovules* numerous, anatropal, horizontally attached to the axis. *Style* simple. *Stigmas* radiating, as numerous as the cells of the ovary. *Fruit* dry or succulent, 3—4—6-celled, many-seeded. *Seeds* thin, with a very minute embryo placed at the base of fleshy albumen—*Herbs* or *shrubs*, the latter often climbing. *Wood* without concentric zones and inseparable wedges. *Leaves* alternate, simple, stalked.

PROPERTIES.—Not important. The roots possess stimulant properties, owing to the presence of volatile oil. Some of them are acrids. Bitter extractive renders them somewhat tonic.

137. ARISTOLOCHIA SERPENTARIA, *Linn.*—THE VIRGINIAN SNAKE-ROOT.

Aristolochia officinalis, *Nees* and *Ebermaier*.

Sex. Syst. Gynandria, Hexandria.

(*Radix*, *L.*—The root, *E. D.*)

HISTORY.—The first writer who distinctly mentions *Virginian snake-root*, or *snake-weed*, is Thomas Johnson, an apothecary of London, in his edition of Gerarde's Herbal, published in 1633.

BOTANY. **Gen. Char.**—*Calyx* tubular, ventricose at the base, dilated at the apex, and extended into a ligula. *Anthers* 6, subsessile, inserted on the style. *Stigma* 6-lobed. *Capsule* 6-angled, 6-celled (*Bot. Gall.*).

Sp. Char.—*Stem* flexuous, ascending. *Leaves* cordate, acuminate, on both sides pubescent. *Peduncles* nearly radical, unifloral. Lip of the *calyx* lanceolate (*Nees* v. *Esenbeck*).

Hab.—North America.

COLLECTION AND PROPERTIES.—The root (*radix serpentariæ*) is collected in Western Pennsylvania and Virginia, in Ohio, Indiana, and Kentucky.¹ It is imported in bales, usually containing about 100 lbs. As met with in the shops, it consists of a tuft of long, slender, yellowish or brownish fibres, attached to a long, contorted head or caudex. The odour is aromatic, the taste warm and bitter.

COMPOSITION.—It was analyzed by Bucholz in 1807;² by Chevallier in 1820;³ and by Peschier in 1823.⁴

<i>Bucholz's Analysis.</i>	
Volatile oil	0.50
Greenish-yellow soft resin	2.85
Extractive matter	1.70
Gummy extractive	18.10
Lignin	62.40
Water	14.45

Serpentary root 100.00

<i>Chevallier's Analysis.</i>	
Volatile oil.	
Resin.	
Extractive.	
Starch.	
Ligneous fibre.	
Albumen.	
Mulute and phosphate of lime.	
Oxide of iron and silica.	

Serpentary root.

1. **VOLATILE OIL.**—Grassmann⁵ obtained only half an ounce from 100 lbs. of the root. Its colour is yellowish, its odour considerable, its taste not very strong.⁶ Grassmann compares the odour and taste to those of valerian and camphor combined.

2. **BITTER PRINCIPLE; Extractive,** Bucholz and Chevallier.—This is very bitter and slightly acrid. It is soluble in both water and spirit. Its solution, which is yellow, is rendered brown by alkalis, but is unchanged by the ferruginous salts.

¹ *United States Dispensatory.*

² *Journ. de Pharm.* vi. 365.

³ Quoted by Dr. W. C. Martius, *Pharmacogn.*

⁴ *Gmelin, Hand. d. Chem.*

⁵ *Gmelin, op. cit.*

⁶ *Lewis, Mat. Med.*

PHYSIOLOGICAL EFFECTS.—These have been examined by Jörg and his pupils.¹

In *small doses*, serpentary promotes the appetite. In *large doses*, it causes nausea, flatulence, uneasy sensation at the stomach, and more frequent but not liquid stools. After its absorption, it increases the frequency and fulness of the pulse, augments the heat of the skin, and promotes secretion and exhalation. Furthermore, it would appear, from the experiments before referred to, that it causes disturbance of the cerebral functions, and produces headache, sense of oppression within the skull, and disturbed sleep.

In these properties, serpentary bears some analogy to, but is much weaker than, camphor. It is more powerful than contrayerva.

USES.—Its employment is indicated in cases of torpor and atony. It was formerly termed *alexipharmic*, on account of its fancied power of curing the bite of a rattlesnake and of a mad dog.² At the present time it is rarely employed. It has been much esteemed as a stimulant in *fevers*, both continued and intermittent. A scruple of serpentary, taken in three ounces of wine, is mentioned by Sydenham³ as a cheap remedy for tertians in poor people. Dr. Cullen⁴ considered it as suited for the low and advanced stage of typhus only. In an epidemical affection of the throat (called the *throat-distemper*), it was given internally as a diaphoretic, and used with sumach berries, in the form of a decoction, as a gargle, with benefit.⁵

ADMINISTRATION.—The dose of it in substance is from ten to thirty grains. The infusion is the best form for the administration of serpentary.

1. INFUSUM SERPENTARIÆ, L. E. [U. S.]; *Infusion of Serpentary, or Snake-root*.—(Serpentary ʒss; Boiling Water Oj. Infuse for four hours in a covered vessel, and strain [through linen or calico, *E.*].)—Dose, fʒj or fʒij every two or three hours, according to circumstances.

2. TINCTURA SERPENTARIÆ, L. E. [U. S.]; *Tincture of Serpentary, or Snake-root*.—(Serpentary, bruised [in moderately fine powder, *E.*], ʒiijss, *L.*; Proof Spirit Oij; and Cochineal, bruised, ʒj, *E.* Macerate for seven days, and filter. “Proceed by percolation or digestion as for the tincture of cinchona,” *E.*—[Take of Virginia Snake-root, bruised, ʒiij; Diluted Alcohol Oij. Macerate for fourteen days, express, and filter through paper, *U. S.*].)—Used as an adjunct to tonic infusions. Dose, from fʒj to fʒij.

138. ASARUM EUROPÆUM, Linn.—COMMON ASARABACCA.

Sex. Syst. Dodecandria, Monogynia.

(Folia, *L. D.*)

HISTORY.—This plant was used in medicine by the ancients. Dioscorides⁶ calls it *ασαρον*.

BOTANY. *Gen. Char.*—*Calyx* campanulate, 3-lobed. *Stamens* 12, inserted on the ovary; *anthers* adnate to the middle of the filaments. *Style* short. *Stigma* stellate, 6-lobed. *Capsule* 6-celled. (*Bot. Gall.*)

Sp. Char.—*Leaves* 2 on each stem, kidney-shaped, obtuse [somewhat hairy] (*Smith*).⁷

The branching *root-fibres* arise from an underground stem or *rhizome*. The aerial *stems* are several from each rhizome. *Leaves* petiolated. From the axil of the two leaves springs a solitary, rather large, drooping *flower*, upon a short peduncle, of a greenish-brown colour and coriaceous substance. Segment of the *calyx* incurved. *Capsule* coriaceous. *Seeds* ovate, with horny albumen.

Hab.—Indigenous. Perennial. Flowers in May.

DESCRIPTION.—The whole plant (root-fibres, rhizome, and aerial stems, with

¹ Wibmer, *Arzneim. u. Gifte*, Bd. i. S. 221; also, *Journ. de Chim. Méd.* t. vii. p. 493.

leaves and flowers) is kept in the shops under the name of *asarabacca* (*radix cum herbâ asari*), but the leaves only are directed to be used in the Pharmacopœia. Dr. Batty¹ states that the plant is gathered for medicinal uses in the woods near Kirkby Lonsdale, Westmoreland. The *rhizome* is about as thick as a goose-quill, grayish, quadrangular, knotted. It has a pepper-like odour, and an acrid taste. The *leaves* are almost inodorous, but have an acrid, aromatic, and bitter taste.

COMPOSITION.—Goerz² published an analysis of the root in 1784; Lassaigne and Feneulle another in 1820;³ Regimbeau a third in 1827;⁴ and Gräger a fourth in 1830.⁵

Gräger's Analyses.

Root.		Herb.

Fresh root of asarabacca	100.813	Fresh herb of asarabacca	100.00

1. VOLATILE OILY MATTERS.—By submitting asarabacca root to distillation with water, three volatile oily matters are obtained; one liquid and two solid, at ordinary temperatures.

a. *Liquid Volatile Oil (Oleum Asari)*.—It is yellow, glutinous, lighter than water, and has an acrid, burning taste, and a penetrating valerian-like odour. It is slightly soluble in water, more so in alcohol, ether, and the oils (volatile and fixed). Its constituents are C⁸H¹⁰O.

β. *Asarite of Gräger*.—In small needles of a silky lustre. It is odourless and tasteless. It is fusible and volatilizable by heat; its vapour being white and very irritating. It is soluble in alcohol, ether, and the volatile oils, but not in water. Both nitric and sulphuric acids dissolve the crystals without the evolution of gas: if water be added to the sulphuric solution, the asarite is thrown down unchanged.

γ. *Asarum-camphor*.—Is distinguished from asarite by the following characters: Water throws it down from its alcoholic solution in cubes or six-sided prisms, whereas asarite is precipitated in delicate flexible needles. It dissolves in nitric acid without effervescence. Water added to its sulphuric solution throws down a brown resin. After fusion, it has the form of a crystalline, striated mass. Its composition is C⁸H⁵O². Blanchet and Sell regard it as the hydrate of the liquid volatile oil.

2. BITTER PRINCIPLE OF ASARABACCA (*Asarin* of Gräger and of some other pharmacologists).—Brownish, very bitter, soluble in alcohol.

PHYSIOLOGICAL EFFECTS.—Every part of the plant possesses acrid properties. Applied to the mucous membrane of the nose, it excites sneezing, increased secretion of mucus, and even a discharge of blood. Swallowed, it causes vomiting, purging, and griping pains. It is also said to possess diuretic and diaphoretic properties. Dr. Cullen has enumerated it in his list of diuretics, but expresses his doubts whether it possesses any specific power of stimulating the renal vessels.

USES.—Asarabacca has been employed in medicine to excite vomiting, and as an emetine. As an emetic, it is now superseded by ipecacuanha and tartarized antimony. As an emetine, to excite irritation and a discharge of mucus from the nasal membrane, it has been used in certain affections of the brain, eyes, face, mouth, and throat, on the principle of counter-irritation: thus in paralytic affections of the mouth and tongue, in toothache, and in ophthalmia.

ADMINISTRATION.—We may administer either the root or leaves, recollecting that the latter are somewhat milder than the former. As an *emetic*, the dose is half a drachm to a drachm. As an *errhine*, one or two grains of the root, or three

¹ Eng. Flora.

⁴ Pfaff, Mat. Med. Bd. iii. S. 229.

⁵ Ibid. t. xiv. p. 299.

or four grains of the dried leaves, are snuffed up the nostrils every night.—The powder of this plant is supposed to form the basis of *cephalic snuff*.

PULVIS ASARI COMPOSITUS; *Compound Powder of Asarabacca*.—(Asarabacca Leaves, dried, ʒj; Lavender Flowers, dried, ʒj. Reduce them together to powder.)—Used as an errhine in headache and ophthalmia. Dose, from grs. v to grs. viij.

139. *Aristolochia rotunda*, *Lim.*; et *A. longa*, *Lim.*—Round and Long Birthwort.

Sex. Syst. Gynandria, Hexandria.

(Radix.)

Both of these plants are natives of the South of Europe. Their roots are still kept in the shops. *The long aristolochia root* is several inches in length, one or two inches broad, and has a more or less cylindrical form. *The round aristolochia root* has a more rounded and knobby form. Both kinds are bitter and acrid, and have, especially when powdered, a disagreeable odour. They contain extractive matter and starch. Lassaigne found ulmin in the long species. Their effects are stimulant and tonic. Their stimulant effects are supposed by some to be principally directed to the abdominal and pelvic viscera. They have been employed in amenorrhœa as an emmenagogue. Their dose is from ʒj to ʒj. Round aristolochia root is a constituent of the *Duke of Portland's powder for the goat*, which consisted of equal quantities of the roots of *Gentian* and Birthwort (*Aristolochia rotunda*), the tops and leaves of *Germander* (*Chamaedrys*), *Ground Pine* (*Chamaepitys*), and lesser *Centaury* (*Chironia Centaurium*), powdered and mixed together.¹

ORDER XXXV. LAURACEÆ, *Lindley*.—LAURELS.

LAURI, *Jussieu*.—*LAURINEÆ*, *Vent.* and *Rob. Brown*.

CHARACTERS.—*Calyx* 4- to 6-cleft, with imbricated aestivation, the limb sometimes obsolete. *Petals* 0. *Stamens* definite, perigynous opposite the segments of the calyx, and usually twice as numerous; the 3 innermost, which are opposite the 3 inner segments of the calyx, sterile or deficient; the 6 outermost scarcely ever abortive; *anthers* adnate, 2- to 4 celled; the cells bursting by a longitudinal persistent valve from the base to the apex; the outer anthers valved inwards, the inner valved outwards [for both valved inwards, *Lindl*]. *Glands* usually present at the base of the inner filaments. *Ovary* single, superior, 1-celled [formed of 3 valvate carpellary leaves, and as many rib-like placentæ stationed at the sutures, all generally imperfect except one, *Endl.*], with 1 or 2 single pendulous ovules; *style* simple; *stigma* obtuse, 2- or 3 lobed. *Fruit* baccate or drupaceous, naked or covered. *Seed* without albumen; *embryo* inverted; *cotyledons* large, plano convex, peltate near the base; *radicle* very short, included, superior; *plumule* conspicuous, 2-leaved.—*Trees*, often of great size. *Leaves* without stipules, alternate, seldom opposite, entire, or very nearly lobed. *Inflorescence* paniced or umbelled (*Rob. Brown*).

PROPERTIES.—The plants of this order owe their most important qualities to the presence of volatile oil, which is found, more or less abundantly, in all parts of the vegetable. This oil is sometimes liquid and highly aromatic, as oil of cinnamon; at others, it is solid in ordinary temperatures, and is endowed with narcotic properties, as camphor. The acrid principle of some species is probably a volatile oil.

In the bark and leaves, the volatile oil is usually associated with tannic acid, which gives them astringency, as in cinnamon. In the fruit and seeds, on the other hand, it is usually combined or mixed with fixed oil, as in bay-berries.

Besides the officinal lauraceous barks, presently to be described, there are several others which have obtained considerable celebrity, in the countries producing them, on account of their aromatic qualities.

Two of these bear the name of *clove bark*, on account of their odour. The *Indian clove bark* or *cortex culilawan* is a large flat bark, and is obtained from *Cinnamomum Culilawan*, Blume, a native of the Indian islands. Its properties are analogous to those of *Cassia-lignea*.² It is rarely met with in London. I have received from Dr. Martiny, of Hesse Darmstadt, a bark marked *Culilawan papuanus*. It is, I presume, the produce of *Cinnamomum xarthonewon* of Blume.

¹ See Dr. Clepliane's *Inquiry into the Origin of the Goat Powder*, in the *Med. Observ. and Inq.* vol. i. Lond. Dr. Clepliane concludes that *Crabus Aurelianus's diacentaureon* and *Actius's antidotus ex duobus centaureis generibus* were the same medicine, and are the old names for the Duke of Portland's Powder.

² See Pereira, in *Lindley's Flora Medica*, p. 331.

The *Brazilian clove bark*, or *clove cassia bark*, *cortex cassiæ caryophyllatæ*, is the produce of *Dicypellium caryophyllatum*, and grows in Para and Rio Negro. Its bark occurs in tubular quills.

Massey bark (in commerce *Misoï*) is the *cortex ovinus* of Rumphius. It is used in the cosmetics of the natives of India.¹ I have never found it in the London shops.

Sintoc bark is the produce of *Cinnamomum Sintoc*, Blume. Its properties are analogous to those of Culilawan.

The *folia malabathri* of India are obtained from *Cinnamomum nitidum*, Hooker and Blume, and from *C. Tamala*. They are aromatic tonics, but are not found in the London market.

140. CINNAMOMUM ZEYLANICUM, Nees.—THE CEYLON CINNAMON.

Laurus Cinnamomum, Linn.

Sex. Syst. Enneandria, Monogynia.

(Cortex; et Oleum c cortice destillatum, L.—Bark; and volatile oil of the bark, E.—The bark, D.)

HISTORY.—Cinnamon (*Kinman*, Hebr.) is mentioned in the Old Testament,² about 1490 years before Christ. In all probability the Hebrews received it from the Arabians, who must, therefore, have had commercial dealings with India at this early period.³ The first notice of cinnamon (*κιννάμωμον*) by the Greek writers occurs in Herodotus,⁴ who died 413 years before Christ. Probably both the Hebrew and Greek names for this bark are derived from the Cingalese *cacyn-nama* (*dulce lignum*), or the Malayan *kaimanis*.⁵ Hippocrates⁶ employed cinnamon externally. Dioscorides⁷ describes several kinds of cinnamon.

BOTANY. **Gen. Char.**—*Flowers* hermaphrodite or polygamous. *Calyx* 6-leafed, with the limb deciduous. *Stamina* 12, in 4 rows; the 9 external ones fertile, the 3 inner ones capitate, abortive; the 3 most internal of the fertile stamina having 2 sessile glands at the base: *anthers* 4-celled, the 3 inner turned outwards. *Ovary* 1-celled, with 1 ovule. *Fruit* (a berry) seated on a cup-like calyx. *Leaves* ribbed. *Leaf-buds* naked. *Flowers* panicled, rarely fascicled. (Condensed from Endlicher.)⁸

Sp. Char.—*Branches* somewhat 4-cornered, smooth. *Leaves* ovate or ovate-oblong, tapering into an obtuse point, triple-nerved, or 3-nerved, reticulated on the under side, smooth, the uppermost the smallest. *Panicles* terminal and axillary, stalked. *Flowers* hoary and silky; segments oblong, deciduous in the middle (Nees).⁹

Botanists admit several varieties of this species; the most important are—

a. *Broad-leaved*, Moon;¹⁰ *Mu-pat* (Cingalese).—The plant above described.

B. *Narrow-leaved*, Moon; *Cinnamomum zeylanicum*, var. *γ*; *Cassia*, Nees; *Heen-pai* (Cingalese).—This variety, which I have received from Ceylon under the name of *Bastard Cinnamon*, has oblong or elliptical leaves, much tapering to the point, and acute at the base.

Percival¹¹ mentions four varieties which are barked: 1st, *Rasse curundu*, or *honey cinnamon*, with broad leaves, yields the best bark; 2dly, *Nai curundu*, or *snake cinnamon*, also with large leaves, not greatly inferior to the former; 3dly, *Capura curundu*, or *camphor cinnamon*, an inferior kind; 4thly, *cabatte curundu*, or *astringent cinnamon*, with smaller leaves; its bark has a harsh taste.

Hab.—Cultivated in Ceylon and Java.

PRODUCTION.—The cinnamon bark of Ceylon is obtained by the cultivation of the plant. The principal *cinnamon gardens* lie in the neighbourhood of Colombo.¹²

Cinnamomum zeylanicum.

The bark-peelers, or *choliahs*, having selected a tree of the best quality, lop off such branches as are three years old, and which appear proper for the purpose. Shoots or branches, much less than half an inch, or more than two or three inches in diameter, are not peeled. The peeling is effected by making two opposite, or, when the branch is thick, three or four, longitudinal incisions, and then elevating the bark by introducing the peeling-knife beneath it. When the bark adheres firmly, its separation is promoted by friction with the handle of the knife. In twenty-four hours, the epidermis and greenish pulpy matter (*rete mucosum*) are carefully scraped off. In a few hours, the smaller quills are introduced into the larger ones, and in this way a congeries of quills formed, often measuring forty inches long. The bark is then dried in the sun, and afterwards made into bundles with pieces of split bamboo twigs.¹

Cinnamon walking-sticks.—The hazel-like walking-sticks, so much esteemed by visitors to Ceylon, are obtained from the shoots which spring almost perpendicularly from the roots after the parent bush or tree has been cut down.²

COMMERCE.—Cinnamon is imported in bales, boxes, and chests, from Ceylon principally; but in part also from Madras, Tellicherry, and rarely from Java and other places.

In order to preserve and improve the quality of the bark, black pepper is sprinkled among the bales of cinnamon in stowing them at Ceylon (Percival). Mr. Bennett states that ships are sometimes detained for several weeks, through the want of pepper to fill the interstices between the bales in the holds.

When cinnamon arrives in London, it is unpacked and examined; all the mouldy and broken pieces are removed from it. It is then re-made into bales. These are cylindrical, 3 feet 6 inches long, but of variable diameter, perhaps 16 inches on the average. These bales are enveloped by a coarse cloth, called *gunny*. The cinnamon in boxes and chests is usually the small, inferior, and mouldy pieces.

DESCRIPTION.—Four kinds of cinnamon³ are distinguished in the London market; namely, *Ceylon*, *Tellicherry*, *Malabar*, and *Java* cinnamon. The latter, however, is rarely met with. A fifth kind, called *Cayenne*, occurs in French commerce.

The *Chinese cinnamon* of continental writers is *Cassia lignea* of English commerce.

1. **Ceylon Cinnamon** (*Cinnamomum zeylanicum* seu *Cinnamomum acutum*).—This is the most esteemed kind. The fasciculi or compound quills, of which the bales are made up, are about 3 feet 6 inches long, slender, and shivery, and are composed of several smaller quills inclosed one within the other. The bark is thin (the finest being scarcely thicker than drawing paper), smooth, of a light yellow-brown or brownish-yellow, moderately pliable, with a splintery fracture, especially in the longitudinal direction. The inner side or *liber* is darker and browner, and contains, according to Nees, small medullary rays filled with a red juice, and which he regards as the peculiar bearers of the aroma. The odour of the bark is highly fragrant. The flavour is warm, sweetish, and agreeable. Inspection and tasting are the methods resorted to for ascertaining the qualities of cinnamon.⁴

Ceylon cinnamon is characterized by being cut obliquely at the bottom of the quill, whereas the other kinds are cut transversely. In the London market three qualities of Ceylon cinnamon are distinguished; viz. *first*, *seconds*, and *thirds*. Inferior kinds are thicker, darker, browner, and have a pungent, succeeded by a bitter taste.

Thin, very much convoluted, smaller quills being inclosed in larger ones. *Ph. Lond.*

2. **Tellicherry or Bombay Cinnamon** is grown on one estate only, at Tellicherry,

¹ Percival, *op. cit.*; and Marshall, in *Thomson's Ann. of Philosophy*, vol. x.

² Bennett, *Ceylon and its Capabilities*, 1843.

³ In the years 1839 and 1840, I examined above 1000 bales of cinnamon in the Dock warehouses. In 1840, I was kindly assisted in my examination by Mr. Carroll, of Mincing Lane, one of the most experienced London dealers, who attended with me, and from whom I derived much practical information.

⁴ See Percival, *op. supra cit.*; also, Marshall, *op. supra cit.*

by Mr. Brown, and is wholly consigned to Messrs. Forbes and Co. Only 120 or 130 bales are annually imported. In appearance it is equal to the Ceylon kinds; but the internal surface of the bark is more fibrous, and the flavour is inferior. It is superior to the Malabar variety.

3. **Madras or Malabar Cinnamon** is of inferior quality. It is grown, I am informed, on the Coromandel coast. It is coarser and inferior in flavour to the other kinds. In thickness it approximates to *Cassia lignea*. Its quality has annually deteriorated since its introduction into the market. It does not meet with a ready sale, and it is expected that its importation will cease.

4. **Java Cinnamon**.—This is said to be equal in quality to the Ceylon sort.¹

5. **Cayenne Cinnamon**.—This is unknown in the London market. Its volatile oil is more acrid and peppery than the oil from Ceylon cinnamon.²

SUBSTITUTION.—In commerce, *Cassia lignea* (called on the continent Chinese cinnamon) is frequently substituted for cinnamon. It is distinguished by its greater thickness, its short resinous fracture, its less delicacy but greater strength of flavour, its shorter quills, and its being packed in small bundles. Moreover, it may be distinguished chemically by the action of iodine on its infusion (see *infra*). The difference of flavour is best distinguished when the barks are ground to powder. The great consumers of cinnamon are the chocolate-makers of Spain, Italy, France, and Mexico, and by them the difference of flavour between cinnamon and cassia is readily detected. An extensive dealer in cinnamon informs me that the Germans, Turks, and Russians prefer cassia, and will not purchase cinnamon, the delicate flavour of which is not strong enough for them. In illustration of this, I was told that some cinnamon (valued at 3s. 6d. per lb.) having been by mistake sent to Constantinople, was unsaleable there at any price; while cassia lignea (worth about 6d. per lb.) was in great request.

COMPOSITION.—In 1817, Vauquelin³ made a comparative analysis of the cinnamons of Ceylon and Cayenne. The constituents of both were found to be *volatile oil, tannin, mucilage, colouring matter* (partially soluble in water and in alcohol, but insoluble in ether), *resin, an acid, and ligneous fibre*. Starch is a constituent of cinnamon, though not mentioned in this analysis.

CHEMICAL CHARACTERISTICS.—Sesquichloride of iron causes a greenish flocculent precipitate (*tannate of iron*) in infusion of cinnamon. Solution of gelatine also occasions a precipitate (*tannate of gelatine*) in the infusion.

A decoction of cinnamon may be distinguished from a decoction of cassia lignea by tincture of iodine; which gives a blue colour (*iodine of starch*) with the latter, but not with the former. Both barks contain starch, but cinnamon appears to contain a larger proportion of some principle (tannic acid?) which destroys the blue colour of iodide of starch; for, if the decoction of cassia lignea rendered blue by iodine be added to the decoction of cinnamon, the blue colour disappears.

PHYSIOLOGICAL EFFECTS.—Cinnamon produces the effects of the spices already described (see *ante*, p. 221). In moderate doses, it stimulates the stomach, produces a sensation of warmth in the epigastric region, and promotes the assimilative functions. The repeated use of it disposes to costiveness.

In full doses, it acts as a general stimulant to the vascular and nervous systems. Some writers regard it as acting specifically on the uterus.⁴

USES.—The uses of cinnamon are those of the species generally, and which have been before noticed. It is employed by the cook as an agreeable condiment. In medicine, it is frequently added to other substances: as to the bitter infusions, to improve their flavour; and to purgatives, to check their gripping qualities. As a cordial, stimulant, and tonic, it is indicated in all cases characterized by feebleness and atony. As an astringent, it is employed in diarrhoea, usually in combination with chalk, the vegetable infusions, or opium. As a cordial

and stimulant, it is exhibited in the latter stages of low fever. In flatulent and spasmodic affections of the alimentary canal, it often proves a very efficient carminative and antispasmodic. It checks nausea and vomiting. It has also been used in uterine hemorrhage.

ADMINISTRATION.—The dose of it in substance is from ten grains to half a drachm.

1. **OLEUM CINNAMOMI**, L. E. D. [U. S.]; *Oleum Cinnamomi veri*, offic.; *Oil of Cinnamon*.—(Obtained in Ceylon by macerating the inferior pieces of the bark, reduced to a gross powder, in sea-water for two days, when both are submitted to distillation.)—As imported, the oil varies somewhat in its colour from yellow to cherry-red; the paler varieties are most esteemed; hence London druggists frequently submit the red oil of cinnamon to distillation, by which they procure two pale yellow oils; one lighter (amounting to about the quarter of the whole), the other heavier than water. The loss on this process is considerable, being near 10 per cent. Percival says that the oil obtained from the finer sorts of cinnamon is of a beautiful gold colour, while that from the coarser bark is darker and brownish.

Its odour is pleasant, and purely cinnamomic. Its taste is at first sweetish, afterwards cinnamomic, burning, and acrid.

Cinnamon oil of commerce is a complex substance, consisting of a mixture or compound of two or more bodies. The principal constituent, and which is considered to be cinnamon oil properly so called, is the *hydruret of cinnamyle*, whose formula, according to Mulder,¹ is $C^{20}H^{11}O^2$; but, according to Dumas and Peligot,² is $C^{18}H^8O^2$. Mulder³ supposes that the differences in these formulæ depend on the oil analyzed by Dumas and Peligot not having been quite fresh.

By exposure to the air, oil of cinnamon absorbs oxygen, and produces cinnamic acid, two resins, and water.

With nitric acid, oil of cinnamon combines to form a white crystalline nitrate ($C^{18}H^8O^2, NO^5$) and a red oil. With ammonia, the oil unites to form a crystalline solid amide, called *cinnhydramide*, whose formula is $C^{18}H^{24}N^2$.

On account of their great difference in commercial value, and resemblance in physical and chemical properties, oil of cassia is sometimes substituted for, or admixed with, genuine oil of cinnamon. The finer and more delicate odour of the latter is the chief distinction between them.

The Edinburgh College gives the following characters of oil of cinnamon:—

“Cherry-red when old; wine yellow when recent; odour purely cinnamomic: nitric acid converts it nearly into a uniform crystalline mass.”

These characters, however, are not peculiar to this oil, as they are also possessed by oil of cassia.

Zetter⁴ says that oil of cinnamon is a thinner and specifically lighter oil, which does not become turbid at a lower temperature than the oil of cassia. Most, if not all, the other characteristic differences which he has given probably relate rather to particular samples of the oils than to their peculiar natures.

Oil of cinnamon root.—In 1848 some of this oil was imported. Its colour was pale yellow, and its odour that of cinnamon; but not so delicate as the oil of the bark.

Oil of cinnamon is sometimes employed as a powerful stimulant in paralysis of the tongue, in syncope, or in cramp of the stomach. But its principal use is as an adjuvant to other medicines. The dose of it is from one to three minims.

2. **OLEUM CINNAMOMI FOLIORUM**; *Oil of Cinnamon Leaf*.—It is exported from Ceylon, and is sometimes called, on account of its odour, *clove oil*.

¹ *Berlinisches Jahrbuch für d. Pharmacie*, Bd. xxxviii. p. 176, 1837.

² *Ann. de Chim. et de Phys.*

³ *Pharmaceutisches Central-Blatt für 1839*, p. 879.

⁴ *Jahrbuch für praktische Pharmacie*, Bd. xix. S. 3, and General-Tabelle, 1819.

I am informed by a gentleman on whose estate in Ceylon it is obtained, that it is procured by macerating the leaves in sea-water, and afterwards submitting both to distillation. It is a yellow liquid, heavier than water, and has an odour and taste analogous to those of oil of cloves.

Bennett¹ declares it to be equal in aromatic pungency to the oil made from the clove at the Moluca Islands. Oil of cinnamon leaf is, however, specifically lighter than genuine oil of cloves; but, like the latter, yields a dark blue colour with the tincture of the sesquichloride of iron. Its effects and uses are similar to those of oil of cloves.

3. **AQUA CINNAMOMI**, L. E. D. [U. S.]; *Cinnamon Water*.—(Cinnamon, bruised, ℥ss; Water *Cong.* ij. Let a gallon distil. Or, Oil of Cinnamon ℥ij; Powdered Flint ℥ij; Distilled Water *Cong.* j. Diligently rub the oil, first with the flint, afterwards with the water, and strain the liquor, *L.*—Cinnamon Bark, bruised, ℥xviiij; Water two gallons; Rectified Spirit ℥iiij. Mix them together, and distil off one gallon, *E.*—Essence of Cinnamon ℥ij; Distilled Water half a gallon. Mix with agitation, and filter through paper, *D.*—[Take Oil of Cinnamon ℥ss; Carbonate of Magnesia ℥j; Distilled Water Oij. Rub the oil of cinnamon, first with the carbonate of magnesia, then with the water gradually added, and filter through paper, *U. S.*]—Cinnamon water is principally employed as a vehicle for other medicines. It is aromatic and carminative. Gœppert says it is poisonous to plants. By dissolving iodine and iodide of potassium in cinnamon water, a crystalline compound is produced, consisting of iodide of potassium 12.55, iodine 28.14, oil of cinnamon 59.31.²

4. **SPIRITUS CINNAMOMI**, L. E.; *Spirit of Cinnamon*.—(Oil of Cinnamon ℥ij; Proof Spirit *Cong.* j; Water Oj. Dissolve, *L.*—Cinnamon, in coarse powder, ℥j; Proof Spirit Ovij. Macerate for two days in a covered vessel; add a pint and a half of water; and distil off seven pints, *E.*)—Stimulant. Dose, ℥j to ℥iv.

5. **ESSENTIA CINNAMOMI**, D.; *Essence of Cinnamon*.—(Oil of Cinnamon ℥j; Rectified Spirit ℥ix. Mix with agitation, *D.*)—Used for making cinnamon water. A few drops may be taken on a lump of sugar as a stimulant.

6. **TINCTURA CINNAMOMI**, L. E. [U. S.]; *Tincture of Cinnamon*.—(Cinnamon, bruised, ℥ijss [in moderately fine powder, *E.*]; Proof Spirit Oij [U. S.]. Macerate for seven days, and strain. [Proceed by percolation or digestion, as directed for tincture of cassia, *E.*]—Commonly used as an adjuvant to cretaceous, astringent, tonic, or purgative mixtures. It has also been employed in uterine hemorrhage.³ Dose, ℥j to ℥iv.

7. **TINCTURA CINNAMOMI COMPOSITA**, L. E. D. [U. S.]; *Compound Tincture of Cinnamon*.—(Cinnamon, bruised [in fine powder, if percolation be followed, *E.*], ℥j [℥ij, *D.*]; Cardamom, bruised, ℥ss [℥j, *E. D.*]; Long Pepper, powdered [ground finely, *E.*], ℥ijss [℥iiij, *E.*] [not used by the *Dublin College*]; Ginger ℥ijss [not used by the *Ed. College* [℥ss, *D.*]]; Proof Spirit Oij. Macerate for seven [fourteen, *D. (U. S.)*] days, express and strain, *L.* “This tincture is best prepared by the method of percolation as directed for the compound tincture of cardamom. But it may also be made in the ordinary way by digestion for seven days, straining and expressing the liquor, and then filtering it,” *E.* [The formula of the *U. S.* is like that of the *London Pharm.*]—Cordial and aromatic. Used in the same cases as the last. Dose, ℥j to ℥ij.

8. **PULVIS CINNAMOMI COMPOSITUS**, L.; *Pulvis Aromaticus*, E. D. [U. S.]; *Compound Powder of Cinnamon*; *Aromatic Powder*.—(Cinnamon ℥ij; Cardamom ℥iiss [℥j, *D. (U. S.)*]; Ginger ℥j [℥ij, *D.*]; [Long Pepper ℥ss, *L.*; Nutmeg ℥j, *D. (U. S.)*]. Rub them together, so that a very fine powder may be made, *L. D.*—

¹ *Ceylon and its Capabilities*, p. 70, 1813.

² Apjohn, *Athenæum*, No. 517, for 1837; and No. 559, 1838.

³ Voigtels, *Arzneim.* Bd. ii. S. 465.

The *Edinburgh College* employs cinnamon, cardamom seeds, and ginger, of each equal parts.)—Aromatic and carminative. Dose, grs. x to grs. xxx. Principally employed as a corrigent of other preparations.

9. CONFECTIO AROMATICA, L. D. [U. S.]; *Electuarium Aromaticum*, E.; *Aromatic Confection*.—(Cinnamon, Nutmegs, each ʒij; Cloves ʒj; Cardamom Seeds ʒss; Saffron ʒij; Prepared Chalk ʒxvj; Sugar ℥ij; Distilled Water as much as may be sufficient. Rub the dry ingredients together to a very fine powder, and preserve in a stoppered vessel. When the confection is required for use, add two fluidrachms of water to each ounce of the powder, and mix them together until they form one mass, *L.* The *Edinburgh College* orders of Aromatic Powder *one part*; Syrup of Orange Peel *two parts*. Mix and triturate them into a uniform pulp.—The *Dublin College* orders of Aromatic Powder ʒv; Dried Saffron, in fine powder, ʒss; Oil of Cloves fʒss; Simple Syrup fʒv; Clarified Honey, *by weight*, ʒij. Rub the aromatic powder with the saffron, add the syrup and honey, and beat them together till thoroughly mixed; lastly, add the Oil of Cloves.)—The preparation of the London Pharmacopœia differs essentially from the aromatic confection of the Edinburgh and Dublin Pharmacopœias, in not containing chalk. The London College directs the water to be added when the preparation is wanted, with the view of preventing fermentation, to which the preparation is subject. Some druggists substitute a strong infusion of saffron for the solid saffron; the volatile oil of the spices for the spices themselves; and precipitated carbonate of lime for chalk.

Aromatic confection, Ph. L., is antacid, stimulant, and carminative. It is usually added to the ordinary chalk mixture in diarrhœa, and is employed on various other occasions where spices are indicated. Dose, grs. x to ʒj.

[The *U. S. Pharm.* directs of Aromatic Powder five ounces and a half; Saffron, in powder, half an ounce; Syrup of Orange Peel six ounces; Clarified Honey two ounces.]

141. CINNAMOMUM CASSIA, Blume.—THE CINNAMON CASSIA.

Cinnamomum aromaticum, Nees.

Sex. Syst. Enneandria, Monogynia.

(Cassia-bark. Oil of Cassia, *E.*—Cassia lignea, and Cassia buds, *offic.*)

HISTORY.—It is highly probable that the bark, now called *cassia lignea*, was known to the ancient Greeks and Romans; but we cannot positively prove this. The barks termed by the ancients cinnamomum (κιννάμωμον) and cassia¹ (κάσσια), as well as the trees yielding these substances, are too imperfectly described to enable us to determine with precision the substances referred to. The cassia tree is called in Chinese *Kwei* (*Qui*). Cassia lignea is called *Kwei Pe*, or Cassia skin; while Cassia buds are termed *Kwei Tsze*, or Cassia seeds. Cinnamon is called *Yuh Kwei* (vulgarly Yoke Qui), or Precious Cassia. It is not a product of China.

BOTANY. *Gen. Char.*—Vide *Cinnamomum zeylanicum*.

Sp. Char.—*Leaves* opposite, sometimes alternate, oblong-lanceolate, triple-nerved; the nerves vanishing at the point of the leaf. *Petioles* and younger *branches* silky-tomentose. *Stem* arborescent (Blume).²

Hab.—China; cultivated in Java.

The tree known in Ceylon as the *Dawul Kurunda* was erroneously supposed by Linnæus to be the source of cassia bark, and hence he termed it *Laurus Cassia*. The Dublin College has been led into the same error. Many years since, Mr. Marshall³ stated that the bark of Dawul Kurunda was not aromatic like cinnamon, but had the bitter taste and the odour of myrrh.

¹ *Psalms* xlv. 9.

² *Ann. of Phil.* vol. x. 1817.

³ *Bijdrag.*

This tree is the *Litsæ Ceylanica* of recent botanists.¹ Mr. Marshall declares² that in Ceylon it is never decorticated, and that the coarse cinnamon (*i. e.* cinnamon procured from thick shoots or large branches of *Cinnamomum zeylanicum*) "has been imported into England, and sold under the denomination of cassia." It has been erroneously inferred from this statement that the cassia lignea of European commerce was merely coarse cinnamon; but if this were the case, it would be somewhat remarkable that cassia lignea is not imported from Ceylon. It is not at all improbable that coarse Ceylon cinnamon may have been sold in the London market as cassia lignea; but this by no means establishes the identity of the two barks. Such an occurrence can now scarcely happen, seeing that all cinnamon (coarse as well as fine) exported from Ceylon pays a duty of 3s. per lb., while the value of cassia lignea in bond is about 6d. per lb.

In the *Pun tsaou* (a Chinese herbal) is a drawing of the Cassia tree. It is represented growing on a hill, and as having a very crooked and knotted stem.

DESCRIPTION.—Two substances are believed to be obtained from this species; namely, the bark called *cassia lignea*, and the flower buds termed *cassia buds*.

1. *Cassia lignea* (*cortex cassiæ*) is regarded on the continent of Europe, and in America,³ as a sort of cinnamon. In English commerce, it is always distinguished. It is imported in chests. It resembles cinnamon in many of its qualities. It is made up in bundles, which are tied with slips of bamboo. It has the same general appearance, smell, and taste as cinnamon; but its substance is thicker, its appearance coarser, its colour darker, browner, and duller; its flavour, though cinnamomic, is much less sweet and fine than that of Ceylon cinnamon, but is more pungent, and is followed by a bitter taste; it is less closely quilled, and breaks shorter, than genuine cinnamon (*see ante*, p. 390). It is imported from Singapore, Calcutta, Bombay, and Manilla.

1. *China cassia lignea* (sometimes called *China cinnamon*) is the best kind. It is usually imported from Singapore, rarely from Canton direct. Mr. Reeves⁴ says vast quantities of both cassia buds and cassia lignea are annually brought to Canton from the province of Kwangse, whose principal city (*Kwei Lin Too*), literally the city of the Forest (or Grove) of Cassia trees, derives its name from the forests of cassia around it.

The Chinese themselves use a much thicker bark (which they call *Gan Kwei Pe*), unfit for the European market. Mr. Reeves informs me that they esteem it so highly as to pay nearly 10 dollars per lb. for it. A very fine quality is occasionally met with, and commands the enormous price of 100 dollars per catty (1½ lb.) A specimen of it, with which he has kindly furnished me, is straight, semi-cylindrical, 11 inches long, rather more than an inch wide, and about one-sixth or one-eighth of an inch thick. Externally it is warted, and covered with crustaceous lichens. Internally, it is deep brown. Its odour and flavour are those of cassia. Mr. Reeves also informs me that the best cassia lignea is cut in the 3d or 4th moon, the second sort in the 6th or 7th moon.

2. *Malabar cassia lignea*.—This is brought from Bombay. It is thicker and coarser than that of China, and is more subject to foul packing; hence each bundle requires separate inspection.⁵ It may, perhaps, be coarse cinnamon; for Dr. White states that the bark of the older branches of the genuine cinnamon plant is exported from the Malabar coast as cassia.

3. *Manilla cassia lignea*.—This, I am informed, is usually sold in bond for continental consumption. I have received a specimen of bark ticketed "Cassia vera from Manilla," the epidermis of which was imperfectly removed.

4. *Mauritius cassia lignea*.—This is occasionally met with.

2. *Cassia buds* (*flores cassiæ immaturæ; clavelli cinnamomi*) are not contained in any of the British Pharmacopœias. They are the produce of China, and are probably procured from the same plant which yields cassia lignea. Mr. Reeves

² *Annals of Philosophy*, vol. x. 1817.

³ In the American pharmacopœia, both cinnamon and cassia lignea are included under the name of cinnamon.

⁴ *Trans. Med. Bot. Society for 1822*, p. 26.

⁵ Milburn's *Orient. Comm.*

tells me that he has always understood and has no doubt that both cassia buds and cassia lignea are obtained from the same trees. The buds are gathered, he informs me, in the 8th or 9th moon. Dr. T. W. C. Martius¹ says "that, according to the latest observations which the elder Nees has made known, cassia buds are the calyces (*Fruchtkelehe*) of *Cinnamomum aromaticum*, about one-fourth of their normal size. It is also said that they are collected from *Cinnamomum dulce* (Nees), which is found in China." Cassia buds bear some resemblance to cloves, but are smaller, or to nails with round heads; they have the odour and flavour of cassia lignea or cinnamon. The exports from Canton in 1831 were 177,866 lbs., and the imports into Great Britain in 1832 were 75,173 lbs.² In 1840, 6,406 lbs. paid duty. Cassia buds have not yet been analyzed; their constituents are similar to those of cassia lignea; they yield a volatile oil by distillation, and contain tannic acid.

COMPOSITION.—*Cassia lignea* was analyzed by Bucholz,³ who obtained the following results: Volatile oil, 0.8; resin, 4.0; gummy (astringent) extractive, 14.6; woody fibre with bassorin, 64.3; water and loss, 16.3 = 100.0.

CHEMICAL CHARACTERISTICS.—Sesquichloride of iron renders decoction of cassia lignea dark green, and causes a precipitate (*tannate of iron*). Gelatine also produces a precipitate (*tannate of gelatine*). If tincture of iodine be added to it, a blue colour (*iodide of starch*) is produced. By this cassia lignea may be distinguished from genuine cinnamon (see *ante*, p. 389).

PHYSIOLOGICAL EFFECTS.—Similar to those of cinnamon. Sundelin⁴ regards it as being more astringent.

USES.—Are the same as those of cinnamon.

ADMINISTRATION.—Dose, grs. x to ʒss.

1. OLEUM CASSIÆ, E.; *Oil of Cassia*; *Oil of Chinese Cinnamon*.—(Obtained from cassia lignea by distillation with water.)—Its properties and composition are similar to those of oil of cinnamon, before described (see *ante*, p. 391). Its odour and flavour, however, are inferior to those of the latter. Its colour is usually pale yellow. Nitric acid converts it into a crystalline mass. Its effects and uses are similar to those of oil of cinnamon. It is employed in the preparation of *Aqua* and *Spiritus Cassiæ*.—Dose, gtt. j to gtt. iv.

2. AQUA CASSIÆ, E.; *Cassia Water*.—(Cassia bark, bruised, ʒxviii; Water *Cong.* ij; Rectified Spirit fʒiiij. Mix them together, and distil off one gallon.)—Used as an aromatic vehicle for other medicines. It is usually prepared from the oil in the same way that cinnamon water is commonly made.

3. SPIRITUS CASSIÆ, E.; *Spirit of Cassia*.—(Cassia, in coarse powder, ℥j; Proof Spirit Ovij. Macerate for two days in a covered vessel, add a pint and a half of water, and distil off seven pints.)—Dose fʒj to fʒiv. It is usually prepared by adding oil of cassia to proof spirit.

4. TINCTURA CASSIÆ, E.; *Tincture of Cassia*.—(Cassia, in moderately fine powder, ʒiiijss; Proof Spirit Oij. Digest for seven days, strain, express the residuum strongly, and filter. This tincture is more conveniently made by the process of percolation, the cassia being allowed to macerate in a little of the spirit for twelve hours before being put into the percolator.)—Dose fʒj to fʒij. Used as an adjuvant to tonic infusions.

142. CAMPHORA OFFICINARUM, *Nees*.—THE CAMPHOR LAUREL.

Laurus Camphora, *Linn.*

Sex. Syst. Enneandria, Monogynia.

(Concretum e ligno sublimatione comparatum, purificatum, *J.*—Camphor, *E. D.*)

HISTORY.—The ancient Greeks and Romans do not appear to have been acquainted with camphor. C. Bauhin and several subsequent writers state that Aëtius speaks of it; but I have been unable to find any notice of it in his writings; and others¹ have been equally unsuccessful in their search for it. Avicenna² and Serapion³ call it *cáfúr*; the latter erroneously cites Dioscorides. Symeon Seth,⁴ who lived in the 11th century, describes it, and calls it *καφουρά* (the name by which it is designated in the *Pharmacopœia Græca*, 1837); and his description is considered, both by Voigtels⁵ and Sprengel⁶, to be the earliest on record.

BOTANY. **Gen. Char.**—*Flowers* hermaphrodite, panicled, naked. *Calyx* 6-cleft, papery, with a deciduous limb. *Fertile stamens* 9, in 3 rows; the inner with 2, stalked, compressed glands at the base; *anthers* 4-celled, the outer turned inwards, the inner outwards. 3 *sterile stamens*, shaped like the last, placed in a whorl alternating with the stamens of the second row; 3 others stalked, with an ovate, glandular head. *Fruit* placed on the obconical base of the calyx. *Leaves* triple-nerved, glandular in the axils of the principal veins. *Leaf-buds* scaly (Lindley).

Sp. Char.—*Leaves* triple-nerved, shining above, glandular in the axils of the veins. *Panicles* axillary and terminal, corymbose, naked.

Flowers smooth on the outside (Nees).

Young *branches* yellow and smooth. *Leaves* evergreen, oval, acuminate, attenuate at the base, bright green and shining above, paler beneath. *Petioles* from 1 to 1½ inches long. *Panicles* axillary and terminal, corymbose. *Flowers* small, yellowish-white. *Berry* round, blackish-red, size of a black currant. *Seed* solitary.

Every part of the tree, but especially the flower, evinces by its smell and taste that it is strongly impregnated with camphor.

Hab.—China, Japan, and Cochin-China. Introduced into Java from Japan.

EXTRACTION AND DESCRIPTION.—Two kinds of *unrefined* or *crude camphor* (*camphora cruda* vel *rudis*) are known in commerce; one is the produce of Japan, the other of China.

1. Japan Camphor.—This is always brought to Europe by the Dutch, and is, therefore, called *Dutch camphor*.

Kæmpfer⁷ and Thunberg⁸ have described the method of extracting this kind of camphor in the provinces of Satzuma, and the islands of Gocho in Japan. The roots and wood of the tree, chopped up, are boiled with water in an iron vessel, to which an earthen head, containing straw, is adapted. The camphor sublimes and condenses on the straw.

Japan or Dutch camphor is brought to Europe by way of Batavia. It is imported in tubs (hence it is called *tub camphor*) covered by matting, and each surrounded by a second tub, secured on the outside by hoops of twisted cane. Each tub contains from 1 cwt. to 1½ cwts. or more. It consists of pinkish grains, which, by their mutual adhesion, form various-sized masses. It differs from the ordinary crude camphor in having larger grains, in being cleaner, and in subliming (usually) at a lower temperature. In consequence of these properties, it generally fetches 10s. per cwt. more. There is not much brought to England, and of that which does come the greater part is re-shipped for the continent.

⁶ *Hist. de la Méd.* t. ii. p. 225.

⁸ *Fl. Japonica.*

2. **China Camphor; Formosa Camphor.**—This is the *ordinary crude camphor*. The method of obtaining crude camphor in China has been described by the Abbé Grosier,¹ Dentrecolles,² and Davis.³ The chopped branches are steeped in water, and afterwards boiled, until the camphor begins to adhere to the stick used in stirring. The liquid is then strained, and, by standing, the camphor concretes. Alternate layers of a dry earth, finely powdered, and of this camphor, are then placed in a copper basin, to which another inverted one is luted, and sublimation effected.

This kind of crude camphor is imported from Singapore, Bombay, &c., in square chests lined with lead-foil, and containing from $1\frac{1}{4}$ to $1\frac{1}{2}$ cwts. It is chiefly produced in the island of Formosa, and is brought by the Chin-Chew junks in very large quantities to Canton, whence foreign markets get supplied.⁴ It consists of dirty grayish grains, which are smaller than those of Dutch camphor. Its quality varies; sometimes it is wet and impure, but occasionally it is as fine as the Dutch kind.

REFINEMENT.—Crude camphor is refined by sublimation. Formerly, this process was carried on only at Venice. Afterwards, it was successfully practised in Holland.⁵ The method at present adopted in this metropolis is, as I am informed, as follows:⁶ The vessels in which this sublimation is effected are called *bomboloes*

(*boimbola*, *Ital.* *βομβυλιός*). They are made of thin flint glass, and weigh about 1 lb. each. Their shape is that of an oblate spheroid, whose shorter or vertical axis is about ten inches, and the longer or horizontal axis about twelve inches. They are furnished with a short neck.⁷ When filled with crude camphor, they are imbedded in the sand-bath, and heated.

To the melted camphor lime is added, and heat raised so as to make the liquid boil. The vapour condenses on the upper part of the vessel. As the sublimation proceeds, the height of the sand around the vessel is diminished. In about forty-eight hours the process is usually completed. The vessels are then removed, and their mouths clothed with tow; water is sprinkled over them by watering-pots, by which they are cracked. When quite cold, the cake of camphor (which weighs about eleven pounds) is removed, and trimmed by paring and scraping. In this process the lime retains the impurities and a portion of the camphor; hence, to extract the latter, the lime is submitted to a strong heat in an iron pot with a head to it, and the sublimed product refined by a second sublimation.

PROPERTIES.—*Refined Camphor* (*camphora raffinata vel elaborata; camphora*, officin.) is met with in the form of large hemispherical or convex-concave cakes, perforated in the middle. It is translucent, has a crystalline granular texture;⁸ a strong, peculiar, not disagreeable, aromatic odour, and an aromatic, bitter, afterwards cooling taste. It is solid at ordinary temperatures, soft, and somewhat tough, but may be readily powdered by the addition of a few drops of rectified spirit. It evaporates in the air at ordinary temperatures; but in closed vessels, exposed to light, sublimes and crystallizes on the sides of the bottle. It burns in the air like the volatile oils generally. It fuses at 347° F., and forms a transparent liquid, which boils at 400° F., and in close vessels condenses unchanged. It is lighter

³ Reeves, *Trans. Med. Bot. Soc.* for 1828, p. 26; Gutzluff and Reed, *China Opened*, vol. ii. p. 84, 1838.

⁴ Ferber (*Journ. de Pharm.* t. i. p. 136, 1815) has described the refining process as practised by the Dutch.

⁵ Dossie, in his *Laboratory laid Open*, 1758, has described the mode of refining camphor.

⁶ Clemandot (*Journ. de Pharm.* t. iii. p. 321, 1817) has described and figured another sort of subliming apparatus. $2\frac{1}{2}$ lbs. of crude camphor, mixed with 6 drachms of powdered quick lime, are placed in a flat-bottomed squat bottle, with a short neck, on a sand-bath: the neck of the bottle fits into a conical tin-plate head, into which the camphor is sublimed.

⁷ A crystal of native camphor in the wood (probably not *laurel camphor*, but *Borneo* or *dryobalanops camphor*) in the collection of *Materia Medica* at the College of Physicians, appears as a flat octohedron, but its primary form is a right rhombic prism (W. Phillips, in *Paris's Pharmacologia*).

⁸ Quoted by Davis.

than water, its sp. gr. being 0.9867; or, according to some, 0.996.¹ Small pieces, when thrown on this liquid, are violently agitated, and present a gyratory motion, which ceases directly a drop of oil is let fall on the water. If a cylinder of camphor, of the $\frac{1}{7}$ th or $\frac{1}{5}$ th of an inch in diameter, be placed vertically in water, it communicates a to-and-fro movement to this liquid, and, in a few days, becomes cut through at the surface of the water. These phenomena are due to the simultaneous evaporation of the camphor and water, and which is most active where the two bodies are in contact.

Camphor is but very slightly soluble in water; 1000 parts of the latter dissolving only one part of camphor at the ordinary pressure of the atmosphere. But under augmented pressure it becomes more soluble.

Alcohol readily dissolves camphor; but if water be added to the solution, the camphor is precipitated. Ether, bisulphuret of carbon, the oils (both fixed and volatile), and the acids, also dissolve it. The liquid obtained by dissolving camphor in nitric acid is sometimes termed *camphor oil*: it is a *nitrate of camphor*, and is decomposed by water, the camphor being precipitated. The camphor absorbs sulphurous and hydrochloric acid gases, with which it unites and forms respectively a *sulphite* and a *hydrochlorate of camphor*. Camphor is insoluble in alkaline solutions. The vapour of camphor passed over red-hot lime is converted into naphthaline, and an oily liquid called *camphrone*.

COMPOSITION.—Camphor has the following composition:—

	Atoms.	Eq. Wt.	Per cent.	Dumas.	Blanchet and Sell.
Carbon	20	120	78.91	78.02	77.96
Hydrogen	16	16	10.53	10.39	10.61
Oxygen	2	16	10.53	11.59	11.43
Camphor	1	152	100.00	100.00	100.00

Dumas has suggested that camphor may be regarded as an oxide of a base (as yet hypothetical) which he calls *camphogen*, and whose composition is $C^{10}H^8$.

CHEMICAL CHARACTERISTICS.—In its combustibility, volatility, powerful odour, solubility in alcohol and ether, and almost insolubility in water, camphor agrees with the volatile oils. Being concrete or solid at ordinary temperatures, it obviously belongs to the class of *stearoptenes*, or *solid volatile oils*.

It is further distinguished by the remarkable character of its odour, by its not blackening in burning, and by its not being converted into resin by the oxygen of the air or by nitric acid. By repeatedly distilling nitric acid from camphor, the latter is converted into *camphoric acid* ($C^{20}H^{14}O^6, 2HO$). Before the whole of the camphor has been converted into camphoric acid, there are produced intermediate compounds of camphor and this acid, which we may regard as camphorates of camphor.

The camphor which we have now described may be designated *common* or *laurel camphor*, in order to distinguish it from *Borneo camphor*, or *camphor of the Dryobalanops*, as well as from *artificial camphor* (see *ante*, p. 294).

Common or laurel camphor absorbs hydrochloric acid gas, and forms a transparent, colourless liquid; Borneo camphor, on the contrary, is scarcely acted on by this acid gas. If Borneo camphor be boiled in nitric acid, it is converted into common camphor.

Artificial camphor (see *ante*, p. 294) usually evolves some hydrochloric acid when volatilized, and burns in the air with a greenish sooty flame: if the flame be blown out, the evolved vapour has a terebinthinate odour. By these characters, artificial camphor may be distinguished from laurel camphor.

OIL OF LAUREL CAMPHOR.—Pelouze and Fremy state that when the branches of *Camphora officinarum* are distilled with water, a mixture of camphor and a liquid essential oil is obtained, which is called *oil of camphor*.—This oil has a density of 0.910: its composition is $C^{24}H^{16}O$.

¹ The density of camphor varies considerably, according to the temperature. At 33°, it is said to be denser than water (*Pharmaceutical Journal*, vol. v. p. 473, 1846).

By exposure to oxygen gas, or to the action of nitric acid, it absorbs oxygen and becomes solid camphor, $C^{20}H^{16}O^2$. It is probable, therefore, that its formation precedes that of solid camphor in the camphor tree. I have met with this oil in commerce under the name of *oil of camphor*. By keeping, it deposits crystals of camphor, and, from this circumstance, may be distinguished from the *oil of Dorneo camphor* (see *Dryobalanops*). By the action of hydrochloric acid, I find that these crystals liquefy, like common or laurel camphor. A considerable quantity of the oil was purchased some years ago by a London manufacturer of scented soap, who submitted it to distillation, and obtained from 60 lbs. of it, 40 lbs. of colourless liquid oil, and 20 lbs. of crystalline camphor. The oil has been described and analyzed by Dr. Th. Martins.¹

PHYSIOLOGICAL EFFECTS. *a. On Vegetables*—Gœppert² has satisfactorily shown—first, that solutions of camphor act in the same deleterious manner on plants as the volatile oils; secondly, that they destroy the mobility of contractile parts without previously exciting them; thirdly, that they have no influence either on the germination of phanerogamia, or the vegetation of the cellular cryptogamia; and fourthly, that the vapour only is sufficient to destroy fleshy plants and ferns. Miquet³ has confirmed these results.

β. On Animals generally.—The action of camphor on animals has been the subject of numerous experiments made by Hillefield,⁴ Monro,⁵ Menghini and Carminati,⁶ Viborg, Hertwich,⁷ Orfila,⁸ and Seudery.⁹

Air impregnated with the vapour of camphor proves injurious to *insects* (the *Tinæ*, which destroy wool, excepted). Sooner or later it causes frequent agitation, followed by languor, insensibility, convulsions, and death (Menghini). To *amphibials* (frogs) the vapour also proves noxious. It produces preternatural movements, difficult respiration, trembling, and stupor (Carminati). Given to *birds* and *mammals*, in sufficient doses, camphor proves poisonous; but the symptoms which it gives rise to do not appear to be uniform. Indeed, there are few remedies whose action on the animal economy is so variable as that of camphor. Three drachms dissolved in oil and given to a dog, the œsophagus being tied, caused violent convulsions, somewhat analogous to those of epilepsy, followed by insensibility and death (Orfila). When administered in substance, it inflamed the digestive tube, caused ulceration, and, after its absorption, gave rise to convulsions (*Ibid.*). Given to horses, in doses of two drachms, it excites spasmodic movements, and quickens the pulse, but does not determine any serious result.¹⁰ Tiedemann and Gmelin¹¹ detected the odour of camphor in the blood of the vena portæ and of the mesenteric vein of a horse to whom they had given camphor; but they could recognize it neither in the chyle nor in the urine. It is evolved from the system principally by the bronchial surfaces; for the breath of animals to which this substance has been administered has a strong odour of camphor. Moiroud¹² observed that the skin of a horse, into whose jugular vein camphor had been injected, smelt of this substance.

“The general sedative effects of camphor on animals are rarely well marked; however, when administered in a proper dose, and in cases really requiring its use, it sometimes causes a diminution in the force and frequency of the pulse, and seems to allay pain” (Moiroud).

Seudery¹³ observed that the convulsions caused in animals by camphor were accompanied with a peculiar kind of delirium, which caused them to run up and down without apparent cause. He also found the urinary organs generally affected, and for the most part with strangury.

γ. On Man.—No article of the materia medica has had more contradictory state-

¹³ Quoted by Dr. Christison.

ments made respecting its effects and mode of action than camphor. These, however, have principally referred to its influence over the functions of circulation and calorification; for, with regard to the modifications which it induces in the other functions, scarcely any difference of opinion prevails.

Its local action on the mucous surfaces, the denuded dermis, and ulcers, is that of an *acrid*. A piece of camphor held in the mouth for half an hour caused the mucous lining of this cavity to become red, hot, swollen, and painful; and it is highly probable that, had the experiment been persevered in, ulceration would have followed.¹ The pain and uneasiness which camphor, when swallowed in substance, sometimes produces in the stomach, are likewise imputed to its local action as an *acrid*. Rubbed on the skin covered with cuticle, Dr. Cullen says that it causes neither redness nor other mark of inflammation;² but Dr. Clutterbuck³ declares this to be "undoubtedly a mistake." When applied to the denuded dermis, or to ulcers, it produces pain, and appears to act as an irritant. These observations respecting the local action of camphor on man are confirmed by the ascertained effects of this substance on other animals.

Camphor has been charged with producing brittleness of the teeth when it has been used for a considerable time as a dentifrice,⁴ but I believe without any valid foundation.

Camphor becomes absorbed, and is thrown out of the system by the bronchial membrane principally, but also by the skin. Trousseau and Pidoux⁵ recognized its odour in every case in the pulmonary exhalation, but failed to detect it in the cutaneous perspiration. Cullen, however, says⁶ that "Mr. Lasonne, the father, has observed, as I have done frequently, that camphor, though given very largely, never discovers its smell in the urine, whilst it frequently does in the perspiration and sweat." The non-detection of it in the urine agrees with the observation of Tiedemann and Gmelin with regard to horses, already noticed.

Camphor specifically affects the nervous system.—Regarding the symptoms of this effect, but little difference of opinion prevails. In moderate doses, it exhilarates and acts as an anodyne.⁷ Its exhilarating effects are well seen in nervous and hypochondriacal cases (see vol. i. p. 237). In large doses, it causes disorder of the mental faculties, the external senses, and volition; the symptoms being lassitude, giddiness, confusion of ideas and disordered vision, noise in the ears, drowsiness, delirium or stupor, and convulsions. These phenomena, which have been observed in several cases, agree with those noticed in experiments on brutes. In its power of causing stupor, camphor agrees with opium; but it differs from the latter in its more frequently causing delirium and convulsions. Epilepsy has been ascribed to the use of camphor.

The quality of the influence which camphor exercises over the vascular system has been a subject of much contention. From my own limited observations of its use in *small or medium doses* (from five to ten grains), I am disposed to regard its leading effect as that of a vascular excitant, though I am not prepared to deny that slight depression may not have preceded this effect. Combined with diaphoretic regimen (warm clothing and tepid diluents), I have seen camphor increase the fullness of the pulse, raise the temperature of the surface, and operate as a sudorific. If opium be conjoined, these effects are more manifest.⁸

In *excessive doses*, it acts as a powerful poison. The best related case is that of Mr. Alexander,⁹ who swallowed two scruples in syrup of roses. In about twenty minutes, he experienced lassitude and depression of spirits, with frequent yawnings:

⁸ See p. 427. for some remarks on the comparative operation of ammonia and camphor.

⁹ *Experimental Essays*, p. 128, 1768.

at the end of three-quarters of an hour his pulse had fallen from 77 to 67. Soon after he felt giddy, confused, and almost incapable of walking across the room. He became gradually insensible, and in this condition was attacked with violent convulsions and maniacal delirium. From this state he awoke as from a profound sleep; his pulse was 100, and he was able to reply to interrogatories, though he had not completely recovered his recollection. Warm water being administered, he vomited up the greater part of the camphor, which had been swallowed three hours previously; and from this time he gradually recovered.

In another case,¹ a man swallowed four ounces of camphorated spirits containing 160 grains of camphor. The symptoms were burning heat of skin, frequent, full, and hard pulse, brilliancy of the eyes, redness of the face, heaviness of the head, anxiety, agitation, violent sense of heat in the stomach; then intense headache, giddiness, indistinctness of sight, and ocular hallucinations. The patient complained of heat only, which he said was intolerable. In the night, copious sweating came on, followed by sleep. The pulse continued full and frequent, and the voiding of urine difficult.

In some other well-reported cases, camphor, in large doses, caused depression of the vascular system. In the instance related by Fred. Hoffmann,² Pouteau,³ Griffin,⁴ Cullen,⁵ Callisen,⁶ Edwards,⁷ and Trousseau and Pidoux,⁸ sedation of the vascular system was observed. It was manifested by a languid, small, and slower pulse, coldness of the surface, and pallid countenance; in some cases with cold sweat. In some of these instances, symptoms of vascular excitement followed those of depression. The pulse became more frequent and fuller than natural, and the heat of the surface augmented. Trousseau and Pidoux⁹ ascribe the symptoms of sedation to the depressing influence which camphor exerts over the system by sympathy; while the sanguineous excitation they refer to the passage of camphor into the blood, and the efforts of the organism to eliminate this unassimilable principle. But in some of the cases in which excessive doses of camphor have been taken, no symptoms of depression were manifested; as in the instance mentioned by Dr. Eickhorn (in whom great heat, rapid but small pulse, copious sweating, and agreeable exhilaration, were produced by 120 grains),¹⁰ by Dr. Wendt,¹¹ by Scudery,¹² and by Bergondi.¹³

Camphor has long been celebrated as an anaphrodisiac; the smell of it even is said to be attended with this effect; hence the verse of the School of Salerno—*“Camphora per nares castrat odore naves.”* Trousseau and Pidoux¹⁴ experienced the anaphrodisiac property of 36 grains of camphor taken into the stomach.

Strangury has also been ascribed to this substance by Heberden,¹⁵ by Scudery,¹⁶ and others.

USES.—The discrepancy among authors as to the physiological effects of camphor has had the effect of greatly circumscribing the use of this substance. Indeed, until its operation on the system be more satisfactorily ascertained, it is almost impossible to lay down general rules which should govern its exhibition. The following are the principal maladies in which it has been found useful:—

1. *Fever*.—Camphor has been employed in those forms of fever which are of a typhoid type. It is chiefly valuable by causing determination to the surface, and giving rise to diaphoresis. Hence those remedies should be conjoined with it which promote these effects: such are ipecacuanha, emetic tartar, and the vegetable alkaline salts. Opium greatly contributes to the sudorific effects of camphor; and, when it is admissible, benefit is sometimes obtained by the administration of one

¹⁶ *Comment. art. Stranguria.*

grain of opium with five or eight of camphor. But in a great number of cases of fever, the cerebral disorder forbids the use of opium. From its specific influence over the cerebral functions, camphor has been frequently used in fever to allay the nervous symptoms—such as the delirium, the watchings, the subsultus tendinum, &c.; but it frequently fails to give relief. Dr. Home¹ did not find any advantage from its use in the low nervous fever; and Dr. Heberden² has seen one scruple of camphor given every six hours, without any perceptible effect in abating the convulsive catchings, or composing the patient to rest.

2. *In inflammatory diseases.*—In the latter stages of inflammation of internal important parts (as the serous and mucous membranes, the stomach, intestines, uterus, &c.), after proper evacuations had been made in the earlier periods of the disease, when great exhaustion is manifested by a small feeble pulse and a cold flaccid skin, small but repeated doses of camphor have been employed to determine to the skin, and to promote diaphoresis. It is particularly serviceable in rheumatic inflammation, and especially when produced by metastasis.³

3. *In the exanthemata.*—Camphor has been employed in smallpox, as also in measles, scarlatina, and miliary fever: but it is admissible only when the circulation flags, and the temperature of the surface falls below the natural standard. In such cases it is sometimes employed along with a diaphoretic regimen to determine to the skin. It is to be carefully avoided when inflammation of the brain or its membranes is feared. It has been asserted that if a camphorated ointment be applied to the face, no smallpox pustules will make their appearance there; but the statement is not correct.

4. *In mania, melancholia, and other forms of mental disorder.*—Camphor is occasionally taken to cause exhilaration. I am acquainted with two persons (females), both of nervous temperament, who use it for this purpose. To relieve despondency I have often found it serviceable. In mania and melancholia, it has now and then proved serviceable by its narcotic effects: it induces mental quiet, and causes sleep. It was used in these affections by Paracelsus and several succeeding writers,⁴ especially, in more modern times, by Dr. Kinnear;⁵ and by Avenbrugger.⁶ The latter regards it as a specific in the mania of men, when accompanied with a small contracted penis, corrugated empty scrotum, or when both testicles are so retracted that they appear to be introduced into the abdominal cavity.

5. *In spasmodic affections.*—The narcotic influence of camphor has occasionally proved serviceable in some spasmodic or convulsive affections; viz., spasmodic cough, epilepsy, puerperal convulsions, hysteria, and even tetanus: its use, however, requires caution.

6. *In irritation of the urinary or sexual organs.*—A power of diminishing irritation of the urinary organs has long been assigned to camphor. In strangury and dysury, especially when produced by cantharides, it is said to have been used with benefit—a statement apparently inconsistent with that more recently made of its producing irritation of the urinary organs. In satyriasis, nymphomania, and onanism, it is said to have proved advantageous by its anaphrodisiac properties. In dysmenorrhœa, it sometimes proves serviceable as an anodyne.

7. *In poisoning.*—Small doses of camphor (administered by the mouth or by the rectum) have been exhibited with apparent benefit in cases of poisoning by opium.⁷ It has also been employed to mitigate the effects of cantharides, squills, and mezereon;⁸ but toxicologists, for the most part, do not admit its efficacy: at any rate, further evidence is required to establish it. Nor does there appear any valid testimony for believing that camphor possesses the power of checking mercurial salivation, as some have supposed.

8. *In chronic rheumatism and gout.*—A mixture of camphor and opium, in the

⁸ Orfila, *Toxicol. Gén.*

proportions before mentioned, is useful in chronic rheumatism, by its sudorific and anodyne properties. Warm clothing and diluents should be conjoined. In chronic gout, also, camphor is said to have proved beneficial.

9. *In cholera*.—The combination of camphor and opium above referred to, I have seen used with benefit in cholera.

10. *Externally*, camphor is employed in the form of vapour, in solution, or, more rarely, in the solid state. The *vapour* is occasionally inhaled in spasmodic cough; and is applied to the skin to alleviate pain and promote sweat, constituting the *camphor fumigations* (*fumigationes camphoræ*). Dupasquier¹ recommended these fumigations in chronic rheumatism. The patient may be in bed or seated in a chair; and, in either case, is to be enveloped by a blanket tied round the neck. About half an ounce of camphor is then to be placed on a metallic plate, and introduced within the blanket (under the chair, if the patient be seated). In *solution*, camphor is used either as an anodyne or a local stimulant. The nitric solution of camphor is used to relieve toothache. A solution of camphor in oil has been used as an injection into the urethra, to relieve ardor urinæ in gonorrhœa, and into the rectum to mitigate tenesmus arising from ascariæ or dysentery. The acetic and alcoholic solutions of camphor are mostly employed as stimulants. In *substance*, camphor is not frequently used. A scruple or half a drachm “added to a poultice, and applied to the perineum, allays the chordee, which is a painful attendant upon gonorrhœa.”² Powdered camphor is a constituent of some tooth-powders, to which it communicates its peculiar odour.

The foregoing are some only of the maladies in which camphor has been extensively used and lauded. I must refer to the works of Murray³ for various other uses which have been made of this substance. It is scarcely necessary to add that camphor-bags possess no prophylactic properties against contagion.

ADMINISTRATION.—The medium dose of it is from five to ten grains; but it is frequently exhibited in much smaller doses (as one grain); and occasionally a scruple has been employed. It is given in the form of a pill or emulsion. That of *pill* is said to be objectionable, “as in this state the camphor is with difficulty dissolved in the gastric liquors, and, floating on the top, is apt to excite nausea, or pain or uneasiness at the upper orifice of the stomach.”⁴ It has been charged with causing ulceration of the stomach when given in the solid form. The *emulsion* is made by rubbing up the camphor with loaf sugar, gum Arabic, and water; and the suspension will be rendered more complete by the addition of a little myrrh.⁵

ANTIDOTE.—In a case of poisoning by camphor, first evacuate the contents of the stomach. Hufeland⁶ recommends the use of opium to relieve the effects of camphor. Phœbus⁷ directs chlorine water to be administered as the antidote, and afterwards purgatives and clysters. Vinegar and coffee, he states, promote the poisonous operation. Wine assists the patient’s recovery.

I. MISTURA CAMPHORÆ, L. E. D.; *Aqua Camphoræ* [U. S.]; *Camphor Mixture*; *Camphor Water*.—(Camphor ℥ss; Rectified Spirit ℥x; Distilled Water Oj. ⁵ *United States Dispensatory.*

⁶ *United States Dispensatory.*

⁷ Marx, *Die Lehre von d. Gift.* Bd. ii. S. 202.

are light, odorous, not fibrous, but spongy or corky. The epidermis is brownish-gray: the cortical layers and inner surface reddish cinnamon brown, or almost rust-red, becoming darker by age. Sometimes small, white, micaceous crystals (like those found on *sassafras nuts*) are observed on the inner surface of the bark. *Sassafras wood* (*lignum radice sassafras vel lignum sassafras*) occurs in the form of large stems or branches, frequently more or less covered with the bark. The wood is soft or spongy, light, of a grayish-reddish tint, and has a fragrant aromatic odour. It is usually sold cut up into chips: *sassafras chips*.

BRAZILIAN SASSAFRAS; Pão Sassafras.—This is the produce of *Nectandra cymbarum* of Nees, the *Ocotea amara* of Martius. It grows in Rio Negro. Its bark is bitter and aromatic, and is used as a tonic and carminative.

SASSAFRAS NUTS; Pichurim Beans; Fabæ Pichurim.—These seeds (or rather cotyledons) are the produce of *Nectandra Puchury major* of Nees, and *Nect. Puchury minor* of Nees, trees growing in the province of Rio Negro. "They were imported from Brazil into Stockholm in the middle of the last century, and were found a valuable tonic and astringent medicine during the continental war they were used as a bad substitute for nutmegs." They are still to be found in some of the old drug-houses of London. By keeping in a bottle, small micaceous crystals form on their surface. These seeds have been analyzed by Bonastre.¹ Their aromatic qualities depend on a volatile oil.

COMPOSITION.—Neither the bark nor the wood have been analyzed. They contain *volatile oil*, *resin*, and *extractive matter*.

PHYSIOLOGICAL EFFECTS.—The wood and the bark are stimulant and sudorific. Taken in the form of infusion, and assisted by warm clothing and tepid drinks, they excite the vascular system and prove sudorific. They owe their activity to the volatile oil, which possesses acrid properties.

USES.—Sassafras is employed as a sudorific and alterative in cutaneous, rheumatic, and venereal diseases. On account of its stimulant properties it is inadmissible in febrile or inflammatory conditions of the system. It is rarely or never used alone, but generally in combination with sarsaparilla and guaiacum.

ADMINISTRATION.—Sassafras is administered in the form of *oil* or *infusion*. The dose of the oil is from two to ten drops. *Sassafras tea*, flavoured with milk and sugar, is sold at daybreak in the streets of London, under the name of *saloop*. Sassafras is a constituent of the *Decoctum Sarzæ Compositum*; but the volatile oil is dissipated by boiling (see *ante*, p. 279).

OLEUM SASSAFRAS, [U. S.]; Volatile Oil of Sassafras officinale, E.; Oil of Sassafras.—(Obtained by submitting the wood to distillation with water.)—It is colourless, but, by keeping, becomes yellow or red. Its smell is that of sassafras; its taste hot. Sp. gr. 1.094. Water separates it into two oils; one lighter, the other heavier than water. By keeping, it deposits large crystals (stéaroptène; *sassafröl*, C¹⁰H⁵O²), which are readily soluble. Oil of sassafras is rendered orange-red by nitric acid. It is said to be adulterated with oil of lavender or oil of turpentine;² but the statement, I suspect, does not apply to the oil found in English commerce. Oil of sassafras is stimulant and diaphoretic. It may be employed in chronic rheumatism, cutaneous diseases, and venereal maladies. It is a constituent of the *Compound Extract of Sarsaparilla* (see *ante*, p. 281).

144. LAURUS NOBILIS, Linn.—THE SWEET BAY.

Sez. Syst. Enneandria, Monogynia.

(Fructus, L.)

HISTORY.—The "green bay-tree" is mentioned, though erroneously in our translation of the Bible;³ the Hebrew word, translated *bay*, meaning *native*.⁴ Hippocrates⁵ used both the leaves and berries of the bay-tree (ἐύφρη) in medicine. Bay-leaf is analogous to the *malabathrum* of the ancients.⁶

¹ *Journ. de Pharm* vol. xi. p. 1, 1825.

² *Psalms*, xxvii. 35. 36

³ *Opera*, pp. 267, 623, 621, &c. ed. Fœs.

⁴ Bonastre. *Journ. de Pharm.* vol. xiv. p. 645, 1829.

⁵ Carpenter's *Script. Nat. Hist.*

⁶ Royle, *Hindoo Med.* p. 32 and 85.

BOTANY. Gen. Char.—*Flowers* diœcious or hermaphrodite, involuerated. *Calyx* 4-parted; segments equal, deciduous. *Fertile stamens* 12, in 3 rows; the outer alternate with the segments of the calyx; all with 2 glands in the middle or above it. *Anthers oblong*, 2-celled, all looking inwards. *Female flowers*, with 2 to 4 castrated males, surrounding the ovary. *Stigma* capitate. *Fruit* succulent, seated in the irregular base of the calyx.—*Umbels* axillary stalked. *Leaf-buds* with valvate papery scales. *Leaves* evergreen (Lindley).

Sp. Char.—The only species.

A bush or small tree. *Bark* aromatic, rather bitter. *Leaves* alternate, lanceolate, acute, or acuminate, wavy at the edge, somewhat coriaceous. *Flowers* yellowish. *Fruit* (called by Nees a 1-seeded flesh berry, by De Candolle, a drupe) bluish-black, oval, size of a small cherry. *Seed* pendulous; *funiculus* compressed, ascending from the base of the fruit, and attached at the top of the testa; *testa* papery; *tunica interna* very thin; *embryo* exalbuminous, composed of two large oleaginous *cotyledons* inclosing superiorly the *radicle*.

Hab.—South of Europe. Cultivated in gardens.

DESCRIPTION.—Bay leaves (*folia lauri*) have a bitter aromatic taste, and a somewhat aromatic odour. Their infusion reddens litmus. Dried bay berries (*baccæ lauri*, offic.) are covered externally by a dark-brown brittle coat, which is produced by the epidermis and succulent covering of the fruit.

COMPOSITION.—In 1824, bay berries were analyzed by Bonastre,¹ who found the constituents to be—*Volatile oil* 0.8, *laurin* 1.0, *fixed oil* 12.8, *wax* (stearin) 7.1, *resin* 1.6, *un-crystallizable sugar* 0.4, *gummy extractive* 17.2, *bassorin* 6.4, *starch* 25.9, *woody fibre* 18.8, *soluble albumen* traces, *an acid* 0.1, *water* 6.4, *salts* 1.5.—The ashes (amounting to 1.2) consisted of carbonate of potash and the carbonate and phosphate of lime.

1. **VOLATILE OIL OF LAUREL BERRIES; Oil of Sweet Bay.**—Obtained from the berries by distillation with water. The crude oil is pale yellow, transparent, readily soluble in alcohol and ether. By redistillation it yields two isomeric oils ($C^{20}H^{16}O$); one having a sp. gr. of 0.857, the other 0.885, while a brown balsamic matter remains in the retort.²

2. **LAURIN; Camphor of the Bay berry.**—A crystalline solid, fusible and volatile. Has an acrid bitter taste, and an odour analogous to that of the volatile oil. It is soluble in ether and in boiling alcohol. Sulphuric acid renders it yellow; nitric acid liquefies it. Alkalies are without action on it. It is extracted from bay berries by rectified alcohol.

3. **FIXED OIL OF BAYS** (see below).

PHYSIOLOGICAL EFFECTS.—The berries, leaves, and oil are said to possess aromatic, stimulant, and narcotic properties. The leaves, in large doses, prove emetic.³

USES.—Bay berries or leaves are rarely, if ever, used in medicine in this country. They might, therefore, with great propriety be expunged from the Pharmacopœia. The leaves are employed by the cook on account of their flavour. Both leaves and berries have been used to strengthen the stomach, to expel flatus, and to promote the catamenial discharge.

ADMINISTRATION.—Both berries and leaves are used in the form of infusion.

OLEUM LAURI; Oleum Lauri expressum; Oleum Laurinum; Laurel Fat; Oil of Bays.—This may be obtained from either the fresh or dried berries. Duhamel⁴ states that it is obtained from the fresh and ripe berries by bruising them in a mortar, boiling them for three hours in water, and then pressing them in a sack. The expressed oil is mixed with the decoction, on which, when cold, the butyraceous oil is found floating. From the dried berries it is procured by exposing them to the vapour of water until they are thoroughly soaked, and then rapidly subjecting them to the press between heated metallic plates. By the latter method they yield one-fifth of their weight of oil.⁵ Oil of bays is imported in barrels from Trieste.

¹ Journ. de Pharm. x. 30.

² Brandes, Pharmaceutisches Central-Blatt für 1840, S. 314.

³ Mérimé and De Lens, Dict. Univ. de Mat. Méd. t. iv. p. 62.

⁴ Traité des Arbres et Arbustes qui se cultivent en France en pleine Terre, t. i. p. 351.

⁵ Soubeiran, Nouveau Traité de Pharmacie, t. ii. p. 32, 2de éd.

In 1839, duty was paid on 1737 lbs. of it. It has a butyraceous consistence and a granular appearance. Its colour is greenish; its odour is that of the berries. It is partially soluble in alcohol, completely so in ether. With alkalies it forms soaps. It is occasionally employed externally as a stimulating liniment in sprains and bruises, and in paralysis. It has also been used to relieve colic, and against deafness.¹ Its principal use, however, is in veterinary medicine.

OLEUM LAURI ÆTHEREUM NATIVUM; *Native Oil of Laurel*, Hancock, Trans. of the Medico-Bot. Society of Lond., p. 18, 1826; *Laurel Turpentine*, Stenhouse, Mem. of the Chemical Society, vol. i. p. 45, 1843.—Imported from Demerara: obtained by incision in the bark of a large tree, called by the Spaniards "*Azeyte de Sassafras*," growing in the vast forests between the Orinoco and the Parime. By Dr. Hancock this tree was thought to belong to the nat. ord. Lauraceæ; but Dr. Stenhouse thinks that it is a species of pine. The oil is transparent, slightly yellow, and smells like turpentine, but more agreeable, and approaching to the oil of lemons. Its sp. gr. at 56° F. is 0.8645. The commercial oil consists of two or more oils isomeric with each other and with oil of turpentine, C²⁰H¹⁶. Its yellow colour is due to a little resin. A volatile acid (formic acid?) is also present in very small quantity. In its medicinal qualities it resembles turpentine; being stimulant, diuretic, and diaphoretic. It has been used externally as a discutient in rheumatism, swellings of the joints, cold tumours, paralytic disorders, &c. It is an excellent solvent for caoutchouc.

145. NECTANDRA RODIÆI, Schomburgk.—THE BIBIRU OR GREENHEART TREE.

Sex. Syst. Dodecandria, Monogynia.
(Cortex.)

HISTORY.—In 1769, Baneroft² noticed the valuable qualities of the wood of this tree, which he called the *Greenheart* or *Sipeira*. In 1834, Dr. Roder³ discovered that the bark was a good substitute for eichhona, and that both it and the fruit contained an alkaloid, which he used with great success in intermittents: he terms the tree the *Bebeeru*, and the alkaloid *Bebeerine*. In 1843,⁴ Dr. Douglas MacLagan published an account of the chemical and therapeutical properties of the bark, and confirmed the discoveries of Dr. Roder. The following year a full botanical description of the tree, which he terms *Bibiru*, or *Sipiri*, was drawn up by Sir Robert Schomburgk, aided by Mr. Bentham.⁵

BOTANY. Gen. Char.—*Flowers* hermaphrodite. *Calyx* 6-parted, rotate; segments deciduous, the 3 outer rather the broadest. *Stamens* 12, in 4 series; the 9 outer fertile, the 3 inner sterile; glands in pairs, globose, sessile, at the base of the 3 inner fertile stamens; the anthers in the first and second series turned inwards, those of the third series turned outwards, all ovate, nearly sessile with 4 cells arranged in a curve, and distinct from the tip of the anther, with as many ascending dehiscent valves; sterile stamens either tooth-shaped and biglandular at the base, or glandless, and then with a small ovule head. *Ovary* 1-celled, with 1 ovule in each cell. *Style* very short; *stigma* short and truncate. *Berry* 1-seeded, more or less immersed in the tube of the calyx changed into a truncated cup.—*Trees* of tropical America, with alternate, feather-veined leaves, and panicles or corymbose, axillary, lax, ample flowers (Endlicher).

Sp. Char.—*Leaves* nearly opposite, oblong-elliptical, shortly acuminate, coriaceous, smooth, shining, and obscurely netted on the upper side; *panicles* few-flowered,

⁵ Hooker's *London Journal of Botany*, December, 1844, p. 624.

axillary, much shorter than the leaves, finely downy; *anthers* all thick oblong, without glands (Bentham).

A large forest tree, of 60 or more feet high, with a trunk frequently above 50 feet high, undivided by branches till near the top, and covered by an ash-gray smooth bark. *Leaves* 5 or 6 inches long, and 2 or 3 inches broad. *Flowers* yellowish-white. *Berry* somewhat obovate, globular, slightly compressed, the longer extension $7\frac{1}{2}$ inches in circumference, the less about $6\frac{1}{4}$ inches: the pericarp grayish-brown, speckled with whitish dots, hard, very brittle, and about a line thick. *Seed* 1 in each fruit, about the size and shape of a walnut, and containing 2 large plano-convex cotyledons.

Hab—British Guiana: on rocky hill-sides on the borders of rivers (the Esse-
quibo, Cuyuni, Demerara, Pomeroon, Berbice, &c.).—The timber is used for ship-
building, under the name of *Greenheart*.

DESCRIPTION.—*Bibiru* or *beeberu bark* (*cortex bibiru*), is derived from the trunk. It consists of large, flat, heavy pieces, from 1 to 2 feet long, from 2 to 6 inches broad, and about 3 or 4 lines thick. It is covered externally with a brittle grayish-brown epidermis. Internally, its colour is dark cinnamon-brown. The fracture is rough and somewhat fibrous. The taste is strong, persistent, bitter, with considerable astringency, but with aroma, pungency, or acridity.

The *fruit* (*fructus bibiru*) commonly called a nut, has been described above. The seeds (*semina bibiru*) yield starch, which is used as food by the Indians. A section of the cotyledons, when moist and fresh, was pale yellow, and became brown by exposure to the air. The juice had an acid reaction, and was intensely bitter.

COMPOSITION.—The bark and seeds have been analyzed by Dr. MacLagan, and his results are as follows:—

	<i>Bark.</i>	<i>Seeds</i> (much dried by keeping).
Alkalies [bibirina and sipirina] (not quite pure) . . .	2.56	2.20
Tannin and resinous matter	2.53	4.04
Soluble matter (gum, sugar, and salts)	4.34	9.40
Starch	—	53.51
Fibre and vegetable albumen	62.92	11.24
Ashes (chiefly calcareous)	7.13	0.31
Water	14.07	18.13
Loss	6.45	1.17
Total	100.00	100.00

1. **BIBIRINA**; *Beeberina*; *Biberine*; *Bebeerine*, $C^{35}H^{20}NO^6$.—Obtained by decomposing commercial sulphate of bibirina by ammonia; the precipitate is washed with cold water, triturated while still moist with moist hydrated oxide of lead, and the magma dried on a water-bath, and exhausted by rectified spirit. In this way is obtained an alcoholic solution of bibirina and sipirina, while the oxide of lead, tannin, and other impurities are left behind. The alcohol is to be distilled off, and the resinous-looking residue treated with pure ether, which dissolves the bibirina, but leaves behind the sipirina.

Bibirina is uncrystallizable. When obtained by evaporation from its ethereal solution, it is a yellow, amorphous, resinous-looking substance; but in the form of powder it is white. It is very soluble in alcohol, less so in ether, and very sparingly in water. Its alcoholic solution reacts as an alkali on reddened litmus paper. It dissolves in acids, and neutralizes them, forming amorphous yellow salts. Colourless or crystallized salts have not yet been procured. According to MacLagan and Tilley,¹ its composition is identical with morphia. Winckler² says, that bibirina resembles in many respects paracine, but differs from the latter in the circumstance of its hydrate being gelatinous.

2. **SPIRINA**; *Siperina*; *Sipirine*; *Sipeerine*.—This substance, which Dr. MacLagan at first thought to be a second alkaloid, he now regards as a product of the oxidation of biberine.

3. **BIBIRIC ACID**; *Bebeeric Acid*.—A white, crystalline, deliquescent, volatile acid obtained from the seeds.

4. **STARCH**.—I am indebted to Dr. MacLagan for some of the starch obtained from the seeds of this plant. It is grayish-white, and almost tasteless. When examined by the microscope, it is found to consist of particles which are somewhat smaller than those of cassava starch, but in their external form quite agree with the latter. Schomburgk states that the Indians are

¹ *Pharmaceutical Journal*, vol. v. p. 228, 1845.

² *Ibid.* vol. vi. p. 493, 1847; also, *Buchner's Repert.* 2ter Reihe, Bd. xlvi. p. 231, 1846.

obliged to live for months on it. It is prepared by grating the seeds and immersing them in water. Repeated washing he found did not deprive the starch of its bitterness. The starch mixed with decayed wood, chiefly of the Walaba tree (*Eperna falcata*), is baked into cakes. Winckler has discovered starch in the bark as well as in the seeds.

5. **TANNIN.**—This agrees very much with that found in the cinchona bark; and, like the latter, it yields a green colour with the salts of iron.

PHYSIOLOGICAL EFFECTS.—Bibiru bark appears to possess the tonic, antiperiodic, febrifuge, and astringent properties of cinchona barks. Like the latter, its bitter, tonic, and antiperiodic powers reside in a vegetable alkaloid; and its astringent property in that kind of tannic acid which strikes a green colour with the salts of iron.

Sufficient experience has not yet been obtained with bibiru bark and its alkaloid (*bibirine*), to enable us to form an accurate opinion of their therapeutical power in comparison with cinchona bark and quinia. In some cases, *bibirina* has appeared to produce its peptic and tonic effects with less tendency to cause headache, giddiness, ringing in the ears, and feverishness, than quinia; and it can in consequence be administered to some patients with whom quinia disagrees. On the other hand, it appears inferior to the latter in febrifuge and antiperiodic power.

USES.—Bibiru bark and *bibirina* (in the form of sulphate) have been used as a peptic in anorexia and dyspepsia; as a general tonic in debility, protracted phthisis, and strumous affections; as a febrifuge in intermittent and remittent diseases; and as an antiperiodic in periodical headache and intermittent neuralgia.¹

BIBIRINÆ SUBSULPHAS; Bebeerinæ Sulphas; Sub-sulphate of Bibirine; Sulphate of Bebeerine.—The process for obtaining this is essentially the same as that of the Edinburgh Pharmacopœia for sulphate of quinia. The bark is first boiled with a solution of carbonate of soda to remove the tannin and colouring matter; it is boiled with water acidulated with sulphuric acid, by which sulphate of *bibirine* is obtained in solution. To the strained liquor carbonate of soda is added, and the impure bases thus thrown down washed, dissolved, and neutralized with sulphuric acid, and the solution decolorized by animal charcoal, concentrated, filtered, and finally evaporated in flat open vessels; excess of acid being avoided in order to prevent charring on evaporation.

There are two compounds of sulphuric acid and *bibirina*—the sulphate (BiSO^2) and the sub-sulphate (Bi^2SO^2): the latter is the commercial salt which has been prepared for medicinal use by Mr. Macfarlane, of Edinburgh:—

<i>Maclagan</i> (Trans. Royal Soc. Edinb.)		<i>Macfarlane's</i> basic commercial sulphate.	
Bibirina	86.39	90.83
Sulphuric acid	13.61	9.17
	100.00		100.00
Neutral sulphate of <i>bibirina</i> . . .	100.00	Sub-sulphate of <i>bibirina</i> . .	100.00

The sub-sulphate of *bibirina* (*Macfarlane's* basic commercial sulphate of *bebeerine*) is not absolutely pure. It contains sub-sulphate of *sipirina*, sulphate of lime, and colouring matter. It occurs in brownish-yellow, thin, glittering scales, which form a yellow powder, and by incineration leave a mere trace of ash only. It has a very persistent bitter taste. It is soluble in alcohol. It is slightly soluble in cold water, with which it yields a turbid solution, partly from the excess of base, partly from the decomposing tendency of the *sipirina*. Its solution in water is rendered more complete by a few drops of sulphuric acid.

Its effects and uses have already been alluded to.

It may be administered in doses of from one to three grains as a tonic, and from

¹ For farther information respecting the therapeutical value of *bibiru* bark and *bibirina*, the reader is referred to Dr. *Maclagan's* papers on this subject, in the *Trans. of the Royal Society of Edinburgh*, vol. xv. 1843; *Cormack's Lond. and Edinb. Monthly Journal of Medical Science*, for August 1843; and the *Edinb. Med. and Surg. Journal*, No. 163. In these papers will be found the observations not only of Dr. *Maclagan*, but also of Drs. *Rodie* and *Watt*, of *Demerara*, Drs. *Bennett* and *Simpson* of *Edinburgh*, and of several army medical officers serving in the East Indies.

five to twenty grains as a febrifuge. In substance, it is given in the form of pill made with conserve of roses; and in solution, with dilute sulphuric acid. The following is given as a convenient form for its exhibition as a tonic: Sub-sulphate of bibirine ℥ss; diluted sulphuric acid ℥xxv; syrup ℥j; tincture of orange-peel ℥j; water ℥iv. Dose, one tablespoonful three times a day.

It has been recommended as an economical substitute for quinia; its price being about 6s. per oz.; while disulphate of quinia has been lately more than double that price.

ORDER XXXVI. MYRISTICACEÆ, Lindley.—NUTMEGS.

MYRISTICÆ, R. Brown.

CHARACTERS.—Flowers completely unisexual. *Calyx* trifid, rarely quadrifid; with vulvular activation. *Males*:—*Filaments* either separate, or completely united in a cylinder. *Anthers* 3 to 12, 2-celled, turned outwards, and bursting longitudinally; either connate or distinct. *Females*:—*Calyx* deciduous. *Ovary* superior, sessile, with a single erect ovule; *style* very short; *stigma* somewhat lobed. *Fruit* baccate, dehiscent, 2-valved. *Seed* nut-like; *albumen* ruminant, between fatty and fleshy; *embryo* small; *cotyledons* foliaceous; *radicle* inferior; *plumule* conspicuous.—*Tropical trees*, often yielding a red juice. *Leaves* alternate, without stipules, not dotted, quite entire, stalked, coriaceous; usually, when full grown, covered beneath with a close down. *Inflorescence* axillary or terminal, in racemes, glomerules, or panicles; the *flowers* often each with one short cucullate bract. *Calyx* coriaceous, mostly downy outside, with the hairs sometimes stellate, smooth in the inside (Lindley, from R. Brown, chiefly).

PROPERTIES.—The bark and pericarp contain an acrid juice. The seed (?) and ariloid abound in an aromatic volatile oil, which is mixed with a fixed oil.

146. MYRISTICA FRAGRANS, Houtt.—THE TRUE NUTMEG TREE.

Sez. Syst. Diœcia, Monadelphia.

(*Seemen* putainine nudatum; oleum esemine expressum, concretum L.—Kernel of the fruit; volatile oil from the kernel; concrete expressed oil from the kernel, E.—The kernel of the fruit, D.)

SYNONYMES.—*Myristica fragrans*, Houttuyn, Nat. Hist. (1774), vol. ii. part iii. p. 333; Blume, Rumphia, I. 180, 1835.—*M. officinalis*, Linn. (1781); Hooker, Bot. Mag. vol. i. N. S. tab. 2756 and 2757.—*M. moschata*, Thunberg (1782)—*M. aromatica*, Lamarek (1788).

HISTORY.—Both nutmegs and mace¹ were unknown to the ancient Greeks and Romans; unless, indeed, the nutmeg be the aromatic Arabian fruit used in unguents, and which Theophrastus² calls κώμακον. Pliny³ says that the *cinnamum quod comacum appellant* is the expressed juice of a nut produced in Syria. Does he refer to the expressed oil of nutmeg, as some have suggested? Both mace and nutmegs are referred to by Avicenna.⁴

The modern Greek names for the nutmeg and mace are respectively *μοσχοκάρνα* and *μοσχομάχερ*.

BOTANY. **Gen. Char.**—*Anthers* united throughout their whole length into a cylindrical column. *Stigma* emarginate, somewhat 2-lobed. *Cotyledons* folded (Blume).

Sp. Char.—Leaves oblong, subacute at the base, smooth. Peduncles axillary, few-flowered. *Calyx* urceolate. *Fruit* nodding, obovoid, globose, smooth (Blume).

A tree from 20 to 25 feet high, similar in appearance to a pear tree. *Bark* dark grayish-green, smooth, with a yellowish juice. *Leaves* aromatic. *Racemes* axillary. *Peduncles* and *pedicels* glabrous, the latter with a quickly deciduous ovate bract at its summit, often pressed close to the flower. *Flowers* usually diœcious, sometimes monœcious. *Males*:—3 to 5 on a peduncle; *calyx* fleshy, pale yellow,

¹ The *μάκρη* of Dioscorides (lib. i. cap. 110), the *macir* of Pliny (lib. xii. cap. 16), was an astringent bark, and not, as some have supposed, our mace.

² *Hist. Plant.* lib. ix. cap. 7. Frans (*Syn. Plant. Fl. classicæ*, p. 135, 1835) considers κώμακον to be our nutmeg.

³ *Hist. Nat.* lib. xii. cap. 63, ed. Valp.

⁴ Lib. ii. tract. ii. cap. 436 and 503.

with a reddish pubescence. *Females*:—scarcely different from the males, except that the pedicel is frequently solitary. *Fruit* pyriform, smooth externally, about the size of a peach, marked by a longitudinal groove. *Pericarp* fleshy, dehiscing by two nearly equal longitudinal valves. *Arillode*¹ (false aril), commonly called *Mace*, large, fleshy, branching, scarlet; when dry, yellow, brittle, and somewhat horny. *Seed* (*nutmeg in the shell*, offic.) within the arilloid, oval or ovate; its outer coat (*testa, tunica externica, or shell*) is dark brown, hard, glossy; its inner coat (*endopleura seu tunica interna*) closely invests the seed, and dips down into the substance of the albumen, giving it a marbled or *ruminated* appearance. The *nucleus or nut* (the *round or true nutmeg* of the shops) consists chiefly of the oleaginous *albumen*; the so-called veins of which are processes of the endopleura, which have a reddish-brown colour, and abound in oil; the *embryo* is at the base of the seed; *radicle* inferior, hemispherical; *cotyledons* 2, large, flat, foliaceous, fan-shaped; *plumule* 2-lobed.

Hab.—Molucca Islands, especially the group called the Banda or Nutmeg Isles.² Cultivated in Java, Sumatra, Penang (Prince of Wales Island), Singapore, Bengal, Bourbon Islands, Madagasear, and some parts of the West Indies.

MYRISTICA FATUA, Houtt, Blume; *M. tomentosa*, Thunberg; *M. dactyloides*, Gært. (the synonyms excluded); *Nux moschata fructu oblongo*, C. Bauh.; *Nux myristica mas*, Clusius.—A native of the Banda Isles.—Fruit elongated, ellipsoidal, rusty, tomentose. Seed elongated, ellipsoidal, covered by a membranaceous fleshy, orange coloured, insipid arilloid (mace); outer coat (*testa*) dark brown, hard; nucleus acerb, slightly aromatic, grayish ash-coloured, cylindrical, ellipsoidal, rugous, marked by a furrow.—Yields the *long nutmeg* of the shops.

Colonel Sykes³ says, that *M. doctyloides* is frequently imposed upon the ignorant for the real nutmeg.

Closely allied to this is the *M. MALABARICA*, Lam., or *Malabar Nutmeg*; it is the *Panam-pálca* of Rheede (*Hist. Malab. part iv. tab. 5*). The latter authority says that the nucleus resembles the *date* in size and figure. Unlike the male or long nutmeg, it has scarcely any flavour or odour. Rheede adds, that “the Turkish and Jewish merchants mix these nutmegs with the true long ones, and the mace with good mace, selling them together. They also extract from these inferior articles an oil, with which they adulterate that of a more genuine quality.”⁴ The Malabar nutmeg, according to Rheede, differs from the long nutmegs in size, hardness, and especially in flavour.

CURING.—In the Banda Isles there are three harvests annually; namely, the principal one in July or August, the second in November, and the third in March or April. The ripe fruit is gathered by means of a barb attached to a long stick; the mace separated from the nut, and both separately cured.

Mace is prepared for the market by drying it for some days in the sun. Some flatten it by the hands in single layers; others cut off the heels, and dry the mace in double blades.⁵ In rainy weather, artificial heat is employed for drying it. At first, the mace is crimson or blood-red, but after a few months acquires the golden colour preferred by the dealers.⁶ The Dutch sprinkle the mace with salt water prior to packing it in the sacks called *sokkol*.⁶

¹ The lacinate envelope of the nutmeg, usually called the aril, and which constitutes the substance called *mace*, is said by M. Planchon to be nothing but an expansion of the exostome, and, therefore, an *arillode or false aril*.

² The Dutch endeavoured to confine the growth of the nutmeg to three of the Banda Isles; viz., Lantoir or Banda proper, Banda-Naira, and Way (Pulo Ay); but their attempts were partly frustrated by a pigeon, called the *nutmeg bird* or *nut-eater* (a species of *Carpophaga*), which, extracting the nutmeg from its pulpy pericarp, digests the mace, but voids the nutmeg in its shell, which, falling in a suitable situation, readily germinates. Young plants thus obtained are used for transplanting into the *nutmeg parks*. During the time that the English had possession of the Molucca Islands (namely, from 1796 to 1802; and, again, from 1810 to 1814), they exported plants to Bencoolen in Sumatra, to Penang, Indis, and other places. In 1819, the nutmeg tree was sent from Bencoolen to Sumatra, where it is now largely cultivated. (For a sketch of the culture and trade in nutmegs, and of the monopolizing policy of the Dutch, the reader is referred to Crawford's *History of the Indian Archipelago*, vol. i. p. 505; vol. ii. p. 437; vol. iii. p. 406.) To keep up the price of this spice, the Dutch used to burn nutmegs when the crops were superabundant! (See Hooker's *Bot. Mag.* vol. i. N. S. i. 1827, t. 2756-2757; also Stephenson and Churchill's *Med. Bot.* vol. iii. pl. 104.)

⁵ Oxley, *Some Account of the Nutmeg and its Cultivation*, in the *Journal of the Indian Archipelago and Eastern Asia*, October 1848, p. 641, Singapore.

⁶ C. B. Valentini, *Indiæ Literatæ*, Epist. xxv., contained in M. B. Valentini's *Historia Simplicium reform.* 1716.

Nutmegs require more care in curing, on account of their liability to the attacks of an insect (the *nutmeg insect*). It is necessary to have them well and carefully dried in their shells, as in this state they are secure from the attack of this insect.¹ In order to effect this they are placed on hurdles or gratings, and smoke-dried for about two months by a slow wood-fire, at a heat not exceeding 140°F. (In the Banda Isles they are first sun-dried for a few days.) When thoroughly dried, the nuts rattle in the shells, which are then cracked with wooden mallets, and the worm-eaten and shrivelled nuts thrown out.

To prevent the attacks of the insect the nuts are frequently limed. For the English market, however, the brown or unlined nutmegs are preferred. The Dutch lime them by dipping them in a thick mixture of lime and water; but this process is considered to injure their flavour. Others lime them by rubbing them with recently prepared, well-sifted lime. This process is sometimes practised in London.

After being garbled, the nutmegs are packed for transportation in tight casks, the insides of which have been smoked and covered with a coating of fresh water and lime. Newbold says the unlimed nutmegs are mixed with cloves.

The dried produce of a nutmeg tree consists of nutmeg, mace, and shell, in the following proportions: In 15 parts of the whole produce there are 2 parts of mace, 5 of shell, and 8 of nutmegs. Hence, although nutmegs in the shell may keep better than the clean or shelled nutmegs, yet the heavy allowance required for the shell (viz. about one-third) is a serious objection to their preservation in this form.

DESCRIPTION. 1. Of *Nutmegs* (*Nuces moschatæ*).—In commerce, two kinds of nutmegs are met with; one called the *true* or *round*, the other the *long* or *wild*.

a. *True or Round Nutmeg*; the *female nutmeg*; *nux myristica fœmina*, Clusius; *nux moschata fructu rotundo*, C. Bauh.—This sort is the produce of *Myristica fragrans*. It is about an inch in length. Its shape is roundish or elliptical, like that of the French olive. Externally, it is marked with reticular furrows. The colour of the *unlimed* or *brown* nutmegs is ashy brown; that of *limed* nutmegs is brown on the projecting parts, and white (from the presence of lime) in the depressions. Internally, nutmegs are pale reddish-gray, with red veins. The odour is strong, but pleasant, peculiar, and aromatic. The taste is agreeable and aromatic.

Occasionally, the round nutmeg is imported *in the shell*. This is dark and shiny.

A very small nutmeg, not larger than a pea, has been described under the name of the *royal nutmeg* (*nux moschata regia*).

In the London Market, the following are the sorts of round nutmegs distinguished by the dealers:—

1. *Penang nutmegs*.—These are unlimed or brown nutmegs, and fetch the highest price. They are sometimes limed here for exportation, as on the continent the limed sort is preferred. According to Newbold, the average amount annually raised at Penang is 400 piculs (of 133½ lbs. each).

2. *Dutch or Batavian nutmegs*.—These are limed nutmegs. In London, they scarcely fetch so high a price as the Penang sort.

3.—*Singapore nutmegs*.—These are a rougher, unlimed, narrow sort, of somewhat less value than the Dutch kind. According to Mr. Oxley, 4,085,361 nutmegs were produced at Singapore, in 1848, or about 252 piculs (of 133½ lbs. each); but the greater number of the trees had not come into full bearing, and it was estimated that the amount would, in 1849, be 500 piculs.

Fig. 299.

True or Round Nutmeg,
surrounded by its mace.
(From a specimen preserved wet.)

¹ Crawford, *Hist. of the Ind. Archip.*

Fig. 300.

Long or Wild Nutmeg,
surrounded by its mace.
(From a dry commercial
specimen.)

β. *Long or Wild Nutmegs*;¹ the male nutmeg; *nux myristica mas*, Clusius; *nux moschata fructu oblongo*, C. Bauhin.—This is the produce of *Myristica fatua*. It is met with in commerce in three forms: in the shelled or clean state (*long or wild nutmegs*), contained within the shell (*long or wild nutmegs in the shell*), and with mace dried around them (*long or wild nutmegs covered with mace*).

The long or wild nutmeg in the shell in shape is oblong, like that of the date; its length about an inch and a half. The shell is bony, somewhat brittle, externally shiny and brown, internally dull, grayish-white. The contained seed is paler coloured and less aromatic than in the preceding sort. Some specimens are almost insipid. Are these the *Malabar wild nutmegs* before referred to (see *ante*, p. 412)? The mace which is sometimes found in the long nutmeg is insipid.

2. **Of Mace** (*Macis*).—Two kinds of mace are found in commerce; one called *true or genuine*, the other *wild or false*.

a. *True or genuine mace*.—This is the produce of the round or true nutmeg. It occurs in single or double blades, flat, irregularly slit, smooth, slightly flexible or brittle membrane, of a pale cinnamon-yellow or golden-yellow colour, and an

odour and taste analogous to those of nutmegs. Although the natural colour of mace is red, yet red-coloured mace is looked on suspiciously.

The London dealers distinguish three sorts of genuine mace:—

1. *Penang mace*.—This fetches the highest price. It is flaky and spread. The annual quantity produced in Penang is about 130 piculs (of 133½ lbs. each).

2. *Dutch or Batavian mace*.—This is a fleshy sort; it scarcely fetches so high a price as the Penang sort.

3. *Singapore mace*.—This is a somewhat inferior kind.

β. *Wild or false mace*.—This is a dark red mace, the produce of the long or wild nutmeg, and is also devoid of aromatic flavour.

COMPOSITION.—Nutmegs were analyzed in 1823 by Bonastre.² In 1824, an analysis of mace was made by N. E. Henry.³

NUTMEG.	
<i>Bonastre's Analysis.</i>	
Volatile oil	6.0
Liquid fat	7.6
Solid fat	24.0
Acid (?)	0.8
Starch	2.4
Gum	1.2
Ligneous fibre	54.0
Loss	4.0
Nutmeg	100.0

MACE.	
<i>N. E. Henry's Analysis.</i>	
Volatile oil.	
Red fat oil soluble in alcohol.	
Yellow fat oil insoluble in alcohol.	
Alcoholic extractive.	
Amidin.	
Ligneous fibre with lime.	
Mace.	

The volatile oils and the fats will be noticed hereafter, as they are employed in medicine. The starch occurs in small compound grains.

CHEMICAL CHARACTERISTICS.—The presence of starch in both nutmegs and mace may be detected by a solution of iodine, which gives them a blue tint (*iodide of starch*). Both of these substances yield, by distillation with water, a volatile oil, characterized by its peculiar odour; and both yield, by expression, a fixed butyraceous oil.

PHYSIOLOGICAL EFFECTS.—The activity of both nutmegs and mace depends on the volatile oil which they contain. Swallowed in moderate quantities, they produce the before-described effects of the spices (see vol. i. p. 250). In large doses

¹ Sir J. E. Smith (*Rees's Cyclopædia*) says that in 1797 they were received from Banda under the name of *New Guinea nutmegs*. A specimen of the fruit and leaves, preserved in spirit in the Banksian collection, is marked the *long nutmeg from Sumatra*.

² *Journ. de Pharm.* t. ix. p. 281, 1823.

³ *Ibid.* t. x. p. 281, 1824.

they prove narcotic, and cause giddiness, delirium, præcordial anxiety, sleepiness, or actual stupor. Instances of this kind are mentioned by Bontius,¹ Rumphius,² Lobel,³ Schmid,⁴ and Cullen.⁵ In the case related by the last-mentioned authority, two drachms of powdered nutmegs produced drowsiness, which gradually increased to complete stupor and insensibility. The patient continued for several hours alternately delirious and sleeping, but ultimately recovered. Purkinje⁶ has confirmed these statements by experiments made on himself. I am acquainted with a case in which the narcotic effects of a whole nutmeg have been several times experienced.

USES.—The principal consumption of nutmegs and mace is for dietetical purposes. They serve to flavour, and, by their stimulant properties, to assist the digestive process. Food highly seasoned with substances may prove these injurious in cerebral affections (apoplexy, for example), on account of their narcotic properties.

Medicinally they are used, like other spices, as stimulants, carminatives, and flavouring ingredients. Nutmeg is an important constituent in the *confectio aromatica* (see p. 393) so frequently employed as a cordial and antacid in bowel complaints. In mild cases of diarrhœa, I frequently employ nutmeg as a substitute for opium. It may be taken in warm brandy and water, unless the use of spirit be contraindicated.

ADMINISTRATION.—Either nutmeg or mace may be taken to the extent of a scruple or half a drachm, in powder obtained by grating; or the volatile oil of these substances may be used in doses of ℥j to ℥v.

1. **OLEUM MYRISTICÆ**, E. D. [U. S.]; *Oleum Nucis Moschatæ*; *Oleum Nucistæ æthereum*; *Essential Oil of Nutmeg*; *Volatile Oil of Nutmeg*.—(Procured by submitting Nutmegs and Water to distillation.)—The usual produce of volatile oil in the distillations at Apothecaries' Hall, London, is 4.5 per cent.; but the oil is generally imported. It is colourless, or pale yellow, has the odour and taste of nutmegs, and a viscid consistence. By agitation with water it separates into two oils, one lighter, the other heavier than water. By keeping, it deposits crystals of stéaroptène (*myristicine*), which are fusible at 212° F., volatile, soluble in alcohol, in ether, and in boiling water; from the latter liquid myristicine separates in a crystalline form as the liquid cools. According to Mulder, the stéaroptène consists of C¹⁶H¹⁶O². Volatile oil of nutmegs is seldom employed medicinally. Its dose is ℥j to ℥v, taken on sugar, or dissolved in spirit.

2. **OLEUM MACIDIS**; *Essential Oil of Mace*.—This is colourless or pale yellow, lighter than water, and has the flavour and odour of mace. Its composition, effects, and uses are similar to those of nutmegs.

3. **MYRISTICÆ ADEPS**, E.; *Myristicæ Oleum*, L.; *Oleum vel Balsamum Nucistæ*; *Butter of Nutmegs*; *Expressed or Concrete Oil of Nutmegs*.—In the shops, it is usually denominated *expressed oil of mace*. It is prepared by beating the nutmegs to a paste (which is to be inclosed in a bag, and then exposed to the vapour of water), and afterwards expressing by heated plates. It is imported in oblong cakes (covered by some monocotyledonous leaves, commonly called *flag leaves*), which have the shape of common bricks, but whose size is somewhat smaller. Its colour is orange, its consistence firm, its odour fragrant, like that of the seeds from which it is obtained. In 1804, it was examined by Schrader,⁷ who found that 16 parts of concrete oil, expressed by himself, consisted of 1 part of volatile oil, 6 parts of brownish-yellow fat, and 9 parts of white fat. In 16 parts of the commercial concrete oil, he found $\frac{3}{4}$ volatile oil, 8 $\frac{1}{4}$ yellow fat, and 7 parts of white fat. The volatile oil and yellow fat are soluble in both cold alcohol and cold ether. The white fat (known by the name of *corpus pro balsamis*, or *mater balsamorum*), is

⁶ *Herb. Amboyn.* vol. ii. p. 21.

⁷ *Ibid.*

soluble in boiling alcohol and boiling ether; but is insoluble in cold alcohol and ether. It has been more recently examined by Dr. L. Playfair,¹ who calls it *myristine* (formerly *sericine*). By saponification it yields glycerine and myristic acid (C²²H⁴²O³, HO). Playfair mentions a false butter of nutmegs, composed of animal fat, boiled with powdered nutmegs, and flavoured with sassafras. The specimen may be relied on as pure, if it dissolve in four times its weight of strong boiling alcohol, or half that quantity of ether.

Expressed oil of nutmegs is occasionally employed externally in chronic rheumatism and palsy. It is a constituent of *Emplastrum Picis* (see *ante*, p. 302).

4. SPIRITUS MYRISTICÆ, L. E. [U. S.]; *Spirit of Nutmeg*.—(Nutmegs, bruised, ʒijss [ʒij. U. S.]; Proof Spirit [Diluted Alcohol, U. S.], Cong. j.; Water Oj. Mix them, then [with a slow fire, L.] let a gallon distil.)—It is frequently prepared by mixing volatile oil of nutmegs with proof spirit. It is cordial and carminative; and is employed in doses of fʒj to fʒiv, as a pleasant addition to stimulant, narcotic, or purgative draughts.

5. ESSENTIA MYRISTICÆ MOSCHATÆ, D.; *Essence of Nutmeg*.—(Volatile Oil of Nutmegs fʒj; Stronger Spirit fʒix. Mix with agitation, D.)—Used as a substitute for the Spirit of Nutmeg. Dose, a few drops on a lump of sugar.

ORDER XXXVII. THYMELACEÆ, Lindl.—DAPHNADS.

THYMELEÆ, Jussieu.—DAPHNOIDEÆ, Endl.

CHARACTERS.—*Calyx* inferior, tubular, coloured; the limb 4 cleft, seldom 5 cleft, with an imbricated æstivation. *Corolla* 0, or sometimes, seale-like petals in the orifice of the calyx. *Stamens* definite, inserted in the tube or its orifice; often 8, sometimes 4, less frequently, 2; when equal in number to the segments of the calyx, or fewer, opposite to them; *anthers* 2-celled, dehiscing lengthwise in the middle. *Ovary* composed of a single carpel, with 1 solitary pendulous anatropal ovule; *style* 1; *stigma* undivided. *Fruit* hard, dry, and nut-like, or drupaceous. *Albumen* 0, or thin and fleshy; *embryo* straight; *cotyledons* plano-convex, sometimes lobed and crumpled; *radicle* short, superior; *plumule* inconspicuous.—*Stem* shrubby, very seldom herbaceous, with tenacious bark. *Leaves* without stipules, alternate or opposite, entire. *Flowers* capitate or spiked, terminal or axillary, occasionally solitary, sometimes unisexual by abortion, often enclosed in an involucre (R. Brown, with some additions).

PROPERTIES.—The prevailing property of the plants of this order is acridity. This depends on a principle contained in the bark and pericarp. The liber of many species is remarkably tough, and is applied to various useful purposes; as for making ropes, whips, a kind of cloth, &c.—The LAGETTA LINTEARIA or the Lace Bark Tree, which possesses the medicinal properties of mezereon, and has been used in the same cases,² is provided with a bark, which may be separated into 20, 30, or more laminæ, which are fine and white like ganze; and of these, caps, ruffles, and even whole suits of ladies' clothes, have been made.³ Some few years since, a quantity of the stiffened lagetta cloth was imported into Liverpool under the name of *guana*.

147. DAPHNE MEZEREUM, Linn.—COMMON MEZEREON OR SPURGE-OLIVE.

Sex. Syst. Octandria, Monogynia.
(Radici cortex, L.—Root-bark, E. D.)

HISTORY.—Tragus⁴ is the earliest author who mentions this plant.⁵ He calls it *Thymelæa*. The *Mezereon* of Avicenna,⁶ and of other Arabian authors, is declared by C. Bauhin to be *Chamelæa tricocca* (now called *Cneorum tricoccon*), a plant of the order Euphorbiaceæ; but it is probably identical with the χαμελαία of Dioscorides, which is declared by Sibthorpe⁷ and Fraas⁸ to be *Daphne oleoides*.

¹ Lond. Ed. Dub. Phil. Mag. vol. xviii. p. 102, 1841; and Ann. de Chim. et de Phys. 3me sér. t. iii. p. 228, 1841.

⁶ Sloane's Nat. Hist. of Jamaica, vol. ii. p. 22.

⁷ Sprengel, Hist. Rei Herb. Præf. xi.

⁸ Prod. Fl. Græc.

BOTANY. Gen. Char.—*Flowers* hermaphrodite. *Calyx* funnel-shaped; limb in 4 segments; throat without scales. *Stamina* 8, inclosed within the tube, inserted in 2 rows near the throat. *Hypogynous scales* 0. *Ovary* 1-celled. *Style* terminal, very short; *stigma* capitate. *Drupe* baccate, 1-seeded, naked, with a crustaceous putamen or stone. *Seed* inverted; *albumen* 0; *embryo* orthotropical; *cotyledons* plano-convex (Endlicher).

Sp. Char.—*Flowers* naked on the stem, sessile, about 3 together. *Leaves* lanceolate, deciduous (Smith).

Stem bushy, 4 or 5 feet high, with upright, alternate, smooth, tough, and pliant branches; leafy while young. *Leaves* scattered, stalked, lanceolate, smooth, 2 inches long, appearing after the flowers, and soon accompanied by flower-buds for the next season. *Flowers* highly, and to many persons too powerfully, fragrant, seated in little tufts on the naked branches, with several brown, smooth, ovate bracteas underneath. *Calyx* like a corolla in texture, crimson all over; the tube, externally hairy. *Berries* scarlet.

Hab.—Indigenous. Plentiful near Andover. Flowers in March. Collected for medicinal purposes in Kent and Hampshire.

Var. *flore albo* has white flowers and yellow fruit.

Var. *autumnale* has larger leaves and flowers in the autumn.

DESCRIPTION OF THE BARK.—The *root-bark* (*cortex radice mezerei*) is alone employed in this country. It is tough, pliable, and when dry fibrous; externally brown and corrugated; internally white, tough, and cottony. It occurs in strips of several inches long. When chewed, the taste is at first sweetish; afterwards an acrid burning sensation is felt in the mouth and fauces, and extends to the gullet and stomach if the bark and saliva be swallowed. This sensation continues for several hours. The odour of the fresh root is faint, but marked.

The *stem-bark* (*cortex caudicis vel caulis mezerei*) is usually considered to be somewhat less active than the root-bark; but in the Dublin, United States, and most of the continental Pharmacopœias, the bark of both root and stem is included under the general name of *mezereon bark* (*cortex mezerei*). The stem-bark, in the fresh state, is externally somewhat darker and rougher than the root-bark; but it is most readily recognized, in the fresh state, by the green colour of the cellular integument beneath the epidermis.

In Germany, the bark of the stem and larger branches is removed in spring, folded in small bundles, and dried for medicinal use. It is imported from Hamburg.

I am informed by Mr. McCulloch, of Covent Garden Market, that the root-bark commands nearly three times the price of the stem-bark. The bark is stripped from the crushed roots while fresh and soft.

Sometimes the entire root (bark and wood) of mezereum is used instead of the root-bark; but this proceeding is highly objectionable, as the wood possesses only a feeble acridity.

The bark of other species of *Daphne* (as of *D. Gnidium* and *D. Laureola*) is said to be sometimes substituted for that of the mezereon.

Mr. Squire¹ states that

13¼ lbs. of fresh mezereon } 3¼ lbs. of wood.
 root produced by drying } 3½ lbs. of bark, dry; equivalent to 8½ lbs. of fresh bark.
 3 lbs. of stems produced } ¼ lb. of dried bark.

COMPOSITION.—The bark of the stem was analyzed by C. G. Gmelin and Bär,² and found to consist of *wax*, an *acrid resin*, *daphnin*, a trace of *volatile oil*, *yellow colouring principle*, *uncrystallizable but fermentable sugar*, *nitrogenous gummy matter*, *reddish brown extractive*, *woody fibre*, *free malic acid*, and *malates of potash, lime, and magnesia*.

¹ *Pharmaceutical Journal*, vol. i. p. 395, 1842.

² L. Gmelin, *Handb. d. Chem.* Bd. ii. S. 1317.

1. **ACRID RESIN.**—Obtained by boiling the bark in alcohol; when the solution cools, some wax is deposited. The supernatant liquid is to be evaporated, and the residual extract washed with water. The resin then left behind is dark green, and soluble in both alcohol and ether. To this substance mezereon owes its acidity. There is, however, some reason to suspect that this resin is itself a compound of two principles, viz. an acrid, vesicating, fixed oil, and another substance. The resin is rendered soluble in water by means of the other constituents of the bark. Mr. Squire could not obtain any blistering effect from the resin extracted by alcohol.

2. **DAPHNIN.**—A peculiar crystalline principle, having a bitter, slightly astringent taste. It is soluble in alcohol and ether, but possesses neither basic nor acid properties. Gmelin and Bar consider it to be analogous to asparagin. It is not the active principle of mezereon.

3. **ACRID VOLATILE OIL?**—According to Mr. Squire, mezereon contains a volatile acrid substance which is carried off by the vapour of water, but not by the vapour of alcohol. He says that “the pungent odour given off by boiling mezereon root in water over a lamp is so powerful, that, after holding my head over it for a short time, great irritation was produced, and it was difficult to carry on respiration.”

PHYSIOLOGICAL EFFECTS.—All parts of the plant, but more especially the bark and the fruit, are endowed with excessive acidity; in virtue of which they cause irritation and inflammation in tissues to which they are applied. When swallowed, therefore, in large quantities, they prove poisonous. The topical action of mezereon bark is that of an irritant, and, when the bark has been applied to the skin, vesicant.

A decoction of mezereon bark, taken in moderate quantities, sometimes appears to promote the action of the secreting and exhaling organs (especially the kidneys and the skin). But Dr. Alex. Russell¹ could not observe, upon the strictest inquiry, “that it sensibly increases any of the secretions, more than the same quantity of any small liquor would do.” In some cases it proves laxative, where the patients are easily moved, and large doses disturb and irritate the stomach. Richter² says that, under the long-continued use of mezereon, the saliva acquires a peculiar odour. In larger doses it causes dryness and heat in the throat, increased saliva, pain in the stomach and bowels, and sometimes vomiting and purging—the stools being occasionally bloody. The urinary organs are sometimes specifically affected by it; irritation, analogous to that produced by cantharides, being set up by it. An affection of the cerebro-spinal system (marked by great feebleness, giddiness, incapability of keeping the erect posture, and slight convulsive movements) is occasionally brought on.³ I am unacquainted with any cases which have proved fatal from the use of mezereon bark. Vicat⁴ mentions the case of a dropsical patient, in whom the wood caused diarrhœa, pain, and vomiting, which continued for six weeks.

USES.—In this country, mezereon is scarcely ever employed alone. It is usually administered in conjunction with sarsaparilla (see *ante*, p. 278), and is employed as a sudorific and alterative in venereal, rheumatic, scrofulous, and chronic cutaneous diseases. Decoction of the root-bark of mezereon was recommended to the notice of the profession, by Dr. Alexander Russell,⁵ as a very efficacious remedy in cases of venereal nodes and nocturnal pains. Dr. Home⁶ also speaks of it as “a powerful deobstruent in all venereal tumours of the scirrhus kind, where mercury has failed.” But Mr. Pearson,⁷ after many years’ observation of it, says, “I feel myself authorized to assert unequivocally, that the mezereum has not the power of curing the venereal disease in any one stage, or in any one form.” Dr. Cullen⁸ employed it with success in some cutaneous diseases.

As a topical remedy, it is sometimes applied to relieve toothache. It is occasionally used as a *masticatory*. Dr. Withering⁹ cured a case of difficulty of swallowing (arising from a paralytic affection) by mezereon, which he directed to be chewed frequently. In France, the bark of both *Daphne Mezereum* and *D. Genkium* is used as a vesicatory.¹⁰ The mode of applying it is this: First soften the

⁹ *Clin. Exper. and Hist.*

¹⁰ *Mat. Med.*

bark by soaking it in hot vinegar and water, and then apply it to the part by a compress and bandage. The application is to be renewed night and morning, until vesication is produced.

ADMINISTRATION.—Mezereon is usually administered internally, in the form of *decoction*. It is a constituent of the *decoctum sarzæ compositum* (see *ante*, p. 278).

As a *masticatory*, a few grains of the bark may be chewed.

For external use, an *ointment* prepared with the *extract* is sometimes employed.

ANTIDOTE.—In a case of poisoning by mezereon, evacuate the contents of the stomach as speedily as possible, and give emollient drinks, opiates, and the vegetable acids. To counteract inflammatory symptoms, the usual antiphlogistic treatment should be adopted.

1. DECOCTUM MEZEREI, E.; *Decoction of Mezereon*.—(Mezereon Bark, in chips, ʒij; Liqueur Root, bruised, ʒss; Water Oij. Mix them, and boil down with a gentle heat to a pint and a half, and strain.)—Stimulant and sudorific. Used in chronic rheumatism, and secondary syphilis. Dose, fʒiv to fʒviij, three or four times a day.

From Mr. Squire's observations, already referred to, it appears that ebullition is injurious to the action of mezereon, by dissipating a volatile active principle.

2. EXTRACTUM MEZEREI ALCOHOLICUM; *Alcoholic or Spirituous Extract of Mezereon*.—A tincture of mezereon is first made with rectified spirit, and the spirit then drawn off by distillation.

In the Prussian Pharmacopœia, the alcoholic extract is directed to be digested in ether, and from the ethereal tincture is obtained by distillation the *extractum mezerei æthereum*.

Extract of mezereon is greenish or brownish-green coloured, and is insoluble in water. Mr. Squire obtained a drachm of dry resin (alcoholic extract) by digesting half an ounce of the bruised bark in ten ounces of alcohol, and then distilling off the alcohol. During the distillation, none of the pungency of the root came over.

Extract of mezereon is used for the preparation of a blistering ointment or tissue.

3. UNGUENTUM MEZEREI [U. S.]; *Mezereon Ointment*.—The Prussian Pharmacopœia directs this to be prepared by mixing ʒj of the ethereal extract of mezereon with ʒj of wax ointment. In the Hamburgh Codex, it is prepared by dissolving ʒij of the spirituous extract in a small quantity of spirit, and then mixing ʒviij of purified lard and ʒj of white wax.—[The *U. S. Pharm.* directs to take of Mezereon, sliced transversely, four ounces; Lard fourteen ounces; White Wax two ounces. Moisten the mezereon with a little alcohol, and beat it in an iron mortar until reduced to a fibrous mass; then digest it, by means of a salt-water bath, with the lard and wax previously melted together, for twelve hours; strain with strong expression, and allow the strained liquid to cool slowly, so that any undissolved matters may subside. From these separate the medicated ointment.]—The ointment is used as an irritant. Applied to ulcers or wounds, it serves to excite suppuration. Mr. Squire states that an ointment made by boiling the root in lard soon spoils by keeping.

148. *Daphne Laureola*, Linn.—Spurge-laurel.

(Cortex.)

Laureola, Gerard; Parkinson, 205.—This is another indigenous species of *Daphne*. It has drooping axillary racemes of green flowers, evergreen lanceolate leaves, and black berries. Mr. Squire says that 7 lbs. of the root yielded 4 lbs. 5 oz. of fresh bark, or 1 lb. 1¼ oz. of dry bark; and 11 pounds of the stems yielded 1¾ lbs. of fresh bark, which, when dried, weighed ¾ lb. The liber is remarkably tough. In odour, and irritating effect on the throat, the bark of the spurge-laurel appeared to him to be weaker than that of mezereon. Half an ounce of the bruised bark yielded him 45 grs. of alcoholic extract. In its effects, spurge-laurel resembles mezereon. Parkinson mentions its emmenagogue properties. Some years ago, a farmer gave a girl, æt. 17, three pills to procure abortion. They caused violent vomiting, convulsions (dur-

ing which she aborted), coma, and paralysis, from which she slowly recovered. A microscopic examination of the fragments of leaves in the pills led the late Mr. Edwin Quekett to believe that the poison was this plant.

149. *Daphne Gnidium*, Linn.—The Flax-leaved Daphne.

(Cortex.)

Θυμλαία, Dioscorides, lib. iv. cap. 173. The berries were the κόκκοι γνιδίου, *grana gnidia* or *gnidian berries* used by Hippocrates.¹ The properties of this species of *Daphne* resemble those of *Mezereon*. In France, the bark (called *garou*) is used in the way before described (see *Daphne Mezereum*) as a vesicatory.

ORDER XXXVIII. POLYGONACEÆ, Lindl.—BUCK-WHEATS.

POLYGOÑÆ, Jussieu.

CHARACTERS.—*Calyx* free, often coloured, imbricated in æstivation. *Stamens* very rarely perigynous, usually definite and inserted in the bottom of the calyx; *anthers* dehiscing lengthwise. *Ovary* free, usually formed by the adhesion of 3 carpels, 1-celled, with a single erect ovule, whose foramen points upwards; *styles* and *stigmas* as many as the carpels. *Ovules* orthotropal. *Nut* usually triangular, naked, or protected by the calyx. *Seed* with farinaceous albumen, rarely with scarcely any; *embryo* inverted, generally on one side, sometimes in the axis; *radicle* superior, long.—*Herbaceous* plants, rarely *shrubs*. *Leaves* alternate, their stipules cohering round the stem in the form of an ochrea (or boot); when young rolled backwards, occasionally wanting. *Flowers* occasionally unisexual, often in racemes (Lindley).

PROPERTIES.—The herbaceous plants are distinguished by their acidulous character. They owe this to the presence of vegetable acids, chiefly oxalic acid. This is found in the form of a superoxalate of potash (or soda), which communicates to the leaves and petioles refreshing and refrigerant qualities. The roots contain colouring and astringent matter, and often oxalate of lime. Some of them are purgative. The seeds of some species serve as a kind of corn for cattle, and, in times of scarcity, for man.

150. RHEUM.—RHUBARB.

Sex. Syst. Enneandria, Monogynia.

(Rheum Sinense; Rhei, species incerta; Radix, L. The root of undetermined species.—E. D.)

HISTORY.—Dioscorides² speaks of a root which he calls *rha* or *rheon* (ῥᾶ ῥῆον), and which has been regarded by some as identical with our rhubarb. "*Rha*, by some called *rheon*, grows," says Dioscorides, "in those countries which are beyond the Bosphorus, and from which it is brought. It is a root which is black externally, like to great centaury, but smaller and redder, odourless, loose or spongy, and somewhat smooth internally." Pliny³ gives a similar account of it, under the name of *rhacoma*; it comes, he says, from the countries beyond Pontus, resembles the black costus, is odourless, and has a hot, astringent taste. Prosper Alpinus⁴ was of opinion that the *rha* of Dioscorides was the root of Rheum rhabarbaricum, which Alpinus obtained from Thracia, in 1608, A. D., and cultivated at Pavia. The later Greek writers are supposed to have been acquainted with our rhubarb. Alexander of Tralles⁵ is the first who speaks of it. He used it in weakness of the liver and dysentery. Paulus Ægineta says that, in the crudities and vomiting of pregnant women, we may give "the knot-grass, boiled in water, for drink; and likewise dill, and the *pontic root*, called *rha* in the dialect of its native country;"⁶ and, in noticing the practice of the ancients, he says, "alvine discharges they promoted by giving turpentine to the extent of an olive, when going to rest; or, when they wished to

⁶ Paulus Ægineta, Syd. Soc. edit. by Dr. Adams, vol. i. book i. Sect. 1, p. 1.

purge more effectually, by adding a little *rhubarb*," [rheon.]¹ This is the first notice of the purgative properties of rhubarb.

In one of the Arabian authors (Mesue, the younger) we find three kinds of rhubarb mentioned: The *Indian*, said to be the best; the *Barbarian*; and the *Turkish*, which is the worst of all.

BOTANY. Gen. Char.—*Calyx* petaloid, 6-parted, withering. *Stamina* about 9, inserted into the base of the calyx. *Styles* 3, reflexed. *Stigmas* peltate, entire. *Achenium* 3-cornered, winged, with the withered calyx at the base. *Embryo* in the centre of the albumen (Lindley).

It is not yet ascertained what species of *Rheum* yields the officinal rhubarb. Several species, now cultivated in this country, have been, at different times, declared to be partially or wholly the source of it. Formerly, *Rheum Rhaponticum* was supposed to yield it.²

In 1732, *R. undulatum* was sent from Russia to the Messrs. Jussieu at Paris, and to Rand of Chelsea, as the true rhubarb. This is the species which Linnæus described as *R. Rhabarbarum*.³ About 1750, at the desire of Kaul Boerhaave, first physician to the Emperor of Russia, the senate commissioned a Tartarian merchant, a dealer in rhubarb, to procure them some seeds of the genuine plant. This he did, or pretended to do; and, on sowing them, two species of *Rheum* were obtained; namely, the *undulatum* and the *palmatum*.⁴ In 1762, seeds of the latter species were received by Dr. Hope, of Edinburgh, from Dr. Mounsey, at Petersburg; they were sown, and the plants cultivated with success.⁵ The root of this species being found to agree, in many of its characters, with that of genuine rhubarb, led to the belief that the *palmatum* was the true species. The inquiries of Pallas, however, raised some doubts about the correctness of this opinion; for the Bucharians declared themselves unacquainted with the leaves of the *palmatum*, and described the true plant as having round leaves, with a few incisions only at the margin. This description agreed best with *Rheum compactum*, the roots of which were declared, by Millar, who cultivated the plant, to be as good as foreign rhubarb.⁶ Georgi says, that a Cossack pointed out to him the leaves of the *R. undulatum* as the true species.⁷ These accounts were not satisfactory to the Russians; and, in consequence, in 1790, Sievers, an apothecary, went to Siberia, under the auspices of Catherine II., with a view of settling the question; but, after four years of persevering attempts to reach the country where the true rhubarb grew, or even to obtain the seeds, he was obliged to be satisfied with negative results only. "My travels," says he, "as well as acquaintance with the Bucharians, have satisfied me that as yet nobody—that is, no scientific person—has seen the true rhubarb plant. All that is said of it by the Jesuits is miserable, confused stuff; all the seeds procured under the name of true rhubarb are false; all the plantations, from those of the Knight Murray down to the flower-pot of a private individual, will never yield true rhubarb. Until further determination, I hereby declare all the descriptions in all the *Materia Medicas* to be incorrect."⁸ Calau,⁹ Apothecary in the Rhubarb Factory at Kiachta, and who, from his appointment, might be expected to know the origin of the rhubarb he receives from the Bucharians, says, "All that we know of the rhubarb plant or its origin is defective and wrong; every sacrifice to obtain a true plant or the seed has been in vain; nor has the author been enabled to obtain it. A severe prohibition from the Chinese government prevents all possibility of eliciting the truth."

Himalayan rhubarb is obtained from several species of *Rheum*: viz. *R. Emodi*, Wallich;¹⁰ *R. Webbianum*, Royle;¹¹ *R. spiciforme*, Royle; and *R. Moorcroftianum*, Royle; but there are no reasons for supposing that they yield any of the rhubarb of European commerce. It is not improbable that the species yielding the officinal rhubarb is yet undescribed. Dr. Royle,¹² after referring to the accounts of different authors, as to the precise locality of the country yielding Russian rhubarb, concludes that it is within 95° of E. long. in 35° of N. latitude—that is, in the heart of Thibet. And he adds, "as no naturalist has visited this part, and neither seeds nor plants have been obtained thence, it is as yet unknown what species yields this rhubarb."

The late Mr. Anderson, of the Apothecaries' Botanic Garden, Chelsea, furnished me with the fresh roots of thirteen species of *Rheum*: viz. *R. palmatum*, *undulatum*, *compactum*, *Rhaponticum*, *Emodi*, *crassinervium*, *caspicum*, *tartaricum*, *hybridum*, *confuens*, *Fischeri*, *bardaniifolium*, and *bullatum*. Having carefully dried these by artificial heat, I found that one species only, viz. *R. palmatum*, closely resembled Asiatic rhubarb in the combined qualities of odour, colour, and marbling: *R. undulatum* agreed tolerably well in colour and marbling, but not in odour. It deserves, however, to be noticed that the specimens examined were of unequal ages—some forming the root-stock, others root-branches of the respective plants—a circumstance which considerably diminishes the value of a comparative examination of them. Furthermore, all the samples were

probably injured by the wet season. The root-branches of *R. crassinerivium* (from a strong plant of six or seven years old, but which had not flowered) did not resemble Asiatic rhubarb in either colour or odour.¹

Species—I. *With compound racemes.*

1. **RHEUM PALMATUM**, Linn. L. D. *Palmated Rhubarb*. Commonly known to gardeners as the *True Turkey Rhubarb*.—"Leaves roundish-cordate, half palmate; the lobes pinnatifid, acuminate, deep dull green, not wavy, but uneven, and very much wrinkled on the upper side, hardly scabrous at the edge, minutely downy on the under side; sinus completely closed; the lobes of the leaf standing forward beyond it. *Petiole* pale green, marked with short purple lines, terete, obscurely channelled quite at the upper end. *Flowering stems* taller than those of any other species," (Lindley.)—Perennial. Grows spontaneously in the Mongolian empire, on the confines of China.² Its leaf-stalks make excellent tarts and puddings.

Prof. Guibourt³ observes that out of the roots of *R. palmatum*, *undulatum*, *compactum*, and *Rhaponticum*, those of the first species possess only the exact odour and taste (grittiness excepted) of the China rhubarb.

2. **RHEUM UNDULATUM**, Linn. D. *Wave-leaved Rhubarb*.—"Leaves oval, obtuse, extremely wavy, deep green, with veins purple at the base, often shorter than the petiole, distinctly and copiously downy on each side, looking as if frosted when young, scabrous at the edge; sinus open, wedge-shaped, with the lower lobes of the leaves turned upwards. *Petiole* downy, bloody, semicylindrical, with elevated edges to the upper side, which is narrower at the upper than the lower end," (Lindley.)—Perennial. Grows in Siberia (Georgi and Pallas, cited by Murray),³ and China (Ammann, quoted by Lindley). Cultivated in France, and yields part of the *French Rhubarb*.⁴ It was formerly cultivated at Siberia as the real officinal plant; but, as genuine rhubarb could not be procured from it, its cultivation has been given up.⁵

3. **RHEUM COMPACTUM**, Linn.; *Thick-leaved Rhubarb*.—"Leaves heart-shaped, obtuse, very wavy, deep green, of a thick texture, scabrous at the margin, quite smooth on both sides, glossy and even on the upper side; sinus nearly closed by

Fig. 301.

*Rheum palmatum.*

Fig. 302.

*Rheum compactum.*

the parenchyma. *Petiole* green, hardly tinged with red, except at the base, semicylindrical, a little compressed at the sides, with the upper side broad, flat, bordered by elevated edges, and of equal breadth at each end," (Lindley.)—Perennial.

¹ In 1831, Geiger (*Pharm. Central Blatt für 1831*, S. 209) made a comparative examination of the roots of *R. Emodi compactum*, *undulatum*, and *Rhaponticum*.

² *Hist. Des. Drog.*

⁶ *Ibid.*

Grows in Tartary and China. Cultivated in France, and yields part of the *French rhubarb*.¹ This rhubarb is a very fair imitation of that from China; but is distinguished by its reddish tint, its different odour (common to it, to *R. undulatum*, and *R. rhaponticum*), its close and radiated marbling, its not tinging the saliva, and its not grating under the teeth.

4. RHEUM EMODI, Wallich; *R. australe*, Don.—“Leaves cordate, acute, dull green, but little wavy, flattish, very much wrinkled, distinctly rough, with coarse short hairs on each side; sinus of the base distinctly open, not wedge-shaped, but diverging at an obtuse angle, with the lobes nearly turned upwards. Petioles very rough, rounded angular, furrowed; with the upper side depressed, bordered by an elevated edge, and very much narrower at the upper than the lower end,” (Lindley).—Perennial. Grows on the Himalayas. It yields part of the *Himalayan rhubarb*. Its stalks make excellent tarts and puddings.

5. RHEUM WEBBIANUM, Royle. Choor Mountain, Niti Pass. Yields part of the *Himalayan rhubarb*.

6. RHEUM RHAPONTICUM, Linn.; *Common or Rhapontic Rhubarb*.—Grows in Thrace; borders of the Euxine Sea; north of the Caspian; Siberia, &c. Cultivated in this country for the leaf-stalks, which are used for tarts and puddings; whence it is frequently termed *culinary* or *tart rhubarb*. Grown largely at Banbury, in Oxfordshire, on account of its roots, which, when dried, constitute *English* or *Banbury rhubarb*.² Cultivated also in France, and yields part of the *French rhubarb*.

7. *R. CRASSINERVIUM*, Fischer.—Habitation unknown. Sent from St. Petersburg to the Apothecaries' Garden, Chelsea. Its roots possess, according to the late Mr. Anderson, the colour and odour of Turkey rhubarb.³

8. *R. LEUCORRHIZUM*, Pallas; *R. nanum*, Sievers. Ledebour, Fl. Pl. Ross. t. 492. Deserts of the Kirghis, and south of Siberia and Altai Mountains. Said to yield *white* or *imperial rhubarb*.

9. *R. HYBRIDUM*, Murray, Comm. Gott. t. i.—Cultivated as a culinary rhubarb.

10. *With spiciform racemes*.

11. RHEUM SPICIFORME, Royle.—Kherang Pass, and other places in Kunawar. Also Thibet.

11. RHEUM MOORCROFTIANUM, Royle; *Small-stalked Rhubarb*.—Niti Pass, in the Himalayas. This and the preceding species have denser and more yellow roots than the two other Himalayan species of *Rheum* above noticed (viz. *R. Emodi* and *R. Webbianum*).

PREPARATION.—The method of curing or preparing Asiatic rhubarb for the market varies somewhat in different localities. In China it is as follows: The roots are dug up, cleansed, cut in pieces, and dried on stone tables, heated beneath by a fire. During the process, the roots are frequently turned. They are afterwards pierced, strung upon cords, and further dried in the sun.⁴ In Tartary, the Moguls cut the roots in small pieces, in order that they may dry the more readily, and make a hole in the middle of every piece, through which a cord is drawn, in order to suspend them in any convenient place. They hang them, for the most part, about their tents, and sometimes on the horns of their sheep.⁵ Sievers, how-

ever, states that the roots are cut in pieces, strung upon threads, and dried under sheds, so as to exclude the solar rays; and the same author tells us that sometimes a year elapses from the time of their collection until they are ready for exportation.¹

VARIETIES AND DESCRIPTION.—The various sorts of rhubarb (*radix rhei*) of commerce may be conveniently arranged in four divisions, respectively distinguished as *Muscovitic* or *Russian*, *Canton*, *Himalayan*, and *European*.

1. Muscovitic or Russian Rhubarb (*Radix Rhei Muscovitici, Ruthenici, vel Rossici*).—Under this head are included those sorts of Asiatic rhubarb which are brought into Europe by way of Russia. The principal and chief sort is the *Crown Rhubarb*. Two other inferior sorts, called respectively *Bucharian* and *Siberian Rhapontic Rhubarb*, are occasionally imported, but are not found in the shops. *Taschkent* and *White Rhubarb* are other Russian sorts which I have not met with.

1. Russia Crown Rhubarb.—This is Chinese rhubarb, which is taken in exchange, on behalf of the Russian crown, at Kiachta. In Russia, it is known as *Chinese rhubarb*; in Europe, it is frequently called *Bucharian rhubarb*, not because it is the growth of Bucharia, but from the circumstance of a few Bucharian families having been the purveyors to the Russian crown for a century. It might with propriety be termed *Chinese-Russian rhubarb*. In English commerce, it is commonly called *Turkey rhubarb* (*radix rhei turcici*), because formerly this description of rhubarb came into Europe by way of Natolia.²

The barter of rhubarb is carried on by the Russian government, under a contract made with Bucharians at Kiachta for ten years, and confirmed by the Chinese government. According to this contract, the Bucharians undertake to furnish a certain quantity of rhubarb annually to the Russian crown, for a certain quantity of goods of a certain quality, and to deliver up all rhubarb not approved of, without remuneration, and permit it to be burnt by the Russian government.

The rhubarb grows wild in Chinese Tartary, especially in the province Kansu. It is collected on that long chain of mountains of Tartary, destitute for the most part of woods, and which arises not far from the town of Sclin, and extends to the south as far as the lake Kokonor, near Thibet.³ It is generally gathered in summer, from plants of six years of age. When the root is dug up it is washed, to free it from earthy particles, peeled, bored through the centre, strung on a thread, and dried in the sun. In autumn, all the dried rhubarb collected in the province is brought in horse-hair sacks, containing about 200 lbs. to Sinin (the residence of the dealers), loaded on camels, and sent over Mongolio to Kiachta, Canton, Macao, and partly to Peking. All the rhubarb brought to Kiachta undergoes an examination, prescribed by the Imperial Russian Medical Council, according to directions of the Russian government. The selection of the rhubarb bartered for by Russian merchants takes place in the custom-house at Kiachta; and of that for the crown, in a house for that purpose on the Chinese borders.

In this selection, the following rules are chiefly to be observed:—⁴

a. To reject pieces obtained from dead plants, which are porous, of a gray colour, and, besides fibre and oxalate of lime, contain little of the other constituents of rhubarb.

b. To reject pieces that are small, derived from young plants, and which are of a pale colour, and without much virtue.

c. To reject roots of other plants, which are casually or purposely mixed with the rhubarb.

d. To pare the rhubarb. This is done, first, to remove remaining portions of the bark and the upper part of the root; and, secondly, to cleanse those parts that may be stained with the sweat of the camels.

e. To perforate all pieces, and examine their interior.

f. To re-dry those roots which may be moist.

As the rhubarb taken in exchange by the crown is not permitted to be imported into the European part of Russia, except in quantities of 1,000 poods, or 40,000 pounds, the roots approved of, after the examination, are packed in bags, and placed where there is a free current of air, until the necessary quantity has accumulated, which is then packed in cases capable of containing 4—5 poods. These chests are covered with linen and pitched, then sewed into skins and marked with the year of the importation of the root, and sent to Moscow.

Crown rhubarb is imported in chests holding from 156 to 160 lbs. each. Each chest is pitched on the outside and covered with a hempen cloth and a hide. On the outside of the chest is a printed paper, stating the year in which the rhubarb

³ Pallas, *Voyages en diffé. Prov. de l'Empire de Russie*, t. iv. p. 216, et seq.

⁴ Calau, *Pharm. Journ.* vol. ii. p. 658, 1843.

was imported into Russia, and the weight of the chest. The following is a literal copy (reduced in size) of one of these papers:—¹

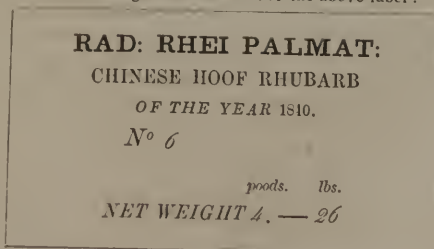

The best prices are obtained for those chests whose rhubarb is in small pieces (for retailing), has a bright colour, and is sound and hard. The shapes of the pieces are various, being angular, rounded, irregular, &c. The flat surfaces and angles which the pieces present show that the cortical portion of the root has been removed by slicing (and not by scraping, as in the Canton rhubarb). Holes are observed in some of the pieces extending completely through; they have been made for the purpose of hanging the pieces to dry; but all traces of the cord have been carefully removed, and the holes scraped or filed to get rid of all decayed portions. The holes which extend only partially through the pieces are borings which have been made to examine the condition of the interior of the pieces.

Externally, the pieces are covered with a bright yellow-coloured powder, usually said to be produced by the mutual friction of the pieces in the chests during their passage to this country; though many druggists believe it is derived from the process of *rouncing* (that is, shaking in a bag with powdered rhubarb), before its exportation. The odour is strong and peculiar, but somewhat aromatic. It is considered by druggists to be so delicate, that in all wholesale drug-houses a pair of gloves is kept in the Russian rhubarb drawer, with which only are the assistants permitted to handle the pieces. When chewed, it feels gritty under the teeth, from the presence of numerous crystals of oxalate of lime; it communicates a bright yellow colour to the saliva, and has a bitter, slightly astringent taste.

Beneath the dust with which the pieces are covered, the surface has a reddish-white tint, owing to the intermixture of white and red parts. The yellowish-white parts have the form of lines or veins, which, by their union with each other, assume a reticular form. Irregularly scattered over the surface we observe small star-like spots and depressions, of a darker colour. The transverse fracture is uneven, and presents numerous brownish-red or dark carmine-coloured undulating veins. The

¹ The following is a translation of the above label:—

longitudinal fracture is still more uneven, and shows the longitudinal direction of the veins, which are often interrupted with white. The surface obtained by cutting is more or less yellow, and often exposes the veins, disposed in groups.

Fig. 304.

Crystals of Oxalate
of Lime in Russian
Rhubarb.

By boiling very thin slices of the root in water, and then submitting them to the microscope, we observe cellular tissue, annular ducts, and numerous *conglomerate raphides* (clumps of crystals of oxalate of lime). From 100 grs. of Russian rhubarb, the late Mr. Edwin Quekett procured between 35 and 40 grs. of these raphides.¹ Turpin considered the presence of these crystals sufficient to distinguish Russian and Chinese rhubarb from that grown in Europe; but in some specimens of English rhubarb I have met with them in as great abundance as in foreign rhubarb. According to Raspail,² they are situated in the interstices of the elongated tissue; but this statement is erroneous, the situation of the crystals being in the interior of the cells.

The small pieces of crown rhubarb are usually picked out and sold as *radix rhei turcici electa*; the larger pieces and dust being employed for powdering.

The powder of Russian rhubarb is of a bright yellow colour, with a reddish tint; but, as met with in the shops, it is almost invariably mixed with the powder of English rhubarb.

2. *White or Imperial Rhubarb*.—When Pallas was at Kiachta, the Bucharian merchants, who supplied the crown with rhubarb, brought some pieces of rhubarb as white as milk, with a sweet taste, and the same properties as rhubarb of the best quality.³ It is not met with in English commerce as a distinct kind; and it is almost unknown in Russia.⁴ But in the chests of Russian rhubarb there are occasionally found pieces having an unusually white appearance; these I presume to be the kind alluded to.⁵ White rhubarb is said to be the produce of *R. leucorrhizum*, Pallas (*R. nanum*, Sievers.)

3. *Taschkent Rhubarb*.—This is the refuse of the true Russian rhubarb, which comes by way of Taschkent. It differs but little from the crown rhubarb. On account of its cheapness, it, like the Bucharian sort, is employed for purposes for which the crown rhubarb of Russia is too expensive. I have not met with it in English commerce.

4. *Bucharian Rhubarb* (*Rheum bucharicum*).—Grassman, an apothecary, at St. Petersburg, who has described this sort,⁶ considers it to be the rhubarb which, according to Pallas, is obtained from *Rheum undulatum*, and which, in the *Pharmacopœia Rossica*, for 1798, was denominated *radix rhabarbi sibirici*. As it is not under the control of the crown, in Russia, it undergoes no examination, and inferior and rotten pieces, therefore, are often met with. On account of its cheapness it is used, in Russia, in veterinary medicine.

In 1840, some of it was received here by Mr. Faber, from Russia, to whom I am indebted for samples of it. It is described as being carried into the latter country by way of Nischny, where it is trimmed for the Moscow market.

This kind of rhubarb is intermediate between the Chinese and Russian or Muscovite rhubarb, but is of inferior quality. The pieces are, more or less, rounded or flattened, and weigh from one to two ounces each. Some of them appear to have been deprived of their cortical portion by scraping, as in the Chinese rhubarb; but in others, the cortex has been removed by slicing. Most of them are perforated by a hole, apparently for the purpose of drying them; but in none of the holes are there any remains of the cord used in suspending the roots. The holes, moreover, appear to have been cleaned out, as in the Russian rhubarb, for no portion of decayed rhubarb is seen in them. Some of the pieces are dense, but most of them are lighter than good Russian rhubarb. Internally, they are often decayed and dark coloured. Their texture is similar to that of genuine rhubarb. The odour is also like that of rhubarb, but much feebler; the taste is bitter and astringent. When chewed, this rhubarb feels gritty under the teeth. Its colour is darker than that of good Russian rhubarb.

5. *Siberian Rhubarb*; *Rheum sibiricum*.⁷—This is the sort which Grassman has described as *Siberian rhapsotic rhubarb*. In 1845, three chests of it came to England from St. Petersburg, under the name of *Bucharian rhubarb*, and were sold by public sale at 6d. per lb.

² *Voyages*, t. iv. p. 219.

In its general appearance, it agreed with rhubarb grown in this country, and known as English stick rhubarb. It had been decorticated, though imperfectly so, as portions of the dark brown cortex were here and there left adherent. The pieces were all more or less cylindrical, seldom exceeding four inches in length and an inch in diameter, and on the average weighed about 100 grains each; the longest piece was six inches in length, and an inch and a half in diameter. The broadest piece was somewhat flattened, and about three inches in its broadest diameter. Its colour was, in general, darker than that of the ordinary rhubarb, but was of the same kind of tint. Its odour was remarkably sweet, similar to what I have perceived when drying the roots of different species of *Rheum* cultivated in England. When chewed it was not gritty. Its taste was mucilaginous, bitterish, but not astringent. The fracture of the smaller and sound pieces was similar to that of English stick rhubarb; the larger pieces were decayed, dark brown, and tasteless in the centre.

2. Canton Rhubarb.—This, like the Russian crown rhubarb, is the produce of China, but is exported from Canton. It is usually known in English commerce as *Chinese* or *East Indian rhubarb* (*radix rhei chinensis seu indici*.) It is imported either directly from Canton, or indirectly by Singapore and other parts of the East Indies, and is probably the produce of the province of Se-tehuen (Du Halde), of Hoo-nan and Hoo-pih, as well as of other provinces (Gutzlaffe and Reed).

Three kinds of Canton rhubarb are known in commerce; these are, the *untrimmed* or *half-trimmed*, the *trimmed*, sometimes called the *Dutch trimmed*, and what I have called *stick rhubarb*.

6. Half-trimmed or untrimmed Canton Rhubarb.—This is usually *Chinese* or *East Indian rhubarb* of the shops. It is called “untrimmed,” or “half-trimmed,” because the cortical portion of the root has been incompletely scraped (not sliced) off; and consequently the pieces have a rounded character, and are devoid of the flat surfaces and angles produced by slicing (as in the Russian and Dutch trimmed rhubarbs). The inferior pieces present the remains of the greenish-brown or blackish cortex. The pieces are frequently cylindrical or roundish, but sometimes flattened; in trade, they are distinguished as *rounds* and *flats*. They are generally perforated with holes, in many of which, we find portions of the cords by which they were suspended. These holes are smaller than those observed in Russian rhubarb, and that portion of the root forming their sides is usually dark-coloured, decayed, and of inferior quality. The best pieces are heavier and more compact than that of the Russian kind; and are covered with an easily separable dust. When this is removed, we observe that the surface is not so regularly reticulated, is of a more yellowish-brown than reddish-white colour, and has coarser fibres than Russian rhubarb. On the finer pieces, we notice numerous star-like spots or depressions. The fracture is uneven; the veins, especially towards the middle, have a less determinate direction, and are of a duller or reddish-brown colour, and, in very bad pieces, of an umber-brown colour, with a gray substance between the veins.

The odour of this species is much less powerful than that of Russian rhubarb, and is somewhat less aromatic. The taste, grittiness when chewed, and microscopic appearances, are similar to those of Russian rhubarb. The colour of the powder is of a more dull yellow or brownish cast.

This sort of rhubarb is imported in chests and half chests; the former contains one picul (133½ lbs.), the latter half a picul. The chests are oblong, have been coarsely put together, and, except in shape, resemble tea-chests; and, like the latter, are lined with sheet-lead. The cover is a double one.

When this sort arrives in London, it is hand-picked, tared, and sorted into three qualities—bright and sound, dark and horny, and worm-eaten. This is not done with Russian rhubarb.

7. Dutch-trimmed or Batavian Rhubarb, offic. (*Rhubarbe de Perse*, Guibourt.)—This kind of rhubarb is closely allied to, if it be not identical with, the preceding in its texture. In commerce, however, it is always regarded as distinct. It is imported from Canton and Singapore in chests, each containing one picul, (133½ lbs.) It has been dressed or trimmed to resemble the Russian crown rhubarb, which it does in shape, size, and general appearance; for the cortical portion of the

root seems to have been separated by slicing, and hence the pieces have the same angular appearance on the surface that the Russian rhubarb has. The pieces are frequently perforated, and in the holes are found the remains of the cord by which the root has been suspended; in this it differs from the Russian crown rhubarb. In the drug-trade, this kind of rhubarb is said to be trimmed, and, according to the shape of the pieces, they are called *flats* or *rounds*. The colour and weight of the pieces are variable.

8. *Canton Stick Rhubarb*.¹—In 1844, five cases of this rhubarb were imported from Canton, and were sold by public sale, at 8s. per pound.

All the pieces but one of my sample are cylindrical, about two inches long, from half to three-quarters of an inch in diameter, and weigh each on the average about 100 grains. The piece to which I have referred as forming the exception is shaped like a flattened cylinder, cut obliquely at one end; its greatest length is about two and a half inches, its greatest breadth two inches and a quarter; while its depth is about one inch, and its weight is about two ounces. Mr. Faber, from whom I received it, tells me, that on the examination of a quantity of Canton stick rhubarb he found several such pieces.

Most of the pieces are decorticated. These resemble English stick rhubarb in their texture and colour, except that they are, perhaps, somewhat paler. The taste is bitter, and somewhat astringent, but considerably less so than that of good, half-trimmed, Canton Rhubarb. By chewing it, little or no grittiness is perceptible.

This kind of rhubarb is probably obtained from the root-branches of the plant which yields the usual Canton rhubarb.

3. *Himalayan Rhubarb* (*Radix Rhei Himalayanensis*; *Radix Rhei Indici*).—Rhubarb, the produce of the Himalayas, which makes its way through the plains of India, through Kahlsec, Almora, and Butan, is probably, from its usual dark colour and spongy texture, the produce of either or both *R. Emodi* and *R. Webbianum*; the roots of *R. spiciforme* and *R. Moorcroftianum* being lighter coloured and more compact in structure.

I have met with two sorts of Himalayan rhubarb:—

9. *Large Himalayan Rhubarb*; *Rhubarb* from *Rheum Emodi*?—I am indebted to Dr. Wallich for some specimens of this sort of rhubarb. He obtained them from the inhabitants of the Himalayas, who had strung the pieces around the necks of their mules. It has scarcely any resemblance to the officinal rhubarb. The pieces are cylindrical, and are cut obliquely at the extremities; the cortex of the root is not removed; the colour is dark-brown, with a slight tint of yellow; they are without odour, and have a coarse fibrous texture.

In November, 1840, when China rhubarb was very scarce and dear, nineteen chests of Himalayan rhubarb were imported from Calcutta into this country. The chests were of the usual Calcutta kind, made of the hard, heavy, brittle Bengal wood. The weight per chest was gross 1 cwt. 2 qrs. 26 lbs.

The pieces varied considerably in size and shape; some were twisted, cylindrical, furrowed pieces, cut obliquely at the extremities, about four inches long, and an inch and a half in diameter. Others were circular disks, about three inches in diameter, two inches thick, and weighed about four ounces each. Besides these, semicylindrical, angular, and other-shaped pieces were met with, and were obviously obtained by slicing the root. Some of the pieces were decorticated, others were coated. The general colour was dark brown; the prominent decorticated and paler parts having an ochre-brown tint. It had a feeble rhubarb odour, and a bitter astringent taste. When broken, it did not present the marbled texture characteristic of ordinary rhubarb. By chewing it, little or no grittiness was perceived. It was exceedingly light, and worm-eaten.

This was the first shipment of Himalayan rhubarb ever made to this country. Two chests sold at 4d. per lb.; the remainder at 1d. per lb.²

10. *Small Himalayan Rhubarb*; *Rhubarb* from *Rheum Webbianum*.—I am indebted to Dr. Royle for this sort. It is the same as that referred to in the ex-

¹ See a paper by the author in the *Pharmaceutical Journal*, vol. iv. p. 446, 1845.

² Dr. Royle (*Illustr. of the Botany of the Himalayan Mountains*, p. 316) says that the Himalayan rhubarb sells for only one-tenth of the price of the best rhubarb, resembling in quality the Russian, and which is found in India.

periments of Mr. Twining.¹ The pieces are short transverse segments of the root-branches, of a dark brownish colour, odourless, or nearly so, with a very bitter astringent taste, and in quality do not essentially differ from the roots given me by Dr. Wallich.

4. *European Rhubarb* (*Radix Rhei Europæi*).—This is rhubarb cultivated in Europe. The only two sorts with which I am acquainted are the English and French.

11. *English Rhubarb* (*Radix Rhei Anglici*).—This is the produce of *Rheum Rhaponticum*, cultivated in the neighbourhood of Banbury in Oxfordshire.

The history of this rhubarb is not a little curious. It appears that Mr. Wm. Hayward, an apothecary at Banbury, was the original cultivator of rhubarb in that locality. From his own statement² it appears that he began to cultivate it about the year 1777.³ In 1789 he obtained a silver medal, and in 1794 a gold medal, from the Society of Arts, for the cultivation of what he terms "the true Turkey rhubarb;"⁴ the plant for which the Society offered the premium being the "R. palmatum, or true rhubarb."⁵ Mr. Hayward died in 1811, and his plants were purchased by the father of one of the present cultivators.

At present there are three cultivators of Banbury rhubarb; viz. Mr. R. Usher of Overthorpe and Bodicot, Mr. T. Tustian of Milcombe, and Mr. E. Hughes of Neithorp. These parties grow altogether about 12 acres of rhubarb. Only one species is in cultivation, and that I find to be *R. rhaponticum*. I have examined specimens of it sent to me by Mr. Rye, surgeon of Banbury, and to the Pharmaceutical Society by Mr. W. Bigg. Mr. Usher states that no other species was ever cultivated at Banbury; and that he cannot produce English rhubarb from the "Giant rhubarb," or any other sort.⁶

At Banbury, the rhubarb is obtained from roots of three or four years old. They are dug up in October or November, freed from dirt, deprived of their outer coat by a sharp knife, exposed to the sun and air for a few days, and dried on basket-work in drying-houses heated by stove-pipes or brick flues. Mr. Hayward accelerated the curing process by scooping a hole in the largest pieces; and dried both these and the smaller pieces strung on packthread, and hung in a warm room.

The root-stock yields the *trimmed English rhubarb*; the root-branches yield the *cuttings* or *stick English rhubarb*. The produce of the process of trimming is called *raspings*, and serves for powdering.

Trimmed or dressed English rhubarb is the kind frequently observed in the show-bottles of druggists' windows, and was formerly sold in Cheapside and the Poultry for "*Turkey rhubarb*," by persons dressed up as Turks. It occurs in various-sized and shaped pieces, which are trimmed and frequently perforated, so as to represent foreign rhubarb;⁷ some of the pieces are cylindrical in their form, and are evidently segments of cylinders; others are flat. This kind of rhubarb is very light, spongy (especially in the middle of the large flat pieces), attractive of moisture, pasty under the pestle, and has a reddish or pinkish hue not observed in the Asiatic kind. Internally it has usually a marbled appearance; the streaks are pinkish, parallel, and have a radiated disposition; and in the centre of some of the larger pieces the texture is soft and woolly, and may be easily indented by the nail. Its taste is astringent and very mucilaginous; it is not at all, or only very slightly, gritty under the teeth; its odour is feeble, and more unpleasant than either the Russian or East Indian kinds. The microscope discovers in it, for the most part, very few crystals of oxalate of lime.

The *common stick English rhubarb* (called at Banbury the *cuttings*) occurs in angular or roundish pieces, of about five or six inches long, and an inch thick. When fractured it presents the radiated appearance, and the red-coloured streaks, of the kind last mentioned. Its taste is astringent, but very mucilaginous; it is not gritty under the teeth; it breaks very short.

¹ *Trans. Med. and Phys. Soc. of Calcutta*, vol. iii. p. 411.

² *Trans. Society of Arts*, vol. viii. pp. 75 and 76, 1790.

³ The cultivation of rhubarb in Britain was long since recommended by Sir William Fordyce, in a work entitled *The Great Importance and Proper Method of Cultivating and Curing Rhubarb in Britain, for Medical Purposes*, Lond. 1784.

⁴ *Trans. Society Arts*, vol. xii. pp. 225-229, 1794.

⁵ *Ibid.* vols. vii. p. 281, and xi. p. 255.

⁶ For further details see Mr. Bigg's *Answers to Queries* (drawn up by the author), and the author's *Note on Banbury Rhubarb*, in the *Pharmaceutical Journal*, vol. vi. pp. 73, 74, and 76.

⁷ Specimens in the Russian or Dutch style of trimming, in the Chinese or East India style of trimming, and of small trimmed pieces like truncated cones, and fine trimmed Banbury rhubarb, are contained in the museum of the Pharmaceutical Society.

English rhubarb is extensively employed by druggists to adulterate the powder of Asiatic rhubarb.

12. *French rhubarb (Radix Rhei Gallici)*.—This kind of rhubarb is procured from *Rheum Rhaponticum*, *undulatum*, and especially *compactum*.¹ These are cultivated at Rheumpole, a place not far from Lorient, in the department of Morbihan. *Rheum palmatum* is no longer cultivated there. Through the kindness of Professor Guibourt, I possess two kinds of French rhubarb. One of these he calls *flat*, and is probably the produce of *R. rhaponticum*; the other he terms *round*, and is the produce of *R. compactum*.

COMPOSITION.—Few, if any, articles of the materia medica have been so frequently the subject of chemical investigation as rhubarb. Many chemists have submitted it to examination for the purpose of discovering all its proximate principles. Among these, may be mentioned Schrader² in 1807, N. E. Henry³ in 1814, Brande⁴ in 1821, Hornemann⁵ in 1822, Peretti⁶ in 1826, Buehner and Herberger⁷ in 1831, Lucae⁸ in 1833, O. Henry⁹ in 1836, Brandes¹⁰ in 1836, and Schlossberger and Doeppling in 1844.¹¹

But several of the more important chemical examinations of rhubarb have been made with the view chiefly of discovering the one or more active principles of rhubarb. Among these I include the investigations of Trommsdorff,¹² Pfaff,¹³ Nani,¹⁴ Caventou,¹⁵ Carpenter,¹⁶ Dulk,¹⁷ and especially of Schlossberger and Doeppling, before quoted.

One hundred grains of the finest Russian rhubarb, according to Mr. Brande, lost 44.2 grs. by being repeatedly digested in alcohol (sp. gr. 0.815). By evaporation, the alcoholic solution yielded a residue of 36 grains (the loss 8.2 grs. may be ascribed to water), of which 10 grains (resin?) were insoluble in water.

The rhubarb left after the action of alcohol weighed, when dried at 212° F., 55.8 grs. It yielded to water 31 grs. (gum?) The insoluble residue, weighing 24.8 grs., must have consisted of woody fibre, oxalate of lime, &c.

Silica	1.0
Woody fibre	25.0
Water	2.0

Rhubarb 100.0

Schlossberger and Doeppling's Analysis.

(Moscow and Chinese Rhubarb.)

1. Chrysophanic acid.
2. Three resins (*aporetine*, *phaoretine*, and *erythroretine*.)
3. Extractive matter.
4. Tannic acid.
5. Gallic acid.
6. Sugar.
7. Pectine.
8. Oxalate of lime.
9. Ashes (containing potash, soda, silica and sand, traces of sesquioxide of iron, phosphate of lime and magnesia, sulphuric, muriatic (chlorine), phosphoric and carbonic acids.

Rhubarb.

Schlossberger and Doeppling conclude that the flavour, relation to chemical reagents, and therapeutical properties of rhubarb, depend on the conjoint operation of the resin, the colouring matter, and the extractive; modified perhaps in some degree by the other ingredients.

1. **ODOROUS MATTER OF RHUBARB** (*Volatile Oil?*).—In none of the analyses of rhubarb is any mention made of a distinct odorous principle; yet it appears to me that such must exist. As the colour and odour bear no proportion to each other in different kinds of rhubarb, it is tolerably clear, that they cannot depend on one and the same principle. The odorous principle is probably a volatile oil, but it has not hitherto been isolated. A few years since, Dr. Bressy announced to the *Académie de Médecine* that he had separated it, but the committee appointed to repeat his experiments was unable to procure it by his process.¹ Zenneck² says that the rhubarb odour is imitated by a mixture of nitric acid, aloes, and chloride of iron.

2. **YELLOW CRYSTALLINE GRANULAR MATTER OF RHUBARB**. *Chrysophanic Acid* (so called from χρυσός, gold, and φαίνω, I shine); *Rheic Acid*. C¹⁰H⁸O⁸. Found in Russian and Canton rhubarb; in the roots of *Rheum Rhaponticum* and *Rumex obtusifolius*; and in *Parmelia parietina* (see *ante*, p. 69). In the pure or more or less impure state, it has been long known under the names of *rhabarberic acid*, *rheumin*, *rhabarberin*, and *rhein*. It may be procured from rhubarb by means of ether in Robiquet's displacement apparatus.

Pure chrysophanic acid is a beautiful, clear, yellow, odourless, and tasteless substance, which separates in granular masses, and shows little disposition to crystallize. It is tolerably soluble in hot rectified spirit of wine; not very soluble in ether, even when boiling; and almost insoluble in cold water, but more soluble in boiling water. Heated, it evaporates, emits yellow fumes which condense and form yellow flocculi, and at the same time a part becomes carbonized. It dissolves in alkalis, producing a beautiful red colour; if the potash solution be evaporated to dryness, the red colour changes to violet, and then to a beautiful blue. It dissolves in oil of vitriol, forming a beautiful red solution, from which water precipitates yellow flocculi.

3. **RESINS**. According to Schlossberger and Doeppling, rhubarb contains three resins, soluble in alcohol, but insoluble in water.

a. *Aporetine* (from ἀπο, from, and ῥητιν, resin) is a product or deposit of the resin of rhubarb. It is black and shining when dry; slightly soluble in hot spirit, ether, cold and hot water; very soluble in ammonia and potash.

β. *Phaoretine* (from φαίος, red brown, and ῥητιν); *Brown resin* of rhubarb. C¹⁵H⁸O⁷. It is yellowish brown, very slightly soluble in water and ether; very soluble in spirit and its alkalis, and may be thrown down from the latter solution by the mineral acids.

γ. *Erythoretine* (from ἐρυθρός, red, and ῥητιν); *Red resin* of rhubarb. C¹⁹H⁸O⁷. It is yellow, soluble in ether, very soluble in alcohol; forms rich purple combinations with potash and ammonia, which are very soluble in water. To this resin, as well as to chrysophanic acid, rhubarb chiefly owes its colour.

4. **BITTER PRINCIPLE; Extractive?** Rhubarb contains a bitter principle; but most of the substances which have been announced as the bitter principle of rhubarb, under the name of *caphopierite* (? from καφίω, I exhale, and πικρός, bitter), or *rhabarberin*, are themselves compounded of two or more principles. Schlossberger and Doeppling describe the extractive matter of rhubarb as having a bitter taste, but not the flavour of rhubarb.

5. **ASTRINGENT MATTER** (*Tannic and Gallic acids*)—The red veins are the seat of the astringent matter. This is proved by brushing the cut surface of rhubarb with a weak solution of a ferruginous salt; the red veins only undergo a change of colour.

6. **INDIFFERENT SUBSTANCES**.—Rhubarb contains a considerable quantity of starch and pectine or vegetable jelly. The starch consists of small grains, with a very distinct nucleus or lulum, and arranged in groups, each of 2, 3, or more grains. Sugar also may be detected by Trommer's test and fermentation (see *ante*, p. 150). Cellulose and mucilage also are present.

¹ *Dict. des Drog* t. iv. p. 425.

² *Pharm. Central-Blatt für 1832*, S. 237.

7. **OXALATE OF LIME.**—The conglomerate raphides before noticed (see *ante*, p. 426) are crystals of oxalate of lime. They may be separated in great abundance by boiling Russian or China rhubarb in water until the cohesion of the tissue is completely destroyed. When the decomposed tissue is well shaken with water, the crystals fall to the bottom of the vessel. Heated to redness, they are changed into carbonate of lime. A solution of them in diluted nitric acid, or a solution obtained by boiling the crystals with a solution of carbonate of soda, forms, with nitrate of silver, a white precipitate (*oxalate of silver*), which explodes when heated. It has been already stated that the late Mr. Edwin Quekett obtained from 35 to 40 per cent. of oxalate of lime from Russian rhubarb.

8. **RHAPONTICIN.**—A yellow, crystallizable, odourless, tasteless substance, obtained from the root of European (English?) rhubarb. It is insoluble in cold water, ether, and the volatile oils, but soluble in 24 times its weight of boiling water, and twice its weight of absolute alcohol.¹

CHEMICAL CHARACTERISTICS.—If the powder of rhubarb be heated in a glass capsule over a lamp, an odorous yellow vapour (*oil² or resin with chrysophanic acid*) is obtained, which communicates a red colour to a solution of caustic potash. The aqueous infusion of rhubarb is rendered green by the sesquichloride of iron (*tannogallate of iron*); with a solution of gelatin it yields a copious yellow precipitate (*tannate of gelatin*), which is dissolved on the application of heat, or by the addition of an excess of gelatin; with a solution of disulphate of quinia, a yellowish precipitate (*tannate of quinia*); with the alkalis (potash, soda, and ammonia), a red-coloured solution (*soluble alkaline chrysophanates*); with lime-water, a reddish precipitate (*chrysophanate of lime*); with the acids (the acetic excepted), precipitates; and with various metallic solutions (as of acetate of lead, protochloride of tin, protonitrate of mercury, and the nitrate of silver), precipitates (principally *metallic chrysophanates and tannates*).

Distinguishing characteristics of rhubarb and turmeric.—Paper stained by a strong decoction of tincture of rhubarb is not affected by boracic acid, or by the borates rendered acid, whereas turmeric paper is reddened by these agents.² Hence the presence of turmeric in powdered rhubarb may be detected by this means.

Differential characteristics of the commercial sorts of rhubarb.—All the different commercial sorts of rhubarb contain the same constituents, but in different proportions; hence the differential characteristics are founded on relative or comparative differences, not on absolute ones. English rhubarb usually contains a smaller quantity of crystals of oxalate of lime, and a larger quantity of starch. It, therefore, is less gritty between the teeth. In general, a decoction of Russian, Dutch-trimmed, or of China rhubarb, becomes, with a solution of iodine, greenish-blue (*iodide of starch*): after a few minutes the colour disappears, and no iodine can be detected in the liquor by starch, unless nitric acid be previously added. A decoction of English rhubarb, however, is rendered, by a solution of iodine, intensely blue (*iodide of starch*), the colour not completely disappearing by standing. These peculiarities, however, are not constant. Some specimens of Russian rhubarb, however, contain so much starch that they react on iodine, like those of English rhubarb.

PHYSIOLOGICAL EFFECTS. *a. On Animals.*—On the *solipedes* rhubarb acts as a tonic, confining its action principally to the stomach, whose digestive power it augments. On the *carnivora* it operates, in doses of half a drachm, in the same way; but, in doses of several drachms, as a purgative. On the larger *herbivora* it may be given to the extent of several ounces without causing purgation.³ Tiedemann and Gmelin⁴ detected it by its yellow colour in the serum of the blood of the mesenteric, splenic, and portal veins, and in the urine of dogs to which rhubarb had been administered by the mouth. They failed to recognize it in the chyle.

β. On Man.—In small doses (as from four to eight grains) it acts as an astringent tonic, its operation being principally or wholly confined to the digestive organs. In relaxed conditions of these parts it promotes the appetite, assists the digestive process, improves the quality of the alvine secretions, and often restrains diarrhœa. In large doses (as from a scruple to a drachm) it operates, slowly and mildly, as a

⁴ *Versuche ü d. Wege auf welch. Subst. aus d. Magen u. Dormk. gelang.* S. 10-12

purgative, sometimes causing slight griping. It never inflames the mucous membrane of the alimentary canal, as jalap, scammony, colocynth, and some other drastic purgatives are capable of doing. The constipation which follows its cathartic effect has been ascribed to the operation of its astringent matter. In febrile complaints and inflammatory diseases it sometimes accelerates the pulse, and raises the temperature of the body; whence the impropriety of its use in these cases.

Under the use of rhubarb the secretions, especially the urine, become coloured by it. According to Heller, the colour which the urine acquires under the employment of this medicine depends on the acid or alkaline condition of this secretion; if acid, it is yellow; if alkaline, it becomes reddish-yellow or blood-red. From Schlossberger's experiments,¹ it appears that the colour is communicated to the urine by the phæoretine and erythroretine, and not by the chrysophanic acid, which, when pure, neither operates on the bowels nor colours the urine. Urine coloured by rhubarb stains the linen, and is reddened by caustic potash.

The cutaneous secretion (especially of the arm-pits) also becomes coloured under the use of rhubarb. The milk of nurses who have taken it is said to acquire a purgative property.

Rhubarb has for a long period been considered to possess a specific influence over the liver, to promote the secretion of bile, and to be used in jaundice. These opinions, which, as Dr. Cullen² correctly observed, have no foundation either in theory or practice, arose from the absurd doctrine of signatures.

Considered in relation to other medicinal agents, rhubarb holds an intermediate rank between the bitter tonics on the one hand, and the drastics on the other. From the first it is distinguished by its purgative qualities; from the latter, by its tonic operation and the mildness of its evacuant effects. As a purgative, it is perhaps more closely allied to aloes than to any other cathartic in ordinary use; but is distinguished by its much milder operation, and its want of any specific action on the large intestines.

The comparative power of the several kinds of rhubarb has scarcely been ascertained with precision. The remarks above made apply to the Russian and Chinese varieties, whose power is about equal. From experiments made by Dr. Parry, at the Bath Hospital, it appears that the purgative qualities of the English rhubarb are scarcely so strong as those of the Russian and Chinese varieties; but the difference is not great.³ For several years past, English rhubarb has been exclusively employed at the London Hospital; and no complaints have been made respecting its operation. Himalayan rhubarb is, according to Dr. Twining,⁴ almost equal to Russian rhubarb in its purgative effects; but is less aromatic, though more astringent.

USES.—The remedial value of rhubarb depends on the mildness and safety of its operation, and on its tonic and astringent influence over the alimentary canal.

1. *As a purgative.*—There are many cases in which the above-mentioned qualities render rhubarb peculiarly valuable as a purgative. In mild cases of *diarrhœa* it sometimes proves peculiarly efficacious, by first evacuating any irritating matter contained in the bowels, and afterwards acting as an astringent. Given at the commencement of the disease, it is a very popular remedy; and though doubtless it is often employed unnecessarily (since, as Dr. Cullen has justly observed, in many cases no further evacuation is necessary or proper, than what is occasioned by the disease), yet it rarely, if ever, does harm. Sulphate of potash is a very useful adjunct to it, and promotes its purgative operation. Antacids (as chalk or magnesia) are frequently conjoined with it. It is not fitted for inflammatory or febrile cases. As an *infant's purgative* it is deservedly celebrated. It is well adapted for a variety of children's complaints; but is peculiarly adapted to scrofulous subjects, and those afflicted with enlargement of the mesenteric glands, accompanied

¹ *Pharmaceutical Journal*, vol. viii. p. 190, 1848.

² Stephenson and Churchill, *Med. Bot.*

⁴ *Trans. Med. and Phys. Soc. of Calcutta*, vol. iii. p. 441.

³ *Mat. Med.*

with tumid belly and atrophy. Magnesia, sulphate of potash, or calomel may be associated with it, according to circumstances. For an ordinary purgative in habitual costiveness it is scarcely adapted, on account of the constipation which follows its purgative effect.

2. As a stomachic and tonic.—In *dyspepsia*, accompanied with a debilitated condition of the digestive organs, small doses of rhubarb sometimes prove beneficial, by promoting the appetite and assisting the digestive process. In *scrofulous* enlargement of the lymphatic glands, in children, rhubarb, in small doses, is often combined with mercurial alteratives (as the *hydrargyrum cum cretâ*), or with antacids (as magnesia or chalk), and frequently with apparent advantage.

3. As an external application.—Sir Everard Home¹ used it as a topical application to promote the healing of indolent non-painful ulcers. The powder is to be lightly strewed over the ulcer, and a compress applied. In irritable ulcers an eighth part of opium is to be added. When applied to large ulcers it has produced pretty active purging.² The powder of rhubarb, incorporated with saliva and rubbed on the abdomen, proves purgative.³

ADMINISTRATION.—The powder of Russian or China rhubarb may be exhibited, as a stomachic and tonic, in doses of from five to ten grains; as a purgative, from a scruple to a drachm. The dose of indigenous rhubarb should be about twice as much as the above.

“By roasting it with a gentle heat, till it becomes friable [*rheum torrefactum*], its cathartic power is diminished, and its astringency supposed to be increased,” (Lewiss.)

1. INFUSUM RHEI, L. E. D. [U. S.]; *Infusion of Rhubarb*.—(Rhubarb, sliced [in coarse powder, E.], ℥ij [℥j, E.; ℥ij, D.]; Boiling [distilled, L.] Water Oj [℥ix, D.; f℥xviiij, E.]; [Spirit of Cinnamon f℥ij, E.]. Macerate for two [one hour, D.] hours in a lightly-covered vessel, and strain [through linen or calico, E.].—[The product should measure about eight ounces, D.] [The U. S. Pharm. directs Rhubarb, bruised, ℥i; Boiling Water Oss. Digest for two hours in a covered vessel, and strain.] Boiling water extracts from rhubarb chrysophanic acid, resin, tannin, gallic acid, sugar, extractive, and starch. As the liquor cools, it becomes turbid. Infusion of rhubarb is stomachic and gently purgative. It is usually employed as an adjunct to, or vehicle for, other mild purgatives or tonics. The alkalies or magnesia are sometimes conjoined. The stronger acids, and most metallic solutions, are incompatible with it. Dose, f℥j to f℥ij.

2. TINCTURA RHEI, E. [U. S.]; *Tincture of Rhubarb*.—(Rhubarb, in moderately fine powder, ℥ijss [℥ij, U. S.]; Cardamom Seeds, bruised, ℥ss; Proof Spirit [Diluted Alcohol, U. S.] Oij. Mix the rhubarb and cardamom seeds, and proceed by the process of percolation, as directed for tincture of cinchona. This tincture may also be prepared by digestion.)—The alcoholic tincture of rhubarb contains chrysophanic acid, tannin, resin, and uncrystallizable sugar. Cordial, stomachic, and mildly purgative. Dose, as a stomachic, f℥j to f℥ij; as a purgative, f℥ss to f℥j.

3. TINCTURA RHEI COMPOSITA, L. D.; *Compound Tincture of Rhubarb*.—(Rhubarb, sliced, ℥ijss [℥ij, D.]; Liquorice, bruised, ℥vi [℥ss, D.]; Saffron ℥ij [℥ij, D.]; [Ginger, bruised, ℥ij, L.]; Cardamom Seeds ℥i, D.]; Proof Spirit Oij. Macerate for seven [fourteen, D.] days, then express and strain.)—Cordial, stimulant, stomachic, and mildly purgative. A popular remedy in various disordered conditions of the alimentary canal, especially at the commencement of diarrhœa, also in flatulent colic. It is a very useful adjunct to purgative mixtures, in cases in which the use of a cordial and stomachic cathartic is required. Dose, as a stomachic, f℥j to f℥ij; as a purgative, f℥ss to f℥jss.

¹ *Pract. Observ. on the Treatment of Ulcers*, p. 96, 1801.

² Arneemann, *Chirurg. Arzneim.* 6ste Aufl. S. 224.

³ Alibert, *Nouv. Elém. de Thérap.* t. ii. p. 275, et seq. 5me. éd.

4. TINCTURA RHEI ET ALOES, E. [U. S.]; *Tincture of Rhubarb and Aloes*.—(Rhubarb, in moderately fine powder, ℥iiss; Socotrine or East Indian Aloes, in moderately fine powder, ℥vj; Cardamom Seeds, bruised, ℥v; Proof Spirit Oij. Mix the powders, and proceed as for the tincture of cinchona.)—[The *U. S. Pharm.* directs Rhubarb, bruised, ℥x; Aloes, in powder, ℥vi; Cardamom, bruised, ℥ss; Diluted Alcohol Oij. Macerate for fourteen days, express, and filter through paper.] A cordial and stomachic purgative, in doses of from f℥ss to f℥j.

5. TINCTURA RHEI ET GENTIANÆ, E. [U. S.]; *Tincture of Rhubarb and Gentian*.—(Rhubarb, in moderately fine powder, ℥ij; Gentian, finely cut or in coarse powder, ℥ss; Proof Spirit [Diluted Alcohol, *U. S.*] Oij. Mix the powders, and proceed as directed for tincture of cinchona.)—Stomachic, tonic, and feebly purgative. Dose, as a tonic, f℥j to f℥iij; as a very mild purgative, f℥ss to f℥j.

6. VINUM RHEI, E. D. [U. S.]; *Wine of Rhubarb*.—(Rhubarb, in coarse powder, ℥v [℥iij, *D.*]; Canella, in coarse powder, ℥ij [Proof Spirit f℥v, *E.*]; Sherry Oj and f℥xv [Oij, *D.*]. Digest for seven days, strain, express strongly the residuum, and filter the liquors.)—[Rhubarb, bruised, ℥ij; Canella, bruised, ℥j; Diluted Alcohol f℥ij; Wine Oj. Macerate for fourteen days, with occasional agitation, then express and filter through paper, *U. S.*]—Cordial, stomachic, and mildly purgative. Used in the same cases as the *compound tincture of rhubarb*. Dose, as a stomachic, f℥j to f℥iij; as a purgative, f℥ss to f℥j.

7. EXTRACTUM RHEI, L. E. D. [U. S.]; *Extract of Rhubarb*.—(Rhubarb, powdered, ℥xv; Proof Spirit Oj; Distilled Water Ovij. Macerate for four days with a gentle heat, afterwards strain, and set by, that the dregs may subside. Pour off the liquor, and evaporate it, when strained to a proper consistence, *L.*—The process of the *Edinburgh* and *Dublin Colleges* is as follows: Take of Rhubarb ℥bj; Water Ov. Cut the rhubarb into small fragments; macerate it for twenty-four hours in three pints of the water, filter the liquor through a cloth, and express it with the hands or otherwise moderately; macerate the residuum with the rest of the water for twelve hours at least; filter the liquor with the same cloth as before, and express the residuum strongly. The liquors, filtered again, if necessary, are then to be evaporated together to a proper consistence in a vapour-bath. The extract, however, is obtained of finer quality by evaporation in a vacuum with a gentle heat.)—[The *U. S. Pharm.* directs Rhubarb, in coarse powder, ℥j; Diluted Alcohol a sufficient quantity. Mix the Rhubarb with an equal bulk of coarse sand, moisten it thoroughly with Diluted Alcohol, and having allowed it to stand for twenty-four hours, put it into a percolator, and add Diluted Alcohol gradually until four pints of filtered liquor are obtained; then, by means of a water-bath, evaporate to the proper consistence.]

The *Edinburgh* and *Dublin Colleges*, it will be observed, employ no spirit in the above process. Great care is required in the preparation of this extract, as both the purgative and tonic properties of rhubarb are very apt to become deteriorated by the process. I have some extract prepared *in vacuo* more than twenty years ago, which still preserves the proper odour and flavour of rhubarb. The dose of extract of rhubarb, as a purgative, is from grs. x to ℥ss.

[8. EXTRACTUM RHEI FLUIDUM, U. S.; *Fluid Extract of Rhubarb*.—(Take of Rhubarb, in coarse powder, ℥vij; Sugar ℥v; Tincture of Ginger ℥ss; Oil of Fennel, Oil of Anise, each m̄iv; Diluted Alcohol a sufficient quantity. To the Rhubarb, previously mixed with an equal bulk of coarse sand, add twelve fluidounces of Diluted Alcohol, and allow the mixture to stand for twenty-four hours. Transfer the mass to a percolator, and gradually pour upon it Diluted Alcohol until the liquid which passes has little of the odour or taste of the rhubarb. Evaporate the tincture thus obtained, by means of a water-bath, to five fluidounces; then add the sugar, and after it is dissolved, mix thoroughly with the resulting fluid extract, the tincture of ginger holding the oils in solution.)—This is an excellent and efficient preparation

in doses of ℥j—ij. It may be given to children in small doses. By addition to magnesia it constitutes an effective combination.]

9. PILULÆ RHEI, E. [U. S.]; *Rhubarb Pills*.—(Rhubarb, in fine powder, nine parts; Acetate of Potash one part; Conserve of Red Roses five parts. Beat them into a proper mass, and divide it into five-grain pills.)—[Rhubarb, powdered, ℥vj; Soap ℥ij. Make a mass with water, and divide into 120 pills. The soap renders them antacid, U. S.]—Stomachic and purgative. The acetate of potash is employed, I presume, to prevent the pills becoming hard by keeping. Each pill contains nearly three and a half grains of rhubarb.

10. PILULA RHEI COMPOSITÆ, L. E. [U. S.]; *Pilulæ Rhei Compositæ*, D.; *Compound Pills of Rhubarb*.—(Rhubarb, powdered, ℥iv [twelve parts, E.]; Aloes, powdered, ℥ij [nine parts, E.]; Myrrh, powdered, ℥ij [six parts, E.]; Soap ℥ss [six parts, E.]; [Oil of Caraway ℥xv, L., Oil of Peppermint one part, E.]; Treacle, q. s. [Conserve of Red Roses five parts, E.]. Mix them, and beat them into a proper mass [and divide this into five-grain pills. [The U. S. Pharm. directs Rhubarb, in powder, ℥i; Aloes, in powder, ℥vj; Myrrh, in powder, ℥ss; Oil of Peppermint ℥ss. Beat them with water so as to form a mass, to be divided into two hundred and forty pills.] This pill may be also made without oil of peppermint, when so preferred, E. The Dublin College orders of Rhubarb, in fine powder, ℥iiss; Hepatic Aloes, in fine powder, ℥ix; Myrrh, in fine powder, Castile Soap, of each, ℥vi; Oil of Peppermint ℥zi; Treacle, by weight, ℥ij.]—Tonic and mildly purgative. Dose, ℞j, or two to four pills.

11. PILULÆ RHEI ET FERRI, E.; *Pills of Rhubarb and Iron*.—(Dried Sulphate of Iron four parts; Extract of Rhubarb ten parts; Conserve of Red Roses about five parts. Beat them into a proper pill mass, and divide into five-grain pills.)—Tonic. Dose, two to four pills.

12. PULVIS RHEI COMPOSITUS, E. D.; *Compound Powder of Rhubarb*.—(Magnesia, lbj [℥vi, D.]; Ginger, in fine powder, ℥ij [℥i, D.]; Rhubarb, in fine powder, ℥iv [℥ij, D.]. Mix them thoroughly, and preserve the powder in well-closed bottles.)—A very useful antacid and mild stomachic purgative, especially adapted for children. Dose, for adults, ℞j to ℥ss; for children, gr. v to gr. x.

[13. SYRUPUS RHEI, U. S.; *Syrup of Rhubarb*.—(Take of Rhubarb, bruised, two ounces; Boiling Water a pint; Sugar two pounds. Macerate the rhubarb in the water for twenty-four hours and strain; then add the sugar, and proceed in the manner directed for syrup.)—This is a mild astringent and laxative, and may be used in bowel affections. The dose is from ℥j to ℥ij.

14. SYRUPUS RHEI AROMATICUS, U. S.; *Aromatic Syrup of Rhubarb; Spiced Syrup of Rhubarb*.—(Take of Rhubarb, bruised, two ounces and a half; Cloves, bruised, Cinnamon, bruised, each half an ounce; Nutmeg, bruised, two drachms; Diluted Alcohol two pints; Syrup six pints. Macerate the rhubarb and aromatics in the diluted alcohol for fourteen days, and strain; then, by means of a water-bath, evaporate the liquor to a pint, and, while it is still hot, mix it with the syrup previously heated; or it may be made by displacement.)—This syrup is cordial, carminative, and slightly laxative. It is well adapted to weak and relaxed conditions of the bowels, as in chronic diarrhœa, dysentery, and infantile bowel complaints, with feeble action. The dose is ℥j to ℥jss.]

151. RUMEX ACETOSA, Linn.—COMMON SORREL.

Sex. Syst. Hexandria, Trigynia.
(Folia.)

HISTORY.—Dioscorides¹ mentions this as the fourth sort (τέταρτον εἶδος) of λάπαθον, which some call ὄζαλις.

¹ Lib. ii. cap. 140.

BOTANY. *Gen. Char.*—*Sepals* 6, the 3 inner (petals) larger, subsequently becoming enlarged (enlarged or permanent petals), converging, and finally concealing the nut. *Stamens* 6. *Stigmas* in many fine tufted segments. *Embryo* lateral.

Sp. Char.—*Leaves* oblong, sagittate or hastate, veiny. *Flowers* diceious. *Inner sepals* (petals) roundish, cordate, with a very minute tubercle at the base.

Hab.—Indigenous. Woods and pastures common. Perennial. Flowers in June.

DESCRIPTION.—Sorrel leaves have an agreeable, acid, slightly astringent taste.

COMPOSITION.—I am unacquainted with any analysis of this plant. The leaves are composed of *superoxalate of potash, tartaric acid, mucilage, fecula, chlorophylle, tannic acid, and woody fibre.*

PHYSIOLOGICAL EFFECTS.—Slightly nutritive. Refrigerant and diuretic. Esteemed antiscorbutic.

USES.—Employed as a pot-herb and salad—from the latter use of it, it has been termed *green-sauce*.¹ Rarely applied medicinally. A decoction of the leaves may be administered in whey, as a cooling and pleasant drink, in febrile and inflammatory diseases. In some parts of Scandinavia bread is made of it in times of scarcity.² But the use of aliments containing oxalic acid may, as suggested by Laugier, under some circumstances, dispose to the formation of mulberry calculi.

152. RUMEX HYDROLAPATHUM, *Hudson.*—GREAT WATER DOCK.

Rumex aquaticus, D.

Sex. Syst. Hexandria, Trigynia.

(Radix.)

HISTORY.—This is not the *R. aquaticus* of Linnæus.

BOTANY. *Gen. Char.*—See *Rumex Acetosa*.

Sp. Char.—*Inner sepals* (petals) ovate-triangular, entire or slightly toothed, all tubercled. *Racemes* panicle, leafless. *Leaves* lanceolate, narrowed at the base; petiole flat on the upper side.—Stem 3—5 feet high. Leaves often more than a foot long.

Hab.—Indigenous. Ditches and river sides. Perennial. Flowers in July and August.

DESCRIPTION.—The herb and root were formerly used under the name of *herba et radix britannicæ*. The root is inodorous, but has an acrid bitter taste. The flowers are called, by Pliny,³ *vibones*.

COMPOSITION.—I am unacquainted with any analysis of the plant. The root contains *tannic acid*.

PHYSIOLOGICAL EFFECTS.—The root is astringent, and is reputed antiscorbutic.

USES.—Scarcely employed. Has been exhibited internally in scurvy, skin diseases, and rheumatism. The powdered root has been used as a dentifrice; the decoction of the root as an astringent gargle for ulcerated or spongy gums. The druids entertained a superstitious veneration for this plant.

153. POLYGONUM BISTORTA, *Linn.*—GREAT BISTORT OR SNAKE-WEED.

Sex. Syst. Octandria, Trigynia.

(Radix)

HISTORY.—It is doubtful by whom this plant is first mentioned. It was certainly noticed by the herbalists of the 16th century.

¹ Withering, *Bot.* vol. ii.

² Clarke, *Travels in Scandinavia*, Part III. S. ii. p. 90, 1823.

³ *Hist. Nat.* lib. xxv. cap. vi. ed. Valp.

BOTANY. Gen. Char.—*Calyx* 4—5-cleft, more or less coloured. *Stamens* 5—8, in 2 rows, generally with glands at the base. *Styles* 2—3, more or less united at the base. *Nut* 1-seeded, lenticular or 3-cornered, inclosed by the calyx. *Embryo* lateral, incurved; cotyledons not contorted.

Sp. Char.—*Stem* simple. *Leaves* oblong-ovate, somewhat cordate and wavy; petioles winged. *Spike* dense, terminal.—*Flowers* flesh-coloured. *Stem* 1—1½ foot high.

Hab.—Indigenous. Meadows. Perennial. Flowers in June.

DESCRIPTION.—Bistort root (*radix bistortæ*) is twice bent on itself—hence its name, from *bis*, twice; and *torta*, twisted or bent. It is rugous and brown externally; reddish internally; almost inodorous; it has an austere, strongly astringent taste.

COMPOSITION.—This root has not been analyzed. The principal constituents are *tannic acid*, *starch*, *oxalate of lime*, *colouring matter*, and *woody fibre*.

PHYSIOLOGICAL EFFECTS.—The local effect is that of a powerful astringent, depending on the tannic acid which it contains; its remote effects are those of a tonic (see vol. i. p. 243). The presence of starch renders the root nutritive—hence in Siberia it is roasted and eaten.

USES.—It is but little employed. A decoction of the root is sometimes employed as an astringent injection in leucorrhœa and gleet; as a gargle in spongy gums and relaxed sore-throat; and as a lotion to ulcers attended with a profuse discharge.

Internally it has been employed, in combination with gentian, in intermittents. It has also been used as an astringent in passive hemorrhages and chronic alvine fluxes.

ADMINISTRATION.—The dose of the powder is from ℥j to ℥ss. The *decoction* (prepared by boiling ℥ij of the root in Ojss of boiling water) may be administered in doses of from fʒj to fʒij.

ORDER XXXIX. SALSOLACEÆ, *Moquin.*—SALTWORTS.

ATRIPLICES, Jussieu.—*CHENOPODEÆ, R. Brown.*—*CHENOPODIACEÆ, Lindl.*

CHARACTERS.—*Calyx* deeply divided, persistent, with an imbricated æstivation. *Corolla* 0. *Stamens* usually inserted into the receptacle or base of the calyx, opposite the segments of the latter, and equal to them in number or fewer. *Staminodia* (squamulæ hypogynæ) in a few genera, very minute, alternate between the filaments and with the segments of the calyx. *Ovary* single, superior, or occasionally adhering to the tube of the calyx, with a single amphitropical ovule attached to the base of the cavity; *style* in 2 or 4 divisions, rarely simple; *stigmas* undivided. *Fruit* membranous, utriculate, sometimes a caryopsis, rarely a berry. *Seed* with or without farinaceous albumen; *embryo* curved or annular (*cyclobœæ*), or in a flat spiral (*spirolobœæ*).—*Herbs* or *under-shrubs* sometimes jointed. *Leaves* usually alternate, without stipules. *Flowers* very small, regular, hermaphrodite or sometimes by abortion unisexual. (From Lindley chiefly.)

PROPERTIES.—The plants of this family are characterized by the large quantity of alkali which they contain, and which is combined with an organic acid. Those which inhabit salt marshes are called *halophytes* (from ἅλς, salt, and φυτόν, a plant), and by combustion yield *barilla* (see vol. i. p. 514). Those in most common use for this purpose belong to the genera *Salsola*, *Salicornia*, and *Chenopodium*.

Many of the plants are esulent, and some of them are used as pot-herbs or salads; as spinach (*Spinacia oleracea*) and beet (*Beta vulgaris*). The latter is extensively cultivated and employed as a source of sugar; and a variety of it, called Mangold-Wurzel, is used for feeding cattle. The seeds of *Chenopodium Quinoa* are employed in Peru as food, under the name of *petty rice*; their starch grains are the smallest known.

Volatile oil is found in several, which owe their aromatic, carminative, stimulant, and anthelmintic properties to it.

[154. *Chenopodium Anthelminticum*, *Linnaeus*.*Sex. Syst.* Pentandria, Digynia.

(CHENOPODIUM, U. S. Wormseed. The fruit of the plant.)

Gen. Char.—*Calyx* five-parted, with five angles. *Corolla* none. *Style* bifid, rarely trifid. *Seed* one, lenticular, horizontal, covered by the closing calyx. (*Nuttall*.)

Sp. Char.—*Leaves* oblong, lanceolate, sinuate, and dentate, rugose. *Racemes* naked. *Style* one, three-cleft (*Elliot*).

The common names by which this plant is known in the United States are Jerusalem Oak, Wormseed, Goosefoot, and Stinkweed.

DESCRIPTION.—The root of the plant is perennial and branched. Stem upright, herbaceous, much branched, deeply grooved, from two to four feet high. Branches fastigiate, giving to the plant a shrubby appearance. Leaves sessile, scattered, and alternate, attenuate at each end, with strongly marked nervures, oval or oblong, deeply sinuate, studded beneath with small globular, oleaginous dots. Flowers small, numerous, of a yellowish-green colour, and collected in long, axillary, dense, leafless spikes.

Hab.—This species of *Chenopodium* is found in most parts of the United States. It grows in old fields, along roadsides, in moist and sandy situations. It flowers in June and July; and from August until cold weather the seeds may be collected.

The seeds are small, not larger than the head of a common-sized pin, irregularly spherical, very light, of a dull greenish-yellow colour, approaching to brown, and having a bitterish, somewhat aromatic, pungent taste. The odour and taste are due to the volatile oil that they contain; this is found in other parts; in fact, the whole plant contains it, and hence the uniform flavour possessed by them.

The properties of the seeds are vermifuge, which appears to have been known soon after the establishment of the British Colonies in America, especially in Virginia, where they were first used for this purpose. The herb is spoken of by Schoepf and Kalm, with others, in terms of commendation. The vermifuge power, by long trial, has been decidedly proved. As an antispasmodic it has also been used. Plenck employed it with success in five or six cases of chorea (*Griffith, On Chen. Anthel. in Am. Journ. of Pharmacy*, vol. v. p. 180), and this success has been confirmed by other writers.

The *Chenopodium anthelminticum* has sometimes been confounded with the *C. ambrosioides*, which is a smaller plant, and distinguished by the leafy spikes of flowers. The sensible properties are similar.

The seeds are given in the form of an electuary, pulverized and mixed with molasses or syrup; but the quantity required to be taken is liable to produce nausea and sickness. Dose ℥j to ℥ij given twice or thrice daily.

The expressed juice is sometimes administered; the dose is ℥ss; or a decoction of the leaves may be employed; this is best prepared with milk, in the proportion of ℥j leaves to Oj of milk or water. It may be flavoured with aromatics.

OLEUM CHENOPODII, U. S.; Oil of Wormseed.—This oil is of a light yellow colour when distilled, but its colour deepens by age and exposure. It has in a high degree the flavour of the plant. Its sp. gr. is 0.908. It is obtained by distilling the seeds; but the whole plant may be used for this purpose, as the oil is abundant in the glands. Sometimes it is adulterated with spirit of turpentine, or other inferior volatile oils; this must be determined by the odour. From the readiness with which it may be given, it is the best for exhibition, as it possesses the vermifuge properties in the smallest possible compass. The dose is from 10 to 20 drops on a lump of sugar, or in emulsion. After several doses have been given, a purgative, as castor-oil, may be interposed.—J. C.]

155. *Chenopodium Vulvaria*, *Lin.*—Stinking Orache.

Sex. Syst. Pentandria, Digynia.

(Herba.)

Chenopodium olidum, Smith, Eng. Flora. *Atriplex fatida*, Cullen, Mat. Med. vol. ii. p. 365. *Stinking Goosefoot*. Indigenous. Cultivated at Mitcham. Sold in the herb-shops as a popular emmenagogue and "strengtheners of the womb." In the fresh state it has a nauseous taste, and a strong offensive odour like that of putrid fish. By drying, it loses its smell, and probably its medicinal qualities also. Dr. Houlton and Mr. Churchill¹ declare that the popular notion of its emmenagogue powers is well founded. Dr. Cullen regarded it as a powerful anti-spasmodic in hysteria. The recent plant has been used in the form of infusion or tea, and conserve. Mr. Churchill gave the inspissated juice or extract in doses of from five to fifteen grains.

CHENOPodium AMBROSIOIDES, *Lin.*, is said to be used indiscriminately with the preceding. Its odour is weaker and less offensive.

CHENOPodium BOTRYS, *Lin.*, is also esteemed anthelmintic.

SUBDIVISION II. COROLLIFLORÆ, *De Cand.*MONOPETALÆ COROLLA HYPOGYNA, *Juss.*, ET COROLLA PERIGYNA (partim).GAMOPETALÆ, *Endl.* (partim).

Calyx gamosepalous, i. e. *sepals more or less united at the base. Petals mostly united, distinct at the base from the calyx. Stamens usually adnate to the corolla. Ovary mostly free, rarely adnate to the calyx.*

ORDER XL. LABIATÆ, *Jussieu*.—LABIATES.LAMIACEÆ, *Lindley*.

CHARACTERS.—*Calyx* tubular, inferior, persistent, the odd tooth being next the axis; regular 5- or 10-toothed, or irregular bilabiate or 3- to 10-toothed. *Corolla* monopetalous, hypogynous, bilabiate; the upper lip undivided or bifid, overlapping the lower, which is larger and 3-lobed. *Stamens* 4, didynamous, inserted upon the corolla, alternately with the lobes of the lower lip, the 2 upper sometimes wanting; anthers 2-celled; sometimes apparently unilocular in consequence of the confluence of the cells at the apex; sometimes one cell altogether obsolete, or the 2 cells separated by a bifurcation of the connective. *Ovary* deeply 4-lobed, seated in a fleshy hypogynous disk; the lobes each containing 1 erect ovule; *style* 1, proceeding from the base of the lobes of the ovary; *stigma* bifid, usually acute. *Fruit*, 1 to 4 small nuts, inclosed within the persistent calyx. *Seeds* erect, with little or no albumen; *embryo* erect; *cotyledons* flat. *Herbaceous* plants or *undershrubs*. *Stem* 4-cornered, with opposite ramifications. *Leaves* opposite, divided or undivided, without stipules, replete with receptacles of aromatic oil. *Flowers* in opposite, nearly sessile, axillary cymes, resembling whorls; sometimes solitary, or as if capitate (*Lindley*).

Fig. 305.

Bilabiate flower.

PROPERTIES.—The medicinal activity of the plants of this family depends on volatile oil, bitter extractive, and astringent matter.

The *volatile oil* resides in small receptacles (by some called *globular glands*) contained in the leaves. "These glands are placed quite superficially, or rather in depressed points, and are commonly of a shining yellow colour. We may regard them as oleo-resinous matter separated from glands lying on the under surface. When macerated in strong spirit of wine they remain unchanged, and appear under the microscope as transparent, probably cellular, vesicles, filled with a yellow granular matter."²

The *bitter extractive* is found, in a greater or less quantity, in all the Labiatæ. It is this principle which communicates the bitterness to the watery infusion of these plants.

The presence of *astringent matter* is shown by the green colour produced when a ferruginous salt is added to the infusion of some of the Labiatæ.

The *volatile oil* gives to these plants aromatic, carminative, and slightly stimulant properties. The bitter extractive renders them tonic and stomachic. The astringent matter is usually in

¹ Stephenson and Churchill's *Medical Botany*, vol. iv. pl. clxxvi. 1831.

² Nees and Ebermaier, *Handb. Med.-Pharm. Bot.* Th. i. S. 524.

too small a quantity to communicate much medicinal activity, though it must contribute to the tonic operation.

The perfumer uses some labiate plants on account of their fragrant odour; the cook employs others for their flavour and condimentary properties; the medical practitioner administers them to relieve nausea and colicky pains, to expel wind, to cover the taste of nauseous medicines, and to prevent or relieve griping pains.

The following species, enumerated by London,¹ are cultivated in this country as *sweet herbs*: Common or Garden Thyme (*Thymus vulgaris*, Linn.), Lemon Thyme (*T. citriodorus*, Schreb.), Sage (*Salvia officinalis*, Linn.), Clary (*S. Sclarea*, Linn.), Peppermint (*Mentha piperita*, Linn.), Spearmint (*M. viridis*, Linn.), Pennyroyal (*M. Pulegium*), Common Marjoram (*Origanum vulgare*, Linn.), Winter Sweet Marjoram (*O. heracleoticum*, Linn.), Sweet Marjoram (*Majorana hortensis*, Mœnel.), Pot Marjoram (*M. Onites*, Benth.), Winter Savory (*Satureja montana*, Linn.), Summer Savory (*S. hortensis*, Linn.), Sweet or Larger Basil (*Ocimum Basilicum*, Linn.), Bush or Least Basil (*O. minimum*, Linn.), Rosemary (*Rosmarinus officinalis*, Linn.), and Garden Lavender (*Lavandula vera*, De Cand.). Some of these species have been, or are, used in medicine, and several of them are officinal.

Besides the labiate plants contained in the British pharmacopœias and to be noticed, a considerable number of other species have been at different times introduced into medicinal use. Some of these are deficient in volatile oil, but abound in a bitter principle, on which account they have been employed as stomachics and tonics; such are Water Germander (*Teucrium Scordium*, Linn.), Wall Germander (*T. Chamædrys*, Linn.), and Ground Pine (*Ajuga Chamæpitys*, Smith); the two last of which have been used, as I have before mentioned, as anti-arthritic remedies (see *ante*, p. 387). Others abound in essential oil and are consequently more aromatic, stimulant, and carminative; such are Cat-Thyme (*Teucrium Marum*, Linn.), Common Hyssop (*Hyssopus officinalis*, Linn.), Dittany of Crete (*Amaracus Dictamnus*, Benth.), &c. *Teucrium Polium* has been used in diarrhœa, dysentery, and cholera.

TRIBE I. OCIMOIDEÆ, Benth.

Stamens bent downwards.

156. LAVANDULA VERA, De Cand.—COMMON OR GARDEN LAVENDER.

Lavandula angustifolia, Ehrenberg. *L. spica*, var. α , Linn.

Scr. Syst. Didynamia, Gymnospermia.

(Oleum e flore destillatum, *L. D.*—The flowering heads; and volatile oil of ditto, *E.* The flowers, *D.*)

HISTORY.—No plant is mentioned, under the name of Lavender, by Hippocrates, Theophrastus, Dioscorides, or Pliny. It is not improbable, however, that lavender may be alluded to, under some other name, by one or more of these authors; but it is impossible now to identify it with any certainty. Sprengel² declares, on the authority of Hesychius, that the *ἰφρον* of Theophrastus³ is *Lavandula Spica*. The *στειχάς* or *στοιχάς* of Dioscorides,⁴ the *stachas* of Pliny,⁵ is the *L. stachas*, Linn.

BOTANY. *Gen. Char.*—*Calyx* ovate-tubular, nearly equal, 13 or rarely 15-ribbed, shortly 5-toothed, with the 4 lower teeth nearly equal, or the 2 lower narrower; the upper either but little broader than the lateral ones, or expanded into a dilated appendage. *Corolla* with the tube exerted, the throat somewhat dilated, the limb oblique and bilabiate; upper lip 2-lobed; lower 3-lobed; all the divisions nearly equal. *Stamens* 4, inclosed in the tube of the corolla, bent downwards. *Filaments* smooth, distinct, not toothed. *Style* shortly bifid at the apex; the lobes complanate, subconnate. *Disk* concave, with 4 fleshy scales at the margin. *Nuts* smooth, adnate to the scales of the disk (Bentham).

Sp. Char.—*Leaves* oblong-linear or lanceolate, quite entire, when young hoary and revolute at the edges. *Spikes* interrupted. *Whorls* of 6 to 10 flowers. *Floral leaves* rhomboid-ovate, acuminate, membranous, all fertile, the uppermost

¹ *Encycl. of Gardening.*

² *Hist. Plant.* lib. vi. cap. 6.

³ *Hist. Nat.* lib. xxvii. cap. 107.

⁴ *Hist. Rei Herb.* t. i. p. 96.

⁵ *Lib.* iii. cap. 31.

shorter than the calyx. *Bracts* scarcely any (Bentham).—An *undershrub* 1 to 2 feet high. *Flowers* purplish-gray.

Hab.—South of Europe. Extensively cultivated at Mitcham, in Surrey, from which place the London market is chiefly supplied.

LAVENDULA SPICA, De Cand. (*L. latifolia*, Villars) or *French Lavender*, formerly considered as a variety only of the preceding species, is not used in medicine. It is distinguished by its lower habit, white colour, the leaves more congested at the base of the branches, the spike denser and shorter, the floral leaves lanceolate or linear, and the presence of bracts (Bentham). It yields by distillation *oil of spike* (*oleum spicæ*) sometimes called *foreign oil of lavender*, or, in order to distinguish it from the oil of *Lavandula Stachas*, the *true oil of spike* (*oleum spica verum*). This oil is distinguished from the genuine oil of *Lavandula vera* by its darker green colour, and its less grateful odour. It is used by painters on porcelain, and by artists in the preparation of varnishes.

PROPERTIES.—*Lavender flowers* (*flores lavandulæ*) have a bluish-gray colour, a pleasant odour, and a pungent bitter taste. The flowering stems are collected in June or July, dried in the shade, and made up into bundles for sale. A cold infusion of the flowers is deepened in colour (*tannate of iron*) by sesquichloride of iron.

COMPOSITION.—The principal constituents of the flowers are *volatile oil*, *resin* (?), *tannic acid*, a *bitter principle*, and *woody fibre*.

PHYSIOLOGICAL EFFECTS.—The flowers are carminative, mildly stimulant, and somewhat tonic. Kraus¹ says that when taken internally they cause griping.

USES.—Lavender flowers are sometimes employed as errhines. They enter into the composition of the *pulvis asari compositus* (see *ante*, p. 387).

1. **OLEUM LAVANDULÆ**, E. D. [U. S.]; *Oleum Lavandulæ* (*Anglicum*), L.; *Oleum Lavandulæ veræ*; *English Oil of Lavender*, offic.—(Prepared by submitting lavender flowers to distillation with water.)—It has a pale yellow colour, a hot taste, and a very fragrant odour. Its sp. gr. varies from 0.877 to 0.905; the lightest oil being the purest. It boils at 397° F.; and is composed, according to Dr. Kane, of C¹⁵H¹⁴O². 1 lb. of oil is obtained from 50 to 70 lbs. of the flowers. 1973 lbs. of the flowers carefully separated from the stalks, yielded Mr. Jacob Bell² at 13 distillations, 28½ lbs. of oil; or 1 lb. of oil from 69½ lbs. of flowers. When the stalks and leaves are distilled with the flowers, the odour of the oil is considerably deteriorated.³ It is a stimulant and stomachic, and is sometimes given in hysteria and headache; but is more commonly employed as a perfume for scenting evaporating lotions, ointments, liniments, &c.—Dose, gtt. ij to gtt. v.

2. **SPIRITUS LAVANDULÆ**, E. [U. S.]; *Spirit of Lavender*.—(Fresh Lavender ßijss; Rectified Spirit Cong. j. Mix them, and, with the heat of a vapour-bath, distil over seven pints. The dried flowers may be substituted for the fresh ones. Druggists frequently prepare this compound by dissolving a few drops of oil of lavender in a fluidounce of rectified spirit. Employed only in the preparation of the *Spiritus Lavandulæ composita*, E.

LAVENDER WATER.—The fragrant perfume sold in the shops, under the name of *lavender water* (*aqua lavandulæ*) is a solution of the oil of lavender and of other odoriferous substances in spirit. It is in fact, therefore, a *compound spirit of lavender*; but this name is already appropriated to another preparation. There are various formulæ for its preparation, scarcely two manufacturers adopting precisely the same one. The following yields a most excellent product: Oil of Lavender, Oil of Bergamot, aa. ℥ij; Otto of Roses, Oil of Cloves, aa. gutt. vj; Musk gr. ij; Oil of Rosemary ℥j; Honey ℥j; Benzoic Acid ℥ij; Rectified Spirit Oj; Distilled Water ℥ij. Mix, and after standing a sufficient time (the longer the better), filter. This agreeable perfume may be employed for scenting spirit-washes, &c., but is principally consumed for the toilet.

3. **TINCTURA LAVANDULÆ COMPOSITA**, L. D.; *Spiritus Lavandulæ compositus*, E. [U. S.]; *Lavender Drops* or *Red Lavender Drops*, offic.—(Oil of Lavender ℥jss [℥jij, D.]; Oil of Rosemary ℥x [℥j, D.]; Cinnamon, bruised, ℥ijss [℥j, D.]; Nut-

² *Pharm. Journal*, vol. v. iii. p. 276, 1842.

meg, bruised, ʒijss [ʒss, *D.*]; [Red Sanders Wood, eut, ʒv, *L.*; Cochineal, in powder, of each ʒij, *D.*]; Rectified Spirit Oij. Macerate the cinnamon, nutmeg, and red sanders wood in the spirit for seven [fourteen, *D.*] days; then express, filter, and to the filtered liquor add the oils, *L.*—Spirit of Lavender Oij; Spirit of Rosemary fʒxij; Cinnamon, in coarse powder, ʒj; Cloves, bruised, ʒij; Nutmeg, bruised, ʒss; Red Sandal Wood, in shavings, ʒijj. Macerate for seven days, and strain the liquor through calico, *E.*)—[The *U. S. Pharm.* directs Spirit of Lavender Oij; Spirit of Rosemary Oj; Cinnamon, bruised, ʒi; Cloves, bruised, ʒij; Nutmeg, bruised, ʒss; Red Sanders, rasped, ʒijj. Macerate for fourteen days and filter through paper.]—Stimulant, cordial, and stomachic. Employed to relieve gastric uneasiness, flatulence, low spirits, languor, faintness, &c. A favourite remedy with hysterical and hypochondriacal persons.—Dose, from fʒss to fʒij, administered in water or on sugar. The red Sanders wood is merely a colouring ingredient.

TRIBE II. SATURIEÆ, *Benth.*

Stamens distant, straight, straggling, or converging under the upper lip, 4 or 2 (in that case the anthers 2-celled and the connective not filiform). Lobes of the *corolla* flat.

157. *Pogostemon Patchouli*, *Pellet.*—Pucha-Pat, or Patchouli.

Sex. Syst. Didynamia, Gymnospermia.
(Herba.)

Patchouly, Virey, Journ. de Pharm. t. xii. p. 61, 1826.—*Puchá Pát*, Wallich, Trans. Med. and Phys. Soc. of Calcutta, 1835.—*Pogostemon intermedius*, Benth., in Wall. Cat. n. 2327.—*Patchouli* or *Puchá Pát*, Pereira, Pharm. Journ. vol. iv. p. 80, 1844.—*Pogostemon Patchouly*, Pelletier-Santelet, in Mém. de la Soc. Roy. des Sc. d'Orl. tom. v. p. 274, 1845 cum Ic.; also Pharm. Journ. vol. viii. p. 574; Benth. in De Cand. Prodr. t. xii. p. 153.—*Pogostemon saavis*, Tenore.—*Pogostemon Patchouli*, Hooker, Journ. of Bot. and Kew Gard. Miscell. vol. i. p. 329 c. Ic.

A pubescent undershrub. Branches vague, decumbent or ascending. Leaves with stalks, opposite, rhomboid-ovate, somewhat obtuse; the lobes crenato-dentate. Spikes terminal and axillary, dense, pedunculated, interrupted at the base. Bracts ovate. Calyx hirsute, twice as long as the bracts, with lanceolate teeth. Corolla bilabiate, smooth and whitish. Stamens 4, didynamous, nearly equal in length; the filaments bearded with violet or bluish purple hairs; the anthers pale yellow, after flowering whitish. Style pale purplish, whitish at the lower part, at the apex deeply cleft. Ovaries 4, distinct.—A native of Silhet, Penang, and the Malayan peninsula.

The wild plant is collected at Penang and the Malayan peninsula, and dried in the sun. If too much dried, it becomes crisp and brittle, and is liable to crumble to dust in packing.

The dried tops (*summitates patchouli*) are imported into England in boxes of 110 lbs. each, and in half boxes. They are a foot or more in length. The large stems are round and woody, and, when cut transversely, show the pith surrounded with a thick layer of wood, which is remarkable for its distinct medullary rays; the smaller branches are obscurely 4-angled. The leaves are covered, especially on their inferior surface, with a soft pallid pubescence, which gives the plant a grayish appearance. The odour is strong, persistent, peculiar, and somewhat analogous to that of *Chenopodium anthelminticum*. It is said to smell more strongly in dry than in damp places. One writer describes the smell of it as being dry, mouldy, or earthy; and states that the Chinese or Indian ink owes its characteristic odour to it. The taste of the dried plant is very slight.

The plant, which has not been analyzed, contains *volatile oil*, *green resin*, *extractive matter*, and *tannin*. By distillation it yields about 2 per cent. of volatile oil (*essential oil of patchouli*), which possesses the odour of the herb.

Patchouli is almost exclusively used as a perfume. To its excessive employment, ill effects have been ascribed. "Very recently," says a French writer,¹ "a young lady was seized with a passion for patchouli. Her linen, her dresses, and her furniture, were saturated with it. In a short time she lost her appetite and sleep; her complexion got pale, and she became subject to nervous attacks."² In India, patchouli is used as an ingredient in tobacco for smoking. The *sachets de patchouli* of the perfumers consist of a few grains of the coarsely-powdered herb mixed with cotton wool and folded in paper. Placed in drawers, they are said to drive away

¹ *Annuaire de Thérapeutique pour 1847*, p. 75.

² For some remarks on the sensitiveness of some female constitutions to odorous emanations, see *ante*, vol. i. p. 66.

insects from linen, shawls, &c. Oil of patchouli is in common use in India for imparting the peculiar fragrance of the leaf to clothes among the superior classes of natives. *Essence de patchouli* is used by perfumers principally for mixing with other scents in the preparation of compounded perfumes, for which purpose it is considered very useful.

158. MENTHA VIRIDIS, Linn.—SPEARMINT.

Sez. Syst. Didynamia, Gymnospermia.

(Herba florens recens et exsiccata. Oleum ex herba florente destillatum, L.—Herb, E. D.)

HISTORY.—See *Mentha piperita*.

BOTANY. **Gen. Char.**—*Calyx* campanulate or tubular, 5-toothed, equal or somewhat 2-lipped, with the throat naked inside, or villous. *Corolla* with the tube inclosed, the limb campanulate, nearly equal, 4-lobed; the upper segment broader, nearly entire or emarginate. *Stamens* 4, equal, erect, distinct; *filaments* smooth, naked; *anthers* with two parallel cells. *Style* shortly bifid, with the lobes bearing stigmas at the points. *Nucules* dry, smooth (Bentham).

Sp. Char.—*Stem* erect, smooth. *Leaves* subsessile, ovate-lanceolate, unequally serrated, smooth; those under the flowers all bract-like, rather longer than the whorls; those last and the calyxes hairy or smooth. *Spikes* cylindrical, loose. *Whorls* approximated, or the lowest or all of them distant. *Teeth of the calyx* linear subulate (Bentham).—Creeping-rooted.

Var. β. angustifolia, Bentham. Leaves of the branches with short petioles. Distinguished from *M. piperita* by the slender elongated spikes.

Var. γ. crispa, Bentham. *Curled Mint*. Cultivated in gardens.

Hab.—Marshy places. Indigenous. A native of the milder parts of Europe; also of Africa and America. Perennial. Flowers in August. Selected for medicinal use when about to flower.

PROPERTIES.—The whole herb, called *green-mint* or *spearmint* (*herba menthæ viridis*), is employed in medicine. It has a strong but peculiar odour, and an aromatic, bitter taste, followed by a sense of coldness when air is drawn into the mouth. Sesquichloride of iron communicates a green colour (*tannate of iron*) to the cold watery infusion.

COMPOSITION.—Its odour and aromatic qualities depend on *volatile oil*. It also contains *tannic acid*, *resin* (?), a *bitter principle*, and *woody fibre*.

PHYSIOLOGICAL EFFECTS.—Aromatic, carminative, mildly stimulant and tonic. Feebler than Peppermint. Said, though without sufficient foundation, to check the secretion of milk, and to act as an emmenagogue.¹

USES.—Employed as a salad and sweet herb. In medicine, it is principally used as a flavouring ingredient, and to alleviate or prevent colicky pains. The following are its officinal preparations, with their uses:—

1. **INFUSUM MENTHÆ VIRIDIS**, D.; *Infusion of Spearmint*; *Spearmint Tea*.—(Spearmint, dried and cut small, ℥iij; Boiling Water Oss.)—Stomachic and carminative. Used in irritable conditions of the stomach; but is ordinarily a vehicle for other remedies. Dose, fʒj to fʒij, or *ad libitum*.

2. **OLEUM MENTHÆ VIRIDIS**, L. E. D. [U. S.]; *Oil of Spearmint*.—(Obtained by submitting the fresh herb to distillation with water.)—It is of a pale yellowish colour, but becomes reddish by age. It has the odour and taste of the plant, and is lighter than water; sp. gr. 0.914. It boils at 320° F.; and is composed, according to Dr. Kane, of C³⁵H²⁶O. The average produce of the essential oil is not more than 1-500th of the fresh herb.² It is carminative and stimulant. Dose, gr. ij to gtt. v, rubbed with sugar and a little water.

3. **SPIRITUS MENTHÆ VIRIDIS**, L.; *Spirit of Spearmint*.—(Oil of Spearmint ℥ij; Proof Spirit Cong. j. Dissolve.) Dose, fʒss to fʒij.—This preparation has no

¹ Linnæus, in Murray's *App. Med.* vol. ii. pp. 150—1.

² Brande, *Dict. Mat. Med.* p. 325.

advantages over, while it is much weaker than, the more simple and elegant preparation, the *essence of spearmint* of the shops.

4. *ESSENTIA MENTHÆ VIRIDIS*, D.; *Essence of Spearmint*.—(Oil of Spearmint f̄ij; Stronger Spirit f̄ix. Mix with agitation.)—It may be coloured green by spearmint or spinach leaves. Dose, gtt. x to gtt. xx, taken on sugar or in water. [This is the same as the *Tinctura Olei Menthæ Viridis* (*U. S. Pharm.*), for which the formula is, Oil of Spearmint f̄ij; Alcohol Oj. Dissolve the oil in the alcohol.]

5. *AQUA MENTHÆ VIRIDIS*, L. E. D. [U. S.]; *Spearmint Water*.—(Spearmint, dried, lbij; Water Oij. Let a gallon distil. If the fresh herb be used, double the weight is to be employed. (The *Edinburgh* process is the same, except that f̄ijij of Rectified Spirit is also used.) Or, Oil of Spearmint f̄ij; Powdered Flint ʒij; Distilled Water Cong. j. First diligently rub the oil with the flint, afterwards with the water, and strain the liquor, *L.*—Essence of Spearmint f̄ij; Distilled Water Cong. ss. Mix with agitation, and filter through paper, *D.*)—Spearmint water is usually made extemporaneously by suspending or dissolving a drachm of the oil in four pints of distilled water, by means of a drachm of rectified spirit and a lump of sugar [or by means of carbonate of magnesia, *U. S.*] (see vol. i. p. 304). Spearmint water is carminative and stomachic. It is commonly used as a vehicle for other medicines. Its dose is f̄ij to f̄ijij.

159. MENTHA PIPERITA, Linn.—PEPPERMINT.

Sex. Syst. Didynamia, Gymnospermia.

(Herba florens et exsiccata. Oleum ex herba florente destillatum, *L.*—Herb; Volatile oil, *E.*—The herb, *D.*)

HISTORY.—The ancient Greeks¹ employed in medicine a plant which they called *Μίνθος*, or *Μίνθη*, and which, on account of its very agreeable odour, was also termed *ἡδύσμον*, or the *sweet-smelling herb*. It was probably a species of *Mentha*; and, according to Fraas,² was the *M. piperita*, Linn.; the *ἡδύσμον πεπερωδες* of the modern Greek Pharmacopœia.

Peppermint came into use in England in the last century; at least Hill,³ in 1751, says that it “has lately got into great esteem;” and Geiger⁴ says it was introduced into Germany as a medicine, through the recommendations of the English, in the latter half of the last century.

BOTANY. *Gen. Char.*—See *Mentha viridis*.

Sp. Char.—*Stem* smooth. *Leaves* petiolated, ovate-oblong, acute, serrate, rounded-crenate at the base, smooth. *Spikes* lax, obtuse, short, interrupted at the base. *Pedicels* and *calyxes* at the base smooth; teeth hispid (Bentham).—Creeping-rooted.

Var. β. *sub hirsuta*, Bentham; *M. hirsuta* δ, Smith. The nerves of the under surface of the leaves, as well as the petioles, hairy.

Hab.—Watery places. Indigenously. Extensively cultivated at Mitcham, in Surrey, from whence the London market is principally supplied. Found in various parts of Europe; also in Asia, Africa, and America.

PROPERTIES.—The whole herb (*herba menthæ piperitæ*) is officinal. It has a peculiar aromatic odour, and a warm, burning, bitter taste, followed by a sensation of coolness when air is drawn into the mouth. Sesquichloride of iron communicates a green colour (*tannate of iron*) to the cold infusion of peppermint.

COMPOSITION.—The principal constituents are *volatile oil*, *resin?* a *bitter principle*, *tannic acid*, and *woody fibre*.

PHYSIOLOGICAL EFFECTS.—Peppermint is an aromatic or carminative, stimulant, and stomachic. It is the most agreeable and powerful of all the mints.

¹ Hippocrates, *De victus rat.* lib. ii. p. 359, ed. Fœs.; Dioscorides, lib. iii. cap. 36.

² *Synop. Plant. Fl. Classicæ*, 1845.

³ *Handb. d. Pharm.* Bd. iii. S. 1230.

⁴ *Hist. of the Mat. Med.* p. 358.

USES.—It is employed in medicine for several purposes, but principally to expel flatus, to cover the unpleasant taste of other medicines, to relieve nausea, griping pain, and the flatulent colic of children. The following are the officinal preparations, with their uses:—

1. OLEUM MENTHÆ PIPERITÆ, L. E. D.; *Oil of Peppermint*.—(Obtained by submitting the fresh herb to distillation with water.)—It is colourless, or nearly so, sometimes having a pale yellow or greenish tint, and becoming reddish by age. It has a penetrating odour like that of the plant, and a burning aromatic taste, followed by a sensation of cold. The vapour of it applied to the eye causes a feeling of coldness.

Oil of peppermint consists of two isomeric oils—one liquid, the other solid; the latter is called *peppermint-camphor*, or the stearoptene of oil of peppermint. Its composition is $C^{20}H^{26}O^2$. It is in colourless prisms, which have the odour and taste of peppermint, are almost insoluble in water, but readily soluble in alcohol and ether, and are fusible at $92^{\circ} F$. Under the influence of phosphoric acid, peppermint-camphor loses $2HO$, and becomes a colourless liquid oil, called *menthene* $C^{20}H^{18}$.

I have met with three varieties of oil of peppermint:—

a. English Oil of Peppermint.—This is the finest sort. Its sp. gr. is 0.902. It is obtained at Mitcham. In a warm, dry, and favourable season, the produce of oil, from a given quantity of the fresh herb, is double that which it yields in a wet and cold season. The largest produce is three drachms and a half of oil from two pounds of fresh peppermint, and the smallest about a drachm and a half from the same quantity.¹ I was informed by a distiller at Mitcham, that twenty mats of the herb (each mat containing about 1 cwt) yields about seven lbs of oil.

β. American Oil of Peppermint.—In odour and flavour it is inferior to the preceding sort. It is said to be prepared from the dried plant gathered when in flower (Brande). It yields a considerable quantity of camphor.

γ. China Oil of Peppermint.—*Po ho-yo*.—For a sample of this I am indebted to Dr. Christison. It comes from Canton. It consists chiefly of peppermint-camphor, and forms a white crystalline solid even in summer.

Oil of peppermint is said to be adulterated with oil of rosemary;² the odour would probably serve to distinguish the fraud.

Oil of peppermint is carminative and stimulant, and is used occasionally as an antispasmodic. It is taken on sugar, in doses of from gtt. ii to gtt. v.

2. SPIRITUS MENTHÆ PIPERITÆ, L.; *Spiritus Menthæ*, E.; *Spirit of Peppermint*.—(Prepared with the Oil of Peppermint, in the same way as the *Spiritus Mentha viridis*, L., before described. The *Edinburgh College* prepares it thus: Peppermint, fresh, ℥iiss; Proof Spirit Ovij. Macerate for two days in a covered vessel; add a pint and a half of water, and distil off seven pints.)—A solution of the oil of peppermint may with great propriety be substituted for the preparation of the Pharmacopœias. The spirit of peppermint is given in doses of from ℥ss to ℥ij.

3. ESSENTIA MENTHÆ PIPERITÆ, D.; *Essence of Peppermint*.—(Oil of Peppermint ℥i; Stronger Spirit ℥ix. Mix with agitation.)—[This is the *Tr. Olei Menthae Piperitæ*, U. S. The Formula as for Tincture of Oil of Spearmint.] Some persons add peppermint or spinach leaves to communicate a green colour. The dose of this essence is from gtt. xx to gtt. xxx, on sugar.

4. AQUA MENTHÆ PIPERITÆ, L. E. D.—(Prepared with the herb or the oil of peppermint, in the same way as the *Aqua Menthae viridis*.)—Carminative and stimulant. Used to relieve flatulency, and as a vehicle for other medicines. Dose, ℥i, to ℥iij.

Besides the above, there are several popular preparations of peppermint extensively used.

a. Infusum Menthae piperitæ (*Peppermint Tea*) is prepared in the same way as spearmint tea.

β. Elæosaccharum Menthae piperitæ, Ph. Bor., is prepared by mixing ℥j of the whitest sugar, in powder, with gtt. xxiv of the oil of peppermint.

γ. Rotulæ Menthae piperitæ (in plano convex masses, called *peppermint drops*—in flattened cir-

¹ Brande, *Dict. of Mat. Med.* p. 356.

² *Pharmaceutical Journal*, vol. i. p. 263, 1841.

cular disks, termed *peppermint lozenges*) should consist of sugar and oil of peppermint only, though flour is sometimes introduced.

The *liqueur* sold at the spirit-shops as *mint* or *peppermint* is used as a cordial.

160. MENTHA PULEGIUM, Linn.—PENNYROYAL.

Sex. Syst. Didynamia, Gymnospermia.

(Herba florens recens et exsiccata. Oleum ex herba florente destillatum, L.—Herb, E. D.)

HISTORY—This plant was employed in medicine by the ancient Greeks and Romans. It is the $\Gamma\lambda\chi\omega\nu$ of Hippocrates¹ and Dioscorides,² and the *Pulegium* of Pliny.³

BOTANY. **Gen. Char.**—See *Mentha viridis*.

Sp. Char.—*Stem* very much branched, prostrate. *Leaves* petiolated, ovate. *Whorls* all remote, globose, many-flowered. *Calyxes* hispid, bilabiate, villous in the inside of the throat (Bentham).—Creeping-rooted.

Hab.—Wet commons and margins of brooks. Indigenous. A native of most parts of Europe, of the Caucasus, Chili, and Teneriffe.

PROPERTIES.—The herb with the flowers (*herba seu summitates pulegii*) is employed in medicine. It has a strong, but peculiar odour; a hot, aromatic, bitter taste, followed by a feeling of coolness in the mouth. Sesquichloride of iron causes a green colour (*tannate of iron*) with the cold infusion of pennyroyal.

COMPOSITION.—Its principal constituents are *volatile oil, a bitter matter, resin?* *tannic acid, and woody fibre.*

PHYSIOLOGICAL EFFECTS.—Its effects are analogous to the other mints. Emmenagogue and antispasmodic properties are ascribed to it by the public, and formerly by medical practitioners.

USES.—A popular remedy for obstructed menstruation, hysterical complaints, and hooping-cough. Rarely employed by the professional man. The following are its official preparations, with their uses:—

1. **OLEUM MENTHÆ PULEGII, L. E. D.**; *Oleum Pulegii*, offic.; *Oil of Pennyroyal*.—(Obtained by submitting the herb to distillation with water.)—It has a pale colour, a warm taste, and the peculiar odour of the herb. It boils at 395° F. Its sp. gr. is 0.925; and is composed, according to Dr. Kane, of C¹⁰H⁸O. The fresh herb yields from 1-120th to 1-100th of its weight of oil.⁴ It is stimulant and carminative, and is used, as an antispasmodic and emmenagogue, in doses of from gtt. ij to gtt. v, taken on sugar.

2. **SPIRITUS MENTHÆ PULEGII, L.**; *Spiritus Pulegii*; *Spirit of Pennyroyal*.—(Prepared with Oil of Pennyroyal, as the *Spiritus Menthæ viridis*.)—Usually prepared by dissolving the oil in spirit. Stimulant and carminative. Employed as an antispasmodic and carminative. Dose, fʒss to fʒij.

3. **ESSENTIA MENTHÆ PULEGII, D.**; *Essence of Pennyroyal*.—(Oil of Pennyroyal fʒj; Rectified Spirit fʒix. Mix with agitation, D.)—May be given in doses of from gtt. x to gtt. xx.

4. **AQUA MENTHÆ PULEGII, L. E. D.**; *Aqua Pulegii*, offic.; *Pennyroyal Water*.—(Prepared with the herb or oil, like *Aqua Menthæ viridis*.)—Carminative and stomachic. Dose, fʒj to fʒiij.

The liquid sold in the shops as **PENNYROYAL AND HYSTERIC WATER** is prepared by adding fʒss of the *compound spirit of bryony* to Oss of pennyroyal water.

161. ORIGANUM VULGARE, Linn.—COMMON OR WILD MARJORAM.

Sex. Syst. Didynamia, Gymnospermia.
(Herb, E.—Oleum ex herba.)

HISTORY.—Fraas¹ is of opinion that this plant is the *ὀρίγανον μέλαν* of Theophrastus,² the *ἀγρορίγανος* of Dioscorides.³

BOTANY. **Gen. Char.**—*Calyx* ovate-campanulate, nearly 13-nerved, 5-toothed or 2-lipped, the upper lip entire or 3-toothed, the inferior lip 2-toothed, truncated, or altogether deficient, the calyx being then obcompressed-flat. Tube of the *corolla* inclosed or exerted, the upper lip emarginate or slightly 2-cleft, the lower lip longer, spreading, 3-cleft. *Stamens* 4, ascending or straggling at the apex, or distant at the base; anthers with 6 distinct diverging or straggling cells. Lobes of the *style* acute, the posterior one usually shorter. *Floral leaves* bract-like. *Flowers* in spikes (Bentham).

Sp. Char.—Erect, villous. *Leaves* petiolate, broad-ovate, obtuse, subserrate, broad-rounded at the base, green on both sides. *Spikes* oblong or cylindrical, clustered in corymbose panicles. *Bracts* (floral leaves) ovate, obtuse, coloured, (commonly glandless), half as long again as the calyx (Bentham).—Creeping-rooted. *Flowers* light purple.

Hab.—In bushy places, on a limestone and gravelly soil. Indigenous. A native of several parts of Europe; also of Asia. Flowers in July and August.

PROPERTIES.—The whole herb (*herba origani*) is officinal. It has a peculiar aromatic odour, and a warm pungent taste. Sesquichloride of iron produces a green colour (*tannate of iron*) with the cold infusion of origanum.

COMPOSITION.—*Volatile oil, resin? tannic acid, a bitter principle, and woody fibre,* are the principal constituents of this plant.

PHYSIOLOGICAL EFFECTS.—Stimulant and carminative, like the other labiate plants.

USES.—Principally employed to yield the volatile oil. The dried leaves have been used as a substitute for China tea.⁴ The infusion of origanum has been used in chronic cough, asthma, and amenorrhœa.

OLEUM ORIGANI, E. [U. S.]; *Oil of Common Marjoram.*—(Obtained by submitting the herb to distillation with common water.)—The average produce of essential oil from the herb is one pound from two hundred weight; but it varies exceedingly with the season and culture of the plant.⁵ According to Dr. Kane, its sp. gr. is 0.867, its boiling point 354° F.; and its composition C⁵⁰H⁴⁰O.

It is a powerful aerid and stimulant; and is applied to carious teeth by means of lint or cotton, to relieve toothache. Mixed with olive oil, it is frequently employed as a stimulating liniment against alopecia or baldness, rheumatic or paralytic affections, sprains, bruises, &c.

The red volatile oil, usually sold in the shops as *oleum origani* or *oil of thyme*, is obtained from *Thymus vulgaris*, and is imported from the south of France (see *Thymus vulgaris*).

162. ORIGANUM MAJORANA, Linn.—SWEET OR KNOTTED MARJORAM.

Majorana hortensis, Manch.
Sex. Syst. Didynamia, Gymnospermia.
(Herba.)

HISTORY.—Fraas⁶ is of opinion that the *ἀμάκον* of Theophrastus,⁷ the *σάμψυκος*

¹ *Synops. Plant. Fl. Classicæ, 1845.*

² *Lib. iii. cap. 34.*

⁷ *Hist. Plant. Fl. Class. p. 153, 154.*

of Dioscorides,¹ and the *Amaracum* or *Sampsuchum* of Pliny,² are identical with our sweet marjoram.

BOTANY. *Gen. Char.*—See *ante*, p. 448.

Sp. Char.—*Branches* smoothish, racemose-paniculate. *Leaves* petiolate, oblong-ovate, obtuse, quite entire, on both sides hoary-tomentose. *Spikelets* oblong, on sessile crowded branchlets. *Calyx* nearly toothless, cleft anteriorly (Bentham).—*Flowers* purple or white.

Hab.—Africa and Asia. Cultivated in kitchen gardens.

PROPERTIES.—The whole plant (*herba majoranæ*) has a warm aromatic flavour, and a peculiar savoury smell. Its watery infusion is deepened in colour (*tannate of iron*) by sesquichloride of iron.

COMPOSITION.—By distillation the plant yields *volatile oil*. The other constituents are *tannic acid*, *resin?* *bitter matter*, and *woody fibre*.

OIL OF SWEET MARJORAM (*Oleum Majoranæ*) is pale yellow or brownish, with the strong odour and taste of marjoram.

PHYSIOLOGICAL EFFECTS.—Tonic and mild stimulant.

USES.—Principally employed as a sweet herb by the cook. Its powder is sometimes used, either alone or mixed with some other powder, as an errhine. *Marjoram tea* is occasionally employed as a popular remedy for nervous complaints.

163. THYMUS VULGARIS, Linn.—COMMON OR GARDEN THYME.

Sex. Syst. Didynamia, Gymnospermia.
(Herba et Oleum.)

HISTORY.—The true Thyme, Θύμος of the ancients, is the *Thymus capitatus*, Hoffm. et Link. (*Satureia capitata*, Linn.)

BOTANY. *Gen. Char.*—*Calyx* ovate, 10—13-nerved, 2-lipped; upper lip 3-toothed, spreading; lower lip 2-cleft, with ciliate, subulate segments; throat villous inside. *Corolla* having the tube inclosed by the calyx or imbricated bracts, naked inside; limb sub-bilabiate; upper lip straight, emarginate, flattish; lower lip spreading, 3-cleft, with equal lobes, or the middle one largest. *Stamens* exserted, or rarely inclosed, straight, distant, nearly equal or didynamous, the lower 2 being the longest. *Anthers* with 2 parallel or at length diverging cells. *Style* about equally bifid at the apex, with subulate lobes (Bentham).

Sp. Char.—Erect or procumbent at the base. *Leaves* sessile, linear, or ovate-lanceolate, acute, with revolute edges, fasciated in the axils. *Bracts* (floral leaves) lanceolate, obtuse. *Whorls* loose, rather distant. *Teeth* of the upper lip of the *calyx* lanceolate; the segments of the lower lip subulate ciliated (Bentham).—Shrub much branched, $\frac{1}{2}$ to 1 foot high, rather hoary with a short down. *Flowers* purplish.

Var. a. latifolius; Broad-leaved Garden Thyme.—Cultivated in gardens for culinary purposes.

Var. b. angustifolius; Narrow-leaved Garden Thyme.

A variegated variety is cultivated for ornament. Lemon Thyme, which is cultivated for culinary purposes, is *T. Serpyllum*, var. *vulgaris*, Bentham.

Hab.—South-West of Europe, in dry, arid, uncultivated places. Cultivated as a sweet herb in England.

DESCRIPTION.—The flowering-tops of garden thyme (*herba et summitates thymi*) are dried, and sold in the shops as one of the herbs used for culinary purposes. The odour is fragrant, and to most persons agreeable.

COMPOSITION.—Similar to that of *Origanum vulgare*. The odour and condimentary properties depend on volatile oil (*oleum thymi*).

EFFECTS AND USES.—Similar to the other sweet herbs. Chiefly used by the

¹ Lib. iii. cap. 47.

² *Hist. Nat.* lib. xxi. cap. 35, ed. Valp.

cook for soups, stuffings, and sauces. In the South of France the herb is used for distillation, to yield the oil of thyme.

OLEUM THYMI; *Oil of Thyme*.—At Milhau, Aujargues, Souvignargues, and near the village of Fontanes, as well as at several other places in the neighbourhood of Nismes, in the department of Gard in the South of France, this oil is largely distilled, and is imported into England and sold as *oleum origani*. Mr. Daniel Hanbury, who visited this district in the summer of 1849, tells me that the plant grows spontaneously in abundance on the arid, rocky, waste hills of that neighbourhood. The entire plants, whether in flower or not, are collected, and, either in the fresh or dried state, submitted to distillation with water. The oil, which is of a reddish-brown colour, is called *red oil of thyme* (*huile rouge de thym*), becomes much paler by redistillation, and is then called *white oil of thyme* (*huile blanche de thym*). The specimen of red oil of thyme obtained by Mr. D. Hanbury is identical with the oil sold as *oleum origani* in the London shops, all of which is imported.¹ Specimens of the plant which yields the oil have been examined by Mr. Bentham, Dr. Lindley, and others; and by all have been pronounced undoubtedly *Thymus vulgaris*.

The medicinal properties and uses of oil of thyme are the same as those of the *oleum origani*, for which it is usually employed (see *ante*, p. 448).

164. MELISSA OFFICINALIS, Linn.—COMMON BALM.

Sex. Syst. Didynamia, Gymnospermia.
(Herba, E.)

HISTORY.—Both Smith² and Sprengel³ consider this plant to be the *μελισσόφυλλον* or *μελίττανα* of Dioscorides;⁴ but Fraas⁵ is of opinion that the *Melissa altissima* is the species referred to by Dioscorides.

BOTANY. **Gen. Char.**—*Calyx* tubular-campanulate, 13-ribbed, 2-lipped, the upper lip nearly flat, 3-toothed, the inferior lip bifid, the throat naked within. Tube of the *corolla* recurved-ascending, enlarged from above, naked within, limb 2-lipped, upper lip emarginate erect, lower ones spreading, 3-cleft, the lobes flat, the middle one entire or emarginate. *Stamens* 4, arched-converging; cells of the anthers at length straggling. Lobes of the *style* nearly equal, subulate. *Nucules* dry, smooth (Bentham).

Sp. Char.—Erect, branching. *Leaves* broad-ovate, crenate, truncate or cordate at the base; the floral ones nearly similar to the cauline ones. *Whorls* axillary, loose, 1-sided. *Braets* (floral leaves) few, ovate. *Corolla* longer by half than the calyx (Bentham).

Hab.—South of France.

PROPERTIES.—The fresh herb (*herba melissæ*) has a strong, peculiar odour, which is somewhat similar to that of lemons. By drying, this is, for the most part, lost. The taste is aromatic, bitter, and somewhat austere. Sesquichloride of iron gives a greenish colour (*tannate of iron*) to the cold infusion.

COMPOSITION.—The principal constituents of balm are *volatile oil*, *resin*, *bitter matter*, *gum*, *tannic acid*, and *woolly fibre*.⁶

OIL OF BALM (*Oleum Melissæ*) is pale yellow, and has the peculiar odour of balm. Its sp. gr. is 0.975. Oil of lemon is said to be frequently substituted for it.

PHYSIOLOGICAL EFFECTS.—The effects of balm are similar to, though milder than, those of the labiate plants already described. The mildness of its operation arises from the small quantity of volatile oil which the plant contains.

¹ The price at which the oil is sold by M. Sagnier, and other exporters at Nismes, is so low as to preclude its distillation in England.

² *Flora Græca Prodromus*, vol. i. p. 423, 1806.

³ *Lib. iii. cap. 118.*

⁴ Pfaff, *Mat. Med.* Bd. iv. S. 270.

⁵ *Hist. Rei Herb.* t. i. p. 100.

⁶ *Synopsis Plantarum Fl. Classicæ*, p. 182, 1845.

USES.—*Balm tea* is sometimes employed as a diaphoretic in fevers, as an exhilarating drink in hypochondriasis, and as an emmenagogue in amenorrhœa and chlorosis.

TRIBE III. MONARDEÆ, *Benth.*

Stamens 2, straight or ascending; cells of the anthers oblong-linear, or solitary, or separated by the filiform connective (very rarely approximate in *Perowskia*).

165. ROSMARINUS OFFICINALIS, *Linn.*—COMMON ROSEMARY.

Sex. Syst. Diandria, Monogynia.

(*Oleum e cacumine florente destillatum, L.*—*Tops, E. D.*)

HISTORY.—The *Λιβανωτίς στεφανωματική*, or *Libanotis coronaria* of Dioscorides,¹ is supposed to be our officinal rosemary, which received its name, *Λιβανωτίς* (from *Λιβανός, Thus*), on account of its odour, and *στεφανωματική* (*στεφανωματικός, coronarius*), from its use in making garlands.² Pliny³ calls it *Rosmarinum*. The flowers are termed *anthos* (from *ἄθος, a flower*), signifying they are *the flowers* par excellence; just as we call cinchona *the bark*, and the inspissated juice of the poppy, *opium* (i. e. *the juice*).

BOTANY. *Gen. Char.*—*Calyx* ovate-campanulate, 2-lipped; the upper lip entire, the lower bifid, the throat naked within. *Corolla* with a protruding tube, smooth and not ringed in the inside, somewhat inflated in the throat; limb 2-lipped; lips nearly equal, the upper one erect and emarginate, the lower spreading, trifid, with the lateral lobes oblong, erect, somewhat twisted; the middle lobe very large, concave, and hanging down. No rudiments of the superior *stamina*; fertile (inferior) ones, 2, ascending, protruding; *filaments* inserted in the throat of the corolla, shortly-toothed near the base; *anthers* linear, subbilocular; the cells straggling, confluent, connate at the margin. Upper lobe of the *style* very short. *Nucules* dry, smooth (Bentham).

Sp. Char.—The only species.—*Leaves* sessile, linear, revolute at the edge, hoary beneath. *Calyx* purplish. *Corolla* white or pale purplish-blue.

Hab.—South of Europe; also Asia Minor.

PROPERTIES.—The flowering-tops (*cacumina rosmarini*) are the officinal parts. They have a strong and remarkable odour, and a warm bitter taste.

COMPOSITION.—The peculiar odour and flavour of this plant depend on *volatile oil*. Besides this, the tops contain *tannic acid*, a *bitter matter*, *resin?* and *woody fibre*.

PHYSIOLOGICAL EFFECTS.—Carminative and mildly stimulant, analogous to the other labiate plants.

USES.—Rarely employed medicinally. *Infusion of Rosemary* (*rosemary tea*) is sometimes used as a substitute for ordinary tea by hypochondriacal persons. The admired flavour of Narbonne honey depends on the bees collecting this substance from rosemary plants, which abound in the neighbourhood of Narbonne: hence sprigs of rosemary are sometimes added to the honey of other places, in order to imitate the flavour of Narbonne honey.

1. OLEUM ROSMARINI, *L. E. D.* [*U. S.*]; *Oleum Anthos*, offic.; *Oil of Rosemary*.—(Prepared by submitting the rosemary tops to distillation with water.)—This oil was first procured by Raymond Lully.⁴ It is transparent and colourless, with the odour of rosemary, and a hot, aromatic taste. Its sp. gr. is 0.897; and it boils at 365° F. It consists, according to Dr. Kane, of C⁴⁵H³⁸O². One pound of the fresh herb yields about one drachm of the oil.⁵ It is rarely taken internally, but

¹ Lib. iii. cap. 89.

² *Hist. Nat.* lib. xix. cap. 62, ed. Valp.

³ Brande, *Dict. of Mat. Med.* p. 460.

⁴ The Arabian name signifies "royal crown."

⁵ Thomson's *Hist. of Chem.* vol. i. p. 41.

is not unfrequently used externally, in conjunction with other substances, as a stimulating liniment; for example, in alopecia, or baldness, and also as a perfume. Dose, gtt. ij to gtt. v.

2. SPIRITUS ROSMARINI, L. E. D. [U. S.]; *Spirit of Rosemary*.—(Oil of Rosemary ℥ij; Rectified Spirit Cong. j. Dissolve, *L.*—The *Edinburgh College* submits the tops, ℔ijss, to distillation with a gallon of Rectified Spirit, so as to obtain seven pints of the distilled spirit.)—It is usually prepared merely by dissolving the oil in spirit, distillation being superfluous. Seldom employed internally. Its principal use is as an odoriferous adjunct to lotions and liniments. It is a constituent of the *Limentum Saponis* (see vol. i. p. 552), and *Tinctura Lavandulæ composita* (see *ante*, p. 442).

3. ESSENTIA ROSMARINI, D.; *Essence of Rosemary*.—(Oil of Rosemary f̄j; Rectified Spirit f̄ix. Mix with agitation.)—Its uses are the same as those of the spirit just noticed.

4. AQUA HUNGARICA; *Aqua Rosmarini seu Anthos composita; Hungary Water*.—Various formulæ for the preparation of this perfume have been given. The following is from the *Pharm. Wurtem. and Bavar.*: Take of fresh Rosemary, in blossom, ℔iv; fresh Sage, in blossom, ℥vj; Zingiber ℥ij. Cut into pieces, and add Rectified Spirit ℔xij; Common Water Oij. Let eleven pints distil by a gentle heat. A hermit is said to have given the formula for the preparation of this perfume to a queen of Hungary; whence this water has been called the *Queen of Hungary's Water (Aqua Regina Hungariæ)*.¹ Hungary water is frequently imitated by mixing Spirit of Lavender f̄vij with Spirit of Rosemary f̄iv.—This liquid is employed principally as a perfume for the toilet; also as an excitant and restorative in fainting. Externally, it is used as a stimulating liniment.

TRIBE IV. STACHYDEÆ, *Benth.*

Stamens 4, ascending under the helmet (which is usually concave).

166. MARRUBIUM VULGARE, *Linn.*—WHITE HOREHOUND.

Sex. Syst. Didynamia, Gymnospermia.
(Herba.)

HISTORY.—This is the plant which is called Πράσιον by Hippocrates, Theophrastus, and Dioscorides;² and *Marrubium* by Pliny.³

BOTANY. *Gen. Char.*—*Calyx* tubular, 5—10-nerved, equal; teeth 5—10, acute, somewhat spinous, nearly equal, erect, or often spreading at maturity. *Corolla* with an inclosed tube, which is naked inside, or somewhat annulated, and a 2-lipped limb; the upper lip erect, flattish or concave, entire or shortly bifid; the lower lip trifid, spreading, the middle lobe the broadest, often emarginate. *Stamens* inclosed within the tube of the corolla; anthers with 2 straggling, somewhat confluent cells, all nearly alike. *Style* bifid at the apex, with short obtuse lobes. *Nucules* obtuse, not truncate at the apex (*Bentham*).

Sp. Char.—*Branches* white-woolly. *Leaves* ovate or rounded, softly villous, greenish or white-woolly beneath, crenate. *Whorls* many-flowered. *Calyx* villose, woolly, with 10 subulate, recurved-spreading or woolly teeth. *Corolla* with an oblong helmet, bifid at the point (*Bentham*). *Flowers* white.

Hab.—Dry waste grounds. Indigenous. Grows in most parts of Europe; also in Asia and America. Flowers in July.

PROPERTIES.—The whole herb (*herba marrubii*) is used in medicine. It has an aromatic odour, and a bitter taste. Sesquichloride of iron communicates an olive-green tint (*tannate of iron*) to the cold watery infusion.

¹ For the history of Hungary water, see Beckmann's *History of Inventions*, translated by Wm. Johnston, vol. ii. p. 107, 1791.

² Lib. iii. cap. 119.

³ *Hist. Nat. lib. xx. cap. 89, ed. Valp.*

COMPOSITION.—Its bitterness depends on *extractive*; its aromatic properties on *volatile oil*. Besides these principles it contains *resin, tannic acid, bitter matter,* and *woody fibre*.

PHYSIOLOGICAL EFFECTS.—Horehound is tonic, mildly stimulant, and, in large doses, laxative. Taken in the form of infusion, it promotes the secretions of the skin and kidneys. It was formerly supposed to possess emmenagogue properties.

USES.—It is rarely employed by medical practitioners. As a domestic remedy it is used in chronic pulmonary complaints, especially catarrh. It was formerly given in uterine and hepatic affections.

ADMINISTRATION.—*Horehound tea* (prepared by infusing an ounce of the herb in a pint of boiling water) is taken in the dose of a wineglassful. *Syrup of horehound* (prepared with the infusion and sugar) is a popular remedy, and is kept in the shops. *Candied horehound* ought to be made of the same ingredients.

BALLOTA NIGRA, Linn., or *Stinking Black Horehound*, possesses similar properties to the *Marrubium vulgare*.

ORDER XLI. SCROPHULARIACEÆ, Lindley.—FIGWORTS.

PEDICULARES ET SCROPHULARIÆ, Juss.—SCROPHULARINÆ, R. Brown.

CHARACTERS—*Flowers* hermaphrodite, usually irregular. *Calyx* free, persistent, 5—4-merous. *Corolla* gamopetalous (monopetalous), hypogynous, pentamerous or (the upper petals being united) tetramerous, very rarely 6—7-merous, or 2-lobed, the lobes being united; bilabedly or irregularly imbricated, very rarely (in a few didynamous or diandrous genera) plaited in æstivation. *Stamens* inserted on the corolla, alternate with its lobes; the upper stamen usually, and the 2 anterior or posterior ones sometimes, sterile or deficient; *anthers* 2 celled, or by growing together or by half disappearing, 1-celled; the cells dehiscing by a longitudinal slit. *Ovary* free, 2-celled; ovules in each cell many (very rarely 2 together), inserted on the dissepiment near the axis, anatropal or amphitropal. *Style* simple, or very shortly bifid, at the apex; the stigmatic part either very thin, or incrassate, entire, or 2-lobed. *Fruit* capsular, dehiscing, variously or rarely baccate. *Placentæ* 4, separate by dehiscence, or united variously with each other, with the edges of the valves, or with the central column. *Seeds* albuminous, indefinite with the radicle towards the basilar hilum, or few and definite with a more or less lateral hilum, and the radicle towards the apex of the fruit; embryo straight, or rarely curved.—*Herbs, undershrubs,* or rarely *shrubs*. *Leaves* opposite, whorled, or alternate. *Stipules* commonly absent. *Inflorescence* centrifugal or centripetal. *Braets* 2, opposite, or solitary; *bractlets* none, or 1 or 2, alternate, or nearly opposite (Bentham).

PROPERTIES.—Juice watery, frequently bitter, astringent or narcotic.

167. VERBASCUM THAPSUS, Linn.—GREAT MULLEIN OR HIGH TAPER.

Sex. Syst. Pentandria, Monogynia.
(Folia.)

HISTORY.—This plant is, according to both Smith¹ and Fraas,² the φλῆμα λευκὸν ἢ ἄρρηθον of Dioscorides.³

BOTANY. Gen. Char.—*Calyx* deeply 5-cleft or 5-partite, rarely 5-toothed. *Corolla* flat, expanded, or rotate, rarely concave; the segments scarcely unequal. *Stamens* 5; the filaments either the 3 posterior ones, or all woolly or bearded, rarely (abnormally?) naked. *Style* compressed dilated at the apex, rather thick. *Capsule* globose, ovoid or oblong, dehiscing (Bentham).

Sp. Char.—Nearly simple, densely yellowish or whitish, tomentose. *Radical leaves* oblong, crenulate; those of the stem decurrent, winged, acuminate. *Raceme* dense, or interrupted at the base. *Throat of the corolla* concave. *Anthers* inferior, shortly decurrent (Bentham).—*Corolla* golden yellow; *stamens* red; *stigma* green.

Hab.—Indigenous; on banks and waste ground. Biennial. Flowers in July and August.

DESCRIPTION.—The leaves (*folia verbasci*) have a mucilaginous, bitterish taste, and a very slight odour. They communicate their virtues to water.

COMPOSITION.—Morin⁴ analyzed the flowers of *Verbascum Thapsus*, and obtained a yellow

² *Lib.* iv. cap. 104.

³ *Synopsis Plant. Fl. Class.* p. 191, 1845.

⁴ *Journ. de Chim. Méd.* t. ii. p. 223.

volatile oil, a fatty acid, free malic and phosphoric acids, malate and phosphate of lime, acetate of potash, uncrystallizable sugar, gum, chlorophyll, and yellow resinous colouring matter.

PHYSIOLOGICAL EFFECTS.—Emollient, demulcent, and supposed to be feebly narcotic. Fishes are stupefied by the seeds of *Verbascum*.¹

USES.—In the form of decoction (prepared of ℥ij of the leaves and Oij of water) mullein has been used in catarrhs and diarrhœas; the dose is f℥iv. Dr. Home² found it serviceable in the later complaint only. Fomentations and cataplasms made of great mullein have been used as applications to hemorrhoidal tumours and indurated glands.

168. SCROPHULARIA NODOSA, Linn.—KNOTTY-ROOTED FIGWORT.

Sex. Syst. Didynamia, Angiospermia.
(Folia.)

HISTORY.—The earliest notice of this plant occurs in the work of Brunfels.³

BOTANY. Gen. Char.—*Calyx* deeply 5-cleft or 5-partite. Tube of the *corolla* ventricose, globular, or oblong; segments of the limb short, the 4 upper ones erect, the lower one spreading, 2 upper ones usually longest. *Stamens* didynamous, declinate, cells of the anthers united transversely into one; the rudiment of a fifth sterile stamen at the apex of the squamiform tube often present. *Capsule* usually acute, the valves entire or bifid at the apex. *Seeds* ovoid, rugose (Bentham).

Sp. Char.—Smooth. *Stem* angular. *Leaves* ovate, ovate oblong, or the upper ones lanceolate, acute, serrate or somewhat incised, broadly cordate or rounded at the base. *Thyrus* oblong, beardless, or scarcely clothed with leaves at the base. *Cymes* pedunculate, loosely many-flowered. Segments of the *calyx* broadly ovate, obtuse, with the margin very narrow. The sterile *anther* broadly orbiculate (Bentham).—*Corolla* dull green, with a livid purple lip.

Hab.—Indigenous; hedges, woods, and thickets. Perennial. Flowers in July.

DESCRIPTION.—The fresh leaves (*folia scrophulariæ nodosæ*) have, when bruised, a fetid odour; their taste is bitter, and somewhat acrid. Water extracts the virtues of the plant; the infusion is darkened by the sesquichloride of iron, but is unchanged by tincture of nutgalls.

COMPOSITION.—The whole plant (root and herb) was analyzed in 1830 by Grandou.⁴ He obtained *brown bitter resin* 0.31, *extractive with gum* 4.84, *extractive having the odour of benzoic acid* 0.88, *chlorophyll* 1.58, *starch* 0.23, *greenish fecula* 0.18, *mucilage* 0.27, *inulin* 0.16, *malic acid* 0.15, *pectic acid* 0.15, *acetic acid* 0.13, *woolly fibre* 19.80, *water* 70.31, *sulphate and carbonate of potash* 0.59, *alumina* 0.20, *oxalate and carbonate of lime* 0.46, *magnesia*, 0.26, *silica* 0.07, *odorous matter and loss* 0.31.

PHYSIOLOGICAL EFFECTS.—But little known. Judging from their taste, the leaves possess acrid properties. When swallowed, they occasion vomiting and purging. They are said to be diuretic and narcotic.

USES.—Rarely employed. In the form of a fomentation, the leaves are sometimes applied to piles and other painful tumours. The ointment is used in skin diseases. The tuberous root was formerly esteemed in serofula.⁵

UNGUENTUM SCROPHULARIÆ; Ointment of Scrophularia.—(Fresh leaves of *Scrophularia nodosa*, Prepared Hog's Lard, of each ℔ij; Prepared Mutton Suet ℔j. Boil the leaves in the fat until they become crisp, then strain by expression.)—Recommended by Dr. W. Stokes⁶ for the cure of a disease of children, commonly termed *burnt-holes*, and which he calls *Pemphigus gangrenosus* [*Rupia escharotica*?]. It has also been used in tinea capitis, impetigo, and other cutaneous affections.⁷

169. Gratiola Officinalis, Linn.—OFFICIAL HEDGE HYSSOP.

Sex. Syst. Diandria, Monogynia.
(Herba.)

A perennial plant, native of the South of Europe. Cultivated in England, and formerly contained in the British Pharmacopœias. The herb (*herba gratiolæ*) is cathartic, diuretic, and emetic, acting in large doses as an acrid poison. It has been used in visceral obstructions, liver affections, dropsies, serofula, and venereal diseases. Dose of the *powder* gr. xv to ℥ss; of the *infusion* (prepared with ℥ij of the dried herb and Oss of boiling water), f℥ss to f℥j, three times a day.⁸

170. DIGITALIS PURPUREA, Linn.—PURPLE FOXGLOVE.

Sez. Syst. Didynamia, Angiospermia.

(Herbæ agrestis Folium caulinum recens et exsiccatum, L.—Leaves, E. D.)

HISTORY.—It appears very improbable that the ancients should have overlooked so common and elegant a plant as foxglove; yet in none of their writings can we find any plant whose description precisely answers to the one now under examination. Fabricius Columna¹ thought that it was the Ἐφῆμερον of Dioscorides,² but the description of the latter does not at all agree with foxglove. The Βάκχαρις,³ of the same writer has also been referred to, but with little more probability of correctness. The term Foxeꝛ glove, occurs in a MS., *Glossarium Ælfrici*, probably written before the Norman Conquest (A. D. 1066), and in a MS. Saxon translation of L. Apulius; both of which are among the Cottonian manuscripts in the British Museum.⁴ Fuchsius⁵ is usually regarded as the earliest botanist who mentions this plant, which he named Digitalis (from *Fingerhut*, a finger-stall, on account of the blossoms resembling the finger of a glove). Fuchsius states that, until he gave it this appellation, the plant had no Greek or Latin name.

BOTANY. Gen. Char.—*Calyx* 5-partite, imbricate. *Corolla* declinate; tube ventriose or campanulate, frequently constricted above the base; upper segment of the limb short, broad, emarginate or bifid, spreading, the external lateral ones narrower, the lowermost one longer than the others, extended. *Stamens* 4, didynamous, ascending, shorter than the corolla, and frequently inclosed within the tube; *anthers* approximated in pairs, their cells diverging and confluent. *Style* briefly bilobed at the apex; the lobes stigmatic within. *Capsule* ovate, 2-valved, with septical dehiscence; the valves entire, curved inwards at the margins, half exposing the placentiferous column. *Seeds* numerous, minute, oblong, somewhat angular (Bentham).

Sp. Char.—*Leaves* ovate-lanceolate or oblong, erenate, rugose; the under surface or both surfaces, as well as the stem, tomentose or woolly. *Raceme* long, lax. Segments of the *calyx* ovate or oblong. *Corolla* enlarged above, campanulate; its segments obtuse, shorter than broad, the lower one longer than the lateral ones.

Herbaceous. *Root* of numerous long and slender fibres; biennial. *Stem* erect, 3 or 4 feet high, commonly simple, roundish, with several slight angles, downy. *Leaves* alternate, downy, veiny, of a dull green; tapering at the base into winged foot-stalks; lower ones largest. *Raceme* terminal, erect, one-sided, simple, of numerous, large, pendulous, odourless flowers. *Corolla* crimson, elegantly marked with eye-like spots, as well as hairy, within.

Var. albiflora.—A variety with white flowers, spotted with shades of cream-colour or pearl, is met with in gardens; it remains tolerably constant from seed.

Hab.—Indigenous; in pastures and about hedges or banks, on a gravelly or sandy soil.

DESCRIPTION.—The officinal parts of the leaves and seeds; the latter, however, are rarely employed. As some doubts have been expressed as to the equal activity of cultivated specimens, wild or native plants are to be preferred.

1. *Foxglove leaves (folia digitalis).*—The leaves should be gathered when the plant is in the greatest perfection—that is, just before or during the period of inflorescence; and those are to be preferred which are full-grown and fresh. As the petioles possess less activity than the laminæ or expanded portions of the leaves, they ought to be rejected. Dr. Withering⁶ directs the leaves to be dried either in the sunshine, or in a tin pan or pewter dish before the fire; but the more

Fig. 306.

First year's leaf.

Fig. 307.

Second year's leaf.

Foxglove Leaves.

The first year's leaves are frequently more tapering than those of the second year's growth; but this character is not much to be relied on; and, therefore, to avoid the substitution, the best and safest plan is to purchase the fresh leaves at the proper season—namely, just before or at the period of inflorescence (which is from the middle of June to the end of July).

The leaves of *Inula Conyza*, De Cand., or *Ploughman's Spikenard*, closely resemble those of Foxglove; but, when rubbed, are readily distinguished by their odour, which, by some, is called aromatic, by others fetid. Moreover, they are rougher to the touch, and are less divided on the edge.

Subsessile or shortly petiolate, ovate-lanceolate or oblong, narrow at the base, crenate, rugose and veined, tomentose beneath or on both sides.

It is to be gathered before the terminal flowers have unfolded. The petiole and midrib being removed, dry the lamina. (*Pharm. Lond*)

2. *Foxglove seeds (semina digitalis)*.—The seeds of the foxglove are small, roundish, and of a grayish-brown colour.

COMPOSITION.—Purple foxglove has been the subject of repeated chemical examination, but, until very recently, with no satisfactory results. Memoirs on its composition, or on its active principle, have been published by Destouches,¹ Bidault de Villiers,² Rein and Haase,³ Le Royer,⁴ Dulong d'Astafort,⁵ Meylink,⁶ Welding,⁷ Radig,⁸ Brault and Poggiale,⁹ Lancelot,¹⁰ Trommsdorff,¹¹ Homolle,¹² Nativelle,¹³ and by Morin.¹⁴ Homolle's memoir gained the prize offered by the Société de Pharmacie of Paris for the isolation of the active principle.

usual, and, I believe, better mode of proceeding, is to dry them in baskets in a dark place, in a drying-stove. Both dried leaves and powder should be preserved in well-stoppered bottles, covered externally by dark-coloured paper, and kept in a dark cupboard. As both undergo changes by keeping, whereby their medicinal activity is considerably diminished, they ought to be renewed annually. Dried foxglove leaves have a dull green colour, a faint odour, and a bitter, nauseous taste.

Although the leaves should be collected just before or at the period of inflorescence; that is, in the second year of the plant's growth, yet not infrequently the first year's leaves, which are considered to be of inferior activity, are sometimes substituted for them.

Morin found a peculiar volatile acid (*antirrhinic acid*), and a peculiar non-volatile acid (*digitalic acid*).

1. **DIGITALINE**; *Bitter Principle of Foxglove*; *Pierin*.—Homolle's process for obtaining digitaline, as simplified by M. Ossian Henry,¹ is as follows: Digest 2½ lbs. of carefully dried and powdered foxglove leaves with rectified spirit; and express the tincture strongly in a press. Draw off the spirit in a still, and treat the residual extract with half a pint of water acidulated with about two drachms of acetic acid. Digest with a gentle heat, add some animal charcoal, and filter. Dilute the filtered liquor with water, partly neutralize with ammonia, and add a fresh-made strong infusion of nutgalls; by this means tannate of digitaline is precipitated. Wash the precipitate with water, mix it with a little alcohol, and carefully rub it with finely powdered litharge. Expose the mixture to a gentle heat, digest with alcohol, decolorize the tincture by animal charcoal, and draw off the alcohol by a gentle heat. The residual extract is then to be treated with sulphuric ether, which takes up some foreign matters and leaves the digitaline. From 1 kilogramme (about 2½ lbs. 8 oz. troy) of the leaves, O. Henry obtained from 140 to 150 grs. of digitaline.

Digitaline is white, inodorous, difficultly crystallizable, and usually occurs in porous mammillated masses, or in small scales. It is intensely bitter when in solution, and excites violent sneezing when it is pulverized. It is soluble in about 2000 parts of water, is very soluble in alcohol, but almost insoluble in ether. It does not contain nitrogen; nor does it neutralize acids. Concentrated sulphuric acid blackens it, and then dissolves it, forming a blackish-brown solution, which, in a few days, becomes successively reddish-brown, smoky amethyst, pure amethyst, and ultimately a beautiful crimson. If during this time a small quantity of water be added, a limpid, beautiful green solution is obtained. In concentrated and colourless hydrochloric acid digitaline dissolves, forming a solution, which passes from yellow to a fine green. This reaction Homolle considers to be sufficiently delicate for medico-legal researches.

The effects of digitaline on both animals and the human subject have been examined by Homolle, and by Bonchardat and Sandras.² From their experiments, it appears that its effects are similar to those of the plant; but that it is at least 100 times as powerful as the powder of the dried plant. In the human subject, doses of from 2 to 6 milligrammes (from about 1-32d to 1-11th of an English grain) diminished the frequency of the pulse, and caused nausea, vomiting, griping, purging, and increased secretion of urine.

Digitaline has been employed in medicine, as a substitute for the plant, in doses of from 1-60th to 1-30th of a grain. It may be administered in substance in the form of pills, or dissolved in alcohol and given in the form of mixture or syrup. But the difficulty of adjusting these small doses, as well as the uncertainty of the purity and activity of the remedy, are great drawbacks to its use.

2. **SCAPTIN**.—Radig has applied the term scaptin to a brown, almost tasteless extractive, which leaves an acid sensation in the throat.

3. **EMPHYREUMATIC OIL OF FOXGLOVE** (*Pyrodigitaline*).—By the destructive distillation of the dried leaves of foxglove, Dr. Morries³ obtained a coloured, disagreeable, emphyreumatic oil, which was semi-solid at 60° F., and soluble in boiling alcohol and ether; the solution, on cooling, let fall a flocculent precipitate composed of two substances; one crystalline, the other globular. Given to a rabbit, it caused paralysis of the hind legs, convulsions, laborious and rapid breathing, and accelerated action of the heart. It does not contain the sedative principle of foxglove.

CHEMICAL CHARACTERISTICS.—Sesquichloride of iron causes a dark precipitate (*tanno-gallate of iron*) with decoction of foxglove leaves, as well as with the tincture diluted with water. A solution of gelatine, added to the decoction, causes, after some time, a scanty precipitate (*tannate of gelatine*). Tincture of nutgalls

¹ *Ibid.* 3e sér. t. vii. p. 460, 1845.

² *Ed. Med. and Surg. Journ.* vol. xxxix. p. 377.

³ *Annuaire de Thérapeutique pour 1845*, p. 60.

has scarcely any effect (perhaps a slight turbidness) when added to the decoction or to the tincture diluted with water.

(By the action of sulphuric or hydrochloric acid on the tincture or decoction of foxglove, I have not been able to detect the presence of digitaline.)

PHYSIOLOGICAL EFFECTS. *a. On Vegetables.*—Marec¹ found that a solution of the watery extract of foxglove killed a haricot plant (*Phaseolus vulgaris*) in twenty-four hours.

β. On Animals generally.—The effects of foxglove have been tried on dogs,² horses, rabbits,³ turkeys,⁴ the domestic fowl, and frogs; and on all it has been found to act as a poison. One drachm of the powder may be given to horses as a sedative in inflammation.⁵ Two ounces have produced death in twelve hours.⁶ According to the experience of Orfila, the first symptoms of poisoning observed in [carnivorous] animals is vomiting. The influence of the poison over the heart does not appear to be uniform; for in some cases he found the pulsations of this viscus unaltered, in others accelerated, while occasionally they were retarded. In the horse killed by two ounces of foxglove, the pulse was 130 per minute, a short time before death (Moiroud)—the standard pulse of the horse being 40 or 42 per minute. The cerebro-spinal symptoms observed in animals, are diminished muscular power, convulsive movements, tremors, and insensibility. The powder acts as a local irritant, giving rise to inflammation of parts to which it is applied (Orfila).

γ. On Man.—We may, for convenience, establish three degrees of the operation of foxglove.

In the first degree, or that produced by *small and repeated doses*, foxglove sometimes affects what are termed the organic functions, without disordering the animal or cerebro-spinal functions. Thus we sometimes have the stomach disordered, the pulse altered in frequency, and sometimes also in fullness and regularity, and the secretion of urine increased, without any other marked symptoms. The order in which the symptoms just mentioned occur is not uniform; sometimes the diuresis, at others nausea, and occasionally the affection of the circulation, being the first obvious effect.

The influence of foxglove over the circulation is not at all constant. In some cases the frequency of the pulse is augmented, in others decreased, while in some it is unaffected. Lastly, in a considerable number of instances, the pulse becomes irregular or intermittent under the use of foxglove.⁷ A few drops of the tincture will, in some cases, reduce the frequency of the pulse, and render it irregular and intermittent, while in other instances much larger doses may be taken without any obvious effect on it. Dr. Withering⁸ mentions one case in which the pulse fell to 40; and I have several times seen it reduced to 50. In some cases the slowness of the pulse is preceded by an increased activity of the vascular system. From Sandras's reports⁹ this would appear to occur more frequently after small than large doses of foxglove. Dr. Sanders,¹⁰ indeed, asserts that foxglove invariably excites the pulse, and refers to an experience of 2000 cases in proof. He says, that he has seen the pulse rise from 70 to 120 under the use of foxglove, and at the end of twenty-four hours, or sooner, fall with greater or less rapidity to forty, or even below this. But an experience of the use of foxglove, in only twenty cases, will, I believe, convince most persons that Dr. Sanders has fallen into an error in the sweeping assertion which he has made. A great deal, however, depends on the position of the patient. If it be desired to reduce the frequency of the pulse, the patient should be kept in a recumbent posture. The important influence of posture was first pointed out, I believe, by Dr. Baildon.¹¹ His own pulse, which had been reduced by this plant from 110 to 40 beats per minute while he was in the recum-

¹¹ *Ed. Med. and Surg. Journ.* vol. iii. p. 270.

bent position, rose to 70 when he sat up, and to 100 when he stood. We have a ready explanation of this fact. In a state of health, the pulsations of the heart are more frequent (usually to the extent of five or six in the minute) in the erect than in the horizontal position; and it is very obvious that greater force is required to carry on the circulation in the former than in the latter, since, in the erect position, the heart and arteries have to send blood to the head against gravity. Now, the power of the heart being enfeebled by foxglove, when a demand is made on this viscus for an increase in the force of contractions by the change from the recumbent to the standing attitude, it endeavours to make up for its diminished force by an increase in the frequency of its contractions. I need scarcely add, that the sudden change of position in those who are much under the influence of this medicine, is attended with great danger, and in several instances has proved fatal; for, in consequence of the heart not having sufficient power to propel the blood to the head against gravity, fatal syncope has been the result.¹ The influence of digitalis over the pulse is more marked in some individuals or cases than in others; thus the reduction of the frequency of the pulse is in general more readily induced in weak and debilitated constitutions, than in robust and plethoric ones. Occasionally, no obvious effect on the number, force, or regularity of the pulse is produced, though the foxglove may be given to an extent sufficient to excite vomiting and cerebral disorder. Shroek² experienced, from two grains of foxglove, nausea, headache, small, soft, and quick pulse, dryness of the gums and throat, giddiness, weakness of limbs, and increased secretion of saliva. Some hours after, he observed sparks before the eyes, his vision became dim, and he experienced a sensation of pressure on the eyeballs.

A most important fact connected with the repeated uses of small doses of it, is the *cumulative effect* sometimes observed. It has not unfrequently happened that, in consequence of the continued use of small doses of this medicine, very dangerous symptoms, in some cases terminating in death, have occurred. The most prominent of these were great depression of the vascular system, giddiness, want of sleep, convulsions, and sometimes nausea and vomiting.³ A knowledge of its occasional occurrence impresses us with the necessity of exercising great caution in the use of this remedy, particularly with respect to the continuance of its administration and increase of dose; and it shows that, after the constitutional effect has become obvious, it is prudent to suspend from time to time the exhibition of the remedy, in order to guard against the effects of this alarming accumulation. I may add, however, that I have used it, and seen others employ it, most extensively, and in full doses, and have rarely seen any dangerous consequences; and I believe, therefore, the effects of accumulation to be much less frequent than the statements of authors of repute would lead us to expect. The experience of Dr. Holland⁴ is to the same effect. "Though employing the medicine somewhat largely in practice," he observes, "I do not recollect a case in which I have seen any injurious consequences from this cause."

The diuretic operation for which we employ foxglove is very inconstant. Dr. Withering stated that this medicine more frequently succeeds as a diuretic than any other, and that if it fail, there is but little chance of any other remedy succeeding. My experience, however, is not in accordance with Dr. Withering's. I have frequently seen foxglove fail in exciting diuresis, and have often found the infusion of common broom (*Cytisus scoparius*) subsequently succeed. It has been asserted by some, that the diuretic effect of foxglove was only observed in dropsical cases, and that it, therefore, depended on the stimulus given to the absorbent vessels, and not to any direct influence exerted over the kidneys; but the statement is not true,

¹ For some interesting remarks on the *Effects produced by Posture on the Pulse*, by Dr. Graves, consult *Dubl. Hosp. Rep.* vol. x. p. 561.

² Quoted by Wibmer, *Wirk. d. Arzneim u. Gifte*, Bd. ii. S. 311.

³ See the cases published by Dr. Withering, *op. cit.*; also a fatal case recorded by Dr. Blackall, *On Dropsy*, p. 175, 4th ed.

⁴ *Med. Notes and Reflections*, p. 514.

since foxglove is sometimes found acting as a diuretic even in health. In some cases the bladder has appeared more irritable than usual, the patient having a frequent desire to pass his urine.

An increased flow of saliva is an occasional consequence of the continued use of moderate doses of foxglove. Dr. Withering¹ first noticed this effect. Dr. Barton² has also seen it produced from ordinary doses.

2. The *second degree of operation of digitalis*, or that ordinarily resulting from the use of too large or too long-continued doses, is manifested by the disordered condition of the alimentary canal, of the circulating organs, and of the cerebro-spinal system. The more ordinary symptoms are nausea or actual vomiting, slow and often irregular pulse, coldness of the extremities, syncope, or tendency to it, giddiness, and confusion of vision. Sometimes the sickness is attended with purging, or even with diuresis; at other times the patient is neither vomited nor purged; and the principal disorder of system is observed in the altered condition of the nervous and vascular organs. External objects appear of a green or yellow colour; the patient fancies there is a mist, or sparks, before his eyes; a sensation of weight, pain, or throbbing of the head, especially in the frontal region, is experienced; giddiness, weakness of the limbs, loss of sleep, occasionally stupor or delirium, and even convulsions, may also be present. The pulse becomes feeble, sometimes frequent, sometimes slow; there may be actual syncope, or only a tendency to it, and profuse cold sweats. Salivation is sometimes produced by poisonous doses of foxglove. It was observed in a case narrated by Dr. Henry,³ and has been known to last three weeks.⁴

The quantity of digitalis that may be given to a patient without destroying life, is much greater than is ordinarily imagined. In one instance I saw twenty drops of the tincture given to an infant labouring under hydrocephalus, three times daily for a fortnight, at the end of which time the little patient was completely recovered, without one untoward symptom. I have frequently given a drachm of the tincture (of the best quality) three times daily to an adult, for a fortnight, without observing any marked effect. I know that some practitioners employ it in much larger doses (as an ounce or half an ounce of the tincture), with much less effect than might be imagined. The following communication on this subject, from my friend Dr. Clutterbuck, illustrates this point: "My first information on this subject was derived from an intelligent pupil, who had been an assistant to Mr. King, a highly respectable practitioner at Saxmundham, in Suffolk, who on a subsequent occasion, personally confirmed the statement. This gentleman assured me, that he had been for many years in the habit of administering the tincture of digitalis, to the extent of from half an ounce to an ounce at the time, not only with safety, but with the most decided advantage, as a remedy for acute inflammation—not, however, to the exclusion of bloodletting, which, on the contrary, he previously uses with considerable freedom. To adults he often gives an ounce of the tincture (seldom less than half an ounce), and awaits the result of twenty-four hours, when, if he does not find the pulse subdued, or rendered irregular by it, he repeats the dose; and this, he says, seldom fails to lower the pulse in the degree wished for; and when this is the case, the disease rarely fails to give way, provided it has not gone the length of producing disorganization of the part. He has given as much as two drachms to a child of nine months. Sometimes vomiting quickly follows these large doses of the digitalis, but never any dangerous symptom, as far as his observation has gone, which has been very extensive. In less acute cases he sometimes gives smaller doses, as thirty drops, several times in a day.

"Such is the account I received from Mr. King himself, and which was confirmed by his assistant, who prepared his medicines. I do not see any ground for questioning the faithfulness of the report. I have myself exhibited the tincture to the

¹ *Op. cit.* p. 184.

² *Ed. Med. and Surg. Journ.* vol. vii. p. 148.

³ *Beck's Med. Jurisprudence.*

⁴ *Rust's Magazin.* xxv. p. 578.

extent of half an ounce (never more), in not more than two or three instances (cases of fever and pneumonia). To my surprise, there was no striking effect produced by it; but I did not venture to repeat the dose. In numerous instances I have given two drachms; still more frequently one drachm; but not oftener than once in twenty-four hours, and not beyond a second or third time. Two or three exhibitions of this kind I have generally observed to be followed by slowness and irregularity of pulse, when I have immediately desisted." Dr. T. Williams¹ states, that a man, in a state of intoxication, took two ounces of tincture of foxglove, in two doses, in quick succession, without the slightest inconvenience.

3. The *third degree* of the operation of foxglove, or that resulting from the use of *fatal doses*, is characterized usually by vomiting, purging, and griping pain in the bowels; slow, feeble, and irregular pulse, great faintness, and cold sweats; disordered vision; at first giddiness, extreme debility; afterwards insensibility and convulsions, with dilated insensible pupils.

If we compare the effects of foxglove with those of other medicinal agents, we find they approximate more closely to those of tobacco than of any other cerebro-spinant. These two agents especially agree in their power of enfeebling the action of the heart and arteries (see vol. i. p. 258). Green tea agrees with foxglove in its property of preventing sleep (see vol. i. p. 247). Considered as a diuretic, foxglove is, in some respects, comparable with squills. I have already pointed out the peculiarities attending the operation of each of these.

USES.—We employ foxglove for various purposes, as—1stly, to reduce the frequency and force of the heart's action; 2dly, to promote the action of the absorbents; 3dly, as a diuretic; and 4thly, sometimes on account of its specific influence over the cerebro-spinal system.

In the following remarks on the uses of foxglove in particular diseases, I refer to the administration of this remedy in the doses in which it is ordinarily employed. I have no experience of its therapeutical effects, when given in the enormous quantities mentioned by Dr. Clutterbuck.

1. *In fever*.—Digitalis is occasionally useful in fever to reduce the frequency of the pulse, when the excitement of the vascular system is out of proportion to the other symptoms of fever, such as the increased temperature, and the cerebral or gastric disorder. It cannot, however, be regarded, in the most remote way, as a curative means; on the other hand, it is sometimes hurtful. Thus, not unfrequently it fails to reduce the circulation; nay, occasionally, it has the reverse effect, accelerates the pulse, while it increases the cerebral disorder, and perhaps irritates the stomach. In estimating its value as a remedial agent for fever, we must not regard it as a sedative means (I refer now to the vascular system) merely; it is an agent which exercises a specific influence over the brain; and, therefore, to be able to lay down correct indications or contraindications for its use in disordered conditions of this viscus, we ought to be acquainted, on the one hand, with the precise nature of the influence of the remedy, and, on the other, with the actual condition of the brain in the disease which we wish to relieve. Now, as we possess neither of these data in reference to fever, our use of foxglove is, with the exception of the sedative influence over the circulation, empirical; and experience has fully shown us it is not generally beneficial. But, I repeat, where the frequency of pulse bears no relation to the local or constitutional symptoms of fever, foxglove may be serviceable.

2. *Inflammation*.—Foxglove has been employed in inflammatory diseases, principally on account of its power of reducing the frequency of the pulse, though some have referred part of its beneficial operation to its influence over the absorbent system. Inflammation, of a chronic kind, may be going on in one part of the body, to an extent sufficient to produce complete disorganization, and ultimately to cause the death of the patient, without the action of the larger arterial trunks (*i. e.* of

¹ *Lond. Med. Gaz.* vol. i. p. 744.

the system generally) being remarkably increased. In such cases, digitalis is, for the most part, of little use. Again, in violent and acute inflammation, accompanied with great excitement of the general circulation, especially in plethoric subjects, foxglove is, in some cases, hurtful; in others, it is a trivial and unimportant remedy; and we therefore rely, in our treatment, on bloodletting, and other powerful antiphlogistic measures; and foxglove, if serviceable at all, can only be used after the other means.

As a remedy for inflammation, foxglove is principally useful in less violent cases, particularly when accompanied with increased frequency of pulse, and occurring in subjects not able to support copious evacuations of blood. Moreover, it has more influence over inflammation of some parts of the body (as the arachnoid membrane, the pleura, the pericardium, and the lungs) than of others. In gastric and enteric inflammation, it would appear to be objectionable on account of its irritant properties; while its specific influence over the brain would make it a doubtful remedy in phrenitis. In arachnitis of children it is certainly a most valuable agent.

In conclusion, then, it appears that digitalis, as a remedy for inflammation, is principally valuable where the disease has a tendency to terminate in serous effusion. But in no case can it be regarded as a substitute for bloodletting. Its powers as an antiphlogistic remedy have, I suspect, been greatly overrated.

3. *Dropsy*.—Of all remedies for dropsy, none have gained more, and few so much, celebrity as foxglove. It has been supposed to owe its beneficial operation to its repressing arterial excitement, to its promoting the functions of the absorbent vessels, and particularly to its diuretic effects. Whatever may be its *modus operandi*, its powerful and salutary influence in many dropsies cannot be a matter of doubt. Dr. Withering has observed, that “it seldom succeeds in men of great natural strength, of tense fibre, of warm skin, of florid complexion, or in those with a tight and eordy pulse.” “On the contrary, if the pulse be feeble or intermitting, the countenance pale, the lips livid, the skin cold, the swollen belly soft and fluctuating, or the anasareous limbs readily pitting under the pressure of the finger, we may expect the diuretic effects to follow in a kindly manner.” In those with a florid complexion, bloodletting and purgatives will often be found useful preparatives for foxglove. In some forms of dropsy, foxglove is more serviceable than in others. Thus, anasæra, ascites, hydrothorax, and phlegmasia dolens, are sometimes benefited by it; whereas ovarian dropsy and hydrocephalus are not relieved by it. Its diuretic effect is greatly promoted by combining other diuretics with it, especially squills (as in the *Pilulæ Digitalis et Scillæ*, Ph. Ed.), calomel, or the saline diuretics (as the acetate of potash). A combination of vegetable bitters (as infusion of gentian or calumba) with foxglove, forms, I think, a valuable form of exhibition in many old dropsical cases. Infusion of common broom (*Cytisus scoparius*) might probably be advantageously conjoined with foxglove, where a powerful diuretic is required. In old cases of general dropsy, in œdematous swellings from debility, and in anasæra following scarlet fever, where, together with weakness, there is still left an excited and irritable state of the arterial system, chalybeates (as the *tinctura ferri sesquichloridi*) may be conjoined with foxglove, with the happiest effects.¹

4. *In Hemorrhages*.—In active hemorrhages from internal organs, accompanied with a quick, hard, and throbbing pulse, foxglove as a sedative is oftentimes serviceable. Epistaxis, hæmoptysis, and menorrhagia, are the forms of hemorrhage more frequently benefited by the use of foxglove.

5. *Diseases of the Heart and Great Vessels*.—An important indication in the treatment of many diseases of the heart and great vessels is to reduce the force and velocity of the circulation. The most effectual means of fulfilling this indication are—the adoption of a low diet, repeated bloodletting, and the employment of foxglove. There are, perhaps, no diseases in which the beneficial effects of foxglove

¹ Holland, *Med. Notes and Reflect.* p. 546.

are more marked than in those of the heart and great vessels. In *aneurism of the aorta*, our only hope of cure is by the coagulation of the blood in the aneurismal sac, and the consequent removal of the distensive pressure of the circulation. To promote this, we endeavour to retard the movement of the blood within the sac, by diminishing the quantity of blood in the system generally, and by reducing the force and velocity with which it circulates. Bloodletting and digitalis are, in these cases, very important agents; and under their use cases now and then recover. Again, in *simple dilatation* of the cavities of the heart, our objects are to remove, if possible, the cause (usually obstruction in the pulmonic or aortic system), to strengthen the muscular fibres of the heart, and to repress any preternatural excitement of the vascular system. Digitalis is useful to us in attaining the latter object. In *simple hypertrophy* or *hypertrophy with dilatation*, we have to reduce the preternatural thickness of the heart's parietes, and this we do by removing, when it can be done, any obstruction to the circulation, by using a low diet, by repeated bloodletting, and by the employment of foxglove. No means, says the late Dr. Davies,¹ excepting the abstraction of blood, diminishes the impulsion of the heart so completely and so certainly as digitalis. "I have been," adds he "in the habit of using it for several years for these affections, and have rarely seen it fail in producing at least temporary relief." "The enlarged and flaccid heart," observes Dr. Holland,² "though, on first view, it might seem the least favourable for the use of the medicine, is, perhaps, not so. At least we have reason to believe, that, in dropsical affections, so often connected with this organic change, the action of digitalis, as a diuretic, is peculiarly of avail." In *some disordered conditions of innervation of the heart and great vessels*—as in *angina pectoris*, nervous palpitation of the heart, and augmented arterial impulsion, foxglove is also at times beneficial. In patients affected with an intermittent or otherwise irregular pulse, I have several times observed this medicine produce regularity of pulsation;—a circumstance also noticed by Dr. Holland. Besides the preceding, there are *various other affections of the heart* in which foxglove may be found serviceable, either by its sedative influence over the circulation, or by its power of relieving dropsical effusion through its diuretic property.

6. *In Phthisis*.—Digitalis has been declared capable of curing pulmonary consumption, and numerous cases of supposed cures have been published. Bayle³ has collected from the writings of Sanders,⁴ Kinglake, Fowler, Beddoes,⁵ Drake, Mossman,⁶ Maclean, Ferriar,⁷ Magennis, Moreton, and others, reports of 151 cases treated by foxglove. Of these, 83 are said to have been cured, and 35 relieved. But a more accurate and extended experience has fully proved that this medicine possesses no curative, and very slightly palliative powers in genuine phthisis: it is totally incapable of preventing or of causing the removal of tubercular deposits, and has little, if any influence, in retarding the progress of consumption. Its power of diminishing the rapidity of the circulation cannot be doubted; but this effect is, as Dr. Holland⁸ justly remarks, "of less real moment than is generally supposed."

7. *In Insanity and Epilepsy*.—In these maladies foxglove may prove occasionally serviceable by repressing excessive vascular excitement, which sometimes accompanies them. Furthermore, the specific influence of this remedy over the cerebro-spinal system may now and then contribute to the beneficial operation of foxglove. But the precise nature of this influence not having as yet been accurately ascertained, while the pathology of the above-mentioned diseases is involved in considerable obscurity, it follows that the therapeutic value of this influence can only be ascertained empirically. In insanity, Dr. Hallaran⁹ recommends foxglove to reduce vascular action after the employment of depletion and purgation. It has

⁷ *Med. Notes and Reflect.* p. 574.

⁸ *Op. ante cit.*

⁹ *Op. cit.* p. 551.

been used in this disease, with success, by Dr. Currie,¹ and by Fanzago.² In epilepsy it is, I conceive, less likely to be serviceable, because this disease is less frequently accompanied with the vascular excitement, against which foxglove is most successful. Accordingly, while in some cases it has appeared to act beneficially,³ in others it has either been unsuccessful,⁴ or has only given temporary relief.⁵

8. *In various other diseases.*—Besides the preceding, there are several other maladies against which foxglove has been employed with occasional benefit, as *scrofula*⁶ and *asthma*.⁷ For other diseases relieved by foxglove I must refer the reader to the works of Murray⁸ and Bayle.⁹

ADMINISTRATION.—The ordinary dose of foxglove, *in powder*, is from gr. ss to gr. iss, repeated every six hours.

ANTIDOTES.—In a case of poisoning by foxglove, or its preparations, expel the poison from the stomach by the stomach-pump or by emetics, if vomiting should not have already commenced; assist the vomiting, when it is established, by the use of diluents; and counteract the depressing influence of the poison on the circulation by the use of ammonia and brandy; and keep the patient in a recumbent posture, to guard against syncope. I am unacquainted with any chemical antidote for foxglove; perhaps infusion of nutgalls might prove serviceable by the tannic acid which it contains.

1. INFUSUM DIGITALIS, L. E. D. [U. S.]; *Infusion of Foxglove*.—(Foxglove leaves, dried, ʒj [ʒij, *E.*]; [Spirit of Cinnamon fʒj, *L.*, fʒij, *E.*]; Boiling [distilled, *L.*] Water Oj [fʒxviiij, *E.*; ʒix, *D.*]. Macerate the foxglove leaves in the water for four [one, *D.*] hours, in a vessel lightly covered, and strain [through linen or calico, *E.*]; then add the spirit.—[The *U. S. Pharm.* directs Foxglove ʒi; Boiling Water Oss; Tincture of Cinnamon fʒi. Macerate the foxglove with the water for two hours in a covered vessel and strain, then add the tincture of cinnamon].—I believe this, when properly made, to be the most effectual of the preparations of foxglove. The dose of it is from fʒss to fʒj, repeated every six hours. I have known it given to the extent of fʒij.

2. TINCTURA DIGITALIS, L. E. D. [U. S.]; *Tincture of Foxglove*.—(Foxglove leaves, dried [in moderately fine powder, *E.*; in coarse powder, *D.*], ʒiv [ʒv, *D.*]; Proof Spirit [Diluted Alcohol, *U. S.*] Oij. Macerate for seven [fourteen, *D.*] days, then express and strain. "This tincture is best prepared by the process of percolation, as directed for the tincture of capsicum. If forty fluidounces of the spirit be passed through, the density is 944 [0.944], and the solid contents of a fluidounce amount to twenty-four grains. It may also be made by digestion," *E.*)—The usual dose of this preparation, for an adult, is ℥x, cautiously increased to ℥xl, repeated every six hours. I usually begin with ℥xx. The largest dose I have employed is ʒj; but, as I have already stated, it has been given to the extent of one ounce! The colour of this preparation is somewhat affected by exposure to strong solar light.

SUCCUS DIGITALIS.—The preserved juice of foxglove may be employed as a substitute for the tincture. From 1 cwt. 2 qrs. 26 lbs. of digitalis gathered in May, 49 pints of juice have been obtained.

3. EXTRACTUM DIGITALIS, E.; *Extract of Foxglove*.—("This extract is best prepared from the fresh leaves of digitalis, by any of the processes indicated for extract of conium," *E.*)—Recently introduced into the pharmacopœia of Edinburgh. Its preparation requires very great care and attention, or the virtues of the plant may be destroyed during the process. Dose, gr. j, cautiously increased.

4. PILULÆ DIGITALIS ET SCILLÆ, E.; *Pills of Foxglove and Squill*.—(*Digitalis*; Squill, of each *one part*; Aromatic Electuary *two parts*. Beat them into a proper mass with conserve of red roses; and divide the mass into four-grain pills.)—A valuable diuretic compound. Used in dropsies. Dose, one or two pills.

ORDER XLII. SOLANACEÆ, *Lindley*.—NIGHTSHADES.

SOLANÆÆ, *Jussieu*.

CHARACTERS.—*Calyx* 5-parted, seldom 4-parted, persistent, inferior. *Corolla* monopetalous, hypogynous; the limb 5-cleft, seldom 4-cleft, regular, or somewhat unequal, deciduous; the æstivation plaited or imbricated. *Stamens* inserted upon the corolla, as many as the segments of the limb, with which they are alternate; *anthers* bursting longitudinally, rarely by pores at the apex. *Ovary* 2-celled, composed of a pair of carpels right and left of the axis, rarely 4—5 or many-celled, with polyspermous placentæ; *style* continuous; *stigma* simple; *ovules* numerous, amphitropal. *Pericarp* with 2 or 4 or many cells, either a capsule with a double dissepiment parallel with the valves, or a berry with the placentæ adhering to the dissepiment. *Seeds* numerous, sessile; *embryo* straight or curved often out of the centre, lying in a fleshy albumen; *radicle* next the hilum. *Herbaceous* plants or shrubs. *Leaves* alternate, undivided, or lobed, sometimes collateral; the floral ones sometimes double, and placed near each other. *Inflorescence* variable, often out of the axil; the *pedicels* without bracts (*Lindley*).

PROPERTIES.—The narcotic properties which many members of this order possess depend on the presence of vegetable alkaloids; but the narcotism which they induce is very different to that caused by opium;¹ hyoscyamus, belladonna, and stramonium, give rise to phantasms and dilatation of the pupil (see the *Solanacea mydriatica*, vol. i. p. 237); nicotiana is a nauseating cardio-vascular sedative (see *ante*, pp. 237 and 258). An acrid resin is found in many species; on this the hot, pungent, burning qualities of capsicum depend. A bitter principle confers on some species (as *S. Pseudoquina* and *crispum*) tonic properties. Starch abounds in potatoes, which owe their nutritive qualities chiefly to it.

171. HYOSCYAMUS NIGER, *Linn.*—COMMON HENBANE.

Sex. Syst. Pentandria, Monogynia.

(*Herbæ* biennis. *Folium* caulinum recens et exsiccatum, *L.*—*Leaves*, *E. D.*)

HISTORY.—This plant is the Ὑοσσύαμος μέλας of Dioscorides,² the *hyoscyamus niger* of Pliny.³

BOTANY. *Gen. Char.*—*Calyx* urceolate, 5-toothed. *Corolla* funnel-shaped; the limb plaited, 5-lobed; the lobes obtuse, unequal. *Stamens* 5, inserted in the lower part of the tube of the corolla, inclosed or exerted, declinate; *anthers* dehiscing longitudinally. *Ovary* 2-celled; placentæ fixed to the dorsal dissepiment; ovules numerous; *style* simple; *stigma* capitate. *Capsule* inclosed by the persistent often enlarged calyx, narrowed from the ventricose base, membranous, 2-celled, circumscissile at the apex, with a 2-celled lid. *Seeds* many, kidney-shaped; *embryo* in fleshy albumen, almost peripherical, curved (*Kudlicher*).

Sp. Char.—*Leaves* oblong, pinnatifid, or sinuate sessile, and subamplexicaule; lower leaves stalked. *Flowers* nearly sessile, axillary, unilateral (*Babington*).

Root spindle-shaped. *Stem* bushy. *Leaves* soft and pliant, sharply lobed. Whole herbage glandular, downy, and viscid, exhaling a powerful fetid and oppressive odour. *Flowers* numerous from the bosoms of the crowded upper leaves, drooping, almost entirely sessile, of an elegant straw colour, usually pencilled with dark purple veins.

Hab.—Indigenous; waste ground, banks, and commons. Flowers in July.

There are two varieties of this species; one biennial, the other annual. Both are cultivated at Mitcham.

¹ The generalizations of some late French writers (Trousseau and Pidoux, *Traité de Thérap.* t. i. p. 266), with respect to the identity of the operation of the narcotic Solanææ, do not appear to me to be founded in fact.

² *lib. iv. cap. 69.*

³ *Hist. Nat. lib. xxv. cap. 17, cd. Valp.*

Var. *a biennis*; Biennial Black Henbane.—This is larger, stronger, more branched, more clammy, than the annual variety. Its root is biennial. Cultivated at Mitcham. During the first year of its growth the plant has no aerial stem, all the leaves being radical and stalked. It is less odorous and clammy than the mature plant; and Dr. Houlton¹ states that it yields less extract. In the autumn the leaves die, but the root survives during the winter; and in the following spring sends up an aerial stem, which grows to the height of from two to four feet. The leaves of the second year are large, deeply sinuate, or pinnatifid. It flowers towards the end of May, or in June.

As this variety is more highly developed than the annual sort, it probably possesses more medicinal activity; and, therefore, should be preferred. I am, however, unacquainted with any experiments demonstrative of its superiority.

This variety flowers earlier than the annual sort. The surest plan of obtaining it, therefore, is to purchase it fresh while in flower.

Var. *β annua*, Sims, Bot. Mag. 2394; *H. agrestis*, Kitaibel ex Schult. Fl. Austr., ed. 2, p. 383, *H. niger*, var. *β minor*, Brandt u. Ratzeburg, Deutschl. phan. Giftgewächse; *H. niger*, var. *β agrestis*, Nees in Linn. Trans. xvii. 77; *Annual or Field Henbane*.—Root annual; stem simple, downy; leaves smoothish, sinuately toothed; flowers sessile; corolla reticulated.—Indigenous; South of Europe; North of India—Cultivated at Mitcham for medicinal use.—Flowers in July and August.

The plant is smaller, the leaves less deeply sinuated (not pinnatifid), less hairy, clammy, and fetid than var. *a biennis*.

* *Corolla non violaceo reticulata*; *H. pallidus*, Koeh; Babing. Man., of Br. Botany.—This is a subvariety of *β annua*, with yellow corolla, without any purple veins. It is said to grow wild at Esher, in Surrey.

HYOSCYAMUS ALBUS, Linn. Ἰοσκυάμος λευκός, Diosc. lib. iv. cap. 69.—Leaves petiolate; lower ones orbicular, entire; the rest from cordate to ovate at the base, sinuated; flowers sessile—South of Europe. Annual. Its medicinal properties resemble those of *H. niger*, for which it has sometimes been employed in medicine.²

DESCRIPTION.—The herb (*herba hyoscyami*), when fresh, has a strong, unpleasant, narcotic odour, a mucilaginous, slightly acrid taste, and a clammy feel. It should be gathered when in full flower. By drying, it almost wholly loses these properties. One hundred pounds of the fresh herb yield about fourteen pounds when dried.³ The leaves (*folia hyoscyami*), when fresh, are pale dull green. The seeds (*semina hyoscyami*) are small, compressed, uniform, roundish, finely dotted, of a yellowish-gray colour, and have the odour of the plant, and an oleaginous, bitter taste.

Sessile, oblong, acutely sinuated, somewhat pubescent, with viscid fetid hairs.

It is to be gathered and dried as ordered for foxglove. The herb which grows wild in waste places is to be preferred to that which is cultivated in gardens, *L*.

COMPOSITION.—The seeds of *Hyoscyamus niger* were analyzed in 1816 by Kirchof,⁴ and in 1820 by Brandes.⁵ The extract of the herb was analyzed by Lindbergson.⁶

<i>Brandes's Analysis.</i>		<i>Lindbergson's Analysis.</i>	
Fatty oil	24.2	Narcotic extractive soluble in water and alcohol.	
Waxy fat	1.4	Bitter extractive.	
Resin insoluble in ether	3.0	Gummy extractive.	
Malate of hyoscyamia with malates of lime and magnesia, and a salt of potash and ammonia	6.3	Malates, phosphates, sulphates, and muriates of magnesia.	
Uncrystallizable sugar	a trace		
Gum 1.2, bassorin 2.4, and starch 1.5.	5.1		
Albumen	4.5		
Vegeto-animal matter	3.4		
Malate, phosphate, sulphate, and muriate of potash	0.4		
Malates of lime and magnesia	0.6		
Phosphates of lime and magnesia	2.4		
Woody fibre	26.0		
Water	24.1		
		Extract of the herb.	
Seeds of hyoscyamus	101.4		

The ashes contained carbonate, phosphate, sulphate, and muriate of potash, carbonate and much phosphate of lime, much silica, manganese, iron, and minute traces of copper.

1. **HYOSCIAMIA OR HYOSCIAMINA.**—This term has been applied to a vegetable alkali procured from the seeds and herbs of *Hyoscyamus niger* by Brandes,¹ whose statements have been confirmed by Geiger and Hesse, as well as by Mein.² However, Chevallier, as well as Brault and Poggiale,³ have failed to procure it. The properties assigned to it are almost identical with those of Atropina, from which it differs in being more soluble in water. It is crystallizable, has an acrid taste, and, when volatilized, yields ammonia. Reisinger⁴ says, that a drop of a solution of one grain of this substance in ten grains of water caused dilatation of the pupil, but did not give rise to irritation of the eye. A solution of double this strength acted as an irritant.

2. **EMPYREUMATIC OIL OF HENBANE (*Pyro-Hyoscyamia?*).**—This was obtained by Dr. Morries⁵ by the destructive distillation of henbane. Its chemical properties are identical with those of the empyreumatic oil of foxglove. It proved a powerful narcotic poison.

PHYSIOLOGICAL EFFECTS. *a. On Vegetables.*—Water holding in solution extract of henbane proved poisonous to *Hyoseyamus niger*.⁶

β. On Animals.—Its effects on herbivorous animals are slight. Given to horses in large quantities, it causes dilatation of the pupils, spasmodic movements of the lips, and frequency of pulse.⁷ On dogs its effects appear to be analogous to those on man.⁸ It does not cause any local irritation. Its constitutional effects are dilatation of pupil, weakness of the posterior extremities, staggering, and insensibility.

γ. On Man.—In small and repeated doses, henbane has a calming, soothing, and tranquillizing effect. This is especially observed in persons suffering with great nervous irritability, and with a too active condition of the sensorial functions. In such it frequently causes quietude, with a tendency to sleep. It frequently allays irritation and preternatural sensibility existing in any organ. It does not quicken the pulse, check secretion, or cause constipation. Large doses sometimes induce sleep. Fouquier,⁹ however, denies this. He says henbane causes headache, giddiness, dimness of sight, dilatation of pupil, a greater or less tendency to sleep, and painful delirium. In some cases these symptoms are followed by thirst, nausea, griping, and either purging or constipation; and in a few instances febrile heat and irritation of skin are induced. But I have frequently seen sleep follow its use, though its hypnotic properties are neither constant nor powerful. It more frequently fails to occasion sleep in those accustomed to the use of opium. Very large doses are apt to be followed by delirium rather than by sleep. Its power of alleviating pain and allaying spasm is greatly inferior to that of opium. In poisonous doses it causes loss of speech, dilatation of pupil, disturbance of vision (presbyopia), distortion of face, coma, and delirium, generally of the unmanageable, sometimes of the furious kind, and phantasms; and paralysis, occasionally with convulsive movements. Irritation of the stomach and bowels (manifested by nausea, vomiting, pain, and purging) is occasionally induced.¹⁰ One author¹¹ says hyoscyamus renders the hair gray, while another¹² states that it darkens it.

In its operation on the body, henbane presents several peculiarities (see vol. i. p. 237). From opium it is distinguished by the sedative rather than stimulant effects of small doses; by its not confining the bowels; by the obscurity of vision (presbyopia); and when swallowed in large doses, by its producing dilatation of the pupil, and by its being more apt to occasion delirium with phantasms. Furthermore, in some individuals opium causes headache and other distressing symptoms which henbane is not so apt to produce. From belladonna and stramonium, to which it is in several respects closely allied, it is distinguished by the very rare occurrence of any symptoms of gastro-intestinal irritation after the ingestion of large doses of it. Sundelin¹³ says "that it wants the resolvent operation and the stimu-

has scarcely any effect (perhaps a slight turbidness) when added to the decoction or to the tincture diluted with water.

(By the action of sulphuric or hydrochloric acid on the tincture or decoction of foxglove, I have not been able to detect the presence of digitaline.)

PHYSIOLOGICAL EFFECTS. *a. On Vegetables.*—Mareet¹ found that a solution of the watery extract of foxglove killed a haricot plant (*Phaseolus vulgaris*) in twenty-four hours.

β. On Animals generally.—The effects of foxglove have been tried on dogs,² horses, rabbits,³ turkeys,⁴ the domestic fowl, and frogs; and on all it has been found to act as a poison. One drachm of the powder may be given to horses as a sedative in inflammation.⁵ Two ounces have produced death in twelve hours.⁶ According to the experience of Orfila, the first symptoms of poisoning observed in [carnivorous] animals is vomiting. The influence of the poison over the heart does not appear to be uniform; for in some cases he found the pulsations of this viscus unaltered, in others accelerated, while occasionally they were retarded. In the horse killed by two ounces of foxglove, the pulse was 130 per minute, a short time before death (Moiroud)—the standard pulse of the horse being 40 or 42 per minute. The cerebro-spinal symptoms observed in animals, are diminished muscular power, convulsive movements, tremors, and insensibility. The powder acts as a local irritant, giving rise to inflammation of parts to which it is applied (Orfila).

γ. On Man.—We may, for convenience, establish three degrees of the operation of foxglove.

In the first degree, or that produced by *small and repeated doses*, foxglove sometimes affects what are termed the organic functions, without disordering the animal or cerebro-spinal functions. Thus we sometimes have the stomach disordered, the pulse altered in frequency, and sometimes also in fulness and regularity, and the secretion of urine increased, without any other marked symptoms. The order in which the symptoms just mentioned occur is not uniform; sometimes the diuresis, at others nausea, and occasionally the affection of the circulation, being the first obvious effect.

The influence of foxglove over the circulation is not at all constant. In some cases the frequency of the pulse is augmented, in others decreased, while in some it is unaffected. Lastly, in a considerable number of instances, the pulse becomes irregular or intermittent under the use of foxglove.⁷ A few drops of the tincture will, in some cases, reduce the frequency of the pulse, and render it irregular and intermittent, while in other instances much larger doses may be taken without any obvious effect on it. Dr. Withering⁸ mentions one case in which the pulse fell to 40; and I have several times seen it reduced to 50. In some cases the slowness of the pulse is preceded by an increased activity of the vascular system. From Sandras's reports⁹ this would appear to occur more frequently after small than large doses of foxglove. Dr. Sanders,¹⁰ indeed, asserts that foxglove invariably excites the pulse, and refers to an experience of 2000 cases in proof. He says, that he has seen the pulse rise from 70 to 120 under the use of foxglove, and at the end of twenty-four hours, or sooner, fall with greater or less rapidity to forty, or even below this. But an experience of the use of foxglove, in only twenty cases, will, I believe, convince most persons that Dr. Sanders has fallen into an error in the sweeping assertion which he has made. A great deal, however, depends on the position of the patient. If it be desired to reduce the frequency of the pulse, the patient should be kept in a recumbent posture. The important influence of posture was first pointed out, I believe, by Dr. Baildon.¹¹ His own pulse, which had been reduced by this plant from 110 to 40 beats per minute while he was in the recum-

¹¹ *Ed. Med. and Surg. Journ.* vol. iii. p. 270.

bent position, rose to 70 when he sat up, and to 100 when he stood. We have a ready explanation of this fact. In a state of health, the pulsations of the heart are more frequent (usually to the extent of five or six in the minute) in the erect than in the horizontal position; and it is very obvious that greater force is required to carry on the circulation in the former than in the latter, since, in the erect position, the heart and arteries have to send blood to the head against gravity. Now, the power of the heart being enfeebled by foxglove, when a demand is made on this viscus for an increase in the force of contractions by the change from the recumbent to the standing attitude, it endeavours to make up for its diminished force by an increase in the frequency of its contractions. I need scarcely add, that the sudden change of position in those who are much under the influence of this medicine, is attended with great danger, and in several instances has proved fatal; for, in consequence of the heart not having sufficient power to propel the blood to the head against gravity, fatal syncope has been the result.¹ The influence of digitalis over the pulse is more marked in some individuals or cases than in others; thus the reduction of the frequency of the pulse is in general more readily induced in weak and debilitated constitutions, than in robust and plethoric ones. Occasionally, no obvious effect on the number, force, or regularity of the pulse is produced, though the foxglove may be given to an extent sufficient to excite vomiting and cerebral disorder. Shroek² experienced, from two grains of foxglove, nausea, headache, small, soft, and quick pulse, dryness of the gums and throat, giddiness, weakness of limbs, and increased secretion of saliva. Some hours after, he observed sparks before the eyes, his vision became dim, and he experienced a sensation of pressure on the eyeballs.

A most important fact connected with the repeated uses of small doses of it, is the *cumulative effect* sometimes observed. It has not unfrequently happened that, in consequence of the continued use of small doses of this medicine, very dangerous symptoms, in some cases terminating in death, have occurred. The most prominent of these were great depression of the vascular system, giddiness, want of sleep, convulsions, and sometimes nausea and vomiting.³ A knowledge of its occasional occurrence impresses us with the necessity of exercising great caution in the use of this remedy, particularly with respect to the continuance of its administration and increase of dose; and it shows that, after the constitutional effect has become obvious, it is prudent to suspend from time to time the exhibition of the remedy, in order to guard against the effects of this alarming accumulation. I may add, however, that I have used it, and seen others employ it, most extensively, and in full doses, and have rarely seen any dangerous consequences; and I believe, therefore, the effects of accumulation to be much less frequent than the statements of authors of repute would lead us to expect. The experience of Dr. Holland⁴ is to the same effect. "Though employing the medicine somewhat largely in practice," he observes, "I do not recollect a case in which I have seen any injurious consequences from this cause."

The diuretic operation for which we employ foxglove is very inconstant. Dr. Withering stated that this medicine more frequently succeeds as a diuretic than any other, and that if it fail, there is but little chance of any other remedy succeeding. My experience, however, is not in accordance with Dr. Withering's. I have frequently seen foxglove fail in exciting diuresis, and have often found the infusion of common broom (*Cytisus scoparius*) subsequently succeed. It has been asserted by some, that the diuretic effect of foxglove was only observed in dropsical cases, and that it, therefore, depended on the stimulus given to the absorbent vessels, and not to any direct influence exerted over the kidneys; but the statement is not true,

time to time to keep the powder covered. Cease to filter when the liquid which passes begins to produce a precipitate as it falls. Distil off the alcohol from the filtered liquor, and evaporate the residue to the proper consistence.)—This preparation is intended as a substitute for the preceding, as the fresh herb cannot be obtained in sufficient quantity in the United States. It is a fine, clear, dark, shining extract, is possessed of the active properties of the drug, and may be employed in lieu of the common extract. The dose is gr. j to gr. v, or larger quantities if required.]

172. ATROPA BELLADONNA, Linn.—COMMON DWALE; DEADLY NIGHTSHADE.

Sex. Syst. Pentandria, Monogynia.

(Atropia; alkali e radice comparatum crystalli; Folium recens et exsiccatum, L.—Leaves, E.—The leaves and root, D.)

HISTORY.—Belladonna, being a native of both Greece and Italy, was doubtless known to, and described by, the ancient Greek and Roman writers. Modern botanists, however, have been unable to identify it with certainty. Fraas¹ is of opinion that it is the *Μανδραγόρας* of Theophrastus,² the *Στρίχνος μανικός* (“*άνθος μέλαν*”) of Dioscorides,³ the third sort of *Strychnos* (*Solanum*) of Pliny.⁴ But this notion is not without its difficulties. The plant which Theophrastus mentions under the above name had a stem like the *νάρθηξ* (*ferula*), and a black racemose fruit with a vinous taste. Now the stem of belladonna certainly does not resemble that of an umbelliferous plant, nor is the fruit racemose. Sibthorp and Smith⁵ have, in my opinion, only exercised a proper precaution in not assigning any ancient synonyme to belladonna.

The earliest undoubted notice of belladonna occurs in the work of Tragus (A. D. 1532), who calls it *Solanum hortense nigrum*.⁶ It has been supposed that it was this plant which produced such remarkable and fatal effects on the Roman soldiers during their retreat from the Parthians.⁷ Buchanan⁸ relates that the Scots mixed the juice of this plant with the bread and drink, which, by their truce, they were to supply the Danes, which so intoxicated them, that the Scots killed the greatest part of Sweno's army while asleep. Shakspeare⁹ is supposed to allude to it under the name of the *insane root*.

BOTANY. **Gen. Char.**—*Calyx* 5-parted. *Corolla* hypogynous, funnel-shaped, campanulate; the limb plaited, 5—10-lobed. *Stamens* 5, inserted into the lower part of the corolla, exerted, or nearly so; filaments filiform; anthers dehiscing longitudinally. *Ovary* 2-celled; placentæ inserted in a line on the dorsal dissepiment; ovules numerous; *style* simple; *stigma* peltato-depressed. *Berry* supported by the spreading calyx, 2-celled. *Seeds* many, subreniform; *embryo* in fleshy albumen, subperipherical, arched or annular (Endlicher).

Sp. Char.—*Stem* herbaceous. *Leaves* broadly-ovate, entire. *Flowers* solitary, axillary on short stalks (C. C. Babington).

Root fleshy, creeping. Whole plant fetid when bruised, of a dark and lurid aspect, indicative of its deadly narcotic quality. *Stems* herbaceous, 3 feet high, round, branched, leafy, slightly downy. *Leaves* lateral, mostly 2 together of unequal size, ovate, acute, entire, smooth. *Flowers* imperfectly axillary, solitary, stalked, drooping, dark full purple in the border, paler downwards, about an inch long. *Berry* of a shining violet black, the size of a small cherry, sweetish, and not nauseous (Smith).

Hab.—Indigenous; hedges and waste ground, on a calcareous soil. Flowers in June.

¹ *Synops. Plant. Fl. Class.* p. 166, 1845.

⁴ See Plutarch's *Life of Antony*.

⁵ *Macbeth*, Act i. Scene 3d.

⁶ *Hist. Plant.* lib. vi. cap. 2.

⁷ *Lib. xxi.* cap. 105; and *lib. xxviii.* cap. 109, ed. Valp.

⁸ Bauhin, *Pinax*.

⁹ *Rerum Scot. Hist.* lib. vii.

DESCRIPTION.—The root (*radix belladonnæ*), when fresh, is one or more inches thick, and sometimes a foot or more long; it is branching, fleshy, internally white, externally grayish or brownish-white. Its taste is slight, sweetish; its odour feeble. It may be collected in the autumn or early in the spring. The flowering stems (*herba belladonnæ*) are collected in June or July; they are then deprived of leaves (*folia belladonnæ*), which are to be carefully dried. The leaves, when fresh, have a feeble, bitterish, sub-acid taste.

Oval, acute, quite entire, smooth, when bruised evolves an unpleasant odour.

The herb which grows spontaneously in hedges and uncultivated places is to be preferred to that cultivated in gardens.—*Ph. Lond.*

COMPOSITION.—The leaves of belladonna were analyzed, in 1808, by Melandri;¹ the expressed juice, in 1809, by Vauquelin;² and the dried herb, in 1819, by Brandes.³ Besides these, there have been several less complete examinations of this plant by other chemists, which have yielded more or less interesting results.

Brandes's Analysis.

Supermalate of atropia	1.51
Pseudo-toxin with malate of atropia and potash salts	16.05
Wax	0.70
Chlorophylle	5.84
Phytocolla (a nitrogenous substance insoluble in alcohol)	6.90
Gum	8.33
Starch	1.25
Albumen	10.70
Lignin	13.70
Salts	7.47
Water	25.50
Loss	2.05

Dried herb of Belladonna 100.00

1. **ATROPIA.**—(See p. 478.)

2. **PSEUDOTOXIN.**—A substance obtained by Brandes from the watery extract of belladonna. It is a brownish-yellow, soluble in water, insoluble in absolute alcohol and ether, is coloured green by the salts of iron, and is totally precipitated from its watery solution by the salts of lead, and by tincture of galls.⁴

3. **BELLADONNIN.**—Under this name, Luebeck⁵ has described a volatile vegetable alkali, which, he says, is distinct from atropia. It is crystallizable, and has an ammoniacal odour. It consists of carbon 28.5, hydrogen 22.4, nitrogen 32.1, oxygen 17.0. The crystals contain three equivalents of water. Two grains caused extreme heat in the throat, and constriction of the larynx.

4. **ATROPIC ACID.**—This name has been given by Richter⁶ to a volatile, crystallizable acid, distinguished from benzoic acid by its not precipitating the salts of iron.

PHYSIOLOGICAL EFFECTS. *a. On Vegetables.*—An aqueous solution of extract of belladonna is poisonous to plants.⁷

β. On Animals generally.—Belladonna proves poisonous to animals and birds; but much less so to herbivorous than to carnivorous animals. Eight pounds (Troy) of the leaves have been eaten by a horse without any ill effects.⁸ The late Mr. Anderson told me that the blackbirds eat the seeds at the Chelsea Garden with impunity. A pound of ripe berries has been given to an ass with very little effect.⁹ Given to dogs, belladonna causes dilatation of pupil, plaintive cries, efforts to vomit, weakness of the posterior extremities, staggering, frequent pulse, a state like intoxication, and death.¹⁰ Forty or fifty grains of the watery extract, injected into the jugular vein of dogs, have proved fatal.¹¹ Flourens¹² thinks that the *tubercula quadrigemina* are the parts of the nervous centres on which this poison specifically acts. His inferences were drawn from experiments made on birds. The topical action of belladonna is that of an acrid, though not a very violent one.¹³

γ. *On Man.*—In the first degree of its operation, belladonna diminishes sensibility and irritability. This effect (called by some *sedative*) is scarcely obvious in the healthy organism, but is well seen in morbid states, when these properties are preternaturally increased. A very frequent, and sometimes the earliest, obvious effect of belladonna is dryness of the mouth and throat, frequently attended with thirst. The other secretions and the circulation are oftentimes not affected, though occasionally they are augmented. Mr. Bailey¹ “asserts that belladonna affects neither the stomach nor bowels, nor any of the secretions nor excretions, those of the salivary glands excepted.” The asserted influence of belladonna over the organic functions is said to be shown by its power of inducing, in some cases, resolution of swellings and tumours of various kinds, as will be presently noticed.

In the second degree of its operation, belladonna manifests, both in healthy and morbid conditions, its remarkable influence over the cerebro-spinal system. It causes dilatation of the pupils (mydriasis), presbyopia, or long-sightedness, with obscurity of vision, or absolute blindness (amaurosis), visual illusions (phantasms), suffused eyes, occasionally disturbance of hearing (as singing in the ears, &c.), numbness of the face, confusion of head, giddiness, and delirium, which at times resembles intoxication, and may be combined with or followed by sopor. These symptoms are usually preceded by a febrile condition, attended with a remarkable affection of the mouth, throat, and adjacent parts. Besides dryness of these parts, it causes difficulty of deglutition and of articulation, a feeling of constriction about the throat, nausea, and sometimes actual vomiting, and, now and then, swelling and redness of the face. The pulse is usually hurried and small. The cutaneous, renal, and mucous secretions are frequently augmented. An exanthematous eruption, like that of scarlet fever, has been noticed; and irritation of the urinary organs, has in some instances occurred.²

In some cases very severe effects have been induced by the application of the extract to abraded surfaces.³ The continued application of it to the sound skin has also been attended with similar effects.⁴

In the third degree of its operation, belladonna produces effects similar to the preceding, but in a more violent form. The following are the symptoms experienced by above 150 soldiers, who were poisoned by the berries of belladonna, which were gathered at Pirna, near Dresden: “Dilatation and immobility of the pupil; almost complete insensibility of the eye to the presence of external objects, or at least confused vision; injection of the conjunctiva with a bluish blood; protrusion of the eye, which in some appeared as if it were dull, and in others ardent and furious; dryness of the lips, tongue, palate, and throat; deglutition difficult or even impossible; nausea not followed by vomiting; feeling of weakness, lipothymia, syncope; difficulty or impossibility of standing, frequent bending forward of the trunk; continual motion of the hands and fingers; gay delirium, with a vacant smile; aphonia or confused sounds, uttered with pain; probably ineffectual desires of going to stool; gradual restoration to health and reason, without any recollection of the preceding state.”⁵

Seven cases (two of which proved fatal) of poisoning by belladonna berries have occurred under my notice in the London Hospital; of these, a report has been published by Dr. Letheby.⁶ The phenomena were tolerably uniform. The following symptoms especially attracted my attention:—

1. *Dryness of the fauces.*—The excessive dryness of all the parts about the throat contributed greatly to the difficulty of swallowing and alteration of voice.

2. *Scarlet eruption.*—In several cases a scarlet eruption appeared on the arms and legs.

3. *Mydriasis and presbyopia.*—Mydriasis, or dilatation of the pupil, was present in every case; and was accompanied, in all the cases in which the patient was in a fit state for observation,

with presbyopia, or long-sightedness. These two symptoms depend, as I have before stated (see vol. i. p. 245), on the paralyzing influence of belladonna on the muscular fibres of the iris, by which mydriasis is produced, and on the ciliary muscle, by which the adjusting power of the eye is impaired. I strongly suspect that the impaired vision which has been ascribed to the use of belladonna is chiefly or entirely presbyopia. In one of the patients (a woman) above alluded to, the vision was so much impaired that she could not see to read; and when I placed the prayer card in her hand, she held it upside down, and declared her inability to distinguish the letters or words on it. But after trying several pairs of spectacles, borrowed of patients and others in the ward, she found one (magnifiers) which enabled her to read with ease. This agrees with the results of experiments of Müller¹ on himself. This physiologist found that, by the local action of belladonna on one eye, he caused presbyopia of that eye, and thus gave rise to an unequal refractive power of the two eyes. Moreover, it accords with the effects experienced on his own person by Dr. Lobb, who informs me that he could see objects at a distance (as on the opposite side of the street), but could not distinguish a letter or a word in a book; but, by the aid of a magnifying-glass or powerful spectacles, he could read distinctly the smallest print.

4. *Delirium; Phantasms.*—The delirium was of the cheerful or wild sort, amounting in some cases to actual frenzy. In some of the patients it subsided into a kind of sleep attended with pleasant dreams, which provoked laughter. The delirium was attended with phantasms; and in this respect resembled that caused by alcohol (*delirium é potu*); but the mind did not run on cats, rats, and mice, as in the case of drunkards. Sometimes the phantasms appeared to be in the air, and various attempts were made to catch or chase them with the hands; at other times they were supposed to be on the bed. One patient (a woman) fancied the sheets were covered with cucumbers. The production of phantasms by belladonna was known to Linæus,² who calls this agent "a phantastic," (see *ante*, p. 237.)

5. *Convulsions; Paralysis; Sopor or Coma.*—In most of the cases, the power of the will over the muscles was so far disordered, that the muscular movements were somewhat irregular, causing a kind of staggering or jerking; but actual convulsions were not general. There was sopor, which terminated in coma, with a weakened or paralytic condition of the muscles.

The active principle of belladonna becomes absorbed and is thrown out of the urine, in which secretion both Runge and Dr. Letheby have detected it (see vol. i. p. 152, foot-note).

In comparing the operation of belladonna with that of other cerebro-spinals (see vol. i. p. 235), the most remarkable symptoms which attract our attention are the dilatation of the pupils, with insensibility of the irides to light, disturbance of vision (presbyopia), giddiness, staggering, the delirium (extravagant, pleasing, or furious), with phantasms, followed by sopor, and the remarkable affection of the mouth and throat (dryness of the throat, difficulty of deglutition and of articulation). Convulsions are rare, and, when they occur, are slight. Lethargy or sopor occurs subsequently to the delirium. Local irritation is not well marked.

These characters distinguish the effects of belladonna from those of any other substance, except henbane, stramonium, and perhaps from some other solanaceous species (see *ante*, p. 237).

When applied to the eyebrow, belladonna causes dilatation of the pupil, without necessarily affecting the other eye or disturbing vision. Segalas³ thought that absorption or inhibition was essential to this effect; but the action on the iris depends, according to Müller,⁴ not on the operation of the belladonna on the central organs of the nervous system, but on its topical, paralyzing influence on the ciliary nerves (see vol. i. p. 234). When, however, belladonna is swallowed, it is obvious that the irides can become affected through the general system only, and in this case the dilatation of the pupil is accompanied with disturbance of vision.⁵ The pneumogastric nerve is obviously concerned in producing the affection of the mouth, and the difficulty of deglutition and articulation.

The disorder of the intellect and of the external senses caused by belladonna proves that the influence of this agent is not limited to the excito-motory system,

² *Materia Medica*.

³ *Physiology*, vol. i. p. 630.

⁴ *Lancet*, 1826—27, vol. xii. p. 170.

⁵ For some interesting observations on the associated functions of the retina and iris, consult Grainger's *Observations on the Structure and Functions of the Spinal Cord*, p. 72, *et seq.*—The power which belladonna possesses of dilating the pupil was discovered by J. A. H. Reimarus, and was made known by Daries in 1776 (*Marx, Lond. Med. Gaz. N. S.* vol. i. p. 185, 1844—45).

but is extended to those portions of the nervous centres which are the seat of the intellect and of sensibility. I have, therefore, classed it among the phrenics (see vol. i. p. 235) and anæsthetics (see *ante*, p. 238).

USES.—Belladonna has been employed to allay pain and nervous irritation (*cretismus nervosus*, of some authors); to diminish the sensibility of the retina to the impression of light; to produce dilatation of the pupil; to counteract that condition of brain which is accompanied with contraction of the pupil; and to lessen rigidity and spasmodic contraction of muscular fibres. These uses obviously arise out of the ascertained physiological effects of the remedy. There are others, however, which may be regarded as altogether empirical; such as its employment to resolve or discuss scirrhus tumours.

The indications and contraindications for its use are not sufficiently established to induce us to place much confidence in them. My own experience leads me to believe that it is not a remedy fitted for plethoric constitutions, or for febrile or acute inflammatory cases; and I am not disposed to admit the observations of Dr. Graves, hereafter to be mentioned, as offering any valid objections to these statements.

1. *To allay pain and nervous irritation.*—As an anodyne in most internal pains, no remedy hitherto proposed is equal to opium; but this agent totally fails us in many of those external pains known as *neuralgia*, *protopalgia*, or *tic douloureux*. In such cases, belladonna occasionally succeeds in abating, sometimes in completely removing pain; while it totally fails to give relief in the internal pains for which experience has found opium so efficacious. It is remarkable, therefore, that while both these cerebro-spinals (narcotics, *auctor.*) agree in lessening pain, they totally disagree as to the cases in which they succeed, and for which they are individually applicable. In the treatment of neuralgia, belladonna is employed both internally and externally. I believe that, to be successful, it requires, in many cases, to be persevered in until dryness of the throat, dilatation of pupil, and some disorder of vision are produced. Just as in many diseases for which mercury has been found a most efficient remedy, it is necessary to continue the use of this mineral until the mouth be affected, and often even to use it for some time afterwards. Of the success of belladonna in the treatment of neuralgia, we have abundant evidence in the published cases of Mr. Bailey,¹ and of several other practitioners.² My own experience of the use of this remedy leads me to regard it as very much inferior to aconite as a local remedy for this disease.

Besides neuralgia, there are many other painful affections against which belladonna is used as a local anodyne. Such are arthritic pains, painful ulcers, glandular enlargements which are tender to the touch, &c. Dr. Osborne³ says that, given internally, it causes an immediate cessation of the migratory or flying pains of rheumatism, without producing any effect on the fixed pains.

2. *As an antispasmodic.*—To relieve rigidity and spasmodic contraction of muscular fibres, belladonna sometimes proves serviceable as a topical remedy. In *rigidity of the os uteri*, during lingering labours or puerperal convulsions, the extract or an ointment of belladonna (see *unguentum belladonnæ*) has been applied to the part by way of friction. Though the practice has been lauded by Chaussier,⁴ and adopted by Velpeau,⁵ Conquest,⁶ and others, yet it has not found much favour with British practitioners. It cannot be regarded as a substitute for, but only an adjuvant to depletion; and its use is not devoid of danger; for, not to insist on the possibility of absorption, and the consequent injurious effects therefrom, it is obvious that the long-continued friction of the tender womb, and the removal of the lubricating mucus, may dispose to inflammation. In *spasmodic stricture of the urethra*, and of the *sphincters of the bladder and rectum*, and in *spasmodic con-*

⁶ *Outlines of Midwifery.*

traction of the uterus, the topical use of the extract (smeared on a bougie, applied to the perineum or other parts, or employed by way of a clyster) has in some cases appeared to give relief.¹ In *strangulated hernia*, it has been employed to produce relaxation of the abdominal muscles.²

In a case of *angina pectoris*, unconnected with organic disease, the application of a belladonna plaster to the chest (before the ulcerations caused by tartar emetic ointment had healed) produced alarming signs of poisoning; but when these had subsided, all symptoms of the *angina* had totally disappeared.³

Considerable relief has been gained in several cases of *hooping-cough* by the use of belladonna.⁴ Its occasional efficacy depends in part, probably, on its lessening the necessity of respiration,⁵ as well also on its power of obviating spasm of the bronchial tubes, and of decreasing the susceptibility of the bronchial membrane to the influence of the exciting causes of the paroxysms. But, like all other vaunted specifics for this peculiar disease, it frequently fails to give the least relief.

3. *In maladies of the eyes*.—Belladonna is applied to the eye for two purposes: the first, and the most common, is to dilate the pupil; the other is to diminish the preternatural sensibility of the retina to the impression of light. *Dilatation of the pupil* is sometimes produced, in certain diseases of the eye, in order to enable us to examine the condition of the refractive humours, and thereby to ascertain the nature and extent of the malady; as in cases of incipient cataract, which might otherwise be occasionally confounded with glaucoma or amaurosis. In the operation of cataract by solution or absorption (*keratonyxis*), the full dilatation of the pupil by belladonna is essential.⁶ In *iritis*, dilatation of the pupil is important, in order to prevent, or in recent cases to rupture, adhesions of the uvea to the capsule of the crystalline lens. Some surgeons consider it an objectionable remedy during the early stage of the disease. In *prolapsus iridis*, benefit is, under some circumstances, gained by the use of belladonna; as, where there is opacity of the cornea covering the pupil, the dilatation of the aperture, so as to get its circumference beyond the opaque spot, is attended with an improvement of vision. These are some of the cases in which dilatation of the pupil by belladonna is advisable. It is usually effected by applying the extract (see *extractum belladonnæ*) to the parts around the eye, or to the conjunctiva. The dilatation usually takes place within a few minutes, and sometimes continues for twenty-four hours.

Belladonna is sometimes employed in inflammatory and other affections of the eye, to diminish the morbid sensibility of this organ to the influence of light.⁷

4. *As a resolvent or discutient*.—In enlargement and induration of the lymphatic glands, in scirrhus and cancer (or diseases which have been supposed to be such), belladonna has gained no slight repute from its supposed resolvent or discutient properties. That it may give relief by its anodyne powers we can easily understand, but that it has any real resolvent or discutient properties in the diseases just enumerated, may be reasonably doubted, notwithstanding the favourable reports of Gataker,⁸ Cullen,⁹ Blackett,¹⁰ and others.¹¹ Bromfield¹² and others have reported unfavourably of it, and no one, I think, now places any reliance on it.

5. *As a prophylactic against scarlatina*.—The introduction of belladonna into practice as a preventive of scarlet fever, is owing to the absurd homœopathic axiom of "*similia similibus curantur*;" for, as this plant gives rise to an affection of the throat, and sometimes to a scarlet rash on the skin, its power of guarding the sys-

tem against the reception of scarlet fever has been assumed; and the assumption has been endeavoured to be established by an appeal to experience. Bayle¹ has collected from various publications 2,027 cases of persons who took this medicine, and were exposed to the contagion; of these 1,948 escaped. Oppenheim² gave it to 1,200 soldiers, and only twelve became affected. To the authorities here referred to may be added Hufeland³ and Koreff,⁴ who admit, from their own personal observations, the efficacy of the remedy, though they have not specified the number of cases in which they have tried it. But bearing in mind the well-known capriciousness evinced by scarlet fever (as indeed by other contagious disorders) in regard to the subjects of its attacks, and the large number of those who, though exposed to its influence, escape, the best evidence hitherto adduced in favour of the notion must be admitted to be inconclusive. While, therefore, the facts brought forward in favour of the existence of this prophylactic power are only negative, those which can be adduced against it are positive. For I conceive twenty cases of failure are more conclusive against the opinion here referred to, than one thousand of non-occurrence are in favour of it. Now Lehman,⁵ Barth,⁶ Wendt,⁷ Muhrbeck,⁸ Hoffmann,⁹ Bock,¹⁰ and many others that I could refer to, declare it has failed in their hands to evince its prophylactic powers. In this country we have no extended series of observations to quote; but the cases which I am acquainted with are decidedly against the efficacy of the remedy. A remarkable failure is mentioned by Dr. Sigmond,¹¹ of a family of eleven persons who took the supposed specific, yet every individual contracted the disease.

6. *In fever, with contraction of the pupil.*—Dr. Graves¹² has recently proposed the use of belladonna in those cases of fever with cerebral disease which are attended with contraction of the pupil. "It is not unreasonable," he observes, "to suppose that the state of the brain which accompanies dilatation of the pupil is different from that which accompanies contraction; and if belladonna has an effect in producing that cerebral state which is attended with dilatation, it is not going too far to infer, that its administration may do much towards counteracting the opposite condition; neither is it unphysiological to conclude, that if a remedy be capable of counteracting, or preventing, one very remarkable effect of a certain morbid state of the brain, it may also counteract other symptoms connected with the same condition." This line of argument, it must be admitted, is ingenious and plausible, and is supported by reference to several apparently successful cases treated on the principles here laid down. But I would observe, if the above reasoning were valid, opium should be serviceable in cerebral diseases attended with dilatation of pupil, since it causes contraction of this aperture. Now this is in direct opposition to our every-day experience of the uses of this important narcotic.

7. *In other diseases.*—Cruveilhier¹³ has found belladonna-smoking relieve some cases of *phthisis*. The fresh leaves were infused in a strong solution of opium, and then dried like tobacco; the patients began by smoking two pipes a day, and the quantity was gradually increased to six pipes. Perhaps this practice would be beneficial in spasmodic asthma and old catarrhs. In *hydrophobia*, notwithstanding the asserted prophylactic powers of this medicine,¹⁴ there is no valid ground for believing in its efficacy. I tried it in one case without success. In *epilepsy*, *mania*, *hysteria*, *chorea*, and some other maladies of the centro-spinal system, occasional benefit has resulted by the use of belladonna. In *ileus*,¹⁵ it has been most successfully used in the form of clyster, as a substitute for tobacco, which is objectionable on account of the horrible sickness and great depression which it causes.

ADMINISTRATION.—The dose of the *powder* for an adult is one grain, which should be gradually increased until dryness of the throat, dilatation of pupil, or some head symptoms, are produced. For children, the dose at the commencement should be one-eighth of a grain. For internal as well as external use the *extract* or *tincture* is, however, commonly employed. For external use an *infusion* of the leaves is sometimes used as a fomentation, or is made into a poultice with bread or linseed meal.

ANTIDOTES.—Similar to those for opium. After the use of evacuaunts the vegetable acids have appeared to give great relief. Decoction of nutgalls or green tea might probably prove serviceable.

I. EXTRACTUM BELLADONNÆ, L. E. [U. S.]; *Succus spissatus Belladonnæ*, D.; *Extract of Belladonna*.—(Fresh Belladonna Leaves ʒj. Bruise them in a stone mortar; then press out the juice, and evaporate it, unstrained, to a proper consistence, L.—The *Edinburgh College* directs the expressed juice to be filtered, and then to be evaporated, in the vapour-bath, to the consistence of firm extract, stirring constantly towards the close.—The *Dublin College* takes of fresh Belladonna Leaves, collected when the plant begins to flower, any convenient quantity. Crush them in a mortar, express the juice, and allow it to stand for twenty-four hours. Pour off the clear liquor, and set it aside for subsequent use; and, having placed the sediment in a calico filter, wash it with an equal bulk of distilled water, and mix the washings with the decanted liquor. When, by the application of a water heat, coagulation has occurred, skim off the coagulated matter, filter the hot liquid through flannel, mix in now the washed sediment, and evaporate to the consistence of a firm extract, by a steam or water bath, constantly stirring, particularly towards the close of the evaporation.)—1 cwt. of fresh belladonna yields from 4 to 6 lbs. of extract.¹ Dose, gr. j to gr. v, cautiously increased. As the strength of the extract is extremely variable, some writers recommend only one-quarter or one-half of a grain to be given at the commencement of its use, and to be repeated three times a day; and the dose to be increased until the well-known effects of the remedy are produced. Mr. Bailey observes that he at first began with one grain, and repeated it every four hours until relief followed; but further experience induced him to commence with three times that quantity, and, if a repetition were necessary, to give it in diminished doses afterwards. Spread upon leather, the extract is frequently used as a plaster to relieve neuralgic and other pains (see *Emplastrum Belladonnæ*). Diluted with water to the consistence of cream, it is applied to the eyebrow to produce dilatation of the pupil; or an aqueous solution of the extract is dropped between the lids. Mixed with lard or spermaceti ointment, it is used as a topical anodyne and antispasmodic in various diseases (see *Unguentum Belladonnæ*). A bougie smeared over with the extract and oil is sometimes used with benefit in stricture.² A drachm or two of the extract, either alone or in the form of ointment, may be applied to the os uteri to diminish rigidity. In irritation of the bladder, urinary organs, or rectum, clysters holding in solution the extract are sometimes used. Rubbed into the perineum or over the track of the urethra, the extract or ointment is useful in preventing chordee, and alleviating spasm of the neck of the bladder.

[As the fresh leaves of Belladonna are with difficulty procured in the United States, as a substitute for the above extract, the Pharmacopœia directs an extract to be made from the dried leaves by means of diluted alcohol. The formula is, Belladonna, in coarse powder, ʒj; Diluted Alcohol Oiv. Moisten first with half a pint of the fluid, and allow to stand for 24 hours. Then transfer to a percolator and displace, driving over the last quantity of fluid with water. Evaporate the solution to the proper consistence. This constitutes the *Extractum Belladonnæ Alcoholicum*, U. S. See a similarly prepared extract from Hyoseyamus.]

² *Lond. Med. Gaz.* vol. v. p. 735.

2. **EMPLASTRUM BELLADONNÆ**, L. E. D. [U. S.]; *Plaster of Belladonna*.—(Extract of Belladonna $\bar{5}j$, *D.*), Soap Plaster, of each, $\bar{5}ij$ [Resin Plaster $\bar{5}ij$, *D.*, $\bar{5}ij$, *E.*]. Add the extract to the plaster, melted by the heat of a water-bath, and mix.)—[The U. S. P. directs of Resin Plaster $\bar{5}ij$; Extract of Belladonna $\bar{5}iss.$]—Anodyne and antispasmodic. Applied for the relief of neuralgic, rheumatic, and other pains. It is said to relieve the pain of dysmenorrhœa when applied to the sacrum. In spreading it, care must be taken not to employ a very hot spatula, or the properties of the extract will be injured.

3. **UNGUENTUM BELLADONNÆ**, L. [U. S.]; *Ointment of Belladonna*.—(Extract of Belladonna $\bar{5}j$; Spermaceti Lard $\bar{5}j$; [Lard $\bar{5}j$ U. S.] Mix.)—A very useful preparation; and may be used as an anodyne and antispasmodic in some of the before-mentioned cases.

4. **TINCTURA BELLADONNÆ**, L. [U. S.]; *Tinctura Foliorum Belladonnæ*, *D.*; *Tincture of Belladonna*.—(Belladonna Leaves, dried, $\bar{5}iv$; Proof Spirit [Diluted Alcohol, U. S.] *Oij.* Macerate for seven [fourteen, *D.*] days, and strain.)—Dose, m_{xx} to m_{xl} . Mr. Blackett¹ prepared a *saturated tincture of belladonna* by macerating, for fourteen days, $\bar{3}x$ of extract of belladonna in $\bar{H}j$ of proof spirit; then straining. The dose of this is m_{ij} or m_{iij} , gradually increased; in the form of lotion, a drachm of it was added to eight ounces of liquid.

SUCCUS BELLADONNÆ.—*The Preserved Juice of Belladonna* may be substituted for the tincture. From 2 cwt. of belladonna leaves, gathered towards the end of June, 36 imperial quarts of juice have been procured.

5. **ATROPIA**, L.; *Atropina*; *Atropium*; *Atropine*. Symbol At . Formula $\text{C}^{24}\text{H}^{23}\text{NO}^6$. Eq. Wt. 289.—Found in all parts of the plant. Discovered in 1819 by M. Brandes. The most improved processes for the preparation of this alkaloid are those of Mein² and Richter.³ The following is a sketch of Mein's process as modified by Liebig:—

Fresh dried and powdered belladonna root is to be exhausted by alcohol, sp. gr. 0.822. To the tincture add slaked lime (in the proportion of one part of lime to 24 parts of dried root). Digest for 24 hours, frequently shaking. Add, drop by drop, sulphuric acid to the filtered liquor till there is a slight excess; then filter again, and distil off rather more than half of the spirit. To the residue add some water, and evaporate the remainder of the alcohol as rapidly as possible, but *by a very gentle heat*; filter again, and continue the evaporation until the liquid is reduced to the 1-12th part of the weight of the root employed. To the cold liquid add, drop by drop, a concentrated solution of carbonate of potash, to throw down a dark grayish-brown precipitate, taking care not to render the liquid alkaline. In a few hours filter again; add carbonate of potash as long as a precipitate (atropia) is produced; and in from 12 to 24 hours collect the crystallized atropia on a filter, press it between folds of blotting-paper, and dry it.

To purify the dry but impure atropia, make it into a paste with water, and again squeeze between folds of blotting-paper; dry it, and dissolve in five times its weight of alcohol. The filtered liquor is to be decolorized by shaking it with purified animal charcoal, then deprived of the greater part of its alcohol by distillation, and afterwards evaporated by a gentle heat, so as to allow the atropia to crystallize; or draw off half of the spirit, add, gradually, water (3 or 4 parts), which renders the liquid milky, heat to boiling, and allow it to cool slowly; or add to the spirituous solution 6 or 8 times its volume of cold water, which renders the liquid milky, and in from 12 to 24 hours the atropia crystallizes, and is to be dried on blotting-paper.

In this process, the alcohol extracts from the belladonna root a salt of atropia; this is decomposed by the lime, which removes the organic acid and colouring extractive matter. Sulphuric acid is then added, to unite with the disengaged atropia;

¹ *Lond. Med. Rep.* vol. xix. p. 458.

² *Journ. de Pharm.* t. xx. p. 57, 1834; also *Thomson's Chemistry of Organic Bodies*. p. 273, 1832.

³ *Pharm. Central-Blatt für 1837*, p. 613.

for this alkaloid, when free, and especially when in contact with alkalies, readily undergoes decomposition by heat. The solution of sulphate of atropia must be evaporated by a very gentle heat, because the atropia salts, especially in the impure state, easily undergo decomposition. A small quantity of carbonate of potash is necessary, to separate a resinous substance which impedes the crystallization of the atropia. An excess of a concentrated solution of carbonate of potash is required to precipitate, as speedily as possible, the atropia, as by long contact with watery fluids this alkaloid disappears.

Messrs. Bouchardat and Cooper¹ recommend the following mode of preparing atropia: The atropia is to be precipitated by a watery solution of iodine in iodide of potassium, and the ioduretted hydriodate of atropia decomposed by zinc and water. The metallic oxide is separated by means of carbonate of potash, and the alkaloid dissolved in alcohol.

Atropia crystallizes from its concentrated hot, watery, or spirituous solution in white, transparent, silky prisms; from its solution in dilute spirit, in needles like those of sulphate of quinia. It is odourless, and has a very bitter, acrid, somewhat metallic taste. Impure atropia is not crystalline, is more or less coloured, and has an unpleasant odour. One part of atropia requires 200 parts of cold water, or 54 parts of hot water, to dissolve it. It is soluble in 1½ times its weight of cold alcohol, but requires, at ordinary temperatures, 25 parts of ether to dissolve it, or 6 parts of boiling ether.

It reacts on vegetable colours as an alkali, fuses by heat, and at a higher temperature is partly volatilized and partly decomposed. Nitric acid dissolves it, forming a yellow solution. Cold oil of vitriol dissolves it without colour; but if heat be applied, the mixture acquires a red colour. When heated with a solution of potash or soda, atropia undergoes decomposition, and gives out ammonia.

White, has the shape of prisms, is soluble in water and in spirit. No characters are at present known by which its purity can be certainly indicated, *L.*

Atropia possesses the property of left-handed circular polarization; but its rotating power is feeble, though it is unaffected by the presence of acids.

A watery solution of a salt of atropia is reddened by tincture of iodine; yields a citron-yellow precipitate with a chloride of gold; a whitish, flocculent precipitate with tincture of nutgalls; and a yellowish-white with chloride of platinum. The *sulphate, hydrochlorate, and acetate of atropia* are crystalline salts.

Atropia is a most energetic poison. Its effects are similar to, but more powerful than those of belladonna. Dogs are readily poisoned by it; but rabbits are less under its influence. A very minute (imponderable) quantity applied to the eye is sufficient to dilate the pupil. Given to dogs it excites vomiting, dilatation of the pupil, and stupor. On man, the effect is much stronger. One centigramme (about 1/6th of a grain) produces the following symptoms: At first, acceleration of the pulse by eight to twenty strokes; after from fifteen to thirty minutes, an affection of the brain is produced. The first and most constant symptom is dry throat, with difficulty of swallowing. The second is dilatation of pupils, with dimness of sight, also giddiness, noise in the ears, hallucination, delirium, and occasionally strangury; numbness of the limbs, a sensation of formication in the arms, rigidity of the thighs, depression of the pulse. The voice is sometimes weakened; or there may be complete aphonia. The unfavourable symptoms disappear after from twelve to twenty hours.

Atropia has recently been employed medicinally (chiefly as an external agent) as a substitute for belladonna, to which it is considered superior, on account chiefly of the uncertainty of the latter. It is of course much more energetic, and, for external use especially, is much cleaner than the extract. As a topical agent, it has been employed as a mydriatic (see vol. i. p. 245) or dilator of the pupil, by Reisinger, Mr. W. W. Cooper,² and Dr. Brookes,³ in cataract, &c. The last-mentioned writer states that, in a case of glaucoma, he succeeded in causing dilatation of the pupil

¹ *Annuaire de Thérapeutique pour 1819.*

² *Ibid.* January 30, 1847.

³ *Lancet*, June 8, 1844.

with an ointment of atropia when belladonna failed. As an anæsthetic or anodyne (see vol. i. p. 238), he used the same preparation with success in a painful affection of the face (neuralgia?).—The local pain which atropia produces when used endermically (see vol. i. p. 174) is of very short duration, and is unattended with any ill consequences. Internally, atropia has been employed in hooping-cough, chorea, and some other nervous diseases.

The dose of atropia for internal use is from about 1-30th to 1-6th of a grain. Its employment requires great caution. The safest mode of administration is in solution, on account of the facility with which the dose may be adjusted; but it has also been given, mixed with sugar, in the form of powder; and, mixed with the powder of marshmallow root and honey, in the form of pills. It may be employed endermically (see vol. i. p. 174) in doses of about the $\frac{1}{30}$ th of a grain gradually increased to $\frac{1}{10}$ th of a grain. For a collyrium, to dilate the pupil, one grain may be dissolved in 400 grs. of water; and a few drops of the solution applied to the eye.

1. *Tinctura Atropiæ*; Tincture of Atropine.—Dissolve one grain of atropia in one fluidrachm of rectified spirit, and then add seven fluidrachms of distilled water. Dose, from fifteen minims gradually and cautiously increased to eighty minims. One drop of this solution, applied to the eye night and morning, was used by Mr. W. W. Cooper to keep up dilatation of the pupil.

2. *Solutio Atropiæ Hydrochloratis*; Solution of Muriate of Atropine.—Dissolve one grain of atropia in a fluidrachm of water acidulated with one minim of hydrochloric acid; then add seven fluidrachms of water. Dose, from fifteen to eighty minims.

3. *Unguentum Atropiæ*; Ointment of Atropine.—Atropia, five grains; lard, three drachms; attar of roses one drop. Mix.—The size of a pea, to be applied three times a day. Used by Dr. Brookes, with great success, in a painful affection of the face, and to dilate the pupil.

6. **ATROPIÆ SULPHAS**, L.; *Sulphate of Atropia*.—(Dilute Sulphuric Acid fʒij; Atropia ʒvijss, or as much as may be sufficient; Distilled Water fʒss. Add gradually to saturation the atropia to the acid mixed with the water. Let the liquor be strained, and evaporate it by a gentle heat that crystals may be formed, *L.*)—The College observes that this salt is intended for external use only. It is employed in the form of solution, prepared by dissolving one or two grains in a fluidounce of water, to produce dilatation of the pupil.

173. DATURA STRAMONIUM.—COMMON THORN-APPLE.

Sex. Syst. Pentandria, Monogynia.
(Folium et Semen, *L.* [*U.S.*]—Herb, *E.*—The seed, *D.*)

HISTORY.—This plant, being a native of Greece, must have been known to the ancient Greek botanists; though it is impossible now to identify it, with certainty, with any of the plants described by them. It appears, however, to agree tolerably well with the *σπράχνος μανικός* of Theophrastus.¹ *Datura Stramonium* is mentioned by Fuchsius in 1542.

BOTANY. *Gen. Char.*—*Calyx* tubular, frequently angular, 5-lobed at the apex, or longitudinally slit, falling off by a circular horizontal incision above the peltate base. *Corolla* hypogynous, funnel-shaped, with a large, spreading, plaited 5-10-toothed limb. *Stamens* 5, inserted into the tube of the corolla, inclosed or somewhat exerted; anthers dehiscing longitudinally. *Ovary* incompletely 4-celled, the alternate dissepiment being lost above the middle, the other one complete; the middle on both sides placentiferous. *Style* simple; *stigma* bilamellate. *Capsule* ovate or sub-globose, mucicate or aculeate, rarely smooth, half 4-celled, incompletely 4-valved at the septa. *Seeds* numerous, reniform. *Embryo* within fleshy albumen, subperipheral, arched (Endlicher).

¹ *Hist. Plant.* lib. ix. cap. 12.

Sp. Char.—Annual. Leaves ovate, angulate-dentate, wedge-shaped at the base, rather smooth. Fruit ovate, erect, densely spinous. Calyx equal to the diameter of the limb of the corolla (Nees).

A bushy, smooth, fetid herb. Stem much branched, forked, spreading, leafy. Leaves from the forks of the stem, large, unequal at the base, variously and acutely sinuated and toothed, simple ribbed, veiny, of a dull green. Flowers axillary, erect, white, sweet-scented, especially at night, about 3 inches long. Fruit as big as a walnut, in its outer coat very prickly. Seeds black (Smith).

Hab.—Indigenous; in waste ground and on dunghills. Annual. Flowers in July.

Several other species of *Datura* are used in the East.

DATURA FEROX, Linn.—Annual. Leaves ovate, angulate-dentate, cuneiform at the base, glaucous. Fruit ovate, erect, pyramidal spinous. Calyx longer than the diameter of the limb of the corolla (Nees).—Nepal. In 1802, General Gent introduced this species into this country as a remedy for asthma. It was employed by smoking it.¹ Waitz² says that half an upright capsule acted violently on a girl.

DATURA FASTUOSA, Mill.—Annual. Leaves ovate, acuminate, repandly-toothed, unequal at the base, and are, as well as the stem, somewhat downy. Fruit nodding, tuberculated (Nees).—East Indies. In 1811, Dr. Christie³ directed attention to this species. Mr. Skipton⁴ administered the decoction of the root of this plant; and Dr. Adams⁵ used a tincture (prepared as tincture of digitalis, *Ph. L.*).

DATURA TATULA, Linn.—Annual. Leaves cordate-ovate, angulate dentate, unequal at the base, smooth. Fruit ovate, erect, spinous (Nees).—Schubarth⁶ gave half a pound of the bruised leaves of this species to a horse without effect; twenty-one ounces of the half-ripe fruit caused dejection, increased secretion, and loss of appetite. Cigars for the use of asthmatics are made of this species.

DATURA ALBA, Rumph.; *D. Metel*, Roxb.—Annual. Leaves ovate, acuminate, repandly-dentate, unequal at the base, rather smooth. Fruit nodding, spinous.—East Indies. Both this and the preceding species have been employed, especially in the East, to cause intoxication for criminal and licentious purposes.⁷

DESCRIPTION.—The herb (*herba stramonii*) should be collected when the plant is in flower. The leaves (*folia stramonii*) are then to be carefully dried. In the fresh state their odour, when bruised, is unpleasant and narcotic; their taste nauseous and bitter. By drying, the odour is lost, but the bitter taste remains. The seeds (*semina stramonii*) are small, compressed, kidney-shaped, roughish, dark-brown or blackish, dull, and odourless; they have a bitter, nauseous, somewhat acrid taste.

COMPOSITION.—The herb was analyzed, in 1815, by Promnitz;⁸ the seeds in 1820, by Brandes.⁹

Promnitz's Analysis.

Resin	0.12
Extractive [containing the daturia]	0.60
Gummy extractive	0.58
Green fecula	0.64
Albumen	0.15
Phosphatic and vegetable salts of lime and magnesia	0.23
Water	91.25
Woody fibre	5.15
Loss	1.28

Brandes's Analysis.

Malate of daturia with some uncrystallizable sugar	1.80
Fixed oil with some chlorophylle	16.05
Wax	1.40
Resin insoluble in ether	9.90
Extractive	0.60
Gummy extractive	6.00
Gum and bassorin with some salts	11.30
Albumen and phytocolla	6.45
Glutenin	5.50
Malates of daturia, potash, and lime, and acetate of potash	0.60
Woody fibre	23.35
Water	15.10
Loss	1.95

Fresh herb of stramonium 100.00

Seeds of stramonium 100.00

1. **DATURIA** (*Daturina*, or *Daturium*)—Formula, $C^{34}H^{23}NO^6$. A vegetable alkali said to exist in stramonium. The properties assigned to it by Geiger and Hesse¹⁰ are the following: It crys-

¹⁰ and vol. xxvi. p. 22.

¹¹ *Ibid.*

tallizes in colourless, odourless, brilliant prisms, which have at first a bitterish, then a tobacco-like flavour. It requires 280 parts of cold, or 72 parts of boiling water to dissolve it; it is very soluble in alcohol, less so in ether. In most of its properties it agrees with hyoscyamia. It strongly dilates the pupil, and has a poisonous action on animals. Dr. Avon Planta¹ has recently submitted *atropia* and *daturia* to comparative examination, and declares that they are identical in composition and chemical properties.

2. EMPYREUMATIC OIL OF STRAMONIUM (*Pyrodaturia*?).—Resembles tar and the aqueous fluid which distils along with its acid. This arises from the woody part of the plant having been employed. The oil itself does not differ, in its physical and chemical properties, from the empyreumatic oil of foxglove before (see *ante*, p. 457) described.²

PHYSIOLOGICAL EFFECTS. *a. On Vegetables.*—A branch of stramonium was killed by immersing it in a watery solution of the extract of its own species.³

β. On Animals generally.—Its influence on herbivorous animals is much less than that on man. Five ounces of the expressed juice given to the horse, cause merely slight drowsiness and gaping.⁴ Two pounds and a half of the seeds killed a horse in fifty-two hours.⁵ From Orfila's experiments with it on dogs,⁶ it does not appear to act powerfully as a local irritant. Its effects were very similar to those caused by belladonna.

γ. On Man.—The symptoms produced on man closely resemble those of belladonna. *In small but gradually increased doses*, it diminishes sensibility, and thereby frequently alleviates pain. It does not usually affect the pulse; it slightly and temporarily affects the pupil, and has no tendency to cause constipation, but rather relaxation. Though it allays pain, it does not usually produce sleep. *In larger doses*, it causes thirst, dryness of the throat, nausea, giddiness, nervous agitation, dilatation of the pupil, obscurity of vision, headache, disturbance of the cerebral functions, perspiration, occasional relaxation of bowels, and in some cases diuresis. It has no direct tendency to induce sleep, and hence it cannot be called *soporific*. But indirectly, by alleviating pain, and thereby producing serenity and ease, it often disposes to sleep. *In fatal doses*, the leading symptoms are flushed countenance, delirium (usually maniacal), dilatation of the pupil, dryness of the throat, loss of voice, difficulty of deglutition, convulsions, and, in some cases, palsy. A very interesting fatal case of poisoning by 100 seeds is related by Mr. Duffin.⁷ The patient (his own child) was two years and a quarter old. In addition to the preceding symptoms, there were a hot, perspiring skin, flushed, slightly swollen face, pulse almost imperceptible, but, as far as could be felt, it was natural in regard to frequency, and coldness of the inferior extremities. The anterior fontanelle was neither tense, hot, nor in the slightest degree raised by the cerebral pulsations; so that there did not seem to be any active determination of blood to the brain. During the continuance of the coma the pulse became extremely rapid. Death occurred twenty-four hours after swallowing the seeds.

Vogt⁸ says stramonium is probably distinguished from belladonna by the following peculiarities:—

1. Its effects are more similar to those of acrid vegetables, especially of *Helleborus*.
2. It operates more strongly, but more in the manner of the acrid substances, on the nervous system, especially on the central organs, viz., the ganglia, spinal cord, and brain.
3. Its secondary effects on the irritable system are not so marked; for most observers have failed to detect any alteration of pulse, and a slow pulse is more frequently mentioned than a quick one.
4. It operates on the organic life more strongly. It more strongly and directly promotes all the secretions, especially the secretion of the skin.
5. Marcet⁹ and Begbie¹⁰ have inferred, from numerous observations, that it possesses an antidote property, which it frequently evinces where opium and belladonna fail.

USES.—A more extended experience of this plant is requisite to enable us to speak with much confidence of its employment. The similarity of its effects with

¹⁰ *Trans. of the Med. Soc. Edinb.* vol. i.

those of belladonna would lead us to expect a similarity of uses. Like the last-mentioned plant, it has been successfully employed to diminish sensibility, and thereby to relieve external pain. Some of the other uses made of it require a more impartial examination ere we can form any just estimate of their value. The indications and contraindications for its employment are probably similar to those of belladonna. In persons disposed to apoplexy it is a very dangerous remedy.

In *neurlogia* (*tic douloureux, sciatica, &c.*), it has been employed with considerable success by Lentin,¹ Marcet,² and Begbie.³ It was given internally in the form of extract. Its external application has scarcely been tried. In *rheumatism*, it has frequently proved serviceable from its anodyne qualities.⁴ In *enterodynia* (that is, spasmodic pain of the bowels unconnected with inflammatory action or the presence of irritating substances), Dr. Elliotson⁵ found it most successful.

In some cases of *spasmodic asthma*, smoking the herb has given at least temporary relief;⁶ but the practice requires very great caution, as it has proved highly injurious, and in some instances fatal. Dr. Bree⁷ tried it in 82 asthmatic cases; in 58 of these it had no permanent effect, and in the remaining 24 it acted injuriously. General Gent, who was instrumental in introducing the practice, fell a victim to it.⁸ Aggravation of the dyspnoea, paralytic tremblings, epilepsy, headache, and apoplexy, are some of the evils said to have been induced in the cases above referred to. In persons disposed to head affections, and in aged persons, it is, therefore, a highly dangerous practice.

The diseases in which stramonium has been principally used are *mania* and *epilepsy*. Bayle⁹ has collected from the works of Storck, Schemalz, Razous, Reef, Meyer, Odhelius, Duronde, Maret, Bergius, Greeding, Schneider, Bernard, and Amelung, fifty-five cases of the first, and forty-five of the latter malady, treated by stramonium; in both diseases, a considerable majority of cases are said to have been either cured or relieved by it. Without denying the occasional benefit of stramonium in these diseases, I believe the cases in which it is serviceable to be very rare, while those in which it is calculated to be injurious are very common. Dr. Cullen¹⁰ observes, that he has no doubt that narcotics may be a remedy for certain cases of mania and epilepsy; but he very justly adds, "I have not, and I doubt if any other person has learned to distinguish the cases to which such remedies are properly adapted."

Stramonium has been used to *dilate the pupil* and to *diminish the sensibility of the retina to the influence of light*; but for both of these purposes belladonna is preferred by British oculists. Wendt¹¹ used it to *lessen venereal excitement*, as in nymphomania. An ointment (made with $\bar{3}$ j of the powdered leaves, and $\bar{3}$ iv of lard) has been used as an anodyne application to *irritable ulcers* and to *painful hemorrhoids*. The application of the leaves to *burns* has been attended with dangerous results.¹²

ADMINISTRATION.—The dose of the powdered *leaves* is one grain; of the *seeds* half a grain. These doses are to be repeated twice or thrice a day, and to be gradually increased until some obvious effect is produced.

1. EXTRACTUM STRAMONII, L. E.; *Extract of Thornapple* [*Extractum Stramonii Seminis*, U. S.].—(Thornapple Seeds $\bar{3}$ xv; Boiling Distilled Water Cong. j. Macerate for four hours in a vessel slightly covered, near the fire; afterwards take out the seeds, and bruise them in a stone mortar; return them, when bruised, to the liquor. Then boil down to four pints, and strain the liquor while hot. Lastly, evaporate to a proper consistence, L. The directions of the *Edinburgh College* are as follows:

¹ Bayle, *Bibl. Théor.* t. ii.

² *Trans. Med.-Chir. Soc. of Edinb.* vol. i.

¹¹ *Mat. Med.*

¹² *Journ. de Chim. Méd.*

Take of the seeds of stramonium, any convenient quantity; grind them well in a coffee-mill. Rub the powder into a thick mass with proof spirit; put the pulp into a percolator, and transmit proof spirit till it passes colourless; distil off the spirit, and evaporate what remains in the vapour-bath to a proper consistence.)—Of the above modes of preparation, that of the Edinburgh College is doubtless the best, as yielding a more efficient preparation. [The *U. S. Pharm.* directs Stramonium Seed, in powder, ℥j; Diluted Alcohol q. s. Displace with the alcohol, and evaporate to the proper consistence.] The product, according to the London and Dublin process, is about 12 per cent.¹ Recluz² states, that 16 oz. of the seeds yield 2 oz. 2 dr. by maceration in dilute alcohol; this is about 14 per cent. The dose of extract of stramonium, at the commencement, is about a quarter of a grain, which should be gradually increased until some obvious effect is produced.

[2. **EXTRACTUM STRAMONII FOLIORUM**, U. S.; *Extract of Stramonium Leaves*.—(Take of Stramonium Leaves a pound. Bruise them in a stone mortar, sprinkling on them a little water; then express the juice, and, having heated it to the boiling point, strain and evaporate to the proper consistence.)—This affords a fine green extract, endowed with the odour and properties of the plant. The dose is from gr. i to grs. v.]

3. **TINCTURA STRAMONII**, D. [U. S.]—*Tincture of Thornapple*.—(Stramonium Seeds, bruised, ℥v [℥ii, U. S.]; Proof Spirit Oij. Macerate for fourteen days, and filter through paper.)—Dose, ℥x to ℥xx twice or thrice a day, gradually increased until it occasions some obvious effect on the system. This preparation is applicable to all the cases for which stramonium is used.

[4. **UNGUENTUM STRAMONII**, U. S.; *Ointment of Stramonium*.—(Take of fresh Stramonium Leaves, cut into pieces, a pound; Lard three pounds; Yellow Wax half a pound. Boil the stramonium leaves in the lard until they become friable; then strain through linen; lastly, add the wax, previously melted, and stir them until they are cold.)—This ointment is used for the same purposes as the belladonna ointment.]

ANTIDOTES.—The same as for belladonna.

174. NICOTIANA TABACUM.—VIRGINIAN TOBACCO.

Sex. Syst. Pentandria, Monogynia.
(Folium, L.—Leaves, E. D.)

HISTORY.—The inhalation of the fumes of burning vegetable substances, both for causing inebriation and for medicinal purposes, seems to have been very anciently practised. Herodotus³ tells us that the Babylonians and Scythians intoxicated themselves by this means; and both Dioscorides⁴ and Pliny⁵ speak of the efficacy of smoking Tussilago in obstinate cough.

Humboldt⁶ says that the tobacco plant has been cultivated, from time immemorial, by the natives of Oronoko. It does not appear, however, to have been known to Europeans prior to the discovery of America; though it is not improbable that the Asiatics were acquainted with it long before that time, as Pallas, Rumphius, and Loureiro have supposed. But it is not probable, I think, that the Europeans learned the use of it from the Asiatics, as Ulloa has endeavoured to show.

When Columbus and his followers arrived at Cuba, in 1492, they, for the first time, beheld the custom of smoking cigars.⁷ Hernandez de Toledo introduced the plant into Spain and Portugal; and, from the latter place, Joan Nicot sent the

seeds or the plant to France, about 1559—60.¹ In 1586, on the return of Sir Francis Drake, with the colonists, from Virginia, the practice of smoking was introduced into England; and, being adopted by Sir Walter Raleigh and other courtiers, soon became common.²

Various attempts, by writings, imposts, or bodily punishments, were made in Europe to restrict or put down its use.³ It is said that upwards of a hundred volumes⁴ were written to condemn its employment; and not the least curious of these is the celebrated *Counterblast to Tobacco* of James I.⁵ Despite, and partly, perhaps, as a consequence of these attempts, the use of tobacco rapidly spread, and is now universal throughout the world.⁶

The generic appellation *Nicotiana* is obviously derived from Nieot, the name of an individual above referred to. The origin of the specific name *Tabacum* is less satisfactorily ascertained. It is probable, however, that the word is derived from *tabac*, an instrument used by the natives of America in smoking this herb; though some derive it from *Tobago*, others from *Tabasco*, a town in New Spain.

BOTANY. Gen. Char.—*Calyx* tubular- campanulate, half 5-cleft. *Corolla* hypogynous, funnel-shaped or hypocrateriform; limb plaited, 5-lobed. *Stamens* 5, inserted on the tube of the corolla, inclosed, of equal length; *anthers* dehiscent longitudinally. *Ovary* bilocular; placenta adnate to the dorsal dissepiment; ovules numerous; *style* simple; *stigma* capitate. *Capsule* covered by the persistent calyx, bilocular, septical-bivalved at the apex; the valves ultimately bifid, retaining the separated placenta. *Seeds* many, small; the embryo slightly arched, in the axis of fleshy albumen (Endlieher).

Sp. Char.—*Stem* herbaceous. *Leaves* sessile (the lower ones decurrent), oblong-lanceolate, acuminate. Throat of the *corolla* inflated-ventriose; the segments of the limb acuminate (Nees).

A viscid herb. *Root* branching, fibrous. *Stem* 3 to 6 feet high, erect, round, hairy, branching at the top. *Leaves* very large, pale green, with glandular short hairs. *Bracts* linear, acute. *Flowers* panicled on the end of the stem and branches. *Calyx* hairy. *Corolla* rose-coloured. *Ovarium* ovate; *style* long and slender; *stigma* capitate, cloven. *Capsule* 2-celled, opening crosswise at the top, loculicidal. *Seeds* numerous, small, somewhat reniform, brown.

Hab.—America. Extensively cultivated in most parts of the world, especially in the United States of America. Virginia is the most celebrated for its culture. North of Maryland the plant is rarely seen.⁷ In England, the cultivation is restricted; not more than half a pole being allowed “in a physic or university garden, or in any private garden for physic or chirurgery.”⁸

This is the only species employed in medicine; but the tobacco used for smoking, chewing, and snuff, is derived from several species, the most important of which are the following:—

1. *N. TABACUM*, Linn.; *Common or Virginian Tobacco*.—Of this species several varieties are cultivated.⁹ The Virginian and most other sorts of tobacco imported from the United States of America, as also Colombian tobacco, are obtained from it.

2. *N. LATISSIMA*, Miller; *N. macrophylla*, Sprengel; *Large-leaved or Oronoko Tobacco*.—This species is very closely allied to, if indeed it be not a variety of, the preceding species.¹⁰ Nees¹¹ describes the leaves as being more erect or horizontal than those of *N. Tabacum*, which drop somewhat, and are thicker and more strongly ribbed. Moreover, the lateral nerves of the mid-

⁵ *Works*, p. 214, fol. 1616.

⁶ *Asiat. Journ.* vol. xxii.

⁷ *United States Dispensatory*.

⁸ Loudon's *Encyclopædia of Agriculture*.

⁹ Schrank (*Botan. Zeitung*, 1807) makes eight varieties, which he respectively calls *attenuatum*, *macrophyllum*, *pallidum*, *alipes*, *serotinum*, *gracilipes*, *Verdon*, and *Lingua*; but it is doubtful whether or not some of these are identical with plants which by others have been described as distinct species.

The cultivated varieties differ in the degree of the thickness of the ribs, of the size and smoothness of the leaf, and in the absence or presence of a petiole (*N. Tabacum* var. *petiolata* is figured in Zenker's *Naturgesch. d. vorzogl. Handelspanzen*, Bd. ii. Taf. xxxix. 1832).

¹⁰ *N. Loensis*, HBK., is probably a variety of *N. Tabacum*.

¹¹ Sprengel, who, in 1807, regarded it as a distinct species, has subsequently (in 1825) declared it to be merely a variety (*Syst. Veget.* vol. i. p. 616).

¹² Geiger's *Handb. d. Pharm.* 2te Aufl. 1839.

rib of *N. latissima* proceed, he says, at right angles; whereas those of *N. Tabacum* are given off at an acute angle.¹ Furthermore, the flowers of *N. latissima* form a dense contracted panicle, whereas those of *N. Tabacum* form a loose spreading one.

This species, like the preceding, has varieties, with broader or smaller, shorter or longer, sessile or stalked leaves. To the latter variety probably belong *N. fruticosa*, Linn., and *N. chinensis*, Fischer.

According to Mr. G. Don,² this species probably yields the large Havana cigars.

3. *N. RUSTICA*, Linn.; *Common Green Tobacco*.—Stem herbaceous, terete. Leaves petiolate, ovate, quite entire. Tube of the corolla cylindrical, longer than the calyx; segments of the limb roundish obtuse.—Corolla greenish-yellow.—Indigenous in America; grows wild in Europe, Asia, and Africa. It grows quicker, ripens earlier, and is more hardy than *N. Tabacum*; and hence it is frequently cultivated in gardens in England, and in several other parts of the world. It is used by peasants as a substitute for the Virginian sort, and by gardeners for the destruction of insects. Nees says that, in smoking, it may be readily distinguished by a peculiar violet odour. Parkinson³ says that, though it is a milder tobacco,⁴ yet he has known Sir. W. Raleigh, when prisoner in the tower, prefer it to make good tobacco.—It yields the tobacco of Salonica (the ancient Thessalonica), and probably also that of Latakia (Laodicea), which is so much esteemed. The tobacco called Turkish, grown on the coasts of the Mediterranean, and highly valued in India, is the produce of this species.

4. *N. PERSICA*, Lindl., Bot. Reg. 1592.—Native of Persia. Yields the celebrated Shiraz or Persian tobacco.⁵

5. *N. REPANDA*, Willd.—Native of Cuba, near Havana. The small Havana cigars, or Queen's, are said to be made of this species.

6. *N. QUADRIVALVIS*, Parsh.—Cultivated and spontaneous on the Missouri; principally among the Mandan and Ricara nations.—The tobacco prepared from it is excellent. The most delicate is prepared by the Indians from the dried flowers.

7. *N. NANA*, Lindl., Bot. Reg. t. 833.—Rocky mountains of North America. The Indians are said to prepare the finest of their tobacco from the leaves of this species.

8. *N. MULTIVALVIS*, Lindl., Bot. Reg. t. 1057.—Cultivated by the Indians who inhabit the banks of the Columbia for tobacco, for which purpose the calyx, which is very fetid, is selected in preference to any other part.

CULTURE.—In Virginia and Maryland, the seeds are thickly sown in beds of finely-prepared earth. When the young plants have five or six leaves, exclusive of the seminal leaves, they are transplanted into fields during the month of May, and set three or four feet apart, in rows. During the whole period of growth the crop requires constant attention; and to promote the development of leaves, the tops are pinched off, by which the formation of flowers and seeds is prevented. The harvest is in August. The ripe plants are cut off above their roots, dried under cover, stripped of their leaves, tied in bundles, packed in hogsheads, &c.⁶

DESCRIPTION.—In commerce, two states of tobacco are distinguished—in the one it is called *unmanufactured* or *leaf tobacco*, in the other it is termed *manufactured tobacco*.

1. **UNMANUFACTURED OR LEAF TOBACCO** (*Folia Nicotianæ*).—Tobacco in this state consists of dried leaves, which have a brownish colour, a strong narcotic but peculiar odour, and a bitter nauseous taste. The darker-coloured sorts are the strongest. For medicinal purposes, Virginian tobacco in leaf (*folia tabaci*) should be employed.

In trade, various sorts of unmanufactured or leaf tobacco are met with, and are distinguished by the name of the country from which they are imported into the United Kingdom. The differences between them depend on the species or variety of plant cultivated, on the soil and climate, and on the mode of curing.

1. **UNITED STATES LEAF TOBACCO.**—This constitutes by far the greater proportion of unmanufactured tobacco imported into the United Kingdom. In 1843, no less than 41,038,597 lbs. were imported.

¹ Nees says that by this character several of the commercial sorts of tobacco may be recognized. By himself and other German writers this species is called "Maryland tobacco;" but I find that, though the lateral nerves of the Maryland tobacco of British commerce are given off at a less acute angle than those of the Virginian tobacco, I cannot find any that proceed at a right angle.

² *Gardeners' Dictionary*, vol. iv.

³ *Theatrum Botanicum*, p. 712, 1610.

⁴ Endlicher (*Medicinal-Pflanzen*, p. 333, 1842) declares that it is more stupefying than other species of *Nicotiana*.

⁵ For a notice of the cultivation of Shiraz tobacco, see a paper by Dr. Riach, in the *Trans. of the Horticultural Society*, 2d series, vol. i. p. 205, 1835.

⁶ Loudon's *Encycl. of Agricult.*; Carver, *Treatise on the Cult. of the Tobacco Plant*, 1779.

Several kinds, named from the States where respectively grown, are distinguished in trade; they are as follows:—

The *Virginian* is one of the strongest kinds, and is, therefore, not fit for cigars, but is adapted for pipes and snuff, and for medicinal use. It is imported in leaves or heads contained in hogs-heads. Its colour is deep mottled brown; the leaves feel unctuous. The *Maryland* is paler, yellower, weaker, and adapted for smoking; the *pale cinnamon* is the best, the *scrubs* the commonest. The *Kentucky* is intermediate between the two preceding; it is paler and weaker than the *Virginian*. The *Carolina* is less frequently met with, and is of inferior quality. The *Missouri* and the *Ohio* are other sorts imported from the United States.

2. **CUBA LEAF TOBACCO.**—In 1843, 494,954 lbs. of leaf tobacco were imported from the island of Cuba. The *Havana* sort is most esteemed for smoking; its colour is yellowish-brown; its odour is musky or spicy. It is imported in heads. The *Cuba* is an excellent kind; it is darker than the *Havana*. Both these kinds, as well as the *Colombian*, are remarkable for the light yellow spots on the leaves.

3. **ST. DOMINGO LEAF TOBACCO.**—In 1843, 93,114 lbs. of leaf tobacco were imported from St. Domingo (Hayti). It comes over in leaves, and is deficient in flavour.

4. **PORTO RICO LEAF TOBACCO.**—Small quantities of tobacco in rolls are sometimes imported from this island. In quality, this sort is allied to the *Varinas*.

5. **COLOMBIAN LEAF TOBACCO.**—In 1843, 1,556,206 lbs. of unmanufactured tobacco were imported from Colombia. Three commercial sorts are brought from that country. Like the *Cuba* sorts, the leaves are marked with light yellow spots. The *Colombian* is imported in heads and leaves, and is much esteemed for cigars, for which it is more used than any other kind. It is dark-brown, but not mottled like the *Virginian*. The *Varinas*¹ is brought over in rolls and in hands. It is a mild tobacco, suitable for smoking only. The third sort imported from Colombia is that called *Cumana*. *Orinoco* comes over in leaves.

6. **BRAZILIAN LEAF TOBACCO.**—In 1843, 128,329 lbs. of unmanufactured tobacco were imported from the Brazils.

7. **DUTCH OR AMERSFOORT LEAF TOBACCO.**—In 1843, 55,686 lbs. of unmanufactured tobacco were imported from Holland. Dutch tobacco is very mild, and deficient in flavour. The darker kind is the strongest, and is much esteemed for snuff; while the lighter and weaker kind is employed in the manufacture of the commonest cigars.

8. **LEVANT LEAF TOBACCO.**—*Turkey* tobacco is pale and yellowish. It occurs in small, short, broad leaves, and is the produce of *N. rustica*. It is a weak tobacco, and is cut for smoking. *Latakia* (Laodiea) is an esteemed Syrian tobacco, the produce of the same species. *Salonica* is also yielded by *N. rustica*. *Persian* or *Shiraz* tobacco is delicate and fragrant. It is the produce of *N. persica*.

9. **EAST INDIAN LEAF TOBACCO.**—*East Indian* tobacco has never obtained a high repute, doubtless from inattention to its culture and curing.² In 1843, 59,158 lbs. were imported.

10. **MANILLA LEAF TOBACCO.**—In 1843, 2,038 lbs. of unmanufactured tobacco were imported from the Philippine Islands. *Manilla* tobacco is dark coloured, and is much esteemed for cheroots.

2. **MANUFACTURED TOBACCO.**—Under this head are included the different forms of tobacco prepared for chewing and smoking, and for taking as snuff.

1. **Chewing and Smoking Tobaccos.**—Manufacturers distinguish chewing tobaccos and those used in pipes into two kinds, called respectively cut and roll tobacco. For smoking in the pipe, cut tobacco is principally used in England; the roll in Scotland and Ireland. Cigars and cheroots form a third kind.

1. **CUT TOBACCOS.**—These sorts are manufactured by moistening and compressing the leaves of tobacco, and cutting the compressed mass, with knife-edged chopping stamps, into small pieces or shreds varying from 16 to 100 cuts in the inch. By the addition of water (or the *liquor*³), cut tobacco increases in weight from 8 to 16 per cent., according to circumstances. *Shag* tobacco is chiefly prepared from the *Virginian* and *Kentucky* sorts deprived of their stalks or midribs. *Returns*⁴ is a lighter coloured and milder smoking tobacco. It derives its name from its being formerly prepared by returning shag for recutting. *Bird's-eye* is prepared like shag, with the exception that it contains the midribs of the leaves, the slices of which have been compared to the eyes of birds. *Maryland* is another kind of cut tobacco. *Canaster* or *Kanaster* is a favourite kind. It received its name from *canastra* (a Spanish word, signifying a basket),

¹ Sir H. Sloane (*Jamaica*, vol. i. p. lxiii.) says that the tobacco "from Nuevo Reyno de Grenada (corruptly called *Verinas* or *Tubac de Verine*) is reckoned the best."

² Royle, *Essay on the Productive Resources of India*, 1840.

³ It is said that tobaccoists employ, in the preparation of tobacco, a solution of sea-salt (sp. gr. 1.107), which is termed the *sauce* or *liquor*, but I am assured that this is not generally the case. This liquor, it is further stated, is sometimes coloured by treacle or liquorice.

⁴ "Returns of tobacco are the small pieces of broken leaf, and the dust and siftings, produced in the various processes of manufacture." (*Tobacco Report*.)

because it was imported in baskets. It is prepared from Varinas tobacco. *Orinoco, Turkey, Persian, and Varinas*, are also cut tobaccos.

2. **SPUN, ROLL, OR TWIST TOBACCOS.**—These are prepared by twisting tobacco into a kind of rope, which is moistened with liquor,¹ and is usually made up into cylindrical or barrel-shaped rolls or sticks, which are subjected to pressure before they are considered fit for sale. *Pigtail, Negro-head, Bogie, Alloa, Cavendish, and Irish twist*, are roll tobaccos for chewing and smoking. During its manufacture, roll tobacco increases in weight from 15 to 25 per cent.

3. **CIGARS AND CHEROOTS.**—These are small rolls of tobacco permeable to air and adapted for smoking. *Cigars* were originally derived from the New World. They are distinguished from cheroots by their pointed extremity, called the *curl* or *twist*. The *Havana cigars* are in great request by smokers. Cigars, however, are extensively made in London. *Cheroots* were originally derived from the East. They are characterized by their truncated extremities. *Mannilla cheroots* are much valued by smokers. Cheroots, however, like cigars, are extensively manufactured in London.

2. **Snuffs.**—In the manufacture of snuff, tobacco, cut in small pieces, is first fermented by placing it in heaps and sprinkling it with water or a solution of salt; the latter prevents the tobacco becoming mouldy. The heaps soon become hot and evolve ammonia. The extent to which this process is allowed to proceed varies with different kinds of snuff. The usual time is two or three months, seldom less than one month. The fermented tobacco is then ground in mills, or powdered with a kind of pestle and mortar. The Scotch and Irish are prepared for the most part from the midribs; the Strasburg, French, and Russian snuffs from the soft part of the leaves. The siftings, sometimes termed *thirds*, are usually reground. Sal ammoniac is occasionally added to snuffs.

The theory of the *tobacco fermentation* is imperfectly known. Decomposition probably first commences in the albuminous constituent, which yields carbonate of ammonia. The organic salts (malates) next suffer change, and are converted into carbonates. The lignin is the last to decompose; it becomes friable, yields ulmic acid, which colours the tobacco, and a little acetic acid. A portion (perhaps two-thirds) of the nicotina disappears during the process, being either decomposed or volatilized by the aid of the carbonate of ammonia. Moreover, while in the fresh plant the nicotina is found in the state of a salt (malate?) insoluble in ether, in the fermented plant it is found chiefly in the state of acetate or subacetate soluble in ether.

The immense varieties of snuffs found in the shops are reducible to two kinds—dry and moist snuffs.

a. **Dry Snuffs.**—These derive their characteristic property from being dried at a high temperature previous to being ground. *Scotch, Irish, and Welsh*, are well-known high-dried snuffs. The latter frequently contains lime, the particles of which may be usually distinguished by the naked eye; hence its desiccating effect on the pituitary membrane.² *Spanish snuff* is also a dry snuff. *Crown Scotch* is Scotch snuff moistened after being ground.

β. **Moist Snuffs; Rappées.**—These are snuffs which have been prepared by grinding the tobacco to powder in a moist state. It is sometimes said that pearlsh is added to these snuffs to keep them moist, but several respectable manufacturers assure me this is not usual. The rappées of the shops may be divided into three classes: *Simple Rappées*—as *Brown, Black, Cuba, Carotte, and Dolangero*; *Mixed Rappées*—as *Hardham's Genuine No. 37*; and *Scented Rappées*—as *Prince's Mixture and Princeza, &c.*

COMPOSITION.—The juice of the fresh leaves of tobacco was analyzed in 1800 by Vauquelin.³ Subsequently, this chemist analyzed manufactured tobacco.⁴ In 1821, Hermbstädt⁵ discovered *nicotianin*. In 1827, the leaves were analyzed by Posselt and Reinmann,⁶ and in 1831 by Dr. Conwell.⁷ In 1845, Messrs. Brande and Cooper⁸ made a series of experiments to ascertain the proportion of soluble and insoluble matters in eight samples of tobacco.

¹ Water and oil are alone allowed by law to be used in the manufacture of roll tobacco; but sugar, molasses, and liquorice are frequently employed.

² The Act of Parliament allows lime-water to be used in the manufacture of Irish and Welsh snuffs; but Mr. Foot (*Tobacco Report*) states that the Lundyfoot or "high-toast snuff" is made of the stalks and leaves of tobacco and water (which latter is afterwards got rid of by drying) without lime.

Vauquelin's Analysis.

An acrid volatile principle (*nicotina*).
Albumen.
Red matter, soluble in alcohol and water.
Acetic acid.
Supermalate of lime.
Chlorophylle.
Nitrate of potash and chloride of potassium.
Sal ammoniac.
Water.

Expressed juice of the leaves.

The leaves contained, in addition to the above, woody fibre, oxalate and phosphate of lime, oxide of iron, and silica. The two latter substances were obtained from the ashes.

Manufactured tobacco contained the same principles, and, in addition, carbonate of ammonia and chloride of calcium, perhaps produced by the reaction of sal ammoniac and lime, which are added to tobacco to give it pungency.

Posselt and Reinmann's Analysis.

Nicotina	0.06
Concrete volatile oil (<i>nicotianin</i>)	0.01
Bitter extractive	2.87
Gum with malate of lime	1.74
Chlorophylle	0.267
Albumen and gluten	1.308
Malic acid	0.51
Lignin and a trace of starch	4.969
Salts (sulphate, nitrate, and malate of potash, chloride of potassium, phosphate and malate of lime, and malate of ammonia)	0.734
Silica	0.088
Water	88.280

Fresh leaves of tobacco100.536

Conwell's Analysis.

Gum.
Mucilage soluble in both water and alcohol.
Tannin.
Gallic acid.
Chlorophylle.
Green pulverulent matter, soluble in boiling water.
Yellow oil, having the odour, taste, and poisonous properties of tobacco.

Pale yellow resin (large quantity).
Nicotina.
A substance analogous to morphia.
An orange-red colouring matter.
Nicotianin.

1. NICOTINA (*Nicotine*). Symbol $\ddot{N}i$. Formula $C^{20}H^{14}N^2$. Eq. Wt. 162.—Exists not only in the leaves (both fresh and fermented), but also in the root¹ and in the seeds,² as well as in the smoke of tobacco. It is obtained by digesting an aqueous extract of the leaves in rectified spirit, which takes up the nicotina salts. The decanted tincture is to be concentrated, mixed with a solution of potash, and briskly shook with ether, which dissolves the nicotina set free by the potash. To purify the alkaloid, add gradually to its solution oxalic acid in powder; oxalate of nicotina, insoluble in ether, forms, at the bottom of the vessel, a syrupy layer, which is to be repeatedly shaken with pure ether. The nicotina may be separated by potash and ether, as before. The ethereal solution is to be distilled in a salt-water bath, then transferred to a retort, through which a current of dry hydrogen circulates; exposed to a temperature of 284° F. in an oil bath, in order to entirely get rid of the water, ether, and ammonia; lastly, the temperature is to be raised to 356°, when the nicotina distils over drop by drop. From 28 lbs. of Virginia tobacco, at least 4 per cent. of nicotina can be obtained by this process.

Nicotina is a colourless liquid alkaloid, with an acrid odour and an acrid burning taste. Its density is 1.024. It restores the blue colour of reddened litmus, and renders turmeric brown. It does not solidify at 14° F.; it boils at 482° F., and at the same time undergoes decomposition. By exposure to the air it becomes brown and thick. It is readily combustible with the aid of a wick. It is soluble in water, ether, alcohol, and the oils (fixed and volatile). It combines with acids, and forms very deliquescent salts; the sulphate, phosphate, oxalate, and tartrate, are crystallizable; the acetate is not. A dilute aqueous solution of nicotina yields a white flocculent precipitate (double chloride) with a solution of bichloride of mercury, and a yellow granular precipitate with chloride of platinum.

Nicotina is an energetic poison, almost equalling in activity hydrocyanic acid.³

The amount of nicotina in leaf or manufactured tobacco may be estimated by Schloesing's process:⁴ Exhaust two drachms of tobacco by ammoniacal ether in a continuous distillatory apparatus, expel the ammoniacal gas from the nicotina solution by boiling, then decant, and after the evaporation of the ether, estimate the amount of nicotina in the residue by the quantity of diluted sulphuric acid of known strength required to saturate it.

The following are the amounts found in various French and American tobaccos:—

100 Parts of Tobacco dried at 212°.	Nicotina.
Virginia	6.87
Kentucky	6.09
Maryland	2.29
Havana (cigars primera), less than	2.00
Lot	7.96
Lot-et-Garonne	7.31
Nord	6.58
Ile-et-Vilaine	6.29
Pas-de-Calais	4.91
Alsace	3.21
Tobacco in powder	2.04

³ An interesting case of poisoning by nicotina has recently occurred in Belgium. See Orfila, *Repert. de Pharmacie*, June, 1851.

⁴ *Chemical Gazette*, vol. v. p. 41, 1817.

2. **ACIDS OF TOBACCO.**—Tobacco is very rich in malic acid; it also contains citric and phosphoric acids, and according to M. Barral, a peculiar acid which he terms *nicotianic acid*.

3. **CONCRETE VOLATILE OIL OF TOBACCO** (*Nicotianin*, Hermbstädt; *Tobacco-camphor*, Gmelin). Obtained by submitting tobacco leaves, with water, to distillation. Six pounds of the leaves yielded eleven grains of oil, which swims on the surface of the liquor. This oil is solid, has the odour of tobacco, and a bitter taste. It is volatile, insoluble in water and the dilute acids, but soluble in ether and caustic potash. According to Landerer,¹ fresh tobacco leaves yield no nicotianin, which, therefore, would appear to be developed by the drying of the leaves under the influence of air and water. Nicotianin excites, in the tongue and throat, a sensation similar to that caused by tobacco smoke. Hermbstädt swallowed a grain of it, and experienced, soon after, giddiness, nausea, and inclination to vomit. Applied to the nose it causes sneezing.

4. **ASHES OF TOBACCO.**—Tobacco yields a very large amount of ashes, but both the quantity and quality of which vary considerably. The ashes obtained from the leaves (including the ribs) vary from 17 to 27 per cent.²

5. **TOBACCO SMOKE.**—The constituents of tobacco smoke, according to Raab,³ are much carbonate of ammonia, acetate of ammonia, nicotianin, empyreumatic oil, carbonaceous matter (soot), moisture and several gases. Unverdorben obtained,⁴ by the dry distillation of tobacco, water, oil, and resin. These products consisted of a volatile oil, an oleaginous acid, an empyreumatic acid, (Brandsäure), resin, traces of a powder insoluble in potash and acids, a small quantity of odour, a base soluble in water (nicotin?), fuscin, red matter soluble in acids, and two extractive matters, one forming a soluble, the other an insoluble compound with lime.

But, more recently, Zeise⁵ has submitted tobacco smoke to a careful analysis, and gives the following as its constituents: A peculiar empyreumatic oil, butyric acid, carbonic acid, ammonia, paraffine, empyreumatic resin, water, probably some acetic acid, more or less carbonic oxide, and carburetted hydrogen. To the absence of creasote is, perhaps, to be ascribed the less acrid quality of tobacco smoke than of wood smoke. Melsens⁶ has subsequently directed *nicotina* in tobacco smoke.

The purified empyreumatic oil of tobacco passes over colourless, but soon becomes yellowish, and ultimately brownish. Its sp. gr. is 0.870. It is soluble in alcohol and in ether, but not in water. Its composition is C¹⁴H¹⁰O².—In the impure state, Dr. Morries⁷ describes the oil as being rather less solid than the empyreumatic oil of foxglove (see p. 457); but it is undistinguishable from the latter by either taste or smell. In this state it probably contained some nicotina. It has been suggested that this oil is “the juice of cursed hebenon,” alluded to by Shakspeare,⁸ who also calls it a “distilment.”

CHARACTERISTICS.—The characteristics of tobacco leaves are partly botanical, partly chemical.

The botanical characters which apply to large and perfect leaves have been before stated (see *ante*, p. 486); those used to detect small fragments will be noticed under the head of adulterations (see *infra*).

The following are the chemical characters, as given by Dr. Ure,⁹ of a filtered cold infusion of tobacco, prepared by macerating 100 grs. of dried Virginia tobacco in 1000 grs. of distilled water: “Infusion pale brown; acid reaction with litmus paper; nitrate of barytes, 0; nitrate of silver, a faint opalescence, but no curdy precipitate; oxalate of ammonia, a faint cloud of calcareous matter; water of ammonia, 0; chloride of tin, a faint white precipitate—hence no sulphuretted hydrogen present; chloride of platinum, a copious white precipitate, from the ammoniacal salt present; acetate of lead, an abundant whitish precipitate, soluble in nitric acid; chloride of iron caused a green tint, and sulphate of copper an olive brown, both resulting from the yellow of the iron, and blue of the copper solutions, with the brown of the tobacco.”

The mode of determining the percentage quantity of nicotina in tobacco has been already mentioned (see *ante*, p. 489).

The peculiar odour of tobacco smoke, as well as the remarkable sensation of acidity which both it and tobacco leaf excite in the throat, may sometimes aid in the detection of tobacco. (See, on this subject, *Lobelia inflata*.)

ADULTERATION.—From the evidence laid before a committee of the House of Commons in 1844, it appears that adulteration of tobacco has been (and probably still is) very general, and has varied from 5 to 40 per cent.; in some cases being carried as far as 100 per cent. of the tobacco.

The substances used for adulterating are numerous and various. *Water* being necessary, in the manufacture of tobacco, and being allowed by law, can scarcely be called an adulterating ingredient, though it serves to increase the weight of the tobacco. In the preparation of Shag tobacco, about 12 per cent. of water is used in this country.¹ *Saccharine matter* (sugar, molasses, honey, &c.), which is the principal adulterating ingredient, is said to be used both for sophistication and for rendering the tobacco more agreeable. *Vegetable leaves* (as of rhubarb and beech), *mosses, bran, malt-combs* (sprout of the malt), *beetroot dregs, liquorice, terra japonica, rosin, salts* (nitre, common salt, and sal ammoniac), *yellow ochre, fuller's earth*, and *sand*, are stated (see the *Tobacco Report*) to have been employed as adulterating agents.

The detection of adulteration is in some cases easy, in others difficult, if not impossible.² Two methods of analysis have been resorted to; one mechanical, the other chemical.³

The presence of foreign bodies may sometimes be detected by the naked eye, at other times the use of a magnifying-glass or microscope is necessary to detect them. Tobacco leaves present several remarkable (though not peculiar) characters which lend important aid in detecting adulterations: these are—1st, the horseshoe or crescentic mark seen on a transverse section of the leaf-stalk;⁴ 2dly, the glandular character of the hairs;⁵ 3dly, the size and shape of the meshes or reticulations of the epidermis;⁶ 4thly, the size, shape, and number, in a given space, of stomata.

The chemical characters or tests on which reliance has been placed in detecting adulterations are chiefly the following: 1st, the relative proportions of matters soluble and insoluble in water. The substances insoluble in water are called by the excise officers "ligneous matters," and for Virginia, Missouri, and Kentucky tobacco amount to from 45 to 55 per cent. Porto Rico tobacco, however, yields 70 per cent. of ligneous matters. The matters soluble in water are termed "extractive," and, of course, make up the difference. It is obvious, however, that no reliance can be placed on this test (on account of the great variations in the proportions of the two constituents) unless a portion of the pure leaf, from which the suspected manufactured tobacco was made, can be obtained for comparison.⁷ 2dly, genuine tobacco mixed with yeast and water, and submitted to a proper temperature, does not undergo the vinous fermentation; but tobacco which has been adulterated with saccharine matter undergoes this kind of fermentation and yields alcohol (see *ante*, p. 150).⁸ Trommer's test is employed to distinguish grape sugar and molasses

¹ On the continent, tobacco is more coarsely cut, and, therefore, less water is required in its manufacture.

² Dr. Ure, in his evidence (Quest. 8949), states that he is quite sure that he "could so adulterate tobacco as to elude every chemical and microscopical examination."

³ Mr. Richard Phillips, Professor Graham, and Mr. George Phillips, employed mechanical means chiefly in the analysis of various samples (some adulterated, others unadulterated) of tobacco submitted to their examination by the Parliamentary Committee (Quest. 7511—12).

⁴ The horseshoe or crescentic mark seen in the centre of the leaf-stalk of tobacco is the mass of woody fibres and vessels which eventually make the veins of the leaf. This character, though much relied on by the excise officers, is not peculiar to tobacco—being found in stramonium, belladonna, and some other leaves. It is, however, absent in rhubarb leaves.

⁵ The hairs of tobacco leaves are tipped by a small spherical or ellipsoidal gland. In rhubarb and potato leaves, the hairs are lymphatic, not glandular.

⁶ In tobacco, the meshes seen on the epidermis are bounded by sinuous lines.

⁷ Dr. Ure (Quest. 8770) declares that the amount of residuum or ligneous matter is as variable from the genuine tobacco as from adulterated specimens furnished him by the Parliamentary Committee; and he, therefore, declares this test as good for nothing.

⁸ Dr. Ure objects to the fermentation test that it might be rendered nugatory by adding to the tobacco substances which are known to prevent fermentation in sugar (see *ante*, p. 81, footnote 8). Thus it has been long known in Burgundy that a little red precipitate of mercury, when added to must (juice of the grape), prevents fermentation. He also observes (*Supplement to his Dictionary*, p. 253), that it would seem from experiments made by Professor Graham and Messrs. Phillips, that infusions of tobacco without sugar, when mixed with brisk yeast, and placed for forty hours in a temperature of about 50° F., undergoes a certain degree of decomposition, attended with a diminution of their specific gravity; or, in the language of the Excise, they suffer attenuation.

from cane sugar (see *ante*, p. 150). 3dly, treating the samples with alcohol, and examining the alcoholic solution and the parts insoluble in alcohol. 4thly, incinerating the suspected sample, and determining the amount and nature of the ashes. According to Mr. Johnston,¹ the percentage of ash left by the dry tobacco leaf varies from 19 to 27 per cent. of its whole weight; Pelouze and Frémy,² on the other hand, state that for leaves and ribs dried at 212° it varies from 17 to 24 per cent., and for stalks from 6 to 16 per cent. The nature and solubility of the ashes, and the proportion of silica in them, are subject to great variation.³ 5thly, the determination of the amount of nitrogen; but Dr. Ure,⁴ who suggested this line of research, has satisfied himself that this method can serve no good purpose. 6thly, special tests are required for the detection of particular substances suspected to be present. Thus for *terra japonica* the tests employed are the salts of iron and gelatine, by which the presence of astringent matter is indicated.

PHYSIOLOGICAL EFFECTS. *a. On Animals generally.*—In the *carnivora*, tobacco causes nausea, vomiting, sometimes purging, universal trembling, staggering, convulsive movements, and stupor. Five drachms and a half of rappee introduced into the stomach of a dog, and secured by a ligature on the œsophagus, caused death in nine hours. In another experiment, two drachms applied to a wound killed the animal in an hour.⁵ Sir B. Brodie⁶ found that the infusion of tobacco, thrown into the rectum, paralyzed the heart, and caused death in a few minutes. But if the head of the animal be previously removed, and artificial respiration kept up, the heart remains unaffected; proving that tobacco disorders this organ through the medium of the nervous system only. In the *herbivora*, the effects of tobacco, as of other vegetable poisons, are much less marked; vomiting does not occur. Schubarth⁷ gave four ounces of the leaves to a horse, at three times within two hours. The pulse became irregular, then slower, afterwards quicker; respiration and the pupils were scarcely affected. For two days the stools and urine were more frequent. Moiroud⁸ observed no remarkable effect from the exhibition of a decoction of four ounces of tobacco to a horse.

It is remarkable that the *empyreumatic oil of tobacco* does not possess the same power of paralyzing the heart. Applied to the tongue of a cat, one drop caused convulsions, and in two minutes death; on opening the body, the heart was beating regularly and with force.⁹ Its operation, therefore, is analogous to that of hydrocyanic acid. Dr. Morries¹⁰ says it has less tendency to induce convulsions than the empyreumatic oils of foxglove, henbane, or the thornapple.

β. On Man.—In small doses, tobacco causes a sensation of heat in the throat, and sometimes a feeling of warmth at the stomach; these effects, however, are less obvious when the remedy is taken in a liquid form, and largely diluted. By repetition it usually operates as a diuretic, and less frequently as a laxative. Accompanying these effects are oftentimes nausea and a peculiar feeling usually described as giddiness, but which scarcely accords with the ordinary acceptation of this term. As dropsical swellings sometimes disappear under the use of these doses, it has been inferred that the remedy promotes the operation of the absorbents. In larger doses, it provokes nausea, vomiting, and purging. Though it seldom gives rise to abdominal pain, it produces a most distressing sensation of sinking at the pit of the stomach. It occasionally acts as an anodyne, or more rarely promotes sleep. But its most remarkable effects are languor, feebleness, relaxation of muscles, trembling of the limbs, great anxiety, and tendency to faint. Vision is frequently enfeebled, the ideas confused, the pulse small and weak, the respiration somewhat laborious, the surface cold and clammy, or bathed in a cold sweat, and, in extreme cases,

¹⁰ *Ed. Med. and Surg. Journ.* vol. lxxix. p. 333.

convulsive movements are observed. *In excessive doses*, the effects are of the same kind, but more violent in degree. The more prominent symptoms are nausea, vomiting, and in some cases purging, extreme weakness and relaxation of the muscles, depression of the vascular system (manifested by feeble pulse, pale face, cold sweats, and tendency to faint), convulsive movements, followed by paralysis and a kind of torpor, terminating in death.

Taken in the form of *snuff*, its principal effect is topical. It causes increased secretion of nasal mucus, and, in those unaccustomed to its use, sneezing. Getting into the throat it produces a feeling of acridity, and sometimes nausea. From some kinds of rappee I have experienced giddiness and great prostration of strength. Lanzoni¹ states that an individual fell into a state of somnolency, and died lethargic on the twelfth day, in consequence of taking too much snuff. Reasonable doubt, however, may be entertained, I think, whether these accidents really arose from snuff. The habitual use of this substance blunts the sense of smell and alters the tone of voice; but I am unacquainted with any other well-ascertained effects, though Cullen² ascribes loss of appetite and dyspepsia to it; and Dr. Prout³ observes, that "the severe and peculiar dyspeptic symptoms sometimes produced by inveterate snuff-taking are well known; and I have more than once seen such cases terminate fatally with malignant diseases of the stomach and liver." I have known several inveterate snuff-takers who, after many years' use of this substance, have discontinued it with impunity; but Dr. Cullen thinks, that when the discharge of mucus is considerable, the ceasing or suppression of it, by abstaining from snuff, is ready to occasion the very disorders of headache, toothache, and ophthalmia, which it had formerly relieved. There do not appear to be any good grounds for the supposed baneful effects of the manufacture of snuff on the workmen.⁴ Sir W. Temple⁵ recommends the introduction of a tobacco leaf into the nostrils for the relief of affections of the eyes and head.

The *smoking* of tobacco by those unaccustomed to it, gives rise to all the before-described effects of large and excessive doses. A very interesting case, which had almost terminated fatally, is related by Dr. Marshall Hall.⁶ It was that of a young man, who, for his first essay, smoked two pipes. Gmelin⁷ mentions two cases of death from smoking, in the one of seventeen, in the other of eighteen pipes at a sitting.

In habitual smokers, the practice, when employed moderately, provokes thirst, increases the secretion of saliva and buccal mucus, and produces a remarkable soothing and tranquillizing effect on the mind, which has made it so much admired and adopted by all classes of society, and by all nations civilized and barbarous. I am not acquainted with any well-ascertained ill effects resulting from the habitual practice of smoking. A similar observation is made by Dr. Christison.⁸ Yet Dr. Prout says it "disorders the assimilating functions in general, but particularly, as I believe, the assimilation of the saccharine principle. I have never, indeed, been able to trace the development of oxalic acid to the use of tobacco; but that some analogous and equally poisonous principle (probably of an acid nature) is generated in certain individuals by its abuse, is evident from their cachectic looks, and from the dark, and often greenish-yellow tint of their blood."⁹ There do not appear to be any good grounds for supposing that smoking is a prophylactic against contagious and epidemic diseases—an opinion at one time entertained.

The practice of *chewing* tobacco is principally confined to sailors, and is less frequently submitted to our observation; so that we are not so competent to speak of its effects, which, probably, are similar to those caused by smoking.

The *application of tobacco to abraded surfaces* is a very dangerous practice, and has in some instances been attended with violent or even fatal results. Mr. Wes-

⁹ Quoted by Christison.

¹⁰ *Op. supra cit.* p. 25.

ton¹ has related a case in which the expressed juice of tobacco was applied to the head of a boy, aged eight years, for the cure of tinea capitis. Death took place three hours and a half after the application.

In the form of *clyster*, tobacco has frequently proved fatal, sometimes from the use of inordinate doses by ignorant persons,² and occasionally in the hands of the well-informed practitioner. Desault³ has witnessed the smoke prove fatal. Sir A. Cooper⁴ has seen two drachms, and even one drachm, destroy life. In a case related by Sir Charles Bell⁵ death probably occurred from the same cause. Dr. Copland⁶ saw half a drachm in infusion prove fatal.

The operation of tobacco resembles that of *Lobelia inflata* (see LOBELIACEÆ). With foxglove, tobacco agrees in several circumstances, especially in that of enfeebling the action of the vascular system, though its power in this respect is inferior to that of foxglove. In its capability of causing relaxation and depression of the muscular system, and trembling, tobacco surpasses foxglove; as it does, also, in its power of promoting the secretions. From belladonna, stramonium, and hyoscyamus, it is distinguished by causing contraction of the pupil, both when applied to the eye and when taken internally in poisonous doses; and also by the absence of delirium and of any affection of the parts about the throat. Vogt⁷ and Sundelin⁸ have considered the effects of tobacco as closely allied to those of aconite; but to me the resemblance is less obvious (see RANUNCULACEÆ). The power possessed by the last-mentioned substance of paralyzing the sentient nerves sufficiently distinguishes it from tobacco.

USES.—The principal remedial value of tobacco consists in its power of relaxing muscular fibres, whereby it becomes a valuable antispasmodic. As a purgative, but especially as an antispasmodic and purgative conjoined, it is exceedingly serviceable in alvine obstructions. As a sedative to the vascular system it has not been much used. I tried it somewhat extensively a few years since, as a substitute for blood-letting, in inflammatory affections; but, while it produced such distressing nausea and depression that it was with difficulty I could induce patients to persevere in its use, I did not find its antiphlogistic powers at all proportionate, and eventually I discontinued its employment. As an anodyne, diuretic, or emetic, it is much inferior to many other articles of the *Materia Medica*.

1. In *colic*, *ileus (volvulus)*, *strangulated hernia*, and *constipation*.—The efficacy of tobacco in these diseases depends principally on its power of relaxing muscular fibres and on its purgative properties. These effects are usually accompanied by nausea and giddiness. The remedy is applied in the form of clyster, consisting either of the infusion or of the smoke. The latter was at one time supposed to be more efficacious. Heberden⁹ says it causes less giddiness than the infusion. It probably extends farther up the intestines than the liquid enema, and, therefore, acts on a larger surface. But the difficulties and inconvenience of applying it, and the uncertainty of its effects, have led, for the most part, to the discontinuance of its use. In *ileus*, the tobacco clyster has been recommended by Sydenham,¹⁰ by Heberden,¹¹ by Abererombie,¹² and by several other distinguished authorities. The earlier it is resorted to, the more successful is it likely to prove. Indeed, when employed in the last stage of the disease, it sometimes hastens the fatal termination by exhausting the already depressed vital powers. As it is occasionally necessary to repeat the injection, it is of importance to begin cautiously. Dr. Abererombie uses only fifteen grains of tobacco infused in six ounces of boiling water for ten minutes, and he repeats this in an hour if no effect have been produced. I have generally employed a scruple, and have not experienced any dangerous effects from

¹³ *On Diseases of the Abdominal Viscera.*

its application; and it is possible that, in persons long accustomed to the use of tobacco, a somewhat larger dose might be required; but I have never met with any cases in which a scruple did not produce the full effect on the system that was desired. In *strangulated hernia*, the tobacco elyster has frequently effected the return of the protruded parts when the operation appeared almost inevitable; and every surgical writer speaks in the highest terms of its use. A tense hernial tumour sometimes becomes soft and relaxed by the diminished force of circulation produced by tobacco. Notwithstanding these facts, this remedy is much less resorted to than formerly. Three circumstances have, I suspect, led to the infrequency of its use—first, the dangerous, if not fatal, consequences which have sometimes resulted from its employment; secondly, the frequency of its failure, and the consequent loss of time, by which the chance of recovery is diminished; thirdly, the operation for hernia being much less dreaded now than formerly, for experience has fully proved that death rarely (Mr. Pott says only once in fifty times) results from it. In *colic* from lead, and in *obstinate constipation* from spasmodic constriction, the tobacco elyster has sometimes proved most beneficial. Of the application, in lead colic, of compresses soaked in a strong decoction of tobacco, to the abdomen, as recommended by Dr. Graves,¹ I have no experience. The practice is, of course, calculated to be beneficial, but is less certain and speedy in its effect than tobacco elysters.

2. *In ischuria and dysuria*.—When retention of urine arises from spasm of the neck of the bladder, or from spasmodic stricture, tobacco, by its powerfully relaxing properties, is an agent well calculated to give relief. Mr. Earle² has published several cases illustrative of its efficacy. In dysury, also, tobacco proves serviceable; it abates pain, relaxes the urinary passages, promotes the secretion of urine, and, by diminishing the sensibility of the parts, facilitates the expulsion of calcareous matter.³

3. *Tetanus*.—The relaxing influence over the muscular system possessed by tobacco, suggested the employment of this remedy in tetanus. Its effects have been, like those of most other medicines in this disease, unequal. Sir J. Macgregor⁴ says, that in the advanced stage of the malady the tobacco elyster had no effect. Mr. Earle⁵, however, thought it afforded temporary alleviation in a case in which he tried it. Since then, several cases have been successfully treated by tobacco. Dr. O'Beirne⁶ obtained most marked relief by its use. He employed it in the form of elyster (containing a scruple of tobacco), which was repeated once or thrice or oftener daily during eighteen days; and it was observed that if by design or accident the remedy was discontinued, the spasms recurred with force. Mr. Anderson⁷ employed a decoction of the fresh leaves in the form of enema, and both with good effect. Mr. Curling⁸ has collected accounts of nineteen cases (including those of Earle, O'Beirne, and Anderson, above referred to) treated by tobacco; of these, nine recovered; and in seven of the fatal cases the remedy had not a fair trial; while in the eighth, organic disease of the brain was found. Mr. Curling observes, that "more has now been advanced in proof of the efficacy of tobacco than can be adduced in favour of any other remedy yet resorted to. I have not," he adds, "succeeded in finding a single case in which, being fully and fairly tried before the constitution had given way, it has been known to fail."⁹

4. *Other spasmodic diseases*.—The success attending the use of tobacco in tetanus has led to its employment in *hydrophobia*, but hitherto without avail. In a case of periodical *epilepsy*, Dr. Currie¹⁰ prevented the return of the disease by the application of a tobacco cataplasm to the scrobiculus cordis half an hour before the expected paroxysm. In a very bad case of *spasm of the rima glottidis*, which resisted powerful depletion by the lancet, Dr. Wood¹¹ applied with success a tobacco

¹¹ *United States Dispensatory*.

cataplasm to the throat. In *spasmodic asthma*, tobacco, either smoked or taken internally, in nauseating doses, has been found occasionally to give relief. My own observation is unfavourable to the use of tobacco smoke, which I have repeatedly found to bring on convulsive cough and spasmodic difficulty of breathing in persons afflicted with chronic catarrh. Dr. Sigmond¹ says the tincture of tobacco has been sold and used to a great extent under the name of tincture of lobelia, and that it proved successful in spasmodic asthma. In *rigidity of the os uteri*, a tobacco clyster failed to produce relaxation, while it caused alarming constitutional symptoms.²

5. In *dropsy*.—Tobacco was recommended as a diuretic in dropsy by Dr. Fowler,³ who published a number of cases of anasarca and ascites which had been relieved by it.⁴ Whatever benefit may have been obtained, in these cases, by the use of tobacco, should be ascribed, I suspect, rather to the sedative powers of this agent than to its influence over the kidneys. In small doses it is an uncertain diuretic, and in larger doses it causes such distressing nausea and depression that practitioners have long since ceased to use it in dropsical cases. The ashes of the tobacco plant have also been used in dropsy.⁵

6. As a *topical remedy*.—Dr. Vetch⁶ recommends the infusion, as an anodyne and sedative topical application, in gouty and rheumatic inflammation of the joints, testicle, and sclerotic coat of the eye, and in erysipelatous inflammation. Bergius⁷ recommends a fomentation of tobacco leaves in phymosis and paraphymosis. An infusion or ointment of tobacco has been used in porrigo and other skin diseases, as well as in some obstinate ulcers. The smoke, applied to the hair, is a popular means of destroying pediculi, and has been used, in the form of clyster, to destroy ascarides. Dr. Sigmond⁸ says tobacco promotes the growth of the hair. Toothache has been relieved by tobacco smoke.

In addition to the preceding, there are various other diseases against which tobacco has been employed. Thus in *soporose affections* and *asphyxia*, tobacco clysters have been employed, but they are more likely to do harm than good. Tobacco has also been used as an *anthelmintic*.

ADMINISTRATION.—Tobacco is rarely administered *in substance*. Five or six grains of snuff have been taken as an emetic, and are said to have operated as effectually as two grains of emetic tartar. For internal administration the *wine of tobacco* is generally employed. Dr. Fowler used an *infusion* (prepared with an ounce of Virginian tobacco to a pound of boiling water), which he gave in doses of from sixty to a hundred drops. The best time for administering it he found to be two hours before dinner, and at bedtime. The usual *tobacco enema* is the infusion prepared according to the Pharmacopœia. The *tobacco smoke clyster* (*clyster e fumo tabaci*) is applied by means of a proper apparatus, formerly kept by the instrument-makers. Various extemporaneous methods of employing it have been devised.⁹ For external use tobacco is used in the form of *cataplasm* (made of the leaves and water and vinegar), *infusion* (the *tobacco water* of the shops), *smoke*, and *ointment*: all these, however, require great caution in their use, especially when applied to abraded surfaces.

ANTIDOTES.—If the poison have been swallowed, let the contents of the stomach be withdrawn as speedily as possible. No chemical antidote has as yet been demonstrated; but the vegetable astringents (infusion of nutgalls, green tea, &c.) deserve examination. As anti-narcotics, the vegetable acids and coffee may be administered. The other parts of the treatment must be adapted to circumstances. When the depression of the vascular system is extreme, ammonia and brandy may be administered with good effect, and frictions employed; even acupuncture of the heart (!) has been suggested.¹⁰ Artificial respiration should not be omitted when other means

have failed. If apoplectic symptoms present themselves, bloodletting may, perhaps, be requisite, as in the case related by Dr. M. Hall.

1. ENEMA TABACI, L. E. D.; *Infusum Tabaci* [U. S.]; *Tobacco Clyster*.—(Tobacco ℥j [grs. xv to ℥ss, E.]; Boiling Water Oss [f℥viii, E. D.]. Macerate for an hour [half an hour, E.], and strain.)—The want of uniformity in the formulæ of the British Colleges is greatly to be regretted; and I cannot but think that the latitude permitted by the Edinburgh College, in the quantity of tobacco employed, is highly objectionable, and calculated to lead to serious errors in dispensing. The tobacco clyster is used, as I have already stated, in ilcus (volvulus), strangulated hernia, obstinate constipation, retention of urine, &c. It is not to be forgotten that two drachms, one drachm, and even half a drachm of tobacco infused in water, have proved fatal, as I have before mentioned. The cautious practitioner, therefore, will not use more than 15 or 20 grains.

[The U. S. Pharm. directs Tobacco ℥i; Boiling Water Oj. Macerate for an hour in a covered vessel, and strain. This is intended to be used cautiously, only portions being administered at a time, in accordance with the above statements.]

2. VINUM TABACI, E. [U. S.]; *Wine of Tobacco*.—(Tobacco ℥iijss; Sherry Oij. Digest for seven days, strain, express strongly the residuum, and filter the liquors.) [The U. S. Pharm. directs Tobacco ℥j; Wine Oj. Digest for fourteen days and filter.]—Sedative and diuretic. Employed in dropsy, dysury, &c. Rarely used. Dose from m℥x to m℥l.

3. UNGUENTUM TABACI, Ph. United States; *Ointment of Tobacco*.—(Fresh Tobacco, cut in pieces, ℥j; Lard lbj. Boil the tobacco in the lard, over a gentle fire, until it becomes friable; then strain through linen.)—Employed as an application to irritable ulcers and skin diseases, especially tinca capitis; but its use requires great caution.

An ointment, prepared with twenty drops of the empyreumatic oil of tobacco and an ounce of simple ointment, has been applied with advantage, by American practitioners, to indolent tumours and ulcers; but like all other preparations of tobacco, when employed externally, must be used with great caution.¹

175. SOLANUM TUBEROSUM, Linn.—COMMON POTATO.

Sex. Syst. Pentandria, Monogynia.

(Herba; Tuber.)

HISTORY.—Pedro de Cieça, in his *Chronica del Peru*, published at Seville, in 1553, is the first writer who mentions potatoes. They probably first came into Europe from the neighbourhood of Quito to Spain. In 1586, they were brought to England from Virginia by the colonists sent out by Sir Walter Raleigh, in 1584.

BOTANY. *Gen. Char.*—*Calyx* 5—10-cleft. *Corolla* hypogynous, rotate or rarely campanulate; tube short; limb plaited, 5—10-, rarely 4—6-cleft. *Stamens* 5, rarely 4 or 6, inserted in the throat of the corolla, exserted; filaments very short; anthers equal or sometimes unequal, converging, dehiscing by two pores at the apex. *Ovary* 2-, rarely 3—4-celled; the placenta attached to the dissepiments, adnate, with numerous ovules. *Style* simple; *stigma* obtuse. *Berry* 2-, rarely 3—4-celled. *Seeds* numerous, subreniform. *Embryo* peripherical, spiral, inclosing fleshy albumen (Erdlicher).

Sp. Char.—Tuberous. Stems herbaceous. Leaves interruptedly pinnate, downy; leaflets entire. Pedicels articulated. Flowers white.

Hab.—West coast of South America. Cultivated everywhere.

The cultivated varieties of the potato are very numerous. They are distinguished according to their precocity, lateness, form, size, colour, and quality.

DESCRIPTION.—1. The part of the plant which is used as food, is the *tuber*

¹ *United States Dispensatory.*

(*tuber solani tuberosi*) attached to the subterranean stem, of which, in fact, it may be regarded as a part in a state of excessive development. It is provided with a number of buds, commonly called *eyes*, which, with contiguous portions of the potatoes, are used, under the name of *sets*, for multiplying the species. The tubers vary in shape; being round, oblong, or kidney-shaped. When boiled, they vary in quality; being watery, waxy, or mealy. When examined by the microscope, the tissue of the potato is found to consist of a mass of cells, between and within which is an albuminous juice.

Fig. 308.

Cells of the Potatoes.

a. Cell before boiling, containing the starch particles.

b. Cell of a mealy potato after boiling.

Each cell also contains about ten or twelve starch grains¹ (Fig. 308, a). By boiling, the cells are separated, the starch grains absorb the albuminous liquid, swell up, and completely fill the cells; while the albumen coagulates and forms irregular fibres, which are placed between the starch grains (Fig. 308, b). Potatoes in which these changes are complete are called *mealy*, while those in which the liquid is only partially absorbed, and

the coagulation imperfectly effected, are denominated *doughy* or *watery*.² By boiling in water, potatoes do not form a jelly or mucilage like mere starch, because the starch grains in the tubers are protected partly by the coats of the cells in which they are contained, and partly by a layer of coagulated albumen.

2. For medicinal purposes the *herb* (*herba solani tuberosi*), including both stems and leaves, has been employed.

COMPOSITION.—Potatoes have been repeatedly subjected to chemical examination. The following are the results of analyses made by Michaelis³ and by Johnston.⁴

(Michaelis.)	Natural.	MEAN OF NUMEROUS ANALYSES MADE IN 1846.		
		(Johnston.)		
		Natural.	Dry.	
Water	66.875	Water	75.52	—
Starch and amylaceous fibre	30.469	Starch	15.72	61.20
Albumen	0.503	Dextrin (gum)	0.55	2.25
Gluten	0.055	Sugar	3.30	13.17
Fat	0.056	Albumen, casein, gluten	1.41	5.77
Gum	0.020	Fat	0.24	1.00
Asparagin	0.063	Fibre	3.26	13.31
Extractive	0.921			
Chloride of Potassium	0.176			
Silicate, phosphate, and citrate of iron, manganese, alumina, soda, potash, and lime (of these potash and citric acid are the prevailing ingredients)	0.815			
Free citric acid	0.047			
Red variety of potato	100.000		100.00	100.00

As a portion of both albumen and gluten adheres to the fibre, and of both, with some of the casein, to the starch, the true percentage of protein matters is somewhat understated in the above table; and Johnston, therefore, gives the following as the representation, in round numbers, of the composition of the dry potato: starch 64, sugar and gum 15, protein compounds 9, fat 1, and fibre 11.

The proportion of water, starch, and protein matters in the potato, according to the investigations of Horsford and Kroecker,⁵ have been already given (see vol. i. p. 119.)

The ultimate composition of the potato, according to Boussingault,⁶ is as follows:—

	Natural.		Dry.
Water	75.9	Carbon	44.0
Solid matter, viz.:—		Hydrogen	5.8
Carbon	10.6040	Oxygen	44.7
Hydrogen	1.3978	Nitrogen	1.5
Oxygen	10.7727	Ashes	4.0
Nitrogen	0.3615		
Ashes	0.9640		
	100.0		100.0

⁵ *Ann. der Chemie u. Pharm.* Bd. xlvi. 1846.

⁶ *Ann. de Chimie et Physique*.

Baup,¹ Spatzier,² and Otto,³ have found solanina in potatoes.

1. SOLANINA; *Solanine*; *Potato-Solanin*.—Found chiefly in the buds and shoots (sprouts) of the potato; also in the leaves, stalks, and fruits. Even sound ripe potatoes (the tubers) contain traces of it; but diseased potatoes, according to Liebig,⁴ do not yield it. (For the properties of *Solanina*, see *Solanum Dulcamara*.)

2. STARCH (see p. 501).

3. PROTEIN COMPOUNDS; *Albumen*, *Gluten*, and *Casein*.—The juice of the potato coagulates when heated, owing to the albumen which it contains. If the washings of a grated potato be heated to coagulate the albumen, and a little acetic acid be added to the strained liquor when cold, a white powder, called casein, is precipitated. If dry potato in powder be boiled in alcohol, the solution evaporated, and water added to it, a substance resembling the gluten of wheat is obtained. In potatoes which have been kept for some time, the proportion of protein matters is diminished.—In diseased potatoes, the protein compounds appear to be the constituents chiefly affected: the albumen is diminished in quantity, and altered in quality, becoming dark, especially on coagulating; while, according to Liebig, the casein is augmented in quantity.

4. FAT.—Ether extracts from dried sliced potatoes a minute portion of fatty matter.

5. GUM (*Dextrine*) AND SUGAR.—Healthy potatoes contain small portions of that variety of gum called dextrine, and also of sugar. When the quantity of these ingredients is unusually large, as in diseased potatoes, the quantity of starch is proportionately small.

6. CELLULOSE; *Fibre*; *Lignin*.—The proportion of this constituent of the potato is subject to great variation. As usually obtained, it contains some adherent starch and protein matters: hence the nutritive qualities of the pulp of potato mills, which is used for feeding cattle.

7. ACIDS AND SALTS.—The vegetable acid which exists in potatoes, and which several chemists⁵ have declared to be citric acid, is, according to Hisch,⁶ *malic acid*. He also detected *phosphoric* and *hydrochloric acids*. By the microscope, crystals of *oxalate of lime* can be detected.⁷ The quantity of ash obtained by drying and burning the potato, varies from 0.76 to 1.58 of the weight of the potato in the natural state. It consists, in large proportion, of *potash* salts, with some *soda* and *lime* salts. These bases are combined with carbonic acid (produced by the decomposition of the malic and oxalic acids), phosphoric acid, sulphuric acid (formed by the oxidation of the sulphur of the protein matters), and hydrochloric acid.

DISEASES OF THE POTATO.—The potato is subject to various diseases, the chief of which are the *curl*, the *scab*, and two sorts of *rot*—one called the *dry rot*, the other the *wet rot*. Martius⁸ mentions two other maladies also; namely, the *rust*, and the *blue pock*, but they are imperfectly known. The disease, called the *potato murrain*, or *potato blight*, which recently raged epidemically among the potatoes of Europe and America,⁹ was a kind of rot, usually of the humid or wet kind. The cause of this, as of the other maladies of the potato, is very obscure.¹⁰

The *scab* (*porrigo tuberum solani*) is characterized by the surfaces of the tubers becoming "covered with pustules, which at length become cup-shaped, and are powdered within with an olive-yellow meal, consisting of the spores of a fungus," which Martius calls *Protomyces Tuberculatum Solani*, but which Mr. Berkeley terms *Tubercinia Scabies* (Sub-order Hyphomycetes—see *ante*, p. 80).

In the *dry rot* (*gangræna sicca tuberum solani*) "the tubers, when stored for winter use, or when planted, become impregnated with a kind of mould, and are at length so hard that they can scarcely be broken, and, instead of producing shoots, merely throw out a few small misshapen tubers." In 1830, this disease was first noticed in Germany. Martius ascribes it to the growth of a peculiar fungus, the *Fusisporium Solani* (Sub-order Hyphomycetes—see *ante*, p. 80).

The *wet rot* (*gangræna humida tuberum solani*) differs from the preceding in the circumstance that the tubers become soft instead of hard; and parasitic fungi, referred by Fries to his genus

¹ *Ann. de Chimie*, 1826.

² Buchner's *Repert.* Bd. xxxix. p. 480, 1831.

⁴ *Pharmaceutical Journal*, vol. v. p. 263, 1845.

⁵ Baup (Buchner's *Repert.* 2te Reihe, Bd. iii. p. 390, 1835) says that the potato yields sufficient citric

acid to admit of its being employed for the preparation of this acid for commercial purposes. He also states that he found succinic acid and a new acid, which he calls *solanotuberic acid*, in potatoes.

⁹ The first notice of the disease in England was by Dr. Bell Salter, in the *Gardener's Chronicle*, Aug.

16, 1845.

¹⁰ The fungal hypothesis of the potato blight has been ably advocated by Mr. Berkeley, in a paper entitled *Observations, Botanical and Physiological, on the Potato Murrain*, published in the *Journal of the Horticultural Society*, vol. i. p. 9, 1846. Most authors ascribe the disease to peculiar atmospheric or meteorological conditions. Mr. Sucee (*The Potato Plant, its Uses and Properties, together with the Cause of the Present Malady*, 1846) attributes it to an animal parasite, the *Aphis vastator*—a species of hemipterous insect, which punctures the leaf, sucks the sap, and thus, by exhausting the plant, causes the death of the leaf or of some other part.

Periola (Sub-order Gasteromycetes—see *ante*, p. 88), appear, for the most part, under the form of hemispherical masses bursting through the cuticle.

The *potato murrain*, or *potato blight*, commonly called the *potato disease*, is closely allied to, if it be not identical with, the rot—usually, the wet rot. But, according to Mr. Berkeley, it is characterized by the presence of *Botrytis infestans* (Sub order Hyphomycetes—see *ante*, p. 80). The malady commences in the leaves, and extends from thence by the stems to the tubers. Both on the inferior surface of the leaves and in the tubers a peculiar fungus has been discovered, called by Dr. Montagne the *Botrytis infestans*, which has been very fully described and figured by Mr. Berkeley.—The malady seems to affect chiefly the protein constituents of the potato. Liebig¹ states that a part of the vegetable albumen which usually prevails in the potato has become converted into casein. The starch appears to be unaltered in quality.

PHYSIOLOGICAL EFFECTS. 1. *Of the herb.*—An extract obtained from the stalks and leaves of potatoes was declared by Dr. J. Latham² to possess narcotic properties in doses of two or three grains, but the cases adduced are not satisfactory. Furthermore, his experiments were repeated by Dr. Worsham³ with very different results, for 100 grains produced no sensible effects. The observations of Nauche,⁴ however, tend to confirm Latham's statements.

2. *Of the tubers.*—Potatoes, when in good condition, and cooked by boiling, form a nutritious and easily digestible article of food. The starch, sugar, gum (dextrine), and fat, serve for the production of fatty matters, sugar, lactic acid, and, by combustion, of heat and carbonic acid. The protein matters (albumen, gluten, and casein) are plastic elements of nutrition, and serve for the production of fibrinous, albuminous, and gelatigenous tissues. According to Gunsford, the non-digestible constituents of the potato, and which he found in the excrements, are the cellular, fibrous, and vascular tissues, with which some undigested starch grains are intermixed.

Potatoes are valuable antiscorbutics. Sir G. Blane, Julia Fontanelle, Nauche, Dr. Baly, and others, have testified to their valuable preservative qualities against scurvy.⁵ These have been ascribed to the vegetable acids contained in the tubers, but Dr. Garrod (see vol. i. p. 461) attributes them to the presence of a large quantity of potash.

From an experiment made at the Glasgow Bridewell, it would appear that baked potatoes are less nourishing than boiled ones.

The process of cooking potatoes is useful in two ways; by effecting changes in the nutritive principles (*e. g.* rendering the starch digestible), and by extracting some noxious matter (solanina). The water in which potatoes are boiled possesses some noxious properties; Nauche found that it augmented the renal and biliary secretions, and slightly affected the nervous system.

USES. 1. *Of the herb.*—The extract has been used as a narcotic and antispasmodic to allay cough, spasm, rheumatic pains, &c. The dose is from one-eighth to half a grain.

2. *Of the tubers.*—Scraped potato is a popular application to burns and scalds. Boiled potatoes have been used for the formation of emollient poultices. They may be employed as an antidote in poisoning by iodine (see vol. i. pp. 202 and 405). For dietetical purposes potatoes are valuable antiscorbutics. In diabetes, however, they are objectionable on account of the large quantity of starch which they contain. But bread made of potato and cellulose (rasped potatoes deprived, by washing, of starch) has been employed as a *bread for diabetic patients*.⁶

Potatoes are used by bakers in the preparation of the ordinary loaf bread of London (see *ante*, p. 126).

⁴ *United States Dispensatory.*

⁵ See my *Treatise on Food and Diet*, 1843.

⁶ Percy, *Chemical Gazette*, vol. vii. p. 119, 1849.—The following is Mr. Palmer's receipt for making this bread: "Take the ligneous matter of 16 lbs. of potatoes washed free from starch, $\frac{1}{2}$ lb. of mutton suet, $\frac{1}{2}$ lb. of butter, 12 eggs, $\frac{1}{4}$ oz. of carbonate of soda, and 2 oz. of dilute hydrochloric acid. This quantity to be divided into eight cakes, and in a quick oven baked until nicely browned." Care must be taken to procure pure hydrochloric acid, as some commercial sorts contain arsenic (see vol. i. p. 350).—This bread may be regarded as a substitute for the *bran bread* already described (see *ante*, p. 127).

1. *AMYLUM SOLANI TUBEROSI*; *Potato Starch*.—Obtained by washing potatoes, then rasping or grinding them to a pulp, and repeatedly washing the latter with water. The washings are strained through a sieve to separate the fibre or cellular tissue, and then allowed to stand at rest, by which the starch is deposited, and is afterwards washed and dried.

The quantity of starch yielded by potatoes varies with the variety or sort, the soil, the climate, and the season. Payen found the same variety of potato to yield, in October, 17.2 per cent. of starch; in November, 16.8; in December, 15.6; in January, 15.5; in February, 15.2, in March, 15.0; and in April, 14.5. In general, the centre of the potato yields the smallest portion, the heel end which is attached to the rootlet the most, and the rose or upper end an intermediate portion of starch.

Potato starch is white and pulverulent, and, on account of the large size of its particles,¹ has a satiny or glistening character. The smaller grains are circular or globular; the larger ones elliptical, oblong, ovate, or obtusely triangular. Frequently, their shape is irregular, and approximates to that of an oyster-shell, or a mussel-shell. Their nucleus, central cavity, or hilum, is very distinct; and their laminated structure is indicated by a system of concentric or excentric rings or zones surrounding the nucleus. It is most allied in appearance to the starches of *Marantaceæ*. The characters by which they are distinguished from West Indian arrowroot, and from *tous-les-mois*, have been before pointed out (see *ante*, pp. 226 and 228). The mode of distinguishing potato starch from wheat starch has likewise been stated (see *ante*, p. 125).

In its general chemical properties it agrees with other starchy bodies. In cold water it is insoluble. If 1 part of potato starch be mixed with 15 parts of water, and heated, the liquid begins to be thick and mucilaginous at about 140° F.; and as the heat augments, especially from 162° F. to 212° F., it acquires a pasty or gelatinous consistence. Starch-paste or starch-mucilage is not, however, a true solution of starch in water; the starch grains are burst and exfoliated, the coats or laminae being hydrated and enormously swollen. In cold water, to which a small quantity of caustic potash or soda has been added, they become enormously swollen (see *ante*, p. 125). Starch-mucilage in the cold becomes intensely blue on the addition of iodine; the colour is destroyed by heat or caustic alkalis.

The greater facility with which potato starch gelatinizes when rubbed in a mortar with a mixture of equal parts of commercial hydrochloric acid and water;² the strong smell of formic acid emitted when it is rubbed with hydrochloric acid; the dove-gray colour which it assumes when exposed to the vapour of iodine;³ and the transparency of the mucilage which it forms with boiling water (whence it has been termed *soluble starch*), are characters by which it has been attempted to distinguish potato starch from other sorts of starch, but with no great success, as they are not to be relied on.

Potato starch, in the pure or anhydrous state, consists of $C^{12}H^{10}O^9$; but, as found in commerce, it contains water.

COMPOSITION OF POTATO STARCH.

Anhydrous starch (as combined with oxide of lead)	=	$C^{12}H^{10}O^9$
Starch dried in a vacuum at from 212° to 284° F.	=	$C^{12}H^{10}O^9, HO$
Starch dried in a vacuum at 68° F.	=	$C^{12}H^{10}O^9, 3HO$
Starch air-dried at 68° F. (hydr. 0.6)	=	$C^{12}H^{10}O^9, 5HO$
Starch dried in air saturated with humidity	=	$C^{12}H^{10}O^9, 11HO$
Starch drained as much as possible	=	$C^{12}H^{10}O^9, 16HO$

¹ The following measurements, in parts of an English inch, of ten particles of potato starch, were made for me by Mr. George Jackson:—

Length. Breadth.		Length. Breadth.	
1.	0.0023 × 0.0016	6.	0.0007 × 0.0006
2.	0.0021 × 0.0014	7.	0.0005 × 0.0005
3.	0.0018 × 0.0013	8.	0.0004 × 0.0004
4.	0.0011 × 0.0009	9.	0.0003 × 0.0003
5.	0.0009 × 0.0007	10.	0.0002 × 0.0002

² Scharling, *Pharmaceutical Journal*, vol. ii p 417, 1842.

³ Goble, *Journ. d. Pharm.* ser. 3me, t. v. p. 299, 1844.

Potato starch is sometimes adulterated. M. Dietrich¹ mentions having received some which was adulterated to the extent of 50 per cent. with comminuted fibre, and which prevented the employment of the starch in the fabrication of yeast for a distillery.

Potato starch possesses the alimentary properties of other starchy substances, and which have been before noticed (see vol. i. p. 119, and *ante*, 107). It does not, however, yield so firm a jelly as some other starches, and has been said to be apt to occasion acidity, especially in infants. It is sold under the various names of *potato flour*, *English arrowroot*, *Bright's nutritious farina*, &c.; and is used as a farinaceous food for infants and invalids, as well as for the preparation of puddings and soufflés, and, as a thickening ingredient, in gravies, sauces, &c.

Potato starch is used in the production of a factitious sago (see *ante*, p. 166), in the preparation of dextrine, and in the manufacture of *potato sugar* (see *ante*, p. 151).

2. DEXTRINA; *Dextrine*; *Dextrinum*; *Starch-Gum*. Formula $C^{12}H^{20}O^{11}$. This substance is called "dextrine," from its property of rotating to the right a ray of plane polarized light. There are three modes of procuring it from starch; viz., by torrefaction, by the action of dilute acids (usually nitric acid), and by the action of diastase. The impure dextrine obtained by torrefying or roasting starch is termed *roasted starch* or *leicomme* (from $\lambda\epsilon\iota\omicron\varsigma$, *smooth*; and *gomme*, the French name for gum!). This sort of dextrine resembles British gum (see *ante*, p. 125), is pulverulent, and has the aspect of starch, but it usually possesses a yellowish tint in consequence of being over-roasted. A second method consists in moistening 1000 parts of potato starch with 300 parts of water, to which 2 parts of nitric acid have been added. The mixture is to be allowed to dry spontaneously, and is afterwards heated, for one or two hours, in a stove at 212° F. or 230° F.; the transformation is then complete.

Dextrine is soluble in water and in dilute spirit, but is insoluble in alcohol. Its solution is perfectly limpid; and, by concentration and solidification, it is obtained in an amorphous form like gum arabic. It is sometimes made up in tear-like masses in imitation of gum arabic, and in this state is called *artificial gum*. This, when fresh, has an odour like that of a cucumber; but, by keeping, I find that it loses this smell. The solution of dextrine yields, with acetate of lead, a precipitate (*dextrinate of lead*). As usually found in the shops, the solution strikes a violet or reddish tint with iodine; but in this case the starch has been incompletely converted into dextrine, which, when pure, is not coloured by iodine.

Dextrine in many of its characters resembles ordinary gum; from which, however, it is distinguished by its right-handed rotation of a ray of plane polarized light, and by its yielding oxalic acid, but not mucic acid, when heated with nitric acid. Saccharine matter, when mixed with dextrine, may be separated by strong spirit, which more readily dissolves sugar than dextrine. The freedom of dextrine from starch is readily shown by the iodine test.

Dextrine is used in the arts as a substitute for gum, size, and paste. The saccharine solution of dextrine obtained by the action of diastase (contained in the infusion of malt) on potato starch is used in Paris in the manufacture of *pains de luxe*, and for the fabrication of beer and other alcoholic liquors. In medicine, dextrine is employed as a nutrient, as an emollient, and as an agglutinant. In the French hospitals it is used in *tisanes* as a substitute for gum. Devergie has employed it with benefit in the treatment of eczema. Velpeau has employed dextrine as a substitute for gum arabic or starch, in the preparation of bandages for maintaining the reduction of fractures by what is called "the immovable apparatus." For this purpose, 100 parts of dextrine are moistened first with a small quantity of

¹ *Chemical Gazette*, vol. ii. p. 20, 1844.

spirit of camphor, and then mixed with 40 parts of water. The bandages are soaked in the thick mucilage thus obtained.¹

176. SOLANUM DULCAMARA, Linn.—WOODY NIGHT-SHADE; BITTERSWEET.

Sex. Syst. Pentandria, Monogynia.
(Ramus novellus, L.—Fwigs, E. D. U. S.)

HISTORY.—Fraas² declares this plant to be the *σπύρχνος ἰππωτικός* of Dioscorides (lib. iv. cap. 73). Sprengel³ considers it to be the *Citocatia* of the Abbess Hildegard, of Bingen, who died A. D. 1180. But the derivation of the word *Citocatia* (*cito* and *cacare*) negatives, in my opinion, this supposition. The first undoubted notice of *Dulcamara* occurs in the work of Tragus.⁴

BOTANY. Gen. Char.—See *ante*, p. 497.

Sp. Char.—Stem shrubby, zigzag. Leaves cordate-ovate; upper ones auriculate-hastate. Flowers drooping (Babington).

Root woody. Stem twining, branched, rising (when supported) to the height of many feet. Leaves acute, generally smooth; the lower ones ovate or heart-shaped; upper, more or less perfectly halfbert-shaped; all entire at the margin. Clusters either opposite to the leaves or terminal, drooping, spreading, smooth, alternately subdivided. Bracts minute. Flowers elegant, purple, with two round green spots at the base of each segment. Berries oval, scarlet, juicy.

Hab.—Indigenous. In hedges and thickets, especially in watery situations. Flowers in June and July.

Var. *β tomentosum*, Koch.—Stem round, almost glabrous throughout.—Woods and hedges; common.

Var. *γ marinum*, Babington; *S. lignosum* seu *Dulcamara marina*, Ray.—Branches of the present year, and leaves fleshy and usually clothed with hairs incurved upwards. Stem angular, prostrate, diffuse, much branched. Leaves all (?) cordate, not hastate.—Pebble sea-beach. Renville, Cunnamara, Galway; Lizard Point, Cornwall; Shoreham, Sussex (glabrous).

DESCRIPTION.—The annual stems (*caules* seu *stipites dulcamaræ*) are collected in the autumn, after the leaves have fallen.

It is to be gathered in autumn when destitute of leaves.—*Ph. Lond.*

When fresh, they have an unpleasant odour, which they lose by drying. Their taste is at first bitter, afterwards slightly acrid and sweet. The epidermis is greenish-gray, the wood light, and the pith very light and spongy.

COMPOSITION.—The stems have been analyzed by Pfaff.⁵ 100 parts of the air-dried stems lost 17.4 parts of water when completely dried. From 100 parts of perfectly dried stems Pfaff obtained *bittersweet extractive* (*piecroglycion*) 21.817, *vegeto-animal matter* 3.125, *gummy extractive* 12.029, *gluten with green wax* 1.4, *resin containing benzoic acid* 2.74, *gummy extractive, starch, sulphate and vegetable salts of lime* 2.0, *oxalate and phosphate of lime with extractive* 4.0, and *woody fibre* 62.0 (excess 9.111). Desfosses⁶ discovered *solanina* in the stems.

1. **DULCAMARIN**; *Piecroglycion*, Pfaff; *Dulcarin*, Desfosses.—Crystalline; has both a bitter and a sweet taste, is fusible, soluble in water, alcohol, and acetic ether, and is not precipitated from its solution by either infusion of nutgalls or metallic salts.⁷ Pelletier⁸ thinks that it is sugar combined with *solanina*.

+
2. **SOLANINA**; *Solanina*; *Solanine*. Symbol So. Formula C⁸⁴H⁶⁸NO²³. Eq. Weight 810?—This alkaloid has been discovered in several species of *Solanum*; viz. *S. Dulcamara*, *S. tuberosum*, *S. nigrum*, and *S. verbascifolium*. It resembles sulphate of quinia, but its needle-like crystals are finer and shorter. It restores the blue colour of litmus paper reddened by an acid. It dissolves

¹ Mr. Smee (*London Medical Gazette*, N. S. vol. i. Feb. 23, 1839), in his paper, "On the Formation of Moulding Tablets for Fractures," says, that "a mixture of carbonate of lime with the solution of dextrine made a composition which answered very well," but it was not equal to a composition of gum and whitening.

⁷ *Syst. de Mat. Med.* Bd. vi. S. 506.

⁸ *Journ. de Pharm.* vii. 416.

in acids, and is precipitated from its solution by the caustic alkalies. Some of the salts (as the acetate and hydrochlorate) have a gummy appearance when evaporated to dryness; others (as the phosphate and sulphate) are crystallizable. Iodine strikes a characteristic turbid brown colour with a solution of solanina or of its salts, owing to the formation of the insoluble brown iodide of solanina.¹ If Blanchet's analysis be correct, solanina differs from the other vegetable alkalies in the small quantity of nitrogen which it contains, and in its very high atomic weight. A grain of solanina, dissolved in dilute sulphuric acid, killed a rabbit in six hours; four grains of the sulphate caused, in an hour, paralysis of the hind legs; and, in eight hours, death.² Soubeiran says it does not dilate the pupils like the other alkalies of Solanaceæ.

CHEMICAL PROPERTIES.—A strong decoction of dulcamara is slightly darkened by tincture of iodine. Iodic acid had no effect on it. Iodide of potassium renders it feebly yellow. Tincture of galls had no effect.

PHYSIOLOGICAL EFFECTS.—Not very obvious. Its decoction operates as a diaphoretic and diuretic. It is said also to promote secretion from the mucous surfaces, and to diminish sensibility. In excessive doses, dulcamara is stated to have acted as an acro-narcotic.³ Chevallier⁴ says a young man experienced narcotism from carrying a bundle of the plant on his head. But the accuracy of all these observations has been called in question by Jos. Frank,⁵ by Dunal, and by Pages.⁶ The first gave the decoction, the latter the extract and fruit, in very large doses, without any obvious effects.

USES.—Dulcamara has been thought serviceable in chronic pulmonary catarrhs, in rheumatic and gouty complaints, in chronic skin diseases, and in various cachectic conditions of the system, in which sarsaparilla has been found beneficial. As a remedy for lepra, it was introduced to the notice of British practitioners by Dr. Crichton. For this disease, it has been declared a most effectual remedy by Bateman;⁷ while Rayer⁸ speaks of its good effects in eczema and psoriasis. In the few cases in which I have tried it, it proved useless.

DECOCTUM DULCAMARÆ, L. E. D. [U. S.]; *Decoction of Bittersweet.*—(Dulcamara, sliced [chopped down, *E.*], ζx [ζj , *E.* [U. S.]; ζss , *D.*]; Water [Distilled, *L.*] Oij [$\text{f}\zeta\text{xxiv}$, *E.*; Oss, *D.*; Ojss, *U. S.*]. Boil [down to a pint, *L. E.*; for ten minutes, *D.*] and strain.)—Diaphoretic and diuretic. The usual dose stated in books is $\text{f}\zeta\text{ss}$ to $\text{f}\zeta\text{j}$. But I have given $\text{f}\zeta\text{iv}$ for a dose. Rayer has given four ounces of the root in decoction in twenty-four hours.

177. *Solanum nigrum*, Linn.—Black Nightshade.

Sex. Syst. Pentandria, Monogynia.
(Herba.)

Στεφύλιον κηπάριον, Dioscorides (lib. iv. cap. 71); *Common or Garden Nightshade*.—Stem herbaceous, with tubercled angles; a foot or more high. Leaves ovate, obtusely dentate or wavy, attenuated below. Flowers lateral, drooping, sometimes with a musky scent; corolla white. Berries globular, black, or rarely green when ripe. Indigenous: waste grounds. No complete analysis of it has been made. Desfosses⁹ has found malate of solanina in the fruit. Black nightshade possesses narcotic properties, but its powers appear to be neither great nor uniform. Its emanations are said to be soporific; and in Bohemia, a handful of the fresh plant is sometimes placed in the cradles of infants to promote sleep.¹⁰ In England, this plant has been employed as a resolvent.¹¹ Smith¹² says, a grain or two of the dried leaf has sometimes been given to promote various secretions, possibly, he adds, by exciting a great and rather dangerous agitation in the viscera.

178. CAPSICUM ANNUUM, Linn.—et C. FASTIGIATUM, Blume.

Sex. Syst. Pentandria, Monogynia.

(*Capsicum Fastigiatum*, *Bl.*—Fructus, *L.*—Fruit of *Capsicum annuum* and other species; *Capsicum* or *Chillies*, *E.*—*Capsicum annuum*; the fruit, *D.*)

HISTORY.—The *piperitis* or *siliquastrum* of Pliny,¹ is declared by Sprengel² to be undoubtedly *Capsicum annuum*. But confidence in this opinion is greatly diminished by the doubt entertained as to this plant being a native of Asia.³ Of course, if it be exclusively a native of America, there is no reason for supposing that Pliny could have been acquainted with it. Fraas⁴ considers it to have been *Capsicum longum*, DC., which Theophrastus⁵ terms *πέπερι ἀπόμηχες*. The term *capsicum* (*κἀψικον*) occurs first in Johannes Aetuarus.

BOTANY. **Gen. Char.**—*Calyx* 5—6-cleft. *Corolla* hypogynous, rotate; tube very short; limb plaited, 5—6-cleft. *Stamens* 5—6, inserted in the throat of the corolla, exserted; filaments very short; anthers connivent, dehiscing longitudinally. *Ovary* 2-, 3-, 4-celled; the placentæ adnate to the base of the dissepiment or central angle. *Style* simple, subclavate; *stigma* obtuse, obsolete 2—3-lobed. *Berry* juiceless, polymorphous, incompletely 2—3-celled, placentæ and septa deliquescent superiorly. *Seeds* many, reniform; embryo within fleshy albumen, peripheral, hemicyclical (Endlicher).

1. *C. ANNUM*, Linn. *Common Capsicum* or *Chilly Pepper*.—Fruit oblong, pendulous, and erect. Petioles glabrous. Stem herbaceous. Calyx obsolete 5-toothed.

Herbaceous annual, 1 to 2 feet high. *Leaves* ovate or oblong, acuminate, long-stalked, almost entire, sometimes hairy on the veins underneath. *Flowers* white. *Berry* scarlet, yellow, variegated with red and yellow, or dark green; variable in shape, being oblong, round, or cordate.

America. A doubtful native of the East Indies. Cultivated in England.

2. *CAPSICUM FASTIGIATUM*, Blume, *Bijdr.* 705, L.; *C. frutescens*, Linn. *Sp. Pl.* but not Hist. Cliff. Frutescent; branches tetragonal, fastigiate, diverging, pubescently scabrous; fructiferous calyx, subcylindrically truncate; fructiferous peduncles, generally twin, erect; berry, oblong-cylindrical, straight; leaves oval or lanceolate, acuminate at both ends, minutely and serrulately ciliated.—India. Shrub 1 or 2 feet high.

DESCRIPTION.—1. The dried fruit, sold by druggists as *chillies* (*fructus vel baccæ capsici annui*), is flat, more or less shrivelled, oblong, blunt or pointed at one end, while the calyx or stalk is usually attached at the other end. The length of the berry (independent of the stalk) is two or three inches, the breadth one-half to three-quarters of an inch, the colour yellowish or reddish-brown, the taste hot and pungent, the odour none. The epidermis is tough and leathery; the seeds are flattened and whitish. The recent fruit, called *capsicum* or *chillies*, grown in this country, and sold for pickling, is, when ripe, yellow or red, but it is frequently gathered green; its size and shape are variable, and it is distinguished as long-podded, short-podded, and heart-shaped.

2. The capsules sold by druggists as *Guinea pepper* (*Capsicum Guineense*, L.) or *bird pepper* (*baccæ capsici*) do not exceed an inch in length, and are about two or three lines broad; their colour is orange-red, their odour aromatic and pungent. Their properties are similar to those of chillies, than which they are much hotter and more fiery. Their powder is *Cayenne pepper*, so extensively employed as a condiment. On comparing these fruits with those of *C. frutescens*, Linn., in the East Indian Solanaceæ belonging to the Linnæan Society, they appeared to me to be identical. But in the *London Pharmacopœia*, 1851, they are referred to *C. fasti-*

⁵ *Hist. Plant. lib. ix. cap. 22.*

giatum, Blume, which is identical with one of the plants described by Linnæus as *C. frutescens*. It deserves notice, however, that the commercial fruit is brought from Western Africa, where *C. fastigiatum* has not hitherto been found. In the *Niger Flora*, Sir W. Hooker gives *C. frutescens*, Var. and Linn. Sp. Pl. p. 271, as having been found by Vogel on the Island of St. Antonio.

Besides the above, several other species of *Capsicum* are employed dietetically and medicinally.

Oblong-cylindrical, straight, less than an inch in length.—*Pharm. Lond.*

CAPSICUM CERASIFORME, Wild.—The fruit of this species is called *cherry chilly* or *cherry pepper*. It is small, round, and cherry-shaped.

CAPSICUM GROSSUM, Linn.; *Bell Pepper*.—Fruit large, oblong or ovate, red or yellow.

COMPOSITION.—The fruit was analyzed, in 1816, by Maurach,¹ in the same year by Bucholz,² and in the following year by Braconnot.³

<i>Bucholz's Analysis.</i>		<i>Braconnot's Analysis.</i>	
Acrid soft resin (<i>capsicin</i>)	4.0	Acrid oil	1.0
Wax	7.6	Wax with red colouring matter	0.9
Bitter aromatic extractive	8.6	Brownish starchy matter	9.0
Extractive with some gum	21.0	Peculiar gum	6.0
Gum	9.2	Animalized matter	5.0
Albuminous matter	3.2	Woody fibre	67.5
Woody fibre	28.0	Salts (citrate of potash 6.0, phosphate of potash and chloride of potassium 3.4)	9.4
Water	12.0		
Loss	6.4		
Fruit of <i>Capsicum annum</i> without seeds	100.0	Fruit of <i>Capsicum annum</i>	100.0

CAPSICIN, Bucholz; *Acrid Soft Resin*; *Acrid Oil*, Braconnot.—Obtained by digesting the alcoholic extract in ether, and evaporating the ethereal solution. It is a thick liquid, of a yellowish red or reddish-brown colour, which becomes very fluid when heated, and, at a higher temperature, is dissipated in fumes. Half a grain of it, volatilized in a large room, causes all who respire the air of the room to cough and sneeze. By exposure to air and light it solidifies. It is decolorized by chlorine. It is slightly soluble in water and in vinegar; but very much so in alcohol, ether, oil of turpentine, and the caustic alkalis. With baryta it forms a solid acrid combination.

PHYSIOLOGICAL EFFECTS.—*Capsicum* belongs to the spices (see vol. i. p. 253), and is more closely allied, by its effects, to the peppers (see *ante*, p. 351) than to any other article of the *Materia Medica*. Sundelin,⁴ however, considers it to be more related to pyrethrum. Its active principle is more fixed, and its operation is more permanent and violent, than mustard or horseradish.

Its hot and fiery taste is familiar to every one. Applied to the skin, *capsicum* proves rubefacient and vesicant. Swallowed *in small doses*, it creates a sensation of warmth in the stomach; and in torpid and languid habits proves a valuable stimulant, and a promoter of the digestive functions. Taken *in somewhat larger quantities*, it produces a glow over the body, excites thirst, and quickens the pulse; the latter effect, however, is not in proportion to its local effect. Like the peppers, it is said to exercise a stimulant influence over the urino-genital organs. *In excessive doses* we can easily believe that vomiting, purging, abdominal pain, and gastric inflammation, ascribed to it by Vogt,⁵ may be induced by it, though I am not acquainted with any cases in which these effects have occurred. Richter⁶ mentions, in addition to the symptoms just mentioned, a paralyzed and altered condition of the nervous influence, an affection of the head, drunkenness, and giddiness, as being produced by large doses.

USES.—*Capsicum* is more employed as a *condiment* than as a medicine. It is added to various articles of food, either to improve their flavour, or, if difficult of digestion, to promote their assimilation, and to prevent flatulence. The inhabitants of tropical climates employ it to stimulate the digestive organs, and thereby to counteract the relaxing and enervating influence of external heat.

As a *medicine*, it is principally valuable as a local stimulant to the mouth, throat,

⁶ *Ausf. Arzneim.* Bd. ii. S. 179.

and stomach. Its constitutional not being in proportion to its topical effects, it is of little value as a general or diffusible stimulant. Administered internally, capsicum has long been esteemed in cases of *cynanche maligna*. It was used, in 1786, with great success by Mr. Stephens¹ and by Mr. Collins.² It promoted the separation of the sloughs, and soon improved the constitutional symptoms. Mr. Headby³ also employed it both internally and by way of gargle. Its use has been extended to *scarlatina anginosa*.⁴ As a gargle, in relaxed conditions of the throat, its efficacy is undoubted. The powder or tincture may be applied, by means of a camel-hair pencil, to a relaxed uvula. It is a very useful gastric stimulant in enfeebled, languid, and torpid conditions of the stomach. Thus in the dyspepsia of drunkards, as well as of gouty subjects, it has been found useful.⁵ In various diseases attended with diminished susceptibility of stomach, capsicum is an exceedingly useful adjunct to other powerful remedies, the operation of which it promotes by raising the dormant sensibility of this viscus; as in cholera, intermittents, low forms of fever, dropsies, &c. Dr. Wright⁶ speaks in high terms of it as a remedy for obviating the black vomit—a symptom of the fever of tropical climates, at one time considered fatal. A capsicum cataplasm may be used with advantage to occasion rubefaction in any cases in which a rubefacient counter-irritant is indicated; as in the coma and delirium of fever, in chronic rheumatism, &c.; unless kept on for a long period it does not vesicate.

ADMINISTRATION.—The powder of capsicum is usually given in doses of from gr. v to gr. x, made into pills with crumbs of bread. The dose of the tincture will be mentioned presently. The infusion (prepared by digesting ℥ij of capsicum in f℥x of boiling water for two hours) may be administered in doses of f℥ss. But, in malignant sore-throat and scarlatina, capsicum has been employed in much larger doses. *Stephen's pepper medicine* consisted of two table-spoonfuls of small red pepper, or three of the common Cayenne pepper, and two teaspoonfuls of fine salt, digested in half a pint of boiling water. To the liquor, strained when cold, half a pint of very sharp vinegar is added. A table-spoonful of this mixture to be given to an adult every half hour. The *capsicum gargle* is prepared by infusing ℥ss of capsicum in a pint of boiling water; or by adding f℥vj of the tincture to f℥viij of the infusion of roses; or, in some cases, *Stephen's pepper medicine* may be used as a gargle.

TINCTURA CAPSICI, L. E. D. [U. S.]; *Tincture of Capsicum*.—(Capsicum, bruised [or, if percolation be followed, in moderately fine powder, E.], ℥x [℥iss, D.]; Proof Spirit Oij [Oj, D.]. Digest for seven [fourteen, D.] days, then express and strain [strain, squeeze the residuum, and filter the liquors. [The U. S. Pharm. directs Capsicum, in powder, ℥i; Diluted Alcohol Oij.] This tincture is best prepared by percolation, which may be commenced so soon as the capsicum is made into a pulp with a little of the spirit, E.]—Dose ℥x to f℥j. Employed in the low stage of typhus and scarlet fevers, and in gangrenous sore-throat, and to prevent the nausea which oil of turpentine is apt to occasion. Properly diluted, it may be used as a gargle, as above mentioned. Externally, it is sometimes used as a local stimulant.

resemblance to the human form, were called *anthropomorphon*, and were supposed to prevent barrenness.¹ The root of *Bryonia dioica* is sold at the herb-shops as a substitute for Maudrake. Dr. Sylvester² has recently drawn attention to the ancient uses of this plant as an anæsthetic.

ORDER XLIII. BORAGINACEÆ, Lindley.—BORAGEWORTS.

BORAGINACEÆ, DC.—BORAGINÆÆ, Endl.

CHARACTERS.—*Calyx* persistent, with 4 or 5 divisions. *Corolla* hypogynous, monopetalous, generally regular, 5-cleft, sometimes 4-cleft, with an imbricated æstivation. *Stamens* inserted upon the corolla, equal to the number of its lobes, and alternate with them. *Ovary* 4-parted, 4-seeded, or 2-parted, 4-celled; ovules attached to the lowest point of the cavity, amphitropal. *Style* simple, arising from the base of the lobes of the ovary; *stigma* simple or bifid. *Nuts* 2 or 4, distinct. *Seed* separable from the pericarp, destitute of albumen; embryo with a superior radicle; cotyledons parallel with the axis, plano-convex, sometimes 4 (!) in *Amsinckia*.—*Herbaceous* plants or *shrubs*. *Stems* round. *Leaves* alternate, often covered with asperities consisting of hairs proceeding from an indurated enlarged base. *Flowers* in 1-sided gyrate spikes or racemes, or panicles, some solitary and axillary (*Lindley*).

PROPERTIES.—The plants of this order are characterized by their mucilaginous quality; they are, therefore, mostly harmless and inert.

Formerly, several borageworts were used in medicine; for example, *Symphytum officinale*, Linn., *Borago officinalis*, Linn., *Cynoglossum officinale*, Linn., *Pubnonuria officinalis*, Linn., *Lithospermum officinale*, Linn., and *Echium vulgare*, Linn. They possess little medicinal value (though formerly many virtues were ascribed to them), and are now obsolete. The only boragewort still found in pharmacæutists' shops is *Alkanna tinctoria*, Linn.

180. *Alkanna tinctoria*, Tausch.—Dyer's Alkanet.

Sex. Syst. Pentandria, Monogynia.

(Radix.)

* *Άρχυσα*, Dioscorides, lib. iv. cap. 23; *Lithospermum tinctorium*, Linn., Herb. Sp. ed. i. non. ed. ii.; *Anchusa tinctoria*,³ Desf., Atl. i. p. 156; Hayne, *Arzneigew.*, 10, t. ii.; *Alkanna tinctoria*, Nees, *Of. Pflanz.*, Suppl. ii. t. 6; *Handb.* ii. 591; *Alkanna tinctoria*, Tausch, in *Flora*, 1824. A deciduous herbaceous plant with a perennial, dark blood-red root. This, when dried, constitutes the *alkanet root* (*radix alkannæ tinctoriæ*) of the shops, and which is sometimes called *spurious alkanet root* (*radix alkannæ spurix*) to distinguish it from the *henna* or *al-henna* of the Arabs (*Lawsonia alba*, Lam.), whose root is called the *true alkanet* (*radix alkannæ veræ*). The plant grows on the shores of the Mediterranean, in Asia Minor, Greece, &c.

Alkanet root was analyzed by John,⁴ who found the constituents to be a *peculiar colouring matter* (pseudo-alkannin) 5.50, *extractive* 1.00, *gum* 6.25, *matters extracted by caustic potash* 65.00, *woody fibre* 18.00=95.75 [loss 4.25]. The colouring matter resides in the cortical part of the root, and was regarded by Pelletier⁵ as a kind of fatty acid (*anchusine acid*); but it is now usually considered to be a resinoid (*anchusine*) whose composition is C³⁵H²⁰O⁸. It is of a dark red colour, fusible at 140° F., insoluble in water, but very soluble in alcohol and in acetic acid. The alkalis colour it blue. Acetate and subacetate of lead, protochloride of tin, the salts of iron and alumina, precipitate it; chlorine and strong acids destroy it. Alkanet root communicates its colouring matter to oily and fatty substances; and hence is used by the pharmacæutist to colour *lip salve* (*unguentum labiale*), *hair oil*, &c.

ORDER XLIV. CONVULVULACEÆ, R. Brown.—BIND-WEEDS.

CONVOLVULI, Jussieu.

CHARACTERS.—*Calyx* persistent, in 5 divisions, remarkably imbricated, as if in more whorls than 1, often very unequal. *Corolla* monopetalous, hypogynous, regular, deciduous; the limb 5 lobed, plaited; the tube without scales. *Stamens* 5, inserted into the base of the corolla, and

¹ Matthioli, *Comm. Dioscor.*

² *Pharmaceutical Journal*, vol. vii. p. 519. 1845.

³ Smith (*Prodr. Fl. Græcæ*, i. 116) and Gussone (*Syn.* p. 218) declare the *Anchusa tinctoria*, Linn., Herb. Sp. ed. ii. p. 192 (*Alkanna controversa*, DC., *Prodr.* x. 103) to be entirely different from the *Alkanna tinctoria*, Tausch.

⁴ *Chemische Schriften*. iv. 85; Kunze, *Waarenkunde*, ii. 37.

⁵ *Bull. de Pharm.* vi. 445, 1814; *Journ. de Pharm.* xix. 105, 1833.

alternate with its segments. *Ovary* simple, with 2 or 4 cells, seldom with 1; sometimes in 2 or 4 distinct divisions; few-seeded; the ovules definite and erect, when more than 1 collateral; *style* 1; usually divided at the top, or as many as the divisions of the ovary, and arising from their base; *stigmas* obtuse or acute. *Disk* annular, hypogynous. *Capsule* with from 1 to 4 cells, succulent or capsular; the valves fitting, at their edges, to the angles of a loose dissepiment, bearing the seeds at its base. *Seeds* with a small quantity of mucilaginous albumen; *embryo* curved; *cotyledons* leafy, shrivelled; *radicle* inferior next to the hilum. *Herbaceous plants* or *shrubs*, usually twining and milky, smooth, or with a simple pubescence; sometimes erect bushes. *Leaves* alternate, undivided or lobed, seldom pinnatifid, with no stipules. *Inflorescence* axillary or terminal; peduncles 1 or many-flowered, the partial ones generally with 2 bracts, which sometimes enlarge greatly after flowering (*Lindley*).

PROPERTIES.—The roots and seeds only have been used in medicine.

The tuberous roots of some species (as of jalap and scammony) contain an acrid, milky, purgative juice, which owes its medicinal qualities to the contained resin. *Mchoacan* and *Turpeth* (*Ipomœa Turpethum*) roots, formerly used as purgatives, are now obsolete. In other tuberous roots (as of *Batalas edulis*) the resin is deficient or absent, and starchy matter predominates; in consequence of which they become edible, and are cultivated for the table.

The seeds of some species (as of *Pharbitis œrulca*) are cathartic.

181. CONVULVULUS SCAMMONIA, *Linn.*—THE SCAMMONY.

Sex. Syst. Pentandria, Monogynia.

(*Gummi-resina e ressectâ radice emissa, L. D.*—Gummy resinous exudation from incisions into the root, *E. D.*)

HISTORY.—A purgative substance called scammony (*σκαμμώνιον*) was known to the Greeks long before the time of Hippocrates.¹ The Father of Medicine, who frequently employed it, says that it evacuates, both upwards and downwards, bile and mucus, and expels flatus.² Dioscorides³ notices the plant which yields scammony, and terms it *σκαμμώνια*. Pliny,⁴ also, speaks of scammony, which he calls *scammonium*.

Dr. Sibthorp⁵ refers the scammony of Dioscorides to *C. farinosus*, a Maderia species! on what ground does not appear, as this supposed species is not in his herbarium.⁶ If the ordinary reading of the text of Dioscorides be correct, this author represents the scammony as having hairy branches and leaves; which applies better to *C. sagittifolius* (*C. Sibthorpii*, Roemer and Schultes), found by Sibthorp in Samos and other islands of the Grecian Archipelago. This species is with great probability adopted by Dierbach⁷ as the source of the ancient scammony.⁸

BOTANY. *Gen. Char.*—*Sepals* 5. *Corolla* campanulate. *Style* 1. *Stigmas* 2, linear-cylindrical, often revolute. *Ovary* 2-celled, with 4 ovules. *Capsule* 2-celled (*Choisy*).

Sp. Char.—Stem smooth. Leaves sagittate, posteriorly truncate with entire or elongated slashed auricles. Peduncles very long, many-flowered. Sepals coloured, ovate, obtusely truncated, mucroulate, the external ones a little smaller, 2—3 lines long. Corolla campanulate, an inch long (*Choisy*).

Root perennial, tapering, 3 or 4 feet long, with an acrid, milky juice. *Stems* numerous, twining, herbaceous, smooth. *Leaves* on long petioles, acuminate, with pointed lobes at the base. *Peduncles* solitary, scarcely twice so long as the leaves. *Bracts* awl-shaped. *Sepals* obovate, truncated, with a reflex point, coloured at the edge. *Corolla* pale yellow, with purple stripes. *Stamina* shorter than the corolla; *anthers* erect, sagittate. *Style* as long as the stamens; *stigmas* white.

Hab.—Hedges and bushy places in Greece and the Levant.

PREPARATION.—The method of procuring scammony is, according to Dr. Russel,⁹

¹ Voigtels, *Arzneimittell.* Bd. i. S. 17; Bischoff, *Handb. d. Arzneimittell.* Bd. i. S. 40.

² *De Morb. Mul.* p. 597, ed. Fœs.

³ *Hist. Nat. lib. xxvi. cap. 38, ed. Valp.*

⁴ *Lindley, Fl. Medica.*

⁵ *Tournefort (Voyage into the Levant, vol. ii. p. 96, 1741)* says that the scammony of Samos is collected from a bindweed (*convulvulus*) whose leaves are larger, hairy, and slashed at their basis not so prettily as those of the Syrian scammony (*C. scammonia*). This doubtless is *C. sagittifolius*, which Sibthorp found in Samos.

⁶ *Med. O.*, and *Inq.* vol. i. p. 13, 1776.

⁷ *Lib. iv. cap. 171.*

⁸ *Prod. Fl. Græcæ.*

⁹ *Arzneimittell. d. Hippokrates, S. 138.*

as follows: Having cleared away the earth from the upper part of the root, the peasants cut off the top in an oblique direction, about two inches below where the stalks spring from it. Under the most depending part of the slope they affix a shell, or some other convenient receptacle, into which the milky juice flows. It is then left about twelve hours, which time is sufficient for the drawing-off the whole juice; this, however, is in small quantity, each root affording but a few drachms. This milky juice from the several roots is put together often into the leg of an old boot, for want of some more proper vessel, when in a little time it grows hard, and is the genuine scammony.

Of this entirely pure scammony, says Dr. Russel, but very little is brought to market, the greater part of what is to be met with being adulterated, if not by those who gather it, by those who buy it of them abroad; for the chief part of what is brought hither passes through the hands of a few people, chiefly Jews, who make it their business to go to the villages of any note near which the scammony is collected (as Antioch, Shogre, Elib, Maraash, &c.), and then buying it while it is yet soft, they have an opportunity of mixing it with such other things as suit their purpose best—as wheat-flour, ashes, or fine sand, all of which he found it mixed with; but there seems, he adds, some other ingredient (possibly the expressed juice), which makes it so very hard and indissoluble that he was not able to discover it to his satisfaction.

Dioscorides thus describes the mode of procuring it: The head being separated, the root is to be excavated in the form of a dome (or vault) by a knife, so that the juice may flow into the cavity, from which it is to be taken out in shells. Others excavate the earth, and, having incised the root, let the juice run into the cavity, which has been previously lined with walnut leaves; when the scammony is dry, it is removed.

I have been informed by a Turkey merchant, who formerly resided at Smyrna, that scammony is brought into Smyrna, in the soft state, on camels. Here it is mixed with various impurities by persons (Jews) who are denominated scammony makers, and who adulterate it, and thereby lower its value to suit the market.

DESCRIPTION—Scammony (*scammonium*; *gummi-resina scammonii*) is usually imported from Smyrna. Occasionally, it comes by way of Trieste. Still more rarely it is brought from Alexandretta (also called Scanderoon or Iskenderún), the port of, and road to, Aleppo. It comes over in boxes and drums, which are frequently lined with tin.

I shall arrange¹ the different sorts of scammony of commerce under three heads: 1st, pure scammony; 2dly, adulterated scammony; 3dly, factitious scammony.

1. PURE SCAMMONY (*Scammonium purum*).—In English commerce one sort only is known under this name—namely, the virgin scammony. Scammony in shells is probably a pure scammony, but is unknown in trade. Trebizon or Samos scammony, though perhaps a pure scammony, differs so much in its external appearance from the ordinary commercial sorts, that it is unsalable here.

a. *Virgin Scammony* (*Lacryma*² *Scammony*; *Superior Aleppo Blackish*

¹ Marquart (*Pharm. Central-Blatt für 1837*, p. 671), who has published an elaborate paper on scammony. He arranges the various sorts as follows:—

1. *Scammony from the Convolvulaceæ*.—Under this head he includes
 - a. Aleppo scammony. Of this he makes five sorts.
 - β. Antioch scammony. Of this he makes three sorts.
 - γ. Samos scammony.
2. *Scammony from the Asclepiadææ*.
 - δ. French or Montpellier scammony.
3. *Scammony from the Apocynææ*.
 - ε. Smyrna scammony of commerce. Of this he makes four sorts.

But the foundation of this arrangement is erroneous. Smyrna scammony is not the produce of Apocynææ, but of a smooth-leaved Convolvulus, as Sherard (Geoffroy, *Tract. de Mat. Med.* ii 667) has shown. Under the head of Smyrna scammony, Marquart includes adulterated and factitious commercial sorts. In English commerce no distinction of Aleppo, Antioch, and Smyrna scammony is made.

² The term ‘lacryna scammony’ I have heard applied to this sort of scammony by a Turkey merchant. It is remarkable that a somewhat similar term was used by the ancients. Cælius Aurelianus (*Acut. Morb.* lib. ii. cap. xxix.) speaks of ‘succum scamoniæ quam diagridium appellamus.’ Now *diagridium* is a corruption from *δακρυδίσιν*, *lacrymula*, a little tear. The word *diagridium* was also applied to a preparation of scammony.

Scammony, Guib.).—It usually occurs in amorphous pieces; but a careful examination of some large lumps has led me to believe that they formed portions of a mass, which, when in the soft state, had a rounded form. The whitish-gray powder, which covers some of the pieces, effervesces with hydrochloric acid; and I have no doubt, therefore, that the masses have been rolled in chalk. Virgin scammony is friable, easily reduced to small fragments between the fingers, or by the pressure of the nail, and has, according to my experiments, a sp. gr. of 1.210. Its fractured surface is resinous, shining, greenish-black; presents small air-cavities, and numerous gray semitransparent splinters, or fragments, when examined by a magnifying glass; and does not effervesce on the addition of hydrochloric acid. When rubbed with the finger moistened with ether, water, or saliva, it readily forms a milky liquid. If we examine thin fragments, or splinters, by transmitted light, we observe them to be semitransparent at the edges, and of a gray-brown colour. In the same piece we sometimes find some portions shining and blackish, as above described; while others are dull grayish. This difference depends probably, as Dr. Russel has suggested, on different methods of drying. Virgin scammony readily takes fire, and burns with a yellowish flame. Its odour is peculiar, somewhat analogous to old cheese; its taste is slight at first, afterwards acrid. The decoction of its powder, when filtered and cold, is not rendered blue by tincture of iodine. When incinerated in a crucible, it leaves a minute portion only of ash.

This sort of scammony is usually imported from Smyrna.

Porous, brittle, glistening on the fractured surface; emits no bubbles when hydrochloric acid is dropped on it; no blue colour is produced by the simultaneous addition of iodide of potassium and dilute nitric acid to water, in which powdered scammony has been digested at 170°. Ether should dissolve 78 grains out of 100 grains of scammony, L.

β. *Scammony in shells or calabashes* (*Scammonium in testis*; *Sc. in calabassis*).—Unknown in English commerce. It is described by continental writers as a very pure sort.

γ. *Trebizon Scammony*.—In 1832, a substance was imported into London, from Trebizon, under the name of scammony, which was unsalable here. The sample which I received is a portion of cake apparently round, flat below, and convex above. Its colour is light-grayish or reddish-brown; when moistened, the surface becomes glutinous and odorous; its taste is sweet, nauseous, and somewhat bitter. In its external appearance it has more resemblance to benzoin than scammony.

This, probably, is the *Scammony of Samos* mentioned by Tournefort;¹ the *Scammony from Mysia* of Dioscorides. It would appear to be obtained from a species of *Convolvulus* (*C. Sagittifolius*) different from that which yields the Aleppo and Smyrna scammony; for both Dioscorides and Tournefort state that the leaves are hairy.

2. **ADULTERATED SCAMMONY** (*Scammonium adulteratum*).—Under this head are included the various sorts of scammony commonly found in the shops, and which English dealers distinguish as *seconds*, *thirds*, &c. To this division belongs the so called *Antioch scammony* (*scammonium antiochum*) of continental writers. What is sometimes called on the continent *Smyrna scammony* (*scammonium smyr-nense*), is either adulterated or factitious scammony. The term *Aleppo scammony* (*scammonium halepense* seu *aleppicum*) is applied by the same writers to virgin scammony, and to the better sorts of adulterated scammony.² The different sorts of adulterated scammony more frequently occur in round flattened or plano-convex cakes of variable size, usually an inch or two in thickness, and about five inches in diameter. Some are met with in amorphous, irregular lumps; others in large cylindrical or drum-shaped masses.

The different sorts of adulterated scammony vary considerably in appearance, but pass so insensibly the one into the other that it is impossible to classify them according to their physical characters. I shall, therefore, arrange them according to their chemical characters.

A. *Adulterated Scammony, which effervesces on the addition of hydrochloric*

¹ *A Voyage into the Levant*, vol. ii. p. 96, 1741.

² I have a specimen of scammony, sent to a friend of mine for sale from Aleppo, which is so adulterated that no offer can be obtained for it. It is in thin flat cakes, which have a sweet smell, and contain the starch of either wheat or barley—probably of the former.

acid.—This is sophisticated with carbonate of lime, and sometimes with starch or dextrine also.

α. Calcareous, Chalky, or Cretaceous Scammony.—Occurs in round flat cakes, or in irregular lumps. It is more ponderous than the virgin sort, and usually breaks with a dull and earthy fracture. Its colour is ash-gray, like common secondary limestone. A specimen in irregular lumps I found to have the sp. gr. of 1.463.

Its chemical characters are as follows: hydrochloric acid applied to a fractured surface causes effervescence; iodine produces no change of colour when added to the filtered decoction after it has become cold.

Lumps of crystallized carbonate of lime are sometimes found in this sort of scammony.

β. Calcareo-Amylaceous Scammony.—This, like the preceding, occurs in round flat cakes or in irregular lumps, which contain carbonate of lime and either wheat or barley starch or meal.¹ I have also met with it in cylindrical or drum-shaped masses.

αα. In irregular lumps.—It sometimes resembles pure scammony in its glossiness and dark resinous appearance; but usually it has a waxy lustre and grayish colour.

ββ. In cylindrical or drum-shaped masses.—This kind is imported either in boxes or drums, into which it seems to have been introduced when soft, and to have hardened subsequently—hence its form is that of the package in which it was imported. A sample of a circular cake (about 12 inches in diameter, and several inches thick) presents a dull-grayish fracture. Its sp. gr., according to my experiments, is 1.359.

γγ. In circular flat cakes.—I have received this sort of scammony in the form of circular flat cakes, about five inches in diameter, and one inch thick. They are heavy, dense, and much more difficult to fracture than the preceding kinds. The fractured surface, in some samples, is resinous and shining, in others dull; it has air-cavities, and numerous small white specks (chalk); its colour is grayish to grayish-black. The sp. gr. varies, in different samples, from 1.276 to 1.543. I have received portions of five cakes of this variety of scammony, on which were marked the actual quantity of chalk which had been intermixed in each sample. In 100 parts of the cakes the proportions of chalk were respectively as follows: 13.07, 23.1, 25.0, 31.05, and 37.54. These numbers were furnished by the Levant importer to one of our most respectable wholesale druggists, from whom I received them.

The chemical characters of calcareo-amylaceous scammony are as follows: hydrochloric acid applied to a fractured surface causes effervescence; iodine produces a blue colour when added to the filtered decoction after it has become cold.

γ. Calcareo-dextrinous Scammony.—This sort differs from the preceding in the circumstance that iodine produces a reddish-purple tint when added to the filtered decoction after it has become cold. It appears to contain carbonate of lime and dextrine.

B. Adulterated Scammony, which does not effervesce on the addition of hydrochloric acid.—This sort of scammony is usually sophisticated with wheat-meal.

δ. Amylaceous Scammony.—This sort of scammony is adulterated with the starch or flower of either wheat or barley—probably the former; it is of less frequent occurrence than the calcareo-amylaceous kind. It occurs in irregular lumps and round flat cakes, which sometimes have a resinous fracture and a dark colour

¹ Dioscorides states that the Syrian scammony is adulterated with *τὸ βύμαλις* (*euphorbia* or *spurge*) and *ἄλευρον ἄρτυρον* (*meal of the ervil or bastard lentil, the Ervum Ervilia of Linn.*) A careful microscopic examination of amylaceous and calcareo-amylaceous scammony has satisfied me that the starch or flour used for adulterating these sorts of scammony, at the present day, is that of either wheat or barley.—I think of wheat.

like pure scammony, but which more commonly have a waxy lustre and a grayish colour. It contains starch and ligneous matter, but not chalk. It does not, therefore, effervesce with hydrochloric acid. Its decoction, when filtered, and cooled, strikes a blue colour on the addition of iodine.

α. *Selenitic or Gypseous Scammony*.—This kind has been described by Marquart. Its sp. gr. was 1.731, and it contained no less than 52 per cent. of gypsum (sulphate of lime).

ζ. *Bassorin Scammony*.—Marquart met with a scammony which had a horny consistence and a sp. gr. of 1.167. After it had been deprived of its resin and extractive, it swelled up in boiling water. The constituent which thus swelled up was soluble in caustic potash; Marquart regarded it as bassorin.

In the Museum of the Pharmaceutical Society is a specimen of scammony which is supposed to be adulterated with tragacanth and some resin.

η. *Indian Scammony*.—From my friend Dr. Royle I have received a sample of scammony met with in the Indian bazaars. It is light, porous, of a greenish-gray colour; gritty under the teeth, as if containing a considerable quantity of sand, and having a balsamic olibanum-like odour.

3. **FACTITIOUS SCAMMONY** (*Scammonium factitium*).—To this division belongs part of the so-called *Smyrna scammony* of continental commerce, as well as *French* or *Montpellier scammony*. I have met with three samples of factitious scammony.

α. Under the name of *Smyrna scammony*, I purchased of a London dealer a sort of scammony in the form of circular flat cakes, about half an inch thick. It is blackish, and has, externally, a slaty appearance; it breaks with difficulty; its fracture is dull and black. Its sp. gr. is 1.412. Moistened and rubbed, it evolves the smell of guaiacum. Boiled with water, it yields a turbid liquor (which is not rendered blue by iodine), and deposits a blackish powder; the latter, boiled with alcohol, yields a solution which becomes greenish-blue on the addition of nitric acid, showing the presence of guaiacum.

It is probably the common *Smyrna scammony* (*Scammonium smyrnense factitium*) of Gray,¹ who directs it to be made with Aleppo scammony, 1 lb.; extract of jalap, 5 lbs.; guaiacum resin, 10 lbs.; sago, 10 lbs.; and ivory black, 4 lbs.

β. Under the name of *Scammonium smyrnense medicinale venale*, M. Batka has presented to the Pharmaceutical Society a spurious scammony said to be made up of gum, bread, scammony, guaiacum, benzoin, wax, sand, and wood.

γ. *French or Montpellier Scammony* (*Scammonium gallicum seu monspeliacum*).—This substance is made, in the southern part of France, with the expressed juice of *Cynanchum monspeliacum*, mixed with different resins and other purgative substances. It occurs in semicircular, blackish, hard, compact cakes, which frequently have the smell of balsam of Peru.

COMPOSITION. α. **Of the Root.**—The dried root of *Convolvulus Scammonia* was analyzed, in 1837, by Marquart,² who obtained from it the following substances: resin 4.12, sugar, convolvulin, and extractive 13.68, resin and wax 0.55, gum, 5.8, extractive 2.4, starch 7.0, extractive soluble in hot, but not in cold water 1.4 [salts and woody fibre 65.05]. The resin, the wax, and a portion of the gum, are contained in the milky juice of the latex vessels (*vasa laticis*); while the sugar, gum, extractive, and salts dissolved in water, constitute the juice of the cells; and in this juice the starch-globules float.

1. **RESIN.**—This is analogous to that of the scammony of commerce.

2. **CONVOLVULIN.**—A substance supposed by Marquart to be a vegetable alkali. It reacts feebly as a vegetable alkali, and is precipitated from its watery solution by tincture of nutgalls. Marquart thinks it probably exists in jalap.

β. **Of Scammony.**—Bouillon-Lagrange and Vogel³ analyzed two kinds; one called Aleppo, the other Smyrna scammony. Marquart⁴ analyzed twelve kinds; of these, eight sorts (five called Aleppo, and three Antioch scammony) he considers to be the produce of *Convolvulus Scammonia*; while the remaining four, which, he says, are called in commerce *Smyrna scammony*, he erroneously ascribes to *Periploca Secamone*, Linn. Three of these, however, appear to be adulterated sorts, and one (the 12th) is obviously factitious.

 Inorganic salts, silica, &c.

Dr. Christison¹ has analyzed both pure and adulterated scammony. His results are as follows:—

	PURE SCAMMONY.			ADULTERATED SCAMMONY.					
	Old.	Old.	Moist.	Calcareous.			Amylaceous.		Calcareo-Amylaceous.
Resin	81.8	83.0	77.0	64.6	56.6	43.3	37.0	62.0	42.4
Gum	6.0	8.0	6.0	6.8	5.0	8.2	9.0	7.2	7.8
Starch (fecula)	1.0	—	—	—	1.4	4.0	20.0	10.4	13.2
Lignin and sand	3.5	3.2	5.0	5.2	7.1	7.8	22.2	13.4	9.4
Chalk	—	—	—	17.6	25.0	31.6	—	—	18.6
Water	7.7	7.2	12.6	6.4	5.2	6.4	12.0	7.5	10.4
	100.0	101.4	100.6	100.6	100.3	101.3	100.2	100.5	101.8

ADULTERATION.—The characters of good scammony are as follows: It readily fractures between the fingers, or by the pressure of the nail; its sp. gr. is about 1.2; its fracture is dark, glistening, and resinous; its fractured surface should not effervesce on the addition of hydrochloric acid; the decoction of the powder, filtered and cooled, is not rendered blue or purplish by tincture of iodine; paper moistened with an alcoholic or ethereal tincture of scammony should undergo no change of colour when exposed to brown nitrous fumes (produced by pouring a drachm of strong nitric acid over some filings of zinc, iron, or copper, contained in a tumbler or wineglass; 100 grains, incinerated with nitrate of ammonia, yield about three grains of ashes (according to my experiments); sulphuric ether separates at least 78 per cent. of resin (principally), dried at 280° F.

“Fracture glistening, almost resinous, if the specimen be old and dry; muriatic acid does not cause effervescence on its surface; the decoction of its powder, filtered and cooled, is not rendered blue by tincture of iodine. Sulphuric ether separates at least 80 per cent. of resin dried at 280°.”—*Ph. Ed.*

Hydrochloric acid detects the presence of carbonates; iodine added to the cooled decoction of scammony detects starch and dextrine; by nitrous fumes the presence of guaiacum resin may be detected, for they give a blue colour to paper which has been moistened with tincture of guaiacum; incineration detects an abnormal amount of inorganic matter, as chalk, gypsum, or sand; ether determines the amount of resinous matter present.² The microscope serves to detect the presence and sort of starch or meal used for adulterating. Hitherto, the only starch I have detected in adulterated scammony is that of a cereal, either wheat or barley—probably the former (see *ante*, p. 512).

PHYSIOLOGICAL EFFECTS. *a. On Animals generally.*—The experiments of Orfila³ lead us to infer that scammony is not poisonous. “We have,” says he, “frequently administered four drachms of it to dogs who had the œsophagus afterwards tied, and have only observed alvine evacuations.” On horses and other herbivorous animals its operation is very uncertain. Gilbert⁴ states that six drachms killed a sheep in twenty days, without having caused purging. Viborg⁵ says half an ounce given to a dog caused several loose stools; the same dose had no effect on a badger. It is probable, however, that in all the experiments now referred to, adulterated scammony was employed.

β. On Man.—The effects of pure scammony are those of a powerful and drastic purgative. As the greater part of the commercial drug is largely adulterated, practitioners are, I suspect, scarcely acquainted with the operation of the genuine article, which appears to me to possess nearly double the activity of that usually

¹ *Dispensatory.*

² For further details, see a paper *On the Adulteration of Scammony*, by the author, in the *Pharmaceutical Journal*, vol. iv. p. 267, 1845.

³ *Toxicol. Gén.*

⁴ *Wibmer, Virk. d. Arzn. u. Gifte*, Bd. ii. S. 151.

⁵ *Moiroud, Pharm. Vét.* p. 271.

found in commerce. As the evacuant powers of scammony depend on its local irritation, it operates more energetically when there is a deficiency of intestinal mucus, and is then very apt to gripe; and *vice versa*, when the intestines are well lined with secretion, it passes through with much less effect. In its operation scammony is closely allied to jalap, than which it is more active, while its odour and taste are less nauseous. It is less irritant than gamboge.

USES.—Scammony is, of course, inadmissible in inflammatory conditions of the alimentary canal, on account of its irritant qualities. It is well adapted for torpid and inactive conditions of the abdominal organs, accompanied with much slimy mucus in the intestines. It is principally valuable as a smart purgative for children, on account of the smallness of the dose necessary to produce the effect, the slight taste, and the energy, yet safety, of its operation. When used for them, it is generally associated with calomel. Where a milder purgative is required, it may be conjoined with rhubarb, sulphate of potash, and an aromatic. It may be employed to open the bowels in constipation; to expel worms, especially of children; to act as an hydragogue purgative, on the principle of counter-irritation, as in affections of the head and dropsies; and for any other purpose for which an active cathartic may be required.

ADMINISTRATION.—For an adult, the usual dose of commercial scammony is ten grains to a scruple; but, of virgin scammony, from ten to fifteen grains. In order to diminish its irritant and griping qualities, it should be finely divided. For this purpose it may be intimately mixed with some bland powder (as gum, starch, sugar, &c.), or made into an emulsion with milk.

1. PULVIS SCAMMONII COMPOSITUS, L. D.; *Compound Powder of Scammony*.—(The *London College* directs it to be prepared with Scammony, Hard Extract of Jalap, of each ℥ij; Ginger ℥ss. Rub them separately to very fine powder; then mix them. The *Edinburgh College* directs it to be made of equal parts of Scammony and Bitartrate of Potash, triturated together to a very fine powder. The *Dublin College* orders of Scammony, in fine powder, ℥j; Compound Powder of Jalap ℥iij. Mix thoroughly by trituration, and pass the powder through a fine sieve.)—The effects of scammony and of extract of jalap being very similar, little or no advantage can be obtained by the intermixture of these substances. The ginger is intended to correct the griping of the other ingredients. The bitartrate of potash, used by the *Edinburgh College*, can do little more than serve to divide the scammony. Compound powder of scammony is cathartic; and is used as a smart purge for children, especially where much mucous slime is contained in the bowels, and in worm cases. The dose of the *London* and *Dublin* preparation, for an adult, is from grs. x. to ℥j; for children under a twelvemonth old, from grs. iij. to grs. v. The dose of the *Edinburgh* preparation, for an adult, is from grs. xv to ℥ss.

2. PULVIS SCAMMONII CUM CALOMELANE; *Powder of Scammony with Calomel*.—(Scammony ℥j; Calomel, Sugar, of each ℥ss. Mix.)—Though this preparation is not contained in any of the British pharmacopœias, yet the frequency of its employment in the diseases of children is a sufficient apology for its introduction here. Dose, for an adult, grs. x to grs. xx; for children, from grs. iv to grs. x, according to the age of the patient.

This preparation may be employed as a substitute for the old *Pulvis Basilicus*, or *Royal Powder*, which consisted of equal parts of scammony, calomel, cream of tartar, and antimonie acid.

3. CONFECTIO SCAMMONII, L.; *Electuarium Scammonii*, D.; *Confection of Scammony*.—(Scammony, powdered, ℥jss; Cloves, bruised; Ginger, powdered, each ℥vj; Oil of Caraway f℥ss; Syrup of Roses as much as may be sufficient. Rub the dry ingredients together to very fine powder, and preserve them; then, whenever the confection is to be used, the syrup being gradually poured in, rub again; lastly, the oil of caraway being added, mix them all, L.—The *Dublin College* orders of Scammony, in fine powder, ℥iij; Ginger, in fine powder, ℥iiss; Oil of

Caraway fʒj; Oil of Cloves fʒss; Simple Syrup fʒiij; Clarified Honey, *by weight* ʒiiss.)—A warm or aromatic cathartic. Dose, for an adult, ʒj to ʒj; for children, grs. iij to grs. x. It is seldom employed.

4. **EXTRACTUM** *sive* **RESINA SCAMMONII**, E.; *Extract or Resin of Scammony*.—(Take any convenient quantity of scammony in fine powder; boil it in successive portions of proof spirit till the spirit ceases to dissolve anything; filter; distil the liquid till little but water passes over. Then pour away the watery solution from the resin at the bottom; agitate the resin with the successive portions of boiling water till it is well washed; and, lastly, dry it at a temperature not exceeding 240°.)—To obtain pure resin of scammony, alcohol or ether should be used instead of proof spirit. It is brownish, and in thin layers transparent; when heated, it evolves a peculiar, not disagreeable odour; it is fusible and combustible. It is soluble in alcohol, ether, and oil of turpentine.

Resin of jalap is insoluble in oil of turpentine, and nearly so in ether; whereas scammony resin is readily soluble in these liquids. By these peculiarities the two resins may be distinguished from each other.

The alcoholic solution of scammony resin is feebly acid; the addition of water causes a white precipitate (*hydrate of resin*). Precipitates (*metallic scammoniates?*) are also produced by alcoholic solutions of the acetate of lead and the acetate of copper. Caustic potash deepens the colour of the solution.¹ Scammony resin may be decolorized by animal charcoal without having its purgative qualities affected.² Its composition, according to Mr. Johnston,³ is C¹⁰H¹¹O²⁰. It is "remarkable for containing the largest quantity of oxygen of any resin hitherto analyzed." (Johnston.) When pure or virgin scammony can be obtained, the resin is an unnecessary preparation. Scammony resin is a drastic cathartic. Dose, grs. viij to grs. xij. When administered, it should be intimately divided, either by some bland powder, or still better by an emulsion.

5. **TINCTURA SCAMMONII**; *Tincture of Scammony*; *Tincture de Scammonée*.—Codex, Pharm. Française, 1837.—(Aleppo Scammony 1 part; Rectified Spirit 4 parts by weight; macerate for fifteen days and filter.)—Dose, fʒss to fʒj diffused through a mucilaginous mixture of milk.

6. **MISTURA SCAMMONII**, F.; *Mixture of Scammony*.—(Resin of Scammony gr. viij; Unskimmed Milk fʒiij. Triturate the resin with a little of the milk, and gradually with the rest of it till a uniform emulsion is formed.)—This is an imitation of *Planché's purgative potion*, except that two drachms of sugar and three or four drops of cherry-laurel water are omitted. It is one of the most agreeable draughts that can be taken.

182. EXOGONIUM PURGA, *Benham*.—TURE JALAP.

Sex. Syst. Pentandria Monogynia.

(Tuber, L. D.—Root, E. D.)

HISTORY.—De Paiva⁴ thinks that Jalap was known to Dodoens in 1552, to Monardes in 1568, and to Clusius in 1574.⁵ But Bauhin⁶ (who calls it *Bryonia Mechoacana nigricans*) says it was brought from India, under the name of *Chelapa*, or *Clapa*, about eleven years before the time he wrote (the date of the preface to his work is 1620); that is, about 1609 or 1610. Its name seems to be derived from Xalapa, a town of Mexico.

The jalap plant has been successively declared to be a *Mirabilis*, a *Convolvulus*, an *Ipomœa*, and an *Exogonium*.

The *Convolvulus Jalapa* described and figured by Woodville⁷ and Desfontaines,⁸

¹ Marquart, *op. cit.*

² *Phil. Trans.* for 1840, p. 311.

³ See some remarks on this subject in *Pharm. Central-Blatt für 1844*, S. 955—6.

⁶ *Journ. de Pharm.* t. xiii. p. 589.

⁷ Voigtel's *Arzneimittell.* Bd. i. S. 117.

⁸ *Med. Bot.* p. 59.

is now well known to yield none of this drug. The real jalap plant was first described by Mr. Nuttall;¹ but the name (*Ipomæa Jalapa*) he gave to it had been already applied by Pursh to another plant. In the same year Dr. Schiede² and Dr. Wenderoth³ noticed it; the latter called it first *Convolvulus Purga*, and afterwards *Ipomæa Purga*. In 1832 it was described and figured by Zuccarini,⁴ under the name of *Ipomæa Schiedeana*.

Choisy, in De Candolle's *Prodromus* (vol. ix. p. 374), has adopted Wenderoth's name of *Ipomæa purga*; but as the jalap plant has a salver-shaped (hypoerateriform) corolla and exerted stamens, it certainly cannot be an *Ipomæa*, a part of whose character is a campanulate corolla and inclosed stamens.

BOTANY. Gen. Char.—*Sepals* 5. *Corolla* tubular. *Stamens* exerted. *Style* 1. *Stigma* capitate, 2-lobed. *Ovary* 2-celled; the cells 2-seeded. (Choisy.)

Sp. Char.—*Root* tuberose; incrassated, perennial. *Stems* annual, twining, branched, smooth. *Leaves* ovate, acuminate, cordate at the base, quite entire, and smooth on both sides. *Peduncles* 1- to 3-flowered. *Sepals* unequal, obtuse, smooth. *Corolla* salver-shaped, with a subclavate, cylindrical tube, and a subpentagonal, horizontally-expanded limb.

Root perennial, irregularly ovate-conical, terminating inferiorly in some subcylindrical fibrous branches; covered by a very thin, dirty, blackish epidermis; internally white and fleshy. *Stem* herbaceous. *Leaves* alternate, petioled. Tube of the *corolla* purplish violet (red lake).

Hab.—In the woods of the Mexican empire, near Chicanquiaco, at an elevation of nearly 6,000 feet above the level of the sea. Jalapa is the only market for the root, from whence it is exported to Europe and the United States by way of Vera Cruz.

IPOMÆA ORIZABENSIS, Ledanois; *Convolvulus, Orizabensis*, Pelletan, Journ. de Chim. Med. t. x. p. 10, 1834. *Ipomæa batatoides*, Bentham, Bot. Regist. Jan. 1841. *Ipomæa? Mestillanica*, Choisy, De Cand. Prodr. ix. 389.—This plant grows in the environs of Orizaba and near Mestitan in Mexico. It yields an inferior sort of jalap, called *light, fusiform, or male jalap*.

DESCRIPTION.—1. The dried tubers of true jalap (*radix jalapæ*; *rad. jalapæ tuberosæ vel ponderosæ*) found in commerce rarely exceed a pound each in weight. They vary in size, from that of the fist to that of a nut. When entire, they are usually more or less oval, and pointed at the two opposite extremities. The larger tubers are frequently incised, apparently to facilitate desiccation. They are covered with a thin, brown, wrinkled cuticle. They should be heavy, hard, and difficult to powder. When broken, good tubers should present a deep yellowish-gray colour, interspersed with deep brown concentric circles. The slices vary in their shape, colour, and other properties. Those of inferior quality, are light, *whitish*, friable; they usually appear to be quarter segments of transverse slices, and are sometimes called *spurious jalap*, or, from their shape, *cocked-hat jalap*. Jalap is very apt to become worm-eaten; but the insects which attack it devour the amylaceous matter and ligneous matter, and leave the resin. Hence *worm-eaten jalap* is well adapted for the preparation of extract.

2. A *spurious jalap*, called in Mexico *male jalap*, is sometimes found intermixed with the genuine sort. It was first described by Mr. D. B. Smith;⁵ and has been termed by Guibourt *light or fusiform jalap*. It is the kind sometimes called in English commerce *woody jalap* or *jalap wood*, and which in Germany has been termed *jalap stalks (stipites jalapæ)*. It is the produce of *Ipomæa Orizabensis*, Ledanois. As met with in commerce, it is in slices or segments, which are more fibrous or woody than genuine jalap. The cut surface is often darker from exposure to the air, and uneven from the unequal shrinking in the drying process. Internally, the colour is whitish. The odour and taste are similar to, but feebler than, the true jalap.

⁴ *Acta Acad. Reg. Monacensis*, vol. x.

⁵ *American Journal of Pharmacy*, vol. ii. p. 22.

3. Guibourt¹ has described a *false rose-scented jalap*. It is in tubercles which are not so dark-coloured as the genuine drug. They are deeply furrowed; the prominent parts of the furrows being white from the friction of the pieces against each other; the depressions being dark coloured. The pieces are but slightly resinous, are amylaceous and saccharine, and have rather an agreeable sweetish odour, which Guibourt compares to that of oil of rhodium or of the rose. It possesses scarcely any purgative action. It is probably the kind known in the American market as *overgrown jalap*.

SELECTION.—Jalap is more active as a cathartic in proportion to the quantity of resin which it contains; plump, firm, heavy, resinous pieces, therefore, are preferable. Light, whitish, amylaceous, shrivelled, or woody pieces are objectionable.

COMPOSITION.—Jalap was analyzed, in 1817, by Cadet de Gassicourt,² and more recently by Gerber.³ Other less complete analyses have been made by Henry,⁴ by Ledanois,⁵ and by Nees v. Esenbeck and Marquart.⁶ In 1835, Canobio analyzed a variety of jalap called *giallappone*,⁷ similar in appearance to galanga.

1. JALAP RESINS.—The resinous portion of jalap is the most important, because it is the active ingredient of this root. The substance generally known as *jalap resin* is obtained by mixing the alcoholic tincture of jalap (prepared by percolation or digestion) with water. The precipitated resin is to be washed with warm water, and then dissolved in alcohol. By evapora-

⁷ *Pharm. Central-Blatt für 1834*, S. 695.

tion the tincture yields the resin. Planché¹ has proposed another process. By digestion with animal charcoal the alcoholic solution of the resin is rendered nearly colourless, and by evaporation yields an almost colourless resin (*resina jalapæ alba* of Martius.)² Jalap resin is soluble in alcohol, but insoluble in water. Triturated with milk, it does not form an emulsion, but its particles unite into a solid mass. By this it may be distinguished from scammony resin.³ It is insoluble in the fixed and volatile oils. Its insolubility in oil of turpentine is a means of detecting the intermixture of some other resins, as of scammony and turpentine.⁴ Jalap resin is sometimes adulterated with guaiacum.⁵ This, unlike jalap resin (rhodoretin) is soluble in ether; and paper moistened with its alcoholic solution is rendered blue by nitrous gas. Decolorized jalap is composed, according to Gœbel,⁶ of carbon 36.62, hydrogen 9.47, and oxygen 53.91; but Johnston⁷ declares this analysis to be incorrect, and gives the following as the formula for the resin, $C^{40}H^{34}O^{15}$.

According to Buchner and Herberger,⁸ as also Kayser,⁹ the so-called jalap resin consists of two distinct resins, one soluble in ether, the other insoluble in this liquid.

a. Jalapin; Rhodoretin (from *ῥόδαιος*, rose-red, and *ῥητίνη*, resin.) $C^{42}H^{35}O^{20}$. Is this the jalapin of Mr. Hume?¹⁰ This resin is insoluble in ether. Kayser obtained it by boiling purified jalap resin in ether, which took up the jalapic acid and left the jalapin. According to Buchner and Herberger it constitutes not quite nine-tenths of jalap resin. It is a transparent, colourless, odourless, and tasteless resin; very soluble in alcohol, but insoluble in water and in ether.

It does not possess basic properties, as Buchner and Herberger supposed; but, on the contrary, possesses acid properties, reddens litmus, and is soluble in ammonia and acetic acid. If the salt which it forms with oxide of lead be decomposed by sulphureted hydrogen, the resin is then found to have combined with the elements of water and to have become converted into *hydrorhodoretin*, $C^{42}H^{36}O^{21}$.

β. Jalapic acid; Odorous Principle of Jalap?—Constitutes thirteen per cent. of jalap resin. It is a brown, soft, and greasy substance, which reacts as an acid, has the odour of jalap, and an acrid taste. By long contact with water it crystallizes. It is soluble in ether, in alcohol, and in alkaline solutions; but is insoluble in hydrochloric acid. It is either a crystallizable soft resin or a fatty acid.

Pararhodoretin; C⁴²H³¹O¹⁸.—This is a simple resin, and is obtained from the male or fusiform jalap (*Ipomœa orizabensis*.) It is soluble in both alcohol and ether.

If jalap resin (rhodoretin or pararhodoretin) be digested in a watch-glass with oil of vitriol, a crimson coloured solution is obtained, from which in a few hours a brown viscid resin will separate. By this test jalap resin is distinguished from other resins.

2. STARCH.—The starch grains vary in size. Their shapes are spheres, semispheres, or that of mullars. The hilum is very distinct.

PHYSIOLOGICAL EFFECTS. *a. On Animals generally.*—Jalap root in powder, as well as the resin obtained from it, is a local irritant. Its operation on the bowels is well seen in the *carnivora*. Cadet de Gassieourt¹¹ found that the resin applied to the pleura, peritoneum, or intestinal canal of dogs, caused fatal inflammation. Two drachms introduced into the stomach, the œsophagus being afterwards tied, killed a dog in a few hours. It is remarkable, however, that the same experimenter observed no particular effect from the application of a drachm of the finely-powdered resin to the cellular tissue of the back. Moreover, 24 grains, with the yolk of an egg, injected into the jugular vein, had, he says, a very slight effect; indeed, at first none was observed, but the two following days the animal had soft, pale evacuations, and lost his appetite, though he soon recovered from this state. In the *herbivora*, it proves a very uncertain purgative. Gilbert¹² gave two ounces to a sheep, without observing any effect. Donnè¹³ administered two or three ounces to horses, without observing any remarkable effect, except increased secretion of urine.

β. On Man.—In the human subject jalap acts as a powerful and drastic purgative, producing copious liquid stools, and, when judiciously exhibited, is both safe and efficacious. Its objectionable effects are, that while in the stomach it causes

frequently nausea, and sometimes vomiting; while, after it has passed into the intestines, it oftentimes gripes.

It is tolerably certain in its operation; more so, indeed, than many other purgatives. In the proper dose, it may be given without the least hesitation to children, in any case requiring an active purge. It has an advantage over some other evacuants, that it does not stimulate or heat the system, its effect being confined, principally, to the alimentary canal—the peristaltic motion, secretions, and exhalations of which it promotes; and it is said that constipation less frequently succeeds its use than of some other purgatives.

My own experience of jalap would lead me to regard it as a perfectly safe, though active cathartic. But Dr. Christison¹ says, that “severe and even dangerous effects have followed its incautious use in the hands of the practical joker.” I am not acquainted with any cases, in the human subject, in which its employment has been attended by serious consequences. It is a more drastic purgative than senna. To scammony it is closely allied, not only by its effects, but also by botanical affinities and chemical properties. It is much less irritant to the intestinal mucous membrane than gamboge; and, therefore, is a much safer purgative. Vogt² regards it as exceeding the last-mentioned substance, but as being inferior to aloes, in its stimulant influence over the abdominal and pelvic bloodvessels; and Sundelin³ observes that, while it is more irritant, it is less heating, than aloes or senna.

USES.—Daily experience proves the value of jalap, as an active purgative, in various diseases both of children and adults. Of course, its irritant properties unfit it for exhibition in inflammatory affections of the alimentary canal, as well as after surgical operations about the abdomen and pelvis. Moreover, it is not an appropriate purgative in irritation of, or hemorrhage from, the uterus; or in piles and stricture, and prolapsus of the rectum. On the other hand, its use is indicated in torpid and overloaded conditions of the intestinal canal, as well as in constipation, attended with retention of the catamenia. When the object is to relieve cerebral congestion and dropsical affections, by a counter-irritant influence on the mucous membrane, jalap is well adapted to fulfil it, both by the energy and safety of its operation. The following are some of the cases in which it is employed:—

1. *In constipation.*—When this condition is not dependent on, or connected with, irritation or inflammation of the alimentary canal or pelvic organs, jalap is admissible. Its efficiency is much increased by association with calomel. It may be employed in febrile and inflammatory diseases (those above mentioned excepted), as well as in chronic maladies.

2. *As a vermifuge.*—The compound of jalap and calomel is a most efficacious anthelmintic, and may be used with the most happy effects in children, especially where there is an excessive secretion of mucus. “Jalap,” says Bremser,⁴ “is, without contradiction, in verminous diseases, one of the best purgatives, and which, perhaps, possesses, at the same time, greater anthelmintic virtues than any other.”

3. *In cerebral affections.*—Jalap, in combination with calomel, is used with the best effect, on the principle of counter-irritation, to relieve cerebral congestion. In inflammatory affections of the brain or its membranes, or in hydrocephalus, it is a valuable purgative.

4. *In dropsies.*—In dropsical affections it is frequently desirable to promote watery stools. Jalap, especially in combination with cream of tartar, may be used for this purpose with the best effects. Marggrave⁵ calls it a *panacea hydropicorum*.

5. *In retention of the catamenia, or of the hemorrhoidal flux,* jalap is one of the purgatives adapted, from their stimulant influence over the pelvic vessels, to promote these discharges.

ADMINISTRATION.—The dose of jalap, *in powder*, is, for an adult, from ten to thirty grains; a scruple usually acts smartly and safely; for children under twelve

months old the dose is from two to five grains. Fifteen grains of jalap and two or three grains of calomel, form an efficient, yet safe, purgative for an adult; but this combination very readily produces salivation by repetition. From two to five grains of ipecacuanha are sometimes substituted for the calomel. To children, jalap is sometimes exhibited in gingerbread cakes. *Purgative cakes* of this kind are kept in the shops. The *Biscuits purgatifs* (*Panes saccharati purgantes*) are composed of Jalap, ℥xx; Flour ℥ij; 24 Eggs; and Sugar ℔j. This quantity is sufficient for 60 biscuits.¹

1. PULVIS JALAPÆ COMPOSITUS, L. E. D. [U. S.]; *Compound Powder of Jalap*.—(Jalap ℥ij [℥ij, D.]; Bitartrate of Potash ℥vj [℥ijss, D.]; Ginger ℥ij [℥ss, D.]. Rub them separately to powder; then mix them, L. The *Edinburgh College* uses the same proportions of jalap and bitartrate of potash as the *London College*, but omits the ginger.)—[This is also the case with the *U. S. Pharm.*]—Hydragogue purgative. Used in habitual costiveness, verminal diseases, and dropsics. Dose, for an adult, ℥j to ℥j.

2. TINCTURA JALAPÆ, L. E. D. [U. S.]; *Tincture of Jalap*.—(Jalap, bruised, ℥v [in moderately fine powder, ℥vij, E.]; Proof Spirit Oij [Oiss, D.]. Macerate for seven [fourteen, D.] days, and strain, L. D. [The *U. S. Pharm.* directs Jalap, in powder, six ounces; Diluted Alcohol two pints. Macerate for fourteen days, express and filter through paper.] “This tincture may be prepared either by digestion or percolation, as directed for tincture of cinchona,” E.)—An active cathartic. Rarely used alone; generally employed as an adjunct to purgative draughts, the activity of which it promotes.—Dose, ℥j to ℥iv. As an adjuvant to a cathartic draught, the dose rarely exceeds ℥ij.

3. EXTRACTUM JALAPÆ, L. [U. S.]; *Extractum sive Resina Jalapæ*, E.; *Extract of Jalap*.—(Jalap Root, powdered, ℔iiss. [℔j, U. S.]; Rectified Spirit Cong. j [Oiv. U. S.]; Distilled Water Cong. ij [a sufficient quantity, U. S.]. Macerate the jalap root in the spirit for four days, and pour off the tincture. Boil down the residue in the water to half a gallon; afterwards strain the tincture and the decoction separately, and let the latter be evaporated, and the former distil, until each thickens. Lastly, mix the extract with the resin, and evaporate to a proper consistence, L. This extract should be kept *soft*, which may be fit to form pills, and *hard*, which may be rubbed to powder, L. The directions of the *Edinburgh College* are the following: “Take any convenient quantity of jalap, in moderately fine powder; mix it thoroughly with enough of the rectified spirit to moisten it well; put it in twelve hours into a percolator, and exhaust the powder with rectified spirit; distil off the greater part of the spirit, and concentrate the residuum over the vapour-bath to a due consistence.”—In this process, the alcohol extracts the resin, and the water subsequently used by the *London College* takes up the gummy extractive; the alcoholic tincture is distilled to save the spirit, while the aqueous decoction is evaporated. The preparation of the *Edinburgh College* is the impure resin of jalap; whereas, that of the *London College* is a mixture of resin with the gummy extractive. It was formerly, and indeed is now by many persons, supposed, that the combination of these ingredients was necessary for the full cathartic effect of jalap. It is, however, well known that the watery extract is inert as a purgative, though it is said to be diuretic; the only advantage, therefore, that can attend the mixture of the two extracts (the watery and the alcoholic), is, that the resin is intimately divided, and thereby prevented from causing violent irritation and griping in any one part of the intestinal tube. But it is obvious that the same advantage can be obtained by mixing the resin with some mild agent (as almonds, sugar or saline matter, as sulphate of potash). Mr. Brande² says, that jalap yields about 66 *per cent.* of extract; that is, 16 of alcoholic, and 50 of watery extract. According to this statement, therefore, the extract of the *Edinburgh Col-*

¹ Jourdan, *Pharmacopée Universelle*.

² *Dict. Mat. Med.* p. 331.

lege possesses four times the activity of that of the London College. The dose of the *resin* (Ph. Ed.) is from grs. iij to grs. vj, in a minute state of division, as above directed; of the extract, *Ph. L.*, from grs. x to ℥j.

183. *Pharbitis Nil*, Choisy.

Sex. Syst. Pentandria, Monogynia.

(Semina.)

Convolvulus Nil, Linn.—A tropical plant, with purgative seeds.—The *Pharbitis Cærulea*, Wallich (*Ipomæa cærulea*, Kœnig, in Roxb. Fl. Ind., vol. i. p. 501), is probably only a variety of it. Its seeds are sold in India under the name of *kala dana*, *hub ul nil*, and *mirchai*. They are black, angular, and weigh on an average half a grain each. Their taste is sweetish, and subsequently acrid. They consist of resin, gum, starch, bland fixed oil, vegetable fibre, and colouring matter. They yield from 15 to 20 per cent. of alcoholic brown extract containing resin and oil. In doses of from 30 to 40 grains the seeds act as a quick and safe cathartic; in some few cases they occasion vomiting and griping. The alcoholic extract may be given in doses of ten grains. The effects of the seeds and extract resemble those of jalap, for which they may be substituted.¹ Roxburgh directs the seeds to be gently roasted like coffee, then powdered, and given in any convenient vehicle.

ORDER XLV. GENTIANACEÆ, Lindley.—GENTIANWORTS.

GENTIANÆ, Jussieu.

CHARACTERS.—*Calyx* divided, inferior, persistent. *Corolla* monopetalous, hypogynous, usually regular and persistent; the limb regular, sometimes furnished with delicate fringes, its lobes of the same number as those of the calyx, generally 5, sometimes 4, 6, 8, or 10; occasionally, extended at the base into a bag or spur, with a plaited, or folded, or imbricated twisted æstivation. *Stamens* inserted upon the corolla; all in the same line, equal in number to the segments, and alternate with them; some of them occasionally abortive. *Ovary* composed of 2 carpels, 1- or partly 2-celled, many-seeded. *Style* 1, continuous with the ovary; *stigmas* 2, right and left of the axis; *ovules* indefinite, anatropal, parietal; *capsule* or *berry*, many-seeded; when two-valved, the margins of the valves turned inwards, and bearing the seeds; in the two-celled genera inserted into a central placenta. *Seeds* small; *testa* single; *embryo* minute in the axis of soft fleshy *albumen*; *radicle* next the hilum.—*Herbaceous* plants, seldom *shrubs*, generally smooth, sometimes twining. *Leaves* opposite, entire, without stipules, sessile, or having their petioles confluent in a little sheath, in most cases 3—5-ribbed; very rarely brown and scale-like; sometimes alternate. *Flowers* terminal or axillary, regular or very seldom irregular. (Lindley.)

PROPERTIES.—This order contains a bitter principle, which is especially abundant in the roots. On this substance depends the stomachic, tonic, and febrifuge properties of the different species.

184. GENTIANA LUTEA, Linn.—COMMON OR YELLOW GENTIAN.

Sex. Syst. Pentandria, Digynia.

(Radix, L.—Root, E. D.)

HISTORY.—Gentian is said to owe its name and introduction into medical use to Gentius, king of Illyria, who was vanquished by the Romans about 160 or 169 years before Christ. It is, therefore, not noticed by either Hippocrates or Theophrastus, but is mentioned by Dioscorides,² who calls it γεντιανή; and by Pliny.³

BOTANY. Gen. Char.—*Calyx* 5—4-parted or split, sometimes dimidiate-spathaceous, valvate. *Corolla* withering, rarely glandular, without epipetalous hollows; the limb 5—4-parted, or spuriously 10-parted. *Stamens* 5—4, inserted in the tube of the corolla; filaments equal at the base. *Ovary* 1-celled; the ovules in rows next the suture. *Stigmas* 2, terminal, revolute, or, if contiguous, funnel-shaped; *style* 0, or persistent with the stigmas. *Capsule* 2-valved, septicidal, 1-celled: the placentæ membranous. *Seeds* immersed in the placentæ. (Condensed from Griseb.)

¹ O'Shaughnessy, *Bengal Dispensatory*.

² *Hist. Nat. lib. xxv. cap. 34, cd. Valp.*

³ *Lib. iii. cap. 3.*

Sp. Char.—Stem tall, straight. Leaves oval and ovate, smooth at the margin. Cymes umbelliform, dense-flowered, axillary or terminal, pedunculate. Corollas yellow; the segments oblong-linear, acuminate (Grisebach).

Root perennial, cylindrical or spindle-shaped, simple or somewhat branched, ringed, wrinkled, externally brown, internally yellow and fleshy. *Stem* simple, erect, 2—3 feet high, roundish, hollow, smooth. *Leaves*, pale green, opposite, ovate or oval, pointed, entire, smooth, 5—7-ribbed, plaited; lower ones on short, sheathing petioles; upper ones amplexicaul; those next the flowers becoming concave yellowish-green *bracts*. *Flowers* on smooth peduncles of 4—6 lines long. *Calyx* yellow; *Corolla* yellow; segments 5—7, lanceolate. *Stamens* as long as the corolla. *Ovary* conical, with 5 greenish glands at the base. *Capsule* conical, 2-valved. *Seeds* numerous, roundish, albuminous, with membranous margins.

Hab.—Subalpine and mountainous meadow, 6500—3000 feet above the level of the sea, of Central and Southern Europe.

COLLECTION.—The roots are collected and dried by the peasants of Switzerland, the Tyrol, Burgogne, and Auvergne. They are imported into this country in bales from Havre, Marseilles, &c.

DESCRIPTION.—Gentian root (*radix gentianæ*) is imported in cylindrical, usually more or less branched pieces, varying in length from a few inches to a foot or more, and in thickness from half an inch to one or two inches. These pieces are marked by transverse annular wrinkles and longitudinal furrows. Externally the root is yellowish-brown, internally it is brownish-yellow; its texture is spongy; its odour, in the fresh state, peculiar and disagreeable; its taste is intensely bitter. The root of other species of *Gentiana* are said to be frequently mixed with those of the official species; their effects, however, are analogous.

Martius¹ says, that the roots of *G. Purpurea* have strong longitudinal furrows, and are of a darker brown colour internally, but want the transverse wrinkles. The roots of *G. pannonica* are similar to those of *purpurea*. Both kinds are met with in Bavaria, and serve in Switzerland for the preparation of a spirit. *Gentiana punctata* has roots which are just as bitter, but of a more yellow colour; they are dug up in great abundance in Moravia. The roots of both the last-mentioned species are dug up at, and exported from, Salzburg; in the fresh state they are white when sliced.
