REGISTRAR-GENERAL'S OFFICE, ONTARIO,

TORONTO, October 29th, 1881.

*To His Honour the Honourable John Beverley Robinson, Lieutenant-Governor of the Province of Ontario.*

MAY IT PLEASE YOUR HONOUR,—

In compliance with the Statute in that behalf, the undersigned respectfully presents to Your Honour the Annual Report of Births, Marriages and Deaths for the year ending 31st December, 1880.

Respectfully submitted,

ARTHUR S. HARDY,

*Registrar-General.*

## RELATING TO THE REGISTRATION OF BIRTHS, MARRIAGES AND DEATHS

IN THE

## PROVINCE OF ONTARIO,

FOR THE YEAR ENDING 31<sup>ST</sup> DECEMBER, 1880.

---

PARLIAMENT BUILDINGS,

TORONTO, October 29th, 1881.

*To the Honourable A. S. HARDY,*

*Registrar-General of the Province of Ontario.*

SIR,—I have the honour to present a Report of the Births, Marriages and Deaths registered in the Province during the year ending 31st December, 1880.

The number of Births registered during the year was 42,312, being an increase of 1,277 over those registered in 1879.

The number of Marriages registered was 12,783, an increase of 274 over the number returned in 1879.

The number of Deaths registered during the year was 19,802, an increase of 1,844 over the number reported in 1879.

The total number of Births, Marriages and Deaths registered in 1880 was 74,897, being an increase of 3,395, or 4·7 per cent., over the registrations in 1879.

The following statements form a complete summary of the Tables found in the Appendix attached to this Report. They shew the total number of Births, Marriages and Deaths in each County, County Town, City and principal Town in the Province, as well as the increase or decrease in the number of registrations in 1880 as compared with 1879.

TABLE SHEWING THE TOTAL NUMBER OF BIRTHS, MARRIAGES AND DEATHS IN EACH COUNTY, WITH THE INCREASE OR DECREASE.

\* The estimated population of the Cities and principal Towns for 1880, above given, is obtained by adding to the population returned by the Census of 1871, nine-tenths of the increase in those places as shown by the Census for 1881, lately published.

## REMARKS ON THE PRECEDING TABLES.

The increase in the number of births registered in 1880 was 1,277, or over 3 per cent. Two-thirds of the counties reported an increase, notably those of Carleton, Essex and Frontenac. Twenty-six counties returned an increase over 1879, and thirteen, apparently, retrograded.

In the return of births, the county towns did not sustain the usual ratio of improvement of former years, only 22 more than in 1879 being registered. Fourteen county towns reported an increase, while 22 fell short. Ottawa and St. Catharines returned the greatest increase in births, while Hamilton and London exhibited a larger falling off in number than any of the other county towns.

The duty devolving upon ministers to register the marriages solemnized by them appears to have been promptly and carefully performed. The increase in the number of reported marriages in 1879 was 274, or 2.1 per cent.

Too much praise cannot be given to clergymen, for they have conscientiously carried out the requirements of the Registration Act.

From twenty counties the number of marriages returned was greater in 1880 than in 1879, but the reverse was true of nineteen counties.

The largest increase, 135, was returned by the County of Carleton, and the maximum decrease, 81, by the County of York.

In the county towns the increase in marriages in 1880 was 118. Ottawa led with 83 more than in 1879; Toronto shewed the greatest decrease—74.

The increase in the number of deaths registered in the Province during 1880 was 1,844, or 10 per cent.

Of the thirty counties which reported an increase, the most noticeable were Carleton, Essex, Wellington, Northumberland and Durham (united), and Frontenac; Carleton stood highest with an increase of 214. Nine counties reported a decrease, that from Huron being greatest, namely, 66.

A large majority of the county towns exhibited a decrease in the number of deaths registered; in former reports they invariably shewed a marked increase. Ottawa had the largest increase, 153; and Hamilton the greatest decrease, 34. The large number of deaths reported from Ottawa is attributable to an epidemic of smallpox, which carried off a large number of persons.

The table of vital statistics registered in the twenty cities and principal towns represents the number of births to be 7,832, an increase of 84; of marriages 3,074, an increase of 162; and of deaths 5,021, an increase of 392.

The united population of these cities and towns in 1880 is estimated at 285,107, and is based upon the census of 1881, as explained in a note at the foot of the table on page 12. The increase of the population in these places over the total number returned by the Assessors in 1879 was 8,264. This gives a ratio of 27.5 births per 1,000 persons living,

---

against 28 for 1879. In regard to marriages the ratio is 10.7 per 1,000, a slight increase over 1879.

The death rate is 17.6 per 1,000, an increase over 1879 of .9 per 1000.

In births, Toronto, Belleville, Guelph, Peterborough, Kingston and Brantford return a larger ratio than the average from the whole of the cities and towns.

Chatham returned the highest marriage rate, viz., 21 per 1,000 of the population, and Stratford the lowest, 7.2 per 1,000.

In Toronto, Ottawa, London, Kingston, Brantford, St. Catharines, Belleville and Windsor the death rate was higher than the average, 17.6. Brockville stood at the foot of the list with 9.1 per 1,000.

---

# BIRTHS.

## BIRTHS BY MONTHS.

(For Table *see* Appendix, page iv.)

The number of males born in 1880 was 22,019, and of females 20,293. For every 100 females there were 108.5 males, or 52 males and 48 females in each 100 children born.

SEX.	January.	February.	March.	April.	May.	June.	July.	August.	September.	October.	November.	December.	Total.
Males .....	1812	1855	2057	1886	1806	1748	1812	1852	2006	1752	1708	1725	22019
Females .....	1706	1695	1925	1685	1630	1590	1627	1842	1754	1682	1606	1551	20293
Male births to 100 Female births .....	106.2	109.4	106.8	111.9	110.8	109.9	111.3	100.5	114.3	104.1	106.3	111.2	108.5

It will be seen by the above table that the proportion of male to female births varied considerably in the different months of the year. The greatest disparity occurred in September, when the ratio was 114 males to 100 females. In 1879, March stood highest, with the same proportion, 114 males to 100 females. In August, the numbers of male and female births were nearly equal, viz., 100.5 to 100.

## ORDER OF BIRTHS BY MONTHS, 1879-1880.

MONTHS.	1879.			MONTHS.	1880.		
	Males.	Females	Total.		Males.	Females	Total.
January .....	2051	1866	3917	March .....	2057	1925	3982
March .....	2027	1764	3791	September .....	2006	1754	3760

ORDER OF BIRTHS BY MONTHS, 1879-1880—*Continued.*

MONTHS.	1879.			MONTHS.	1880.		
	Males.	Females	Total.		Males.	Females	Total.
February .....	1872	1753	3625	August .....	1852	1842	3694
September .....	1855	1717	3572	April .....	1886	1685	3571
August .....	1858	1638	3496	February .....	1855	1695	3550
December .....	1755	1661	3416	January .....	1812	1706	3518
July ....	1763	1614	3377	July .....	1812	1627	3439
October ..	1717	1632	3349	May .....	1806	1630	3436
November ...	1666	1552	3218	October .....	1752	1682	3434
April .....	1628	1560	3188	June .....	1748	1590	3338
May .....	1641	1529	3170	November .....	1708	1606	3314
June .....	1510	1406	2916	December .....	1725	1551	3276
	21343	19692	41035		22019	20293	42312

In 1880 more births were returned for March than for any other month; the opposite was true of December. In 1879, January stood highest and June lowest in this respect.

## QUARTERLY RETURN OF BIRTHS, 1879-1880.

	1879.			1880.		
	Males.	Females	Total.	Males.	Females	Total.
Quarter ending March 31st .....	5950	5383	11333	5724	5326	11050
“ June 30th .....	5468	5016	10484	5440	4905	10345
“ September 30th .....	5146	4798	9944	5670	5223	10893
“ December 31st .....	4779	4495	9274	5185	4839	10024
Total .....	21343	19692	41035	22019	20293	42312

In each year the largest number of births occurred in the first quarter. This appears to be also true of England, where, as in Ontario, the second quarter usually stands next highest, and the fourth quarter lowest.

The number of births within the several specified periods was as follows:—

For the year . . . . .	42,312—Males, 22,019 ;	Females, 20,293.
	Average.	Average.
“ month . . . . .	3,526	“ 1,835 ; “ 1,691.
“ week . . . . .	813	“ 423 : “ 390.
“ day . . . . .	116	“ 60 ; “ 56.

The difference between the male and female births reported during the past nine years is shewn by the following table:—

In 1872 . . . . .	1,027	more male children were born than female.
“ 1873 . . . . .	1,037	“ “ “
“ 1874 . . . . .	1,073	“ “ “
“ 1875 . . . . .	1,064	“ “ “
“ 1876 . . . . .	987	“ “ “
“ 1877 . . . . .	1,361	“ “ “
“ 1878 . . . . .	1,780	“ “ “
“ 1879 . . . . .	1,651	“ “ “
“ 1880 . . . . .	1,726	“ “ “

The following statement shews the total number of births in each quarter for the last seven years, with percentages:—

QUARTER.	1874.	1875.	1876.	1877.	1878.	1879.	1880.	Total for 7 years.	Percentage of the whole 7 years.
January to March . . .	7610	6998	10012	12580	10652	11333	11050	70235	27.4
April to June . . . . .	7048	6481	9566	9899	9688	10484	10345	63511	24.8
July to September . . .	7034	6474	9623	9854	10075	9944	10893	63897	24.9
October to December . .	6546	6015	9257	7624	9821	9274	10024	58561	22.8

1880.....	671	“ “ 63 “	15.8	407	6
Average for the nine years..	394	One in every 97 Births.	10.1	307	Nearly 3.

## ILLEGITIMATE.

The registered births of illegitimate children in 1880 were largely in excess of those in 1879. In the latter year 524 were reported; in the former year, 671; an increase of 147—an increase particularly undesirable, if it is to be accepted as an indication of further decline in the morality of the people, but there is little doubt it was largely due to more accurate returns.

It is generally admitted by statisticians that when the marriage rate is higher than the average, a corresponding decrease in the number of illegitimate births may be anticipated. In 1880 the marriage rate in the Province was larger than in previous years, but the number of illegitimate children was also larger. Compared with other countries, however, our ratio of illegitimate per 1,000 of all births registered was small. The Massachusetts rate for 1879 was 17.8 per 1,000; England, 47 per 1,000; in Ontario, 15.8 per 1,000.

The four counties, York, Wentworth, Carleton and Middlesex, having within their limits the largest cities, Toronto, Hamilton, Ottawa and London, returned, in all, 380 illegitimate births, or 56 per cent. of the whole number registered in the Province. In York there were 170 illegitimate births, or 25 per cent. of the whole; Carleton 126, or 18 per cent.; Wentworth 44, or nearly 7 per cent.; and Middlesex 40, or 6 per cent. The large number of illegitimate children returned as having been born in the chief cities is principally due to the fact that many unfortunate women from outlying municipalities

---

revert to them, either for the purpose of better concealment, or, from sheer necessity, to take advantage of the hospital and lying-in accommodation and superior treatment so generously provided, and which, under the circumstances, is obtained wholly or nearly free of charge.

#### TWINS AND TRIPLETS.

The number of twins registered in 1880 was 29 more than in 1879, and 18 less than in 1878. That year, with its total of 425 pairs of twins, stands higher than any other year since 1872, or the highest in nine years.

Six births of triplets were returned in 1880 ; in 1879 only one such birth was recorded.

There was therefore one pair of twins to every 104 births, and one case of triplets to every 7,052 births ; or of every 52 children born one was a twin, and of every 2,351 one was a triplet.

---

---

MARRIAGES.

---

## MARRIAGES.

### MARRIAGES BY DENOMINATIONS.

(For Table *see* Appendix, page xii.)

Of the whole number of persons married in 1879, the percentages of those whose religious denominations were given were as follows :—

37.37	per cent.	(or 1 in every 2.67)	were	Methodists.
20.87	“	(“ 1 “	4.80)	“ Presbyterians.
16.98	“	(“ 1 “	5.88)	“ Episcopalians.
12.78	“	(“ 1 “	8.13)	“ Roman Catholics.
5.64	“	(“ 1 “	17.72)	“ Baptists.
1.94	“	(“ 1 “	51.51)	“ Lutherans.
1.88	“	(“ 1 “	53.06)	“ Bible Christians.
.77	“	(“ 1 “	128.79)	“ Congregationalists.
.57	“	(“ 1 “	172.92)	“ Mennonites.
.05	“	(“ 1 “	1902.15)	“ Quakers.
1.64	“	(“ 1 “	61.46)	“ of other denominations.

The percentages in 1880 were as follows :

36.19	per cent.	(or 1 in every 2.76)	were	Methodists.
20.38	“	(“ 1 “	4.92)	“ Presbyterians.
16.70	“	(“ 1 “	5.98)	“ Episcopalians.
12.66	“	(“ 1 “	7.89)	“ Roman Catholics.
5.43	“	(“ 1 “	18.39)	“ Baptists.
2.78	“	(“ 1 “	35.90)	“ Lutherans.
2.15	“	(“ 1 “	46.48)	“ Bible Christians.
.82	“	(“ 1 “	120.59)	“ Congregationalists.
.52	“	(“ 1 “	192.22)	“ Mennonites.
.45	“	(“ 1 “	220.40)	“ Quakers.
1.12	“	(“ 1 “	89.08)	“ of other denominations.

The whole number of marriages recorded during 1880 was 12,783—25,566 persons. This was an increase over 1879 of 274 couples, or 548 persons. Of those who were married in the former year, 211 belonged to no religious denomination ; the officiating ministers failed to record anything to the contrary.

It appears from the Table that 9,253 Methodists were married, or more than one-third of the whole number reported ; the majority of these was composed of females, the

respective totals being 4,704 and 4,549 males. According to numbers, the Presbyterians, Episcopalians and Roman Catholics respectively came next in order, but more males than females, professing to belong to these denominations, were married; the three bodies in the aggregate returned 6,452 males to 6,250 females. In all the other denominations the females exceeded the males.

### MARRIAGES CLASSIFIED BY MONTHS.

(For Table *see* Appendix, page xx.)

#### QUARTERLY RETURN OF MARRIAGES, 1879 AND 1880.

	1879.		1880.

Quarter ending 31st March.....	3295	26.3	3304	25.9
“ 30th June .....	2632	21.1	2740	21.5
“ 30th September .....	2496	19.9	2523	19.7
“ 31st December .....	4029	32.2	4155	32.5
Date of marriage omitted.....	57	.5	61	.4
	12509	100.0	12783	100.0

#### MARRIAGES BY MONTHS IN NUMERICAL ORDER, 1879-1880.

1879.		1880.	
December .....	1513	December .....	1696
October .....	1357	October .....	1317
January .....	1223	January .....	1205
November .....	1159	September .....	1162
February .....	1096	November .....	1142
September .....	1067	March .....	1070
March .....	976	February .....	1029
April .....	943	April .....	955
June .....	878	June .....	943
July .....	838	May .....	842
May .....	811	July .....	686
August .....	591	August .....	675

The average number of marriages per quarter for 1880 was .. 3196  
 “ “ month “ .. 1065  
 “ “ week “ .. 245  
 “ “ day “ .. 37

For the same months as 1879, viz., December and October, the largest number of marriages was returned, and for the same month, August, the lowest.

In those counties in which the cities and large towns are situated the largest number of marriages took place. York, including Toronto, headed the list with 1,153 marriages; Middlesex, including London, came next with 628; Wentworth, including Hamilton, and Carleton, including Ottawa, followed with nearly the same numbers, viz., 517 and 503 respectively. Halton returned the smallest number, 140, but it is a small county and has no large town within its limits.

### MARRIAGES BY AGES.

(For Table *see* Appendix, page xxii.)

Of the 12,783 men married during 1880, only 129 were under the age of 20 years, while 2,698 women entered the matrimonial state before arriving at that age. From the ages of 20 to 25 the number of women wedded was still largely in excess of men, viz., 6,492 females to 5,051 males. Between the ages of 25 and 30 this condition was naturally reversed, and we find a larger number of men than women married during this period, viz., 4,464 of the one to 2,202 of the other sex. Throughout every other period of life more males than females entered the married state.

Between the ages of 70 and 75 years only one woman was married, while 30 men who had reached that advanced age found wives. Above the age of 75 years no woman was married, but fifteen men of patriarchal years, being between the ages of 75 and 87, found partners.

The proportion of males to females married during the different quinquennial periods of life, for the years 1879–80, to the whole number of marriages, is shewn in the appended table:—

QUINQUENNIAL PERIODS OF LIFE.	1879. Whole number of marriages, 12509.				1880. Whole number of marriages, 12783.			
	Males.		Females.		Males.		Females.	
	Number married.	Per cent. of the whole.	Number married.	Per cent. of the whole.	Number married.	Per cent. of the whole.	Number married.	Per cent. of the whole.
Under 20 years . . . . .	130	1.04	2842	22.71	129	1.00	2698	21.10

For the past eight years there was reported each year at least one man marrying when 80 or over 80 years of age, but in 1880 four were so returned. One of them was 86, and his partner 60 years of age; another 85 and his wife 41; while in the third case the husband was 81 and the wife 31. In the fourth instance, the husband was 80 years of age, and the girl he wedded only 20. In only three cases the bride was older than the bridegroom, and the difference in their ages was not great. The united ages of the oldest couple married was 146 years, and of the youngest 31.

## NUMBER OF DEATHS AT VARIOUS PERIODS OF THE YEAR.

As in 1879, more deaths were registered during the first quarter of 1880 than during any of the other quarters of that year. But while in 1879 there were 525 more deaths in the first than in the second quarter, in 1880, owing to a low death rate in January, there were only 143 more in the first than in the second. During the second quarter of that year 263 more deaths were registered than during the third quarter; in 1879 the difference in the registrations during these two quarters was just two more, or 265. In

the third quarter of 1880, there were 55 more deaths than in the fourth, and 45 more in the third than in the fourth quarter of 1879.

During the first half of 1880, 724 more deaths were registered than during the second half, while in 1879 the difference between the same periods was 1,100.

In 1880, as in 1879, the largest monthly death rate was recorded in March; in the year 1878 August stood highest in this respect. In Massachusetts it appears the greatest mortality occurs usually, if not always, in August, September or July, and in England in March, February or January. In Massachusetts the greatest mortality takes place during the third quarter, the fourth comes next and the second last.

In 1880 the smallest monthly record was for June, when 685 less deaths were reported than in March, which had the heaviest death rate. The corresponding month 1879 was October, but the difference between it and March was 534, or 151 less than the difference between March and June, 1880.

For Causes of Death, classified by Months, by Ages and by Sexes, and by Counties, *see* Appendix, Tables E and F, pages xxx. and lvi.

#### THE DEATH WAVE FOR THE YEAR.

In following the rise and fall in mortality from month to month in the year under review, we find the invariable two high points and two low points. Commencing with January, and the low rate of mortality of 1,451 deaths (55 less than in the previous December), we trace a rapid rise in the short month of February, 232 more deaths being recorded than in January, giving a death rate for that month over 23 per cent. greater than for January, taking into consideration the length of the months. In March the increase was not proportionately so great, being only about 15 per cent., though 386 more deaths were recorded in that month than in February. April, which is a day shorter than March, returned nearly as heavy a mortality, though there were 59 less deaths than in March. In May there was a marked fall, and 344 less deaths were registered than in April. In June, though not quite to such an extent, the marked fall continued and 282 less deaths were recorded, the mortality being then lower than in any other month in the year. In July there was a rise, and 147 more deaths were reported than in June. In August the rise continued, there being 106 more deaths than in July. In September, a month shorter by a day, the rate of mortality was actually higher than in August, though there were 8 less deaths registered. Throughout October, November and December the high rate of mortality was maintained, with only a slight fall of about 3 per cent. in November, which was followed with a proportionate rise in December.

The most marked feature in the death wave for the year was perhaps the low point to which it subsided in January. Of the total deaths recorded in the year only 7.3 per cent. were registered in that month. In the four preceding years the average percentage for January was 8.5, and 8.3 per cent. was the lowest for any one of those years. The wave rose rapidly, however, through February, 1880, and in March there were 618, or 42 per cent. more deaths than in January. This altitude, the highest in the year,

extended into April, but in May the wave sank lower than in February, and in June fell to the lowest point in the year, being the second low point. In July it rose again, though not so high as in May; but in August and early in September it had nearly attained the May altitude, where it remained until the end of the year, with the exception of the slight downward curve in November already alluded to.

Among the peculiar features in the death wave for 1880 may be mentioned the facts (1) that the first high point reached in March (from which the wave usually recedes a good deal in April) was maintained throughout April and did not fall until May; and (2) that the wave, having risen to its second high point in August, did not recede again during the year except slightly in November; in other words, there was an absence of the usual marked fall or low point after the summer high point.

Again, in 1880, as in 1879, the high point in the death wave during the cold wet weather of early spring was much higher than the high point during the hot dry weather in summer. Usually there is little difference in the height of these two high points, though sometimes that of the summer is highest.

Almost invariably the two low points in the wave are reached, in the one case, before the summer high point, or about June, and in the other after that high point, or in September, October or November; in 1880 one of these low points was in January, though the other, the lower of the two, was in June.

The returns shew that in that year, as in 1879, the mortality in March, and also in April, was very high, and, as will be seen further on, that this was largely due to deaths from lung diseases, especially from inflammation of that organ.

The causes of the invariable two high points in mortality every year have been referred to at length in the two preceding reports.

#### CERTIFIED CAUSES OF DEATH.

In regard to the certified specific causes of death, no marked improvement in diagnosis can be claimed in 1880 for physicians, unless it be concealed behind the fact that there were nearly 100 less fatalities attributed to Old Age. It also appears to be a discredit and reproach upon diagnostic medicine that, while 4,379 deaths of those under the age of one year were registered, 1,300, or nearly 30 per cent. of this number, were registered under the indefinite head of Infantile Debility. Of these 1,300, 1,131 were deaths of children under the age of one year, and hence over one-fourth, or 26 per cent. of those dying under one year, were registered under an almost meaningless head. Nearly one-fifth of the total number of deaths recorded were certified to as resulting from old age, infantile debility, convulsions, or dropsy. For a large proportion of these cases doubtless a more specific and satisfactory cause might have been returned if the certifying physicians had given due thought and consideration to this part of their duty; and especially if, along with this, there had existed a due appreciation of the importance, both as relates to the science of medicine and the public health, of preciseness in all matters pertaining to vital statistics, particularly those relating to the causes of

---

death. Those physicians who are lax in this respect are respectfully appealed to to give, whenever possible, more definite information on this point. There were 518 deaths returned under the head of Convulsions, and 406 of Dropsy. It would be much more satisfactory to know the nature of the convulsions, and whether the dropsy was caused by heart, or kidney, or other disease.

In reference to old age as a cause of death, an improvement is noticed. This, it is to be hoped, is owing, and no doubt may fairly be attributed, to greater care on the part of medical men in certifying to the specific causes of death. In 1880 there were 135 more deaths registered than in 1879 of persons who had reached the age of 70 years, and 444 more than in 1878, yet there were 91 less in the former year and 64 less in the latter year recorded under the head of Old Age, as a cause of death. In 1878, 154, and in 1879, 147 of the deaths recorded under the head of Old Age were of individuals between the ages of 60 and 70, but in 1880 only 38 of those who died during that period of life were so returned.

No Report in 1875.

## TEN HIGHEST CAUSES OF DEATH.

In the list of the ten highest causes of death in 1880, Bronchitis, Croup and Congestion of the Lungs are found for the first time. They are the three lowest in the list, and usurp the places, as it were, in previous years, of Dropsy, Enteritis, Diarrhœa and Typhoid Fever. The other seven causes hold places almost identical with their relative positions in the three or four preceding years; Consumption, Old Age and Infantile Debility respectively being the first three now for the fourth consecutive time. Consumption invariably heads the list.

## PHTHISIS (CONSUMPTION).

Consumption is such a terribly fatal disease, that it demands a large share of attention. During the two years preceding 1880 there was a slight increase in the proportion of deaths of consumptives, but 1880 shews a slight decline in this respect, though 89 more deaths from that disease were recorded than in 1879. The proportion, however, was exactly the average of the four years 1877-80, viz., 10.8 per cent.

Though Consumption causes nearly one-ninth of all the deaths which occur in Ontario, the Province compares very favourably in this respect with many other countries. In Nova Scotia this disease, it appears, causes one-fifth, or 20 per cent., of all the deaths; while in Scotland and in Massachusetts it is quite or nearly as fatal. These facts support the theory that high inland countries are less favourable to the development of this affection than low sea-bordering countries.

There was in 1880 a slight decline, too, in the proportion of deaths of females from Consumption, as compared with males; though 280, or about 30 per cent. more of the former than the latter died of the disease. The returns give 1,217 deaths of females, and 937 deaths of males from this cause.

Between the ages of 10 and 50 the proportion of females dying of this disease, as compared with males, was much greater, being over 45 per cent., or 935 females to 642 males. In 1879, however, over 57 per cent. more females than males died of Consumption during this period of life.

It would probably be found that nearly the same proportion died between the ages of 15 and 45, or during the period of child-bearing. Between the ages of 10 and 15, 11 males and 25 females died of Consumption, or about 127 per cent. more of the latter than of the former. Between the ages of 15 and 20, 155 per cent. more females than males died of this disease, viz., 61 males and 156 females. Between the ages of 10 and 20 the proportion was about the same. During this period of life the proportion of deaths of females, as compared with those of males, was 11 per cent. greater in 1880 than in 1879.

Between the ages of 20 and 30, on the other hand, the proportion of deaths of women, as compared with those of men, was not nearly so great in 1880 as in 1879, there being only 40 per cent. more in 1880 as against 58 per cent. more in 1879. The deaths from Consumption of males and females between these ages were respectively 243 and 384 in 1879, and 280 and 394 in 1880.

Between the ages of 30 and 40 in 1880, 174 males and 222 females died, or 27 per cent. more of the latter than of the former, as against 34 per cent. more in 1879.

Between the ages of 40 and 50, 116 males and 138 females died, or less than 20 per cent. more of females, as against 27 per cent. more in 1879.

In this Province, invariably, more males than females die of Consumption in infancy and after the age of 50 years.

In 1880, between the ages of 60 and 70, 80 males and 47 females died of the disease; and between the ages of 50 and 60, 80 males and 75 females. After the age of 60, 120 males and 81 females died of it.

Briefly, then, in 1880, between the ages of 10 and 50 years, 45 per cent., or 12 per cent. less than in 1879, more females than males died of Consumption; between the ages of 10 and 15, 127 per cent. more; between 15 and 20, 155 per cent. more; and between 20 and 30, 40 per cent. more; while after the age of 50 years, nearly 30 per cent. more males than females died of it.

Although in most countries, as stated last year, many more females, especially during the period of child-bearing, die of Consumption than males, the returns from some of them do not show so great a difference as is exhibited from year to year by the returns of this Province. This is a subject which appears to demand investigation.

By far the largest number both of males and females die of Consumption between the ages of 20 and 30; *i.e.*, a much larger number than during any other decennial period. Of the 2,154 of all ages who died of the disease in 1880, 674, or 31 per cent., died between those of 20 and 30 years; 396, or 18 per cent., died between the ages of 30 and 40; 254, or 11 per cent., died between the ages of 40 and 50; and nearly the same number (253) and proportion died between 10 and 20 years of age, while most of these, or 217, died between the ages of 15 and 20, only 36 dying between 10 and 15.

Every month claims a large share of victims from this disease; though in most years March or April secures the largest proportion. In the year under notice, as in 1878 and 1879, the largest number died in March, 219 dying during that month; while in September, when the smallest number of deaths occurred, there were 146 victims—just 50 per cent. less than in March. April came next, with the largest number of deaths from Consumption, 199; then November, with 196; and next, February, with 186. January's number was considerably smaller, 158. In every month more females than males died of this disease.

In 1879 there was a marked difference between the death average per month during the five months, July to November inclusive, and the other seven months, December to June—the former showing an average of 144 and the latter an average of 192, an increase of 33 per cent. In 1880 there was not nearly so great a difference in the averages, that of the five months (July to November) being 170, and that of the seven months (December to June) being 186, or only 9 per cent. In the two years prior to 1879 the differences were 17 per cent. for 1877 and 15 per cent. for 1878. In the year under consideration the disparity was greater between the average of the six summer and autumn months and that of the six winter and spring months, the average of the former being 169 and that

---

of the latter 190, or a difference of 12 per cent. The average number for each of the twelve months was 180. This shews that, though in the winter and spring months of 1880 (as will be seen further on) there were more than the usual number of deaths from other lung diseases, or those of an inflammatory character, such as inflammation and congestion of the lungs and bronchitis, the average number of deaths from Consumption during that period was not greater than usual.

## PROPORTION OF DEATHS FROM CONSUMPTION IN THE DIFFERENT COUNTIES.

Of the total number of deaths recorded in the whole Province (19,802), 10.8 per cent. were from consumption. As usual, however, some counties returned a much larger and others a much smaller proportion than that.

It must be borne in mind that the returns from some counties are much more complete than from others, and that the recorded death rate per 1,000 of living population is therefore proportionately greater in those counties than in the others; but this fact does not affect the relative proportion of deaths from consumption as compared with the total number of deaths returned from such a county, as it may reasonably be assumed that when the number of deaths registered in any county increases, the registrations of deaths from consumption may be considered to have increased proportionately.

The County of Brant, in 1880, returned a proportion somewhat greater than in the preceding year, when it was considerably lower, however, than during any of the three years prior to that. The five years, 1876-80, give a percentage of  $2\frac{1}{2}$  above the average of the Province.

Frontenac, in 1880, returned a proportion of 14 per cent., or 3 per cent. above the average, as it also did in 1879; in 1877 and 1878 it returned a proportion, in total deaths from this disease, of only 4 per cent. and 9 per cent. respectively.

Haldimand, which during the four years prior to 1880 had returned  $4\frac{1}{2}$  per cent. above the average, returned in the year under notice less than the average, or only about 10 per cent.

For Hastings the proportion is still high—15 per cent., or 4 per cent. above the Provincial average. It has maintained this excessive average the past five years.

Leeds and Grenville (united) returned the same high proportion as the previous year, namely, 17 per cent. For five years these united counties have returned a death rate from consumption over 6 per cent. above the average of the Province.

Lennox and Addington returned a percentage of 18, or over 7 per cent. above the average. The proportion in 1879 was 17 per cent.; in 1877 and 1878, 12 and 13 per cent. respectively.

Northumberland and Durham (united), as they did in 1879, shewed a marked increase in the proportion of deaths from consumption in 1880, the rate being 15 per cent. for each year; 12 per cent. being the average for the two or three previous years.

Prescott and Russell (united) shew an increase from 7 to 8 per cent. in 1878 and 1879, respectively, to 13 per cent. in 1880.

From Prince Edward County the returns for 1880 shew a large falling off in the death rate from this disease, as compared with 1879, when it gave the alarming proportion of 21 per cent. Last year it was 15.7 per cent. The average had been 18 per cent. for the four previous years. For five years it has shewn a proportion about 7 per cent. above the average for the Province.

Grey County returned the smallest percentage of deaths from this disease during the year under notice; in 1879 Muskoka and Parry Sound stood at the foot of the list,

Muskoka and Parry Sound shew an increase from an average of 6 per cent. for four years—1876 to 1879—to 8 per cent. in 1880.

Several other counties returned a proportionate death rate from consumption—1, 2 and 3 per cent. below the average.

It may be observed, then, that during the past four or five years the percentage of deaths from consumption has been fully three or 200 per cent. greater in Prince Edward County than in Grey County.

In 1880, the proportion of deaths from this disease in the first named county was 15 per cent. of the total number of deaths returned, while in Grey the proportion was but 5 per cent. of the total; in 1879 the proportions were 21 per cent. and 7 per cent. respectively, and in a like proportion in previous years.

It would be well by careful investigation to ascertain the cause or causes of this great apparent difference in the death rate from consumption in two such well-settled Provincial districts.

The total death rate per 1,000 of population returned from the County of Grey is only about one-half as great as that from the County of Prince Edward, being 6 and 12 per 1,000 respectively. If the returns were more complete from Grey, the proportion of deaths from consumption would, no doubt, be about the same—there would also probably be as large a proportion of deaths from other diseases.

#### CONSUMPTION IN THE CITIES AND TOWNS.

For the cities and principal towns, 20 in all, the returns for 1880 shew an average mortality from consumption nearly one-half per cent. below the average of the whole Province; in 1879 it was nearly one per cent. below. Some of these towns, however, like the counties, registered a mortality very much above and others much below the average.

Toronto returned a proportion of about 10 per cent., or about the average of these 20 places; Hamilton only 8 per cent., or 2 per cent. below the average; Ottawa 10.6 per cent., or near the average of the Province; London hardly 7 per cent. Kingston and Belleville, on the other hand, returned a proportionate mortality from the disease of over 16 per cent. of the total. Brantford shewed nearly 14 per cent., and Woodstock 14.6 per cent. For the towns about or below the average, see the table, page 12.

#### OLD AGE.

Again in 1880, for the fifth time in succession, Old Age, so recorded, is second on the list of the ten highest causes of death, 1,658 victims being registered under this head. As already observed, however, the proportion is considerably less than it was in 1879, being about 8.5 per cent. of the total in 1880, and 10 per cent. in 1879. This was not because a smaller proportion died at advanced age, for, as already stated, a much larger number of deaths were recorded in 1880 than in the previous year of those who exceeded 70 years of age. It must have been either because a much smaller proportion of those who died in advanced age manifested symptoms of senile decay, or because greater care was taken by physicians to certify to the cause of death, a duty they owe to science, and

the faithful performance of which is so essential to the collection of satisfactory vital statistics. It is to be hoped that more of this care will be exercised by medical men, who have a deep and unabiding interest in this matter.

#### INFANTILE DEBILITY.

Under this indefinite and, withal, unscientific head, 1,300 deaths were recorded in the year under notice.

Of these, 169 were of children over one year old. In every month were recorded from 62 (in December) to 155 (in August) deaths from this cause. Of the 1,300 victims, 725 were males and 575 were females, or 26 per cent. more of the former than of the latter.

#### PNEUMONIA (INFLAMMATION OF LUNGS).

Fourth on the list, as in 1879, comes Pneumonia, or inflammation of the lungs, with 1,257 victims, being 33.4 per cent., or over one-third more than in 1879, when 943 deaths from this ailment were recorded.

As intimated last year, more careful diagnosis and greater precision in certifying to the causes of death would probably result in proving that not a few of the victims credited to Old Age and Infantile Debility should belong to Pneumonia, which would then most likely stand second in the list, or next after Consumption.

Of the 1,257 deaths from Pneumonia in 1880, 704 were of males and 553 of females; or over 27 per cent. more males than females. Many more of the former than of the latter die every year of this disease.

In every decennial period, excepting that between the ages of 20 and 30, more males died of the disease than females. In the quinquennial period between the ages of 5 and 10 more females died of it than males, but this was more than counterbalanced by the larger number of males between the ages of 1 and 5 which died of it.

Under the age of one year 36 per cent. more males died of pneumonia than females—155 males and 114 females. Between the ages of 40 and 50, 129 per cent. more males died of it than females—62 males and 27 females. These proportions correspond for the most part with those of the later ages or periods of life.

The largest number of deaths in any one month—210, over one-sixth of the whole—occurred in March, the same proportion as in the same month of 1879. The smallest number, 38, took place in August. The second largest number of victims, 209, died in April, but as this month is one day shorter than March, the proportion for April was greater than for March. In May 175 died of this disease; in December, 122; in February, 117 (this being a shorter month the proportion was larger than in December); in January, 82; November, 78; June, 67; October, 65; July, 53; and September, 41. More than five times as many persons died of pneumonia in March and April as in August and September. This disease helped, therefore, in a large measure to swell the high total death wave in March and April.

The year under notice claims the largest number of deaths recorded from this disease, namely, 6.5 per cent. of the whole number of deaths from specified causes—a proportion about one-fifth greater than any previous year; 33 per cent. more, as above stated, than in 1879.

As usual, a much larger number of victims (namely, 269) died of this disease under one year than at any other age. The next largest number, 199, died at ages between 1 and 5. The next period in which the largest number died is shewn to be that between 60 and 70, with 119; the previous decade, from 50 to 60, gave 118. Only 38 died between 5 and 10 years of age; 70 between 10 and 20; and 60 between 40 and 50; 89 died between 20 and 30.

If, however, we take into consideration the total number of deaths at these different ages we find that, as in 1879 and other years, the period of life during which this disease is most fatal is that between the ages of 50 and 60 years of age; and the period least fatal, that between 5 and 10 years of age. In the first named period (between 50 and 60), of the total number of all deaths, about 10 per cent. resulted from pneumonia, or one from this cause in every ten from all causes; in the other period (between 5 and 10) only 3.8 per cent. of the totals, or one in every 26, died from this disease.

#### DIPHTHERIA.

While 1879 exhibited a large decrease, as compared with previous years, in the number of deaths from diphtheria, 1880 shews a large increase, and this disease, in consequence, stands fifth in the list, instead of sixth, as in 1879. There were 822 deaths in 1880, as against 574 in the previous year.

This disease was much more fatal in 1880, in rural than in urban districts.

The 20 cities and large towns returned one death from diphtheria in every 36 deaths from all causes; while the rest of the Province registered one from diphtheria in every 22 from all causes.

Of the cities and large towns, the greatest registered mortality from this disease was reported from Stratford, where one death in every 6 from all causes was due to it; or in a total of 99 deaths 16 were from diphtheria. In 1879, of the cities and towns, Belleville returned the greatest proportionate mortality from it, shewing one death in every 16 from all causes. In 1880 it returned only one in every 66.

In 1880, Barrie returned one death from diphtheria in every 8 from all causes; Ottawa one in 17 from all causes (only one in 68 in 1879); Windsor one in 20; Chatham one in 21 (about the same as in 1879); Hamilton one in 34; and Toronto one in 60 from all causes.

Of the counties, Perth returned the largest proportion of deaths from diphtheria—one in every 7.7 from all causes. Stratford, it may be observed, where the mortality from the disease was so great, as shewn above, is situated in this county. Prescott and Russell (united) come next to Perth, and return a mortality from this disease of one in 8.4 from all causes. Next come Essex, giving one in 9.7; Simcoe with one in 13; Waterloo one in 14; Carleton one in 17; Wentworth and Middlesex one in 30; York one in 40. Lennox and Addington, in 1879, returned no deaths from this cause; in 1880 they returned 8, or one in every 33 from all causes.

The month in which the smallest number of deaths from this cause were recorded in 1880, in the Province, as in 1879, was July, during which 23 victims died. November

gave the greatest mortality, 147 deaths ; October, 134 ; September, 87 ; December, 79 ; and January, 62.

With the exception of April, when 67 deaths were returned, there was a gradual decrease in mortality month by month from January to July, and thence a gradual increase to November. Of the 822 deaths, 451, or considerably over one-half, were of persons under 5 years of age ; 82 under 1 year ; 225 between 5 and 10 years ; 81 between 10 and 15 ; 20 between 15 and 20 ; and 17 between 20 and 30 years. Of those above 30 years of age only 10 died, of whom 7 were between 30 and 40. These proportions correspond closely with those of the previous years. The ravages of this disease are most fatal between the ages of 1 and 20 years. In 1880, of its 882 victims, 675 had not reached 21.

#### HEART DISEASE.

A smaller number of deaths by 24 was recorded under the head of Heart Disease in 1880 than in 1879 ; 760 being the number for the year under notice, or about 4 per cent. of the whole number of deaths from all causes. Of this number 374 were males and 386 females. In 1879 more males by 48 than females died of this disease.

Heart disease is not alike fatal in all seasons. The majority of its victims die in cold weather, or in early spring. By months, in 1880, the largest number, 78, died in February ; and the next largest, 73, in March. The smallest number, 48, died in June.

But few, comparatively, as usual, died of this disease under 20 years of age, *i.e.*, 91 in all, or less than 8 per cent. In the next six decennial periods, up to 80, there was a gradual increase, viz., 60, 69, 76, 104, 145, 147 ; between the ages of 80 and 90 years 41 died.

Under the age of 20 years, there was one death from heart disease in every 102 from all causes ; exactly the same proportion as in 1879.

Between the ages of 20 and 30 there was one death from this cause in every 29.7 from all causes (27.5 in 1879). In the next five decades of life, 30 to 80, one person died of heart disease in every 17, 15, 10.7, 10.2 and 12 respectively from all causes. In the previous year, 1879, the numbers in the same five decades were 18.5, 13, 10.7, 10, 10.5, respectively. Thus the proportion in the two years is shewn to be very nearly the same ; the most critical period of life to sufferers from this disease lying between the ages of 60 and 70.

After the age of 80 years the proportion in 1880 was one death from it in 32 from all causes.

In 1880, as in 1879, the proportion of deaths from heart disease was somewhat smaller in the cities and large towns than in the Province as a whole.

#### CONVULSIONS.

Under this head 518 deaths were registered, 73 more than in 1879, the total being made up of 288 males and 230 females ; 373 victims were under one, and 119 were under five years of age. Of the remaining 25, 12 were between 5 and 10 years of age. The number of deaths in the different months vary from 30, in July, to 58, in April.

Besides the above, 91 deaths were registered under the head of Epilepsy ; probably nearly all of the cases under the head of Convulsions were epileptic convulsions. Of the 91 deaths from "epilepsy" only 3 were of persons under one year of age ; there were

none between 1 and 5 years; 2 were between 5 and 10; 15 between 10 and 20; 25 between 20 and 30; and 13 between 30 and 40.

#### BRONCHITIS.

This is the first year in which Bronchitis has appeared in the list of the ten highest causes of death, and it now ranks eighth, with a record of 438 cases. For the three years previous, 1877-78-79, the record of deaths was 392, 332 and 331 respectively.

The victims consisted of 245 males and 193 females. During the first year of life twice as many males as females (106 to 53) died of the disease. Between 1 and 5 years of age, however, 45 males and 55 females died of it. The most fatal period after this to both sexes, especially to males, was between 70 and 80 years, when 38 deaths were caused by bronchitis—22 males and 16 females. During each decennial period of life immediately on either side of this last-mentioned one—60 to 70 and 80 to 90—34 deaths took place from this cause. There were 13 victims between 20 and 30; 11 between 5 and 10; and 5 between 10 and 20 years of age.

As to the months during which the largest number of deaths occurred, January had a record of 33; February, of 53; March, of 69; April and May, of 66 each; the next four months, of 28, 20, 16 and 16 respectively; the death rate increased in the next three months to 21, 27 and 23. March was, therefore, the most fatal month, as it almost always is; occasionally April leads in this respect.

#### CROUP.

This is the first time, too, that Croup is to be found in the list of ten, though in 1880 there were only 37 more cases than in 1879, but nearly a hundred more than in 1878 or 1877. In the year under notice 429 deaths were recorded under this head—238 of males and 191 of females.

All who die of this disease die young. With the exception of one male, who was registered as over 30 years of age, all its victims in 1880 were under 15 years, and all but nine under 10 years of age; 85 were between 5 and 10 years; 239 between 1 and 5 years, and 88 under one year of age; so that over 74 per cent. of the total deaths were of children between one and five years of age.

The last months of the year were much the most fatal. While only 10 and 12 persons respectively died of croup in July and August, 82 died in December and 63 in November, in which months, or in January or February, the greatest number of deaths usually occur.

#### CONGESTION OF THE LUNGS.

Congestion of the Lungs stands tenth, and is for the first time in the list of the ten highest causes. In 1880 there were about 50 per cent. more deaths from it than in any previous year, it having 419 victims—231 males and 188 females. Of the 419, 117 (70 males and 47 females) died under the age of one year, and 71 between 1 and 5 years. A much smaller number died at the other ages until late in life; 44 persons died of this disease between 70 and 80, and twenty odd in each of the other decades, except that between 30 and 40, when 10 died.

The smallest number of deaths in any one month (13) occurred in September ; and the largest number (74) in April ; 55 and 67 were registered in February and March respectively.

#### TYPHOID FEVER.

Though Typhoid Fever is not in the list of ten for 1880, more deaths (namely, 372—196 males and 176 females) were caused by it than in 1879, and about as many as in 1878 ; of its victims, 210 died at ages between 15 and 40, and 111 between 20 and 30. It is peculiarly a disease of the middle or prime of life.

In May there were 15 deaths, the smallest number in any month, and in September 53, the largest number.

As usual, in 1880 there were fewer deaths from this fever in the twenty cities and large towns than in the remainder of the Province. The difference, however, was small, there being 1 death from it in every 53 deaths from all causes in the whole Province, and 1 in 54 in the cities and towns.

The report for 1879 shewed that this disease had been very fatal in Toronto, Hamilton, St. Catharines and Lindsay, and the returns for 1880 shew no marked abatement. In St. Catharines the fever was nearly twice as fatal in 1880 ; in the other cities the death rate was about the same as in the previous year. The four cities respectively returned 1 death from this disease in every 41, 36, 17 and 14 from all causes. St. Thomas gave 1 in 15 ; Stratford, 1 in 25 ; and Chatham, 1 in 41, the same as Toronto.

In the seven cities and towns above named, collectively, there was 1 death from typhoid fever in every 33 deaths from all causes ; while in the 13 other cities and towns, there was only 1 in every 185 from all causes. Kingston returned 5 in a total of 299, or about 1 in 60.

#### DIARRHŒA.

In 1880, the deaths of 220 males and 187 females were recorded as caused by Diarrhœa, being 67, or 20 per cent. more than in the previous year. 238 of the deaths were of children under 1 year of age, and 85 between 1 and 5 years ; 10 between 5 and 10 years, but between the ages of 10 and 20 no one died of the disease. Between 20 and 60 years of age—the 40 years of middle life—only 23 persons died of it ; between 60 and 70, 13 ; between 70 and 80, 18 ; and between 80 and 90, 10.

Diarrhœa, then, as usual, was especially a disease which attacked infancy and old age. Of the total deaths, 286, or about 70 per cent., occurred during July, August and September, there being respectively 86, 111 and 100 in those months. Only 4 deaths were recorded in February, and 7 each in January and December. It was, therefore, particularly prevalent during the warm weather.

In the 20 cities and large towns diarrhœa was about 50 per cent. more fatal than in the rest of the Province ; in the former there was 1 death from it in every 37 from all causes, and in the latter 1 in every 55. In Toronto 1 person died of it in every 25 from all causes ; in Windsor, 1 in 20 ; and in Brockville, 1 in 18.

---

---

 ENTERITIS (INFLAMMATION OF THE BOWELS).

In 1880 inflammation of the lining membrane of the bowels, or enteritis, caused 408 deaths, about the average annual number. Many deaths from this disease occurred in all the decennial periods of life, though 116 were of children under one year. The seasons of the year seemed to make no marked difference in the number of deaths from this cause.

## SCARLET FEVER.

In the two years preceding 1880 there was a large decrease in the number of deaths from scarlet fever, but in 1880 there was a large increase—from 259 (in 1879) to 409. Of these, 203 were of males and 206 of females; 235 were of children between 1 and 5 years, and 102 between 5 and 10 years. Only 32 deaths occurred under 1 year, and 15 between 10 and 15 years; 8 between 15 and 20; 7 between 20 and 30; and 1 at a greater age or over 40. The fever was prevalent the year round, the record ranging from 21 deaths in September to 52 deaths in March.

While there was a somewhat smaller death rate in 1880 in the rural districts, in proportion to the totals from all causes in the cities and towns, the difference was not great, except in a few of the cities. The average of the cities and towns was 1 death from scarlet fever in every 45 from all causes; in Brantford and St. Catharines the proportion was 1 in 10; and in Belleville 1 in 11, less than half of that of the previous year. Only 10 deaths from it were returned by Toronto in 1880, and 5 the previous year; and 14 by Hamilton, with 40 for the previous year.

## MEASLES.

Measles claimed 265 victims in 1880, viz., 139 males and 126 females. During the three previous years—1877-78-79—there were only 29, 5 and 67 deaths respectively registered from this cause, so that last year there were about four times as many as in 1879.

Of the 265, 140 were of children between the ages of 1 and 5 years; 54 under 1 year, and 28 between 5 and 10 years of age. Of the remainder (40), 22 died at ages between 10 and 20, and 18 at more advanced years, 3 and 2 being registered of persons over 50 and 60 years of age respectively.

The most fatal season of the year was April, May and March, and in that order, during which period 166 of the 265 victims died.

The largest number of deaths from this cause (40) was returned from the County of Carleton; York returned the next largest number, 27; Essex and Hastings, 21 each; Wentworth, 15; Northumberland and Durham (united), 13; Wellington and Middlesex, 12 each; Huron, 11, and Peterboro', 10. With the exception of Ontario and Renfrew, which returned no deaths from measles, the remaining 83 were distributed over the other counties, from 1 to 8 dying in each.

## SMALL-POX.

In 1880 there were 143 deaths in the Province from this dreadful disease, viz., of 76 males and 67 females. 50 were of children under 5 years of age, and 29 between 5 and

10 years ; 22 persons died between 10 and 20, and 20 between 20 and 30 years ; the remaining 20 were at different ages up to 70 years.

Of the 143 deaths, 97 were returned from the County of Carleton, 18 from the United Counties of Prescott and Russell, 7 from Brant, 6 from Kent, and 5 from York. The remaining few were from 9 other counties, so that most of the cases were confined to 6, and all to 15 counties. Of the total deaths, 127 took place in the first five months of the year, viz., 22, 40, 33, 16 and 16 respectively.

#### BRAIN DISEASES.

Under the headings of Brain Disease, Inflammation of Brain, and Congestion of Brain, 441 deaths were registered in various parts of the Province—viz., of 253 males and 188 females. It is worthy of special notice that 117 of these, or about one-fourth, died in the 20 cities and large towns. In the cities and towns, in every 42 deaths from all causes, 1 was the result of brain disease, while in the rest of the Province there was only 1 in every 45 from all causes.

The victims of brain diseases die at all ages. In 1880, there were 125 under the age of 1 year, 125 more between 1 and 10 years, and from 15 to 30 in each of the other decennial periods of life. The season of the year, apparently, had not a marked effect ; in May 54 persons died, this number being larger by 10 than that of any other month.

It should be observed that there were many other deaths not included in the above, which were caused by brain disease. From apoplexy, due in almost all cases to a disordered state of vessels proper to the brain, there were 326 deaths ; from hydrocephalus (a diseased state of the brain and its membranes), 150 (being of children) ; and 352 from paralysis, which is usually a result of brain disease. With these may also be included meningitis, which caused 105 deaths.

#### LUNG DISEASE.

Under this indefinite heading were registered, in 1880, 91 deaths—more than has been recorded for a number of years. In the three previous years, 1877–79, there were 65, 75 and 84 respectively. About half of these occurred in March, April and December.

But besides the above indefinitely described cases, the mortality in 1880 from defined lung diseases was much greater than usual, as may have been observed by the reader in looking over the deaths from these causes. From the four lung affections—inflammation of the lungs, congestion of the lungs (diseases very nearly akin to each other), bronchitis, and “lung disease” (excluding consumption)—there were 2,205 deaths—33 per cent. more than the average number, 1,656 ; for the four previous years, the total number of deaths did not vary very much in any of these years.

#### OTHER DISEASES.

Cancer caused 278 deaths—13 less than in 1879.

Dysentery caused 110 deaths—25 per cent. more than the average of the three preceding years ; 76 of its victims died in August, September and October ; 85 were children under 5 years of age, and the others were chiefly of persons of advanced years.

Erysipelas was the cause of 108 deaths—31 per cent. more than the average of the three previous years. The majority of those who were attacked by it were either quite young or aged.

There was about the average number of deaths from cholera infantum and from accidents, and somewhat more than the average from or during childbirth.

AVERAGE AGE AT DEATH of Males and Females in the Counties of Ontario, for the year 1880.

## DEATHS BY AGES.

(For Table, *see* Appendix, page lxxvi.)

This Table is a comparative statement of the number of male and female decedents in each year, from 1 to 100 inclusive, also of those dying under the age of 1 year.

The average age of all decedents was 31.2 years—of males 31.6, and of females 30.7. In 1879, the averages were higher—males 32.2, and females 31.4 years.

Deducting all who died under 1 year, the average age at time of death becomes for males 40.3, for females 38.2, and for both sexes 39.3. In 1879, these averages were, males 41.8, females 40.7, total 41.3, so that the average duration of life in Ontario during the year 1880 was shorter than in the previous year. No satisfactory data by which to account for this decrease can be obtained, and speculation, interesting as it might be, would be idle. It may, however, be mentioned that for obvious reasons the deaths of adults are more likely to be registered than those of infants and young children, and therefore, as the returns become more complete, and all deaths, of young and old, become registered, there will apparently be a shorter average in the length of life.

In 1880, 17 counties returned a higher, and 19 counties a lower average than the total average, viz., 31.2 years. The counties which reported the highest average age at time of death were Peel, Halton, Leeds and Grenville, Lennox and Addington, and Northumberland and Durham. The counties which returned the lowest average at time of death were Carleton, Prescott and Russell, York, and Essex. As in previous years, the births of males in 1880 exceeded those of females, there being born 1,726 more of the former than of the latter; but the deaths of the males were also in excess of the females by 778. It is, therefore, a not unreasonable conjecture, that the number of males of all ages in Ontario is considerably larger than that of females.

Under the age of 1 year there were 459 more deaths amongst males than females. From 1 to 5 years of age the excess was 135. From 5 to 10 years it was 60; and from 10 to 15 years, 8. Between the ages of 15 and 20 the female decedents were more numerous by 83. Between 20 and 30 this excess increased to 257. From 30 to 40 it was greater by 154. In the next decennial period, from 40 to 50, the returns shew a change again, there being 14 more deaths of men than of women, and this preponderance continues through the next four decennial periods of life, as follows: From 50 to 60 years of age, 95 more males than females; from 60 to 70, 220 more; from 70 to 80, 237 more; and from 80 to 90, 116 more. In the last period, from 90 to 100 and upwards, there was one more death amongst females than amongst males.

The percentages of the differences in 1880 between the deaths of males and of females in the various decades of life were as follows:—

Under 1 year	23	per cent. more males than females died.		
From 1 to 5	10	“	“	“

The returns shew that 22.8 per cent. of all the deaths recorded were of children under the age of 1 year—a slight increase in the percentage of deaths at this age, as compared with 1879, of 0.7 per cent.; though the proportion was slightly less (0.1 per cent.) than in 1878, and 1.3 per cent. less than in 1877. The average percentage of the four previous years, 1876–79, was 22.6; that of 1880 being 22.8, was 0.2 per cent. more than the average of the four years. In Scotland the average appears to be only 19 per cent.; in England about 24 per cent.; and in Massachusetts 21 per cent.

In the proportion of deaths in 1880 between the ages of 1 and 5 years, there was a marked increase of over 1 per cent. more than the average of the four previous years, and 2.3 per cent. more than that of 1879.

In the total deaths under 5 years there was an increase in 1880 of 3 per cent. over those of 1878; and an increase of 1.3 per cent. above the average of the four previous years. Of all the deaths returned in 1880, 37.4 per cent. were of children under 5 years of age; in 1879, 34.4 per cent. were under this age.

Turning to the cities, we find that of all the deaths therein recorded, 28.5 per cent. were of infants under the age of 1 year; or 5.7 per cent. more than were returned by the whole Province, which, as stated above, was 22.8 per cent.

In Toronto the death rate of children under one year of age was nearly 33 per cent., or almost one-third of the total registered mortality; in Hamilton it was a little more than 33 per cent.; in Ottawa, a little less than, and in St. Thomas a little over, 30 per cent. In London and Brantford the proportion was greater than the average of the Province; while in the other four cities, Kingston, St. Catharines, Belleville, and Guelph, it was less. In Toronto, Hamilton, and Ottawa, the proportion for 1880 was considerably greater than that of 1879.

Between the ages of 5 and 10 years there was a larger proportion of deaths in 1880 than in 1879, and also between the ages of 10 and 20; after this age, at all periods of life, the proportion was smaller in 1880 than in 1879. This is just the reverse of what occurred in 1879, when the smaller proportion of deaths took place under 20, and the larger proportion at ages above 20.

The proportion of deaths at ages under 20 years, in 1880, was 48.7 per cent., or little short of one-half of the whole number recorded. In 1879 it was 44.8 per cent., or nearly 4 per cent. less—though the average of the three previous years (1876, 1877 and 1878) had been 49.3 per cent. In 1877 it was 51.4 per cent.

There is food for sad contemplation in the fact, now indisputably proven by reliable statistics, that nearly one-half of the human race dies before reaching perfect manhood and womanhood. Were it to be discovered that but one-quarter, or even one-eighth, of all the sheep, hogs, cattle or horses which come into life, were dying of preventive disease before they reached maturity, would not the interested public take alarm, and clamour at the doors of Parliament for sanitary measures looking to relief by removal of the causes of so terrible a fatality? Much has been done by legal enactment for the protection of human life, but much remains to be done, and will be done when public sentiment—having been aroused by the knowledge of the portentous fact just alluded to—will support the adoption by Legislatures of the laws found to be necessary to the prolongation of life.

It is worthy of notice that those counties which return a high mortality from consumption shew a length of life above the average, with the single exception of Hastings, in which it is slightly below the average.

Those counties in which, after deducting all who died under the age of 1 year, the average duration of life was apparently the shortest, returned, almost invariably, a larger total death rate than those in which the average was longest. This appears to confirm what has been suggested above, that where the value of registration is imperfectly understood, the young are more likely not to be registered than those more advanced in years.

Taking the six counties which returned the shortest average duration of life (from 4 per cent. as in York, to 11 per cent. as in Carleton), below the average of the Province, and deducting those who died under 1 year, we find that the total average registered mortality was 9 per 1,000 of population; while the six counties, excepting Peel, which shewed the longest average of life (from 4 per cent. to 9 per cent.), above the average of the Province, the total average mortality returned was only 7.5 per 1,000 of population. Peel County, which returned much the largest average duration of life, has all the elements for promoting longevity; it is settled, seemingly, by a hardy class of people, probably of good ancestry in this regard, almost all of whom are engaged in agriculture, and it contains not one large town, and only a few small villages. It returned a total mortality of 11 per 1,000 of population. But even including Peel, and taking the six counties shewing the longest average duration of life, the mortality registered was only 7.8 per 1,000, or 1.2 per 1,000 less than the six counties shewing the shortest average.

The returns from the six counties which return the shortest average duration of life shew that 28 per cent. of the total number of deaths therein were of children under the age of 1 year, while in the other six counties only 17 per cent. of the deaths were under one year; indicating that the average length of life in these places was shortened, not so much by the decease of persons a few years younger than the average duration of life given, as by the death of a large number of very young children; and further, that by the registration of these deaths of the very young, the average duration of life was rapidly reduced.

## CENTENARIANS.

A list of those persons who have been returned as having attained the age of 100 years and over is given below by counties, and although it may be difficult for the friends of the deceased to prove that they were centenarians, inquiries will be instituted at once for the purpose of verifying these ages, as nearly as may be, and the result will be given in the next annual report.

Milliners and Dressmakers .....	30	39	Book-keepers .....	24	47

The average age at death of those persons whose occupations were given, for the last seven years is as follows:—

For 1873.....	52.8 years.
“ 1874.....	55.2 “
“ 1876.....	55.7 “
“ 1877.....	56.0 “
“ 1878.....	57.1 “
“ 1879.....	57.6 “
“ 1880.....	57.3 “

The deaths in 1880 of persons whose occupations were given reached 8,251, or 41.6 per cent. of the whole number of deaths registered.

The returns shew that during the seven years which the table covers, there was an increase of 4.5 years in the duration of life of those whose occupations were recorded. This increase was present in every year excepting 1880, when there was a slight decrease of 0.3 of a year in the average length of life. This corresponds with the shorter average duration of life, in 1880, reported in a previous page. The greatest increase, as shewn by the above table, occurred during the years 1873 and 1874, when it was 2.4 years, or more than half of the total increase of the seven years.

Amongst the ten occupations returning the highest average duration of life in 1880, many changes will be found, as compared with a similar list given last year. Farmers, who were seventh in the list in 1879, are not in the list for 1881 at all; their average age apparently decreased from 64 to 61 years.

In the list, Contractors and Builders, Bakers, and Public Officials replace, as it were, the Farmers, Hunters, Fishermen and Paupers. This last mentioned class of persons, however, although according to their average age they are entitled to the sixth place on the list, is not included this year, because, generally speaking, paupers do not become recipients of charity until far advanced in life, and as there are few, if any, young paupers, an undue average length of life is given to these people as a class, for the reason that in all other occupations a certain number die when young, thus reducing the average of those who live to advanced age; nearly all paupers are old when they die, and therefore their average age is apparently proportionately greater. Moreover, in this country pauperism cannot justly be regarded as an occupation.

Bakers and Confectioners appear in the list for the first time. Their trade is generally regarded as unhealthy, therefore it will be satisfactory for them to know that they have for one year returned an average age of 64 years; still the number of deaths recorded is not large enough to afford much evidence in support of the contention that their occupation is conducive to health.

Nine Telegraph Operators died at an average age of 24 years, the lowest average of any occupation. It must be observed, however, that many persons engaged in telegraphy leave it while young, as the remuneration is small, and the work is fast falling into the hands of women; therefore the deaths amongst this class are generally of the young, which will partly account for the apparently low average duration of life in this class.

In the five occupations on this list giving low averages of life—viz. : Printers, 32 years; Milliners and Dressmakers, 34; Bankers, 35; Seamstresses, 39 years; Salesmen and Clerks, 39 years—the nature of their occupations readily accounts for their early death. In this respect, 1880 corresponds with other years, and likewise with other countries. Under the head of Bankers are included several bank clerks who died young, and who can hardly be said to have become bankers, although reckoned as members of that profession.

A STATISTICAL CLASSIFICATION of the Number of persons whose Occupations were specified, giving the Number, Average and Aggregate Ages.

Analysis of the tables in which the deaths by occupations are thus classified, shews that the cultivators of the soil rank highest. The second class—mechanics—embraces many callings which are regarded as detrimental to health, yet the average duration of life of those engaged in 32 different trades is 54 years. Labourers come next, with an average of 53 years. The average age would doubtless have been greater if many of them had not lost their lives by accidents. Out of the total number of deaths of 719 labourers from all causes, 51, or 7 per cent., were due to accident. As these accidents generally happened to young men, or to those in the prime of life, the average duration of life for this class was thus considerably affected.

Merchants, financiers, etc., form the next class, and their average age at death is only 48—the lowest but one on the list of classes. Book-keepers, salesmen, tavern-keepers, and telegraph operators, are included in the list, and as they are almost invariably short-lived, the average age at death of the whole class is, as a matter of course, lowered.

The class of professional men has not so many divisions as classes 2, 3 and 4. Their average length of life, 58 years, is higher than the total average age of all other occupations taken together.

In the three leading professions—those of divinity, law and medicine—we find that 26 clergymen died at the average age of 62 years—the same as in 1879; 22 lawyers at the average age of 45 years; and 38 physicians at the average age of 48 years; so that in this, as in other countries, of the three professions, clergymen live to the greatest age.

The average age at death of the 22 lawyers is one year more than in 1879, but less than in the years 1876 and 1877, when it was 50 years. The deaths of 38 physicians are recorded at an average age of 48 years, or two years less than those who died in 1879; so that the falling off from year to year in the length of the life of physicians, noticed in last year's report, still continues.

Twenty-one engineers enjoyed the same average duration of life as the physicians—48 years.

The number of deaths of clergymen registered in 1880 is not nearly so large as in 1879, but, as stated, the average age is the same—62 years.

The term "gentlemen," given in reply to the question in the schedule "Of what occupation?" must generally be accepted as including those who have ceased to follow any occupation for the purpose of gaining a livelihood. Being free from care and want, their lives are naturally prolonged to a greater average age than are those of others not so favourably situated. It would be satisfactory to know what had been the previous occupations of those who had any. 144 "gentlemen" died at the average age of 67 years.

That public officials are long lived is evident from the return of 57 of them who died in 1880, at an average age of 63. 48 teachers died at an average age of 44 years. This is the same average at which 56 died in 1879; though in 1878, 38 died averaging only 42 years.

Of Class VI., 28 railroad employees died at the average age of 42 years. Nine of these deaths, however, resulted from accident.

The average age of milliners and dressmakers at time of death was less by 5 years in 1880 than in 1879, the average in 1879 being 39 years, and this year only 34 years. Seamstresses live, however, longer by 2 years. Servants averaged 45 years, which is an increase of 8 years in their length of life over 1879.

## DEATHS BY OCCUPATIONS.—CAUSES OF DEATH.

(For Table see Appendix, page cxxii.)

## Ten Highest Causes of Death amongst those whose Occupations are given.

Gentlemen.....	184	13	7.0	Tavern-keepers.....	53	13	24.5
Shoemakers.....	94	13	13.8	Salesmen and Clerks.....	36	13	36.1

Old age retains its place as first of the ten highest causes of death amongst those whose occupations are given. Of the 811 persons returned under this heading, 480, or 59 per cent., were farmers. Phthisis is second on the list, and claims its victims impartially from all classes, but more especially from amongst persons whose occupations are sedentary, necessitating confinement in-doors.

As the number of deaths registered in 1880 from all causes was greater than in 1879, so was the number returned as dying of this disease; 769 deaths were due to it in 1880, against 749 in 1879.

As farmers form so large a class of the community—returning nearly 29 per cent. of all the deaths by occupations—it is not surprising that the victims among them of phthisis should outnumber those returned by other occupations; but the percentage of deaths from phthisis among farmers, as compared with the whole number of deaths among them from all causes, is much less than in any of the other nine classes given in the table. Out of 2,373 deaths of farmers—who for the most part live out-of-doors—from all causes, 296, or 12.4 per cent., were registered under the head of phthisis; while of 36 salesmen and clerks—who are confined in-doors—whose deaths were recorded, 13, or 36.1 per cent., were from phthisis. The mortality amongst teachers from this disease was very great in 1880, causing 14 out of 48 deaths, or 29.1 per cent. This, however, is a much smaller percentage than in 1879. In that year the number of teachers who died from all causes was 56, and of this number 23, or 41 per cent., were returned as dying from consumption.

The total number of deaths returned in the ten highest causes of deaths amongst those whose occupations are given was 3,202; of this number 769, or 24 per cent., were from phthisis.

Appended to this Report will be found a brief review of the births, marriages and deaths registered in Ontario, and returned to the Department of the Registrar-General, since the Act came into force, especial attention being paid to the returns for the last ten years, 1871 to 1880 inclusive. In this Supplementary Report, the increases or decreases which have from year to year taken place in the proportion of deaths from certain diseases are shewn, together with the mortality recorded amongst persons engaged in the various occupations usually specified. The effect of these statistics on the death rate during a number of years, with other matters of public interest and importance are given.

The registration of vital statistics, according to law, has now been sufficiently long established in Ontario to afford authentic data as to the Provincial birth and death rates, upon which to base future estimates of the natural increase in the population. The returns from many localities to which due reference is made are now, doubtless, as complete as it is possible to obtain them.

The undersigned presents the Report in the hope that it will be found not uninteresting, and of some practical value.

I have the honour to be, Sir,

Your obedient servant,

H. S. CREWE,

*Inspector.*

REGISTRAR-GENERAL'S OFFICE,  
TORONTO, DECEMBER 15TH, 1881.

TO THE HONOURABLE A. S. HARDY, M.P.P.,  
*Registrar-General of the Province of Ontario.*

SIR,—I have the honour to present a Review of the Births, Marriages and Deaths registered in this Province since the Act came into operation, especial attention being paid to the returns for the last ten years—1871 to 1880 inclusive.

#### GENERAL REMARKS ON REGISTRATION OF VITAL STATISTICS.

A learned writer says, "Vital statistics furnish most unerring lessons as to the health, prosperity and morals of the people; they teach the influence of marriage on illegitimacy and morality, the vital force of the children, the duration of life with its expectation and value for all ages and races, the influence of meteorology, occupation and locality in generating disease and improving health, and thereby the removal of unfavourable conditions, often found where least expected, and the approach of morbid storms, by ignorance of which negligent cities and even nations have been destroyed. They serve alike to guide the resident and the immigrant, the capitalist and the labourer, the politician and the statesman, the moralist and the scientist. Ignored or disparaged too often, they have been advocated and supported by Napoleon and Thiers, by Bismarck and Cavour, by Gladstone and Disraeli, and their establishment has become a test of the degree of civilization reached by a people and their rulers."

Forty years' experience of the registration of births, marriages and deaths in Great Britain has more than justified the hopes and expectations formed of the system there, more especially as relates to its bearing upon the public health. There, from materials at first and for years necessarily imperfect, yet continually improving, a series of annual, quarterly and weekly reports have been, from time to time during the forty years, published by the Registrar-General, under Dr. Farr's admirable superintendence, affording an insight into the various conditions of life, health and disease, which, previous to such registration, was impossible.

The subject is one in which every man who takes an interest in the welfare of his country or of the community in which he lives must feel concerned. Most people desire to know, and it is of great importance for the State to know the number or *quantity* of its people or inhabitants; and it is just as necessary to know the numbers of those who are born and of those who die; the causes of their deaths and at what ages these took place, for it is in this way that the *quality* of the people becomes known.

Indeed, it is only by the registration of vital and health statistics that knowledge can be obtained of the more prevalent diseases and causes of death—knowledge which is indispensable to the practical application of preventive measures by the hygienist.

Buckle says, "Statistics, as a branch of knowledge, have already thrown more light upon the study of human nature than all the sciences put together." Certainly human life statistics are of the first importance.

Registration laws have long been enforced in all the other European countries as well as in England. They have been in force forty years or more in Massachusetts, and for a long or short time in the other principal States of the Union. Such a law came into effect in Nova Scotia in 1865.

#### REGISTRATION OF VITAL STATISTICS IN ONTARIO.

The first Act providing for the registration of births, marriages and deaths in Ontario went into operation on the 1st day of July, 1869. During the following half year 14,126 registrations were made, viz.: 8,416 births, 2,934 marriages, and 2,776 deaths—or at the rate of 28,252 registrations for the year.

From the year 1869 to the present time the annual increase in the number of registrations was gradual and almost unvarying, until in 1880 there were within about 100 of 75,000 registrations, instead of the 28,252 of twelve years before. On the 1st of January, 1881, an amendment to the Registration Act came into force, and the first half year's returns received at the Department indicate that the result will be a still larger ratio of increase for that year.

The returns from the Province, as a whole, are not yet perfectly satisfactory, but those from most of the cities and large towns are nearly as accurate as it is possible to obtain them.

#### AIM AND SCOPE OF THIS REPORT.

The aim of this Report is to briefly review the vital statistics of Ontario returned to the Registrar-General for the ten years, 1871 to 1880, inclusive. It will also refer to the registration events of 1870, but only when specially mentioned as belonging to that

year, and in such a way as not to interfere with a clear comprehension of the decennial report. Of the latter half of 1869 little or no use can be made, and it will not be included; but, with that exception, the report may be regarded as embracing in its scope, for all practical purposes, the whole period of time since registration was enforced in this Province. Therefore, though a complete decennial report, it will be something more, and include, in occasional instances, the eleven years.

#### PRESENT VALUE OF THE RETURNS.

It has been stated by some medical men that, being incomplete, the returns are of no practical value whatever. Probably this has been said without due consideration, for it is not true. Many important and highly instructive deductions may be drawn from even incomplete returns—as, for example, deductions from the relative proportion of deaths registered from certain diseases, and from that proportion's relation to the total number of deaths returned from all diseases; and also from the proportion of deaths at different ages or periods of life, etc.

#### BASIS FOR ESTIMATING THE ACTUAL BIRTH, MARRIAGE AND DEATH RATES IN ONTARIO.

There is satisfactory evidence that from Toronto and some other cities the returns of births, marriages and deaths are, as before stated, about or nearly as complete as it is possible to obtain them. In these places, the Registrars have been active in the discharge of their duties, and but very few, if any, births or deaths, it is believed, have escaped registration. The returns from the cities, therefore, and especially from Toronto, may fairly be accepted as a satisfactory basis upon which to frame estimates for the whole Province—that is, as regards births and deaths. There is much corroborative evidence, as I shall shew further on, which tends, I think, to establish this contention. For marriages, the urban rate would be too high, it being a common practice for many persons who reside in the country to go into neighbouring cities and towns to get married—thus abnormally swelling the returns from those places.

Toronto is neither a very large or overcrowded city; it is fairly drained, and in other respects, is in as good a sanitary condition as any other part of the Province, and probably much better than some other parts.

So far as the birth rate and death rate throughout the Province are concerned, it is unlikely that they vary much from those in Toronto from year to year. The high summer infantile mortality in Toronto is probably fully counterbalanced by a high mortality in the rural districts from inflammatory affections of the respiratory organs, in the early spring, and from diphtheria.

In Toronto there were registered in 1880, 2,650 births and 1,510 deaths. We may fairly estimate the average population of the city in that year at not less than 82,000 in round numbers.

With a population of 82,000, then, Toronto in 1880 returned a birth rate of 32.3, and a death rate of 18.4 per 1,000 of population. No other place returned so high a birth rate in that year—not one, indeed, attaining even 30 per 1,000. Ottawa, London,

Kingston, St. Catharines, Belleville and Windsor returned a higher mortality than she did, while the city of Brantford returned about the same proportion.

With reference to the birth rate in 1879, Toronto returned about 35 per 1,000, and Belleville 33.7 per 1,000. In 1878, Toronto returned a birth rate of 37 per 1,000; Guelph, 34; Belleville, 31.3; and Hamilton and Woodstock each 30 per 1,000. In 1877, the birth rate of Toronto was 32.9 per 1,000; and of Guelph and Woodstock each 35 per 1,000.

As regards the death rate in 1879, the returns from Toronto shewed a mortality of 19 per 1,000; from Belleville, of 23 per 1,000; and from London, Kingston and St. Catharines each of over 18 per 1,000. In 1878, Toronto returned a mortality of 20 per 1,000; Ottawa, 19 per 1,000; and Belleville, 23 per 1,000, as in the previous year. In 1877, Toronto registered a mortality of 23; Hamilton, 20; London, 19; and Belleville, 21 per 1,000. In all of these years Belleville, it may be stated, was suffering from an epidemic of diphtheria, which raised the mortality above the average.

Taking the returns from the 20 cities and largest towns in the Province for 1880, the total average mortality was nearly 18 (17.8) per 1,000 of population. If we omit two or three of the towns from which the returns must have been very incomplete, the average mortality of the others was considerably over 18 per 1,000. The birth rate for the 20 was about or nearly 28 per 1,000; but, if we eliminate a few of the towns from which the returns of births were very low and evidently very imperfect, the remainder shew an average of about 29 per 1,000; some of the towns, including Toronto, exceeded this. In each of the three previous years, 1877-78-79, the returns from these places shewed just about the same average birth and death rates. In 1877, with 4 of the 20 cities and towns omitted, the mortality was 18 per 1,000 of population, though the birth rate was somewhat less than 29 per 1,000.

I may here state that in the above estimates, in all cases, the population of the various cities and towns was taken from the Assessment Rolls; and I may add, that in 1880, with two exceptions, the population of the 20 places, as returned by the Assessors, corresponds very closely with that of this year's census: the exceptions are Toronto, as above mentioned, and Ottawa, which, according to the census, is somewhat over 2,000 greater than that returned by the Assessors.

There is, then, reason to believe that the actual average annual birth rate of this Province is 32 per 1,000 of the population, or perhaps 1 birth to every 31 persons (there is no evidence that it exceeds this), and that the actual average annual death rate is not higher than about 18 per 1,000, or, at most, one death in 55 of the population; it appears evident it is not less than this. I will now briefly refer to the respective rates in other countries in support of the above.

The following table shews that in Sweden the average birth rate for twenty years, 1853-1872, was 32 per 1,000, while in Denmark it was a little less, 31.6 per 1,000. In England and Wales it was 34.8; in Scotland, 34.6; in the Netherlands, 34.3; in Prussia, 37.7; and in Austria over 40 per 1,000. In Massachusetts it was only 27.3. During the five years, 1856-1860, the average in that State was 29.5; and in 1857 it was over 30 per 1,000, the highest upon record there.

In Queensland, in 1878, the annual report shewed one birth to each 28 of the population, or nearly 36 per 1,000.

In New South Wales, in 1878, the rate was 37.50 per 1,000 of population; a little below the average of ten years, 1869–1878, for which the rate had been 38.6.

In Nova Scotia, the only Province in Canada except Ontario which has had a system of statutory registration, the Secretary of Statistics reported for 1873, one birth per 32 of the population, or 32.25 per 1,000. In 1874 the rate was not so high.

TABLE SHEWING RATES OF INCREASE OF POPULATION.

COUNTRIES.	Birth Rate to 1,000 persons for 20 years, 1853-1872.	Death Rate for 20 years.	Excess of Births over Deaths.
England and Wales .....	34.8	22.4	12.4
Sweden .....	32.0	20.4	11.6
Denmark .....	31.6	20.3	11.3
Prussia .....	37.7	27.2	10.5
The Netherlands .....	34.3	25.7	8.6
Massachusetts .....	27.3	19.1	8.2
Austria .....	40.2	31.9	8.1
France .....	26.1	24.4	1.7

The above table shews that in all the countries named therein the death rate has long been higher than that estimated for Ontario, namely, 18 per 1,000. In Sweden, Denmark and Massachusetts it was not much higher in 1877; and in Massachusetts, in 1878, the latest returns to hand, it was only 18.78. In Sweden, in 1873, it was only 17.2 per 1,000. In the rural districts of Great Britain—Westmoreland, Dorset, Rutland, Kent and Hereford—the mortality is less than 18 per 1,000.

In Queensland, in 1878, the mortality was 20.5 per 1,000 of population—considerably higher than in any year during the last decennium, excepting only that of 1875.

In New South Wales, in 1878, the mortality was only 15.93 per 1,000 of population, as against 15.2 per 1,000 for the ten years, 1869–1878.

The mortality of Nova Scotia is estimated by the Secretary of Statistics there to be about 17 per 1,000; although the returns were only shewing about 12 per 1,000, as in Ontario.

It may here be observed that applied sanitary science is credited with having gradually reduced the death rate in most of these countries; the table shows that there has been a decrease, though public health work has not much more than fairly been commenced.

## AVERAGE ANNUAL MORTALITY RATES IN THE SEVERAL COUNTRIES NAMED—1853-77.

COUNTRIES.	In the 20 years 1853-72.	1873.	1874.	1875.	1876.	1877.
England and Wales .....	22.4	21.1	22.3	22.8	21.0	20.4
Denmark .....	20.3	18.6	19.9	21.0	20.0	18.7
Sweden .....	20.4	17.2	20.3	20.2	19.5	18.5
Prussia .....	27.2	28.0	25.9	26.4	25.4	25.5
Austria .....	31.9	38.5	31.3	29.7	29.4	31.1
The Netherlands .....	25.7	24.0	26.6	25.4	23.3	22.0
France .....	24.4	23.3	21.4	23.1	22.7	21.7
Massachusetts .....	19.1	21.6	19.8	21.2	20.1	18.9

It appears, therefore, that until the returns of deaths in Ontario shew an annual mortality for the Province of 18 per 1,000 of population, they must be regarded as incomplete. Likewise, that until the total returns of births shew an annual natural addition to the population of 32 per 1,000, they cannot be regarded as complete.

It must be borne in mind, however, that the birth rate and death rate vary, not only in different years, but in different localities or counties. This is true of all countries where vital statistics are carefully collected and tabulated. In England, it is stated, the counties of Durham and Stafford are noted for their high birth rate. In Massachusetts, births, in proportion to the population, are most numerous in the counties of Suffolk, Hampton and Worcester, while the opposite is the case in Dukes, Franklyn and Nantucket. In Ontario, as time rolls on, it will doubtless be found that some counties constantly return a higher birth rate than others.

The birth rate, of course, largely depends upon the marriage rate, which again is, no doubt, more or less influenced by the financial condition of the country. In years of prosperity there are usually more than the average number of marriages; in years of depression there are less.

The fluctuations in the mortality of a country are due to the more or less favourable climatic or meteorological conditions, acting upon public health through insanitary or other environments, as well as to conditions of individual constitution and habits of body. Hence in Ontario, as in other countries, the death rate is found to be constantly higher in some localities than in others, while in some the rate will vary, and be higher in some years than in others.

The returns of marriages have doubtless, from the first, been more complete than those of births and deaths. In 1880, as the report shews, there were registered in the whole Province 12,783 marriages, which, with an estimated population based upon the census of this year (1881), would shew nearly 7 marriages per 1,000 of population. The

20 cities and largest towns returned 10.9 marriages per 1,000 of population. Toronto and Hamilton returned less than 10 per 1,000, while Ottawa and London returned over 12 per 1,000. Other cities returned 13 and 14, and the town of Chatham returned 21 per 1,000. It is therefore not easy to arrive at a correct estimate of the actual average marriage rate of the Province. It will probably range between 8 per 1,000 and 9 per 1,000 of population, being one marriage to every 112 or 125 persons, as the case may be, though it may be less even than this. There are now but few marriages which are not registered. Families of children, in Ontario, are for the most part, it appears, large, each marriage being productive of the average number—and the actual marriage rate may be less, possibly, than 8 per 1,000.

In England the average rate for many years has been about 8.5 per 1,000. In Denmark it has been a fraction less than this. In Sweden the average has been only a fraction above 7 per 1,000. In Massachusetts it had long been about 10 per 1,000, but of late years it has fallen to 8, and even less, per 1,000. In 1875 in that State it was, in the 16 largest cities, 9.31 per 1,000, and in the rest of the State 7.28 per 1,000, being 8.27 for the whole State.

In Nova Scotia the rate is a fraction less than 8 per 1,000, or one marriage to each 126 of the population; in 1871, the registrations reached that point which is regarded as about the average for the Province.

#### MARRIAGE RATES IN DIFFERENT COUNTRIES—TWENTY-FIVE YEARS.

Annual average number married (not marriages) per 1,000 of population in the years 1853 to 1877.

---

---

 THE DECENNIAL RETURNS IN ONTARIO.

During the 10 years which this report covers, 1871-1880 inclusive, there were registered in this Province 332,025 births, 116,342 marriages, and 145,124 deaths—593,303 registrations in all.

There were 186,901 more births than deaths registered, or 229 births to every 100 deaths; and 285 births to every 100 marriages, or an average of 2.85 births to every marriage, during the ten years.

It is quite obvious that from the first a much larger proportion of the births and marriages than of the deaths which have occurred has been registered. The marriages registered are now but little short of the actual number which occur; at least such was the case in 1880, yet in that year there were only 28 per cent. more registered than there were ten years before, in 1871. There were in 1880, 70 per cent. more births and 115 per cent. more deaths registered than in 1871, yet the returns of births are now more perfect than the returns of deaths.

In 1871 about 75 per cent. of the estimated number of marriages which occurred were registered, or over 6 per 1,000 of the population; nearly 50 per cent. of the estimated number of births, or 15.3 per 1,000 of population; and less than 32 per cent. of the deaths, or 5.66 per 1,000 of population, were registered.

In 1880 over 90 per cent. of the marriages were registered—6.8 per 1,000 of population; fully 70 per cent. of the births—22.4 per 1,000 of population; and nearly 60 per cent. of the deaths—or 10.6 per 1,000 of population. So that, as shewn by the table, the proportion of deaths registered per 1,000 has nearly doubled during the ten years, and the actual number registered has more than doubled (9,182 in 1871, and 19,802 in 1880); the registrations of births have increased from 50 per cent. to 70 per cent.; and the registrations of marriages from 75 per cent. to over 90 per cent. of the numbers estimated.

The total annual number of registrations of births, marriages and deaths increased during the ten years from 40,403 to 74,907, or over 85 per cent.

Assuming the average population of the Province during the ten years to have been that of a number midway between that given by the census returns of 1871 and that of 1881, which would be 1,767,155, the average annual birth rate returned for the ten years was 18.8 per 1,000 of population, or 59 per cent. of the estimated number; the average marriage rate returned for the ten years was 6.6 per 1,000 of population per annum, or about 80 per cent. of the estimated number; and the average death rate returned for the ten years was 8.2 per 1,000 of population per annum, or 45 per cent. of the estimated number. The above statistics may be tabulated as follows:—

YEAR.	BIRTHS.		MARRIAGES.		DEATHS.	
	Number per 1,000 of Population.	Per cent. of estimated number.	Number per 1,000 of Population.	Per cent. of estimated number.	Number per 1,000 of Population.	Per cent. of estimated number.
1871.....	15.3	49	6.1	75	5.6	32
1880.....	22.4	70	6.8	90	10.6	60
Average for the 10 years .....	18.8	59	6.6	80	8.2	45

In the first (full) year of registration, 1870 (Table A), the difference between the registered birth rate and death rate was greatest; there were then 282 births to every 100 deaths. On an average, the difference between the number of births and the number of deaths registered has been gradually decreasing from year to year as the registrations approached nearer and nearer to the number of births and deaths which actually occurred. During the last five years, as the table shews, the difference was less than the average of the ten years—236; while during the first five years the difference was greater than the average, excepting the year 1872, when the number was 227; this would be more than counterbalanced were 1870 included.

While the returns, then, shew a natural increase of population, in excess of births over deaths, of only 186,901, the actual increase was obviously much greater than this, though the proportionate increase was not nearly so great as shewn by the returns (229 births to 100 deaths).

#### PROBABLE ACTUAL NATURAL INCREASE OF POPULATION BY EXCESS OF BIRTHS OVER DEATHS.

The population of Ontario in 1871, according to the census of that year, was 1,620,851. I think I have shewn that a birth rate of 32 per 1,000 of population per annum is a fair estimate for the Province, and that there is ample evidence that the actual number of births reaches this estimate. A birth rate of 32 per 1,000 in a population of 1,620,851 would give 51,867 births per annum. It appears from what I have pointed out that the average annual death rate will reach 18 per 1,000 of the population, and that there is no reason to believe that it will exceed this number. A death rate of 18 per 1,000 of population in 1871 would give 29,175 deaths. Subtract this number from the number of births (51,867 - 29,175), and we have an excess of births over deaths for that year of 22,692. This number, therefore, may be fairly taken as the actual increase of population in Ontario from births alone in 1871.

In 1880, according to the census of that year, the population had increased to 1,884,200. If there were 32 births per 1,000 of population, as estimated, and as no doubt there were, the actual number of births was 60,294. The number of deaths at 18 per 1,000 of population was 33,915. Deducting this number from the number of births (60,294 - 33,915), we have 26,379—the actual increase of population from births alone in 1880.

Now, the mean of 22,692 and 26,379, the number of births in excess of deaths in 1871 and 1880 respectively, is 24,538 ; or in other words, the difference between 22,692, the natural increase in population in 1871, and 26,379, the increase in 1880, is 3,687 ; and the half of this number, 1,843, added to the increase for 1871, 22,692, produces 24,538 ; and this last number represents, as near as it is possible to estimate, the actual average natural increase of population, by excess of births over deaths, per year, for the ten years under notice. This number, multiplied by 10 (24,530 × 10), gives 245,300, which number represents the actual natural increase of population, by births alone, during the ten years. This is shewn more at length in the following table :—

YEAR.	Estimated Population.	Estimated No. of Births.	Estimated No. of Deaths.	Excess of Births over Deaths—Natural increase.	Increase per cent.
1871 .....	1,620,851	51,867	29,175	22,692	1·40
1872 .....	1,650,111	52,803	29,701	23,102	1·40
1873 .....	1,679,371	53,739	30,228	23,511	1·39
1874 .....	1,708,631	54,676	30,755	23,921	1·40
1875 .....	1,737,891	55,612	31,282	24,330	1·40
1876 .....	1,767,151	56,548	31,808	24,740	1·39
1877 .....	1,796,411	57,485	32,335	25,150	1·40
1878 .....	1,825,671	58,451	32,862	25,589	1·40
1879 .....	1,854,931	59,357	33,388	25,969	1·39
1880 .....	1,884,200	60,294	33,915	26,379	1·40
.....	.....	560,832	315,449	245,383	.....

It appears then, from the above estimates, that there was in Ontario during the last decennial period an actual natural increase in the population, by births alone, of 245,000 persons, in round numbers. The last census shews an increase in the population of 292,000 and over, in round numbers, for the ten years, including a part of the year 1871 and a part of 1881. This would leave only about 47,000 persons to be accounted for by immigration—an average of 4,700 immigrants per year remaining in the Province. True, the report of the Department of Immigration shews that more than three times this number of immigrants have settled in Ontario every year, on an average, for a number of years ;

but it must be borne in mind that a large proportion of these but take the place of others who are about to leave the Province, and that there has during the past few years been a large emigration from it to the north-western parts of the Dominion. With these facts in view, it appears highly probable at least that the natural increase of population by births has been as great as shewn by the above figures; and we have therefore further evidence in the census and immigration statistics that the average annual birth rate for this Province reaches about 32 per 1,000 of population.

#### THE INCREASE OF MALES GREATER THAN THAT OF FEMALES.

Every year during the ten years there were registered from about 5 to 9 per cent. more births of males than of females. During the decennium there were registered the births of 172,245 males and 159,692 females, or 12,553 more males than females—an excess of males over females of 7.8 per cent.

It is not likely that, of all the male births which actually occurred, any larger proportion of them was registered than of the female births which actually occurred, there being no conceivable reason why the registration of male children should have been more perfect than that of female children, and therefore it may be assumed that there was the same proportionate excess of male births over female births, in the actual number of births which took place, as in those only which were registered; or in other words, while there was an excess of males over females of 7.8 per cent., amongst the births which were registered there was doubtless the same proportionate excess of males over females amongst the births which were not registered.

It has been estimated that on an average, during the ten years, 59 per cent. of all the births which took place were registered. There were 332,025 births registered, but the actual number which took place, according to that estimation, was therefore, 560,832. If then, in the 332,025 births which were registered there were 12,553 more males than females, there were in the 560,832 births which actually took place, 21,877 more males than females; and this number then we may accept as representing the actual excess of males over females born during the ten years.

A larger number of males than of females died, too, every year during the ten years, but the difference between the number of deaths of males and of females was not so great as the difference between the number of births of males and of females. There was, therefore, in the natural increase of the population of the Province, as above estimated, a larger number of males than of females.

During the decennium, the deaths of 7,606 more males than females were recorded (76,355 males and 68,749 females, 68 no sex given). But as only 45 per cent. of the actual number of deaths which occurred were recorded, as has been shewn, there were actually in the Province 321,091 deaths instead of 145,124 as recorded. With the same proportion of deaths of males and females amongst the unrecorded as amongst the recorded events, there must have been 16,783 more deaths of males than of females.

If, then, as appears to be evident, there were during the ten years 21,877 more males than females born in the Province, and that 16,783 more males than females died, there was in the natural increase of the population 5,094 more males than females; that is, of the 245,380 individuals by which the population of the Province was increased, by excess

of births over deaths, and aside from the increase by immigration, 136,028 were males and 109,352 were females.

The proportions of males to females who are born or who die, differ somewhat in different countries. In England the mean ratio of births is 103.6 males to 100 females, and of deaths 106 males to 100 females. As there are there about 35 births and 22 deaths per 1,000 of population per annum, the numbers of males and females in the natural increase in population remain nearly about equal. In Massachusetts the ratio of births has been for many years 105.7 males to 100 females, while of deaths the ratio has been 99.8 males to 100 females. In 1873, in that State, the proportion was 100 deaths amongst females to 103.6 amongst males, but the proportion of deaths amongst females gradually increased, and in 1878, 100 females died to every 95.6 males. In Nova Scotia the average proportions in regard to sex, in both births and deaths, appear to be nearly the same as in Ontario.

#### IMPROVEMENTS IN THE RETURNED SCHEDULES.

Amongst the many thousands of schedules returned to the Department, there are always a few which are not complete; for instance, the age of a person married or deceased, or the cause of death, etc., may be omitted, but, on the whole, there has been a marked though gradual improvement in this respect, a feature which is noted with pleasure.

In 1870, in 5.5 per cent. of all the marriages returned, the religious denominations of the contracting parties were not specified; in 1880, in less than one per cent. of them (0.8) did the omission occur. In 1873, the age of the persons married was omitted in 1.3 per cent. of the returned schedules; while in 1880 the omission occurred in but 0.4 per cent. The omissions by the officiating clergyman to state whether the ceremony was performed by banns or otherwise, have decreased from 2 per cent. to almost nothing at all. There has, however, for some unaccountable reason, been an increase in the number of omissions to record the month in which marriages took place.

In regard to deaths, the number of instances in which the month in which death occurred was omitted from the schedules, has decreased within the last two or three years from 0.4 per cent. of the totals to almost nothing. In 1870 the cause of death was omitted in 8.5 of the total schedules returned; in 1880 it was omitted in but 3.2 per cent. There has, on the other hand, been no improvement, but rather the reverse, in omitting the ages of decedents.

#### BIRTHS.

##### BIRTHS AS REGARDS SEX.

During the ten years under notice, of the 332,025 births registered, 172,245 were of males and 159,692 of females. There were 12,553 more males than females born, or 107.8 males to each 100 females—nearly 52 males and 48 females (51.8 and 48.2) in each 100 children born.

In 1876 there was less difference between the number of male and female births than in any other year, viz., 105.2 males to 100 females; while in 1878 there was the greatest disparity between the numbers, viz., 109.205 males to 100 females, though the numbers or proportions in 1872 were almost precisely the same, being 109.203 males to 100 females. The numbers and proportions varied each year between these extremes.

The average difference of the last five years, 1876 to 1880, was slightly less than that of the first five, 1871 to 1875, viz., 7.66 in the last five and 8.10 in the first.

In Massachusetts, amongst the still-born there are nearly 50 per cent. more males than females. Amongst illegitimates, there, the average for many years has been about 97 males to 100 females, though the proportion is changing, and in 1877 and 1878 there was but little difference, the numbers being almost equal.

BIRTHS IN EACH QUARTER OF THE YEAR.

Usually, in this Province, the largest number of births takes place in the first quarter of the year. This has been the case, according to the returns, every year for the past seven years, or since 1874, the first year in which the number in each quarter is given in the Annual Report. The next largest number was registered in the second quarter in four of the years, 1874-75-77-79; while in the other three years, 1876-78-80, the second largest number of births was recorded in the third quarter. In the four years first above named, the third largest number was recorded in the third quarter; and in every year the smallest number was in the last quarter. The average quarterly percentages for the seven years were 27.42, 24.78, 24.94, and 22.86 in the first, second, third and fourth quarters respectively. This shews, therefore, that with comparatively very few more births in the

second quarters of the years 1876-78-80, the total percentage for the seven years, singly and collectively, would shew a gradual decrease with each succeeding quarter, from the first to the last.

NUMBER OF BIRTHS IN EACH QUARTER FOR THE SEVEN YEARS, 1874 TO 1880.

QUARTER.	1874.	1875.	1876.	1877.	1878.	1879.	1880.	Totals.	Percentages of the 7 years.
January to March .....	7610	6998	10012	12580	10652	11333	11050	70235	27.42
April to June .....	7048	6481	9566	9899	9688	10484	10345	63511	24.78
July to September ....	7034	6474	9623	9854	10075	9944	10893	63897	24.94
October to December ...	6546	6015	9257	7624	9821	9274	10024	58561	22.86
	28238	25968	38458	39957	40236	41035	42312	256204	100.00

In England, the largest number of births frequently occurs in the second quarter of the year, though, on the average, for a number of years the births are most numerous in the first quarter, next in the second, and least numerous in the fourth quarter. In Massachusetts, it appears the births are more numerous in the last quarter, the third comes next, the first third, and the second last.

BIRTHS IN THE DIFFERENT MONTHS.

The returns shew that in this Province, in most years, there are more births in March than in any other month.

Below is a comparative statement of the total number of births registered in each of the months during the last seven years, 1874 to 1880 inclusive:—

January .....	23,154	March .....	24,855
February .....	22,090	January.....	23,154
March .....	24,855	April.....	22,168
April.....	22,168	August.....	22,098
May.....	20,657	February.....	22,090
June.....	19,551	September.....	21,767
July.....	20,814	October.....	21,059
August.....	22,098	July.....	20,814
September.....	21,767	May.....	20,657
October.....	21,059	June.....	19,551
November.....	19,529	November.....	19,529
December.....	18,968	December.....	18,968

Of the seven years in which the reports shew the number of births in each of the months (in the three first reports of the decennium the numbers are not given), in but two does the month of March not stand highest. In 1877 and 1878, January returned the largest number, and March the second largest. February being a short month, the birth

rate in it, on an average, was proportionately nearly as high as that of any other high month, and higher than that of January. In other words, if each February in the seven years had contained 31 days instead of 28 (allowing for both leap-years), with the same average birth rate per day (about 110), it would have given a total of over 24,000 births—over 1,000 more than January, and about 2,000 more than either April or August.

The birth rate in February and March, it appears from the returns, fluctuated much less than in other months. In January, though high in the two years above named, the rate was not infrequently low—lower at times than in April, August, September or October, and sometimes standing fifth or sixth in the list of months.

March was, therefore, the most prolific month in the seven years, and probably of the decennium; and February, taking its shortness into consideration, came next; then January and April. December returned the smallest total number of births in the seven years, though in two of them the smallest number was returned in June, and in two others in November.

In the seven years there was a proportion of over 31 per cent., or little short of one-third, more births in the month of March than in December.

TABLE B.

SHewing the number and Sex of the Births in the Province of Ontario for 11 years from 1870 to 1880 inclusive.

Year.	Males.	Females.	Sex not given.	Total.	Illegitimate.	Still-born.	No. of Pairs of Twins.	No. of Males to 100 Females.	No. of Illegitimate to each 1,000 Births.	No. of Still-born to each 1,000 Births.	Triplets.

---

---

## PLURAL BIRTHS.

### TWINS.

During the nine years, 1872 to 1880, there were 2,600 births of twins—5,200 children. Of the 307,195 children born in these nine years, the births of which were registered, one in every 59 was therefore a twin. A larger proportion of twins was registered during the later than during the earlier years of that period.

### TRIPLETS.

Of triplet births, there were 26 during the same nine years, the numbers varying from one to nine births in each year. Three of the years, 1877-78-80, returned 20 of these 26 triplet births. The 26 births gave to the Province 78 children. Of the 307,195 children which were born in the Province in the nine years, one in every 3,945 was one of a triplet birth.

### ILLEGITIMATE BIRTHS.

For some reason, the number of illegitimate births registered in Ontario is increasing from year to year. During the nine years above mentioned (the illegitimates, and twins and triplets were not given in the Report of 1871), there were 3,549 illegitimate births registered, or one to each 87 of the total births. During the four first years, 1872 to 1875 inclusive, there was, on an average, one illegitimate in every 122 births; and during the last five years, 1876 to 1880 inclusive, there was one in every 75 births—a proportion over 60 per cent. greater than that of the first four years. In 1880 there were registered nearly 100, or 20 per cent., more illegitimate births than in any one of the other years, or one in every 63 births. It may be observed in this connection, that there were fewer marriages in 1879 than in 1878 or in 1880; and, for obvious reasons, the number of illegitimate children is influenced by the number of marriages.

In Nova Scotia, the registrations for nine years, 1866 to 1874, shewed a mean ratio of one illegitimate birth in every 48 births. The Secretary of Statistics in that Province stated that there was an endeavour on the part of mothers and interested relatives to evade the registration of the child as illegitimate, or to register it as not illegitimate. There is doubtless a strong natural tendency in this way in all countries.

In England the average proportion of illegitimates for a large number of years was about one in every 16 births; in some counties, indeed, it was as high as one in every 10, while in others not more than one in every 20 births was illegitimate. Of late years, however, there has been a marked tendency toward improvement in this respect, and one illegitimate in about every 21 births is now the average.

In Scotland the ratio of illegitimates has been still higher than in England, being about one in every 10 births; though varying a good deal in the different sections of that country. In that country, also, it appears there has been a decrease in the proportion of these births.

In Massachusetts for the ten years ending 1878, the average proportion was one in every 83 births. This was about 50 per cent. greater than that shewn by the ten years ending 1868, when it was one in every 122 births. Later returns from that State shew a still further increase; in the three years, 1876-77-78, the average proportion was one in every 62 births, or a little higher than the highest of any year in Ontario, including 1880.

In the different counties of Ontario, the proportion of illegitimate births varied very much. Those counties in which are situated the largest cities returned the largest proportions, due in a great number of instances to the fact that country girls found their way to the lying-in hospitals, which are only to be found in the large cities. Taking the last five years, 1876 to 1880, the average proportion for the whole Province was one illegitimate in every 75 births, as above stated. The county of Frontenac, in which is the city of Kingston, returned one illegitimate in each 23 births. This is the highest rate recorded. York, with Toronto, came next, with one in each 27. Carleton, with Ottawa, returned one in each 29. Wentworth, with Hamilton, returned one in 35. Next come Waterloo, giving one in 54; Brant, giving one in 65; Middlesex, one in 66. Several counties returned about the average, and many below it.

The smallest proportion of illegitimates was returned by the county of Grey, which gave only one in each 252 births. Next come Essex, with one in each 208; Lambton, with one in 200; Kent, one in 199; Perth, one in 185; Lennox and Addington, one in 173; Welland, one in 170; Peel, one in 166; then Peterboro', Haldimand, and Elgin, with about half the average of the Province.

It would be satisfactory, as before intimated, to know the nativity of the mothers in these cases.

---

## MARRIAGES.

### NUMBER OF MARRIAGES.

There were registered in Ontario, during the ten years under review, 116,342 marriages. From a careful estimate of the number of marriages per 1,000 of population in other countries and in certain localities in this Province, it appears that this number is about 80 per cent. of the actual number of marriages which took place. In 1871, as appears from the estimates, only about 75 per cent. of the marriages were registered; while in 1880 the proportion had increased to at least 90 per cent., or perhaps more—an increase during the ten years on the number registered in 1871 of 20 per cent., or of 15 per cent. on the whole estimated number of marriages registered from year to year.

In 1870 there were 8,668 marriages registered, making the total number reported in the eleven years of registration 125,010.

There was an increase in the number of registrations of nearly 50 per cent. between 1870 and 1880, or from 8,668 in 1870 to 12,783 in 1880. The increase was so constant from year to year, that in seven of the eleven years there was in each an increase over the previous year; while in but four of them was there a slight decrease as compared with the previous year. The last year, 1880, returned a larger number than any other year. (*See Table D, page 22.*)

TABLE C.—MARRIAGES.

SPECIFYING whether by License or Banns.

Year.	By License.	By Banns.	Not Stated.	Total.	Per cent. by License.	Per cent. by Banns.
1872	8,699	1,554	197	10,450	83.2	14.8

Totals..	83,593	11,258	670	95,521	87.5	11.7

\* No report in 1875.

## HOW MARRIED—LICENSE OR BANNS.

More than seven-eighths of the marriages in Ontario, it appears, are by license. The report for 1871 does not give the number married by license, nor that by banns, but Table C shews the respective numbers for the eight years 1872 to 1880, omitting 1875. In these eight years there were 95,521 marriages registered. Of these, 83,593, or 87.5 per cent., were by license, and 11,258, or 11.7 per cent., by banns. Of 670 of the marriages, it was not stated by the officiating clergymen whether they were by license or banns. As shewn by the table, there was a gradual and almost yearly increase in the number married by license during the eight years, and a decrease in the number married by banns. The decrease in the latter does not quite correspond with the increase in the former, because, as the table shews, there was a very large decrease in the number of marriages in which the returns from the clergymen were incomplete: a decrease from 197—almost 2 per cent. of the whole—in 1872 to only 6 in 1880, and this seems, as it were, to have increased the proportion of those married by license. So that, whereas the number married by banns decreased in the eight years 4 per cent., or from 14.8 per cent. in 1872 to 10.8 per cent. in 1880, the number married by license increased in the same period nearly 6 per cent., or from 83.2 per cent. in 1872 to 89.0 per cent. in 1880. The decrease of the publication of banns was caused by the new Marriage Act.

TABLE D.  
MARRIAGES by Months for Seven Years.

\* No report in 1875.

MARRIAGES ACCORDING TO MONTHS AND SEASONS.

Of all periods of the year, that approaching the end of it and including the Christmas season appears to be the most popular for getting married. In every year of the seven, 1873 to 1880 (omitting 1875), December returned more marriages than any other month. More marriages, indeed, were registered in this month, taking the totals for the seven years, by over 13 per cent. than in any other month, as shewn by Table D. Next to December, October returned the largest number of marriages, giving for the seven years a little over 5 per cent. more than January, which was third on the list of months as to numbers returned. In every year save one (1874), October returned more marriages than any other month, excepting December; in 1874, January returned a few more than October. Fourth in the list we find November, in which month, taking the totals of the seven years, over 9 per cent. less marriages were registered than in January. Next follow respectively, for the seven years, September, February, March, June, April, May, July and August. In the seven August months only 4,523 marriages were registered, while in the seven Decembers there were 10,060 registered, or 122 per cent. more than in August; and the registrations in December were little short of double those of July. The number of marriages registered in August, in each year, was considerably less than in any other month.

It is interesting, if not instructive as well, to observe how nearly the proportions in each month in almost every year tally with the totals of the corresponding months of the eight years; that is, in whatever position a month stands in the list as regards the totals—first, third, fifth, etc.—it stands in the same position in most of the eight years.

TABLE E.—MARRIAGES, BY AGES, FOR SEVEN YEARS.

YEAR.	Under 20.		20 to 25.		25 to 30.		30 to 35.		35 to 40.		40 to 45.		45 to 50.		50 to 60.		60 to 70.		70 to 80.		Over 80.		Age not given.	Total number of persons married.

## MARRIAGES AS RELATE TO AGES.

During the seven years, 1873 to 1880 (omitting 1875), there were registered in this Province the marriages of 170,142 individuals.

Of these 170,142 persons, 20,453, or 12 per cent., married under the age of 20 years. Of these 20,453, the returns shew that about 4.5 per cent., or 45 in each 1,000, were males—so that comparatively few males marry under 20 years of age.

Between the ages of 20 and 25 years, 74,684 persons were married, or 43.8 per cent. of the whole number married during the seven years. Of these, about 43.5 per cent. were males and 56.5 were females.

In Ontario, therefore, much more than half of those who are married (or between 55 and 56 per cent. of the total number), are wedded before reaching the age of 25 years—that is, of males and females together—though of males alone, only about 40 per cent. of the totals were under this age when married; while of females, over 70 per cent. were under 25 years. In other words, in about 40 of each 100 marriages the bridegroom is under 25 years of age, while in about 70 of each 100 the bride is under that age.

During the next five years of life, or between the ages of 25 and 30, taking males and females together, a little more than one-fourth of the total number of marriages took place. Between these ages, more than twice as many males as females were married.

Taking males and females together, more than 80 of every 100 persons who were married were under 30 years of age. Of the remainder, 8 or 9 in each 100 married between the ages of 30 and 35 years of age, and about 4 between the ages of 35 and 40 years. Only 5 or 6 in each 100 were over the age of 40 years.

## RELIGIOUS DENOMINATION OF PERSONS MARRIED.

The proportions to the whole number of marriages of the members of the various religious denominations who were married, were strikingly uniform from year to year, with three exceptions, viz., the Episcopalians, Roman Catholics and Methodists. Table G shews that the number of Episcopalians married (*i.e.*, the number of persons) decreased from 4,443, or 17.8 per cent. in 1876, to 4,271, or 16.8 per cent., in 1880; just 1 per cent. in the latter five years. The number and proportion of Presbyterians remained almost unchanged. The proportion of Methodists married increased from 34.8 per cent. to 36.5 per cent. in the same period. The Roman Catholic marriages decreased from 13.6 per cent. to 12.7 per cent. The numbers amongst the Baptists did not vary appreciably; there were a noticeable decline in the proportion of Congregationalists, an increase amongst the Bible Christians and a singular periodical rise or fall from year to year in the number of marriages of Quakers or "Friends."

In the first five years, 1870 to 1874, in those instances where the bride and bridegroom belonged to different Churches, the reports did not designate definitely the number of persons of each religious denomination married, but they gave the number of couples in those cases where the bride and bridegroom were of the same denomination. This divides the numbers of the two quinquennial periods, and, as it were, excludes from the calculations a large proportion of marriages where bride and bridegroom were members of different denominations. Below are tabulated the proportions of the couples married in the four principal denominations (as regard numbers) where bride and bridegroom were adherents of the same Church:—

YEAR.	EPISCOPALIAN.	PRESBYTERIAN.	METHODIST.	ROMAN CATHOLIC.
	Per ct. of the totals.	Per ct. of the totals.	Per ct. of the totals.	Per ct. of the totals.
1870.....	16.4	20.0	35.0	11.7
1871.....	18.0	19.2	38.1	13.4
1872.....	17.2	19.1	37.6	14.9
1873.....	17.2	19.0	37.9	14.0
1874.....	16.3	19.9	38.6	12.7

This shews that there was in the first five years also a slight decrease in the proportion of Episcopalians, as well as of Presbyterians who were married; while there was a marked increase in the proportion of Methodists, and a slight increase in that of the Roman Catholics.

## DEATHS.

## NUMBER OF DEATHS.

During the ten years under review there were 145,124 deaths registered in Ontario—76,355 males and 68,769 females. This gives an annual average provincial death rate of 8.2 per 1,000 of estimated living population, or 45 per cent. of the estimated number of deaths which actually took place.

Much more than twice as many deaths were registered in 1871 as in 1880, viz.: 9,182 in 1871, and 19,802 in 1880. In 1870, the first full year of registration, only 6,905 deaths were registered. The most marked increase in the returns of deaths took place in 1876, when an amended Registration Act came into force.

During the last half of the decennium, or since 1876, the most marked increase in the returns is shewn by the cities, towns and the more densely populated places, and from these, with few exceptions, the returns are now very complete.

### SEASON AND THE DEATH RATE.

It is interesting to observe, and might be made profitable to study, the regularity with which the mortality rises and falls with certain seasons of the year. In every year, six in all, in which the reports of vital statistics in Ontario shew the number of deaths which occurred in the different months, we find there were two periods in which the mortality was high, and two periods in which it was low.

#### THE TWO HIGH PERIODS.

Invariably one of the two periods of high mortality occurred during the cold, damp weather in early spring, and the other during the warm and usually dry weather in the latter part of summer. The spring high period is usually confined to the month of March. In 1874 and in 1880, however, this period continued into April; and in the former year, when the returns were much less complete than now, a few more deaths were registered in April than in March; but in all the other of the six years, March returned a larger number of deaths than any other month in the first half of the year. The second high period, following one of low mortality, has invariably occurred in August, this month always returning a larger number of deaths than any other month in the second half of the year.

Sometimes the highest death rate of the year occurs in the early spring, sometimes in late summer. Of the six years, however, in which the number of deaths in each month can be readily obtained, in two (1876 and 1878), the high mortality period was a little higher in August than in March, while in the other four years the mortality in March exceeded that of August. In three of the four years, the mortality was much higher in March than that in August, and in one it was but little higher.

Taking the total registrations of these two months for the six years, we find that March returned 10,380 deaths and August 9,609; or March 771, or over 8 per cent., more deaths than August. The six March months returned 489, or 5 per cent., more deaths than the six April months—or indeed than any other six months.

In the same period of time, there were in March 3,039, or 41 per cent., more deaths than in June, the month which invariably gave the lowest mortality; and 2,705, or 35 per cent., more than November, the month giving the second lowest mortality. In August there were 2,262, or 31 per cent., more deaths than in June; and 1,934, or 25 per cent., more than in November.

April came next to March in the number of deaths recorded, and returned only 489 less than March. Were April a month as long as March, with the same rate of mortality, there would only have been a difference of about 160 deaths for the six years, or 1.5 per cent. more deaths in March than in April.

Why there should be in March 35 per cent. more deaths than in November, or 30 per cent. more than in December—both being cold, changeable months—is worthy of investigation. One would suppose that the human system should be so fortified by several months of cold, bracing winter weather as to resist March changes and winds better than those of November, but this does not appear to be the case. Does not confinement, more or less constant, in ill-ventilated, over-heated rooms account for this?

### THE PERIODS OF LOW MORTALITY,

and especially as regards one of them—that after the summer high period—are more variable as to time. The mortality in June was invariably comparatively low. In every one of the six years the one low point which comes between the two high points always came in June. In two of the years, 1877 and 1880, the June mortality was considerably lower than that of any other month in the year, the death curve sinking very low; in two other years, 1874 and 1876, the mortality in June was almost as low as that of any other month, while in the other two years the difference in this respect was not great.

The second low period, which usually follows the summer high period, occurred in 1874 in December (though the mortality was not much lower than in June or November); in 1876 and 1877 it was in November; in 1878 it was again in December; in 1879 it was in October (much lower than in the December of that year); and in 1880, the second low point in the mortality, or rather the first one that year, was in January. There was in that year but a slight fall in the curve of death after the summer high point, the curve occurring in November, when it did not, however, sink nearly so low as in the previous January. The year 1880 was, therefore, an exceptional year, the mortality in January being unusually low—much lower than in the following autumn, when there was, indeed, but a slight fall in the death curve after the August high point.

The three months returning the largest average number of deaths for the six years are respectively March, April and August; but February, being a short month, comes next to April in the proportion of deaths returned. The three months, therefore, in which there was the greatest proportionate mortality are March, April and February. The three in the second half of the year shewing the greatest mortality are respectively August, September and July.

The diseases to which the greater mortality in the spring was due were invariably those of the respiratory organs, usually of an inflammatory character, such as inflammation, bronchitis, and congestion of the lungs. Invariably, too, a larger number of consumptives died in the early spring, after the winter's confinement in-doors, than at any other season. Heart diseases, too, were also more than usually fatal, and there was a larger proportion of deaths from diseases of the brain and nervous system.

The diseases which caused the summer high mortality were those of the alimentary canal or digestive organs—chiefly diarrhœa and dysentery, cholera infantum and “infantile debility,” so called.

The above remarks apply to all ages, but it is found that a larger proportion of the aged died in the cold season, and a larger proportion of young children in the warm season.

### SEX OF DECEDENTS.

During the ten years, on the average, 111.6 males died to every 100 females, or in all 76,355 males and 68,749 females.

As it might seem to some, at first, that as there were 111.6 deaths of males to every 100 females, and only 107.8 births of males to every 100 females, there would be a gradual decrease in the number of males as compared with that of females, it may here

be observed that, owing to there being on the whole such a large excess of births over deaths—32 births per annum per 1,000, and 18 deaths per annum per 1,000 of population—such apparent decrease does not take place, the excess of the deaths of males being more than counterbalanced by the larger number of births, while there is, as previously stated, a gradual increase instead of decrease in the number of males in proportion to that of females.

In Massachusetts and Rhode Island, while there are more males than females born, more females than males die each year. Hence the male population would soon be greatly in excess of the other were it not counterbalanced by immigration. In Great Britain, the numbers and proportions resemble those in Ontario.

In Ontario, during the first five years of the decennium, 1871 to 1875, the average number of males dying to each 100 females was a fraction less than 112 (111.8), while during the last five years, 1876 to 1880, the average number was 110 males to 100 females. This indicates a decline in the excess of male decedents over female decedents, though the decline may not be continuous or of long duration.

In a late Report of the Registrar-General of Great Britain, it is mentioned as a noteworthy fact that the mortality of males as compared with the mortality of females has been increasing for many years past. From the commencement of civil registration, the mortality of males as compared with that of females diminished until about the year 1851, when a change began, and has continued in the opposite direction to the present time. In 1879, the proportion was 113 males to 100 females.

In 1871,	4,856	males died and	4,326	females, or	112	males to	100	females.
1872,	5,633	“ “	5,103	“	110	“	“	“

## AGE OF DECEDENTS.

In the ten years, 1870 to 1880 (excepting 1875), there were 142,497 deaths registered, and of these 56,153, or very nearly 40 per cent., died under the age of 10 years.

The proportion of deaths under 10 years of age was somewhat greater during the latter five years, 1876 to 1880, than during the former five, 1870 to 1874. During the first mentioned period, 1876 to 1880, 94,254 deaths were registered; of these, 38,075, or

40.3 per cent., were of children under 10 years of age; while during the other period (1870 to 1874), 48,253 deaths in all were registered, of which, 18,078, or 37.3 per cent., were of persons under 10 years of age. This may be due to more complete returns being made during the more recent years; for, as I have before stated, in incomplete returns the registration of the young is more likely to be neglected than that of those more advanced in years. Complete returns may shew a still greater proportion of deaths amongst the young.

The above is the only age at which the young died, in which it is possible to make comparisons for so large a number of years. Previous to 1875, the tables shewed the numbers dying under the age of 3 years, between 3 and 10 years, and between 10 and 21 years; after 1875, or from 1876, the tables give the numbers dying under the age of 1 year, between 1 and 5 years, from 5 to 10 years, and in each decennial period of life thereafter.

During the first five years of the decennium, 1870 to 1874, of the 48,253 deaths registered, 22,208, or 46 per cent., were of those under 21 years of age. A somewhat larger proportion died under the age of 20 years during the latter five years of the decennium, 1876 to 1880; during that period a total of 94,254 deaths were registered, and 44,284, or 46.9 per cent., were of persons under 20 years of age. It is therefore evident that either the proportion of deaths amongst the young is increasing, or, as the returns become more complete the deaths of a greater proportion of young persons are registered; which, if the latter be true, goes to prove that with incomplete returns a larger proportion of young than of old persons escape registration.

The returns shew that not much less than one-half of all the deaths during the last five years were of persons under 20 years of age, but it is probable that fully one-half, if not a little more, of the deaths occurred at ages under 21 years, or before reaching the average period of adult life. Were the returns complete, it is probable they would shew that one-half of those who die in this Province die before reaching manhood or womanhood, or the age of 20 years.

In 1877, more than half of all the deaths were of persons under 20 years of age.

In Norway, it appears, only 25 per cent. of the deaths are of those under the age of 20 years.

Of those who died during the last five years in Ontario, as the returns shew, 22.5 per cent. were infants under the age of 1 year, and 36.1 per cent., or much more than one-third of children under the age of 5 years.

In England, about 25 per cent. of the deaths are of infants within the first year of life; in Scotland, 19 per cent.; in Massachusetts, 21 per cent.; and in Nova Scotia, as appears from returns from that Province some years ago, only about 17 per cent. At different ages under 5 years, in England, 42 per cent. die; in Scotland, 38 per cent.; in Massachusetts, 34 per cent.; and in Nova Scotia, 27 per cent. A smaller proportion, therefore, die in Ontario at the above ages than in either England, Scotland or Massachusetts, but a larger proportion than in Nova Scotia.

In looking down the column giving the percentage of deaths at the different ages for the last five years, we find that 22.5 per cent. of all the deaths recorded were of infants

under the age of 1 year ; that 12 per cent. were of children between 1 year and 5 years of age, and only 4 per cent. of children between 5 and 10 years of age. Between the ages of 10 and 20 years there was a further fall in the mortality. Though 6 per cent. of the deaths occurred between these ages, the period, it must be remembered, is twice the length of the previous one. A rise then took place between the ages of 20 and 30, 9 per cent. of the deaths occurring during this period of life, or a ratio of 50 per cent. more than in the previous decennial period. After the age of 30 there was another fall in the mortality, which continued without change up to the age of 60 years, when there was a second increase up to 80 years ; and then another decrease to the end of all—100 years old and over.

The rises and falls in the mortality at different ages or periods of life took place, as the table shews, in each of the five years under notice, though the proportion varied somewhat from year to year.

Hence, in Ontario, it appears there are fewer deaths between the ages of 40 and 50, and between 50 and 60 years, than during any of the other decennial periods ; though in the second and fourth periods, or between the ages of 10 and 20, and between 30 and 40, the mortality is but little greater than in those between 40 and 60. The most critical period of life between the ages of 10 and 70 years, is that between 20 and 30 ; this period is about 50 per cent. more critical than any between the ages of 10 and 60. When one reaches the age of 40 years, therefore, his or her chances of living to the age of 60 years are about 50 per cent. greater than they were at the age of 20 years.

#### AGES OF MALE AND FEMALE DECEDENTS.

The rate of mortality at the different ages amongst males and females, when considered separately, differs materially from that shewn when they are considered together.

For example, in 1880, of males and females estimated together, 22.5 per cent. of the total number of deaths were of infants under the age of 1 year ; while of all the male decedents, 23.5 per cent. were under 1 year ; and of all female decedents, only 20.6 per cent. were under that age. So that a much larger proportion, or about one-seventh more, of males than of females died at this early period of life. In 1879 the difference was still greater, the proportions being 23.3 per cent. of males to 19.5 per cent. of females. In 1877 the respective proportions were 25.6 per cent. and 20.9 per cent.

The averages of the five years, 1876 to 1880, in this respect, were : of males and females together, 22.5 per cent. died under the age of 1 year ; of males alone, 23.6 per cent., and of females 20.3 per cent. ; or a difference of more than one-seventh, or 16 per cent. The proportions in 1880 were much the same as those of the average of the five years, as may have been observed.

Later in life, on the other hand, as for instance at ages between 15 and 40—with mothers the period of maternity—many more females than males died. Of males and females together, during the latter half of the decennium, 9.2 per cent. of the deaths were of persons between the ages of 20 and 30 ; whereas of males alone, only 7.4 per cent., and of females, 10.5 per cent., died during this period of life—about 42 per cent. more females than males.

---

---

It would doubtless be found that about the same proportions, as regards the deaths of males and females, prevailed between the ages of 15 and 35 years, or probably between 17 or 18 years and 37 or 38 years. During this period of life, in most countries, many more females than males usually die. This does not seem to be in accordance with nature, and must be due largely, if not wholly, to unhygienic habits of life, fashion, etc.

The returns shew that in Ontario 28 per cent. more females than males died, in 1879, between the ages of 20 and 40; and that in 1874, about 50 per cent. more died between the ages of 21 and 40.

It is worthy of note that in every one of the five years (1876 to 1880), over 10 per cent. of all the females who died were between the ages of 20 and 30 years—the proportion ranging during the five years only between 10.1 per cent. and 10.8 per cent. Of males, too, in every year except one, over 7 per cent. died at these same ages; in 1877, 6.8 per cent. of the deaths were of males in this period of life—shewing that the proportion in both sexes was very constant from year to year.

#### RECAPITULATION.

Of all the deaths recorded during the ten years, 1870 to 1880, excluding 1875, (in over 2 per cent. of the total deaths recorded in the ten years the age was omitted in the Schedule), 47.8 per cent. were of those under 20 years of age; 17.0 per cent. were of those between 20 and 40 years of age; 12.6 per cent. adults between 40 and 60 years; 7.7 per cent. were between 60 and 70 years; and the remainder, 15 per cent., were of persons more than 70 years of age.

---

---

 ON CAUSES OF DEATHS.

In noticing the various causes of deaths it will be necessary to deal chiefly with totals only, omitting for the most part details as to seasons, sex and age; this partly is due to want of space, and partly to the difficulty of obtaining from the reports the necessary details for each disease.

There are two points in this connection which may be noticed and borne in mind:

1st. As a rule, much the largest proportion of young children die during the very warm season, and from diseases incident to it; while the largest proportion of old people die during the very cold season, and from diseases most peculiar to that period of the year. The deaths of individuals approaching middle life occur most frequently in early spring.

2nd. Of those diseases most prone to destroy life in the very young, a larger number of males than of females die; while of those diseases which are most common and fatal during middle life, or from 15 or 20 years of age to 45 or 50 years of age, most females die.

Five classes only of diseases, as classified in the reports, will be dealt with, namely: Zymotic or Miasmatic, Tubercular, diseases of the Nervous System, of the Respiratory Organs, and of the Urinary Organs. These comprise the principal diseases, and cause by far the largest proportion—the great bulk, indeed—of all the deaths. After these all the principal diseases will be noticed separately.

## ZYMOTIC OR MIASMATIC DISEASES.

Of the 142,497 deaths from all causes registered in the Province during the ten years (1870 to 1880, omitting 1875), 32,498, or 22.3 per cent., were caused by zymotic or miasmatic diseases, so recorded.

The diseases included in this class (called Zymotic from a Greek word signifying fermentation, or Miasmatic from another Greek word signifying a noxious or poisonous exhalation floating in the air) are for the most part more or less contagious in character, and communicable from one person to another. The class comprises the various fevers—typhoid, malarial and scarlet fevers—and diarrhœa, dysentery, cholera infantum, diphtheria, croup, whooping-cough, measles, and small-pox.

The proportion of deaths from these diseases is manifestly not on the increase in the Province, but, on the other hand, is apparently decreasing somewhat. The proportion to the total death rate of deaths from all diseases of this class during the last five of the ten years, was 21.9 per cent., and of the first five 24.4 per cent. It is found that during the last three years, 1878–80, there was a still more marked decrease, the proportion for the period being only 20.6 per cent. of the totals, or a fraction over 20 deaths from these causes in every 100 from all causes. In 1872 the proportion for the year was 28.4 per cent., and was largely due to an epidemic of scarlet fever which prevailed.

This decrease, it is probable, may be owing in a measure to improved drainage in certain localities; but the absence of any severe or special epidemic of any of the diseases in the later years is doubtless the chief cause of the decrease. Such epidemics are more or

less periodical, but their spread may in a large measure be prevented and their ravages curtailed by proper sanitary precautions and measures applied in schools and families.

As a class these diseases destroy life at all ages: but some, as diphtheria, croup and scarlet fever, more especially attack the young; while others, as typhoid and malarial fevers, are more prevalent amongst those who are more advanced in life. The difference between the number of deaths of males and of females from these diseases is not marked nor worthy of special notice, beyond reference to the common rule mentioned in the early part of this section.

#### TUBERCULAR DISEASES.

During the decenniad under notice 17,939 deaths were recorded from tubercular diseases alone—12.3 per cent of the total number upon record. Consumption (of lungs) and hydrocephalus (water on the brain) are the principal diseases of this class, and caused 17,421 of the 17,939 deaths. From the former alone, there were 16,016 deaths recorded, and from hydrocephalus 1,405. The remaining 518 deaths were chiefly from tabes mesenterica, commonly known as consumption of the bowels.

The proportion of deaths from all the tubercular diseases together was somewhat less during the last five years of the decenniad than during the first five, shewing an apparent decline in the mortality from this class of diseases of from 12.9 per cent. to 12.4 per cent.; the proportion of deaths from consumption, however, was greater during the last five years than during the first five, as will be mentioned further on. The decrease in the number of deaths from diseases of this class was mainly owing to a decrease in the mortality from hydrocephalus. During the first five years, the deaths from this disease alone amounted to 1.2 per cent. of the total number of deaths recorded from all causes, and during the last five years to only 0.9 per cent. It is difficult to assign any cause for this decline, amounting to one-fourth, or 25 per cent., in the mortality from this disease.

Many more females than males died of diseases of this class, though the excess in the mortality amongst females as compared with the mortality amongst males was owing to many more females than males dying of consumption. From hydrocephalus and tabes mesenterica about 50 per cent. more males than females died; while from consumption, on an average, from 20 per cent. to 25 per cent. more females than males died, in 1879, 34 per cent. more, and in 1880, 30 per cent. more, of the former than of the latter died of this disease.

A much larger proportion of the victims of hydrocephalus and tabes mesenterica die young than do those of consumption, which, on the other hand, is most fatal during early manhood and womanhood and middle life.

#### DISEASES OF THE NERVOUS SYSTEM.

From diseases of the nervous system, chiefly of the brain, there were during the decenniad 14,678 deaths registered, or 10 per cent. of the total number recorded from all causes.

During the first five years there was a much greater mortality returned from diseases of this class than during the second five years; the proportion being 11.7 per cent. in the

former five and 9.2 per cent. in the latter five. This excess in the mortality was, it appears, chiefly, if not wholly, due to an epidemic of cerebro-spinal meningitis which prevailed in the years 1872 and 1873. In 1873, 324 deaths were recorded from this disease alone, while in the following year only 93 were so recorded. In 1879 only 27, and last year 32 deaths from this disease were registered.

In 1873, 1,019 deaths from this disease and from "convulsions" (so recorded), brain disease, spinal disease and meningitis, were registered. Cerebro-spinal meningitis was, it appears, a new disease at that time in this Province; it had not been then generally recognized here, and it is probable that not a few of the deaths registered from convulsions, meningitis, etc., were from true cerebro-spinal meningitis, many symptoms being common to all these diseases—cerebro-spinal meningitis being indeed, it appears, an inflammatory condition or a congestion of the brain and spinal cord. During the last two years, 1879–80, there were in each year only between 600 and 700 deaths from these five above-mentioned diseases; and it is probable, therefore, that besides the 324 deaths recorded in 1873 as from cerebro-spinal meningitis, there were really many more which fell under the head of one or the other of the diseases referred to.

In 1873 the deaths from nervous diseases amounted to 13.6 per cent. of the total number of deaths upon record for that year, while the average for the ten years was only 10.1 per cent. of the totals. This shews that there was in that year considerably over a third more than the average proportion of deaths from these affections.

It is satisfactory to find so marked a decline in the number of deaths from this very fatal malady, and it is to be hoped that measures may be employed that will prevent it becoming again epidemic in this Province.

Of the deaths from the usual nervous diseases there were, on the average, many more of males than of females. In 1876, for example, there were 1,026 deaths of males and 851 of females, or more than 20 per cent. more males than females.

#### DISEASES OF THE RESPIRATORY ORGANS.

Though there was a decrease in the latter years of the decennium in the proportion of deaths from the diseases included in the above three classes of disease, there was an increase in the proportion of deaths from diseases of the respiratory organs—an increase from 9.8 per cent., of the total number of deaths recorded from all causes, in the first five years, to 10.2 per cent. in the last five.

Exclusive of consumption, 14,347 deaths were registered during the ten years as from these diseases; or just 10 per cent. of the total number of deaths recorded. From consumption alone, which further on will be considered by itself and more fully, 16,016 deaths were registered; making in all, 30,363 deaths from lung diseases.

The difference between the number of deaths recorded or classified under this head in 1870 and in 1880 is very great, there being a proportion of about 35 per cent. more in the latter than in the former year, or 8.9 per cent. of the totals in 1870 and 12 per cent. in 1880. In 1879, however, the proportion was only 10 per cent. of the totals. The great increase in 1880 was chiefly owing to the large mortality from acute lung diseases, congestions and inflammations, which occurred in the early spring.

During the five years, 1870 to 1874, the proportion of deaths recorded from diseases of the respiratory organs, exclusive of consumption, was 9.7 per cent. of the total number of deaths from all causes; during the five years from 1876 to 1880, the proportion was 10.2 per cent. of the totals—an increase in the last five over the first five of between 5 and 6 per cent.

Quite different from tubercular disease of the respiratory organs, or consumption, were the diseases under this head, exclusive of consumption, as regards the proportion of deaths in the two sexes. While from consumption many more females than males died, from 20 to 25 per cent. more males than females died of the other diseases of the respiratory organs, chiefly inflammation and congestion of the lungs, bronchitis and pleurisy.

By far the largest proportion of deaths from all these diseases took place in March, April and May.

#### DISEASES OF THE URINARY ORGANS (BLADDER AND KIDNEYS).

The total number of deaths recorded in this class of diseases in the ten years was 2,027, or 1.3 per cent. of the total number of deaths from all causes. There was a proportion of about 30 per cent. more deaths in 1880, and over 40 per cent. more in 1879, than in 1870. The difference was very little, however, between the number of deaths in the first five years of the ten, and in the last five, and showed but a slight increase, or from 1.41 per cent. to 1.42 per cent. of the totals for each period respectively.

From the above one may learn the value of basing calculations, in regard to vital statistics especially, upon the results of a series of years, as the ultimate conclusions thereby supported may be very different from those based upon the results of only a few years.

In the four years, 1871 to 1874, the proportionate mortality was somewhat greater still than in the three years 1876 to 1878.

Of diseases of the kidneys and bladder about 170 per cent. more males than females died; or more than 2.5 males to 1 female.

No deaths from these diseases occurred in the very young, indeed nearly all of the decedents were considerably advanced in years; few were under 20 years of age, not many were under 40, and the greater proportion were over the age of 60.

#### PHTHISIS (WASTING)—CONSUMPTION OF LUNGS.

From this most destructive disease 16,016 deaths were registered in the decenniad; being 11 per cent. more than from any other single disease, 11.6 per cent. more than from all other diseases of the respiratory organs together, and nearly 13 per cent. more than from all the diseases of the nervous system, including the brain.

As it has been pretty conclusively shewn that only about 45 per cent. of all the deaths which took place during the ten years were recorded, there were probably not less than 35,000 deaths from consumption alone in the Province during the decenniad.

There was a somewhat larger proportion of deaths from this disease (compared with the totals) during the last five years of the ten than during the first five; in the former period, 11.15 per cent. of the totals, and in the latter, 11.28 per cent., were caused

by it ; that is, a difference of one-thirteenth of one per cent., or one more death from it in each 1,300 deaths from all causes.

Very many more females than males died of consumption during the decenniad. The disease is always, everywhere, it appears, much the most fatal amongst females. During the last five years, 1876 to 1880, 35 per cent. more females than males died of this disease—5,952 females and 4,382 males, or 1,570 more of the former than of the latter. During the period of maternity in females, or from the age of 17 or 18 years to that of 48 or 50 years, as the annual reports shew, nearly 50 per cent. more females died than males of like ages ; while during the still more critical period of womanhood and manhood, the difference was vastly greater than this, being more than two females to one male.

Another marked feature in connection with this disease is that, on an average, over 30 per cent., or nearly one-third, of the deaths from it were of those between the ages of 20 and 30 years.

#### CANCER.

The returns shew a large increase during the decenniad in the mortality from cancer, though last year, 1880, there was a slight decrease.

The first five years gave one death from cancer in every 82 from all causes ; the last five, one in 62 ; the average for the ten years was one in 67 from all causes. (In these special diseases which cause fewer deaths, it will be more convenient to give the proportions and make the comparisons in this way than to give the rate per centum, as in those diseases which cause a very large proportion of deaths.) In 1870 there was only one death from cancer in every 90 from all causes ; in 1871, one in every 85 ; in 1872, one in 79 ; in 1873, one in 89 ; in 1874, one in 72 ; in 1876, one in 57 ; in 1877, one in 58 ; in 1878, one in 62 ; and in 1879, one in 61 ; and in 1880 one in every 71 from all causes. Nearly 30 per cent. more females than males died of this disease. The age at which the disease is most common and fatal is that between 50 and 65 or 70 years, which may be called the cancer period of life ; very many more victims, proportionately, die of it at this period than at any other. It is very rarely manifested under the age of 20 years.

#### HEART DISEASE.

During the ten years 5,079 deaths were recorded under the head of "heart disease." During the first five years, 1871 to 1875, 3.4 per cent. of all the deaths recorded from all causes were of this nature, or one in every 29 deaths from all causes ; in the last five years, 1876 to 1880, 3.6 per cent. of the totals were from heart disease, or one in every 27 from all causes. Of the first three years, 1871 to 1873, the average mortality from heart disease was about one death in each 30 from all causes ; of the last three years, 1878 to 1880, the average was one in each 25 from all causes. There was, therefore, a notable increase during the period under notice in the number of deaths from the different forms of heart disease.

More males than females died of heart disease. The most critical period of life in this disease, or that giving the greatest mortality, was in the seventh decennial period of life—that between the ages of 60 and 70 years, though many died between the ages of 50 and 60 years, and also between those of 70 and 80 years ; few comparatively died of it under 20 years of age.

## LUNG DISEASE.

Under the indefinite head of "lung disease" there were 3,296 deaths. These, including congestion of the lungs, are all diseases not included under the more definite heads of "inflammation of the lungs" and "bronchitis." The mortality from the affections included under the head of "lung disease" was very fluctuating. In 1870 only 42 deaths were so recorded, or one in every 164 deaths from all causes. In 1874 there were 533 deaths, or one in every 21 from all causes. In 1876 there was one in about every 30 of the totals. The average for the ten years was one in every 43. During the first five years the average was one in every 44, and in the last five, one in every 42; thus shewing a slight increase in the mortality.

## PNEUMONIA—INFLAMMATION OF LUNGS.

In the ten years, 7,212 deaths were recorded under this head, the proportion varying each year from one death from pneumonia in every 15, to one in every 25 from all causes, and in 1873, to one in 40 from all causes; the average for the first five years was about one in 20, and for the last five, one in 19, thus shewing a slight increase in later years of about 5 per cent. The year of greatest mortality was 1880, which gave one from pneumonia to every 15 from all causes, though 1870 was nearly about the same proportion.

About 33 per cent. more males than females died of this disease. These were, indeed, the exact proportions in totals for the last six years, varying somewhat each year. Very much the largest proportion died in the winter and early spring months, especially in March and April; many died of it in February, May and January.

The proportions dying at different ages do not vary much in this or other lung diseases (excepting in the tuberculous), one age not being much more exempt than another. A large number of young children in this climate, however, fall victims to this disease from exposure after being housed in unventilated and too warm rooms.

## LIVER DISEASE.

From liver disease, including inflammation of the organ (not at all a common disease) and jaundice, there were 2,097 deaths during the decenniad; one in every 68 from all causes in the first five, and one in every 67 from all causes in the second five years, or an increase of about 1.5 per cent. Many more males than females died of disease of this organ. By far the largest proportion of the deaths occurred between the ages of 50 and 70; but many persons died between 40 and 50, and between 70 and 80 years of age.

A good many young children, chiefly under the age of one year, died of jaundice.

## KIDNEY DISEASE.

From diseases of the kidney, including diabetes and nephria, or Bright's disease, there were recorded in the decenniad 1,409 deaths, or .9 per cent. of the total number of deaths recorded, being one from one or other of these affections in every 101 deaths from all causes. In the first five years there was one in every 112 deaths, and in the last five years one in every 96 deaths from all causes.

There were 356 deaths, or about one-fourth of the whole, from diabetes alone, being an average for the ten years of one in each 400 deaths from all causes. In this disease there was a decided increase in the average in the last five years, which gave one from diabetes in every 384 from all causes, while the first five gave one in every 434. The increase was especially marked in 1879, and to a large extent in 1880.

From Bright's disease there was a very large increase of cases in the later years, but it would appear from the fact that so few deaths were registered under this head in the first two or three years of the decenniad that many of those who died from this cause were registered as having died of kidney disease simply.

About twice as many males as females died of kidney diseases. Taking the six years in which the reports give the sexes as they relate to the different diseases, the deaths from these affections of 705 males and 355 females were registered. Of deaths from diabetes during the six years, 174 were of males and 93 of females; and from Bright's disease, 172 males and 132 females. It appears, therefore, that a greater proportion of females die of Bright's disease than of any other kidney disease, the difference in the number of deaths of males and of females from this affection being less than from any of the others. By far the largest proportion of deaths from affections of the kidneys were of individuals advanced in years. A few young persons in their teens died from diabetes, but few victims died of the other diseases before the age of 30.

#### APOPLEXY.

From this disease 1,950 deaths were registered during the ten years. There was a much larger proportion of deaths from it registered during the first than during the last five years; in the former period there was one death from this cause in every 61, and in the latter, one in every 81 from all causes. A larger number of males than of females died of the disease. It is especially a disease of advanced life; very few persons die of true apoplexy before reaching the age of 40 years.

#### PARALYSIS.

This disease, on the other hand, shews a slight increase in later years, of from one death from it in every 59 from all causes in 1870, to one in every 56 from all causes in 1880; or one in every 60 for the first five years, to one in every 57 for the last five. In 1872 there was only one death from this cause in every 68; and in 1879 there was one in every 61; while in 1878 there was one in every 52.

The returns shew a gradual increase from 1872 to 1878, except in 1876, when the proportion was less than in the previous year.

#### DIARRHŒA.

During the decennium there were 3,784 deaths from diarrhœa. A much smaller proportion of persons died of it on an average during the last than during the first five years; or one in every 33 of the total number of deaths in the first five, and one in each 40 in the last five. Much more than one-half of decedents whose ages are given in the

reports died under the age of one year; few died of it in middle life. About three-fourths died during the months of July, August, and September.

#### DYSENTERY.

From this disease 1,555 deaths were registered in the ten years, but there was nearly three times as large a proportion on the average in the first five as in the second five; one death being recorded from dysentery in every 52 in the former period, and only one in every 151 in the latter period. In 1872 there was a large proportion of deaths from this cause, as well as from diarrhœa; there being one fatal case from dysentery in each 31 deaths. More than 3.1 per cent. of the total number of deaths for the year resulted from this disease. It sometimes prevails epidemically. While many young children die of dysentery, it is also a common and fatal disease among the aged.

#### CHOLERA INFANTUM.

The returns shewed 2,380 deaths of infants or very young children from cholera infantum; nearly all, indeed, were under the age of one year. A somewhat larger proportion of deaths from this disease occurred in the last as compared with the first five years of the ten, viz., one in 59 and one in 60 respectively. Almost all of the deaths occurred in July, August and September; either in the very warm weather, or in the period immediately following it. On an average, during the last six years, 28 per cent. more males than females died of cholera infantum. This is one among several proofs, that of those diseases which especially attack the young, more males than females die.

#### SCARLET FEVER.

By this destroyer of young life, the deaths of 4,320 persons were caused in the decennium, or about 3 per cent. of all the deaths recorded, the average being 432 per year, or one from scarlet fever in every 33 from all causes. But this is one of those diseases which frequently prevail epidemically, and, as a result, the mortality from it fluctuates very much from year to year. In 1870 there were 228 deaths from scarlet fever in a total of 6,905 deaths from all causes, or one in every 30—somewhat more than the average of the ten years. In the next two years, 1871–72, there were 1,272 deaths recorded, nearly a like proportion in each year, or much more than a fourth (nearly 30 per cent.) of the whole number in the ten years from the same cause; thus giving one in 15 from all causes. In the next year, 1873, there were only 176 deaths from scarlet fever, or one in every 62 from all causes for the year. There was, therefore, more than four times as large a proportion of deaths from this disease in 1871 and 1872 than in the following year. In 1874, for every 43 deaths recorded there was one from scarlet fever; in 1876 the proportion was the same, though both the number of deaths from this disease and the total number of registrations of deaths were nearly double what they were in 1874. In 1877 there was a large increase in the mortality from scarlet fever, and the proportion increased to one in every 24 from all causes; in 1878 it fell to one in 40, and in 1879 to one in about 70, the lowest in the decade; in 1880 it rose again, and gave one in every 48

The first five years gave an average of one from this disease in every 25 from all causes, and the last five one in every 39.

In 1871-72 the epidemic was much more marked and fatal in some counties than in others. In 1872, ten of the forty counties, or united counties—namely, Essex, Halton, Huron, Leeds and Grenville (United), Oxford, Peel, Simcoe, Waterloo, Wellington and York—returned 410 deaths, or little short of two-thirds of the 642 cases. Parry Sound, Thunder Bay and Prince Edward were the only counties in which there were no deaths recorded.

In the severe epidemic of 1877, when 858 deaths were recorded as from the disease, five of the above counties (Peel, Simcoe, Waterloo, Wellington and York) suffered severely. In York there were three times as many deaths from this disease registered as in 1872 ; indeed, more than one-sixth of the total number of deaths from this cause were in York. The other four counties suffered on an average about as in 1872. Next to the five counties mentioned, the extreme eastern counties of Lanark, Prescott and Russell, Renfrew, Stormont, Dundas and Glengarry suffered most in 1877, as if the disease had spread east and north, from Leeds and Grenville, during the intervening five years, sporadic cases causing a few deaths in each of the counties in each year until 1878. The above counties, with York and Wentworth, returned more than one-half of the total deaths from this disease in this epidemic. Excepting Wentworth and York, none of the central or western counties suffered very severely in 1877 ; Northumberland and Durham, Ontario and Lincoln, were, however, the greatest sufferers. Algoma and Thunder Bay alone escaped its ravages.

#### MEASLES.

Though by many this is not regarded as a disease much to be feared, it caused in the ten years 736 deaths, or one in 195 of the total from all causes. The largest proportion of these was of children between the ages of one and 5 years, though many of the deaths were of infants under one year ; a few died at ages above 30 and even 40 years.

The number of deaths from this disease varied much, too, from year to year. In 1870 there were 47 deaths recorded, or one in every 147 of the total recorded for the year ; in 1871 there were 40 deaths, or one in every 259 of the totals ; in 1872, 61 deaths, or one in every 176 ; in 1873 the mortality rose to one death from measles in every 133, and in 1874 to one in every 96 deaths from all causes. The five years gave one death from measles in 141 from all causes. In 1876 there were only 31 deaths recorded from measles, or one in 600 of the total ; in 1877 there was a still smaller proportion ; and in 1878 only five deaths from measles were recorded in a total of 17,808 ; in the next year, 1879, there were 67 deaths from the disease, or one in every 268 ; and in 1880, 265 deaths, or one in every 74 of the total, the largest proportion on record. So few deaths, however, occurred from this disease in the three previous years, that the proportion in the last five was not nearly so great as in the first five, being one in every 237. In 1874, when a much larger proportion of deaths from measles took place than in any other of the first five years, just one-half of them occurred in the counties of Brant, Essex, Kent, Middlesex, Simcoe and York, which returned 10, 6, 12, 6, 9 and 11 respectively.

In the epidemic of measles of 1880, Carleton suffered most, returning 40 deaths

from the disease; Essex and Hastings came next, giving 21 each; Huron returned 11; Middlesex, 12; Northumberland and Durham, 13; Peterborough, 10; Prince Edward, 8; and Wellington, Wentworth and York, 12, 15 and 27, respectively; these twelve counties returned 190 of the 265 deaths.

#### WHOOPING-COUGH.

From this disease, which is also too often thought lightly of, there were 1,803 deaths in the decenniad, or one in every 78 from all causes. The year in which the smallest number died of this disease was 1871, when 73 deaths from it were returned, or one in every 125 of the totals. From this there was a gradual increase from year to year till 1876, when one death in 50 of the total was from whooping-cough. There was then a gradual decline in the mortality during the next three years, until in 1879 there was but one from this cause in every 106. In 1880 the mortality increased to one in every 66 from all causes. In the most fatal year, 1876, York returned 60 deaths from whooping-cough; Wentworth, 46; Wellington, 29; Frontenac, 26, and Simcoe, 21; about half of the total number of deaths from this disease occur in these five counties. Northumberland returned 18; Grey, 17; Oxford, 15; and Waterloo, 13. From the counties of Prince Edward, Hastings, Thunder Bay and Muskoka, only, no deaths were returned; the other counties returned from 2 to 4, 8, 10 and 11 deaths each. In 1880, York, Wellington, Wentworth and Kent suffered most from this disease, and returned respectively 40, 27, 17, and 19 deaths; from Prince Edward, Renfrew, Lanark, Victoria and Peel, no deaths were returned from this cause.

Many more females than males died of whooping-cough. More than one-half of the decedents were under the age of one year, and nearly all were under 5 years. There were deaths during the summer as well as during the cold weather.

#### CROUP.

From this disease 2,603 deaths were registered in the ten years; in the first five years 659, and in the last five 1,944—or one death from croup in every 73 and 48 respectively, for each period, of the total number of deaths returned from all causes. This shews a very large increase in the latter years in the mortality from this disease. The increase was from one in every 101 of the total in 1870, to one in every 45 in 1880. The increase was not marked until 1876, when the mortality was as great as in 1880, though it was less than in 1877 and 1878. More than half the deaths from this disease were of children between the ages of 1 and 5 years, and nearly as many died of it above the age of 5 years as under 1 year.

#### DIPHTHERIA.

During the ten years, 5,001 deaths were registered as caused by diphtheria. There was an average of one death from this cause in about every 28 deaths from all causes. The first five years gave only one death in every 61 of the total, and the second five one in every 22 of the totals, or nearly three times as large a proportion. With one exception, in 1872, there was a gradual and constant increase from year to year in the proportion of deaths

from diphtheria, for the nine years 1870 to 1878, inclusive. The proportions were one death in each 94, 55, 65, 64, 47, 31, 22, 20, and 18 of the totals in each of the nine years respectively. In 1879 there was one death from diphtheria in every 31 from all causes; and in 1880, one in every 23. There was, therefore, more than five times as large a proportion of deaths—five times as many deaths in proportion to population,—from this cause in 1878 as in 1870, and more than four times as large a proportion in 1880 as in 1870.

Every part of the Province suffered much from this disease, and in every county many deaths were recorded. In certain years some of the counties suffered less than others, while in the next, or another year, those counties which had to some extent escaped, suffered in their turn, and so on throughout the decenniad. No county wholly escaped, and on the whole the average or proportion of deaths in the different counties did not vary much.

As in croup, a large proportion of the victims of diphtheria were under 5 years of age; but a large proportion were of deaths over 5 years, between 5 and 10 years, and between 10 and 20 years.

Much has been written of late in reference to the identity of croup and diphtheria. In 1879 a Special Committee of the Royal Medico-Chirurgical Society, after examining into the relations existing between the so-called two diseases, arrived at the conclusion that they are virtually identical, in corroboration of which view it may be here noted that most of the counties in this Province, and also those seasons which have returned a high mortality from diphtheria, have also returned a high mortality from croup. It is not easy to explain the great increase in the mortality from croup within the last few years, except on the theory that it is either identical with diphtheria, or has somewhat of a contagious character, and prevails epidemically in certain localities and seasons.

#### TYPHOID FEVER.

During the ten years under notice there were 3,648 deaths registered as from typhoid fever, and in the eleven, including 1875, there were 3,871 deaths. There was a much smaller proportion of deaths from this disease during the last five years than during the five from 1870 to 1874; the decrease in the mortality from it in late years was, indeed, marked. In the five years 1870 to 1874, there were recorded 1,676 deaths from typhoid fever in a total of 48,253 deaths from all causes, or one death from this disease in every 28 from all causes; in the five years from 1876 to 1880, there were 1,972 deaths from typhoid fever in a total of 94,354, or one death from this cause in every 47 of the total.

This is especially a disease which attacks persons in the prime of life; the majority of its victims are between the ages of 15 and 40 years. Between the ages of 20 and 30 a much larger proportion of deaths occurred than during any other decennial period of life. The mortality in both sexes was much the same. While every month contributed a large share of victims to the disease, the autumn months gave the greatest average mortality from it.

#### SMALL-POX.

The mortality from this disease has fluctuated very much during the ten years, as shewn by the table. In 1870; there were only two deaths recorded as caused by it; 38

occurred in 1871, and 187 in 1872; then came a marked fall in the mortality, and in 1873 there were only 72 deaths, while in 1874 there were 112. Again in the years 1876-77-78 there were only 31, 45, and 36 deaths, respectively recorded as from small-pox. In 1879, however, there were 195 deaths—the highest in the decenniad—and in 1880, 143 deaths. In the first five years there were 411 deaths from small-pox, and in the last five, 450 deaths, while there were nearly twice as many deaths registered from all causes in the last, as in the first five; thus shewing a large proportionate decrease in the mortality from this most loathsome disease. Comparatively few died of it after the age of 40 years, and a large proportion of the deaths were of those between one year and 10 years of age.

#### RECAPITULATION.

It is found then, from the returns, that there was in the proportion of deaths from zymotic diseases as a class, as compared with the total number of deaths from all causes, a decided decrease in the ten years, though in some of the diseases of the class—in croup and diphtheria, for instance—there was an alarming increase; in cholera infantum there was a slight increase. As the diseases of this class for the most part prevail at times epidemically, an increase, small or great, is at any time liable to take place from the breaking out and spread of an epidemic of any one or more of them. The decrease, therefore, during so short a period does not necessarily, by any means, shew the commencement of a permanently improved condition of the public health, nor that such condition will follow. These are regarded as the more especially preventable diseases, and the aim of the sanitarian is to prevent, if possible, their outbreak and their spread in communities.

In tubercular diseases, the next class, there was a slight decrease also. In diseases of the nervous system there was a marked decrease, owing to the subsidence of an epidemic of cerebro-spinal meningitis which prevailed in 1872-73, and which has been placed in this class, but which has the characteristics of a zymotic disease.

In the fourth class in the list, diseases of the respiratory organs, there was, on the other hand, an increase in the decennium in the proportion of deaths registered; and in diseases of the urinary organs there was a slight increase.

As to the special diseases, there was a slight increase in the proportion of deaths from consumption; a large increase from both heart disease and cancer, and a slight increase from inflammation of the lungs, liver disease, kidney disease and paralysis.

With a decrease in the proportion of deaths from any disease or class of diseases, there would necessarily follow a corresponding increase in the proportion from some other disease or diseases. Hence we may account for the increase in the proportion from many of the diseases last above referred to by the decrease in the proportion from zymotic diseases.

It may be observed, however, that the increase in the proportion of deaths from heart disease and from cancer was very great, being at the rate of about 20 per cent. and 33 per cent. respectively, and therefore much beyond what can be accounted for by the decrease in the proportion from other diseases.

TABLE K.

## AGES AT DEATH IN CERTAIN OCCUPATIONS.

Amongst the many causes of disease and too early death are found many of the occupations in which people engage. Many occupations tend to shorten life in a variety of ways. Some of them give rise to such a condition of the surrounding air that to breathe it is more or less injurious to health, and interferes with the healthy functions of different organs, and thus life is cut short. Many avocations necessitate too much confinement indoors, and the want of sufficient pure fresh air and sunlight shortens the lives of those engaged in them. Modern society demands that everything in art shall be perfect; hence labour is greatly divided and muscular action restricted. Thousands overwork a small portion of their bodies, while the other portions are hardly used at all, and exercise, so necessary to health, is greatly restricted. The seamstress and the telegraph operator get hardly any physical exercise whatever, while the weaver, at every sweep to or fro of the shuttle, brings into action nearly every muscle in his body; and it is not surprising that the average age of those engaged in the two former occupations is less than half that of those engaged in the latter.

It is the work of the hygienist to learn by statistics the evil effects of the various occupations upon the human organism, and to combat them as far as possible.

Attention may here be drawn to what has already been stated in annual reports, viz., that the evils attending certain callings sometimes seem greater than they really are. Some occupations which seem unfavourable to longevity *per se* (while in a large measure of this character), are less so than the physical constitutions of the persons engaged in them. Those who are delicate and weakly are most disposed to choose indoor, sedentary occupations; while the more vigorous and the well constituted usually manifest greater wisdom and caution, or more of the instinct of self-preservation, and select pursuits more favourable to longevity.

The occupation which in this Province has been most favourable to long life, as shewn by the returns of deaths, and in Table K, is that of soldier or volunteer, the former often registered as pensioner. During the last seven years of the decennium, 267 deaths which were registered under the above heading shewed that the decedents had reached the average age of 68.6 years. Of these 26 died in 1874, at an average age of over 70 years, and 51 in 1879, at an average age of over 71 years; on the other hand, 48 died in 1878, averaging 67 years. Doubtless, a large proportion of the 267 had been in the British army, and in early life were picked men, well developed, of vigorous constitution, and good health, and for the most part spent an easy life, with regular habits, and hygienic environments; all contributing to prolong life. It must be observed that probably but few of these soldiers were Canadian born, or had lived the greater part of their lives in Canada.

The occupation in which the next longest average of life is found in this Province is that of weaver, and it may really be regarded as the employment here most promotive of longevity. There were 192 weavers whose deaths were registered during the seven years above named, and who had lived to the average age of 68.2 years. Theirs was evidently a healthy occupation. The groups or numbers engaged in it dying in each of the seven years varied in the average individual ages from 62 years in 1873, the lowest average

to 72 years in 1874, the highest average ; the deaths of 15 only, however, were registered in each of these two years. In 1877, the deaths of 31 were registered at an average age of 70 years ; and in 1880, 32 at an average of 68 years. The occupation of weaving brings into moderate and not severe action nearly all parts of the body, especially the upper extremities and most of the muscles of the trunk ; there is usually considerable walking out of doors connected with it, and yet there are not necessarily exposures of any kind. Those engaged in it, too, are mostly frugal in their habits—all conditions favourable to health and long life.

There were registered during the seven years 191 deaths of paupers at an average age of 68.1 years. Pauperism cannot properly be termed an occupation, and few become paupers before they have reached a good age, with an expectation or probability of long life. They, moreover, are of that class which for the most part has taken life easily, without overwork or great anxiety.

Fourth, as regards longevity, in the list of the various occupations, come clergymen. The deaths of 231 who had reached the average age of 68 years were registered during the seven years. The circumstances which most contribute to the longevity of clergymen are, their temperate, tranquil lives, their freedom from exposure and severe toil, and their possession usually of all the ordinary or essential comforts, if not commonly the luxuries of life, while most of them are much in the open air.

Next to clergymen come those registered as "gentlemen," whose average individual age was 67.7 years, of whom 947 died within the seven years. So far as regards some of the circumstances of life and habit favouring health and longevity, gentlemen may be regarded as in a condition not unlike that of paupers. They have really no occupation ; they take life quietly ; most of them, doubtless, were once engaged in some pursuit, perhaps a healthy one, and in which they accumulated the means upon which to live without labour. Doubtless they were somewhat advanced in years, with a good expectation of life before they became what is in this connection called gentlemen.

Not classed with these, nor to have the years of their shorter lives computed with the years of the longer life of "gentlemen," are the hundreds and thousands who fell by the way, perhaps much earlier in the race for competency, striving to become possessed of sufficient means to enable them to live at some future time as "gentlemen." It was only the few (a goodly number on the whole, it is true, supplying 135 lives, each of 67.7 years per annum, for seven years, yet few, comparatively, after all) who, having lived past the critical periods of their earlier years and reached to a good expectation of life, and obtained the competency upon which to live at ease, could be classed under this head, which shows for its individuals such good average longevity.

Coming next to the above, as regards length of life, are gardeners, 144 of whom died in the seven years, each at an average age of 61.8 years ; and farmers, 14,583 of whom died, each shewing an average age of 61.4 years, both of which classes may be considered together. These in their average failed to reach, by six years, the average length of the life of the gentlemen, and by nearly eight years the average of clergymen. Farming should be about the most healthy of all occupations and promotive of longevity. With less severe labour and careless exposure, and a little less anxiety to acquire riches, the life of the farmer might be much prolonged.

Farmers' wives, of whom 10,022 died in the same period, were shorter lived by nearly two years than the farmers themselves, the average being 59.6. What but indoor life for the most part can account for this difference? True, the wife of many a farmer has more real drudgery, more constant work than the farmer himself, aside from the trials and duties of maternity, but confinement indoors is doubtless the chief cause of her shorter life.

The deaths of 340 "public officials" were registered during the seven years, each at an average age of 60.2 years. Of tanners 34 died, each averaging 59.5 years of age; 21 provincial land-surveyors died at an average age of 59.1 years; 64 millwrights, at 58.8 years; 317 tailors, at 58.3 years; 251 masons, at 58.2 years; and 144 waggon-makers, at 58.1 years. 500 shoemakers died, who each averaged the age of 55.7 years; and 153 millers, who averaged 55.1 years. 905 carpenters lived to only an average of 51.3 years; and 399 blacksmiths, to only 50 years. 108 bakers and confectioners, and 4,166 labourers, each reached an average of 52.3 years; and 130 coopers, 56.3 years; 1,010 women, who were registered under the head of "housewives," died at the average age of 53 years.

Of physicians, who it may be thought should show a better record as to longevity, 187 died during the seven years, at an average age of only 51.2 years. But physicians while attending to the health and lives of their patients are too often neglectful of their own. 120 members of the legal profession died at the early average of 45.3 years.

Of merchants, 740 deaths were registered at an average age of 49.3 years; and of book-keepers and clerks, 484 deaths, at an average of only 39.3 years; they lived a shorter life by ten years, or about 20 per cent., than the merchants.

Of servants, probably mostly females, 615 died during the seven years at an average age of only 41.9 years; of seamstresses, 146 died whose average age was 38 years; and of milliners, 136 died, averaging only 35 years.

In the seven years there were 295 registrations of deaths of teachers, whose average of life was only 43.3 years; 81 of printers, whose average of life was 36.2 years; and 230 of railroad employees, the average of whose lives was 36.4 years. A large proportion of the deaths of the last were the result of accident. 188 painters and 68 moulders, averaged 42.6 years, or over six years more than printers.

MORTALITY IN CERTAIN OCCUPATIONS FROM CERTAIN DISEASES.

In looking over some of the more common diseases in their relations to, or their mortality amongst, those engaged in certain occupations, as illustrated in Table L, we find some interesting and instructive facts.

**APOPLEXY and PARALYSIS**, together, according to the returns of the four years, 1877 to 1880, which alone can be conveniently reached, were more fatal, proportionately, amongst physicians than amongst those who were engaged in any other occupation. During those years, 105 physicians died, 12 of whom, or 11.4 per cent., died from apoplexy or paralysis. During the same period, the deaths of 633 "gentlemen," so-called, were registered, of which 68, or 10.7 per cent., were from apoplexy or paralysis. Next came merchants, of whom 452 died in the four years, and 45, or about 10 per cent., from apoplexy or paralysis. Of painters, 10, or 9.8 per cent., in a total of 102, died from either one or the other of these affections, doubtless chiefly from paralysis, to which disease they are very liable. Amongst tavern-keepers, 8.7 per cent. of the deaths were from apoplexy or paralysis; amongst masons, 8.6 per cent.; amongst clergymen, 8.1 per cent.; and amongst public officials and engineers each, 7.7 per cent. On the other hand, of teachers, saddlers, harness-makers, and stone-cutters, only 1.6 per cent. of the deaths were from these diseases, which also caused nearly 6 per cent. of the deaths amongst the large class of farmers.

**BRAIN DISEASE.**—Of the 40 moulders who died in the four years, there were four deaths from brain disease, other than the above, or 10 per cent. of the whole. Next come waggon-makers, amongst whom, of 92 total deaths, 5, or 5.4 per cent., and then lawyers, amongst whom, of 79 deaths, or 4, or about 5 per cent., were from brain disease. Of 187 teachers who died, only one death, or 0.5 per cent., was from brain disease; and of 246 soldiers and pensioners who died, only one death, 0.4 per cent., was from the same. Amongst clergymen, 3.3 per cent.; of physicians, 3.8 per cent.; of gentlemen, 2.8 per cent., and of farmers, 1.8 per cent. of the deaths were from this cause.

**CANCER.**—While 8, or 5.4 per cent., of the clergymen who died in the four years, died of some form or other of cancer, only one sailor in 132, or 0.7 per cent., died of it. Clergymen and sailors shew the highest and lowest mortality from this disease. Of painters, in a total of 102 deaths, or nearly 5 per cent.; of gardeners whose deaths were registered, 3.9 per cent.; of merchants, 3.3 per cent.; and of farmers and physicians, each 2.8 per cent. died of cancer; while on the other hand, less than 2 per cent. of book-keepers and clerks, engineers, bakers and confectioners, blacksmiths, tavern-keepers, and millers died of it. As this is a disease more peculiar to advanced life, few who are young die of it.

**CONSUMPTION.**—Of all soldiers and pensioners who died in the period under notice, only 5.6 per cent.; of gentlemen, 6.4 per cent.; of public officials, 7.3 per cent.; and of gardeners 7.8, per cent., died of consumption; while on the other hand, of the 68 printers, in all who died, 34, or 50 per cent.; of saddlers and harness-makers, 45 per cent.; of stone-cutters and seamstresses, each over 38 per cent.; of book-keepers, clerks, and moulders, each over 37.5 per cent.; and of milliners and dressmakers, and teachers, over

35 per cent., died of it. The mortality from this disease amongst servants, tinsmiths, waggon-makers, bakers and confectioners, merchants and lawyers, was much above the average. Of all physicians who died, 10 per cent., and of farmers 13 per cent. died of consumption. Of all who died, and had been engaged in any of the 36 occupations mentioned in Table M, an average of  $16\frac{1}{2}$  per cent. died from this disease. More than the average of all the decedents in 23 of the occupations, and less than the average of all the decedents in 13 of the occupations, died of it. Abundant work for the public hygienist is indicated by the above facts.

**HEART DISEASE.**—The proportion of the deaths from heart disease to the total deaths from all causes, in all the occupations named in the table, during the four years, was 6.3 per cent. Of a total of 75 bakers and confectioners who died from all causes during that period, 13, or 17.3 per cent., died of that disease. This is a much larger proportion of deaths from it than in any other occupation, being nearly three times the average. Next come public officials, of whom 246 died from all causes, and 30, or 12.2 per cent., from this affection. Of all the cabinet-makers who died, 10.4 per cent. died of heart disease; and of all the gentlemen, milliners and dress-makers, millers and tailors, who died, 8.5 per cent. died of it. Of all the blacksmiths, printers, saddlers and harness-makers, seamstresses and teachers who died, only a little more than 3 per cent. died from heart disease, or little more than half the average for all the occupations. The mortality from this disease amongst clergymen, physicians, gardeners, farmers, and those of some other of the occupations, was nearly about the average of the whole, or 6 per cent.; that amongst lawyers was 7.6 per cent., or 1.3 per cent. above that average.

**KIDNEY DISEASE.**—From this disease the proportionate mortality was greater amongst clergymen than amongst those engaged in any other occupation, or more than two and a half times as great as the average for the whole; it was also large amongst lawyers and millers.

**LIVER DISEASE.**—From this the greatest mortality was amongst engineers, and next in order stand tavern-keepers, tailors, physicians, public officials and blacksmiths. The lowest mortality was amongst sailors, and next lowest amongst servants, gardeners, milliners and dressmakers, and teachers.

**LUNG DISEASE** in the table refers to diseases of those organs other than those which are otherwise specified, as consumption, inflammation, etc.; and being so indefinite in character but little interest can attach to it as a cause of death. A large proportion of engineers, gardeners, lawyers, tavern-keepers and tinsmiths died from "lung disease," so-called.

**PNEUMONIA.**—Of all the deaths from all causes amongst those engaged in all the occupations, 5.3 per cent. were from inflammation of the lungs; while of all deaths amongst butchers, 14 per cent.; amongst moulders, 12.5 per cent.; and amongst saddlers and harness-makers, 12.9 per cent., were from the same. 10 per cent. of the deaths of engineers and seamstresses were from this cause.

**ACCIDENT.**—Of all the deaths from all causes in all the occupations, 4.3 per cent. were from accident. The returns shew that of all deaths amongst railroad employees, 41.5 per cent. were of this character. Of the deaths of sailors, 21.9 per cent. were accidental; of labourers, 8.5 per cent.; of waggon-makers, 7.6 per cent.; of lawyers, butchers, millers,

---

---

masons and tailors, over 6 per cent. were from accident. Of clergymen, saddlers and harness-makers, and seamstresses, only between 1 and 2 per cent., each, of the deaths were registered under this head.

INTEMPERANCE, according to the returns, caused the death of 6 per cent. of all the tinsmiths who died in the four years, or about nine times as large a proportion as the average in all the occupations together, which was .67. 2.4 per cent. of the deaths of tavern-keepers, 2.1 per cent. of those of butchers, 1.8 per cent. of servants, and 1.4 per cent. of labourers, were from this cause.

SUICIDES were most common amongst gardeners ; next amongst engineers, weavers, book-keepers and clerks, blacksmiths, and printers, respectively ; and next, somewhat strange to record, come clergymen, of whom double the average proportion died of suicide.

PROPORTION OF SEXAGENARIANS DYING IN THIS PROVINCE WHOSE NATIONALITIES ARE GIVEN, AND WHO LIVED TO ADVANCED AGES.

It is of importance to note, according to the returns for Ontario shewn in the above table, that while as large a proportion of Canadians as of English, Irish, Scotch, Americans and Germans lives to be 60, and even almost 70 years old, a much smaller proportion lives on to exceed the ages of 80 and 90 years.

The table shews that during the five years, 1876 to 1880, 3,989 English people died at the age of 60 years or over, and that 1,010, or over 25 per cent. of that number, lived to exceed the age of 80 years; that 6,725 Irish people died at the age of 60 years or over, and 2,032, or 30 per cent. of that number, lived to exceed the age of 80 years; that 3,807 Scotch people died at the age of 60 years or over, and 1,261, or 33 per cent. of that number, lived to exceed the age of 80 years; that 1,650 Americans, so called, died at the age of 60 years, and 688, or 41 per cent. of that number, lived to exceed 80 years; and that 3,743 Canadians died at the age of 60 years, and only 899, or 24 per cent. of that number, lived to exceed the age of 80 years. The difference is still more marked in those who lived to be 90 years old and over. A proportion of only 3.7 per cent. of Canadians lived to this age, while of English, Irish, Scotch and Americans there were 4.1 per cent., 6.7 per cent., 6.7 per cent., and 8.1 per cent. respectively. Up to the age of 70 years the difference was not so marked. The Germans were considerably shorter lived than the Canadians. The Americans show the most favourable record; next come the Scotch, then the Irish and English, and next to the English the Canadians—between whom and the English there is not much difference—and lastly the Germans. The number of Americans registered is not so large as that of any of the others, the Germans excepted, and they are most probably of the well-to-do class or of the very low class—both of whom take life easy—and not of the more hard-working people, who are usually most exposed, or perhaps often indifferent, to the influences which shorten life. The hardy, plain-living Scotch and Irish come next in order. It would be interesting and profitable to know whether lager beer and tobacco, to which most Germans are partial, and more or less addicted, exerted any influence in preventing a larger proportion of them reaching an advanced age in this Province.

It is interesting to observe that the proportions are nearly the same as regards the totals of the five years, and those for each individual year.

#### A BRIEF LIFE HISTORY OF A CANADIAN GENERATION.

NOTE.—It should be observed here that the population of 1880, as estimated above, at 1,890,000, besides being put in round numbers, and as an approximation only, is intended to represent the average of the year, or that on the 1st of July; whereas the estimation on page 11, putting it at 1,884,200, refers to the time of taking the census in April, two months and more previous, when the numbers would be considerably less.

Taking the average of the returns for the last five years, 1876 to 1880, as a basis, so far as they afford information, the life history of a generation in Ontario may be briefly traced in the following manner:—

Estimating the average population of the Province in 1880 to be 1,890,000 in round numbers—about which it evidently was, according to the decennial census of this year—and taking the estimate of 32 births per 1,000 of population, in accordance with the calculations in the early part of this Report, there were born in the Province during the year 60,480 children; there were 42,312 registrations of births during the year, but it appears that about 70 per cent. of the whole number which actually occurred were registered.

Of all the deaths which were recorded in the Province during the last five years, 22.5 per cent. were of children under one year. The number of deaths last year (for which see also the early pages of this Report), estimated at 18 per 1,000 of population was 34,020; 19,802, or about 55 per cent., were registered. In incomplete returns the registration of the deaths of children is more likely to be neglected than that of older persons; had all the deaths been recorded, doubtless not less than 23 per cent. of them

would be found to be of infants under the age of one year. In England, about 26 per cent. of all the deaths are of children under one year. Therefore, we may reasonably assume that at least 23 per cent. of the 34,020 estimated deaths last year, or 7,824 of them, were of children under the age of one year, leaving 52,656 of the 60,480 infants born during 1880 to enter upon their second year.

At birth, the 60,480 children of 1880 were unequally divided as regards sex, there being 107.8 boys to each 100 girls, or 32,428 males and 28,052 females; but the mortality of the first year, being over 40 per cent. greater amongst males than amongst females, went far to reduce this disparity.

Of the 7,824 who died during the first year of life, a large proportion, about one-fifth (being more than from any other one cause), according to the returns, died of "debility"—"infantile debility." These, doubtless, chiefly died at a very early period of existence, aged only a few weeks or a few days, or, it may be, a few hours, and from want of sufficient assimilative power to nourish the body, or from obscure affections difficult to diagnose correctly. Diarrhœa and dysentery, enteritis and cholera infantum—diseases of the intestinal track, or stomach and bowels—destroyed the life of a large proportion, or about one-eighth of the 7,824. The next largest proportion, about one-tenth, of the deaths among these infants, or about half as many as from debility, so-called, was from some one disease of the respiratory organs, chiefly inflammation and congestion of the lungs and bronchitis. From convulsions and diseases of the brain, too, a large proportion died. These diseases, together with whooping-cough, diphtheria, and scarlet fever and measles, carried off the great majority of the 60,480 who died at the early age of one year or under.

After passing the age of one year, the chances of life become vastly greater—existence, as it were, is an established fact. During the next four years, of the 52,656 children who entered upon their second year of life, but 5,100 died—an average of 1,277.5 per year, leaving 47,546 to enter upon their sixth year. The diseases which are most fatal to this period of life, between 1 and 5 years, and which carry off the largest numbers of children, are diphtheria and croup, and diseases of the respiratory organs and of the brain. At this period of life a much larger proportion die of diphtheria and croup, and of scarlet and other fevers, than of the same ailments in the earlier period, viz., under one year. A good many more males than females die between the ages of 1 and 5, and the difference between the number of boys and that of girls is still further reduced.

Large numbers of the 47,546 who enter upon the sixth year of life have passed through attacks of one or more of the diseases of childhood, scarlet fever, whooping-cough, measles, etc., and are in the more vigorous period of boyhood and girlhood, and for the most part more robust and healthy. Only 2,035 of them, an average of 407 per year, die during the next five years, that is, between the ages of 5 and 10 years, so that 45,511 enter the third quinquennial period of life, and their eleventh year. The 2,035 die of diseases similar to those which destroyed life in the period between the ages of 1 and 4 years.

Still fewer die in life's third quinquennial period, but during the fourth, between the ages of 15 and 20 years, the period of development of manhood and womanhood, a larger number, more especially of females, succumb to the numerous and varied influences

which prey upon life at this critical age. During the decenniad, between the ages of 10 and 20 years, the 45,511 persons are reduced, by the death of 3,015, to 42,496, who enter upon the twenty-first year of their life. During this period, the proportion of deaths from heart disease, rheumatism, and typhoid fever increases, and in the latter five years the mortality from consumption quadruples that of the first five of the decenniad. During the latter part of the period a goodly number, especially of females, enter the married state, and before reaching their twentieth year about one-eighth of the emales—that is, more than one-eighth of all who ever marry—but only a little more than one-hundredth part of the males marry.

Over 70 per cent. then—42,496—of the 60,480 enter upon the third decennial period of life, and exceed the age of twenty years. They drop off, however, more rapidly now, so that 4,812 of those who entered upon this period will not reach the end of it, but will die from many various causes. From 20 to 30 years is the period in which consumption—that most fatal and deadly of all diseases—seizes upon and destroys the greatest proportion of its many victims. Many more females than males die, especially from this disease, during this decennial period. From the age of 20 to that of 25 large numbers both of males and females—little short of half of all who ever marry—enter the wedded state, but still a good many more females than males. During the next five years large numbers of both sexes enter upon married life, but more than twice as many males as females. During the ten years about seven-tenths of the survivors marry. This is the “age of love and of war, of dangerous work and of crime!” It is the age, too, of fatal accidents, especially from drowning; deaths from typhoid fever are also most common.

Upon the fourth decenniad of life 37,684 enter, and 33,643 pass through it—many of them, doubtless, too, through weary days of sickness, and numerous trials and tribulations. The remaining 4,041 succumb entirely and drop out by the way. This we may regard as the prime period of life, “the athletic age, the age of poetry.” Large numbers marry in this period, but many more males than females. Consumption is still by far the most destructive disease; the mortality is still much greater amongst females than amongst males, and diseases of the heart, brain, and organs of respiration (excepting consumption) grow more and more common. This period of life with the previous one, between 20 and 30 years of age, are the maternal periods, and many mothers give up their life, as it were, to their offspring—either suddenly, passing from active, vigorous life to the cold stillness of death: or slowly and gradually, owing to too frequent pregnancies and lactation periods, along with too large a measure of the toils and duties of life.

Of the 33,643 who live beyond the age of 40 years, and enter the fifth decennial period, 4,168 die under the age of 50 years, leaving 29,475, or considerably less than one-half of the 60,480 who started out together on life’s journey, to enter the sixth decenniad of life. From 45 to 55 is regarded by Dr. Farr as the “middle arch of life” in England. There, a few months after the age of 45, Dr. Farr says, each million who are born are reduced to half a million. This corresponds closely with what vital statistics show us to be true of Ontario, for considerably less than one-half of the population reaches the age of 50 years. In the fifth decenniad consumption is less destructive, but the mortality from diseases of the heart, kidneys, and liver becomes greater, and deaths

from apoplexy, paralysis, and dropsy are much more frequent, while cancer, which had been of rare occurrence, destroys many lives. Still, even at this period of life, a good many, but many more men than women, marry; the difference between the number of men and the number of women who marry is, however, not so great as during the two previous decennials.

At the end of 60 years, the 29,475 who entered upon their fiftieth year are reduced to 24,762, 4,713 of them having died between the ages of 50 and 60. Cancer is much more fatal in this decennial period than in any other. The mortality from apoplexy, too, and from paralysis, heart disease, kidney disease, and dropsies, becomes still greater. Suicides are most common in this decenniad. And all these, and other less common causes of death, each take their share in the destruction of the 4,713 lives. About one-seventy-fifth part of all who marry are married between the ages of 50 and 60 years; but now the men outnumber the women by three to one.

In the next decenniad, between the ages of 60 and 70 years, a much larger proportion drops out by the way, and 6,865 of the 24,762 do not live to see the anniversary of their seventieth birthday; only 17,897 of the 60,480 who, 60 odd years before, started out together in the race of life reach the Psalmist's allotted period. The lives of these 6,865 are destroyed chiefly by heart disease (that disease being most fatal during this period of life), by pneumonia, by apoplexy and paralysis, and by dropsies. This is the most fatal period, too, in diseases of the liver and kidneys; while in it also many die of cancer, asthma, and bronchitis, and from the effects of tumours and abscesses, which become of more frequent occurrence. Notwithstanding advanced age, about one in every 200 people who wed marry during this period of life; and again, the men outnumber the women three to one.

After threescore and ten years, the survivors drop off more rapidly and in much greater proportion as the now nearly-finished race of life draws to a close, and 9,440, more than half of those who have attained 70 years, fall victims to diseases or accidents of one sort or another before the end of the eighth decenniad—victims, for the most part, to the various diseases last above mentioned, but more especially to paralysis, dropsies, bronchitis, pneumonia, and heart disease; while not a few are destroyed by erysipelas and by the effects of calculus (stone in the bladder) and hernia. Only 8,457 survive to the age of 80 years. About one man in each 400 who marry, marries after the age of 70 years; but not so many as one woman in 5,000.

According to Dr. Farr, in England, where registration is most perfect, most men who have become septuagenarians die at the age of 72 years. This agrees closely with what statistics in this Province show to be the case here. Doubtless a large proportion of the 9,440 who die between 70 and 80 years of age die soon after the age of 70 years.

After 80 years, the "aged pilgrims" rapidly disappear; of the 8,557 who reach this age only 1,677 live on to the advanced age of 90 years. Before the age of 95 years more than two-thirds of the 1,677 survivors of 90 years have paid the last debt of Nature, and are gathered to their fathers; while of the remainder less than one-fourth, or about 135, live to exceed the great age of one hundred years.

In this Province, most of those who die at ages exceeding 80 years, and too many of those who die before reaching fourscore, are registered as having died of "old age."

---

While some even after 80 years are registered as having died of paralysis, of cancer, of heart disease, or of other of the above-named maladies most peculiar to aged persons, it is most probable that many of those, both over and under 70 years, registered as having died of old age, were really victims of one or another of these maladies, and of such, "untimely died." Few, with less than 90 years of Time's changes upon them, die of true and natural euthanasia—true old age; though after this age doubtless not a few, die Nature's death, die without "pain, anger, or sorrow." "Dying thus," says an eminent physician, "the intellectual faculties of the fated man lose their brightness. Ambition ceases or sinks into desire for repose. Ideas of time, of space, of duty, lingeringly pass away. To sleep and not to dream is the pressing—and, step by step, still pressing—need, until at length it whiles away nearly all the hours. The awakenings are shorter and shorter; painless, careless, happy awakenings to the hum of a busy world, to the merry sounds of children at play, to the sounds of voices offering aid, to the effort of talking on simple topics and recalling events that have dwelt longest on the memory; and again the overpowering sleep. Thus, on and on, until at length the intellectual nature is lost, the instinctive and merely animal functions, now no longer required to sustain the higher faculties, in their turn succumb and fall into the inertia. This is death by nature, and when mankind has learned the truth, when the time shall come—as come it will—that 'there shall be no more an infant of days, nor an old man who hath not filled his days,' this act of death—now, as a rule, so dreaded because so premature—shall, arriving only at its appointed hour, suggest no terror, inflict no agony.'

I have the honour to be,

Sir,

Your obedient Servant,

H. S. CREWE,

*Inspector.*
