## **EXECUTIVE SUMMARY**

The goal of this study is to develop an updated version of the Malpractice Geographic Practice Cost Index (MGPCI) used in the Medicare Fee Schedule (MFS) for physician services. The index measures geographic differences in malpractice costs by comparing premiums charged for a mature claims-made insurance policy with \$1 million/ \$3 million limits of coverage. Adjustments are made to acknowledge states that require mandatory contributions into a fund set up to cover large settlements. The MGPCI originally used in the Medicare physician payment system relies on premium data from 1985 and 1986 from a relatively limited number of insurance companies and is based on premiums for three specialties that were selected to represent low, middle, and high degrees of malpractice risk.

In order to improve the index, data are required that are both more recent and more broadly representative of the insurers in each state. As such, the first part of this report discusses the data collection efforts. A state-by-state survey allowed us to collect information for 1990-1992 from 59 insurers, including both for-profit and physician-owned companies. The market shares of the insurers that provided data totalled at least 65 percent in all states. In many states, over three-quarters of the market was represented. With this large a share of the insurance markets represented, policymakers can feel more confident that the most important premiums in each state are, in fact, determining the MGPCI.

These data are then used to develop alternative updates of the MGPCI. These updates vary the number of specialties whose premiums are included in the computation (the original three specialties versus the 20 most important Medicare specialties) and the number of years of data upon which the index is based (a three-year average versus the single most recent year). For all options, there would be large changes in most MGPCI values. Even for an

option that relies on the same three specialties that are currently used and averages across all three years of recent data, 60 out of 232 localities would have MGPCIs that change by more than 40 percent. Of course, it is important to keep in mind that the MGPCI accounts for only about 5 percent of the overall geographic adjustment factor in the MFS. Therefore, a 40 percentage point change in the MGPCI would result in only about a 2 percent change in a fee.

The magnitude of these changes could raise questions about the validity of the MGPCI update options. We examined every state whose index changed by more than 10 percentage points and concluded that most of the large changes were the result of replacing apparently unrepresentative data with data that better reflected the state's insurance market. There were some exceptions to this, however. For example, California's premiums have fallen dramatically relative to the rest of the country. This seems to be associated with the tort reforms, particularly the cap on non-economic awards, that California implemented during the 1970's.

The choice of approach for updating the MGPCI needs to be guided by the soundness of the methodology and the data as opposed to the actual index values. Given the potential volatility in premiums over time and the cyclical nature of premium changes, it is preferable to develop a cross-sectional index based on an average of several years of data. A two-year average, as is used in the current MGPCI, is the minimum acceptable approach that could smooth fluctuations. More years of data would further enhance stability. There is a risk, however, of incorporating outdated information by using too many years of data. To balance the desire to use current data against the need to smooth fluctuations, we favor an index based in three years of data; in this case premiums from 1990-1992.

Decisions on the number of specialties whose premiums are directly incorporated into the index are dependent on the extent of geographic variation in the numbers of risk classes used to establish premiums and the mapping between specialties and risk classes. The results show that there is sufficient variation in these factors so as to make the MGPCI somewhat sensitive to the number of specialties directly represented in the index. Given this, it seems hard to defend an index that is based on a small number of specialties. As such, we propose an MGPCI that is based on premiums from the top twenty Medicare specialties, defined in terms of 1990 Medicare spending.

The decision-making process at HCFA has concurred that the updated MGPCI should be based on 1990-1992 premium data for twenty specialties. In addition, the index values should be derived relative to a weighted national average premium that uses total service volume (measured in terms of malpractice relative value units) as the weights. The index currently in the MFS uses population as the basis for computing national average premiums. In order to ensure that the MGPCI updating does not affect the total amount spent for malpractice RVUs through the MFS, HCFA actuaries developed a multiplicative scaling factor to be applied to all MGPCI values. The factor raised all values by 2.3 percent. The final set of updated MGPCI values that will be used in 1996 are displayed in Appendix G, by locality. When this updating is not carried out annually, Congress requires that there be a transition years in which index values are a simple average of the current and updated indices. This transition year will be 1995. Values for this year are also shown in Appendix G.

## I. INTRODUCTION

The Malpractice Geographic Practice Cost Index (MGPCI) is used to adjust physician payments made under the Medicare Fee Schedule (MFS) for differences in the cost of medical malpractice insurance. Other Geographic Practice Cost Index (GPCI) components adjust for differences in employee wages, office rents and the costs of physicians' own time. In this report, we present options for updating and revising the methodology used in the MGPCI. The index currently being used is based on 1985 and 1986 premium data for three specialties from a relatively small number of insurers. The changes considered here relate to improving the timeliness and validity of the data upon which the index is based and expanding the number of specialties whose premiums are captured by the index. These revisions are intended to strengthen the methodological foundation of the MGPCI so that it more accurately measures differences in the costs of medical malpractice insurance across areas.<sup>1</sup> Any changes in the MGPCI will have a much smaller impact on fees in a locality than is suggested by the size of the index change, because malpractice RVUs represent only about 5 percent of the total RVUs upon which payment rates are based.

The original MGPCI measures geographic differences in malpractice costs by comparing premiums charged for a \$1 million/ \$3 million mature claims-made policy.<sup>2</sup> An exception to this occurs in three states - Kansas, Pennsylvania, and Wisconsin - that have established mandatory Patient Compensation Funds (PCFs). PCFs are a way of limiting the physician's liability in the event of large suits and are funded through a surcharge on the

---

<sup>1</sup>Using more recent data would address one of the major comments HCFA received in response to the preliminary MFS rules. Moreover, having premium data that could be defended as being representative of each state would make it more difficult for any one state to argue that the data somehow misrepresented its position relative to other states.

<sup>2</sup>The phrase "original MPGCI" refers to the malpractice cost adjuster used in the MFS from 1992 through 1994.

malpractice premium the physician pays for a required minimum level of coverage. The MGPCI treats the costs of the required coverage plus the surcharge as the relevant premium for comparison purposes. (A complete discussion of how the PCF adjustment was incorporated in the original MGPCI can be found in Zuckerman and Norton (1991)).

The data used to compute the original index was derived from HCFA's Survey of Insurers designed to collect data capable of estimating the update in the malpractice component of the Medicare Economic Index, essentially an index of input price change. These data are largely drawn from a single nationwide insurer (St. Paul) and are supplemented by several state-specific carriers in major states in which St. Paul does not offer coverage. At the time the MGPCI was developed these were the best premium data available. Unfortunately, subsequent analyses suggest that these data are likely to be unrepresentative of the insurers operating in many states (see Zuckerman, Norton and Wadler, 1992). In particular, the HCFA survey data does not include many physician-owned insurance companies that have grown rapidly throughout the 1980s and that tend to price coverage differently than for-profit insurers (Zuckerman, Bovbjerg and Sloan, 1990). To the extent that the importance of physician-owned companies varies across states, their exclusion could distort MGPCI values leading to overpayment in some areas and underpayment in others. The data used in this revision of the MGPCI were collected through a state-based survey designed to be representative of each state. These new data are discussed in more detail below.

The decision to use three specialties' premiums in the original index, as opposed to a broader set of specialties, was based on the observation that relative premiums from different specialties were highly correlated across geographic areas. In large part, this may have been

due to the fact that St. Paul, the single large insurer in the HCFA data, created the risk classification system in most areas. By relying on the premiums for general practitioners, general surgeons, and orthopedists (a low-, middle-, and high-risk specialty), the data base construction and the computation of the index was simplified. Each specialty's premium was weighted by the share of Medicare spending accounted for by the risk class containing that specialty.<sup>3</sup> However, analyses of premium data in Zuckerman, Norton, and Wadler (1992) show that variations in companies' risk classification systems may mean that the MGPCI is sensitive to the number of specialties whose premiums are reflected in the index. Therefore, we present indices based on premiums for a broader set of Medicare specialties as well as for the three specialties used previously.

As part of the overall revision of the MGPCI, HCFA requested that the current locality structure and an alternative weighting scheme be used to compute the index. To create the MGPCI, it is necessary to express each area's premium relative to the national average premium. Because all areas are not of equal size (measured in terms of population, numbers of physicians, or Medicare spending or service volume), it is desirable to compute the national average premium as a weighted average. In the original MGPCI, the weight applied to each premium is the area's population in 1980. As an alternative, HCFA has expressed interest in using weights that better reflect the geographic distribution of service volume as reflected in the total number of relative value units (RVUs) provided in the area.

---

<sup>3</sup>The weights were based on 1983 Medicare physician spending as reported in Burney and Scheiber (1985). The weight was 55 percent for general practitioners, 33 percent for general surgeons, and 12 percent for orthopedists.

In addition, the final revised index needs to incorporate changes in the locality structure that have taken place between 1992 and 1994.<sup>4</sup>

Using alternative weights does not affect any area's position relative to another area. However, to the extent that new weights affect the national average premium, they can affect each area's index value. An increase in the weighted national average, for example, would lower index values by the same percentage in all areas. Specifically, all values would be lowered by the percentage increase in the national average resulting from a change in the weights. In this report, we use population weights to analyze revised MGPCIs so that they can be easily compared to the original MGPCIs. The impact of reweighting based on the preferred RVU-weight alternative is considered separately.

This report is organized as follows: Section II describes the new data collection effort in detail. It is the availability and use of these new data that are the central elements of the revised MGPCIs. Other methodological revisions and a series of alternative MGPCIs are presented in section III. In addition to more recent data, the revisions consider using a three-year average of premiums (instead of the two-year average in the current index), basing the index on the single most recent year of data, and expanding from 3 specialties to the 20 most important Medicare specialties. Section IV explores the impact of each option on MGPCI values. Section V concludes with an assessment of the options, taking into account that there is a mandated transition period when the MGPCIs are revised less frequently than annually. Section VI concludes the report by showing the effect of replacing the population weights with RVU weights and structuring the index around the locality configuration that is in place

---

<sup>4</sup>The major changes in the locality structure are the Ohio and North Carolina are now statewide localities. In addition, two localities in the state of Washington have been combined. These changes reduce the number of localities from 232 to 216.

as of 1995. This final section focuses on the index that appears to be the preferred option, given HCFA's decisions based on the earlier analyses in the report.

## **II. NEW DATA COLLECTION**

The data collection approach used in this project replicates that used in Zuckerman, Norton, and Wadler (1992). They collected premium data for 1989, 1990, and 1991 in a process involving two phases. In the initial phase, they conducted telephone interviews with staff at state insurance departments. These interviews were designed to identify the major physician liability insurers in each state, as well as other significant characteristics of the insurance market. The characteristics that were reported related to the existence of Patient Compensatory Funds (PCFs) or Joint Underwriting Associations (JUA) and the approximate market share for each of the major insurers in the physician liability market for the state.<sup>5</sup> In particular, they acquired information that allowed them to determine how a PCF or JUA might affect physician costs (discussed below). The survey update undertaken for this study extended the earlier data base through 1992.

Where possible, the state insurance department provided \$1 million/ \$3 million mature claims-made premiums by risk class, risk class specifications, and sub-state malpractice pricing area definitions for the major insurers. However, in most instances this was not possible and the process entered a second company-level phase. In this phase, using data on

---

<sup>5</sup>Joint Underwriting Associations (JUAs) were established as a reaction to the availability crisis of the 1970s. These organizations usually function as the insurer of last resort--covering providers who cannot obtain coverage from other sources, much like assigned risk pools in automobile insurance. The stated purpose of JUAs is to assure availability of malpractice insurance coverage to health care providers at affordable levels. The JUA derives its income from premiums assessed policyholders. However, if premium income is insufficient to cover loss payments and expenses, each member company is assessed to make up the shortfall.

key personnel at each company provided by the state, we contacted insurers and requested premium data directly. Virtually every insurer suggested by the state was willing to provide the necessary data. Despite refusals from some minor insurers (discussed below), there was no difficulty in meeting our goal of having premium data from companies representing at least 50 percent of the market in all states.

**Sample of Insurance Companies.** Premium information was collected for 59 companies. Insurers operating in more than one state are only counted once in this total. Table 1 displays the names of the insurers in the sample and their approximate market shares by state. In addition to a target of at least 50 percent of the market, the process was designed to collect information from at least one for-profit company and from at least one physician-owned mutual or reciprocal operating in each state. This would provide both the major insurers in all states and a mix of insurer types. However, due to the nature of some markets, this goal was not always relevant. In five states -- Arkansas, Delaware, Kansas, Vermont and West Virginia -- there was not a major physician-owned company. On the other hand, in Alaska, California, Colorado, Hawaii, Maryland, Massachusetts, Michigan, Nevada, New Hampshire, New York and Rhode Island we found no for-profit company. In both sets of states the excluded type of insurer either did not operate or had an insignificant share of the market according to the state insurance department.

In 47 of the states we collected information from at least two companies. In five states we collected only 1 company, but that company represented over 70 percent of the market in all cases. On average we collected information from companies which represented approximately 82 percent of the physicians insured in a particular state. Using the market

shares supplied by the state insurance agencies and information on the numbers of doctors in each state, we computed the national market shares of the companies in our sample.<sup>5</sup> Table 2 displays the results of these computations. These figures are quite similar to those published by AM Best for 1991. For example, in our data St. Paul has a national market share of 10.2 percent, whereas Best reports their share at about 12 percent. Differences may be attributable to Best's inclusion of the hospital insurance market in their analysis.

This 1992 follow-up of the initial survey to collect representative premium information identified changes in insurance markets which resulted in a slight modification of our sample of companies. Except in New York, Nevada and Puerto Rico, the insurance companies and their market shares were the same as those in our previous study. In New York, Physicians Reciprocal Insurers, who supplied approximately 20 percent of the insurance to physicians in New York was added. In Nevada, state insurance officials suggested that the Medical Insurance Exchange of California no longer provided a significant share of the liability insurance and did not provide us with data. In Puerto Rico, Corporacion Insular De Seguros was replaced by Seguro Triple-S. According to officials at the Puerto Rican Medical Association, SIMED, the other primary supplier of liability insurance increased its market share to 60 percent by 1992. Overall, we collected premium information from 59 companies, 46 physician-owned, 9 for-profit and 4 JUAs.

**PCF Costs.** Eight states have PCF programs. In four states -- Kansas, Pennsylvania, New Mexico and Wisconsin -- participation in the fund is mandatory. In the rest of the states -- Indiana, Louisiana, Nebraska and South Carolina -- participation in the fund is optional. Knowing the required basic limits and the surcharge by year allows us to compute the

premium reflecting PCF costs. These relevant characteristics of the PCF programs in 1990, 1991 and 1992 are displayed in Table 3. All the companies in these states provided a premium for the required privately-purchased coverage limits. These premiums are then multiplied by the PCF surcharge to arrive at the costs of malpractice coverage in each PCF state.

Following the methodology for the index used in the MFS, we only apply the PCF factors in those states that mandate contributions. In this way, the MGPCI captures geographic cost differences that are beyond the physicians control. However, it may not be appropriate to assume that PCF coverage is necessarily equal to that provided by a \$1 million/ \$3 million policy. This is especially true when the maximum PCF coverage limits are substantially lower than \$1 million per claim. In New Mexico, a mandatory PCF state, coverage is only up to \$500,000 per claim, suggesting that the PCF adjustment should not be applied to the base premiums. This means that New Mexico, and the optional PCF states, will be treated as non-PCF states. Their MGPCIs will be based on the premium for a \$1 million/ \$3 million policy charged by their major insurers.

**JUA Costs.** In four states -- New Hampshire, South Carolina, Rhode Island and Massachusetts -- physicians are insured largely through JUAs. During the period covered by our data, only two of these JUAs (New Hampshire and Massachusetts) imposed retroactive premium adjustments for the purposes of covering a deficit from a previous year, and as a result, require adjustment for use in the MGPCI computation. In South Carolina, the JUA

Source: Urban Institute Survey of State Insurance Agencies.

1. Three limits offered; 65 percent chose 1m/3m policy shown.
2. Wisconsin has specific premiums by class which it charges for PCF coverage.
3. Starting July 1, 1991, 150/450 instead of 100/300.

typically recovers underwriting losses by adjusting premiums charged to policy holders each year, much as other insurance agencies adjust premiums to reflect market conditions.<sup>6</sup>

In Rhode Island, physicians are required to pay an amount equal to 1/3 of their first year premium into a contingency fund to cover potential shortfalls. Because this is a one-time payment, it would have to somehow be amortized over the career of a physician to be included in the annual premium for a malpractice policy. Rather than making some arbitrary decisions regarding how to allocate these up-front payments, we have not included it in the premium data. This is analogous to excluding the costs of "tail" coverage that physicians are required to purchase to insure against as yet unmade claims when they retire or change companies.

In 1987, the Massachusetts JUA began billing policy holders for deficits accumulated for the years 1983 through 1985. The recovery was completed over a five year period, ending in 1991. Surcharges were computed as a percentage of each year's premiums and varied both over time and according to the physician's risk class. In New Hampshire, physicians have been paying 15 percent in excess of their premiums to a stabilization reserve fund since 1986. These payments will not end until the state determines that deficits incurred prior to 1986 have been paid-off. All relevant years of Massachusetts and New Hampshire data are adjusted to reflect these surcharges.

**Other Adjustments and Caveats.** Five companies could not supply 1m/3m premiums because they did not offer a 1m/3m policy at some point during the survey period. The three companies that offered or are offering only 1m/1m are: in Oklahoma (Physicians

---

<sup>6</sup>South Carolina also has provisions for retroactive assessment, where policy holders can be charged up to 100 percent of their current premium, and insurance companies may be assessed for lost funds. These options, however, have never been utilized.

Insurance Liability Company); in Iowa (Iowa Physician Mutual Insurance Trust); and in Virginia (Virginia Insurance Reciprocal). In Puerto Rico, SIMED and Corporacion Insular de Seguros offered only 100/300 limits of coverage. In order to facilitate comparisons across areas, we use the St. Paul excess coverage factors to adjust premiums from 100/300 in Puerto Rico and 1m/1m in Iowa, Oklahoma, and Virginia to the 1m/3m used for the rest of the states. In Hawaii, the Doctors' Company, representing 20 percent of the market, could not provide policy information for 1990. This limited the information available to the MGPCI calculation in Hawaii in 1990.

### **III. ALTERNATIVE UPDATES OF THE MGPCI**

The goal of the MGPCI is to accurately measure geographic differences in the cost of malpractice insurance providing a uniform level of coverage. The original index uses the premium for a \$1 million/ \$3 million mature claims-made policy for 1985 and 1986 as the basis for comparison because it is the modal level of coverage purchased by physicians. For each area, geographic differentials for general practitioners, general surgeons, and orthopedists are averaged to arrive at a differential relevant to a range of risk classes. In addition, in three states (Kansas, Pennsylvania, and Wisconsin) that mandate that their physicians join PCFs, premiums have been adjusted to reflect these costs. Each specialty's index value is equal to the ratio of the area's premium to the population-weighted average premium across all areas. In order to capture intra-state variations in premiums, the premium data are mapped from county-specific observations to the locality level using a crosswalk developed by the Urban Institute. (This crosswalk has been updated for this report by Health Economics Research, Inc. to reflect the distribution of population in 1990.)

In developing updates of the MGPCI, there are several changes that are common to all alternatives. First, all of the population data used in creating state-level or national averages are drawn from the 1990 Census. The earlier indices used U.S. population weights from 1980. Second, premiums in Massachusetts and New Hampshire are adjusted to take into account the "deferred premium liability" assessments imposed by the JUA in these states. These are mandatory payments that affect physician costs in a manner analogous to the PCF surcharges and are similarly incorporated into the MGPCI. Third, premium information for Puerto Rico is used in the computation of the national average premiums. In earlier versions, Puerto Rico premiums were compared to national averages computed without data from Puerto Rico.

The three areas of potential revisions in the MGPCI that generate the options to be considered relate to the number of years of data upon which to base the index, the number of specialties whose premiums are represented, and the use of population weights versus relative values for weighting purposes. When developing the original MGPCI, Welch, Zuckerman, and Pope (1989) observed a substantial amount of variability in the geographic differentials between 1985 and 1986. This led them to base the MGPCI on an average of two years of data in order to reduce its sensitivity to atypical patterns in any single year. This was important because of the significant lag between the year of the data and the year of the implementation of the Fee Schedule. The new data available allows us to further reduce the impact of year-to-year variations and enhance the MGPCI's stability by basing the index on a three-year average of geographic differentials in malpractice costs.

In addition, the completeness of the new premium data affords us the opportunity to expand the number of specialties from the three used originally to all of the major Medicare

specialties. The goal of expanding the number of specialties included in the MGPCI would be to enhance its credibility as a representative measure of the average differential in premiums across all specialties. The reason for wanting the MGPCI to be representative of all specialties is that the MFS uses the same index to adjust the malpractice component of all fees. Selecting the precise number of specialties to include is somewhat arbitrary. We decided to develop an index based on the 20 specialties accounting for the largest shares of Medicare physician spending. These specialties accounted for 74 percent of total Part B spending in 1990 and an even larger share of spending covered under the Medicare Fee Schedule.

**Specific MGPCI Alternatives.** There are four specific MGPCI alternatives that we consider. The first two rely on using the three-year average of premiums for 1990, 1991, and 1992. One is based on the same three specialties (i.e., risk classes) used previously and the other is based on the 20 specialties shown in Table 4. As can be seen, the weights assigned to each of the 20 specialties can be combined into the weights used for the three specialties. Conceptually, as discussed above, there is reason to favor the three-year, 20-specialty option for the revised MGPCI.

Perhaps the major drawback of this approach is that it incorporates data that would be five years old in 1995, the likely update year. If there were another three year period before further updating, HCFA would be using an MGPCI with seven year old data in 1997. These concerns might suggest that updates be based on the most recent year of available data. This would keep the gap between the data and the current year to a minimum. Therefore, we develop two MGPCI options using only 1992 data; again with one based on three specialties and one based on 20 specialties. Although this approach runs the risk of basing the MGPCI

Table 4

**MGPCI Weights by Low, Medium and High risk  
for Top 20 Medicare Specialties (1990)**

Source: 1990 Medicare Part B Annual Data Procedure File

Note: The weight for low-risk is used as the weight for GP premiums in the 3-specialty MGPCI, medium risk for general surgeons, and high risk for orthopedic surgeons. In the original MGPCI the weights are 0.55, 0.33, 0.12 for the low-, middle-, and high-risk specialties, respectively.

- a. Obstetrics is listed as a medium-risk specialty because this specialty does not generally provide high-risk services (i.e., obstetrics) to the Medicare population. The premium used for this specialty in the MGPCI is the one insurers charge to OB/GYNs who provided gynecologic care only.

on a single, potentially atypical year, it may be acceptable because of the mandated transition that requires HCFA to blend updated GPCIs with current GPCIs if the indices are not revised annually. This transition will give equal weight to the updated and current indices in the first year and reduces the initial change in the magnitude of the index value by 50 percent. This process reduces the impact of possible anomalies in a single year index and may make employing a "most recent data" approach more feasible than it might have been otherwise.

**Computation Method.** Data from the 59 companies were compiled into 52 individual state-specific files (including Puerto Rico and District of Columbia). In each file, there was a unique observation for each company/rating area/year combination that is present. Using the risk classification definitions provided by each insurer, we translated the risk class premiums into individual specialty premiums. These raw data were used as the input into a county-level file that is the basis for the analyses that follow.

The state files were mapped to the county-level according to the rating area definitions used by each company. In 39 states, the rating area was the entire state for all companies (i.e., every county in the state received the same premium value). For the remaining 13 states, company-level rating area definitions were applied to create an accurate mapping algorithm.<sup>7</sup> In states where malpractice rates vary, the insurer charges rates based on the county within which the physician practices. The Southern California Physician Insurance Exchange (SCPIE), for example, has separate premiums for five areas -- defined by groupings of counties -- in California. Within our sample, sub-state insurance pricing areas are not uniform across companies within a state, nor in some cases, consistent across

---

<sup>7</sup>The 13 states with sub-state rating areas are California, Florida, Illinois, Indiana, Louisiana, Maryland, Michigan, Missouri, New York, Ohio, Pennsylvania, Texas, and Virginia.

time within a company. Thus, while SCPIE has a sub-state pricing area that includes only Los Angeles county, the Doctor's Company has a sub-state pricing area that includes Los Angeles, San Bernadino and San Diego.

For each specialty on this county-level file, the premiums for different companies are aggregated to a "market-weighted" average. The weights are equal to the overall market share of each company, as reported by the state insurance departments. Although each insurer may not have the same market share for all specialties, we had no alternative but to assume the company's overall market share applied to all specialties. In addition to premium information, the analysis files contain specialty expenditure weights from the 1990 BMAD Procedure File. Table 4 displays the twenty specialties with the greatest share of Medicare allowed charges and their shares of Medicare physician spending used as weights in the MGPCI. From these data, the weights for the three specialties used in the original MGPCI--general practitioners (a low risk group), general surgeons (a moderate-risk group), and orthopedic surgeons (a high risk group) -- can also be derived.<sup>8</sup> Each weight represents the approximate share of Medicare allowed charges for each risk grouping.

The steps involved in computing the actual index follow our earlier work and are fairly straightforward. Given the county-level premiums for each specialty, we computed a population-weighted national average premium by specialty using 1990 population as the weights. A county-level, specialty-specific index is derived by dividing each premium by the

---

<sup>8</sup>When three specialties are used to compute the MGPCI, the weight for general practitioners equals the weight for that specialty plus the weights for cardiology, dermatology, gastroenterology, internal medicine, neurology, pathology, psychiatry, pulmonary diseases, and radiology. The weight for general surgeons equals the sum of the weights for general surgery, anesthesiology, obstetrics/gynecology, ophthalmology, plastic surgery, thoracic surgery, urology, and otorhinolaryngology. The weight for orthopedic surgeons also includes the weight for neurosurgeons. This is the same approach used to derive weights for the three specialties used in the current MGPCI.

national average for that specialty. These county-level indices are combined to either the state or locality based again on the population in each county. To create a single MGPCI from the specialty-specific indices, we aggregate across specialties using each specialty's national share of 1990 Medicare allowed charges as the weight. These are the weights shown in Table 4. As can be seen, the 20 specialties can be aggregated to the 3 specialties used previously.

#### **IV. IMPACT OF MGPCI ALTERNATIVES**

To assess the impact of the various alternatives, we compute the changes in the MGPCI value that would occur in each locality as a result of moving from the original index to each option. The changes are presented on a locality-by-locality basis in Appendices A through D. In each appendix the localities are listed in ascending order from those losing the most to those gaining the most. It is important to think about these changes in the MGPCI in the context of the overall geographic adjustment factor (GAF) in the MFS. Given that the share of the GAF that is associated with malpractice costs is only about 5 percent, any change in the MGPCI only applies to about 5 percent of the fee on average. Therefore, fee changes resulting from MGPCI changes will only be one-twentieth as large as the MGPCI change. For example, the 75 percentage point decrease in the MGPCI in some of the smaller California localities (using the 20-specialty, 1990-1992 approach in Appendix B) would result in a less than 4 percentage point decrease in fees, on average, in those localities. At the other extreme, is the Detroit, MI locality. Though the corresponding MGPCI increases by 148 percentage points, the area's average fees would be projected to rise by about 7 percentage

points. We summarize the contents of Appendices A through D in Table 5 in order to contrast the options more easily.

Table 5 shows that the changes associated with all of the options are large in most localities. At least 70 percent of the localities will experience changes greater than 10 percentage points no matter which option is selected. Over one-fifth of localities would see their MGPCI value change by over 40 percentage points. There tend to be more gaining than losing localities because of some large reductions in premiums in several populous state that reduced the population-weighted national average premiums. In addition, relatively low premiums in Puerto Rico - that are now included in the MGPCI computation - lower the national average slightly, adding to the number of gaining localities.

Looking across all of the options it is hard to favor one over another in the interest of keeping the MGPCIs stable. However, there are some differences worth noting. The single-year, 20-specialty index causes changes of over 40 percentage points in 92 out of the 232 localities. The three-year, 20-specialty index, on the other hand, results in changes of over 40 percentage point in only 55 localities; a large number but well below the single-year version. If a decision is made to expand the number of specialties represented in the MGPCI, it appears that using an index that averages across three years will result in smaller changes and may be preferable.

If the 3-specialty approach is retained, then these distributions indicate that choosing an index based on the single most recent year of data may be feasible. Although there are fewer changes of less than 10 percentage points associated with the single-year index than the three-year average, the changes are not so large as to make it obviously less desirable in this instance. The main arguments against selecting an update based solely on 1992 data is that

Table 5

Distribution of Changes in MGPCI Values by Update Alternative  
 (Total Number of Localities = 232)

| <b>Change</b>                       | <b>1990-1991-1992</b> |                     | <b>1992</b>        |                     |
|-------------------------------------|-----------------------|---------------------|--------------------|---------------------|
|                                     | <b>3 Specialty</b>    | <b>20 Specialty</b> | <b>3 Specialty</b> | <b>20 Specialty</b> |
| <b>Greater than 40% Decrease</b>    | <b>39 (17%)</b>       | <b>30 (13%)</b>     | <b>40 (17%)</b>    | <b>37 (16%)</b>     |
| <b>25% to 40% Decrease</b>          | <b>22 (9%)</b>        | <b>26 (11%)</b>     | <b>21 (9%)</b>     | <b>19 (8%)</b>      |
| <b>10% to 25% Decrease</b>          | <b>17 (7%)</b>        | <b>26 (11%)</b>     | <b>21 (9%)</b>     | <b>33 (14%)</b>     |
| <b>10% Decrease to 10% Increase</b> | <b>70 (30%)</b>       | <b>39 (17%)</b>     | <b>41 (18%)</b>    | <b>38 (16%)</b>     |
| <b>10% to 25% Increase</b>          | <b>22 (9%)</b>        | <b>54 (23%)</b>     | <b>39 (17%)</b>    | <b>27 (12%)</b>     |
| <b>25% to 40% Increase</b>          | <b>43 (19%)</b>       | <b>32 (14%)</b>     | <b>46 (20%)</b>    | <b>23 (10%)</b>     |
| <b>Greater than 40% Increase</b>    | <b>21 (9%)</b>        | <b>25 (11%)</b>     | <b>24 (10%)</b>    | <b>55 (24%)</b>     |

geographic differentials in premiums have been shown to be volatile (see Welch, et.al., 1989) and that premiums during the 1990-1992 period have been stable or falling in many areas. It could be that future updates would be done at different points in the malpractice premium cycle eliminating the similarities between a three-year and a single-year approach. This suggests that basing the decision to update with a single-year index on the empirical findings from the period covered in this study is not advisable.

**Explaining the Changes.** Beyond merely contrasting the alternatives with each other, it is useful to explore the causes of the widespread changes in the MGPCI values more closely. Because of the largely state-based nature of malpractice markets and the premium data being used, this discussion can focus on the types of changes in state-level indices that were explained in Zuckerman, Norton, and Wadler (1992). Using a 3-specialty index based on 1989-1991 data, they found 33 states whose MGPCI changed by more than 10 percentage points when the representative data set was used instead of the original data. In 28 of these 33 states, they found that the large changes could be traced to the source of premium data. We compute similar state-level indices for a 3-specialty, 3-year (1990-1992) MGPCI to facilitate discussion of the changes.

According to data in Table 6, we find 32 states with changes in excess of 10 percentage points. Though the composition of states is not identical to the earlier study, it is still the case that 28 of these 32 states are based on substantially different companies' data than used in the original index. In most of these instances, this means replacing St. Paul premiums with either other companies' premiums or a combination of premiums from St.

**Table 6**  
**Impact of 3-Specialty 1990-92 Data on MGPCI, by State**  
**(ascending order of change)**

| State                | Original MGPCI | 3-Specialty<br>1990-92 MGPCI | Change |
|----------------------|----------------|------------------------------|--------|
| California           | 1.370          | 0.789                        | -0.58  |

Note: District of Columbia, Maryland, and Virginia are based on state boundaries, not Medicare carrier designations.

Paul and another company.<sup>9</sup> For example, for the MGPCI option used in Table 6, the new data source suggests an increase of 39 percentage points in Texas, a state where St. Paul data was replaced by data from three other insurers. In the case of New Jersey, completely replacing the St. Paul data leads to a 40 percentage point decrease in the MGPCI. Partially replacing St. Paul can lead to similarly diverse effects. For example, substantially reducing St. Paul's importance results in a 37 percentage point reduction and a 21 percentage point increase in Illinois and Tennessee, respectively.

Of the remaining 4 states whose MGPCI value changes by more than 10 percentage points in Table 6, two experienced large increases (Massachusetts and Arkansas) and two experienced large decreases (California and Puerto Rico). The increase in Massachusetts is due to the inclusion of the JUA deferred premium liability adjustment that was relevant in 1990 and 1991. Arkansas is simply an example of a state which experienced substantial premium growth relative to the rest of the country; there were no changes in the source of premium data. The reduction in Puerto Rico is due to the fact that nominal premiums in that area have not changed since 1986.<sup>10</sup>

Given its population size and the magnitude of the reduction in its MGPCI, California is the state that warrants careful attention. Medical Liability Monitor (MLM) -- a professional liability industry newsletter -- cites the state's tort reform program as the reason for its move from being one of the most expensive states in the country to one of the least

---

<sup>9</sup>We had no premium data for 1985 or 1986 in five states included in the original index. These were Alaska, Hawaii, New Hampshire, New Mexico, and Rhode Island. Premiums were imputed in these states. As Table 1 shows, we now have actual premiums for all areas. With the exception of Hawaii, the MGPCI changes by more than 10 percentage points in these states (Table 6).

<sup>10</sup>Our survey of insurers suggests that premiums are likely to rise substantially in 1993. This is probably worth keeping in mind in light of the low MGPCI value in Puerto Rico and the likelihood that an update will not occur until 1995.

expensive. While MLM's attribution of the reduction to the tort reforms appears to be based on anecdotal evidence, a premium survey conducted by the newsletter shows that California's premiums were among the lowest in the country by the late 1980's. Data presented in Welch, Zuckerman, and Pope (1989) also showed the beginning of this downward movement in this state. In 1985, California's premiums were 65 percent above the national average. However, by 1986, this differential had fallen to 12 percent. In light of the fact that the updated MGPCI is based on three years of data, it appears to provide an accurate estimate of the current relative costliness of malpractice premiums in California.

The decision regarding the number of specialties to include in the MGPCI should not be viewed as being without empirical consequence. As shown in Zuckerman, Norton, and Wadler (1992), expanding the number of specialties can increase or decrease MGPCI values substantially. For example, they found that moving from the 3-specialty approach to the 20-specialty approach raised the MGPCI by 28 percentage points in the District of Columbia and lowered it in Arizona and New York by 26 and 24 percentage points, respectively. However, it is worth noting that in 45 of 52 states (including DC and Puerto Rico) the change in the numbers of specialties changed the MGPCI by less than 10 percentage points. They showed that, in the areas where changes were large, the relative premiums for some or all of the specialties not included in the 3-specialty approach differed considerably from the 3 included specialties. In the District of Columbia, for example, GPs had premiums that are 35 percent below the national average for GPs, whereas internists and radiologists (2 of the 10 specialties represented by GPs) had premiums 12 percent above their respective national averages. Table 7 shows the state-level differences between the 3-specialty and 20-specialty MGPCI using

**Table 7**  
**Impact of Expanding Number of Specialties in MGPCI Based on 1990-92 Data, by State**  
**(ascending order of change)**

| State Name           | 3 Specialty<br>1990-92 MGPCI | 20 Specialty<br>1990-92 MGPCI | Change |
|----------------------|------------------------------|-------------------------------|--------|
| Arizona              | 1.603                        | 1.373                         | -0.230 |
| New York             | 1.627                        | 1.436                         | -0.191 |

Note: District of Columbia, Maryland, and Virginia are based on state boundaries, not Medicare carrier designations.

1990, 1991 and 1992 premium data. These differences identify the same states as the earlier analysis as being most affected by the specialty decision.

## V. ASSESSMENT OF MGPCI ALTERNATIVES

As has been true at all stages of the development of the GPCIs, decisions about the best approach to follow need to be based on the soundness of the methodology and the data as opposed to the resulting GPCI values. This is equally true in updating the MGPCI. All of the updates differ substantially from the original index, although the conceptual basis of the options - a comparison of premiums for a \$1 million/\$3 million mature claims made policy - has not changed. The main methodological refinements relate to the source of the data and the range of risk classes represented in the index. Given the magnitude of the changes associated with the 3-specialty, 3-year MGPCI option (the approach closest to the original index), it appears that relying on a new source of data that is both more recent and drawn from a more representative set of companies is the primary cause of the changes.

However, given geographic (i.e., insurer) variation in the classification of specialties into risk groups, the specific MGPCI values that are used in the update are sensitive to the choice of specialties included in the index. In some areas (e.g., District of Columbia, Arizona, and New York), the geographic differentials in premiums for general practitioners, general surgeons, and orthopedists (the three original specialties) relative to each specialty's national average are quite different than the differentials that exist for other specialties. This means that choosing to expand the range of specialties used to compute the index on the grounds that it provides a better method for deriving an index to be applied to all specialties is a decision that will have some redistributive impact (discussed below). However, it might

be difficult to defend the 3-specialty approach in areas whose index values would increase as result of incorporating more specialties' premiums in the MGPCI. Moreover, areas that are hurt by a move to a 20-specialty index will find it difficult to argue that major Medicare specialties (e.g., thoracic surgeons, ophthalmologists, and cardiologists) should be excluded from the MGPCI. This leads to the conclusion that expanding the number of specialties from 3 to 20 is a desirable refinement of the MGPCI methodology.

In terms of the number of years of data to be used in the computation of the MGPCI, the potential for instability in geographic differentials across years makes it desirable to average across several years. This update expands the number of years of data used in the averaging from 2 to 3.<sup>11</sup> The main argument against using additional years of data is that it increases the resources required for data collection. In the limit, using the most recent single year could seem like an attempt to keep the MGPCI as current as possible. However, given the lags between development and implementation of the MGPCI and the inherent instability of an annual index, an index based on a single year of data runs the risk of introducing inappropriate anomalies into the malpractice adjuster. Based on the options presented here, this suggests a preference for the 3-year index based on data from 1990, 1991, and 1992.

To gauge the extent of the redistribution that would be caused by an expansion of the number of specialties and years of data used in the index, we computed an overall GAF assuming only the MGPCI component had been revised. We replaced the original MGPCI with the revised index based on 20 specialties and 1990-1992 data. In the original GAF, malpractice costs represents about 5.6 percent of total costs, on average. Therefore, to conduct this simulation, we assign the MGPCI a weight of 5.6 percent. Locality-level results

---

<sup>11</sup> Analysis not discussed above shows that moving from 2 to 3 three years has little impact on the MGPCI.

are shown in Appendix E. This simulation indicates that no locality will experience an average fee reduction of greater than 4.2 percent. In fact, about 84 percent of localities (194 out of 232) would see their fee fall, on average, by less than 3 percent. Although changes associated with this revision of the MGPCI would not be trivial, these results show that average fees would change by much less than the MGPCI itself.

## VI. RVU WEIGHTING AND CURRENT LOCALITIES

In order to facilitate comparison between the original MGPCI used during the first three years of MFS and the options for revision, the previous sections in this report have used both population weighting to derive national average premiums and the locality structure that was in place in 1992 (the year the MGPCI was first used). However, a revised MGPCI that can be used in 1995 needs both to reflect the locality structure that will be in effect in 1995 and, given HCFA's interest in weights based on service volume, to compute national average premiums using RVU weights, as opposed to population. As a result of Ohio and North Carolina deciding to use statewide payment areas in 1994, the number of localities has been reduced from 232 to 216. The tables in this section reflect this locality configuration.

Appendix F shows the MGPCI values from the population-weighted MGPCI based on 20 specialties and three years of premium data and an otherwise similar index that uses RVU weighting. As can be seen, all of the MGPCI values decline as a result of moving to RVU weighting.<sup>12</sup> The reason for this is that the RVU-weighted national average premiums are all higher than the population-weighted average premiums. In fact, averaging across all

---

<sup>12</sup>The reader may note some small differences between the population-weighted values presented in this section and those presented in earlier sections. This is caused by revisions in the 1990 population counts that occurred at the time the revised county-to-locality crosswalk (that results in 216 localities) was being finalized.

specialties, the national average premium is about 6.6 percent higher using RVU weights. This results in a near-uniform percent reduction across all areas.<sup>13</sup> In absolute terms, however, the MGPCI value falls by more in the high-premium areas than in low-premiums areas. This narrows the range of MGPCI values, i.e., the low-premium areas gain relative to the high-premium areas. Recall that all changes in fees will be substantially smaller than the changes in the MGPCIs.

Based on the analysis presented in this report, HCFA has decided to revise the MGPCI by replacing the original index with one computed from 1990-1992 premium data for 20 specialties using RVU weights. Given this decision, there are two issues that must be addressed. First, because the MGPCI is simply designed to distribute payments for malpractice costs across localities according to actual premiums differences, a revision should not affect the total payments made for malpractice RVUs under the MFS. However, HCFA actuaries determined that the changes embodies in the RVU-weighted index presented in Appendix F would result in a reduction in malpractice payments. To correct this unintended consequence of the revision, the actuaries derived a rescaling factor that raises the MGPCI in all areas. The value of this multiplicative rescaling factor is 1.02307, suggesting that the revision might have reduced payments by 2.3 percent. The rescaled MGPCI revision is presented in Appendix G.

---

<sup>13</sup> At the county-level, all of the MGPCI values fall by the same amount in percentage terms when RVUs replace population as the basis of weighting. However, within localities (aggregations of counties or parts of counties) the distribution of RVUs differs from the distribution of population. This can cause the locality-level change in the MGPCI to differ from the change in the component counties. These differences can be large when the counties have dramatically different relative malpractice costs. For example the Rockford, IL locality is made up of Boone, Winnebago and McHenry counties. Premiums are about 60 percent higher in McHenry than in the other two counties. But, McHenry county gets a smaller weight based on RVUs than based on population. As a result the RVU-weighted MGPCI for the Rockford, IL locality is reduced by more than the county-level MGPCIs. This occurs because the higher-cost locality gets a smaller weight using RVUs.

The second issue relates to the Congressionally-required transition. If any of the GPCIs are not updated annually, when they are revised there must be a transition year during which the GPCI is the simple average of the old and new index numbers. The effect of this rule is that only 50 percent of the impact of the revised index will be experienced during the transition year. The transition year index is also presented in Appendix G. The revised index would be fully implemented in 1996, with 1995 being the transition year. The labelling of the indices in Appendix G reflects this timing.
