**Some notes on lateral growth of jack pine crowns, T. SCHANTZ-HANSEN.** (Univ. Minn.). (*Jour. Forestry*, 38 (1940), No. 7, pp. 598-600).—Measurements of crown spread in 40-year-old jack pine showed little relationship between number of trees and crown density. Measurements of crown spread in thinned plats and check plats showed that thinned plats had not reached the probable crown density attained before thinning. Measurements of lateral growth of crowns in five locations in Minnesota showed an exceedingly slow rate of growth. Further studies are said to be needed to solve the problem of what constitutes a closed stand and how rapidly it can be brought about after the stand is opened.

**Longevity of ponderosa pine, F. P. KEEN.** (U. S. D. A.). (*Jour. Forestry*, 38 (1940), No. 7, pp. 597, 598).—A careful ring count on a sound stump section of a tree felled in Klamath County, Ore., showed the tree to be 726 yr. old.

This was the oldest tree recorded, with another 714 yr. next in order. The oldest trees were slow-growing, were located on relatively poor-quality sites, and had been exposed to many forest fires.

## DISEASES OF PLANTS

**The Plant Disease Reporter, [June 1 and 15, 1940] (U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr., 24 (1940), Nos. 10, pp. 189-208, figs. 1; 11, pp. 209-231, figs. 2).**—The following items of interest to phytopathology are included:

*No. 10.*—*Acer* section of revised plant disease check list, by F. Weiss; *Rehmiellopsis bohémica* needle blight of balsam fir in Maine, by A. M. Waterman and K. F. Aldrich; three new locations for the *Ceratostomella* sycamore (plane-tree) disease, by P. V. Mook; gray bulb rot (*Rhizoctonia tuliparum*) and *Botrytis* blight on tulips, by C. Westcott; *Rhizoctonia solani* on strawberries in transit, by I. H. Crowell; and reports on cereal diseases in Virginia and Texas.

*No. 11.*—Relative prevalence and geographic distribution of various ear rot fungi in the 1939 corn crop, by P. E. Hoppe; *Botrytis cinerea* blight of flax in California, by B. R. Houston; *Botrytis cinerea* in California flax fields, by W. W. Mackie; reports on diseases of small grains in Virginia, Arkansas, Iowa, and Nebraska; reports on tobacco diseases, including red rot and downy mildew in Massachusetts, downy mildew in Connecticut, first serious outbreak of downy mildew in Pennsylvania, and widespread appearance of wildfire, downy mildew and bacterial leaf spots in Kentucky, downy mildew in Tennessee, and severe attack of downy mildew in North Carolina; brief reports on the effectiveness of cottonseed treatment in Arkansas, and downy mildew on hops in New York; notes on diseases of ornamental plants in southern California, by P. A. Miller; *Mycosphaerella citrullina* on ornamental gourds (*Cucurbita pepo*), by K. Longrée; strawberry dwarf in Massachusetts and New York; other reports on fruit diseases, including apple and peach diseases in Massachusetts, fruit diseases in New York, fire blight in Nebraska, fruit diseases not important in Arkansas, parts of lamina missing from fig leaves in Texas, and *Botrytis* sp. on strawberries in transit; halo blight of beans in Florida, by L. O. Gratz; rolling of tomato leaves, strongly suggesting curly top, in Texas, by P. A. Young; and brief notes on diseases of ornamentals in Massachusetts, some new plant disease records from Nebraska (leaf curl of chokecherry and near wilt of peas), potato production in Utah threatened by the bacterial ring rot, bacterial ring rot in New York, downy mildew on spinach in New York, and drought injury to trees in Nebraska.

**Bureau of plant pathology [report], D. G. MILBRATH (Calif. Dept. Agr. Bul., 27 (1938), No. 6, pp. 765-777).**—Brief reports on work with storage troubles of apples, chestnut blight eradication, control of western celery mosaic, tuberose bulb treatments for root knot, control of spotted wilt of lettuce, peach mosaic eradication, peach mosaic State-wide survey, grape disease resembling the formerly prominent California vine disease, seed potato diseases, laboratory diagnoses and summary of causes of plant diseases on specimens received, white pine blister rust, *Coryncum* canker of cypress, gardenia canker, date palm decline, citrus psorosis, hop downy mildew, and sugar beet nematodes.

**[Studies in plant pathology], P. L. GUEST, G. K. PARRIS, J. E. WELCH, K. KIKUTA, [M.] MATSUURA, H. F. CLEMENTS, [L.] MACHLIS, and H. G. HEGGENESS (Hawaii Sta. Rpt. 1939, pp. 57, 58, 69-74, 77, 78).**—Brief reports are included on the following: The results of a foliar diagnosis of chlorotic and nonchlorotic

macadamia trees, virus disease of papaya, bean rust, virus of yellow spot of pineapple on tomatoes, nematodes on potatoes and early blight of potatoes, bordeaux toxicity, damping-off control, seasonal list of fungus diseases in Hawaii, and arsenic toxicity to Sudan grass and bush bean.

[**Report of the pathology department**], J. P. MARTIN (*Hawaii. Sugar Planters' Assoc. Proc.*, 59 (1939), *Expt. Sta. Com. Rpt.*, pp. 28-38).—Progress reports are given on foreign cane diseases; sugarcane quarantine, plantation inspection, and consultation services; potato nematode infestation; and sugarcane diseases in Hawaii (brown stripe, chlorotic streak, *Helminthosporium sacchari* eye spot, leaf scald, stem galls induced by the green leafhopper and soil extracts, mosaic, red rot, red stripe, root rots, and physiological disorders.

[**Phytopathological work by the Kentucky Station**] (*Kentucky Sta. Rpt. 1939, pt. 1, pp. 31, 32, 35-38*).—Reports of progress are given on phony peach disease eradication (coop. U. S. D. A.); and on tobacco diseases, including control of wildfire and angular leaf spot in plant beds, experimental production of blackfire, relation of stomata to wildfire infection, low soil fertility predisposing to leaf spot diseases, blackshank spread by drainage water, mosaic damage in 1939, field tests of mosaic-resistant dark fired tobaccos, tests of mosaic-resistant Burley hybrids, *Fusarium* wilt-resistant Burley tobacco, tobacco streak in relation to a similar virus disease in sweetclover, and blue mold (downy mildew) during the past 3 yr. in the State.

[**Plant disease studies by the Ohio Station**] (*Ohio Sta. Bul. 600 (1939), pp. 20-24, 25, 75, 76, figs. 3*).—Progress reports are included on development of new sprays for fruit diseases; disease control for tomatoes, cucurbits, and other vegetables; fixed copper substitutes for bordeaux mixture; bacteriophage as a factor in disease resistance; roguing and selection for control of *Verticillium* wilt of chrysanthemums, tree disease control, including *Verticillium* on elms and maples, and virus phloem necrosis of elms; and white pine blister rust control.

[**Plant disease studies by the South Carolina Station**], G. M. ARMSTRONG, C. C. BENNETT, C. C. MILEY, W. B. ALBERT, W. B. KELLER, C. H. ARNDT, G. W. BOOZER, E. E. HALL, J. R. MATTISON, J. M. JENKINS, JR., W. C. BARNES, and C. J. NUSBAUM. (Partly coop. U. S. D. A. et al.). (*South Carolina Sta. Rpt. 1939, pp. 65-71, 72-76, 137-140, 173, 174, 176, 185-189, figs. 7*).—Progress reports are given on cotton wilt-variety tests, cross-inoculation experiments with *Fusarium* strains from cotton and Burley tobacco, mineral nutrition and wilt resistance of wilt-susceptible and wilt-resistant cotton varieties, cotton varietal selection for wilt resistance and fiber quality, seed treatment for cotton seedling diseases, distribution of the anthracnose fungus on the cotton plant, cotton disease survey, tests for controlling tobacco blue mold or downy mildew, varietal tests with downy mildew of cucumbers, fungicidal control and epidemiology of the disease on cucumbers and cantaloups, and fungicidal control of anthracnose on honeydew melons.

[**Plant pathology**, C. D. SHERBAKOFF (*Tennessee Sta. Rpt. 1938, pp. 76-80*).—Brief reports are presented on wheat breeding for disease resistance, with special reference to scab and root rot; breeding for resistance to *Fusarium* wilts of cotton (U. S. D. A.), tomato, and tobacco; testing of hybrids and segregates for resistance to strawberry black root; breeding of red clover for resistance to diseases; host specialization in root knot nematodes; testing of the newer "insoluble" copper fungicides; field tests for resistance to tomato leaf diseases; and testing of lots of apple trees for reactions to black root rot.

[**Plant disease work by the Wyoming Station**] (*Wyoming Sta. Rpt. 1939, pp. 6-8, 38, 39*).—Progress reports are included on the control of psyllid yellows

or purple top in potatoes; varietal reactions and control tests with common and halo blight of beans; ferric phosphate control of chlorosis in cottonwood trees; control of diseases of potatoes; and yields of garden pea varieties in relation to various disease control treatments.

**Cytological basis of killing plant tumors by colchicine**, H. DERMEN and N. A. BROWN. (U. S. D. A.). (*Jour. Hered.*, 31 (1940), No. 4, pp. 197-199, figs. 2).—This is a preliminary report of studies indicating the response to lie in an increase in nuclear and cell volume, and final disintegration, shriveling, and drying up of the bacterially induced tumor.

**The effects of carcinogenic substances on plants (preliminary contribution)** [trans. title], J. KISSER (*Ber. Dent. Bot. Gesell.*, 75 (1939), No. 10, pp. 506-515).—This is a review, with 23 references.

**Unusual chytridiaceous fungi**, F. K. SPARROW, JR. (*Mich. Acad. Sci., Arts, and Letters, Papers*, 24 (1938), pt. 1, pp. 121-125).—Many algae (Chlorophyceae and Heterokontae) are frequently attacked by fungi belonging to the Chytridiales. Some algae, when first invaded, appear to be healthy, but in others unmistakable signs of moribundity are visible, and the extraneous fungus is probably weakly if at all parasitic. Certain of these "chytrids" may also be induced to live on boiled filaments of their apparent hosts, and of these it can be said definitely that they are capable of living saprophytically. *Diplophlyctis laevis* and two species of *Rhizophidium* are the chytrids here dealt with.

**A note on the status of the generic name Urocystis**, G. L. ZUNDEL, J. A. STEVENSON, C. M. TUCKER, D. S. WELCH, and E. WEST (*Phytopathology*, 30 (1940), No. 5, pp. 453, 454).

**The chemistry of resistance of plants to Phymatotrichum root rot.—V. Influence of alkaloids on growth of fungi**, G. A. GREATHOUSE and N. E. RIGLER. (Tex. Expt. Sta.). (*Phytopathology*, 30 (1940), No. 6, pp. 475-485).—Continuing their investigation of resistance (E. S. R., 83, p. 203), the authors report studies of 62 alkaloids from 15 families and 50-70 plant species differing in susceptibility to *P. omnivorum* relative to their influence on its growth. The comparative influence of 6 alkaloids on 6 fungi other than *P. omnivorum* was also determined. Sanguinarine proved the most toxic alkaloid studied, completely inhibiting growth of *P. omnivorum* at a concentration of 2.5 p. p. m. In general, the relative toxicity of the alkaloids to the *Phymatotrichum* root-rot fungus followed the relative resistance rating of the plant from which isolated.

**Experimental Phymatotrichum root rot of retama and corn**, G. M. and M. O. WATKINS. (Tex. Expt. Sta.). (*Bul. Torrey Bot. Club*, 67 (1940), No. 6, pp. 489-501, figs. 27).—Young retama (*Parkinsonia aculeata*) and corn seedlings grown aseptically in vitro and inoculated with sclerotia from pure cultures of *Phymatotrichum omnivorum* were readily infected, although these plants have been reported as immune against infection by this fungus at maturity in the field. Histological study of roots of both species in various stages of infection indicated widespread degeneration of cell walls and protoplasts in advance of actual hyphal penetration. The disorganization and collapse of host cells in this manner proceeded from the epidermis inward, finally resulting in breakdown of the entire cortex. In advanced stages the hyphal network was found in the central cylinder.

**Rootrots of cereals** (*Canada Dept. Agr. Pub. 699* (1940), pp. 4, fig. 1).—An informational leaflet.

**Bacterial wilt resistance and genetic host-parasite interactions in maize**, R. E. LINCOLN. (Iowa Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 60 (1940), No. 4, pp. 217-239, figs. 5).—Passage of stock or single-cell cultures of *Phytomonas stewartii* through susceptible inbred lines of corn decreased their virulence,

whereas passage through resistance lines increased it. Single-cell colonies from an old stock culture indicated it to be composed of many variants differing in virulence. Successive passages of this stock culture through susceptible corn decreased the proportion of virulent variants, whereas passage through resistant lines increased it. When mixtures of known proportions of virulent and avirulent bacteria were inoculated into corn, a differential selection for the virulent type in the resistant host and for the avirulent type in the susceptible host followed. The rate and direction of this change in virulence are thus functions of both host resistance and bacterial virulence. After growth in nutrient broth, mutation in colony color and type occurred at rates of 1 in 20,000 to 1 in 800,000 cells. Both increases and decreases in virulence were also found. It is concluded that mutation and selection alone are capable of effecting the observed changes in virulence of this pathogen—mutation providing the variation while the microenvironment of the host is a directional selective agent. There are 22 references.

**Host selection by *Uromyces graminis*** [trans. title], E. GÄUMANN (*Ber. Deut. Bot. Gesell.*, 58 (1940), No. 2, pp. 92-96).—The host selectivity of physiologic races of the rust fungus *U. graminis* is tabulated and discussed.

[Wheat diseases] (6. *Hard Spring Wheat Conf., Minneapolis, 1939, Rpt.*, pp. 58-65, 68).—The following are of interest to disease problems for wheat: Results From Disease Garden and Root Rot Studies at University Farm, St. Paul, Minn., by E. W. Hanson (U. S. D. A.); What Is Known About Wheat Scab and What Can Be Done About It, by J. J. Christensen, and Seed Treatment, by M. B. Moore (both Minn. Expt. Sta.); Uniform Bunt Nursery, by J. A. Clark, and Results From Leaf Rust Studies, by M. N. Levine (both U. S. D. A.); Distribution and Importance of Physiologic Strains of Stem Rust, by E. C. Stakman (Minn. Sta. and U. S. D. A.); and Disease Problems.

**Barberry eradication**, G. C. MAYOUE. (Coop. U. S. D. A.). (*North Dakota Sta. Bimo. Bul.*, 2 (1940), No. 5, pp. 5-7, figs. 2).—A general discussion of black stem rust of cereals in relation to the barberry host, and a progress report on barberry eradication in North Dakota, begun in 1917.

**Reaction of winter wheat varieties to loose smut infection at Texas Substation No. 6, Denton, Tex., 1938 and 1939**, I. M. ATKINS (*U. S. Dept. Agr., Bur. Plant Indus.*, pp. 4).

**The dissemination of the spores of loose smut of wheat (*Ustilago tritici*) through the air**, A. J. P. OORT (*Tijdschr. Plantenziekten*, 46 (1940), No. 1, pp. 1-18, pl. 1, figs. 2; *Eng. abs.* pp. 16-18).—Evidence from the two experiments reported indicates that *U. tritici* spores may be disseminated and cause infection for at least 100 m. from the point of origin. In winds of high velocity the dissemination occurred almost in a horizontal plane and the infection was heavy but regularly diminishing with distance from the source of the spores. In winds of low velocity vertical air currents were associated. In this case infection was, in general, much less and showed smut islands alternating with more or less smut-free spots.

**Summary of the Great Plains uniform winter wheat bunt nursery, 1939**, H. A. RODENHISER and K. S. QUISENBERRY (*U. S. Dept. Agr., Bur. Plant Indus.*, 1940, pp. 3).—A summary of data obtained in 1939, together with averages for the varieties grown during different periods, 1932-39.

**Results from the uniform bunt nurseries in the western region in 1939, with averages for 1938**, C. S. HOLTON and C. A. SUNESON (*U. S. Dept. Agr., Bur. Plant Indus.*, 1940, pp. 2).—Seed of 28 varieties and hybrid selections of winter wheat was inoculated and sown in 10 localities in the 1938-39 season to determine their reactions to bunt other than the "dwarf" race of *Tilletia tritici*,

and noninoculated seed was sown at 3 places to determine the reactions of the varieties to the last-named race. The resulting data are tabulated and discussed.

**Studies on oat blast, T. JOHNSON and A. M. BROWN** (*Sci. Agr.*, 20 (1940), No. 9, pp. 532-550, figs. 4).—Evidence is presented that the amount of blast is readily influenced by the nutritional conditions of the oat plant from the time the spikelets are initiated until just before emergence of the panicle. Any influence adverse to normal nutrition during this period tended to increase the amount of blast. At this growth stage the amount was experimentally increased by reducing the water supply, withholding certain mineral nutrients, artificially injuring the leaves, leaf injury due to rusts, and growing the plants under progressively diminishing day length. Field tests relative to the influence of date of sowing on blast incidence (1934-39) indicated that in some varieties there is a tendency for early sown oats to have a lower incidence than oats sown later. Data over a 3-yr. period showed that the yield per acre is highest for the earliest date of sowing and progressively decreases with later sowings. This decrease in yield was accompanied by a diminution in panicle size and frequently by an increase in the percentage of blasted spikelets. The yield decreases appeared to be largely the consequence of diminished vigor of growth, though the higher incidence of blasted spikelets was perhaps also a contributing factor.

**Occurrence of a disease of side-oats grama, R. L. FOWLER and J. E. WEAVER.** (*Univ. Nebr.*). (*Bul. Torrey Bot. Club*, 67 (1940), No. 6, pp. 503-508, figs. 3).—The beginning of this disease of *Bouteloua curtipendula* was first observed in 1937 but reached alarming proportions in 1939. The fact that this grass has increased during the past 6 yr. from a rank of seventh or eighth among dominants of true prairie to one of the two or three most important species adds unusual economic interest. Furthermore, it has a wide distribution, is one of the most drought-resistant among the best grasses for rejuvenating depleted pastures and reseeding abandoned lands, and is being grown abundantly in grass nurseries of the U. S. D. A. Soil Conservation Service. For these reasons the authors give a rather complete account of its occurrence and increase. The disease symptoms, based on field observations, include the appearance in early spring of rosette-like clumps or portions of bunches containing large numbers of tillers. These plants do not elongate normally, and the stem bases develop a distinctly reddish color. The leaves are dwarfed to one-third or less of their usual width. The general appearance suggests the virus mosaic disease of wheat. The leaves are yellowish and turn brown after death. Where there are any, the flower stalks are markedly reduced in number and attain only about two-thirds their normal height. Whether this disease is due to insect damage, fungi, bacteria, a virus, or to physiological conditions only is as yet unknown. Whatever the cause, it is believed reasonable that the extreme conditions resulting from the years of drought may have been a contributing factor.

**The occurrence of *Helminthosporium turcicum* in the seed and glumes of sudan grass, S. J. P. CHILTON.** (U. S. D. A. et al.). (*Phytopathology*, 30 (1940), No. 6, pp. 533-536, figs. 1).—*H. turcicum* was isolated from surface-sterilized seed or glumes of 21 out of 52 lots of Sudan grass seed, the percentage ranging from 1 to 20 with seed and from 1 to over 50 with glumes. The fungus was still viable in seed lots nearly 2 yr. old. Surface sterilization with HgCl<sub>2</sub> (1-1,000) for 1 hr. greatly reduced the number of infected seed without seriously affecting germination. Infection somewhat reduced germination.

**Variation in pathogenicity and cultural characteristics of the cotton-wilt organism, *Fusarium vasinfectum*, G. M. ARMSTRONG, J. D. MACLACHLAN, and R. WEINDLING.** (S. C. Expt. Sta.). (*Phytopathology*, 30 (1940), No. 6, pp. 515-

520, figs. 2).—Thirteen single-spore cultures were grown on nonacidified potato-dextrose agar at 28° C., and 17 successive transfers were made, each time 3-6 single spores from each culture being transferred to agar in petri dishes to distinguish variants as they appeared. Of the 13 isolates, 11 exhibited variation in cultural characteristics, and in the 2 directions of less aerial mycelium and a slower rate of growth. No variant studied reverted to the parent type. Fifteen of the single-spore isolates were used to infest soil in pots in which a susceptible variety and resistant varieties of cotton were grown, an average of 25 plants being used for each isolate and cotton-variety combination during each of 2 yr. Results were noted as regarded external and internal symptoms, and reisolation of the fungi. Isolates long in culture proved decidedly less pathogenic than those of recent origin, and some variants were markedly less pathogenic than the parent, while others varied little. A single passage of an isolate through the host failed to modify its pathogenicity. The high percentage of reisolation from resistant cotton varieties showing no external symptoms suggests that the mechanism of resistance is not involved in the process of infection. It is believed that variants of *F. vasinfectum* differing in pathogenicity may occur in the field.

**Disease resistance tests and seedling selections in 1938 and 1939, R. D. RANDS, E. V. ABBOTT, and E. M. SUMMERS.** (U. S. D. A.). (*Sugar Bul.*, 18 (1940), No. 15, pp. 5-9).—This reviews the disease development in commercial and test-field varieties of sugarcane, and summarizes disease resistance and other tests enabling the selection of C. P. numbers among the many new seedlings received since the last report at the U. S. Sugar Plant Field Station, Houma, La. (E. S. R., 80, p. 500). A partial acreage census of commercial varieties is included for better evaluation of the present disease situation.

**A chytrid in relation to chlorotic streak disease of sugar cane, C. W. CARPENTER** (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.]*, 44 (1940), No. 1, pp. 19-33, figs. 12; *abs. in Science*, 91 (1940), No. 2364, pp. 382, 383).—The intracellular chytrid fungus discussed in this preliminary paper apparently has not hitherto been observed, nor did a brief search of the available literature reveal any species closely resembling the various phases of its life cycle observed in many varieties of sugarcane and here described and illustrated. The history of chlorotic streak, its symptomatology, etiological studies, and current observations are also discussed and presented as a progress report, which may serve as an introduction to the etiology of the disease. "Whether the chytrid described is the agent causing the symptoms may not be as significant as that this intracellular parasite, apparently hitherto unknown, may, in the absence of any gross symptoms, contribute to growth depression, poor germination, and thin stands of cane in plant and ratoon crops, and the deterioration of mature cane, in localities where wet conditions prevail."

**Diseases of tobacco in Canada, G. H. BERKELEY and L. W. KOCH** (*Canada Dept. Agr. Pub.* 667 (1940), pp. 29, figs. 19).—A handbook.

**Further experiments on control of downy mildew, P. J. ANDERSON** (*Connecticut [New Haven] Sta. Bul.* 433 (1940), pp. 166, 193-206, figs. 9).—Reporting further progress (E. S. R., 83, p. 354) on the control of *Peronospora tabacina*, detailed experimentation indicated the great importance and some of the difficulties in obtaining and keeping the proper concentration of benzol gas necessary. Wet cloth covers were found much more effective in confining the air than the glass sash commonly in use, but wet cloth over the top and edges of the glass sash also proved satisfactory. In comparing cloth covers with 56 by 60 and 80 by 80 threads to the inch, the thicker quality increased the gas concentration maintained throughout the night but both produced concentrations

well above the safety point for effective control. Sprinkling the glass sash increased the concentration, provided the wind did not dry off the moisture during the night. Glass sash covered with wet cloth proved most independent of wind effects. Variations in air temperatures commonly encountered in the Connecticut region were apparently not of great importance so far as benzol control was concerned. The evaporation surface ratio, the volume of benzol needed, the time and frequency of application, and the use of wick evaporators are discussed, and brief notes on more limited tests of paradichlorobenzene control are included.

**Toxicity of paradichlorobenzene in relation to control of tobacco downy mildew,** J. A. PINCKARD, R. McLEAN, F. R. DARKIS, P. M. GROSS, and F. A. WOLF. (Va. Expt. Sta. et al.). (*Phytopathology*, 30 (1940), No. 6, pp. 485-495, figs. 2).—A quantitative method permitting joint medication of host and parasite (*Peronospora tabacina*) under controlled environal conditions was used in this study. The minimum concentration of paradichlorobenzene vapor fungicidal to downy mildew was 0.01-0.02 volume percent, equivalent to saturation pressures at 0°-7° C. For effective fungicidal action, 3-4 consecutive treatments within this range were requisite, a single application not eradicating the parasite. The maximum concentration tolerated by tobacco seedlings for a single 12-hr. fumigation was  $\pm 0.0375$  volume percent, equivalent to saturation at 12°. Temperature is also an important factor in delimiting the concentration of vapor obtainable. Further evidence is presented to show that paradichlorobenzene vapor acts as an eradicant fungicide without appreciable injury to the host. The concept of penetrant fumigants is developed and its implications are discussed.

**The use of paradichlorobenzene in seedbeds to control tobacco downy mildew,** R. McLEAN, J. A. PINCKARD, F. R. DARKIS, F. A. WOLF, and P. M. GROSS. (Va. Expt. Sta. et al.). (*Phytopathology*, 30 (1940), No. 6, pp. 495-506, fig. 1).—Applied either on successive nights or over longer intervals between successive applications, paradichlorobenzene has given satisfactory control of downy mildew in tobacco seedbeds. The authors regard it as an effective fungicide against this disease when employed under the following conditions: The proper amount to use is 1.5-3 lb. per application per seedbed area of 100 sq. yd. The crystals should be distributed widely on the loose-texture cloth ordinarily used for seedbed covers. Sheeting of  $\pm 60$  threads each way per inch should be used as a covering during fumigation. Under seedbed conditions temperatures above 7° C. are necessary for sufficient vaporization to maintain effective vapor concentrations. Moisture on the seedbed covers is desirable to aid in retaining effective concentrations of vapor within.

**The prevention of brown rootrot and black rootrot of tobacco in Canada,** L. W. KOCH and R. J. HASLAM (*Canada Dept. Agr. Pub.* 700 (1940), pp. 4, figs. 2).—An informational leaflet.

**Frenching of tobacco distinguished from thallium toxicity by spectrographic analysis,** G. M. SHEAR and H. D. USSERY. (Va. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 60 (1940), No. 2, pp. 129-139, pl. 1).—Spectrographic analyses of ash from healthy, frenched, and thallium-treated tobacco plants disclosed thallium only in those grown in nutrient solutions containing it. Thallium could be detected in ash samples in amounts of less than 0.0001 percent and in ash samples from plants receiving 0.016 p. p. m. in the nutrient solution—too minute to cause toxic symptoms. Thallium is fixed in the tissues in such a way as to produce a gradient, decreasing from roots to youngest leaves. The plant therefore must have a continuous supply if toxicity symptoms are to appear on the new growth. Gallium appeared to have no relationship with frenching or thallium toxicity.

**Potato diseases and their control**, O. D. BURKE (*Pa. State Col. Ext. Cir.* 218 (1940), pp. [2]+30, figs. 15).—A handbook of information on potato diseases, with general and specific control measures, and identification key to the diseases.

**Potato production in Utah threatened by bacterial ring rot**, B. L. RICHARDS (*Farm and Home Sci. [Utah Sta.]*, 1 (1940), No. 2, p. 5, fig. 1).—This is a general statement concerning this disease and its distribution in the United States since first found in Maine in 1933. During 1939 it was located in 10 Utah counties, and it is believed definitely possible that it will be found in every potato district in the State into which seed has been imported from outside areas.

**Rôle of peroxidase in immunity against *Phytophthora infestans* de Bary**, A. I. GRECHUSHNIKOV (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser.*, 25 (1939), No. 8, pp. 683-687).—On infection, potato varieties resistant to *P. infestans* exhibited dark necroses and higher peroxidase activity than susceptible sorts. When factors unfavorable to resistance came into play (e. g., increased humidity and short days), the peroxidase activity decreased. Furthermore, changes in the cystoamylase (cytoamylase?) values paralleled those in the peroxidase values. It is claimed that under similar growing conditions the resistance of a potato plant to *Phytophthora* may be safely based on the cystoamylase and peroxidase indexes.

**Aphids and their significance as virus vectors on beets and potatoes** [trans. title], S. G. LARSSON (*Tidsskr. Planteavl.*, 45 (1940), No. 1, pp. 97-139).—A general discussion of the subject, with 14 references.

**Relation of boron to heart rot in the sugar beet**, T. R. COX. (Mich. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 5, pp. 354-370, figs. 3).—Seedlings grown in jars without borax developed characteristic deficiency symptoms, viz, blackening of tips of heart leaves, followed by death of the crown; shortening and twisting of the petioles associated with crinkling of the heart leaves and some of the outer leaves; abnormally dark green and thicker leaves, accompanied by more rapid wilting under deficient water supply; pimpled condition of the petioles in early stages, followed by cross and linear checking; yellowing and final death of the outer leaves, following death of the heart leaves; stunted second-growth leaves after the death of the first leaves; breakdown of the heart of the root; darkening of the layer under the skin of the root and development of surface cankers in advanced stages; and restriction of the fibrous root system. The available B of the quartz sand and seed was adequate to prevent deficiency symptoms for 2 mo. after transplanting. Root yields were increased as much as 80 percent by applying 11.9 mg. of borax per 5 kg. of sand in divided applications. Seedlings in advanced stages of heart rot recovered definitely on application of 4.9 mg. of borax per pot. Halves of field-grown mother beets planted in quartz sand cultures without borax produced stunted leaves with marked symptoms of B starvation, whereas the corresponding halves plus borax at the rate of 2 mg. per 1-gal. pot produced a more abundant leaf growth free of deficiency symptoms. Soil tests for available B showed that a crop of sugar beets in pot cultures removes an appreciable amount of B from the soil. By determining the amount of  $B_2O_3$  in leachates from pot cultures it was found relatively easy to remove added borax from soils by leaching with distilled water, even a year after its application. There are 38 references.

**Borax as a control for heart rot of sugar beets**, R. L. COOK. (Mich. Expt. Sta.). (*Better Crops With Plant Food*, 24 (1940), No. 5, pp. 12-16, 39-46, figs. 10).—Borax applied to Thomas sandy loam pot cultures at the rate of 10 lb. per acre prevented heart rot, practically doubled yields, and increased the sucrose

content of the sugar beet roots. Heart rot was not prevented by Cu, Mn, or Mg, nor did they affect the yield and sucrose content. Applied broadcast in the field at rates as high as 80 lb. per acre, borax did not injure the stands or reduce the yields. Applied with the seed at the rate of 10 lb. per acre it injured the stand on one field in 1939 but did not affect the stand on seven other fields in 1938 and 1939. As much as 40 lb. per acre applied in the row did not reduce the stand on some soils. Applied in a band at the side but not in contact with the seed, borax was much less harmful to the stand than when applied with the seed. Applied broadcast or with the seed it did not significantly increase sugar beet yields. Applied as a side dressing on an area where heart rot was very severe, borax significantly increased the total sugar beet yields and more than doubled the yield of normal beets. Heart rot was almost completely prevented by borax applied in the row at the rate of 10 lb. per acre. Broadcast at the same rate it was somewhat less effective, and on one field the 20-lb. application produced significantly better results than the 10-lb. rate. Heart rot reduced the sucrose content of sugar beets. On one field the beets with heart rot had a lower percentage of purity than did normal beets.

**The action of boron on the plant with direct application of boric acid to the shoot** [trans. title], W. MAIER (*Chron. Bot.*, 5 (1939), No. 4-6, pp. 334-336).—According to a brief review of the results of experiments by the author and others the appearance of boron deficiency symptoms in boron-free nutrient solution can be prevented by adding boron to the shoot.

**Boron problems of apple orchards**, A. B. BURRELL. (Cornell Univ.). (*Mass. Fruit Growers' Assoc. Rpt.*, 46 (1940), pp. 137-140).—From experiments in New York State over a 14-yr. period, together with results reported elsewhere, it is found that application of fine granular borax in a ring beneath the tips of the branches in early spring offers a cheap and dependable method of preventing internal cork even in dry years. This method has been used on some 75,000 trees in the Champlain Valley and with some variations in many orchards of the United States and other countries. Its use is suggested for entire blocks in which some internal cork has occurred. The four major symptoms of boron deficiency in apples are described, viz, internal cork, external cork, dieback, and rosette.

**Magnesium deficiency of apple trees in sand culture and in commercial orchards**, H. HILL and F. B. JOHNSTON (*Sci. Agr.*, 20 (1940), No. 9, pp. 516-525, figs. 8).—Following a review of the occurrence, symptoms, and control measures found effective for Mg deficiency, studies of the effects on the foliage and growth of Melba, Fameuse, and McIntosh apples grown in sand cultures are described and illustrated. The occurrence of Mg deficiency in commercial orchards is reported, and growth and foliage symptoms are compared with those induced in sand culture. Associated soil conditions are reported, viz, dark brown decidedly acid loams occasionally showing traces of podsolization, surface soil rich in organic matter and total N, and soils low in Ca and Mg but with a satisfactory K level. The compositions of leaves of terminal shoots from trees with typical symptoms and of those from average normal trees of the same variety were compared, the former showing a very low Mg content, a normal P and Ca level, and a somewhat higher K content than the latter. Attention is called to possible influences of Mg deficiency in increasing susceptibility to spray injury to the foliage. Soil applications of MgSO<sub>4</sub>, sulfate of potash magnesia, and dolomite limestone failed to affect the Mg content of the leaf petiole or terminal shoot, or to prevent the disorder from appearing in the year of their application. There are 16 references.

**Recent developments on eradicant sprays**, H. W. ANDERSON. (Univ. Ill.). (*Ill. State Hort. Soc. Trans.*, 73 (1939), pp. 235-247).—The author discusses the

history of eradicant sprays, their use in apple scab control, and experiments during the past season, based on the fact that scab perithecia are more easily penetrated by liquids as they approach maturity in spring and the leaves after decay during winter. It is concluded that eradicant spraying for apple scab is still in the experimental stage, and that a successful control program should be based on a material which is relatively cheap, easy to apply, and noninjurious to the tree over a period of years but toxic enough to kill most of the inoculum. The method is believed likely to be limited to fungus pathogens with a vulnerable stage in their life history. At best it is expected that only a partial control of the disease can be secured, but that certain summer sprays may be safely omitted.

**Eradicant fungicides**, A. J. RIKER (*Chron. Bot.*, 5 (1939), No. 4-6, pp. 384, 385).—A review of work in Wisconsin centered briefly about apple scab, and believed to indicate far-reaching potentialities for modification not only in the basic philosophy but also in the methods for control of an important group of plant diseases.

**Control of apple scab after harvest**, E. F. GUBA. (Mass. State Col.). (*Mass. Fruit Growers' Assoc. Rpt.*, 44 (1938), pp. 234-239).—This paper summarizes data on eradicant sprays for scab.

**Some suggestions concerning the apple spray schedule for 1940**, H. W. ANDERSON. (Univ. Ill.). (*Ill. State Hort. Soc. Trans.*, 73 (1939), pp. 345-351).—This discussion is confined to that part of the spray schedule pertaining to disease control and spray injury, and some of the suggestions are based on the results of spray tests of the preceding summer.

**Foliage and fruit injury from spray materials**, F. J. SCHNEIDERHAN (*Mass. Fruit Growers' Assoc. Rpt.*, 44 (1938), pp. 81-90).—With particular reference to apples and based on experimental work, the author discusses the factors involved in spray injury due to sulfur and to lead arsenate, chemistry of spray injury, symptoms induced on fruit and foliage, and cumulative effect of spray injury on fruit trees. Suggestions for relief from lime-sulfur injury are also given.

**Spray injury on apples, 1939 experiments**, D. POWELL and H. W. ANDERSON. (Univ. Ill.). (*Ill. State Hort. Soc. Trans.*, 73 (1939), pp. 252-260).—As a result of certain treatments in spray tests, the midseason defoliation formerly ascribed to *Physalospora obtusa* is believed to be due to lead arsenate-lime-sulfur injury rather than to fungus infection. Harvest-time data on calyx-injured fruit, defoliation, and leaf injury proved that this spray was most injurious of the treatments used on the Jonathan variety. It is assumed that Ben Davis and Gano and probably other varieties would react similarly to the same treatments. It is advised that full strength liquid lime-sulfur be not used on the three above-named varieties in Illinois. Detailed results are tabulated.

**A physiological study of soft scald in Jonathan apples**, E. V. MILLER and H. A. SCHOMER. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 60 (1940), No. 3, pp. 183-192, fig. 1).—Conditions known to be conducive to soft scald consisted of immediate storage at 32° and 36° F., delays of 3-11 days at 65°-75° prior to storage at these temperatures, and a CO<sub>2</sub> or heat treatment following the delay but prior to storage at 32° and 36°. Fruit stored at once usually evolved small amounts of acetaldehyde during the early part of the storage. Treatment following delay increased the acetaldehyde content of the fruit. Delay at 65°-75° tended to increase the sucrose and total sugar in both juice and pulp at the beginning of storage, while the CO<sub>2</sub> treatment did not greatly influence reducing sugar and sucrose. Delay reduced the acidity of the juice at the beginning of storage, and CO<sub>2</sub> treatment had no immediate additional

effect. Lots treated with CO<sub>2</sub> showed a slightly lower acidity in November, which was about the middle of the storage period. Heating the fruit to 98.6°–104° for 1 day following an 11-day delay at 70° lowered the total acidity and pH. This lot showed less soft scald but more internal breakdown than the others. Though changes in the sugar, acid, and acetaldehyde content of apples are believed to be an index of physiological activity, no correlation was found between these substances and the occurrence of soft scald.

**Growth restriction as an aid to fire blight control**, F. S. HOWLETT. (Ohio Expt. Sta.). (*Amer. Fruit Grower*, 60 (1940), No. 5, p. 20, fig. 1).—Observations and experiments appear to indicate that for fire blight control provision must be made for restricting the growth of pear trees to a much greater degree than has ever been the practice in the past.

**Virus diseases of the peach**, H. H. THORNBERRY. (Univ. Ill.). (*Ill. State Hort. Soc. Trans.*, 73 (1939), pp. 247–252).—The distribution, economic importance, and methods of spread of eight virus diseases of peaches are discussed. Only a few of them are known to occur in Illinois.

**Production of epinasty by emanations from normal and decaying citrus fruits and from *Penicillium digitatum***, E. V. MILLER, J. R. WINSTON, and D. F. FISHER. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 60 (1940), No. 4, pp. 269–277, figs. 4).—Epinasty in test plants (e. g., potato or tomato) is generally conceded to indicate ethylene in plant tissue emanations. Tested for ethylene evolution by this method, positive results were obtained with oranges, tangerines, limes, lemons, and grapefruit. Oranges and grapefruit inoculated with *P. digitatum* and oranges with stem-end decay produced epinasty in test plants sooner than normal fruits under the same conditions. Positive results were also obtained with pure cultures of *P. digitatum*.

**Notes on *Botryosphaeria ribis*** [trans. title], C. G. DA LUZ (*Agron. Lusitana*, 1 (1939), No. 4, pp. 361–372, pl. 1; *Eng. abs.*, pp. 369, 370).—A series of inoculations was made on several plant species, using *Dothiorella* sp. isolated from a gummed trunk of lemon from Madeira. In some cases the perfect stage developed, and was identified as *B. ribis*. Observations indicated that size of fructifications varied according to thickness of bark of the particular host used. The various stages of the fungus are described. There are 16 references.

**Diseases of the pecan**, J. B. DEMAREE, J. R. COLE, H. E. PARSON, and J. R. LARGE (U. S. Dept. Agr., *Farmers' Bul.* 1829 (1940), pp. 36–70, figs. 21).—Superseding Farmers' Bulletin 1672 (E. S. R., 66, p. 242), information is given on pecan scab (*Cladosporium effusum*), downy spot (*Mycosphaerella caryigena*), vein spot (*Gnomonia nerviseda*), leaf blotch (*M. dendroides*), brown leaf spot (*Cercospora fusca*), liver spot (*G. caryae pecanae*), powdery mildew (*Microsphaeria alni*), nursery blight (*Sphaceloma* sp.), gnomonia leaf spot (*G. dispersa*), wood rots, crown gall (*Bacterium*=*Phytophthora tumefaciens*), rosette, little leaf, bunch disease or witches'-broom, and winter injury and sun scald. The importance of good orchard care and disease control is stressed, and spraying materials, methods, and equipment are discussed.

**Black end and anthracnose of the banana, with special reference to *Gloeosporium musarum* Cke. and Mass.**, J. H. SIMMONDS and R. S. MITCHELL (*Austral. Council Sci. and Indus. Res. Bul.* 131 (1940), pp. 63, pls. 2, fig. 1).—In this monographic study *G. musarum* was found to be the most important organism with black end under Queensland conditions, it being responsible for the epidemic development of both black end and anthracnose during the months of January and February, with losses to a lesser degree at other seasons.

*Nigrospora sphaerica* may induce a similar type of black end during winter and spring, but is less serious, and *Fusarium* spp. are responsible for a minor type throughout the year. Studies of the fungi concerned, factors contributing to the two phases of the disease, and experiments directed toward control are presented in detail.

**Fruit diseases in 1937**, O. C. BOYD (*Mass. Fruit Growers' Assoc. Rpt.*, 44 (1938), pp. 224-230).—A seasonal survey for Massachusetts on diseases of apples, stone fruits, and small fruits, with a summary of weather conditions.

**Fruit diseases in 1939**, O. C. BOYD (*Mass. Fruit Growers' Assoc. Rpt.*, 46 (1940), pp. 22-25).—A seasonal survey of weather conditions and diseases of apples, stone fruits, and small fruits for Massachusetts.

**The dry disinfection of seed: References covering the period 1930-1939** (*Sci. Mus. [London]*, *Sci. Libr. Bibliog. Ser. No. 499* (1939), pp. [1]+19).

**Sprays and dusts for florists and gardeners** (*U. S. Dept. Agr., Bur. Plant Indus.*, pp. 4).—An informational leaflet.

**The fixed coppers as a new weapon for use in the fight against vegetable diseases**, J. D. WILSON. (Ohio Expt. Sta.). (*Market Growers Jour.*, 66 (1940), No. 8, pp. 206-209, 210).—A general survey of the fixed copper fungicides in relation to control of diseases of vegetable crops.

**Progress in the development of vegetable varieties resistant to disease**, H. A. JONES (*Chron. Bot.*, 5 (1939), No. 4-6, pp. 381-383).—A review.

**A new virus disease of snap beans**, W. A. JENKINS. (Ga. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 60 (1940), No. 4, pp. 279-288, figs. 3).—An apparently new disease of snap beans in the vicinity of Experiment, Ga., is described and designated black root. The symptoms at first consist of incipient wilt of a part of the plant, followed by permanent general wilt of all the leaves, and final death. Accompanying these symptoms is an extensive vascular discoloration of the roots, stem, leaves, and pods, and the lower leaves exhibit a faint checkerboard pattern of light and dark areas. The disease was transmitted only by hypodermic injections of fresh juice from affected pods in the snap bean stage and through the seed. Thus far, insect transmission tests have given negative results, with one possible exception in which the tarnished plant bug (*Lygus pratensis*) was used. The present host range includes several varieties of bunch and pole beans and a variety of lima beans.

**Relation of the near-wilt fungus to the pea plant**, W. J. VIRGIN and J. C. WALKER. (Idaho Expt. Sta. coop. Wis. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 60 (1940), No. 4, pp. 241-248, pl. 1, figs. 3).—The causal fungus *Fusarium oxysporum* usually invades garden pea plants at the root tip and at the cotyledonary node, although occasionally it may enter at other points on the seedling root and epicotyl. Under some conditions a definite seedling root rot occurs, but generally the fungus progresses promptly to the xylem initials, becoming established in the larger vessels. It advances up the xylem much farther than does *F. orthoceras pisi* of common wilt. In many susceptible varieties it may travel the full length of the stem and into the pods and seeds. There is no difference in the mode of penetration of susceptible and resistant varieties, but progress up the stem is more limited in the latter. Dwarf, late-maturing varieties are much more likely to bear infected seed when grown on infested soil than are early-maturing varieties.

**A virus strain of mosaic disease of the aucuba-type in tomato**, M. I. GOLDIN (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser.*, 25 (1939), No. 7, pp. 630-632, fig. 1).—The author reports finding in tomato a strain of aucuba-type virus and also the enation virus responsible for the accessory leaf blades on the lower surfaces of tobacco and tomato leaves. Detailed study of the inclu-

sions is deemed important for identifying plant viruses and, in particular, for differentiating strains as well as for studying the so-called virus mutations.

**A rot of Winter Queen watermelons caused by *Phytophthora capsici*,** J. S. WIAW and C. M. TUCKER. (U. S. D. A. and Mo. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 60 (1940), No. 2, pp. 73-88, figs. 6).—This decay on the New York City market was found to be due to *P. capsici*, the cardinal temperatures of which in culture were 45°-47.5°, 80°-85°, and (for a 4-day period) 95°-100° F. Development of decay on artificially inoculated melons was greatest at 85°, and in 4 days lesions 2.5-3 in. in diameter developed at 63°-70°. Old lesions enlarged only slowly at 50°, although no decay was evident in melons held constantly at this temperature after inoculation and no decay developed in similar melons held at 45° for 14 days. The fungus penetrated the unbroken skin of the melon so that decay was spread by contact from melon to melon within the container. The fungus proved pathogenic for pepper plants and penetrated and rotted unwounded fruits of pepper, tomato, apple, cantaloup, cucumber, and squash, and unwounded carrot roots. It also produced rots of wounded orange and lemon fruits and wounded potato tubers. Control suggestions based on field and harvesting practices are presented. Reduction of transit temperatures to 50° should greatly retard decay, and maintenance at 45° should completely arrest development and spread during transit.

**The practicability of detecting Dutch elm disease by trunk sampling,** W. E. AHRENS. (U. S. D. A.). (*Phytopathology*, 30 (1940), No. 6, pp. 521-527, fig. 1).—Tools and methods were developed for removing samples 0.5 in. in diameter, suitable for culturing, from trunks of suspected elms. During the dormant season (1936-37) this sampling was applied to 6,031 elms considered disease-free when inspected for foliar symptoms the preceding summer. The 45 new infections discovered constituted 28.3 percent of all infections found in the plats by scouting for foliar symptoms and by trunk sampling. Dormant-season trunk sampling was less expensive than intensive summer scouting. Several studies of trunk sampling during the growing season indicated that  $\pm 80-92$  percent of infected elms showing foliar symptoms could be found by trunk sampling  $\pm 2$  weeks after symptoms were observed. Those with vascular discoloration insufficient for detection were usually not severely affected. Trunk sampling during the dormant season at 6-in. intervals did not appear to injure the trees. Five ways in which trunk sampling might be used in control of Dutch elm diseases are enumerated.

**Some resupinate polypores from the region of the Great Lakes, X, D. V.** BAXTER (*Mich. Acad. Sci., Arts, and Letters, Papers*, 24 (1938), pt. 1, pp. 167-188, pls. 7).—There is said to be great variation among northern wood-inhabiting fungi in their ability to grow on different tree species. Although some of them exist naturally under widely different forest conditions, certain of them are found only on conifers, whereas others occur only on hardwoods. The synopsis of the resupinate polypores included in this paper of the series is based chiefly on collections in the various forest regions of the Great Lakes and elsewhere in the continental United States, Alaska, the Yukon Territory, and the Mackenzie District of the Northwest Territories. Nine species of *Poria* and four of *Polyporus* are described, including some new taxonomy.

**Polyporus ellisianus (Murr.) Sacc. and Trott and Polyporus anceps Pk. in culture: A study of isolates from widely separated forest regions, D. V.** BAXTER and W. E. MANIS (*Mich. Acad. Sci., Arts, and Letters, Papers*, 24 (1938), pt. 1, pp. 189-195, pls. 3, figs. 2).—The western red rot, which has been attributed to *P. ellisianus*, is said to be one of the most common rots of *Pinus ponderosa*. *P. anceps* is also widely distributed throughout the West (and East) on various

coniferous woods, but generally no serious losses in standing timber have been attributed to it in the East. The numerous variations in cultures of eight isolates of these two fungi point to the fact that different races or strains exist, even though the fungi may have come from the same region. These differences were as great as any morphological distinctions that could be determined from the fragmentary type material of *P. ellisianus* and the known *P. anceps* material. For the present and until the authors have had opportunity to restudy the type material further, it is believed that the known morphological distinctions (largely in growth habit) are not great enough to separate the two as distinct species.

**A pink stain of wood caused by a species of Geotrichum**, M. S. CHIDESTER. (U. S. D. A.). (*Phytopathology*, 30 (1940), No. 6, pp. 530-533, pl. 1).—*Geotrichum* sp. was isolated from pink-stained sapwood and heartwood of southern yellow pine lumber. Experimentally it produced the same color in heartwood and sapwood of silver fir (*Abies amabilis*), yellow birch (*Betula lutea*), black spruce (*Picea mariana*), loblolly pine (*Pinus taeda*), Douglas fir (*Pseudotsuga taxifolia*), red oak (*Quercus borealis* [= *Q. rubra ambigua*]), southern cypress (*Taxodium distichum*), and western hemlock (*Tsuga heterophylla*).

**Spread of canker in California threatens existence of Monterey cypress and columnar Italian cypress**, L. R. TEHON (*Amer. Nurseryman*, 71 (1940), No. 7, p. 28).—Note on the *Coryneum cardinale* canker of *Cupressus macrocarpa* and *C. sempervirens stricta* now prevalent in California and New Zealand.

**Chlorotic cypress**, L. R. TEHON (*Amer. Nurseryman*, 71 (1940), No. 7, p. 29).—Note on successful control of chlorosis of baldcypress by trunk injection of 5 percent ferric chloride.

**Studies on the biology of Valsa sordida and Cytospora chrysosperma**, C. M. CHRISTENSEN. (Minn. Expt. Sta.). (*Phytopathology*, 30 (1940), No. 6, pp. 459-475, figs. 3).—The structure of pycnidia formed on sterile bark and on agar, size of conidia, rate of growth of agar, and general cultural characters were compared for numerous isolates of *C. chrysosperma* from *Populus* and other hardwood genera, and for *V. sordida* from *P. tremuloides*. No consistent differences were noted among isolates from different hosts or among isolates of *C. chrysosperma* from the various hosts and *V. sordida* from *P. tremuloides*, nor was any legitimate basis found for separating *C. chrysosperma* from other so-called species of *Cytospora*. *C. chrysosperma* was found commonly inhabiting the bark of apparently healthy trees of several species of poplar and willow as well as mountain ash and some other trees. On these hosts it fruited only when the trees were dying or dead. The author therefore considers its parasitism on these trees open to question. It is suggested that control of *Cytospora* canker on ornamental poplars should be approached by attempting to develop varieties more suited to their general environment than the ones at present used.

**Two serious diseases of shade trees**, B. O. DODGE (*Jour. N. Y. Bot. Gard.*, 41 (1940), No. 484, pp. 93, 94).—Brief notes on the London plane tree blight due to *Ceratostomella* sp. and the bleeding canker of maples due to *Phytophthora cactorum*.

**New stages of Sporocybe azaleae**, W. H. DAVIS. (Mass. State Col.). (*Phytopathology*, 30 (1940), No. 6, pp. 506-514, figs. 2).—A general study of the twig and bud blight of azaleas and rhododendrons due to *S. azaleae* has been noted (E. S. R., 81, p. 388). The fungus has been imperfectly known but is usually recognized by coremia on the infected host parts. Experimental evidence is here presented to indicate that *S. azaleae* possesses mycelial, chlamydo-sporic, cephalosporic, penicilloid, coremial, and probably also ascogenous stages.

Scientific descriptions of these stages, together with drawings and photomicrographs are given.

**Monilinia causing a brown rot and blight of the common azalea, E. E. HONEY.** (Univ. Wis.). (*Phytopathology*, 30 (1940), No. 6, pp. 537, 538).—*M. azaleae* n. sp. pathogenic on leaves, shoots, and fruits of *Rhododendron roseum* (= *R. maximum roseum*) collected near Ithaca, N. Y., is described. It is believed that a monilioid conidial stage collected on the leaves of *R. canescens* (= *Azalea canescens*) at Winterville, near Athens, Ga., belongs to the same species.

**Diseases of bulbs, W. C. MOORE** ([*Gt. Brit.*] *Min. Agr. and Fisheries Bul.* 117 (1939), pp. VI+176, pls. 20).—This handbook (709 references) considers diseases of Liliaceae (hyacinth, tulip, lily, etc.), Amaryllidaceae (narcissus and snowdrop), and Iridaceae (gladiolus, iris, crocus, etc.).

**Fusarium leaf spot of Sansevieria, L. K. JONES.** (Wash. Expt. Sta.). (*Phytopathology*, 30 (1940), No. 6, pp. 527-530, figs. 2).—A leaf spot of *S. zeylandica* and its variety *laurentii*, shown to be due to *F. moniliforme*, is reported common in many of the greenhouses of Washington State. Inoculations with a number of other fungi and bacteria indicated that *Botrytis allii* and *Penicillium gladioli* can also induce lesions on the leaves.

## ECONOMIC ZOOLOGY—ENTOMOLOGY

**Hawks in the hand, F. and J. CRAIGHEAD** (Boston: Houghton Mifflin Co., 1939, pp. XIII+290, pls. 57; rev. in *Jour. Forestry*, 38 (1940), No. 3, pp. 291, 292).—Observations of the life and habits of many wild fowls, particularly predaceous fowl, including eagles (bald and golden), hawks (duck, red-shouldered, broad-winged, red-tailed, Cooper's, sparrow, pigeon, marsh, and goshawk), owls (barn, great horned, long-eared, barred, short-eared, burrowing, and screech), osprey, northern raven, prairie falcons, and others, based upon studies in nature, are presented. Methods of study, including the photographic technic employed, are included. The review is by J. S. W[ade].

**Adaptive coloration in animals, H. B. COTT** (London: Methuen & Co., [1940], pp. XXXII+508, pls. [49], figs. 84).—The three parts of this work deal with concealment (pp. 1-186), advertisement (pp. 187-307), and disguise (pp. 309-424). A bibliography of 685 titles is included.

**Life and habits of field mice, W. J. HAMILTON, JR.** (Cornell Univ.). (*Sci. Mo.*, 50 (1940), No. 5, pp. 425-434, figs. 8).

**Observations on the life history of the red squirrel in New York, W. J. HAMILTON, JR.** (*Amer. Midland Nat.*, 22 (1939), No. 3, pp. 732-745, figs. 2).

**Life history notes on the Piute ground squirrel, J. R. ALCORN.** (Univ. Calif.). (*Jour. Mammal.*, 21 (1940), No. 2, pp. 160-170, fig. 1).—These notes relate to the life history and habits of *Citellus townsendii mollis* under observation near Fallon, Nev.

**Food of central Wisconsin horned owls, F. HAMERSTROM and O. MATTSO.** (Univ. Wis.). (*Amer. Midland Nat.*, 22 (1939), No. 3, pp. 700-702).—The results of analyses of 678 horned owl (*Bubo virginianus*) pellets picked up in central Wisconsin and data on some prey species of particular interest are given in detail in two tables. "Pinnated, sharp-tailed, and ruffed grouse populations were low in the first winter and of these sharptails seemed to be most noticeably starting the upswing of the cycle in 1936-37, at which time Hamerstrom [E. S. R., 81, p. 804] estimated the combined pinnate and sharptail population at 1 bird to 85-100 acres, with a ratio of 3 sharptails to 1 pinnate. No grouse remains were found in any pellets of the first winter but several occurred in the 1936-37 pellets. Meadow mice were markedly less abundant in the second winter than in the first; this was very evident from the number of runways exposed after

the snow melted. A total of 466 trap nights in the autumn of 1936 and the early spring of 1937 caught only 2 meadow mice and 18 deer mice. However, there were more mice in the pellets of the second winter. Cottontails were scarce the first winter, but appeared to be even scarcer during the second. Unfortunately we made no cottontail field counts the first year, but in the autumn of the second only 20 were seen in 100 hr. in the field."

**The birds of Buckeye Lake, Ohio,** M. B. TRAUTMAN (*Mich. Univ., Mus. Zool. Misc. Pub.* 44 (1940), pp. 466, pls. 16, figs. 2).—In this work the author has attempted to present a complete conception of the status of bird species in the Buckeye Lake area. A systematic account is given of the 282 species and 6 additional subspecies recorded from this area, with data on their arrival and departure, and life history and habits, together with a 6-page list of references cited and an index of common and scientific names.

**Lead shot: Its danger to water-fowl,** T. L. G. OSMER. (*Minn. Expt. Sta.*). (*Sci. Mo.*, 50 (1940), No. 5, pp. 455-459).

**Curtailment of egg production in the common ring-necked pheasant due to experimental infection with the oviduct fluke *Prosthogonimus macrorchis*,** R. W. MACY (*Jour. Parasitol.*, 26 (1940), No. 2, p. 158).

**Nesting habits and causes of nest mortality of the ringneck pheasant,** P. E. RANDALL. (*Pa. State Col.*). (*Game Breeder & Sportsman*, 45 (1940), No. 4, pp. 53, 54, 59-61, figs. 2).

**Feeding habits of the Franklin's gull in North Dakota,** S. SAUGSTAD (*North Dakota Sta. Bimo. Bul.*, 2 (1940), No. 5, pp. 14-16, figs. 2).—Studies of the feeding habits of *Larus pipixcan*, one of the more popular birds of the State, are reported. Its habits are said to be commonly accepted as particularly beneficial to agriculture, since it feeds largely upon obnoxious insects. Gulls collected near Moffit largely in mid-July of the preceding 2 yr. had consumed an average of about 27 adult grasshoppers. *Melanoplus mexicanus* (stubble or migratory grasshopper), the two-striped grasshopper, and the differential grasshopper were commonly represented in the crop contents. Although grasshoppers were the most readily available insects in that area, they were not sufficiently numerous locally to seriously threaten the crops. It is concluded that the feeding habits of these gulls would not be an important check against grasshopper damage over an extensive area during periods of severe infestations when populations range up to 30 or more per square yard. In years when the grasshopper population is moderate or light, this foraging would act as a check over limited areas adjacent to large colonies of gulls. Of the 8 gulls examined, 5 were found to have consumed some 21 Say's plant bugs, indicating that they act as a check on this pest of cereal and forage crops. The bulk of the crop and gizzard contents of the gulls collected in late September and early October was found to consist of predaceous ground beetles (Carabidae). The limited investigation is considered to indicate that on the whole this gull is distinctly beneficial to agriculture in the State.

**Proceedings Eighteenth Annual Meeting of the North Central States Entomologists** (*North Cent. States Ent. Proc.*, 18 (1939), pp. 6-22, 24-40, 50-60, 62-65, 68-88).—Among the contributions presented at the annual meeting (E. S. R., 81, p. 806) held in St. Paul, Minn., in March 1939 and included in this mimeographed report are: Some Ecological Aspects Concerning the Forest Tent Caterpillar on the National Forests in Minnesota—The Recent Forest Tent Caterpillar Outbreak on the Chippewa and Superior National Forests (Minnesota), by R. H. Nagel (pp. 6-10); Forest Tent Caterpillar, by A. C. Hodson (p. 10); New Facts on the Biology of Grasshopper Parasites and Natural Enemies, by R. H. Painter (p. 10); The Oriental Fruit Moth Situation—Progress in Oriental Fruit Moth Control, by R. Hutson (p. 11); The Oriental

Fruit Moth Situation, by S. C. Chandler (pp. 11, 12); Recent Contributions to the Study of Insect Transmission of Plant Diseases, by A. A. Granovsky (pp. 13-15); Recent Advances in Pea Insect Control, by E. M. Searls (pp. 15, 16); Pea Aphid Control, by H. F. Wilson and C. E. Dieter (pp. 16-21); Grasshopper Control Research—U. S. D. A. Grasshopper Research Program, by J. R. Parker (pp. 24-26); Grasshopper Bait Moisture Experiments, by J. Medler (pp. 26, 27); Grasshopper Research in Wisconsin in 1938, by J. H. Lilly (pp. 27-30); Review of Research Program on Range Grasshoppers, by F. A. Morton (pp. 30-35); Method of Conducting Field Tests of Grasshopper Baits, by E. J. Hinman (pp. 35, 36); Grasshopper Surveys, by R. L. Shotwell (pp. 36-38); Grasshopper Surveys in Manitoba With Reference to Their Development in the Prairie Provinces, by R. D. Bird (pp. 38-40); The Present Status of the White Grub [*Phyllophaga* sp.] Problem, by T. R. Chamberlin (pp. 50, 51); White Grubs and Maintenance of Lawns and Pastures, by W. P. Flint (p. 52); The Identification of White Grubs, by W. P. Hayes (pp. 52, 53); White Grubs and Soil Conservation, by D. B. Whelan (pp. 53, 54); Effect of Drought on White Grub Populations, by A. A. Granovsky (pp. 55, 56); Spraying of Trees and Laboratory Tests With Insecticides to Control the Adult June Beetles, by C. L. Fluke (p. 57); Recent Progress in the Study of Mothproofing, by C. L. Metcalf (p. 59); Insects and the Ever-Normal Granary, by R. T. Cotton, W. P. Flint, and P. N. Annand (pp. 62, 63); New Developments in the Control of Termites, by W. E. McCauley (pp. 63, 64); Recent Work With Methyl Bromide as a Fumigant, by H. H. Shepard (p. 65); Estimating the Value of Bees as Pollinators—Relationship of Bees to Agriculture, by F. B. Paddock (pp. 68, 69); Possibilities of Pollen Substitutes, by M. H. Haydak and R. L. Parker (pp. 69-71); The European Spruce Sawfly Problem, by H. J. MacAloney (p. 72); The Insect Problem in Shelterbelt Plantations, by J. A. Munro (pp. 73, 74); The Poplar Borer (*Saperda calcarata* Say) in the Parkland Regions of the Prairie Provinces of Canada, by L. O. Peterson (pp. 76-78); The Control of Bark Beetles and Borers by Means of Chemicals, by S. C. Chandler (p. 79); The Insect Problem in Forest Nurseries, by R. H. Nagel (p. 80); The Problem of Resistance to Defoliation by Deciduous and Coniferous Trees, by A. C. Hodson (pp. 81, 82); The Use of Oil Sprays on Coniferous Trees for the Control of Scale Insects, by R. Hutson (pp. 82, 83); The Equine Encephalomyelitis Problem—Clinical Manifestations of Equine Encephalomyelitis, by W. L. Boyd, W. A. Riley, and G. D. Jones (pp. 84, 85); Observations on Screwworm Outbreaks in the Territory Beyond Winter Survival, by W. E. McCauley (p. 86); Bot Control Campaigns—Horse Bot Control, by F. G. Butcher (p. 87); and Mosquito Problem in a Metropolitan Area, by W. A. Riley (pp. 87, 88).

**Some blood parasites from Montana birds**, G. R. COATNEY and W. L. JELLISON (*Jour. Parasitol.*, 26 (1940), No. 2, pp. 158-160).

**The eggs of Japanese birds, XII-XV**, K. KOBAYASHI and T. ISHIZAWA (*Rokko, Kobe, Japan: Keisuke Kobayashi, 1938, pts. 12-13, pp. [1]+145-175, pls. 11; 14, pp. [1]+177-201, pls. 7; 15, pp. [1]+203-232, pls. 6*).—A continuation of the work previously noted (*E. S. R.*, 74, p. 810).

**The rattlesnakes, genera *Sistrurus* and *Crotalus*: A study in zoogeography and evolution**, H. K. GLOYD (*Chicago Acad. Sci., Spec. Pub. No. 4 (1940), pp. VII+266+[4], pls. 31, figs. [32]*).—This work includes references to their nomenclature; distribution, including locality records; variation, etc; and is presented with a 17-page list of references to the literature.

**The fauna of the soil**, A. P. JACOT (*Quart. Rev. Biol.*, 15 (1940), No. 1, pp. 28-58).—This contribution is presented with a list of 104 references.

**Insect problems of the New York fruit grower**, H. GLASGOW (*Pa. State Hort. Assoc. Proc.*, 81 (1940), pp. 69-74).

The different factors affecting the temperature of a heap of grain in the open, R. ATTIA (*Egypt. Min. Agr., Tech. and Sci. Serv. Bul. 192 (1939), pp. [3]+50, pls. 43*).—A study relating to the effects upon insect infestation, the details being given in 18 tables and 43 graphs.

Some ecological observations on the insect-fauna of dung, M. HAFEZ (*Bul. Soc. Fouad 1. Ent., 23 (1939), pp. 241-287, figs. 8*).—Included in this account is a classified list of dung insects found, a discussion of the power of attraction of different kinds of dung to insects, the results of several oviposition experiments, etc., and a four-page list of references.

[Contributions on economic insects] (*Ill. State Acad. Sci. Trans., 32 (1939), No. 2, pp. 46, 204, 205, 227, 228*).—Contributions presented at the annual meeting held in Springfield in May 1939 include: Insect Abundance Around Wild Life Area, by M. D. Farrar and W. P. Flint (p. 46); The Relation of Body Size and Egg Size in *Drosophila*, by H. J. Eigenbrodt and P. A. Zahl (pp. 204, 205); and The Silverfish in a New Role, by R. E. Slabaugh (pp. 227, 228), and Notes on the Predaceous Stink Bug *Apateticus cynicus* Say, by P. C. Stone (p. 228) (both Univ. Ill.).

[Contributions on injurious and beneficial insects and rodent pests of fruit] (*Mass. Fruit Growers' Assoc. Rpts., 44 (1938), pp. 26-32, 213-223; 45 (1939), pp. 34-36, 70-74, 156-170; 46 (1940), pp. 15, 16, 18-21*).—Contributions presented at the forty-fourth meeting include: The Mouse Control Project, by W. W. Dykstra (p. 26); Insect Pests in Massachusetts Orchards in 1937, by A. I. Bourne, W. D. Whitcomb, and W. H. Thies (pp. 213-217), and Report of Committee on Disease and Insect Pests, by A. I. Bourne (pp. 218-220) (both Mass. State Col.); and Progress Report on Rodent Control, by W. W. Dykstra (pp. 221-223).

Those presented at the forty-fifth meeting include: Report on Peach Parasite Project, by A. I. Bourne (pp. 34-36); Effectiveness of Parasites for Controlling the Oriental Fruit Moth, by P. Garman (pp. 70-74); New Insect Problems of Massachusetts Fruit Growers—What Are They? by W. D. Whitcomb (pp. 156-163) (Mass. State Col.); and Spraying for Red-Banded Leaf Roller and Eye-Spotted Budmoth, by S. W. Harman (pp. 165-170) (N. Y. State Expt. Sta.).

Those presented at the forty-sixth meeting include: Oriental Fruit Moth Parasite Project, 1939, by A. I. Bourne (pp. 15, 16); and Orchard Insect Pests in 1939, by W. D. Whitcomb and A. I. Bourne (pp. 18-21).

Report on insect investigations for the 1939 season, A. W. MORRILL, JR., and D. S. LACROIX. (Coop. U. S. D. A.). (*Connecticut [New Haven] Sta. Bul. 433 (1940), pp. 186-193, figs. 3*).—A progress report of work carried on since 1936 (E. S. R., 81, p. 540) in which reference is made to that with the potato flea beetle, the tobacco thrips, and wireworms (chiefly the eastern field wireworm), and to the abundance of insects during the year. A brief report on thrips and flea beetle control experiments, by Lacroix, is included (pp. 191-193).

[Work in economic entomology and parasitology by the Hawaii Station] (*Hawaii Sta. Rpt. 1939, pp. 36-42, 64-68, 79, figs. 1*).—Reporting for the year (E. S. R., 81, p. 671) the work referred to includes the ecology of the tomato bug *Cyrtopeltis varians* and possible vectors of a virus disease of papaya, both by F. G. Holdaway and [W. C.] Look; biological control of the imported cabbageworm, by Holdaway and A. Suehiro; miscellaneous insect pests of crops in Hawaii (five of which are of recent occurrence, namely, the striped datura beetle *Lema nigrovittata*, vegetable weevil, bean pod borer *Maruca testulalis*, harlequin bug, and the fire ant), by Holdaway, Suehiro, and Look; treatment of fluky cattle with Distol and with kamala, poultry parasites, including relation of nutrition to tapeworm infection and the life cycle of the

cecal fluke *Postharmostomum gallinum* and the pinworm *Subulura brumpti*, and parasites of horses in Hawaii, all by J. E. Alicata; and vaccination of day-old chicks for control of fowl pox and control of coccidiosis in wire-floored batteries and houses, both by C. M. Bice.

[**Work in economic entomology by the Kentucky Station**]. (Partly coop. U. S. D. A.). (*Kentucky Sta. Rpt. 1939, pt. 1, pp. 24, 25, 28-31, 32, 38, 39*).—The work of the year reported upon (E. S. R., 81, p. 540) includes tests on the effectiveness of nicotine in controlling poultry lice, control of the green June beetle larvae in plant beds, resistance of adapted and nonadapted red clover to pea aphid injury, the codling moth and its control, rosy apple aphid and the apple grain aphid, field tests with oil nicotine spray, oriental fruit moth parasites, the strawberry crown borer, distribution of white grubs (*Phyllophaga* sp.), control of May beetles, life cycle of *P. ephilida*, the Japanese and the white-fringed beetles, and control of injury to tobacco plants by wireworms (*Aeolus dorsalis* (Say) and *Conoderes auritus* (Herbst)).

[**Contributions on orchard pests**] (*N. Y. State Hort. Soc. Proc., 84 (1939), pp. 13-26, 179-183; 85 (1940), pp. 12-38, 58-63, 281-306, figs. 2*).—Contributions relating to orchard pests presented at the eighty-fourth meeting are Fruit Insect Problems in 1938, by J. A. Evans (pp. 13-23) (Cornell Univ.); and Mouse Control, by W. B. Robinson (pp. 179-182) (U. S. D. A.).

Contributions presented at the eighty-fifth meeting include Insect Pest Problems of Importance to the Fruit Industry in 1939, by P. J. Chapman (pp. 12-29) (N. Y. State Expt. Sta.); Rodent Control in the Orchard and in the Cold Storage, by W. B. Robinson (pp. 31-38) (U. S. D. A.); Essentials and Non-essentials in a Non-wash Spray Program, by M. E. Buckman (pp. 58-60); Fundamentals of Codling Moth Control With Special Reference to Nicotine, by W. S. Hough (pp. 281-286) (Va. Sta.); Codling Moth Control From the Western New York Point of View, by S. W. Harman (pp. 286-295), and Codling Moth Problems in the Hudson Valley, by P. J. Chapman (pp. 295-302) (both N. Y. State Sta.); and Extension Aspects of the Codling Moth Problem, by J. A. Evans (pp. 303-306) (Cornell Univ.).

**Present status of some Ohio peach pests**, R. B. NEISWANDER. (Ohio Expt. Sta.). (*Ohio State Hort. Soc. Proc., 73 (1940), pp. 32-40*).

[**Work in economic entomology by the Ohio Station**] (*Ohio Sta. Bul. 600 (1939), pp. 18, 26-34, figs. 6*).—The work of the year (E. S. R., 79, p. 650) reported upon includes a study of damage to inbred lines of corn by the larvae of the southern corn rootworm; control of the oriental fruit moth by larval parasites, particularly *Macrocentrus ancylivorus* Roh.; experiments for the control of the roundheaded apple tree borer and the potato leafhopper; tests with insecticides for control of the imported cabbageworm, the cabbage looper, and the diamondback moth; insect control on plants by means of poison supplied through the roots; a study of the response to lights of the tomato fruitworm (officially known as the corn earworm), the armyworm, and the tomato worm; and experiments with a modified two-queen system for honey production.

[**Work in economic entomology by the South Carolina Station**]. (Partly coop. U. S. D. A.). (*South Carolina Sta. Rpt. 1939, pp. 77-80, 124-134, 142-146, 177-180, 189-194, figs. 7*).—Work at the station and substations briefly reported upon (E. S. R., 81, p. 68) relates to the cowpea curculio, by F. Sherman and O. L. Cartwright; the oriental fruit moth, by Cartwright; poison tests with the tomato fruitworm, by Sherman; bollweevil and miscellaneous cotton insect investigations, including tests of presquare treatments for bollweevil control, small plot experiments for bollweevil and leaf aphids, toxicity of calcium arsenate to predaceous Coccinellidae, effect of cryolite on soils and plant growth,

and experiments on control of cotton root aphids, by F. F. Bondy and C. F. Rainwater; control of the tobacco flea beetle in tobacco plant beds, by N. Allen, L. A. Schifino, and J. M. Webb; cabbage insect investigations, by W. J. Reid, Jr., and C. O. Bare; and insect control investigations, particularly with the pickle-worm and the asparagus beetle, by J. G. Watts.

**Entomology, S. MARCOVITCH** (*Tennessee Sta. Rpt. 1938, pp. 62, 63*).—The work of the year reported upon (E. S. R., 80, p. 223) relates to the plum curculio, magnesium oxide as a corrective for cryolite injury of fruit, control of the tobacco hornworm, and the more important insects (armyworm, corn earworm, and Mexican bean beetle) of the year.

[**Work in apiculture by the Wyoming Station**] (*Wyoming Sta. Rpt. 1939, pp. 17-19*).—The work of the year, which again relates to breeding for resistance to American foulbrood (coop. U. S. D. A. and other experiment stations), outside wintering of bees, and two-queen colonies, is briefly considered in this report (E. S. R., 81, p. 553).

**Field crop insects and their control, A. V. MITCHENER** (*Manitoba Dept. Agr. and Immigr. Cir., 140 (1940), folder*).—A practical account of field crop insects and their control is presented as a chart, and a key is given to assist in the identification of the injurious stages of insects commonly destructive to field crops in Manitoba.

**Cotton pests in the Philippines, F. Q. OTANES and F. L. BUTAC** (*Philippine Jour. Agr., 10 (1939), No. 4, pp. 341-371, pls. 13*).—This is a summary (with 25 references) of the more important insect pests of cotton in the Philippines.

**Insects of the pecan, G. F. MOZNETTE, C. B. NICKELS, W. C. PIERCE, and T. L. BISSELL** (*U. S. Dept. Agr., Farmers' Bul. 1829 (1940), pp. 1-36, 37, figs. 43*).—A practical illustrated summary of information on the important insect enemies of the pecan, which supersedes Farmers' Bulletin 1654 (E. S. R., 64, p. 749).

**Insect pests of azaleas and camellias and their control, L. L. ENGLISH and G. F. TURNIPSEED** (*Alabama Sta. Cir. 84 (1940), pp. 18, figs. 13*).—A practical account of the insects (azalea lacebug *Stephanitis pyrioides* Scott, azalea mealybug *Eriococcus azaleae* Comst., the greenhouse thrips, peony scale *Pseudaonidia paeoniae* Ckll., azalea whitefly *Aleyrodes azaleae* B. & M., azalea leaf miner *Gracilaria azaleella* Brants, red mite *Paratetranychus ilicis* McG., yellow mite (*Tetranychus* sp.), and *Colaspis favosa* Say) in Alabama that attack azaleas and of those (tea scale *Fiorinia theae* Green, camellia scale *Lepidosaphes camelliae* Hoke, the chaff scale, Florida red scale, soft scale, peony scale *Pseudaonidia paeoniae* Ckll, and the cotton aphid) that attack camellias. Information on sprayers, spraying, spray schedules and dilutions, and proportions for mixing sprays is included.

**Control of stored grain pests in Nebraska, M. H. SWENK and D. B. WHELAN** (*Nebraska Sta. Cir. 62 (1940), pp. 11, figs. 9*).—A practical account of control measures for the stored grain pests of the State.

**Study of some forest insects of Nanking and its vicinity.—III, Observations on the gypsy moth (*Porthetria dispar* L.), C. P. MIAO** (*Sci. Soc. China, Biol. Lab. Contrib., Zool. Ser., 13 (1939), No. 5, pp. 57-77, figs. 14; Chin. abs., p. 77*).—This further report of studies (E. S. R., 82, p. 219) relates to observations of the gypsy moth in Nanking.

**Entomological conditions in 1939, J. R. WATSON.** (Fla. Expt. Sta.). (*Citrus Indus., 21 (1940), No. 2, pp. 11, 14*).

**Field sampling for the comparison of infestations of strawberry crops by the aphid *Capitophorus fragariae* Theob., R. M. GREENSLADE and S. C. PEARCE** (*Jour. Pomol. and Hort. Sci., 17 (1940), No. 4, pp. 308-317*).

**Dusting peanuts to control pests, L. I. MILLER.** (Va. Expt. Sta.). (*South. Planter, 101 (1940), No. 5, pp. 20, 21, figs. 2*).—This practical contribution is based

upon experimental work conducted during 1938 and 1939, and that reported in Bulletin 316 (E. S. R., 79, p. 508).

**Toxicity studies on 2-4-dinitro-6-cyclohexyl-phenol, a new insecticide,** A. K. HRENOFF and C. D. LEAKE. (Univ. Calif.). (*Calif. Univ. Pubs. Pharmacol.*, 1 (1939), No. 12, pp. [2]+151-159).—Studies aimed at the determination of the public health hazard of this new insecticide, experiments with which by Kagy and Richardson (E. S. R., 75, p. 225) have shown that a 1-percent petroleum oil solution of the chemical is powerful enough to kill San Jose scale and eggs of various orchard pests without damage to trees or fruit, are reported. The feeding experiments quite clearly indicate that there is no danger to consumers from fruits from trees dusted with preparations containing 1 percent of the chemical. This is given with 18 references to the literature.

**The case for deodorized insecticide oils,** A. B. WEINGARD (*Soap and Sanit. Chem.*, 15 (1939), No. 9, pp. 109, 113).

**Derris dust for control of cucumber insects,** C. LYLE (*Miss. Farm Res. [Mississippi Sta.]*, 3 (1940), No. 4, p. 8).—A derris dust containing 0.5–0.75 percent rotenone is the best means of control thus far found by the station for striped cucumber beetles, which attack the plants as they come through the ground and serve as overwintering hosts for bacterial wilt of cucurbits. It was found in tests that copper oxychloride added to derris is helpful in checking the disease. Where derris is not available, a mixture of 1 part calcium arsenate and 9 parts talc, gypsum, or hydrated lime applied once or twice a week when the beetles are most numerous will be very helpful. During the past season a mixture of 1 part basic copper arsenate and 19 parts talc was as effective as a 10 percent calcium arsenate dust. Some experiments in 1939 indicate that derris dust reduces pickleworm infestation of cucumbers, but it has not been definitely determined that its control is sufficient to justify the expense.

**Toxicity of Tephrosia,** A. F. SIEVERS and W. N. SULLIVAN. (U. S. D. A.). (*Soap and Sanit. Chem.*, 15 (1939), No. 9, pp. 111, 113).—The results of toxicity tests on flies of extracts of the roots of *T. virginiana* prepared by several methods, in which the extracts were tested at such a concentration that 1 cc. contained the extractive from 4 mg. of root, are reported in table form.

**Tests on crawling insects: Tentative methods for evaluating liquid household insecticides against the German cockroach and the bedbug,** E. N. WOODBURY and C. S. BARNHART. (Ohio State Univ. et al.). (*Soap and Sanit. Chem.*, 15 (1939), No. 9, pp. 93, 95, 97, 99, 101, 103, 105, 107, 113, figs. 9).

**Chemical effect on lead arsenate of certain salts which may be present in soil and spray waters,** J. M. GINSBURG. (N. J. Expt. Stas.). (*Jour. Agr. Res. [U. S.]*, 60 (1940), No. 3, pp. 199–205).—The increased application during recent years of lead arsenate to the soil in large quantities for destroying Japanese beetle larvae and other grubs and the possibility of accumulating large amounts of arsenic in certain soils led to these studies. The results of analyses to determine the soluble arsenic formed from this insecticide (2 gm. in 500 cc.) when mixed with different salts in approximate stoichiometrical proportions are tabulated. Some 50 salts generally present either in soils or spray waters were tested in the laboratory to determine to what extent they form soluble arsenic when in contact with acid lead arsenate. The salts were mixed in various concentrations with constant quantities of lead arsenate (about 3 lb. per 100 gal.) and allowed to stand 24 hr. with frequent shaking. The filtrates were analyzed for soluble arsenic. Of the 10 groups of salts tested, the nitrates, sulfates, and acetates, without exception, proved relatively nonreactive with  $PbHAsO_4$ . The chlorides, silicates, and bicarbonates produced

moderate quantities of soluble arsenic. Salts of carbonates and sulfides usually formed large percentages of soluble arsenic. In the phosphate group, the 3 phosphates of calcium and the monobasic phosphates of sodium and potassium formed inappreciable quantities of soluble arsenic, whereas the dibasic and especially the tribasic phosphates of either sodium or potassium formed large amounts. The percentage of solubility of a salt in water is, by itself, not a determining factor in forming soluble arsenic. But, of a group of salts capable of decomposing lead arsenate, the salt which is highly soluble in water will form more soluble arsenic than one only slightly soluble in water. The H-ion concentration of the salt solution plays, with few exceptions, an important role in decomposing lead arsenate. Salts with pH values of 8.0-11.4 produced, with two exceptions, more soluble arsenic than did salts with lower pH values. A list of 18 references is included.

**Insecticidal properties of extract of male fern (*Aspidium filix-mas* [L.] Sw.),** FRANK WILCOXON, A. HARTZELL, and FREDERICKA WILCOXON (*Contrib. Boyce Thompson Inst.*, 11 (1939), No. 1, pt. 1, pp. 1-4, fig. 1).—In a test of the insecticidal properties of oleoresin of male fern on mosquito larvae (southern house mosquito), bean aphid, and housefly, it was found to be four times as toxic as crude filicin. Satisfactory control of bean aphid was obtained with a spray containing 0.03 percent of crude filicin and 0.5 percent Penetrol. "When tested by the Peet-Grady method on houseflies a grade 'B' insecticide was obtained with a spray containing 0.05 percent pyrethrins and 0.2 percent crude filicin in 'Deobase' as a solvent. No injury was observed when 10 species of common plants were sprayed with a solution containing 0.05 percent crude filicin and 0.5 percent Penetrol." A list is given of 14 references to the literature.

**Preliminary studies on the comparative value of some sprays and dusts in potato insect control,** H. C. MANIS and I. LEFFERT. (Iowa Expt. Sta.). (*Iowa State Col. Jour. Sci.*, 14 (1940), No. 2, pp. 155-161, figs. 3).—In spraying and dusting experiments conducted during the summer of 1938 on station plats in which leafhoppers alone were sufficiently abundant throughout the season to affect the results obtained, "sulfur dust (325 mesh) and 4-4-50 bordeaux mixture were effective in reducing the leafhopper population and the amount of damage due to 'hopperburn.' The use of these two insecticides resulted in a significantly increased yield over all the other plats with the exception of the yield obtained on derris-treated plats. Sulfur dust containing paris green was as effective as sulfur dust and 4-4-50 bordeaux mixture in reducing leafhopper populations and the amount of damage, but the yield was lowered significantly possibly because of some harmful action of paris green on the plant. Counts on plats treated with paris green applied as a dust, with talc as the inert carrier, show a pronounced reduction in leafhopper populations comparable to that obtained with sulfur-paris green dust. The amount of damage was higher than on any of the other plats partially because of burning caused by the insecticide. The yield on these plats was significantly lower than any of the others. Counts on plats sprayed with paris green-hydrated lime show little, if any, reduction in leafhopper populations. Damage is high, and there is a considerable reduction in yield. The derris-talc dust is not consistent in its reduction of leafhopper populations. Damage was relatively high, but the yield also was high. Plats treated with a high calcium hydrated lime spray gave somewhat similar results to those obtained on derris-treated plats with a slightly, but not significantly, lower mean yield."

**Insect olfactory responses: Construction and use of an olfactometer for muscoid flies, and a discussion of interpreting results,** C. EAGLESON.

(U. S. D. A.). (*Soap and Sanit. Chem.*, 15 (1939), No. 12, pp. 123, 125, 127, fig. 1).—An olfactometer, in which muscoid flies are imprisoned in a U of adjustable length, one arm of which is perfused with the odor of the attractive or repellent material tested, is described and figured. It has given consistent results in testing the reactions of the housefly, the stablefly, and the screw-worm to certain chemicals. At regular intervals counts are made of the number of insects resting on the wire-screen septa closing the arms of the U.

**Some temperature coefficients for insect oviposition, F. H. HARRIES.** (U. S. D. A.). (*Ann. Ent. Soc. Amer.*, 32 (1939), No. 4, pp. 758-776, figs. 4).—Studies of the effect of temperature on oviposition and reproduction of different insects show that the rate of activity is not proportional to the temperature through any appreciable temperature range as would be described by a straight-line graph. "Data on different species define S-shaped curves similar to those found for many other types of physiological activity. The general nature of the accelerative influence of temperature is illustrated by curve segments of increasing slope in which successive increases of the same difference in temperature apparently produce progressively greater increases in velocity. In comparison with definite types of curves commonly used to describe biological processes, data for the rising portions of the curves apparently favor the van't Hoff formula or analogous expressions in which the percentage increase in activity is proportional to the difference in temperature."

**Studies on *Strongyloides agoutii* sp. nov. from the agouti (*Dasyprocta agouti*), H. J. GRIFFITHS** (*Canad. Jour. Res.*, 18 (1940), No. 5, Sect. D, pp. 173-190, figs. 19).—Report is made of a morphological and biological study of a hitherto unrecorded form of nematode genus *Strongyloides*, described as *S. agoutii* n. sp., from the golden-rumped agouti (*D. aguti*), a rodent native to Trinidad and northern South America. A brief résumé of the classical studies on species of the genus is included, together with a summary of existing hypotheses and theories on the biology of the group, as is a list of species and hosts for this genus.

**On the life cycle and other aspects of the snail, *Campeloma*, in the Speed River, J. C. MEDCOF** (*Canad. Jour. Res.*, 18 (1940), No. 5, Sect. D, pp. 165-172, figs. 2).—Report is made of a study of the biology of what appears to be a new species of fresh water snail, closely allied to *C. decisum*, found living in the Speed River at Hespeler, Ont. A statistical study indicates that its life span is 5 yr. Parturition occurs in summer, and year classes are recognizable. Sizes of approximately 12, 17, and 23 mm. are reached in 1, 2, and 3 yr., respectively. Sexual maturity is reached in 2 yr., and reproduction is parthenogenetic. Some snails hibernate and some aestivate. Rest marks on shells and opercula and a limy deposit in the protoconch were studied.

**Studies in insect biology.—I, The brood provision and rearing instincts of beetles, H. VON LENGERKEN** (*Ergebnisse der Insektenbiologie.—Band I, Die Brutfürsorge- und Brutpflege-Instinkte der Käfer. Leipzig: Akad. Verlagsgesell.*, 1939, pp. VIII+285, figs. 188).—The first section of this volume (pp. 5-240) deals in part with provision, the second (pp. 240-274) with the rearing instinct, and the third (p. 274) with brood parasitism. The work is presented with a list of 97 references to the literature and a subject index.

**[Contributions on fruit insect control in Nova Scotia]** (*Nova Scotia Fruit Growers' Assoc. Ann. Rpt.*, 76 (1940), pp. 19-25, 27-29, 31, 32, 57-60).—Contributions presented at the annual convention of the association held at Kentville in February 1940 include: The Insect Outlook for 1940, by J. McB. Cameron and A. D. Pickett (pp. 19-22); Emergency Spray Programs, by J. F. Hockey (pp. 22-25, 27); Remarks on the Control of Some of the More Important Apple

insects, by A. D. Pickett (pp. 27-29, 31, 32); and Nova Scotia Apple Maggot Control Board Report for Year Ending November 30, 1939, by V. B. Leonard (pp. 57-60).

[Contributions on orchard insects and rodent pests and their control] (*Ill. State Hort. Soc. Trans.*, 73 (1939), pp. 273-277, 351-364, 406-415, fig. 1).—Contributions presented are: Rodent Control in Orchard and Vegetable Garden, by G. C. Oderkirk (pp. 273-277); The Apple Insect Outlook for 1940, by W. P. Flint and S. C. Chandler (pp. 351-360) (*Ill. Expt. Sta. et al.*); Use of Nicotine and Other Sprays in Test Plots, by F. Chatten (pp. 362-364); and Peach Insect Studies of 1939, by S. C. Chandler (pp. 406-414).

A major cycle in insect flights, J. M. VALENTINE (*Science*, 91 (1940), No. 2371, p. 544).

The embryology and affinities of the Symphyla, based on a study of *Hanseniella agilis*, O. W. TIEGS (*Quart. Jour. Micros. Sci.* [London], n. ser., 82 (1940), No. 325, pp. 225, pls. 9, figs. 41).

Diphenylamine promising as soil poison against subterranean termites, M. W. SMITH. (Ohio State Univ.). (*Pests*, 8 (1940), No. 2, pp. 19, 20).

Auditory perception in insects, with special reference to the cockroach, P. RAU (*Quart. Rev. Biol.*, 15 (1940), No. 2, pp. 121-155).—This contribution is presented with a list of 92 literature references.

Sodium fluoride a proven method of roach control, C. LYLE (*Miss. Farm Res.* [Mississippi Sta.], 3 (1940), No. 5, p. 1).—Reference is made to the value of sodium fluoride in the control of roaches and to pyrethrum products and derris as substitutes. It has been found that derris will retain its toxic properties to roaches for a long time when not exposed to sunlight. Pyrethrum is very toxic when first applied.

The geographic distribution of Acrididae in northern Oklahoma, J. H. BRAGG (*Amer. Midland Nat.*, 22 (1939), No. 3, pp. 660-675, fig. 1).

Poison bran bait recommended for grasshopper control, C. LYLE (*Miss. Farm Res.* [Mississippi Sta.], 3 (1940), No. 5, p. 8).

Review field studies of citrus thrips control, C. O. PERSING, A. M. BOYCE, and F. G. McCARTY. (Calif. Citrus. Expt. Sta.). (*Citrus Leaves*, 20 (1940), Nos. 3, pp. 1, 2, figs. 2; 4, pp. 5, 14, 20, 26, 30, figs. 2).

Studies in the biology and ecology of *Retithrips syriacus* Mayet, with special attention to its occurrence in Palestine (Thysanoptera), E. RIVNAY (*Bul. Soc. Fouad 1. Ent.*, 23 (1939), pp. 150-182, figs. 11).—A report (with 28 references) of studies of *R. syriacus*, a polyphagous thrips enemy of several plants of economic importance, a heavy attack of which causes defoliation and as a rule hinders the normal development.

Cultural practices seem to offer best control of lygus bugs in alfalfa seed fields, C. J. SORENSON (*Farm and Home Sci.* [Utah Sta.], 1 (1940), No. 2, pp. 6, 10, fig. 1).—A practical account of the biology and control of true bugs of the genus *Lygus*, family Miridae, which attack the blossoms and seed of alfalfa, including *L. elisus* Van Duzee and *L. hesperus* Knight.

Influence of the physiological age of the pea plant on its recovery from aphid damage, C. D. HARRINGTON and E. M. SEARLS. (Wis. Expt. Sta.). (*Jour. Agr. Res.* [U. S.], 60 (1940), No. 3, pp. 157-161, figs. 2).—Report is made of the results of tests conducted during 1938 with 335 lots of peas comprising 275 field, garden, and canning varieties that were planted and infested with pea aphids with a view to eliminating susceptible varieties. The aphid population maintained damaging proportions for a 10-day period but was suddenly destroyed by disease. Following this decline of the aphids regeneration occurred in varying degrees among the varieties. The degree of recovery was found to be con-

trolled by the physiological age of the plants at the time of aphid damage and could not be attributed to aphid resistance. The authors were led to conclude that recovery data and yield records cannot safely be employed to determine comparative aphid resistance of pea varieties.

**Biological control of long-tail[ed] mealybug**, S. E. FLANDERS. (Calif. Citrus Expt. Sta.). (*Citrus Leaves*, 20 (1940), No. 2, pp. 3, 4).

**Toxicants and solids in oil used against the red scale**, W. EBELING. (Calif. Citrus Expt. Sta.). (*Citrus Leaves*, 20 (1940), No. 2, pp. 1, 2, 11, figs. 3; also in *Calif. Citrog.*, 25 (1940), No. 4, pp. 98, 130, figs. 2).

**The louse**, P. A. BUXTON (London: Edward Arnold & Co., [1939], pp. IX+115, figs. 28).—The chapters of this work deal with the Anoplura or sucking lice (pp. 1-4); the anatomy (pp. 5-22), biology (pp. 23-53), medical importance (pp. 54-81), and control of *Pediculus humanus* (pp. 82-92); and the crab louse (*Phthirus pubis*) (pp. 93-98). Methods of rearing, feeding, and infecting lice by rectal injection are included in an appendix. A list of 108 references is given.

**Biology and morphology of some North American Bittacidae (order Mecoptera)**, L. R. SETTY (*Amer. Midland Nat.*, 23 (1940), No. 2, pp. 257-353, figs. 178).—This report of studies of the biology and morphology of some North American Bittacidae or scorpion flies is presented with a list of 68 references.

**Field control of the codling moth by electric and other traps**, G. E. MARSHALL and T. E. HENTON. (Purdue Univ.). (*Rural Electrification*, n. ser., 3 (1940), No. 2, pp. 38, 39, figs. 2).

**The present status of the codling moth in Indiana**, G. E. MARSHALL (Ind. Expt. Sta.). (*Ind. Hort. Soc. Trans.*, 1939, pp. 77-83).

**Practical supplementary measures in codling moth control**, J. O. PEPPER. (Pa. State Col.). (*Pa. State Hort. Assoc. Proc.*, 81 (1940), pp. 67-69).

**The migration of codling moth larvae from one apple to another**, W. G. GARLICK (*Canad. Ent.*, 72 (1940), No. 4, p. 87).—The author reports having clearly proved that codling moth larvae will leave one apple and enter another, that this happens much more frequently than at first supposed, and that it involves larvae in all stages of growth. Its importance lies mainly in the fact that partly grown larvae are not apt to be poisoned on entering fresh fruit no matter how much spray may be on the latter, thus two or more fruits may be ruined by a single larva. Further, since migration always takes place in the dark, there is less danger to the exposed larva from predators. An accompanying note by Garlick and H. R. Boyce records the observation that in the majority of cases larvae seeking places to spin up leave the fruit only during darkness.

**Spraying for grapeberry moth control, 1939**, R. HUTSON (*Michigan Sta. Quart. Bul.*, 22 (1940), No. 4, pp. 263-265).—A tabulation of experimental spraying conducted at Paw Paw in 1939 reveals calcium arsenate to be as effective against the grape berry moth as lead arsenate used in the same way. It is pointed out that the use of calcium arsenate offers a possibility of cutting the cost and eliminating the lead residue. It is also apparent that the fixed nicotine and cuprous cyanide offer alternatives and that the controls obtained with these materials, particularly the fixed nicotines, are satisfactory.

**Preliminary studies of the nutritive requirements of the European corn borer**, G. T. BOTTFER. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 60 (1940), No. 4, pp. 249-257).—Preliminary studies of the nutritive requirements of the European corn borer that consisted in feeding test larvae different kinds and forms of plant tissue selected to represent different types in physical structure, stage of maturity, chemical composition, and both resistant and susceptible strains of corn are reported. Approximately 400 corn borer eggs incubated until ready to hatch were employed to infest each food medium for testing its

nutritive effects on the survival, weight, and pupation of larvae under controlled laboratory conditions. As measured by statistically significant physiological differences, food materials rich in glucose fulfilled the borer's nutritive requirements far better than did those containing high percentages of either sucrose or starch. Supplementary tests for enzymes in the cellular tissue of the digestive tracts of hibernating larvae indicated the presence of both sucrose- and protein-splitting enzymes. No enzymes capable of hydrolyzing starch were found. Physical characters of plants which were associated with low survivals and weights of larvae were profuse pubescence, thick epidermis, and the greater number and coarse nature of fibrovascular bundles, especially in the peripheral region of the stems.

**Experimental infection of *Hyphantria cunea* with *Nosema bombycis*,** R. R. KUDO and J. D. DECOURSEY. (Univ. Ill.). (*Jour. Parasitol.*, 26 (1940), No. 2, pp. 123-125).—An infection test revealed that the fall webworm is easily parasitized by *Nosema bombycis* when mature spores are ingested. Heavily infected larvae show symptoms characteristic of pébrine in silkworms. Schizogony and sporogony in *H. cunea* are similar to those known to occur in *Bombyx mori*.

**Cutworm injury controlled by use of poisoned bait,** C. LYLE (*Miss. Farm Res. [Mississippi Sta.]*, 3 (1940), No. 4, p. 7).

**The relation of shade to *Anopheles quadrimaculatus* breeding: A preliminary report,** E. H. HINMAN and H. S. HURLBUT (*Jour. Parasitol.*, 26 (1940), No. 2, pp. 145-156, figs. 3).—In work reported the common malarial mosquito has been reared through its entire life cycle in an incubator room at 20° C. in the complete absence of light.

**The life history of *Leptocera digitata* Duda (Diptera: Borboridae),** M. HAFEZ (*Bul. Soc. Fouad 1. Ent.*, 23 (1939), pp. 326-332, figs. 7).

**The life history of *Sepsis impunctata* Macq. (Diptera: Sepsidae),** M. HAFEZ (*Bul. Soc. Fouad 1. Ent.*, 23 (1939), pp. 319-325, figs. 5).

**A hormone which induces pupation in the common house fly (*Musca domestica* Linn.),** P. DE BACH. (Calif. Citrus Expt. Sta.). (*Ann. Ent. Soc. Amer.*, 32 (1939), No. 4, pp. 743-746).

**The Lemna fly and some of its parasites,** M. B. SCOTLAND (*Ann. Ent. Soc. Amer.*, 32 (1939), No. 4, pp. 713-718).—A report of observations of the dipteran *Lemnaphila scotlandae* Cress., an obligate resident of duckweed (*Lemna minor*), with notes on its parasites, including *Opius lemnaphilae* Muesebl., *Trichopria angustipennis* Muesebl., and *T. paludis* Muesebl.

**New North American Siphonaptera,** H. E. EWING. (U. S. D. A.). (*Biol. Soc. Wash. Proc.*, 53 (1940), pp. 35-37).—The genera *Paratyphloceras* and *Aptilopsylla* are erected, with *P. oregonensis* n. sp. from mink, Mercer Lake, Oreg., and *A. carlsbadensis* n. sp. from an unknown host, Carlsbad, N. Mex. The subgenera *Euhoplopsyllus* and *Acediopsylla* are erected, of which *Hoplopsyllus affinis* Baker and *Ctenocephalus inaequalis* Baker, respectively, are type species.

**Methods of collecting and shipping *Larra americana* Sauss., a parasite of the Puerto Rican mole-cricket,** L. F. MARTORELL. (P. R. Col. Expt. Sta.). (*Ann. Ent. Soc. Amer.*, 32 (1939), No. 4, pp. 703-712, figs. 8).

**Field movement of sugar cane beetle borer adults,** R. H. VAN ZWALUWENBURG and J. S. ROSA (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.]*, 44 (1940), No. 1, pp. 3-6).—In order to obtain information on the distance and rate of the adult New Guinea sugarcane weevil movement, the influence of prevailing winds, etc., an experiment was commenced in February 1939 and carried on in continuation of earlier work at Kailua (E. S. R., 80, p. 374). It

has shown that there is a constant movement of the weevils to and from the cane fields. The adults move mainly by flight for considerable distances to a known maximum of about one-third of a mile. "Winds are probably the main influence affecting their field movement. In the absence of air currents beetles fly in any direction, but even light winds appear to influence the direction, extent, and rate of their movement. Heavy winds probably carry them long distances. Adult borer beetles can survive in the field for 176 days, or 25 weeks, and may live even longer. Borer damage to each crop of cane in a given field is independent of the preceding infestation in the same field. Infestation is begun by beetles coming into the field from adjacent fields and is not continued from crop to crop by beetles bred in that particular area. Infestation begins only after the plants have formed cane. At Kailua this occurred in ratoon cane between 5 and 6 mo. of age."

**A destructive infestation in lodgepole pine stands by the mountain pine beetle, J. C. EVENDEN and A. L. GIBSON. (U. S. D. A.).** (*Jour. Forestry*, 38 (1940), No. 3, pp. 271-275, figs. 2).—A brief history is given of the destruction of standing timber resulting from an outbreak of the mountain pine beetle in lodgepole pine stands of the Beaverhead National Forest, Mont. It was shown that during the past decade this outbreak has swept through an area of 1,341,860 acres, killing approximately 57,756,000 trees above 3 in. in diameter. The total loss of merchantable trees 9 in. and above in diameter at breast height is estimated at 77.3 percent.

**The life history of *Philonthus quisquiliarius* Gyllh. (Coleoptera: Staphylinidae, M. HAFEZ** (*Bul. Soc. Fouad 1. Ent.*, 23 (1939), pp. 302-311, figs. 8).

**The life history of *Sphaeridium scarabaeoides* L. (Coleoptera: Hydrophilidae), M. HAFEZ** (*Bul. Soc. Fouad 1. Ent.*, 23 (1939), pp. 312-318, figs. 6).

**A new phytophagous lady beetle in the Philippines, S. S. GONZALES** (*Philippine Jour. Agr.*, 10 (1939), No. 4, pp. 415-417, pls. 3).—A brief account is given of the coccinellid beetle *Plagioderma metallica* Er., which for some time has been seriously injuring the Governor plum or cerali *Flacourtia indica* (Burm. fil.) Merr. in the Los Baños Economic Garden.

**Vertical migration of Japanese larvae, A. HARTZELL and G. F. MCKENNA** (*Contrib. Boyce Thompson Inst.*, 11 (1939), No. 1, pt. 1, pp. 87-91, figs. 2).—It was found that "daily air temperatures influence the movement of Japanese beetle larvae in soil, but vertical migrations of the larvae were from 4 to 6 days behind temperature fluctuations. In general, the movement was only a few inches, although the greatest vertical movement observed was 11.5 in. The probable average movement for individual larvae was between 4 and 7 in. There appears to be a correlation between mean air temperature up to about 60° F. and mean depth of the larvae. Lateral movement seems to take place as the grubs move out of the injured areas to areas of good turf."

**Methyl bromide as a fumigant.—A preliminary report, D. B. MACKIE and W. B. CARTER** (*Calif. Dept. Agr. Bul.*, 26 (1937), No. 2, pp. 153-162, figs. 4).—A preliminary report is made of the results of a series of investigations of methyl bromide (CH<sub>3</sub>Br 99.5 percent) as an insecticide that are in the nature of range finding tests. The details of the tests to which the several stages of many insect species and plant forms were submitted are given in table form.

**Methyl bromide fumigation for Japanese beetle control, H. C. DONOHUE, A. C. JOHNSON, and J. W. BULGER. (U. S. D. A.).** (*Jour. Econ. Ent.*, 33 (1940), No. 2, pp. 296-302).—Need for means of freeing fresh fruits and vegetables for shipment to points outside infested areas during the period of adult activity led to the investigation of methyl bromide here reported, in continuation of the work by Mackie and Carter above noted. As a result commercial bases for application have been developed for use both in fumigation vaults and in loaded

refrigerator cars. "In especially constructed fumigation vaults it has been shown that complete mortality of Japanese beetle adults can be obtained in both vault space and load in fumigations with a 2-hr. exposure period, and that dosage is dependent upon temperature. Complete mortality was obtained with dosages of 2 lb. of methyl bromide per 1,000 cu. ft. at 65° to 90° F., of 1 lb. at 76° to 89°, and of 0.75 lb. at 77° to 86°. These are the results obtained in experimental fumigations involving 108,000 beetles. A successful method for fumigating loaded refrigerator cars was developed in 1938 and put into immediate commercial use. The treatment requires the use of a multivane blower with an air blast rating of 700 cu. ft. per minute free air, the introduction of a part of the dosage into each bunker of the car, and the release of methyl bromide through a disc-type spray nozzle. As used commercially in 1938 the nozzle was directed downward, and in 1939 upward to discharge toward the ceiling. Work in 1939 indicates that a dosage of 3.5 to 4 lb. per car at temperatures of 80°, or above, results in complete mortality. In the experimental car fumigations, over 5,000 grubs and about 110,000 adults of the Japanese beetle were used. The treatment has been commercially applied to almost 4,000 cars of produce during the 1938 and 1939 seasons of beetle activity."

**Tests on certain organic compounds for control of adult Japanese beetle,** A. HARTZELL and FRANK WILCOXON (*Contrib. Boyce Thompson Inst.*, 11 (1939), No. 1, pt. 1, pp. 83-86).—Report is made of preliminary tests of a number of organic compounds as possible contact insecticides for the control of the adult Japanese beetle. "Tergitol 7 penetrant, a sulfated alcohol, can function both as a solvent and as a spreading agent for pyrethrum resins and possesses definite insecticidal properties of its own. It is an excellent spreading agent for pyrethrum sprays made up in acetone and methyl isobutyl ketone. Tergitol 7 penetrant at a concentration of 0.5 percent gave a kill of adult Japanese beetle of about 50 percent. An aqueous solution containing 0.02 percent of total pyrethrins and 0.5 percent Tergitol 7 penetrant gave a satisfactory control of the adults (85-100 percent kill). Plant tolerance to these sprays has been tested on 26 species of plants, of which 21 species were tolerant, 1 species was severely injured, and 4 species only slightly injured."

**The life history of *Aphodius lividus* Oliv. (Coleoptera: Scarabaeidae),** M. HAFEZ (*Bul. Soc. Fouad 1. Ent.*, 23 (1939), pp. 288-300, figs. 9).—The morphology and biology of this scarabaeid is presented, with 15 references.

**The depletion of starch from timber in relation to attack by *Lyctus* beetles, III, IV** (*Forestry*, 12 (1938), No. 2, pp. 117-124, fig. 1; 13 (1939), No. 2, pp. 134-145).—Two further contributions (E. S. R., 80, p. 520) are presented: A Second Experiment Upon the Girdling of Standing Oak Trees, by E. A. Parkin, and A Third Experiment on the Girdling of Standing Oak Trees, by E. A. Parkin and E. W. J. Phillips.

**Mid-summer sprays with lead arsenate to control the hickory bark beetle,** E. I. McDANIEL (*Michigan Sta. Quart. Bul.*, 22 (1940), No. 4, pp. 243-245).—This is a brief practical account of the midsummer use of lead arsenate for controlling hickory bark beetles. One thorough application, 4 lb. in 100 gal. of water plus a sticker-spreader, proved effective because timeliness is the important element in effecting control of this pest with sprays.

**Control measures for the plum sawfly *Hoplocampa fulvicornis*** [trans. title], P. BOVIEN and C. STAPEL (*Tidsskr. Planteavl*, 44 (1940), No. 4, pp. 700-730, figs. 5; *Eng. abs.*, p. 729).—In field work with the plum sawfly, a serious pest in Denmark, Quassia yielded excellent results, and was far superior to nicotine, lead arsenate, cryocid (natural cryolite), and derris.

**Ticks (*Ornithodoros* spp.) in Arizona bat "caves",** C. B. PHILIP (*Pub. Health Rpts. [U. S.], 55 (1940), No. 16, pp. 680-682*).

**Eriophyid studies, VIII,** H. H. KEIFER (*Calif. Dept. Agr. Bul., 29 (1940), No. 1, pp. 21-46, figs. 22*).—This further installment of the series of contributions (E. S. R., 82, p. 803) includes descriptions and illustrations of 22 additional species, of which 20 are described as new.

## ANIMAL PRODUCTION

[**Experiments with livestock in Hawaii**] (*Hawaii Sta. Rpt. 1939, pp. 19, 26-31, 79-82, figs. 3*).—Brief progress reports (E. S. R., 81, p. 687) are presented for the following investigations: Comparative palatability of forage grasses, by R. A. Lyman and J. C. Ripperton; the value of molasses as a supplement to Napier grass, and a comparison of Rhodes grass and Sudan grass for dairy cows, both by L. A. Henke and C. I. Maruyama; soybean oil meal v. cottonseed meal as protein supplements for milking cows, by Henke and S. H. Work; the value of cane molasses for the pasture fattening of beef cattle, by Henke, Work, and A. W. Burt; a comparison of fish meal, roasted soybeans, and soybean oil meal as protein supplements in swine rations, the value of algarroba beans for fattening swine, the use of avocados, papayas, and pineapple bran in swine rations, and the utilization of urea nitrogen by cattle and by swine, all by Work and Henke.

From experiments with poultry, results are noted on the rate and efficiency of gain of New Hampshire chickens, the egg production of Japanese Shamo Game pullets, the comparative fertility and hatchability of eggs from hens in cages and on the ground, all by C. M. Bice; and the utilization of urea nitrogen by chickens, and the salt balance of molasses feed for poultry, both by Bice and L. A. Dean.

[**Livestock investigations in Kentucky**] (*Kentucky Sta. Rpt. 1939, pt. 1, pp. 10-13, 22-24, 54, 55, 56*).—Results are briefly presented for the following lines of investigation: A comparison of alfalfa-molasses silage and alfalfa hay as roughages for dry-lot fattening of steers; comparative analyses of corn, red clover, and alfalfa silages; a mixture of distillers' corn dried grains and tankage v. cottonseed meal as protein supplements for fattening steers; distillers' corn dried grains v. cottonseed meal for pregnant and nursing beef cows; beef production per acre of variously fertilized permanent pastures; lespedeza hay v. alfalfa hay for bred ewes; rye v. bluegrass pasture for breeding ewes; a comparison of rations for creep-fed lambs; the quality of lambs produced by individuals representing the five most common types of western ewes; continuous v. rotational grazing of bluegrass pastures for ewes and their lambs and for dairy heifers; tankage v. a mixture of tankage and soybean oil meal in swine rations; a comparison of pasture crops for hogs; the optimum date at which to discontinue turning turkey eggs during incubation; the use of body measurements for predicting quality of turkey carcasses; the relation of the quality of protein in meat scrap to rate of growth of chicks; characteristics of the oil of the uropygial gland in chickens and turkeys; a comparison of feeding methods for laying pullets; and free-choice feeding v. all-mash feeding for chicks.

[**Livestock investigations in Mississippi**] (*Miss. Farm Res. [Mississippi Sta.], 3 (1940), Nos. 4, pp. 2, 7, 8; 5, pp. 2, 7*).—The results of experiments with livestock are briefly reported in articles as follows: No. 4, Grazing, Balanced Ration, Produced Economical Pork, by P. G. Bedenbaugh; Silage Economical, Fits Well Into the Dairy Program, by J. S. Moore; Lespedeza Hay Found Satisfactory for Wintering Mature Beef Cows and Yearling Heifers in 1940 Test,

by A. E. Cullison; Substitutes for Dried Milk in Poultry Feeding, by G. R. Sipe; No. 5, Holding Turkeys for the Spring Market at Present Price Level Unsound for Toms, Depends on Value of Eggs Produced by Hens, by G. R. Sipe; Profit on Lambs Depends Largely on Early Weaning, by H. H. Leveck; and Wheat Shorts for Feeding Pigs—Price, Finish Are Factors, by P. G. Bedenbaugh.

[**Livestock investigations in Nevada**] (*Nevada Sta. Rpt. 1939, pp. 24, 36–38, fig. 1*).—Included are progress reports on the use of barley as a supplement to alfalfa for range ewes and lambs, by C. E. Fleming; and the rate and economy of gain of purebred v. crossbred pigs, comparative values of first-, second-, and third-cutting hay for steer feeding, and variations in earliness of maturity and size and quality in four strains of turkeys, all by F. B. Headley.

[**Livestock investigations in Ohio**] (*Ohio Sta. Bul. 600 (1939), pp. 51–53, 54, 55, 56, 57*).—Included are brief reports on the effect of decreasing corn and increasing hay in the rations of fattening yearling steers, the desirability of limiting coconut oil meal for pigs, the value of iron-treated cottonseed meal as a partial source of protein for pigs, the value of dried skim milk for young pigs, a comparison of hybrid and open-pollinated corn for swine, cross-breeding tests with swine, the toxicity of gossypol for pigs and guinea pigs, the influence of various concentrates in the ration on the occurrence of “apoplexy” in fattening lambs, the livability and egg production of pullets as affected by previous management, and the riboflavin requirement of the chicken and effective sources and levels of this substance in the poultry ration.

[**Experiments with livestock in South Carolina**] (*South Carolina Sta. Rpt. 1939, pp. 82, 85–87, 93–95, 100–104*).—Results are briefly reported for the following lines of investigation, by E. G. Godbey, L. V. Starkey, E. D. Kyzer, R. L. Jones, and G. W. Anderson: Cottonseed meal and hulls v. corn and lespedeza hay for fattening steers; a comparison of rye (pasture) v. sorghum silage in wintering stocker steers; the value of pearl millet as a temporary pasture for beef cattle; the rate and economy of gains of crossbred v. purebred pigs; the relative value of menhaden fish meal, meat-and-bone scraps, tankage, and sardine meal as protein supplements for fattening pigs on rye pasture; and the relation of economy of gain in fattening swine to certain morphological and physiological factors.

Reports of poultry investigations, by C. L. Morgan, R. C. Ringrose, J. H. Mitchell, and E. J. Lease, include the deleterious effect of cottonseed oil on hatchability of eggs and the effect of various fractions of the oil in this regard, and the value of sweetpotato flour as a source of carotene for chickens.

[**Livestock investigations in Tennessee**]. (Partly coop. U. S. D. A. et al.). (*Tennessee Sta. Rpt. 1938, pp. 4–7, 34–40, 41, 42, 81–83, 89, figs. 2*).—Experiments at the main and branch stations, for which results are briefly reported, include: The costs and profitableness of acre-beef yields from corn harvested in various forms and fed in various forms and combinations, the feed requirements for fattening 2-year-old steers on pasture, the comparative value of shelled corn, ground shelled corn, and corn-cob-shuck meal for winter finishing of baby beeves, silage v. alfalfa hay for fattening yearling steers, and cottonseed meal alone v. mixtures of protein concentrates as supplements to silage for fattening steers, all by M. Jacob; the economy of beef production on bluegrass, alfalfa, and clover pastures, by L. R. Neel and F. S. Chance; the effect of nitrate fertilization on the carrying capacity of permanent pastures, the effect of shade trees on the carrying capacity of permanent pastures, and the effect of stage of maturity on the pasture value of lespedeza, all by Neel; the value of grain feeding for breeding ewes in the production of early spring lambs, and corn v. barley for fattening pigs on crimson clover or crimson clover plus ryegrass

pastures, both by Jacob; the availability of phosphorus in *Lespedeza sericea* and alfalfa hays of varying phosphorus content, by D. E. Williams and E. Morrell; and the utilization of legume silage as a feed for poultry, by P. W. Allen and Jacob.

[**Livestock investigations in Wyoming**]. (Partly coop. U. S. D. A.). (*Wyoming Sta. Rpt. 1939*, pp. 11-13, 22, 23, 32, 34, 36, 37, 39).—Investigations at the central and substations, for which results are briefly reported, include: The effect of phosphorus deficiency in the ration of beef heifers; a comparison of chopped corn fodder, native hay, and native hay plus cottonseed meal for wintering beef calves; wet beet pulp v. corn silage, each with and without cottonseed meal as a supplement, and other comparisons of rations for fattening beef steers; the rate and economy of gain of Hereford steers representing three selected blood lines; soybean lecithin as a supplement to hay and barley for sheep; the wool- and mutton-producing qualities of crossbred sheep resulting from the crossing of native ewes with Corriedale, Columbia, Romney, and Lincoln rams; lamb feeding experiments, including the use of sugar beet byproducts, Russian-thistle hay, Sudan grass hay, alfalfa, corn silage, and concentrates in various combinations; factors affecting the shrinkage of wool and wool-sampling methods; the value of skim milk in pig feeding; a comparison of alfalfa pasture v. dry lot for fattening pigs on corn and tankage; the influence of types of poultry house, artificial lighting, and artificial heating on the rate and economy of egg production; the relative cost of raising pullets in sexed and unsexed groups; the comparative effects of different cereal grains on the growth and quality of turkeys; and the value of rye for turkeys.

**Comparison of a chemical and a biochemical method for determining the biological value of proteins and an evaluation of the endogenous nitrogen**, F. C. OLSON and L. S. PALMER. (Minn. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 60 (1940), No. 5, pp. 331-342, figs. 4).—Using the nitrogen-retention method of Mitchell and Carman (*E. S. R.*, 56, p. 188), the following biological values for proteins from different sources were obtained: Whole egg 94, casein 63, whole wheat 47, wheat gluten 42, whole corn 52, corn-gluten meal 42, liver meal 56, meat-and-bone tankage 38, solvent-extracted soybean meal 61, and heated solvent-extracted soybean meal 68. The protein quality index of the same foods was determined by the chemical method of Almquist et al. (*E. S. R.*, 74, p. 529). These values showed no comparison with the biological values in case of the isolated proteins. For the natural foodstuffs the comparison was fair providing the enzymatic digestion most similar to that in vivo was used for calculating the protein index value. No difference was found in the digestion of raw and heated soybean meal, although the latter showed a higher biological value. Correction of the endogenous urinary nitrogen according to body surface was found to give less variation than correction according to body weight.

**Tomato pomace in the diet**, C. M. McCAY and S. E. SMITH. (Cornell Univ. and U. S. D. A.). (*Science*, 91 (1940), No. 2364, pp. 388, 389).—Tomato pomace of relatively high initial carotene content when held for 1 yr. at room temperature showed no evidence of rancidity and very little decrease in carotene content. One hundred mg. daily per animal of either fresh or aged material provided an adequate amount of vitamin A for normal growth and maintenance of rats. In feeding tests with dogs, foxes, and minks tomato pomace at a 5-percent level in the ration had a very beneficial effect on the character of the feces.

**Vitamin A content of the livers of a hundred healthy dogs**, R. G. LINTON and A. BROWNLEE (*Nature [London]*, 144 (1939), No. 3658, pp. 978, 979).—Livers obtained from healthy dogs of varying age and condition were found to contain an average of 678 blue units per gram. However, wide individual variations were noted and the medial figure based on the average of the six central figures

was 153.5 blue units per gram. There appeared to be no association between the vitamin A reserve and the body condition of the dogs.

**The vitamin A activity and the vitamin B<sub>1</sub> content of soybeans and cowpeas,** J. O. HALVERSON and F. W. SHERWOOD. (N. C. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 60 (1940), No. 2, pp. 141-144).—Employing the rat-growth technic, nine common varieties of soybeans and eight of cowpeas (mostly from a local seed store) were assayed for vitamin A and vitamin B<sub>1</sub>. None of the varieties of either plant contained appreciable quantities of vitamin A, the maximum content recorded being 1.3 International Units per gram. The soybeans contained from 3.2 to 4.8 (average 3.8) I. U. of vitamin B<sub>1</sub> per gram, and the cowpeas from 2.3 to 3.7 (average 3) I. U. per gram. There were no marked differences between varieties.

**The production of uncomplicated riboflavin deficiency in the dog,** A. E. AXELROD, M. A. LIPTON, and C. A. ELVEHJEM. (Wis. Expt. Sta.). (*Amer. Jour. Physiol.*, 128 (1940), No. 4, pp. 703-708, figs. 2).—A basal ration composed of purified casein, sucrose, cod-liver oil, and salt mixture was found to be adequate for growing dogs when supplemented with thiamin, nicotinic acid, vitamin B<sub>6</sub>, riboflavin-free liver extract, and riboflavin. When riboflavin was omitted from the diet an acute characteristic deficiency syndrome was produced in from 6 to 8 weeks. If administered sufficiently early in the development of this syndrome, the riboflavin supplement exerted a marked curative effect.

**The biological activity of synthetic pantothenic acid,** H. H. WEINSTOCK, JR., A. ARNOLD, E. L. MAY, and D. PRICE (*Science*, 91 (1940), No. 2365, p. 411).—Using a microbiological assay method, good agreement was obtained between the expected values for the biological activity of pantothenic acid as supplied by rice bran filtrate and that supplied as a crude synthetic product. The yield of pantothenic acid of the synthetic material was approximately 25 percent.

**Further studies on the effectiveness of arsenic in preventing selenium poisoning,** K. P. DUBOIS, A. L. MOXON, and O. E. OLSON. (S. Dak. Expt. Sta.). (*Jour. Nutr.*, 19 (1940), No. 5, pp. 477-482, fig. 1).—Continuing this series of investigations (E. S. R., 82, p. 660), rats receiving from 14 to 18 p. p. m. of selenium in their diet in the form of seleniferous wheat were fully protected against selenium toxicity by adding 10 p. p. m. of arsenic in their drinking water supplied either as sodium arsenite or sodium arsenate. The addition of 5 p. p. m. of arsenic from these sources gave only partial protection. Arsenic in the form of sulfides was ineffective in this respect. Arsenic as sodium arsenite was equally effective against selenium supplied as seleniferous wheat, sodium selenite, or selenium-cystine. The response to arsenic supplement varied with the length of time the animals had received selenium before arsenic administration. The arsenic was effective when rats had received selenium for 20 days but was of little value after 30 days of selenium feeding.

**Boron in animal nutrition,** E. HOVE, C. A. ELVEHJEM, and E. B. HART. (Wis. Expt. Sta.). (*Amer. Jour. Physiol.*, 127 (1939), No. 4, pp. 689-701, figs. 2).—A colorimetric method for determining boron in biological materials is described. Employing this technic a large number of milk and egg samples were analyzed. No significant breed differences in boron content of milk were observed, but it was found possible to markedly increase the boron content of milk by feeding boric acid. Likewise, the boron content of eggs was greatly increased by increasing the boron content of the ration, although the ratio of boron in the white to that in the yolk (8-10:1) was not altered. Preliminary feeding trials with rats indicated that ingested boric acid is eliminated very rapidly. Addition of boron to milk or to a dry ration providing only 0.8  $\mu$ g. of boron per animal daily did not improve the growth rate of young rats.

indicating that if boron is required for this species the requirement is relatively very low.

**Beef production in California**, H. R. GUILBERT and L. H. ROCHFORD. (Coop. U. S. D. A.). (*Calif. Agr. Col. Ext. Cir. 115 (1940)*, pp. 125, figs. 25).—"This circular deals with the principal factors that influence beef-cattle production, management, and marketing practices in California, and the efficiency of the animals in performing their specific functions." The physical conditions and economic background influencing the industry and the methods used by stockmen, the general requirements for proper nutrition of beef animals, and the characteristics of the principal feeds grown in the State are described. Management of a breeding herd and young animals for production of feeder cattle, and the fundamental principles to be observed in finishing beef cattle are discussed and suggestions and recommendations made.

**The digestibility of ground prunes, winery pomace, avocado meal, asparagus butts, and fenugreek meal**, A. H. FOLGER (*California Sta. Bul. 635 (1940)*, pp. 11).—Employing wether sheep as test animals as in earlier trials (E. S. R., 56, p. 261), coefficients of digestibility were determined for dried prunes, winery pomace, avocado meal, and asparagus butts. The calculated digestible crude protein and total digestible nutrient values for these products are as follows: Prunes 0.7 and 66.1, winery pomace (samples A and B) 1.3 and 24.5, winery pomace (sample C) 1.9 and 30.7, solvent-extracted avocado meal 9 and 57.3, and asparagus butts 9.7 and 47.1. The fenugreek meal because of its laxative properties could not be fed in sufficient quantities to yield accurate data on its digestibility. The prunes were very palatable, avocado meal and asparagus butts reasonably palatable, and the winery pomace was readily consumed by sheep but was not relished by cows.

**Rice and rice products for fattening lambs**, M. G. SNELL and F. L. MORRISON. (La. Expt. Sta.). (*Rice Jour.*, 43 (1940), No. 4, pp. 13, 14).—In the lamb feeding experiments described ground corn was compared with a number of rice products. Rice straw, cottonseed meal, a small amount of alfalfa hay, and minerals were common to all rations. Comparative values based on the amount of concentrate required per 100 lb. of gain, with corn assuming the value of 100, were for ground rough rice 76, chicken feed rice 102, rice polish 73, rice bran 32, and mixtures of rice polish and rice bran from 59 to 63. Lambs receiving corn and chicken feed rice made average daily gains of 0.25 and 0.26 lb., respectively. Lambs on the other rice products made somewhat slower though reasonable gains, except those receiving rice bran which gained an average of only 0.09 lb. per head daily.

**The synthesis of nicotinic acid in the body of sheep**, A. H. WINEGAR, P. B. PEARSON, and H. SCHMIDT. (Tex. Expt. Sta.). (*Science*, 91 (1940), No. 2369, pp. 508, 509).—Lambs maintained on a nicotinic acid deficient basal diet for a period of approximately 8 mo. were found to yield significant quantities of nicotinic acid in their urine, the quantity being of a similar magnitude to that in lambs receiving nicotinic acid supplements in their diet. It appeared that synthesis of this substance occurs in the body of the sheep.

**Estimates of value of wool based on grease weights unreliable**, M. MADSEN (*Farm and Home Sci. [Utah Sta.]*, 1 (1940), No. 2, p. 7, fig. 1).—Comparisons of average shearing weights and scoured weights of fleeces from range and farm groups of sheep over an 8-yr. period showed an advantage in shearing weight of farm flocks in 6 of the 8 yr. The average wool shrinkage was 66 and 59 percent for range and farm, respectively. It is concluded that the usual practice of wool buyers to pay higher prices for range wool than for farm wool is unjustified.

**Studies on the bacteriology of Wiltshire bacon.—I, Methods for quantitative analysis of curing pickle,** G. B. LANDERKIN (*Food Res.*, 5 (1940), No. 2, pp. 205-214, figs. 4).—Summarizing the results of 5 years' study by the Science Service, Department of Agriculture, Canada, it was found that the flora of Wiltshire pickle is heterogeneous and requires at least two media for its enumeration, i. e., a nutrient agar to indicate the degree of contamination and 10-percent salt agar to reveal the natural or halophilic flora. With either nutrient agar or 5-, 10-, and 15-percent salt agars higher counts were obtained at an incubation temperature of 20° C. than at 37° or 5°. The limitations of other media tested are discussed.

**Capon production in South Dakota,** W. E. POLEY (*South Dakota Sta. Bul.* 335 (1940), pp. 31, figs. 13).—In addition to a general discussion of caponizing and the feeding, management, and marketing of capons, the results of experiments to determine the effect of production cost factors upon market profits from capons and to compare the business of producing capons with that of producing cockerels for roasters are summarized. The net returns from capons varied considerably over a period of 4 yr., mortality, feed costs, rate of growth, weight at marketing time, and meat prices, all having an appreciable effect on the labor income from capon production. The average weight of feed consumed per pound of gain was 8 and 8.3 lb. for cockerels and capons, respectively. The average mortality of all birds reared was 16.5 and 22 percent for cockerels and capons, respectively. Under the conditions of these trials the production of capons proved more profitable than the production of cockerels for roasters.

**Factors affecting the market quality of poultry meat,** W. A. MAW (*U. S. Egg and Poultry Mag.*, 46 (1940), No. 7, pp. 412-414, 445-448, fig. 1).—A general summary, with 27 references to the literature (*E. S. R.*, 83, p. 388).

**The effect of cold drinking water on chick growth and yolk absorption,** B. W. HEYWANG. (U. S. D. A.). (*Poultry Sci.*, 19 (1940), No. 3, pp. 201-204).—In a series of short-time tests at the Southwest Poultry Experiment Station, Glendale, Ariz., young chicks were allowed access to warm drinking water (75°-90° F.) v. chilled drinking water (slightly above 32°). The drinking of cold water did not interfere with the normal absorption of yolk material or adversely affect the growth of young chicks. There was no significant difference in the average feed required per unit of gain in the two lots.

**The influence of whole wheat, bran, and shorts on body weight and feather growth in chicks,** F. E. MUSSEHL, C. W. ACKERSON, and M. J. BLISH (*Nebraska Sta. Res. Bul.* 119 (1940), pp. 11, figs. 5).—Fed as supplements (equivalent protein basis) to a basal ration containing corn, barley, oats, meat scrap, fish meal, and soybean meal, the proteins of the whole wheat kernel, bran, and shorts were apparently utilized with equal efficiency by growing chicks. In another series in which the vegetable constituents of the basal ration were autoclaved, the chicks receiving bran as a supplement showed markedly superior feather development, while those on shorts were intermediate in this respect and those on whole wheat were poorly feathered. However, growth was more rapid among chicks receiving shorts, followed in order by those on bran and whole wheat.

**The essential nature of a new growth factor and vitamin B<sub>6</sub> for chicks,** D. M. HEGSTED, J. J. OLESON, C. A. ELVEHJEM, and E. B. HART. (*Wis. Expt. Sta.*). (*Poultry Sci.*, 19 (1940), No. 3, pp. 167-176).—The results of a series of experiments employing six different simplified basal diets with numerous supplements are described. Evidence was obtained to indicate the requirement of the chick for a new growth factor which is distinct from factor U, chondroitin, arginine,

or any of the water-soluble factors recognized as being required by the chick or rat. Certain properties of the factor are described, but efforts to concentrate it from kidney or brain tissue or from wheat middlings have been unsuccessful to date. It was further shown that vitamin B<sub>6</sub> is required by the chick for maintenance and growth. Two other deficiency symptoms encountered in this trial are described, one a characteristic spastic paralysis, the other yellow livers which are not associated with any deficiency known to cause fatty degeneration.

**The cannibalism preventing properties of the fiber fraction of oat hulls,** G. E. BEARSE, V. L. MILLER, and C. F. McCLARY. (West. Wash. Expt. Sta.). (*Poultry Sci.*, 19 (1940), No. 3, pp. 210-215).—Continuing this series (E. S. R., 80, p. 674), efforts were directed toward determining what fraction of the oat hull prevented or retarded development of cannibalistic tendencies in chickens. Oat hull fiber obtained by dilute acid digestion of oat hulls fed at a level to provide 11 percent fiber in the complete ration effectively controlled cannibalism and improved feather development. Neither oat hull ash nor the dilute acid extract were of significant value in preventing cannibalism.

**The pH and cloudiness of egg albumen in relation to albumen quality,** L. A. WILHELM. (Wash. Expt. Sta.). (*U. S. Egg and Poultry Mag.*, 46 (1940), No. 7, pp. 397-401, figs. 2).—Determination of the pH of various fractions of strictly fresh eggs gave the following values: Thin albumen 7.9, thick albumen 7.76, albumen with yolk removed 7.62, albumen still containing the yolk 7.61, and yolk 5.94. A study was made of the albumen quality of some 400 eggs ranging from 0 to 21 days of age as related to pH and cloudiness of albumen. The albumen index declined  $\pm 10$  percent during the first 24 hr. after the eggs were laid, this drop being closely associated with loss of CO<sub>2</sub> as measured by pH of albumen. Cloudiness of albumen appeared to be an indication of excellent interior egg quality, being associated with a low pH of albumen and a high albumen index and indicating freshness and/or that the egg had been held at low temperatures.

**The porosity of the egg-shell in relation to hatchability,** C. D. MUELLER and H. M. SCOTT. (Kans. Expt. Sta.). (*Poultry Sci.*, 19 (1940), No. 3, pp. 163-166, fig. 1).—Employing loss in egg weight per unit of shell area as a measure of eggshell porosity, it was found that the porosity of White Leghorn eggs was not correlated with hatchability. The average loss in weight for the eggs laid during the normal hatching season was 7.28 mg. per square centimeter of shell area (range 3.52-13.99) during the first 24 hr. of incubation. No correlation was found to exist between egg weight and loss in weight per unit of surface area.

**Malformation of the tarso-metatarsal and phalangeal bones of chicks,** L. C. NORRIS, C. D. CASKEY, and J. C. BAUERNFEIND. (Cornell Univ.). (*Poultry Sci.*, 19 (1940), No. 3, pp. 219-223, figs. 2).—A deformity commonly called crooked toes, observed on poultry farms with increasing frequency in recent years, is described and illustrated. Experimental work on its cause revealed that the type of floor on which chicks are confined has a marked effect on the development of the disorder, smooth paper-covered floors resulting in a much higher incidence than hard wire-covered floors. The probable effect of inherent defects and nutritional deficiency on its development is discussed.

**The difference in serum calcium and inorganic phosphorus content of normal turkeys affected with a bone deformity,** H. M. NIELSEN and D. E. MADSEN. (Utah Expt. Sta.). (*Poultry Sci.*, 19 (1940), No. 3, pp. 198-200).—Young turkeys suffering from a bone deformity similar to, if not identical with, perosis were found to have a significantly lower percentage of calcium and a higher percentage of inorganic phosphorus in the blood serum than normal birds. No explanation is offered regarding the manner in which these differences may relate to the development of the disorder (E. S. R., 83, p. 391).

Utah conditions especially favorable for turkey production, B. ALDER (*Farm and Home Sci. [Utah Sta.]*, 1 (1940), No. 2, pp. 3, 10, figs. 2).—A general discussion of turkey production in Utah, with emphasis on the use of locally grown feeds.

### DAIRY FARMING—DAIRYING

[Dairy cattle investigations in Kentucky] (*Kentucky Sta. Rpt. 1939, pt. 1, pp. 21, 22*).—The results are briefly noted on factors responsible for delayed conception and sterility in dairy heifers, the effect of excitation on the ejection of milk from the bovine udder, and the bacterial and leucocyte content of aseptically drawn milk samples.

Dairying in Mississippi agriculture, J. S. MOORE and W. C. COWSERT (*Miss. Farm Res. [Mississippi Sta.]*, 3 (1940), No. 5, pp. 3-6, figs. 2).—This article, which is a part of the director's annual report, summarizes the findings during the first 10 yr. on a 14.25-acre farm with 6 acres in pasture, 2 in cotton, and 6.25 acres in feed crops, with an average of 4.8 cows.

[Dairy investigations in Ohio] (*Ohio Sta. Bul. 600 (1939), pp. 45-51, figs. 3*).—Included are brief reports on the quality and carotene content of silages other than corn in various types of silos and with various treatments, a rapid method for determining moisture in green roughages and hays, feeding milk fat substitutes to veal calves, raising heifer calves on limited amounts of whole milk, grain in pellet form v. meal for heifer calves, and the effect of vitamin A deficiency on the structure of the gonads and the pituitary gland.

[Dairy cattle investigations in South Carolina], G. H. WISE, J. P. LAMASTER, J. H. MITCHELL, and E. J. LEASE (*South Carolina Sta. Rpt. 1939, pp. 81, 82, 83, 84, 89-92, fig. 1*).—Brief progress reports (E. S. R., 81, p. 97) are presented on a comparison of rotational v. continuous grazing of Bermuda grass pastures, the relative quality and feeding value of corn-soybean silages and sorghum-soybean silages, the influence of these silages and of sweetpotato flour in the dairy ration on the carotene content of the butterfat produced, and a comparison of the open-pail v. nipple-pail methods of feeding milk to dairy calves.

[Dairy cattle investigations in Tennessee] (*Tennessee Sta. Rpt. 1938, pp. 83, 87, 88*).—Results are briefly presented on a comparison of winter pasture v. silage for milking cows, by L. R. Neel; and the quality and palatability of crimson clover silage, and the use of an all-roughage ration v. roughage and grain feeding for milking cows, both by B. P. Hazlewood.

[Experiments with dairy cattle in Wyoming] (*Wyoming Sta. Rpt. 1939, pp. 11, 24, 25*).—Results are briefly noted for the following investigations: The value of beet molasses as a supplement to native hay and to alfalfa hay, dried beet pulp v. sunflower silage as a supplement to native hay for dairy heifers, the economy of limited grain (barley) feeding v. a sole roughage ration for milking cows, and open-shed v. stable milking.

Artificial insemination, J. P. LAMASTER and G. W. ANDERSON (*South Carolina Sta. Rpt. 1939, pp. 88, 89*).—Artificial insemination proved successful with dairy cattle even following storage of semen for 24, 48, and 96 hr. under mineral oil and refrigeration.

Absorptive capacity of different materials ordinarily used for bedding, T. M. OLSON. (S. Dak. State Col.). (*Jour. Dairy Sci.*, 23 (1940), No. 4, pp. 355-360).—Ten-lb. samples each of whole and cut oat straw, wheat straw, rye straw, and of sawdust and shavings were allowed to soak in urine or in water for 2 hr., and then were weighed to determine their water-absorbing capacity. The various cereal straws were very similar in this respect, and no significant differences were noted between the absorptive capacity of the whole and cut

straws. The shavings absorbed less moisture than the straws, while the very dry sawdust absorbed somewhat more.

**Effects of feeding various lots of legume grass silage to dairy cattle,** A. R. SCHUBERT, B. R. CHURCHILL, and J. G. WELLS, JR. (*Michigan Sta. Quart. Bul.*, 22 (1940), No. 4, pp. 238-241).—Five lots of grass-legume silages, varying as to stage of maturity, moisture content, and type of preservatives used, were compared in the trial reported. Three similar groups of dairy heifers and cows were fed (1) all silage, (2) half silage and half hay, and (3) all hay. All lots of silage were palatable and consumed with little refusal. Substituting silage for hay either in part or entirely did not produce any significant difference in body weights of the cows during the feeding trial. Heifers fed all silage made greater gains than those fed half silage and half hay and much greater gains than those fed all hay of a medium quality.

**A test of the economic efficiency of alfalfa hay as a sole ration for dairy cattle, and its relation to sterility,** F. B. HEADLEY (*Nevada Sta. Rpt.* 1939, p. 36).—A progress report.

**Bloat in dairy cattle,** T. M. OLSON. (S. Dak. Expt. Sta.). (*Jour. Dairy Sci.*, 23 (1940), No. 4, pp. 343-353).—Data are presented on the analyses of rumen gases collected from cows (both live and dead) which had bloated on sweetclover or alfalfa, also on the composition of gases generated under laboratory conditions from a number of legumes and nonlegumes. No significant difference was noted in the composition of rumen gases from sweetclover and alfalfa or in the composition of gases from legume and nonlegume plants generated under laboratory conditions except for the relatively low percentage of carbon dioxide in gases from corn plants, marsh grass, and brome grass. The rumen gases differed from those generated in the laboratory, mainly in their higher methane content. No single factor was found which would seem to explain the cause of bloat or the cause of death from bloat.

**Milk and butterfat production by dairy cows on four different planes of feeding,** R. R. GRAVES, G. Q. BATEMAN, J. B. SHEPHERD, and G. B. CAINE. (Coop. Utah Expt. Sta.). (*U. S. Dept. Agr., Tech. Bul.* 724 (1940), pp. 36).—Of the four rations compared in this experiment the control ration consisted of full-grain feeding (1 lb. of grain for each 4.33 lb. of milk produced), with alfalfa hay, corn silage, and pasture in season. Ration 1 consisted of pasture in season and alfalfa hay; ration 2, ground barley at the rate of 1 lb. to each 6.03 lb. of milk produced, with alfalfa hay and pasture; and ration 3, alfalfa hay, corn silage, and pasture. Twelve Holstein cows each completed one full lactation on each of the above rations. Compared to the full-grain ration, ration 1 produced 69.8 and 65.8 percent; ration 2, 86 and 80.2 percent; and ration 3, 73.6 and 69.9 percent as much milk and butterfat, respectively (mature basis). The relatively low butterfat content of milk produced on rations 1, 2, and 3 is not in agreement with earlier trials conducted by the Bureau of Dairy Industry. The rate of decline in milk production after the month of highest production was more rapid on the high roughage rations than on the full-grain ration. The cows appeared to be more regular breeders and produced heavier calves while receiving the all-roughage rations than when on the rations containing grain.

**A rapid multiple color test for the approximation of available chlorine,** H. SCHARER (*Jour. Milk Technol.*, 3 (1940), No. 2, pp. 84-87, fig. 1).—A colorimetric test for the approximation of available chlorine and which will distinguish between a hypochlorite and a chloramine is described.

**High-temperature (steam-injection) pasteurization of cream for butter-making,** W. M. ROBERTS, S. T. COULTER, and W. B. COMBS. (Minn. Expt. Sta.). (*Jour. Dairy Sci.*, 23 (1940), No. 4, pp. 315-323, fig. 1).—Duplicate samples of

sweet and of neutralized sour creams were pasteurized at 260° F. with a high-temperature steam-injection pasteurizer and at 160° for 30 min. in a vat pasteurizer, respectively. Both salted and unsalted butters prepared from creams pasteurized at high temperature received the same initial flavor score as those from the comparable lots of vat-pasteurized cream. Despite the lower initial bacterial counts neither the salted nor unsalted butter from the high-temperature cream kept better in storage at 40° than butter from the low-temperature cream. The high-temperature pasteurizer resulted in much greater losses of butterfat in the buttermilk than did the vat pasteurizer.

**Potentiometric studies with resazurin and methylene blue in milk, C. K. JOHNS and R. K. HOWSON** (*Jour. Dairy Sci.*, 23 (1940), No. 4, pp. 295-302, figs. 6).—In studies by the Science Service, Department of Agriculture, Canada, a comparison of time-potential curves for milk, milk plus resazurin, and milk plus methylene blue showed that the curve for milk plus resazurin had a sharper initial drop in Eh than those for the other samples. This was followed by a flattening of the curve at a point near that at which the full pink color appeared. Later the curve again declined so that eventually all samples reached the same final Eh. Resazurin reduced to the pink stage in approximately three-fourths of the time required for methylene blue to decolorize, probably attributable to the change in shape of the time-potential curve in the presence of resazurin. Hourly inversion of the tubes during incubation generally shortened the reduction time of good milk considerably. Resazurin appeared more useful than methylene blue in detecting milk containing large numbers of weakly reducing organisms.

**“Oxidase reaction” of bacteria in relation to dairy products, C. H. CASTELL and E. H. GARRARD** (*Food Res.*, 5 (1940), No. 2, pp. 215-222).—This contribution from the Ontario Agricultural College describes the oxidase, Gram, proteolytic, lipolytic, and other reactions of 30 pure cultures of bacteria. Organisms of the *Pseudomonas* and *Achromobacter* genera proved to be the most strongly oxidizing types; those of the *Alcaligenes* and *Brucella* were somewhat less oxidizing, although still strongly positive; members of the *Aerobacter*, *Escherichia*, and *Proteus* bacilli were weakly positive, variable, or negative; while the cocci and one anaerobic type were definitely oxidase-negative. In general, strong oxidizers were Gram-negative, while those not strong oxidizers were Gram-positive. The significance of the oxidase test in relation to microbial spoilage of dairy products and other foods is discussed at length.

**Effect of lactic acid on the hydrolysis of fat in cream by pure cultures of lipolytic micro-organisms, E. L. FOUTS.** (Okla. A. and M. Col). (*Jour. Dairy Sci.*, 23 (1940), No. 4, pp. 303-306).—Samples of sterilized cream to which various amounts of sterilized lactic acid had been added were inoculated with various lipolytic micro-organisms and incubated for 6 days at 21° C. *O[ospora] lactis*, *myc[obacterium] lipolytica*, and *Ach[romobacter] lipolyticum* were definitely inhibited by adding excessive amounts of the acid to cream. However, all grew well in cream containing sufficient acid to give a titratable acidity of 1 percent, and the first two produced lipolysis in cream having an acidity of 2.08 percent. The action of most lipolytic species was inhibited by growth of butter culture organisms in cream, but *M. lipolytica* showed increased growth under these conditions, and all organisms caused a significant amount of lipolysis even in high-acid creams. The acid number of the fat after 6 days at 21° was not significantly affected by the presence of large amounts of lactic acid.

**Relation of volatile acidity of butterfat to rancidity, E. L. FOUTS.** (Okla. A. and M. Col). (*Jour. Dairy Sci.*, 23 (1940), No. 4, pp. 307-314).—Studies of butters varying widely in degree of rancidity revealed no close correlation between the percentages of total acid in the fat that were volatile and the degree of

rancidity. However, the different organisms studied showed considerable variability in percentages of total fat acid that were volatile and nonvolatile, the percentage that was volatile ranging from 1.9 percent with *O[ospora] lactis* to 14.7 percent with *Ps[eudomonas] fluorescens*. The ratio of volatile to non-volatile acid was quite constant for a given species, regardless of age of culture, incubation temperature, or degree of fat hydrolysis. Synthetic media containing sodium or calcium salts of butyric, caproic, and caprylic acid as the sole source of carbon supported good growth in certain lipolytic organisms, particularly *O. lactis*, but little or no growth in other species.

**Improvement of the Hotis test for the detection of mastitis streptococci,** J. F. CONE and F. M. GRANT. (U. S. D. A.). (*Jour. Milk Technol.*, 3 (1940), No. 2, pp. 75-79).—A method for the detection of mastitis streptococci consisting essentially of a combination of the Hotis test (E. S. R., 76, p. 391) and the Bryan microscopic examination (E. S. R., 73, p. 103) is described. In the examination of a large number of milk samples this procedure detected 96.8 percent of the samples from quarters infected with streptococci and 99.5 percent of the samples from streptococci-free quarters.

**The deterioration of the bovine udder in the absence of streptococci,** E. G. HASTINGS and E. H. PETERSON. (Wis. Expt. Sta.). (*Jour. Agr. Res.* [U. S.], 60 (1940), No. 3, pp. 145-156).—Eleven Holstein cows milked by machines were observed during the first, second, and third lactation periods as to kinds and numbers of bacteria present and chlorine and catalase content in the fore-milk. The milk yield per quarter was also determined at frequent intervals. In each instance the percentage of chlorine and catalase increased in each lactation period and from period to period. In some cows these changes occurred approximately simultaneously in each quarter and were of a similar magnitude in all four quarters. In other cases the milk produced by the different quarters did not change at the same time or to the same extent, indicating that the causal agent was acting with varying intensities in the different quarters or was absent from some. The udder of each animal remained free from streptococci throughout the three lactation periods, and no other organism was found with sufficient constancy or in sufficient numbers to be responsible for the changes noted in the composition or level of production of milk and in the structure of the udder. The apparent complex nature of the causes of mastitis or of deterioration of the udder and the need for further long-time studies in this field are stressed.

**The use of annatto as a tracer in cream for manufacturing purposes and its detection,** C. W. ENGLAND and N. E. YONGUE. (Md. Expt. Sta.). (*Jour. Dairy Sci.*, 23 (1940), No. 4, pp. 331-335).—Repeated tests have demonstrated annatto (vegetable cheese color) to be satisfactory as a tracer for cream intended for manufacturing purposes. The described test for detecting annatto in cream is based on the simultaneous extraction of fat with gasoline and extraction of annatto with alcohol, removal of alcohol serum by centrifuging, absorption of annatto by an alkaline filter, and confirmation with stannous chloride. The test is sensitive to 1 part of annatto in 500,000 parts of cream.

**The density at 140° F. of the materials expressed as fat by various volumetric tests of cream,** P. G. MILLER, S. T. COULTER, and W. B. COMBS. (Minn. Expt. Sta.). (*Jour. Dairy Sci.*, 23 (1940), No. 4, pp. 285-288).—Determinations of the density at 140° of the materials read as fat with various tests of cream gave the following mean values: Filtered butterfat, 0.8917; Mojonner, 0.8935; Babcock, 0.8951; Minnesota Nafis, 0.8909; Minnesota 202, 0.884; *n*-butyl alcohol, 0.8926; and amyl alcohol, 0.8914. Calculated temperatures at which the density of the fat column would be approximately 0.9 ranged from 72° for the Minnesota 202 test to 127° for the Babcock test.

**Milk energy yield and the correlation between fat percentage and milk yield**, W. L. GAINES. (Ill. Expt. Sta.). (*Jour. Dairy Sci.*, 23 (1940), No. 4, pp. 337-342, fig. 1).—The author has attempted to develop an estimate of the expected coefficient of correlation between butterfat percentage and milk yield ( $r_{Mf}$ ) based on the theory that milk yield is inversely proportional to milk energy per unit of milk, or milk-energy yield is independent of milk composition. The equation  $-r_{Mf} = \frac{V_f}{V_M} \frac{\bar{f}}{2\frac{2}{3} + \bar{f}}$ , where  $V$  is variability and  $\bar{f}$  is mean fat percentage, has been derived. Stress is laid on "the fact that the correlation between fat percentage and milk yield is low does not detract from its biological significance or warrant its neglect in a practical breeding philosophy."

**Official flavor criticisms of dairy products in the National Contest**, G. M. TROUT, W. WHITE, P. A. DOWNS, M. J. MACK, and E. L. FOUTS (*Jour. Dairy Sci.*, 23 (1940), No. 4, pp. 325-330, figs. 4).—A further report of this committee (E. S. R., 82, p. 675), which lists the predominating flavor criticisms of butter, cheese, milk, and ice cream used by official contest judges over a period of years.

**Influence of feeds on lecithin content of milk and possible relationship of lecithin content to susceptibility of milk to copper-induced oxidized flavor**, I. A. GOULD, W. K. FOX, and G. M. TROUT. (Mich. Expt. Sta.). (*Food Res.*, 5 (1940), No. 2, pp. 131-139, figs. 3).—Milk samples analyzed in this study were obtained from groups of cows representing four dairy breeds, alternately fed high-fat and low-fat rations, also from animals receiving a corn-alfalfa ration and a balanced ration with and without pasture supplement. The average lecithin content of the milk under the various feeding regimes was: High-fat ration 0.0474, low-fat ration 0.0461, corn-alfalfa 0.0411, dry feed 0.043, and pasture 0.0445, indicating that feed has little influence on the lecithin content of milk. The average of 198 samples without regard to feed was 0.046 percent. A negative correlation of  $-0.7406$  was found to exist between the percentage of fat in the milk and the percentage of lecithin in the fat, indicating a fairly constant amount of lecithin in the milk irrespective of changes in the fat test. The correlation between percentage of lecithin in milk and percentage of fat in milk was only 0.3693. No relationship was observed between the susceptibility of milk to copper-induced oxidized flavor and the lecithin content.

**Influence of sunlight on flavor and ascorbic acid content of milk exposed in three different types of paper containers**, J. L. HENDERSON, D. C. FOORD, and C. L. ROADHOUSE. (Univ. Calif.). (*Food Res.*, 5 (1940), No. 2, pp. 153-159, figs. 2).—Paper containers fabricated from (1) a thin white bleached paper, (2) a cream-colored paper of intermediate thickness, and (3) a relatively thick paper with the inner plies unbleached and light brown in color, were compared in this study. Milk samples in clear glass bottles and in each of the three types of paper containers were exposed to midday sun for varying periods, placed in cold storage, and scored for flavor at 2 and 20 hr. after exposure. The ascorbic acid content of the samples was also determined. The paper containers, while varying in protective capacity, all exhibited greater protection from the effects of sunlight than clear glass. The thick unbleached paper gave complete protection against flavor defect and nearly complete protection against ascorbic acid destruction during 2 hours' exposure to sunlight. The degree of ascorbic acid destruction proved to be a useful index of the effect of sunlight on milk flavor.

**Reduction of curd tension of milk by the addition of sodium salts**, P. H. TRACY and W. J. CORBETT. (Univ. Ill.). (*Jour. Dairy Sci.*, 23 (1940), No. 4, pp. 289-294).—Experiments involving the use of sodium citrate, sodium

pyrophosphate, and sodium hexametaphosphate gave evidence that the addition of small amounts of any of these sodium salts to milk resulted in a permanent reduction in the curd tension of the milk. Amounts necessary to reduce the curd tension from approximately 50 to 0–10 gm. were 0.075, 0.15, and 0.2 percent for the hexametaphosphate, pyrophosphate, and citrate, respectively. A lower curd tension resulted when the salts were added after pasteurization to the cooled milk. Normal creaming of the milk was not affected until sufficient salt was added to change the viscosity, and titratable acidity remained practically unchanged. The flavor of milk was somewhat affected by the addition of these salts.

**Influence of neutralizers upon the curd content of butter**, R. C. TOWNLEY and I. A. GOULD (*Michigan Sta. Quart. Bul.*, 22 (1940), No. 4, pp. 245, 246).—Six neutralizers were compared, each being added in amounts sufficient to reduce the acidity of cream containing 35 percent butterfat from approximately 0.5 percent to acidities of 0.25, 0.15, 0.1, 0.05, and 0 percent. It was found that the curd content of the butter was not materially affected by the kind of neutralizer used or by the point of acid reduction except when calcium lime was used to neutralize to a theoretical acidity of approximately 0.15 percent or below, in which cases pronounced increases in the curd content of the butter occurred.

**Use of frozen fruits in ice cream investigated**, A. J. MORRIS (*Farm and Home Sci. [Utah Sta.]*, 1 (1940), No. 2, pp. 2, 11, figs. 1).—Preliminary surveys on consumer acceptance of a wide variety of fruit ice creams indicate the possibility of utilizing significant quantities of frozen fruits in ice cream manufacture.

## VETERINARY MEDICINE

**[Work in animal pathology by the Kentucky Station]** (*Kentucky Sta. Rpt. 1939, pt. 1, pp. 16–21*).—The work of the year reported upon (E. S. R., 81, p. 569) includes a study of paratyphoid bacilli, periodic ophthalmia in horses and the relation of *Brucella* to the disease, virus abortion in mares, incoordination in horses, corynebacteria in domestic animals, listerellosis of sheep, isolation of the causative organism (*Erysipelothrix rhusiopathiae*) of swine erysipelas from pigs, and nutritional deficiency as a direct or contributing factor in the illness or death of animals.

**[Work in animal pathology by the Nevada Station]** (*Nevada Sta. Rpt. 1939, pp. 23, 31–33*).—The work of the year briefly reported upon includes poisonous range plants, particularly *Astragalus speirocarpus* and *Corydalis cascana*, by C. E. Fleming, M. R. Miller, L. R. Vawter, and A. Young; hemorrhagic disease and lymphangitis in cattle and encephalomyelitis in equines, all by E. Records and Vawter; and a study of types of malnutrition, diminished reproductive activity, and lowered resistance to disease in cattle which appear to be due to deficiencies in the content of certain forms of mineral matter in soil, water, and forage, by Records, Vawter, Miller, and V. E. Spencer.

**[Work in animal pathology and parasitology by the Ohio Station]** (*Ohio Sta. Bul. 600 (1939), pp. 53, 54, 55, 56*).—The year's work (E. S. R., 79, p. 679) reported upon includes experiments for controlling gastrointestinal parasites in sheep and tests with crystal violet vaccine for preventing hog cholera.

**[Work in animal pathology by the South Carolina Station]** (*South Carolina Sta. Rpt. 1939, pp. 87, 88, 95, 96*).—The work of the year reported (E. S. R., 81, p. 103) relates to bovine trichomoniasis, by G. W. Anderson and J. P. LaMaster, and fowl paralysis, by Anderson, R. C. Ringrose, and C. L. Morgan.

[Work in animal pathology and parasitology by the Wyoming Station] (*Wyoming Sta. Rpt. 1939*, pp. 14-16, 21, 22, 23, 24).—The work of the year briefly referred to (*E. S. R.*, 81, p. 569) includes forage poisoning due to salt-peter; arrowgrass and other plants which are dangerous because of hydrocyanic acid; investigations of the relationship between various plants and minerals (selenium, vanadium, molybdenum, and cobalt) in the soil and the health of domestic animals; poisonous plants, particularly *Salvia lanceolata* and locoweed (*Oxytropis bilocularis* and *O. besseyi*); vaccination for infectious soremouth of sheep and for coryza (roup) in chickens; abortion in ewes; fowl paralysis; coccidiosis of the domestic fowl; and tapeworms of sheep.

**Permanent distemper immunization by vaccine alone**, L. F. WHITNEY (*Vet. Med.*, 35 (1940), No. 7, pp. 408-414, figs. 3).

**The genus *Listerella* Pirie**, J. H. PIRIE (*Science*, 91 (1940), No. 2364, p. 383).—The name *Listeria* is proposed as a substitute for the preoccupied name *Listerella* given in 1927 to a genus of bacteria that has acquired some importance in both human and veterinary pathology.

**The use of oxalated blood for cytological studies**, L. B. SHOLL. (Mich. Expt. Sta.). (*North Amer. Vet.*, 21 (1940), No. 4, pp. 211, 212).

**Transmission of epidemic influenza virus in mice by contact**, M. D. EATON (*Jour. Bact.*, 39 (1940), No. 3, pp. 229-241).—It is concluded that intranasal instillation of influenza virus into mice produces a disease which is essentially a virus pneumonia. Normal mice placed in jars with mice infected with epidemic influenza virus will, under certain conditions, contract an infection which is evident as moderate to extensive consolidation of the lungs but which is seldom fatal. The two strains of human influenza virus are more readily transmitted by contact than are the Melbourne and swine strains. The degree of infection of the contact mice is related to the concentration of virus given to the inoculated mice and to the time of contact. External application of virus does not cause demonstrable infection of mice, but ingestion of virus may produce lung lesions in a certain percentage of a group of mice.

**Ticks and disease, with special reference to spotted fever and tularaemia in the eastern States**, R. MATHESON. (Cornell Univ.). (*Cornell Vet.*, 30 (1940), No. 2, pp. 167-177, figs. 6).—A general discussion of the subject.

**Studies on the intradermal method of vaccination against equine encephalomyelitis**, H. W. SCHOENING, M. S. SHAHAN, O. L. OSTEEEN, and L. T. GILTNER. (U. S. D. A.). (*Vet. Med.*, 35 (1940), No. 7, pp. 377-380, figs. 2).—In the three experiments reported the intradermal injection of guinea pigs with regular, commercially prepared, chick embryo equine encephalomyelitis vaccine produced as good, if not better, immunity than when the same vaccine in the same amounts was injected subcutaneously. Vaccine injected intradermally in various amounts in horses produced a better immunity than the same vaccine in similar amounts when injected subcutaneously. In horses the immunity produced by intradermal injection of vaccine in two 1 cc. doses was as good as that produced by two 10 cc. doses subcutaneously. Vaccines reported to have caused severe, undesirable reactions in horses in the spring of 1940, when injected into 20 horses intradermally, produced very little local reaction, while the same vaccine injected subcutaneously or intramuscularly in 20 horses produced in some of the animals rather marked, extensive swellings at the site of injection. The greater number of these untoward reactions appeared in horses which had been vaccinated in 1939.

**Studies on equine encephalomyelitis in Iowa during 1939**, H. E. BIESTER and L. H. SCHWARTE. (Iowa State Col. and U. S. D. A.). (*Jour. Amer. Vet. Med. Assoc.*, 96 (1940), No. 759, pp. 719-723).—The authors report that during

the summer of 1939 1 squirrel and 32 horse brains were examined for virus encephalomyelitis in Iowa. "Seventeen, or 53.1 percent, of the horses studied presented histological evidence of virus encephalomyelitis. From 8, or 25 percent, virus of the western type was recovered. Seven histologically positive cases were contaminated. Guinea pigs inoculated with brain tissue from these died within 8 or 10 hr. following injection. Berkefeld filtrates prepared from some of the contaminated brains failed to infect guinea pigs. The 17 histologically positive cases occurred in unvaccinated horses. In 8 unvaccinated horses, no evidence of virus infection was found. A case of mouldy corn poisoning and 1 presenting a teratomatous cyst in the cranial cavity were included in the last-mentioned group. Seven specimens from vaccinated horses were examined, and no evidence of a virus infection was found in them."

**A field experiment in the use of prontosil for the treatment of horse sickness**, W. RAINEY (*Jour. So. African Vet. Med. Assoc.*, 10 (1939), No. 4, pp. 180, 181).—An outstanding cure of a case of horse sickness by the administration of prontosil is reported.

**A method for preserving *Trypanosoma equiperdum***, W. S. STONE and A. T. THOMPSON (*Science*, 91 (1940), No. 2362, p. 344).—A method by which *T. equiperdum*, the cause of dourine of the horse, has been kept viable and infective for a period of 14 mo. through freezing and storing infected rat blood in a dry ice alcohol bath is described.

**A study of the agglutination titres of milk serum from known infectious abortion reactor cows**, H. D. PRITCHETT and S. T. WALTON (*Jour. Amer. Vet. Med. Assoc.*, 96 (1940), No. 759, pp. 709-713, 714).—The details of studies conducted by the authors are presented in two tables.

**Studies on genetic resistance in swine to *Brucella* infection: Preliminary report**, H. S. CAMERON, E. H. HUGHES, and P. W. GREGORY. (Univ. Calif.). (*Cornell Vet.*, 30 (1940), No. 2, pp. 218-222).—During the course of investigations in California of *Brucella* infection in swine, "two sows were apparently resistant to repeated oral administrations of *B. suis*. These sows were mated to a boar which showed, by the agglutination test, a resistance of a lesser degree. An attempt was made to infect 33 progeny from such matings. As judged by the agglutination test, a high percentage were resistant, while the remainder were divided between the susceptible and the undetermined."

**A report on Bang's disease vaccinated heifers in an infected herd**, A. M. MILLS (*Cornell Vet.*, 30 (1940), No. 2, pp. 195, 196).

**The proper collection of milk samples for streptococcic mastitis test**, C. S. BRYAN and H. H. RUHLAND (*Michigan Sta. Quart. Bul.*, 22 (1940), No. 4, pp. 259-263).—It is pointed out that milk samples for the microscopic test for streptococcic mastitis should be submitted from lactating cows only, excluding those near the beginning or end of lactation. They should be collected by milking directly into the mastitis vial. The milk sample must include a small quantity of milk from each quarter of the cow if the test result is to indicate the status of the cow. The samples must not be collected within a period of 2 hr. following the regular milking. A description is given of the technic for the proper collection of such milk samples.

**A study of an outbreak of acute swine erysipelas in one herd**, H. W. SCHOENING, J. E. PETERMAN, and C. G. GREY. (U. S. D. A.). (*Jour. Amer. Vet. Med. Assoc.*, 96 (1940), No. 759, pp. 714-718, fig. 1).—Report is made of a field and laboratory investigation of an outbreak of swine erysipelas that occurred on a farm in eastern Nebraska in October 1939.

**Lymphoblastoma in the bovine**, E. R. FRANK and W. W. THOMPSON. (Kans. State Col.). (*North Amer. Vet.*, 21 (1940), No. 4, pp. 217-221, figs. 6).

**On the question of the intra-uterine transmission of *Anaplasma centrale*,** K. ENIGK (*Jour. So. African Vet. Med. Assoc.*, 10 (1939), No. 3, pp. 130, 131).—From observations on a calf, the author concludes that intrauterine infection of *Anaplasma* and *Theileria mutans* does not take place.

**Efficacy of nonconditioned phenothiazine in removing worms from the alimentary canal of cattle,** L. E. SWANSON, D. A. PORTER, and J. W. CONNELLY. (U. S. D. A.). (*Jour. Amer. Vet. Med. Assoc.*, 96 (1940), No. 759, pp. 704-707).—In work conducted at the U. S. D. A. Bureau of Dairy Industry laboratory at Moultrie, Ga., "unconditioned phenothiazine removed 100 percent of mature *Haemonchus contortus* and *Trichostrongylus axei* as well as 99.8 percent of *Oesophagostomum radiatum* from calves when the drug was administered in doses varying from 50 to 80 gm. (0.44 to 1.1 gm. per kilogram of body weight). In limited tests unconditioned phenothiazine at a dose rate of 0.44 to 0.55 gm. per kilogram of body weight in calves weighing over 91 kg. (200 lb.) was less effective against hookworms (= *Bunostomum phlebotomum*) than when given to lighter calves at a dose rate of from 0.66 to 1.1 gm. per kilogram of body weight. The chemical was approximately 84 percent effective against *Ostertagia osterlagi*, slightly effective against *Cooperia* spp., and ineffective against *Trichuris* sp., *Strongyloides papillosus* and *Moniezia* sp. A larger percentage of *C. pectinata* than of *C. punctata* was removed by the treatment. Phenothiazine was found to be comparatively nontoxic for calves. This drug shows considerable promise as an anthelmintic for gastrointestinal nematodes in these host animals."

**The anterior pituitary lobe hormones in the treatment of ketosis in the dairy cow,** M. G. FINCHER and C. E. HAYDEN (*Cornell Vet.*, 30 (1940), No. 2, pp. 197-217).—In work conducted in New York State, 17 cases in the series led the clinician to suspect "some degree of acetonemia from observed symptoms and through the use of the qualitative test for acetone bodies in the urine of the patient. The quantitative test for acetone bodies in the blood and urine indicates that the major percent of the cases showed varying degrees of acetonemia. Some were marked, some medium, and some slight. In a small percent the acetone body content seemed to be at normal. The anterior lobe hormone preparation was administered to 13 of the cases in the series. Two cases received gonadotropes in the form of gonadin. Of the remaining 2 cases 1 received an anterior pituitary-like preparation, 1 received the anterior pituitary lobe preparation in addition to the anterior pituitary-like preparation. Some of the cases received additional treatment such as glucose, molasses, and chloral. Data are too few to substantiate any claim that these hormone preparations are specific in the treatment of ketosis, but in some cases their use would appear to have had some merit. All helpful treatment is justified in treating highly bred, sensitive, and high-producing cows. In addition to other agents that have been found useful the anterior, pituitary lobe hormones may have a definite place in the treatment of disorders that afflict the dairy cow at or near parturition. A few of our most marked cases recovered with no other therapy."

**Zephiran in the treatment of foot-rot in cattle,** J. W. SCALES. (Va. A. and M. Col.). (*Vet. Med.*, 35 (1940), No. 6, pp. 335, 336).—The author has found that Zephiran, a mixture of high molecular alkyl-benzyl-ammonium-chlorides derived from the fatty acids of coconut oil, is an effective antiseptic for treating foot rot in cattle, most cases recovering after one application. It has proved far superior to remedies previously used for this condition and is considered to merit trial in other necrophorus infections.

**Minimum lethal dose of selenium, as sodium selenite, for horses, mules, cattle, and swine,** W. T. MILLER and K. T. WILLIAMS. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 60 (1940), No. 3, pp. 163-173).—In the course of work con-

ducted in 1934 and 1938 with a view to determining the effect of continued feeding of small doses of selenium in various forms to small experimental animals, in which five horses, three mules, five cattle, and seven swine were used, data were obtained, the details of which are tabulated in part. It was administered orally in the feed, as a drench or by stomach tube, dosage being calculated as milligrams of selenium per pound of body weight. Large doses were given at the beginning of each test, and the quantity was reduced for other animals until the minimum lethal dose was reached. Although all but two of the horses and mules used in the work had been used previously in infectious-disease experiments, they appeared healthy on clinical examination. The minimum lethal dose of selenium was found to be about 1.5 mg. per pound of body weight. In the experiments with cattle, one calf and four cows were included. The calf was 5 days old. Two of the cows were between 3 and 4 yr. of age and the other two were several years older. All appeared healthy clinically and were not known to have been exposed to any infectious disease. The minimum lethal dose for this species was found to be between 4.5 and 5 mg. per pound of body weight. In the experiments with swine, apparently healthy pigs varying in age from 4 to 6 mo. were used. For these animals the minimum lethal dose of selenium was found to be between 6 and 8 mg. per pound of body weight.

**Toxicity to sheep of lead arsenate and lead arsenate spray residues,** J. L. ST. JOHN, E. C. McCULLOCH, J. SOTOLA, and E. N. TODHUNTER. (Wash. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 60 (1940), No. 5, pp. 317-329).—Occasional reports received by the station of the illness or death of livestock, principally cattle and sheep, that had been pastured in sprayed orchards during the fall led to the experiments here reported, the details of which are given in five tables. In the course of the work nine sheep were fed lead arsenate orally in capsules in amounts varying from 0.25 to 2 gm. per day. Animals receiving 1 and 2 gm. per day died within a few days, in most cases after having received about 1.5 gm. of arsenic (2 gm.  $As_2O_3$ ). One animal receiving 0.25 gm. of lead arsenate per day survived 35 days and another continued to live after receiving this amount for 94 days and was in good condition at the end of 10 mo. About 1.5 gm. of arsenic in the form of lead arsenate appears to be approximately a lethal dose when fed in small amounts daily. This is equivalent to about 41 mg. of arsenic (As) or 192 mg. of lead arsenate per kilogram of body weight. Analytical results of stomach contents, a number of organs, and on urine and feces did not account for all lead and arsenic consumed. A larger proportion of the lead and arsenic remaining in the body was found in the stomach contents. Inclusion of apples in the ration had no apparent effect on the toxicity or elimination of lead and arsenic. Small amounts of these elements were found in the liver, kidney, heart, lungs, gall bladder, bones and marrow, and wool.

**Tuberculosis in sheep,** E. L. STUBBS (*Jour. Bact.*, 39 (1940), No. 3, p. 339).—A brief report is made of a case of ovine tuberculosis, a rare disease in the sheep, that was found due to the bovine type of the tubercle bacillus, in which the organism was pathogenic for the chicken, which is of uncommon occurrence. It is stated that most of the cases of tuberculosis in the sheep thus far typed have been due to the avian form of the organism.

**Poisoning in sheep and goats by sacahuiste (*Nolina texana*) buds and blooms,** F. P. MATHEWS. (Coop. U. S. D. A.). (*Texas Sta. Bul.* 585 (1940), pp. 19, figs. 4).—Report is made of poisoning of sheep, goats, and cattle from feeding on the buds and blooms of a plant (*N. texana*) relatively common on the ranges of western Texas. When these parts are consumed by sheep and goats in amounts greater than 1 percent of their body weight the animals become sick and usually die. If only dry feed is available at this time they will be very much depressed and icteric due to a marked degeneration of the

liver cells and by obstruction of the bile ducts. If some green feed is consumed at the same time, then, in addition, the animals will become photosensitive and if they are exposed to the sun will develop itching of the skin and, marked swelling of the skin and subcutaneous tissue of the head, including the ears. Losses from this source may be prevented by removing the animals from infested pasture during the blooming season or by concentrating them on a smaller area in the pasture or removing them to less heavily infested areas so that they will not be able to consume a toxic dose during a day's grazing.

**Coccidia and coccidiosis in feeder lambs**, A. W. DEEM and F. THORP, JR. (Colo. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 96 (1940), No. 759, pp. 733-735).—Further studies of the various factors influencing coccidiosis in Colorado (E. S. R., 80, p. 826), carried on during 1938-39, are reported, the details being given in table form. Fecal examinations from individual lambs show, in general, a marked increase in the numbers of coccidia during the first month in the feed lot, then the number declines, either rapidly or gradually, for 2 or 3 mo., after which few coccidia can be found. Some evidence is presented which indicates that the ration fed is a factor in the cause of clinical coccidiosis and has a definite influence on the mortality.

**Failure of dietary magnesium imbalance to produce urinary calculi in wethers**, D. W. JOHNSON, L. S. PALMER, and J. W. NELSON. (Minn. Expt. Sta.). (*Vet. Med.*, 35 (1940), No. 6, pp. 353-357, fig. 1).—The loss of  $\pm 10$  percent of a flock of 2,600 wether lambs from urinary calculi over a period of about 6 weeks led to these studies. Analyses of stones from a lamb that had the disease and of the ration fed the lambs suggested that the high magnesium content of the ration was the cause of the trouble. Of 20 lambs from the flock used in the study, one-half were fed a ration the dry matter of which contained 1.5 percent of magnesium. "The remaining lambs received the same ration plus sufficient limestone to give a calcium content of 5.1 percent. The rations were fed for 154 days. Urine specimens for pH determinations and observations as to crystal formation and blood samples for calcium, magnesium, and inorganic phosphorus analyses were obtained before the start of the experiment and at intervals thereafter. There was a threefold increase in the blood magnesium of both groups of sheep as the result of feeding the experimental rations. In spite of this increase, which apparently was responsible for crystal formation in the urine of a few of the lambs, calculi were not produced."

**Listerella encephalitis (circling disease) of sheep, cattle, and goats**, P. OLAFSON (*Cornell Vet.*, 30 (1940), No. 2, pp. 141-150, figs. 6).—This summary of information on an acute specific, infectious encephalitis of sheep, cattle, and goats caused by a short, Gram-positive bacterium of the genus *Listerella* includes a history of the disease in New York State and the results of some experimental studies.

**Effect of commercial phenothiazine on a heavily-parasitized ram**, R. T. HABERMANN and W. H. HUNT. (U. S. D. A.). (*Vet. Med.*, 35 (1940), No. 5, pp. 298-300, figs. 3).—In the studies reported, 25 gm. of commercial phenothiazine was very effective in removing the nematodes from the gastrointestinal tract of a sick, heavily parasitized ram. The percentage of red blood cells and the weight of the ram increased rapidly after the nematodes were removed. Photographs taken before and after treatment, and here reproduced, show the marked improvement in the ram's general condition.

**Anaplasmosis-like disease of swine**, R. SPENCER. (Kansas State Col.). (*Vet. Med.*, 35 (1940), No. 5, pp. 294, 295).—It is concluded from observations by the author and by others that the anaplasmosislike disease of swine reported several times during the last 10 yr. is an acute disease of young pigs consisting

of an ictero-anemia with hepatic degeneration and splenic enlargement, probably caused by the *Anaplasma* or *Rickettsia* bodies found in the erythrocytes.

**The enteritis syndrome in swine**, L. P. DOYLE. (Purdue Univ.). (*North Amer. Vet.*, 21 (1940), No. 4, pp. 213-216, fig. 1).

**Icterus in a garbage-fed hog due to a foreign body**, G. C. HOLM. (Idaho Expt. Sta.). (*Vet. Med.*, 35 (1940), No. 6, p. 363, fig. 1).

**Differentiation of viruses of canine distemper and fox encephalitis**, R. G. GREEN (*Vet. Med.*, 35 (1940), No. 6, p. 365).—A brief description is given of canine distemper and fox encephalitis and their differentiation.

**Methods of diagnosis and treatment of the intestinal parasites of small animals**, R. E. REBRASSIER. (Ohio State Univ.). (*Cornell Vet.*, 30 (1940), No. 2, pp. 133-140, figs. 5).

**An inquiry into the influence of environment on the incidence of poultry diseases**, L. VAN ES and J. F. OLNEY (*Nebraska Sta. Res. Bul.* 118 (1940), pp. 57, figs. 15).—An investigation aimed at the evaluation of hygienic measures and the gathering of available data pertaining to the relation of certain disorders to a given fowl population after its exposure to their specific etiologic factors is reported, the details being given in 34 tables.

"An experimental attempt to determine whether or not healthy, nonreacting fowls exposed to others affected with bacillary white diarrhea would acquire positive blood titers by environmental contact yielded negative results. The sanitary restrictions adopted afforded a manifestly favorable influence on morbidity in the face of a fowl typhus hazard present in an environment occupied by the flocks concerned. Although some evidence of the environmental transmission of fowl cholera was encountered, it appears that the character of a given environment exercises no manifest influence. The benefits of sanitary restrictions are apparently canceled by the intensity and virulence of direct contact infection. In the transmission and dissemination of fowl cholera, apparently healthy birds, as infection carriers, play a dominant part. A given environment may be either reasonably sanitary or the very opposite without greatly modifying the incidence of avian tuberculosis after tuberculous fowls have been introduced. Healthy, older fowls showed a rather well marked resistance to avian tuberculosis when exposed by direct and indirect contacts in an environment in which the opportunities for doing so were ample. In the evaluation of sanitary measures in connection with coccidiosis of chicks, mortality alone cannot be accepted as a final criterion. The determination of coccidial infestation proved to be a more dependable criterion by which to judge the sanitary fitness of a given environment. By the use of hardware cloth panels combined with adequate protection of the food and water supply against fecal contamination, it was possible to reduce the incidence of coccidiosis to a bearable minimum. Turkey poults were raised to maturity with a minimum blackhead hazard when maintained in an environment covered by coarse gravel, when food and water were provided in sanitary utensils, and when contacts with common fowls were avoided. Turkey poults may be raised to maturity in a restricted area covered by hardware cloth panels without a blackhead risk even after the poults affected with the disease are introduced among them. Poults maintained under a rather intense exposure to blackhead from 1 to 4 weeks may, to a considerable extent, find sanctuary when transferred to an environment where sanitary restrictions prevail. The common fowl and its body wastes must be regarded as the fountainhead of blackhead infection. The blackhead hazard was still present in soil 2 yr. after common fowls were removed from the lot concerned. In an insalubrious environment, exclusively occupied by turkeys during 6 mo. of each year, blackhead morbidity progres-

sively declined in the course of 7 yr., until a temporary occupancy by fowls of the lot concerned caused morbidity to exhibit an upward trend."

**Relationship of ruptured yolk to fowl paralysis**, E. N. MOORE. (W. Va. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 96 (1940), No. 759, pp. 727-732).—Ruptured yolk does not represent a separate disease entity. In a flock of 500 birds studied the mortality for the 10 pens the first 9 mo. was 20.8 percent. "The losses from fowl paralysis or fowl paralysis associated with ruptured yolk accounted for 11.2 percent of the deaths. Seven percent were due to fowl paralysis, and 4.2 percent showed the two conditions present in the same bird. Only 1.8 percent of the birds showed ruptured yolk alone. By chance we could expect 11 birds to show the two conditions in the same individual (after deducting those birds with fowl paralysis and without ruptured yolk which did not lay for 3 or more weeks prior to autopsy). Actually, there were double the number we could expect by chance if they were independent of each other."

**Coccidiosis of domesticated birds, with special reference to the common fowl**, E. R. BECKER. (Iowa State Col.). (*Vet. Med.*, 35 (1940), No. 7, pp. 401-407, figs. 2).

**The significance of biological types of *Salmonella typhi-murium* (*Salmonella aertrycke*)**, P. R. EDWARDS and D. W. BRUNER (*Kentucky Sta. Bul.* 400 (1940), pp. 41-70).—Studies of the biological characteristics of types of *S. typhimurium* and the zoological distribution of such types are reported, the details being given in six tables. The biochemical and serological tests employed have shown this organism to be divisible into a number of types. "The types established are epizootically significant, and all the cultures from a single outbreak of the infection belong to the same type. The non-rhamnase-fermenting strains which certain European workers have associated with ducks are not prevalent in ducks in the United States. They occur rarely and were found in turkeys and a pheasant. The 'ammonia-weak' strains which Hohn and Herrmann have associated with pigeons are found only occasionally in pigeons in the United States. They occur rarely in other animal species. Practically all cultures isolated from pigeons in the United States lack antigen V of the Kauffmann-White schema. It is suggested that the lack of this antigen in a culture indicates that the outbreak of infection from which it was derived was directly or indirectly connected with infection of pigeons."

**The transmission of and resistance to fowl paralysis (lymphomatosis)**, E. M. GILDOW, J. K. WILLIAMS, and C. E. LAMPMAN (*Idaho Sta. Bul.* 235 (1940), pp. 22, figs. 6).—In the experiments reported fowl paralysis was found to be readily transmissible to young chicks by contact. Chicks from susceptible stock contracted the disease regardless of attempts to isolate them on the premises where paralysis-affected stock existed. Pullets from paralysis-susceptible stock showed a distinct age resistance when not introduced before 6 weeks of age to premises now or recently occupied by affected stock. Definite evidence is presented that certain families are more resistant than others to the disease. A high degree of resistance to fowl paralysis has been developed through intensive selection. The progeny of hens was shown to be more resistant to the disease than the progeny of pullets in the same affected flock. Confined rearing did not reduce the occurrence of the disease below that attained by range rearing. The details of the work are given in five tables.

**Fowl typhoid**, L. D. BUSHNELL. (Kans. Expt. Sta.). (*Vet. Med.*, 35 (1940), No. 5, pp. 313-315, fig. 1).

**A method of raising turkeys in confinement to prevent parasitic diseases**, E. P. JOHNSON (*Game Breeder & Sportsman*, 45 (1940), Nos. 4, pp. 50-52, 62, fig. 1; 5, pp. 68, 78, 79).—The data here presented have been noted from another source (E. S. R., 82, p. 827).

## AGRICULTURAL ENGINEERING

[Agricultural engineering investigations by the Nevada Station]. (Partly coop. U. S. D. A. and Univ. Nev.). (*Nevada Sta. Rpt. 1939, pp. 33-35*).—These have included work of the department of irrigation, by G. Hardman and H. G. Mason, on an inventory and history of the agricultural land resources of the basins of the Truckee, Carson, and Humboldt Rivers and minor streams, reported under the subheads cooperation with Elko County range conservation study and land-classification maps, and on an inventory and history of the water resources of these basins, reported under the subheads tree-ring studies and studies of variation in lake level.

[Agricultural engineering investigations at the Ohio Station] (*Ohio Sta. Bul. 600 (1939), pp. 64-66, figs. 3*).—Report is made on experiments with various wheats, in which it was found that sagging of grain heads due to weak straw causes heavy cutter-bar losses, and ready breaking up of straw by the cylinder causes much rack and shoe loss, the sagging being worse than the straw breakage; and on cornerrib pressures, which were found to be greatly increased by expansion of previously dry corn during the damp weather of late spring.

[Agricultural engineering investigations of the South Carolina Station] (*South Carolina Sta. Rpt. 1939, pp. 54-60, 104, 105*).—Use of electrically heated beds in sweetpotato plant production is reported upon by J. B. Edmond and G. H. Dunkelberg under the captions influence of type of cover, insulation of frames, horizontal spacing of heating cable, position of heating cable, high and low soil temperatures, and "crowded" and regular bedding of roots. Temporary v. permanent silos are discussed by E. D. Kyzer and J. E. Love.

Putting down and developing wells for irrigation, C. ROHWER (*U. S. Dept. Agr. Cir. 546 (1940), pp. 86, figs. 41*).—It is pointed out in a brief introduction that for irrigation, as distinct from domestic supply, wells capable of supplying large quantities of water at a reasonable cost are required. This circular is intended for the information of farmers, well drillers, and others concerned with the construction of pumping plants for irrigation.

The principal phases of the subject here dealt with are factors affecting the feasibility of pumping plants, including legal status of pumping from wells, water supply, pumping lift, and well contract; factors affecting flow of ground water into wells; hydraulics of wells, under which heading are given formulas for the approximate computation of the discharge in gallons per day of the artesian and nonartesian types; battery wells; interference of wells; test-hole drilling by the sand-bucket, standard-tool, hydraulic-rotary, jetting, hollow-rod or self-cleaning, and auger methods; irrigation wells and their construction by various methods; gravel-envelope or gravel-screen wells; development of wells by pumping, by surging, with air, by backwashing, and with solid carbon dioxide; testing wells; and the cost of constructing wells in 12 western States.

Irrigation and drainage research, O. W. ISRAELSEN (*Farm and Home Sci. [Utah Sta.], 1 (1940), No. 2, p. 8, fig. 1*).—This is a popular summary of the objectives of the irrigation and drainage research of the station. Under the primary objective of the more efficient and economical utilization and control of the State's water resources are listed 10 secondary objectives constituting essential phases of the solution of the primary problem.

Series of factors involved in study of erosion control, T. N. JONES (*Miss. Farm Res. [Mississippi Sta.], 3 (1940), No. 4, p. 7*).—Factors emphasized as of special importance in farm water disposal are (1) soil type and slope, (2) cropping system, (3) terraces, (4) terrace outlets, (5) woods, (6) ponds, etc. Effects of interplanting *Crotalaria* species with corn on 2.5, 5, 7.5, 10, and 12.5 percent

slopes are shown in terms of the losses resulting from a rainfall of 2.74 in. during 2.5 hr. The crotalaria had reached a height of 6 in. at the time of the storm. It lessened the losses of soil very markedly as compared with those from the plats under corn alone.

**Wind erosion and sand dune control: A selected list of references, R. W. MOATS** (*U. S. Dept. Agr., Soil Conserv. Serv. Bibliog. 1 (1940), pp. II+66*).

**Contour farming for soil and water conservation, C. H. VAN VLACK and L. E. CLAPP** (*Iowa Sta. Bul. P11, n. ser. (1940), pp. 321-335, figs. 17*).—Reports from farmers were found to indicate that contour farming lessened power consumption, whereas on terraced fields about an equal number reported increases and decreases in tractor fuel used. The power saving effected by contouring was generally considered to offset any increase in the time required, as compared with cultivation up and down the slope. The soil conserving value of the contour-cropping system is pointed out, and contour cropping is preferred to terracing, because of the greater cost and less convenience of tillage operations on terraced lands, except in the management of lands which must be used for crops and are so subject to erosion that adequate control can only be obtained by terracing.

A simple type of level, practical for contour lay-out work, has its line of sight across the tops of two liquid columns which are interconnected and so must always be at the same level. A simply constructed "walking A" for laying out contour lines is also described, and its construction is shown in a dimensioned drawing.

**Land-saving plans for conservation in the Pacific Southwest** (*U. S. Dept. Agr., Soil Conserv. Serv., 1939, Region 10, pp. 24, figs. 23*).—Illustrations and brief accompanying statements indicate the nature of and damage done by sheet erosion and gullyng and the means of preventing or checking it. Irrigation water as an erosive agent is mentioned.

**Mechanized dusting equipment for pea weevil control, E. N. HUMPHREY.** (Coop. U. S. D. A.). (*Idaho Sta. Bul. 234 (1940), pp. 11, figs. 28*).—From a study of the effectiveness, cost of operation, and other factors involved in the use of 13 machines operating under commercial conditions, it was found that no material difference resulted in the use of low- and high-pressure machines, nozzle velocities varied greatly with little appreciable difference in effectiveness, and blower power requirements ranged from 1.5 to 8 hp., depending upon the type of blower and accompanying mechanism.

Dusters were mounted on 2- or 4-wheel carts pulled by team or trailed behind a truck or tractor, or were mounted on wheel tractors, crawler tractors, or trucks. They were driven by power take-offs from the tractors or by auxiliary motors. Distribution nozzles and pipes were carried on long booms, varying from 30 to 60 ft. The outer ends of the booms were supported on caster wheels or suspended from a boom tower. Use of the caster wheel required one less man for operation and maintained the hood at a fixed height above the pea vines. Each machine protected an average of approximately 1,093 acres by dusting from one-third to one-fourth of each field. The most satisfactory method of transportation on steep or hilly ground was the crawler tractor.

Cost for operation varied from 21 to 38 ct. per acre. Twenty lb. of dust, the minimum applied, cost \$1.50 per acre. The cost of custom dusting averaged 50 ct. per acre for machine operation.

Actual field damage from the use of dusting equipment varied from 1.99 to 3.5 percent. The greatest amount of damage was done by horse-drawn equipment for wide-tread crawler tractors.

**Rubber-tiring farm machines, D. K. STRUTHERS and A. H. BENNETT** (*Iowa Sta. Bul. P9, n. ser. (1940), pp. 273-287, figs. 18*).—In a brief statement concern-

ing the advantages of rubber tires over steel wheels for farm machines, this bulletin notes an experiment in which at 2.5 miles per hour a steel-wheeled machine received approximately 6 times as many shocks in passing over 5 miles of graveled road as did a rubber-tired machine of the same model. With the steel wheels there were 4,431 shocks ranging from 350 to 1,988 lb. force, while the rubber-tired machine received only 709 shocks ranging from 350 to 1,288 lb. force. At 5 miles per hour the rubber-tired machine received only 528 shocks compared with 18,261 for the steel-wheeled machine, or 34.5 times as many. The shocks ranged from 1,050 to 3,425 lb. force for each machine. Two manure spreaders of the same model were used in this experiment.

A method for cutting out the hub and spokes of steel wheels and welding them into drop-center rims is described. Each stage of this operation is illustrated by a photograph.

**Adjusting corn planters and listers for sorghums**, L. W. HURLBUT (*Nebraska Sta. Cir. 64 (1940), pp. 14, figs. 10*).—Directions for determining the number and size of holes to be drilled in a blank seed plate for proper seeding of sorghums with a corn planter or lister previously used for corn are given. This procedure is recommended in preference to adjusting the seeding rate and spacing of a corn seed plate because it was found that corn plates tend to produce a seeding rate of from two to three times the recommended weight of seed per acre. If a corn plate is used, some device for spreading the seed along the row should be added because of the larger number of sorghum seed dropped from each cell. The spacing, drilling, and reaming of the holes for a sorghum plate is fully dealt with, the shaping of reamers from sections of a three-cornered file being included. Checking for seed box leakage, causes of cracking of seed, and calibration of the seeding mechanism are also taken up.

**The relation of wall construction to moisture accumulation in fill-type insulation**, H. J. BARRE (*Iowa Sta. Res. Bul. 271 (1940), pp. 509-569, figs. 24*).—The permeability of numerous wall construction materials with respect to water vapor was determined, measurements being so made as to simulate conditions under which building materials are used. Materials found to be of high permeability are rosin sheathing paper and fiber insulation boards which are not vapor proofed. Those shown to be of low permeability are heavy asphalt saturated felts and sisal kraft papers. Aluminum paint, applied in two coats, served as a good vapor seal. Other building materials, including plaster, wood, and concrete, were found permeable to water vapor.

Thirty-three test walls, including frame, brick veneer, double tile, and concrete L-block walls, and uninsulated as well as insulated walls, were subjected to controlled conditions of temperature and humidity. A number of the walls were constructed to give wide variation in the water-vapor permeability properties of both the warm and cold sides of the wall to determine the effect of these properties on moisture accumulation. A constant temperature-humidity room was constructed to control the conditions on the warm side of the walls, and mechanical refrigeration was used to maintain low temperatures on the cold side. The conditions maintained were 75° F. and 50 percent relative humidity on the warm side, and a temperature of from 12° to 16° and a r. h. of 80 percent on the cold side. The period of test for different walls varied from 25 to 72 days. At the end of the test period, moisture samples of the insulation were taken, and the inside of the cold side of the wall inspected for free moisture. The frame walls were weighed at intervals throughout the test to observe the rate of moisture accumulation.

In general, the results of the tests on the wall sections also show that to prevent accumulation the permeability of the cold side of the wall must be many

times that of the warm side. A water-vapor barrier in the form of two coats of aluminum paint on the inside surface of the wall reduced the rate of accumulation but did not eliminate it. A similar result was obtained with a wall which had a cold face of high permeability. Uninsulated walls accumulated moisture as well as insulated walls. The accumulated moisture was always found on the inside of the cold wall.

## AGRICULTURAL ECONOMICS

[Investigations in agricultural economics by the Kentucky Station, 1939] (*Kentucky Sta. Rpt. 1939, pt. 1, pp. 5-8, 40-42*).—General findings are reported on (1) the factors affecting receipts, profits, etc., from farming in the outer bluegrass area, based on a detailed analysis of 127 farms for the year 1938; (2) systems of farming in the inner bluegrass region; (3) factors affecting profits of farming in type-of-farming area No. 5 of the State, based on records from 92 farms in the Pennroyal Plains section of Sampson, Logan, Todd, Christian, and Caldwell Counties; and (4) costs and returns from lamb and wool production, based on records of 99 flocks in the inner bluegrass region and in Owen, Grant, Meade, and Larue Counties, and of beef cattle based on records from 29 herds in Union, Todd, Christian, and Logan Counties.

The changes in the seasonal movements of Burley tobacco prices and sales and factors contributing to the changes are described.

[Investigations in rural economics by the Ohio Station, 1937-38] (*Ohio Sta. Bul. 600 (1939), pp. 60-63*).—Brief general findings are reported on studies of (1) agricultural conservation program in Licking County and six surrounding counties, (2) milk marketing in five areas where farmers were selling whole milk for city consumption or for manufacture, (3) transportation cost in marketing livestock at the Cleveland, Columbus, and Cincinnati markets, and (4) State legislation dealing with agriculture.

[Investigations in agricultural economics at the South Carolina Station, 1938-39]. (Partly coop. U. S. D. A. et al.). *South Carolina Sta. Rpt. 1939, pp. 9-22, figs. 3*).—Results of investigations not previously noted are included as follows: (1) Chart, by H. A. White, showing the percentage distribution of staple lengths of cotton produced in South Carolina in the crop years 1928-38; (2) findings, by E. Riley, as to farm real estate tax delinquency in the State with chart showing the average percentages 1932-37 of total delinquent properties and of total delinquent taxes by amount of annual delinquency, and table showing total farm real estate taxes becoming delinquent in 1932-37, amount paid as of January 1, 1939, and amount and percentage of total unpaid January 1, 1939; (3) findings, by G. H. Aull and Riley, in a study of the relation of sale price to assessed value of farm real estate with table showing for 30,814 transfers 1900-1937 the total sale price and assessed value per property and per acre grouped by sale value and the relation of assessed to sale price; (4) findings, by W. T. Ferrier, in a study of the cost of farm credit obtained from production credit associations and commercial banks; and (5) findings, by Aull, of the trend of industry in the State with table showing for 1909 and 1937 the number of establishments and wage earners, wages paid, value of products, and value added by manufacture, and chart showing fluctuations in manufacturing activities from 1925 to 1937 as shown by the United States census.

[Investigations in agricultural economics by the Wyoming Station, 1938-39] (*Wyoming Sta. Rpt. 1939, pp. 8-10*).—Data are included on the distribution of gross receipts, production, percentage of butterfat, uses made of milk, gross returns per cow, etc., on 198 farms in Lincoln County in 1938; on the

effect of acreage of wheat on returns on 151 dry farms in the northeastern part of the State; and on the value of lands for grazing and dry farm wheat production.

**International yearbook of agricultural legislation, 1939** [trans. title] (*Inst. Internatl. Agr. [Roma], Ann. Internatl. Lég. Agr., 29 (1939), pp. XLVII+965*).—This is a continuation of the series (E. S. R., 82, p. 124).

**Forces causing dairy farmers to make changes in their farm organizations in Barron County, Wisconsin, R. P. CHRISTENSEN.** (Coop. Wis. Expt. Sta.). (*U. S. Dept. Agr., Bur. Agr. Econ., 1939, pp. [4]+70, fig. 1*)—This is a study of some of the problems of interregional competition in dairying. The milk responses between 1928-29 and 1937-38 as shown by accounting records and case studies of 21 farms are analyzed.

**An economic study of the baby beef enterprise in southern Iowa, J. A. HOPKINS, W. D. GOODSSELL, and R. K. BUCK** (*Iowa Sta. Res. Bul. 272 (1940), pp. 573-620, figs. 3*).—This bulletin is based on farm records covering the period March 1932 to December 1934 and certain supplementary and more recent data. Part 1 discusses the methods and costs in the beef enterprise and part 2 the relation of the enterprise to the farm as a whole.

Ability of operator seems to be more important than type of land in determining the number of cattle carried and the cost of raising calves. Regardless of topography and percentage of land in crops, the average size of herd was 10 cows per 100 acres. Farms with a large number of spring calves obtained a 9 percent greater calf crop, and the cost of raising calves per 100 lb. was 33 percent less. The cost per 100 lb. of calf varied little between the breeding herds fed and not fed silage. No significant differences were found in rate of gain or cost of gain between lots of fattening cattle fed and not fed silage or those receiving the least and most protein. Labor requirements were generally less per head for the larger herds. Except in years of abnormal conditions, the average farmer could raise feeder calves about as cheaply as they could be purchased. Generally the roughest farms were used for raising beef calves and the smoothest for commercial feeding. Except on commercial feeding farms, 40-60 percent of the corn produced was fed to hogs, and the income from hogs was about equal to that from cattle. On baby beef farms about one-third of the gross income was from cattle, one-third from hogs, 15 percent from dairy products, sheep, and poultry, and the balance from miscellaneous sources.

**A study of legume-grass silage on Ohio farms, F. L. MORISON** (*Ohio State Univ., Dept. Rural Econ. Mimeog. Bul. 127 (1940), pp. [2]+25*).—Data were obtained from 120 farms making legume or grass silage in 1939. The farm management problems, methods, labor requirements, costs, cost of silage as compared with other feeds, etc., are discussed.

The average silage yields per acre were alfalfa 5 tons, soybeans 7.5, and corn 9 tons, and the estimated costs per ton of producing silage were alfalfa \$2.69, soybeans \$3.91, and corn \$3.14.

**Irrigation interval control as an aid in lowering production costs, J. A. SWEZEY and H. A. WADSWORTH** (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.], 44 (1940), No. 1, pp. 49-68, pls. 3, figs. 10*).—A 20-acre field of sugarcane was laid out into 30 plats, approximately  $\frac{1}{2}$  acre in size, in block arrangement suitable for interpretation of results by analysis of variance. Part of the plats were irrigated so as to provide 8 days (average 10.9) growth between irrigations, part to provide 4 days (average 4.2), and part no days (average 0.2). Observations were made as to soil moisture, cane growth, etc., and records kept as to number of days of labor, amount of water used, rainfall, etc. The yields of sugar per acre were the same on the plats with 10.9 and 0.2 days between irrigations. The results for the two sets of plats per ton of sugar were, respectively: Man-days irrigating 1.03 and 1.79, million gallons of water used 0.52 and 0.86, cost of labor

(\$2 per man-day) \$2.06 and \$3.58, cost of water (\$12 per million gallons) \$6.24 and \$10.32, and total cost of irrigating \$8.30 and \$13.90.

**North Dakota farm prices**, W. L. ETTESVOLD (*North Dakota Sta. Bimo. Bul.*, 2 (1940), No. 5, pp. 7, 8).—This article continues the series (E. S. R., 83, p. 267). The average farm prices of the 14 products, and indexes and ratios of North Dakota agriculture are given for March and April 1940 and comparisons made with 1939 and the averages 1910-14.

**Factors affecting farm profits in Area 3, West Tennessee**, C. E. ALLRED, B. D. RASKOPF, P. T. SANT, and B. H. LUEBKE (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog. 107 (1940), pp. [1]+III+33, figs. 11*).—"This report is based on a farm management and soil conservation survey of profitable farm combinations on 150 farms in Crockett County in 1935, and analysis of the records of 208 successful farms in 7 counties of Area 3, West Tennessee, in 1934." The labor incomes on the 10 farms in each county with the highest income ranged from \$673 to \$1,955 and those on the 10 farms in each county with the lowest income from —\$230 to \$96. For the two groups of farms the years required for total receipts to equal investment were from 3.1 to 3.9 and from 5.9 to 7.7, size of farm from 105 to 390 acres and from 64 to 314 acres, acres in cotton from 19.3 to 69 and from 7.6 to 35, acres in corn from 19.2 to 77 and from 9.4 to 35, pounds of lint cotton per acre from 235 to 384 and from 169 to 310, bushels of corn per acre from 15 to 40 and from 14 to 22, and livestock receipts from \$221 to \$1,090 and from \$138 to \$436.

**Regional prices received for farm products in Tennessee and United States**, C. E. ALLRED, B. D. RASKOPF, and P. T. SANT (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog. 110 (1940), pp. V+48, figs. 29*).—Tables and charts are included and discussed summarizing the percentages that prices in different sections of the State of corn, small grains, cowpeas, soybeans, peanuts, tobacco, potatoes, apples, peaches, strawberries, livestock, wool, dairy products, chickens, and eggs are of the highest and lowest State prices and that the Tennessee prices are of the United States average prices.

**Regional prices paid by Tennessee farmers for foods**, C. E. ALLRED, B. H. LUEBKE, and W. S. CRAWFORD (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog. 108 (1940), pp. [1]+III+20, figs. 23*).—This preliminary report includes tables and charts showing by regions and for the State the average prices 1935-38 paid by farmers for sugar, flour, rice, pork (fresh), bacon (smoked), lard, beef (fresh), butter, cheese (American), apples, oranges (216's), lemons (360's), bananas, coffee, and raisins. Some of the factors causing regional variations in prices are discussed.

**Agricultural relief measures relating to the raising of farm prices—74th Congress, January 3, 1935 to June 20, 1936**, M. E. WHEELER (*U. S. Dept. Agr., Bur. Agr. Econ., Agr. Econ. Bibliog. 84 (1940), pp. VI+75*).—This is the fifth bibliography in the series previously noted (E. S. R., 81, p. 131). The bills are classified under the major agricultural relief plans considered by the Seventy-fourth Congress. Extracts from the Congressional hearings on the bills are included. Bills to raise prices through the national monetary or banking systems, with one exception, are omitted. An author and subject index and a numerical index to the bills and resolutions are included.

**Considering farm adjustments in Subarea 33, Type of Farming Area VII, Montana**, N. W. JOHNSON. (Coop. Mont. Expt. Sta. et al.). (*U. S. Dept. Agr., Bur. Agr. Econ., 1939, pp. [6]+34, figs. 13*).—A continuation and more detailed study of the subarea included in the previous study (E. S. R., 81, p. 586). It illustrates the relationships "in place" that can be made over most of the plains area of Montana. It deals chiefly with farms having long-time gross income expectancies of \$1,000 or less under present organization.

**Corn Belt Conference on Land Tenure, Davenport, Iowa** (*Chicago: Com. Corn Belt Land Tenure, 1939, pp. [2]+63*).—This is a report of the conference held at Davenport, Iowa, June 2-3, 1939. It includes reports of the committees on fundamental principles of land tenure, suggested research, and future meetings and plans, and reports on land tenure research in the different States in the Corn Belt and in the U. S. D. A. Bureau of Agricultural Economics.

**West South Central Conference on Land Tenure, Texarkana** (*Texarkana: W. So. Cent. Conf. Land Tenure, 1939, pp. [2]+28+6*).—This report of the conference at Texarkana December 6-7, 1939, includes reports on the farm tenancy and land tenure research in Arkansas, Louisiana, Mississippi, Oklahoma, and Texas.

**Farm tenancy in the United States, 1937-1939: A selected list of references, J. M. McNEILL** (*U. S. Dept. Agr., Bur. Agr. Econ., Agr. Econ. Bibliog. 85 (1940), pp. VI+160*).—This bibliography supplements a similar one for 1918-36 (*E. S. R., 77, p. 713*), and includes 433 references to books, pamphlets, and periodical articles on farm tenancy, leases, leasing systems, and the southern sharecropping system published during the period 1937-39, together with a few references to publications issued in 1935, 1936, and 1940. It is divided into three sections—general references relating to the United States as a whole, and references arranged by geographical divisions and by States. An author and subject index is appended.

**Legal aspects of farm tenancy in Illinois, H. W. HANNAH and J. ACKERMAN** (*Illinois Sta. Bul. 465 (1940), pp. 237-276*).—The constitutionality of farm-tenancy legislation in Illinois, the existing statutes, and landlord-tenant relationships under common law are discussed and summarized and suggestions made for a farm-tenancy code for the State.

**Hill land and people in Ross County, Ohio: A study of selected areas, H. R. MOORE**. (Coop. U. S. D. A.). (*Ohio State Univ., Dept. Rural Econ. Mimeog. Bul. 125 (1940), pp. [3]+44, fig. 1*).—This is a study of the economic and social factors related to land use in five selected areas of the county representative of different combinations of physical resources, economic development, and social conditions. The present land use and agricultural production, potential land use, land classification by slope, tenure, condition of buildings, water supply, dependence on land, population, occupational pattern, attitude toward governmental activities, etc., are discussed for each area.

**Some of the economic effects of soil conservation in the Salt Creek Watershed, Zanesville, Ohio, 1934-38, R. H. BLOSSER**. (Coop. U. S. D. A.). (*Ohio State Univ., Dept. Rural Econ. Mimeog. Bul. 124 (1940), pp. [2]+30, fig. 1*).—An analysis is made of the economic effects of soil conservation practices adopted from 1934 to 1938 on 35 demonstration farms in the area. The farms are grouped on the basis of the recommended changes in land use as follows: (1) Depleting crops decreased and conserving crops increased, (2) both types of crops increased, (3) both types of crops decreased, and (4) depleting crops increased and conserving crops decreased.

**Relation of land use to land class in Jefferson County, Tennessee, 1938, C. E. ALLRED, H. J. BONSER, R. G. MILK, and J. D. RUSH**. (Coop. U. S. D. A.). (*Tennessee Sta. Agr. Econ. and Rural Sociol. Dept. Monog. 104 (1940), pp. VI+59, figs. 26*).—This study, made to determine the variations in land use on farms with soils of different productivities, is based on work sheets for 2,391 farms obtained by the A. A. A. in its 1938 agricultural conservation program. In the analysis the farms were grouped by land classes, civil districts, and size of farms. Comparisons are made with the 1935 agricultural census data.

**Land classification: A selected bibliography, O. E. GOODSSELL** (*U. S. Dept. Agr., Bur. Agr. Econ., Agr. Econ. Bibliog. 83 (1940), pp. VII+95*).—This bib-

liography consists of 780 references included in the Bibliography on Land Utilization, 1918-36 (E. S. R., 79, p. 266), and from files in the Bureau, catalogs of the libraries of the Department, and indexes to current literature. The material is limited mainly to reports, bulletins, monographs and articles on land classification studies, and reports of field investigations. Also included are references on descriptions and analyses of land-utilization patterns in particular areas, classifications of present land use, inventories of present and potential resources, classifications of land in terms of use capabilities, and general discussions of land classification in its theoretical aspects, and its relation to land policies, forestry, soils, irrigation, etc. It does not deal with classification of lands according to types of farming, vegetation, soils, tenure, erosive conditions, etc. An authors' index is appended.

**Foreign Agriculture, [May-June 1940]** (*U. S. Dept. Agr., Off. Foreign Agr. Relat., Foreign Agr.*, 4 (1940), Nos. 5, pp. 273-330, figs. 25; 6, pp. 331-379, fig. 1).—No. 5 includes articles on Inter-American Agricultural Cooperation, by H. A. Wallace (pp. 275-286), Tobacco in Principal Producing Countries of the Far East, by J. B. Gibbs (pp. 287-300), and Denmark's Agriculture as Affected by War, by P. G. Minneman (pp. 301-326); and notes on recent developments in foreign agricultural policy as follows: Sicilian colonization project, and France establishes a ministry of supplies.

No. 6 includes articles on Canada's Wartime Agricultural Measures, by C. C. Taylor (pp. 333-354), Japan's Food Self-Sufficiency, by W. Ladejinsky (pp. 355-376), and Control of Agricultural Prices in the United Kingdom, by R. B. Schwenger (pp. 377-379).

**The world food supply: A partial list of references, 1925-1939**, M. T. OLCOTT (*U. S. Dept. Agr., Bur. Agr. Econ., Agr. Econ. Bibliog.* 82 (1939), pp. VI+164).—This bibliography of 437 references supplements one of the same title (E. S. R., 53, p. 896). In preparing the bibliography the following subjects were checked: Foods and foodstuffs, raw materials, geography, oils and fats, sugar, and wheat. "The bibliography is arranged geographically—first references on the world subdivided under general, economic geography, grain, nutrition, oils and fats, raw materials, and sugar; [and] then alphabetically by continent, in most cases subdivided by country."

**Supply responses in milk production in the Cabot-Marshfield area, Vermont**, R. H. ALLEN, E. HOLE, and R. L. MIGHELL. (*Coop. Vt. Expt. Sta. et al.*). (*U. S. Dept. Agr., Tech. Bul.* 709 (1940), pp. 60, figs. 11).—This study is based primarily on farm management data covering the 2 yr. 1926 and 1936, and is part of a study of interregional competition in the production of dairy products in the New England and midwestern dairy regions. It is an intensive study with respect to past trends of milk production and their causes and prospective responses to different prices. Considerable emphasis is placed on research methodology for the analysis of long-time supply responses. The procedure used in the study is described. In general, it considered "first a most profitable farm organization for each price situation in as realistic terms as possible and then on the basis of personal acquaintance with the farmer and his past record of performance to estimate the effect of subjective factors in causing him to fall short of the point arrived at in the first approximation." The agriculture of northern New England and the Cabot-Marshfield area is described.

The prices per pound for butterfat were 53.7 ct. in 1926 and 44.4 ct. in 1936, and those of feed per ton \$49.99 and \$35.89, respectively. The index (an unweighted annual average of monthly indexes) of deliveries of milk and cream corrected for farm abandonment was 94 in 1926 and 100 in 1936. The estimated increases in different factors from 1936 to 1946 with present prices and 15 percent higher milk prices are: Number of cows 4 and 8 percent, production per

cow 3.6 and 6.8, total milk production 7.8 and 15.3, total milk sold 8.8 and 16.7, value of dairy products sold 8.6 and 35.3, and total cash receipts 5 and 21.7 percent, respectively. With 15 percent lower prices the estimated decreases are 8.9 percent, 0.4, 9.3, 23.8, and 13.3 percent, respectively.

**Production and consumption of manufactured dairy products, E. E. VIAL.** (Coop. State Expt. Stas.). (*U. S. Dept. Agr., Tech. Bul. 722 (1940), pp. 77, figs. 16*).—This study was made “to learn (1) the changes in production and consumption of dairy products, and (2) the relationships between production, foreign trade, and consumption of the individual products, as well as all combined.” It was limited to manufactured products. The production, consumption, exports, and imports of butter and cheese are discussed for the period 1849–1938, with shorter periods for other products. Dairy production v. total agricultural production is also discussed. A brief discussion is included of sources of data and technic employed in determining production and consumption of the products. The appendix includes tables showing production, consumption, exports, imports, etc., by years.

The per capita production of different products and the milk equivalent used for each during the periods 1870–79 and 1930–37 were: Butter 13.4 and 17.5 lb.; cheese 4.94 and 4.46; condensed and evaporated milk 0.18, condensed 1.79, and evaporated 13.51 lb.; commercial ice cream 0.002 and 1.638 gal., malted milk 0 and 0.134 lb.; dried whole milk 0 and 0.119; and dried cream 0 and 0.0011 lb. The milk equivalent used for manufactured products is 331 and 467 lb., respectively. For the two periods the milk equivalents of the total exports of manufactured products were 1,258,000,000 and 179,000,000 lb., respectively, and the percentages for the different products were: Butter 19.2 and 16.6, cheese 80.8 and 8.4, condensed and evaporated milk 0 and 59.9, dried milk 0 and 11.6, and other products 0 and 3.5. For imports the amounts were: Milk equivalents 66,000,000 and 711,000,000 lb., butter 44.2 and 15.8 percent, cheese 55.8 and 82.7, condensed and evaporated milk 0 and 0.4, and other products 0 and 1.1 percent. From 1869 to 1914 manufactured dairy products increased at a rate of about 2.99 percent per year as compared with 3.03 percent for general crop production and 2.97 percent for food and feed crops. From 1918–32 the annual increases were 2.49, 0.29, and practically no change.

**Crops and Markets, [April 1940]** (*U. S. Dept. Agr., Crops and Markets, 17 (1940), No. 4, pp. 73–92, figs. 2*).—Included are reports on the number of cattle on feed, crop conditions, farm real estate values, farm wages, grain stocks on farms, prices received by farmers, sugar crop statistics 1939, and indicated yield of winter wheat; and market reports on cotton, dairy and poultry products, feeds, seeds, grains, and livestock and livestock products.

**Seasonal market variations and their importance to Iowa farmers, E. HAMILTON** (*Iowa Sta. Bul. P5, n. ser. (1940), pp. 181–208C, figs. 28*).—Charts are included and discussed showing by months, usually for the years 1929–38, (1) the prices (a) at Chicago of beef steers (different grades), choice heifers (1928–37), slaughter cows, veal calves (1901–37), hogs, sheep and lambs, corn, and oats (marketing years 1924–38), (b) at Kansas City for stocker and feeder steers and calves (1933–38), (c) at New York City for 92-score butter, eggs, top prices of dressed chickens and hens, and (d) farm prices of chickens (four markets), and soybeans; (2) receipts of beef steers at Chicago, eggs at New York City, and dressed poultry (four markets); (3) shipments from public markets of stocker and feeder cattle and calves, and sheep; (4) slaughter under Federal inspection of cows and heifers, hogs, and sheep and lambs; (5) cold storage holdings of pork and lard; (6) creamery butter production; and (7) sales of corn and oats in Iowa (1928–37 marketing years).

Other charts included and discussed show the seasonal changes in hog prices in years of increasing and decreasing production, the average weight of hogs marketed, the Iowa butter-feed and egg-feed ratios, the year-to-year changes 1925-38 in these ratios, and the year-to-year changes 1913-38 in Iowa and United States hog-corn ratios.

**Survey of cooperative poultry and egg marketing in Ohio**, R. L. BAKER and C. B. McBRIDE. (Coop. U. S. D. A.). (*Ohio State Univ., Dept. Rural Econ. Mimeog. Bul. 126 (1940), pp. [3]+41, figs. 6*).—The development of cooperative poultry and egg marketing in the State, the types of cooperatives, the methods used, quality grading of eggs, basis of payments, distribution methods and outlets, and problems of cooperatives are discussed.

## RURAL SOCIOLOGY

**[Investigations in rural sociology by the Kentucky Station, 1939]** (*Kentucky Sta. Rpt. 1939, pt. 1, pp. 8, 9*).—Included are general findings in studies of the natural increase and migration of the population of the State from 1920 to 1930 and of the movement of population to and from farms in 1938.

**Social organization in Arizona's irrigated areas**, E. D. TETREAU. (Univ. Ariz.). (*Rural Sociol., 5 (1940), No. 2, pp. 192-205*).—In Arizona's irrigated areas the value of land for agriculture depends primarily upon water rights. Here the irrigation enterprise is a basic institution. Probably the most potent regulator of human relationships in the irrigated areas is the family. More than 10 agricultural households were found per square mile of irrigated farm land. "Since more than two-thirds of all agricultural households were laborers, and since commercialized agriculture bids fair to continue a severe competition with family farming and possibly further increase the proportions of laborers, it seems timely to advance tentatively a principle of balance between family and commercial farming. This principle may be stated as a proportioned relation between family and commercial farming by which are locally retained sufficient numbers of farm owners' families to maintain local government and public education at accepted standards and to carry resident laborers' families normally through the year without public or private assistance."

**Social factors associated with land class in Overton County, Tennessee.**—**A preliminary report**, C. E. ALLRED, H. J. BONSER, and F. M. FITZGERALD (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog. 105 (1940), pp. V+36, figs. 22*).—Families on poor lands moved more often than did families on good lands. Over one-third of the rural families, outside of Livingston town, received public relief of some kind during the year 1938. All classes of relief except aid to the blind were heaviest on the poor lands, with work relief showing the closest association with land quality. Public relief was greater for nonfarm than for farm families. In 1935, 3.4 percent of the relief families conducting farming operations had one or more members who had returned to the county from a nonfarm occupation.

**Population trends and adjustments in Arkansas**, W. H. METZLER (*Arkansas Sta. Bul. 388 (1940), pp. 59, figs. 15*).—Migration to other States has exceeded 100,000 persons in each decade since 1890, and between 1920 and 1930 exceeded 280,000, or twice the State's increase in population during that time. Heaviest losses through emigration have been from the northwestern half of the State. Approximately 80 percent of the people were classified by the census of 1930 as rural and 60 as living on farms. The decline in farm population has been both relative and absolute, most of the decrease being in the upland counties.

Birth rates in the rural districts are high in relation to the ability of the area to support population. Average farm wealth per person varied from \$346.71 in Stone County to \$1,130.63 in Arkansas County; per capita farm incomes from \$102.76 to \$414.56. Nonfarm incomes in the State averaged \$503 in 1929 and farm incomes \$185. The population in many of the upland counties is so sparse that efficient community institutions cannot be maintained. The average length of the school term was 124.6 days as compared with 160.3 days in more thickly settled areas. The population process from 1930 to 1935 was in the direction of maladjustment rather than adjustment. Farm population increase was most rapid in those areas already overpopulated, and family farms which were already too small had to be divided. Farm people in those areas where the farm base was most adequate moved to town, and urban migrants moved into adjacent rural areas without particular regard for the actual farming possibilities.

**Migration of Minnesota rural youth, L. NELSON and D. MITCHELL.** (Univ. Minn.). (*Rural Sociol.*, 5 (1940), No. 2, pp. 229-232).—In 1938 a survey was made of 881 rural youth living in 9 selected townships in 3 counties of Minnesota. It was found that these youth had 470 siblings who were not living at home and who were in the age group 15 to 29. There were 189 young men between the ages of 15 and 29, brothers of youths in the survey, who had left home. Of the 178 for whom this information was available, 70, or 39.3 percent, moved to other open country localities; 54, or 30.3 percent, were living in cities; 35, or 19.7 percent, in towns; and 19, or 10.7 percent, in villages. When these figures are compared with those for young women given in the section following, it is apparent that the young men tend to remain on the land in much larger proportions than do the young women. Of the 470 siblings who were not living at home at the time of the survey, 281, or 59.8 percent, were females. The majority of these (197) had entered "domestic" occupations of one form or another. The next largest group entered professional occupations. These are chiefly teachers. It appears that the larger the center the greater its attraction for the women. Of 266 girls away from home, 114 were living in cities, 53 in towns, 44 in villages, and 55 in the open country. The contrast between the last and the first figures is all the more striking when it is realized that the open-country group includes the wives of farmers. In the recovery period from 1933 to 1937, the pattern of migration from farms to towns and cities has not changed. As has been shown in other studies, the urbanward migration tends to select a larger proportion of young females. As to the volume of this migration, which presumably had slowed down considerably during the early years of the depression, these data seem to suggest that it is swinging back toward normal.

**Basic trends of social change in South Dakota.—V, Public health facilities, W. F. KUMLIEN** (*South Dakota Sta. Bul.* 334 (1940), pp. 30, figs. 27).—This is one of the series previously noted (*E. S. R.*, 81, p. 729). There seems to be a slow but sure trend toward public health facilities replacing those operating under private auspices. South Dakota has a high average length of life. This is due largely to the low death rate, which in turn is based upon a number of other factors such as decreasing infant mortality rate, favorable age distribution of the population, nonindustrialization of the State, and lack of overcrowded conditions. The functions of the State Board of Health are becoming of increasing importance. The main hospital problem in South Dakota is not to add to the number but to improve the quality and completeness of service rendered by those already in existence and to educate more people to the idea of hospitalization.

**Fertility in rural areas in relation to their distance from cities, 1930,** W. S. THOMPSON and N. E. JACKSON (*Rural Sociol.*, 5 (1940), No. 2, pp. 143-162).—"No two areas present identical pictures of the relationship between fertility, as measured by the ratios of children under 5 to persons 15 to 44, and the influence of urban influence on fertility is somewhat discredited in a few areas." influence, the economic status of the family, and the demographic characteristics of the population. Even when two areas extending out from the same city are compared they are found to differ in many respects, and the age-old acceptance of urban influence of fertility in somewhat discredited in a few areas."

**House over-crowding prevalent in many rural Utah communities: Bedroom space found inadequate in most Utah homes,** J. A. GEDDES (*Farm and Home Sci. [Utah Sta.]*, 1 (1940), No. 2, p. 12, figs. 2).—In a study of seven rural communities in which conditions were believed similar to those in many rural areas, it was found that in many homes the house is too small. A house with one room per person exclusive of halls and bathrooms is held adequate by housing authorities. The average number of people in the household for these communities was 4.8, and for the two communities where the one- and two-room houses were greatest the average size of household was larger still, being 5.1 and 5.2. Only a little over half of the families possessed houses reaching the standard of one room per person, the percentage for farm families being 52.5 and for nonfarm families 54.6.

## AGRICULTURAL AND HOME ECONOMICS EDUCATION

**History of the North Carolina State College of Agriculture and Engineering of The University of North Carolina, 1889-1939,** D. A. LOCKMILLER (*Raleigh: Edwards & Broughton Co.*, 1939, pp. [XVIII+310, [pls. 19, figs. 9]).—This volume was prepared on the occasion of the fiftieth anniversary of the founding of the college.

**A history of agriculture in Europe and America,** N. S. B. GRAS (*New York: F. S. Crofts & Co.*, 1940, 2. ed., pp. XXVII+496, [figs. 5]).—This second edition of the book previously noted (*E. S. R.*, 53, p. 397) includes a chapter covering the period 1920-40 and minor changes in several chapters.

**Elements of farm management,** J. A. HOPKINS (*New York: Prentice-Hall*, 1940, rev. ed., pp. XXI+489, [pl. 1], figs. 89).—This revised edition (*E. S. R.*, 75, p. 130) includes additional information on labor, feed, power, and other crop and livestock requirements, and discussions of the principles of farm appraisal, opportunity, costs, and size of farm as related to farm management and income.

**Practical farming for beginners,** H. A. HIGHSTONE (*New York and London: Harper & Bros.*, 1940, pp. X+199, [pls. 10]).—"This volume is an outline of agriculture addressed primarily to the city man who is convinced that he will be better off earning his livelihood from the land. In part, it is a narration of why city families usually fail in their attempts to find rural independence."

**Workers in subjects pertaining to agriculture in land-grant colleges and experiment stations, 1939-40,** M. A. AGNEW (*U. S. Dept. Agr., Misc. Pub.* 378 (1940), pp. V+170).—This is the usual annual list (*E. S. R.*, 81, p. 300) showing the workers in agriculture and home economics, the personnel of the Office of Experiment Stations, and the officers and standing committees of the Association of Land-grant Colleges and Universities.

## FOODS—HUMAN NUTRITION

The effect of different wrappings, temperatures, and length of storage on keeping qualities of frozen pork chops, R. M. GRISWOLD and L. H. BLAKESLEE. (Mich. Expt. Sta.). (*Amer. Soc. Anim. Prod. Proc.*, 32 (1939), pp. 305-314; *abs. in Michigan Sta. Quart. Bul.*, 22 (1940), No. 4, p. 296).—The hogs used in this test were a good grade of market hogs, the animals including several pure- and cross-breeds and all having received the same ration. The chops, cut  $\frac{5}{8}$  in. thick from the carcasses immediately after cooling at 32°-36° F. for 48 hr., were assembled in representative groups of 4 from different hogs, each chop being identified by number as to carcass and treatment to be given. The chops were frozen in a cabinet type of freezer at -15° for 24 hr., after which each group of 4 was taken from the quick freezer and wrapped for storage. Seven different types of wrappings were used and 4 packages of each type of wrapping were stored at 0°, 5°, and 15°, respectively, thus permitting sampling for each wrapper and temperature after 60, 120, 180, and 240 days of storage. The wrappings included a kraft wrapping paper, a brown waxed whalehide, a moisture-proof cellophane, peach cartons lined with a latex rubber-coated, heat-sealing paper (Thermo M), and coatings obtained by dipping individual chops in a mixture of pure lard and 0.5 percent oat flour, or in a mixture of  $\frac{1}{4}$  tallow,  $\frac{3}{4}$  lard, and 0.5 percent oat flour, or in water at 32°. The chops, which had been weighed before and after freezing, were weighed again upon removal from storage, thawed at room temperature, braised by standard procedure, and graded by an experienced panel of judges, using the palatability chart of the National Cooperative Meat Project. The data on shrinkage, calculated as the difference between the weight before storage and the weight after storage divided by the weight before freezing, and the scores for the various palatability factors are tabulated.

The results, subjected to statistical analysis for determination of significance, permitted the following conclusions: "Wrappings had little effect on the palatability of the chops under the experimental conditions used, but had a decided effect on moisture loss. Kraft wrapping paper permitted the greatest moisture loss, whalehide was next, Thermo M, lard, and lard and tallow were about the same, while cellophane allowed less moisture to escape than any of the other materials. The palatability of the chops decreased and shrinkage increased as the storage period lengthened. Most of the chops were still edible after 180 days' storage, although the fat of some of the chops was rancid. Several palatability factors seemed better in chops stored at 15° than in those stored at 0°, probably due to temperature fluctuations in the 0° box. Little difference was found between chops stored at 5° and 15°."

Sharp freezing of N. D. grown vegetables and fruits for cold storage lockers, D. KNOWLES and O. GROTTODDEN (*North Dakota Sta. Bimo. Bul.*, 2 (1940), No. 5, pp. 10-13, figs. 2).—This report of the first year's investigation of adaptability to quick freezing of varieties of North Dakota fruits and vegetables and on the selection of methods of preparing and freezing to give best results is written in such a way as to serve as a useful manual on the selection of varieties and preparation for freezing. Of 11 varieties of peas tested, 5 proved satisfactory under North Dakota growing conditions—Topnotch, Gilbo, Glacier, Thomas Laxton, and Laxton Progress; of 7 varieties of sweet corn, 3—Golden Bantam, Golden Gem, and Kingscross; and of 6 varieties of wax beans, 3—Topnotch, Golden Wax, and Webber Wax. The 2 varieties of lima beans tested (Fordhook Bush and Jackson Wonder) and the 4 varieties of green beans (Bountiful, Green Pod Stringless, Dwarf Horticultural, and Plentiful) proved satisfactory.

A table is included of recommended types of pack and containers for corn (whole-cut and on-the-cob), green beans, lima beans, wax beans, peas, and raspberries. Corn proved better when frozen off-the-cob than on-the-cob, lima beans and corn when frozen in 2 percent salt solution than in dry pack, and wax beans, green beans, and peas in dry pack. Raspberries were best when frozen in a 50 or 60 percent sirup. Glass jars were recommended for all except the corn-on-the-cob.

**Home production of food supplies, J. J. BIRD** (*Tennessee Sta. Rpt. 1938, pp. 28-34*).—This report summarizes the data for 1938 on the dietary, food consumption and costs, and health records and on the yield of various subsistence crops and livestock in the 12 Crossville Homestead farms.

**Data on the chemical composition of the more important varieties of Hungarian plums** [trans. title], E. BECKER (*Ztschr. Untersuch. Lebensmtl., 78 (1939), No. 5, pp. 403-407*).—Data on the percentage of dry matter, total sugar, and total acid are reported for 91 samples of plums of four native varieties, designated as to the region (Hungarian) in which they were grown.

**Some effects on animal nutrition of the ingestion of mineral oil, M. C. SMITH and H. SPECTOR** (*Arizona Sta. Tech. Bul. 84 (1940), pp. [2]+371-395, figs. 3*).—Rats and dogs were used as experimental animals in studies designed to determine the effect of mineral oil ingestion, at 5 and 10 percent levels and incorporated in the daily ration, on the assimilation of vitamins A and D. In groups of rats carefully matched as to litter mates and distribution of the sexes and placed at weaning on a basal diet of one-third dry whole milk, two-thirds whole wheat, and 1.6 percent salt, no difference as to growth rate was observed between the control group and those receiving the two levels of mineral oil over a period of 1 yr. The reproductive performance of the females was markedly affected, however. At the 10 percent level of feeding the females showed a shortened period of fertility, produced only one-third as many litters as their nonoil-fed litter mate sisters, and were less successful in raising their young to weaning age. Moreover, the young of female rats reared on rations containing mineral oil were less able to withstand subsequent deprivation of vitamin A, as indicated by an earlier break in resistance to respiratory infections and shorter survival periods on a vitamin A-free regime. This behavior of the young was indicative of small stores of vitamin A.

Further evidence of low vitamin A reserves in rats receiving mineral oil was obtained by analysis of the livers of the animals; whereas the livers of rats on the basal diet averaged 130 and 73 blue units for the females and the males, respectively, the corresponding values for rats receiving 5 and 10 percent of mineral oil were 16 and 11 and 8 and 6, respectively. Mineral oil ingestion was also found to interfere with the utilization of vitamin D fed separately as cod-liver oil. Three times as much cod-liver oil was necessary to induce healing of the rachitic lesions of rats when the basal ration contained 5 percent of mineral oil as was necessary with the control animals receiving no mineral oil; between 5 and 10 times as much cod-liver oil was required for healing when the basal ration contained 10 percent of mineral oil.

“Balance studies” showed that mineral oil ingestion by young dogs interfered with the retention of both calcium and phosphorus so seriously that normal calcification of the bony structure was not possible. The mineral oil-fed dogs showed the characteristics of severe rickets even though they received adequate amounts of calcium and phosphorus and were given a supposedly minimum protective dose of cod-liver oil. Increasing the amount of cod-liver oil fivefold did not provide for optimum retention of the mineral elements in the dog receiving the ration containing 10 percent mineral oil.

"These findings lead to the conclusion that the continuous ingestion of mineral oil in amounts probably not greater than the corresponding therapeutic dose for humans seriously interferes with the utilization of vitamins A and D in rats and dogs and thus adversely affects animal nutrition."

**Nutrition [at the Hawaii Station]** (*Hawaii Sta. Rpt. 1939, pp. 61-63*).—Progress is reported (E. S. R., 81, p. 736) on chemical analyses, by C. D. Miller and L. Louis, of Hawaiian-grown vegetables; an extension of the study by M. Potgieter of the dietary habits of independent farmer families in Hawaii and the nutritional condition of the children of these families; and anemia and blood studies by C. J. Hamre, including the influence of iron on blood-forming organs of anemic animals, the capillary hematocrit method of determining blood cell volume, hemoglobin and blood cell levels of preschool children, and a survey of blood values of young men and women.

**Soybeans valuable in the diet**, D. DICKINS (*Miss. Farm Res. [Mississippi Sta.], 3 (1940), No. 5, p. 1*).—This brief descriptive article is based on cooking tests made on 134 varieties of edible soybeans grown at the station from seeds furnished by the U. S. D. A. Bureau of Plant Industry.

**Food needs of young adults object of study** (*Ohio Sta. Bul. 600 (1939), pp. 58, 59*).—This progress report on certain phases of the North Central States cooperative project on the nutritional status of college women discusses the significance of the investigation and refers in general terms to some of the comparative results already obtained.

**Food consumption studies [by the South Carolina Station]**, A. M. MOSER (*South Carolina Sta. Rpt. 1939, pp. 22-24, fig. 1*).—In this progress report (E. S. R., 81, p. 141) a summary is given of a comparison of the diet patterns of groups of farm families in the Piedmont and Coastal Plains areas, as obtained from earlier studies (E. S. R., 73, p. 557; 81, p. 866) and the tobacco-cotton farming area from figures secured by the U. S. D. A. Bureau of Home Economics in the consumer purchases study.

**[Food and nutrition studies by the Wyoming Station]** (*Wyoming Sta. Rpt. 1939, pp. 19-21*).—This progress report (E. S. R., 81, p. 591) notes some of the findings in studies on the home canning of green beans, the effect of storage on the ascorbic acid content of potatoes, the preservation of freezing of compressed yeast for bread making, and the basal metabolism of male college students.

**The metabolism of calcium and phosphorus**, C. I. REED. (Univ. Ill.). (*Jour. Amer. Dietet. Assoc., 15 (1939), No. 8, pp. 667-674*).—This discussion, presented as an address, is concerned with the physiological importance of calcium and phosphorus. The demands for these elements, their functions, the factors governing absorption, and the controlling mechanisms in calcium and phosphorus metabolism are discussed. Special reference is made to the thyroids, the parathyroids, the pituitary, and the relation of pituitary and thyroid to vitamin D as controlling factors.

**Iron, copper and manganese in human organs at various ages**, G. BRÜCKMANN and S. G. ZONDEK (*Biochem. Jour., 33 (1939), No. 11, pp. 1845-1857, fig. 1*).—Values for total and nonhemin iron and for copper, determined in the livers and kidneys of a series of 75 autopsy cases, are reported according to the age of the individuals. Manganese determined in a number of livers is similarly reported. Occasionally other organs were also examined. The methods used, some of them representing improvements on existing procedures, are discussed. The results also are discussed in detail in the light of present knowledge.

The results for liver and kidney indicated a characteristic life curve for the percentage of total iron and particularly for nonhemin iron. The values found at birth were high, averaging in the case of nonhemin iron within the age of 0 to 15 days 1,770 and 205 mg. per kilogram of dried liver and kidney tissue, respectively; they then dropped to a minimum at the age of about 2 yr., averages of 170 and 78 mg. of nonhemin iron per kilogram of dried liver and kidney tissue being found for this period (15 mo. to 3 yr.). Above this age the values increased slowly at first and then more rapidly, remaining at about the same level from the age of 20 yr. to the end of life. In the case of healthy adults the nonhemin iron contents of the liver and kidney were remarkably constant, the mean values being 800 and 160 mg. per kilogram of dried substance, respectively.

Although the values in the newborn were in general quite high, it is pointed out that there were exceptions. Other work is cited to indicate that the bulk of the nonhemin iron is not accumulated until after birth, when the postnatal blood destruction reduces hemoglobin values liberating large amounts of iron, some of which is excreted and much of which is mobilized in the liver. It is also pointed out that the minimum iron values are not reached after weaning, as would be expected from the classical theory that iron stores are drawn upon during the period of lactation, but are reached at about the age of 2 yr. after the child has lived on a normal diet for some time. Severe anemias appeared to reduce the iron content of organs to a minimum identical with the minimum values of childhood. Blood transfusion was found to increase definitely the nonhemin iron of both liver and kidney.

The life curve of the liver-copper content showed the familiar maximum at birth, the average value for liver in 14 infants (0-1½ mo.) being 230 mg. per kilogram of dried substance. This level was followed by a sharp decline after the second month. The average value for adults was 34.6 mg. per kilogram of dried substance. Kidney and brain did not show maximum values at birth. The copper values for thymus, hypophysis, and thyroid were very low, between 4 and 20 mg. per kilogram of dried substance; the iron content of the same organs was between 100 and 300 mg. per kilogram of dried tissue. The copper content of the liver was found to be markedly increased in a case of tuberculosis. The manganese content of the liver was constant throughout the life span, 7.0 mg. per kilogram of dried material being the average value obtained. Several samples of blood serum gave values for manganese from 1 to 3 µg. per 100 cc.

**A manual for diabetic patients**, W. D. SANSUM, A. E. KOEHLER, and R. BOWDEN (*New York: Macmillan Co., 1939, pp. X+227, pls. 2, figs. [10]*).—This book, written to familiarize the patient with the nature of diabetes, is intended to serve as a guide to augment the specific and individual instruction he receives as a patient. The first part of the book deals with food utilization and its relation to diabetes; the diagnosis of the disease; the treatment, by diet and with insulin; general factors in management; insulin reaction, acid-base balance, acidosis and coma, and the distinctions between severe insulin reaction and diabetic coma; complications; surgery and pregnancy in diabetes; and laboratory tests for the patient.

The second part gives detailed consideration to the dietary management of diabetes. The weighing and measuring of foods, their composition and calorie value, and practical translation of dietary treatment in terms of actual menus, recipes, and substitutions are matters included in this section. The diet plan presented aims to supply ample amounts of minerals and vitamins and to meet

the normal weight and energy requirements. In order to parallel more closely the slow liberation of insulin by the new insulin compounds, diets have been arranged with frequent feedings and with reference to the distribution of foods. A table of food values, height-weight-age tables, and a glossary of terms are appended.

**Vitamin A values**, F. L. MACLEOD and E. UTLEY (*Tennessee Sta. Rpt. 1938*, p. 64).—This progress report summarizes the results obtained in a completed study of the effects of cooking and storage on the vitamin A values of Porto Rico sweetpotatoes, Chantenay carrots, Amber Globe turnips, and rutabagas. Preliminary work on the Nancy Hall variety is also noted.

**Studies in vitamin A: Relation of vitamin A and carotene to serum lipids**, H. W. JOSEPHS (*Bul. Johns Hopkins Hosp.*, 65 (1939), No. 1, pp. 112-124, figs. 6).—In the introduction to this paper attention is called to the fact that there is as yet no method for determining storage deficiency in vitamin A, and "not everyone agrees on the propriety of defining vitamin A deficiency in terms of adaptation tests." In the hope of clearing up some of the doubtful points in the use of blood tests for the assessment of the body's supply of vitamin A, a survey was made of the relation between total lipide content of the blood and the blood levels of vitamin A and carotene. Blood samples were obtained from patients suffering from a variety of pathological conditions and with lipide values ranging from high to low. Vitamin A and carotene determinations were made by essentially the method of Clausen and McCoord (*E. S. R.*, 76, p. 585) both with direct comparisons of color and with the use of the photoelectric colorimeter. The technics for this method and for the methods for determining total lipides and cholesterol are described in detail.

The results obtained showed a good correlation between carotene and total lipides, a fairly close relationship between vitamin A and lipides, and a close relationship between lipides and cholesterol. The only definite conclusion that could be drawn, however, is that there is an obvious relationship between vitamin A, carotene, and total lipides of the blood. It is suggested that the basis for this is the fat-solubility of vitamin A and carotene. Whether the concentration of vitamin A in the fat of the plasma is more significant than in the plasma itself cannot be stated with certainty, although certain observations indicate that such is the case. In some instances of low blood fat there was almost no increase in blood vitamin A after the ingestion of a large amount of the vitamin. In others high values in blood fat were associated with high carotene and vitamin A values, but in certain cases of dietary deficiency of vitamin A the blood fat was not low.

**Simple method of measuring brightness threshold of dark adapted eye at all ages**, C. HAIG and J. M. LEWIS (*Soc. Expt. Biol. and Med. Proc.*, 41 (1939), No. 2, pp. 415-418, fig. 1).—The apparatus and procedure described with working diagram were developed during the course of an investigation of the vitamin A requirements of infants (*E. S. R.*, 79, p. 711). The procedure, as followed with infants, involves the determination of the final or equilibrium threshold for dark adaptation by the use of a portable instrument with the test light unit so constructed as to fit into the hand of the operator. The infant is placed on his back and a radium paint pendant such as is used on electric light chains is attached to the center of the forehead with adhesive plaster. After 30 min. of darkness the operator moves the test light unit slowly from side to side through an arc of 180° at a distance of about 10 cm. from the eyes of the infant, increasing the intensity of the light with each move until the infant sees it in the periphery of his visual field and turns his head in a corresponding direction, the motion being indicated by the luminous tube. When used for children and adults, violet light differentiates between the cones and rods, and

an approximate measure of the speed of dark adaptation is obtained by exposing the eyes to a bright light for 2 or 3 min., after which observations of the descending threshold are made at frequent intervals until the dark adaptation is relatively complete.

**Influence of vitamin A upon urea clearance in the rat,** R. C. HERRIN. (Univ. Wis.). (*Soc. Expt. Biol. and Med. Proc.*, 42 (1939), No. 3, pp. 695-699).—In rats on a high protein diet, deprivation of vitamin A led, with one or two exceptions, to a 23-77 percent decrease and the administration of carotene to a 30-170 percent increase in urea clearance. Examination of the urine and histological sections of the kidneys showed no marked morphological alterations.

**Metabolic interdependence of vitamin B<sub>1</sub> and manganese: Reciprocal neutralization of their toxic effects,** D. PERLA and M. SANDBERG (*Soc. Expt. Biol. and Med. Proc.*, 41 (1939), No. 2, pp. 522-527, fig. 1).—This report elaborates upon and extends the observations presented in a preliminary communication (E. S. R., 82, p. 279). The experiments for which the data are here presented had shown that rats receiving normal adequate diets and a large excess of vitamin B<sub>1</sub> exhibited interference with the capacity of the mother to rear her young and with the nursing instinct. These toxic manifestations were prevented by the addition of small amounts of manganese to the diet. Further studies confirmed these observations. With an excess of 400 $\gamma$  of vitamin B<sub>1</sub> given parenterally, the toxic manifestations were pronounced in the parent generation but became progressively worse in the F<sub>1</sub> and F<sub>2</sub> generations, the young in the latter case being neglected and eaten in over 90 percent of the litters. The addition of manganese to the diet at the level of 2 mg. per rat per day prevented these toxic manifestations over three generations. At the level of 0.5 mg. per rat per day the manganese was apparently even more effective. Without any excess of vitamin B<sub>1</sub>, supplements of manganese alone in amounts of 2 mg. per rat per day interfered with lactation and favored cannibalism, particularly after one generation. "It is inferred that manganese acts as an essential catalyst in oxidative processes in which vitamin B<sub>1</sub> is concerned. The vitamin B<sub>1</sub> requirement of an animal varies with the manganese content in its diet."

**Interdependence of vitamin B<sub>1</sub> and manganese, II, III** (*Soc. Expt. Biol. and Med. Proc.*, 42 (1939), No. 2, pp. 368-371, 371-374).—This is a continuation of the study noted above.

II. *Manganese, copper, iron metabolism in B<sub>1</sub> deficient rats,* M. Sandberg, D. Perla, and O. M. Holly.—This study deals with the metabolism of manganese during the development of and recovery from vitamin B<sub>1</sub> deficiency. Young rats being brought to depletion during a 5-week period on a vitamin B<sub>1</sub>-free diet admitting of an average daily intake of 0.064 mg. of manganese retained on an average 18 percent of the ingested manganese. Control groups on the basal diet plus a supplement of crystalline vitamin B<sub>1</sub> retained 19 percent of the ingested dietary manganese. When 1 mg. of manganese per rat per day was fed with the diet, manganese was stored, the retention over a 3-week period averaging 72 percent. Vitamin B<sub>1</sub> deficiency symptoms having developed at this stage, vitamin B<sub>1</sub> (400 $\gamma$  per rat per day) was given intraperitoneally, the oral manganese supplements being continued. During a 4-week period on this regime, the storage of manganese in the test group averaged only 34 percent. Controls during these two latter periods retained 25 percent of the manganese intake. With discontinuation of the manganese supplement on this high vitamin regime, the manganese previously stored continued to be excreted, negative balances being obtained. These findings illustrate the effect of excess vitamin B<sub>1</sub> in exhausting manganese stores.

III. *Manganese, copper and iron metabolism in normal rats*, D. Perla, M. Sandberg, and O. M. Holly.—Data are presented on the average daily manganese and copper metabolism of rats during several experimental periods. During the 5-week control period on a stock diet supplemented with 10 percent of whole milk powder and 3 percent of dried brewers' yeast and furnishing about 100 $\gamma$  of manganese and 74 $\gamma$  of copper daily, the animals did not store any manganese but did retain about 30 percent of the copper. In the first monthly test period that followed, the manganese intake was raised by about 50 percent, the copper intake remaining unchanged. On the slightly higher manganese level there was a retention of about 25 percent, which was not increased even when the manganese intake was raised to over 13 mg. On these higher manganese intakes the copper retention dropped. This relationship suggests that less copper may be required for oxidative purposes if large amounts of manganese are available. The administration of 400 $\gamma$  of vitamin B<sub>1</sub> along with the high level of manganese (13.64–14.82 mg.) increased the retention of this element to 41 percent in the first week and to as much as 54 percent in the second week; the copper retention was not affected during the first week but increased after that to 21 percent of the intake. It is suggested, therefore, that large amounts of manganese and vitamin B<sub>1</sub> offered simultaneously may permit a better utilization of copper as well as manganese. When manganese addition was stopped while the vitamin B<sub>1</sub> administration continued, the manganese retention became negative, and the copper dropped again to 15 percent of the intake, for 1 week; during the following weeks both manganese and copper retentions dropped to normal levels, and continued administration of vitamin B<sub>1</sub> failed to influence copper metabolism as long as the manganese intake remained at 100 $\gamma$  daily.

**The usefulness of the thiochrome procedure for the study of vitamin B<sub>1</sub> metabolism** [trans. title], J. BAUCKE (*Klin. Wchnschr.*, 18 (1939), No. 33, pp. 1128–1131, figs. 2).—It is considered that this method, applied to the urine of persons in a normal nutritional state, gives values that, on an average, are about 7 $\gamma$  percent too high. This is due to the lack of specificity of the reaction. Individuals on a diet furnishing about 600 $\gamma$  of the vitamin were found to eliminate about 6 to 18 percent of it in the urine. With higher intakes, higher percentages seemed to be eliminated, and upon the injection of from 1,000 $\gamma$  to 5,000 $\gamma$  of the vitamin about 20 to 36 percent was found to be excreted in the urine.

**Injection studies with vitamin B<sub>1</sub>** [trans. title], I. MAGYAR (*Klin. Wchnschr.*, 18 (1939), No. 34, pp. 1157–1160).—Values reported for 24-hr. urinary elimination of vitamin B<sub>1</sub>, as determined by a thiochrome procedure of Ritsert, showed great variability in the spontaneous elimination on a mixed diet with or without oral vitamin B<sub>1</sub> supplements. These values are considered as only approximately indicative of the vitamin B<sub>1</sub> status of the body. Single doses of vitamin B<sub>1</sub>, usually in 10-mg. amounts, were injected intravenously in normal and sick persons, some of the latter of known dietary history being in a state of hypovitaminosis. Individuals considered normal with respect to vitamin B<sub>1</sub> were found to eliminate various proportions of the injected vitamin in the 24-hr. period, but the amounts were always above 18 percent, in contrast with those in a state of hypovitaminosis who always eliminated less than this percentage of the injected dose. Multiple doses injected upon successive days were found to be eliminated in increasingly greater amounts in conditions of hypovitaminosis. Under the same circumstances, however, the elimination in the case of normal persons was very erratic, and if anything the proportion eliminated appeared to decrease as the amount injected increased. The data

reported are interpreted to indicate that the best procedure for detecting vitamin B<sub>1</sub> hypovitaminosis is that of investigating the percentage of elimination of a single intravenously injected dose.

**Is pantothenic acid essential for the growth of rats?** J. J. OLESON, D. W. WOOLLEY, and C. A. ELVEHJEM. (Univ. Wis.). (*Soc. Expt. Biol. and Med. Proc.*, 42 (1939), No. 1, pp. 151-153).—Using a basal ration similar to those used in earlier work on the differentiation of the vitamin B complex (E. S. R., 81, p. 450), the authors have demonstrated that the rat needs in addition to the crystalline factors supplied in the ration (thiamin, riboflavin, synthetic vitamin B<sub>6</sub>, nicotinic acid, and choline) an alkali-labile factor, which is probably pantothenic acid. A relatively crude preparation from liver extract containing about 10 percent of pantothenic acid as determined by bacterial assay, a small sample of crude crystalline material made from the lactone of the hydroxy acid portion of the pantothenic acid molecule and reconjugated with  $\beta$ -alanine, and the original liver extract were used as sources of pantothenic acid.

Liver extract fed at a level of 250 mg. daily promoted growth at a rate of 3.4 gm. per day over a 6-week period in rats which had ceased to grow at weights varying from 40 to 60 gm. The crude preparation of pantothenic acid fed in amounts sufficient to supply 100  $\mu$ g. of pantothenic acid promoted a growth rate of 2.4 gm. and the alkali-treated concentrate a growth rate of 1.5 gm. when fed in amounts equivalent to 50  $\mu$ g. of pantothenic acid, and only 1.7 gm. when the dosage was tripled. The crude crystalline material gave an average growth rate of 1.1 gm. per day when fed at a level equivalent to 50  $\mu$ g. The failure of the concentrates completely to replace the original liver extract or crude filtrate preparation is attributed to lack of factor W. Since the alkali-treated concentrate contained both  $\beta$ -alanine and the dihydroxy fractions, it is concluded that the rat apparently requires the intact pantothenic acid molecule. There was no significant stimulation due to the  $\beta$ -alanine as present in the alkali-treated concentrates.

**The relationship of the P-P factor to gastrointestinal motility,** L. A. CRANDALL, JR., F. F. CHESLEY, D. HANSEN, and J. DUNBAR (*Soc. Expt. Biol. and Med. Proc.*, 41 (1939), No. 2, pp. 472-474).—Favorable results obtained in the treatment with vitamin B complex of functional digestive tract disorders, characterized by distress, flatulence, and constipation at times alternating with loose stools, led to attempts to determine if thiamin, riboflavin, or nicotinic acid alone might be responsible for the effectiveness of the complex. Negative results were obtained with thiamin and riboflavin, but in 40 cases treated with nicotinic acid in doses ranging from 75 to 200 mg. daily, satisfactory results were obtained in 60 percent of the number as compared with 70 percent in 45 treated with the B complex. Marked intestinal hypermotility was noted on roentgen ray examination of several of the patients before treatment, and was also shown in dogs after 3-5 weeks on a blacktongue-producing diet. In 3 of the dogs the periods of hypermotility were interrupted by periods of hypomotility. It is concluded that nicotinic acid or any of its derivatives capable of replacing it in the diet "is essential to the maintenance of normal gastrointestinal motility, and that absence of this factor leads to motor dysfunction of the intestinal tract prior to the appearance of the usually accepted deficiency symptoms." It is thought possible that other factors of the vitamin B complex may also be concerned with gastrointestinal function.

**Nutritional achromotrichia,** J. J. OLESON, C. A. ELVEHJEM, and E. B. HART. (Wis. Expt. Sta.). (*Soc. Expt. Biol. and Med. Proc.*, 42 (1939), No. 1, pp. 283-285).—This term is used to describe the loss of hair pigmentation in rats

first described by Morgan and Simms (E. S. R., 81, p. 743) and Lunde and Kringstad (E. S. R., 82, p. 853) as due to lack of one of the filtrate factors of the vitamin B complex. It is noted that nicotinic acid and vitamin B<sub>6</sub> as well as the chick antidermatitis factor have been eliminated as causative factors by Lunde and Kringstad. The present study was concerned with the possible identity of the factor with factor W (E. S. R., 78, p. 285), pantothenic acid, and the spectacled eye factor (E. S. R., 81, p. 450). Various concentrates of these factors of known potencies were used in the cure and prevention of achromotrichia in piebald rats. The basal ration on which achromotrichia usually developed in 6-10 weeks consisted of sucrose 67 percent, purified casein 18, salt mixture III of Arnold and Elvehjem (E. S. R., 81, p. 876) 4, butterfat 9, and cod-liver oil 2 percent, with individual daily supplements of thiamin 10 $\gamma$ , riboflavin 20 $\gamma$ , and vitamin B<sub>6</sub> 10 $\gamma$ .

Liver extract and the fuller's earth filtrate of the liver extract were very effective at a level of 250 mg. daily. The fuller's earth eluate, which had proved effective in preventing paralysis and hemorrhagic disease in rats, was inactive when fed at a level equivalent to 1 gm. of the liver extract daily. Synthetic nicotinic acid, adenylic acid, and vitamin B<sub>6</sub> were without effect. Corn oil capable of preventing symptoms of acrodynia in rats and of preventing and curing the spectacled eye condition curable with fuller's earth filtrate was ineffective in doses of 3-4 drops daily. Of three pantothenic acid concentrates tested, the acid-ether extract and chloroform residue fractions of Woolley et al. (E. S. R., 80, p. 673) and the barium salts preparation described by Oleson et al. (E. S. R., 81, p. 450) were fed at levels equivalent to 1 gm. of liver extract daily for the first two and at a level equivalent to 100 $\gamma$  of pantothenic acid for the third concentrate. None of these preparations prevented the appearance of achromotrichia, although in most instances the time of onset of the symptoms appeared to be delayed. This effect was not observed when the concentrate was treated with alkali to destroy pantothenic acid. Two preparations of factor W, a hexane butanol extract and an acetone eluate of liver extract, proved inactive. Rusting of the fur of albino rats and lack of correlation of the appearance of achromotrichia with growth were also observed.

**Experiments on the antidermatitis component of the filtrate factor in rats,** P. GYÖRGY, C. E. POLING, and Y. SUBBAROW (*Soc. Expt. Biol. and Med. Proc.*, 42 (1939), No. 3, pp. 738-740).—Rats fed a basal diet deficient in vitamin B [complex] and supplemented with vitamin B<sub>1</sub> and riboflavin and treated with pure vitamin B<sub>6</sub> until the specific acrodynia was modified or cured still presented certain skin lesions. Most commonly these began as sores around the mouth and as scaly dermatitis visible at first around the axillae, the groin, and over the back between the scapulae. Later, alopecia followed. Complete cure of these manifestations was effected by liver or yeast or by a filtrate fraction from extracts of wheat germ, yeast, or rice polishings that had been adsorbed on fuller's earth.

To determine whether the curative component corresponds to the chick antidermatitis factor recently identified with pantothenic acid, a purified but still crude zinc salt of pantothenic acid was tested. This proved to be active in the cure of the specific skin lesions and in promotion of growth in rats fed a diet devoid of the filtrate fraction. Autoclaving at pH 10 destroyed the activity of the preparation.

**Pathology of B<sub>6</sub> deficiency in the rat and response to treatment with 2-methyl-3-hydroxy 4,5-dihydroxymethyl-pyridine (vitamin B<sub>6</sub>),** W. ANTOPOL and K. UNNA (*Soc. Expt. Biol. and Med. Proc.*, 42 (1939), No. 1, pp. 126, 127).—In this preliminary report the histopathology of vitamin B<sub>6</sub> deficiency in

the rat and the histogenesis of the changes effected by synthetic vitamin B<sub>6</sub> are described. The results are considered to make possible differentiation of lesions due to B<sub>6</sub> deficiency from those of the remaining members of the B complex.

**Determination of vitamin C nutrition by means of a skin test:** A critical evaluation, G. A. GOLDSMITH, D. F. GOWE, and A. T. OGAARD (*Soc. Expt. Biol. and Med. Proc.*, 41 (1939), No. 2, pp. 370-374, fig. 1).—Further evidence is given in support of the conclusions of Poncher and Stubenrauch (*E. S. R.*, 80, p. 565) and of Jetter that the intradermal ascorbic acid test of Rotter, as described by Portnoy and Wilkinson (*E. S. R.*, 79, p. 570), is not a satisfactory method for determining the state of vitamin C nutrition. In 100 observations on 45 subjects there was no correlation between the ascorbic acid in the blood in the fasting state and the time of decolorization of the injected dye either in single tests or in repeated tests during a period of saturation.

**Determination of ascorbic acid in feces: Its excretion in health and disease,** H. CHINN and C. J. FARMER (*Soc. Expt. Biol. and Med. Proc.*, 41 (1939), No. 2, pp. 561-566).—A full description is given, with an example and necessary calculations, of a procedure which has been developed for the application of the Farmer and Abt method of determining ascorbic acid in blood (*E. S. R.*, 74, p. 135) to its determination in feces. In principle the method consists in estimating the total indophenol-reducing substances of the feces, treating an aliquot of the feces with an ascorbic acid oxidase, and again determining the reducing value. The difference between the two values represents the ascorbic acid present.

Data are reported on the recovery of added ascorbic acid by this method, an average of  $98.2 \pm 0.6$  percent being obtained in 13 cases, and on a series of plasma, urinary, and fecal ascorbic acid determinations on a single subject following the administration of varying amounts of *l*-ascorbic acid by mouth over a 4-week period. With ascorbic acid intakes averaging 73, 255, 547, and 1,054 mg. for the 4 successive weeks, average values for plasma ascorbic acid were 0.85, 1.43, 1.71, and 1.61 mg. per 100 cc., respectively; urinary ascorbic acid 21.67, 119.18, 315.10, and 405.55 mg., respectively, and fecal ascorbic acid 5.53, 9.81, 13.80, and 11.34 mg., respectively. In 12 normal young male medical students on their customary mixed diet, an average daily fecal excretion of 4.92 mg. ascorbic acid was obtained. Although large variations in the dietary intake appeared to affect the fecal excretion only slightly, there was great variation in patients suffering from various gastrointestinal disorders. In the case of esophageal stricture the daily fecal excretion over a period of 14 days averaged 1.5 mg., although 1,000 mg. had been given intravenously. In a case of colitis, with many liquid stools, the fecal excretion amounted to 34 mg. following an intake of only 450 mg.

**How much vitamin C is needed by the normal person?** A. P. BROWN (*Farm and Home Sci. [Utah Sta.]*, 1 (1940), No. 2, pp. 1, 10).—Using 50 mg. of ascorbic acid as the minimum requirement of vitamin C, the author has calculated from ascorbic acid analyses made at the station of some common foods the amounts in ordinary servings required to furnish 50 mg. of ascorbic acid. The foods studied included grapefruit; lemons; Valencia and navel oranges; canned orange juice; raw fresh peas; frozen peas; raw and home-canned raspberries; garden-grown, greenhouse-grown, and early market tomatoes; and home-canned, commercially canned, and frozen tomato juice.

**Recovery of vitamin C from the human bladder,** S. SHERRY and G. J. FRIEDMAN (*Soc. Expt. Biol. and Med. Proc.*, 42 (1939), No. 3, pp. 707-709).—By instilling known amounts of ascorbic acid into the bladders of patients with a very low blood serum ascorbic acid content, removing the urine by catheter at

varying intervals, and determining its ascorbic acid content, it was shown that no appreciable destruction of the vitamin occurs in the bladder. The recoveries amounted to from 92 to 107 percent on doses ranging from 0.5 to 30 mg.

**Relation between the vitamin C content of the blood and fever metabolism** [trans. title], F. X. HAUSBERGER and N. NEUENSCHWANDER-LEMMER (*Klin. Wchnschr.*, 18 (1939), No. 33, pp. 1119-1123, figs. 2).—Using normal and sick subjects, numerous determinations were made of the change in vitamin C content of blood following the injection of the pure crystalline vitamin (10 mg. per kilogram). In normal subjects with blood not highly depleted in the vitamin, there followed a gradual decrease in the vitamin after injection, the decrease being dependent upon the time. In patients with diseases leading to febrile conditions and in those with original large vitamin C deficits, the decrease in the vitamin C content of the blood following injection was greatly accelerated. The rapid disappearance from the blood stream is caused by the rapid transfer to the impoverished tissues.

**The tissue content of highly unsaturated cephalin in C-avitaminosis** [trans. title], Y. SUEYOSHI and H. MICHIMOTO (*Jour. Biochem.*, 30 (1939), No. 1, pp. 155-157).—Accepting Michimoto's<sup>1</sup> findings that cephalins with highly unsaturated fatty acid side chains were activators of blood coagulation, and using his method of determining them as the bromo derivatives, the present study was undertaken to determine these compounds in the tissues of normal and scorbutic guinea pigs. Much smaller amounts of bromocephalin were obtained from the tissues of scorbutic animals than from corresponding tissues of normal animals. This difference was especially marked in the blood vessels where only 10.8 mg. percent was found in scorbutic guinea pigs as compared with 631.8 mg. percent in normal animals. It is concluded, therefore, that this great deficiency of cephalins with unsaturated fatty acid side chains as activators of blood coagulation is responsible for the persistent bleeding in scorbutic guinea pigs.

**The retention of calcium by the rat in the presence and in the absence of vitamin C**, K. M. HENRY and S. K. KON (*Biochem. Jour.*, 33 (1939), No. 10, pp. 1652-1654).—A basal diet, low in calcium (0.1561 percent), adequate in phosphorus (0.2413 percent), and devoid of vitamin C, was fed for 5 weeks to paired groups of young male rats, the one group receiving the basal diet and the other the basal diet plus a daily supplement of 2 mg. of ascorbic acid per rat. The calcium was mainly derived from  $\text{CaHPO}_4 \cdot 2\text{H}_2\text{O}$ . The food intakes of paired groups were equalized.

Data on weight gains and on calcium and phosphorus balances show that both groups grew at the same rate and consumed 5.8 mg. of calcium and 10.5 mg. of phosphorus per gram of gain in weight. Calcium retentions amounted to 91.95 and 92.31 percent for the control and vitamin C groups, respectively; phosphorus retentions amounted to 44.25 and 42.98 percent, respectively. The differences were not statistically significant, and the findings, confirmed by carcass analyses, show no effect from the ascorbic acid on the retention of calcium with the type of diet used.

**Effects of vitamin C deficiency and diphtheria toxin on cellular blood constituents of guinea pig**, A. SIGAL (*Soc. Expt. Biol. and Med. Proc.*, 42 (1939), No. 1, pp. 163-167).—During studies of the effects of vitamin C depletion (*E. S. R.*, 78, p. 136) and diphtheria toxin injections on glucose tolerance in guinea pigs, the author, with the assistance of S. Bailey, investigated the parallel changes in cellular blood constituents.

<sup>1</sup> *Jour. Biochem.*, 30 (1939), No. 1, pp. 147-153.

The development of scurvy in the guinea pigs was accompanied by a decrease in hemoglobin and erythrocytes and a slight increase in leucocytes. Animals receiving 3 mg. of ascorbic acid daily and given subcutaneous injections of diphtheria toxin showed a moderate reduction in hemoglobin and erythrocytes and a moderate increase in leucocytes. With 0.5 mg. or no ascorbic acid and the same injections of toxin, the changes in blood constituents were more marked, and the differential counts showed an increase in polymorphonuclear leucocytes, a decrease in lymphocytes, and the presence of many nucleated red cells and abnormal cell forms. The animals receiving higher doses of ascorbic acid were able to withstand the effects of the toxin to a greater degree. It is thought, however, that the increased protection afforded by the higher vitamin intake is due to the general physiological benefits of a better state of nutrition rather than to a direct chemical inactivation of the toxin by the vitamin.

**The biological vitamin D assay of low-potency materials with special reference to the role of the mineral content of the diet,** N. T. GRIDGEMAN, H. LEES, and H. WILKINSON (*Biochem. Jour.*, 33 (1939), No. 5, pp. 645-654, fig. 1).—In order to determine the best method of assaying the low-potency butters and margarines, a study was made of the effect, if any, of large quantities of dietary fat on the vitamin D therapy of rat rickets. In the studies described rats made rachitic by a 16- to 18-day period on a standard rachitogenic diet were dosed with equal quantities of vitamin D (0.5 International Unit per day) in conjunction with various levels of the standard rachitogenic salt mixture and in some cases with large quantities of fat. The salt mixture was composed of calcium carbonate 75 percent, sodium chloride 15, magnesium sulfate 7.5, ferric citrate 2.4, and potassium iodide 0.1 percent. Since phosphorus was furnished by the meat meal and the corn in the diet, any variation in the proportion of salt mixture affected the calcium:phosphorus ratios.

It was found that the presence of excess fat in the diet influenced the degree of calcification produced by the vitamin D only indirectly by lowering the consumption of salts. The healing produced by the vitamin D, as measured by the line test, was found to be inversely proportional to the intake of the salt mixture. A very low intake of the salt mixture through effecting a more favorable Ca:P ratio produced healing in the absence of vitamin D. For the experimental conditions described it was considered, therefore, that low-potency butters could be accurately tested only by equalization of the salt mixture intakes of the standard rats receiving the test substance.

**Effect of A. T. 10 (dihydotachysterol) on various types of experimental rickets in rats,** A. T. SHOHL, C. H. FAN, and S. FARBER (*Soc. Expt. Biol. and Med. Proc.*, 42 (1939), No. 2, pp. 529-534).—Rats on a high calcium-low phosphorus diet (Ca:P ratio of 4.0:1) failed to receive protection against rickets even when the daily A. T. 10 supplement amounted to as much as  $\frac{1}{8}$  m. l. d., and the gains in weight were far less than those of normal controls. Rats on a low calcium-high phosphorus diet (Ca:P ratio of 0.05:1) receiving doses of  $\frac{1}{800}$ ,  $\frac{1}{80}$ , and  $\frac{1}{8}$  m. l. d. in various groups showed progressively less rickets as the dose was increased and those receiving  $\frac{1}{8}$  m. l. d. showed absence of rickets. On this diet, the A. T. 10, like cod-liver oil, caused gains in weight. Administered as a curative supplement to rats that had developed rickets on the low calcium-high phosphorus diet, the A. T. 10 at the level of  $\frac{1}{8}$  m. l. d. daily caused healing to be far advanced in 7 days. The data presented show, however, that the effects of the A. T. 10 in the dosages used can be interpreted only by a study of the bone histology, since the roentgenograms, blood serum, and bone ash show but slight changes as compared with

negative controls maintained on the rachitic diet without supplement. This is in contrast with the animals, particularly those on the high calcium-low phosphorus diet, receiving cod-liver oil supplements (9 units of vitamin D daily), in which deposition of minerals was marked. The results indicate that A. T. 10 and vitamin D affect calcium and phosphorus metabolism to a different degree, and that the A. T. 10 is more effective in preventing rickets induced by the low calcium-high phosphorus diet because it facilitates the elimination of phosphate in the urine and hence renders this type of diet less rachitogenic.

**Effect of choleic acid of vitamin K on prothrombin levels of bile fistula rats,** E. T. COHN and C. L. A. SCHMIDT. (Univ. Calif.). (*Soc. Expt. Biol. and Med. Proc.*, 41 (1939), No. 2, pp. 443, 444).—The oral administration of the choleic acid of vitamin K to bile fistula rats in doses of 10–20 mg. per 100 gm. was found to produce an increase in the prothrombin value. At these doses, however, the prothrombin levels were still below normal.

**The hemoglobin synthesizing value of egg yolk** (*Kentucky Sta. Rpt.* 1939, pt. 1, p. 24).—In preliminary studies with several groups of children with subnormal hemoglobin and red blood cell count, it was found that the addition of  $\frac{1}{2}$  pt. of milk to the diet per day effected a definite improvement in hemoglobin and cell count, although only a subnormal plateau of hemoglobin was reached. Apparently, therefore, other deficiencies [notably protein] besides iron were present in the diets. Experiments are now in progress to determine the effect of adding egg yolk to the daily diet of the children lowest in hemoglobin in the groups examined.

**Valine and isovaleric acid show positive influence upon hemoglobin production in anemia due to blood loss,** F. S. ROBSCHET-ROBBINS and G. H. WHIPPLE (*Soc. Expt. Biol. and Med. Proc.*, 41 (1939), No. 2, pp. 361–363).—In continuation of earlier studies on the effect of natural and synthetic amino acids on hemoglobin regeneration in dogs (E. S. R., 78, p. 574), the authors have demonstrated that the anemic dog can use valine, in both the naturally occurring form and its optical isomer, and at times the related fatty acid, isovaleric acid, in building new hemoglobin. It is suggested that occasional failures to utilize the specific amino acid are due to the unavailability at that particular time of one or more of the many supplements, which must be derived from the food intake, or body stores, or protein catabolism.

**Effect of fluorine on solubility of enamel and dentin,** J. F. VOLKER (*Soc. Expt. Biol. and Med. Proc.*, 42 (1939), No. 3, pp. 725–727, fig. 1).—To determine whether fluorine is able to combine with the mineral substance of teeth as it does with bone and calcium phosphate, for example, human enamel and dentin, powdered to pass a 100-mesh screen and separated and purified by centrifugal flotation, were each suspended in 500-mg. amounts in 250-cc. portions of sodium fluoride solutions and shaken for 1 hr. The recovered samples, thoroughly washed, were compared with untreated control samples as to the weight losses sustained by 50-mg. portions after 1 hr. in 20 cc. of a 0.2 M acetic acid-sodium acetate buffer at pH 4.0. "Of enamel samples washed with 1:25, 1:100, 1:1,000, and 1:10,000 sodium fluoride solutions, averages of 13.2, 14.1, 15.6, and 18.5 mg., respectively, dissolved as compared with an average of 27.3 mg. for untreated samples. Normal dentin and dentin treated with 1:1,000 sodium fluoride lost 36.1 and 26.0 mg., respectively." Confirmatory figures were obtained in other tests using decalcification periods of different lengths. Five- to 10-min. applications of the fluoride reduced the solubility almost as effectively as the 1-hr. treatment. The diminished solubility of the enamel was not affected by washing in water or saliva for periods up to 70 hr. The natural surfaces of whole teeth treated with sodium fluoride were much less affected by acid

than those of untreated teeth. These observations indicate that fluorine reacts with tooth substance to produce a less soluble product.

**Xylose as a cataractogenic agent**, W. J. DARBY and P. L. DAY. (Univ. Ark.). (*Soc. Expt. Biol. and Med. Proc.*, 41 (1939), No. 2, pp. 507, 508).—In this preliminary report it is announced that xylose in 35 percent concentration has been found as effective as galactose in producing in young rats the type of cataract attributed by Mitchell and associates (E. S. R., 78, p. 571) to galactose. "It is suggested that the cataractogenic activity of sugars may be dependent upon certain molecular configurations."

## TEXTILES AND CLOTHING

**Structure of the rayon fibre**, H. MARK (*Nature [London]*, 144 (1939), No. 3642, pp. 313, 314, figs. 9).—A series of 9 illustrations representing decreasing magnifications is presented to convey a picture of the structure of the rayon fiber. The first of these depicts the molecular configuration of the fundamental chemical unit, the glucose molecule; the second, the crystallographic unit of the fiber, namely the elementary cell of the cellulose lattice, as revealed by X-ray investigations; the third, the micellar structure, showing that the fiber is differentiated into crystallographic and amorphous parts; and fourth, the fringe and net structure of the cellulose. These 4 pictures represent theoretical magnifications of 50,000,000 down to 50,000. At a magnification of 5,000, the utmost limit of normal microscopic resolving power, the picture shows the fibrillar structure of the fiber in which the morphological units are visible. The next pictures at magnifications of 500 (the maximum under normal light) and 50 show the viscose rayon thread; and the last 2 pictures, with a magnification of 5 and 1, respectively, show the familiar aspect of an artificial silk yarn. The significance of the various structural units depicted is discussed briefly.

**Viscose rayon: Stress-strain properties.—I, Effect of specimen length**, H. R. BELLINSON (*Textile Res.*, 10 (1940), No. 7, pp. 287-297, figs. 3).—This report is the first in an investigation of the effects of testing conditions on the load-stretch properties of viscose rayon.

The apparatus, an inclined-plane testing machine, is illustrated by a diagram and described. The tests were performed on viscose rayon yarn 150/42, and 48 specimens, representing 12 taken at random from each of 4 skeins, were tested at 5, 10, 15, and 20 in. for average breaking strength and percentage of stretch. Averages of 274.32 gm., 271.02, 270.77, and 271.49 gm. were reported for those four lengths and the percentage stretch as 24.31, 23.45, 22.83, and 22.51.

The decrease in breaking strength with longer length is explained by the fact that the number of weak points in a yarn will increase as the test length is increased; and as the number of weak points increases the probability that a very weak place will be present also increases. As a result the longer specimens may break at a lesser load, and the breaking strength of long specimens will be less than that of shorter ones. Increase in length was found to produce an apparent decrease in the percentage breaking strength. This is probably the result of a jaw effect in that some extension of the portion of the yarn gripped by the jaws may occur.

**Compare glass curtain fabrics** (*Ohio Sta. Bul.* 600 (1939), p. 59).—This progress report of a study of the selection and care of cotton and rayon glass curtain fabrics lists those being studied and the laboratory tests used.

**Comparison of the accuracy of two methods of estimating fineness of wool fibers**, R. W. PHILLIPS, R. G. SCHOTT, J. I. HARDY, and H. W. WOLF. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 60 (1940), No. 5, pp. 343-349, fig. 1).—

In comparing the accuracy of two methods for estimating diameters of wool fibers (E. S. R., 83, p. 141), in method A diameters of cross sections of 100 wool samples, after projection to 1,000 diameters, were estimated by comparing with a standard set of known diameters enlarged to the same magnitude, while in method B diameters of wool fibers from the same 100 samples were estimated by comparing with a standard set of wool samples of known diameters. By method A, 45 of 100 samples were placed correctly, based on the average scores for judges, and only 4 deviated as much as 2 classes from the actual measurements. By method B only 13 samples were placed correctly, and 6 samples deviated 4 classes from the classes in which they were placed by direct measurements. Judges tended to underestimate diameter by method A and to overestimate by method B. Analysis of variance showed that 82.3 percent of the variance in scores obtained by method A was due to differences among wool samples, and only 70.7 percent in method B. Intra-class correlations between scores of samples on different days, between scores of the same judge on different days, and between scores of the same sample by different judges were all highly significant for both methods. Indications were that use of method A results in estimates of fiber diameters nearer the actual measurements, and that this method is more desirable than method B in all types of work in which detection of small differences in fiber size is essential.

**The provision and use of household textiles by farm families, M. E. FRAYSER** (*South Carolina Sta. Rpt. 1939, pp. 24-26*).—A brief summary of the results of a study previously noted as in progress (E. S. R., 81, p. 155).

## MISCELLANEOUS

**Report of the Hawaii Agricultural Experiment Station, 1939, [J. H. BEAUMONT ET AL.]** (*Hawaii Sta. Rpt. 1939, pp. 89, figs. 13*).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

**Fifty-second Annual Report [of Kentucky Station], 1939, I, II, T. P. COOPER ET AL.** (*Kentucky Sta. Rpt. 1939, pts. 1, pp. 63; 2, pp. [2]+393+4, figs. 82*).—Part 1 includes the report of the director, the experimental work not previously noted being for the most part abstracted elsewhere in this issue. Part 2 contains reprints of Bulletins 389-397 and Circular 50, previously noted.

**Annual Report of [Nevada Station], 1939, S. B. DOTEN ET AL.** (*Nevada Sta. Rpt. 1939, pp. 46, figs. 5*).—Following a discussion of station policy, experimental work for the most part noted elsewhere in this issue is briefly described.

**Progress of agricultural research in Ohio: Fifty-seventh Annual Report of [Ohio Station], 1938, E. SECREST** (*Ohio Sta. Bul. 600 (1939), pp. 90, figs. 34*).—The experimental work reported not previously referred to is for the most part noted elsewhere in this issue.

**Fifty-second Annual Report of the South Carolina Experiment Station, [1939], H. P. COOPER ET AL.** (*South Carolina Sta. Rpt. 1939, pp. 199, figs. 30*).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

**Fifty-first Annual Report [of Tennessee Station], 1938, [C. A. MOOERS ET AL.]** (*Tennessee Sta. Rpt. 1938, pp. 94, figs. 18*).—The experimental work reported is for the most part noted elsewhere in this issue.

**Forty-ninth Annual Report of [Wyoming Station, 1939], J. A. HILL** (*Wyoming Sta. Rpt. 1939, pp. 47*).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

## NOTES

---

**Colorado College and Station.**—The resignations are noted of Dr. C. Guinn Barr, associate in botany; Carl H. Metzger, associate in horticulture, to assume charge of a potato improvement program in Kern County, Calif.; Drs. Frank Thorpe, Jr., and Herbert W. Reuszer as associates in pathology and bacteriology; and J. Karl Lee as assistant professor and assistant in economics. Recent appointments include Dr. M. E. Paddick as assistant in botany; Dr. J. G. McLean as associate in horticulture; Dr. Hilton A. Smith as associate professor of pathology; and Dr. Thomas D. Kroner as assistant bacteriologist.

**North Carolina College and Station.**—Robert M. Salter, associate director and chief in agronomy of the Ohio Station and chairman of the department of agronomy at Ohio State University, has been appointed director of the station, effective October 1. Dr. L. D. Bayer, associate in agronomy in the Ohio Station and professor of agronomy in Ohio State University, has been appointed associate director. Dr. C. Horace Hamilton, head of the section of community organization and in charge of the section of community organization and change of the U. S. D. A. Bureau of Agricultural Economics, has been appointed head of the department of rural sociology, which was separated on September 16 from the department of agricultural economics.

**Ohio State University.**—Chester O. Reed, associate in agricultural engineering in the station since 1922 and professor of agricultural engineering in the university, died June 11 at the age of 54 years.

**South Dakota College and Station.**—Dr. G. L. Brown, dean of the faculty and acting president for the past year, as well as on several other occasions, has been appointed president following the retirement of President C. W. Pugsley because of illness. Drs. L. D. Hiner, pharmacologist, and R. L. Woolbert, assistant professor of sociology and assistant sociologist, have resigned and have been succeeded by Dr. Raymond P. Ahlquist and Walter L. Slocum, respectively. Other appointments include Dr. W. F. Buchholtz as plant pathologist, Dr. Harlan D. Anderson as associate agricultural economist, Guilford C. Gross as pharmaceutical chemist, and Alvin E. Coons and Gerald E. Korzan as assistant economists.

**Texas Station.**—C. H. McDowell, joint superintendent for the station and the U. S. D. A. Soil Conservation Service of the Blackland Substation, has been appointed vice director and agronomist of the station, effective September 1, vice Dr. Paul C. Mangelsdorf, resigned to become professor of economic botany and assistant director of the Botanical Museum of Harvard University. H. O. Hill, project supervisor of the Soil Conservation Service at the Blackland Substation, has been appointed joint superintendent. Byron C. Langley, agronomist in soil and water conservation investigations at the Spur Substation, has been appointed superintendent of the substation (No. 20) recently established at Stephenville to serve the West Cross Timbers region of the State.

**Virginia Polytechnic Institute and Station.**—Ten buildings constructed or remodeled during the past 2 years with P. W. A. and W. P. A. aid were dedicated on July 30. Among them were two units of the agricultural building, an agricultural engineering laboratory, and a home economics building.

A ninth substation was authorized by the 1940 legislature, which appropriated \$6,460 for the purchase of land and the construction of buildings and \$3,900 per annum for the current biennium for maintenance. This substation is designed to study forage and other farm crops in northern Virginia. A tract of 43 acres near Orange has been selected as its site.

Edmund C. Magill, associated with the institution since 1918 and professor of agricultural education since 1924, died June 20 at the age of 50 years.

Appointments effective July 1 included Dr. H. M. Love as agricultural economist and the following assistants: E. H. Glass, entomology; J. B. Elrod, agricultural engineering; L. I. Miller, plant pathology; and C. E. Addy, biology. Mary S. Ehehart, associate home economist, has been transferred to the instruction staff for full-time teaching.

**Necrology.**—Hon. David F. Houston, Secretary of Agriculture from 1913 to 1920, died in New York City September 2 at the age of 74 years. A native of North Carolina and a graduate of the University of South Carolina in 1887, he received the M. S. degree from Harvard University in 1892 and later honorary degrees from several institutions. He was president of the Texas College from 1902 to 1905, the University of Texas from 1905 to 1908, and chancellor of Washington University of St. Louis from 1908 to 1913. His service with the Department of Agriculture covered the World War period. He was widely recognized as an authority on financial matters, serving as chairman of the Federal Reserve Board and the Federal Farm Loan Board, as Secretary of the Treasury from 1920 to 1921, and subsequently with several large corporations with headquarters in New York City.

Dr. Lee Cleveland Corbett, prominently associated with the horticultural work of the U. S. Department of Agriculture from 1901 till his retirement as principal horticulturist in 1938, died July 13 at the age of 72 years. A native of New York and a graduate of Cornell University in 1890, he received the M. S. degree from the same institution in 1896 and an honorary degree of doctor of agriculture from the University of Maryland in 1921. Dr. Corbett was assistant horticulturist at the Cornell Station from 1891 to 1893, professor of horticulture and forestry at the South Dakota College in 1893-95 and the West Virginia University in 1895-1901, and horticulturist in the respective stations. While with the Department he developed the Arlington (Va.) Farm for experimental purposes, served as administrative head of the horticultural work of the Bureau of Plant Industry for many years and as Assistant Chief of the Bureau from 1913 to 1915, and for the decade beginning with 1928 was engaged mainly in research into the causes leading to the development of horticultural industries in particular areas and their subsequent history. Besides numerous station and Department bulletins and articles, he was the author of *Garden Farming* (1913) and *Intensive Agriculture* (1913).

Nils Andreas Olsen, Chief of the U. S. D. A. Bureau of Agricultural Economics from 1928 to his resignation in 1935, died in Bronxville, N. Y., on July 28 at the age of 53 years. A native of Illinois and a graduate of Luther College, Iowa, in 1907, he received A. M. degrees from the University of Wisconsin in 1909 and from Harvard University in 1912. He was instructor in history and economics at Muhlenberg College in 1909-10 and assistant in history at Harvard University in 1910-12; from 1912 to 1919 he managed several farms. Entering the Department of Agriculture in 1919 as an assistant agricultural economist, Mr. Olsen became Assistant Chief of the Bureau in 1925 and Chief 3 years later. A tribute by ex-Secretary Wallace states that he was "one of the strong leaders who made the Bureau of Agricultural Economics the outstanding research institution which it is today."

VOL. 83

NOVEMBER 1940

No. 5

## THE DEPARTMENT OF AGRICULTURE APPROPRIATION ACT, 1941

In 1891, the year for which the *Record* began its analysis of the annual appropriation acts for the support of the Department, the total appropriations were \$3,028,153.80. For the fiscal year ended June 30, 1941, the appropriations and reappropriations thus far provided aggregate \$1,220,239,732.

The latest act was signed by President Franklin D. Roosevelt on June 25, 1940, and became effective on July 1. As in 1939, it was immediately modified by reorganization changes affecting the Department, notably the transfer of the Weather Bureau and the Food and Drug Administration to the Commerce Department and the Federal Security Agency, respectively, under the terms of the President's Reorganization Plan No. IV. The total amount transferred from the Department to other agencies was \$11,372,221.

Supplementary legislation in other acts also became effective, and the sum eventually available to the Department as at present constituted through the act itself will be \$907,264,838 as compared with \$1,030,698,141 for the fiscal year 1940. Reappropriations have brought \$67,946,161 additional, deficiency acts \$20,537,000, the so-called permanent appropriations \$107,447,024, the Emergency Relief Act \$108,992,084, and trust funds, service charges, and flood control grants transferred from the War Department \$8,052,625. In addition, Reconstruction Finance Corporation loans up to \$100,000,000 for rural electrification, \$125,000,000 for rural rehabilitation, and \$50,000,000 for tenant purchases will be available in connection with Department programs for which funds for similar loans were included in the Department's total appropriation last year. When these recoverable items are taken into account, the aggregate for 1941 becomes \$1,495,239,732. This is an increase of \$716,076 over the comparable total for 1940.

The action programs of the Department account for \$1,116,853,822 of its total funds. One of the largest items in the new act is \$458,554,297 (including \$19,997,557 reappropriated) for the agricultural conservation program as authorized by the Agricultural Adjustment

Act of 1938. The corresponding figure for 1940 was \$559,556,740. Other large items of appropriation and reappropriation are \$212,000,000 for parity payments to producers of wheat, cotton, corn, rice, and tobacco; \$235,924,611 for the disposal of surplus commodities, an increase of \$30,247,047; and \$47,975,000 for payments and administration under the Sugar Act of 1937. The Farm Credit Administration is granted \$41,344,394, a decrease from \$48,420,029, which is due largely to the fact that a direct appropriation of \$15,000,000 for emergency crop and feed loans was not repeated. For administrative expenses the Rural Electrification Administration receives \$3,650,425, an increase from \$2,698,425, and the Commodity Credit Corporation \$2,000,000. Under the Water Facilities Act of 1937, \$500,000 is again available.

The Special Research Fund of the Department under the Bankhead-Jones Act (E. S. R., 73, p. 289) is again maintained at the \$1,400,000 level. The four regional research laboratories (E. S. R., 80, p. 289) authorized by the Agricultural Adjustment Act of 1938 were limited to not to exceed \$3,000,000, a reduction of \$200,000 from the previous year. It is estimated that the funds available for laboratory operation and research will approximate \$1,600,000. It is expected that all the laboratories will be completed by the beginning of the calendar year 1941 at a cost of about \$5,700,000 for construction and \$1,775,000 for equipment.

Under the Office of Experiment Stations a total of \$7,107,235 is granted, of which \$6,862,500 represents payments to the States, Hawaii, Alaska, and Puerto Rico for agricultural experiment stations. This is an increase of \$13,750 in the payments to Hawaii, Alaska, and Puerto Rico. For the administrative expenses of the Office, a total of \$189,735 (including an allotment of \$28,000 from the Special Research Fund) will again be available, as will also be the sum of \$83,000 for the maintenance of the Federal Experiment Station in Puerto Rico.

The funds administered by the Extension Service are decreased from \$19,320,549 to \$19,288,083. The amount available for payments to the States and Territories in the fiscal year 1941 is \$13,796,918 (plus the permanent Smith-Lever Act appropriations of \$4,701,165), which provides a net increase over 1940 of \$27,500 in the funds for Alaska and Puerto Rico. The allotment for administration and coordination of extension work is diminished from \$586,416 to \$550,000, and that for extension information from \$263,550 to \$240,000.

A decrease from \$16,663,712 to \$12,449,340 in direct appropriations available for the Bureau of Animal Industry is largely attributable to a reduction in the direct appropriation for eradicating tuberculosis and Bang's disease from \$8,300,000 to \$4,300,000; in those for eradicating cattle ticks from \$475,000 to \$325,000; in hog cholera control from

\$122,000 to \$112,728; and for inspection and quarantine work from \$680,000 to \$603,500. These reductions reflect the progress being made in overcoming the major animal diseases. On the other hand, the allotment for animal husbandry investigations is increased from \$802,880 to \$824,380 to develop, in cooperation with the Forest Service, the raising of beef cattle, primarily for local consumption, in the Southeastern States cutover regions.

The total for the Bureau of Plant Industry carried by the act shows a reduction from \$5,415,509 to \$5,171,455, but this does not take account of deficiency act appropriations of \$7,000 for continuation of the U. S. Yuma Field Station at Bard, Calif., and \$500,000 for new investigations directed toward the development of rubber production in the Western Hemisphere. The rubber investigations may include production, breeding and disease research, surveys of potential rubber-producing areas, and the establishment and operation of experiment and demonstration stations in suitable locations, and the appropriation is made available to other Government agencies cooperating or assisting. The reductions in the Bureau's funds are divided among 12 of the 24 major subdivisions of its work, with the largest decreases those of \$51,121 for investigations of cereal crops and diseases and \$48,982 for fruit and vegetable crops and diseases. Among the items which continue unchanged is that of \$226,828 for dry-land agriculture studies. There is an increase of \$15,000 for fertilizer investigations, a project transferred to the Bureau from the Bureau of Agricultural Chemistry and Engineering.

The Forest Service is granted a total of \$19,632,955 in addition to \$9,000,000 (a reduction of \$1,000,000) for the construction of forest roads and trails and \$400,000 (a decrease of \$77,898) for cooperative farm forestry. A net reduction from the previous year of \$2,498,431 (leaving out of consideration supplemental appropriations) is a resultant mainly of decreases from \$3,000,000 to \$1,000,000 in the funds for acquisition of lands for national forests, from \$12,002,400 to \$11,500,000 for national forest administration and from \$643,403 to \$605,000 for forest management studies. A new item is the allotment of \$300,000 for clean-up work in connection with the New England hurricane of 1938.

The appropriations for the Bureau of Agricultural Chemistry and Engineering are curtailed from \$1,145,169 to \$905,225. Its funds for agricultural chemical investigations are reduced from \$411,500 to \$379,606, agricultural engineering investigations from \$349,469 to \$304,469 (by the elimination of dust explosion studies), and for studies of the industrial utilization of farm products and byproducts from \$189,600 to \$22,550 in the expectation that most of these investigations will be taken over by the four regional research laboratories.

An increase of \$4,000 is accorded the Bureau for its naval-stores investigations.

The act appropriates \$5,732,917 for the Bureau of Entomology and Plant Quarantine, an apparent reduction from \$6,199,509. There are, however, supplementary appropriations in deficiency acts which provide \$3,300,000 additional for the fiscal years 1940 and 1941 for the control of incipient and emergency outbreaks of insect pests and plant diseases, such as grasshoppers, mormon crickets, and the white-fringed beetle, and \$30,000 additional for Japanese beetle control. The 1941 allotments for most of the Bureau projects are continued unchanged, the chief differences being in those for Dutch elm disease eradication, reduced from \$500,000 to \$400,000; combating of forest insects, reduced from \$253,100 to \$212,500; blister rust control, increased from \$300,000 to \$400,000; and pink bollworm and *Thurberia* weevil control, reduced from \$909,608 to \$526,800.

The Agricultural Marketing Service receives \$6,297,808, a decrease from \$6,347,070. Many of its allotments are modified, the most significant including increases of \$32,500 and \$22,707 for the administration of the U. S. Warehouse and the Federal Seed Acts and reductions of \$22,510 and \$31,470 in the funds for crop and livestock estimates and the marketing of farm products.

The appropriations of the Soil Conservation Service were reduced from \$21,422,374 to \$18,792,540. Of this reduction, \$131,185 is in the allotment for soil and moisture conservation and land-use investigations and \$2,496,599 in that for soil and moisture conservation operations, demonstrations, and information.

The remaining work of the Department is provided for much as at present. The Bureau of Agricultural Economics receives a decrease of \$64,100 in its funds for economic investigations, the Commodity Exchange Administration a decrease of \$48,380, the Bureau of Dairy Industry an increase of \$10,000 for dairy investigations, the Bureau of Home Economics a decrease of \$2,040, the Library a decrease of \$2,970, and the Beltsville Research Center an increase of \$1,620, making their new allotments \$863,900, \$575,000, \$731,305, \$323,045, \$102,000, and \$86,620. The Office of Foreign Agricultural Relations is continued at \$196,396. The Secretary's Office is granted \$826,427, the Office of the Solicitor \$206,355, and the Office of Information \$1,917,994, of which \$1,573,111 (a reduction of \$16,435) is for the printing and binding of the Department.

## RECENT WORK IN AGRICULTURAL SCIENCE

### AGRICULTURAL AND BIOLOGICAL CHEMISTRY

[Chemical investigations at the Florida Station] (*Florida Sta. Rpt. 1939*, pp. 83, 84, 85, 86).—These have included a study of the chemical composition of the ash of Florida fruits and vegetables with reference to the more unusual constituents, by L. W. Gaddum and L. H. Rogers; the development of quantitative spectrographic methods for agricultural research, by Gaddum, Rogers, and R. A. Carrigan; and mineral content of vegetable crops with special reference to iron, by H. W. Winsor.

[Chemical investigations at the Puerto Rico College Station] (*Puerto Rico Col. Sta. Rpt. 1939*, pp. 37-45, figs. 3).—The following topics are dealt with briefly: The Birectifier in rum manufacture, by R. Arroyo, F. Marrero, and L. Igaravidez; radiant energy from bacterial cells new factor in symbiotic phenomena, and the natural rum aroma, both by Arroyo; rum types greatly modified through variations in fermentation technic—creation of new types also possible, by Arroyo, Marrero, and Igaravidez; prospects on the establishment of cellulose industry in Puerto Rico look very favorable, by Arroyo and V. L. Quiñones; studies on the possibilities of industrial utilization of the cocoon, by J. H. Ramírez; and cassava bread, by H. E. Cruz Monclova.

Colorimetric method for determination of barium, H. A. FREDIANI and B. J. BABLER. (*La. State Univ.*). (*Indus. and Engin. Chem., Analyt. Ed.*, 11 (1939), No. 9, pp. 487-489, fig. 1).—Barium may be rapidly determined by precipitating as the chromate, dissolving in hydrochloric or nitric acid, and comparing the resultant solution with a colorimetric standard. In analyzing a solid sample containing barium a sufficient weight of sample should be taken to yield a final solution (for comparison) containing from 0.2 to 1 mg. of barium per cubic centimeter of solution. Though such filters were not available for accurate trial, it is believed that the use of green and blue filters may extend these limits. For the lower concentrations, heights of 30 mm. in the colorimeter yield most consistent results, while for the higher concentrations heights of 15 and 20 mm. are recommended.

The presence of strontium ion leads to erroneously high results. Its effect may be obviated, as in the gravimetric method, by careful double precipitation. The presence of sodium, potassium, calcium, and magnesium ions in equivalent amounts does not affect the determination of barium. The concentration of acid used to effect solution is not critical.

A study of gluten protein fractionation from sodium salicylate solution, II-IV. (N. Dak. Expt. Sta.). (*Cereal Chem.*, 15 (1938), No. 1, pp. 80-90; 16 (1939), Nos. 1, pp. 78-88; 2, pp. 279-289).—These three papers cover further applications of the sodium salicylate dispersion method as used by the author in the first contribution of this series (*E. S. R.*, 78, p. 441).

II. *Bread wheat gluten fractionation*, R. H. Harris.—A series of 30 samples of flour experimentally milled to a 70-percent extraction from hard red spring

wheat was analyzed for crude flour protein, ash, moisture, and wet crude gluten content. The gluten nitrogen was determined and the protein in the gluten computed. The flours were also baked by the standard A. A. C. C. method using 5 percent of sucrose. The glutens washed from the flours were then dispersed in 10 percent sodium salicylate solution, and fractionated by successive additions of 3, 8, and 10 cc. of magnesium sulfate solution. The first fraction was highly correlated with loaf volume. The remaining two fractions had little relationship with flour strength. Crude flour protein was not related to loaf volume, but the percentage of wet crude gluten and gluten protein were positively correlated with this variable. The same relationship was also apparent between total protein removed by magnesium sulfate and loaf volume. A smaller correlation coefficient between loaf volume and the total quantity of protein dispersed by sodium salicylate solution was found. The proportion of total protein removed from the salicylate dispersion appeared to vary with the solubility of the gluten in the dispersion medium. The first magnesium sulfate precipitate gave more information with respect to loaf volume than did wet crude gluten content.

A comparison between hard red spring and durum wheats showed the crude protein content of wheat and flour to be higher for the durums. The durum as a class had a smaller quantity of protein in the first fraction. This difference was less for fraction 2, and in the final fraction the hard red spring varieties had less protein precipitated. Both total protein removed and protein solubility are lower in durum wheat than in the hard red spring varieties. In similar work on 6 flours milled from a sample of hard red spring wheat to approach as closely as feasible to commercial millstreams the first protein fraction isolated appeared to vary among the different flours, the sample baking into the best loaf having the largest quantity of protein precipitated, while the poorest quality flour had the smallest proportion of protein thrown down. The fractions from the other flour samples varied between the 2 limit values. The 6 flours described appeared to approach quite closely to corresponding commercial samples in their chemical characteristics.

III. *The effect of proteolytic enzymes*, R. H. Harris.—Proteolytic enzymes added to dough may profoundly affect the relative distribution of the gluten protein fractionated from the washed-gluten dispersion of such doughs. Marked dissimilarities among different enzymes are shown. Papain, malt diastase, and takadiastase show evidences of a disruptive action upon the gluten complex, causing the formation of smaller protein particles in the dispersion, with consequent shifts in the quantities of protein contained in the various fractions. Flour proteases, when activated by glutathione in concentrations present in the yeast water used in this work, appear to coagulate rather than disperse the gluten complex. Pancreatin may have a similar effect when present in moderate quantities.

IV. *Effect of proteolytic enzymes, as influenced by class of wheat*, R. H. Harris and J. Johnson, Jr.—Four flours milled from hard red spring, hard red winter, soft red winter, and durum wheat were analyzed for ash, total protein, and dry crude gluten and were mixed into doughs in the customary manner, with the exception that appropriate concentrations of papain, pancreatin, and yeast water were incorporated in the dough mix in all except the control doughs. The gluten was washed from these doughs immediately after mixing, and the percentages of gluten moisture and dry crude gluten were determined. A portion of the wet crude gluten was dispersed in 10 percent sodium salicylate solution, and the final concentration of dispersed gluten protein determined. The dispersed protein was then fractionally precipitated by successive additions of magnesium sulfate solution and the quantity of protein determined in each fraction.

The proteolytic enzymes affected the relative distribution of the protein fractions in different classes of wheat flour in the same general manner. The first fraction was progressively reduced in quantity as the concentration of enzyme increased. The second fraction decreased as the severity of the treatment was increased. The quantity of protein removed in fraction 3 was augmented by this treatment.

The effect of papain and pancreatin upon the proportion of gluten protein contained in fraction 1 differed somewhat among the 4 samples of wheat flour included in this study. Hard red spring wheat gluten when dispersed in sodium salicylate apparently lost the largest quantity of protein from fraction 1 following the addition of substantial quantities of enzyme to the doughs. Hard winter wheat glutes have the least removed, although the soft winter results were quite close to the hard winter. The durum wheat gluten approached closest to the hard red spring in quantity of gluten in this fraction.

**Effects of low topping and diastatic malt extract on composition and quality of sorgo sirup,** C. F. WALTON, JR., E. K. VENTRE, and S. BYALL. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 60 (1940), No. 6, pp. 427-432).—Sirups made from whole and from topped stalks of eight varieties of sorgo and from tops alone were compared with sirups made by modifications of this procedure, special attention being given to the use of starch-hydrolyzing enzymes. The topped stalks consistently produced sirup of better quality than the whole stalks, which, in turn, gave better sirup than did the tops alone.

Relatively little improvement in quality resulted from simply allowing the semisirup to settle, without malt-extract treatment, before completing the evaporation. All sirups produced by the process in which malt extract of high-diastatic power was used were of better color, flavor, and clarity than the sirups made from corresponding parts of the stalk by the standard procedure. The sirups of the highest quality were produced by using starch-hydrolyzing enzymes to supplement suitable topping.

**Soybean amylase.—I, The concentration and characterization of soybean amylase,** J. M. NEWTON and N. M. NAYLOR. (Iowa State Col.). (*Cereal Chem.*, 16 (1939), No. 1, pp. 71-78, fig. 1).—Methods for determining the saccharogenic power of soybeans and soybean-amylase concentrates and for preparing amylase concentrates from soybeans are given. The analytical methods are shown to be adaptable to the same determination in other seeds. The amylase content of soybeans was found to decrease slightly during germination. Characterization by various methods indicated that the concentrates contain principally  $\beta$ -amylase.

**Dextrose in the preserving industry,** E. H. WIEGAND. (Oreg. State Col.). (*Canner*, 90 (1940), Nos. 10, pp. 12, 13, 18; 11, pp. 26, 27, 32).—Advantages in commercial canning practice gained by using dextrose in place of a part of the sucrose are pointed out, together with the fact that crystallized dextrose of high purity and uniformity of properties is now available for commercial processes.

**Tartar emetic on leaf and fruit surfaces: Distributional and semi-quantitative analysis, using an iodine-starch paper,** D. STAER. (U. S. D. A.). (*Indus. and Engin. Chem., Analyt. Ed.*, 11 (1939), No. 9, pp. 519-521, figs. 2).—The iodine-starch paper used was dark blue or brown, and the reaction with tartar emetic reduced the iodine and whitened the paper. A semiquantitative estimation of the tartar emetic was made possible by preparing, as a standard of comparison, small slips of paper containing a known quantity of tartar emetic on the surface. The tartar emetic paper and the citrus leaves were tested with the same iodine-starch paper, and by roughly integrating and comparing the whitened area due to the standard with that due to the unknown the approximate quantities of tartar emetic on the citrus leaves were obtained. The test may

also be used for roughly estimating tartar emetic residues on citrus fruit surfaces. The test was found sensitive to 0.9  $\mu\text{g}$ . per square centimeter. Substances that reduce iodine interfered with the test. Some other interfering substances are noted.

**Determination of small amounts of copper in spray residues, D. E. H. FREAR.** (Pa. Expt. Sta.). (*Indus. and Engin. Chem., Analyt. Ed.*, 11 (1939), No. 9, pp. 494, 495, fig. 1).—Two methods for rapid determination of copper on surfaces sprayed with insecticide or fungicide mixtures are presented. The first, for quantities greater than 2 mg., is a modification of the usual procedure of weighing the metal directly after electrodeposition. The second, for smaller quantities of copper, is based on the photoelectric measurement of the color produced by sodium diethyl dithiocarbamate.

**The organic acids of rhubarb (*Rheum hybridum*).—III, The behavior of the organic acids during culture of excised leaves, G. W. PUCHER, A. J. WAKEMAN, and H. B. VICKERY.** (Conn. [New Haven] Expt. Sta. et al.). (*Jour. Biol. Chem.*, 126 (1938), No. 1, pp. 43-54).—A further extension of this study (E. S. R., 78, p. 748) has shown that the organic acids of rhubarb leaves diminish during water culture in darkness, and evidence is presented that the change is due to respiration of a large part of the malic acid in the petiole. Water culture in light brings about a temporary increase in the organic acids in the petiole, which is shown to be due to an increase in malic acid. Culture in glucose solution in darkness brings about a similar but more prolonged and even more extensive change, and the evidence is clear that the newly formed malic acid arises directly or indirectly from the carbohydrate.

The organic acid metabolism of rhubarb leaves differs fundamentally from that of tobacco leaves during culture under similar conditions, and the behavior of the malic acid in both differs from its behavior in succulent plants. Accordingly, generalizations upon the chemical relationships of malic acid in green leaves are difficult. Neither citric nor oxalic acid appears to be extensively involved in the chemical changes of the organic acids of excised rhubarb leaves during culture, and the acids of the so-called unknown group were likewise but little involved. No evidence was found to link any of these acids with protein metabolism.

**The distribution of uncombined hexosamine in pineapple plants supplied either with ammonium sulfate or calcium nitrate salts, C. P. SIDERIS, H. Y. YOUNG, and B. H. KRAUSS.** (Hawaii. Pineapple Prod. Expt. Sta.). (*Jour. Biol. Chem.*, 126 (1938), No. 1, pp. 233-239).—Possible interference by glycine and lysine in hexosamine determinations was indicated. A modification limiting the time to 20 min. between heating and reading the color value in a Pulfrich photometer was necessary because it was found that with longer time intervals reducing sugars (2 mg. per cubic centimeter) interfered with the accuracy of the method.

Hexosamine was present in considerably greater quantities in the advanced and mature leaves of plants supplied with ammonium sulfate than in those of plants supplied with calcium nitrate. In the active and young leaves of both lots of plants the hexosamine contents were approximately the same.

**Silicotungstic acid determination of nicotine: Errors involved and a new technique for steam-distillation of nicotine, A. W. AVENS and G. W. PEARCE.** (N. Y. State Expt. Sta.). (*Indus. and Engin. Chem., Analyt. Ed.*, 11 (1939), No. 9, pp. 505-508, fig. 1).—The authors show that, although variations in solubility of nicotine silicotungstate with changes in acid concentration of the precipitating medium are insignificant for any but microdeterminations, there is a retention of silicotungstic acid by the filter paper such that when a highly

refined determination of the absolute amount of nicotine in a given material is desired, it becomes essential to estimate and correct for this error. Low results may also be obtained in the determination of nicotine, because the solubility of nicotine silicotungstate varies directly with temperature. For best results one should allow the nicotine silicotungstate precipitate to stand overnight at 0°-10° C. before filtering. Better crystallization is effected if the mixture is placed on the steam bath for a short time before holding at the lower temperature. The main revision of the method, however, consisted in the device of a new and less cumbersome distillation apparatus and distillation technic, reducing the volume required to be distilled from 1,000 or 1,500 cc. to about 100 cc. A steam pressure of 456-608 kg. per square meter throughout the run is specified. The new apparatus not only proved to be timesaving but seemed to give more consistent results.

**Estimation of gossypol in crude cottonseed oil**, F. H. SMITH and J. O. HALVERSON. (N. C. Expt. Sta.). (*Indus. and Engin. Chem., Analyt. Ed.*, 11 (1939), No. 9, p. 475).—The assumption that, in precipitating dianilinogossypol with aniline with the aid of pyridine, pure dianilinogossypol can be obtained is stated to be invalid, the gossypol complex crystallizing out with 2 molecules of pyridine to 1 of the complex. The pyridine could be driven off by heating to constant weight, a process requiring from 18 to 24 hours' heating at 110° C. The time needed depended on the quantity of precipitate. Attempts to weigh the dipyridine compound were not accurate because of loss of a part of the pyridine in washing and drying the precipitate.

**Hemicelluloses from cottonseed hulls**, E. ANDERSON, J. HECHTMAN, and M. SEELEY. (Univ. Ariz. et al.). (*Jour. Biol. Chem.*, 126 (1938), No. 1, pp. 175-179).—The authors obtained perfectly white hemicelluloses from cottonseed hulls. The analyses and specific rotations of these substances are given. They were found to be polyuronides of *d*-glucuronic acid and *d*-xylose in which 1 molecule of the acid is combined with from  $\pm$  10-16 molecules of the sugar.

**Studies in the synthesis of the antirachitic vitamins.**—I, **The synthesis of 3-[2'-methylenecyclohexylidene-1']-propene-1**, N. A. MILAS and W. L. ALDERSON, JR. (*Jour. Amer. Chem. Soc.*, 61 (1939), No. 9, pp. 2534-2537, fig. 1).—A successful synthesis was accomplished for the triene noted. The conjugated system possessed by this triene is identical with that present in all antirachitic vitamins, and represents the least stable portion of the vitamin molecule. The molecular extinction coefficient of this triene is nearly identical with that reported for the antirachitic vitamins.

**Synthetic and natural antihemorrhagic compounds**, H. J. ALMQUIST and A. A. KLOSE. (Univ. Calif.). (*Jour. Amer. Chem. Soc.*, 61 (1939), No. 9, pp. 2557, 2558).—In continuance of the work noted previously (E. S. R., 83, p. 14), assay results are presented on the antihemorrhagic activity of a number of naphthoquinones and related compounds. 2-Methyl-3(?)—phytyl-1,4-naphthoquinone prepared by condensation of 2-methyl-1,4-naphthoquinone with phytol, and purified by repeated molecular distillation, gave analytical results in good agreement with values calculated for the formula  $C_{31}H_{40}O_2$ . The various properties noted for the compound were similar to those noted for vitamin K from alfalfa. When administered orally to vitamin K-deficient chicks 3 weeks old, at a level of 0.2 mg. per chick, the synthetic compound restored blood-clotting power to normal within a few hours. The product, when exposed to an argon light, showed the white fluorescence observed as characteristic of solutions of the vitamin, the purified pigment derived from the vitamin by alkaline hydrolysis, the low temperature distillate from the molecular still (contains no vitamin K), and pure phytol. The 2-methyl-1,4-naphthoquinone did not show this fluorescence.

The constitution and synthesis of vitamin  $K_1$ , S. B. BINKLEY, L. C. CHENEY, W. F. HOLCOMB, R. W. MCKEE, S. A. THAYER, D. W. MACCORQUODALE, and E. A. DOISY (*Jour. Amer. Chem. Soc.*, 61 (1939), No. 9, pp. 2558, 2559).—This communication presents further evidence bearing on the nature of the semicarbazone and the quinone acid noted in the previous communication (*E. S. R.*, 83, p. 15). The nature of the semicarbazone was established by mixed melting point determination with an authentic specimen, and the quinone acid, prepared in sufficient quantity for more satisfactory study, was identified as 2-methyl-1,4-naphthoquinone-3-acetic acid. Further confirmatory experiments here reported are considered to demonstrate conclusively that the structure of vitamin  $K_1$  is correctly represented by the formula 2-methyl-3-phytyl-1,4-naphthoquinone. This structural formula was confirmed by synthesis; the hydroquinone of the vitamin was formed (using the method of Claisen) by reaction of phytyl bromide with a benzene suspension of the monosodium salt of 2-methyl-1,4-naphthohydroquinone. After oxidation by the air to the quinone, the product was purified and then subjected to reductive acetylation. The diacetate formed in this manner and crystallized from methyl alcohol gave analytical values for carbon and hydrogen corresponding to those calculated for the formula  $C_{35}H_{52}O_4$ ; the mixed melting point with an authentic specimen of diacetate from the natural vitamin showed no depression.

Synthetic approach to vitamin  $K_1$ , L. F. FIESER, W. P. CAMPBELL, E. M. FRY, and M. D. GATES, JR. (*Jour. Amer. Chem. Soc.*, 61 (1939), No. 9, p. 2559).—In seeking a method for the introduction of the phytyl group into the 3-position of 2-alkyl-1,4-naphthoquinones, it was found that, with anhydrous oxalic acid in dioxane solution, methylnaphthohydroquinone could be condensed with simple  $\beta$ -unsaturated alcohols and dienes to give considerable amounts of the uncyclized substituted hydroquinones. Several examples of such condensation are cited, including one in which phytol entered into condensation giving viscous oils of the composition of the substituted hydroquinone or of tocopherol. One such preparation upon purification appeared to be the tocopherol. Synthesis by the addition of a Grignard reagent to 2-alkyl-1,4-naphthoquinone oxide did not appear promising.

Synthesis of 2-methyl-3-phytyl-1,4-naphthoquinone, L. F. FIESER (*Jour. Amer. Chem. Soc.*, 61 (1939), No. 9, pp. 2559-2561, fig. 1).—In applying the method noted above, it was found possible to produce a considerable amount of the substituted hydroquinone by using a large excess of methylnaphthohydroquinone to accelerate the bimolecular condensation reaction and by operating at a temperature of 75° [C.] where cyclization is slow. Such a preparation, separated from the unchanged hydroquinone and oxidized in dry ether with silver oxide, gave 2-methyl-3-phytyl-1,4-naphthoquinone as a pure yellow, rather mobile oil, which, upon analysis, gave carbon and hydrogen values in good agreement with those calculated for  $C_{33}H_{46}O_2$ . Trichloroacetic acid was also found to be satisfactory in place of oxalic acid.

The preparation gave the Dam-Karrer test with alcoholic alkali, and an absorption spectrum closely resembling that reported for vitamin  $K_1$  by Dam et al. (*E. S. R.*, 82, p. 441), the positions of the maxima corresponding closely with the values given by Dam et al. and by Doisy et al. (*E. S. R.*, 83, p. 13). The substance subjected to bio-assay (by W. L. Sampson) was found to have marked antihemorrhagic activity, 2 $\gamma$ -4 $\gamma$  of the quinone being equivalent to approximately 75 mg. of alfalfa. Reductive acetylation gave the quinone diacetate, which upon recrystallization from methanol melted at 57°-59°. The corresponding diacetyl derivative of the natural vitamin  $K_1$  was found by Doisy et al. to melt at 59°. A number of reasons are advanced for considering that the phytyl group is probably linked to the terminal carbon atom.

**Identity of synthetic 2-methyl-3-phytyl-1,4-naphthoquinone and vitamin K<sub>1</sub>**, L. F. FIESER (*Jour. Amer. Chem. Soc.*, 61 (1939), No. 9, p. 2561).—The synthetic product, prepared as noted in the above abstract, was compared with the natural vitamin (supplied by B. Riegel) prepared as a highly purified 3–5 percent alfalfa concentrate by the method of Riegel et al. (E. S. R., 83, p. 445). An alcoholic solution of this concentrate was shaken with aqueous hydrosulfite, and the vitamin hydroquinone was taken up in petroleum ether from which it was extracted with Claisen's alkali containing hydrosulfite, and recovered from the resulting yellow liquor by dilution with water and extraction with ether. Upon digestion with ether and centrifugation, a white solid was obtained which, upon oxidation, yielded 60 mg. of K<sub>1</sub> as a yellow oil. This product and the synthetic product were alike in the matter of elementary composition, both gave the characteristic Dam-Karrer color test, their absorption spectra agreed closely, they showed similar antihemorrhagic activity when subjected to bio-assay, and they gave, upon reductive acetylation, diacetates which were apparently identical as judged by determination of the mixed melting point. This latter point was confirmed by Doisy who also found that the synthetic diacetate did not depress the melting point of a purified sample of his diacetate from natural vitamin K<sub>1</sub>.

Ten mg. of the synthetic vitamin given by mouth with 3 gm. of ox bile to a patient with a complete malignant biliary obstruction markedly reduced the clotting time, and given intravenously successfully carried the patient through operation without abnormal bleeding.

In contrast with the synthetic compound of the methyl series, the ethyl compound did not separate from the petroleum ether, and upon bio-assay was found inactive in a fairly high dosage. It is concluded that vitamin K<sub>1</sub> is 2-methyl-3-phytyl-1,4-naphthoquinone.

**Changes of nitrogen content brought about by denaturation of proteins**, B. M. HENDRIX and J. DENNIS (*Jour. Biol. Chem.*, 126 (1938), No. 1, pp. 315–322, figs. 5).—In a further study of protein denaturation (E. S. R., 73, p. 5) it has been shown that denaturation of crystalline egg albumen by alkali, acid, or shaking results in a decrease in its percentage nitrogen. Edestan contains less nitrogen per mole than does edestin. The nitrogen removed from the protein during denaturation is insufficient to account for the observed effects. It is suggested that these effects are explainable by a hydrolysis with direct addition of water to the protein molecule.

**The decomposition of cystine in aqueous solution**, J. I. ROUTH (*Jour. Biol. Chem.*, 126 (1938), No. 1, pp. 147–154).—Cystine was decomposed by boiling with distilled water. From 96.3 to 100.6 percent of the original sulfur could be accounted for in the various fractions. Not all of the sulfur present at the end of the experimental period could be accounted for as cystine, cysteine, hydrogen sulfide, and elementary sulfur. The formation of acid decomposition products was suggested by the progressive decrease in the pH of the solutions as the time of heating was increased. The fact that the total nitrogen content of the cystine solution remained unaltered indicated that no ammonia was liberated from the reaction mixture and presumably no deamination had occurred.

**The fat acids in the lecithin and glyceride fractions of egg yolk**, R. W. RIEMENSCHNEIDER, N. R. ELLIS, and H. W. TITUS. (U. S. D. A.). (*Jour. Biol. Chem.*, 126 (1938), No. 1, pp. 255–263).—Lecithin and glyceride fractions of high purity were prepared from egg yolk, in quantities sufficient to permit a study of the fat acid composition. Palmitic and stearic acids were the only saturated acids identified. Some evidence of small amounts of a lower saturated acid was found in the glyceride fraction. Oleic, linoleic, and clupanodonic acids were found in lecithins and glycerides, and 9,10-hexadecenoic acid was isolated from the glycerides.

**Quantitative studies of carnosine and anserine in mammalian muscle.—**  
**I, A method for the determination of carnosine and anserine; II, The distribution of carnosine and anserine in various muscles of different species,** J. A. ZAPP, JR., and D. W. WILSON (*Jour. Biol. Chem.*, 126 (1938), No. 1, pp. 9-18, 19-27).—In the first paper a method is proposed in which carnosine is determined by a diazo method after mercury precipitation, and anserine is calculated from the increase in  $\alpha$ -amino nitrogen after hydrolysis.

In the second paper quantitative studies of the distribution of carnosine and anserine in various muscles are reported. It is noted that in animals from which carnosine and anserine, or both, have been isolated the amounts found by isolation are roughly proportional to the amounts found by quantitative determination.

**Some characteristics of the androgenic fractions from bull urine,** L. W. BUTZ and S. R. HALL. (U. S. D. A.). (*Jour. Biol. Chem.*, 126 (1938), No. 1, pp. 265-271).—The androgens excreted in the urine by the bull were found to be  $\alpha,\beta$ -unsaturated ketones or substances with very similar properties. Their instability toward alkali "emphasizes again the inadvisability of employing alkaline hydrolysis during the isolation of natural androgens."

**A device to prevent bumping and promote boiling,** S. PALKIN and T. C. CHADWICK. (U. S. D. A.). (*Indus. and Engin. Chem., Analyt. Ed.*, 11 (1939), No. 9, pp. 509, 510, figs. 2).—A test tube of suitable size is modified for this purpose by drawing in the convex end to form a slightly reentrant surface, onto the center of which is sealed a small knob of glass to serve as the point of attachment for the winding of glass thread. The glass-thread winding is run up the outside surface of the tube above the level of the liquid in the distilling flask, and the tube is provided with an internal electric heating coil of asbestos-covered resistance wire immersed in oil. Alternatively, the tube and glass-thread winding may be heated by passing steam into the tube, if the boiling point of the liquid to be distilled is not above about 90° C. The boiling promoter may be inserted into the distilling flask through a stopper or expanded at a suitable point, such that the end will just clear the bottom of the flask, and fitted into the ground joint neck.

**Electric melting point microapparatus,** R. E. DUNBAR. (N. Dak. Agr. Col.). (*Indus. and Engin. Chem., Analyt. Ed.*, 11 (1939), No. 9, pp. 516, 517, figs. 3).—A device which may be used with a hand lens or on the stage of a microscope is described, and its construction is shown in a partially dimensioned drawing. A circular block of aluminum,  $\frac{7}{8}$  in. thick and  $2\frac{1}{2}$  in. in diameter, is provided with a central depression fitted to hold two microscope cover glasses under a heavier and slightly larger circular cover glass concentric with a small central vertical opening drilled through the block for transmitted light from below. The thermometer is inserted horizontally so that its bulb lies close under the cover glasses and a little to one side of the center. The heating element is let into a groove cut around the cylindrical block near its base. The rate of heating is controlled by a rheostat. The projecting part of the thermometer is protected by a metal tube screwed into the block, which is mounted on a transit base provided with a 10-w. bulb under the illuminating opening.

**Vial holder,** J. A. QUENSE and W. M. DEHN (*Indus. and Engin. Chem., Analyt. Ed.*, 11 (1939), No. 9, p. 483, fig. 1).—The device described, made from 13-gage spring brass or from 16-gage coppered steel wire, has jaws of the test-tube holder type, but the handle part of the holder is replaced by a ring of the same wire from 3 to 4 in. or more in diameter under the jaws and concentric with the vial or test tube held in them. The device supports small vials or test

tubes above the surface of a hot plate (the use illustrated) or projecting downward through the ring and into a steam bath. The value of this holder for preventing vials or tubes from upsetting during the process of filtering into them is also pointed out.

**Paints and plasters for rammed earth walls, R. L. PATTY** (*South Dakota Sta. Bul. 336 (1940), pp. 39, figs. 22*).—Cement stuccoes satisfactory for ordinary stucco work were found satisfactory for application to rammed earth walls. The wall should season for several months, however, before stucco is applied, and for walls more than 8 ft. in height bonding wire or mesh should be used, as on frame walls. Two inexpensive plasters which proved quite satisfactory on rammed earth walls were dagga-cement plaster and dagga plaster with an admixture of asphalt emulsion.

Paints on exterior rammed earth walls were generally disappointing. Only a comparatively small number of paint panels proved satisfactory. Good quality lead-oil paints have shown satisfactory results on high-quality walls only, for exterior work. Paints should be tried only after careful study of the paint-panel results and with a thorough knowledge of the soil used in the construction of the wall. Linseed oil and glue sizing proved equally satisfactory for priming coats for lead-oil paints, and possibly fish oil may be equally good. Priming coats that penetrate the wall were found definitely unsatisfactory. No transparent paint has been found satisfactory as yet. Linseed oil did little damage to the wall surface, but showed low durability. Other transparent paints, except some extremely temporary ones, damaged the wall deeply. Most good quality paints were quite successful on interior walls. Cold-water paints, except whitewash, were satisfactory. Common wall plaster was quite successful on interior walls, and nailing the scratch coat to the wall was satisfactory on all panels tried.

It is further noted that "the most valuable and most practical admixture yet tried for rammed earth walls is ordinary sand. It may or may not contain a reasonable amount of coarse aggregate. Some coarse aggregate in the admixture will neither be an advantage nor disadvantage to the weathering quality of the wall nor to the success of the covering. A well-graduated sand and aggregate will increase the strength of the wall, slightly, over an admixture of sand containing uniform-sized particles."

## AGRICULTURAL METEOROLOGY

[**Meteorological work by the Florida Station**] (*Florida Sta. Rpt. 1939, pp. 135-138, 149-151, 173, 174, 175, 181, fig. 1*).—This work included horticultural protection services by the station in cooperation with the U. S. Weather Bureau (forecast and frost warning service, accuracy of forecasts, shippers' bulletin, and research work on critical temperatures, temperature inversion, cost of grove heating, supplemental frost protection, forecasting research, and temperature survey), by E. S. Ellison; meteorological records by the Everglades Substation, with tables and curves, relative to temperatures, rainfall and evaporation, drought effects on soils and crops, and wind velocity and barometric pressure; notes on rainfall, and tables showing precipitation and monthly mean temperature at the North Florida Substation; and drought conditions at the Subtropical Substation.

[**Weather data at the Georgia Coastal Plain Station**] (*Georgia Coastal Plain Sta. Bul. 30 (1939), pp. 14, 15*).—Tabulated data are presented on rainfall in inches by months and years, 1923-38; dates on which the first and last killing frosts occurred and the number of growing days at Tifton, 1923-38; and the temperature by months, 1938.

**Monthly Weather Review [March–April 1940]** (*U. S. Mo. Weather Rev.*, 68 (1940), Nos. 3, pp. 63–94, pls. 14, figs. 12; 4, pp. 95–124, pls. 15, figs. 4).—In addition to the usual detailed summaries of climatological data, solar and aerological observations, observations on weather on the Atlantic and Pacific Oceans and on rivers and floods, and other information, these numbers contain articles on page 591 and the following contributions:

No. 3.—On the Distortion of Stream Fields by Small Heat Sources, by J. J. George (pp. 63–66); and Floods in the Sacramento Valley, February 27–March 6, 1940, by E. H. Fletcher (pp. 71–74).

No. 4.—An Instrument for the Spectroscopic Determination of Precipitable Atmospheric Water Vapor, and Its Calibration, by I. F. Hand (pp. 95–98).

**Climatological data for the United States by sections, [January–December 1939]** (*U. S. Dept. Agr., Weather Bur. Climat. Data*, 26 (1939), Nos. 1–12, [about 200 pp., 2 pls., 8 figs. each]).—These numbers contain the usual brief summaries and detailed tabular statements of climatological data for each State.

**Precipitation and evaporation in New Mexico**, E. L. HARDY, J. C. OVERPECK, and C. P. WILSON. (Coop. U. S. D. A.). (*New Mexico Sta. Bul.* 269 (1939), pp. 68, figs. 41).—While much the larger part of New Mexico is either arid or semi-arid, somewhat below the summits of the highest mountains the average annual precipitation is probably 30 in. or more. It is usually higher on the east and south sides of mountains than at similar elevations on the west and north sides. The average annual precipitation for the State as a whole is 14.43 in. In the dry-farming regions, about three-fourths of the annual precipitation usually occurs during the growing season and a large percentage as brisk showers. Despite the aridity of the climate, however, torrential rains occasionally occur. Snowfall in the mountains, especially in northern New Mexico, furnishes a large percentage of the water used for irrigation. This water carries a comparatively small amount of sediment. Except in mountainous regions, little snow falls in the southern part. Hail occurs in all sections, but the area covered by destructive hailstorms is generally very limited. Of the stations for which records are available throughout the entire year, the highest evaporation, 130.670 in., is at Florida in Luna County, and the lowest, 51.443 in., is at Farmington, in San Juan County. Included are tabulations of normal precipitation by months for all U. S. Weather Bureau stations at which at the close of 1938 such records had been kept for at least 9 yr., average annual and seasonal precipitations and total precipitation for each county, and evaporation data for various sections of the State. An appendix presents detailed precipitation data for State College, N. Mex.

**Hydrologic studies: Compilation of rainfall and run-off from the watersheds of the Missouri Valley Loess Region Conservation Experiment Station, Clarinda, Iowa, 1934–38**, L. H. SCHOENLEBER (*U. S. Dept. Agr., Soil Conserv. Serv.*, 1940, *SCS-TP-31*, pp. [99], pls. 6, figs. 48).—Preceding the presentation of the data (tables and curves) compiled from hydrologic investigations on small watersheds of this region, making up the main body of the report, the author gives the history of the station, histories and descriptions of the watersheds, and discussion of the methods and instruments used.

**Interception of rainfall by prairie grasses, weeds, and certain crop plants**, O. R. CLARK. (*Univ. Nebr.*). (*Ecol. Monog.*, 10 (1940), No. 2, pp. 243–277, figs. 8).—In these studies at Lincoln, Nebr., pans were placed beneath the plants with minimum disturbance of the foliage, and water applied at predetermined rates to simulate rainfall or natural rain which penetrated the plant cover was measured. The percentage of interception was found to vary with intensity of rainfall, density of foliage, and enviroal conditions. Wind

movement and condition of sky proved especially important because of their effects on evaporation. Detailed data are presented for individual plant species under varying intensities and amounts of rainfall. Lowland forbs withheld from the soil nearly half of the water during heavier showers and about two-thirds during the lighter ones. Upland forbs intercepted 20-50 percent or more of the water falling on them, depending on the intensity. Interception by common weeds varied from 34 percent with half-inch rains to nearly 70 percent with eighth-inch showers. Mat-forming weeds held on their leaves and stems 9-50 percent of the water falling during applications of different intensities. The maximum capacity of interception ranged from 47 to 261 gm. of water per square-foot area of living plant materials, while dead plants held 156-446 gm. on similar areas.

Water is held on plants as thin films or as drops forming on the surface, at the tips, or along the margins of leaves. It also adheres to the stems. Extent of leaf surface and number of levels at which water may be held are important in determining interception. Prairie vegetation has a foliage area 3-20 times as great as the soil surface, and leaves are displayed at many levels. In these studies the amount of water reaching the soil by running down the stems was found to be small. Interception by prairie grasses, weeds, and crop plants results in an important loss of water to the soil, and light showers are ineffective in replenishing the soil water. Annual losses of water due to interception, transpiration, and evaporation are as high in certain grasslands as in adjacent forested areas. However, interception by herbaceous plants has an important retarding effect on run-off and indirectly on soil erosion, and grassland is important for the conservation of water through its effect on run-off and percolation as well as in checking evaporation by shading the soil.

**Advantages in the nonuniform hour of observation in the interpretation of published precipitation data, J. R. MILES (*U. S. Mo. Weather Rev.*, 68 (1940), No. 4, pp. 99, 100, figs. 2).**—"By a juxtaposition of the 24-hr. precipitation records of nearby stations of varying times of observation, the maximum probable period of precipitation for a given storm will, in many cases, be considerably shorter than that possible to be determined if all stations took observations at a uniform hour."

**The relation of weather factors to wheat yields on Levan Ridge, Utah, N. E. ZINK (*U. S. Mo. Weather Rev.*, 68 (1940), No. 3, pp. 66-71, figs. 8).**—For the 25 yr. for which data were available, 120 different combinations of weather factors, and yields and dates for planting, emergence, heading, and ripening of wheat were studied for the Levan Ridge, a 24-square-mile area near the center of Utah. Results were especially disappointing for the planting period, commonly considered one of the critical periods. However, the relation of planting period to climatic factors in the fall appears to be obscured by 2 facts, viz, that it is actually soil moisture which is most important, and that the data concerning the period after planting should be treated in 2 groups—one when the wheat emerges in the fall and the other when it fails to emerge before snowfall. In half the years under study it emerged in the fall, and in all but one of these years yields were above average. It was further evident that a large amount of rain did not increase the yields proportionately.

The study emphasized the high importance of spring conditions and especially in the period 2-3 weeks before heading, the date of which varied from June 4 to 30. Correlations between yields and factors of several other periods were also significant. These periods were (1) April 1 to heading, (2) 5-25 days preceding heading, (3) a 5-day period just preceding the last-named

period, and (4) a group of general factors including rainfall from planting to heading, 40 percent of the fallow rain plus the rainfall from planting to ripening, lowest temperatures of April, and average temperature for April, May, and June. The highest correlations were with evaporation, length of drought period, and rainfall. It is because evaporation represents the integration of several other factors, such as temperature, humidity, and wind velocity, that its coefficient of correlation is consistently so high. It was evident that one weather factor is highly correlated with others, that relations between weather factors and yields are not necessarily linear, and that there can be strict proportionality over only a very narrow range of variation. Yields above or near the average seemed to show this proportionality, while very low yields were frequently due to unmeasurable causes, or to a combination of causes. Correlations for plant-growth stages gave somewhat higher coefficients than those obtained by use of seasonal or monthly data.

When the date of planting varies  $1\frac{1}{2}$  mo. and the heading date 1 mo., and when the critical stage of plant growth covers a very short period, the importance of using plant-growth periods rather than calendar months is seen. The graphs presented "show the advantages of using plant growth stages, the lack of relation between rainfall of the harvest year and yield, the closer relationship between extreme temperatures and yield than average temperatures and yield, that early June rain is important, that too heavy rainfall at planting time is not desirable, and that late planting usually lowers yields."

### SOILS—FERTILIZERS

[Soil investigations at the Florida Station] (*Florida Sta. Rpt. 1939, pp. 81-83, 86-91, 142, 143, 155, 156, 169, fig. 1*).—The report contains notes on soil and water conservation; determination of the effect of green manures on the composition of the soil, by F. B. Smith; the occurrence and behavior of less abundant elements in soils, by R. M. Barnette; a study of the so-called quick methods for determining soil fertility, by R. V. Allison and C. E. Bell; soil and vegetation surveys in relation to pasture development in Florida, by J. R. Henderson; types and distribution of micro-organisms in Florida soils, the metabolism and functional relationships of soil micro-organisms, and interrelationships of micro-biological action in soils and cropping systems in Florida, all by Smith; methods of inoculating legumes in Florida soils, by Smith and R. E. Blaser; the effect of type and treatment of Florida soils on the yield and composition of farm crops, by Allison and Bell; effect of type and treatment of Florida soils on the yield and composition of truck, bush, and tree crops (other than citrus), by Allison and H. W. Winsor; effect of type and treatment of Florida soils on yield and composition of citrus fruits, by Allison; classification and mapping of Florida soils according to modern survey methods, by Allison and Henderson (coop. U. S. D. A.); citrus soils investigations, by M. Peech; soil investigations, by J. R. Neller and W. T. Forsee, Jr.; and relation of organic composition of crops to growth and maturity, by Forsee, Jr.

[Soil investigations at the New Jersey Stations] (*New Jersey Stas. Rpt. 1939, pp. 118-125*).—These have included soil testing, elimination of arsenical residues from the soil, influence of minor elements on plant growth, nitrogen availability studies, a comparison of magnesian and nonmagnesian forms of lime, the influence of organic matter on crop yields and on the composition of the soil, influence of potash on the weight of grains and forage crops, the movement of water and soil constituents in the soil profile, base exchange in soils, survey of soil ingredients in the soil profile, humus and soil conserva-

tion, production of organic acids by fungi, a study of the *Actinomyces* population of the soil, and the interrelations between soil micro-organisms and higher plants.

[Soil investigations at the Puerto Rico College Station] (*Puerto Rico Col. Sta. Rpt. 1939*, pp. 75-78).—Subjects reported upon briefly are as follows: Chemical comparison between soils of humid and arid areas, and the nature of laterization as revealed by chemical, physical, and mineralogical studies of a lateritic soil profile from Puerto Rico, both by J. A. Bonnet; and fertilizer and soils studied with Mitscherlich's pot tests, by B. G. Capó.

[Soil Survey Reports, 1933 and 1934 Series] (*U. S. Dept. Agr., Bur. Plant Indus. [Soil Survey Rpts.], Ser. 1933, No. 32, pp. 40, figs. 2, map 1; 1934, No. 19, pp. 45, figs. 3, map 1*).—These surveys were made in cooperation with the Iowa Experiment Station: 1933, No. 32, Davis County, Iowa, C. L. Orrben and G. A. Swenson; and 1934, No. 19, Osceola County, Iowa, C. L. Orrben et al.

The relations of soils and surface in the South Carolina Piedmont, D. H. EARGLE. (*U. S. D. A. (Science, 91 (1940), No. 2362, pp. 337, 338)*).—Examinations of recently exposed gullies largely in Spartanburg County, S. C., revealed deposits of organic matter as much as 12 ft. thick and buried under 20 ft. or more of soil. Most of these deposits were rich in pollen and contained quantities of stem fragments, trunks, stumps, and roots of trees as well as sedges and other herbaceous plants, usually well preserved. Pollen analyses showed an abundance of fir and spruce, indicating a considerably colder climate at the time the deposits were formed. The author states "that the material which overlies the organic deposits has migrated down slope en masse as soil creep, earth flow, and slumping, and perhaps to some extent as sheet wash, cannot be questioned." Previously, most Piedmont soils were thought to have developed from material of residual origin, but the discovery of organic matter underlying many of them and the existence within the soils themselves of the evidence of migration show that they are not everywhere residual. It is pointed out that physiography and land forms should be emphasized in the mapping and interpretation of soil types, and conversely the influence of soil considered in the development of surface configuration.

The identification of minerals in soil colloids, G. NAGELSCHMIDT (*Jour. Agr. Sci. [England], 29 (1939), No. 4, pp. 477-501, figs. 5*).—The X-ray, optical, dehydration, and chemical methods used in the identification of minerals in soil colloids have been studied and their limitations noted, particularly the uncertainty with regard to the variation of physical properties of standard minerals with decreasing grain size and the possible existence and importance of amorphous material. The author points out the advantages of combining various chemical methods with X-ray analysis, gives standard data for several minerals, and reviews the evidence for their occurrence in soil colloids.

Effect of lime on the nitrogen content of cow manure, A. R. MIDGLEY and W. O. MUELLER (*Vermont Sta. Bul. 456 (1940), pp. 20, figs. 6*).—Caustic forms of lime, if mixed with fresh manure, may actually help save nitrogen. The high basicity temporarily retards ammonia production so that less nitrogen is subject to loss by field drying. However, the caustic lime must be added to the cleaned gutter where it comes in direct contact with fresh unammonified manure. As soon as the lime becomes carbonated it loses its excess basicity and is of little or no use. A substantial saving of nitrogen may be effected if the manure is incorporated into the soil before carbonation of the lime is complete. Caustic forms of lime should not be mixed with fermented manure as they readily drive off the ammonia already present. Ground limestone is quite indifferent when applied to fresh manure, and but slightly detrimental when applied to

fermented manure. Ground limestone may be spread with either fresh or fermented manure on the loaded spreader with little loss of nitrogen, since it comes in direct contact with only a small portion of the manure. Plant-growth studies in greenhouse and field plats substantiated these findings.

**Inspection of fertilizers**, W. L. ADAMS, T. WRIGHT, JR., and R. L. SWALLOW (*Rhode Island Sta. Ann. Fert. Cir.*, 1940, pp. 19).—This report on analyses of commercial fertilizers sampled in 1939 notes the acid-forming or non-acid-forming character of each commercial mixture listed and contains a separate tabulation of the magnesium content as the oxide in the 15 fertilizers offering a guaranteed content of this element.

**Decomposition of dolomitic limestone in fertilizers**, E. R. COLLINS and F. R. SPEER. (N. C. Expt. Sta.). (*Jour. Assoc. Off. Agr. Chem.*, 23 (1940), No. 2, pp. 373-388, figs. 7).—Buffer capacity and pH are the major soil factors involved in the decomposition of dolomitic limestone. The most satisfactory index of carbonate decomposition is the determination of the residual carbonates. According to the authors, "calcined, 80-mesh and finer, and composite dolomitic limestones of the quality used in these experiments should supply at least a large part of the magnesium needs of plants."

**Absence of reversion in ammoniated and limed superphosphates of low fluorine content**, W. H. MACINTIRE and L. J. HARDIN. (Tenn. Expt. Sta.). (*Jour. Assoc. Off. Agr. Chem.*, 23 (1940), No. 2, pp. 388-398).—"This paper deals with the effect of ammoniation and of four liming materials upon  $P_2O_5$  availability in standard and triple superphosphates made from starting phosphates of variant fluoride content." In superphosphates derived from starting materials of normal fluoride content processed and aged 1 mo. at 45° C., marked reversion occurred, while none developed in superphosphates processed from phosphates low in fluoride. Those superphosphates having a meager fluoride content can be ammoniated or mixed with ordinary high calcic liming materials without loss of  $P_2O_5$  availability.

**Peat and swamp muck for soil improvement in Connecticut**, M. F. MORGAN (*Connecticut [New Haven] Sta. Cir.* 142 (1940), pp. 85-96).—Estimating on the conservative basis of an average depth of 6 ft., the author finds the muck and peat deposits of Connecticut available for soil improvement use to amount to about 500 million cubic yards. On the basis of prices paid for imported baled peat moss, the value of the State peat deposits would be from \$4 to \$5 per cubic yard, giving swamplands otherwise of very low value a potential production of from 2 to 2.5 billion dollars.

The various types of peat are briefly discussed, and it is noted that the greater part of the Connecticut peats is of the woody type. The value of peat and muck as soil improvement material lies in the ability of such organic matter to increase available water-holding capacity, to improve the tilth of soils either stiff and sticky when wet or hard when dry, or both, and to provide organic matter more stable than that furnished by organic fertilizers or manures. The acidity of most peats is pointed out, and the need for liming soils treated with peats, except for growing of acidophilous plants, is emphasized. The stimulating effect on growth of cuttings observed when peat is added to sand is also noted.

## AGRICULTURAL BOTANY

**Plant material introduced by the Division of Plant Exploration and Introduction, Bureau of Plant Industry, January 1 to March 31, 1936** (*U. S. Dept. Agr., Inventory 126* (1940), pp. 32).—This number lists 801 lots of plant material, with descriptive notes in many cases.

**Advances in botany**, F. E. DENNY (*News Ed. (Amer. Chem. Soc.)*, 18 (1940), No. 2, pp. 59-63, figs. 5).—This is a critical review (46 references) of recent contributions on growth and differentiation; mineral nutrition; grass, milkweed, and fungus studies; and diurnal cycles, synergesis and symbiosis, chimeras, plant disease viruses, plastids, and nitrogen fixation.

**Recent investigations on economic plants**, A. F. HILL (*Chron. Bot.*, 5 (1939), No. 4-6, pp. 372-375).—A brief review.

**The cultivation of plant species from seed to flower and seed in different agar solutions**, G. GENTCHEFF and A. GUSTAFSSON (*Hereditas*, 26 (1940), No. 1-2, pp. 250-256, pl. 1, figs. 4).—The authors describe a method by means of which it is said that plants may be grown in hormonal media during the whole life cycle. It is believed that this type of artificial cultivation will give a normal response of the plant under certain controlled environmental conditions, even if the hormone or salt concentrations are sometimes detrimental to the organism.

**A sterile transfer chamber**, A. F. ROE (*Jour. Bact.*, 39 (1940), No. 5, pp. 589-592, fig. 1).—The chamber described and illustrated is said to permit pouring of plates, inoculating them, examining and picking colonies, and other phases of open technic in a sterile atmosphere. The confined air is sterilized by contact with the free flame of the burner and by a continuous condensation of water-vapor particles against the cooler side walls of the chamber.

**The distribution of self-sterility in the flowering plants**, E. M. EAST (*Amer. Phil. Soc. Proc.*, 82 (1940), No. 4, pp. 449-518).—This question was investigated in over 800 species of flowering plants. Report of its occurrence in the various orders is based on the author's studies and such information as was available in the scattered literature (nearly 4 pages of references). Self-sterility proved to be widespread among the orders, but more so in the more specialized groups and especially in the orders including only or primarily herbaceous plants. A greater incidence among herbaceous forms was to be expected, since these types are derived from the more primitive woody species and self-sterility must be a relatively recent innovation in sexual reproduction. Self-sterility in promoting variation and in perpetuating heterozygosity has apparently played an important role in the evolutionary development of flowering plants.

**The nomenclature of cultivated plants**, A. B. STOUT (*Amer. Jour. Bot.*, 27 (1940), No. 5, pp. 339-347).—Noting that the application and significance of the botanical names of species and varieties should be kept clearly in mind, the author presents the concepts of the species, and of variation and the variety. With reference to cultivated plants, he discusses the production of cultivated varieties or "cultivars" by artificial selection, the utilization of natural processes in artificial selection, and individual and clonal propagation. The rules for nomenclature of cultivated plants are next reviewed, and evaluated, certain defects are pointed out as pertaining to cultivated plants, the whole problem is summarized, and certain recommendations are made.

**Stability in nomenclature**, A. C. SMITH (*Science*, 91 (1940), No. 2372, pp. 572, 573).—A discussion of various proposals for a new series of beginning dates for botanical nomenclature. It is believed that the confusion will be decreased without legislation and indeed is becoming clarified with every careful monograph.

**The new systematics**, edited by J. HUXLEY (*Oxford: Clarendon Press*, 1940, pp. VIII+583, figs. [55]).—The following chapters are of special interest to botany: *Experimental and Synthetic Plant Taxonomy*, by W. B. Turrill (pp. 47-71); *Ecological Aspects of Plant Taxonomy*, by E. J. Salisbury (pp. 329-340); *Taxonomic Problems in Fungi*, by J. Ramsbottom (pp. 411-434); *Taxonomic*

Botany, With Special Reference to the Angiosperms, by T. A. Sprague (pp. 435-454); The Origin and Behaviour of Cultivated Plants, by M. B. Crane (pp. 529-547); and The New Systematics of Cultivated Plants, by N. I. Vavilov (pp. 549-566).

The concept of the genus, I-V, (*Bul. Torrey Bot. Club*, 67 (1940), No. 5 pp. 349-389).—This symposium consisted of the following papers: I, History of the Generic Concept in Botany, by H. H. Bartlett (pp. 349-362); II, A Survey of Modern Opinion, by E. Anderson (pp. 363-369); III, Genera From the Standpoint of Morphology, by J. M. Greenman (pp. 371-374); IV, The Delimitations of Genera From the Conservative Point of View, by E. E. Sherff (pp. 375-380); and V, Our Changing Generic Concepts, by W. H. Camp (pp. 381-389).

Taxonomy and floristics of the Americas, H. N. MOLDENKE (*Chron. Bot.*, 5 (1939), No. 4-6, pp. 367-372).—A brief summary of the work represented in some 450 papers.

Fungi Imperfecti (Deuteromycetes): A guide to the study of the secondary spore forms of fungi, N. F. BUCHWALD (*Fungi Imperfecti (Deuteromycetes): En Vejledning i Studiet af de sekundære Sporeformer hos Svampene. København (Copenhagen): K. Vet. og Landbohøjsk., 1939, pp. [6]+144, [pl. 1]*).—This is a taxonomic monograph of the group, with copious classified bibliography and author and subject indexes.

Fungi of the genera *Fusarium* and *Cylindrosporium* in Indo-China, F. BUGNICOURT (*Les Fusarium et Cylindrocarpon de l'Indochine. Paris: Paul Lechevalier, 1939, pp. [3]+206, pls. 10, figs. 36*).—A monograph on these genera as they occur in Indo-China including new taxonomy. The preface is by A. Guilliermond.

Cultural histories of *Melanconis* and *Pseudovalsa*, IV, L. E. WEHMEYER (*Mycologia*, 32 (1940), No. 3, pp. 321-330, figs. 22).—Continuing this series,<sup>1</sup> *M. juglandis caryae* n. var. on *Carya alba* was found to produce hyaline conidia in *Melanconium*-like pustules. *M. corni* n. sp., from *Cornus florida*, produced four-celled hyaline conidia in locules within loosely compacted stroma. *M. nigrospora* and *M. everhartii* failed to produce conidia but developed perithecia freely in culture.

Ascomycetes from the State of Minas Geraes (Brazil), C. E. CHARDON, J. H. MILLER, and A. S. MULLER (*Mycologia*, 32 (1940), No. 2, pp. 172-204, figs. 37).—The present paper, based almost exclusively on collections by the junior author aggregating ±1,150 numbers deposited in the herbaria of the Escola Superior de Agricultura at Viçosa and of the department of plant pathology at Cornell University, lists 114 species, 21 of which are described as new, in the genera *Meliola*, *Dothichloe*, *Guignardia*, *Ophiodothella*, *Hypoxyylon*, *Penzigia*, *Xylaria*, *Catacauma*, *Phyllachora*, *Coscinopeltis*, and *Ellisiodothis*.

Arizona plants: New species, varieties, and combinations, F. J. HERMANN, T. H. KEARNEY, and R. H. PEBBLES. (U. S. D. A.). (*Jour. Wash. Acad. Sci.*, 30 (1940), No. 5, pp. 217-219).—The genera *Juncus*, *Astragalus*, and *Echinocereus* are represented.

A supplement to the catalogue of Iowa plants in the Iowa State College herbarium, A. HAYDEN. (Iowa Expt. Sta.). (*Iowa State Col. Jour. Sci.*, 14 (1940), No. 2, pp. 199-213).—This supplements the annotated list of R. I. Cratty.<sup>2</sup>

Annotated list of the plants of Kansas: Ferns and flowering plants, F. C. GATES (*Kansas Sta.*, 1940, pp. 266, figs. 82).—Introductory to the list, the author discusses the history of floristic work in the State, location and area, physiographic regions, drainage, topographic divisions, climate, geology, general

<sup>1</sup> Mich. Acad. Sci., Arts, and Letters, Papers, 23 (1937), pp. 233-242, pls. 3.

<sup>2</sup> Iowa State Col. Jour. Sci., 7 (1933), No. 3, pp. 177-252.

considerations on the flora, ecological classification, native and artificial habitats, growth forms, various lists of plants, and statistics of the Kansas flora. Maps indicate the local distribution of individual species, and an index is provided for the list, which is arranged by taxonomic groupings.

**Flora of the Patuxent Research Refuge, Maryland, N. HOTCHKISS (U. S. Dept. Int., Bur. Biol. Survey, Wildlife Leaflet BS-154 (1940), pp. [2]+34, fig. 1).**—In this area, wildlife problems relating to the production of agricultural crops and to forestry are to receive careful study. This check list is the first of a number of reports that will deal with the natural history of this research refuge. It includes a description of the refuge, its location and size, topography and water supply, geology and soils, and a general description of the vegetation.

**Notes on plants of New Mexico, II, A. L. HERSHEY. (N. Mex. Col. Agr.). (Leaflets West. Bot., 2 (1940), No. 15, pp. 257, 258).**—Notes on plant collections in the Guadalupe Mountains of southern New Mexico.

**Miscellaneous new American grasses, J. R. SWALLEN. (U. S. D. A.). (Jour. Wash. Acad. Sci., 30 (1940), No. 5, pp. 209-217, figs. 4).**—Descriptions are given of 12 new species in the genera *Chusquea*, *Poa*, *Stipa*, *Digitaria*, *Mesosetum*, and *Panicum*, 4 of them from the United States.

**The botany and history of *Zizania aquatica* L. ("wild rice"), C. E. CHAMBLISS. (U. S. D. A.). (Jour. Wash. Acad. Sci., 30 (1940), No. 5, pp. 185-205, figs. 6).**

**[Plant physiological work by the New Jersey Stations] (New Jersey Stat. Rpt. 1939, pp. 100-106).**—Reports of progress are presented relative to preliminary studies on the effect of aeration on plant growth, the relation between the calcium content of plants and the boron concentration of the nutrient substrate, influence of the level of the boron supply on nitrogen and carbohydrate metabolism in young cotton plants, relation of the pH value of the culture solution to the availability of boron for the growth of radish plants, and the availability of potassium in bentonite clay materials for the growth of tomato plants.

**Elements of plant physiology, P. BOYSEN JENSEN (Die Elemente der Pflanzenphysiologie. Jena: Gustav Fischer, 1939, pp. XX+458, figs. 162).**—This textbook is a somewhat enlarged translation by F. Mattick of the Danish text published in 1938.

**The transverse reactions of plants: Outlines of a new interpretation of the significance of growth hormones for life-processes in plants, G. BORGSTRÖM (Lund: C. W. K. Gleerup, [1939], pp. 230, figs. 58; Ger., Russ. abs., pp. 195-200).**—According to the author, the discussions in this book are based partly on his experiments of the last 2 yr., but largely on a vast amount of work by other scientists (over 26 pages of references). Attention is called to the fundamental significance of transverse distribution of hormones in nature, the relative strength of their polar and lateral passage regulating most processes in plants.

**Investigations of the thermolabile growth-factor-oxidizing substance in *Phaseolus* seedlings [trans. title], P. LARSEN (Planta, Arch. Wiss. Bot., 30 (1940), No. 4, pp. 673-682, figs. 3).**—From this study, the growth-factor-inactivating action of the expressed sap of etiolated *Phaseolus* epicotyls is characterized as follows: It is a thermolabile substance precipitable by alcohol-ether, the inactivation does not take place instantaneously but depends on the duration of the action, and the inactivation of auxin cannot take place without oxygen. It is thus concluded that the auxin-inactivating factor is an oxidation enzyme.

**B.: Its use as a growth regulating substance for green plants, J. W. SHIVE (New Jersey Stat. Cir. 399 (1940), pp. 7).**—The author brings together briefly such information as is now available in the scientific literature about

the use of vitamin B<sub>1</sub> as a growth stimulant in plant production, and summarizes the authoritative experimental evidence relating to its practical value for general plant culture.

**Ascorbic acid (vitamin C) in fungous extracts**, R. W. LEWIS. (Mich. State Col.). (*Mich. Acad. Sci., Arts, and Letters, Papers*, 24 (1938), pt. 1, pp. 31-35).—Using *Cephalothecium roseum*, *Citromyces (Penicillium) ramosus*, *Aspergillus* spp., and *Poecilomyces* sp., it was found that they produce relatively large amounts of ascorbic acid when grown on either a synthetic or a nonsynthetic medium. The amounts varied with the kind and age of the fungus colony. Most of the ascorbic acid was intracellular, but there was for each species a relatively constant amount present in the fluid substrate, regardless of age of culture. The intracellular ascorbic acid varied with age of culture, but from species to species was not constant in its variation.

**Colchicine-induced tetraploidy in Lilium**, S. L. EMSWELLER and P. BRIERLEY. (U. S. D. A.). (*Jour. Hered.*, 31 (1940), No. 5, pp. 223-230, figs. 5).—Treated stem apices of *L. formosanum* produced bulblets, most of which were tetraploids. The tetraploids produced on one plant were all slightly fertile, but only 1 of 9 produced on another was fertile. Tetraploid flowers varied in size but averaged  $\pm 25$  percent larger than diploid flowers. From selfing the induced tetraploids, 606 seedlings were secured, and 7 of the original 22 tetraploids were increased by scaling.

**Variation of cystoamylase in potato due to different conditions of growing**, A. I. GRECHUSHNIKOV (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser.*, 25 (1939), No. 8, pp. 688-690).—The amount of cystoamylase (cytoamylase?) in the potato was found to vary with growing conditions, decreasing when the day length is curtailed to 8 hr. and increasing under potassium fertilization. On the other hand, the amount decreased in response to nitrogen and phosphorus, though varietal differences in this respect were noted.

**The role of potassium in plants.—III, Nitrogen and carbohydrate metabolism in potassium-deficient plants supplied with either nitrate or ammonium nitrogen**, M. E. WALL. (N. J. Expt. Stas.). (*Soil Sci.*, 49 (1940), No. 5, pp. 393-408, pl. 1, fig. 1).—In further studies (*E. S. R.*, 83, p. 174), young Rutgers tomato seedlings were grown in nutrient solutions containing nitrate and ammonium N, with and without K, and harvested weekly or biweekly for a 2-mo. period. The nitrate plants grew better than the corresponding NH<sub>4</sub> plants. The K-deficient plants grown with nitrate gradually developed typical deficiency symptoms, whereas the K-deficient plants with NH<sub>4</sub> suddenly exhibited leaf break-down symptoms totally unlike those in the nitrate plants. From chemical evidence, this rapid break-down was due to the toxic effect of high internal NH<sub>4</sub> concentrations. The K-deficient plants of both series accumulated NH<sub>3</sub>, amide, and amino N, while the protein concentration decreased. Simultaneously the plants showed an initial carbohydrate accumulation which finally decreased, becoming less than in plants supplied with complete K. It seemed that protein synthesis from an elaborated form of N was affected by K deficiency, which would account satisfactorily for the increased NH<sub>3</sub>, amide, and amino N concentrations, for the decrease in protein, and for the initial accumulation of carbohydrates in K-deficient plants. The analytical data strongly suggested that the N metabolism is affected by K deficiency prior to the carbohydrate metabolism. The final drop in carbohydrate content of K-deficient plants may be due to a direct need for K in CO<sub>2</sub> assimilation or to the indirect effects on protoplasm brought about by the interference with the N metabolism in K-deficient plants.

**X-ray diffraction analysis and its application to the study of plant constituents**, W. A. Sisson (*Chron. Bot.*, 5 (1939), No. 4-6, pp. 344, 345).—A review and general discussion of the subject.

**The importance of minor elements in vegetable crop production, R. H. WHITE-STEVENS.** (Cornell Univ.). (*Veg. Growers Assoc. Amer. Ann. Rpt.*, 1939, pp. 146-174, pls. 5).—This is a general discussion of the subject, with specific reference to deficiencies in Mg, N, P, K, B, Ca, Al, Cu, Fe, Mn, Zn, and their interrelationships. The effects of a deficiency in the first five elements noted above are illustrated in color, and the minor element deficiencies commonly found in vegetable crop production, their symptoms, and general control methods are tabulated.

**Minute amounts of chemical elements in relation to plant growth, D. R. HOAGLAND.** (Univ. Calif.). (*Science*, 91 (1940), No. 2372, pp. 557-560).—An analytical review, with bibliographic footnotes, including reference to the soil and plant interrelations in their bearing on problems of animal nutrition.

**Aluminum in plants** [trans. title], J. BABIČKA (*Chron. Bot.*, 5 (1939), No. 4-6, pp. 336-338).—A review.

**Copper as a trace element** [trans. title], B. RADEMACHER (*Chron. Bot.*, 5 (1939), No. 4-6, pp. 338, 339).—The author briefly summarizes data on copper as a trace element, in contrast to its stimulative and toxic effects.

**Astragalus artemisiarum Jones as a selenium absorber, H. W. LAKIN and F. J. HERMANN.** (U. S. D. A.). (*Amer. Jour. Bot.*, 27 (1940), No. 4, pp. 245, 246).—Collections of this plant at six locations in Nevada yielded 35-970 p. p. m. of Se, although the soils were of relatively low content. The results of these analyses are tabulated and discussed, along with the value of the seleniferous habit in the systematic grouping of plants.

**On the relationship of selenium to sulfur and nitrogen deposition in cereals, E. P. PAINTER and K. W. FRANKE.** (S. Dak. and N. Dak. Expt. Stas. and Univ. Minn.). (*Amer. Jour. Bot.*, 27 (1940), No. 5, pp. 336-339).—A number of proteins were isolated from cereal plants and the Se, S, and N contents determined and compared with analyses on the whole cereal. For comparison the results are calculated as molar S:Se and N:Se ratios. Although there was evidence indicating that metabolism of Se by plants is similar to that of S, the metabolism of these elements is not identical because a seleniferous plant with a high sulfate content contained no selenate, and the S:Se ratios of different parts of the same plant were not always constant. Deposition of Se in cereal proteins followed that of S in most cases, but there were a few wide variations in the S:Se ratios. These may have been due to a greater cleavage of S than of Se by the reagent used in separating the proteins. The deposition of Se in cereal proteins apparently follows the deposition of S more closely than that of N.

**Translocation in plants, A. S. CRAFTS.** (Univ. Calif.). (*Chron. Bot.*, 5 (1939), No. 4-6, pp. 340, 341).—A review (with references) of recent work bearing on the mechanism of translocation.

**Studies of the transpiration stream in the leaves of *Secale cereale* and *Triticum vulgare*** [trans. title], S. STRUGGER (*Ztschr. Bot.*, 35 (1940), No. 3-4, pp. 97-113, pls. 2).—The author critically analyzed the method of dye ascent, using a macroscopic optical fluorescence procedure for measuring the rate of the vascular components of the transpiration stream in the veins of thin leaves. Measurements in the wheat leaf indicated that the rate of water movement in the veins depends largely on the stomatal openings. The method described is said to be especially suited to class demonstrations. With berberine sulfate as indicator, the extra-vascular components of the transpiration stream were also followed, it being found that numerous small partial streams are led through the palisade cell walls into the epidermis and up to the transpiring surface of the cereal leaf. These observations further demonstrate the applicability of the Sachs imbibition theory to the parenchyma. In the graminaceous leaf the stomata react particularly well to the berberine test. The presence of especially

large submicroscopic pores was also demonstrated. Since the upper surface of the leaf especially is wettable only with difficulty, it frequently happens that on placing in a sugar-KCNS-gelatin solution only the tips of the surface hairs become immersed in the absorbing solution. Though at the beginning of the sugar-gelatin test the membranes of the leaf hairs have become stained at their bases only through free transpiration, it is observed that later a shifting of the berberine sulfate within the membranes has taken place so that the stain finally reaches the tips of the membrane hairs. This is taken to be further proof of the permeability of the membrane system. The relations of the free transpiration stream have thus been reproduced by a locally acting absorption effect. Other dyes tested produced similar results in microtopographical distribution. The 2-phase Primulin O is also split up in the cereal leaf into its two components. The yellow fluorescent coarse disperse component remains in the conductive elements, whereas the fine disperse blue fluorescing phase spreads into the submicroscopic conductive routes of the parenchyma membranes. There are 16 references.

**Causes of decreased absorption of water by plants in poorly aerated media**, P. J. KRAMER (*Amer. Jour. Bot.*, 27 (1940), No. 4, pp. 216-220, fig. 1).—Exposing sunflower and tomato roots to high concentrations of CO<sub>2</sub> for 1-2 hr. reduced transpiration 34-52 percent, exudation from detopped root systems 63-74 percent, and water movement through root systems attached to a vacuum pump 35-56 percent. Bubbling O<sub>2</sub>-free nitrogen through the water around the roots reduced transpiration in tomato only  $\pm 8$  percent, exudation from detopped root systems of sunflower  $\pm 9$  percent, and water intake through sunflower and tomato root systems attached to a vacuum pump 1-13 percent. Aeration with laboratory air failed to affect exudation the first hour, but materially increased it the second. The small decreases in water intake in the presence of N are believed to result from O<sub>2</sub> deficiency. If this is true, it appears that an excess of CO<sub>2</sub> reduces absorption much sooner than a deficiency of O<sub>2</sub>. Active absorption never exceeded 5 percent of the amount lost by transpiration. The effect of high CO<sub>2</sub> concentrations in decreasing active absorption is, therefore, much too small to explain the reduced absorption found in intact, transpiring plants. It is believed that the rapid reduction in water intake induced by high concentrations of CO<sub>2</sub> results largely from decreased passive absorption caused by physical changes in the protoplasm and protoplasmic membranes. These changes decrease the permeability of the protoplasm and increase the resistance to water movements across the cortex from epidermis to xylem.

**Bibliography on cold resistance in plants** (*Cambridge, Eng.: Imp. Bur. Plant Breeding and Genet.*, 1939, pp. [2]+22).—The bibliography covers the general subject as well as specific crop plants, and an author index is provided.

**The mechanism of injury and death by low temperature**, B. J. LUYET and P. M. GEHENIO (*Biodynamica*, No. 60 (1940), pp. 33-99, figs. 2).—A review, with over three pages of references.

**A contribution to the question of cold injuries to plants at temperatures above the freezing point** [trans. title], D. SEIBLE (*Beitr. Biol. Pflanz.*, 26 (1939), No. 3, pp. 289-330, figs. 7).—Of the plants studied, *Episcia*, *Achimenes*, and *Gloxinia* exhibited after some hours, and at most after a day, the formation of spots traceable to the death of the plasma and infiltration of the intercellular spaces. On the contrary, *Tradescantia*, *Solanum*, and *Coleus*, which are resistant, remained constantly and fully turgid after a day's exposure, but after 5-6 days they suddenly softened and wilted. As a rule the older leaves changed first, the injury advancing toward the growing point. Plants exposed to the cold only at night proved resistant. Rises in osmotic

values were demonstrated by water loss from the leaves, and in *Coleus* the development of osmotically active substances was shown by determining the threshold of plasmolysis. The content of the expressed sap in sugar, organic and inorganic salts, soluble nitrogen, ammonia, and organic acids was investigated before and after cold treatment, and it was concluded that if there is any direct influence of osmotic values, it must lie in the total salts. The proportion of protein N to soluble N was shifted in favor of the latter, and the process was checked in the heat-retaining dark plants. Thus cold injury cannot be ascribed to such change. A change in plasma permeability was proved for *Coleus*. Potassium nitrate penetrated into the cooled plants more rapidly than into the controls. The previously lighted cold-room plants behaved like those held in the dark.

**The oxygen consumption of isolated woody tissues**, R. H. GOODWIN and D. R. GODDARD (*Amer. Jour. Bot.*, 27 (1940), No. 4, pp. 234-237, figs. 3).—Thin sections were cut from the trunks of ash and maple trees and their O<sub>2</sub> consumption was measured. In those collected before bud break the O<sub>2</sub> consumption was most rapid in the cambial region, while values for adjacent secondary phloem and xylem were somewhat lower. In the xylem the O<sub>2</sub> consumption became progressively lower in passing toward the center of the tree. In the heartwood there was a very low basal rate of O<sub>2</sub> consumption which was not destroyed by boiling. This is believed due to slow oxidation of organic compounds in the dead cells. Phloem and sapwood exhibited similar oxidations of comparable magnitude after boiling. After bud break the O<sub>2</sub> consumption of the cambium, phloem, and heartwood of ash was essentially the same as before, but in the newly formed, differentiating xylem it appeared to exceed considerably the cambial rate. The relations described remained essentially the same whether O<sub>2</sub> consumption was expressed per gram of wet weight or per milligram of nitrogen.

**Effect of algae in relation to aeration, light, and sources of phosphorus on growth of tobacco in solution cultures**, H. B. ENGLE and J. E. McMURTBREY, JR. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 60 (1940), No. 7, pp. 487-502, figs. 5).—Connecticut Broadleaf tobacco showed marked growth responses in complete nutrient solutions to the aerating effect of common green algae (principally *Protococcus viridis angulosa* and *Ulothrix parietina*). Using combinations of darkened solutions, those exposed to light, three sources of P, and with roots previously disinfected with AgNO<sub>3</sub> (1:1,000) or not disinfected, greatest total growth occurred in darkened solutions aerated with compressed air. The beneficial effect of aeration by algae was most marked in the earlier growth stages, especially without previous disinfection. Average increases in dry weight over unaerated plants in darkened solutions were 82 percent for those aerated by green algae and 92 percent for those by compressed air. Algal growth was not correlated with pH. Ratios of leaf weight to total plant weight were somewhat greater with darkened, artificially aerated solutions than with those aerated by algae. The P from di- and tricalcium phosphate produced growth of tobacco plants in aerated solutions equal to that obtained from monocalcium phosphate, possibly because the roots were more nearly in direct contact with the material. The blue-green alga *Nostoc muscorum*, in a parallel test without added N was unable to fix sufficient atmospheric N significantly to increase the growth of tobacco in the nutrient solutions used.

**Leaf xanthophylls**, H. H. STRAIN (*Chron. Bot.*, 5 (1939), No. 4-6, pp. 339, 340, pl. 1).—A brief statement of present knowledge on the chemistry and functions of the leaf xanthophylls.

**The structure of the chloroplast and the location of the chlorophyll,** E. A. ROBERTS (*Bul. Torrey Bot. Club*, 67 (1940), No. 6, pp. 535-541, figs. 11).—The photomicrographs presented in this preliminary paper show some of the results of a 10-years' series of investigations. The early studies were made on young sporophytes and gametophytes of some 25 species of native ferns. Later, representatives of the Thallophyta, Bryophyta, and Spermatophyta were investigated. The chloroplasts of all the plants studied were found to be made up of units for which the term "plastidules" is proposed. The latter are composed of globular bodies, here called "plastid granules." It is possible to separate the plastidules into their respective plastid granules. The chlorophyll occurs in the colloidal substance of each plastid granule, and the greenness of each chloroplast represents the sum of the color contributed by the chlorophyll of each plastid granule.

**The mechanism of photosynthesis in green plants,** K. WOHL (*New Phytol.*, 39 (1940), No. 1, pp. 33-64, figs. 4).—A comprehensive, critical review (93 references) dealing almost entirely with the consideration of assimilation in a steady state and under conditions of CO<sub>2</sub> excess.

**Studies on the induction period of photosynthesis and light respiration in green algae,** H. GAFFRON (*Amer. Jour. Bot.*, 27 (1940), No. 4, pp. 204-216, figs. 2).—Using pure cultures of *Scenedesmus* and *Chlorella*, the course of photosynthesis was studied during the induction period in plants first subjected for some hours to darkness and anaerobiosis. On illumination in the absence of oxygen, photosynthesis started immediately and at an abnormally high and quickly varying rate. These changes in rate were accompanied by very significant divergencies of the assimilatory quotient from the supposedly constant value of unity. These measurements are taken as proof of the existence of oxidation reactions inside the assimilatory mechanism. Production of 1 molecule of O<sub>2</sub> in photosynthesis would be the result of reduction of 1 molecule of CO<sub>2</sub> only if no such reaction was interfering. The rapid interception of the O<sub>2</sub> of photosynthesis by reducing substances appears to depend on a special "reduced" state in the assimilatory mechanism. Another kind of light or photo-oxidation occurs in the chloroplast at high light intensities in the presence of free O<sub>2</sub>. Here molecular O<sub>2</sub>—instead of, or in addition to, the "photoperoxides"—is consumed in oxidation reactions, which again differ from the normal dark respiration. It remains to be seen whether or not the consumption of photoperoxides and the absorption of molecular O<sub>2</sub> in the light are caused by the same catalytic mechanism.

There are 25 references.

**Carbon dioxide reduction with molecular hydrogen in green algae,** H. GAFFRON (*Amer. Jour. Bot.*, 27 (1940), No. 5, pp. 273-283, figs. 3).—Oxygen and CO<sub>2</sub> are the only gases participating in large amounts in the metabolism of green plants. It has now been found that the algae *Scenedesmus* and *Rhaphidium* can activate and utilize molecular H, normally inert for all plants. Incubated in H for a few hours in the dark, these algae absorb it in connection with several metabolic processes, and reduce metabolites as well as O<sub>2</sub> provided the latter is given in low concentrations. Even more important seems the reduction of CO<sub>2</sub> with H in the light. The photosynthetic quotient, —H<sub>2</sub>/—CO<sub>2</sub>, is 2, as in the purple bacteria, and this similarity is said to be more than superficial. The studies reported show that the hydrogenase system in *Scenedesmus* reacts directly with the intermediate photoperoxides of photosynthesis, no O<sub>2</sub> being liberated. The rate of CO<sub>2</sub> reduction with H was proportional to the light intensity and at constant intensity, with both reactants in excess, the reaction proceeded at a constant rate, but if the light exceeded a certain limit H absorption stopped, and after a few minutes normal photo-

synthesis came into full activity with  $O_2$  production. Apparently a formation of surplus intermediate photoperoxides brings the system from a reduced into an oxidized state. In this aerobic state the splitting of photoperoxides leading to  $O_2$  liberation is the preferred reaction. There are 27 references.

**The synthesis of sucrose by excised blades of sugar cane: Time and temperature**, C. E. HARTT (*Hawaii. Planters' Rec. [Hawaii Sugar Planters' Sta.]*, 44 (1940), No. 2, pp. 89-116, figs. 9).—Evidence for sucrose synthesis by sugarcane leaf blades from simple sugars has been previously noted (E. S. R., 77, p. 462). Continuing the investigation, it is here reported that supplying the blades with both glucose and fructose hastens and increases sucrose formation in darkness, as compared with supplying only one of the simple sugars. Detached blades continued to form sucrose from glucose for nearly 2 weeks, reaching over 16 percent cane sugar on the dry weight basis. Temperature affected the absorption of simple sugar, the interconversion of glucose and fructose, and the formation of sucrose. Absorption of simple sugar was much the same at 6° and at 20° C., but was considerably increased at 20°-40°. The interconversion of glucose and fructose failed to occur at 6°, it kept pace with sucrose formation at 20°, and at 30°-40° it was increased. The optimum temperature for sucrose formation proved to be 30°. The temperature coefficients obtained suggest that absorption at 6°-20° is a purely physical process, but at 20°-40° absorption was limited by a chemical reaction. However, sucrose synthesis was limited by a chemical reaction at the lower but by a physical process at the higher temperatures. The evidence is believed to indicate that the simple sugars are fleeting intermediates in the leaf and that cane sugar is a storage product.

**Photoperiodism in the plant kingdom**, R. O. WHYTE and M. A. OLSHOVNIKOV (*Chron. Bot.*, 5 (1939), No. 4-6, pp. 327-331).—This is a critical review (with 29 references) and discussion of the present status of the subject.

**Yellowing and dying of leaves in soya as related to daylength**, G. M. PSAREV (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser.*, 25 (1939), No. 8, pp. 679-682).—The author reports that in soybean plants under short days aging and yellowing of the leaves are delayed, but that there are varietal differences in this response which may be useful in selection for breeding purposes.

**The protein and fat problem in German agricultural-chemical investigation** [trans. title], K. SCHMALFUSS (*Chron. Bot.*, 5 (1939), No. 4-6, pp. 378, 379).—A brief review of data on protein and oil formation as influenced by plant nutrition.

**A phytosociological study of an evergreen oak forest in the vicinity of New Orleans, Louisiana**, W. T. PENFOUND and J. A. HOWARD (*Amer. Midland Nat.*, 23 (1940), No. 1, pp. 165-174, figs. 5).—Evergreen oak forest is characteristic of alluvial ridges in this area. The forest studied was young (50 yr.), the crown cover  $\pm 55$  percent, and the basal area 96 sq. ft. The dominant trees averaged 69 ft. in height and 15 in. in diameter. Water oak (*Quercus nigra*) and live oak (*Q. virginiana*) were the dominant trees. Distinctive characteristics of the forest were the widespread live oaks with their mantle of Spanish moss, a shrub layer in which dwarf palmetto (*Sabal louisiana*) was the only common species, and the abundance of oak forest grass (*Oplismenus setarius*) in the herbaceous stratum.

**The ecology of the larger fungi**.—IV, **The seasonal frequency of grassland fungi with special reference to the influence of environmental factors**, W. H. WILKINS and S. H. M. PATRICK (*Ann. Appl. Biol.*, 27 (1940), No. 1, pp. 17-34, figs. 5).—The experimental methods of recording temperature, rainfall, soil water, and pH of a given area on each of three grassland stations over

a 12-mo. period are given, together with lists showing the seasonal distribution of the fungi on these three areas. The relation between temperature and water content of the soil and the numbers of fungus sporophores throughout the year was examined critically, and it is suggested that the summer and fall fungus seasons are conditioned by these factors. An alphabetical list of species showing their seasonal frequency is given. The seasonal distribution of individual species of fungi and the effect of these species in determining the mycological floras characteristic of the summer and fall seasons are discussed. The main point made by this study appears to be that the seasonal variation of the fungi of grasslands is conditioned by environal factors, and it is believed reasonable to assume that probably the same factors are also responsible for the seasonal variation of fungi in any other habitat or vegetation community.

**A study of the root system of the beech in woodland soils, with especial reference to mycorrhizal infection, J. L. HARLEY** (*Jour. Ecol.*, 28 (1940), No. 1, pp. 107-117, fig. 1).—The results of this study of the root systems and mycorrhizal relations of beech in three soil types indicated that mycorrhizal infection is more abundant on poor soils where the C:N ratio remains high, and the rates of mobilization of nitrogenous material and nitrification are low. Studies of the mineral make-up and of other micro-organisms in these soils made it apparent that the extent of mycorrhizal formation is a function of the soil system, i. e., that mycorrhizas are an integral part of it. Variations in the vigor of beech growth on the soils investigated indicated that where mycorrhizas are abundant the tree vigor is poor; where they are few, trees of the same order of vigor are found; whereas in intermediate soils, in which mycorrhizas are present but not in great abundance, trees of the greatest vigor occur. These variations in vigor are not attributed primarily to differences in mycorrhizal equipment or conditions affecting mycorrhizal formation, but to the available rooting depth of the soil. Furthermore, analyses of buds and leaves indicated that nitrogenous substances are apparently more available in escarpment soils, which have high rates of N mobilization and fewer mycorrhizal roots than in raw humus soils which have slow N mobilization and large numbers of mycorrhizal roots. The effect of the mycorrhizas on N absorption does not therefore equalize the availability of this element on these two widely differing soils.

**Radioactive nitrogen in the study of N<sub>2</sub> fixation by non-leguminous plants, S. RUBEN, W. Z. HASSID, and M. D. KAMEN.** (Univ. Calif.). (*Science*, 91 (1940), No. 2372, pp. 578, 579).—Using barley plants and radioactive nitrogen, apparently positive evidence for nitrogen fixation was obtained.

**Macrosporogenesis and embryology of *Portulaca oleracea*, D. C. COOPER.** (Wis. Expt. Sta.). (*Amer. Jour. Bot.*, 27 (1940), No. 5, pp. 326-330, figs. 38).—This study follows in detail the differentiation of an archesporial cell from a single apical hypodermal cell, division of the former into a primary parietal cell and a primary sporogenous cell, which functions directly as a macrospore cell, and so on through to the fully developed embryo, which forms a well-defined arc in the mature campylotropous seed.

**Developmental studies with *Brassica* seedlings, A. L. HAVIS.** (Ohio Expt. Sta.). (*Amer. Jour. Bot.*, 27 (1940), No. 4, pp. 239-245, figs. 7).—In the hypocotyl of kohlrabi seedlings the point of maximum growth was found to progress upward from the base to the cotyledonary node, with cell division persisting longest near the node. Cell elongation occurred during and after cell division. The number of epidermal cells increased very little during hypocotyl elongation. The outer cortical layer was the last to cease division in any given time region and in the hypocotyl as a whole. There was a trend toward increasing division progressing from the outermost to the innermost cortical cells. The rate of cell

division was evidently not highest in the region of most rapid elongation. Usually, only cell elongation was taking place where the growth was most rapid. There was a definite tendency for all cells in any given layer to reach the same length at maturity. There was no increase in radius of the epidermis or cortex during hypocotyl development. The factors inducing differential growth rates in these seedlings are not yet known. Several drastic seedling treatments tried failed to change the constant growth relations described.

**Investigations of the early developmental period of the young cereal plant** [trans. title], K. ZIJLSTRA (*Dept. Econ. Zaken [Netherlands], Verslag. Landbouwk. Onderzoek., No. 45 (17) A (1939), pp. 439-493, pls. 2, figs. 12; Ger. abs., pp. 492, 493*).—This monograph presents the results of a study of the morphological-developmental stages of the germinating seed and young seedling in the small grains.

**Studies on the developing cotton fiber.—I, Relation of development of crude cotton fiber to the other principal boll constituents**, J. COMPTON and F. E. HAVER, JR. (*Contrib. Boyce Thompson Inst., 11 (1940), No. 2, pp. 105-118, figs. 3*).—In a study of the relationship between certain basic components of the developing cotton fiber those arbitrarily chosen were dry fiber residue, reducing sugars in the fiber, fats and waxes soluble in alcohol-benzene, and total fiber moisture. In Coker Super Seven (*Gossypium hirsutum* strain 4), other than the slower rate of maturation and higher moisture content of the fibrous greenhouse material no essential differences seemed to exist between the ratios of the wet crude fiber constituents of bolls grown under field and greenhouse conditions. During the period of active fiber development the ratio, dry crude fiber: reducing sugars; waxes, on a constant-moisture basis, varied as follows: As the dry crude fiber mass increased the reducing sugars decreased, whereas the extractable fats and waxes remained practically constant. There are 18 references.

**Lamellate structure of cellulose membranes in cotton fibers**, F. L. BARROWS (*Contrib. Boyce Thompson Inst., 11 (1940), No. 2, pp. 161-179, figs. 4*).—In studying cellulose membrane development from the day of flowering to maturity in the epidermal seed coat hairs of a genetically pure line of *Gossypium hirsutum* (var. Super Seven), it was found that the fiber contains cellulose particles laid down in successive lamellae, thus gradually increasing the thickness of the wall. The number of lamellae at the base and tip varied in fibers on the same seed, the larger number of lamellae being at the base of the older fibers. There was no evidence found to correlate these lamellae with the so-called daily "growth rings." The lamellae were of remarkably uniform thickness ( $\pm 1\mu$ ), whether grown under daylight in the greenhouse or under continuous light. The microscopical and microchemical evidence indicated that each lamella consists of a single layer of cellulose particles held together by a colloidal cementing substance. X-ray diffraction patterns of fibers developed under continuous light and under daylight in the greenhouse showed the same general type of structure with only slight differences in orientation and amounts of cellulose. There are 61 references.

**Contributions to the study of the cell wall.—I, Methods for demonstrating lignin distribution in wood**, H. E. DADSWELL and D. J. ELLIS (*Jour. Council Sci. and Indus. Res. [Austral.], 13 (1940), No. 1, pp. 44-54, pls. 4*).—In this survey, normal and compression woods of numerous conifers and a wide range of tropical and temperate dicotyledonous woods, many Australian, were used. The methods involved treatment of thin cross and tangential sections with 72-percent  $H_2SO_4$ . In some cases the sections were pretreated with a solution of I in KI. Gentle warming of the slide proved essential for revealing the cell wall patterns clearly, though species varied in clearness. The degree

of lignification indicated by the cell wall lignin pattern was correlated with that supposedly revealed by staining reactions using safranin and light green. In species where a lignin pattern was observed in cross section, the pattern was predominantly radio-concentric in nature. Exceptions to this were found with compression wood tracheids and anomalous fibers from several dicotyledonous woods. The importance of this work as a starting point for various investigations is stressed.

**Experimental cytology, H. H. PFEIFFER** (*Experimentelle cytologie. Leiden: Chron. Bot. Co., 1940, pp. XII+243, figs. 28*).—This is a monographic text of the subject, with particular reference to the plant kingdom.

**Cytoplasmic behavior during division of vacuolate plant cells, E. W. SINNOTT and R. BLOCH** (*Natl. Acad. Sci. Proc., 26 (1940), No. 4, pp. 223-227, fig. 1*).—Study of cell division in vacuolate plant cells indicated that from very early prophase the cytoplasm tends to become aggregated into a plate of more or less fused strands, the phragmosome, which occupies the position of the future cell wall. The fact that the entire cell body rather than the nucleus alone appears concerned in establishing the plane of division and the location of the new wall is deemed of general importance for developmental problems.

**The cytology of sporangium development in *Azolla filiculoides*, R. E. DUNCAN.** (Univ. Maine). (*Bul. Torrey Bot. Club, 67 (1940), No. 5, pp. 391-412, figs. 30*).—This is a contribution to the life history of this salvinaceous plant.

**The Merton catalogue: A list of the chromosome numerals of species of British flowering plants, P. F. MAUDE** (*New Phytol., 38 (1939), No. 1, pp. 1-31*).—The threefold purpose of this list is to provide the systematist with a new instrument in classifying and determining the species of British flowering plants, the cytologist with the references to chromosome studies on these species and indications as to the work still remaining to be done, and the naturalist with the means of understanding the conformities and unconformities of chromosome number underlying the classification of these plants by their external form into species and larger groups. The data are arranged by families, genera, and species. Over eight pages of references are provided.

**Chromosome numbers in some British plants, P. F. MAUDE** (*New Phytol., 39 (1940), No. 1, pp. 17-32, figs. 10*).—New chromosome counts are given for 74 species of British plants.

**Stem anatomy of chaparral shrubs, K. S. WATKINS.** (Univ. Calif.). (*Bot. Gaz., 101 (1939), No. 2, pp. 391-402, figs. 14*).—The author presents a comparative study of the stem anatomy of 10 species dominant in the chaparral formation of southern California. There are 31 references.

**The seed of the spider lily, *Hymenocallis occidentalis*, M. R. WHITEHEAD and C. A. BROWN.** (Ia. State Univ.). (*Amer. Jour. Bot., 27 (1940), No. 4, pp. 199-203, figs. 13*).—A study of the morphology and development of the seed and plant.

**Fruits and seedlings of *Ceratophyllum*, W. C. MUENSCHER.** (Cornell Univ.). (*Amer. Jour. Bot., 27 (1940), No. 4, pp. 231-233, figs. 2*).—The fruits and seedlings of *C. demersum* and *C. echinatum* are described. The seedling of *C. demersum* agreed with the description of seedlings based on European material, while that of *C. echinatum* differed in not developing simple leaves on the lower nodes.

**On the classification of actinomycetes, S. A. WAKSMAN.** (N. J. Expt. Stas.). (*Jour. Bact., 39 (1940), No. 5, pp. 549-558*).—The accumulating knowledge on the morphology of the Actinomycetales is believed to lead more and more to a recognition that its members constitute an independent group of organisms closely related to the bacteria through some of its constituent forms, but which

has adopted a funguslike form of growth. The mode of growth and spore formation of these organisms are described, and the various proposals that have been made for their classification are reviewed. It is concluded that each of these systems has some favorable characteristics but tends to give undue emphasis to certain particular groups. The author proposes a system in which an attempt is made to meet these limitations, to indicate the relationship of the various constituent groups to the true bacteria, and to include forms not considered by the other authors. Owing to the great variability and abundance of transition forms among the actinomycetes, the term "species" is applied more in the sense of "species groups." However, certain type species may be established, around which the closely related forms may be grouped. The various genera among the Actinomycetales form a natural group of micro-organisms with a variety of transitional forms. A characterization of the group and its main subdivisions and a key for the classification of the order are presented. The genera *Mycobacterium* and *Corynebacterium* are included under the family Mycobacteriaceae, *Cohnistreptothrix* and *Proactinomyces* under the Proactinomycetaceae, *Actinomyces* under the Actinomycetaceae, and *Micromonospora* under the Micromonosporaceae.

**Relation between temperature growth range and size in the genus *Bacillus*, C. LAMANNA.** (Cornell Univ.) (*Jour. Bact.*, 39 (1940), No. 5, pp. 593-596).—From a 3-yr. study of 105 cultures of aerobic, nonthermophilic, spore-forming rods of the genus *Bacillus*, it is concluded that the large-celled species have lower minimum and maximum temperatures of growth than the small-celled species.

**Description of a dextro-lactic acid forming organism of the genus *Bacillus*, A. A. ANDERSEN and C. H. WERKMAN.** (Iowa Expt. Sta.). (*Iowa State Col. Jour. Sci.*, 14 (1940), No. 2, pp. 187-193, pl. 1).—A spore-forming organism producing large amounts of *d*-lactic acid was isolated and is described as *B. dextralacticus* n. sp.

**Sensitivity of *Escherichia coli* to cold-shock during the logarithmic growth phase, C. P. HEGARTY and O. B. WEEKS.** (Oreg. State Col.). (*Jour. Bact.*, 39 (1940), No. 5, pp. 475-484, figs. 3).—The sensitivity of *E. coli* to cold shock appeared to be related in some manner to cell division and to changes within the individual cell.

**The adaptive production of enzymes by bacteria, R. J. DUBOS** (*Bact. Rev.*, 4 (1940), No. 1, pp. 1-16).—A critical review (87 references). Certain substances increase the yield of a given enzyme by contributing the necessary molecules for its synthesis. In other cases production of a given enzyme is greatly stimulated when the substrate attacked is a constituent of the culture medium. All available evidence indicates that the production of these adaptive enzymes involves the synthesis of new protoplasm. It is suggested that the synthetic process, so to speak, is oriented or guided by the chemical structure of the substrate which thus determines the specificity of the enzyme. Adaptive enzymes exhibit a remarkable specificity toward the substrates which have stimulated their production, and it is believed, therefore, that they will serve as useful tools in the analysis of many biological and biochemical problems.

**Preparation of an active juice from bacteria, W. P. WIGGERT, M. SILVERMAN, M. F. UTTER, and C. H. WERKMAN.** (Iowa State Col.). (*Iowa State Col. Jour. Sci.*, 14 (1940), No. 2, pp. 179-186, fig. 1).—"A technic for the preparation of active cell-free glucolytic enzymes based on the use of powdered glass in the proper proportions for the disruption of the bacterial cell is described. Juices active on mixtures of hexosediphosphate and glucose have been prepared from *Aerobacter indologenes*, *A. aerogenes*, *Escherichia coli*, *Citrobacter freundii*,

and *Clostridium butylicum*. Various dehydrogenases have been detected in juices of *A. indologenes*."

**Acetylmethylcarbinol enzyme-system of *Aerobacter aërogenes*, M. SILVERMAN and C. H. WERKMAN.** (Iowa State Col.). (*Soc. Expt. Biol. and Med. Proc.*, 43 (1940), No. 4, pp. 777, 778).—Using the technic of Wiggert et al. (see above), an enzyme preparation was extracted from cells of *A. aerogenes*, apparently possessing no hydroclastic activity but capable of converting pyruvic acid into CO<sub>2</sub> and acetylmethylcarbinol. The presence of inorganic phosphate was found essential for pyruvate break-down by this enzyme preparation.

## GENETICS

**Mammalian genetics, W. E. CASTLE** (*Cambridge, Mass.: Harvard Univ. Press, 1940, pp. VIII+169, [pls. 40], figs. 17*).—Following the principles of genetics and the laws developed, a summary is given of present knowledge of the inheritance of characters in mammals. Special consideration is given to those characters of practical importance.

[Papers on genetics, reproduction, and lactation in dairy cattle] (*Jour. Dairy Sci.*, 23 (1940), No. 6, pp. 530–533, 534–536, 537, 538, 540–543, 544–550, 576–579).—In addition to papers noted elsewhere (see p. 672), brief abstracts are given of the following reports presented at the 1940 meeting of the American Dairy Science Association: The Storage of Dairy Bull Spermatozoa, by H. A. Herman and E. W. Swanson (pp. 530, 531) and Some Observations on the Morphological Variations in the Spermatozoa of Dairy Bulls, by E. W. Swanson and H. A. Herman (pp. 531, 532) (both Mo. Expt. Sta.); Fecundity and Certain Other Characteristics of Fresh and Stored Bovine Semen, by H. P. Davis, G. W. Trimberger, and G. K. L. Underbjerg (pp. 532, 533) (Univ. Nebr.); An Assay Method for Thyrolactin, by W. W. Heathman and C. W. Turner (pp. 534, 535) and Thyrolactin, a New Source of Thyroxine for Dairy Cattle, by C. W. Turner (pp. 535, 536) (both Mo. Sta.); The Effect of Thyroxine Injections on the Physiological Processes of Dairy Cattle, by V. Hurst, R. P. Reece, and J. W. Bartlett (p. 536) (N. J. Stas.); Effect of Post-Hypophyseal Extract on Lactation in Hypophysectomized Post-Gravid Rats, by E. T. Gomez (pp. 537, 538) (U. S. D. A.); The Hormone Control of Mammary Duct Growth, by A. A. Lewis (pp. 540, 541) and The Mammogenic Lobule-Alveolar Factor of the Anterior Pituitary, by J. P. Mixner (pp. 542, 543) (both Mo. Sta.); A Study of Some Methods for the Prediction of Butterfat Percentage in Herds of Ayrshire Cattle, by G. A. Bowling and D. N. Putnam (pp. 544, 545) (W. Va. Sta.); The Use of Cellular Antigens in the Blood of Cattle for Determining Parentage, by L. C. Ferguson and M. R. Irwin (pp. 545, 546) (Univ. Wis.); Effects of Inbreeding in Dairy Cattle (Progress Report), by G. E. Dickerson (pp. 546, 547) (Wis. Sta.); Results of Twenty Years Work on Proving Bulls at the Huntley, Montana, Field Station, by R. R. Graves, J. R. Dawson, and D. V. Kopland (p. 547) (U. S. D. A.); Average Useful Life-Span, and Causes of Losses of Dairy Bulls, by R. B. Becker and P. T. D. Arnold (p. 548) (Fla. Sta.); The Inheritance of the Solids-Not-Fat Percentage in Dairy Cattle, by H. C. Moore and K. S. Morrow (pp. 548, 549) (N. H. Sta.); Some Factors Affecting Breeding Efficiency in Dairy Cattle, by R. E. Erb, J. W. Wilbur, and J. H. Hilton (p. 549) (Purdue Univ.); Early Recognition of the Freemartin Condition in Heifers Twin-Born With Bulls, by W. W. Swett, C. A. Matthews, and R. R. Graves (p. 550) and The Nation-Wide D. H. I. A. Proved-Sire Program, by J. F. Kendrick (pp. 576, 577) (both U. S. D. A.); The Importance of Selective Registration to the Dairy Industry, by L. Copeland (p. 577); and Utilization of Proved Sires and Sons of Proved Sires, by F. Arnold (pp. 578, 579) (Iowa State Col.).

**Color genes in Holstein-Friesian by Brown Swiss crosses, R. J. BUSHNELL.** ([Conn.] Storrs Expt. Sta.). (*Jour. Hered.*, 31 (1940), No. 5, pp. 252-256, figs. 3).—In crosses of Holstein-Friesian ♀♀ with Brown Swiss ♂♂ there were produced 4 dun ♂♂ and 8 dun ♀♀, 2 black ♂♂ and 4 black ♀♀, and 1 reddish-brown ♀. It is concluded that the color genotype of the Brown Swiss was *bbiiWWininSSbrbr*, with *Bs* and *D* heterozygous or homozygous dominant. The whitening gene (*W*) of Holstein-Friesians was expressed in the absence of black. Some Holstein-Friesians carried a white star gene (*Ws*) but not the brindling gene (*Br*).

**Contribution to the genetics of colour and spotting in the goat, E. V. EYDRIGEVICH** (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser.*, 25 (1939), No. 9, pp. 784-786, figs. 6).—From observations on color and spotting in Kirghiz goats it is pointed out that white is epistatic to other colors. Fawn coat color in its several variations from white to fawn is epistatic to black. Dappled black was found to be epistatic to solid black. Gray varied from dark gray to light gray to white and was epistatic to black and hypostatic to white and fawn. Red was also epistatic to black and hypostatic to white and fawn. Spotting was dominant to the solid colors.

**"Streamlined" pigs—a new legless mutation, L. E. JOHNSON.** (Iowa Expt. Sta.). (*Jour. Hered.*, 31 (1940), No. 5, pp. 239-242, figs. 2).—Among 112 Poland China pigs sired in 7 litters by 1 boar bred to daughters of another presumably closely related boar there were 15 legless pigs. In subsequent litters by some of the same sows bred to the same boar there were produced 60 pigs, of which 7 pigs in 3 litters showed the legless defect. Considering the different facts about the occurrence of the abnormal pigs, the condition seemed to be due to a recessive gene.

**Genetics of the fowl.—XI, A linkage map for six chromosomes, F. B. HUTT and W. F. LAMOREUX.** (Cornell Univ.). (*Jour. Hered.*, 31 (1940), No. 5, pp. 231-235, figs. 2).—In continuation (E. S. R., 83, p. 181), the six linkage groups in the fowl previously noted by title (E. S. R., 82, p. 610) are described and illustrated. Attention is called to the more recent additions to the chromosome map in the fowl and especially the need for clarifying the relationship of *B* (barring) and *Id* (inhibitor of dermal melanin), at one end of the sex chromosome, and *S* (silver) and *K* (slow feathering), located at its other end.

**A study of fecundity in the domestic fowl: The behaviour of persistency in individual hens, A. W. GREENWOOD, J. S. S. BLYTH, and N. GALPIN** (*Jour. Agr. Sci. [England]*, 30 (1940), No. 2, pp. 202-209, fig. 1).—Records of the last egg laid by 269 hens in the Brown Leghorn flock of the Institute of Animal Genetics, Edinburgh, were furnished to supply evidence of inheritance. Different birds varied in laying the last egg from July 22 to December 31. One-fourth of the population was found to differ by not more than 6 days in the dates of last egg in the first and second years, but more than half differed by more than 13 days. From the analysis of variance it was evident that the date of cessation of production at the end of the pullet year was not a reliable indication of the bird's potentiality in this respect, but the true date was more closely approximated the longer the birds were kept. The termination of the cycles of the birds over such a wide range showed that multiple factors operated or that the genes showed a considerable range of expression.

**Breed determined differences in blood indices of fowls, O. N. KITAEVA** (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser.*, 25 (1939), No. 4, pp. 304-307).—The number of erythrocytes, hemoglobin content, and blood alkalinity in several breeds of fowls increased with age, but the size of the erythrocytes decreased. In general, ♂♂ showed higher blood values than ♀♀, and the

larger breeds of fowls showed higher hemoglobin contents and more erythrocytes than medium and small breeds.

**Research on frizzle plumage in the Rumanian fowl** [trans. title], G. K. CONSTANTINESCO and V. DERLOGEA (*Sci. Genet.*, 1 (1939), No. 2-3, pp. 219-227, figs. 6; *Lat., Eng., Ger. abs.*, p. 227).—Frizzle plumage in the local breed in Rumania and southeastern Europe behaved as dominant to normal. Contrary to findings of Landauer and Dunn (*E. S. R.*, 65, p. 523), the homozygous condition was not lethal, but homozygotes were more extremely frizzled.  $F_2$  and backcross ratios closely approximated expectations in several matings.

**Brachydactyly and syndactyly in ptilopod domestic fowl, *Gallus domesticus***, R. G. JAAP. (*Okla. Expt. Sta.*). (*Okla. Acad. Sci. Proc.*, 19 (1939), pp. 27-29).—In the fowls hatched during 2 yr., only 2 out of 161 ptilopod chicks were free of any evidence of brachydactyly or syndactyly. Among 5,000 nonptilopod individuals, no cases of brachydactyly or syndactyly and only about 1 percent of slight leg feathering were observed. From an analysis of the characters of the progeny from matings of Brahmas the indications were that brachydactyly, syndactyly, or ptilopody result from the action of the same genes but that the final expression is apparently produced by modifying factors the exact physiological mechanics of which were not worked out.

**The endocrine system and plumage types, II-V** (*Jour. Genet.*, 39 (1940), No. 3, pp. 485-524, pls. 6, fig. 1).—In continuation of this series (*E. S. R.*, 79, p. 617), four papers are presented as follows:

II. *The effects of thyroxin injections to normal, caponized, and thyroidectomized caponized birds*, C. W. Emmens and A. S. Parkes (pp. 485-492).—Daily injections in the breast muscles of 0.5 mg. of thyroxine were found to replace the normal and hyperthyroid feather types in Silver-Gray Dorking, Barnevelder, and Ancona capons and Sebright cocks and hens. The results fully confirmed the earlier study in the series on barbule formation as a result of thyroxine injection. Lack of thyroxine produced fringed feathers, but in no cases were the feathers of thyroxine-injected birds markedly fringed. Loss of melanin occurred in thyroidectomized Sebrights. In birds with normally white-tipped feathers the tip was extended by thyroid injection. In general, melanin formation was stimulated. The increased white tipping in Ancona and Speckled Sussex from thyroxine was thought to be indicative of a low threshold level. The more rapidly growing feathers or parts of feathers were most sensitive to specific effects.

III. *Further experiments on the relation between the thyroid gland and plumage patterns in domestic fowls and ducks*, J. P. Chu (pp. 493-501).—The effects of thyroidectomy and thyroid feeding on feather type and color in Silver Duckwing Game Bantams, Partridge Game Bantams, and Barred, White, and Silver-Black Plymouth Rocks were investigated. The different species reacted somewhat differently, and these results are discussed. Modifications in feather structure were noted in Plymouth Rocks, and modifications in color occurred, especially in Duckwing Bantams and mallard ducks, both in ♂♂. Sex dimorphic plumage was intimately related to thyroid-gland endocrines.

IV. *Feminization of plumage, with especial reference to henny cocks and eclipse drakes*, C. W. Emmens and A. S. Parkes (pp. 503-515).—Castration of henny dark-gray and Duckwing Old English Game cocks caused elongation in the saddle hackle feathers. Injection of testosterone propionate induced both quantitative and qualitative breed and sex differences in the responses. Injection or implantation of testosterone into Silver Campine capons induced inhibition and slowing in the development of plucked saddle feathers. Large doses of testosterone into Brown Leghorn and Duckwing Bantam capons produced effects of thyroid deficiency, but similar results were produced in hen-

feathered breeds with low doses. The appearance of eclipse plumage in mallard drakes was inhibited by castration before the end of April, but if castration was delayed until after eclipse plumage formation started, the plumage formation continued. Testosterone did not affect characters of the castrated mallard plumage, but oestrone produced a type of feminization intermediate between nuptial and eclipse plumage.

V. *The production of eclipse plumage in the mallard by injection of anterior pituitary extract and dehydroandrosterone*, J. P. CHU (pp. 517-524).—Feather samples which grew after plucking individual feathers on two mallard drakes after injections with sheep pituitary powder showed eclipse characters as a result of considerable hypertrophy of the testes. Feathers regenerated about 10 days after plucking from ♂ and capon mallards which had received 5 mg. of crystalline dehydroandrosterone for 20 days were typically eclipse.

Sex determination of day-old chicks, T. H. CANFIELD. (Univ. Minn.). (*Poultry Sci.*, 19 (1940), No. 4, pp. 235-238, figs. 4).—The Japanese method of sexing day-old chicks is described, and the ♂ and ♀ types of external sex organs are illustrated.

A recessive slate plumage color of turkeys, V. S. ASMUNDSON. (Univ. Calif.). (*Jour. Hered.*, 31 (1940), No. 5, pp. 215-217, figs. 2).—Mating of a slate ♀ with a Bronze ♂ produced 151 nonslate and 45 slate progeny in the F<sub>2</sub> generation. Mating slate ♀♀ with nonslate ♂♂ produced in the F<sub>2</sub> and backcross generations close approximations of the 3:1 and 1:1 ratios expected. These results suggest that slate is due to a simple autosomal gene recessive to nonslate. The Bronze color gene *R*, when present in slates, caused barring of the flight feathers and penciling in the tail feathers. The Bourbon Red gene *r*, when homozygous, produced nearly white, nonbarred flight feathers and nonpenciled tail feathers in genotypic slates.

Some experimental matings of color-bred white bull terriers, L. C. BRIGGS (*Jour. Hered.*, 31 (1940), No. 5, pp. 236-238, figs. 2).—Observations on several litters showed matings of both white parents, regardless of ancestral color, to produce only white pups, indicating the recessive nature of white. Citation is made of only one litter showing irregularity in this respect.

An independent recurrence of the blue mutation in the Norway rat and a blue-black mosaic, M. R. CURTIS and W. F. DUNNING (*Jour. Hered.*, 31 (1940), No. 5, pp. 219-222, figs. 2).—A blue-black hooded mosaic ♀ was observed in the F<sub>2</sub> population of a cross of intense hooded × self blue, a recessive character described by Roberts (*E. S. R.*, 62, p. 822). The mosaic was attributed to a somatic mutation of blue to black, the opposite of that which happened in the germ cell in the origin of the blue mutation. This resulted in an intense black area in the blue hood on the left shoulder and a less clearly defined black area on the right side of the face. The mosaic mated to a blue-selfed ♂ produced only blue-selfed progeny. The mosaic was genotypically homozygous dilute.

Breed, age, and sex variations in blood value of rabbits, K. B. ALPEROVICH (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser.*, 25 (1939), No. 5, pp. 410-413).—Age and breed variations in large and small breeds of rabbits and F<sub>1</sub> crosses between them showed that high hemoglobin values and the diameter of the erythrocytes observed in young rabbits were gradually reduced until the animals were about 2 mo. of age, after which the blood values increased. These increases were usually higher in ♂♂ than in ♀♀. The larger breeds had a higher hemoglobin value and a smaller number of erythrocytes than smaller rabbits. The F<sub>1</sub> ♂♂ were intermediate between parents, but the hemoglobin values and erythrocyte counts were greater than in their full-blooded ♀ parents.

**Gonadotropic hormone in the non-pregnant mare, H. H. COLE and H. Goss.** (Univ. Calif.). (*Amer. Jour. Physiol.*, 127 (1939), No. 4, pp. 702-709).—Samples of between 2 and 3 l. of blood were drawn every 4 to 7 days from non-pregnant thoroughbred and draft mares throughout the recurring oestrous cycles and tested on immature ♀ rats for the presence of gonadotropic hormone. The cycles of the mares and the concentration of the gonadotropic hormone in the serum of the same and different mares varied. Only rarely was a response obtained with less than the extract from 100 cc. of serum. The time of highest gonadotropic concentration seemed to be in metoestrus.

**Effect of estrogens and androgens alone and in combination with chorionic gonadotropin on the ovary of the hypophysectomized rat, R. I. PENCHARZ.** (Univ. Calif.). (*Science*, 91 (1940), No. 2371, pp. 554, 555).—Study is reported of the ovarian weight of immature rats in which were implanted pellets of oestrogens and androgens following hypophysectomy and Antuitrin-S injection. The most striking results were obtained in animals injected with diethylstilboestrol and Antuitrin-S (chorionic gonadotropin). From 130 to 170 µg. of diethylstilboestrol pellets were absorbed per day, as compared with from 40 to 63 µg. of the oestradiol dipropionate per day.

**Effects of testosterone propionate on pregnancy and on passage of ova through the oviducts of mice, H. O. BURDICK, B. B. EMERSON, and R. WHITNEY** (*Endocrinology*, 26 (1940), No. 6, pp. 1081-1086, figs. 6).—Daily doses of 5 mg. of testosterone propionate beginning after mating were found to cause retention of ova in the tube, whereas 0.025 mg. had no effect on pregnancy or passage of the ova. The ova were partly in the uterus and partly in the tubes in ♀♀ given doses of 0.5 and 2 mg. There was no evidence of retardation in blastocyst development except the degeneration resulting from tubal retention.

**The comparative assay of gonadotropic substances on rats, mice, and chicks, J. S. EVANS, L. HINES, R. VARNEY, and F. C. KOCH** (*Endocrinology*, 26 (1940), No. 6, pp. 1005-1011, figs. 3).—Comparison was made of the immature ♀ rat and mouse and day-old chick for assaying gonadotropic substances in sheep pituitaries, ♂ and menopause urine, and pregnant-mare serum. The results showed the mouse uterus to be 66 times as sensitive as the rat ovary and about 10 times as sensitive as the chick testis to injections of unfractionated pituitary extracts. The mouse uterus was also most sensitive to injections of pregnant-mare serum and the normal ♂ and menopause urine preparations. The response of the chick testis to ♂ urine and menopause urine was doubtful.

**Clinical and experimental observations on reproduction in the mare, F. T. DAY** (*Jour. Agr. Sci. [England]*, 30 (1940), No. 2, pp. 244-261, fig. 1).—Observations are reported on the oestrous cycles of 8 pony mares from early spring until pregnancy ensued in the summer. Study was made on changes in the ovary and on time of ovulation, clinical examination of the developing fetus, and changes in the oestrous cycle following injections of gonadotropic hormones. The oestrous periods were determined by trying the mares daily with vasectomized stallions. Vaginal examination with a speculum was made of the developing fetuses. Insemination was by artificial means. Oestrus in the spring usually varied from 11 to 20 days and in the summer from 7 to 8 days. Dioestrus ranged from 5 to 30 days, as determined by palpation. Ovulation did not occur in the early spring. Of 31 ovulations, 27 occurred within 48 hr. before the end of oestrus, 2 on the first day after, and 2 on the fourth and fifth days before the end of oestrus. Pregnancy was detected by rectal examination from 16 to 23 days after ovulation. In the 11 mares, doses of from 1,000 to 2,000 mouse or rat units of pregnancy-urine extract given intravenously induced ovulation in from 20 to 40 hr. in most mares, independent

of the time of the administration during the oestrous cycle. Artificial insemination was equally effective 24, 48, and 72 hr. before ovulation but was unsuccessful from 2 to 4 hr. after ovulation. The duration of oestrus was shortened when ovulation occurred. The gonadotropic hormone administration had, therefore, no deleterious effect on subsequent oestrous cycles.

**Experiments on the use of chorionic gonadotrophin (pregnancy urine extract) for the treatment of sterility in dairy cattle, A. C. BOTTOMLEY, S. J. FOLLEY, and H. M. S. WATSON** (*Jour. Agr. Sci. [England]*, 30 (1940), No. 2, pp. 235-243).—Three sterile bulls with few motile sperm in their semen were found, after 2 intramuscular injections of 2 cc. of pregnancy-urine extract, to produce large numbers of sperm and were able to get cows in calf. Oestrus was induced in several cows, and calves were produced following injection intravenously and intramuscularly with from 3 to 5 cc. of pregnancy-urine extract. A total of 59 cows showing regular oestrus but failing to conceive were treated with 3 intramuscular injections of 2 cc. of pregnancy-urine extract at 2-day intervals. Pregnancy was induced in 57.6 percent of the treated animals but in only 6.9 percent of the untreated control cows. Treatment with Antuitrin-S at the time of service increased the fertility of cows showing regular oestrus but failing to conceive. The prevention of conception in such animals was attributed to the failure to ovulate and to deficiencies in the production of progesterone following ovulation.

**Effect of mare serum hormone on the male and female mouse, W. F. STARKEY and J. H. LEATHEM** (*Amer. Jour. Physiol.*, 127 (1939), No. 4, pp. 751-754, figs. 7).—Immature, mature, and castrate ♂ and ♀ mice were injected for 10 days with 0.5 rat unit of hormone from mare serum, and study was made of the weights of the gonads and changes in the histology of the secondary sex organs. As much as ninefold increase in ovarian weight with good-sized follicles and uterine tissue was produced in 12- to 18-day-old mice. Ovarian weight was increased sixfold in 34- to 41-day-old mice. Ovaries of 78-day-old control mice averaged 9.4 mg., as compared with 26.7 mg. in injected animals. There was practically no effect of the treatment on testis weight or spermatogenesis in ♂♂, although in young animals growth of interstitial tissues was stimulated. Gonadectomized ♀♀ and ♂♂ showed no effects.

**Pregnancy diagnosis in mares by colorimetric estimation of estrogens, S. KOBER** (*Endocrinology*, 26 (1940), No. 5, pp. 914, 915).—Pregnancy in 3,597 mares was chemically diagnosed by the presence of oestrogen in the urine between 141 and 190 days after mating, with an error of less than 1 percent.

**Presence of a principle with progesterone-like activity obtained from a plant source, G. DE SÜTÖ-NAGY** (*Soc. Expt. Biol. and Med. Proc.*, 43 (1940), No. 4, pp. 674, 675).—Replacement of 15 percent of the basic diet of rats with bean flour was found to inhibit the occurrence of normal oestrous cycles. Extraction of bean flour with a Soxhlet apparatus or with fat solvents removed the inhibiting factor. This factor was concentrated so that 1.7 percent was effective on subcutaneous injection. The extracted material seemed antagonistic to the oestrogenic hormone, and crude bean oil gave a specific test for progesterone. The progesterone-like principle was sensitive to heat, oxidative agents, and alkalies.

**Action of progesterone on the gonadotropic activity of the pituitary, E. B. ASTWOOD and H. L. FEVOLD** (*Amer. Jour. Physiol.*, 127 (1939), No. 1, pp. 192-198, fig. 1).—Doses of 1.5 mg. of progesterone did not prevent the occurrence of pseudopregnancy after stimulation of the cervix electrically. However, 4 mg. of progesterone per day on 3 or 4 days largely prevented the occurrence of pseudopregnancy as a result of this stimulation. Injection of 0.1 mg. of pro-

gesterone for from 4 to 10 days into normal immature rats decreased the ovarian weight responses and inhibited luteinization from the gonadotropic hormone. Since no inhibition of luteinization was obtained from progesterone administered to hypophysectomized animals, it is concluded that the release of the luteinizing hormone from the pituitary was prevented by progesterone.

**Hormonal inhibition of lactation**, R. P. REECE, J. W. BARTLETT, I. L. HATHAWAY, and H. P. DAVIS. (N. J. and Nebr. Expt. Stas.). (*Soc. Expt. Biol. and Med. Proc.*, 43 (1940), No. 1, pp. 183-186).—The daily administration of 200 rat units of pregnancy-urine extract (Antuitrin-S) and 100 rat units of oestrogen (Progynon-B) to lactating ♀ rats was found to prevent 16 of 17 litters from gaining weight on 3 successive days (E. S. R., 81, p. 361). The ovaries were heavier and the pituitary weight less than in control ♀♀ and in ♀♀ injected with the gonadotropic hormones or oestrogen alone. Assays by pigeon crop-gland response showed that the effectiveness of oestrogens in inhibiting lactation was increased by simultaneous administration of pregnancy urine, which also augmented the lactogen content of but not its release from the pituitary gland.

**The relation of mating, ovulation, and the estrous smear in the house mouse to time of day**, G. D. SNELL, E. FEKETE, K. P. HUMMEL, and L. W. LAW (*Anat. Rec.*, 76 (1940), No. 1, pp. 39-54, figs. 2).—As copulation was generally associated with darkness, mice were kept in a dark room from 6:15 a. m. to 3 p. m. and subjected to artificial light during the rest of the day. Vaginal examination was then made for the occurrence of oestrus or vaginal plugs. Willingness to mate usually occurred in the period of darkness which approximated that from 10 p. m. to 1 a. m., but occasionally occurred in the latter part of the night or perhaps in the early morning. Mating during the light period was rare. Ovulation usually occurred between 12 m. and 2 or 3 a. m., with the range from 11:30 p. m. to 4:40 a. m. The average interval between the onset of oestrus and ovulation was from 2 to 3 hr. The second post partum oestrus occurred on the fifth or sixth day, or rarely on the fourth day. Dissection of the Fallopian tubes and sections of the ovaries for the presence of follicle cells and expansion of the first loops of the Fallopian tubes were employed for the determination of ovulation. Ovulation was not affected by mating, although the cornified cell content of the vaginal smear varied from 25 to 95 percent. The duration of oestrus probably does not exceed 24 hr.

**"Signet-ring" or "castration" cells in the chick**, F. PAYNE (*Anat. Rec.*, 76 (1940), No. 1, pp. 29-37, pl. 1).—Study was made of more than 500 pituitaries of White Leghorn chicks ranging from embryonic ages to over 13 yr. Signet-ring cells were found in the pituitaries of both ♂♂ and ♀♀, varying from 30 days of age to maturity but not in 13-year-old hens and 6- to 9-year-old roosters. There were no signet-ring cells in castrated chickens. Since the pituitaries of such birds are less potent in gonad stimulation, the plausibility that the signet-ring cells caused the increased potency is suggested. Attention is called to the presence of two types of basophile cells, one with vacuoles.

**Effect of extracts of gelding urine on reproductive system of the rat**, C. E. REA. (Univ. Minn.). (*Endocrinology*, 26 (1940), No. 5, p. 913).—The weights of the prostates and reproductive organs of adult ♂ rats to which extracts of gelding urine were administered on alternate days for 15 injections were not significantly different from rats to which no extracts from normal human ♂ urine were administered.

**Biological indicators of androgenic activity**, D. NELSON and R. R. GREENE (*Endocrinology*, 26 (1940), No. 5, pp. 824-826).—Weights of the seminal vesicles (full and empty), the ventral prostate, and the vesicular fluid were obtained on 191 castrated rats treated for 21 days with testosterone or testosterone propionate. The statistical analysis of the results showed the weights of the ventral prostate

to be the most suitable measure for assaying small amounts of androgen. Because of the high correlation coefficients between different measures, there seemed to be no advantage in ascertaining data on more than one gland for a single assay.

**The histogenesis of tissues sensitive to oestrogens, S. ZUCKERMAN** (*Biol. Rev. Cambridge Phil. Soc.*, 15 (1940), No. 2, pp. 231-271).—From a study of the histological changes in the various tissues in ♂♂ and ♀♀ of different animals it was found that individual tissues and even histogenetically related tissues differ markedly in their response to oestrogen. Growth was stimulated in the epithelial and fibromuscular tissues of the urogenital tracts and in certain nonreproductive tissues. Responses were designated as glandular, involving proliferation of the cylindrical secretory cells, and squamous, consisting of proliferation, cornification, and desquamation of stratified epithelium. Differences in the tissue responses were pointed out.

**Effect of testosterone propionate upon thyroid and parathyroid glands of intact immature female rat, I. T. NATHANSON, A. M. BRUES, and R. W. RAWSON** (*Soc. Expt. Biol. and Med. Proc.*, 43 (1940), No. 4, pp. 737-740).—Injection of immature rats with 5 mg. of testosterone, followed in 12 hr. by 0.05 mg. of colchicine per 50 gm. live weight stimulated the number of mitoses in the thyroid and parathyroid glands and the mean acinar cell height. This stimulation was found to be through the pituitary because the changes closely paralleled those of the ovary, which is known to be influenced by the anterior pituitary.

**The effect of testosterone propionate on the black-crowned night heron, G. K. NOBLE and M. WURM** (*Endocrinology*, 26 (1940), No. 5, pp. 837-850, figs. 13).—Injection of testosterone propionate induced sexual changes in immature and in gonadectomized adult herons normally associated with the breeding season. Oestrogen did not have this effect. Male sexual behavior was induced in adult females and in immature birds of both sexes. Differences in the amounts of androgen seemed to regulate variations in the sexual behavior of the adults.

**The artificial production of seminal ejaculation, T. DURFEE, M. W. LERNER, and N. KAPLAN** (*Anat. Rec.*, 76 (1940), No. 1, pp. 65-68).—Data are presented on the artificial induction of ejaculation in rats and rabbits by electrical current with from 5 to 31 v. and from 10 to 80 ma. The high voltages of from 24 to 31 brought about the desired ejaculations, but the chance of electrocution was high, especially with stimulation about the cranial areas. Optimum treatment appeared to be 13 v. and about 15 ma. for from 2 to 4 sec. with the rectal-third sacral electrode poles. The electrodes consisted of a copper wire inserted into the rectum and a fine steel needle fastened under the skin. Tetanic contractions of all the muscles followed the first application of the current, but recovery was rapid.

**A yolk-buffer pabulum for the preservation of bull semen, P. H. PHILLIPS and H. A. LARDY.** (*Wis. Expt. Sta.*). (*Jour. Dairy Sci.*, 23 (1940), No. 5, pp. 399-404, fig. 1).—A yolk-buffer was developed by the Wisconsin Station which was effective in maintaining motility in bull semen for over 300 hr. after ejaculation. Yolk-buffered semen, after storage for from 150 to 180 hr., was successfully used for breeding cows.

**The longevity of sperm in the female bat, G. E. FOLK, JR.** (*Anat. Rec.*, 76 (1940), No. 1, pp. 103-109, pl. 1).—One of five ♀ bats kept in hibernation by refrigeration and isolated from ♂♂ from January 8 to April 7 was found to have blastodermic vesicles in the uterus when killed on April 28. These are assumed to have resulted from spermatozoa carried from a mating during the previous fall.

**Animal sex control, C. WARREN** (*New York: Orange Judd Pub. Co.*, 1940, pp. 174, pl. 1, figs. 42).—A review of sex control by modification of the acid-

alkali reaction of the vaginal tract before coitus and the results of experiments in sex control with animals are briefly presented.

The endocrine literature of 1939, H. M. EVANS and B. COWLES. (Univ. Calif.). (*Endocrinology*, 26 (1940), No. 5, pp. 906-912).—A review of the numbers and sources of publications in 1939 of articles on endocrinology.

## FIELD CROPS

[Field crops research in Florida]. (Partly coop. U. S. D. A., Ga. Coastal Plain Expt. Sta., et al.). (*Florida Sta. Rpt. 1939*, pp. 4, 39-63, 153, 154, 157, 158, 159-165, 175, 177-179, 187, 188, 189, 194, figs. 5).—Progress is reported from continued experimentation (E. S. R., 81, p. 200) at the station and substations by W. A. Carver, F. H. Hull, G. E. Ritchey, W. E. Stokes, W. A. Leukel, J. L. Stevens, J. P. Camp, J. D. Warner, R. M. Barnette, H. Mowry, R. E. Blaser, J. R. Neller, J. R. Beckenbach, W. T. Forsee, Jr., F. T. Boyd, T. Bregger, R. W. Kidder, F. D. Stevens, R. R. Kincaid, and W. M. Fifield, including breeding work with corn, sweet corn, oats, Napier grass, sugarcane, and peanuts; variety tests with corn, oats, sugarcane for sugar and sirup, potatoes, peanuts, cowpeas, soybeans, clover, lespedeza, and miscellaneous forage and pasture grasses and legumes and cover crops; strain tests with pearl millet, Napier grass, and white clover; production tests with ramie; fertilizer tests with sea-island cotton, corn, oats, sugarcane, potatoes, ramie, peanuts, sorghum, clover, redbud, Dallis grass, and carpet grass; a study of "chlorosis" in corn; field tests on effects of preceding crops, wastepond phosphate, legume inoculation, seed treatment, and sulfur dusting on runner peanuts; study of the development and deterioration of roots in relation to growth of pasture plants (Sudan grass) under different fertilizer and cutting treatments; response of corn and other crops to less common elements on Everglade peat and muck soils; composition factors affecting the value of sugarcane for forage and other purposes; water requirements of sugarcane; cultural tests with potatoes, soybeans, and peanuts; effect of interplanting corn with velvetbeans at various spacings; seed storage; comparative production of large grasses grown for silage; ensiling of grasses with and without molasses; germination of tobacco seed after 7 yr. in different types of storage, and tobacco plant bed fertilization; and crop rotation studies under Everglades conditions with corn, cotton, crotalaria, and Austrian winter peas, corn and runner peanuts rotating with crotalaria and with native cover crops, and corn in a 2-yr. rotation with crotalaria species and weeds or natural land cover.

Other pasture investigations dealt with the value of centipede grass pastures as affected by soil characteristics and other factors; the effect of fertilizers on yield, grazing value, chemical composition, and botanical make-up of pastures; eradication of weeds in tame pastures and methods of ridding land of objectionable growths and obstacles; forage nursery and plant adaptation studies and forage and pasture grass improvement, especially with Napier grass and woolly fingergrass; growth behavior and relative composition of range grasses as affected by burning and the effect of burning on maintenance of natural grass stands and upon the establishment of improved grasses; studies of pasture legumes, of Napier grass for pasture purposes, and of water pasture; methods of establishing permanent pastures under various conditions; and pasture studies on peat and muck soils of the Everglades.

[Field crops experiments by the Georgia Coastal Plain Station, 1938]. (Partly coop. Ga. Expt. Sta., U. S. D. A., Univ. Ga., et al.). (*Georgia Coastal Plain Sta. Bul. 30* (1939), pp. 16-45, 78-81, 115-121, 127-130, figs. 9).—Research with field crops again reviewed briefly (E. S. R., 81, p. 362) for 1938 and for dif-

ferent periods of years comprised variety tests with cotton, corn for yield and resistance to weevils, oats, wheat, rye, grain sorghum, sorgo, sweetpotatoes, perilla, peanuts, lespedeza, soybeans for seed and forage, cowpeas, velvetbeans, crotalaria, winter cover crops, pasture grasses, and miscellaneous summer forage crops; breeding work with corn, cotton, oats, peanuts, soybeans, and pasture grasses; fertilizer experiments with corn, oats, and peanuts; winter cover and green manure crops for cotton and corn; cultural (including planting) experiments with oats, wheat, peanuts, soybeans, velvetbeans, crotalaria, lespedeza, and winter cover crops; and development of sea-island cotton production. Fertilizer work dealt with formulas and carriers of nitrogen, phosphorus, and potassium with cotton and sweetpotatoes, and also with fertilizer placement for cotton and tobacco; nitrogen and potassium top dressings for cotton and sweetpotatoes; secondary nutrient elements for cotton and tobacco; boron, potash and sulfur relation, and acid, basic, and neutral fertilizer tests with tobacco; and ratios of organic : nonorganic nitrogen with sweetpotatoes. General recommendations on soils, varieties, plant beds, fertilizers, spacing and topping, and curing for flue-cured tobacco are also included. In addition to the above work with flue-cured tobacco, progress reports are made from research at the Shade Tobacco Substation near Attapulcus, Ga., including fertilizer formulas, with variations in nitrogen, phosphorus, potassium, calcium, magnesium, sulfur, boron, chlorine, varying ratios of nutrients and of nitrogen carriers, rates of stable manure, and organic nitrogen and phosphorus carriers; and seed production.

[Farm crops work in Mississippi] (*Miss. Farm Res. [Mississippi Sta.]*, 3 (1940), No. 6, pp. 1, 2, 3-6, 7, figs. 4).—The progress of experiments with farm crops is noted in Persian Clover Shows Advantage for Early Pasture, by H. W. Bennett (pp. 1, 7); Purpose of Cultivation Is To Control Weeds—Least Cost to Grower and Least Injury to Plants Are Main Objectives, by I. E. Hamblin (p. 2); and Legume Nitrogen for Cotton Production in the Yazoo-Mississippi Delta, by R. Kuykendall (pp. 3-6, 7).

[Farm crops research in New Jersey] (*New Jersey Stat. Rpt. 1939*, pp. 21-26, 87, 88).—Work with field crops (E. S. R., 82, p. 175) reported on briefly comprised breeding studies with corn, barley, alfalfa, and red and white clover; variety tests with corn (and hybrids), wheat, barley, potatoes, soybeans, alfalfa, and red and white clover strains; combinations for spring-sown hay crops; production of high-protein timothy through nitrogen fertilization; fertilizer tests with potatoes; comparison of lime-complete fertilizer and lime-phosphate-potash systems of pasture treatment, and palatability tests; and experiments on establishing and maintaining fine turf, including studies on lawn, soils, and durability of grasses.

[Experiments with field crops by the Puerto Rico College Station], A. ROQUE, J. ADSUAB, P. RICHARDSON KUNTZ, F. CHARDÓN, C. J. CLAVELL, J. PASTOR RODRÍGUEZ, E. MOLINAR SALÉS, F. JULIÁ, and F. MÉNDEZ (*Puerto Rico Col. Sta. Rpt. 1939*, pp. 10-12, 13, 17, 18, 60, 61, 65-69, 73, 89, 92-96, 98, figs. 3).—Agronomic studies (E. S. R., 81, p. 502) reported on from the station and the Isabela Substation included variety, irrigation, fertilizer, and green manuring (*Crotalaria striata*) tests, all with sugarcane; forage production of variously fertilized grasses; a staking test with yams and a seed piece test with yautias; an irrigation test with corn; fertilizer tests with beans, alfalfa, yautias, and cassava; breeding work with corn, cotton, beans, and sugarcane; and variety trials with sweetpotatoes, soybeans, beans, lupines, and legumes for cover crops and green manure.

Varieties of oats, barley, and spring wheat in Nebraska, T. A. KIESSELBACH, O. J. WEBSTER, and K. S. QUISENBERRY. (Coop. U. S. D. A.). (*Nebraska*

*Sta. Bul. 328 (1940), pp. 23, figs. 6*).—Yields and other agronomic data, reported from varietal tests with oats, barley, and spring wheat at Lincoln, North Platte, and Alliance, 1931–39, supplementing earlier studies (E. S. R., 52, p. 529; 65, p. 432; 68, p. 320), are reported with brief descriptions of important varieties. Recent changes in acreage among the spring small grains in Nebraska were a reduction in acreage of oats and increases in those of barley and spring wheat. Increases in spring wheat, likely temporary, seemed due to heavy abandonment of winter wheat in western Nebraska caused by drought. The increase in barley acreage is due to superior varieties and recognition of its higher productivity compared with oats.

Recommended varieties include oats: Bruncker for central and western Nebraska, Iogold and Burt selection (Nebr. No. 518) for the southeastern section and in irrigated areas, and Burt selection (Nebr. No. 518) and Kanota for early seeding in central and northeastern Nebraska; barley: Spartan, Short Comfort, Trebi, and Club Mariout; and spring wheat: Thatcher and Ceres.

**Comparative values of green manures and nitrate of soda as measured by the growth of small grains**, A. W. BLAIR and A. L. PRINCE (*New Jersey Sta. Bul. 677 (1940), pp. 8*).—Use of soybeans as a green manure and of sodium nitrate as a top dressing on wheat and rye grown continuously on poor Sassafras loam in experiments, 1909–38, were very effective in increasing acre yields of grain and straw. The sodium nitrate top dressings, either at the rate of 160 or 300 lb. per acre, were the more effective. Indications from chemical examination were that the green manure was maintaining the nitrogen content of the soil. Sodium nitrate top dressings did not increase significantly the nitrogen content of the topsoil or subsoil, but the pH of the soil was raised consistently as a result of its use.

**Restoring Colorado's range and abandoned croplands**, E. W. NELSON and W. O. SHEPHERD (*Colorado Sta. Bul. 459 (1940), pp. 31, figs. 6*).—Ways to restore Great Plains range pastures, abandoned croplands, and depleted mountain ranges are described, with particular attention to seedbed preparation and seeding practices; recommended species, with characteristics, adaptations, and cultural needs, including blue grama, slender, western, and crested wheatgrasses, smooth brome, and sweetclovers; and seeding mixtures for unirrigated pastures for high mountains, lower mountainous and foothill plains, and for plains of eastern Colorado. Features of recommended practices have been noted earlier (E. S. R., 81, p. 39).

**Processing seed of grasses and other plants to remove awns and appendages**, J. L. SCHWENDIMAN, R. F. SACKMAN, and A. L. HAFENRICHTER. (Coop. Wash. Expt. Sta.). (*U. S. Dept. Agr. Cir. 558 (1940), pp. 16, figs. 7*).—Bluebunch wheatgrass (*Agropyron spicatum*), blue wild-rye (*Elymus glaucus*), Canada wild-rye (*E. canadensis*), Siberian wild-rye (*E. sibiricus*), tall oatgrass (*Arrhenatherum elatius*), bulbous barley (*Hordeum bulbosum*), squirreltail (*Sitanion hystrix*), alfileria (*Erodium cicutarium*), and virgins-bower (*Clematis ligusticifolia*), species adapted to the Pacific Northwest, were processed by milling threshed seed in a hammer mill (E. S. R., 82, p. 181) and cleaning it with a seed cleaner.

The successful deawning of the seed was found to depend on optimum speed of cylinder, a screen with diameter of perforations slightly greater than the seed length, and the full rate of feeding at the determined speed, e. g., the optimum speed ranged from 590 to 1,120 r. p. m. for seeds processed with a 26-in. diameter swinging-hammer type of mill. For medium-sized mills the periphery speed of the cylinder in feet per minute determines the effectiveness of the operation. For machines of different diameters the speed of the cylinder varies inversely about 40 r. p. m. for each inch of increase in diameter.

For the seed of the grasses processed a table shows percentages of seeds deawned and injured, of loss in weight, and of purity and germination, pure live seed, number of seeds per pound, test weight per bushel, and cost of processing per 100 lb. Injured seed was less than 3 percent, although that of bulbous barley was 15 percent and squirreltail 20 percent. Cylinder speeds greater than the determined optima or feeding at half capacity increased the percentage of injured seed. The volume of processed grass seed as shown by test weight per bushel was between about one-half and one-eighth that of untreated samples. Loss in weight was largely offset by increases in the percentage of live pure seed or number of seed per pound. Direct costs ranged between 67 ct. and \$1.50 per 100 lb. of original seed, and included milling, cleaning, and 30 percent for supervision and normal overhead.

**Partial self-incompatibility and the collapse of fertile ovules as factors affecting seed formation in alfalfa**, D. C. COOPER and R. A. BRINK. (Wis. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 60 (1940), No. 7, pp. 453-472, figs. 6).—Following self-pollination in the greenhouse, an average of 14.6 percent of the ovules of alfalfa became fertile as compared with 66.2 percent after cross-pollination on the same plants. Individuals were found to vary significantly in the proportion of ovules that become fertile after selfing, whereas the variability is less after cross-pollination. A rather uniform gradient of fertility occurs from the apex of the ovary downward after self-pollination, the basal ovules seldom containing fertilized eggs. A parallel gradient in fertility is found after cross-pollination, although the proportion of ovules becoming fertile in each position is much higher than after selfing. Pollen tube growth is more rapid in the cross matings. Low fertility following self-pollination is attributed to slow pollen tube growth, failure of the pollen tubes to effect fertilization, and collapse of fertilized ovules. About one-third of the fertile ovules in the selfed series were found to collapse between 72 and 144 hr. after self-pollination as against 7.1 percent in the crossed series. Partial incompatibility associated with self-pollination and high incidence of abortion of ovules containing inbred embryos during the first 6 days after pollination appears adequate to account for most of the difference in seed production following selfing and crossing. See also earlier notes (E. S. R., 77, p. 618; 80, p. 613).

**Pinto bean improvement**, G. N. STROMAN, J. CARTER, JR., and J. C. OVERPECK (*New Mexico Sta. Bul.* 270 (1940), pp. 18, figs. 7).—The pinto, the most widely grown field bean in New Mexico, is brown and white mottled and has a distinctive flavor not found in other field beans. The color markings of commercial beans are variable and affect the market price; often as many as from 20 to 25 percent are off-color. In bean improvement research begun in 1934 with strains from several localities in New Mexico and from Colorado, selections were made for plant type, early maturity, and uniformity of pod setting and color markings. Strains Nos. 291, 295, and 308 have shown superiority in the irrigated sections, and No. 247, an early-maturing strain, in the dry farming sections. Seed has been distributed to farmers through the New Mexico Crop Improvement Association.

**A survey of variability in white clover (*Trifolium repens* L.) and its relation to pasture improvement**, G. H. AHLGREN and H. B. SPRAGUE (*New Jersey Stas. Bul.* 676 (1940), pp. 42, figs. 4).—Examination of nursery-grown commercial and native strains of white clover revealed a high degree of variability in all morphological and physiological characters studied. The variations appeared due primarily to heredity. The Ladino strain, and Kent to a lesser degree, represented distinct morphological types. The other strains were not different essentially in form but showed variations ranging from the giant or Ladino type to the dwarf type. The mean values for characters studied

showed that the commercial strains, including Ladino and Kent, had the greatest range in type. Native strains were more intermediate, indicating that natural selection had not produced distinct morphological types in New Jersey. A rapid-spreading ability was associated with an increased size of all plant organs. That rapid-spreading plants usually do not form a dense mat or growth was evidenced by the reduced number of leaves per unit area on such plants. A high percentage of plants deficient in the small white marking (watermark) on the leaflets was found. Giant types similar to Ladino appeared occasionally in nearly all the commercial and native strains. Average coefficients of variability for spread of plant, height of petiole, leafiness, and number of stolons signified as much variation in native as in commercial strains.

One native and five commercial white clover strains were grown in a permanent pasture grass mixture of timothy, redtop, and Kentucky bluegrass, and the strains were studied by dividing the plats into two series and cutting one series regularly at 2-week intervals, simulating close grazing, and the other when the forage was from 4 to 6 in. high. The dwarf type of white clover, Kent, increased in abundance and in comparative yield performance when subjected to close clipping for 2 yr., but decreased in abundance and gave a reduced yield when the sod was not cut until from 4 to 6 in. high. Ladino decreased in percentage abundance when cut every 2 weeks, but maintained itself under the tall cutting treatment. It yielded somewhat more with deferred cutting. The Louisiana strain performed well under both high and low cutting treatments, but was somewhat superior in abundance and in yield under deferred cutting. An 8-percent increase in dry matter was obtained from plats cut at from 4- to 6-in. heights compared to those cut every 2 weeks. High yield performance was associated with percentage of white clover in the vegetation when mineral fertilization was practiced.

In a greenhouse study on differential utilization of lime, phosphate, and potash made by growing six commercial strains of white clover on a soil originally low in these minerals, four soil amendments, consisting of LPK, PK, LK, and LP, were made. With all strains the LPK series was significantly superior, as measured by yield of top growth. Clover strains on the LP and LK treatments were significantly superior to the PK and no-treatment series (which approached each other) in many yield values as measured by top and root growth. Indications were that lime and pH values may be comparatively more important in white clover cultures on poor soils than is phosphate and potash fertilization. The Wisconsin strain was superior to all other strains, except Polish, in root yield when subjected to an LPK treatment. The Ladino and Louisiana strains surpassed the Wisconsin and Oregon strains in yields of tops when grown under an LPK treatment, and the Louisiana strain was superior in yield of tops to the Wisconsin strain on a phosphate-deficient soil. The Wisconsin strain produced greater root growth than top growth under all fertilization treatments. All other strains, when subjected to the LPK treatment, produced greater top growth than root growth. Deficiency of lime, phosphate, or potash tended to eliminate differences between strains in root and top growth of young white clover plants.

**Time and temperature relations of germinating flax, O. VEERHOFF.** (N. C. Expt. Sta.). (*Amer. Jour. Bot.*, 27 (1940), No. 4, pp. 225-231, figs. 6).—Seed of the Bison and Albidum (an Indian variety) oil flaxes grown under similar conditions were incubated at maintained temperatures of 8°, 13.5°, 17.5°, 22°, 26°, 31°, 34.5°, 38.5°, and 43° C. The two lots were similar in that 31° was most favorable for early production of seedlings, onset of which was greatly delayed by low incubation temperatures. Optima for early completion of

seedling production were 26°, 31°, and 34.5°. Almost complete germination occurred in samples of each lot incubated at 8°. Albidum gave equally high germination percentages at progressively higher temperatures up to 34.5°. Bison was evidently the more sensitive to heat injury, its germination being more and more incomplete at successively higher temperatures. Germination of both lots was markedly reduced at 38.5° and none occurred at 43°. Both lots of seeds began seedling production after the same incubation periods at 38.5°. At each lower temperature seedlings appeared earlier in Bison. At 8° both lots completed seedling production about the same time. At all higher temperatures Bison continued to produce seedlings after germination had ceased in Albidum. Seeds of Albidum showed greater physiological uniformity.

**Poor germination of mechanically dehulled oats, N. I. HANCOCK** (*Tennessee Sta. Cir. 67 (1940), pp. 4, figs. 2*).—Field and laboratory germinations showed that the viability of oats may be impaired greatly by mechanical dehulling, the loss of germination being largely due to injury at the junction of glume, kernel, and peduncle. Since varieties differ in the way the kernel is enclosed in the glume, this is a factor in the amount of injury caused by dehulling. Threshers, or combines should be so adjusted that the percentage of dehulled oats will be kept at a minimum. Hand-dehulling reduced germination to a lesser extent than mechanical dehulling. Cutting off the brush end of the kernel did not cause a reduction in germination in the laboratory.

**Factors affecting the germination of sugar cane, H. F. CLEMENTS** (*Hawaii Expt. Sta.*). (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.], 44 (1940), No. 2, pp. 117-146, figs. 27*).—Results of experiments dealing with factors affecting germination of sugarcane, i. e., those external to the seed piece, including soil temperature, aeration, and moisture, and internal, including age and composition, length of seed piece, position of the buds relative to one another, and presence of trash, are presented.

Some practical suggestions derived from the studies include determination of soil temperatures before planting and adjusting practices to unfavorable conditions, e. g., shallow planting of previously treated top seed pieces, careful planting on heavy soils tending to puddle, and choice of top seed pieces. Body material, where it must be used, should be segregated from top material and planted very heavily. Increase in length of seed piece is accompanied by lower germination percentage and lower average shoot vigor. To use pieces with more than three buds is to waste the extra buds, and planting seed pieces with buds in any position wastes nearly all of the buds in the "down" position. The presence of trash on the seed piece slows up emergence and also reduces germination and may conceal plant material without buds. As to composition of planting material, it is desirable that cane for planting be grown for that purpose. Of several treatments available for treating seed pieces before planting, particularly in unfavorable conditions, mere soaking in warm water (85°-95° F.) for 24 or 48 hr. gives improved germination and vigor, but soaking in a warm 1-percent solution of calcium nitrate assures an improved stand and vigor. The "hot-water dip" (20 min. at 52° C.) results in stimulation but appears somewhat less effective than the latter treatment.

**Forms of nitrogen for sugar cane, R. J. BORDEN** (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.], 44 (1940), No. 2, pp. 81-88*).—Controlled studies in which three forms of nitrogen, as originally supplied in ammonium sulfate, sodium nitrate, and urea, were compared for their effects upon several characteristics commonly measured in experiments with sugarcane pointed out certain interacting factors which may influence direct effects of the nitrogen fertilizer. Although superphosphate used with the nitrogen carriers did not significantly influence their comparative effects upon cane yield or total dry weight, it seemed

to modify their effects upon cane quality and sugar. The phosphate had little effect upon the comparative percentages of nitrogen and phosphate in the crusher juice of cane fertilized with these different forms of nitrogen, yet it modified their relative effects upon the potash composition. The respective effectiveness of the three sources upon the cane quality was not influenced by the soil, which did, however, alter their comparative efficiencies as producers of cane and of sugar. Both the phosphate and potash juice comparisons from the three nitrogen sources were altered by soil differences, although the interaction of different soils with different nitrogen forms had no significant influence on the percentage of nitrogen in the crusher juice.

**Relation of the depth to which the soil is wet at seeding time to the yield of spring wheat on the Great Plains, J. S. COLE and O. R. MATHEWS.** (Coop. Mont., N. Dak., Wyo., Nebr., and Colo. Expt. Stas.). (*U. S. Dept. Agr. Cir. 563 (1940), pp. 20, figs. 2*).—Soil moisture data at or near planting time on the methods of preparation for spring wheat, obtained, 1907–38, at 15 stations in the Great Plains for a total of 261 station years, were used to place each plat or method each year in 1 of 3 groups—soil wet 1 ft. deep or less, wet 2 ft. deep, and wet 3 ft. deep or more. Yields were assembled according to this placement. On plats continuously cropped and spring plowed, the average yield from soil wet to the different depths at seeding time were 1 ft., 6.3 bu.; 2 ft., 11.7 bu.; and 3 ft., 15.5 bu. On the plat continuously cropped and fall plowed, yields from similar conditions were 6.7, 11.7, and 15.9 bu., respectively, and on plats alternately cropped and fallowed, the corresponding yields were 6.9, 12.6, and 19.9 bu. Under the limited precipitation of the Great Plains, the initial water content of the soil, which can be approximated by the depth to which the soil is wet, has been a strong determinant of the yield that will be produced.

Frequent failures, low average yields, and seldom good yields from spring wheat sown on soil wet to only 1 ft. deep or less show that planting is not warranted when that condition exists in the area. Two ft. of wet soil may be safe in some localities but not in others. The best assurance of good yields is afforded by an initial condition of 3 ft. or more of wet soil, a condition found much oftener on fallowed land than on land cropped the previous year.

**Varieties of winter wheat in Nebraska, K. S. QUISENBERRY, O. J. WEBSTER, and T. A. KIESSELBACH.** (Coop. U. S. D. A.). (*Nebraska Sta. Bul. 326 (1940), pp. 28, figs. 5*).—Yields, other agronomic characters, milling and baking qualities, winter hardiness, and smut resistance are reported from comparative studies of winter wheat varieties, 1930–39, supplementing earlier work (*E. S. R., 70, p. 42*); wheat improvement at the station is reviewed briefly; and important varieties are described. Although spring wheat constituted over 80 percent of the total wheat acreage in Nebraska before 1900, its proportion has decreased until at present more than 90 percent of the State acreage is in winter wheat. The change was primarily due to introduction of Turkey wheat and to development of other adapted hard red winter wheats, as Nebraska No. 60, Cheyenne, and Nebred.

At Lincoln, 1930–39, Cheyenne made the highest average yield and was followed by Kawvale, Tenmarq, Turkey (S. Dak. No. 144), and Nebred. At North Platte, 1933–36 and 1938–39, Cheyenne, Nebraska No. 60, and a local Turkey returned highest yields, with Tenmarq and Nebred closely approaching. At Alliance, Cheyenne and Nebraska No. 60 have given good yields. Varieties recommended for Nebraska are Nebred, Cheyenne, and Turkey. Nebred, a station selection from Turkey (S. Dak. 144) released in 1938, is resistant to forms of bunt now known to be present in Nebraska, has given good average yields, is more winter hardy than ordinary Turkey, and has acceptable milling and baking qualities. Cheyenne, selected from Crimean and distributed in 1933, is characterized by high yield, stiff straw, erect head, and tolerance to hessian fly, but is susceptible

to bunt and to both leaf and stem rust. Turkey, grown most widely in the State, usually compares fairly well with other varieties, giving a fair yield. It has average winter hardiness, is medium in time of maturity, and the grain quality is more or less standard with the trade.

**The Federal Seed Act and its relation to Montana farmers and dealers: Form of label prescribed for Montana, W. O. WHITCOMB** (*Montana Sta. Cir. 156 (1940), pp. 15*).—Features of the Federal Seed Act approved August 9, 1939, are summarized, with comments on records and labels for agricultural seeds under the act, exemptions, a comparison of the act with the Montana Seed law, and remarks on how the Federal Act may benefit Montana shippers and dealers.

**Just weeds, E. R. SPENCER** (*New York: Charles Scribner's Sons, 1940, pp. XVI+317, figs. 102*).—The popular presentation of the characteristics of the principal weed plants of the United States is supplemented by technical descriptions and appropriate illustrations. The book is featured by habitat indexes in which grasslike and nongrasslike weeds are grouped according to kind of crop, situation, and season.

**Organic reserves in the roots of bindweed, C. G. BARR.** (Colo. Expt. Sta. and U. S. D. A.). (*Jour. Agr. Res. [U. S.], 60 (1940), No. 6, pp. 391-413, figs. 10*).—Effects of different cultural practices and chemical treatments on the trend of organic reserves in roots of *Convolvulus arvensis* were studied, 1936-38.

The maximum reducing-sugar content did not exceed about 2 percent of the fresh weight of the roots of undisturbed plants. Total sugars reached a maximum of about 7 percent in late October, with a minimum value in May. The percentage of starch increased gradually, reaching a maximum in August or September, followed by a sharp decline coincident with a rapid increase in percentage of total sugar. This behavior suggested the shift of polysaccharides to soluble carbohydrates which commonly occurs in plants during the cold season. Cultivating the plants at 2-week intervals held the total sugar and starch content to about 1 percent each. In roots of cultivated plants the readily available carbohydrate accumulation was reduced to 2.3 percent, about one-sixth of that of undisturbed plants. One cultivation early in May 1937 reduced the sugar and starch contents to about 2 percent each, while cultivation in late July reduced the starch content almost 50 percent without an important effect on total sugars. Similar tests in 1938 showed comparable results, indicating the advantage of early fallowing.

Colloidal nitrogen in the roots of undisturbed plants increased gradually from May until the last of October. Cultivation checked this accumulation. The total soluble, amino, amide, nitrate, and nitrite nitrogen fractions showed no consistent variations. Results obtained for total nitrogen and nitrogen fraction determinations suggested that the importance of nitrogen in a study of root reserves in bindweed is open to question.

The carbohydrate content was held to a lower value by cultivation than by application of sodium chlorate. The combined treatment of sodium chlorate following early-season cultivation did not increase the effectiveness of chlorate in reducing the carbohydrate reserve. Sodium chlorate applied in fall to uncultivated plants was relatively more effective than that in early applications in reducing the root reserves and in controlling the weed. Plants cultivated systematically all season at emergence and 3, 6, 9, 12, or 15 days after emergence were uniformly low in starch content, from 1 to 2 percent, as determined by takadiastase digestion. Cultivating at emergence evidently had no greater effect than the less frequent cultivations in reducing the carbohydrate content of bindweed roots in the top foot of soil.

**Russian knapweed and perennial peppergrass, E. A. HELGESON** (*North Dakota Sta. Bul. 292 (1940), pp. 26, figs. 9*).—Russian knapweed and perennial peppergrass and their distribution and characteristics are described, together

with reports on experiments designed for their control. Promising control measures for the two weeds and precautions in the use of chlorates are outlined.

*Russian knapweed*.—In studies of the root system of Russian knapweed (*Centaurea repens*) begun in 1936 on an old infestation in southeastern North Dakota, vertical roots were lost at a depth of 6 ft. but evidently penetrated much deeper, while horizontal roots usually were in the upper 8 in. of soil. Dormant buds or vegetative shoots were not found on roots much below the 8-in. level. The extent of the root system suggested that this plant could store large quantities of reserves. Excellent control was obtained with sodium chlorate and Atlacide applied in solution or dry at rates varying from 2 to 6 lb. per treatment per square rod usually in one spring and one fall treatment. No appreciable difference was noted between chemicals or methods of application. With chlorate at 8 ct. per pound, control would cost from 40 to 60 ct. per square rod for chemicals alone.

*Perennial peppergrass*.—Tests of the effectiveness of chlorates in the control of perennial peppergrass (*Lepidium draba*) were begun in 1937 near Leonard, N. Dak. Numerous horizontal roots mostly in the upper regions of the soil level were found to produce deeply penetrating vertical branches. Excavation 6 ft. deep in Fargo clay found these vertical roots still about  $\frac{1}{8}$  in. in diameter, tapering very little, and evidently penetrating much deeper. Buds apparently were not present on these vertical roots. The root system as a whole seemed enormous in comparison with the aerial portion. Sodium chlorate was applied in spring and fall in solution and dry and Atlacide in solution at rates of 2, 3, 4, and 5 lb. per square rod per treatment, and some plats were mowed before treatment and others left undisturbed. Spraying unmowed plats seemed to give the best control with both chemicals. Applications totaling from 8 to 10 lb. were usually needed for satisfactory control, although in some cases the 6-lb. liquid applications sufficed. The Atlacide in solution about equaled sodium chlorate in toxicity in some cases. Dry sodium chlorate gave excellent control with 10 lb. and fair control with 8 lb. per square rod. Control of the weed with chlorates at 8 ct. per pound cost from 60 to 80 ct. per square rod for chemicals alone. Under the experimental conditions this weed was very resistant to chlorates.

## HORTICULTURE

[Horticultural studies by the Florida Station], G. H. BLACKMON, R. D. DICKEY, R. J. WILMOT, F. S. JAMISON, V. F. NETTLES, A. L. STAHL, J. C. CAIN, J. V. WATKINS, D. G. A. KELBERT, A. N. BROOKS, J. H. JEFFERIES, A. F. CAMP, W. REUTHER, G. R. TOWNSEND, J. R. BECKENBACH, J. R. NELDER, W. T. FORSEE, JR., S. J. LYNCH, and W. M. FIFIELD. (Partly coop. U. S. D. A. et al.). (*Florida Sta. Rpt. 1939, pp. 102-113, 114-116, 132, 141, 142, 143, 144, 147, 148, 152, 153, 154, 170, 171, 181-184, 185-187, 188, 189, figs. 6*).—Included are progress reports on the following investigations: Fertilizer and cover crop tests with pecans; varieties of pecans and other nuts; propagation, planting, and fertilizer trials with tung-oil trees; varietal and propagation trials with shrubs and ornamentals; fertilizer studies with truck crops; relation of N absorption to food storage, growth, and reproduction in the pecan; varieties of blackberries, grapes, peaches, and other fruits; preservation of citrus juices and pulps; cold storage in citrus; physiology of maturity processes in citrus; relation of soil reaction to growth and yield of vegetable crops; development of varieties and strains of vegetables adapted to commercial use; effects of green-manure crops on growth, yield, and quality of vegetables; effect of mineral deficiencies on the adaptability of certain vegetable varieties; value of certain root-inducing substances in rooting cuttings of various plants; methods of fertilizer placement for

vegetables; testing of tomato varieties; and the response of strawberries to  $MgSO_4$ .

From the Citrus Substation are reported studies on variety testing and breeding of citrus, rootstocks for citrus, nutritional needs of citrus, and the effect of Zn and other unusual mineral supplements on the growth of horticultural plants.

From the Everglades Substation are reported studies on fruit and forest trees, soil fertility investigations with truck crops and citrus, growth of celery at different fertility levels, and variety tests of vegetables.

Reports from the Subtropical Substation dealt with the culture of citrus and avocados, reforestation, improvement of tomatoes through selection of new hybrids, minor fruits and vegetables, pollination of mangoes, varieties of papayas and of miscellaneous fruits and ornamentals, pruning and staking of tomatoes, maturation of the tomato, and variety tests of vegetables.

[**Horticultural studies by the Georgia Coastal Plain Station, 1938**] (*Georgia Coastal Plain Sta. Bul. 30 (1939), pp. 82-88, 90-111, 131-133, fig. 1*).—Information is offered on the progress of cultural, varietal, and fertilizer studies with the tomato, watermelon, lima bean, and cabbage; on the breeding of watermelons resistant to wilt and snap beans resistant to root and leaf diseases and nematodes; the fertilizer needs of asparagus; variety trials with sweet corn and other vegetables; and varieties of peaches, pecans, pears, grapes, strawberries, figs, jujubes, blueberries, citrus fruits, tung oil, and other crops

[**Horticultural investigations by the Puerto Rico College Station**], A. ROQUE, J. ADSUAR, F. JULÍA, J. GUISCAFRÈ ARRILLAGA, L. A. GÓMEZ, J. SIMONS, A. RIOLLANO, L. A. SERRANO, N. A. SCHAPPELLE, J. A. B. NOLLA, F. MÉNDEZ, and E. MOLINARY SALÉS (*Puerto Rico Col. Sta. Rpt. 1939, pp. 61-64, 69-73, 78-92, 98, figs. 5*).—Information is presented on the progress of the following studies: Breeding of cucumbers for resistance to downy mildew; breeding peppers for resistance to mosaic disease; selection of papaya with relation to sex; breeding of the papaya; an analysis of production practices on coffee plantations; fertilizer needs and light requirements of the coffee plant; comparison of the Columbian and Puerto Rican varieties of coffee; the need of coffee for lime; root studies of the coffee plant; studies of fruit crops, including the avocado, citrus fruits, grapes, guavas, mangos, papaya, and pineapple; and investigations on asparagus, beans, cantaloups, cucumbers, eggplant, lettuce, onions, peas, plantain, squash, and tung-oil tree.

**Vegetative propagation of tropical and sub-tropical plantation crops**, G. ST. CLAIR FEILDEN and R. J. GARNER (*Imp. Bur. Hort. and Plant Crops [East Mall, Kent], Tech. Commun. 13 (1940), pp. 99, figs. 22*).—Discussing different methods of vegetative propagation, the authors present specific information on the propagation of a large number of plants, with literature references.

[**Vegetable studies by the New Jersey Stations**] (*New Jersey Stas. Rpt. 1939, pp. 65-75, 126-128*).—Included are progress reports on the following: The effect of lime, fertilizer, and organic matter on the yield of Rutgers tomatoes; the effect of fertilizing the preceding cover crop on the yield of the Rutgers tomato; relation of K to vegetable crop yields; the phosphoric acid requirements of the tomato; the relation of liming material to overliming injury to celery; methods of fertilizer placement for tomatoes; mulching materials for the tomato; effect of root temperatures on the development of nutrient deficiencies in asparagus; a survey of tomato fields in Cumberland County; production of lima bean seed on nutrient-deficient plants; relation of irrigation water to celery growth on a Collington sandy loam; tomato and asparagus breeding; and spray residue investigations with apples and tomatoes.

**Manure experiments with vegetable crops in Arkansas, J. R. COOPER and V. M. WATTS** (*Arkansas Sta. Bul.* 392 (1940), pp. 40).—Used alone or in combination with complete fertilizers, barnyard manure increased returns from vegetable crops growing on Clarksville silt and Ruston fine sandy loams, particularly on the latter. A large part of the increases in yield from manure treatments plus commercial fertilizer are attributed to improvement in physical condition of the soil, notably in improved water-absorbing and water-holding capacity. The addition of P to manure increased crop yields on Clarksville silt loam, but not to the extent of appreciably increasing net returns. Different vegetables responded differently in any given year, and there was considerable annual variation in the response of any one kind. On Clarksville loam, strawberries, sweetpotatoes, tomatoes, and peppers failed to respond profitably to the use of manure, in addition to fertilizer, even when only the cost of handling manure produced on the farm was considered. Asparagus, spinach, and cabbage showed a profit with the cost of manure as high as \$1 per ton. On Ruston loam, no crop failed to pay the cost of handling manure produced on the farm, and such crops as potatoes, green-wrap tomatoes, watermelons, cucumbers, spinach, and cantaloups returned a profit with manure at \$1 per ton. The best time to apply manure was in December or early January. Working the manure into the soil as soon as practicable facilitated decomposition. For cantaloups, manure was used most efficiently when placed in a broad, deep furrow, covered with 3–4 in. of soil, and allowed to settle for about 6 weeks before the seed was planted.

**Effect of spacing on asparagus production in California, H. A. JONES and G. C. HANNA.** (U. S. D. A. and Calif. Expt. Sta.) (*Canner*, 90 (1940), Nos. 15, pp. 14, 15; 16, pp. 17–19, fig. 1).—Based on investigations at Davis and Ryer Island, Calif., in which the rows were 7.5 ft. apart and the plants spaced 12, 18, 24, 30, and 36 in. in the row, the authors conclude that close spacing is preferable. Under the conditions of the study, crowns placed 12 and 18 in. apart produced significantly higher yields than those spaced farther apart. In California, planting is usually done during the rainy season, when the soil is in poor physical condition, with the result that many plants fail to survive. With close spacing, these skips are less serious than with wide spacing. Regardless of spacing, the average size of the spears was essentially the same, and the plants reached a peak as to size of spear and began to decline at about the same time.

**Tenderometer readings as an index of quality of fresh asparagus.—A preliminary paper, R. R. JENKINS and F. A. LEE.** (N. Y. State Expt. Sta.) (*Food Res.*, 5 (1940), No. 2, pp. 161–166, fig. 1).—Observations on fresh samples of Mary Washington asparagus taken at three periods during the cutting season from three types of soil showed that for a given variety grown under known conditions the tenderometer gave a high correlation for tenderness and quality, as compared with crude-fiber-content and taste tests. Although no definite limits of tenderometer readings are yet possible for different commercial grades of asparagus, the authors suggest that, as a tentative maturity standard, a tenderometer reading of 150 or lower indicates fancy quality. It was apparently not essential to separate asparagus into the various commercial sizes.

**Yellows-resistant varieties of cabbage suitable for New York State, O. A. REINKING and W. O. GLOYER** (*New York State Sta. Bul.* 689 (1940), pp. 28, figs. 4).—Discussing the nature of the cabbage yellows organism and its widespread distribution, the authors present the results of trials of numerous yellows-resistant cabbage varieties. The following midseason varieties are recommended for yellows-infested fields: Racine Market, Early Copenhagen

Resistant, Marion Market, Glory Yellows Resistant, Globe, All Head Select, and Wisconsin All Season. Of early varieties, Jersey Queen was found highly resistant but not heavy in yield. Detroit Resistant and Resistant Golden Acre yielded well but needed further selection for resistance. No late kind was found which met the needs of growers. The late varieties lacked in quality, were unproductive, or were not sufficiently resistant to the disease. Wisconsin Ballhead was almost completely resistant but did not yield sufficiently or store well.

As to cultural practices, it is recommended that great care be taken not to introduce the disease into clean soil since it survives a long time even if no cabbage is grown. On clean soil, as a general rule, the resistant varieties did not yield as well as susceptible kinds.

**Descriptions of types of principal American varieties of orange-fleshed carrots, R. MAGRUDER, V. R. BOSWELL, S. L. EMSWELLER, J. C. MILLER, A. E. HUTCHINS, J. F. WOOD, M. M. PARKER, and H. H. ZIMMERLEY.** (Coop. Cornell Univ. and Calif., La., Minn., Tex., and Va. Truck Expt. Stas.). (*U. S. Dept. Agr., Misc. Pub. 361 (1940), pp. 48, pls. 22, fig. 1*).—The fifth of a series (E. S. R., 80, p. 624) dealing with descriptions of types of the principal varieties of vegetables, this paper discusses the leading varieties of the cultivated carrot. Information is given on the relative importance of varieties for specific uses and geographical regions, based on the resistance of certain varieties to disease and insects and responses to different environmental factors.

**The nutrition of lettuces grown as sand cultures under glass, R. M. WOODMAN** (*Ann. Appl. Biol., 27 (1940), No. 1, pp. 5-16*).—Grown in jars of sand supplied with cultural solutions of known concentrations, May King lettuce was found "to respond well to N and P, both as regards yield and earliness of maturity, but to make practically no response to K over a wide range of concentrations. Cheshunt Early Giant lettuce behaved similarly, but no development of purple flushes or tints took place with this nontinted lettuce when there was a deficiency of P or N. A deficiency of N, however, resulted in a light-green lettuce of a characteristic and abnormally regular and smooth appearance. Lack of Ca . . . did not cause deficiency symptoms other than that of decreased yield. A deficiency symptom noted with Mg was a tendency to an etiolated plant and to a bleached whitish-pink appearance of the older leaves."

**Determining the grade of peas from the raw product, E. P. WALLS, W. B. KEMP, and H. L. STIER.** [Md. Expt. Sta.]. (*Canner, 90 (1940), No. 15, pp. 28, 30*).—Continuing the project (E. S. R., 81, p. 515), the authors made tenderometer readings in 1939 on 632 samples of peas graded previously by expert technologists and again reported a high degree of correlation between tenderometer readings and the results of standard methods of grading. The tenderometer readings agreed more closely with the actual grades than did those obtained with a texturemeter.

**A chlorophyll deficient pimiento, H. L. COCHRAN.** (Ga. Expt. Sta.) (*Jour. Hered., 30 (1939), No. 3, pp. 81-83, figs. 2*).—A description is presented of a chlorophyll-deficient pimiento plant in which leaves, buds, flowers, and fruit were involved. The patterns of the chlorophyll-deficient areas were not constant as to shape or time of expression. Due to the premature abscission of fruits, it was not possible to secure viable seed with which to grow a subsequent generation.

**New Illinois sweet-corn hybrids: Country Gentleman and Narrow Grain Evergreen varieties, W. A. HUELSEN** (*Illinois Sta. Cir. 504 (1940), pp. 20, figs. 8*).—Discussing the status of sweet corn breeding at the station and the methods followed in distributing breeding material, the author describes the

performance of certain Country Gentleman and Narrow Grain Evergreen crosses, their regional adaptation, and principal characteristics.

[**Pomological studies by the New Jersey Stations**] (*New Jersey Stas. Rpt. 1939, pp. 31, 32, 34, 35, 36, 54-64, 65*).—Among investigations noted are the effect of weeding and sanding on rebuilt cranberry bogs; use of chemicals for killing weeds in cranberry bogs; methods of harvesting cranberries; fertilizers for the cranberry and blueberry; mulching v. cultivation for the blueberry; pruning and spacing of blueberries; climatic factors in fruit production; peach breeding and distribution; growth of peach trees from embryos grown in sterile media; catechol tannin content of different peach varieties; apple breeding; relation of growth status to potential production of the apple; pruning of the apple; blooming data on the Elberta peach; nutrient-deficiency symptoms in the peach; root development of 3-year-old apple trees on Coastal Plain soil; strawberry breeding for general improvement, resistance to red stele, and everbearing characteristics; growth standards for strawberry varieties; blackberry and dewberry breeding; soil management for raspberries; and varieties of blueberries and other small fruits.

**The internal temperatures of fruit tree buds.—III, Trials with humidified heat for the control of frost damage, J. GRAINGER** (*Ann. Appl. Biol., 27 (1940), No. 1, pp. 1-4, figs. 4*).—In continuation of this series (E. S. R., 82, p. 483), "an account is given of the distributions of heat and relative humidity from three methods of orchard heating, together with the results of experiments with a simple type of humidified heating. Ignited balls of papier mâché, which had been soaked in crude oil, were humidified with saturated garden refuse, such as long grass or lawn clippings. This arrangement heats the air, and at the same time either maintains or enhances the relative humidity. No lowering of the internal temperature of the bud is produced, and the method helps to control a frost at its source by diminishing radiation of heat from the earth to an open sky. Frosts may therefore be controlled in practice by the expenditure of about one-third the fuel used in the flame-type heaters. Lateral distribution of heat from orchard heaters is not great. Suggestions are made for the alternate disposition of fruit trees and heaters upon a slope. Advantage may thereby be taken of the katabatic wind, which occurs during a radiation frost, to direct the heated air toward the trees."

**Small fruit and vegetable trials in toxic orchard soils, C. L. VINCENT**. (Wash. Expt. Sta.). (*Wash. State Hort. Assoc. Proc., 35 (1939), pp. 82-85*).—Of a considerable number of crops planted in 1939 on soil which for many years had been in orchards prior to the initiation of the experiment, certain species, notably rye, potatoes, asparagus, and tomatoes, were shown to be more resistant than others to arsenical residues in the soil, the result of many years of intensive tree spraying. The thinnest stand of rye was on the soil containing the most arsenic. Lima beans appeared particularly subject to seed injury, apparently due to arsenic in the soil. The more years elapsing between removal of trees and planting to horticultural crops, the better were the results.

**Total yields of apples in bushels upon young trees, M. A. BLAKE** (*N. J. State Hort. Soc. News, 21 (1940), No. 5, p. 1247*).—Stayman, Rome, and Delicious trees, producing their first crop in their fifth summer, yielded  $\frac{4}{5}$  bu.,  $1\frac{1}{8}$  bu., and a scattering of fruits, respectively. At the close of 9 yr. the average yield of all fruit for five seasons was  $1\frac{2}{3}$ , 2, and 1 bu., respectively. In the tenth year the average yields were  $6\frac{3}{4}$ ,  $8\frac{1}{8}$ , and  $5\frac{1}{8}$  bu., respectively.

**The optimum life of an apple orchard, C. W. ELLENWOOD**. (Ohio Expt. Sta.). (*Ohio State Hort. Soc. Proc., 73 (1940), pp. 95-101*).—Based on an analysis of returned questionnaires from growers and records taken in the

station orchard, the conclusion is given that apple trees beyond 35 yr. of age should be carefully watched as to declining yields and returns. Varieties differed in their attainment of full production, and the environment was also a factor. About three-fourths of the growers were of the opinion that from 15 to 25 yr. was the period of most economical production for apple trees. Plans for maintaining a succession of age classes in the orchard are discussed.

**Preliminary studies on the effect of tar oil spray for the prevention of fruit set in apples**, C. P. HARLEY and J. E. MOORE. (U. S. D. A. and Wash. Expt. Sta.). (*Wash. State Hort. Assoc. Proc.*, 35 (1939), pp. 47, 48).—Studies (spring of 1939) on the use of a spray containing 2 percent of actual tar oil for preventing fruit set of apples indicated the need of thorough coverage if anywhere near 100-percent kill is anticipated. The tar oil caused abscission by injury to the pedicels or stems. The late cluster-bud stage, when the central blossoming was just beginning to open, appeared to be the most effective time for treatment. Varieties reacted differently to treatment, depending on their blooming habits. Considerable injury was done to the primary leaves, and some spur killing, chiefly of the weaker spurs, was noted on all varieties.

**Reduction and delay of fruit abscission by spraying with growth substances**, A. E. MURNEEK. (Mo. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 432-434).—Using  $\alpha$ -naphthaleneacetic acid and  $\alpha$ -naphthaleneacetamide sprays in concentrations of 0.0005 and 0.001 percent, the author observed, in both Delicious and Stayman Winesap, material reduction of the preharvest fruit dropping as a result of treatment. In one orchard of Delicious trees sprayed with 0.0005 percent naphthaleneacetic acid, a drop of 24 percent was recorded, as compared with 84.4 percent in the controls. Increasing the concentration from 0.0005 to 0.001 percent still further decreased dropping. There was some indication that the acetamide was more effective than the naphthaleneacetic acid. The author believes that the chemicals have an immediate, conspicuous, and valuable effect in preventing excessive abscission of apples during the preharvest and harvest periods.

**Spur nitrogen and pre-harvest McIntosh drop**, L. SOUTHWICK. (Mass. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 435-437).—By labeling in late August all the spurs on an 11-year-old McIntosh tree and recording thereon the date of fruit abscission, the author was able to segregate spurs for total N analysis on the basis of date of fruit drop. The general trend of N percentage values indicated an inverse relationship to fruit-holding capacity. Spur size in terms of fresh weight appeared to be associated positively with a tendency for the spur to drop its fruit prematurely. The data support the theory that a high state of soil fertility tends to increase preharvest dropping of the McIntosh apple.

**The pre-harvest drop of mature McIntosh apples as influenced by applications of nitrogen carrying fertilizers**, M. B. HOFFMAN. (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 438-442).—Observations in an orchard near Red Hook, N. Y., in which McIntosh trees, 16 yr. old in 1935, received 8 lb. of sulfate of ammonia each for 4 successive years showed that N applications increased the abscission of fruit in the preharvest period. In 1935, 1936, and 1937, with rainfall relatively normal or below, the trees receiving N dropped from 15 to 20 percent more of their total crop than controls. In 1938, with excessive rainfall, the N trees dropped 32 percent more fruit than the unfertilized. Over the 4 yr., N had increased total yield and preharvest dropping approximately in the same amounts. In 1939, by decreasing and, in certain trees, omitting the N application, the percentage of preharvest dropping was de-

creased. With no spring application, dropping was about the same on trees fertilized the 4 preceding years as on those never fertilized. Determinations of soil collected in the upper 6 in. revealed no nitrates present on June 1 or September 1 except beneath trees fertilized the current year.

**Observations on effects of soil covers as conservation practices in peach orchards**, J. T. BREGGER and A. M. MUSSEY. (U. S. D. A. and S. C. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 1-6).—Stating that there is accumulating evidence that certain conservation practices, such as continuous vegetative and mulch covers, modified sod, or abbreviated annual cultivation, are practical and successful in peach orchard management, the authors cite examples in which certain of these practices have been used with good results. Plats laid out in 1939 in a commercial orchard near Inman, S. C., permitted the comparison of cultivation with early seeding of annual lespedeza. Soil moisture readings during droughts showed no significant difference in subsoil moisture between the different plats. Growth and fruiting were also apparently comparable.

**Harvesting and handling freestone peaches for canning**, E. L. OVERHOLSER. (Wash. Expt. Sta.). (*Wash. State Hort. Assoc. Proc.*, 35 (1939), pp. 71-79).—A number of varieties are discussed with relation to their outstanding characteristics and adaptability for canning, and information is given as to methods of picking and handling fruit designed for canning use. Common storage has little possibility for holding peaches for any considerable length of time. Fruit harvested at the proper stage of maturity may be held at from 32° to 34° F. for several days and still yield a satisfactory canned product.

**Citrus culture in California**, R. E. CARYL (*Calif. Agr. Col. Ext. Cir. 114* (1940), pp. 48, figs. 19).—The author discusses the history and development of the industry, types and varieties, propagation, establishment of orchards, fertilization and cultural care, irrigation, pruning, frost protection, control of pests, harvesting and handling, and costs of production.

**The oriental persimmon**, H. P. GOULD (*U. S. Dept. Agr. Leaflet 194* (1940), pp. 8).—This leaflet contains information on the distribution, varieties, pollination requirements, cultural needs, pruning, marketing, and uses.

**Papaya chemistry and flavor**, S. J. LYNCH and W. M. FIELD. (Fla. Expt. Sta.). (*Subtrop. Gard.*, 2 (1940), No. 10, pp. 6, 14).—Comparing sweet-tasting with flat-tasting papaya fruits, the authors found almost negligible differences in acid, moisture, and ash contents. There was a definitely higher percentage of total sugars in the sweet fruits, due largely to the appreciably higher percentage of hydrolyzable sugars. The ratio of free reducing to hydrolyzable sugars is considered an indication of sweetness. Analyses of fruits from 10 trees of the Betty variety showed about as much variation among fruits on a single tree as among those on different trees. The average of 26 fruits for 10 trees showed 0.039 percent acid, 90.6 percent moisture, 0.46 percent ash, 4.71 percent free reducing sugars, 1.32 percent hydrolyzable sugars, and 6.03 percent total sugars. The range in total sugars was from 4.46 to 7.6 percent. Definitely sweet-tasting papaya fruits had about 8.09 percent total sugars, and the definitely flat-tasting fruits about 5.41 percent.

**Grape growing in California**, H. E. JACOB (*Calif. Agr. Col. Ext. Cir. 116* (1940), pp. 80, figs. 20).—Information is presented on types of grapes, climatic requirements, viticultural regions of the State, establishment of vineyards, pruning and training, cultural care, fruit thinning, girdling, irrigation, propagation and grafting, harvesting and handling, control of insect and disease pests, and varieties.

**Pruning of the low-bush blueberry**, F. B. CHANDLER and I. C. MASON. (Maine Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 609, 610).—Stat-

ing that low-bush blueberries, *Vaccinium angustifolium*, are pruned by burning the plants to the soil every 2 or 3 yr., the authors report the results of a study of four treatments all initiated in 1930 and including 2- and 3-yr. burning with hay or oil, and 2- and 3-yr. pruning by clipping the tops at the ground. In the burned plants, new growth issued from underground stems, and in the clipped plants from above-ground stubs. There was no significant difference in yield between the 2- and 3-yr. oil burns, and the 2-yr. burns (hay or oil) showed a decreased yield in the 1937 crop as compared with the 1931 crop. Cutting every 2 yr. produced significantly smaller yields than hay or oil burning practiced every 2 or 3 yr. Two-yr. burning is not recommended as a general practice.

**The inheritance of certain characters in the cultivated blueberry, G. M. DARROW, J. H. CLARK, and E. B. MORROW.** (U. S. D. A. and N. J. and N. C. Expt. Stas.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 611-616).—Records taken on a large number of seedlings produced from crosses of known parentage showed that certain parents have apparent capacities for transmitting definite characteristics. For example, Stanley proved to be a source of large size, light-blue color, and fair-to-good scars. Russell and Allen varieties transmitted small size, good scars, very dark-blue-to-black color, and early maturity. Grover gave bad scars and very dark-blue-to-black color. Cabot seedlings were generally small and early maturing. Jersey, selections of *Vaccinium virgatum*, and hybrids of *V. virgatum* and *V. corymbosum* transmitted late maturity.

**The effect of growth substances on the rooting of blueberry cuttings, F. B. CHANDLER and I. C. MASON.** (Univ. Maine). (*Science*, 92 (1940), No. 2376, p. 35).—Extensive experiments conducted with summer cuttings of *Vaccinium corymbosum* and using various forms of growth-promoting substances led to the conclusion that it does not appear advisable to recommend the use of such materials for stimulating the rooting in this high-bush blueberry.

**Growing gooseberries and currants, H. G. SWARTWOUT** (*Missouri Sta. Cir.* 208 (1940), pp. 12, figs. 6).—General notes are presented relating to varieties, planting stocks, propagation, soil adaptation, planting, cultivation, pruning, harvesting, and control of pests.

**Is it possible to devise a satisfactory judging schedule for black walnuts? L. H. MACDANIELS** (*North. Nut Growers Assoc. Proc.*, 30 (1939), pp. 24-27).—Cracking tests with a considerable number of black walnut varieties showed, in general, a fair degree of correlation between percentage of meat and suitability of variety for a given environment. Stambaugh, Thomas, Todd, and Creitz, varieties best adapted to western New York, averaged the best scores based on percentage of meats. A test of different samples of Snyder nuts taken from the same tree showed considerable difference in score because of variation in cracking operations. A schedule of points for judging nuts is outlined.

**The shuck-nut ratio in black walnut varieties, L. H. MACDANIELS** (*North. Nut Growers Assoc. Proc.*, 30 (1939), pp. 74-76).—Observations on samples of nuts collected mostly from young grafted trees and shucked while still firm and green showed great differences in the shuck:nut ratio. In certain samples of Todd, Mintle, and Wiard the nut equaled half the initial weight, while in others with thick, spongy husks the nuts were only from 27 to 30 percent of the total weight. There was a considerable difference in samples of a single variety collected from trees under different conditions. The varietal data are tabulated.

**[Ornamental horticultural studies by the New Jersey Stations]** (*New Jersey Stas. Rpt.* 1939, pp. 75-85).—Progress statements include the following studies: Adaptation of the subirrigation method of supplying nutrients to carnations, roses, and snapdragons; the mineral nutrition of the rose; physical factors

of root media affecting growth of roses; depth of media of various natures and textures in the greenhouse culture of roses; influence of root and air temperatures on growth and metabolism of gardenias; the depth of tile as related to the growing of sweet peas; and miscellaneous culture and variety tests.

**Peony studies**, E. R. HONEYWELL, F. C. GAYLORD, and K. I. FAWCETT (*Indiana Sta. Bul.* 444 (1940), pp. 47, figs. 22).—As a result of trials with a number of varieties cut at different stages of bud development and held for 2–4 weeks in cold storage under known temperature conditions it was found that certain varieties are better adapted than others to this method of handling. The following varieties proved most satisfactory: *Edulis Superba*, *Felix Crousse*, *Festiva Maxima*, *Floral Treasure*, and *Monsieur Jules Elie*. Several factors, such as variety, soil treatment, weather conditions, time of day at cutting, and methods of handling, were involved in determining the proper stage of maturity at which to cut peonies for storage. In general, the buds of the full, double-flowered varieties need to be more fully expanded and to show more color than do single or partly double varieties. Buds of red varieties need to be more fully expanded than those of white varieties. The rapid, careful handling of peonies during the operations of cutting, grading, and storing was important in their conservation. Dry-packing proved less expensive and more satisfactory than moisture application prior to storage. Peonies responded favorably to applications of commercial fertilizers. Detailed information as to procedure in handling peonies designed for shipment is included.

## FORESTRY

**A guide to forestry activities in North Carolina, South Carolina, and Tennessee**, W. MAUGHAN (*Asheville, N. C.: Miller Ptg. Co., 1939, pp. [6]+287. [pls. 29]*).—General information is presented by the Appalachian Section, Society of American Foresters, with relation to various activities.

**On the tree-area ratio and certain of its applications**, H. H. CHISMAN and F. X. SCHUMACHER (*Jour. Forestry, 38 (1940), No. 4, pp. 311–317, figs. 2*).—A method is outlined and illustrated for allocating tree area according to diameter at breast height of individual trees by means of a quadratic equation fitted by the method of least squares to sample plot data. Two applications are exemplified—the pine-hardwood type on the Piedmont Plateau and a fully stocked loblolly pine. The investigation in the loblolly pine brought out the fact that there was no perceptible effect of age or site index upon the tree-area ratio.

**Use of the cull caliper in scaling white oak stave bolts**, M. C. BONNEY (U. S. D. A.). (*Jour. Forestry, 38 (1940), No. 4, pp. 351–355, figs. 2*).—Discussing the construction and use of the cull caliper, the author states that it should simplify the task of training inexperienced men to scale white oak and provide the check scaler with a standard which will not become less accurate or consistent from lack of use, such as is the case of the human eye.

**The hammer mill as an important nursery implement**, H. A. STEAVENSON (U. S. D. A.). (*Jour. Forestry, 38 (1940), No. 4, pp. 356–361, figs. 3*).—The use of the hammer mill to extract and clean hardwood seeds, as a seed scarifier, and for pulverizing peat and compost is described.

**Studies in raising southern pine nursery seedlings**, M. A. HUBERMAN (U. S. D. A.). (*Jour. Forestry, 38 (1940), No. 4, pp. 341–345*).—Studies conducted in the Stuart Forest Nursery, Louisiana, upon various cultural factors, such as mulching, time of sowing, and watering, which might affect germination indicated that these are not as important in respect to tree percentage as are methods of handling the seed prior to germination. In 1935 and 1936 the total losses following germination for longleaf pine and, in most cases, for

shortleaf pine were not nearly as great as the number of seeds failing to germinate. Neither root pruning nor shading of seedlings had any significant effect on percentage of plantable trees. Spacing of the young plants did affect the number of plantable trees, both plantable percentage and green weight increasing significantly with decreased density.

**Base exchange properties of nursery soils and the application of potash fertilizers**, S. A. WILDE and J. C. KOPITKE. (Wis. Expt. Sta. and U. S. D. A.). (*Jour. Forestry*, 38 (1940), No. 4, pp. 330-332, fig. 1).—Of all the exchangeable ions, K is said to present the greatest interest from the standpoint of nursery soil fertility. Except for a negligible amount in the soil solution, available K occurs in the form of an exchangeable ion, making the content of available K retained in the soil despite leaching dependent directly on the level of base-exchange capacity. Heavy applications of K to soils of low exchange capacity may result in considerable leaching losses. Based on the results of nearly 1,000 determinations made over a 7-yr. period on soil samples from 14 forest nurseries, suggested rates of application of K fertilizers to soils of different exchange capacities are presented. In case the base-exchange capacity of a nursery soil is low and there is need for a high level of available K, its maintenance is possible through the use of catch crops, composts, or liquid manures. The inclusion of peat or other matter of high base-exchange capacity may be helpful.

**Frost depth in forest and open in Connecticut**, R. KIENHOLZ (*Jour. Forestry*, 38 (1940), No. 4, pp. 346-350, fig. 1).—Determinations of frost penetration and emergence in northwestern Connecticut during the winters of 1937-38 and 1938-39 showed that it penetrated about twice as deep in the open as in the forest. Material on the forest floor lessened the depth of penetration, delayed the time of freezing of the mineral soil, and retarded thawing. Except in one instance, frost did not begin to emerge from the soil in both the forest and open until the snow cover had entirely disappeared. In every case, frozen soil began to thaw from both the top and bottom at the same time.

**The role of forest fires in the reproduction of black spruce**, R. K. LE-BARRON. (U. S. D. A. and Univ. Minn.). (*Minn. Acad. Sci. Proc.*, 7 (1939), pp. 10-14, fig. 1).—Black spruce, said to be the most valuable species in the making of paper, was observed to occur in many instances as even-aged stands on burned-over land. Over a period of 8 yr., 1931-38, not one complete cone crop failure occurred near Ely, Minn. The mature cones remained attached to the trees for several years, and the seeds were disseminated slowly over a period of at least 2 or 3 yr. Old and freshly matured cones picked in 1936 were sorted by age classes and the seeds extracted. Germinations of 60, 36, and 30 percent were recorded for fresh, 1-yr., and older cones, respectively. In 1937, collections of new and 1-yr. cones yielded seed of the same viability, 76 percent. Fires do not often reach the top cones of trees and they also destroy the surface vegetation and litter which normally interfere with germination of the seed and survival of the seedlings. Thus fires may permit black spruce to occupy sites where the species would normally occur in mixture with other species.

**Growth and mortality of ponderosa pine in relation to site of trees and method of cutting**, G. A. PEARSON. (U. S. D. A.) (*Jour. Forestry*, 38 (1940), No. 4, pp. 323-327, figs. 3).—Three experimental areas of *Pinus ponderosa* on the Coconino National Forest in Arizona, aggregating 455 acres, were logged by different methods in 1913, leaving volumes of 1,833, 2,846, and 4,510 bd. ft. per acre, respectively. In each case the trees left were selected for physical soundness and capacity for growth and seed production. Increment in board feet over a period of 20 yr. has been computed by diameter classes and expressed in percentage of the original volume of each diameter class. Death losses have been com-

puted in the same manner. Increment percentage is highest in the 12-in. class and declines rapidly as diameter increases, while mortality changes in the opposite direction. When plotted on the same scale, the curves of increment and mortality cross each other in the 30-in. class, indicating that, in general, trees above 30 in. diameter at breast height contribute only a net loss to the growth of the stand. This relation is almost identical on the three areas. Net increment per acre is highest on the light-selection cutting area on which the reserved volume was 4,510 bd. ft., and lowest on the scattered-seed-tree cutting where only 1,833 bd. ft. per acre were left.

**Progress of breeding investigations with *Hevea brasiliensis*: The Pilmoor crosses, 1928-1931 series, C. C. T. SHARP** (*Jour. Rubber Res. Inst. Malaya, 10 (1940), Commun. 248, pp. 34-66, fig. 1*).—Records taken on seedlings resulting from controlled crosses between selected parents and upon open-pollinated seedlings, of which only one parent was known, showed that the former were significantly superior in yield. These seedlings of known parentage are considered equal to the best clones, but it was not found that they were superior.

## DISEASES OF PLANTS

[Phytopathological studies by the Florida Station]. (Partly coop. U. S. D. A.). (*Florida Sta. Rpt. 1939, pp. 83, 94, 117-122, 123-132, 133, 134, 139-141, 144, 165-169, 171, 172, 180, 184, 185, 190-193, fig. 1*).—Brief reports of progress by various members of the station and substation staffs (R. M. Barnette, J. R. Beckenbach, H. E. Bratley, A. N. Brooks, A. H. Eddins, B. R. Fudge, D. G. A. Kelbert, R. R. Kincaid, K. W. Loucks, J. R. Neller, A. S. Rhoads, G. D. Ruehle, W. B. Shippy, W. B. Tisdale, G. R. Townsend, R. K. Voorhees, M. N. Walker, J. R. Watson, G. F. Weber, and E. West) are included on chlorosis in corn plants and other field crops; root knot nematode control on vegetable crops by mulches and by resistant varieties; control of various diseases of potatoes, including bacterial wilt and soft rot, scab, virus diseases, blackleg, and seedling cross and variety test; brown rot of potato and related plants; comparative study of forms of *Diplodia* resembling *D. frumenti*; control of *Fusarium nivium* wilt and other diseases of watermelon; *Fusarium* tomato wilt control; *Clitocybe tabescens* root rot of citrus trees and other woody plants; a bark disease of Tahiti lime trees (cause unknown); fruit rots of grapes; host relations and factors influencing the growth and parasitism of *Sclerotium rolfsii* on various host plants; a hitherto unreported disease of beans due to an aerial species of *Rhizoctonia*; causes of failure of seed and seedlings in various Florida soils, with special reference to *Pythium* and *Rhizoctonia*, and preventive methods; comparative study of the pathogenicity and taxonomy of *Alternaria*, *Macrosporium*, and *Stemphylium*; control of diseases of potato and vegetable crops due to *Rhizoctonia*; *Sclerotinia sclerotiorum* pink rot and other diseases of celery and their control, including early blight; citrus gummosis and psorosis; dusting cucumbers for downy mildew; control demonstrations with tobacco downy mildew; *Colletotrichum* leaf spot of Nephthytis; *Sphaeropsis*-induced witches' broom of oleander; control of *Cercospora* leaf spot and powdery mildew of *Zinnia*; downy mildew resistant cantaloup and cucumber; control of dieback and scab of citrus trees, and of melanose and stem-end rots of the fruits; seed- and soil-borne diseases of vegetable crops, including potato seed-piece decay, and halo blight of beans; leaf blights of vegetable crops, including bean rust, bean breeding for quality and resistance to rust and powdery mildew, early blight of potato, and tomato spraying; physiological phases of plant nutrition, including the "puffing" disorder of tomato, bud drop of lima beans in the fall, and failure of pods of English peas to fill properly; weather conditions in relation to field and plant-bed diseases

of tobacco, and disease-resistant tobacco varieties; control of tobacco downy mildew; diseases of minor fruits and ornamental plants; control of potato diseases in Dade County; diseases of avocado and mango and their control; and tomato disease control.

[Plant disease studies by the Georgia Coastal Plain Station]. (Partly coop. U. S. D. A.). (*Georgia Coastal Plain Sta. Bul. 30 (1939)*, pp. 89, 90, 111-114, 121-127, 130, 131, figs. 3).—Brief progress reports are included on studies of tomato early blight as influenced by rainfall and humidity, seed treatments and sprays, and shipping conditions; root knot nematodes—their chemical control, active migration, spread from an infested area, and control in the field on various crop plants; diseases of flue-cured tobacco and their control, and a seasonal survey for 1938; and shade tobacco diseases.

[Phytopathological studies by the New Jersey Stations] (*New Jersey Stas. Rpt. 1939*, pp. 33, 34, 36, 37, 86, 87, 89-99).—Brief reports are included on studies of fungus diseases and the virus-induced false blossom of cranberries (coop. U. S. D. A.); blueberry disease studies; potato diseases, including dips for seed potatoes and soil treatments with particular reference to *Rhizoctonia* and scab, and spray and dust treatments of the vines; mercurial dips for scurf, the effect of soil reaction on pox, and dips for enhancing color and preventing rots of sweetpotatoes; vegetable disease control work, including bean rust, club root of crucifers, cantaloup spraying test for various diseases, eggplant wilt, lettuce diseases, mushroom bubbles or *Mycogone* disease, root knot on cucumbers, pepper mosaic, pea root rot, and sweet corn bacterial wilt; copper and sulfur sprays for apple scab and life history and ecological studies of the causal fungus; fungicidal control of cherry leaf spot; investigation of the principles underlying the cause of injury by copper fungicides; control of spur blight (*Mycosphaerella rubina*) on raspberries; and diseases of ornamentals, including *Sphaeropsis ellisii* on conifers, *Phomopsis* canker and bacterial leaf spot of gardenias, dieback of *Daphne cneorum*, and diseases of various ornamentals due to *Pestalotia* spp., *Colletotrichum* sp., and *Gloeosporium* spp.

[Phytopathological studies by the Puerto Rico College Station] (*Puerto Rico Col. Sta. Rpt. 1939*, pp. 57-60).—Brief reports of progress are given on diseases of bananas and plantains, banana leaf spot (*Cercospora musae*), pineapple diseases, and controlling diseases of yams, all by M. T. Cook and A. R. López; frequency of bordeaux injury on cucumbers, by A. Riollano; and diseases of papayas as limiting factors in their culture, by F. Julia, Riollano, and L. A. Serrano.

The Plant Disease Reporter, [July 1 and 15, 1940] (*U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr.*, 24 (1940), Nos. 12, pp. 233-250; 13, pp. 251-276, figs. 4).—The following items of interest to phytopathology are included:

No. 12.—First report of bacterial ring rot in Arkansas, by S. B. Locke; appearance of azalea flower spot in Texas, by A. A. Dunlap; tulip failures due to fungi; tobacco diseases in Kentucky, by W. D. Valleau and E. M. Johnson; reports on bacterial wilt of sweet corn on Long Island, cereal diseases for Georgia, cereal rusts in the southern Plains States, and stem rust severe on wheat in California; reports on fruit diseases in New York and Wisconsin; plant disease check list revision, including *Abutilon* through *Aleurtites*, by F. Weiss; and scab destructive on winter wheat in Maryland, Delaware, and Virginia, by A. G. Johnson.

No. 13.—First report of bacterial ring rot in Virginia, by H. T. Cook; some new or unusual occurrences of potato diseases in Louisiana, by L. H. Person; tomato curly top more severe in Utah than in 1939, by H. L. Blood; tomato curly top and other noteworthy plant diseases in the lower Rio Grande Valley, by G. H. Godfrey; plant disease notes from Massachusetts, by O. C. Boyd;

plant disease notes for Georgia, by J. H. Miller; some plant diseases reported from New York; a survey of cotton seedling diseases in 1940 and the fungi associated with them, by P. R. Miller and R. Weindling; and check list revision, including map of plant growth regions of the United States, use of *Corticium solani*, and plant disease check list of *Alnus* through *Ampelopsis*, by F. Weiss.

**Plant biology applied to agriculture.—III, Mycology—parasitic diseases, R. PEROTTI** (*Biologia vegetale applicata all'agricoltura.—III, Micologia—malattie parassitarie. Torino: Rosenberg & Sellier, 1940, vol. 3, 2, ed., pp. X+[2]+1191, figs. 401*).—This, one of a five-volume monograph on the biology of crop plants, discusses the general question of parasitic diseases, including morbid anatomy, and then proceeds to a consideration of specific diseases arranged by their causes—bacteria, ultramicroscopic parasites (viruses), Myxomycetes, and the various groups of the true fungi. A section on immunity in plants and general control measures, and author and subject indexes conclude the work.

**The rusts of Minas Geraes, Brazil, based on collections by A. S. Müller, H. W. THURSTON, JR.** (Pa. State Col.). (*Mycologia, 32 (1940), No. 3, pp. 290-309*).—This annotated check list includes descriptions of new species in the genera *Aecidium*, *Endophyloides*, *Prospodium*, and *Uredo*.

**Uredinales of New Guinea, G. B. CUMMINS.** (Ind. Expt. Sta.). (*Mycologia, 32 (1940), No. 3, pp. 359-375, figs. 14*).—Of the 34 species included, 20 are described as new in the genera *Puccinia*, *Uromyces*, *Corbulopsora* n. gen., *Sphaerophragmium*, *Kuehneola*, *Crossopsora*, *Uredo*, and *Aecidium*.

**The toxicity of certain chemicals in aqueous solutions to spores of *Penicillium expansum*, R. H. WELLMAN and F. D. HEALD.** (Wash. Expt. Sta.). (*Phytopathology, 30 (1940), No. 8, pp. 638-648, fig. 1*).—Spores 7-15 days old were exposed to solutions of the chemicals for 1 min., placed in distilled water to prevent further action, and plated out with 2 percent potato-dextrose agar. Toxicity was measured by the relative number of colonies formed in treated v. control Petri dishes. Sodium ortho-phenylphenate at 4,000 p. p. m. or 2,500 p. p. m. of a mixture of sodium tetrachlorophenate and sodium 2-chloro-ortho-phenylphenate killed a high percentage of *P. expansum* spores. Of 9 triphenylmethane dyes tried, only crystal violet, gentian violet, and malachite green proved toxic, indicating a relationship between fungicidal activity and the number of methyl groups attached to the amino nitrogens. None of the 12 miscellaneous dyes tested exhibited fungicidal activity at 1,000 p. p. m. Sodium salicylate and thymol were the only 2 of 20 miscellaneous organic fungicides tested that completely inhibited colony formation at 10,000 p. p. m. Of the 25 inorganic chemicals tested, chromium trioxide, potassium dichromate, and sodium thiosulfate were fungicidal at 10,000 p. p. m. Iodine, mercuric chloride, and potassium mercuric iodide were effective at 1,000 p. p. m.

**The carbon and nitrogen metabolism of *Stereum gausapatum* Fries, J. A. HERRICK** (*Ohio Jour. Sci., 40 (1940), No. 3, pp. 123-129*).—"The fungus was found to grow well in culture with the following compounds as the only source of carbon: Xylose, dextrose, galactose, levulose, mannose, maltose, sucrose, raffinose, glycogen, inulin, and soluble starch. Rhamnose and arabinose were much less effective, and glycerine was found to be of very little value but did support some growth. That lignin and tannins may serve as food for the fungus is indicated by various experiments and observations. Synthetic media containing peptone supported a heavy growth of mycelium, but when the nitrogen was furnished only in the form of inorganic salts ( $\text{NH}_4\text{NO}_3$ ,  $\text{NH}_4\text{Cl}$ ,  $(\text{NH}_4)_2\text{SO}_4$ ,  $\text{KNO}_3$ ,  $\text{NaNO}_3$ ,  $\text{NaNO}_2$ ) or asparagine growth was not significantly greater than on a nitrogen-free medium. The fungus is therefore not able to

use appreciable amounts of nitrogen from such inorganic compounds.  $\text{NaNO}_3$  is definitely quite toxic. The other compounds were shown to be nontoxic."

**Factors affecting spore germination and growth of *Urocystis occulta* in culture,** L. LING (*Phytopathology*, 30 (1940), No. 7, pp. 579-591, figs. 2).—Chlamydospores of *U. occulta* germinated at  $\pm 10^\circ$ - $25^\circ$  C., but not at  $5^\circ$  and  $30^\circ$ . The optimum was  $\pm 15^\circ$ . Temperature affected the rapidity more than the final percentage of germination; the substrate and certain chemicals affected both rapidity and percentage. Solid media, distilled water, tap water, and sugar solutions proved unfavorable, but the spores germinated well in soil infusions. Benzaldehyde at  $\pm 3:2,000,000$  had a decidedly stimulating effect, while organic acids (malic, lactic, citric, and oxalic) failed to stimulate germination, and the effects of plant tissues were erratic. In general, spores germinated better in darkness or diffuse light than in direct sunlight, although this may have been partly a temperature effect. The optimum pH for spore germination was  $\pm 6.86$ , and there was no germination at 3.8, but 5 percent of the spores still germinated at 8.95.

*U. occulta* grew slowly on artificial media, the colonies of monosporous cultures attaining a maximum diameter of 45 mm. only after 10 weeks, with sectors commonly though not abundantly produced. Distinct lines were obtained by transferring from these sectors, but the origin of the sectoring is unknown, as the hyphal cells were binucleate or multinucleate and various combinations of nuclei may have occurred. Several hundred sporidial branches were cut from promycelia in attempts to isolate haploid lines, but only two were obtained. The latter differed from monosporous lines in cultural characters and failed to infect rye, either singly or in combination. Monosporous cultures grew on potato-dextrose and malt-extract agars at  $5^\circ$ - $25^\circ$ , the optimum being about  $20^\circ$ , which is  $\pm 5^\circ$  higher than the optimum for spore germination. The organism grew moderately well on potato-dextrose agar initially at pH 5-9, the optimum being 6.2. On the solid media tried, potato-dextrose agar appeared best. Many carbohydrates (except rhamnose and levulose) supported fair growth, but levulose appeared toxic. Of the mineral elements, P, N, and Mg were indispensable. Expressed juices of sugar beet, dahlia, potato, and rye did not appreciably promote growth.

**Seed treatments for corn, oats, and barley in Arkansas,** V. H. YOUNG and C. K. McCLELLAND (*Arkansas Sta. Bul.* 389 (1940), pp. 27).—Using five fungicidal dusts on Neal Paymaster corn (1928-30 and 1932) and taking data on total seedling emergence, final stands, and yields, no correlation was found between results and weather conditions during the planting season and under the test conditions no assured benefits were obtained from any of the treatments.

In a 6-yr. study of oat-seed treatments, certain dusts (1931-32) gave excellent control of loose smut, whereas others tried gave only fair or negligible control. None of the treatments used appeared to affect the stand or to have any marked effect on the ratio of straw to grain. Almost perfect control of smut was obtained by either formaldehyde spray or ethyl mercury dust methods (1933-36), and in addition (1931-32) to various experimental organic mercury dusts, the formaldehyde-dip and dust methods also gave practically perfect control of oat smut. Although yield increases were essentially in proportion to reductions in smut incidence when heavily smutted seed was used, differences in results from various treatments were insufficient to indicate that any of the treatments were more efficient than others in their effects on yields. Combined treatments using first a formaldehyde spray and then ethyl mercury dust with either badly smutted or clean seed gave no evidence of beneficial effects from ethyl mercury chloride dust other than through smut control. No evidence of stimulatory

effects or benefit on yields from the control of other seed- or soil-borne organisms was secured. It appears then that cost, ease of applying, and freedom from danger of seed injury are the determining factors in selecting a seed treatment for oats.

In tests (1936-38) with Missouri Beardless barley seed, both covered and loose smuts being present, the latter was controlled to a considerable degree by both the formaldehyde-soak and ethyl mercury phosphate dust treatments, as well as by the hot-water method. Partial control of loose smut by surface treatment indicated that a portion of the loose smut was due to *Ustilago nigra*. In the last 2 yr. there were indications that, in addition to infection from seed-borne smut, infection also resulted from spores (*U. hordei* and *U. nigra*) of the preceding season remaining over summer in the soil. There was also strong evidence that ethyl mercury phosphate dust gave definite protection against infection from soil-borne spores of both covered and loose smut, as well as from seed-borne spores of these fungi. The hot-water treatment and the formaldehyde-soak method afforded protection against seed-borne infection only. No significant differences in yield were noted. The extreme variation in yields among the control plats indicated that soil inequalities were probably the greatest factor in such variations.

**The influences of sowing depth and moisture on smut diseases, and the prospects of a new method of control, G. H. JONES and ABD EL GHANI SEIF-EL-NASEB** (*Ann. Appl. Biol.*, 27 (1940), No. 1, pp. 35-57, figs. 11).—The incidence of flag smut of wheat, covered smut of barley, and grain smut of millet and broomcorn in Egypt was found to depend very largely on methods of planting, analyzed into factors of depth of sowing and soil moisture. It is concluded that the influence of depth of sowing is probably due to lengthening of the susceptible stage of the host by deeper planting and to shortening of this stage by rapid emergence into unfavorable aerial conditions by shallow planting. On this assumption, theoretical curves of infection plotted against depth of planting were constructed, these curves bearing some resemblance to the actual curves of observed disease. The smaller influence of soil moisture proved to be constant, wet soil discouraging disease increasingly with depth, presumably due to lack of aeration. However, in exceptional cases, occurring only in deeper plantings in wet soil, the influence of moisture became so great that there was apparently a reversal of the influence of depth. The probable causes of such exceptions are discussed. It is believed that variation in depth of planting may be found useful in studies of seed- or soil-borne seedling diseases, since it seems to enable the effect of time to be separated and varied, within limits, independently of other factors. In the smuts it seems to operate by delaying the rupture of the coleoptile and the consequent onset of resistance of the seedling. In irrigated regions these results can be applied fully by sowing on the surface of water-soaked soil. The probable relative practical values of the three means of control—special planting methods, seed disinfection, and the selection of resistant varieties—are discussed. There are 36 references.

**Delayed reduction of the diploid nucleus in promycelia of *Ustilago zaeae*, S. P. CHILTON.** (U. S. D. A. and Minn. Expt. Sta.). (*Phytopathology*, 30 (1940), No. 7, pp. 622, 623, fig. 1).—Inoculations with monosporidial cultures from promycelia of chlamydospores of *U. zaeae* germinating abnormally, made alone and in various combinations into young corn plants, indicated that both haploid and diploid sporidia (based on whether segregation for sex or compatibility factors had or had not occurred) were produced by the same chlamydospore in three cases. It is thus concluded that in *U. zaeae* reduction of the diploid nucleus may be delayed past the first division.

**The initiation of infection by bunt of wheat (*Tilletia caries*), J. G. CHURCHWARD** (*Ann. Appl. Biol.*, 27 (1940), No. 1, pp. 58-64, pl. 1, figs. 3).—The mode of penetration of wheat coleoptiles by *T. caries* was studied and a special method adopted for inoculating the coleoptiles to insure abundant mycelium. Cultures from single as well as from masses of secondary basidiospores and from chlamydospores were used as inocula. Two distinct types of superficial mycelium were observed on the coleoptile. One, derived from germinating secondary basidiospores, was narrow, not deeply stained, regular in outline, and occasionally branched. The other, resulting from fusion of two of the narrow-type hyphae, was shorter, irregular in outline, and more deeply stained. In it the nuclei were associated in pairs. No fusions occurred between hyphae of single spore cultures derived from a secondary basidiospore, so that in plants inoculated with these cultures "fusion hyphae" were absent. Attempts to induce hyphal fusion of compatible strains on media of various kinds failed. An appressorium formed below the fusion hypha. Where this contacted the plant cuticle between the epidermal cells, a small peg developed, and penetration, always intercellular, was effected. Immediately after penetration there was formed an irregular, swollen fungus cell into which the contents of the appressorium passed. In it the nuclei were associated in pairs. At the first cross wall this swollen cell bifurcated to form narrow, intercellular mycelium in which the nuclei were no longer associated. There are 19 references.

**Longevity of urediospores of crown rust of oats, H. R. ROSEN and L. M. WEETMAN** (*Arkansas Sta. Bul.* 391 (1940), pp. 20).—To determine the importance of urediospores of *Puccinia coronata avenae* produced in carrying the parasite from one crop season to another in the same general locality, oat leaves heavily infected with this stage were subjected to uncontrolled, natural conditions as well as to 45 combinations of controlled temperature and humidity, the range being from 5° to 40° C. and from  $\pm 0$  to 90 percent relative humidity. Urediospores gathered in June and kept outdoors were found to survive less than 15 days. During each of the 2 yr. of these tests, the average temperature and humidity were high and were characteristic of average Arkansas conditions at that season. Spores kept at 5° and 10° and at 25 and 50 percent humidities showed greater longevity than those at higher temperatures or humidities. The difference in life span was very marked, ranging from less than 15 days under the higher temperatures and humidities to over 300 days under the lower conditions. Both humidity and temperature influenced longevity to a marked degree. Thus, below 25 percent or above 50 percent r. h. the spores were short-lived, irrespective of temperature.

The evidence indicates that no predictions are possible as to the severity of crown rust on a future crop based on the prevalence of rust on the current crop, so far as longevity of urediospores is concerned. It is concluded that, so far as race 1 is concerned (the common race in Arkansas), the urediospores produced on one oat crop are incapable of living long enough to perpetuate the disease on the succeeding crop under the existing climatic conditions, and that additional work is necessary to determine the sources of infection.

**A study of the relation between the seedling and mature-plant reaction to *Puccinia graminis tritici* in durum wheat crosses involving Iumillo, W. H. WADDELL** (*Canad. Jour. Res.*, 18 (1940), No. 6, Sect. C, pp. 258-272, fig. 1).—The seedling reaction to race 21 of *P. graminis tritici* in the greenhouse was compared with the mature-plant reaction to all races present in the field, in three intradurum crosses involving Iumillo. All lines resistant in the greenhouse proved resistant in the field, but a large number of lines were susceptible at both seedling and mature stages. Another group contained lines susceptible

as seedlings but resistant as mature plants. However, increasing susceptibility in the seedling stage usually indicated the same trend in the mature plant. Most of the lines highly resistant as mature plants could have been selected as seedlings. Iumillo apparently possesses a factor or factors for mature-plant resistance as well as for resistance at both stages. The stem rust reactions in the hybrid lines did not appear to be inherited in a simple Mendelian manner, due apparently in the Iumillo × Mindum crosses to the presence of two types of resistance in Iumillo, while in the Pentad × Iumillo crosses the inheritance was complicated still more by the additional factors for resistance in the Pentad parent. In the cross Iumillo × Mindum there was apparently no correlation between seed color and resistance, and seed color was inherited in a simple 3:1 ratio, with red seed dominant. The results of the study indicate that simple and inexpensive greenhouse tests, in which but one physiologic race is used, may be employed to eliminate susceptible lines in the field in durum crosses involving Iumillo.

**Unseasonable germination of teliospores of *Puccinia graminis tritici*,** R. U. COTTER. (U. S. D. A. and Minn. Expt. Sta.). (*Phytopathology*, 30 (1940), No. 8, pp. 689-691).—Teliospores from durum wheat collected at St. Paul, Minn., in late summer (1939) germinated in November of the same year, although according to 10 years' previous observations germination would not have been expected until the following March or April. Not all collections germinated in November, nor did teliospores of other stem rust varieties germinate early. The basis for this case of germination without the usual rest period is unknown, but it is suggested that their formation on durum wheat late in the year may have been the factor responsible.

**Studies on browning root rot of cereals.—VI, Further contributions on the effects of various soil amendments on the incidence of the disease in wheat,** T. C. VANTERPOOL (*Canad. Jour. Res.*, 18 (1940), No. 6, Sect. C, pp. 240-257, figs. 4).—These further studies of the effects of soil amendments on browning root rot are said to have substantiated earlier findings<sup>3</sup> as showing that phosphatic fertilizers and farm manure will give adequate control of *Pythium* root rot of wheat in infested prairie soils. The growth improvement induced is believed due to the production of a larger number of more rapidly growing roots, lessening the chances for infection and leaving more roots healthy, though the same percentage may be affected as in diseased plants exhibiting severe leaf discolorations. No actual increase in resistance was noted. Nitrogenous materials applied singly had virtually no effect on growth, but once ample P was added, further N applications gave substantially greater increases than phosphate alone, i. e., P was apparently the chief limiting factor. In preliminary tests, no difference was noted in the phosphate-fixing power of browning and normal soils. Typical browning soils responded irregularly to small applications of B, Cu, Mn, or Zn, but were not found seriously lacking in these elements. Moderate benefits resulted from heavy applications of gypsum and of S. Browning soil was also found deficient in phosphate for noncereals such as alfalfa, buckwheat, carrots, flax, lettuce, and sweetclover, though these crops were not attacked by the *Pythium* species pathogenic on cereals. The poor growth of the noncereals in browning soil thus appears due to nutrient deficiencies, whereas that of cereals is due to root-destroying fungi as well. In both cases P is believed the chief limiting factor. Ground cereal straw, sweetclover hay, and weed hay amendments gave moderate increases in the growth of wheat. No consistent differences were found in the C : N ratios of browning v. normal soils. The results as a whole suggest that two of the most practical means of

<sup>3</sup> *Canad. Jour. Res.*, 13 (1935), No. 4, Sect. C, pp. 220-250, pl. 1, figs. 5.

meeting the browning root-rot problem are to supply supplemental nutrients as artificial fertilizers and to add organic residues or farm manure regularly to subject fields.

**Varied rice diseases**, E. M. CRALLEY. (Ark. Expt. Sta.). (*Rice Jour.*, 43 (1940), No. 4, pp. 11, 12).—This is a brief progress report on studies of varietal resistance and the effects of fertilizers, irrigation methods, and sulfur treatments on stem rot; control of leaf spot by developing resistant varieties; and the effects of the Mg:Ca ratio and irrigation methods on white tip, and its control by resistant varieties.

**Selenophoma on grasses**, R. SPRAGUE and A. G. JOHNSON. (U. S. D. A. and Oreg. Expt. Sta.). (*Mycologia*, 32 (1940), No. 3, p. 415).—*Septoria bromigena* and *S. donacis* are transferred to the genus *Selenophoma*.

**Notes on Septoria scalds of vetch and peas in Oregon**, R. SPRAGUE. (Oreg. Expt. Sta. and U. S. D. A.). (*Phytopathology*, 30 (1940), No. 6, pp. 541, 542, fig. 1).—*S. viciae* causes an important stem scald and leaf spot of winter vetches in western Oregon. A similar disease of Austrian winter peas is due to *S. pisi*.

**Powdery mildew of lespedeza**, H. W. JOHNSON, C. L. LEFEBVRE, and T. T. AYERS. (U. S. D. A.). (*Phytopathology*, 30 (1940), No. 7, pp. 620, 621, fig. 1).—A powdery mildew on various strains of annual lespedeza at Arlington, Va., was identified as due to *Microsphaera diffusa*. Though it has usually developed too late to cause serious losses, it appears to induce a certain degree of premature defoliation. From greenhouse data and field observations it is apparent that strains of *Lepedeza striata* are more susceptible than are those of *L. stipulacea*.

**Phytophthora cactorum as a cause of root rot in sweetclover**, M. W. CORMACK (*Phytopathology*, 30 (1940), No. 8, pp. 700, 701).—*P. cactorum*, shown to cause a root rot of sweetclover in Alberta, Canada, appears responsible also for the root rot of this host in the United States, previously attributed to *P. megasperma*. Moderate damage occurred in several widely separated areas of Alberta during early spring and summer. Mature sweetclover plants proved more susceptible than seedlings. Alfalfa was not attacked.

**Behavior of Phoma betae in the presence of boron** [trans. title], O. VERONA and I. DE MARCHI (*Ann. Facoltà Agr. R. Univ. Pisa, n. ser.*, 2 (1939), pp. 645-654, figs. 5; *Fr., Ger., Eng. abs.*, pp. 645, 646).—The studies reported led to the conclusion that boric acid in small doses stimulates growth of *P. betae*, whereas in comparatively large doses boric acid and sodium tetraborate (the latter more than the former) inhibit and even prevent growth. The fungus grew under comparatively acid conditions and was not injured by strongly alkaline agents. Antagonism was noted between *P. betae* and *Bacillus subtilis*.

**The effect of Cercospora beticola on the chemical composition and carbon assimilation of Beta vulgaris**, C. M. NAGEL and O. A. LEONARD. (Iowa Expt. Sta.). (*Phytopathology*, 30 (1940), No. 8, pp. 659-666).—In these experiments both field- and greenhouse-grown sugar beet plants were analyzed, diseased and healthy roots, crowns, petioles, and blades being compared. Results indicated that leaf spot materially reduces the percentage of sucrose in the crowns, roots, petioles, and blades. Total nitrogen in diseased roots was greater than in comparable healthy and pruned tissues, and small differences in pectin content were found. Roots and crowns of diseased plants were higher in soluble nitrogen than similar healthy and pruned tissues. Analysis of diseased and healthy leaves showed that the percentage of total nitrogen decreases with severity of infection. As leaves became more severely affected, their ability to assimilate CO<sub>2</sub> diminished.

The winter carry-over of angular leaf spot infection in Arizona cotton fields, J. F. HARE and C. J. KING. (U. S. D. A.). (*Phytopathology*, 30 (1940), No. 8, pp. 679-684, figs. 2).—The angular leaf spot bacterium (*Phytomonas malvacearum*) may overwinter in Arizona on cottonseed remaining in the fields. Greenhouse plantings from seed collected in spring from old diseased areas exhibited a high proportion of infected seedlings, whereas control plantings of seed from disease-free fields remained healthy. Volunteer seedlings arising from diseased bolls plowed under proved to be sources of infection to cotton subsequently planted, probably through irrigation water or wind-driven rains. Preventive measures suggested for diseased fields include pasturing or burning the plant remains and early cultivation to destroy volunteers.

Variation in the tolerance of certain physiologic races of *Actinomyces scabies* to hydrogen-ion concentration, L. A. SCHAAL. (Minn. Expt. Sta.). (*Phytopathology*, 30 (1940), No. 8, pp. 699, 700, fig. 1).—*A. scabies* isolates from potato tubers growing in soils at pH 5.4 and 6.8, respectively, were each inoculated to potato dextrose agar cultures adjusted to pH 5.0 and 8.5. Both appeared identical on this medium when adjusted to pH 7. The strain from the more acid soil grew in this medium adjusted to pH 5.0, whereas the one from the less acid soil failed to grow at this pH value, appreciable growth being noted only on the medium at pH 6-8.5. Both isolates proved pathogenic on Katahdin and Green Mountain tubers grown in the greenhouse in a soil at pH 6.8. The isolate from the more acid soil produced only a shallow pustule, whereas the other produced a deep pustule. These strains are thus physiologic races which can be differentiated by pH tolerance in culture and by differences in pathogenicity.

Some notes on a suspected variant of *Solanum virus 2* (potato virus Y), K. M. SMITH and R. W. G. DENNIS (*Ann. Appl. Biol.*, 27 (1940), No. 1, pp. 65-70, pl. 1).—The authors describe and discuss an apparent variant of *Solanum virus 2* (potato virus Y) differing slightly from the type virus in the symptoms induced and sharply in its longevity in vitro. This virus was accompanied in the tobacco plant by a necrotic symptom suspected of being due to a separate but very unstable virus.

Relation of food translocation to movement of virus of tobacco mosaic, C. W. BENNETT. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 60 (1940), No. 6, pp. 361-390, figs. 9).—In vegetative Turkish tobacco plants with a main stem horizontally and a basal sucker vertically placed, basipetal movement of tobacco mosaic virus in the main stem was rapid and acropetal movement slow, while in similar plants maturing seeds on the main stem acropetal movement was rapid. In vegetative plants acropetal movement was accelerated by darkness and by defoliation, but basipetal movement was very slow in main stems in the dark. In *Nicotiana glauca* plants having top and basal grafts of Turkish tobacco separated by 3 ft. of stem, the virus moved from top to basal grafts and produced symptoms in 6-9 days, whereas, in 7 of 10 plants it failed to move from basal to top grafts in periods of 224-252 days. Upward movement was relatively rapid when the tops were defoliated. Turkish tobacco roots proved susceptible to infection, but usually long periods were required for the virus to move into the tops and induce symptoms. Removal of the tops hastened this upward movement. Tobacco mosaic virus moved through rings that broke the phloem continuity in the Turkish tobacco stems, but passage was delayed. In certain *N. glauca* plants the virus failed to pass such rings in periods some of which exceeded 250 days. However, cucumber mosaic virus passed such rings in all cases, although passage was delayed.

Since tobacco mosaic virus usually fails to induce mottling on *N. glauca*, it is suggested that the parenchymatous tissue of this species may be unfavorable for movement and multiplication, which may account for the inability of the virus to pass rings breaking the phloem continuity. The fact that the virus of cucumber mosaic, which causes mottling on *N. glauca* and therefore probably occurs abundantly in the parenchyma, passed such rings in all instances lends support to this concept. The evidence indicates that the movement of tobacco mosaic virus is correlated with food transport. The factors involved in movement probably do not differ fundamentally from those responsible for the movement of other plant viruses.

**Evidence of passive immunization of tobacco, *Nicotiana tabacum*, from the virus of curly top, J. M. WALLACE. (U. S. D. A.). (*Phytopathology*, 30 (1940), No. 8, pp. 673-679, fig. 1).**—After recovery from this disease Turkish tobacco plants exhibited mild symptoms and were not visibly affected on reinoculation. However, when the insect vector transferred the virus from recovered to healthy plants the latter developed severe symptoms, indicating that the recovered plants contained the virus unaltered in virulence. On the other hand, healthy plants infected by grafting with scions from recovered plants developed mild symptoms only. It is therefore suggested that protective substances or properties transferable by grafting may be present in recovered plants. When scions were taken from leafhopper-inoculated plants at 5-day intervals after inoculation and grafted to healthy plants, it was indicated that 20 days or more were required for inoculated plants to develop maximum effectiveness in affording protection. Since this acquired tolerance of recovered plants was apparently not due to the presence of an attenuated or mildly reacting virus strain, and because it was transferable by grafting, these plant-virus reactions are described as "acquired" immunity. The protection to healthy plants afforded by grafting to recovered plants is said to resemble certain types of passive immunization as understood in the animal field.

**The thixotropic character of the tobacco-mosaic virus protein, V. L. FRAMPTON. (Cornell Univ.). (*Phytopathology*, 30 (1940), No. 8, pp. 666-673, figs. 3).**—This virus protein was found to form thixotropic sols when dispersed in water. The protein particles in "solution" not only failed to show all the properties of molecules, but they also failed to exhibit the most characteristic property of molecules in solution, viz, that of unrestricted thermal motion. The question is thus raised as to the validity of some interpretations of physical measurements hitherto made on the protein.

**Infectivity of tobacco mosaic virus in liquids over 14 years old, E. M. JOHNSON and W. D. VALLEAU. (Ky. Expt. Sta.). (*Phytopathology*, 30 (1940), No. 8, pp. 697, 698).**—As measured by ability to cause necrotic spots, this virus proved about one-third as infective when stored for 14 yr. in cork-stoppered flasks to which benzene and xylene, respectively, had been added as fresh material diluted similarly with water. Under the test conditions, toluene had no preservative effect. Ground frozen shoots of mosaic tobacco and air-dried mosaic tobacco, each mixed with water and stored without preservative, retained a low degree of infective power after 14 yr.

**The history of tobacco downy mildew in the United States in relation to weather conditions, N. E. STEVENS and J. C. AYRES. (Univ. Ill.). (*Phytopathology*, 30 (1940), No. 8, pp. 684-688, fig. 1).**—On the assumption that weather conditions in Florida and Georgia during the years of epidemic incidence of tobacco downy mildew (1937 and 1932) must have been very favorable to the disease, it is pointed out that the years of initial outbreak in these regions

(1921-31) were apparently not particularly favorable and the appearance of the disease in those years may well have resulted from independent introductions.

**Seasonal occurrence of tomato diseases in Florida**, G. F. WEBER and D. G. A. KELBERT (*Florida Sta. Bul.* 345 (1940), pp. 36, figs. 22).—This handbook considers the losses due to tomato diseases, environmental effects on them, and their seasonal development, including discussions of seed selection and disinfection, seedbed preparation, soil disinfection, damping-off, soil preparation and plant setting, fungicides and their application, rotation, fertilizers and their application, cultivation, harvesting, and packing and transportation.

**Fruit stripe of tomato caused by a tobacco type 1 virus**, L. K. JONES. (Wash. Expt. Sta.). (*Phytopathology*, 30 (1940), No. 6, pp. 538-540, figs. 2).—A virus infection of tomato exhibiting mosaic of the foliage and chlorotic to necrotic stripes on the fruit appeared spontaneously in field plats at Pullman, Wash. The virus characteristics were similar to those of tobacco type-1 virus.

**The effect of zinc deficiency upon the root of *Lycopersicum esculentum***, E. T. ELTINGE and H. S. REED. (Univ. Calif. et al.). (*Amer. Jour. Bot.*, 27 (1940), No. 5, pp. 331-335, figs. 4).—Using three methods found to give harmonious results in studying Zn deficiency, the authors investigated its effects on the growth of cells and tissues of tomato roots, and compared the systemic effects with those in the leaves. Roots exhibited a series of swellings and an irregular distribution of root hairs. The roots themselves were moniliform in shape, and the swellings were marked with tufts of root hairs, many of which were extremely crooked and showed other abnormal characteristics. Secondary roots tended to develop at such nodular enlargements. The tip of the main root often died, and elongation was continued by the growth of a cluster of secondary roots breaking through near the dead tip. These secondary roots exhibited signs of Zn deficiency, consisting mainly of enlarged cells and necrotic areas. Microscopically, more profound evidences of abnormality were seen. Cells in the meristematic region were seriously deranged, as evidenced by their hypertrophy, by numerous air spaces among them, and by irregular arrangements of the cell layers. The cytoplasm in affected cells contained many spiral and elongated mitochondria, and the nuclei very small nucleoli. Under appropriate tests, it was noted that there were several abnormal products of metabolism in the cell vacuole, tannin, calcium oxalate, and fats being abnormally abundant. On the contrary, starch was absent. The changes indicated very serious derangement of the normal cellular metabolism. There are 19 references.

**Effects of calcium deficiency upon the roots of *Pisum sativum***, H. SOROKIN and A. L. SOMMER. (Ala. Expt. Sta.). (*Amer. Jour. Bot.*, 27 (1940), No. 5, pp. 308-318, figs. 13).—Using seedlings grown in Pyrex containers and in nutrient solutions of water redistilled from Pyrex plus carefully purified salts, the effects of the absence of Ca and of concentrations of 0.06, 0.125, and 0.25 p. p. m. were studied on the development of shoots and roots and on changes in the tissues and cells of the root system. No appreciable difference was found in the development of shoots under the treatments noted, and all were dead after 3 weeks. However, in the roots without Ca the normal mitotic processes were disturbed, polyploid nuclei, binucleate cells, constricted nuclei, and stages of amitotic division being observed. The tissues lacked resistance to infection. In roots fed 0.06 p. p. m. of Ca, there were normal cell divisions after 7 days, but after 15 days the cells were like those without Ca. Fed 0.125 p. p. m. Ca, normal divisions occurred after 15 days, but after 20 days aberrant types were seen. At 0.25 p. p. m. Ca, normal mitotic divisions were present to the end of the test, failure of the plants to develop normally being attributed to Ca functions not indicated by cell changes. The complex reactions of cells and tissues to the absence of Ca may be divided into two types, viz, those also induced by other agencies and

those peculiar to Ca deficiency alone. Polyploidy, formation of binucleate cells, and premature development of tracheal elements and primordia of lateral roots occur after treatment of tissues by agents causing changes in viscosity, surface tension, and permeability, and thus such changes in Ca-deficient solutions could be ascribed to similar properties of the Ca ion. However, the suppression of mitotic processes in the absence of Ca and the gradual appearance of aberrant types of division as traces of Ca are removed from the solution suggest that a very small amount may be required as a chemical constituent of the protoplast. There are 22 references.

**Three previously undescribed mosaic diseases of pea, W. J. ZAUMEYER.** (U. S. D. A.). (*Jour. Agr. Res. [U. S.], 60 (1940), No. 7, pp. 433-452, figs. 4*).—These 3 new viruses, together with an earlier described mosaic virus from alsike clover, also infectious to pea, are described and identified. They were pea mosaic virus 4, pea mosaic virus 5 (pea stunt mosaic), alsike clover mosaic virus 1, and alsike clover mosaic virus 2. Pea mosaic virus 4 and alsike clover mosaic virus 1 produced comparatively mild symptoms on pea. Pea mosaic virus 5 produced considerable stunting of Dwarf Telephone and Tall Telephone peas. Alsike clover mosaic virus 2 caused the most severe symptoms on peas, producing necrosis and leaf drop. The 4 viruses were inoculated into 12 varieties of peas, all proving susceptible except Horal, Little Marvel, Perfection, Surprise, and Wisconsin Early Sweet. The 4 viruses were also infectious on certain bean varieties, but with considerable varietal differences in susceptibility and symptoms. Stringless Green Refugee was susceptible to the 4 viruses. Great Northern U. I. No. 1 was resistant to all except pea mosaic virus 5. Pea mosaic virus 4 was the only one infecting red clover. Susceptible hosts were restricted to the Leguminosae. With few exceptions, hosts susceptible to one virus were susceptible to all.

**Probability of sweet corn wilt in 1940** (*New Jersey Stas. Plant Disease Notes, 17 (1940), No. 12, pp. 45-48, fig. 1*).—On the basis of the preceding winter weather records and backed by similar observations since 1926, the indications are said to be that bacterial wilt of sweet corn will not be severe in 1940. Details are discussed, and curves of wilt severity and winter temperature indexes (1926-40) are presented.

**Additional facts regarding bacteriophage lytic to *Aplanobacter stewartii*,** R. C. THOMAS. (Ohio Expt. Sta.). (*Phytopathology, 30 (1940), No. 7, pp. 602-611*).—In continuation of these studies (E. S. R., 73, p. 492), a nonspecific phage precursor inactivated by heating at 56° C. for 30 min. was found in many kinds of plants, e. g., rye. When it came into contact with susceptible bacteria, a reaction occurred resulting in the formation of a transmissible lytic principle not inactivated at 60° and only partly so at 65°. This is believed to be the origin of the bacteriophage in plants and to function as a mechanism of resistance. These lytic principles varied with differences in cultures of the bacteria used to produce them. In corn varieties susceptible to bacterial wilt, the phage precursor was lacking or very weak, whereas in resistant varieties it was strong. Several methods were found effective in rendering cultures of *A. stewartii* (= *Phytomonas stewartii*) free from the bacteriophage.

**A method of inducing spore production by *Cercospora apii* Fres. in pure culture,** R. W. LEWIS. (Mich. State Col.). (*Phytopathology, 30 (1940), No. 7, p. 623*).—Young or old cultures of *C. api* formed abundant conidia on sterilized celery leaves in contact with moist, sterilized soil, but cultures losing their characteristic color failed to develop spores under these conditions.

**Fruit diseases in 1938,** O. C. BOYD (*Mass. Fruit Growers' Assoc. Rpt., 45 (1939), pp. 41-45*).—A brief seasonal survey of weather conditions and diseases of pome, stone, and small fruits for Massachusetts.

**Observations on the varietal susceptibility of apples to *Gymnosporangium juniperi-virginianae*, J. S. NIEDERHAUSER and H. H. WHETZEL.** (Cornell Univ.). (*Phytopathology*, 30 (1940), No. 8, pp. 691-693).—During a severe cedar-apple rust epidemic (1939), 25 apple varieties were examined as to relative susceptibility. Although 3 rust species (*G. juniperi-virginianae*, *G. globosum*, and *G. clavipes*) were abundant on a cedar tree apparently serving as the source of inoculum, only the first species seemed to be involved in the rust attack on the apple trees studied. It was also remarkable that only one fruit from all the trees examined showed a rust lesion. A table is presented comparing the authors' observations on the relative susceptibility of apple varieties to *G. juniperi-virginianae* with records by others. It is suggested that only one race was involved in the studies presented, and that this race is the same as that reported by Bliss in Iowa for 1928-30 (E. S. R., 70, p. 790).

**The *Coryneum* disease of stone fruits in Argentina, *C. carpophilum* n. comb.** [trans. title], C. JAUCH (*Rev. Argentina Agron.*, 7 (1940), No. 1, pp. 1-26, pls. 6, figs. 3; *Eng. abs.*, p. 24).—The paper presents descriptions of the disease and of the parasite, discussing the taxonomy of the latter and proposing the new combination *C. carpophilum* for it. The injuries caused are pointed out and the reasons why the disease varies in economic importance among the hosts—peach, almond, plum, apricot, and cherry. In Argentina, the geographical distribution of the disease is general in all fruit-producing districts. The characteristics of the fungus in single-spore cultures were studied, including the influence of temperature on growth and spore germination. Cross-inoculations of the fungus from leaf, twig, bud, or fruit among the host species and different plant organs are reported as successful, and the comparative varietal reactions are presented. There are 20 references.

**Effects of H-ion and Al-ion concentrations on damping-off of conifers and certain causative fungi, L. W. R. JACKSON.** (U. S. D. A. et al.). (*Phytopathology*, 30 (1940), No. 7, pp. 563-579, figs. 3).—Sodium glycerophosphates as phosphate sources produced a nutrient solution stable in the presence of Fe- and Al-ions at pH 2.5-8.5 and satisfactory for growth of the fungi and hosts studied. The growth of the *Pythium* isolates in liquid culture was zero at pH 2.5 and 3.5, increased to maxima at pH 5.5 and 6.5, and at pH 8.5 it was again zero in all but one series. Chlamydospore and oospore production was definitely less at pH 4.5 than at 6.5 in the absence of sugar. The growth of the *Rhizoctonia* isolates in liquid culture was zero at pH 2.5, very small at pH 3.5, definitely more at pH 4.5, 5.5, and 6.5, less at 7.5, and very small at 8.5. The amount of sclerotia was zero at pH 3.5 and 4.5, more at pH 5.5 and 6.5, and zero at pH 7.5 and 8.5.

The amount of damping-off by *Pythium* and *Rhizoctonia* isolates on ponderosa pine and Douglas fir grown in liquid cultures was lowest at pH 2.5 and 3.5, increased to maxima at 6.5, or less often 5.5, and decreased at 6.5 or 7.5. In the quartz-sand cultures the relationship between pH and damping-off was not so consistent. The amount of damping-off was low in all the series run at pH 2.5, the maxima occurring in the series as follows: 1 at pH 3.5, 2 at 4.5, 2 at 5.5, 3 at 6.5, 4 at 7.5, and 2 at 8.5. There were 2 maxima in 2 of the series. Aluminum exhibited only barely or doubtfully significant effects on damping-off in sand cultures at pH 3.5 with a 0.0005 M concentration of  $Al_2(SO_4)_3$ . The Al concentrations showed no effect in the series at pH 6.5. Both with and without Al the damping-off percentages were definitely higher at pH 6.5 than at 3.5. Practically the lower limit for the roots of the hosts in the liquid and quartz-sand cultures was at pH 2.5. Seedling growth was excellent at pH 3.5-6.5, but many cultures showed definite decreases, espe-

cially in root growth, at pH 2.5, 7.5, and 8.5. The strongest concentration of  $Al_2(SO_4)_3$  used (0.0005 M) was near the limit for roots of the hosts. There are 26 references.

**Atropellis species from pine cankers in the United States, M. L. LOHMAN and E. K. CASH.** (U. S. D. A. et al.). (*Jour. Wash. Acad. Sci.*, 30 (1940), No. 6, pp. 255-262, figs. 2).—"The genus *Atropellis* is revised to include, along with *A. pinicola* Zeller and Goodding, of the Pacific Northwest, two new species, namely, *A. tingens* and *A. arizonica*, and *Cenangium piniphilum* Weir, all of which cause characteristic cankers of pines. Of these, *A. tingens* is of widest occurrence on various species of native and introduced pines in the eastern half of the United States, and *A. arizonica* is most limited in distribution, being known only from the type locality, Safford, Ariz. Each of the species produces a localized, dark stain of the wood in cankered twigs or stems."

**Mycelial extent beyond blister rust cankers on *Pinus monticola*, J. EHLICH and R. S. OPIE.** (Univ. Idaho). (*Phytopathology*, 30 (1940), No. 7, pp. 611-620, fig. 1).—*Cronartium ribicola* mycelium in the distal ends of 116 cankers on green stems and branches and proximal ends of 146 cankers on green stems and green and flagged branches from three ecologically comparable areas in one northern Idaho locality was found to extend  $\pm 0.5$  to 3 (mean 1.66) cm. beyond the externally visible canker margins. No practical mean difference was found between distal and proximal measurements, or, for each type of canker, between measurements for the different areas. Mean extents were  $\pm 2.3$  cm. for cankers on green stems,  $\pm 1.5$ -1.6 cm. for cankers on green branches, and  $\pm 1.2$  cm. for cankers on flagged branches. Of 4 possibly related and readily determinable canker characters studied, diameter of cankered internode at the outer limits of surface discoloration was found to be most closely correlated with mycelial extent and to be most readily and accurately determinable in the field.

**A needle-cast of Douglas fir associated with *Adelopus gäumanni*, J. S. BOYCE** (*Phytopathology*, 30 (1940), No. 8, pp. 649-659, figs. 2).—This disease of *Pseudotsuga taxifolia* (= *P. douglasi*), reported first in Switzerland in 1925, has also been found in southern Germany, Denmark, Great Britain and Northern Ireland, and in New England. Severe infection induces progressive defoliation followed by death of the tree. No control method is known, but there is said to be a possibility of resistant races or individual trees. The fungus is present but nonpathogenic on living *P. taxifolia* on the Pacific coast, and it may have been introduced into New England and Europe from this region.

**Galls on *Pseudotsuga macrocarpa* induced by *Bacterium pseudotsugae*, C. O. SMITH.** (Calif. Citrus Expt. Sta.). (*Phytopathology*, 30 (1940), No. 7, p. 624, fig. 1).—Galls were induced on seedlings of *P. macrocarpa* and seedlings of *P. taxifolia glauca* by a culture of *B. pseudotsugae* furnished by H. N. Hansen, University of California. These galls resembled those described by Hansen and Smith (*E. S. R.*, 69, p. 541; 77, p. 648).

**Coryneum blight of oriental arborvitae caused by *Coryneum berckmanii* n. sp., J. A. MILBRATH.** (Oreg. Expt. Sta.). (*Phytopathology*, 30 (1940), No. 7, pp. 592-602, figs. 3).—A *Coryneum* with 5-septate spores is reported to have caused enormous losses of Oriental arborvitae in nurseries of the Pacific Northwest. Its chief host is *Thuja orientalis conspicua*, but all varieties of this species appear susceptible. The disease is characterized by blighting of small branchlets, which turn a reddish brown, fading to light gray. Black spore pustules are scattered on the infected scale leaves or in groups where small stems have been girdled by the fungus. The fungus, described as *C. berckmanii* n. sp., can be readily distinguished from other 5-septate spore

species reported on conifers, including *C. cardinale* on *Cupressus macrocarpa*. Spray tests during 1938-39 on several hundred infected trees demonstrated that the disease can be controlled by one application applied before infections are started by early fall rains. Basic  $\text{CuSO}_4$  and red copper oxide gave better control than the other fungicides tried.

**Isolation of *Ceratostomella ulmi* from *Scolytus multistriatus* adults stored at different temperatures**, C. S. MOSES and C. H. HOFFMANN. (U. S. D. A.). (*Phytopathology*, 30 (1940), No. 8, pp. 701, 702).—Artificially contaminated adult bark beetles were placed in individual capsules and stored in lots of 50 at 70°, 60°, 40°, 28°, and -10° F., and one lot from each temperature was cultured at the end of 30, 60, 90, and 120 days. Storage temperatures did not materially affect recovery of the Dutch elm disease fungus at the end of 60 days. For longer intervals, temperatures of 40° F. or lower were needed. In all cases, storage at -10° yielded cultures with fewer contaminants.

**A new host for *Taphrina dearnessii* and geographic distribution of *Taphrina* on North American maples**, A. E. JENKINS and W. W. RAY. (U. S. D. A. and Okla. A. and M. Col.). (*Mycologia*, 32 (1940), No. 3, pp. 408-414, figs. 4).—A *Taphrina* species found on mountain maple (*Acer spicatum*) near Ithaca, N. Y., was identified as the *T. dearnessii* recently described on red maple from the United States and Canada (E. S. R., 81, p. 390). In the *Taphrina* group on North American maples this is said to be the second case of one species infecting two different hosts, and the first of two species infecting the same host. The other species described on mountain maple is *T. lethifera*. The first record of *T. dearnessii* west of the Mississippi River, in Oklahoma, is given, and the known distribution of the entire group is mapped.

**A leafspot fungus on *Nyssa***, F. A. WOLF (*Mycologia*, 32 (1940), No. 3, pp. 331-335).—The fungus associated with this leaf spot of tupelo (*Nyssa* spp.) has usually been identified as *Phyllosticta nyssae*, which is apparently limited to the southeastern United States. However, studies have indicated that *P. nyssae* is not a pycnidial stage but a spermogonial stage. Lesions appear during later summer when punctiform fructifications develop on the lower leaf surface. They occur singly and consist of interspersed spermogonia and perithecial primordia. The spermogonial stage was found to be identical with *P. nyssae*. By the following spring the perithecial primordia are transformed into mature perithecia of *Mycosphaerella nyssaecola* n. comb. Evidence of the presence of conidia in the developmental cycle of *M. nyssaecola* is lacking.

**Fern diseases and pests**, B. O. DODGE (*Jour. N. Y. Bot. Gard.*, 41 (1940), No. 485, Sect. 1, pp. 116, 117, fig. 1).—Prothallium maladies, leaf spots, black molds, nematodes, thrips, and scale insects are briefly discussed as being the more important troubles of ferns in greenhouse or outdoor plantings.

**Lily mosaic**, C. H. GADD and C. A. LOOS (*Trop. Agr. [Ceylon]*, 94 (1940), No. 3, pp. 160-167, pls. 3).—The authors describe a mosaic disease of Easter lilies in Ceylon, shown to be transmissible by aphids to other lily plants. The virus was also experimentally transmitted to cucumbers, tomatoes, and turnips, but in these plants the mosaic symptom failed to become systemic. The symptoms induced are not exactly like those described for cucumber virus 1 elsewhere, but, though a critical study of the Ceylon virus has not yet been made, it is believed to be a variant of cucumber virus 1 rather than an entirely unrelated virus.

**Clean soil for clean corms solves gladiolus yellows problem**, L. McCULLOCH. (U. S. D. A.). (*Florists' Rev.*, 86 (1940), No. 2214, p. 29).—Though only two experiments, one in the greenhouse and one out-of-doors, had been carried

out, the results in controlling the *Fusarium* yellows with chloropicrin were so clean-cut that they are here briefly reported.

**Diseases of the gardenia**, P. P. PIRONE (*New Jersey Stas. Bul.* 679 (1940), pp. 10, figs. 7).—A summary of information on the parasitic and nonparasitic diseases and their control and on the cultural requirements of gardenias.

**Gardenia leaf spot caused by *Rhizoctonia*** (*Florists' Rev.*, 86 (1940), No. 2217, p. 22).—This is believed to be the first report of a *Rhizoctonia* leaf spot of cultivated gardenias. Preliminary studies afford evidence that the fungus is at least a new strain, and its pathogenicity for gardenia has been demonstrated by pure culture inoculation. Various strains and varieties proved susceptible, though under natural conditions the disease has thus far been confined largely to the variety Pride of Daisy Hill. Suggested control measures are given.

**Fumigation injury of chrysanthemum**, L. K. JONES. (Wash. Expt. Sta.). (*Phytopathology*, 30 (1940), No. 6, pp. 540, 541, fig. 1).—Following fumigation with Nico-fume for aphid control, a ring of brown, dead, floral parts appeared on Whittier chrysanthemum blooms. No injury was observed on 25 other varieties grown under similar conditions.

**The inefficacy of methyl bromide fumigation against the chrysanthemum foliar nematode**, J. R. CHRISTIE and G. S. COBB. (U. S. D. A.). (*Helminthol. Soc. Wash. Proc.*, 7 (1940), No. 1, p. 62).—The test reported is believed to eliminate methyl bromide fumigation as a method of treating chrysanthemum or other plants infested with this nematode, *Aphelenchoides ritzemabosi*, nor is it deemed likely that such treatment will be effective against the strawberry bud nematode, *A. fragariae*.

**Methods of clearing screen residues in separating nematodes from soil**, G. THORNE. (U. S. D. A.). (*Helminthol. Soc. Wash. Proc.*, 7 (1940), No. 1, pp. 53, 54).—*Opuntia* sp., saliva, and milk are reported as successfully used to settle screenings.

**Three fungi destructive to free-living terricolous nematodes**, C. DRECHSLER. (U. S. D. A.). (*Jour. Wash. Acad. Sci.*, 30 (1940), No. 6, pp. 240-254, figs. 3).—*Haptoglossa heterospora* n. gen. and sp. and *Meristacrum asterospermum* n. gen. and sp., two phycomycetous fungi, and *Cephalosporium* sp. are described and discussed. There are 26 references.

**Some host plants of the reniform nematode in Hawaii**, M. B. LINFORD and F. YAP. (Hawaii. Pineapple Prod. Expt. Sta.). (*Helminthol. Soc. Wash. Proc.*, 7 (1940), No. 1, pp. 42-44).—A list of 65 host plant species representing 30 families mostly among the angiosperms is presented, and the host-parasite relationships of this nematode (*Rotylenchulus reniformis*) are discussed briefly.

**Duboscqia penetrans** n. sp. (Sporozoa, Microsporidia, Nosematidae), a parasite of the nematode *Pratylenchus pratensis* (de Man) Filipjev, G. THORNE. (U. S. D. A.). (*Helminthol. Soc. Wash. Proc.*, 7 (1940), No. 1, pp. 51-53, fig. 1).—*D. penetrans*, a new species of sporozoon, is described and its life history and host specificity to *P. pratensis* are discussed.

**Onion bloat or eelworm rot, a disease caused by the bulb or stem nematode, *Ditylenchus dipsaci* (Kühn) Filipjev**, B. G. CHITWOOD, A. G. NEWHALL, and R. L. CLEMENT. (U. S. D. A., Cornell Univ., et al.). (*Helminthol. Soc. Wash. Proc.*, 7 (1940), No. 1, pp. 44-51, figs. 5).—The authors give the history and symptoms and present general control considerations.

***Rotylenchulus reniformis*, nov. gen., n. sp., a nematode parasite of roots**, M. B. LINFORD and J. M. OLIVEIRA. (Hawaii. Pineapple Prod. Expt. Sta.). (*Helminthol. Soc. Wash. Proc.*, 7 (1940), No. 1, pp. 35-42, figs. 3).—The taxonomy and life history of this nematode from cowpea roots are discussed, including the characterization of this new genus and species of the Tylenchidae.

## ECONOMIC ZOOLOGY—ENTOMOLOGY

**The warblers of New Jersey.—II, The transient warblers, L. A. HAUSMAN** (*New Jersey Stas. Bul.* 678 (1940), pp. 32, figs. 15).—This second part of the author's contribution on warblers (*E. S. R.*, 80, p. 69) is the eleventh in the station series dealing with the birds of New Jersey. Following a discussion of the head patterns of transient warblers, a simplified key for their identification and a key to the common songs of such warblers are presented. Thirteen forms additional to the 23 noted earlier are then dealt with, particular attention being given to their identification and occurrence in the State, namely, Tennessee, Nashville, magnolia, Cape May, myrtle, bay-breasted, black polled, palm, yellow palm, Kentucky, Connecticut, mourning, and Wilson's warblers.

**External parasites of sheep in Illinois: A portable dipping vat, W. E. McCauley and H. G. RUSSELL** (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 547-550, figs. 5).—Following a report of a survey to determine the prevalence of sheep parasites in which lambs chosen at random from representative flocks were examined, a description is given of a portable dipping vat constructed at a cost of approximately \$270 for materials and labor.

**The genus *Hymenolepis* Weinland 1858, R. C. HUGHES** (*Oklahoma Sta. Tech. Bul.* 8 (1940), pp. 42).—A compendium of the tapeworm genus *Hymenolepis* which contains more than 300 recognized species and subspecies parasitic in various birds and mammals as definite hosts. Offered as an introduction, it is to be supplemented by a descriptive key to the genus now in preparation.

Following a brief introduction, the work takes up the synonymy of the genus (pp. 5, 6), the forms belonging thereto, of which 320 are noted (pp. 6-24), nonvalid *Hymenolepis* specific names, some 159 in number (pp. 24-27), a host catalog of the species of the genus arranged by orders (pp. 27-36), and a bibliography of recent work (pp. 36-42).

**A comparative study of the insect food of trout, W. F. MOROFKY.** (*Mich. State Col.*). (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 544-546).—The investigation here reported was conducted with a view to comparing the number of insects eaten by brook, brown, and rainbow trout. The data presented were obtained from the examination of 1,548 trout stomachs collected in both northern and southern Michigan streams. The details of the findings are presented in 6 tables.

[Work in economic entomology by the Florida Station]. (Partly coop. U. S. D. A.). (*Florida Sta. Rpt.* 1939, pp. 93, 94-99, 113, 114, 145-147, 154, 155, 158, 159).—The work of the year (*E. S. R.*, 81, p. 238) referred to includes miscellaneous observations, particularly on the pepper stem weevil *Collabismodes cubae* Boh.; the Florida flower thrips *Frankliniella cephalica bispinosa* Morg. and the onion thrips, both by J. R. Watson; the introduction and propagation of beneficial insects, by Watson and W. L. Thompson; the larger plant bugs (the southern green stinkbug, *Trichopoda pennipes*, and the leaf-footed bug), by H. E. Bratley; control of fruit and nut crop insects, particularly the nut case-bearer, by S. O. Hill, Watson, and Bratley; the gladiolus thrips, by Watson and J. W. Wilson; biology and control of Florida aphids, including *Aphis tulipae* Fonsc. and *A. nociadae* Ckll., by A. N. Tissot; the pepper weevil, by Watson and R. N. Lobdell; life history, food preferences, ecological distribution, and control of the eastern lubber grasshopper, by Watson and Bratley; studies of *Orthaea longulus*, the striped cucumber beetle, the melon-worm, and the pickleworm, by Lobdell; fumigation of pecans, nursery stock, and seeds, by R. J. Wilmot; control of purple scale and whiteflies with lime-sulfur, by W. L. Thompson at the Citrus Substation; and control of the bean

jassid, the fall armyworm, and wireworms (*Melanotus communis* (Gyll.)) affecting sugarcane, corn, and truck crops and studies of the prevalence and control of the sugarcane borer and of rodents under field and village conditions, all by Wilson at the Everglades Substation.

[Work in economic zoology and entomology by the New Jersey Stations] (*New Jersey Stas. Rpt. 1939, pp. 27-29, 32, 33, 35, 36, 45-54, 64, 125, 126*).—The work of the year (E. S. R., 82, p. 217) with oysters reported upon relates to the production of oyster seed, open shore culture of oysters, pest control, and studies of the filtration of water by oysters and the factors which influence it. The entomological work includes that with the cranberry leafhopper *Ophiola striatula* Fall. and blueberry insects (the cranberry fruitworm, cherry fruitworm, and Putnam's scale); mosquito investigations and control; climate and insect investigations; orchard insect investigations and study of the biological control of the codling moth; insecticidal investigations; vegetable insect investigations (the corn earworm, European corn borer, parsley stalk weevil, pea aphid, and mushroom insects); investigations of soil-infesting insects, bees, and insects injurious to ornamental plants (the greenhouse red spider, the hawthorn and cherry leaf-miner *Profenusa collaris*, the rhododendron midge *Giardomyia rhododendri*, and the cyclamen mite); miscellaneous investigations, including the discovery of a new insect pest of tobacco, *Aglossa cuprealis*, and control of the German cockroach and the common termite *Reticulitermes flavipes* (E. S. R., 82, p. 357); control of the raspberry crown borer; and diseases of the Japanese beetle.

[Work in entomology by the Puerto Rico College Station] (*Puerto Rico Col. Sta. Rpt. 1939, pp. 46-52, 73-75, 98, fig. 1*).—The work of the year (E. S. R., 81, p. 541) reported upon includes control of the sugarcane borer through release of artificially reared native egg parasites (*Trichogramma minutum* Riley) and the establishment in Puerto Rico of *Larra americana* Sauss., a specific parasite of the changa, both by G. N. Wolcott and L. F. Martorell; studies on poison bait for the control of the "hormiguilla" *Myrmelachista ramulorum* Wheeler in coffee groves and a study of the dry-wood termite *Cryptotermes brevis* Walker, both by Wolcott; maintenance of a supply of the vedalia, a specific predator on the cottony-cushion scale, by Wolcott and F. Séin, Jr.; a study of the coffee leaf-miner *Leucoptera coffeella* Guer., observations on other insects in coffee groves, and the guamá leaf-miner, all by Séin; the pink bollworm, by J. P. Rodríguez; and attack by the aphid *Cerataphis lantaniae* Boisd. on spadices and flower buds of yellow dwarf coconut.

Connecticut State entomologist, thirty-ninth report, 1939, R. B. FRIEND. (Partly coop. U. S. D. A.). (*Connecticut [New Haven] Sta. Bul. 434 (1940), pp. 211-322, figs. 8*).—The report opens with a biographical sketch of the life work of the late W. E. Britton, member of the staff of the experiment station since 1894 and State Entomologist from 1901 to the time of his death, February 15, 1939, by Friend (pp. 215-221), followed by an account of the insect record for the year (pp. 223-225), a brief reference to and program of the annual conference of the Connecticut entomologists held in October (pp. 225, 226) (E. S. R., 82, p. 216), and reports on inspection of nurseries, by M. P. Zappe (pp. 227-236) and of apiaries, by Friend (pp. 237-239), control of the gypsy moth, by J. T. Ashworth and O. B. Cooke (pp. 239-247), the Japanese beetle, by J. P. Johnson (pp. 248-250); mosquito control, by R. C. Botsford (pp. 251-254), rodent control, by H. A. Merrill (pp. 254-258), and parasite work, by P. Garman, J. C. Schread, W. T. Brigham, and G. R. Smith (pp. 258-260).

Accounts are given of tests of apple sprays (pp. 260-264) and further observations of the effect of salt water spray on foliage (pp. 287-293), both

by Zappe and E. M. Stoddard; continued experiments on control of the apple maggot, by Garman and J. F. Townsend (pp. 264-269); continued study of stickers for standard spray mixtures, by Garman and C. E. Shepard (pp. 269-272); experiments with manganese sulfate as safener for lime-sulfur-lead arsenate spray mixtures, by Garman (pp. 272, 273); corn borer insecticide investigations (pp. 273-275) and biology and control of the potato flea beetle (pp. 277-283), both by N. Turner; effect of corn borers on potato yield (pp. 275, 276), survey of wireworm injury to potatoes (pp. 283, 284), and control of squash insects (pp. 285-287), all by R. L. Beard; and the smaller European elm bark beetle, by P. Wallace (pp. 293-311).

The report concludes with miscellaneous insect notes (pp. 311-318) dealing with the crazy ant *Paratrechina longicornis* Latr., dermestid larvae in composition board, the house cricket, Asiatic garden beetle damage in a field of sweet corn, results of trapping rose chafers, the European earwig, bark beetle damage to plantation pine, clover mite in dwellings, and *Calomycterus setarius* Roelofs in Connecticut.

**Effect of fruit growth and weather on deposits of insecticides on apples in southern Indiana**, J. E. FAHEY and H. W. RUSK. (U. S. D. A.). (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 505-511, figs. 4).—Investigations carried on in southern Indiana during the period 1935-38 to determine the effect of fruit growth and weathering on spray residue deposits on apples are reported. The insecticide studies were conducted in a block of Grimes trees in 1935 and 1938 and in a block of Jonathan trees in 1936 and 1937. "Fixed nicotine was found to be less susceptible to weathering than phenothiazine, and lead arsenate was the least susceptible of the three insecticides. Fruit sprayed with lead arsenate retained at harvest from 51.5 to 76.1 percent of the total residue deposited during the season. Fruit sprayed with fixed nicotine retained from 8.4 to 32.6 percent of the total residue, depending on the interval between the final cover spray and harvest and on the rainfall."

**Summer months draw attention to cotton insects**, C. LYLE (*Miss. Farm Res. [Mississippi Sta.]*, 3 (1940), No. 6, pp. 1, 2).

**Recent changes in agriculture and their effect on insect problems**, P. N. ANNAND. (U. S. D. A.). (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 493-498).

**Evaluation of insect damage under the crop insurance plan**, W. P. FLINT (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 499-501).

[Notes on economic insects and their control] (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 578-585).—The contributions presented (E. S. R., 83, p. 363) are: Mosquito Collections at Charleston, South Carolina, Using the New Jersey Light Trap, by F. W. Fisk and J. H. Le Van (pp. 578, 579); Tartar Emetic Sprays Against [the Common] Red Spider, by C. A. Weigel and G. V. Johnson (pp. 579, 580) (U. S. D. A.); Inheritance of Resistance to Hessian Fly, by W. B. Noble, W. B. Cartwright, and C. A. Suneson (pp. 580, 581) (U. S. D. A. and Univ. Calif.); Destruction of an Experimental Population of Bean Weevil by *Pediculoides ventricosus* Newport, by R. J. Bushnell (pp. 581, 582) (Univ. Conn.); Minimum Size of Openings Through Which Clothes Moth Larvae Can Pass, by W. Colman (p. 582) (U. S. D. A.); The Golden Codling Moth [*Carpocapsa pomonella* (L.) *simpsonii* Busck.].—A Second Note, by E. O. Essig (p. 582) (Univ. Calif.) (E. S. R., 82, p. 646); Effect of Lime Sulfur and of Oil Sprays on Treehopper Eggs and Emergence, by M. A. Yothers (p. 583) (U. S. D. A.); Food Habits of Sparrow Hawks in Utah, by G. F. Knowlton and F. C. Harmston (p. 583) (Utah Expt. Sta.); Leafhopper [*Kolla fasciata* Walk.] Reaction to Lawn Sprinkling, by G. N. Wolcott and L. F. Martorell (p. 584) (P. R. Col. Sta.); and Dichloroethyl Ether in Mineral Oil for Corn Earworm Control in Sweet

Corn, by B. B. Pepper and G. W. Barber (pp. 584, 585) (N. J. Stas. and U. S. D. A.).

**Toxicity of nicotine administered internally to several species of insects,** R. HANSBERRY, W. E. MIDDLEKAUFF, and L. B. NORTON. (Cornell Univ. and N. Y. State Expt. Sta.). (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 511-517).—In the toxicity studies reported nicotine was administered in measured doses in two ways: (1) By feeding leaf sandwiches containing known amounts of nicotine and measuring the areas eaten and (2) by injection of the nicotine directly into the blood or gut with a microsyringe. "Larvae which were not susceptible to nicotine were *Malacosoma americana* (F.), *Hyphantria cunea* (Drury), *Lycophotia margaritosa saucia* Hbn., *Mamestra picta* Harr., *Estigmene acrea* (Drury), *Halisidota caryae* (Harr.), *Carpocapsa pomonella* L., *Protoparce sexta* (Johan.), *P. quinquemaculata* (Haw.), *Cacoecia cerasivorana* (Fitch), *Ascia rapae* (L.), *Datana integerrima* G. & R., and larvae and adults of *Leptinotarsa decemlineata* (Say). Contrasted to these resistant species which survived doses ranging from 0.04 to 9.8 mg. nicotine per gram of body weight, *Bombyx mori* L. larvae survived no doses of nicotine above 0.017 mg./gm. A compound of Reinecke's salt with nicotine was highly toxic to adults of the Colorado potato beetle and to larvae of the silkworm, moderately toxic to larvae of the tobacco worm, but not appreciably toxic to larvae of imported cabbageworm, hickory tussock moth, ugly-nest caterpillar, walnut caterpillar or to larvae of the Colorado potato beetle. *Euchaetias egle* (Drury), *Nymphalis antiopa* L., *C. cerasivorana*, and *H. caryae* were repelled by nicotine in both soluble and insoluble forms. The first two species would not eat measurable doses, the ugly-nest caterpillar ate small amounts which, although they affected the larvae rapidly, were regurgitated before death occurred, and the hickory tussock moth larvae were not affected visibly by the small doses taken.

"There seemed no highly significant difference in toxicity between the soluble and insoluble forms of nicotine or between ingested and injected nicotine. Third instar larvae of the walnut caterpillar were moderately susceptible to nicotine poisoning, whereas fifth instar larvae of the same species were not."

A list is given of 21 references to the literature.

**Replacing cresylic acid with tar oil in the delayed dormant spray on apple trees,** J. M. GINSBURG. (N. J. Expt. Stas.). (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 440-443).—The fact that many orchardists have found it convenient or necessary due to unfavorable weather to start orchard spraying at the delayed dormant period (with 3 percent petroleum oil and 0.5 percent cresylic acid) in combating the apple aphids (the apple grain aphid, apple aphid, and rosy apple aphid) and the European red mite, notwithstanding that the author and his associate (E. S. R., 79, p. 651) have definitely shown the superiority of a dormant spray (3 percent petroleum oil and 2.5 percent tar oil), led to the investigation here reported. The work was devoted largely to the determination of the minimum concentration of tar oil required to kill eggs of apple aphids in the delayed dormant stage in place of 0.5 percent cresylic acid. It was found that "the addition of 0.66 percent tar oil gave as good control of all species of apple aphids as did the addition of 0.5 percent cresylic acid with no greater injury to the buds. Eggs of rosy [apple] aphids were more resistant to control by delayed dormant sprays than by dormant sprays. Delayed dormant sprays containing 1 percent or more tar oil retarded the development of fruit buds in general and severely injured many lateral buds. The addition of tar oil at the delayed dormant stage did not interfere with the efficiency of petroleum oil in control of European red mite."

**Fumigation of sacked grain with chloropicrin,** K. L. KNIGHT. (Univ. Ill.). (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 536-539).—Need for an efficient method

of treating insect-infested grain stored in various types of bags, of special importance to commercial seedsmen, led to the fumigation control work with chloropicrin here reported. Two methods of application were employed, namely, injection of the fumigant into the sack and the release of the fumigant into a vault holding the sacks. Mixed cultures of coleopterous stored grain insects were used, including the red flour beetle, the lesser grain borer *Rhizopertha dominica* F., the rice weevil, the granary weevil, and the flat grain beetle, the red flour beetle, in all its stages, being the most resistant to chloropicrin fumigation. The dosages found necessary for 100-percent mortality of all stages of the red flour beetle have shown that the tight bags are best fumigated by the injection method and the porous bags are most efficiently treated by the vault method. With either type of fumigation considerable post-fumigation mortality resulted when the grain could be left undisturbed in the sack for a period of at least 7 days. Each of the two methods of fumigation was found to have certain advantages not possessed by the other. It is believed that supplementing one method by the other will adequately care for any situation where it may be necessary to treat for the control of insects infesting sacked grain. There is need for more comprehensive work on the effect of chloropicrin upon the germination of seeds fumigated by the two methods. However, the viability of the seeds of corn, oats, wheat, and soybeans (with moisture content low enough for safe storage) was not significantly decreased by chloropicrin fumigation with dosages necessary for complete insect control in sacked grain.

**Introduction of selenium into plant tissues as a toxicant for insects and mites,** C. R. NEISWANDER and V. H. MORRIS. (Ohio Expt. Sta.). (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 517-525, figs. 7).—In studies made of the effect upon insects and mites of selenium introduced into the plant tissues use was made of the common red spider on tomatoes, stocks, roses, and carnations grown in nutrient solution and on carnations grown in selenized soil and of the chrysanthemum aphid on chrysanthemums grown in nutrient solutions. Following a presentation of the methods and materials employed, the details are reported in seven tables. It was found that when the selenium concentration of foliage approached from 90 to 100 p. p. m. the common red spider population was practically eliminated. In the one experiment conducted with the chrysanthemum aphid similar results were obtained with a selenium content of 45 p. p. m. Even with half these quantities of selenium in the leaf tissues significant reductions of both mites and insects resulted. Since the experiments were conducted on artificially infested plants, it is thought probable that under natural conditions still smaller amounts of selenium might prevent destructive populations from developing. In the experiments in which the pests were not eliminated comparatively small quantities of selenium were found in the foliage of the host plants. "Experimental results have demonstrated that selenium can be used effectively against some organisms. If by its use an animal as resistant to insecticides as is the [common] red spider can be controlled, it would seem that economic entomologists might well afford to give the matter of its further development serious consideration. The method offers a new approach in pest control, particularly with plants which are grown for ornamental purposes." It is pointed out that because of the known toxicity of selenium to higher animals, the question as to whether it can be handled safely by commercial growers of ornamental plants should be given due consideration.

**Cotton insect investigations.** (Coop. U. S. D. A.). (*Georgia Coastal Plain Sta. Bul.* 30 (1939), pp. 76-78, fig. 1).—The progress (E. S. R., 81, p. 393) of control work with the bollweevil on upland and sea-island cotton is briefly reported.

**Grasshoppers, a factor in soil erosion in Michigan,** C. B. DIBBLE. (Mich. State Col.). (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 498, 499).

**The effect of arsenical grasshopper poisons upon pheasants, J. H. LILLY.** (Wis. Expt. Sta.). (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 501-505, fig. 1).—In work aimed at the determination of the effect of grasshopper control practices on the ring-necked pheasant it was found that in nature young pheasants are apparently not menaced directly by arsenical baits as they are commonly recommended and used. "Not only are the baits spread too thinly to make them readily available but even the better ones are decidedly unpalatable to the birds. Caged pheasants consumed grasshoppers dead and dying as a result of eating arsenical baits almost as readily as they did unpoisoned grasshoppers, and there are no indications that they will not do so in nature. A young pheasant that had eaten comparatively large quantities of the U. S. D[epartment of] A[griculture] standard bait and another one fed exclusively on poisoned grasshoppers for a period of 12 days showed no gross pathological symptoms when autopsied, and neither of them retained significant quantities of arsenic in the body tissues subsequently analyzed. The results presented here indicate that grasshopper poisoning campaigns are not an important menace to young ringneck pheasant or to individuals who may eventually consume birds so exposed."

**Field control of the gladiolus thrips, G. V. JOHNSON and F. F. SMITH.** (U. S. D. A.). (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 490-493).—Control work with the gladiolus thrips indicates "that the quantities of tartar emetic and brown sugar previously recommended [E. S. R., 72, p. 223] may be reduced considerably without reducing the efficiency of the spray. Both U. S. P. and technical grades of tartar emetic were satisfactory, with a price differential in favor of the latter. A calcium antimony tartrate spray gave results comparable with those for a tartar emetic spray of equal antimony content and was appreciably cheaper. Tartar emetic in combination with powdered karaya or sodium oleyl sulfate plus synthetic resins was unsatisfactory. Nicotine sulfate plus karaya was also unsatisfactory. Derris powder in combination with peanut oil and either sodium oleyl sulfate or varnish in combination with sodium lauryl sulfate gave poor control. The spray containing peanut oil retarded the growth and flowering of the gladiolus plant."

**The black hunter, *Leptothrips mali* (Fitch), S. F. BAILEY.** (Univ. Calif.). (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 539-544, fig. 1).—This contribution on one of the most common and widely distributed predaceous thrips in North America, presented as a companion paper to that on *Scolothrips sexmaculatus* (Perg.) (E. S. R., 81, p. 245), brings together the known facts concerning *L. mali* as a contribution to the knowledge of beneficial insects. There are 34 references.

**Control of the squash bug by calcium cyanide, D. ISELY.** (Univ. Ark.). (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 475-477).—Calcium cyanide dust having burned squash foliage, the flakes were tested experimentally in 1939. Applications of the flakes made from June 27 to August 2 under a canvas cover, dragged over two rows of vines as the insecticide was applied, gave an average kill of 98.3 percent when 1 oz. of flakes and water was applied to each hill and held for 5 min. If water was not used, an exposure of 10 min. was necessary to secure satisfactory results. "When the same dosage and exposure was used on a large section, 91.1 percent of the bugs were killed. The bugs which escaped were usually found hanging on the canvas. Exposures of 3 and 4 min. were tried, but in both instances the percentage of bugs apparently killed was less than 80, and some of these were only stupefied. The short exposures which were effective in 1938 when only hills were treated were not satisfactory when entire rows were involved. When 0.5 oz. of cyanide was used at a 10-min. exposure, 56 percent of the bugs were killed. The percentage of mortality at shorter exposures was still less satisfactory. The practical utility of cyanide in the control of the squash bug was not given adequate trial. The high cost may pre-

vent its use. Since cyanide has no apparent effect on squash bug eggs, a second application after the eggs have hatched will be necessary in heavily infested fields. It cannot be expected that a part of the cost can be charged to the incidental control of other pests. . . . In the control of the squash bug, fumigation under canvas has an advantage over the use of contact insecticides in that it is not necessary to hit the bugs and consequently a much more satisfactory kill can be secured. The nearly complete kill of the bugs reduces the required number of applications. . . . The dosage required will doubtless vary depending upon the size of the plants and the temperature and moisture at the time the application is made. Probably a dosage of 1 oz. to a hill will be the maximum required."

**How to stop chinch bug losses**, W. P. FLINT, G. H. DUNGAN, and J. H. BIGGER. (Coop. U. S. D. A.). (*Illinois Sta. Cir.* 505 (1940), pp. 16, figs. 6).—This practical account which replaces Circular 431 (E. S. R., 73, p. 209) gives complete directions for combating the chinch bug. It is pointed out that the cheapest and most effective method of fighting this pest consists in the use of chinch-bug-proof crops.

**Certain host plants of the cotton flea hopper**, R. K. FLETCHER. (Tex. Expt. Sta.). (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 456-459).—The studies reported have shown great variations in the abundance of the cotton flea hopper due to variations in its preferred host plants of the genus *Croton*. The studies revealed the part played by *Oenothera laciniata* in the development of an early spring generation of flea hoppers and the importance of *O. speciosa* and the monardas in increasing the flea hopper populations. The effect of agricultural practices on the number and average height of plants of *C. capitatus*, its preferred host, per acre in 10 different fields at College Station, Tex., from 1934 to 1939, inclusive, is shown in an accompanying table.

**Technique in control experiments with apple aphids**, C. R. CUTRIGHT. (Ohio Expt. Sta.). (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 443-445, figs. 2).—An account is given of the technic employed in ovidical tests and in testing materials against active aphids.

**Rate of reproduction of the pea aphid on different alfalfa plants**, R. G. DAHMS and R. H. PAINTER. (Kans. Expt. Sta.). (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 482-485, fig. 1).—Studies conducted at Manhattan, Kans., in 1935, the details of which are given in tables, have shown the optimum temperature for pea aphid reproduction and life to be several degrees higher on alfalfa plants that appear to be susceptible under field conditions than on plants that appear to be resistant. "The pea aphid reproduced more rapidly and the mortality was less on alfalfa plants that appeared to be susceptible under field conditions than on those that appeared to be resistant. Aphids reproduced more rapidly on selfed progeny of susceptible selections than on the selfed progeny of resistant selections, but the progenies varied considerably in this respect. Some alfalfa plants which appeared to be resistant in the field furnished satisfactory food for aphid reproduction. These plants may be resistant because of their ability to withstand the feeding of aphids. When aphids were confined to flowering and vegetative branches of the same plant, they reproduced much faster on the flowering branches. Although in this summary of the experiments, plants have been classed as resistant or susceptible, there was considerable range in mortality and rate of reproduction within the two groups."

**Pea aphid control in Maryland during 1939**, L. P. DITMAN, C. GRAHAM, and E. N. CORY. (Md. Expt. Sta.). (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 477-481).—The details of a study of pea aphid control on Alaska peas in Maryland, which consisted of a replicate plot experiment and a set of control demonstration plots, both located on the Eastern Shore at Ridgely, are reported in seven

tables. "From observations of the results of sweep records . . . and from a statistical analysis of the results, derris appears to be superior to ordinary cubé in effectiveness against the pea aphid. Good kill obtained with micronized cubé indicates that fine grinding may increase the toxicity. Dusts appear to be slightly better than sprays under the conditions of application on these plats. Dusts applied at high humidity when dew was on the plants gave slightly better results than dusts applied later in the day when temperature was higher, humidity lower, and plants dry. At 300 lb. pressure, Agicide nozzles give a better coverage than the ordinary type of spray nozzles. At 600 lb. pressure, the ordinary nozzles gave as good results as the Agicide nozzles, even though only one-half as many of the ordinary nozzles were used on a boom of the same length."

**Comstock's mealybug on apple and catalpa**, J. A. COX. (Va. Expt. Sta.). (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 445-447).—This is a brief summary of information on *Pseudococcus comstocki* Kuw., now a pest in many orchards in some of the principal apple-growing regions of Virginia, as reported by Woodside (E. S. R., 75, p. 665) and by Schoene (E. S. R., 83, p. 221), and also of catalpa in the State, as reported upon by Hough (E. S. R., 53, p. 756). The parasites reared from this mealybug in 1939 are *Clausenia purpurea* Ishii, *Thysanus nigra* Ashm., *T. elongatus* Gir., *Pachyneuron altiscuta* How., and *Lygocerus* sp., of which the first mentioned is the most important.

**Winter mortality of the black scale (*Saissetia oleae* Bern.) on oranges in California**, R. H. SMITH. (Univ. Calif.). (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 534, 535).—The author found winter mortality to be an important factor that has apparently been overlooked in the control of this pest. The success or failure of a treatment, as judged by the degree of infestation in spring and early summer of the following year, depends to a large extent upon the number of insects that die of natural causes subsequent to the treatment. The work reported includes the results of (1) mortality studies based on black scale counts on every tree in two 10-acre orange groves and showing the number of live black scale per "unit" at intervals from the time of spraying, August 27, 1935, to June 10, 1936, and (2) mortality studies on black scale on two orange trees, counts of which were made, one each per month, in October, January, March, and June.

**Commercial control of cabbage caterpillars near Charleston, S. C.**, C. O. BARE. (U. S. D. A. and S. C. Expt. Sta.). (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 463-467).—Report is made of a study from 1935 to 1938 of the insecticidal methods of control employed by different commercial growers in fields near Charleston and their effectiveness.

**The value to uninfested States of gypsy moth control and extermination**, A. F. BURGESS. (U. S. D. A.). (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 558-561).

**The spruce budworm in Minnesota**, S. A. GRAHAM and L. W. ORR (*Minnesota Sta. Tech. Bul.* 142 (1940), pp. 27, figs. 6).—A report is made of work with the spruce budworm, which has been responsible for the most disastrous forest losses due to insect attack. The favorite host is balsam fir. This native budworm is always present in the northern coniferous forests and at times increases tremendously and an outbreak results. Following a brief discussion of the damage caused by the pest and its life history and habits, the effect of an outbreak on various host species, the course of an outbreak, effects of defoliation, tree reproduction following budworm outbreak, the increased fire hazard, causes of a budworm outbreak, and control of the pest are considered. In dealing with its control the authors consider forest types in which balsam fir does not occur at present, forest types containing balsam fir, combinations

of spruce and fir, pure stands of balsam fir, and reduction of budworm hazard by logging operations.

**Biological control of the codling moth and the oriental fruit moth, J. E. WEBB, JR., and C. H. ALDEN** (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 431-435, figs. 2).—Report is made of parasite control work conducted during a 10-yr. period, commencing in 1930, in a laboratory of the Georgia Department of Entomology. The greater portion of the time and effort was devoted to mass production of and experimental work with the egg parasite *Trichogramma minutum* Ril. as a supplemental control for these two pests. More than 300 million egg parasites were colonized in commercial peach and apple orchards during this period and over a million and a half laboratory host eggs (angoumois grain moth) were produced in a single day with the wheat cabinets here described and illustrated. "Of 37,057 codling moth eggs collected, 56.2 percent were parasitized, and of 2,101 [oriental] fruit moth eggs collected, 36.3 percent were parasitized by *T. minutum*. About 40,000 *Macrocentrus ancylivorus* [Roh.] have been colonized in commercial peach orchards for [oriental] fruit moth control. Of 3,450 [oriental] fruit moth-infested twigs collected in these colonized orchards, 1,340 total emergences were obtained with an average of 29.6-percent parasitism, mostly *M. ancylivorus*. Of 2,593 total emergences from codling moth larvae, 19.1 percent were parasites, mostly *Ascogaster carpocapsae* [Vier.]. It is estimated that the egg and larval parasites of the [oriental] fruit moth destroy 55.2 percent of its total population and those parasitizing the eggs and larvae of the codling moth destroy 64.6 percent of its population. The scoring of 2,000 harvested fruits each year, from 1932 to 1939, inclusive, in an experimental Elberta peach orchard where both *T. minutum* and *M. ancylivorus* have been colonized, shows an almost continuous decline of [oriental] fruit moth infestation."

Other data included are: Combating *Habrocytus cerealellae* Ashm. and other pests of the grain moth breeding rooms; the production, colonization, and method of handling *Macrocentrus*; and a new ice box for transporting live insect material.

In the parasite production two grain moth breeding rooms each 15 by 15 by 7.5 ft. were made use of, each being equipped with seven breeding cabinets that hold about 1.5 bu. of wheat per cabinet. The cabinets measured 27.5 by 29.5 by 21.5 in., outside dimensions, with 14-in. legs and four trap cans in the upper corners. The account includes a description of the technic employed.

**Codling moth flight habits and their influence on results of experiments, L. F. STEINER.** (U. S. D. A.). (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 436-440).—In a study of the flight habits of the codling moth, releases of marked moths made during the years 1934-38 both outside and inside of baited areas in southern Indiana and their subsequent recapture in traps or in dusted unbaited trees proved conclusively that extensive intertree and interplat movement of moths is normal and common. "The average distance traveled away from their points of release was approximately 200 ft. in baited areas, where the distance to the outer rows of traps and the stoppage of flight by capture placed a limit on the length of normal flights. Normal movement of 200 ft. would be equivalent to a mass migration of all moths from the center to the outside of a 3-acre plat. Individual flights of more than 2,000 ft. were recorded, proving the ability of the insect, if emerging within a 100-acre orchard, to travel to any part of it. The replication of spray treatments, regardless of whether single-tree or 10-tree replicates are used, will not eliminate the influence of migration. Spray treatments with nicotine bentonite which are highly effective in the first brood but which may weaken shortly before harvest (unless additional sprays are applied) have given control superior to that obtained with

lead arsenate when tested on a large enough area so that their effects on the first brood would not be lost, but when tested in small replicated plats the early survivors in the plats sprayed with lead arsenate later provided a population which reinfested the nicotine-treated plats late in the season. Consequently small-plat tests in a two-brood or three-brood area will often show the relative effectiveness of the treatments against only the latest brood, if reliance is placed solely on records from drop and harvest fruit.

"Late-season moth migration proved capable of obscuring a large part of the effectiveness of orchard sanitation and banding or of the use of bait traps in tests involving 20-acre and 12-acre plats, respectively. The control obtained after the end of the first-brood period was more than offset by the more rapid build-up of the population in the treated areas late in the season, largely as a result of moth movement.

"The evidence suggests that there is a normal leveling off of the population between areas of heavy and of lower density, with movement occurring in both directions proportional to the population. There is also evidence that some moths make long flights and that under favorable conditions some of the population may extend its normal movement to considerable distances, giving the effect of a mass migration."

**Substitute spray material, II**, C. G. VINSON and S. A. MCCROBY (*Missouri Sta. Res. Bul. 316 (1940), pp. 14*).—Results of further experiments (E. S. R., 80, p. 224) with nicotine-bentonite combination cover sprays are said to be in harmony with previous findings, such sprays, beginning after the calyx spray with lead arsenate, having been as fully effective as lead arsenate in controlling codling moth and producing clean fruit. "The percentage of stings in 1939 on fruit from plats sprayed with nicotine-bentonite combinations was very greatly reduced under the number of stings on fruit from the plat sprayed with lead arsenate. The addition of a spreader and sticker such as summer oil, whole-milk powder, and Vatsol O. T. increased the effectiveness of the nicotine-bentonite combinations. The addition of Floor Seal did not make for increased effectiveness of the spray, although it did increase the deposit and retention of nicotine on the fruit and foliage. The dry-mix method of preparing nicotine-bentonite preparations produced a product which gave no obvious and objectionable residue on the fruit."

**The corn ear worm and its control**, L. A. CARRUTH (*New York State Sta. Cir. 190 (1940), pp. 14, figs. 8*).—Means of control of the corn earworm on Long Island, where it is most destructive, and in other parts of the State are described.

**A method for production of cutworms in greenhouses**, W. D. WYLIE and C. E. PALM. (Cornell Univ.). (*Jour. Econ. Ent., 33 (1940), No. 3, pp. 462, 463*).—A method devised for rearing cutworms in sufficiently large numbers and of satisfactory uniformity for laboratory toxicological studies is described.

**Studies of mosquito repellents.—I, Test procedure and method of evaluating test data. II, Relative performance of certain chemicals and commercially available mixtures as mosquito repellents**, P. GRANETT. (Rutgers Univ.). (*Jour. Econ. Ent., 33 (1940), No. 3, pp. 563-565, figs. 2; pp. 566-572*).—In the first part of this report a description is given of a method of testing mosquito repellents in the field comparable to the normal use of such materials. In the second part the relative effectiveness of various repellent substances and various proprietary repellents tested in the field against mosquitoes, principally the salt-marsh mosquito and the brown salt-marsh mosquito, and the composition of certain proprietaries are reported upon, the details being given in tables.

**Spray residue and substitutes for lead arsenate in control of cherry fruitflies**, D. W. HAMILTON. (U. S. D. A.). (*Jour. Econ. Ent., 33 (1940), No. 3, pp. 447-451, figs. 2*).—In control work with the cherry fruitfly and the black

cherry fruitfly lead arsenate was used effectively, but the residues at harvest were above the minimum tolerance. When used at the rate of 2.5 lb. per 100 gal. of spray at shuck fall, use of arsenicals in the maggot sprays will create excessive residues. Where danger of arsenical injury prevents use of more than 1 lb. of lead arsenate per 100 gal. at shuck fall, a pound of basic zinc arsenate may be applied in the first maggot spray. In field tests with both cubé root and phenothiazine as substitutes for arsenicals, heavy populations of fruitflies were satisfactorily reduced when at least three applications were made at the rate of 2 lb. per 100 gal. of spray. In one test a 15-percent phenothiazine dust appeared nearly as effective as these sprays. Basic zinc arsenate only partially controlled cherry fruitflies when two light applications were made.

**The life history of *Phyllophaga lanceolata* (Say) and *Phyllophaga crinita* Burmeister, H. J. REINHARD.** (Tex. Expt. Sta.). (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 572-578).—This is the first in a series of papers based upon life history studies of species of *Phyllophaga* commenced as a project at the station in 1937. The details are presented in eight tables. The work has shown the complete life cycle of *P. crinita* to be as follows: "The beetles begin to emerge in May and are commonly active throughout June. Earliest oviposition in the laboratory was noted on May 25 and the last on July 13. About 13 days are required for the eggs to hatch. The larvae continue to feed for 2 or 3 mo. and attain full growth during September or October, after which they remain quiescent throughout the winter season. Pupation begins about mid-April and pupae occur commonly in May. Approximately 20 days are required for the pupal stage, from which the beetles begin to emerge in May to complete a 1-yr. life cycle. Under favorable rearing conditions the average duration of the developmental stages was determined as follows: Egg 13 days, larva 281 days, and pupa 20 days. These periods total 314 days as compared with 365 days for *P. lanceolata*."

**Feeding habits of the adult Japanese beetle, I. M. HAWLEY and F. W. METZGER** (*U. S. Dept. Agr. Cir. 547* (1940), pp. 31, figs. 11).—Studies of the feeding habits of the adult Japanese beetle, which attacks various plants by eating the leaf tissue between the veins, giving the leaf a skeletonized or lacelike appearance, are reported. The beetles feed most actively between 9 a. m. and 3 p. m. on sunny days. Feeding is light below 70° and above 95° F. and when the relative humidity is below 60 percent. There is a seasonal variation in the choice of food plants, early feeding being on low-growing vegetation, later feeding on the taller trees favored for food, and toward the close of the season the beetles again preferring the lower plants, especially roses, weeds, and plants putting out new foliage. Two hundred and seventy-seven plants are listed as fed upon by the beetles. Of these, 43 species are severely attacked, 58 moderately attacked, 67 fed upon generally but lightly, and 109 occasionally and lightly attacked. In addition to these lists there is a list of 89 plants that are not known to be attacked under any condition. There is a complete index of the plants by common and scientific names.

**Methyl bromide fumigation for control of Asiatic beetle grubs attacking azalea plants, C. C. HAMILTON.** (N. J. Expt. Stas.). (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 486-490).—Report is made of the results of tests of the killing effect of methyl bromide on the oriental beetle grub attacking the roots and stems of azalea plants. Three methods of applying this insecticide were developed, namely, "(1) fumigation under a box which confines the charge of methyl bromide to a definite area; (2) the dilution of methyl bromide, 1 part in 5 parts of either methyl alcohol or ethyl alcohol, and injecting this mixture into the soil at rates equivalent to 1 and 2 cc. of methyl bromide per square foot; and

(3) the use of methyl bromide, 1 part in 5 parts of either methyl alcohol or ethyl alcohol and diluting this mixture in water and sprinkling it over the soil to be treated for the grubs. . . . Tests conducted to kill the Asiatic [oriental] beetle grubs in fallow soil in the azalea greenhouses showed that satisfactory kill could be obtained with chloropicrin applied 2 cc. per square foot if injected 3 to 4 in. from the surface, with carbon bisulfide at the rate of 0.75 oz. per square foot applied in shallow furrows about 10 in. apart, and with a mixture of methyl bromide and methyl alcohol injected into the soil equal to 1 cc. of methyl bromide per square foot. All three materials are probably equally effective in killing the Asiatic [oriental] beetle grubs. However, the soil cannot be planted until after all the carbon bisulfide or chloropicrin has escaped from the soil, which may be 10 days to 2 weeks for the carbon bisulfide and 2 to 3 weeks for the chloropicrin. Soil treated with the methyl bromide may be planted, without injury to the plants, within 2 to 3 days after treatment."

**Particle size of paris green as related to toxicity and repellency to the Mexican bean beetle**, E. R. MCGOVAN, C. C. CASSIDY, and E. L. MAYER. (U. S. D. A.). (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 525-531, figs. 2).—In the experiments reported paris green particles with an average diameter of  $1.1\mu$  caused higher mortalities of the Mexican bean beetle and permitted less feeding when applied, either as a spray or as a dust, to bean foliage than did particles of  $12\mu$ , which were intermediate, and  $22\mu$ , which caused the lowest mortality and permitted the greatest amount of feeding.

**Breeding hosts of the tobacco flea beetle**, C. LEVIN. (U. S. D. A.). (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 473-475).—In studies at Oxford, N. C., of tobacco in plant beds and of potatoes in the field as breeding hosts of the tobacco flea beetle it was found that both crops were breeding hosts of great importance, particularly during the early part of the season. The first generation of beetles began to emerge soon after tobacco was transplanted to the field. The evidence obtained showed that the beetles soon moved from the plant beds because the numbers that emerged in the beds were sufficiently large to have caused severe foliage injury to the plants had the beetles not moved.

**Host plants of the tobacco flea beetle**, E. H. GLASS. (Va. Expt. Sta.). (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 467-470, figs. 2).—Surveys were made and rearing experiments conducted in Pittsylvania County, Va., in 1939 in order to determine the host plants of the adults and the larvae of the tobacco flea beetle and their importance in maintaining or increasing the beetle population in the State. The adult beetles were found in the spring feeding on 13 hosts. During the growing season they occurred principally on tobacco, and in the late summer and early fall 52 host plants were recorded. "The insect was reared on all plants of the family Solanaceae tested but not on 16 species of plants representing 10 other families. The beetles developed most readily on tobacco, potato, and jimson weed. Tobacco plants in the bed and potato in the field were important in building up the beetle population in nearby fields in the spring before the tobacco plants were set in the field."

**Migration of the tobacco flea beetle**, C. B. DOMINICK. (Va. Expt. Sta.). (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 470-472, fig. 1).—Through the use of adhesive screens it was shown that upon emergence from hibernation tobacco flea beetles migrate to the first available host plants. "At the time of the transplanting of tobacco the insects tend to migrate from other host plants to newly set tobacco plants. The largest number of beetles were captured on adhesive screens at a height of 2 to 4 ft. above the ground, although some were caught at an altitude of 22-24 ft. It was demonstrated that the most extensive migration takes place after the tobacco has been harvested."

The potato flea beetle and the potato psyllid in Nebraska, M. H. SWENK and H. D. TATE (*Nebraska Sta. Bul.* 327 (1940), pp. 19, figs. 6).—The two insects of greatest importance in the profitable production of potatoes in Nebraska are dealt with, namely, the potato flea beetle (pp. 3-9), and the potato psyllid responsible for the psyllid yellows disease (pp. 9-17).

Notes on *Oncideres* twig girdlers, E. G. LINSLEY. (Univ. Calif.). (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 561-563).—Notes are given on the more important economic species of tree girdlers in the United States, including the huisache girdler *O. pustulata* Lec., the twig girdler *O. cingulata* (Say), the Texas twig girdler *O. texana* Horn, the Arizona oak girdler *O. quercus* Skinner, and the mesquite girdler *O. rhodosticta* Bates.

Some factors in natural control of the southern pine beetle (*Dendroctonus frontalis* Zimm.), L. A. HETRICK. (Va. Expt. Sta.). (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 554-556).—A brief report is made of the results of a study of the high mortality of the southern pine beetle in eastern Virginia in 1939. "Two species of nematodes were found infesting living and dead bark beetles of all stages. Five species of mites were found on the bodies of adult beetles in the insectary. Insect parasitism was negligible for the overwintering brood but amounted to 10 percent for the first brood."

[Smaller] European elm bark beetle and Dutch elm disease control, E. P. FELT (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 556-558).

Control of plum curculio on peach in Illinois, S. C. CHANDLER (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 451-453, fig. 1).—In the experiments reported lead arsenate applied to peach in the form of oil dust produced much less injury than when applied as a liquid spray, although excessive numbers of dust applications (five or more) may cause serious injury. "Eight seasons' tests with oil dust containing 10 percent lead arsenate and 5 percent oil show practically no difference in control of plum curculio from lead arsenate sprays used at 3 lb. to 100 gal. Cryolite is an unreliable and sometimes dangerous substitute for lead arsenate for control of plum curculio on peach. Jarring shows considerably more curculios at the edge of a peach orchard than are present even a few rows in from the edge. The best procedure from the standpoint of economy, efficiency, and safety to fruit and foliage is to use a minimum number of oil dust applications over the entire orchard with others at the edges or where jarring indicates abundance, and orchard tests show this procedure to be practical."

Further studies of the plum curculio in the Georgia peach belt, O. I. SNAPP. (U. S. D. A.). (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 453-456).—The results of further studies (E. S. R., 64, p. 58) of the life history and habits of the plum curculio in the Georgia peach belt, conducted at Fort Valley during the years 1936-39, are reported. It was found that "approximately one-half to three-fourths of the females of the first generation deposited eggs during the year of emergence. Dissections at the end of each season showed practically no egg development in females that had not oviposited. Following emergence from the soil and appearance from hibernation, about 1 mo. was required for eggs to mature. The movement of first-brood adults following their emergence from the soil was confined mostly to the tree from which they came and to trees nearby. Overwintered adults were found to travel from tree to tree even if there was fruit for food and oviposition, but after they became disseminated throughout the orchard their travel appeared to be confined to but a few adjacent trees. These adults did not seem to travel from an orchard, after the peaches were harvested, to other orchards before entering hibernation. The plum curculio was found to enter hibernation in midsummer within a

month after peach harvest and to hibernate in debris along the edges of woods bordering and near peach orchards. In 5 of the last 7 yr. this insect appeared on peach trees before full bloom and in 6 of these years they were disseminated throughout the orchards by the time three-fourths of the petals had fallen."

**Methyl bromide in aqueous solution to control *Pantomorus leucoloma* and *P. peregrinus***, E. M. LIVINGSTONE, S. S. EASTER, and G. R. SWANK. (U. S. D. A.). (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 531-533).—In the work with the white-fringed beetle reported "an aqueous solution containing 0.3 percent of methyl bromide and 0.6 percent of denatured ethyl alcohol was found to be of value in destroying larval infestations of *P. leucoloma* and *P. peregrinus* in burlapped balls of earth such as would be encountered on the roots of nursery stock. Results of a limited number of experiments showed that when infested balls were plunged in sand boxes that were 1 ft. deep, with a 2-in. sand space on all sides of the balls, and the insecticide applied at the rate of 40 gal. per 100 sq. ft. of surface area, complete mortality of larvae of *P. leucoloma* was obtained in balls 6 in. and smaller in diameter with an 18-hr. exposure, and complete mortality of larvae of *P. peregrinus* was obtained with a 4-hr. exposure. This apparent difference in the susceptibility of the larvae of these two species of *Pantomorus* is due to the different types of soil found in the two localities where the experimental work with the fumigant was carried on."

**Soil fumigation for control of the alfalfa snout beetle**, H. H. SCHWARDT and C. G. LINCOLN (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 460-462).—This report on soil fumigation control work with the alfalfa snout beetle, which supplements the biological work reported by Palm in 1935 and 1936 (*E. S. R.*, 76, p. 368), was conducted with a view to the development of a system of soil fumigation that would eradicate the beetle from small isolated spots. The beetle, introduced from central Europe some 40 yr. ago, is now present in more than 3,000 acres of alfalfa in Oswego and Jefferson Counties, N. Y., and from time to time isolated spots removed several miles from the continuous area appear. In these spots soil fumigation has been found effective in eradicating both beetles and larvae. "Preliminary tests with carbon bisulfide, chloropicrin, methyl bromide, carbon tetrachloride, dichloroethyl ether, and orthodichlorobenzene indicate that only carbon bisulfide can be depended upon to eradicate both larvae and adults under the various weather and soil conditions encountered in northern New York. Approximately 3,500 lb. of carbon bisulfide per acre injected in holes 15 in. apart and 8 in. deep has given a complete kill in all tests. Eighteen hundred lb. per acre gives a nearly complete kill, and it is believed that a dosage of 2,500 lb. per acre will prove to be completely effective."

**The apparent climatic limitations of the alfalfa weevil in California**, A. E. MICHELbacher and J. LEIGHLY (*Hilgardia [California Sta.]*, 13 (1940), No. 3, pp. 103-139, figs. 11).—It is apparent from the authors' observations and studies made throughout the world where the alfalfa weevil occurs that high temperature sends the adult weevils into estivation. Because of the failure of the pest to spread readily into the hotter portions of the San Joaquin Valley since its appearance in lowland middle California in 1932, it is the belief that the pest is encountering a climatic barrier. High temperature is said to retard or inhibit the maturing of the sexual organs. "The temperature range favorable for sexual development appears to fall between the limits of 10° and 25° C. Using this temperature range as a basis, the portion or portions of the year favorable to adult weevil activity have been plotted for stations in America and in a part of the Old World where the weevil is known to occur. By so

doing the weevil was found to exist in areas having four distinct types of climate: (1) Type *u* in areas where temperatures favorable to adult activity are present throughout the entire year; (2) type *w* where, owing to cold winters, there is a winter interruption in adult activity; (3) type *s* where, owing to hot summers, there is a summer interruption; and (4) type *ws* where both cold winters and hot summers cause a summer and a winter interruption.

"Areas having a winter interruption (type *w*) are further divided into two subtypes: (1) Those having a short winter interruption and (2) those having a long winter interruption. In climates of the latter type the alfalfa weevil is very destructive. This is the result of the short growing season which brings about a mass attack of the weevil on the alfalfa. Climates of this type are characteristic of the intermountain region of the United States which includes northeastern California. In this subtype the principal adverse factor affecting the weevil is low winter temperature. In climates of the first subtype where the winter interruption is short, adult weevils are active early in the year and before midsummer there is time for one full generation and at least a partial second generation. Alfalfa is seriously attacked only occasionally. This subtype appears in California in the coastal valleys north of southern California, in the lower extremities of the San Joaquin and Sacramento Valleys, and along the coast of the northern half of the State. Areas having both a winter and a summer interruption (type *ws*) are also divided into two subtypes: (1) Those having cold winters and (2) those having relatively mild winters. The first subtype is represented by the continental stations in the Old World where the alfalfa weevil is destructive because of mass feeding by the larvae and the factor that limits the weevil is cold and severe winters. In the second subtype with mild winters the limiting factor is high summer temperatures, as is also the case in the climatic type *s* where there is a summer interruption but no winter interruption."

Basing their view upon the reported distribution of the alfalfa weevil in the hotter portions of its range in the Old World the authors are led to conclude that the pest can adapt itself to almost all climates of California. "Certainly the climates of the hot California deserts would appear to be favorable, but we hardly think that this is the case, for evidence is presented that would tend to indicate that a second species closely related to the alfalfa weevil is involved. The species *Hypera brunneipennis* was recently found [E. S. R., 83, p. 93] in the neighborhood of Yuma, Ariz., and adjacent part of California. Very likely this species, which is adapted to hot climates, has been confused with *H. postica* in the hotter portions of the Old World and has been referred to the latter species. Judging from the behavior of the alfalfa weevil in California and the lack of reported damage in places such as Italy, we are inclined to believe that the pest will not be able to survive in the hotter portions of California."

**Effect of *Bathyplectes curculionis* on the alfalfa-weevil population in lowland middle California, A. E. MICHELbacher (*Hilgardia* [California Sta.], 13 (1940), No. 3, pp. 81-99, figs. 7).**—The larval parasite *B. curculionis* (Thoms.) of the alfalfa weevil was introduced into Utah from southern Europe during the years 1911 to 1913, and into the lowland infested area of middle California during the seasons of 1933 and 1934 by the U. S. D. A. Bureau of Entomology. It became readily established in California and was recovered at Pleasanton in 1933 and in the San Francisco Bay area in 1934 but was not found in the San Joaquin Valley until 1935, at which time about 30 percent of the large alfalfa weevil larvae were discovered to be parasitized. The progress of its

parasitism was determined by studies conducted in three different climatic areas, namely, the San Francisco Bay and Pleasanton areas and the northwest portion of the San Joaquin Valley, through field collections of last-instar alfalfa weevil larvae and the rearing through of their parasites in the laboratory. "In each field 2 lots of 100 sweepings were made with an insect net, and the average number of larvae and adults collected per 100 sweeps was used as a population index for the alfalfa weevil. The highest alfalfa weevil larval peak generally occurs on the first crop, but it may occur on the second or even later crops. Weevil activity begins early in the growing season, and a second generation generally makes its appearance during the latter part of June and through July.

"*B. curculionis* produces short- and long-cycle forms. Individuals of the latter form are produced at any time during the active period of the parasite. Climate apparently greatly influences the behavior of *Bathyplectes*. Its active period is limited by the hot climate of the San Joaquin Valley. In the cooler portions of the weevil-infested areas of lowland middle California the parasite is able to continue activity throughout the growing season. The most active period ranges from early season until about the first of July. For summer and fall activity to be noticeable two conditions are apparently necessary, namely, a certain host density and a cool climate."

The information gathered concerning parasitism and alfalfa weevil population trends is shown by graphs for the different regions studied. These graphs indicate that the San Joaquin Valley is less suited to *Bathyplectes* than the cooler areas. Definite predictions concerning the final effect of *Bathyplectes* upon the alfalfa weevil population cannot be made as yet, but in 1938 the parasite showed considerable promise. From all indications it will exert a marked controlling influence in the cooler weevil-infested areas.

Notes on the life history of *Baeus californicus* Pierce, an egg parasite of the black widow spider, C. E. PEMBERTON and J. S. ROSA (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.]*, 44 (1940), No. 2, pp. 73-80, figs. 4).—The successful introduction and establishment in Hawaii of the egg parasite of the black widow spider, described by Pierce from California in 1938 as *B. californicus* (E. S. R., 81, p. 253), as a control measure for that spider is reported upon. Its life cycle, determined at the station, averages about 22 days during the warm months of the year and from 25 to 29 days during winter. A spider egg sac collected at Lualualei, Oahu, in December 1939, which had been attacked by parasites previously liberated in that locality, produced 348 parasites and no spiders and is said to be the first record of field work with the parasite in Hawaii.

The effects of ingestion of black widow spiders with canned food, W. B. HERMS, B. C. McIVOR, and C. LADENHEIM. (Univ. Calif.). (*Jour. Econ. Ent.*, 33 (1940), No. 3, pp. 550-554).—Tests with white mice, guinea pigs, and a monkey, here described, furnish evidence that ingestion of the venom through consuming the black widow spider *Latrodectus mactans* causes no harm to experimental animals. Numerous tests made with experimental animals by allowing them to feed on canned spinach or drink liquid from canned spinach produced no ill effects which could be recognized by careful observation.

## ANIMAL PRODUCTION

[Experiments with livestock in Florida], A. L. SHEALY, W. G. KIRK, R. M. CROWN, R. W. KIDDER, L. O. GRATZ, W. F. WARD, R. B. BECKER, W. M. NEAL, P. T. D. ARNOLD, L. L. RUSOFF, N. R. MEHRHOF, O. W. ANDERSON, JR., E. F. STANTON, and D. F. SOWELL. (Partly coop. U. S. D. A. et al.). (*Florida Sta.*

*Rpt. 1939, pp. 68-71, 73-78, 79, 80, 169, 170, 172, 175-177, 179, 180, 194*).—Brief progress reports (E. S. R., 81, p. 254) are presented for the following lines of investigation: The improvement of beef cattle herds through the continuous use of purebred sires of different breeds on grade cows, and other beef and dual-purpose cattle investigations; mineral deficiencies in feeds used in cattle rations; a comparison of the loss of nutrients in ensiled corn, Napier grass, sugarcane, and sorghum; a comparison of silages for wintering beef calves and yearlings; the value of Napier grass for pasture purposes; the digestibility of fresh Napier grass and of sugarcane silage; the digestibility and feeding value of dried grapefruit and dried orange refuse; the comparative value of sugarcane silage, shocked sugarcane, and pasture, supplemented with cottonseed meal for wintering beef cattle; the value of molasses in steer-fattening rations; the effectiveness of cottonseed meal in preventing a ricketslike nutritional disorder in cattle on pasture; a comparison of ground v. unground mixtures of corn and velvetbeans with and without molasses for fattening steers; a comparison of the progeny performance of native, grade Columbia, and purebred Columbia sheep; deficiencies of peanuts when used as a feed for swine; methods of handling sows and young pigs; a comparison of various grazing crops for fattening feeder pigs; and the utilization of citrus meal as a swine feed.

From poultry investigations results are noted on poultry breeding experiments with reference to egg production, egg size, livability, hatchability, broodiness, and disease resistance; the utilization of citrus byproducts for poultry; the vitamin content of shark-liver oil; and different methods of feeding grain to layers.

[**Investigations with livestock in Georgia**]. (Partly coop. U. S. D. A.). (*Georgia Coastal Plain Sta. Bul. 30 (1939), pp. 45-73, figs. 4*).—Progress reports (E. S. R., 81, p. 404) are presented for the following lines of investigation: The value of fertilizing lowland and upland permanent pastures and also the returns secured from various annual summer and winter pastures as measured by grazing tests with steers; ground snapped corn, sorghum silage, cottonseed meal, and oat straw as a winter ration for beef cows; the returns secured from the winter grazing of corn and velvetbeans after corn had been harvested; the profitableness of veal production; feed requirements for wintering feeder calves; the management of brood sows and their litters; the value of various summer crops for spring litters; and the returns secured from hogging off corn, runner peanuts, and sweetpotatoes. An additional year's results of previously described steer-fattening experiments are reported in detail.

[**Livestock investigations in Mississippi**] (*Miss. Farm Res. [Mississippi Sta.], 3 (1940), No. 6, pp. 1, 7, 8*).—The results of experiments with livestock are briefly reported in articles entitled: Corn and Tankage for Finishing Pigs Leads in Another Test, by P. G. Bedenbaugh; Sweetpotatoes Show Merit as Feed for Dairy Cows in Test, by W. C. Cowsert; and Cottonseed Meal and Shrimp Meal Used to Advantage as Protein Sources in Balanced Feed for Broiler Production, by H. D. Polk.

**Commercial feeding stuffs**, L. S. WALKER and E. F. BOYCE (*Vermont Sta. Bul. 458 (1940), pp. 46*).—The usual report of the analyses for protein, fat, and fiber of 2,093 samples of feeding stuffs collected for official inspection during December 1939 (E. S. R., 82, p. 805).

[**The production and nutritive value of forage plants in Puerto Rico**], F. MÉNDEZ, D. H. COOK, J. AXTMAYER, G. RIVERA, and J. GOYCO (*Puerto Rico Col. Sta. Rpt. 1939, pp. 95-98*).—Results are briefly presented on the adaptability of various legumes to Puerto Rico conditions and the digestibility and vitamin content of various native grasses and legumes.

The conservation of alfalfa, timothy, and soybean nutrients as silages and as hays, J. A. NEWLANDER, H. B. ELLENBERGER, O. M. CAMBURN, and C. H. JONES (*Vermont Sta. Bul.* 459 (1940), pp. 42).—Comparable lots of alfalfa, timothy, and soybeans were ensiled and made into sun-cured and artificially dried hays. The silages were prepared without preservatives and with added preservatives, including molasses, phosphoric acid, and a mixture of sulfuric and hydrochloric acids. The dry matter of the ensiled material ranged from 28 to 45 percent for alfalfa, from 30 to 49 percent for timothy, and from 21 to 33 percent for soybeans. All groups were satisfactorily ensiled without preservatives providing the dry matter content was at an optimum level. The most desirable alfalfa silage was molasses preserved, with 40 percent dry matter and a pH of 4.76. Three lots of timothy silage, one without preservative (dry matter 37 percent, pH 4.94) and two molasses preserved (dry matter 31 and 43 percent, pH 4.58 and 4.79, respectively), were adjudged of equal quality. Acid-preserved samples were also of good quality. Soybeans containing approximately 25 percent dry matter made poor silage either with or without molasses, but soybeans wilted to from 31 to 33 percent dry matter made good silage even without preservative. Soybeans of low dry matter content were well preserved when treated with phosphoric acid. The nutrients in hays and silages were about equally digestible except for ether extract in sun-cured hay which was relatively very low. Losses of nutrients under different methods of storage are indicated. The conservation of nutrients in hay under ideal weather conditions equaled that secured in the best preserved silages.

Abstracts of papers, 98th meeting, American Chemical Society (*Amer. Chem. Soc. Mtg.*, 98 (1939), *Abs. Papers*, pp. A5, B4-6, 8, 13, 14).—Abstracts of the following papers, dealing with subjects of significance in animal nutrition from the agricultural and food chemistry and biological chemistry sections, are noted: Meeting the Protein Requirements of Swine With Rations Containing Low Protein Tankage, by R. C. Miller and T. B. Keith (Pa. State Col.); The Role of Xanthophylls in the Ration of the Fowl, by W. J. Peterson, J. S. Hughes, and H. M. Scott (Kans. State Col.); The Absorption of Vitamin A by Dogs, by S. W. Clausen, B. B. Breese, Jr., and A. B. McCoord; The Anti Gray Hair Vitamin, a New Factor of the Vitamin B-Complex, by G. Lunde and H. Kringstad; The Role of Vitamin B Complex With Respect to Weight Restoration in the Pigeon, by A. D. Emmett, G. E. Peacock, and R. A. Brown; and Cystine and Methionine as Dietary Lactagogues, by J. R. Haag and L. D. Wright (Oreg. State Col.).

[Abstracts of papers on animal nutrition presented at the 34th annual meeting of the American Society of Biological Chemists] (*Jour. Biol. Chem.*, 133 (1940), No. 3, pp. v, vi, xv-xvi, xxvii, xli, xlii, xlv, lvi, lxv, lxvi, lxviii, lxix, lxxi-lxxiv, lxxviii, lxxxvi, lxxxix, xc, xcii).—Abstracts of the following papers pertaining to animal nutrition are noted: Some Observations on Pantothenic Acid (Chick Antidermatitis Factor), by S. H. Babcock, Jr., and T. H. Jukes (Univ. Calif.); The Effect of Adrenalectomy on the Deposition in the Liver of Spectroscopically Active Fatty Acids, by R. H. Barnes, E. S. Miller, and G. O. Burr (Univ. Minn.); Influence of Parathyroid Deficiency on Reproductive Success in the Albino Rat, by M. Bodansky and V. B. Duff; Nutritive Value of Zein Hydrolysates, by R. Borchers and C. P. Berg; Glycocyamine and Methionine as Precursors of Creatine in Animal Tissues, by H. Borsook and J. W. Dubnoff; Intravenous Fat Is Not a Precursor of Cholic Acid in the Dog, by M. E. Doster-Virtue and R. W. Virtue; Studies on Additional Factors Required by the Chick, by D. M. Hegsted, J. J. Oleson, C. A. Elvehjem, and E. B. Hart (Univ. Wis.); Anemia From Lysine Deficiency in Deaminized Casein, by A. G. Hogan, E. L. Powell, and R. E. Guerrant (Univ. Mo.); A Rapid Photoelectric Method for the Determination of

Vitamin A and Carotene in Milk, by C. J. Koehn (Ala. Polytech. Inst.); Synthesis of Members of the Vitamin B Complex in the Rumen of the Cow, by L. W. McElroy and H. Goss (Univ. Calif.); The Effect of Iodine and Other Mineral Supplements on Cholesterol-Induced Atherosclerosis in Rabbits, by H. S. Mitchell, M. F. Goldfaden, and G. J. Hadro (Mass. State Col.); The Nature of the Blood and Tissue Changes Produced by Feeding Cholesterol to Guinea Pigs, by R. Okey and V. D. Greaves (Univ. Calif.); The Nutritive Value of Cottonseed Meal, by H. S. Olcott; Factor W and Pantothenic Acid in the Nutrition of the Rat, by J. J. Oleson and S. Black (Univ. Wis.); The Supplementary Relationship of Vitamin B<sub>6</sub> and Unsaturated Fatty Acids, by W. D. Salmon (Ala. Polytech. Inst.); Evidence of the Complex Nature of the Alcoholic Precipitate Factor Required by the Chick, by A. E. Schumacher, G. F. Heuser, and L. C. Norris (Cornell Univ.); Effect of Certain Fats Upon the Utilization of Carotene, by W. C. Sherman (Ala. Polytech. Inst.); and Pantothenic Acid Content of Tissues of Chicks on Diets Deficient in This Substance, by E. E. Snell, D. Pennington, and R. J. Williams.

**The applicability of the quantitative indicator method as determined by a study of the movement of food in the gastrointestinal tract** [trans. title], L. PALOHEIMO (*Biedermanns Zentbl., Abt. B, Tierernähr., 11 (1939), No. 4-5, pp. 370-388, figs. 3; Eng. abs., pp. 386, 387*).—A critical study was made concerning the use of the quantitative indicator method for determining the digestibility of feeds. Chromium oxide was used as an indicator in trials involving both rats and cattle. In addition to the conventional analyses of feeds and feces, animals were sacrificed at various intervals after the ingestion of feed, and the contents of various sections of the alimentary tract were analyzed for the presence of chromium. With both species a tendency was observed for irregular movement of food through the tract and a piling up by the different portions of ingested feed in certain sections of the tract. It was evident that the stomach contents were not emptied in the same succession with which the food entered the stomach. A high percentage of the chromium present in feed was still present in the rumen and reticulum of cattle from 21 to 25 hr. after it was ingested. The level of feed intake also apparently increased the rate of emptying of the forestomachs of cattle.

**The carotene (provitamin A) content of Oklahoma feeds**, R. WALL (*Oklahoma Sta. Bul. 242 (1940), pp. 15*).—Data are presented on the carotene content of a wide range of Oklahoma forage plants in the green state, immediately after drying, and after varying periods of storage. The range of carotene values is similar to that reported from other areas, with a relatively wide variation due to the variable type of climate characteristic of that State. In general, carotene content of the plants increased up to the time of blooming, and then decreased. It was influenced by the season in accordance with the favorableness of conditions for growth. Properly cured hay contained about one-half as much carotene as that in the green forage. It dropped to about one-third that of the green plant after 6 months' storage under good conditions. Carotene in silage was quite stable over long storage periods, averaging at least one-half of the initial value after 6 mo. The intensity of green color proved to be a useful qualitative index of the carotene content of the feed. Samples stored in alcohol at 0° C. showed rather high carotene losses, indicating that this method of preservation is not suitable for holding samples for carotene determination.

**Biochemical studies on B<sub>1</sub> avitaminosis in animals and man** [trans. title], B. CARLSTRÖM, K. MYRBÄCK, N. HOLMIN, and A. LARSSON (*Biedermanns Zentbl., Abt. B, Tierernähr., 11 (1939), No. 4-5, pp. 322-356; Eng. abs., pp. 354, 355*).—

The authors discuss the origin of vitamin B<sub>1</sub> deficiency and present information on the blood picture and characteristic deficiency symptoms of B<sub>1</sub> avitaminosis in blue foxes, cattle, horses, and man.

**The prevention of nutritional muscular dystrophy in guinea pigs with vitamin E**, N. SHIMOTORI, G. A. EMERSON, and H. M. EVANS. (Univ. Calif.). (*Jour. Nutr.*, 19 (1940), No. 6, pp. 547-554).—A more comprehensive report of research previously noted (E. S. R., 82, p. 372).

**Iodine in animal nutrition**, B. W. FAIRBANKS and E. CURZON. (Univ. Ill.). (*North Amer. Vet.*, 21 (1940), No. 1, pp. 25-28).—Review, with 32 references.

**Cystine and methionine for growth and lactation**, J. R. HAAG and L. D. WRIGHT. (Oreg. Expt. Sta.). (*Jour. Nutr.*, 19 (1940), No. 6, pp. 563-568).—A more complete report of research previously noted (E. S. R., 82, p. 371).

**Feeding trials with dried whey** [trans. title], H. BÜNGER, E. FISSMER, W. HARRE, H. SCHMIDT, K. BOEHM, and F. REISING (*Biedermanns Zentbl., Abt. B, Tierernähr.*, 11 (1939), No. 4-5, pp. 276-300, fig. 1; *Eng. abs.*, p. 300).—Dried whey containing 90 percent of dry matter, 9 percent of digestible crude protein, and from 67 to 68 percent of total digestible nutrients was successfully fed as a supplement to the regular ration to pigs and dairy heifers, providing the daily intake per animal did not exceed about 0.5 kg. of the whey. Larger quantities in the diet tended to depress the appetite of the animals. The presence of dried whey in the ration increased the water consumption of both species.

**The utilization of different feeding stuffs by rabbits as compared with wethers and pigs** [trans. title], K. NEHRING and W. SCHRAMM (*Biedermanns Zentbl., Abt. B, Tierernähr.*, 11 (1939), No. 4-5, pp. 301-321, figs. 2; *Eng. abs.*, p. 321).—In a series of trials the relative digestion and utilization of dry roughages, silages, grain, and potatoes by these three species were compared. With dry roughages similar coefficients of digestibility for all nutrients except crude fiber were obtained in trials with rabbits and wethers. The digestibility of crude fiber was significantly lower by the rabbit than by the wether. The two species were about equally efficient in digesting all components of silage, indicating that the digestibility of crude fiber in green plants by rabbits is higher than that from dried plants. Rabbits and pigs utilized grains and potatoes with approximately the same degree of efficiency. It appeared that digestibility coefficients obtained with one species could be applied to the others, except that for crude fiber.

**Variations in the blood calcium and phosphorus with the age of the dog**, H. D. ANDERSON and C. A. ELVEHJEM. (Wis. Expt. Sta.). (*Jour. Biol. Chem.*, 134 (1940), No. 1, pp. 217-223, figs. 3).—Analyses of blood samples drawn from dogs at periodic intervals from birth to 2 yr. of age revealed a progressive decrease in inorganic phosphorus throughout the growing period. The level of blood calcium was highly variable, but showed a slight downward trend during the period of maturation. Following a mild vitamin D deficiency in dogs, the administration of cod-liver oil produced a rise in inorganic phosphorus and a fall in the calcium level of the blood. A sharp rise in calcium invariably accompanied a sharp fall in inorganic phosphorus. The trends noted are considered normal for dogs.

**Four centuries of Florida ranching**, G. H. DACY (*St. Louis, Mo.: Britt Ptg. Co.*, [1940], pp. 310+[1], [figs. 90]).—An interesting nontechnical history of the beef cattle industry in Florida.

**The estimation of methane production by cattle**, J. W. BRATZLER and E. B. FORBES. (Pa. Expt. Sta.). (*Jour. Nutr.*, 19 (1940), No. 6, pp. 611-613, fig. 1).—Based on 130 measurements of methane by combustion, each representing 2 or 3 days of continuous collection, methane production bore a close rela-

relationship to the intake of digestible carbohydrates. This relationship is expressed by the formula  $E=4.012X+17.68$ , in which  $E$  represents grams of methane produced and  $X$  hundreds of grams of carbohydrate digested. This formula is applicable over a digestible carbohydrate intake range of from 900 to 5,800 gm. per day.

**Destruction of ascorbic acid in the rumen of the dairy cow, C. A. KNIGHT, R. A. DUTCHER, N. B. GUERRANT, and S. I. BECHDEL.** (Pa. Expt. Sta.). (*Soc. Expt. Biol. and Med. Proc.*, 44 (1940), No. 1, pp. 90-93, figs. 2).—In the described experiments, a Holstein cow having a rumen fistula was fed measured amounts of synthetic ascorbic acid mixed with corn silage; also ascorbic acid was placed directly in the rumen through the fistula opening. In no instance was any increase in ascorbic acid values of the blood plasma or milk observed as compared with values obtained when the cow was on a standard ration without vitamin supplement. A slight increase occurred in the amount of ascorbic acid found in the 24-hr. sample of urine for the periods during which the vitamin was administered. Analyses of samples of the rumen contents taken at regular intervals after the administration of ascorbic acid revealed a rapid and pronounced destruction of ascorbic acid in the rumen. Ascorbic acid added to rumen contents in vitro stored in dark-glass stoppered bottles at 39°-42° C. disappeared at much the same rate as that in the in vivo experiments.

**The protein requirements of working horses at rest and at various rates of work, I, II** [trans. title], H. NITSCHKE (*Biedermanns Zentbl., Abt. B, Tierernähr.*, 11 (1939), Nos. 3, pp. 214-244, figs. 2; *Eng. abs.*, p. 244; 4-5, pp. 245-272, fig. 1; *Eng. abs.*, pp. 270, 271).—A modification of the Kellner feeding standard for working horses is presented, based on the results of 15 years' work at the university of Breslau. The protein requirement of the resting horse is affected by environmental conditions varying with breed, age, state of nutrition, and especially with the biological value of the feed protein. With a ration of oats, hay, and straw, the requirements of the resting horse amounted to 53-63 gm. of digestible crude protein and 48-59 gm. of digestible pure protein per 100 kg. of live weight. Employing a new type of apparatus for measuring force, as described, it was found that the requirements of the horse for digestible pure protein did not increase proportionately with increasing rates of work, the requirements per unit of work decreasing as the rate of work increased.

**Indiana stallion enrollment.—Report of stallion enrollment board for the year 1939, with lists of stallions and jacks enrolled** (*Indiana Sta. Cir.* 253 (1939), pp. 44, figs. 3).—A directory of enrollments and renewals issued from January 1 to December 31, 1939, classified by counties, and a brief résumé of stallion laws in other States (E. S. R., 81, p. 259).

**Some factors in lamb production associated with size and type in mutton sheep, G. A. BRANAMAN.** (Ill. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 60 (1940), No. 7, pp. 473-486).—Trials were conducted to compare the rate and efficiency of gain and the quality of carcass produced by purebred Southdown and Hampshire lambs and by crossbred lambs from grade western ewes mated to Southdown, Hampshire, and Shropshire rams. When full-fed appropriate rations the purebred ewes of each breed consumed feed approximately in proportion to body weight. However, the feed consumption of the lambs when fed a maintenance ration or when full-fed for rapid growth and fattening was more nearly in proportion to the three-fourths power function of body weight. Hampshire yearling lambs on full feed digested nitrogen significantly more efficiently than Southdown lambs. Coefficients of digestibility for other nutrients were similar for the two lots. A 120-percent Hampshire lamb crop was found necessary to produce lean meat in Choice carcasses as efficiently with

respect to total feed as a 100-percent Southdown lamb crop. Well-fed Hampshire single lambs attained Choice market finish approximately 6 weeks younger than Southdown single lambs or Hampshire twins. Southdown lambs of Choice market quality gave higher yields of dressed carcass, boneless meat, and separable lean meat than Hampshire lambs of similar finish.

In tests with crossbred lambs, those sired by Southdown rams were of greatest value, followed in order by those sired by Hampshire and Shropshire rams. The Hampshire-sired lambs were slightly heaviest, while the Southdown-sired lambs were highest in market grade.

**The feeding value of artificially dried sweet lupines** [trans. title], W. KIRSCH and H. JANTZON (*Biedermanns Zentbl., Abt. B, Tierernähr., 11 (1939), No. 4-5, pp. 273-275; Eng. abs., p. 275*).—Digestion trials with wethers revealed the following coefficients of digestibility for artificially dried sweet lupines (free of bitter principle): Crude protein 60.2, true protein 61.5, amide 47.3, crude fat 76.5, crude fiber 65.1, and nitrogen-free extract 75.2. The material contained 11.82 kg. of digestible crude protein and 10.93 kg. of digestible pure protein per 100 kg. of dry matter.

**[Poultry investigations in New Jersey]** (*New Jersey Stas. Rpt. 1939, pp. 9, 10, 109-114*).—Progress results (E. S. R., 82, p. 236) are briefly presented for the following: Fat requirements and metabolism of the chicken; changing trends in egg production and mortality of layers in the State egg-laying contests; economic significance of inherited longevity tendency in chickens; value of short-season egg production performance as a basis for selecting layers; development of a strain of White Leghorns especially suited to individual cage management; merits of a stud-mating system; practicability of year-round hatching of chicks; comparison of the effects of slow, medium, and fast growth in White Leghorn pullets; rate and efficiency of egg production by Khaki-Campbell ducks; and breeding and feeding for improved squab production.

**Factors in mixing rations for poultry**, C. S. PLATT (*New Jersey Stas. Hints to Poultrymen, 27 (1940), No. 4, pp. 4*).—Practical considerations are discussed.

**Proso millet and oats in poultry rations**, W. O. WILSON and W. E. POLEY (*South Dakota Sta. Bul. 337 (1940), pp. 31, figs. 7*).—Tests with proso millet and oats in starting, growing, and laying rations for chickens are summarized. From the results of 16 trials (62 lots) with young chicks comparing the various single grains and grain mixtures in starting rations, it was found that there were only slight differences in the pounds of feed required per pound of gain when corn, wheat, barley, and oats were compared with millet. Best results were obtained when equal parts of proso millet and any one of the other grains were fed. Fed singly, millet and oats each proved to be  $\pm 93$  percent as efficient as yellow corn. There was no apparent difference in the value of white and red proso millet. Better growth of chicks was evident with 15 percent each of wheat bran and wheat middlings included in the ration than with 30 percent of ground wheat. Amber cane was equally as effective as proso in promoting growth to 8 weeks of age, but resulted in higher mortality than did millet. Used in growing rations, red proso was equal to yellow corn, while oats had about 80 percent the value of corn. Growing birds consumed proso more readily than cracked yellow corn. From the results of 5 tests with laying hens (18 lots), it is concluded that red or white proso was approximately equal to either yellow corn or oats for egg production and maintenance of body weight. Use of whole millet instead of ground millet supported good egg production but resulted in a somewhat higher feed requirement per dozen eggs produced. Neither egg production nor hatchability was improved by increasing the amount of alfalfa leaf meal or meat and bone scraps in the mash mixture. Suggested feed mixtures using proso millet are included.

**Fat requirements of the growing chick,** W. C. RUSSELL, M. W. TAYLOR, and L. J. POLSKIN. (N. J. Expt. Stas.). (*Jour. Nutr.*, 19 (1940), No. 6, pp. 555-562).—The growth rate of chicks maintained on an ether-extracted ration composed of natural feeding stuffs and containing approximately 0.1 percent fat was compared with that of chicks on a normal ration containing 4.1 percent fat. The growth rate of chicks to 14 weeks of age on the low-fat diet supplemented with all known essential dietary factors was not significantly below that of the control group. Chicks on the low-fat diet utilized crystalline carotene despite the very low level of fat intake. Analyses of body fat showed that that formed on a low-fat diet was more saturated than that for normally fed chicks. However, liver fat from the two groups showed essentially the same degree of saturation.

**Growth and development, with special reference to domestic animals.—LI, Seasonal metabolic and endocrine rhythms in the domestic fowl,** C. F. WINCHESTER (*Missouri Sta. Res. Bul.* 315 (1940), pp. 52, figs. 8).—This series is here continued (E. S. R., 81, p. 99). The design and construction of a four-chamber Regnault-Reiset metabolism apparatus adapted to chickens and also the adaptation of an electric stethoscope to measurement of heart rates of fowls while resting in closed chambers are described. Measurements of the heat production and heart rates of laying pullets of the New Hampshire breed revealed a rough parallelism between fasting heat production, heart rate, and egg production. The correlation between heart rate and metabolism was not great enough, however, to permit prediction of one from the other. Considerable daily fluctuations in the metabolism and heart rate of individuals suggested the need of observations on relatively large numbers of individuals if statistically significant results are to be obtained.

The influence of the thyroid on egg production was also studied. Following thyroidectomy birds which had been producing at a high level dropped to a very low rate. Weekly injections of 1 and 2 mg. of thyroxine per kilogram<sup>0.73</sup> restored these hens to 40 and 60 percent normal production, and preoperative fasting metabolism was restored. Thyroidectomized hens not receiving thyroxine remained at a low production level throughout. A critical review of the literature on photo- and thermoperiodicity and an extensive bibliography are included.

## DAIRY FARMING—DAIRYING

[Abstracts of papers presented at the 35th annual meeting of the American Dairy Science Association] (*Jour. Dairy Sci.*, 23 (1940), No. 6, pp. 487-530, 536, 537, 538-540, 543, 544, 550-576).—Following are listed the titles and authors of papers pertaining either to dairy manufacturing or dairy production, presented at the annual meeting of the association (E. S. R., 81, p. 701) held at West Lafayette, Ind., June 24-28, 1940: The Relation of Acidity and Total Solids Contents per Gallon to the Physical and Chemical Properties of High Serum Solids Ice Cream, by C. W. Decker and W. C. Hall (p. 487) (Mo. Expt. Sta.); Characteristics of Base Exchange Treated Skimmilk Powder in Ice Cream, by J. H. Erb, R. B. Hornberger, and J. D. Bowers (pp. 487, 488) (Ohio State Univ.); Fresh and Frozen Plain, Superheated, and Sweetened Condensed Skimmilk for Ice Cream, by L. K. Crowe, D. D. Deane, and H. H. Winn (pp. 488, 489) (Univ. Nebr.); Replacing Cane Sugar With Variable Increments of Dextrose Sugars and the Effect Upon the Physical and Chemical Properties of Ice Cream at Different Serving Temperatures, by R. J. Cooley, W. H. E. Reid, and W. C. Hall (pp. 489, 490) (Mo. Sta.); Use of High Conversion Corn Sirup in the Manufacture of Ice Cream and Ices, by G. J. Edman and P. H. Tracy (p. 490) (Univ. Ill.); Corn Sugar and Sirups for Frozen Desserts, by A. C. Dahlberg

and E. S. Penczek (pp. 490, 491) (N. Y. State Sta.); Factors Affecting the Viscosity of Ice Cream Mixes Containing Sodium-Phospho-Alginate, by J. H. Hetrick and J. H. Erb (pp. 491, 492) (Ohio State Univ.); Influence of Drawing Temperature as a Factor Affecting the Stabilizing Action of Gelatin and the Body and Texture of Batch and Continuous Frozen Ice Cream, by R. E. Heyl and P. H. Tracy (pp. 492, 493) (Univ. Ill.); The Application of Motion Pictures as a Medium in Showing the Influence of Several Factors Upon the Stability and Meltdown Properties of Ice Cream, by W. S. Arbuckle, C. W. Decker, and R. J. Cooley (p. 493) (Mo. Sta.); A Study of the Coliform Group in Ice Cream, by H. J. Fournelle and H. Macy (pp. 493, 494) (Univ. Minn.); Prevention of Oxidized Flavor in Frozen Cream by Homogenization and High Temperature Pasteurization, by G. C. McFarland and L. H. Burgwald (pp. 494-496) (Ohio State Univ.); A Survey of the Objectionable Feed Flavors in Milk Throughout the North American Continent, by P. A. Downs (p. 496) (Univ. Nebr.); Interrelation of Certain Metals and Metallic Ions and the Development of Oxidized Flavor in Milk, by O. F. Garrett (pp. 496, 497), and A Comparison of the Effects of Seven Different Types of Roughages on the Color and Flavor of Milk, by O. F. Garrett, R. B. Arnold, and G. H. Hartman (pp. 497, 498) (both N. J. Stas.); Recent Studies on Oxidized Flavor in Milk, by W. J. Corbett and P. H. Tracy (pp. 498, 499) (Univ. Ill.); Milk Flavor Study, by H. B. Henderson, T. B. Harrison, and C. E. Wylie (pp. 499, 500) (Univ. Tenn.); The Relationship of Quality of Hay to the Development of Oxidized Flavor in Milk, by W. C. Brown, A. H. VanLandingham, and C. E. Weakley, Jr. (pp. 500, 501) (W. Va. Sta.); The Effect of Feeding Cod-Liver Oil on the Goaty and Oxidized Flavors, and Vitamin C in Milk, by E. S. Guthrie (pp. 501, 502) (Cornell Univ.); Resistance of Thermoduric Bacteria to Chlorine Disinfection, by A. C. Maack and M. J. Prucha (p. 502) (Univ. Ill.); Is the Standard Plate Count a Proper Yardstick of Quality? by M. E. Parker (pp. 502, 503); Control of Sediment in Homogenized Milk, by A. J. Hahn and P. H. Tracy (pp. 503, 504) (Univ. Ill.); A Study of the Effect of Added Iodine and Hydrogen Peroxide to Milk on the Enzymes, by M. Glickstein, W. S. Mueller, and J. H. Frandsen (p. 504) (Mass. State Col.); A Study of the Time-Temperature Relationships in Pasteurization of Milk as Regards Creaming, Phosphatase, and Bacterial Destruction, by R. F. Holland and A. C. Dahlberg (pp. 504, 505) (N. Y. State Sta.); The Relationship of Changes in the Chemical Composition of Milk to the Development of Mastitis, by A. H. VanLandingham, C. E. Weakley, Jr., and E. N. Moore (pp. 505, 506) (W. Va. Sta.); The Determination of Copper in Butter, by W. F. Epple and B. E. Horrall (pp. 506, 507) (Purdue Univ.); The Uniformity of Butter Composition as Related to Type of Churn, by S. L. Tuckey and P. H. Tracy (pp. 507, 508), and Changes in the Bacterial Flora of Butter, by C. A. Wilson and M. J. Prucha (pp. 508, 509) (both Univ. Ill.); Some Preliminary Observations on the Effectiveness of Propionates as Mold Inhibitors on Dairy Products, by J. D. Ingle (p. 509); Propionic Acid and Its Calcium and Sodium Salts as Inhibitors of Mold Growth, by J. C. Olson and H. Macy (pp. 509, 510) (Univ. Minn.); Some of the Factors Affecting the Phosphatase Values of Butter, by W. H. Brown (pp. 510, 511) (Purdue Univ.); Effect of Salt on the Keeping Quality of Cream, by W. J. Caulfield, F. E. Nelson, and W. H. Martin (pp. 511, 512) (Kans. Sta.); The Chemical and Bacteriological Changes in Brick Cheese During Manufacture, by J. C. Garey, E. M. Foster, and W. C. Frazier (pp. 512, 513) (Univ. Wis.); The Control of Abnormal Bacterial Fermentations in the Manufacture of Swiss Cheese, by L. A. Burkey, M. Rogosa, and R. R. Farrar (pp. 513, 514) (U. S. D. A.); The Effect of Heat-Treatment of Milk on the Activity of Swiss Cheese

Starters, by M. E. Tyler and H. H. Weiser (pp. 514, 515) (Ohio State Univ.); The Standardization of Fat in Swiss Cheese and the Relationship of Fat to Quality, by G. P. Sanders, R. R. Farrar, F. Feutz, and R. E. Hardell (pp. 515, 516) (U. S. D. A. coop. Univ. Wis. and Ohio State Univ.); Improving the Quality of Swiss Cheese Through Applied Research and Technical Control, by R. R. Farrar (pp. 516, 517) (U. S. D. A.); Relation of Salt Content to Bitter Flavor Development in Cheddar Cheese, by S. L. Tuckey and H. A. Ruehe (pp. 517, 518) (Univ. Ill.); More Accurate Determinations of Volatile Fatty Acid and Other Changes as a Means to Study Cheddar Cheese Curing, by J. C. Marquardt and A. C. Dalhberg (pp. 518, 519) (N. Y. State Sta.); Effect of Lipolytic Enzymes on the Ripening of Cheddar Cheese, by C. B. Lane and B. W. Hammer (p. 519) (Iowa Sta.); The Purification of Rennin, by C. L. Hankinson and L. S. Palmer (p. 520) (Univ. Minn.); The Effect of Standardizing the Acidity on the Methods and Physical and Chemical Properties of Cottage Cheese and Cultured Buttermilk, by L. E. Mull and W. H. E. Reid (p. 521) (Mo. Sta.); The Use of Homogenized Milk in the Manufacture of Cottage Cheese, by D. W. Glover and L. H. Burgwald (pp. 521, 522) (Ohio State Univ.); The Effect of Temperature Upon Score Value and Serving Properties of Cheese, by W. S. Arbuckle, J. E. Edmondson, and L. E. Mull (pp. 522, 523) (Mo. Sta.); Economic Barriers Affecting the Dairy Industry, by H. A. Ruehe (pp. 523, 524) (Univ. Ill.); The Effect of Cocoa Upon the Digestibility of Milk Proteins, by L. D. Lipman and W. S. Mueller (pp. 524, 525) (Mass. State Col.); The Acid Hydrolysis of Lactose and the Preparation of Hydrolyzed Lactose Sirup, by G. A. Ramsdell and B. H. Webb (p. 525) (U. S. D. A.); Some Properties of Different Combinations of Whey and Other Materials Which Dry Satisfactorily on the Atmospheric Drum Drier, by E. L. Jack and A. J. Wasson (pp. 525, 526) (Univ. Calif.); A More Precise Method for Estimating Fat in the Babcock Test, by E. O. Herreid (pp. 526, 527), and The Effect of Specific Gravity and Coefficient of Expansion of Butterfat on the Accuracy of the Babcock Test, by R. Jenness (pp. 527, 528) (both Vt. Sta.); Observations on the Distribution of *Pseudomonas fragi*, by H. B. Morrison and B. W. Hammer (pp. 528, 529) (Ky. and Iowa Stas.); The Serological Integrity of *Streptococcus lactis*, by J. M. Sherman, K. L. Smiley, and C. F. Niven, Jr. (pp. 529, 530) (Cornell Univ.); Vitamin C for Sterile or Partially Sterile Sires, by P. H. Phillips and H. A. Lardy (p. 530) (Univ. Wis.); The Ejection of Milk From the Mammary Gland, by F. Ely and W. E. Petersen (pp. 536, 537) (Ky. and Minn. Stas.); The Fat Metabolism of the Mammary Gland of the Cow, by J. C. Shaw and W. E. Petersen (pp. 538, 539), Some Factors Influencing the Completeness of Milking, by K. Miller and W. E. Petersen (p. 539), and The Effect of Dinitrophenol Administration on Milk and Milk Fat, by G. O. Graf, L. M. Ludwick, and W. E. Petersen (pp. 539, 540) (all Univ. Minn.); The pH of the Bovine Mammary Gland, by P. L. Kelly (p. 540) (Ark. Sta.); The Effect of Nembutal Anesthesia on the Rate of Milk Secretion, the Respiratory Quotient, and Uptake of Milk Precursors by the Lactating Mammary Gland, by E. P. Reineke (pp. 543, 544) (Mo. Sta.); A Modification of the Allen Blood Fat Procedure, by J. C. Shaw (p. 544) (Univ. Conn.); Some Factors Relating to Bloat in Cattle, by D. Espe and C. Y. Sta.); The Effect of Carotene Consumption on the Milk Yield of Jersey Cows, by O. C. Copeland (p. 575) (Tex. Sta.); and The Vitamin A Requirements of Dairy Cows for the Production of Butter of High Vitamin A Value.—II, Relative Efficiency of Carotene (Dehydrated Alfalfa Hay) and Vitamin A, by J. W. Wilbur, J. H. Hilton, and S. M. Hauge (pp. 575, 576) (Purdue Univ.).

[Investigations with dairy cattle and dairy products in New Jersey] (*New Jersey Stat. Rpt. 1939, pp. 6-9, 38-42, 43-45*).—Brief progress reports (E. S. R., 82, p. 239) are presented for the following: Color pigmentation in the skin and milk of Guernsey cattle, including the effects of feeds on these characters; results of continued inbreeding in Holstein cattle; growth rate of dairy heifers on a sole roughage ration; citrus pulp as a carrier for molasses in preserving grass silage; phosphoric acid as a preservative and other aspects of grass silage production; improvement of pastures and grasslands; relation of dietary factors to milk flavor; influence of various endocrine secretions on milk and milk fat production; and sterilization of dairy equipment by irradiation.

**Roughage feeding of dairy cattle, H. S. WILLARD** (*Wyoming Sta. Bul. 237 (1940), pp. 27, figs. 7*).—The results of long-time experiments with dairy cows maintained solely on good-quality roughage rations as compared with grain and roughage feeding are further summarized (E. S. R., 72, p. 96). The reproduction and milk production records of cows fed only alfalfa hay and sweet-clover pasture for several consecutive lactation periods indicate that satisfactory performance and a reasonably high level of production can be maintained under such a feeding regime. It appeared doubtful if Holstein cows with an inherent producing capacity of only from 30 to 40 lb. of milk at the peak of production will benefit by being fed grain to supplement good roughage rations. With the prices used for feed and dairy products in this experiment, grain feeding paid only with cows having an ability to produce from 50 to 60 lb. of milk daily soon after freshening. The marked stimulating effect of good pasture on milk production was shown. The increase in milk yield when cows were changed from alfalfa alone or alfalfa and grain to pasture was greater as the time from freshening lengthened. Grain had little effect in lowering hay consumption, suggesting that grain feeding should be considered as a means of increasing the total feed intake.

**Rate of growth by dairy calves and heifers on different rations, R. R. GRAVES, J. R. DAWSON, D. V. KOPLAND, J. A. SIMMS, A. G. VAN HORN, and S. L. CATHCART** (*U. S. Dept. Agr. Cir. 560 (1940), pp. 23, figs. 3*).—The results of four separate investigations are summarized. Skim milk was included in otherwise comparable rations fed to four groups of Holstein calves and heifers to ages of 6, 12, 18, and 24 mo., respectively. Average weights of heifers at 24 mo. of age were 1,061, 1,154, 1,108, and 1,159 lb., respectively, indicating that from the standpoint of growth there was little advantage in feeding skim milk after 12 mo. of age. Those receiving milk for 18 or 24 mo. showed somewhat higher breeding efficiency as heifers and produced slightly more milk during the first lactation than the other groups.

In another experiment sumac sorgo silage fed as a sole roughage plus 1 or 2 lb. of cottonseed meal per head daily was found to be an economical and efficient winter ration for Holstein heifers.

In two other trials Jersey heifers over 12 mo. of age fed unlimited quantities of artificially dried legume hay of good quality with pasture in season compared favorably in rate of growth with heifers receiving a conventional-type ration of grain and hay.

**The relation of bacteria and of oxygen to the flavor of milk susceptible to becoming oxidized, J. G. LEEDER and E. O. HERREID** (*Vermont Sta. Bul. 457 (1940), pp. 15, figs. 5*).—Milk from cows known to consistently produce milk susceptible to oxidized flavor development was variously handled and treated in the trials described. Samples drawn from milking machine pails and stored under a reduced pressure of from 23 to 25 in. mercury showed a greatly reduced tendency for oxidized flavor development as compared with samples stored at

atmospheric pressure. The inoculation of samples held at normal pressure with incubated milk having a natural microflora resulted in a decreased oxygen content of milk due to bacterial growth, which in turn inhibited or prevented the development of oxidized flavor in 48 hr. Bacteria did not appear to be an important factor in the decrease of oxygen or prevention of oxidized flavor in the evacuated milk samples. No correlation was established between any given bacterial count and oxygen content or intensity of oxidized flavor.

## VETERINARY MEDICINE

**A textbook of bacteriology**, H. ZINSSER and S. BAYNE-JONES (*New York and London: D. Appleton-Century Co.*, [1939], 8. ed., rev., pp. XXVIII+990, figs. 116).—In the preparation of this new edition of the work (E. S. R., 72, p. 381) the authors have made many changes and have rewritten large sections in order to incorporate the newer knowledge which has been gained in almost every division of the field covered. The section on pathogenic protozoa has been omitted. Each of the 73 chapters includes a copious list of references.

[**Work in animal pathology by the Florida Station**] (*Florida Sta. Rpt. 1939*, pp. 72, 73, 78, 79).—The work of the year (E. S. R., 81, p. 273) referred to includes the etiology of fowl paralysis, leukemia, and allied conditions in animals, by M. W. Emmel; a study of plants poisonous to livestock in Florida, by D. A. Sanders and E. West; and enzootic broncho-pneumonia (pneumoenteritis) of dairy calves, by Sanders (see p. 680).

[**Work in animal pathology by the New Jersey Stations**] (*New Jersey Stas. Rpt. 1939*, pp. 42, 43).—The work (E. S. R., 82, p. 249) reported relates to tests for determining mastitis in dairy cattle and a study of Bang's disease.

[**Work in animal parasitology by the Puerto Rico College Station**] (*Puerto Rico Col. Sta. Rpt. 1939*, pp. 52-56).—The work reported upon relates to studies of internal parasites of cattle and horses, and observations on parasites of various domestic animals and fowl, including the goat, monkey, pig, pigeon, and chicken.

[**Contributions on veterinary medicine**] (*U. S. Livestock Sanit. Assoc. Rpt.*, 43 (1939), pp. 18-69, 106-143, 145-221, 224-256, 275, 276, 278-284, figs. 9).—Among the contributions presented at the annual meeting of the association held at Chicago in December 1939 are the following: Some Relations of Kidney Physiology to the Diagnosis of Kidney Disease, by R. M. Watrous (pp. 18-27); The Present Status of the Federal-State Bang's Disease Program, by A. E. Wight (pp. 28-35) (U. S. D. A.); Bang's Disease Control From the Standpoint of the Animal Breeder, by R. E. Short (pp. 35-38); Problems Arising in Bang's Disease Control in the Western States, by W. H. Hendricks (pp. 38-54); Preparation of *Brucella* Antigen, by A. Eichhorn and H. I. Thaller (pp. 55-66) (U. S. D. A.); Report of the Committee on Bang's Disease, by C. P. Fitch et al. (pp. 67-69); The General Tuberculosis Situation, by A. E. Wight (pp. 106-114) (U. S. D. A.); The Pathogenicity for Cattle of the Avian Tubercle Bacillus, by W. H. Feldman and A. G. Karlson (pp. 114-133); Reaccreditation of Modified Accredited Counties in the State of New York, by E. T. Faulder (pp. 133-137); Fundamentals of Animal Disease Control, by D. M. Campbell (pp. 137-143); Infectious Equine Encephalomyelitis in 1939, by H. W. Schoening, L. T. Giltner, and M. S. Shahan (pp. 145-150) (U. S. D. A.); Report of the Committee on Rabies, by H. W. Schoening et al. (pp. 151-161); Rabies Control From the Clinician's Viewpoint, by R. V. LaCroix (pp. 162-166); Some New Facts on Rabies Control in Europe, by A. Eichhorn (pp. 167-173); Field Control and Eradication of Avian Tuberculosis in Poultry and Swine in the Midwest, by J. P. Simmons (pp. 173-176), and Progress of the National Poultry Improvement Plan With Special Reference to

the Control of Pullorum Disease, by B. Winton (pp. 176-185) (all U. S. D. A.); Equine Encephalomyelitis in Avian Hosts, by F. R. Beaudette (pp. 185-203) (N. J. Expt. Stas.); The Control of Poultry Diseases by the Veterinarian—A Challenging Situation, by C. D. Carpenter (pp. 203-211); Turkey Disease Control in Commercial Flocks, by L. D. Frederick (pp. 212-217); Report of Committee on Transmissible Diseases of Swine, by C. N. McBryde et al. (pp. 218-221); Infectious Types of Swine Enteritis, by L. P. Doyle (pp. 224-231) (Ind. Sta.); Swine Enteritis in Veterinary Practice, by J. B. Bryant (pp. 231-242); Discussion of Swine Enteritis, by J. S. Koen (pp. 243-245) (U. S. D. A.); So-Called Protein Poisoning in the Feeding of Swine, by A. F. Schalk (pp. 245-254) (Ohio State Univ.); Report of Committee on Tick Eradication in 1939, by T. O. Booth et al. (pp. 275, 276); Report of the Committee on Transmissible Diseases of Poultry, by E. Jungherr et al. (pp. 278-282); and Report of the Committee on Miscellaneous Transmissible Diseases, by E. Records et al. (pp. 283, 284).

[Studies in comparative physiology and pathology in Japan] (*Jap. Jour. Vet. Sci.*, 1 (1939), No. 6, pp. 575-632, pls. 11, figs. 6).—Contributions here presented (E. S. R., 83, p. 105) are: Complement Fixation in Rat Leprosy [trans. title], by T. Itihara (pp. 575-582, Ger. abs. p. 582); Artificial Infections of the Goat, Sheep, and Dogs With *Bacillus mallei*, by O. Itikawa (pp. 583-601, Eng. abs. pp. 599-601); Studies on Ticks Found in Manchoukuo—I, On Two Species of Tick From Cattle [*Dermacentor reticulatus* and *Hyalomma detritum albipictum*] at the Yamuyingtzu Stock-Farm Near Wangyehmiao, Inner Mongolia, Manchoukuo, by J. Yamashita (pp. 602-609, Eng. abs. p. 609); A Simple Method for Supplying Carbon Dioxide Gas to Culture Tubes, by R. Nobata (pp. 610-616, Eng. abs. pp. 615, 616); and Experimental Studies on Anthelmintics for the Stomach Worm *Haemonchus contortus* in Sheep—II, Experiments on the Anthelmintic Action of Carbon Tetrachloride Emulsion and Critique on the Efficacy of Copper Sulphate, by M. Yoshikawa and K. Somazawa (pp. 617-632, Eng. abs. pp. 631, 632) (see p. 682).

The recovery of *Vibrio foetus* from aborted bovine fetuses and the significance of this organism as a cause of abortion in cattle, A. D. McEWEN (*Vet. Rec.*, 52 (1940), No. 18, pp. 337-340).—During the 6 preceding years bacteriological examinations were made of 247 fetuses from 45 herds in which efforts were being made to control infectious abortion. *V. fetus* infection was found in 5 fetuses that came from 3 of the herds. The evidence from the 3 herds has shown that it was not responsible for any serious outbreak of abortion. It is thought that abortions due to *V. fetus* are generally sporadic and of little importance. The source of infection is said to remain obscure.

Further observations on the wild rat as a carrier of *Brucella abortus*, T. J. BOSWORTH (*Jour. Compar. Pathol. and Ther.*, 53 (1940), No. 1, pp. 42-49).—In further work (E. S. R., 79, p. 390) the author has found the incidence of *B. abortus* infection among rats in Great Britain to be low, it having been recovered once only as the result of examining 167 individuals caught on infected farms. "It was not possible to determine the percentage of carriers of *Leptospira icterohaemorrhagiae* in this series of rats as they were not examined for some time after death. In three instances, however, the *Leptospira* was found to have remained alive in the tissues for more than 24 hr. and in two others for more than 48 hr. after the rats were killed. Two of the rats were carriers of tubercle bacilli. One of the strains concerned was shown to be of the bovine type; the other, though not fully examined, was probably identical. An attempt to convey *B. abortus* infection to cows by exposing their food for a period of 3 mo. to contamination by infected rats was unsuccessful."

The presence of a capsule on *Brucella* cells, I. F. HUDDLESON. (Mich. State Col.). (*Jour. Amer. Vet. Med. Assoc.*, 96 (1940), No. 759, pp. 708, 709,

*fig. 1*).—The technic which has given the most uniform success in the demonstration of capsules in *Brucella* cells is described. The capsule of *Brucella* cells possesses physical and chemical properties different from *Diplococcus pneumoniae* in that it is not easily removed and its size is not affected by incubation with specific serum.

**The treatment of streptococcic mastitis by infusion of the udder with entozon, O. W. SCHALM.** (Univ. Calif.). (*Jour. Amer. Vet. Med. Assoc.*, 97 (1940), No. 760, pp. 20-27, *figs. 2*).—The author has found entozon, a new compound that is composed of a mixture of nitroacridine rivanol lactate, amylose, saccharine, and sodium bichromate, to be highly lethal to *Streptococcus agalactiae*. In the work reported, 11 lactating and 11 dry cows, in 1 herd, having a total of 61 quarters shedding *S. agalactiae*, were treated. All quarters, 88 in number, were infused with entozon by gravity pressure. This resulted in the disappearance of *S. agalactiae* from 90 percent of the quarters. It is thought that entozon may prove to be useful in herds in which a mastitis-control program based on segregation is in force. The details of treatment, including cow histories, methods of application, and results obtained, are given in a table.

**Musca domestica, a vector of bovine mastitis (preliminary report), D. A. SANDERS.** (Fla. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 97 (1940), No. 761, pp. 120-122, 123, *figs. 3*).—Report is made of observations of the habit of the housefly of crawling over the surface of the teats of cattle in the milking line to feed at the external teat orifices and then flying to the udder of other cattle in the same milking line. The flies were noted to crawl or fly alternately from one teat orifice to another of the same and of different individual cows in the corrals and milking sheds. Experiments conducted, a description of which is presented, have shown conclusively that the housefly is a natural vector of bovine mastitis.

**The differentiation of bovine and human strains of tuberculosis by the method of Bertrand, Bablet, and Bloch, M. BEATTIE and R. NICEWONGER.** (Univ. Calif.). (*Jour. Lab. and Clin. Med.*, 24 (1939), No. 12, pp. 1310-1312).—The results of experiments conducted have led the authors to conclude that the reaction of the bovine strain of *Mycobacterium tuberculosis*, when inoculated into the brain of rabbits, is not unique since 19 strains obviously human in origin and proved by intravenous inoculation to be of the human type induced symptoms similar to those produced by known bovine strains and described by I. Bertrand, J. Bablet, and F. Bloch.<sup>4</sup> It is considered unwise to discard hastily the classic technic of intravenous injection in order to differentiate the bovine from the human type of *M. tuberculosis*.

**Tuberculin reactions in cattle due to infection with the human type of the tubercle bacillus, F. W. NIELSEN and N. PLUM** (*Skand. Vet. Tidsskr.*, 30 (1940), No. 3, pp. 245-274; *Swed. abs.*, pp. 272, 273).—Considered in the course of this report is the question relating to cows infected with the human type excreting tubercle bacilli with the milk. The authors were unable to obtain growth of human tubercle bacilli in cultures from the milk of 90 cows of this category. On 3 farms where the animals were reacting on account of human infection, samples of mixed milk were examined daily for 1 week by inoculation of guinea pigs and by cultivation. It was not possible to demonstrate that the milk samples had contained tubercle bacilli. A list of 12 references is given.

**Bovine pseudorabies or "mad itch" virus, R. GRAHAM, C. C. MORRILL, and L. E. BOLEY.** (Univ. Ill.). (*Science*, 91 (1940), No. 2374, pp. 623, 624).—Attempts made to determine the relation of mad itch virus, described by Shope from cattle in Iowa (E. S. R., 65, p. 872) and subsequently shown to have an

<sup>4</sup> Compt. Rend. Soc. Biol. [Paris], 124 (1937), No. 2, pp. 108-111.

immunological relation to pseudorabies (E. S. R., 69, p. 266), to that of a rarely occurring but fatal bovine pruritic syndrome met with in Illinois are reported. The clinical observations and pathological, bacteriological, and immunological tests with a syndrome resembling that of pseudorabies in a well-nourished Hereford steer in Illinois are considered to support the preliminary deduction that the virus is the same as that of pseudorabies or mad itch.

**Enzootic bronchopneumonia of dairy calves**, D. A. SANDERS (*Florida Sta. Bul.* 346 (1940), pp. 11).—Enzootic broncho-pneumonia in young animals, known also as septic pneumonia or pneumoenteritis, a report on which has been noted (E. S. R., 80, p. 684), causes heavy loss among dairy calves confined in crowded insanitary permanent lots. Such conditions are favorable to development of various bacterial infections of the gastrointestinal tract and the umbilicus and to infestations with external and internal parasites. These parasites lower the body resistance of calves sufficiently to permit the micro-organisms colonizing in the respiratory passage to exert a pathogenic action resulting in development of broncho-pneumonia. Enzootic broncho-pneumonia has not been found on premises where strict sanitary methods of rearing calves are used. Incidence of the disease on affected premises has been reduced in proportion to employment of hygienic methods.

**The toxicity of red-stemmed peavine (=Astragalus emoryanus) for cattle, sheep, and goats**, F. P. MATHEWS. (Tex. Expt. Sta. and U. S. D. A.). (*Jour. Amer. Vet. Med. Assoc.*, 97 (1940), No. 761, pp. 125-134, fig. 1).—Report is made of an investigation of sheep and cattle losses resulting from grazing on red-stemmed pea vine, an annual plant of common occurrence in Texas from near Alpine on the west and north to El Paso and the New Mexico State line. The plant has been reported as occurring from western Texas to southeastern California and southward into Chihuahua and Coahuila, Mexico. It has been proved by the author to be toxic for cattle, sheep, and goats, the young plant being more toxic than those older or more mature. The characteristic symptoms were muscular incoordination and loss of weight with slow and doubtful recovery. In sheep difficult respiration also was observed. The plant was collected from three limestone areas and found to be toxic in all cases; that collected near Alpine from soil of igneous origin produced no toxic effects when fed to goats. The toxic principle was destroyed by drying the plant for 4 mo.

**Toxicity of selenium-cystine and some other organic selenium compounds**, A. L. MOXON. (Univ. Wis.). (*Jour. Amer. Pharm. Assoc.*, 29 (1940), No. 6, pp. 249-251).—The author has found that the minimum lethal dose of selenium in the form of selenium-cystine when injected intraperitoneally into albino rats is 4 mg. per kilogram of body weight. This is equivalent to 8.44 mg. of selenium-cystine per kilogram of body weight.

**Reactions in horses following inoculation of chick-embryo vaccine**, R. GRAHAM. (Univ. Ill.). (*Jour. Amer. Vet. Med. Assoc.*, 97 (1940), No. 760, pp. 38, 39, figs. 2).—Reference is made to the possibility that some horses may become sensitized to certain chick proteins or substances in chick-embryo vaccine. It should not be concluded that only old vaccines are capable of inducing untoward reactions, since unfavorable reactions from fresh vaccines have occasionally been reported. Quite apart from the possible role played by hypersensitiveness of some horses to the vaccine, the possibility of sepsis incident to inoculation of vaccine cannot be entirely disregarded. Three fatal cases observed have led the author to urge the use of aseptic methods in inoculating vaccine.

**Reactions following administration of equine encephalomyelitis vaccine**, H. W. SCHOENING. (U. S. D. A.). (*Jour. Amer. Vet. Med. Assoc.*, 97 (1940),

No. 760, pp. 39, 40, figs. 2).—Reference is made to some severe reactions and losses of horses that have followed the second injection of encephalomyelitis vaccine. The exact cause or causes of these unfavorable reactions in horses following the injection of chick-embryo encephalomyelitis vaccine are not yet definitely known, but it appears probable that there is a relationship between the reaction and the age of the vaccine (and/or its handling) and the individual horse. Present observations indicate that apparently more reactions have occurred in animals that have been previously vaccinated. Attention is called to the author's earlier consideration of the causes of reactions that follow vaccination (E. S. R., 82, p. 107). The importance of a good technic of administration of the vaccine was stressed and also the fact that the injections should be given in widely separated places. It is desired again to emphasize these points. "There is laboratory evidence to show that a considerable immunity is engendered even with one injection of vaccine. A number of reports received this year indicate that some animals, following the second injection of vaccine, show a typical anaphylaxis, evidenced within a few hours following the administration of the second injection. More of these have been reported than in previous years. It is advisable to be prepared to give appropriate treatment to animals that might show typical anaphylaxis—2 cc. of 1:1,000 epinephrine subcutaneously, in extreme cases intravenously."

**Blood changes and post-mortem findings following intravenous inoculation of sheep with culture filtrates of *Cl. welchii*, types A, C, and D,** W. S. GORDON, J. STEWART, H. H. HOLMAN, and A. W. TAYLOR (*Jour. Pathol. and Bact.*, 50 (1940), No. 2, pp. 251-269, figs. 9).—The experiments reported have led to the conclusion that whereas the toxin of *Clostridium welchii* type C produces no specific blood changes, that of type A produces a marked hemolytic anemia, while that of type D produces an anhydremia.

**"Swayback:" A demyelinating disease of lambs with affinities to Schilder's encephalitis in man,** J. R. M. INNES and G. D. SHEARER (*Jour. Compar. Pathol. and Ther.*, 53 (1940), No. 1, pp. 1-41, pls. 7, fig. 1).—This contribution reports upon the history and geographical distribution, pathology, etiology, etc., of swayback, a nervous disorder of newborn and young lambs of different breeds occurring in many parts of England, Scotland, and Wales. It is presented with a list of 96 references to the literature.

**"Warfa" ("swayback") in lambs in North Derbyshire and its prevention by adding copper supplements to the diet of the ewes during gestation,** G. DUNLOP and H. E. WELLS (*Vet. Rec.*, 50 (1938), No. 37, pp. 1175-1182, fig. 1).—Large scale field experiments to determine if warfa or swayback, a disease which affects lambs in a severe form in North Derbyshire, could be prevented are reported upon, the details being given in table form. The results show that the incidence of the disease has been greatly reduced among the offspring of ewes receiving licks with copper supplements. Cobalt and manganese had no effect. It is concluded that the disease can be controlled by feeding licks containing 0.3 percent copper to the ewes during the gestation period.

**Observations on copper poisoning,** A. EDEN (*Jour. Compar. Pathol. and Ther.*, 53 (1940), No. 1, pp. 90-111).—The wide use of copper salts in agricultural and veterinary practice and the possibility of prophylactic use of copper for pregnant ewes in "swayback" areas, based on the recent association of copper deficiency with enzootic ataxia in Australia, as reported by Bennetts and Chapman (E. S. R., 78, p. 837), and with swayback in lambs in Great Britain, as reported above by Dunlop and Wells, have led to the present observations of acute and chronic copper poisoning in animals.

In the work reported the copper content of the fresh tissues of normal adult rabbits and sheep was found to lie "between 0.1 and 0.5 mg. percent except for sheep's liver which may have a range of from 0.2 to 29 mg. percent without any evidence of associated pathological change, although the greater proportion of values appear to lie under 2 mg. per 100 gm. Under conditions of acute copper poisoning the principal changes in the copper content of tissues lie in greatly increased values for liver and kidney. The relatively high liver content of the newly born animal is confirmed for rabbits, the figure falling to the adult level long before weaning, suggesting the mobilization of this copper for physiological purposes. The relevant literature on chronic copper poisoning is reviewed. Attempts to induce this condition in rabbits by feeding copper sulfate dried on to food were unsuccessful although evidence of considerable copper storage in the liver was obtained. Chronic intoxication was induced in sheep by daily quantities of 1.5 gm. copper sulfate either in the form of a drench or damped on to a palatable mixture of concentrates, the condition developing in periods of from 30 to 80 days. Clinical symptoms included dullness, depression, and anorexia, and post-mortem examination showed generally icterus, cirrhotic liver, and swollen and congested kidneys. Chemical studies on the blood during the course of chronic intoxication showed a slow rise in blood copper content to about twice the initial value until a day or two before death when a sharp 'premortar' rise to about 10 times the normal value occurred. There were no significant changes in blood sugar, inorganic phosphorus and calcium values, and only a slight rise in serum magnesium content at the terminal phase. Hemoglobin values showed considerable fluctuations. The copper content of the liver and, to a lesser extent, the kidneys [was] very considerably increased but relatively little change occurred in that of the remaining soft tissues examined."

Various factors such as form of administration of copper and species of animal are considered in the induction of experimental chronic copper poisoning, and the course of the disease is generally discussed. The invalidity of diagnosis of copper intoxication, either acute or chronic, by liver analysis per se is emphasized.

**Management for prevention of sneezeweed poisoning, J. T. CASSADY.** (U. S. D. A. and Colo. State Col.). (*Natl. Wool Grower*, 30 (1940), No. 5, pp. 12-14, figs. 2).

**Scrapie, J. R. GREIG** (*Highland and Agr. Soc. Scot. Trans.*, 5. ser., 52 (1940), pp. 71-90, figs. 2).

**Experimental studies on anthelmintics of the stomach worm *Haemonchus contortus* in sheep.—I, On the resistance of the *Haemonchus contortus* to various medicaments** [trans. title], M. YOSIKAWA (*Res. Bul. Agr. Expt. Sta. So. Manchuria Ry. Co.*, No. 21 (1937), pp. 93-111).

**Blood studies in normal hogs, R. RODRIGUEZ MOLINA and J. OLIVER GONZALEZ** (*Puerto Rico Jour. Pub. Health and Trop. Med.*, 15 (1940), No. 4, pp. 383-386).—In the work reported, details of which are given in two full-page tables, peripheral blood studies were performed in two young, healthy, and apparently normal hogs during periods of 22 and 25 weeks at intervals of 1 week. "Erythrocyte and reticulocyte counts, hemoglobin determinations, volume of packed red cells, mean corpuscular volume, mean corpuscular hemoglobin, mean corpuscular hemoglobin concentration, leucocyte counts, [and] differential and platelet counts were performed each week. Observation on the morphology of all cell types was made also."

**Experimental liver damage associated with hematologic changes in hogs, R. RODRIGUEZ MOLINA** (*Puerto Rico Jour. Pub. Health and Trop. Med.*, 15 (1940), No. 4, pp. 362-372, figs. 4).—Report is made of a series of blood

examinations of five hogs, including three experimental and two control animals, before and after ingestion of repeated and variable amounts of carbon tetrachloride. Similar studies were performed in one animal before and after repeated negative attempts at infestation with the cercaria of the trematode *Schistosoma mansoni* had been made. The changes in the blood of the hogs in which hepatic damage was produced by the administration of carbon tetrachloride are described. It was intended to produce chronic hepatic damage (cirrhosis), but it was believed the animals died before such changes were effected. "Macrocytosis (spherical) of the red cells and polycythemia were the most important changes in the blood observed during the course of carbon tetrachloride poisoning. A slight decrease in number of red cells in some animals was found, also. Macrocytosis was similar to that described by the author in advanced schistosomiasis mansoni in man. It is suggested that changes in red cell morphology and polycythemia are the result of liver damage and hemoconcentration respectively. The latter phenomenon was coincident with diarrhea and vomiting. It is assumed that macrocytosis occurred as a consequence of altered metabolism in the liver of the antianemic principle. Central necrosis of liver with fatty changes and bile stasis was observed post mortem in all animals dying from the effects of carbon tetrachloride."

**Observations on polyarthritis and on experimental Erysipelothrix infection of swine, D. H. COLLINS and W. GOLDIE** (*Jour. Pathol. and Bact.*, 50 (1940), No. 2, pp. 323-353, pls. 6).—Pathological and bacteriological studies of nine cases of natural polyarthritis of swine resulted in the detection of swine erysipelas infection in four of the animals. "A similar arthritis followed repeated intravenous injections of cultures of *E. rhusiopathiae* in all of eight experimental swine. Subcutaneous injections of *E. rhusiopathiae* failed to produce arthritis in four swine, but observations on these animals were continued for only a short time. Both the experimentally induced and the naturally occurring disease can be described as a chronic proliferative arthritis. Its course and the sequence of pathological events in the joints are described. Arthritis in the experimental swine resulted from bacteriemia, and organisms were cultivated from joint material, particularly in the early stages of the disease. Some animals harbored viable organisms up to 8 mo. after injection, but many grossly arthritic joints were sterile. Arthritis followed single injections in six pigs, only three of which had been rendered hypersensitive to an autolysate of *E. rhusiopathiae*. This would suggest that a state of hypersensitivity is not essential for the development of the arthritis. In agglutination tests against *E. rhusiopathiae*, high titers were not always found in the presence of infection. In animals experimentally infected with *E. rhusiopathiae*, focal inflammatory polyarteritis, focal necrosis of liver and myocardium, lymphadenopathy, circulatory monocytosis, and endocarditis were found, but no skin manifestations were ever encountered. Comparisons are made between swine arthritis and chronic arthritis in man." A list is given of 46 references to the literature referred to.

**Studies on Erysipelothrix rhusiopathiae, P. S. WATTS** (*Jour. Pathol. and Bact.*, 50 (1940), No. 2, pp. 355-369).—The fact that outbreaks of swine erysipelas are usually though not always successfully controlled by the use of immune serum led to a study of the differences between 43 strains of *E. rhusiopathiae* collected from America, Japan, and England and other parts of Europe, with a view to determining if the occasional failures might be due to antigenic differences between strains. It was not possible to separate strains of *E. rhusiopathiae* on the basis of morphological or cultural examination. Of the 43 strains studied serologically, 38 appeared to be of one antigenic type and 5 of another. Of these 5, 3 were from Japan, 1 was from England, and 1 from

America. "There was no correlation between animal host and serological group or between group and virulence. Each group possesses a heat-stable specific antigen. In addition, each probably contains two heat-labile antigens which are present in different proportions in the two groups and are responsible for cross agglutination; they are also the important antigens with regard to resistance to infection. Serums of low potency containing antibodies to these antigens will protect mice against many lethal doses of an organism of the same group but not against a strain from the other group. An intradermal test was used to test active immunization of pigs with a formolized vaccine. In the doses used this vaccine failed completely to protect the pigs against a minimal infecting dose."

**Moderate amounts of lead-arsenate-sprayed apples noninjurious to swine** E. C. McCULLOCH, J. L. ST. JOHN, and K. GROVES. (Wash. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 97 (1940), No. 760, pp. 51, 52, fig. 1).—Experiments in which lead-arsenate-sprayed apples were fed to swine are summarized in table form. The data indicate "that lead-arsenate-sprayed residue, representing 1.47 gr. of arsenic and 3.2 gr. of lead, which are equivalent to the consumption of 7.2 lb. of apples carrying an average residue of 0.205 gr. of arsenic trioxide and 0.445 gr. of lead per pound, fed daily for 140 days to a pig weighing between 101 lb. and 164.5 lb. had no detectable effect. This suggests the possibility that the arsenic and the lead which remain on apples as spray residue are relatively nontoxic."

**Acetonemia in swine**, F. E. HULL and A. F. NOLAN. (Ky. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 97 (1940), No. 761, pp. 162-164).—Report is made of three cases of acetonemia in swine received at the station for diagnosis.

**On the division of the genus *Oesophagostomum* Molin 1861 into subgenera and the creation of a new genus for the oesophagostomes of the wart-hog**, P. L. LEROUX (*Jour. Helminthol.*, 18 (1940), No. 1, pp. 1-20, figs. 23).

**Salmonella infections of ducks and ducklings**, J. S. GABSIDE and R. F. GORDON (*Jour. Compar. Pathol. and Ther.*, 53 (1940), No. 1, pp. 80-89).—Description is given of an extensive outbreak of salmonellosis in ducklings in which *S. typhimurium* and *S. enteritidis gaertner* were found to be responsible. The history of the outbreak and the symptoms observed closely resemble those recorded by previous writers on this subject and termed by them "Keel" disease. Ducklings up to 4 weeks of age were most susceptible to natural infection. Few losses were experienced after this age or in adult ducks, but a high percentage of carriers of both organisms was demonstrated in the breeding flock by means of the agglutination test. Control measures outlined are described in detail, and with improvement of hygiene and general management on the rearing farm the mortality was successfully reduced from 30 percent to below 3 percent. Attempts to eradicate carriers in the breeding flock by blood testing were unsuccessful, owing to lack of correlated effort on the part of the owners. Breeding experiments carried out at the laboratory and the cultural examination of eggs laid by carrier birds gave negative results. This, together with observations on the course of the disease in the field tends to indicate that egg transmission was not the most important factor in the dissemination of infection, and that adult carriers served only as a possible means of introducing the disease occasionally, in spite of the fact that on post-mortem examination of 68 carrier birds the organisms were successfully isolated from the ovary on 37 occasions. Possibly, as with pullorum disease, such carrier birds lay comparatively few eggs, with a low percentage of infected ones, or none at all. In this, as in other outbreaks of *Salmonella* infection observed, vermin seem to play an important part in appearing to act as natural reservoirs and disseminators of infection.

**Value of repeated testing for pullorum disease**, C. R. HOLLAND (*Md. Agr. Soc., Farm Bur. Fed., Rpt., 24 (1939), pp. 258, 259*).—This includes a summary of pullorum testing work by a chick hatchery at Frederick, Md.

**Limberneck (botulism) in fowls**, A. J. DURANT (*Missouri Sta. Cir. 207 (1940), pp. 6, figs. 2*).—A practical account including methods of treatment.

**Grasshopper-poison bait and turkey-poult mortality**, P. D. DELAY (*Jour. Amer. Vet. Med. Assoc., 97 (1940), No. 761, pp. 149, 150*).—This report relates to an investigation of turkey poult mortality following their exposure to improperly spread grasshopper-poison bait. Poults of the same age which were confined and fed a mixture similar to that reported as used in the field died within 12 hr. after exposure.

**A case of pseudotuberculosis in a blackbird**, F. R. BEAUDETTE. (N. J. Expt. Stas.). (*Jour. Amer. Vet. Med. Assoc., 97 (1940), No. 761, pp. 151-157*).—Following a review (with 28 references) in which pseudotuberculosis is shown to be a rather common disease of birds in France and Germany, report is made of a case observed in a blackbird found in a yard in New Brunswick, N. J.

**On wild birds as transmitters of helminth parasites to domestic stock**, P. A. CLAPHAM (*Jour. Helminthol., 18 (1940), No. 1, pp. 39-44*).—Evidence is presented "to show that eggs of helminth parasites are being constantly reintroduced to land and transferred from one pasture to another. In this way land which has not previously carried poultry for years may yet carry viable eggs which can and do infect chickens when they are introduced to such runs. The starling and rook are probably important transmitting agents as these congregate among poultry at feeding times. Rabbits and other small rodents may also be carriers but no evidence for this has been looked for yet. Young poultry stock may also become infected with helminths which are normally parasites of wild birds but such parasites, except one acanthocephalan, have not yet been recovered from or transmitted to older birds experimentally."

**A case of tuberculosis in elk (moose)** [trans. title], Å KÄMPE and T. HONTWEDT (*Skand. Vet. Tidskr., 30 (1940), No. 3, pp. 275-279, figs. 2; Eng. abs., p. 279*).—Report is made of a case of tuberculosis in a 4-year-old elk cow shot in the government district of Örebro in 1939.

**A Salmonella strain isolated from camels in Palestine**, L. OLITZKI and V. ELLENBOGEN (*Jour. Compar. Pathol. and Ther., 53 (1940), No. 1, pp. 75-79*).—Experiments are reported which have demonstrated the presence in Palestine of an infection of camels due to a *Salmonella* strain. This strain was isolated from the blood and organs of three camels showing enteric symptoms and cachexia. The camel strains showed the serological structure of *S. kentucky* described by Edwards (E. S. R., 80, p. 102) but did not attack glycerol and inositol in plain broth. "From 19 sera of camels, 9 contained H- and O-agglutinins for *S. kentucky* and the camel strain, the 10 other sera only O-agglutinins. Four camel sera which contained H- and O-agglutinins for *S. kentucky* and the camel strain contained only O-agglutinins for other *Salmonella* strains. Infection of mice per os with both strains gave a low mortality, but residual infections of the abdominal organs and the mesenteric glands varying from about 20 to 40 percent of the infected animals were found 3 weeks after the infection."

**The hematology of avitaminosis A in dogs and rabbits**, M. W. EMMEL. (Fla. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc., 97 (1940), No. 761, pp. 145-148, figs. 2*).

**Listerella monocytogenesis and its importance in human- and in veterinary-medicine** [trans. title], A. NYFELDT (*Skand. Vet. Tidskr., 30 (1940), No. 3, pp. 280-285; Eng. abs., pp. 284, 285*).—An historical account is given of the knowledge of *L. monocytogenes*, first observed in necrotic foci in the liver of a

rabbit in Sweden in 1911, which is pathogenic in man, sheep, and other animals. It occasions serious and frequently mortal infections localized in the blood, liver, and central nervous system.

**Allergy in the domestic animals: Survey of (a) factors incidental to domestication probably favouring absorption of native food protein [and] (b) a number of disease conditions possibly associated with sensitisation to food and other proteins,** A. BROWNLEE (*Jour. Compar. Pathol. and Ther.*, 53 (1940), No. 1, pp. 55-74).—In this contribution several diseases met with among the domestic animals have been collated and evidence has been submitted that sensitization to food protein, to tissue protein or metazoan parasite protein may be common to all of these conditions. There is a two-page list of references.

**Case report on botulism type C in minks,** E. R. QUORTRUP and A. L. HOLT (*Jour. Amer. Vet. Med. Assoc.*, 97 (1940), No. 761, pp. 167, 168).—Report is made of a disease outbreak of serious proportions that appeared on two mink ranches near Ogden, Utah, and was found to be *Bacillus botulinus* type C intoxication. Botulinus antitoxin is of value for treatment only when used in the early stages of poisoning. The importance of careful selection of food material in preventing botulinus intoxication is emphasized.

**Contribution to our knowledge of parasites in domestic animals and wild in Sweden, II** [trans. title], M. KOFFMAN (*Skand. Vet. Tidskr.*, 30 (1940), No. 3, pp. 286-366, figs. 71; *Eng. abs.*, pp. 365, 366).—In this second contribution (E. S. R., 81, p. 838) the author presents a review of the parasites discovered at the State Veterinary-Bacteriological Institute at Stockholm from January to June 1938, inclusive, in the course of examination of material received, which included sheep, swine, cattle, and horse. A description is given of the parasites and their development, together with information on preventive measures taken to combat them. A list of the parasites found is included.

**Haematological studies on the gut contents of certain nematode and trematode parasites,** W. P. ROGERS (*Jour. Helminthol.*, 18 (1940), No. 1, pp. 53-62).—The examination of *Strongylus edentatus* and *S. vulgaris* has shown that these parasites ingest the hosts' blood and that hematin is the result of the digestion of hemaglobin. The amounts of blood necessary to form the quantities recorded as being present in the parasites' intestines have been calculated. Evidence has been presented to show that the hosts' blood probably forms a large proportion of the diet of fourth stage *S. vulgaris* larvae. A small proportion of the specimens of *Ascaris lumbricoides* examined contained hematin in the intestine. The intestines of most of the specimens of *Toxocara mystax* and *T. canis* investigated contained hematin. Figures are given to show the amounts found. Even immature forms of the former species were found to be blood suckers. *Syngamus trachea* was found to have hematin in its intestine, but no trace of blood pigments could be found in *Oxyuris equi*. Results indicate that the black pigment present in the intestines of *Schistosoma mattheei* and *S. mansoni* was probably hematin formed by the digestion of the hosts' hemaglobin.

**Studies on Coenurus glomeratus,** P. A. CLAPHAM (*Jour. Helminthol.*, 18 (1940), No. 1, pp. 45-52).—Studies of the larval stage of the tapeworm *Multiceps glomeratus* reveal that while rabbits and mice are not true vectors of this parasite they are facultative vectors and that the parasite can proceed with its full development in these animals. Infection with *C. glomeratus* of the dog and gerbille was accomplished but not of the cat.

**Sulfanilamide—Merck** (*Rahway, N. J.: Merck & Co. [1939], pp. [2]+14*).—Included in this compilation are data on the solubility, stability, specifications, etc., of sulfanilamide.

## AGRICULTURAL ENGINEERING

[**Agricultural engineering investigations at the New Jersey Stations**] (*New Jersey Stat. Rpt. 1939, pp. 19, 20, 35, 129-132*).—These have included poultry housing—mainly insulation and protective covering for the insulating material; silos and grass silage, under which is noted the much greater lateral pressure exerted by grass than by corn silage; studies of temperatures in grass silage, in which it was found that a preservative is necessary and that molasses and phosphoric acid serve this purpose well; farm buildings plan service; and a mechanical blueberry fertilizer distributor, consisting of a combination of an “endgate” centrifugal distributor and a positive feed from a potato planter.

Under sewage treatment are taken up principles underlying activated sludge process ((1) clarification and (2) enzymes), methods, methane-producing organisms, growth-promoting substances, sewage-clarifying organisms, and properties of hydrated lime. Water treatment and stream pollution are also reported upon.

**Water control investigations [at the Florida Station], B. S. CLAYTON and J. R. NELLER.** (Coop. U. S. D. A.). (*Florida Sta. Rpt. 1939, pp. 156, 157*).—Pumping records, work on water-table plats, evaporation studies, subsidence investigations, and the keeping of automatic water-table variation records are noted under this head.

**Soil and erosion changes on the Dalhart sand dune area, L. K. EBY and C. J. WHITFIELD.** (U. S. D. A.). (*Jour. Amer. Soc. Agron., 32 (1940), No. 4, pp. 290-296, figs. 5*).—The area discussed consists of about 2,000 acres in which dune formation and other effects of wind erosion are believed to have originated on an 80-acre field cultivated from 1907 to 1914 and then grazed, the remainder of the area never having been under cultivation. Treatment consisted in listing the bare subsoils exposed between the dunes and in planting suitable vegetation about the dunes to catch and hold sand blown from their tops. It is indicated that, “although these medium textured to sandy soils have suffered from extreme wind erosion, the treatment applied has sufficiently modified their physical condition so that their productive capacity very nearly equals the productive capacity prior to accelerated wind erosion.”

**The permeability of building papers to water vapour, J. D. BABBITT** (*Canad. Jour. Res., 18 (1940), No. 5, Sect. A, pp. 90-97*).—Various types of building papers roughly grouped into 13 classes were tested as to their permeability to water vapor. It is apparent that a continuous film of some impermeable material, such as wax or asphalt, is necessary if the paper is to be impervious to water vapor, while the presence of the impermeable material as an absorbed phase in the paper is not sufficient. Evidence from this study indicates that diffusance is independent of such factors as thickness, weight, or type of paper.

**Methods of ventilating wheat in farm storages, C. F. KELLY** (*U. S. Dept. Agr. Cir. 544 (1940), pp. 74, figs. 37*).—Under typical temperature conditions, low moisture content was found the most important requirement for safe storage, design and materials of the storage structure being of little importance except in their effect on moisture content and temperature. Experiments further indicated that sound wheat can be stored safely in unventilated bins for 1-yr. periods in western Kansas with from 13 to 13.5 percent of moisture, in Illinois and Maryland with from 13.5 to 14 percent of moisture, and in North Dakota with from 14 to 14.5 percent of moisture. The higher moisture content permissible in North Dakota is due primarily to the lower temperatures.

Bins ventilated with suitable horizontal flues ordinarily are safe for storing wheat with initial moistures 1 percent higher than would be safe in nonventilated bins. The cost of material for such flues spaced 18 in. on centers horizontally

and 24 in. vertically is from 6 to 8 ct. per bushel, of bin capacity. Since they can be made easily removable they are not as much of a nuisance as they may seem. They must be provided with hoods to shed rain and stoppers to close the flues tightly to keep out driving snow and humid air or to hold fumigation gases. Closely spaced flues with pressure and suction cowls, which can be made still more efficient, are also discussed. These should be safe for storing wheat of 2 percent more moisture than is safe in unventilated bins. The cost of material for such a system will range between 15 and 25 ct. per bushel, being lower for the larger bins. Other types of ventilation using power will ordinarily be more economical. Vertical flues did not prove as effective as horizontal flues with similar spacing.

Bins having perforated floors were effective for equalizing the moisture content of wet and dry layers, but removed little moisture from the content of the bin as a whole except when the ventilation efficiency was increased by adding a suction cowl on the roof of the bin and tightly closing all openings above the wheat. In western Kansas such bins may be safe for wheat of 1.5 percent higher moisture content than in nonventilated bins, but their effectiveness in regions of high humidity is limited. In the drier areas the efficiency of a bottom-ventilated bin can be further increased to take care of wheat of higher moisture content by forcing air in either direction through the wheat by means of a grain blower, silo-filler blower, or any other heavy-duty fan that may be available. Because of the uneven drying resulting from power ventilating such a bin, ventilating should be continued until the layers of wheat farthest from the inlet have dried to a safe moisture content. For more efficient drying by power ventilation, means should be provided so that the air need not flow through the full depth of wheat, as by the use of a central pressure chamber, perforated floor, and perforated walls. With a blower of adequate capacity and a few hours of reasonably dry weather each day, such a system should dry wheat of 18 percent moisture content without damage. Quicker and more even drying can be obtained by use of ducts instead of the central air chamber.

## AGRICULTURAL ECONOMICS

[Investigations in agricultural economics by the Mississippi Station] (*Miss. Farm Res. [Mississippi Sta.]*, 3 (1940), No. 6, pp. 1, 7, 8).—Included are the following articles, which are part of the director's annual report: Farm Buying Distributed Three Ways, by A. Bowie, giving findings in the study of purchases and place of purchase of 74 farms families during 1939; and Growers of Starch Potatoes Do Well in Jones County Area, by M. Guin, D. W. Parvin, and J. Huff, on farm receipts, expenses, income, etc., on two groups of farms in Jones County, one of which grew sweetpotatoes for sale to a starch factory and one did not.

[Investigations in agricultural economics by the New Jersey Stations, 1938-39]. (Partly coop. U. S. D. A.). (*New Jersey Stat. Rpt. 1939*, pp. 10-18).—Some data are included as to yields, costs per bushel, prices received, markets, etc., for apples in Sussex and Warren Counties, 1934 and 1936, as shown by the reports of 10 growers, and factors affecting costs, prices, and profits from tomato production in 1938.

Ohio agricultural statistics, 1938, G. S. RAY, O. M. FROST, and P. P. WALLRABENSTEIN. (Coop. U. S. D. A.). (*Ohio Sta. Bul. 612 (1940)*, pp. [1]+64, fig. 1).—The bulletin continues the series (*E. S. R.*, 81, p. 727). Tables show (1) by counties and districts for the years 1937 and 1938 (preliminary) the acreages, yield per acre, and production of different crops, and for January 1,

1928 and 1939, the numbers of different kinds of livestock: (2) for the State by years 1924-38, inclusive, the acreages, yield per acre, production, season average price, and farm value of different crops, and on January 1, 1925-39, the number, value per head, and total value of different kinds of livestock and livestock products; (3) State average monthly prices received by farmers 1934-38 for crops and livestock; and (4) by districts for the State or by districts by years or quarter years data as to eggs produced per 100 hens, farm wages, farm labor supply and demand, prices received by farmers, estimated gross cash income from sale of agricultural products, and Government payments.

**Investigations in agricultural economics by the Puerto Rico College Station, 1938-39** (*Puerto Rico Col. Sta. Rpt. 1939, pp. 26-37, figs. 3*).—Data are included as to the receipts, expenses, farm and labor incomes, etc., on 270 tobacco farms studied in 1937-38, by R. Colon Torres, and on 90 small farms averaging about 25 acres, studied by E. del Toro, Jr., D. Haddock, and J. O. Morales (pp. 26-29); earnings on about 150 coffee farms, studied by del Toro, Jr., Haddock, and M. Hernández (pp. 29-31); studies of coffee and raw sugar prices, by J. J. Serralés, Jr., and M. Vélez, Jr. (p. 32); studies, by S. Díaz Pacheco and J. R. Noguera, of the per capita consumption of different foods by different income groups in 22 towns, of retail agencies selling minor crops, and of home tenure and rental payments in 1938 (pp. 34-37).

**Current Farm Economics, [June 1940]** (*Oklahoma Sta., Cur. Farm Econ., 13 (1940), No. 3, pp. 49-76, figs. 2*).—Besides the usual tables, these articles are included: The Agricultural Situation (pp. 51-57); Oklahoma's Experience With Graduated Land Tax Legislation, by R. T. Klemme (pp. 57-59); Quality of Cotton Produced in Oklahoma Crop of 1939-1940, by K. C. Davis (pp. 60-66); Land-Use Planning in Oklahoma, by H. A. Miles (pp. 67-70); and Salaries of Managers in Cooperative Elevators, by A. L. Larson (pp. 71-73).

**Levels of training for service in agricultural economics, R. J. SAVILLE** (*Louisiana Sta., 1940, M-M 1, pp. 11+20*).—Tables are included and discussed showing the academic training: distribution as to services—teaching, extension, and research; load; training for heads of departments; etc., of workers in agricultural economics in the land-grant colleges and universities in the United States.

**Farm accountancy statistics for 1936-37, U. PAPI** (*Inst. Internatl. Agr. [Roma], Comptab. Agr. Rec. Statis., 1936-37, pp. XIX+93*).—This is the ninth volume of the series (E. S. R., 82, p. 412).

**Rural regions of the United States, A. R. MANGUS** (*Washington: Work Proj. Admin., 1940, pp. IX+230, figs. 17*).—This report "provides a geographic background for analyses of the problems of relief and unemployment. . . . On the basis of carefully selected cultural indices, the counties of the United States have been classified into 218 rural-farm subregions. These in turn have been combined into 32 general rural-farm regions. Taking into account the characteristics of the rural-nonfarm population as well as of the rural-farm population, 264 rural subregions have been delineated and combined into 34 general rural regions." The different regions and subregions and the delineation and selection of sample counties representative of regions and subregions are described and discussed.

**Agricultural production and types of farming in Minnesota, S. A. ENGINE and G. A. POND.** (Coop. U. S. D. A.). (*Minnesota Sta. Bul. 347 (1940), pp. 70, figs. 71*).—"The purposes of this bulletin are (1) to describe the important factors affecting agricultural production in Minnesota, (2) to present a factual picture of the agricultural production patterns in the State that have resulted from the operations of these factors, and (3) to delineate and describe the more or less

distinct type-of-farming areas in the State at the present time." The material, so far as possible, is presented graphically. The natural, economic, and social factors affecting agricultural production, the agricultural development, utilization of land in farms, distribution of livestock, etc., are covered. The State is divided into nine type-of-farming areas, and the cropping systems, livestock production, and types of farming for each area are discussed, and tables included presenting data as to size of farms, value of land, tenure, and value of products, etc., for different types of farms.

**Statistical supplement: Agricultural production and types of farming in Minnesota**, S. A. ENGENE and G. A. POND. (Coop. U. S. D. A.). (*Minnesota Sta. Bul.* 347 (1940), *Sup.*, [pp. 25], *fig. 1*).—This supplement to the bulletin noted above includes data by counties grouped by type-of-farming areas.

**Rural rehabilitation progress in Stearns County, Minnesota.—I, A summary analysis**, W. R. BAILEY. (Coop. Minn. Expt. Sta. et al.). (*U. S. Dept. Agr., Bur. Agr. Econ., Farm Mangt. Rpt.* 3 (1940), pp. [2]+31).—The causes of distress in the county, previous income of Farm Security Administration clients, their resources, the use made of borrowed funds, progress made by clients, fitting plans to clients' needs, supervision, etc., are discussed.

**An economic study of farming in Tompkins County, New York. 1937**, P. A. HENDERSON ([*New York*] *Cornell Sta. Bul.* 728 (1940), pp. 65, *fig. 1*).—This bulletin is based on records for 544 farms for the year ended March 31, 1938, obtained by the survey method. In the analysis the farms were grouped on the basis of type of market for milk. The climate, physical features, price conditions, etc., of the county are described. Analysis is made of the costs of operating trucks and tractors, use of land, crops, livestock, farm capital, value of farm privileges, receipts, expenses, income, etc., and of the factors affecting labor income—type of farming, size of business, rates of production, diversity of business, labor efficiency, and land use. An arbitrary standard for a successful farm is outlined.

Size of business, milk production per cow, crop yields, and labor efficiency were the most important factors affecting labor income. The labor incomes for the different types of farms (382 farms) with none of the 4 factors above the average and with all 4 factors above the average were Grade A milk farms —\$194 and \$1,493, Grade B milk farms —\$532 and \$624, and other dairy farms —\$389 and \$176. The average labor incomes for all farms in the study were Grade A milk farms \$407, Grade B milk farms —\$28, and other dairy farms —\$150; poultry farms \$282; and miscellaneous type of farms \$29.

**Operation of agricultural conservation programs in Illinois**, G. E. TOBEN and H. C. M. CASE. (Coop. Ill. Expt. Sta.). (*U. S. Dept. Agr., Bur. Agr. Econ. and Agr. Adjust. Admin., Farm Mangt. Rpt.* 4 (1940), pp. [1]+8).—This is a digest of the manuscript for a detailed report, the basic data for which were obtained from 507 nonselected farms in and adjoining Gridley Township, McLean County, Wethersfield Township, Henry County, and Pin Oak Township, Madison County. The major emphasis is on the 1938 Agricultural Adjustment program.

**Farm operating efficiency investigations in Virginia, 1931–1938: Progress report**, A. T. HOLMAN, J. L. MAXTON, and G. D. KITE (*U. S. Dept. Agr., Bur. Agr. Chem. and Engin., and Va. Polytech. Inst., 1940, ACE-29, pp. 57, pls. 12, figs. 20*).—This study was made to determine practical means and methods whereby land, farm improvements, power, machinery, labor, farm enterprises, and marketing of products can be brought into balance for most efficient operation of the farm. Seventeen typical dairy, beef, truck, fruit, and general farms in the Coastal Plain, Piedmont area, and Shenandoah Valley and 8 in southwestern Virginia were studied. The areas, farm development, crops, livestock,

labor efficiency, power, farm equipment, finances, and living conditions are discussed.

**Organization and crop production practices on grain farms in selected areas of the northern Great Plains, R. S. WASHBURN** (*U. S. Dept. Agr., Bur. Agr. Econ., Farm Mangt. Rpt. 2 (1939), pp. [3]+94, figs. 17*).—This report deals with the major wheat-producing areas of the northern Great Plains and "discusses (1) the physical and economic factors affecting agricultural production in the region; (2) wheat yields and frequency of damage to wheat from different causes; (3) the farm organization from the standpoint of size of farm, livestock kept, and the place of the different crops in the cropping system; (4) the practices employed in the production of different crops; (5) the duty of farm machinery; and (6) the labor and power involved in the production of crops."

**Agricultural labor requirements and supply: Kern County, R. L. ADAMS** (*California Sta. Mimeog. Rpt. 70 (1940), pp. [1]+20, figs. 4*).—This report supplements Bulletin 623 (E. S. R., 80, p. 262), and deals more exhaustively with the labor requirements for the 20 major crops grown in Kern County.

**Report of the Committee of Enquiry Into Land Settlement** (*London: Govt., 1939, pp. VI+158*).—This is the report of the committee appointed "to inquire into the working of the various schemes of land settlement for unemployed men undertaken in England and Wales since November 1934 by the Land Settlement Association, the Welsh Land Settlement Society and County Councils." A general description of the land settlement schemes and the committee's findings are included.

**Farm leases for Illinois, including father-son agreements, H. C. M. CASE and J. ACKERMAN** (*Illinois Sta. Cir. 503 (1940), pp. 55, figs. 3*).—This circular supersedes that previously noted (E. S. R., 78, p. 122). It discusses four types of leases commonly used in the State, father-son agreements, leases used in the Corn and Wheat Belts, the major problems needing adjustments in leasing in the State, and tenant-landlord contributions under different forms of leases.

**Rural property tax problems in Alabama, C. M. CLARK** (*Alabama Sta. Bul. 247 (1940), pp. 64, figs. 7*).—The long-time trends and regional variations in rural property taxes in the State; the relation of taxes to farm prices, purchasing power of farm products, rural real estate values, and farm receipts, expenses, and income; the extent of rural real estate tax delinquency and the factors associated with it; the extent of sales of rural property for taxes and the factors associated with such sales; and the assessments of farm property for taxes are analyzed and discussed.

Assessed valuation and taxes per acre rose from \$2.97 and 0.6 ct. in 1849 to \$9.76 and 20.8 ct. in 1929 and then dropped to \$7.42 and 14.9 ct. in 1934 and 1935. From 1931 to 1935 the purchasing power of farm products has been only from 49 to 79 percent of that during the period 1910-14. In 1932 approximately 60,000 rural properties, including more than one-third of the land of the State, were delinquent. Over 75 percent of the properties delinquent were from 20 to 174 acres in size. The sales of rural real estate property taxes increased from 570 pieces involving 71,470 acres in 1928 to approximately 6,700 pieces involving 1,126,310 acres in 1932. The indexes (1910 equals 100 percent) of rural real estate, urban real estate, public utility, and personal property assessed values in the period 1881-90 were 48, 23, 24, and 34; in 1911-20, 151, 122, 107, and 118; and 1921-30, 212, 160, 153, and 164. The assessed valuation of farm real estate and taxes per \$100 of farm value for different counties ranged from 16 to 87 percent and from 67 ct. to \$1.27. In 5 counties of the State the percentages of assessed value of farm value for different sized farms with different values were: Less than 50 acres, value less than \$2,100, 39 percent, value over

\$2,699, 26 percent; 50 to 99 acres, value less than \$3,100, 38 percent, value over \$4,499, 29 percent; 100 to 149 acres, value less than \$4,200, 41 percent, over \$6,299, 29 percent; 150 to 199 acres, value less than \$5,400, 40 percent, value over \$3,299, 30 percent; and 200 acres or more, value less than \$8,400, 38 percent, value over \$14,999, 34 percent.

**Income parity for agriculture.—V, Population, farms, and farmers: Sect. 1, Farm population, nonfarm population, and number of farms in the United States, 1910–39, E. W. GROVE (U. S. Dept. Agr., Bur. Agr. Econ., Agr. Adjust. Admin., and Bur. Home Econ., 1939, pt. 5, sect. 1, pp. [2]+11+39, figs. 7).**—This preliminary report includes a table showing the farm population, nonfarm population, and number of farms by years, 1910–39, and a table and chart showing the indexes for each year, and describes the data and methods followed in making the estimates.

**Receipts and expenditures of rural New York counties, O. H. WHITE ([New York] Cornell Sta. Bul. 729 (1940), pp. 75, figs. 2).**—The development and variations in county government in the State and the general and financial administration of county government are described and discussed. An analysis is made of the receipts and expenditures, 1936 and 1937, in 49 counties with populations less than 150,000 and of the indebtedness of counties of the State for different lengths of time.

The total income for the 49 counties in 1937 was approximately \$1,000,000, of which nearly 60 percent came from property taxes, 35 percent from State and Federal aid or State-shared revenues, and the remainder from departmental earnings, refunds, etc. The expenditures averaged slightly over \$1,000,000, of which approximately 38 percent was for welfare, 30 percent for highways, 11 percent for debt service, 8 percent for protection, and 9 percent for general government. As the population increased average receipts and expenditures increased, expenditures per capita decreased, relatively welfare costs became more important and highway costs less important, and the percentage of expenditures financed from sources other than property taxes decreased. Most of the rural counties were not heavily bonded. Per capita indebtedness decreased with population in the counties with less than 100,000 population and increased in the counties with larger population.

**Nevada farm prices, 1910–1939, and a Nevada farm price index, C. VENSTROM. (Coop. U. S. D. A.). (Farm Managt. Bul. [Nev. Sta.], 1 (1940), No. 1, pp. [1]+43, figs. 4).**—Included are monthly and annual price indexes, usually for the period 1910–39, for beef cattle, lambs, wool, sheep, butterfat, hogs, eggs, chickens, calves, alfalfa hay, wheat, barley, potatoes, and all farm prices, and annual group indexes for range livestock (beef cattle, sheep, and all range livestock) and general farm products (livestock and livestock products, crops, and all products). The 13 commodities represent 95.6 percent of the agricultural income from farm production. The index is of the weighted aggregative type with 1910–14 as the base period. The base period prices are weighted by average quantity of products marked 1924–33. No correction is made for seasonal variations in prices.

**Statistical analysis of the annual average f. o. b. prices of canned clingstone peaches, 1924–25 to 1939–40, H. R. WELLMAN (California Sta. Mimeog. Rpt. 71 (1940), pp. [1]+11, figs. 2).**—An analysis is made of the relationship from 1924–25 through 1939–40 between f. o. b. prices of canned clingstone peaches and three major factors influencing such prices. On an average a change of 1,000,000 cases in domestic shipments of canned peaches was accompanied by a change in the opposite direction of 15 ct. per case in the price of canned clingstone peaches, a change of 10 points in the index of nonagricultural income in the United States was accompanied by a 47 ct. change in price in

the same direction, and a change of 10 points in the prices of competing canned fruits was accompanied by a change of 25 ct. in price in the same direction.

**Food, feed, and southern farms: A study of production in relation to farm needs in the South**, O. STEANSON and E. L. LANGSFORD (*U. S. Dept. Agr., Bur. Agr. Econ., Farm Mangt. Rpt. 1 (1939)*, pp. [2]+25).—The amounts of farm-grown feed needed and used and the quantities of livestock, cropland, and pasture in 1937, and the amounts needed to supply specified diets are analyzed and discussed.

**Determining input-output relationships in milk production**, E. JENSEN (*U. S. Dept. Agr., Bur. Agr. Econ., Farm Mangt. Rpt. 5 (1940)*, pp. [1]+12, figs. 3).—Preliminary results of a study made in cooperation with 10 agricultural experiment stations of feed input and milk output are reported.

**Should net-weight trading and standards for tare be adopted for American cotton?** J. W. WRIGHT (*U. S. Dept. Agr., Agr. Market. Serv., 1939*, pp. [2]+21).—Information is presented in question and answer form.

**Grade, staple length, and tenderability of cotton in the United States, 1938-39.** (Coop. Ariz., Calif., Ga., N. C., Okla., S. C., and Tenn. Expt. Stas. and partly coop. Ala., Ark., Fla., La., Miss., Mo., N. Mex., and Tex. Stas.). (*U. S. Dept. Agr., Agr. Market. Serv., 1940*, pp. [4]+70, figs. 10).—This publication continues the series previously noted (*E. S. R.*, 80, p. 553). Tables are included for the first time showing by States by years, 1933-38, the preparation for ginning of different staple lengths prior to October, during October and November, December 1-January 15, and after January 15.

**Report of the Chief of the Sugar Division, 1939**, J. BERNHARDT (*U. S. Dept. Agr., Sugar Div. Rpt., 1939*, pp. 19).—This report for the year ended June 30, 1939, is presented under the headings Sugar Act of 1937, effect of program on income of domestic producers, position of consumers under sugar program, administration of sugar quota provisions, sugar marketing allotments, administration of conditional payment programs, and finances for the sugar program.

**Cost of production and grove organization studies of Florida citrus**, Z. SAVAGE and C. V. NOBLE (*Florida Sta. Rpt. 1939*, pp. 36, 38).—A table shows the average costs of production, returns, profits, amounts of fertilizers used, etc., on 12- to 14-year-old late orange groves studied.

**Proceedings of the annual meeting of the New England Research Council on Marketing and Food Supply held on April 24 and 25, 1940, at Boston, Massachusetts** (*Boston: New England Res. Council Marketing and Food Supply, 1940*, pp. 1-30, 33-53, 57-73, figs. 6).—Included are committee reports and the following papers with discussions presented at the meeting held at Boston April 24 and 25, 1940: An Appraisal and Evaluation of Research in New England Now Under Way or Recently Completed, by F. Griffiee (pp. 1-24); The New England Milk Marketing Study—Review of Work Completed and Present Status of the Country [Dairy] Plant Study, by R. G. Bressler, Jr. (pp. 25-28) (Univ. Conn.); The New England Milk Marketing Study—Plans for Preparation of a Report on the Supply Side of New England Milk Markets, by A. MacLeod (pp. 29, 30); The New England Milk Marketing Study—Should the Emphasis of the New England Milk Marketing Research Program be Changed? by H. B. Rowe (pp. 33-36); Report of a Study on Consumer Preferences for Potatoes in the Boston Market.—I, Sampling Procedure Used in the Study of Consumer Preferences for Maine Potatoes in Part of the Metropolitan Boston Area, by M. A. Hincks (pp. 37-53) (Maine Expt. Sta.); The Use of Agricultural Surpluses to Overcome Nutritional Deficits, by A. C. Hoffman (pp. 57-67) and The Marketing Research Program of the Bureau of Agricultural Economics and Its Relationship to the Work of the Experiment Stations, by H. R. Tolley (pp. 71-73) (both U. S. D. A.).

The organization and management of 95 dairy and cash crop farms in Androscoggin and Oxford Counties, Maine, A. E. WATSON and E. RAUCHENSTEIN. (Coop. U. S. D. A.). (*Maine Sta. Bul.* 398 (1940), pp. [4]+72, figs. 5).—Data for the year ended April 30, 1937, were obtained by interviews. The area and farms studied are described and data included as to size and value of farms, crops, livestock, value of buildings, farm capital, sources of income, expenses, farm and labor incomes, returns on capital, etc. An analysis is made of the effects on labor income of size of business, production rates, labor efficiency, combination of enterprises, fertility practices, and man labor. The use of farm power, the dairy enterprise, history of operators, family living obtained from the farms, types of farming, etc., are discussed.

The average size of farms was 180 acres. The average dairy herd consisted of 9 cows, 2.8 heifers 1 yr. old or over, and 1.7 heifers less than 1 yr. old. The average receipts were \$1,976, of which 45.1 percent was from dairying, 24.4 from crop sales, 11.8 from livestock products other than dairy, 5.8 from forest products, and 12.9 percent from miscellaneous sources. The average labor income was \$37. Labor income increased from —\$50 where less than 32 acres were cropped to \$137 with 52 acres or more cropped, from —\$33 with herds of less than 6 cows to \$68 with herds of 10 cows or more, from —\$116 with less than 260 man-work units per farm to \$314 with 400 or more units, from —\$192 for herds producing less than 4,300 lb. of milk per cow to \$304 for those producing 5,800 lb. or over, from —\$108 where the crop index was less than 90 to \$282 where it was 110 or higher, and from —\$23 where there were less than 7 animal units per man to \$134 with 10 or over units per man. Combination of enterprises and increased use of fertilizers and lime increased labor income, which decreased from \$396 where less than 33 percent of the total receipts were dairy products to —\$198 where 53 percent or more were from that source. The average annual cost per cow for labor was \$34.55, of which \$12.16 was during the pasture season. The average cost per 100 lb. of 4-percent milk for feed and man labor was \$1.99, varying from \$2.51 for low-producing herds (less than 4,300 lb.) to \$1.66 for higher-producing herds (5,800 lb. and over). The average value of products produced on the farms and consumed by the farm families was \$235.

**Crops and Markets, [May–June 1940]** (*U. S. Dept. Agr., Crops and Markets*, 17 (1940), Nos. 5, pp. 93–108, fig. 1; 6, pp. 109–128, fig. 1).—Included are crop and market reports of the usual types (*E. S. R.*, 83, p. 556) for May (No. 5) and June (No. 6), 1940.

**The first world agricultural census (1930), I–V, A. BRIZI** (*Roma: Internatl. Inst. Agr.*, 1939, vols. 1, pp. 267; 2, pp. 493; 3, pp. 590; 4, pp. 505; 5, pp. 479).—Volume 1 describes and discusses the standard form proposed and documents relating to its preparation, a methodological study of the questions contained in the forms, and notes on the tabulation of the census results. Volumes 2 to 5 include the data obtained from different countries as follows: Volume 2, Austria, Belgium, Czechoslovakia, Denmark, Estonia, Finland, and France; volume 3, Germany, Greece, Irish Free State, Italy, Latvia, Lithuania, Netherlands, Norway, Spain, Sweden, Switzerland, and United Kingdom; volume 4, Canada, United States (including outlying territories and possessions), Mexico, Argentina, Chile, Peru, and Uruguay; and volume 5, India, Japan, Algeria, Egypt, French West Africa, Kenya, Mauritius, Mozambique, Union of South Africa, Australia, and New Zealand. The data for most of the countries have been previously noted (*E. S. R.*, 79, p. 703).

**The world agricultural situation in 1938–39** (*Roma: Internatl. Inst. Agr.*, 1940, pp. [VII]+373, figs. 34).—The general economic background of the agricultural situation, international economic relations, the production and supply

of and world trade in agricultural products, and the agricultural policies of different countries are described and discussed.

**World trade in agricultural products: Its growth, its crisis, and the new trade policies**, L. B. BACON and F. C. SCHLOEMER (*Roma: Internatl. Inst. Agr.*, 1940, pp. XIX+1102).—Part 1 (pp. 1-514) deals with the market developments on a world-wide scale for wheat, rice, sugar, meat, fats and oils, coffee, tea, tobacco, cotton, wool, silk, and rubber, and the dispersion and divergencies in movements of volumes and prices for the different commodities. Part 2 (pp. 515-1102) deals with the national policies affecting external trade in farm commodities in the United Kingdom, Germany, France and her overseas possessions, Italy, Netherlands, Denmark, Rumania, Hungary, Yugoslavia, Bulgaria, U. S. S. R., the United States, Argentina, Australia, Canada, and Asiatic exporters of agricultural products, and divergencies among national developments.

**Olives and olive products: Production and trade**, U. PAPI (*Internatl. Inst. Agr. [Roma], Studies Princ. Agr. Prod. World Market, No. 6 (1940), pp. [5]+223, pls. 19*).—Continuing the series (E. S. R., 81, p. 727) on principal agricultural products on the world market, the area in olive trees, number of trees, production for oil extraction and for table use, production of edible and nonedible oil, world trade in olive oil and table olives, etc., are discussed for each of the 27 countries in which olives are cultivated.

**Almond production abroad: Statistics, technique, and economics**, R. L. ADAMS (*Sacramento: Calif. Almond Growers Exch., 1939, pp. V+74, figs. 23*).—Almond production in Italy, France, Spain, northern Africa, Greece, and Portugal is discussed, special attention being given to the economics of almond growing in Italy and France.

**Cooperative egg and poultry auction associations**, J. J. SCANLAN and R. W. LENNARTSON (*Farm Credit Admin. [U. S.], Coop. Res. and Serv. Div., Bul. 37 (1939), pp. VI+101, figs. 27*).—This is a general and nontechnical discussion of egg and poultry auction associations. The development of such associations, types of organization, methods of operating, operating results, and the conditions favorable to the success of such associations are discussed. Appendixes include a list showing the location of the associations studied and the marketing rules of the Bucks County, Pa., Producers' Cooperative Association.

**Cooperative creamery accounting**, D. D. BRUBAKER (*Farm Credit Admin. [U. S.], Coop. Res. and Serv. Div., Bul. 39 (1939), pp. IV+99, figs. 4*).—Accounting forms and procedure, their installation by an operating association, the procedure for a new association, and producers' and producer-settlement records are described and discussed. Copies of different forms and records are included.

**Cooperative purchasing by Indiana farmers**, G. M. FRANCIS (*Farm Credit Admin. [U. S.], Coop. Res. and Serv. Div., Bul. 38 (1939), pp. VI+84, figs. 18*).—The development of farm bureau purchasing cooperatives in the State and the organization structure and status of county associations are discussed. An analysis is made of the operating methods and financial and operating conditions in 1934 and 1937 of 30 selected county associations.

**Bulk handling in Australia**, J. S. DAVIS (*Wheat Studies, Food Res. Inst. [Stanford Univ.], 16 (1940), No. 7, pp. [2]+301-364, figs. 9*).—Country and terminal grain elevators had been long discussed but never introduced in Australia before New South Wales, in 1916, provided for a state system. Opened for partial use in 1920-21, this system was slow to find favor with farmers, merchants, and millers; and for 10 yr. other states were content to observe the operating and financial experience in the pioneer state. In 1930-31, ocean

freight differentials in favor of bulk wheat were established, and bulk shipment oversea soon became the rule. With this change, bulk handling within Australia has expanded materially. The New South Wales plant has been extended, is more widely used, and yields operating surpluses, but has been cursed by recurring congestion. In Western Australia, progressive farmers' cooperatives have developed a cheaper, more flexible, unorthodox system which has worked well. Since early in 1936, when this received delayed official sanction, it has expanded rapidly despite poor terminal facilities and grudging cooperation from the state railways. Bag handling and storage, however, still have a large place in Australian practice and may long persist in some degree. This year, as in 1916, Australia faces the task of dealing with a bumper crop under conditions that severely restrict exports.

## RURAL SOCIOLOGY

**Rebuilding American community life, C. P. LOOMIS. (U. S. D. A.)** (*Amer. Sociol. Rev.*, 5 (1940), No. 3, pp. 311-324, fig. 1).—The author concludes that planned revitalizing of community life must take into consideration the cultural backgrounds of the people involved. Existing cultural traits or processes should be used where possible in the nurturing of community development. "Governmental action and planning agencies should, where possible, make local communities functional units. If communities are disregarded by action agencies dealing with local people, support for these programs will not be on as permanent a basis as if the community were made the center of planning and administration. If communities are not now sufficiently vocal and powerful to demand a place in administration and planning, disregarding them will certainly not strengthen them. To revitalize community life, existing communities should be made functional units in constructive programs."

**Basic trends of social change in South Dakota.—VI, Education in transition, W. F. KUMLIEN** (*South Dakota Sta. Bul.* 338 (1940), pp. 47, figs. 22).—This is one of the series previously noted (*E. S. R.*, 83, p. 558). Following are some of the trends noted: Elementary school enrollments are decreasing and high school and college enrollments are increasing, as was the proportion of persons of school age actually attending school. Both the compulsory school age and attendance requirements have been raised. School costs have risen not only with increased attendance but also with increased demand for educational services and facilities. Centralization results in fewer but better schools, and the qualifications of teachers have been raised progressively. There is a tendency toward more practical curricula, for example, vocational courses on a secondary school and college level.

**The construction and standardization of a scale for the measurement of the socio-economic status of Oklahoma farm families, W. H. SEWELL** (*Oklahoma Sta. Tech. Bul.* 9 (1940), pp. 88, figs. 2).—"The purpose of the study was to construct and standardize a simple scale that would give quantitative expression to the nature and extent of the variations existing in the socio-economic status of Oklahoma farm families."

**The theory and consequences of mobility of farm population, O. D. DUNCAN** (*Oklahoma Sta. Cir.* 88 (1940), pp. 22).—The author concludes that a high degree of mobility brings together conflicting points of view and dislodges vested interests. There is no surer index of subjugation and servility of the masses of human beings than absolute fixity of place and social condition. While there are thought to be no new continents to be discovered, it remains that new frontiers must be discovered if a large portion of the present popu-

lation of this country is not to die without issue. Perhaps migration holds the solution for the present debacle, but who knows?

**Distribution and extent of unemployment among farm laborers in the United States, L. NELSON.** (Univ. Minn.). (*Social Forces*, 18 (1939), No. 2, pp. 180-187, figs. 2).—The author shows that the supply of agricultural wage workers in November 1937 totaled approximately 3,222,000 persons. Adjustment by 30 percent for under-registration gives a figure of 3,439,500. There is reason to believe, however, that the available supply would be higher, perhaps approximating 4,000,000 workers during periods of peak agricultural activity. Approximately three-quarters of a million wage workers registered as totally unemployed or on emergency work in November of 1937. The unemployment rate was higher than the average for the United States in the small grain, middle eastern, and the cotton farming areas, while the lowest rates were in California and Florida, corn and dairy areas. The rates in the range and northwestern areas were slightly lower than for the country as a whole. Emergency work opportunities apparently were irregularly distributed by regions, with some tendency toward higher percentages being on work projects in areas of least unemployment.

**Economic aspects of remedial measures designed to meet the problems of displaced farm laborers, M. R. BENEDICT.** (Univ. Calif.). (*Rural Sociol.*, 5 (1940), No. 2, pp. 163-182).—"The problem of the agricultural migrant lies only partly in the realm of agriculture. Much of the distress of recent years has resulted from a decrease in urban employment which in earlier periods absorbed large numbers of workers of rural origin. The bad effects of these tendencies have been increased by rapid mechanization and drought in the farm areas. The problem is likely to increase in the years just ahead. The numbers now seeking a living on the land cannot be absorbed as agricultural entrepreneurs and workers except by vast changes in the structure of the agricultural economy. Tenant-purchase and the breakup of large holdings offer only limited possibilities. Cooperative farming does not provide an adequate solution. Improved tenancy legislation would help. Publicly sponsored development of small industries along the lines of the British Trading Estates program might provide substantial betterment in some areas."

**Private and public costs of isolated settlement in the cut-over area of Minnesota, J. E. MASON.** (U. S. D. A.). (*Rural Sociol.*, 5 (1940), No. 2, pp. 206-221).—"Private costs of isolated settlement appear as inconveniences and hardships resulting from poor roads and poorly equipped homes, lack of social contacts, and direct money outlays for snow plowing and transfer of products to or supplies from the markets. Distances to neighbors, grocery stores, doctors, churches, schools or school bus routes, shipping points, and to all-weather roads are translated into high costs both to the taxpayers forced to foot the bills for public services and to the individual settler who must bear the costs in the conduct of normal, everyday activities. Paramount in the public costs of isolated settlement are the expenditures for roads and schools. Other public costs, though difficult of measurement in dollars and cents, include extra costs incurred by the county nurse, county agent, and teachers of vocational agriculture when they must visit remote places in the performance of their duties; also election and assessment costs, rural mail delivery, administration of game and other laws, and forest fire protection costs are increased as a result of scattered, isolated settlement. The results of this study indicate that public costs are sufficiently excessive to justify relocation; and when all the disadvantages of isolated settlement are considered, a program of some sort seems not only necessary but imperative."

**Trends in community organization and life**, T. L. SMITH. (La. State Univ.). (*Amer. Sociol. Rev.*, 5 (1940), No. 3, pp. 325-334) —It is concluded that "the locality-group structure of society is undergoing a rapid transformation. The future promises a social structure in which the horizon of the individual family is greatly extended, and its relations with locality groupings are much wider and more complex than in the past. Group cohesion seems likely to be based even more on conscious recognition of mutual interdependence; social conflict promises to be more prevalent but more intermittent and less deep-seated; and mutual aid is likely to give away still more to cooperation of the contractual type."

**Problems of farm youth—a point of view**, P. H. LANDIS. (Wash. State Col.). (*Social Forces*, 18 (1940), No. 4, pp. 502-513).—The author concludes that "farm youth in many communities are in that interesting transitional stage between a rigidly controlled rural social order and a freedom-giving emancipated urban social order, struggling to make the step from an intimate locality group in which group purposes dominate individual action to a nonlocal, impersonal secondary group in which individualization has become highly developed. And they are moving more rapidly toward the goals of an urbanized social order than the parent generation in most areas, often bringing the parent generation along although not without great effort, but in far too many cases leaving the older generation behind after a period of struggle and conflict during which the new freedom has been gained. This seems to be the essence of the youth problem in the farm community of today."

## AGRICULTURAL AND HOME ECONOMICS EDUCATION

**Agricultural education: Organization and administration** (*U. S. Dept. Int., Off. Ed., Vocat. Div. Bul. 13* (1939), pp. VI+50).—This revision (E. S. R., 63, p. 787) gives information on the organization and administration of vocational education in agriculture under the Smith-Hughes and George-Deen Acts. The parts deal with the general provisions of the acts, developing a program within a State, and development of comprehensive local programs.

[**Abstracts of papers on agricultural and home economics education**] (*Assoc. South Agr. Workers Proc.*, 41 (1940), pp. 54-58, 64, 101-104, 138, 139, 178-181, 212, 213).—Included are abstracts of papers presented at the forty-first annual convention of the Association of Southern Agricultural Workers at Birmingham, Ala., February 7-9, 1940, on teaching and 4-H club and other extension work in farm structures, electrification, cotton ginning, animal production, diseases of crops, etc.

**Studies in home economics education, 1918-1940, reported in published form** (*Fed. Security Agency, U. S. Off. Ed., Vocat. Div. Misc. 2381* (1940), pp. III+20).—The publications are grouped by sources—colleges and universities, State and city departments of education, periodicals, U. S. Office of Education, and miscellaneous, with an index by subjects.

**For better rural living: A report of cooperative extension work in agriculture and home economics in 1938** (*U. S. Dept. Agr., Ext. Serv.*, 1940, pp. III+45).—Various activities and results are described and tabulated, including the Federal and State funds available and the purposes for which used.

**Statistical techniques adapted to home economics problems**, C. M. BROWN and H. M. HATCHER (*Minneapolis, Minn.: Burgess Pub. Co.*, [1939], pp. [1]+VI+104, figs. 32).—This handbook discusses the value of statistical knowledge to home economics teachers, simple statistical technics adapted to problems encountered in home economics, interpretation of data, and preparation of a technical report.

**The Pacific Northwest: A selected bibliography, 1930-1939**, J. B. APLETON (*Portland, Oreg.: Northwest Region. Council, 1939, pp. [6]+XX+5-456*).—This selected bibliography of 4,635 references deals with the physical and human resources of the Pacific Northwest. Part 1, completed research—published and unpublished, deals with topics on natural resources under the following headings with critiques: (1) General concepts of the Northwest (critique by R. F. Bessey), (2) agriculture (critique by H. E. Selby), (3) forest resources and utilization (critique by S. A. Wilson), (4) mineral resources (critique by E. T. Hodge), (5) water resources (critique by S. B. Morris), (6) power resources (critique by I. Bloch), (7) fisheries (critique by J. A. Craig), (8) human resources and problems (critique by J. F. Steiner), (9) commerce and industry (critique by J. C. Rettie), (10) Government (critique by R. Barthell), (11) education (critique by W. L. Uhl), (12) planning (critique by P. Hetherington), (13) maps and diagrams (critique by O. W. Freeman), and (14) bibliographies.

Part 2, research in progress, gives information as to probable date of completion, address of researcher, scope and purpose of project, and type of reader for whom the manuscript is being prepared. Part 3 lists contemplated projects.

### FOODS—HUMAN NUTRITION

[**Foods and nutrition studies by the Florida Station**] (*Florida Sta. Rpt. 1939, pp. 85, 86, 100, 101*).—In this annual report summaries, representing for the most part an extension of earlier work (E. S. R., 81, p. 300), are given by R. B. French on the vitamin C content of Florida fruits and vegetables (p. 85); by H. W. Winsor on the mineral content of vegetable crops with special reference to iron (pp. 85, 86); by O. D. Abbott, M. R. Overstreet, and C. F. Ahmann on the extent of nutritional diseases, particularly anemia, among children (E. S. R., 83, p. 274), young girls, women, and college students, and the mineral composition of water, vegetables, and soil from homes of selected children in this study (pp. 100, 101); and by Abbott on the chemical composition and nutritive value of several Florida honeys, and the standardization of home-canned tomatoes and tomato juice (p. 101).

**Proximate composition of American food materials**, C. CHATFIELD and G. ADAMS (*U. S. Dept. Agr. Cir. 549 (1940), pp. 91*).—This compilation, superseding the tables of Atwater and Bryant (E. S. R., 11, p. 379), gives new average values for over 1,100 plant and animal foods on American markets. The values, offering a working basis for diet calculations, are reported in terms of percentage of refuse, water, protein, fat, ash, total carbohydrates, and fiber; sugars, starch, and acid are reported for some foods. Fuel value is given in terms of calories per 100 gm. and per pound. The constituents are reported on the edible portion and the as-purchased bases. The table on composition is prefaced by brief statements on sources and derivation of the data and the meaning of the terms, and by notes on certain classes of foods, and on the use of the data. For the benefit of persons preparing diabetic diets, a classification of fruits and vegetables according to their carbohydrate content is included.

**The proximate constituents and the composition of the ash of the principal African cereals** (*Triticum durum, Zea mays, Hordeum distichon, Sorghum aethiopicum, Eragrostis abyssinica, Pennisetum typhoideum, and Eleusine coracana*) [trans. title], G. FABRIANI (*Quad. Nutr., 6 (1939), No. 1, pp. 72-81*).—Moisture, nitrogen, protein (N×6.25), total and reducing sugars (as glucose), sucrose, starch, pentosans, crude fiber, fat, and ash are reported for these cereals, together with data on K, Na, Ca, Mg, Fe, S, P, and Cl reported as percentage of the air-dry cereals and as percentage of the ash, the milligram equivalents of these elements, and the calculated acid or base values. Informa-

tion is given for each cereal on the weight per 1,000 kernels and on the weight per hectoliter. The analyses were carried out by the methods adopted by the commission for the study of nutrition problems of the [Italian] National Research Council.

**Proximate and mineral constituents of some seeds of African legumes** [trans. title], G. FABRIANI (*Quad. Nutr.*, 6 (1939), No. 2, pp. 219-226).—*Canavalia ensiformis*, *Lens abyssinica* (whole and also decorticated seeds in each case), *Cicer amaricum* (two varieties), *Phaseolus mungo*, *Cordeauxia edulis* (decorticated seeds), and *Linum minus* were the legumes studied. Proximate constituents, including total and reducing sugars and sucrose, starch, pentosans, and crude fiber, and the minerals K, Na, Ca, Mg, Fe, S, P, and Cl were determined, and the base or acid values calculated from the mineral equivalents.

**The chemical composition of the banana of the variety "Giuba" cultivated in Italian Somaliland** [trans. title], G. FABRIANI (*Quad. Nutr.*, 6 (1939), No. 2, pp. 199-208).—This variety, Giuba, belonging to the species *Musa nana* is noted as being cultivated commercially. The percentage of edible portion and the proximate constituents, including total and reducing sugars, sucrose, and starch, are reported for the fruit at four stages of maturity, and the values for the mature fruit are compared with analyses quoted from various sources (cited). Data on Na, K, Ca, Mg, Fe, S, P, and Cl, expressed as percentages of the fresh edible portion, are reported for this variety and similar data are quoted for other varieties. Milligram equivalents and calculated base values are given for the green and ripe fruits.

**The chemical composition of products derived from the banana of the variety "Giuba"** [trans. title], G. FABRIANI (*Quad. Nutr.*, 6 (1939), No. 2, pp. 209-218).—The data on proximate and mineral constituents and the calculated base value of the banana flour at its normal moisture content (12.5 percent) are reported and compared with cited figures for similar products. Moisture, determined at 45°-50° C. in vacuum, and proximate constituents reported on this moisture basis are also given for banana flours from unripe, partially ripe, semiripe, and fully ripe fruits of this variety. Original and quoted data are also given for the proximate constituents of the fig banana and for so-called marmalades and gelatin prepared from it, and on both proximate and mineral constituents of its skin.

**Analysis of Ceylon foodstuffs.—VIII. Further analyses of local food stuffs with particular reference to their mineral composition**, A. W. R. JOACHIM, S. KANDIAH, and D. G. PANDITSEKERE (*Trop. Agr. [Ceylon]*, 93 (1939), No. 6, pp. 336-342).—Continuing studies noted earlier (E. S. R., 80, p. 130), analyses are presented for the edible portion of additional Ceylonese-grown foods designated by botanical, English, and native names. The methods of analysis were the same as in the earlier studies except that a Lovibond tintometer was used for making color comparisons in the iron determinations. Data are reported on the proximate constituents of a number of grains, seeds, roots and tubers, and coconut water, calcium, phosphorus, and iron also being reported for these same foods. A number of leafy vegetables and fruit forms were studied with particular reference to their mineral (Ca, P, and Fe) composition and the variation of the latter with place of origin of the foodstuff. Results are tabulated.

**The food of the present-day Navajo Indians of New Mexico and Arizona**, T. M. CARPENTER and M. STEGGERDA (*Jour. Nutr.*, 18 (1939), No. 3, pp. 297-305).—Data on moisture, fat, total nitrogen, and calories per gram (as determined by oxycalorimeter) are reported on the air-dry basis for 66 typical Navajo foods designated by the common English names. These include dry and roasted corn

and corn flour; breads, dumplings, and mush; a few vegetables; fruits, nuts, and berries; seeds of grasses and weeds; meats; juniper ashes; and clay. The weight lost in drying to the air-dry condition is also reported to permit calculations to the fresh basis. The diet of the Navajo Indian was found to consist chiefly of mutton (goat or sheep), practically all parts of the animal being eaten. A study of the character and amount of food eaten by 5 Navajo families indicated that the average family (6 or 7 persons) eats one goat each week and in addition about 10 kg. of flour, 2.5 kg. of white sugar, 1 kg. of coffee, and such vegetables as may be available.

**The canned food reference manual** (*New York: Amer. Can Co., [1939], pp. 242, figs. [50]*).—This manual conveniently brings together technical information issued by the American Can Co. since 1935 in various professional journals, summarized under the following headings: Canning technology, canned foods in human nutrition, public health aspects of canned foods, the past 20 yr. of canning research, useful facts about commercially canned foods, and the Federal Food, Drug, and Cosmetic Act. The appendix presents many useful data and tabulations, including a list of commercially canned foods; information on case capacities for common can sizes; canned food production figures; compilations of proximate analyses, of vitamins, and of pH values of canned foods; and pertinent data on other common foods, together with other dietary information, all adapted from quoted sources. Literature citations are given throughout.

**Keeping foodstuffs fresh with special regard to the use of cold** (18. *Internatl. Cong. Agr., Dresden, 1939, Sect. 7, Main Rpts., pp. 15-28, figs. 4; Rap. Spéc., pp. 25-69, fig. 1*).—Under this topic the main report of a general nature was presented by O. Notevarp (Norway). Special reports were presented by R. Heiss (Germany), A. v. Osztrovszky (Hungary), C. A. Giambelli (Italy), D. Delić (Yugoslavia), H. W. Weedon (Norway), J. L. van Uffelen (Netherlands), D. St. Emilian (Rumania), G. Radulesco-Calafat (Rumania), and J. B. Verlot (France).

**Freezing and storage of foods in freezing cabinets and locker plants**, D. K. TRESSLER and C. W. DUBOIS (*New York State Sta. Bul. 690 (1940), pp. 60, figs. 20*).—The authors have brought together in this bulletin useful information from various sources on the construction and management of frozen food locker plants and farm freezing storage cabinets; freezing and storage temperatures; packages and wrapping materials; the preparation and freezing of meat, poultry, fish, shellfish, and game, fruits, and vegetables; and the preparation of frozen foods for the table. Information, based on studies carried out through the cooperation of the pomology and vegetable crops divisions of the station and Frosted Foods investigators, is tabulated on the varieties of New York State fruits and vegetables which give satisfactory frozen products. Other tabular material includes steps in the preparation of fruits and vegetables for freezing and cooking times for fresh and frozen vegetables.

**The effect of cooking and canning on the mineral constituents of certain vegetables**, G. HORNER (*Jour. Soc. Chem. Indus., Trans., 58 (1939), No. 3, pp. 86-90*).—Vegetables of known variety and origin prepared for cooking or canning were analyzed in the raw state, as cooked vegetables (500 gm. of vegetable in 1,500 cc. of water or dilute brine), and as canned products; the weights of vegetable per A2 can, the nature of the brine, and the blanching procedure are noted. Cooking and canning were carried out in water of medium hardness. The drained solids and liquor were analyzed separately and the data so reported in the case of the cooked and canned vegetables, the weight of drained solids and the weight and specific gravity of the liquor being determined in each case. These latter data, though not reported, were used in calculating losses and in

calculating the weights of the blanched, cooked, and canned vegetables (drained solids) to a basis corresponding to 100 gm. of the raw vegetable. Ca, Mg, K, and P were the elements determined, and fresh and dried peas, stringless beans, dried beans, carrots, potatoes, and spinach were the vegetables analyzed. Mineral losses from the vegetables as incurred in the blanching, cooking, and canning processes are calculated and discussed.

The results indicate that vegetables cooked or canned in water of appreciable hardness gained Ca but lost other inorganic constituents in the process. Salt in the canned material had no appreciable effect on the distribution of the minerals between solid and liquid portions except in the case of Ca, and therefore is not of value in diminishing losses. Considerable loss, particularly of K, occurred in the blanching process.

**Comparative data obtained on some 1938 hard red spring wheat varieties by the use of four baking formulas, R. H. HARRIS. (N. Dak. Expt. Sta.). (Cereal Chem., 16 (1939), No. 4, pp. 533-540).**—Twenty-six samples of hard red spring wheats, differing in generic origin and analyzed for grade, test weight, and crude protein content, were milled into straight flours in an Allis-Chalmers experimental mill, and the resultant flours were analyzed for crude protein and ash and baked by four procedures. The wheat protein ranged from 13.3 to 17.0 percent and the flour protein from 12.5 to 16.2 percent. The ash in the flours was quite variable.

The baking procedures included the standard basic method with 5 percent sucrose; a milk-shortening formula, including 4 percent dry skim milk and 3 percent shortening; a milk-shortening-bromate formula, which included the milk-shortening formula plus 0.001 percent  $\text{KBrO}_3$ ; and the malt-phosphate-bromate formula. The three latter formulas were all superimposed upon the standard basic. Statistical analysis of the findings indicated a significant difference in mean loaf volume, these mean volumes increasing in the order noted for the methods. The mean texture scores also differed significantly between methods, whereas crumb color did not. If a random selection of methods were assumed, differences between varieties were significant in respect to loaf volume, color, and texture scores, indicating variability in baking strength among hard red spring wheat varieties. Correlation coefficients for flour protein and loaf volume for the four baking methods were significant except for the milk-shortening-bromate method.

**Sweet potato starch in the bakery, D. SCRIVANICH (Bakers Tech. Digest, 14 (1939), No. 4, pp. 63-65, 67, figs. 7).**—To determine the effect of sweetpotato starch on bread, baking tests were carried out in which 0, 1, 2, or 4 percent (based on flour) of the starch was used in a standard formula prepared as a straight dough. Data on loaf weight when fresh and when 3 days old, on relative loaf volume, and on compressibility after 3 days showed that the loaf containing 1 percent of sweetpotato starch based on flour, although lighter in weight than the others, had the greater volume and the greater compressibility after 3 days. Grain, texture, color of crumb, and appearance of crust were also superior in this loaf. Subsequent tests on a large scale and under practical bake shop conditions confirmed the initial experimental results.

The effect of sweetpotato starch when added to a cake batter was also determined. The starch was added at levels of 0, 0.36, 0.73, 1.47, 1.83, 2.20, and 3.65 percent of the weight of the flour in the formula given. The cake containing 1.83 percent of the starch based on flour showed the least loss of moisture in 4 days, retaining at the same time the greatest compressibility of all test cakes. Moisture loss was retarded, however, when as little as 0.36 percent of the sweetpotato starch was used, although at least 1 percent of the starch was

necessary to appreciably affect the compressibility after 4 days. Crust, texture, taste, and flavor received the best scores in cakes containing 1–1.5 percent of sweetpotato starch. With the formula used, additions in excess of 2 percent had an adverse effect on the final product. Exploratory tests indicated further that this starch gave satisfactory results when used in pie fillings.

**Losses on boiling milk**, M. ANDROSS (*Jour. Soc. Chem. Indus., Trans.*, 58 (1939), No. 7, pp. 252–254).—Data are reported on volume and weight losses incurred in boiling milk for different periods; on the wet and dry weights of skin and residue; and on the solids, ash, calcium, phosphorus, protein, albumin, and fat in the skin and residue and in the raw and boiled milk. Lactose was also determined in certain samples of milk before and after boiling. In all cases a pint of the milk in an aluminum pan was brought to a boil in 10 min.

Losses, as calculated from the data on the raw and boiled milks, amounted to 13.29 percent, 5.75, 13.73, 5.4, 13.58, 74.83, 23.50, 1.91, and 15.7 percent for total solids, ash, calcium, phosphorus, protein, albumin, fat, carbohydrate, and calories, respectively. Somewhat different values (chiefly lower) were obtained when the calculations were based on analyses of the skin and residue as compared with the raw milk. It is not considered an overstatement, however, to say that 10 percent of the nourishment of milk is lost on boiling. Except in the case of albumin, the change in composition is completely masked by the volume lost on boiling the milk. As far as the distribution of the losses is concerned, the data indicated that the fat was mainly in the skin, while protein and calcium occurred to a greater extent in the residue.

**The nutritive value of foodstuffs** [trans. title], H. G. KOEFOED, S. POSTMUS, and A. G. VAN VEEN (*Landbouw [Buitenzorg]*, 15 (1939), No. 4, pp. 193–226, pl. 1; *Eng. abs.*, pp. 221, 222).—Standard food tables for calculating diets are presented to cover the commonly used foods of the Dutch East Indies. Rounded values are given for the percentages of protein, fat, and carbohydrate, for calories per gram, and for vitamins A and B<sub>1</sub> expressed as International Units per gram. Fruits, vegetables, and animal products are included, the values for the latter being very general to cover such broad classes as fresh meat, dried meat, fresh fish, salted fish, etc. Food values and dietary calculations are discussed.

**The influence on agricultural production of actual or recommended changes in diet** (18. *Internatl. Cong. Agr., Dresden, 1939, Sect. 1, Main Rpts.*, pp. 29–35; *Rap. Spéc.*, pp. 69–92).—Under this topic the main report of a general nature was presented by W. Staniewicz (Poland). Special reports were presented by E. J. Kinnunen (Finland), R. Dumont (France), L. Randoin (France), and C. Jornescu (Rumania).

**Meat and meat products as sources of essential dietary factors**, C. A. ELVEHJEM. (Univ. Wis.). (*Amer. Soc. Anim. Prod. Proc.*, 31 (1938), pp. 343–350).—An address.

**Milk is effective in a reducing diet**, J. H. FRANSEN. (Mass. State Col.). (*Milk Plant Mo.*, 28 (1939), No. 7, pp. 27–29).—Suggestions on use of milk in reducing diets have been brought together from various sources.

**The effect of different percentages of protein in the diet of six generations of rats**, J. R. SLONAKER (*Stanford Univ. Pubs., Univ. Ser., Biol. Sci.*, 6 (1939), No. 4, pp. 67).—It was hoped to determine what percentage of protein in an otherwise well-balanced diet was best suited to produce the greatest efficiency of the various physiological functions of the rat and by so doing to establish certain principles that might possibly be used in experiments with other animals, including man. The five experimental diets used furnished, respectively, 10.3, 14.2, 18.2, 22.2, and 26.3 percent of protein of mixed origin; 43, 62, 75, 81,

and 85.5 percent of the total protein in these several cases, respectively, was of animal origin.

The results of the extended study are tabulated and discussed in detail under the following headings: Energy consumption and utilization; spontaneous activity; growth and development, including eruption of incisors, opening of eyes, opening of vagina, mated pairs, offspring, and stature; sterility; reproduction, including reproductive span and effect of lactation on mothers; offspring, including sex ratio and mortality of offspring; autopsies with special reference to kidneys; life span and weight at death; and cause of death. A general summary is given of the findings, which are considered to warrant the conclusion that the 14.2 percent protein diet, supplemented by a higher percentage of protein for rearing the young, was more efficacious than any of the others with respect to the physiological functions of the rat. However, since the diets used varied by 4-percent intervals, it is considered that possibly a slightly richer protein diet would have been better.

**The metabolic behaviour of phosphorus.**—[I], Balance sheets of phosphorus in full-grown rats fed with tri-stearine and ammonium phosphate; II, Balance sheets of phosphorus in full-grown rats fed with tri-stearine and sodium phosphate, A. WESTERLUND (*Lantbr. Högsk. Ann. [Uppsala]*, 7 (1939), pp. 131–154, figs. 4, *Swed. abs.*, pp. 152, 153; pp. 229–245, figs. 5, *Swed. abs.*, pp. 244, 245).—In the first study seven adult male albino rats were given a diet very low in calcium, phosphorus, and fat-soluble vitamins and containing about 9.5 percent of tristearin (to render calcium insoluble in the intestinal tract) to which different quantities of  $(\text{NH}_4)_2\text{HPO}_4$  had been added. This diet was fed during a 10-day period. Intake of calcium and phosphorus, as well as excretion of these elements in the feces and urine, were measured for the last 5 days.

There was wide variation between the animals with regard to the urinary and the fecal elimination of phosphorus, but the variation was less pronounced in the case of the calcium. No reason for the variation in the fecal output of calcium was evident, and, in particular, varying consumption of phosphorus was not considered responsible. Variation in the intake of phosphorus, and this alone, was responsible for the wide variation in urinary phosphorus. The amounts of phosphorus consumed were excreted practically quantitatively by the kidneys. In spite of this the content of calcium in the different samples of urine was rather uniform and not related to their varying content of phosphorus. The excretion of urinary calcium accounted for about 2.5 percent only of the total excretion of this element.

In the second study  $\text{Na}_2\text{HPO}_4 \cdot 2\text{H}_2\text{O}$  replaced the  $(\text{NH}_4)_2\text{HPO}_4$ . The results obtained were essentially the same as in the first experiments except that urinary elimination of phosphorus was found to be controlled not only by consumption of phosphorus but apparently also by the varying consumption of sodium.

**The total and available iron in vegetable foods**, E. F. YANG and M. Y. DJU (*Chin. Jour. Physiol.*, 14 (1939), No. 4, pp. 479–487).—Total and available iron, determined by methods outlined and using *aa*-dipyridyl, and glucose as a reducing agent, are reported for 10 cereals and cereal products, 16 legumes and legume products, and 31 vegetables, including cucurbits, roots, leaves, and others. Moisture is also reported, together with values for ionizable iron calculated as percentage of total iron, the latter values being compared with available data cited from other sources. "Matured cereal grains contain 45–70 percent of iron in ionizable form, matured legumes about 85 percent, while fresh and sprouted beans and fresh corn contain much less ionizable iron. Green vegetables show great variation in the amount of available iron present. Alfalfa, water celery,

celery, lettuce, shephards-purse, spinach, calabash, and loofah are very good sources of available iron. Peiping cabbage, small cabbage, mustard leaves, turnip, and water bamboo are moderately good."

**Iron metabolism in infancy.—I, Factors influencing iron retention on ordinary diets; II, The retention and utilization of medicinal iron, H. W. JOSEPHS** (*Bul. Johns Hopkins Hosp.*, 65 (1939), No. 2, pp. 145-166, figs. 5; pp. 167-195, figs. 10).—The work presented in these two papers represents a continuation of an earlier study on iron metabolism in infants (*E. S. R.*, 73, p. 876).

The first paper is concerned with iron balance studies made to ascertain the factors influencing retention of iron on milk and cereal diets. Data with regard to age, hemoglobin (grams per 100 cc.), body weight, duration of metabolism period, and iron intake, retention, and excretion, all three expressed as milligrams per kilogram per day, are reported in detail, and with comments for each infant; the numerous cases are classified as under 3 mo. of age, between 3 and 6 mo., and over 6 mo. Iron intake was calculated from actual analyses of aliquots of the food consumed; retention was calculated as intake minus output, the latter, also a determined value, representing the total iron occurring in the stools. This iron output was considered to be made up of any food iron not absorbed and whatever iron might be excreted into the gut. Since there was evidence that on an average 60 percent of the iron taken in with the food was absorbed, excretion was expressed as  $(\text{intake} \times 0.6)$  minus retention.

Excretion tended to vary with age, being somewhat greater in the first 3 mo. of life but thereafter relatively constant. Infections and lack of vitamin D tended to diminish retentions, although the deviation from normal was never enough to contribute significantly to iron deficiency. In the case of infection, lower retention appeared to be caused by lower food intake due to loss of appetite. In anemia, on the other hand, retention of iron tended to be slightly above the average even though hemoglobin was falling. This is evidence against an iron deficiency in the ordinarily accepted sense, but suggests that the tissues may possess an "avidity" for the iron. One possibility is that the iron is thus held in the tissues in an unavailable form, but another possibility is that it is merely stored there to be utilized when the conditions are right.

The second paper reports on a series of 47 short iron metabolism studies conducted on infants, some normal, others suffering from nutritional anemia, and varying in age from 3 weeks to 27 mo. During these periods of 5 or 6 days, inorganic iron was given in varying but relatively small amounts.

Retention of iron was found to be enhanced when the intake was above a level of 2 mg. per kilogram of body weight per day. Below this level the body was usually in iron balance until the intake fell to about 0.1 mg. per kilogram, when the balance tended to become negative. Age had little influence on retention, but anemic infants retained iron better than nonanemic infants. Excretion of increased intakes did not take place until 24-36 hr. after the discontinuance of medication, this being merely the time required for passage through the intestinal tract. Reexcretion of the ingested iron at the low level studied was, therefore, at a minimum, and for all practical purposes retention was equal to absorption. Below the age of 6 mo. utilization of retained iron for hemoglobin formation depended on age or rate of growth; above this age it appeared to depend on retention. It is considered that this correlation would not apply if retention were great enough to more than satisfy the requirement for hemoglobin formation.

Administration of copper along with the medicinal iron caused an increase in the total utilization of iron but not in the rate of utilization; nor did the

copper influence the amount of iron retained. A period of high iron feeding did not result in an immediate increase in hemoglobin. Apparently, therefore, iron taken into the body was deposited in the tissues or "stored" for several days preceding utilization. Percentage of utilization charted against retention indicated that anemic infants utilized iron more efficiently at lower levels of retention. The utilization was about 100 percent with retentions of about 2 mg. or less per kilogram of body weight. The utilization of freshly retained iron appeared to end in about 2-3 weeks, even though all of the iron had not been used up and even though a new period of iron medication could elicit a further hemoglobin increase. It is considered possible, therefore, that the iron might have been changed to a less available form, or more likely that the "stimulation" produced by medicinal iron may have lasted only through this period. The period of rising hemoglobin coincided roughly with that of reticulocyte increase. It was concluded that the medicinal iron had an important "regulatory" function in addition to that of supplying a building stone for hemoglobin.

**The retention and excretion of selenium after the administration of sodium selenite to white rats,** R. A. GORTNER, JR., and H. B. LEWIS (*Jour. Pharmacol. and Expt. Ther.*, 67 (1939), No. 3, pp. 358-364).—Young white rats, over periods ranging from 28 to 143 days, were fed basal diets containing sodium selenite at levels of 25, 35, and 50 p. p. m. The diets were deficient in the sulfur-containing amino acids, but were fortified with cystine or methionine in amounts adequate to promote good growth. The selenium content of the combined liver, kidneys, and spleen of the individual rats ranged from 0.03 to 0.17 mg. or from 0.4 to 2.8 percent of the selenium ingested. No correlation between the selenium concentration of the diet and that of the organs could be demonstrated, and apparently the ingested selenium was rapidly eliminated. From 20 to 50 percent of the amount ingested was excreted in the feces, but here again there was no correlation with the selenium concentration in the diet. It is believed that the greater part of the fecal selenium originates from the dietary selenium escaping absorption.

**Distribution of fluorosis in India and in England,** D. C. WILSON (*Nature [London]*, 144 (1939), No. 3638, p. 155, fig. 1).—A brief note is made of the recognition of endemic fluorosis in men and animals in the Madras Presidency, the Hyderabad, and the Punjab. Analyses indicated the presence of fluorine in the well waters. In the Punjab the afflicted areas lay over a buried ridge of larvas associated with granites and rhyolites. Dental fluorosis was also observed in a number of areas in England; in some of these, analyses of the water had been made and fluorine was found present. In one region, the Marston Valley, the "knotts" clay was found to contain more than 450 p. p. m. of fluorine.

**The basal metabolic rate of normal individuals in New Orleans,** A. G. EATON. (La. State Univ.). (*Jour. Lab. and Clin. Med.*, 24 (1939), No. 12, pp. 1255-1263).—Basal metabolic rates of middle-class white persons long resident in New Orleans were determined on 98 women and 62 men, all of whom were in good health and none of whom exhibited endocrine disturbances. The values, representing first determinations for the most part and expressed as Calories per square meter per hour, are tabulated, together with deviations (calculated as percentage variations) from Aub and DuBois, Harris and Benedict, Dreyer, and Mayo Foundation standards. The deviations indicate that all four standards are too high for the New Orleans subjects. The data show, however, that the metabolic rates of subjects living in this area can be satisfactorily expressed by applying a correction factor of -10 percent to all values of the Aub and DuBois standards or of -11 percent for men and -7 percent for

women to the Mayo Foundation standards. These corrections are shown to be valid statistically.

**The vitamine-content of the most important foodstuffs in the different seasons** (18. *Internatl. Cong. Agr., Dresden, 1939, Sect. 9, Main Rpts., pp. 23-30, figs. 3; Rap. Spéc., pp. 37-46*).—Under this topic the main report of a general nature was presented by M. van Eekelen (Netherlands). Special reports were presented by A. Scheunert (Germany), O. Turpeinen (Finland), and S. Baglioni (Italy).

**Vitamins and related substances in yeast**, M. A. JOSLYN. (Univ. Calif.). (*Brewers Digest, 14 (1939), No. 12, pp. 26, 27*).—This is a brief survey leading to the conclusion that "different yeasts exhibit decidedly different capacities for the elaboration of vitamins, and these capacities may be attained or repressed by manipulation of cultural conditions."

**Mineral constituents and vitamins of wheat** [trans. title], G. QUAGLIARIELLO (*Quad. Nutr., 6 (1939), No. 3, pp. 276-289*).—A review with 56 references. Data on mineral constituents are quoted from a number of sources.

**The content of vitamin A-active compounds in Danish foodstuffs.—III, The content of carotenoids, chiefly  $\beta$ -carotene, in some raw and cooked vegetables** [trans. title], H. WILLSTAEDT and H. B. JENSEN (*Ztschr. Vitaminforsch., 9 (1939), No. 1-2, pp. 8-13, fig. 1; Fr., Eng., abs., p. 13*).—Calibration curves are presented for  $\beta$ -carotene determined colorimetrically by means of the step photometer and with the use of several different filters. Determination of carotene in vegetables by this method is considered to give more accurate values than determination of total carotenoids, the values for the latter being too high. Total carotenoids and in most cases also  $\beta$ -carotene were determined in various samples of raw, cooked, and canned carrots, in raw and cooked cabbage and brussels sprouts, and in raw turnips, kohlrabi, and sugar beets. In brussels sprouts separate analyses of the outer green leaves for total carotenoids showed very high values (191.9 $\gamma$  per gram of fresh substance) as compared with samples analyzed after trimming (3.3 $\gamma$  per gram). The cooking procedures used were found to cause no appreciable decrease in the content of carotenoids.

**The content of vitamins A and B<sub>1</sub> in walnuts, hazelnuts, almonds, and peanuts** [trans. title], L. DE CARO and J. FRANCESCHINI (*Quad. Nutr., 6 (1939), No. 1, pp. 82-86, figs. 4*).—Fresh and dry walnuts (*Juglans regia*), peanuts (*Arachis hypogaea*), hazelnuts (*Corylus rostrata*), and almonds (*Amygdalus communis*), assayed by a rat growth method, are reported to contain 1.2, 1.3, 3.6, 4.4, and 5.8 International Units of vitamin A per gram, respectively. In the vitamin B<sub>1</sub> assays the daily quantity of the nut required to permit a 60-day survival of vitamin B<sub>1</sub>-deficient rats was determined, the B<sub>1</sub> content per gram of nut being calculated from these results as 1.4, 1.4, 0.6, and 1.0 I. U. for walnuts, hazelnuts, almonds, and peanuts, respectively.

**The minimum vitamin-A requirements of normal adults.—II, The utilization of carotene as affected by certain dietary factors and variations in light exposure**, L. E. BOOHER and E. C. CALLISON. (U. S. D. A.). (*Jour. Nutr., 18 (1939), No. 5, pp. 459-471, fig. 1*).—In continuation of the series noted previously (E. S. R., 83, p. 278), comparative minimum vitamin A requirements were determined for one adult subject for carotene in cottonseed oil and in cooked peas, one for carotene in cottonseed oil, cooked peas, and cooked spinach, and one for carotene in cottonseed oil and cooked spinach. In another subject the requirement was determined for carotene in cooked spinach alone. For further comparison, earlier values showing the relationship of vitamin A in cod-liver oil and carotene in cottonseed oil are included in the tabulated data.

The earlier figures showed a ratio of carotene requirement to vitamin A requirement ranging from 1.61 to 1.84. The two values obtained in the present study for the ratio of pure carotene to carotene in cooked green peas were 1.62 and 1.68 and for pure carotene to carotene in cooked spinach of 1.24 and 1.22. In terms of the minimum daily quantities of vitamin A required for normal dark adaptation, 47 and 57 units per kilogram of body weight, respectively, were required for the two subjects receiving practically all of their vitamin A from the carotene in cooked green peas; and 77, 87, and 101 units per kilogram of body weight for three subjects on cooked spinach.

Studies of the possible effect of other factors in modifying the requirement or utilization of carotene in vegetables, with one or two subjects for each test, are also reported, with the conclusion that a daily intake of thiamin in excess of 400-600 International Units, or of riboflavin in excess of about 1,800-2,400  $\mu\text{g.}$ , or of dietary fat in an ordinary mixed diet in excess of 30-35 percent of the total calorie intake did not improve the utilization of carotene by adults or decrease their minimum physiological requirement for vitamin A. A marked increase or decrease in the exposure of the eyes to ordinary light sources was not accompanied in the single subject tested by altered requirements for vitamin A.

Data are included on the average composition of the experimental diets, dark adaptation values for one subject, and the influence of the factors studied in terms of average light thresholds after 6 and 30 min. of dark adaptation.

**Vitamin A in the blood of normal adults.**—The effect of a depletion diet on blood values and biophotometer readings, G. STEININGER, L. J. ROBERTS, and S. BRENNER (*Jour. Amer. Med. Assoc.*, 113 (1939), No. 27, pp. 2381-2387, figs. 3).—Chemical determinations of the carotene content of the blood by the method of Clausen and McCoord (*E. S. R.*, 76, p. 585) and the vitamin A content by a modification of the Carr-Price antimony trichloride method, and biophotometer dark adaptation tests are reported for four women subjects during a 4-mo. period of vitamin A depletion and subsequent treatment with small doses of vitamin A. Similar determinations were made on a control subject and single blood determinations on 34 adults on uncontrolled diets, with half receiving a vitamin A supplement. Biophotometer readings were made on 31 of this group. In the first group the levels of vitamin A in the fasting blood at the beginning of the study ranged from 7.1 to 22.1 blue units and the carotene from 60 to 85  $\mu\text{g.}$  per 100 cc. of serum, the levels being related to the dietary history. Continuance of the depletion diet caused a marked fall in vitamin A and carotene levels, with a tendency for the values of all of the subjects to approach that of the subject with the lowest original value. At the end of the depletion period small supplements of vitamin A in the form of U. S. P. standard cod-liver oil caused the vitamin A in the blood to rise rapidly but had no effect on the carotene content. The vitamin A levels reached and the length of time the higher levels were maintained depended upon the size of the supplement given. No correlation was evident between the amount of vitamin A in the blood and the biophotometer readings.

**The photocolometric determination of vitamin A and carotene in human plasma,** M. S. KIMBLE. (Univ. Wis.). (*Jour. Lab. and Clin. Med.*, 24 (1939), No. 10, pp. 1055-1065, figs. 2).—The method described in detail as to reagents, procedure, calculations, and corrections is essentially the Carr-Price method adapted for use with the Evelyn photoelectric macrocolorimeter with filters 440 and 620. Plasma (3.5-5.0 cc.) from oxalated blood is extracted with alcohol and petroleum ether, the pigments being retained in the alcohol layer, with the carotene and vitamin A going quantitatively into the petroleum ether layer. At this stage the yellow color of the carotene in the solution is deter-

mined in the colorimeter, using the 440 filter (blue). The reading obtained is used later to apply a correction, since the blue color of the Carr-Price reaction is due to vitamin A and carotene. The petroleum ether is removed from the colorimeter tube by aeration, and the residue taken up in chloroform. An  $\text{SbCl}_3$  blank and the tube containing the extract are placed in reading position in the colorimeter with filter 620 (red), the  $\text{SbCl}_3$  is added all at once to the unknown, and the reading of the galvanometer is recorded at the moment of momentary stability (which coincides with the height of the color formation). The rapidity of fading occurring after this rather than the point of color maximum is altered by impurities of the reagents; repurification and anaerobic handling of the latter were, therefore, not necessary with the use of the macro-instrument. The method gave consistent and reproducible results, the significant part of the experimental error being in the original extraction rather than in the subsequent steps of the determination.

"Results for plasma carotene and vitamin A are given for 30 men and 34 women in good health. While the figures for carotene were slightly higher on the average in the female group, those for vitamin A were found distinctly higher for the males than for the females, with averages 2.18 and  $1.56 \times 10^{-3}$  'L value' units roughly equivalent to 127 and 91 International Units of vitamin A per 100 cc. of plasma, respectively. Coefficients of variability for the vitamin values in the two groups were 0.229 and 0.237. Vitamin A appears to be present in the plasma in a relatively stable form, and to vary little under constant physiologic conditions in individuals who are not taking oil concentrates."

**The pathogenic and diagnostic significance of the carotene and vitamin A picture in serum** [trans. title], W. THIELE and I. SCHERFF (*Klin. Wchnschr.*, 18 (1939), No. 36, pp. 1208-1211).—Carotene and vitamin A were determined in the blood serum of patients suffering various pathological conditions. The photometric methods used are discussed briefly. Values for carotene in milligrams and vitamin A in International Units per 100 cc. of serum are reported, and the results are interpreted as permitting the following rather general conclusions:

A lower serum content of provitamin and vitamin A may be encountered as a transient condition in practically all diseased states. A higher vitamin A value is as good as never encountered in cases of malignancy. Simple enlargement of the thyroid gland (colloid goiter) does not in general lead to a decrease in serum vitamin A, although hyperthyroidism frequently leads to a lowering of the vitamin A level. The height of the carotene-vitamin A level in the serum in diabetes mellitus is probably not conditioned by diet alone but is often associated with lipemia.

**Experimental study of the influence of vitamin A on the thrombocytes and the bone marrow** [trans. title], J. ANAGNOSTU (*Klin. Wchnschr.*, 18 (1939), No. 38, pp. 1277-1279, figs. 3).—Young rats were used as the experimental animals. Of the six rats selected from each litter, four were given a vitamin A-free diet and two were continued as normal controls. At the beginning of avitaminosis (about 25 days), a count and qualitative study were made of the thrombocytes in all of the animals. This was repeated from time to time and finally, as the rats were killed, at intervals from the thirty-fifth to the fifty-second day of the diet period. At this time observations were made as to macroscopic changes in the organs and histological changes in the marrow of the femur.

It is concluded from the findings that vitamin A influences thrombocyte formation, and that a deficiency of the vitamin causes a decrease of 31-69 percent in the count. This decrease as a rule is independent of A-avitaminosis due to infection. Vitamin A also acts on the bone marrow. Under conditions of

A-avitaminosis there is a decrease in the cells, as well as a characteristic decrease in the eosinophiles, a complete atrophy of the bone marrow occurring at the same time. Vitamin A also apparently acts on the megakaryocytes, since vitamin A deficiency causes a decrease in the number of these cells and interferes with their development to the mature stage.

**Instruments and technics for the clinical testing of light sense, I-III,** L. L. SLOAN (*Arch. Ophthalmol.*, 21 (1939), No. 6, pp. 913-934; 22 (1939), No. 2, pp. 223-232, figs. 2; pp. 233-251, figs. 20).—This paper, which is of value to those undertaking dark adaptation studies to determine nutritional status with respect to vitamin A, is presented in three parts.

I. *Review of the recent literature.*—A critical review of the literature is presented, with numerous footnote references. In the evaluation of the instruments and methods reviewed, the following requirements of an ideal clinical instrument for testing light sense were considered: "(1) A preexposure field of constant brightness is desirable in order that the initial level of adaptation of the eye may be standardized. (2) Means should be provided for illuminating the test field with light of a known composition, variable in intensity by known amounts over a wide range. (3) Since retinal illumination increases with the area of the pupil, there should be some method of eliminating or correcting for this variable factor. (4) Means should be provided for the control of fixation, since the light sense varies in different regions of the retina. (5) In order to distinguish between pathologic and normal sensitivity to light, the range of variation in a sufficiently large group of nonpathologic eyes should be known."

In the opinion of the author a number of problems require further investigation before tests of light sense can be considered of much value in clinical ophthalmology. Among these are the standardization of variable factors such as the level of previous light adaptation, pupil size, region of the retina tested, and means of controlling fixation; suitable criteria for distinguishing between pathologic and normal sensitivity to light; and the range in variation in normal eyes and determinations of the borderline between normal and pathologic.

II. *Control of fixation in the dark-adapted eye.*—A comparison is reported of the adequacy of different methods of fixation control for use in tests of the dark-adapted eye. By the use of the location of the Mariotte blind spot as an indicator of the direction of fixation, it was demonstrated that foveal fixation is maintained in the dark-adapted eye with a luminous red-fixation target, and that this device can be used in testing the light sense of any region of the retina except the fovea itself. For this point a perifoveal fixation target composed of four spots of luminous paint, with a 6° angular distance between the upper and lower and the right and left spots, was devised and found to be fairly satisfactory.

III. *An apparatus for studying regional differences in light sense.*—An instrument devised to fulfill the five requirements enumerated in part 1, and also to provide means for testing the light minimum in any region of the retina, is described and illustrated by photographs and diagram, and the results obtained with its use in preliminary tests on one normal subject and five with various pathological conditions of the eye are presented. In these tests two of the specific requirements of the ideal instrument were ignored—standardization of pupil size and norms for distinguishing between pathologic and normal light thresholds.

It is concluded from these preliminary studies that different forms of ocular pathologic conditions may be associated with deficiencies in sensitivity to light which differ both qualitatively and quantitatively, but that further detailed studies are needed to determine the types of defect in light sense characteristic

of different forms of ocular pathologic conditions. "Previous studies have emphasized chiefly the rate of dark adaptation and have paid little attention to regional differences in sensitivity."

**The water-soluble B-vitamins, XIII, XIV, M. M. EL-SADR, T. F. MACRAE, and C. E. WORK** (*Biochem. Jour.*, 33 (1939), No. 4, pp. 601-610, 611, 612).—This is a continuation of the series of papers, most of which have been noted previously.

**XIII. Alloxazine-adenine-dinucleotide, adenylic acid, nicotinamide, and pimelic acid in the nutrition of the rat.**—Experiments are reported in which the possibility was studied of replacing for the nutrition of the rat certain of the recognized members of the vitamin B<sub>2</sub> complex by other biologically important substances, including (1) alloxazine-adenine-dinucleotide as a substitute for riboflavin and possibly some other member of the complex, (2) a combination of yeast adenylic acid and nicotinamide as a substitute for yeast filtrate or yeast eluate factors or the additional unidentified factor in the vitamin B<sub>2</sub> complex, and (3) pimelic acid as a substitute for yeast filtrate factor.

Alloxazine-adenine-dinucleotide proved capable of replacing equimolecular amounts of riboflavin but no other member of the complex. The combination of adenylic acid and nicotinamide proved incapable of replacing either the yeast eluate factor or the yeast filtrate factor for growth and did not prevent the development of dermatitis in rats deprived of the eluate factor. Pimelic acid had no growth-promoting effect when substituted for the yeast filtrate factor.

**XIV. Note on the yeast eluate factor of the vitamin B<sub>2</sub> complex.**—By means of a comparison of a sample of the Lepkovsky crystalline factor I (E. S. R., 80, p. 239) with the authors' yeast eluate factor, it was definitely proved that the two are identical. When the Lepkovsky fractionation method for factor I was applied to concentrates of the eluate factor, a small amount of crystalline material was obtained which had the same melting point as factor I and also gave similar red coloration with FeCl<sub>2</sub> to that reported for vitamin B<sub>2</sub>. In rat growth experiments crystalline factor I promoted growth of the same order as previously observed with the yeast eluate factor. In unpublished experiments by H. Chick, factor I also cured the florid type of rat dermatitis. "The identity of vitamin B<sub>2</sub>, factor I, and yeast eluate factor is therefore established."

**The site of action of four water-soluble vitamins, S. MAURER** (*Jour. Amer. Dietet. Assoc.*, 15 (1939), No. 8, pp. 659-666).—This brief review, presented as an address, is concerned with the action in the cells of vitamins C, B<sub>1</sub>, and B<sub>2</sub> and nicotinic acid as part of the oxidation-reduction enzyme system.

**Some clinical neurologic aspects of vitamin B deficiencies, C. D. ARING, J. P. EVANS, and T. D. SPIES** (*Jour. Amer. Med. Assoc.*, 113 (1939), No. 24, pp. 2105-2110, figs. 4).—The use of vitamin B<sub>1</sub> and nicotinic acid in the treatment of various neurological diseases is discussed, and practical dietary advice is given for decreasing vitamin B<sub>1</sub> deficiencies among the general population in government or other institutions where mass feeding is required and among persons with chronic debilitating diseases. Indications, with recommended dosage, are also given for supplementary treatment with pure vitamin B<sub>1</sub> and nicotinic acid orally and parenterally.

**The need for the addition of vitamin B<sub>1</sub> to staple American foods, G. R. COWGILL** (*Jour. Amer. Med. Assoc.*, 113 (1939), No. 24, pp. 2146-2151).—This report, authorized for publication by the Council on Foods of the American Medical Association, brings together evidence from the examination of available food statistics and recently collected American dietaries and the observations of clinicians leading to the conclusion that American dietaries as a whole are unsatisfactory with respect to their content of vitamin B<sub>1</sub>. Practical methods

of improving the situation are suggested, with particular emphasis on the addition of the vitamin in suitable quantities to wheat flour. "It is believed that prosecution of a program fostering addition of vitamin B<sub>1</sub> to staple American foods according to the principles discussed in the present report would be definitely in the interests of the public."

**The chemical determination of vitamin B<sub>1</sub> and cocarboxylase in organs** [trans. title], F. WIDENBAUER (*Klin. Wchnschr.*, 18 (1939), No. 52, pp. 1613, 1614).—A thiochrome method somewhat similar to that of Westenbrink and Goudsmit (*E. S. R.*, 81, p. 454) is described. The present procedure eliminates the adsorption of the vitamin on fuller's earth and subsequent extraction with isobutanol, thereby eliminating any error from this step. Total vitamin B<sub>1</sub> may be determined directly on the extract of the tissue prepared by weak acid digestion followed by peptic digestion; with the omission of the isobutanol and of the ferricyanide reagent in this determination, it is claimed that the development of fluorescence by nonspecific substances from the animal tissue is lessened and that the test solution and the standard are more nearly comparable. Greater ease of determination is further attained in that the method permits of the reading of the intensity of fluorescence with the naked eye. Figures for total and free aneurin are reported for liver, kidney, brain, heart, and lung of normal guinea pigs and of normal rats and those in conditions of hypovitaminosis and avitaminosis.

**The glycogen content of the liver in vitamin B<sub>1</sub>-deficient rats** [trans. title], V. S. HERMANN (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 262 (1939), No. 3-5, pp. 95-102).—Groups of rats on a vitamin B<sub>1</sub>-free diet were sacrificed at weekly intervals from the second to the sixth week for determinations of the glycogen content of their livers. Average values for from 4 to 7 animals in each group were 3.59, 4.97, 3.01, 2.92, and 2.12 mg. percent. In two other series groups of 3 animals each on a vitamin B<sub>1</sub>-free diet were given subcutaneous injections of vitamin B<sub>1</sub> in doses of 5 $\gamma$  for one group and 1 mg. for the other on the tenth, twentieth, and fortieth days of subsistence on the vitamin B<sub>1</sub>-free diet. In the groups receiving 5 $\gamma$  the glycogen values were 4.00, 3.10, and 6.90 and in the groups receiving 1 mg., 5.04, 3.52, and 4.05 mg. percent respectively.

**Reduction of the d-amino-acid oxidase content of rat tissues in riboflavin deficiency**, A. E. AXELROD, H. A. SOBER, and C. A. ELVEHJEM. (Univ. Wis.). (*Nature [London]*, 144 (1939), No. 3650, pp. 670, 671).—Rats were depleted for 6 weeks on the riboflavin-deficient diet of Elvehjem, Koehn, and Oleson (*E. S. R.*, 78, p. 285) and then fed for 2 weeks in groups of 5-7 each supplements of the W factor and riboflavin, alone and combined, after which they were sacrificed, and d-amino acid oxidase content was determined in suspensions of liver and kidney cortex. As controls other groups were fed the basal diet alone and a normal stock diet. The liver values increased in the order basal diet alone, with factor W, and with flavin, normal stock diet, basal diet+factor W+flavin ad libitum, and the same with food intake restricted to that of the animals on the basal diet alone. Values for kidney cortex increased in essentially the same order. "These results indicate the importance of riboflavin in the synthesis of the prosthetic group of d-amino acid oxidase, and that other members of the B complex may also be related to the formation of this enzyme."

**Flavin-adenine-dinucleotide in tissues of rats on diet deficient in flavin**, S. OCHOA and R. J. ROSSITER (*Nature [London]*, 144 (1939), No. 3653, p. 787).—Attention is called to the demonstration by Ochoa and Peters (*E. S. R.*, 82, p. 278) of a decreased content of cocarboxylase in the tissues of pigeons fed

a vitamin B<sub>1</sub>-deficient diet, and by Axelrod and Elvehjem (E. S. R., 81, p. 877) of a decrease in the cozymase content of tissues of dogs and pigs on a nicotinic acid-free diet. Evidence is now furnished of a similar diminution in the flavin-adenine-dinucleotide content of boiled extracts of tissues of rats fed a flavin-deficient diet. Differences were shown in all of the tissues tested (brain, heart, kidney, and liver), but were particularly marked in heart and liver tissues. The differences in the means of these tissues were clearly significant by the Fisher *t* test and are thought to "afford direct evidence of a further instance of a deficiency in the vitamin B complex affecting biological oxidation systems." A note added in proof calls attention to the similar findings of Axelrod, Sober, and Elvehjem noted above.

**Experimental contribution to the question of the relation between vitamin B<sub>2</sub> (lactoflavin) and the thyroid gland** [trans. title], H. WAHL (*Klin. Wchnschr.*, 18 (1939), No. 42, pp. 1363-1365, figs. 2).—The effect of injected lactoflavin on basal metabolism, weight curves, and histological changes in the thyroid was studied in 47 guinea pigs, some of them having normal thyroid activity and others having hyperthyroidism induced experimentally by thyrotropic hormone. The results are interpreted to indicate that the increase in metabolic rate brought about by the injection of thyrotropic hormone was enhanced by the lactoflavin, which of itself exerted no apparent effect on the basal metabolism of normal animals. The course of the weight curves as affected by the hormone was not appreciably changed by the simultaneous administration of lactoflavin. The lactoflavin alone did not influence the histological picture of normal thyroids, nor did it appear to change the picture characteristically produced by the action of the thyrotropic hormone alone.

**Vitamin B<sub>3</sub> and skin lesions in rats**, P. GYÖRGY and R. E. ECKHARDT (*Nature [London]*, 144 (1939), No. 3646, p. 512).—Three more or less distinct types of lesions observed in a group of over 100 rats on a vitamin B<sub>3</sub>-free diet after cure of the specific dermatitis or acrodynia by natural or synthetic vitamin B<sub>3</sub> are described. These include, in addition to the type described in a previous note (E. S. R., 83, p. 568), a type characterized by matting of the hair over the abdomen, loss of hair around the chin, nose, and eyes, brown scales on the cheeks, abdomen, and forehead, emaciation, and inanition; and a type more rarely seen which corresponds to descriptions by the California (E. S. R., 76, p. 839) and Wisconsin (E. S. R., 81, p. 450) investigators of rats with watery eyes which stick together and sore mouth. It is pointed out that, in view of the fact that the part played by the vitamin B<sub>2</sub> complex in skin conditions has extended beyond vitamin B<sub>2</sub> the designation of this vitamin as adermin is misleading. "In accordance with the chemical nature of vitamin B<sub>3</sub>, which is a pyridine derivative containing several oxy (methoxy) groups, the term pyridoxin appears to be appropriate."

**Nicotinic acid content of some foodstuffs** [trans. title], F. DEL REGNO (*Quad. Nutr.*, 6 (1939), No. 4, pp. 368-373).—Nicotinic acid was determined in 43 samples of foods, including cereals and cereal products, legumes, fruits, vegetables, nuts, and milk. The determinations were made on water extracts and four values are reported in each case; these represent the results of determinations made by acid (0.1 N H<sub>2</sub>SO<sub>4</sub>) and by alkaline (0.1 N KOH) hydrolysis of the extract, combined with removal of the products of protein hydrolysis by precipitation with lead acetate or barium hydroxide. Recovery experiments indicated that acid hydrolysis combined with defecation with lead acetate gave the most satisfactory results, although all four procedures agreed fairly well. The nicotinic acid was determined finally by photocolometric procedure employing the reaction with cyanogen bromide and aniline.

**Nicotinic acid amide and cozymase in blood** [trans. title], H. V. EULER and F. SCHLENK (*Klin. Wchnschr.*, 18 (1939), No. 33, pp. 1109-1111).—Cozymase in blood, determined by a fermentation procedure after preliminary inactivation of blood enzymes by heating, amounted to from 40 $\gamma$  to 80 $\gamma$ , 50 $\gamma$ , 60 $\gamma$ , 100 $\gamma$ , and 150 $\gamma$  per cubic centimeter in human, rat, rabbit, ox, and horse blood, respectively. Nearly all of it was in the corpuscles. Quantities of 200 $\gamma$ , 150 $\gamma$ , 160 $\gamma$ , and 220 $\gamma$  per gram of fresh tissue were found in rat muscle, heart, kidney, and liver, respectively, while 140 $\gamma$  and 150 $\gamma$  per gram were found in rabbit brain and nerve.

Nicotinic acid amide, determined by a colorimetric procedure with cyanogen bromide and aqueous aniline as reagents, was found in human blood and erythrocytes, and in ox, rabbit, and rat blood, for which values of 1.5 $\gamma$  per cubic centimeter, 3 $\gamma$  per gram, and 2 $\gamma$ , 3.3 $\gamma$ , and 3 $\gamma$  per cubic centimeter, respectively, are reported.

Intravenous injection of 40 mg. of nicotinic acid in one subject failed to increase the free nicotinic acid amide, which amounted to 1 $\gamma$  per cubic centimeter of blood before and after the injection, but did increase the cozymase content in 40 min. from 40 $\gamma$  to 50 $\gamma$  per cubic centimeter. This increase in cozymase corresponded to 1.8 $\gamma$  of nicotinic acid amide per cubic centimeter. Assuming a total blood volume of 4.5 l., the 40-mg. injection should have amounted to about 9 $\gamma$  of nicotinic acid per cubic centimeter. Apparently, therefore, about four-fifths of the injected nicotinic acid amide disappeared from the blood stream in 40 min. A study of human urine indicated that nicotinic acid amide and the acid itself occurred in about equal quantities, varying from 5 to 25 mg. per day. Following oral administration of 1 gm. of nicotinic acid, about 10 percent of it was excreted in the urine in 2 days, urinary values returning to normal after that time.

**The retention of nicotinic acid in the body fluids in pellagra and in health** [trans. title], W. W. KÜHNAU (*Klin. Wchnschr.*, 18 (1939), No. 41, pp. 1333, 1334, figs. 2).—Nicotinic acid in human blood was found to vary from 250 $\gamma$  to 450 $\gamma$  percent in normal persons and from 75 $\gamma$  to 180 $\gamma$  percent in four pellagrins studied. In the normal individuals urinary elimination varied from 50 $\gamma$  to 300 $\gamma$  percent and in the four pellagrins from 64 $\gamma$  to 105 $\gamma$  percent. Tests on a normal individual in an optimal nutritional state and on a pellagrin, both receiving 0.1 gm. of nicotinic acid daily, showed that urinary elimination in the two subjects was very similar, amounting to from 2 to 4 percent of the daily intake. Upon remission of symptoms in the pellagrin there was still no change in the urinary elimination. Upon increase of dosage to 0.3 and 0.5 gm. daily in another patient no greater increase in urinary excretion was observed. Two pellagrins with decided neurological symptoms gave the unexpectedly high values of 100 $\gamma$  and 220 $\gamma$  percent, respectively, of nicotinic acid in the cerebral spinal fluid. The blood content amounted to 180 $\gamma$  and 140 $\gamma$  percent, respectively. Another pellagrin presented, however, the low blood value of 70 $\gamma$  percent.

**Avitaminosis occurring in diabetic patients under insulin therapy**, V. P. SYDENSTRICKER, L. E. GEESLIN, and J. W. WEAVER. (Univ. Ga.). (*Jour. Amer. Med. Assoc.*, 113 (1939), No. 24, pp. 2137, 2138).—Three case reports are presented in substantiation of the hypothesis that the glossitis and stomatitis frequently occurring in diabetes with insulin treatment is an avitaminosis caused by abnormal carbohydrate metabolism. Two of the patients developed clinical signs of pellagra when the carbohydrate content of the diet was increased and added insulin was given. The glossitis and mental symptoms were controlled by nicotinic acid. In the other patient both riboflavin and nicotinic acid were required for improvement in the symptoms of avitaminosis. The rapid metabolism of

carbohydrate brought about by the use of insulin is thought to have resulted, in the cases reported, in a rapid depletion of coenzymes.

**Determinations of ascorbic acid content of fruits and fruit products, some vegetables, and other plants** [trans. title], E. JOHANSSON (*Årsskr. Alnarps Lantbr., Mejeri- o. Trädgårdsinst., 1939, pp. 53, figs. 2; Eng. abs., pp. 48-52*).—Ascorbic acid, as determined by titration with 2,6-dichlorophenolindophenol, is reported for about 150 varieties of apples, 50 of pears, 25 of plums, 9 of cherries, and a number of varieties of gooseberries, currants, raspberries, and strawberries; values are also reported for rose hips and fruits of *Cotoneaster*, *Crataegus*, *Sorbus*, *Berberis*, and a few other plants including rhubarb. Most of the fresh fruits were analyzed at the most suitable stage of ripeness. Among the vegetables, data are reported for potatoes (raw and cooked), tomatoes, radishes, cucumbers, and lettuce. Nearly all of the material analyzed was grown at Alnarp.

**The photochemical decomposition of ascorbic acid in black-currant sirup**, H. T. FAWNS (*Jour. Soc. Chem. Indus., Trans., 58 (1939), No. 5, pp. 193, 194*).—The process followed in making black-currant sirup on a commercial scale is outlined, and data are reported on the ascorbic acid content of samples of the sirup kept for nearly a year in the light and dark at room temperature and in a refrigerator and on the losses of ascorbic acid in sirup kept in bulk storage in the dark for 435 days and a sample from the same lot kept in the light for 152 days. Color measurements were made on diluted samples of this sirup at the same time as the ascorbic acid determinations.

The preliminary small-scale study showed a considerably lower content of ascorbic acid in the samples exposed to light than in those stored in the dark but with little difference between the latter and the sample kept in the refrigerator. The sirup used in the later tests had an original reduced ascorbic acid content of 80 mg. per 100 cc. Bulk storage in the dark resulted in an ascorbic acid loss of 14.7 percent, while storage in the light for a shorter period resulted in a loss of 21.7 percent. No reversibly oxidized ascorbic acid could be detected in the original sample, but values of 1.0 and 1.6 mg. per 100 cc. were obtained for the samples stored in the dark and light, respectively.

Noticeable fading of the sirup in the light was confirmed by the color tests, which showed total color losses of 19.2 percent in the dark and 38.3 percent in the light. The color pigment was composed chiefly of red, with a small admixture of yellow. It is thought that the dark color of the juice may act as a protective pigment for the vitamin.

The extremely high content of ascorbic acid in black currants and sirup has been reported previously by Olliver (E. S. R., 78, p. 430).

**One hundred and sixty days on a vitamin C-free diet: Observations on humans** [trans. title], H. RIETSCHEL and H. SCHICK (*Klin. Wchnschr., 18 (1939), No. 39, pp. 1285-1289*).—This report presents the case history of a man maintained on a diet of vegetables, cooked with soda, and fresh well-cooked meat for a period of 160 days. Erythrocyte and differential count, plasma ascorbic acid, and general physical condition were observed carefully over this period. The plasma ascorbic acid fell from 0.9 mg. percent at the beginning of the study to 0.5 mg. percent on the twenty-first day, then rather gradually to 0.15 and 0.05 mg. percent on the eighty-fifth and one hundred and sixteenth days, respectively, and remained at the lower level until the end of the experiment. No symptoms were observed that were considered indicative of scurvy. The behavior of this man and the experiences of the polar explorers Nansen and Stefansson that are cited are interpreted to indicate that such meat-containing diets must furnish at least traces of vitamin C. It is the opinion of the authors that ordinary diets are almost never deficient in vitamin C.

**The influence of nicotine on vitamin C metabolism** [trans. title], L. H. STRAUSS and P. SCHEER (*Ztschr. Vitaminforsch.*, 9 (1939), No. 1-2, pp. 39-48, figs. 5; *Fr., Eng. abs.*, p. 47).—Thirty healthy men and women from 18 to 40 yr. of age were used as subjects in this study of the effect of nicotine, as obtained from cigarette smoking, on ascorbic acid excretion. The subjects, in a state of vitamin C saturation, were given a test dose of 200 mg. of ascorbic acid and samples of urine collected immediately preceding the test dose and 1, 3, 5, 7, and 24 hr. after. The same subjects were tested without smoking and after smoking from one to three cigarettes. The smoking was followed by constant and marked reduction in urinary ascorbic acid. Similar results were obtained with vitamin B<sub>1</sub>. The changes are thought to be related to the endocrine mechanism (thyroid and adrenal) and to the vegetative nervous system and to involve an increase of endocrine activity and a higher level of general oxidative processes.

**The vitamin C picture in blood and the question of vitamin C deficiency** [trans. title], W. v. DRIGALSKI (*Klin. Wchnschr.*, 18 (1939), No. 31, pp. 1056-1058).—Long-time studies of 7-14 weeks' duration were made of the vitamin C content of the blood of several men of approximately the same age receiving the same institution diet poor in vitamin C. For different periods (8 days to 9 weeks) daily vitamin C supplements varying from 50 to 400 mg. were given orally, synthetic vitamin C or lemons serving as the supplement. The vitamin C determinations were carried out on 2 cc. of oxalated blood immediately after withdrawal by the method (slightly modified) of Farmer and Abt (*E. S. R.*, 75, p. 588).

The results showed spontaneous variations in the blood picture of any one individual on a constant regime, the highest value obtained being as much as twice the minimum. Variations from person to person on the same regime were also noted, the average value on the vitamin C-poor diet being 0.2 mg. percent, 0.4, 0.2, 0.5, and 0.7 mg. percent, respectively, for the various individuals. During the course of the study all of the subjects suffered from infections similar to grippe, but neither the onset nor the course of the attack seemed to bear any relation to the vitamin C level, nor did the vitamin C level of the blood seem to be influenced by the infection. The blood picture was always low on the vitamin C-poor diet and high on the diet rich in vitamin C. It is considered that the most that can be claimed is that values over 1.0 mg. percent are indicative of a C-rich diet and those below 0.5 mg. percent of a C-poor diet, further distinctions not being tenable. It is concluded that individual variations in the vitamin C blood picture are not referable to diet but to constitutional differences in individual vitamin metabolism and that low vitamin C content of the serum cannot be considered as indicative of hypovitaminosis.

**The condition of the blood in malaria under treatment with vitamin C injection** [trans. title], I. GERDJKOFF (*Klin. Wchnschr.*, 18 (1939), No. 36, pp. 1214-1217, figs. 7).—Blood and temperature changes were followed in 12 malaria patients receiving 0.5 gm. of vitamin C daily (0.2 gm. by intramuscular injection and 0.3 gm. orally) and specific malaria therapy at given times. Reticulocyte and erythrocyte counts, hemoglobin percentage, percentage of hemolysis, and sedimentation rate were observed. The findings, presented by graph, are related to periods of vitamin and specific therapy and to the occurrence (above 5 mg. percent as representative of saturation) of vitamin C in the urine.

The results are interpreted as indicating that considerable vitamin C deficiency occurs in malaria, this retarding the usual increase in reticulocytes under specific therapy; that disturbances in the course of recovery can lead to renewed reticulocyte rise associated with increased need for vitamin C, as shown by

decreased elimination; and that in vitamin C-saturated cases, more quickly than in nonsaturated cases, the reticulocyte values tend toward normal after building up to a maximum. It is considered advisable, therefore, to employ vitamin C therapy along with specific therapy in the treatment of malaria.

**The influence of vitamin C (l-ascorbic acid) on immunity processes** [trans. title], H. J. JUSATZ (*Ztschr. Vitaminforsch.*, 9 (1939), No. 1-2, pp. 75-95).—An extensive review, with numerous literature references.

**The vitamin-D potency of different fish and fish products**, V. ASCHEHOUG, H. KRINGSTAD, and G. LUNDE (*Jour. Soc. Chem. Indus., Trans.*, 58 (1939), No. 6, pp. 220-223).—The oil obtained by ether extraction of the various fish and fish products was assayed for vitamin D potency. The method involved the radiographic measurement of the initial degree of rickets produced in rats on the Sherman and Pappenheimer diet and of the subsequent healing through calcification produced over a test period of 10 days by daily doses of 70-117 mg. of the test oil (diluted with peanut oil).

The 12 samples of "sild" sardines (small herring) packed in olive oil in tin and aluminum containers had a vitamin D potency in the extracted oil varying from 15 to 45 International Units per gram, equaling 390-1,000 I. U. per 100 gm. of the canned product. Storage apparently had no unfavorable influence, since some of the samples were 7-9 yr. old. The assay values for the other products calculated as I. U. per 100 gm. are reported as follows: Canned cod (*Gadus morrhua*) roe, 85; mackerel (*Scomber scombrus*) liver, 11,300; mackerel flesh, 1,100; red char (*Salmo alpinus*), salted, 1,120; tuna (*Thunnus thynnus*), ventral part, 1,570, dorsal part, 430; dogfish (*Squalus acanthias*) liver, 2,420; and shrimp (*Pandalus borealis*), 150 I. U.

## TEXTILES AND CLOTHING

**Diameter relationships of wool fibers from five breeds of sheep raised in South Dakota**, B. BAILEY. (S. Dak. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 60 (1940), No. 6, pp. 415-426).—Data are presented on average diameters and average fiber contour ratios of wool fiber samples from the shoulder, middle, and thigh regions of 11 Hampshire, 11 Southdown, 6 Rambouillet, 6 Shropshire, and 20 crossbred individuals. Wide variations in diameters existed between sheep within a breed and, in most instances, between breeds. Contour ratios were generally higher than 1:1.20. In about half the cases (except crossbreds) the fiber contour increased positively as fiber diameters of the various portions of the individual fleece increased. In 3 breeds standard deviation tended to increase as the contour increased, but no such relationship existed for the other 2 breeds. Sheep representing a breed were shown to be heterogeneous groups, so that it was impossible to report a single value for the breeds, with the possible exception of Shropshire.

**Quality control in a woolen mill**, W. VON BERGEN (*Amer. Dyestuff Rptr.*, 29 (1940), No. 4, pp. P84-P92, figs. 19).—This general survey, presented as an address, indicates briefly the work done in the chemical, physical, and optical departments toward control of the wool as it changes from the raw stage and loose form into sliver, top, yarn, and fabric. The determination of shrinkage, fat, size, and acid content; control of light fastness; moisture determination; control of count, twist, strength, and abrasion; and grading of the wool are considered. Methods are outlined and the instruments are illustrated.

**Quality in cotton fabrics determined by research**, E. H. WHARTON. (U. S. D. A.). (*Forecast*, 56 (1940), No. 4, pp. 186, 187, 224-226, figs. 5).—This survey briefly the work of the Bureau of Home Economics in determining physical

structure and durability of various cotton materials, in establishing quality guides and buying standards for cotton materials and manufactured cotton goods, in the study of waterproofing and crease-resisting processes, in developing hose designs, in improving the construction of cotton hose, and in studying various phases of the problem of more effective household utilization of cotton.

### MISCELLANEOUS

**Annual Report [of Florida Station], 1939**, W. NEWELL ET AL. (*Florida Sta. Rpt. 1939*, pp. 195-VII, figs. 15).—The experimental work not previously referred to is for the most part abstracted elsewhere in this issue.

**Nineteenth Annual Report [of the Georgia Coastal Plain Station], 1939**, S. H. STARR (*Georgia Coastal Plain Sta. Bul. 30 (1939)*, pp. 133, figs. 20).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

**Mississippi Farm Research, [June 1940]** (*Miss. Farm Res. [Mississippi Sta.], 3 (1940), No. 6*, pp. 8, figs. 5).—In addition to articles noted elsewhere in this issue, this number contains one entitled Varied Attacks Successfully Used for Control of Ants, by C. Lyle.

**Organization for agricultural research and problems under investigation: Forty-fifth Annual Report of the Montana Agricultural Experiment Station, [1938]**, C. MCKEE ET AL. (*Montana Sta. Rpt. 1938*, pp. 64, fig. 1).—This gives brief statements regarding the functions of the various departments and substations, with a list of active projects and their objectives.

**Sixtieth Annual Report of the New Jersey State Agricultural Experiment Station and the Fifty-second Annual Report of the New Jersey Agricultural College Experiment Station for the year ending June 30, 1939**, W. H. MARTIN (*New Jersey Stas. Rpt. 1939*, pp. [7]+183, pl. 1).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

**Annual Report of [Puerto Rico College Station, 1939]**, J. A. B. NOLLA ET AL. (*Puerto Rico Col. Sta. Rpt. 1939*, pp. XIII+102, figs. 22).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

## NOTES

---

**Georgia Station.**—A six-room brick building has been completed for the nutrition laboratory of the department of home economics. L. N. Skold has been appointed assistant agronomist for work with small grain and soybean breeding.

**Illinois University and Station.**—Additions to the staff include Dr. K. E. Gardner as associate in dairy husbandry extension; Dr. Nellie L. Perkins, associate professor of home economics; and the following assistants: L. D. Malotky in agricultural economics, E. G. Mosbacher in rural sociology, Julia Ann Franklin in soil survey publications, M. H. Nelson in soil experiment fields, S. W. Melsted in soil survey analysis, F. C. Francis in animal husbandry, U. S. Garrigus in animal genetics, and June Y. Foster in home economics.

**Maryland Station.**—A new set of buildings is being erected for station work with W. P. A. aid to cost approximately \$30,000. A new building has been occupied by the poultry department. New greenhouses have also been completed, and experiments are in progress.

**Minnesota University and Station.**—Dean E. M. Freeman, head of the division of plant pathology and botany, relinquished administrative direction of the division on July 1 to Dr. E. C. Stakman, but is continuing as professor of plant pathology. A. J. Schwantes, acting chief of the division of agricultural engineering, has been appointed professor and chief.

**North Dakota Station.**—The station is cooperating with the State Water Conservation Commission and other agencies in conducting experimental work in irrigation on the Lewis and Clark Irrigation Project in the northern part of McKenzie County. Funds for the purchase of the land were obtained by the Williston Chamber of Commerce. The National Youth Administration is supplying labor and some materials, and the department of vocational agriculture in the Williston High School the immediate field supervision.

**Rhode Island Station.**—Andrew E. Stene, pomologist, retired effective August 31. Bradford D. Crossmon, assistant agricultural economist, resigned August 15. Recent appointments include Dr. Alexander Joss, Lyle M. Murphy, and Dr. Wendell L. Bartholdi as assistants in agricultural economics, pomology, and agronomy, respectively.

**Washington College and Station.**—Dr. R. E. Ward, acting assistant professor and assistant in dairy husbandry, has resigned to accept a position in Massachusetts. Recent appointments include Dr. Jennie A. McIntosh as nutrition chemist in the home economics division vice Ruth C. Robbins, resigned, and the following research assistants: F. J. Meade in animal husbandry vice William H. Burkitt, resigned; Dr. Robert J. Evans in poultry husbandry vice L. A. Wilhelm, resigned; J. Roberts in farm electricity vice W. A. Junnila, resigned; Clayton Plueger and Harris O. Van Orden in dairy husbandry; and Harold H. Dodge in entomology.

**Wisconsin University and Station.**—Leonard A. Salter, Jr., a senior agricultural economist in the Division of Land Economics of the U. S. D. A. Bureau of Agricultural Economics, has been appointed professor of agricultural economics, beginning September 1. and will give special attention to teaching and research in land economics.

**Wyoming Station.**—New station greenhouses are nearing completion. These greenhouses consist of three glass units, each 26 by 60 ft., and a head house

115 ft. long and 18 to 24 ft. wide. Two of the glass units are equipped with benches, while the third will be filled with soil to the ground level, a portion with selenium shales for use in studies of various selenium problems. One of the bench houses will be used for the testing of certified seed potatoes in tuber-index and hill-index work and the growing of potato seedlings. The remaining bench unit is for the use of research chemistry, botany, soils, and agronomy workers. The head house includes on the main floor a large workroom for general greenhouse work, a research laboratory, and a classroom, with adjacent storerooms or workrooms and an office. Beneath this portion are several cold-storage rooms, a room for caretakers, and a fumigation and steam-sterilization room. The central portion of the building will be higher and wider than the end wings, providing space for dry storage for seeds, grain, specimens for class use, and the like and connecting with the lower floor by stairs and elevator.

Robert F. Eslick and John F. Cykler have been appointed instructors in the department of agronomy and agricultural economics.

**University of the Philippines.**—Dr. N. B. Mendiola, professor and head of the department of agronomy, has been appointed director of research in the College of Agriculture. Dr. Leon G. Gonzalez has been appointed acting head of the department of agronomy.

**V. R. Williams Prizes.**—According to a note in *Nature*, the Timiryazev Agricultural Academy in Moskva has founded three prizes in memory of the late Prof. V. R. Williams. These prizes are 5,000, 3,000, and 1,500 rubles, respectively, and are to be awarded annually for work on soil study and cultivation.

**Journal Changes.**—The publication of *Chronica Botanica* has been transferred from the Netherlands to the United States. The journal will contain the same type of material as formerly, but will be published fortnightly. Its editor, Dr. Frans Verdoorn, will continue in charge, his address being P. O. Box 151, Waltham, Mass. Announcement is further made that his new series of Plant Science Books is also being continued, and that the first American list will be issued early in 1941.

*International Bulletin of Agricultural Law* is being issued by the International Institute of Agriculture at Roma, supplementing *Annuaire International de Législation Agricole* by discussions of important agricultural measures and their judicial interpretation. The opening article in the initial number is entitled All-Risk Wheat Crop Insurance in the United States of America Under the Federal Crop Insurance Act of 1938, by R. H. Shields and H. Donoho.

*The Virginia Journal of Science* is being published monthly from October to May, inclusive, at Charlottesville, Va., as the official journal of the Virginia Academy of Science. The botanical journal *Claytonia* has been merged with it, and it is hoped to include other phases of sciences. The initial number contains as its leading article Mixed Deciduous Forests of the Appalachians, by E. L. Braun.

*Revista de la Sociedad Mexicana de Historia Natural* is being published quarterly by the Mexican Society of Natural Science at Apartado Postal 1079, México, D. F. Among the articles in the initial number is one on the Introduction of Para Grass Into Mexico, by G. Itie.

Owing to a shortage of paper, it has been decided to suspend the publication of the *Cyprus Agricultural Journal* for the present.

## DEAN MUMFORD'S EVALUATION OF THE LAND-GRANT COLLEGE MOVEMENT

Some months ago the suggestion was made in these columns (E. S. R., 82, p. 433) of the desirability of utilizing in agricultural historical research "competent persons no longer available for full-time employment." A striking illustration of the possibilities in this direction is now at hand following the publication as Bulletin 419 of the Missouri Experiment Station of a unique contribution from the pen of Dean and Director Emeritus Frederick B. Mumford. This publication was undertaken by him when he retired in 1938 because of the university age limit for regular service. The bulletin contains 140 pages, is entitled "The Land Grant College Movement," and is announced as the first of what it is hoped will be a series which he will prepare covering the field of agricultural education.

Dean Mumford states that he "has not attempted to write another history or duplicate the many excellent treatises relating to the land-grant colleges and universities." Attention has rather been concentrated on "the underlying philosophy of the colleges of agriculture and their influence upon the social, intellectual, and economic life of rural people and the public generally." Some effort has also been made "to evaluate the influence of the land-grant college and university on all education."

For the task thus undertaken, the author "claims no special qualification," although acknowledging that he has been "associated with colleges of agriculture for 50 years as student, instructor, and dean and director," and that during this period he has been "permitted to be an active participant in an educational movement of major importance." An introduction to the bulletin by Dean and Director M. F. Miller adds to this modest statement the well-recognized fact that Dean Mumford "is one of those men who has been very influential in determining the remarkable development of these institutions," and that he "brings to the task of evaluating the work of the land-grant colleges not only a great faith in their future, but a wealth of administrative experience in the field of agricultural education and a knowledge of these institutions possessed by very few men. It

is his exceptional familiarity with this entire field that makes his statements authoritative."

The material in the bulletin is arranged in four parts. Of these, part 1, *The American Land Grant College*, discusses the legislation establishing these institutions, their objectives, early struggles and criticisms, the evolution of the agricultural curriculum, and the relation which this group bears to vocational education and to liberal culture. Part 2, *Development of the Land Grant Colleges*, takes up such matters as requirements for admission, experience with the manual labor requirement, motives and underlying spirit activating the colleges, their contribution to economic life and to society, Federal relations and Federal-State cooperation, and the Association of Land-Grant Colleges and Universities. Part 3 is devoted to the agricultural experiment stations, and part 4 to the agricultural extension service. This arrangement subordinates chronology to functional organization and has many advantages in a critical evaluation of this type.

Dean Mumford finds that from very humble beginnings, considerable opposition and misunderstanding, and much groping and uncertainty, the American land-grant college has come to occupy "a position of exceptional influence and popularity in our modern life. It is unique among educational institutions of the United States in its insistence upon democracy in education; its close cooperation with a basic industry; the completeness of its educational program; its reliance upon scientific research; the training of its students to prepare them for specific and practical service; its comprehensive program of adult education of a kind which is directly usable by the farmer and his family; its direct relation to government; its interest in the common affairs of life; its great contributions to the conservation of our natural resources; its recognized leadership in the progress, development, and permanent improvement of the rural population; and indirectly, but no less certainly, its contribution to the broader purpose of the public welfare." Among the fundamental reasons for the rapid development, continued progress, and present popularity and approval of these institutions, he enumerates the major objectives of their educational program, their plan of organization, their Federal origin and the successful cooperation of the Federal and State governments, and their effectiveness in administration.

Readers of the *Record* will find much of immediate interest in the section on the experiment stations. Dean Mumford points out that the passage of the Hatch Act of 1887 represented "an entirely new governmental policy; it was the recognition of the responsibility of the Federal Government for the progress and development of the

agricultural industry through research. It was also a recognition of the developing importance of science in the national economy. The results of this legislation, after 50 years of experience, have fully justified the faith of the founders in the value of science for solving the problems of the farm, and in the economic and social returns from the activities of these agencies. The discoveries of the agricultural experiment station have had a profound influence upon agriculture as an industry, the economic and social life of farm people, the commerce in agricultural commodities, and upon education itself." When coupled with the work of the Federal Department of Agriculture and its hundreds of cooperative agreements with the individual States, "it is not too much to claim that this national system of scientific research in the interests of agriculture is an educational phenomenon without parallel in the history of science."

Among the distinctive services of the stations has been their emphasis on "the value of science as an instrumentality for the successful solution of the problems of agriculture. 'Science for the sake of science' is not a principal motive in agricultural research. The experiment station has revolutionized the attitudes of farm people toward the practical values of scientific research in the modern world. From an attitude of suspicion and even antagonism toward science, these agencies have won the enthusiastic support and approval of farmers, the most conservative element in our democracy; and along with this, the approval and support of the public generally. They have popularized science not by any superpublicity methods but by utilizing science as an instrument to solve the intricate and difficult problems of agriculture. This has been a real contribution to all science."

One aspect which receives considerable attention in the discussion is the relation of Federal control to the administration of station research. On this point, Dean Mumford states in part that "it must be admitted, I think, that the administrative relation of the Secretary of Agriculture to the research funds appropriated by Congress has been exercised with discretion. No attempt has been made to dominate or control the work of agricultural experiment stations. The minimum amount of administrative supervision has been the rule. As a result of this policy, local initiative has been encouraged. Proper emphasis has been placed on the solution of local and regional problems. The State institutions have been able to harmonize the use of Federal funds with State laws and institutional requirements. After 50 years of experiment with this type of successful and satisfactory Federal administration, the State administrators of agricultural experiment stations have expressed general satisfaction with the results."

As for the agricultural experiment station of the future, it is pointed out that this "has a broad duty to perform. It is not only to make individual farmers more successful. It is not, as some thoughtless persons have claimed, 'to make two blades of grass grow where but one grew before.' Its duty is much broader and more important. It has the duty and responsibility of insuring the permanency of agriculture as an industry and the continued well-being of rural people. It must accomplish this purpose in such manner as to also serve the public welfare. If this can be accomplished—and it can be and is already being achieved—the agricultural experiment station will justify its national origin and more firmly establish its national destiny."

Not only was the land-grant college "a pioneer in its emphasis on scientific research as an instrumentality for the solution of the common everyday needs of farm people," it was also "a pioneer in the organization and administration of a special type of extension teaching, not for college credit but for immediate use in the everyday life of a people." Dean Mumford finds that "the impact of the work of the agricultural extension service on the farm practices, intellectual and social life of farm peoples has been very great." Through this service, "the college of agriculture has made it clear that the influence of an institution of higher learning may extend far beyond the limits of the college campus. The program of adult education, intelligently organized and efficiently administered, has influenced more adult people and changed more practices than any similar educational movement in all history."

In conclusion, Dean Mumford attributes the notable progress of the colleges of agriculture as a whole largely to the completeness of their educational plan. "The college education prepares young men and women for successful achievement in rural affairs; the agricultural experiment station utilizes the methods of science for adding constantly to our store of knowledge relating to agriculture; and the agricultural and home economics extension service has assumed the responsibility of educating the farmer and his family by extending the influence of the college to all engaged in agricultural enterprise. This triad of education has made the college of agriculture what it is and is an important factor in the widespread approval of these institutions." He predicts that "it may well be that when the history of the colleges of agriculture is finally written, their substantial and enduring contribution will be a significant improvement in every phase of rural life and especially the rural community and the rural home. If it be so, then it will be also a great contribution to the national welfare."

## RECENT WORK IN AGRICULTURAL SCIENCE

### AGRICULTURAL AND BIOLOGICAL CHEMISTRY

[Chemical investigations by the Massachusetts Station] (*Massachusetts Sta. Bul.* 369 (1940), pp. 28, 29, 31, 32, 33, 73, 74, 75, 76).—The report notes analyses of off-flavored eggs, flotation sulfur, a roach powder, and lubricating oils; methods for the determination of zinc in foodstuffs; studies on the effect of borax in preventing dark centers in rutabagas, by E. B. Holland, W. S. Ritchie, and C. P. Jones; lignin and its relation to the absorption of minerals by plants, by E. Bennett; and an investigation of the progressive decomposition of haddock muscle, by Ritchie and P. N. Simon. Also noted are cranberry storage and byproducts research, by C. R. Fellers, A. S. Levine, F. Yourga, and J. Lubitz; work on the antiseptic action of acetic acid, by Levine; and glass-container research, by Fellers and K. R. Newman.

The infra-red absorption spectra of amino acids, N. WRIGHT (*Jour. Biol. Chem.*, 127 (1939), No. 1, pp. 137-141).—Differences among the infrared absorption spectra of powder layers of nine different amino acids, and of five of these acids both in the racemic form and in an optically active form, in the range from  $3\mu$  to  $24\mu$  have shown that in each case the racemic form, as crystallized from solution, is a compound, not a mixture of *l*- and *d*-crystals.

Shifts in the position of the C=O band indicated a strong interaction between carboxyl and amino groups in the crystalline amino acids.

A rapid micromethod for the quantitative estimation of sugar alcohols, W. R. TODD, J. VREELAND, J. MYERS, and E. S. WEST (*Jour. Biol. Chem.*, 127 (1939), No. 1, pp. 269-273).—The ferricyanide method of Hagedorn and Jensen (E. S. R., 74, p. 590) was so modified that it could be applied to the determination of sorbitol, mannitol, dulcitol, erythritol, pentaerythritol, and inositol, and probably to the other sugar alcohols. By determining reducing sugars, which react with the ferricyanide reagent if they are present in determinable quantities and also affect the sugar-alcohol equivalents, from 0.1 to 0.7 mg. of sugar alcohols in 5 cc. of solution may be determined in properly clarified filtrates of blood, urine, etc.

Determination of cholesterol, F. E. KELSEY (*Jour. Biol. Chem.*, 127 (1939), No. 1, pp. 15-22, fig. 1).—A micromethod for quantitative isolation of the digitonin-precipitable sterols from biological samples permits an accurate colorimetric analysis showing the true cholesterol content of the sample, because of the absence of the naturally occurring contaminants which usually affect the Liebermann-Burchard reaction. Both free and total cholesterol analyses can be made on the same sample.

The dissimilation of glycerol by coli-aerogenes intermediates, M. N. MICKELSON and C. H. WERKMAN. (Iowa State Col.). (*Jour. Bact.*, 39 (1940), No. 6, pp. 709-715).—In a study of glycerol fermentation by several species of *Citrobacter*, the yields of trimethylene glycol varied from  $\pm 30$  to 60 percent of the fermented glycerol. Isolation of acrolein and its possible importance in the fermentation process is discussed. The effect of adding sulfite as a fixative

and fumaric acid as an H acceptor was determined. Sulfite did not diminish the formation of trimethylene glycol and in its presence considerable acrolein accumulated. The latter was not attacked when added to fermenting glycerol. Fumaric acid, though reduced, did not retard trimethylene glycol formation.

**Extraction methods in relation to hormone content of maize endosperms,** G. S. AVERY, JR., H. B. CREIGHTON, and B. SHALUCHA (*Amer. Jour. Bot.*, 27 (1940), No. 5, pp. 289-300, figs. 3).—In studying comparatively the various proposed methods for single-solvent extraction and using dormant corn endosperms and those removed from germinating seeds at intervals up to 7 days, wide differences in yield of growth hormones were obtained, depending on the solvent and the extent of hydration of the tissue. The water and alcohol extraction methods gave the most reliable results. Water gave the highest yields and proved to be the only method not involving drying down of the residue. Only preliminary studies were made of the extent to which growth inhibitory substances were involved in the yields reported. In general, the amounts of extractable growth hormone decreased as germination proceeded. Multisolvent extraction is proposed for assaying total hormone content. This method of successive extractions of the same tissue with several solvents indicated that not all growth-promoting substance (or substances) is extracted by any one solvent. Some of the difficulties and uncertainties met with in hormone extraction are discussed. There are 20 references.

**Microincineration and ash analysis,** F. M. UBER. (Univ. Mo.). (*Bot. Rev.*, 6 (1940), No. 5, pp. 204-226).—This monographic review (74 references) deals with technical factors, including the preparation of material, the incineration process, and ash observation and analysis, and the results as applied to systematic botany, cytology, and phytopathology.

**Spectroscopic analysis of the mineral content of yeast grown on synthetic and natural media,** O. W. RICHARDS and M. C. TROUTMAN (*Jour. Bact.*, 39 (1940), No. 6, pp. 739-746).—"A pure strain of *Saccharomyces cerevisiae* was grown in Williams' medium, in Williams' medium enriched, and in malt extract medium. After washing, the yeasts were ashed in platinum and spectroscopic plates were made of them and of the components of the medium, of autolyzed yeast, and yeast extract to determine which elements were present. The following elements were found in the yeast ash: Ba, Bi, B, Ca, Cr, Cu, Au, Fe, La, Pb, Mg, Mn, P, Pt, K, Ag, Na, Tl, Sn, and Zn. Autolyzed yeast contained Al in addition. The elements in the different preparations are given with information on their toxicity. Most of the trace elements were present as impurities of the asparagine and these impurities may be a more important reason for the growth-promoting value of asparagine for micro-organisms than its nitrogen content."

**A method for the determination of small amounts of potassium,** T. E. WEICHELBAUM, M. SOMOGYI, and H. A. RUSK (*Jour. Biol. Chem.*, 132 (1940), No. 1, pp. 343-356, figs. 2).—The method described is based upon the precipitation of potassium as silver potassium cobaltinitrite, with subsequent manometric determination of nitrite, and titrimetric determination of silver by the use of the Volhard procedure. Special precautions are noted with regard to the purity of the reagents and the equilibrium conditions. For estimation on blood serum special care must be observed in taking and handling the blood sample in order to avoid passage of potassium from corpuscles to serum. Preparatory to the precipitation of the potassium, the serum may be wet ashed or proteins and chlorides may be removed by use of the cupric sulfate-sodium tungstate method. These procedures, as well as those involved in the precipitation of potassium and the determinations of nitrite and silver, are noted in detail.

The results obtained by the gasometric and the titrimetric determinations were in good agreement; the two procedures are considered interchangeable, the gasometric technic being preferable for its precision, the titrimetric for the ease and rapidity of performance. Results by the gasometric technic compare very favorably with those obtained by a reliable chloroplatinate method, and recovery experiments indicate that no losses occur with the operations involved.

Values reported for the serum potassium content of 40 healthy individuals show a range from 18 to 20.6 (average 19.3) mg. percent.

**A new method for the microdetermination of manganese in biological materials, A. C. WIESE and B. C. JOHNSON.** (Wis. Expt. Sta.). (*Jour. Biol. Chem.*, 127 (1939), No. 1, pp. 203-209).—The authors showed that the blue color produced by benzidine in the presence of the permanganate ion, though it is an exceedingly sensitive qualitative test for manganese, fades so rapidly as to be useless in photometric analysis. However, when solutions of benzidine were added to permanganate solutions made strongly acid with nitric acid, a yellow-green color instead of the blue was obtained. In tests of this color with the photoelectric colorimeter, with a 4,200- $\mu$  filter, it was found to be a great deal more stable. The maximum color develops in 3-5 min. and is stable for 5 min. The method utilizing the yellow-green color and providing for the elimination of oxidizing agents other than the permanganate ion, as well as for the removal of halides which also interfere, was elaborated. Sodium bismuthate was used as oxidant, and the use of silver nitrate, which resulted in a soluble complex of silver bismuthate and brought about an interference, was eliminated through expelling halides by repeated evaporation with nitric acid. The metals found to interfere with the benzidine blue reaction did not interfere with the modified reaction used as a basis for the present method.

**The selenium content of Saskatchewan wheat, T. THORVALDSON and L. R. JOHNSON** (*Canad. Jour. Res.*, 18 (1940), No. 5, Sect. B, pp. 138-150, figs. 3).—The average selenium content of 230 composites made from 2,230 samples of pure varieties of wheat from Saskatchewan soils of known type was 0.44 p. p. m. The maximum was 1.5 p. p. m. and was found in 10 of the 230 composites, representing 3.2 percent of the individual samples. It is thought that methods used in bulk handling of wheat for export would prevent the Se content of such cargoes materially exceeding the average content, which is less than one-tenth the minimum concentration found to affect growth in young animals. The results indicate that wheat produced on glacial lacustrine soils tends to higher Se content.

**The preparation of a vitamin-A rich concentrate from butter and the determination of the vitamin in a Pulfrich photometer** [trans. title], J. EFFERN (*Vorratspfl. u. Lebensmitl. Forsch.*, 3 (1940), No. 1-2, pp. 53-58, figs. 7).—One hundred gm. of butter in a 500-cc. Erlenmeyer flask fitted with an upright condensing tube are saponified by heating for 15 min. on a boiling water bath with 150 cc. of alcoholic potash (30 gm. caustic potash in 150 cc. of 96 percent alcohol). The reaction mixture amounting to 270 cc. is halved for duplicate determinations, which are carried out in succession.

The half of the saponification mixture is shaken in a separatory funnel with 150 cc. of petroleum ether, and extracted 3 times with alcohol. The alcohol is removed from the combined extracts by distillation in vacuum, and the residue is taken up in chloroform (water- and alcohol-free). Carotenoids and any lecithin present are removed from this chloroform concentrate by adsorption on precipitated calcium carbonate. A diagram of the adsorption apparatus is given, and the procedure is described. This consists essentially in permitting the chloroform solution, placed in a separatory funnel under an atmos-

phere of nitrogen or carbon dioxide, to be drawn, by application of vacuum, through a closely packed column of the calcium carbonate. A column 10 cm. in length and 1 cm. in diameter suffices for adsorption of 50 cc. of the concentrate. After adsorption, a 0.5-cc. portion of the chloroform concentrate is treated with 2 cc. of the Carr-Price reagent in the cell of the Pulfrich photometer, and after 5-10 sec. the percentage of light transmission is determined, using the S 61 filter. This filter permits transmission in the region of 610-620  $m\mu$  where the characteristic absorption band of the antimony trichloride reaction occurs. The amount of vitamin A (International Units) in the 0.5 cc. of the concentrate employed is read off from a standard curve of light transmission established with pure vitamin A (Vogan). This curve and one established for the Erdelyi modification of the Carr-Price reaction are presented.

This modification is applicable in the presence of carotenoids and in the absence of lecithin; it employs 1.0 cc. of a 5 percent solution of pyrocatechol in chloroform, with 1 cc. of the antimony trichloride reagent and 0.5 cc. of the vitamin solution (or the chloroform concentrate), and the reaction mixture is heated at 60° C. for 3 min. The color developed shifts from the blue to the violet red region, necessitating use of the S 47 filter. If lecithin is absent, as indicated by lack of turbidity of the chloroform concentrate, this modification may be employed directly without preliminary adsorption on the calcium carbonate.

The vitamin A content, as determined by the methods outlined, is reported for 11 samples of butter, the amounts varying from 0.68 to 2.06 mg. percent (1,140-3,440 I. U. per 100 gm.). One sample of margarine contained 0.048 mg. percent (80 I. U. per 100 gm.).

**The purity and activity of vitamin A preparations** [trans. title], P. KARRER (*Helvetica Chim. Acta*, 22 (1939), No. 5, pp. 1149, 1150).—Referring to the work of Mead, Underhill, and Coward (*E. S. R.*, 83, p. 297) on crystalline esters of vitamin A, the present article points out as a matter of priority that certain of these esters had been prepared and described earlier by Karrer et al. (*E. S. R.*, 68, p. 151). Evidence is presented to show that the vitamin A preparation (Axerophthol) of Karrer purified by chromatographic separation, the product of Mead et al. purified by distillation and recrystallization from methyl alcohol at a low temperature, and the crystalline product of Holmes and Corbet (*E. S. R.*, 77, p. 150) [purified by fractional freezing from methyl alcohol and cold filtration] had similar properties and were, therefore, of equal purity.

**Studies on the determination of vitamin A by destructive irradiation**, B. DEMAREST (*Ztschr. Vitaminforsch.*, 9 (1939), No. 1-2, pp. 20-31, figs. 6; *Ger., Fr., abs.*, p. 31).—Absorption curves made at intervals during the irradiation of solutions containing vitamin A were studied to determine the validity of destructive irradiation methods, as proposed by De<sup>1</sup> and by Chevallier.<sup>2</sup> By the former method solutions of food extracts or low-potency oils are irradiated with the total irradiation of the quartz mercury arc until the vitamin is completely destroyed. The decrease in extinction at 3,280 a. u. is then taken to be equal to the extinction at 3,280 a. u. of the vitamin A originally present in the solution. This method assumes (1) that the vitamin A is thus destroyed, yielding no end products having absorption at 3,280 a. u.; (2) that substances present other than vitamin A do not change in their absorption at 3,280 a. u. during irradiation; and (3) that the irradiation is continued long enough to insure destruction of all of the vitamin A present in the solution. The present

<sup>1</sup> *Indian Jour. Med. Res.*, 24 (1937), No. 3, pp. 737-749.

<sup>2</sup> *Ztschr. Vitaminforsch.*, 7 (1938), No. 1, pp. 10-16.

investigation showed that with solutions of high-potency vitamin A concentrates the vitamin A was almost entirely destroyed, a 98 percent loss in extinction at 3,280 a. u. resulting, with no increase in the extinction at any other part of the ultraviolet spectrum during irradiation. With low-potency fish-liver oil solutions, however, the destruction of the vitamin by total mercury arc radiations was much slower than in the case of the high-potency material, due apparently to the screening effect of other substances present; moreover, there were other changes in the absorption spectrum which did not occur with the high-potency oils. These results, which did not bear out assumptions (2) and (3), indicated that the total mercury arc spectrum did not exert selective destruction of vitamin A. In addition, the change in the absorption spectrum of an irradiated milk extract was radically different from the change that should have resulted from a selective destruction of vitamin A.

In other irradiation experiments employing filters having various ultraviolet transmission limits, it was found that short wave length ultraviolet mercury lines were much more effective than the long wave length lines, both in the destruction of vitamin A and in producing the extraneous photochemical reactions. By filtering out the shorter wave length ultraviolet mercury lines, this latter effect could possibly be retarded or eliminated. The use of a Woods filter, as in the Chevallier method, offered the probability of a more selective destruction of vitamin A. The equilibrium point claimed for the Chevallier method was not attained, however, in the present experiments in which an absolute ethyl alcohol solution of a high-potency material was irradiated with the mercury arc and Woods filter. No equilibrium point was found for the extinction at 3,280 a. u. down to a value of 16 percent of the original extinction at this wave length. While the results indicate that there are objections to the De and Chevallier methods for the determination of vitamin A, it is considered that irradiation by filtered radiation offers a promising avenue of investigation.

**The determination of vitamin A and carotene with the photoelectric colorimeter, C. J. KOEHN and W. C. SHERMAN.** (Ala. Expt. Sta.). (*Jour. Biol. Chem.*, 132 (1940), No. 2, pp. 527-538).—The procedures and the calculations involved in the determination of vitamin A, employing the Carr-Price reaction, and of carotene by the use of a direct reading photoelectric colorimeter are given in detail. The relationship between  $L_{1\text{cm}}^{1\%}$  (620  $m\mu$ ) and biological activity in terms of units of vitamin A was determined. For this purpose the  $L_{1\text{cm}}^{1\%}$  (620  $m\mu$ ) of the U. S. P. reference cod-liver oil was determined (and found to be 3.45) and the potency of the oil then checked by biological assay against  $\beta$ -carotene. This reference oil was found to have the assigned potency of 3,000 International Units.

The calculations for converting the colorimetric reading, i. e., galvanometer readings, using filters 620 and 440, respectively, into I. U. of vitamin A and micrograms of carotene, are presented. The  $L_{1\text{cm}}^{1\%}$  (440  $m\mu$ ) of  $\beta$ -carotene was determined as 1,645 and 1,980 in chloroform and Skellysolve solutions, respectively. From the results of the biological assays, the determined value of 3.45 for  $L_{1\text{cm}}^{1\%}$  (620  $m\mu$ ) of the U. S. P. reference oil and factor 0.41 suggested by Dann and Evelyn<sup>3</sup> for converting  $L_{1\text{cm}}^{1\%}$  (620  $m\mu$ ) into  $E_{1\text{cm}}^{1\%}$  (328  $m\mu$ ), a factor of 2,120 was obtained for converting  $E_{1\text{cm}}^{1\%}$  (328  $m\mu$ ) into I. U. of vitamin A.

**Comparison of vitamins A and A<sub>2</sub> by distillation, E. L. GRAY** (*Jour. Biol. Chem.*, 131 (1939), No. 1, pp. 317-326, figs. 7).—Molecular distillation characteristics of vitamins A and A<sub>2</sub> were compared. The comparison was made in a single distillation of both vitamins as they occurred in the unsaponifiable fraction of Atlantic salmon-liver oil. Check distillations were made on liver oil of

<sup>3</sup> *Biochem Jour.*, 32 (1938), No. 6, pp. 1008-1017, figs. 3.

wall-eyed pike for vitamin A<sub>2</sub> and on pollack-liver oil for vitamin A, the oils being saponified and distilled analytically with celanthrene red. By the elimination curve technic employed, it was found that the elimination maximum of vitamin A<sub>2</sub> was only 3° above that of vitamin A. Since the temperatures of the elimination maxima of homologous compounds differ by only 10°, this small difference observed in the distillation temperatures indicates that the molecules of the two vitamins contain the same number of carbon atoms and differ only in the degree of saturation.

**Cyclization of vitamin A<sub>2</sub>**, N. D. EMBREE and E. M. SHANTZ (*Jour. Biol. Chem.*, 132 (1940), No. 2, pp. 619-626, figs. 3).—Vitamin A<sub>2</sub> in the unsaponifiable matter of perch-liver oil was cyclized by dissolving this portion in alcohol, making the solution  $\frac{1}{30}$  N with HCl and allowing it to stand at room temperature for 15 min. The solution, after neutralization with aqueous NaOH and dilution with water, was extracted with ether. The cyclized vitamin A<sub>2</sub> obtained as the residue from the ether extract had, like the cyclized vitamin A<sub>1</sub>, an ultraviolet absorption spectrum with maxima at 350, 368, and 390 m $\mu$ . The product formed by the reaction of cyclized vitamin A<sub>2</sub> with SbCl<sub>5</sub> had, like the vitamin A<sub>2</sub>, an absorption spectrum with a maximum near 690 m $\mu$ . The cyclized vitamin A<sub>2</sub> was more strongly adsorbed by alumina than cyclized vitamin A<sub>1</sub>, thus permitting the chromatographic separation of the two cyclized derivatives. Based on this separation, a method is outlined for the estimation of relative amounts of vitamins A<sub>1</sub> and A<sub>2</sub>.

**Preparation of vitamin B<sub>6</sub> from natural sources**, R. D. GREENE (*Jour. Biol. Chem.*, 130 (1939), No. 2, pp. 513-518).—The method described for preparation of the crystalline vitamin involved an initial concentration from an aqueous rice bran extract by employing immiscible solvent systems. Preliminary determination of distribution coefficients of pure vitamin B<sub>6</sub> in a number of such systems indicated that propanol, butanol, and ethyl ether, the latter particularly, were very useful as selective solvents. In order further to remove readily adsorbable substances that would interfere with fuller's earth adsorption of the vitamin, concentrates were treated with silver and copper salts which served to remove purines and nicotinic acid. From the concentrate thus derived, the vitamin B<sub>6</sub> was adsorbed on Lloyd's reagent and eluted with 0.2 N barium hydroxide. After adjustment of the pH to 3 (using sulfuric acid and barium chloride and removing the barium sulfate by centrifugation), the aqueous solution was concentrated to a thick sirup and taken up in boiling absolute alcohol; after cooling and removal of insoluble material, the alcoholic solution was evaporated and taken up in boiling acetone, from which crystallization occurred, the second crop of crystals being obtained from the mother liquor by the addition of ether. Recrystallization from absolute alcohol gave crystals that melted at 207°-208° [C.], gave an intense red-brown color with the ferric chloride reagent, showed strong absorption in the range of 2,750-3,070 a. u., and gave a positive response in the biological test for vitamin B<sub>6</sub>. Yields of 10-15 percent were obtained.

**The determination of vitamin C in urine**, H. N. HOLMES and K. CAMPBELL (*Jour. Lab. and Clin. Med.*, 24 (1939), No. 12, pp. 1293-1296).—The addition of a slightly rounded teaspoonful (about 3 gm.) of precipitated calcium carbonate and a fragment of marble the size of one or two grains of corn (about 2 gm.) to a 500-cc. bottle of fresh urine into which 50 cc. of glacial acetic acid had previously been measured is suggested as a means of preventing oxidation of ascorbic acid in samples of urine collected for ascorbic acid determinations. Directions are given for the titration procedure.

**Standardization of 2,6-dichlorophenolindophenol with ferrous compounds**, A. J. LORENZ and L. J. ARNOLD (*Indus. and Engin. Chem., Analyt. Ed.*, 10 (1938), No. 12, p. 687).—The use of ferrous ammonium sulfate (Mohr's salt) in the presence of metaphosphoric acid or oxalic acid is suggested as a basic standard for the titration of 2,6-dichlorophenolindophenol. The solution is made up, using 1 gm. of the ferrous salt and 10 cc. of concentrated sulfuric acid in 1 l. To 2–5 cc. of this solution are added 5–10 cc. of a saturated solution (about 4 percent) of oxalic acid or a 3 percent solution of metaphosphoric acid. One mg. of  $\text{FeSO}_4(\text{NH}_4)_2\text{SO}_4 \cdot 6\text{H}_2\text{O}$  is equivalent to 0.2247 gm. of ascorbic acid.

**On the mechanism of cocarboxylase action**, K. G. STERN and J. L. MELNICK (*Jour. Biol. Chem.*, 131 (1939), No. 2, pp. 597–613, figs. 4).—This study was concerned with an investigation of two possibilities suggested as the mechanism by which the coenzyme exerts its catalytic activity. The first of these was suggested by the model experiments of Langenbeck which had shown that primary amines were capable of decarboxylating  $\alpha$ -ketocarboxylic acid. It seemed possible, therefore, that the amino group of the thiamin pyrophosphate (cocarboxylase) would function in the decarboxylation of pyruvic acid. In the present work it was shown, however, that thiamin is not a typical primary amine since it reacts with ketene to yield not an N-acetyl but an O-acetyl derivative and it does not readily give up its nitrogen in the Van Slyke manometric apparatus when treated with nitrous acid. Moreover, in an actual test of the cocarboxylase activity of thiamin as a model under the conditions employed by Langenbeck pyruvic acid failed to be decarboxylated.

As a second possibility it was suggested that the catalytic activity of cocarboxylase might involve a reversible reduction and oxidation of the double bond adjoining the quaternary nitrogen in the thiazole nucleus. In this study, however, it was found that neither dihydrothiamin nor dihydrococarboxylase is autoxidizable in vitro. These dihydro derivatives were prepared by several means, the reduction curves indicating different rates of reduction with the different conditions used. The dihydrothiamin tested for biological activity was found to have no antineuritic activity in pigeons. Dihydrococarboxylase, however, was highly active both in the pigeon and in the yeast test system. These findings suggested that the coenzyme in the course of its physiological function goes through an oxido-reductive cycle.

**Ultraviolet absorption spectra of cocarboxylase, thiamine, and their reduction products**, J. L. MELNICK (*Jour. Biol. Chem.*, 131 (1939), No. 2, pp. 615–620, figs. 2).—The present measurements on the oxidized and reduced forms of thiamin and cocarboxylase were made with a view to their usefulness in demonstrating the occurrence of dihydrothiamin or its phosphorylated derivative in the tissues. A spectroscopic demonstration of the presence of these compounds would lend support to the view presented in the study noted above that the biological activity of thiamin pyrophosphate (cocarboxylase) depends upon the reversible oxidation and reduction of the coenzyme.

Ultraviolet absorption spectra of thiamin and cocarboxylase were measured under conditions in which the hydron concentration was controlled either at pH 7.4 or at pH 2.3. Upon reduction of the vitamin or its pyrophosphate ester there occurred at pH 7.4 a lowering of the extinction at the maximum at 235–237  $m\mu$ , while the maximum at 265–266  $m\mu$  was lowered only slightly but was shifted to 280  $m\mu$ ; at pH 2.3 the band at 243  $m\mu$  was still present, but it was lowered and not as sharp.

**Chemical determination, stability, and form of thiamine in urine**, D. MELNICK and H. FIELD, JR. (*Jour. Biol. Chem.*, 130 (1939), No. 1, pp. 97–107,

fig. 1).—The determination is based on the specific method previously described (E. S. R., 83, p. 11), making use of the reaction in alkaline solution between the vitamin and diazotized *p*-aminoacetophenone. The urine, collected with acid-toluene preservative, is concentrated in vacuo and then subjected to benzyl alcohol extraction to largely eliminate salts which interfere with the subsequent permutite adsorption. The distillation unit for concentration of the urine is illustrated. Treatment of the alcohol extract with acidulated water and ether removes the vitamin to the aqueous phase from which it is adsorbed on permutite eluted with 25 percent KCl solution and treated with the reagent in an alkaline medium in the presence of thymol blue as an internal indicator; the colored vitamin derivative is finally extracted with xylene. A number of urine samples are run at one time, it being convenient to read the xylene layers of several unknowns against the xylene layer of the standard in a microcolorimeter.

The method applied to urines collected from six normal men during a 3-day period gave reproducible results with recoveries of added thiamin, averaging about 90 percent. In these six subjects thiamin in 24-hr. urine samples varied from 128 to 350  $\mu$ g. The method is apparently specific for thiamin in urine, since a large number of drugs often administered in medication were found to give no interfering color reactions. Urine preserved with acid and toluene showed no decrease in thiamin over a 28-day period of storage, indicating the stability of the vitamin under these conditions. Likewise, there is apparently no destruction of the vitamin in bladder storage in vivo, since freshly voided urine adjusted to various pH levels over the physiological range and incubated for 6 hr. at 37.5° C. to simulate the conditions of the bladder showed no decrease in thiamin content. The vitamin is excreted in the urine entirely in the free form, since the method (which does not detect the phosphorylated vitamin) gave the same results before and after treatment of the urine with phosphatase, which would have liberated any bound vitamin. Moreover, only free thiamin was detected in the urine even after the injection of large amounts of the phosphorylated vitamin.

**A colorimetric method for the determination of nicotinic acid and nicotinamide in foodstuffs** [trans. title], H. KRINGSTAD and T. NÆSS (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 260 (1939), No. 3-4, pp. 108-118, figs. 5).—The reaction of nicotinic acid with cyanogen bromide and an aromatic amine to form a colored compound served as the basis of the method. Of the various amines studied, aniline proved most satisfactory. On the basis of preliminary studies, reported in detail, the following procedure was devised:

A portion of the finely divided substance was extracted 3 times by heating for 1 hr. on the water bath with 2-3 parts of water, the extracts being filtered off with suction. The combined extracts were treated with sulfuric acid to a concentration of about 0.1 N and heated for 2 hr. at 100° C., this hydrolysis serving to convert coenzyme, which was not reactive, to the amide; the acid was then neutralized with barium hydroxide and the barium sulfate removed by filtration. For determination of the amide the test solution was prepared by bringing a 20-cc. portion of the extract to a pH of  $\pm 6.3$  by adding 5 cc. of a phosphate buffer solution and filtering off any precipitated phosphate. For determination of the acid another portion of the extract was treated with barium hydroxide (15 gm. per 100 cc. of extract) and heated on the water bath for 2 hr., this hydrolysis serving to convert the amide to the acid. The solution was then neutralized with sulfuric acid, and the precipitated barium sulfate removed by centrifugation and washed 3 times with 25-cc portions of water. The combined supernatant liquid and washings were made to definite volume and treated with phosphate buffer as above.

Determinations were carried out on 10-cc. portions of the test solutions, prepared as noted and containing 1 $\gamma$ –50 $\gamma$  per cubic centimeter, by adding 4 drops of a saturated solution of aniline in water, mixing, adding 0.35 cc. of cyanogen bromide solution (prepared according to Scholl<sup>4</sup> and Baum<sup>5</sup>) and mixing again. The development of the color was followed in the step photometer, using the S 45 filter. The reading at the point of maximum color development was applied to a standard extinction curve established for the nicotinic acid (or its amide), and the concentration of the constituent read off directly from the curve.

Dry brewers' yeast containing 44.0–45.5 mg. of nicotinic acid per 100 gm. and fresh beef liver containing 15.5–20 mg. per 100 gm. were found to be good sources of this constituent. Values of 10.2 and 11.0 mg. per 100 gm. are reported for moist brewers' and bakers' yeasts, respectively; and of 6.0, 5.0, 4.2, 4.9, and 3.3 mg. per 100 gm. of canned salmon, wheat bran, wheat germ, beef (flesh), and pork (flesh), respectively. Lower values (1–3 mg. per 100 gm.) are reported for cod (flesh, roe, and liver), herring (flesh), potatoes, whole rye meal, and corn. The results obtained were found to parallel the findings of Goldberger et al. in biological determinations of the P–P factor.

**The isolation of  $\alpha$ -phyloquinone (vitamin K from alfalfa) and the history of its discovery** [trans. title], P. KARRER, A. GEIGER, R. LEGLER, A. RÜEGGER, and H. SALOMON (*Helvetica Chim. Acta*, 22 (1939), No. 6, pp. 1464–1470, fig. 1).—Previous work (E. S. R., 83, p. 298) dealt briefly with the isolation of vitamin K from alfalfa and with the physical and chemical behavior of the vitamin. The present paper gives a detailed description of the method used for the isolation, this method consisting of a combination of adsorption procedures and molecular distillation. Spectrographic study with particular reference to the determination of the coefficient of extinction for the wavelength 248  $\mu$  served as the criterion for judging progressive purification of the preparations. The earlier descriptions of the  $\alpha$ -phyloquinone were confirmed by the data obtained in the present study. Argument and evidence are presented in support of the conclusion that the preparation as isolated represented pure vitamin K; this is in refutation to the claim of Binkley et al. noted below that the product of Dam was only 50 percent pure.

**The isolation of vitamin K<sub>1</sub>**, S. B. BINKLEY, D. W. MACCORQUODALE, S. A. THAYER, and E. A. DOISY (*Jour. Biol. Chem.*, 130 (1939), No. 1, pp. 219–234, fig. 1).—Crude extracts of dried alfalfa meal or leaf meal were obtained by percolation with petroleum ether, this solvent being preferred since it removed the vitamin without removing excessively large amounts of solids. These crude preparations were purified by a modified chromatographic adsorption method employing one or two adsorptions on Decalso (a synthetic zeolite) which increased the concentration of the vitamin about 20–40 times; adsorption on permutite which gave a five- to tenfold concentration; further adsorption on a 5.0 $\times$ 580 cm. column of permutite to give a two- to fivefold concentration; and final adsorption on Darco (an activated charcoal), which was found to be advantageous with preparations containing more than 10 percent of the vitamin. Elution of the vitamin was effected with petroleum ether, followed by benzene in petroleum ether, and finally with acetone which served to prepare the adsorbent for future use. These several processes are described in detail and illustrated by a type experiment. The product isolated was purified by crystallization or molecular distillation and crystallization.

<sup>4</sup> Ber. Deut. Chem. Gesell., 29 (1896), No. 12, pp. 1822–1825.

<sup>5</sup> Ber. Deut. Chem. Gesell., 41 (1908), No. 3, pp. 523, 524.

The pure vitamin  $K_1$  was converted by reductive acetylation into the diacetate of dihydro vitamin  $K_1$  (m. p.  $62^\circ$ – $63^\circ$  C., potency 500 units per milligram). By means of the Grignard reaction the diacetate was converted back to vitamin  $K_1$  with 100 percent enhancement of potency (1,000 units per milligram). Elementary analyses and molecular weight determination indicated a possible formula of  $C_{32}H_{48}O_2$  or  $C_{31}H_{46}O_2$ . The analyses and the adsorption curve and extinction coefficient for the product isolated are discussed in comparison with the findings of Dam et al. (E. S. R., 82, p. 441) with respect to their product.

**Identification of vitamin  $K_1$  (alfalfa)**, D. W. MACCORQUODALE, R. W. MCKEE, S. B. BINKLEY, L. C. CHENEY, W. F. HOLCOMB, S. A. THAYER, and E. A. DOISY (*Jour. Biol. Chem.*, 130 (1939), No. 1, p. 433).—This brief note reports that chromic acid oxidation of the synthetic diacetate of dihydro vitamin  $K_1$  yields the same acid, 1,4-diacetoxy-2-methylnaphthalene-3-acetic acid, as is obtained by similar oxidation of the natural vitamin; the mixed m. p. ( $209^\circ$ – $210^\circ$  [C.]) of the two products showed no depression. The isolation of this acid from the oxidation products is evidence that the nuclear structure, the positions of the substituents, and the location of the ethylenic double bond are the same in both the natural and synthetic compounds. Bio-assay of the natural and synthetic vitamin gave identical results and indicated a potency of 660 units per milligram.

**The constitution and synthesis of vitamin  $K_1$** , D. W. MACCORQUODALE, L. C. CHENEY, S. B. BINKLEY, W. F. HOLCOMB, R. W. MCKEE, S. A. THAYER, and E. A. DOISY (*Jour. Biol. Chem.*, 131 (1939), No. 1, pp. 357–370).—This paper gives a full report (see preliminary communications (E. S. R., 83, pp. 586, 857, and above)) on the degradation and synthesis of vitamin  $K_1$ . The experimental procedures and results are described, and the implications discussed. It was shown that vitamin  $K_1$  was a 2,3-disubstituted  $\alpha$ -naphthoquinone with an unsaturated side chain. Oxidation of the vitamin with chromic acid yielded phthalic acid, indicating the presence of a benzenoid ring carrying no side chain. A second acid identified as 2-methyl-1,4-naphthoquinone-3-acetic acid was also obtained. This product indicated that the quinone nucleus carried a methyl group at the 2 position and, at the 3 position, a side chain with an ethylenic linkage between the second and third carbon atoms from the quinone ring. These conclusions were confirmed by the degradation products obtained from the diacetyl dihydro derivative of the vitamin. Ozonolysis or chromic acid oxidation of the diacetyl dihydro vitamin gave a ketone,  $C_{18}H_{30}O$ , which was identified as 2,6,10-trimethylpentadecanone-14, which proved the arrangement of the remaining carbon atoms of the unsaturated side chain. The constitution of vitamin  $K_1$  as 2-methyl-3-phytyl-1,4-naphthoquinone was indicated by these results and confirmed by synthesis in which phytyl bromide was condensed with the mono-sodium salt of 2-methyl-1,4-naphthohydroquinone, the vitamin being isolated as the diacetyl dihydro derivative. The synthetic compound upon degradation by the same procedures as applied to the natural vitamin derivative gave the same degradation products.

**The blue alkali salt of  $\alpha$ -phyloquinone (vitamin  $K_1$ ) and similar compounds** [trans. title], P. KARBER (*Helvetica Chim. Acta*, 22 (1939), No. 5, pp. 1146–1149).—Argument is presented in favor of the view that the blue color reaction (E. S. R., 82, p. 441) obtained upon mixing solutions of vitamin  $K_1$  and sodium alcoholate is due to the vitamin itself and not, as suggested by Fernholz et al. (E. S. R., 83, p. 14), to some impurity present. This blue color reaction is similar to the Liebermann reaction characteristic of naphthoquinones with a reactive -CH group as a substituent in the 2- or 3-position. With the postulation of a phytol residue (- $CH_2$ .CH:CR'R'') in the molecule, it

appears probable that the  $\text{CH}_2$  group of the side chain is activated by the adjacent ethylene linkage to give the reactive  $\text{CH}$  group responsible for the Liebermann reaction. A number of examples of such influence of the ethylene linkage are presented from the field of organic chemistry. It is noted that a number of naphthoquinone derivatives with vitamin K activity have been synthesized in the author's laboratory.

**Nor- $\alpha$ -phyloquinone (nor-vitamin  $\text{K}_1$ ) and related compounds** [trans. title], P. KARBER, A. GEIGER, A. RÜEGGER, and H. SALOMON (*Helvetica Chim. Acta*, 22 (1939), No. 6, pp. 1513-1516, fig. 1).—This preliminary report presents the scheme of the reactions employed in the synthesis of compounds closely related to phyloquinone (vitamin K). The nor- $\alpha$ -phyloquinone, formed by a series of reactions starting with  $\beta$ -naphthyl-ethylmagnesiumbromide and 2,6,10-trimethyl-pentadecanone-14, differs from  $\alpha$ -phyloquinone only by the lack of a methyl group in the 3-position. The nor- $\alpha$ -phyloquinone is described as a viscous yellow oil crystallizing at lower temperatures; empirical formula  $\text{C}_{30}\text{H}_{44}\text{O}_2$ ; molecular weight 448 (determined), 438 (calculated); absorption maxima 242, 248, 261, 265, and 326  $\text{m}\mu$  (as compared with 243, 248, 261, 270, and 328  $\text{m}\mu$  for phyloquinone).

**Naphthoquinones of the vitamin  $\text{K}_1$  type of structure**, L. F. FIESER, W. P. CAMPBELL, E. M. FRY, and M. D. GATES, JR. (*Jour. Amer. Chem. Soc.*, 61 (1939), No. 11, pp. 3216-3223).—This paper discusses the methods of synthesis and presents the details of experimental work already noted (E. S. R., 83, p. 586).

**Synthesis of vitamin  $\text{K}_1$** , L. F. FIESER (*Jour. Amer. Chem. Soc.*, 61 (1939), No. 12, pp. 3467-3475).—This paper presents, with considerable detail in discussion and in presentation of the experimental work, a connected account of the synthesis of vitamin  $\text{K}_1$  and the identification of the product with the natural vitamin. This work, much of which has been given briefly in a series of preliminary reports (E. S. R., 83, p. 586 and above), has led to the synthesis of 2-methyl-3-phytyl-1,4-naphthoquinone, essentially as a one-step process utilizing 2-methyl-1,4-naphthohydroquinone and phytol. A technic similar to that employed in the separation and purification of the synthetic product when applied to alfalfa concentrates was found useful in isolating the natural vitamin  $\text{K}_1$ . The identity of the synthetic product with the naturally occurring vitamin was established by a direct comparison of the samples with regard to analysis, spectrum, antihemorrhagic activity, color reaction, and the melting point and mixed melting point of a crystalline derivative.

A number of naphthoquinone derivatives similar to the vitamin were synthesized but found inactive, while 2-methyl-3-geranyl-1,4-naphthoquinone, also synthesized, showed moderate potency. Indications of a certain structural specificity are discussed, and it is suggested tentatively that the activity of the remotely related 2-methyl-1,4-naphthoquinone may be due to the ability of the organism (chick) to utilize the compound as a component for synthesis of the vitamin.

**A derivative of vitamin  $\text{K}_1$** , H. J. ALMQUIST and A. A. KLOSE. (Univ. Calif.). (*Jour. Biol. Chem.*, 130 (1939), No. 2, pp. 791-793).—The pigment (yellow in solution as the acid, reddish-brown in alkaline solution in the form of the ion) observed in earlier studies (E. S. R., 83, p. 14) on the alkaline hydrolysis of vitamin  $\text{K}_1$  was prepared by hydrolysis of the vitamin in dilute sodium methylate, followed by extraction of the pigment in hexane, subsequent recovery from this solution, and final purification by molecular distillation. Molecular weight determinations on the product indicated values in the neighborhood of 500, and the results of elementary analysis indicated the provisional formula  $\text{C}_{31}\text{H}_{46}\text{O}_4$ . In comparison the formula  $\text{C}_{28}\text{H}_{40}\text{O}_2$  and the

molecular weight 450.4 for vitamin  $K_1$  were indicated by earlier studies by the authors (E. S. R., 83, p. 585) and by Binkley et al. (E. S. R., 83, p. 536). Apparently, therefore, the alkaline hydrolysis caused no appreciable splitting of the vitamin, but produced instead an increase in molecular weight and a change in analysis, suggesting the addition of 2 oxygen atoms (at least 1 probably phenolic) and perhaps several hydrogen atoms. The stability of the side chain to alkaline hydrolysis suggested that this side structure was held to the 1,4-naphthoquinone nucleus by a carbon-to-carbon bond. Such would be the case with the phytyl group previously postulated for vitamin  $K_1$  and introduced in the synthesis of active preparations of 2-methyl-3-phytyl-1,4-naphthoquinone.

**Vitamin K activity in the benzoquinone series**, S. ANSBACHER and E. FERNHOLZ (*Jour. Biol. Chem.*, 131 (1939), No. 1, pp. 399, 400).—In assays of compounds of the benzoquinone series it was found that benzoquinone, toluquinone, trimethylquinone, and duroquinone had no potency at the 1-mg. level. However, phlorone, the 2,5-dimethylbenzoquinone, had vitamin K activity, exhibiting a potency of 1 unit (E. S. R., 83, p. 12) in about 1 mg. Unit for unit, however, the speed of action and period of efficacy, as measured by the blood-clotting time of individual chicks, was practically identical with that of the much more active compound 2-methyl-1,4-naphthoquinone, which showed unit activity at a level of  $\frac{1}{2}\gamma$ .

**Antihemorrhagic activity of 2-methyl-1,4-naphthoquinone**, H. J. ALMQUIST and A. A. KLOSE. (Univ. Calif.). (*Jour. Biol. Chem.*, 130 (1939), No. 2, pp. 787-789).—In the assay of 2-methyl-1,4-naphthoquinone it was found that the apparent activity of the compound when dissolved in ethanol, cod-liver oil, Wesson oil, mineral oil, or methyl laurate, and incorporated in the diet, was far below the activity determined by daily oral administration of the test dose dissolved in ethyl laurate. Moreover, in the former method the apparent activities were much greater in the cases of cod-liver and Wesson oil and lowest in the case of ethanol.

The 2-methyl-1,4-naphthoquinone, two vitamin  $K_1$  preparations, one furnished by Karrer, the other by Doisy, and a standard supplement were administered in oral doses (the test substances dissolved in 1 drop of ethyl laurate) according to the procedure of the dietary assay method of the authors (E. S. R., 82, p. 88). The two vitamin  $K_1$  preparations were of equivalent high activity, such that on an average 1 gm. of the vitamin equaled 63,000 cc. of the reference standard solution. The activity of the 2-methyl-1,4-naphthoquinone was approximately 240,000. These results indicate that vitamin  $K_1$  has less activity than its equivalent content of 2-methyl-1,4-naphthoquinone (38 percent), and that the presence of the phytyl side chain in the 3 position detracts from the activity of this quinone nucleus. It is suggested, therefore, that the synthesis of the more expensive and less active vitamin  $K_1$  would have little practical value.

**The ultraviolet absorption of vitamins  $K_1$ ,  $K_2$ , and some related compounds**, D. T. EWING, J. M. VANDENBELT, and O. KAMM. (Mich. State Col. et al.). (*Jour. Biol. Chem.*, 131 (1939), No. 1, pp. 345-356, figs. 11).—This work, begun after isolation of vitamin  $K_1$  from alfalfa and vitamin  $K_2$  from putrefied fish meal, was undertaken to aid in the elucidation of the structure of the compounds. The compounds used were prepared by Doisy et al. in the course of their work (E. S. R., 83, p. 13). Absorption curves are presented for vitamins  $K_1$  and  $K_2$ , for their reduction products, for the corresponding diacetates, and for the hydrolyzed diacetates of dihydro vitamin  $K_1$ . In addition, absorption curves are presented for certain 1,4-naphthoquinone derivatives, 1,4-benzoquinone, and 2,3-disubstitution products of 1,4-naphthoquinone. The maxima,

minima, and other characteristics of the curves for vitamins  $K_1$  and  $K_2$  were quite similar and were analogous to the naphthoquinone curves. Evaluation of the various curves led to the conclusion that vitamins  $K_1$  and  $K_2$  are derivatives of 2,3-dimethylnaphthoquinone and that the side chains contain no conjugated double bonds.

**The isolation of vitamin  $K_2$ ,** R. W. MCKEE, S. B. BINKLEY, S. A. THAYER, D. W. MACCORQUODALE, and E. A. DOISY (*Jour. Biol. Chem.*, 131 (1939), No. 1, pp. 327-344, fig. 1).—The isolation of vitamin  $K_2$ , referred to briefly in earlier reports (E. S. R., 83, p. 13), is considered in detail in the present paper. The method is discussed at length and illustrated by a typical experiment employing the isolation process. Commercial sardine meal served as the starting material. This was extracted with isopropyl ether as a preliminary step to remove natural lipides and then subjected to repeated (5 or 6) putrefactions of about 15 days' duration, followed each time by drying and extraction with petroleum ether, which served to remove the vitamin developed by bacterial action during the process of putrefaction. The solvent was removed by vacuum distillation, and the residue taken up again in sufficient petroleum ether to make a 3- to 5-percent solution of the solids. From this solution the vitamin was adsorbed on Decalso in a large adsorption column, petroleum ether being used to "develop" the column. After layering of the pigments the vitamin was eluted with 20 percent benzene in petroleum ether, the main portion being concentrated in the first three or four fractions. By several repetitions of the adsorption and elution, using medium and small permutite columns, a fairly pure preparation of the vitamin could be obtained. The product was further purified by crystallization from various solvents. Satisfactory crystals could be obtained by two crystallizations from a mixture of chloroform and methanol (1:1). The operations were carried out in diffuse light because of the instability of the vitamin to light.

The vitamin isolated in pure form as light yellow microcrystalline plates melted at 52°–53.5° C. and assayed 600 units per milligram. Calculations from elementary analysis indicated a possible formula of  $C_{40}H_{54}O_2$  (or  $C_{38}H_{50}O_2$ ,  $C_{39}H_{52}O_2$ ,  $C_{41}H_{56}O_2$ , or  $C_{42}H_{58}O_2$ ). Catalytic hydrogenation caused the yellow compound to become colorless; the yellow color returned upon exposure to air, the resulting compound being capable of absorbing 2 atoms of hydrogen. The pure vitamin was converted by reductive acetylation to the diacetate of dihydro vitamin  $K_2$ , m. p. 59.5°–60.0° C., with a potency of one-half that of the vitamin. The halogen uptake of the diacetate of dihydro vitamin  $K_2$  indicated the presence of six double bonds in the side chain. Ultraviolet absorption studies indicated that the diacetates of dihydro vitamin  $K_1$  and vitamin  $K_2$  were similar. These various findings are considered as evidence that the vitamin is a 2,3-disubstituted naphthoquinone with six double bonds in the side chains.

**Simultaneous production of wood pulp and the conversion of the non-cellulosic constituents of wood into alcohols, oils, and resins,** E. E. HARRIS and E. C. SHERRARD. (Coop. Univ. Wis.). (*U. S. Dept. Agr., Forest Serv., Forest Prod. Lab., 1940, R1218, pp. [4]*).—Wood chips of various species were hydrogenated at 1,000 or at 3,000 lb. pressure in suspension and in an aqueous medium with the help of a nickel catalyst. Sufficient alkali (from 8 to 10 percent or more of the weight of the wood) to keep the solution alkaline at all times was necessary to prevent the acidic substances formed from inhibiting the activity of the catalyst. Pulp of good quality, requiring only a mild chlorine treatment, was produced, together with methanol, propanol, propyl cyclohexane derivatives, and an oily resin. Data from experiments with aspen, maple, slash pine, and red gum are tabulated.

## AGRICULTURAL METEOROLOGY

Soc.*, 21 (1940), No. 2, pp. 63-65, figs. 2).—The apparatus described and illustrated consists essentially of a centrifugal exhaust fan with special inlet duct, mounted on a standard split-phase induction motor of capacitor type.

**Relative humidity gradient and the form of cloud bases**, C. E. DEPPERMAN (*Bul. Amer. Met. Soc.*, 21 (1940), No. 2, pp. 43-45).—An abstract.

**Diurnal pressure differences in regions of high pressure**, G. W. C. TAIT (*Bul. Amer. Met. Soc.*, 21 (1940), No. 2, pp. 39-43).—"The differences between morning and evening pressures in a region of high pressure have been observed to be greater than normal differences. This was checked using Toronto station pressures. The effect is often explained as due to the expansion of warmed air, a direct result of increased insolation. Another explanation here suggested is based on changes in the surface divergence in a high, which are shown to be an indirect result of insolation. The latter explanation is shown to lead to pressure differences of appreciable magnitude."

**Ten years of large-scale studies of the weather** [trans. title], H. PHILIPPS (*Naturwissenschaften*, 27 (1939), No. 50, pp. 825-834, figs. 2).—This is a review of 10 years' work in the preparing of 10-day forecasts at Homburg, involving the determination of mean pressure distributions and tracks and causes of variations in the depressions.

**Recent Australian papers on long-range forecasting**, C. F. BROCKS (*Bul. Amer. Met. Soc.*, 21 (1940), No. 3, pp. 129, 130).—A review.

**Problems of stream-flow forecasting on tributaries of the upper Mississippi**, B. S. BARNES. (U. S. D. A.). (*Bul. Amer. Met. Soc.*, 21 (1940), No. 3, pp. 95-100).—"The satisfactory solution of most of our river forecasting problems in the Mississippi Valley will come only with more complete basic data, a unified and systematic service of reports and routine computations, and, most important of all, more study. Some of the problems appear impossible of solution, notably the prediction of the formation and breaking up of ice gorges, and whether the uppermost one of a series of gorges will break first or the lowest one."

**Hydrologic studies: Compilation of rainfall and run-off from the watersheds of the Red Plains Conservation Experiment Station, Guthrie, Oklahoma, 1931-38**, J. W. SLOSSER (*U. S. Dept. Agr., Soil Conserv. Serv.*, 1940, *SCS-TP-32*, pp. [168], figs. [71]).

**Snow surveying**, J. C. MARR (*U. S. Dept. Agr., Misc. Pub.* 380 (1940), pp. 46, figs. 7).—For over 30 yr. forecasts have been made on the data obtained by measuring the water content of the snow accumulating during the winter, the accepted method of making these measurements being termed "snow surveying." This general treatise on the subject discusses the method and its reliability, when the surveys are taken and how the forecasts are made, the uses for water-supply forecasts, snow-sampling equipment and its care, snow-sampling and field office procedures, improvement and maintenance of snow courses and facilities for snow surveys, winter travel, and first aid. The success achieved in snow surveying is said to be due largely to the precautions always taken to insure that incoming cooperators appreciate the uses to which the data can be put and understand the

fundamental principles involved. This publication provides some of the needed information.

**Melting snow as a flood factor in the Sierra Nevada, E. H. FLETCHER.** (U. S. D. A.). (*Bul. Amer. Met. Soc.*, 21 (1940), No. 2, pp. 59-63).—Based primarily on observation and experience of the past several years and applying mainly to the western slope of the central Sierra Nevada, it is concluded that the ultimate effect of snow on the flood situation depends on the rate of water drainage from the snow cover as well as on the melting rate, and the melting of snow depends primarily on the air temperature, though modified by rainfall. For snow covers of different depths the run-off per unit of time varies roughly with the density of the snow. Rainfall readily penetrates the snow cover, but the latter is capable of absorbing considerable water and thus of retarding the ground surface drainage. The surface freezing of the ground along and below the snow line effectively halts drainage from the saturated soil. The more rapid melting up to the 5,000-ft. level is a much greater flood hazard than is present at the higher elevations. The most destructive floods are possible in the absence of a consequential snow pack in the mountains. During a warm-front storm period the snow line may recede over a 1,000-ft. altitudinal belt, releasing a large volume of snow water over a limited area without being particularly menacing if it occurs only at low or intermediate altitudes and provided the storm is not unduly prolonged. However, if the belt of receding snow extends to comparatively high levels, the area of effective run-off is proportionately increased. The higher the snow line at the beginning of heavy, general rains, the greater the possibility of floods from rapid run-off. The ultimate effect of water from melting snow on the flood situation depends on the rapidity of melting, the soil conductivity, and the width and elevation of the zone over which the snow line recedes during the general storm. The magnitude and effectiveness of the run-off area are thus determined.

**The problem of world climate, R. H. WHEELER** (*Bul. Amer. Met. Soc.*, 21 (1940), No. 2, pp. 46-58, figs. 2).—"This paper in part abstracts a lengthy and detailed investigation of climate and human behavior now in progress." While the viewpoint relates largely to the implications for psychology and social science, considerable climatological data are given, including tabulations of temperature and rainfall correlations among various regions and a schematized summary of world climate since 1800. It is concluded that probably since 1800, certainly since 1860, the status of climate the world over, where information is available, justifies the concept of "world climate." Temperatures and rainfall, the former more definitely, tend to rise and fall together over the world as a whole. World climate tends to fluctuate in accordance with a definite pattern, presented in detail.

**Studies in solar radiation and their relationship to biophysics and the general problem of climate and health, G. W. KENRICK and G. DEL TORO, JR.** (*Puerto Rico Jour. Pub. Health and Trop. Med.*, 15 (1940), No. 4, pp. 387-431, figs. 22; *Span. abs.*, pp. 420-431).—The paper describes work directed toward the contribution of quantitative physical data useful in biological problems, particularly those related to climate and health, and their applications to some of the problems to which it is believed such a program should contribute. The text considers the historical development of the program at the School of Tropical Medicine, the results obtained from solar radiation measurements, applications of solar radiation data, intercomparison of ultraviolet measuring equipment, and the scope and applications of a measurement program. There are 18 references.

**The use of solar energy for the melting of ice, H. LANDSBERG.** (Pa. State Col.). (*Bul. Amer. Met. Soc.*, 21 (1940), No. 3, pp. 102-107, fig. 1).—That the self-perpetuation of an area covered by ice or snow is largely determined by the

radiation properties of the surface was indicated by experiments with blocks of ice covered with coal dust as compared with uncovered controls. It was clear that if the albedo of a snow or ice cover is changed toward a greater absorption of incident energy, considerable amounts may be gained. It is believed that the direct use of solar energy by changing albedos of larger or smaller parts of the earth's surface has been neglected, and that some success in influencing climate on a small scale can at least be hoped for.

**Micro-climate and the agricultural engineer**, C. LORENZEN, JR. (*Bul. Amer. Met. Soc.*, 21 (1940), No. 3, pp. 114, 115).—An abstract.

**Physico-chemical studies on the nature of cold resistance in crop plants.** (Partly coop. U. S. D. A.). (*Nebraska Sta. Rpt.* [1939], pp. 29, 30).—A progress report on work with various types of plants.

**Papers on fruit-frost studies in Florida by the U. S. Weather Bureau** (*Bul. Amer. Met. Soc.*, 21 (1940), No. 2, pp. 65-70).—Temperature Survey Work in Florida, by M. L. Blanc (pp. 65, 66); Critical Temperatures of Florida Citrus Fruits, by A. L. Griggs (p. 66); Instrumental Equipment and Grower Education in Florida, by L. G. Pardue, Jr. (pp. 66, 67); Study of Surface Temperature Inversions at Seville, Florida, by C. G. Reeves (pp. 67, 68); Frost Protection by Sprinkler Irrigation, by R. T. Sherouse (p. 68); A Study of the Influence of the Lake Okeechobee Levee on Temperatures Over the Surrounding Mucklands, by P. J. Powell (pp. 68, 69); Radiational Factors Affecting Temperatures in Lake Okeechobee Mucklands, by J. W. Milligan (pp. 69, 70); and A Comparison of Cold Night Temperatures Over Muck and Sand Soils, by M. L. Blanc (p. 70).

**State crops severely injured by weeks of unseasonable rainfall—cotton suffers most; fertile bottoms of wide area flooded**, C. DORMAN (*Miss. Farm Res.* [*Mississippi Sta.*], 3 (1940), No. 7, pp. 1, 8).

**A bibliography of tree-ring analysis**, E. SCHULMAN (*Tree-Ring Bul.*, 6 (1940), No. 4, pp. 27-39).—This bibliography (412 titles) is largely limited to papers dealing in whole or part with the analysis of tree rings in relation to climatic and archaeological studies.

**Estimated ring chronology, 150-1934 A. D.**, A. E. DOUGLASS (*Tree-Ring Bul.*, 6 (1940), No. 4, insert, pp. [7], figs. 12).—Charts are given showing the estimated tree-ring chronology of the western Pueblo area of the United States.

**Climatological survey for Ohio and Wooster, 1938 and 1939**, J. T. MCCLURE (*Ohio Sta. Bimo. Bul.* 204 (1940), pp. 109-111).—A brief discussion of weather for 1938 and 1939 and a tabulated climatological summary for Wooster and for the State covering these 2 yr.

## SOILS—FERTILIZERS

[Soil investigations by the Massachusetts Station] (*Massachusetts Sta. Bul.* 369 (1940), pp. 8-10, 11-14, 52, fig. 1).—The report notes studies on the use of nitrogen as an aid in decomposing old sod, by K. J. Kucinski and W. S. Eisenmenger; the relative rate of nitrification of nitrogen materials on certain tobacco soils, by Eisenmenger and J. Richard; the absorption by food plants of chemical elements important in human nutrition, and the intake by plants of elements applied to the soil in pairs compared to the intake of the same elements applied single, both by Eisenmenger and Kucinski; the relative intake of certain elements by calciphile plants and calciphobe plants grown on soils at varying pH, by Eisenmenger and W. H. Bender; magnesium requirements of plants, by Eisenmenger and Kucinski; the effect of arsenious oxide ( $As_2O_3$ ), arsenic oxide ( $As_2O_5$ ), and antimony oxide ( $Sb_2O_3$ ) on soil and plant growth, by H. M. Yegian and Eisenmenger; relationship of natural vegetation to physico-

chemical properties of soils of Massachusetts, by Eisenmenger and W. S. Colvin; a survey of erosion problems arising from changes in land use, an investigation of the source and nature of erosional damage on the alluvial soils of Massachusetts, a study of the physical and chemical properties of wind-blown soils, and the relation between the rate of wind erosion and the principal factors affecting it, all by Kucinski and Eisenmenger; and Podzols of Massachusetts, by A. B. Beaumont.

[Soil investigations by the Nebraska Station] (*Nebraska Sta. Rpt.* [1939], pp. 5-9).—This report notes work on soil-erosion control and soil-moisture conservation (coop. U. S. D. A.), use of commercial fertilizers for cereals, revegetation of abandoned land, studies on the solubility of soil phosphorus, factors affecting permeability of soils to water, and determination and composition of soil organic matter.

**A survey and discussion of lysimeters and a bibliography on their construction and performance**, H. KOHNKE, F. R. DREIBELBIS, and J. M. DAVIDSON (*U. S. Dept. Agr., Misc. Pub. 372 (1940)*, pp. 68, fig. 1).—Lysimeter types are classified; the history of their installation and use for soil investigations and for water movement studies is outlined from the experiments of P. de la Hire in France, set up in 1688, to the equipment of the present time; established lysimeter findings are summarized; and suggestions for the construction, experimental plan, etc., of future lysimeters are offered. It is concluded that, despite the limitations pointed out, "many questions concerning pedology, soil fertility, and hydrology can be answered by the correct use of lysimeters. Filled-in lysimeters may fulfill useful tasks in fertility investigations if a sound water balance is maintained in the soil, but for pedologic and hydrologic studies carefully designed monolith lysimeters seem to be indispensable."

The bibliography of 489 titles, geographically classified, indicates by a letter code the type of information to be found in each publication listed.

**Some principles of accelerated stream and valley sedimentation**, S. C. HAPP, G. RITTENHOUSE, and G. C. DOBSON (*U. S. Dept. Agr., Tech. Bul. 695 (1940)*, pp. 134, pls. 16, figs. 19).—This bulletin presents results of a study of the principles of stream and valley sedimentation under the influence of culturally accelerated soil erosion, a step in a research project of which the ultimate objective is a sound and scientific program to prevent or alleviate damage to valley resources by such sedimentation. The present report is based chiefly on detailed studies of sedimentation in the drainage basins of Tobitubby and Hurricane Creeks, in Lafayette County, Miss., representative of one of the areas of most severe soil erosion and associated sediment damage in the Gulf Coastal Plain. The first of the two main parts of the bulletin is devoted to a description of conditions in these valleys and their tributary drainage areas. In the second part, 45 principles developed by analysis of the results of this investigation and less detailed studies in other parts of the United States are outlined and discussed.

"Accelerated stream and valley sedimentation is much more widespread and progressive accumulation is taking place much more rapidly than has been commonly realized either by the general public or by specialists in allied fields of scientific inquiry. The past and prospective future damage resulting from such sedimentation is of sufficient importance to be of national concern. Damage has been of many diverse kinds, but so far as is now known the most important have been (1) impairment of the productive capacity of agricultural valley lands by changes in soil texture, composition, or drainage, (2) aggravation of flood danger and flood damage by filling of channels and aggradation of flood plains with consequent increases in height and frequency of overbank floods, and (3) impairment of the effectiveness or usefulness of artificial structures and improvements. The amount of damage varies greatly according to the area and value of

the land and the size and value of structures or improvements within the areas of excessive sediment accumulation, as well as according to the rates of sedimentation.

"Texture of sediment is a major factor in determining the nature of sedimentation and the extent of the damage. Largely on this account gulying, valley trenching, and stream-bank erosion are judged to be relatively more important, in comparison with sheet erosion, as sources of harmful sediment than as causes of erosional damage alone. It also appears that the erosional areas responsible for the most serious sediment damage may not be the areas that have been most seriously damaged by erosion."

**The determination of run-off and erosion from New Hampshire upland soils.** (Coop. U. S. D. A.). (*New Hampshire Sta. Bul.* 319 (1940), pp. 22, 23).—This contains brief notes on the comparative benefits of different species of riverbank vegetation in checking stream-bank cutting and an analysis of erosion in relation to potato soil types.

**Relation of surface soil acidity to activity of *Azotobacter* in Fargo clay soils,** T. O. BERGE (*North Dakota Sta. Bimo. Bul.*, 2 (1940), No. 6, pp. 16-18).—*Azotobacter* appeared to be fairly abundant in alkaline soils in and near Fargo, particularly where lime content is high. However, in 37 long-term plats, where soil reaction varied between pH 4.90 and 6.80, typical *Azotobacter* were found to be markedly deficient both in number and in activity. Even in certain rotation plats where lime and phosphates are added at 4-yr. intervals and a reaction as high as pH 6.4 to 6.8 (second year after addition of lime) was found, the *Azotobacter* showed relatively poor development.

Preliminary investigations at this station have indicated that anaerobic Clostridia may play a larger role in the nonsymbiotic fixation of nitrogen in the soils examined than do organisms of the *Azotobacter* type.

**Soil testing: Operation, interpretation, and application,** F. G. MERKLE (*Pennsylvania Sta. Bul.* 398 (1940), pp. [2]+34, figs. 7).—It is the purpose of this bulletin to review the present status of soil testing, to show what the tests are adapted for and how to interpret them, and to point out their limitations as well as present knowledge permits. The conclusions reached are supported by determinations in some 6,000 soil samples obtained from soils in various uses over a period of 8 yr. They are based largely upon soil conditions in Pennsylvania.

The procedures used at the station and described in this bulletin are partly adaptations of the methods of others and partly direct applications of microchemical methods. As an extracting solution, 0.25 N sodium acetate is prepared by dissolving 10 gm. of pure stick sodium hydroxide in water and diluting the solution to about 600 cc., to which is added 19 cc. of glacial acetic acid, and the solution is made up to a volume of 1 l. When this solution is cool, the pH value is determined and finally adjusted to 5 by adding acid or alkali as needed. Exact normality is not important, but the pH must be correctly adjusted. For the extraction, 10 gm. of air-dry soil, which has been sieved through a 2-mm. sieve, is placed in a lipped tumbler and 50 cc. of the extracting solution added. When only approximate results are wanted the soil may be measured in a brass cup having a volume of 9 cc. The soil and solution are mixed with a glass rod, with care to break all granules, and allowed to settle for 10 min. from the time of adding the solvent. The mixture is then filtered through a phosphate-free filter paper. The filtrate is usually clear, but occasionally it is necessary to pour it through a second time. This extract is used for all determinations.

**Recent work concerning rapid soil tests in relation to crop yields in the United States,** M. S. ANDERSON. (U. S. D. A.). (*Chron. Bot.*, 5 (1939), No. 4-6, pp. 379-381).—A brief review and evaluation of the methods in use.

**Types of vegetation in Escalante Valley, Utah, as indicators of soil conditions,** H. L. SHANTZ and R. L. PIEMEISEL (*U. S. Dept. Agr., Tech. Bul. 713* (1940), pp. 46, pls. 16, figs. 7, map 1).—From an extensive study of soil-plant relationships, the authors found that most reliable indicators of soil conditions are the stable plant communities that have occupied the soil over a long period of time and have nearly reached equilibrium with soil and climate. The mixed growth of a variety of species that ordinarily are not associated with one another indicates disturbed soil conditions that may include a wide range of soil types from low dunes of sand to hummocks of heavy soil. The temporary communities of annuals, such as Russian-thistle, indicated damaged or destroyed original plant covers with or without a pronounced disturbance of the soil.

“In Escalante Valley, lands covered with a large bushy growth of sagebrush or sagebrush-greasewood indicate two of the best types for crop production under irrigation. Little rabbitbrush, galleta, winterfat, and shadscale land can become productive under irrigation. The first-mentioned may need special handling because of its light texture. Lands with a very poor growth of sagebrush or shadscale are less desirable because of a gravelly or a saline subsoil. With these leaching and draining may be necessary, as well as irrigation, as is the case with greasewood or greasewood-shadscale lands. Saltgrass already subirrigated is valuable for grazing. Both saltgrass and pickleweed lands are wet and saline and need draining and leaching before crops can be produced. The expense would usually be prohibitive. In this valley most of the juniper land is too stony and rough for crop production. Most of the irrigated land lying near the mountains was formerly covered with sagebrush.”

**The relation of nitrogen, phosphoric acid, and lime in the soils of east Texas to those constituents in Bermuda and little bluestem grasses,** J. F. FUDGE and G. S. FRAPS. (*Tex. Expt. Sta.*). (*Soil Sci. Soc. Amer. Proc.*, 3 (1938), pp. 189-194).—Significant correlation coefficients with respect to nitrogen were secured in Bermuda grass when the nitrogen content of the soil was less than 0.11 percent and in bluestem with all soils, with respect to phosphoric acid in Bermuda grass and young bluestem only when soils high in active phosphoric acid were included, and with respect to lime in Bermuda grass and mature bluestem when soils high in active lime were included and in young bluestem at all levels of active lime in the soil. Within a given forage group, significant positive correlations between protein and phosphoric acid were found in all groups, and also between protein and lime in young bluestem. A significant negative correlation between phosphoric acid and lime was found in mature bluestem. By partial correlation, additional significant correlations were found between protein and lime in Bermuda grass and between phosphoric acid and lime (negative) in Bermuda grass on soils of low fertility. Both young and mature bluestem grasses were deficient in phosphoric acid, and mature bluestem was deficient in protein.

**Retention by soils of the nitrogen of various compounds as shown by subsequent plant response,** J. P. CONRAD. (*Calif. Expt. Sta.*). (*Jour. Agr. Res. [U. S.]*, 60 (1940), No. 9, pp. 617-630, figs. 3).—The technic of Conrad and Adams (*E. S. R.*, 81, p. 171), consisting in the percolation of a solution of the nutrient to be tested through a column of successive pots of soil, followed by cropping of the pots to show the relative quantities of the nutrient retained in each, was used to indicate the relative retention of nitrogen in anionic, in cationic, and in nonionizing combinations.

Calcium nitrate, sodium nitrate, sodium nitrite, potassium cyanide, and potassium cyanate were not retained by the solids in the soils tested, as was shown by beneficial plant response in all pots of the respective columns. Nonretention

of sulfamic acid, picric acid, and sodium thiocyanate was shown by injury to the growth throughout the pots of the respective columns.

Ammonium acetate, ammonium carbonate, ammonium hydroxide, ammonium phosphate (monohydrogen), ammonium sulfamate, ammonium sulfate, hydrazine sulfate, hydroxylamine sulfate, tetramethylammonium chloride, and the hydrochlorides of trimethylamine, dimethylamine, methylamine, choline, and arginine were completely or almost completely retained in the top pots of their respective columns. Most of the nitrogen of semicarbazide hydrochloride and of guanidine carbonate was retained in the top pots of their respective columns. Small but significant quantities penetrated to lower pots.

There was no evidence of any retention of the nitrogen of acetonitrile, acetoxime, or acetamide. The nitrogen of glycine, cysteine hydrochloride, glutamic acid, formamide, urea, and  $\text{CaCN}_2$  was retained to a certain degree. "Indications are that decomposition to liberate ammonia and the resultant retention of this form of nitrogen during the period of actual percolation are important factors in retention with these compounds." Peptone, egg albumin, and blood albumin showed the same type of retention, whereas the nitrogen of gelatin and that of theobromine were completely retained in the top pots of their respective columns.

**Bibliography of literature on potash as a plant nutrient, reviewed July 1939 to September 1939**, D. H. JAMESON and C. M. SCHMIDT (*Washington, D. C.: Amer. Potash Inst., Inc., 1940, pp. [3]+80+XVII*).—A copiously annotated bibliography.

**The cause and nature of overliming injury**, A. R. MIDGLEY and D. E. DUNKLEE (*Vermont Sta. Bul. 460 (1940), pp. 22, pls. 4, fig. 1*).—Overliming injuries may occur if applications of lime are not thoroughly mixed with certain soils, plants developing distinctive pathological symptoms or being killed. Injury occurs particularly on acid upland podzolized soils, on some sandy soils, and on acid peat bogs. It may occur on any field soil if limed to excess after leaching with a dilute mineral acid and then with distilled water.

Certain soils when overlimed were shown to fix much boron in a form unavailable to crop growth. This appeared to be the cause of the overliming injury. The application of increasing rates of lime caused increasing fixation. Neither lime itself nor the soil itself fixed appreciable quantities, but when mixed together they were active irrespective of the form of boron or lime used. Bark, leaves, decayed wood, crop, and lignin residues fixed boron when overlimed. These appeared to be the main sources of organic boron-fixing material in soils. Certain synthetic organic boron-fixing substances similarly activated by excess lime were prepared and tested. Fixation seemed to be chemical rather than biological in its nature.

Applications of superphosphate, manure, calcium, or aluminum silicates correct the trouble, although pure soluble phosphates do not. Boron alone, of the many single elements tried, was effective. The corrective action of other materials seemed to be due to their boron content. Borax applications benefited certain crop plants which suffer injury from excess lime, but did not appreciably benefit timothy, oats, corn, or other grasses. Borax may be broadcasted or used as a spray. Rates of from 10 to 40 lb. per acre broadcast were found satisfactory for alfalfa. It is emphasized that great care must be exercised, since even a small excess may prove harmful. The need in Vermont seems confined to certain local areas where soils once acid have been generously limed, and to apple orchards showing internal cork and other symptoms of boron deficiency. Soils on which manure or wood ashes have been liberally used are not apt to need special applications.

**Second annual report of the Arizona fertilizer control office, year ending December 31, 1939**, W. T. MCGEORGE, E. O. FOSTER, and R. D. TAYLOR (*Ari-*

*zona Sta. Bul. 169 (1940), pp. [1]+127-133).*—In connection with the annual tabulation (E. S. R., 82, p. 23) of registrations and fertilizer analyses, 1939, this bulletin calls attention to the special type of fertilizer need shown in general by semiarid soils. Arizona soils are stated to have a considerable supply of insoluble phosphate but to be very deficient in available phosphate. They are also deficient in nitrogen but are well supplied with available potassium, and "few fertilizers sold in the State contain any potash."

**Registration, labeling, and inspection of commercial fertilizers, 1939,** M. F. MILLER, L. D. HAIGH, E. W. COWAN, and L. L. WISEMAN (*Missouri Sta. Bul. 417 (1940), pp. 51*).—The usual tabulation, for 1939, of the analytical data and information concerning the requirements and operation of the State fertilizer law are here given.

## AGRICULTURAL BOTANY

[**Botanical reviews**] (In *Annual Review of Biochemistry, IX*, edited by J. M. LUCK and J. H. C. SMITH. *Stanford University, Calif.: Ann. Rev., Inc., 1940, vol. 9, pp. 459-508, 529-592*).—The following critical reviews of recent research are of special interest to botany: Plant Pigments, by G. Mackinney (pp. 459-490), and Aspects of Inorganic Metabolism in Plants, by C. B. Lipman (pp. 491-508) (both Univ. Calif.); Organic Acids of Plants, by H. B. Vickery and G. W. Pucher (pp. 529-544) (Conn. [New Haven] Expt. Sta.); The Biochemistry of Viruses, by W. M. Stanley (pp. 545-570); and Biochemistry of the Lower Fungi, by H. Raistrick (pp. 571-592).

[**Botanical papers**] (*Iowa Acad. Sci. Proc., 46 (1939), pp. 97-117, 127, 129-140, 161-165, 167-179, 180, 181, figs. 26*).—The following papers are included: Iowa Species of *Agropyron*, by D. W. Augustine (pp. 97-104), and Plants New to Iowa, by G. J. Goodman (pp. 105, 106) (both Iowa State Col.); The Relation Between Chlorophyll Concentration and the Internal Surface of Mesomorphic and Xeromorphic Leaves Grown Under Artificial Light, by F. M. Turrell (pp. 107-117) (Calif. Citrus Expt. Sta.); and Teaching Aids in Botany—I, The Placement Test, by S. M. Dietz and C. J. Gould, Jr. (p. 127), and II, Diagrams, by S. M. Dietz (pp. 129-140), The Genus *Arabis* in Iowa, by C. D. Paris (pp. 161-165), A Preliminary List of Plants of the Sand Mounds of Muscatine and Louisa Counties, Iowa, by M. E. and R. G. Brown (pp. 167-178), A Quantitative Study of the Early Weed Stage of Secondary Plant Succession in Central Iowa, by J. M. Aikman and H. F. Barr (p. 179), Histology of a Genetic Malformation in Corn, by J. E. Sass and A. A. Bryan (p. 180), and Cytoplasmic Structures in the Basidium Revealed by Silver Impregnation, by J. E. Sass (p. 181) (all Iowa State Col.).

[**Abstracts of theses**] (*La. State Univ. Bul., n. ser., 32 (1940), No. 1, pp. 29, 30, 33, 98, 99*).—The following are of interest to botany: Studies on the Toxicity of Cerium Compounds for Bacteria, by S. C. Burkes (pp. 29, 30); Studies on Bacterial Antagonism, by C. L. Mixon (p. 33); and Vegetation of the South-western Part of Puerto Rico, by I. Velez (pp. 98, 99).

[**Botanical studies by the Massachusetts Station**] (*Massachusetts Sta. Bul. 369 (1940), pp. 21, 22*).—Studies of the effects of soil temperature on gardenias, by L. H. Jones, and soybean root temperature effects in a nutrient solution, by Jones and G. E. O'Brien, are reported upon briefly.

[**Abstracts of papers on plant physiology**] (*Assoc. South. Agr. Workers Proc., 41 (1940), pp. 159, 188, 207, 208*).—The following papers are of interest to agricultural botany: The Effect of Foliar Conditions on the Photosynthetic Activity of Pecan Leaves, by H. Lutz and M. B. Hardy (p. 159), and Use of Hormone Treated Cuttings and Special Type Grafts in Cotton Breeding, by W. H. Jenkins, D. C. Harrell, and J. O. Ware (p. 188) (both U. S. D. A.); Carotene and Vitamin

C in Forage Crops, by A. O. Leonard (p. 207) (Miss. State Col.); Abstract of Effect of Nutrient Deficiencies of Young Pine Seedlings, by L. J. Pessin (pp. 207, 208) (U. S. D. A.); and Properties of Nielson's So-Called Substance-B, by C. L. Worley (p. 208).

**Experimental designs to increase accuracy of greenhouse studies**, W. J. YODEN (*Contrib. Boyce Thompson Inst.*, 11 (1940), No. 3, pp. 219-228).—It has been shown that even in the comparatively well-controlled cultural conditions available in greenhouses the proper disposition of the test pots contributes markedly to the accuracy of the results obtained. In the first example it was found that 84 percent of the total sum of squares was accounted for by differences between complete replications along the bench and differences between the incomplete blocks across the bench. Expressed another way, the standard deviation of a single pot was reduced from 7.2 to 3.1 gm. These amounts are 21.5 and 9.4 percent, respectively, of 33.5 gm., which is the average yield of a single pot. The examples given exemplify the effectiveness of experimental design when account is taken of the characteristics of the material or environment encountered. It is apparent that much depends upon an apt selection of an arrangement which will take the fullest possible advantage of either known or suspected similarities in the material or environment. Experimenters are usually aware of the existence of such groupings of their material but have, until recent years, been unable to make much use of these groups. This paper makes available a number of new arrangements of Latin squares with missing rows which should be found useful in greenhouse studies.

**A speedier and less costly method of concentration in nitrocellulose imbedding**, H. W. JENSEN (*Science*, 91 (1940), No. 2369, pp. 509, 510, fig. 1).—This is a modification of the Jeffrey-Wetmore technic<sup>6</sup> by means of which used celloidin may be employed again and the time factor may be reduced.

**An inexpensive microphotographic camera**, E. M. ABRAHAMSON (*Science*, 91 (1940), No. 2369, p. 510, fig. 1).—An adaptation of the inexpensive Univex camera, model AF, to photomicrographic work.

**Morphology of the vegetative organs of sugarcane**, E. ARTSCHWAGER. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 60 (1940), No. 8, pp. 503-549, pls. 10, figs. 14).—In continuation of previous studies (E. S. R., 53, p. 324; 64, p. 618), the author attempts to evaluate certain vegetative characters from the standpoint of their usefulness in taxonomic description of sugarcane varieties. Stability of vegetative characters is only relative, since a character which appears fixed in one variety may show great fluctuation in another. Abnormal environmental conditions may intensify normal variability or they may have little or no effect, depending on whether a given character is conservative or a more recent adaptation. There are 32 references.

**Floral initiation in Biloxi soybeans as influenced by age and position of leaf receiving photoperiodic treatment**, H. A. BORTHWICK and M. W. PARKER. (U. S. D. A.). (*Bot. Gaz.*, 101 (1940), No. 4, pp. 806-817).—"Individual leaves on a Biloxi soybean when subjected to photoperiodic stimulation differ in their capacities to cause floral initiation. The most effective leaf on the plant is the one that has most recently attained its full size. Young leaves increase in their capacity to effect floral initiation until they attain full size, after which they gradually decline in effectiveness. The most active leaf, operating alone, is able to cause initiation of as many flower buds per plant as are formed when all leaves function simultaneously. The capacities of different leaves to supply a flower-forming stimulus are correlated with their relative states of maturity

<sup>6</sup>R. H. Wetmore. *Stain Technol.*, 7 (1932), No. 2, pp. 37-62, figs. 6.

and not with their distances from the growing points where flowers are formed. When the flower-forming stimulus from the third compound leaf passes downward through two internodes to the bud in the axil of the first compound leaf, it induces the formation of more flower primordia there than does the stimulus from the first compound leaf which is situated immediately adjacent to the bud. The flower-forming stimulus produced by the leaves of soybeans moves readily both up and down the stem."

**Absorption of soil moisture by maize roots, C. H. DAVIS.** (Univ. Ariz.). (*Bot. Gaz.*, 101 (1940), No. 4, pp. 791-805, figs. 3).—Observations of roots of corn plants in a glass-front box gave reasonably good estimates of the numbers in a narrow greenhouse box. Roots of established plants absorbed water from the soil more rapidly near the plant than at 3-4 ft. Roots of growing plants extracted water below the wilting percentage in soil near the plant when similar numbers of roots were present in moisture above the wilting percentage 4 ft. away. Water 4 ft. from the plant was eventually absorbed after the soil near the plant had dried below the wilting percentage. Growth of young plants under the test conditions was slowed by decreasing soil moisture and was stopped when the soil moisture percentage was still above the wilting percentage and the calculated wilting coefficient. Water absorption by roots is apparently a dynamic activity depending on the amount of water in the soil and the distance between the water and the transpiring plant tops.

**The factors determining the resistance to the movement of water in the leaf, C. L. MER** (*Ann. Bot. [London]*, n. ser., 4 (1940), No. 14, pp. 397-401, figs. 8).—The effect of severing the midrib and parts of the lamina on the absorption and transpiration of leaves (*Pelargonium zonale* variety used) is described. It is concluded that the resistance to water movement through the net veins is very small compared with the resistance to its passage out of the veins into the mesophyll cells.

**Observations on the anaerobic respiration of potato tubers, J. G. BOSWELL and G. C. WHITING** (*Ann. Bot. [London]*, n. ser., 4 (1940), No. 14, pp. 257-268, figs. 4).—As far as potato tubers are concerned, the results reported suggest that neither the forms of the CO<sub>2</sub> output curve during the hours immediately after transference from air to nitrogen nor the ratio of anaerobic to aerobic CO<sub>2</sub> output is evidence of the existence of oxidative anabolism during aerobic respiration. The form of the CO<sub>2</sub> output curve for whole tubers under anaerobiosis is considered the resultant of the output of the gas from the cells and that liberated from chemical combination with the tissue due to a decrease in tissue basicity under anaerobic conditions. On this interpretation the rate of CO<sub>2</sub> output from the cells is always lower under anaerobic than under aerobic conditions.

**An experimental study of the permeability to gases of the seed-coat membranes of Cucurbita pepo, R. BROWN** (*Ann. Bot. [London]*, n. ser., 4 (1940), No. 14, pp. 379-395, fig. 1).—"An apparatus is described by which the absolute rates of diffusion of gases across the seed coat can be measured. The seed coat of *Cucurbita* consists of two membranes, of which the outer is much less permeable to gases than is the inner. It is the inner, however, that controls the gaseous exchange since the outer is perforated by the micropyle. The mean values for diffusion in cc./cm.<sup>2</sup>/hr. are as follows: Outer membrane, CO<sub>2</sub> 3.0, O<sub>2</sub> 0.35, N<sub>2</sub> 0.31; inner membrane, CO<sub>2</sub> 15.5, O<sub>2</sub> 4.3, N<sub>2</sub> 3.2. The absorption of water increases the permeability to gases of the inner membrane by (1) providing a medium in which the gases can dissolve, (2) removing in solution some impermeable constituent. The saturated membrane is less permeable than one which has been partially dried, since in the first the lumina and intercellular spaces are occupied by water, whereas in the second free paths for diffusion

exist. There is in the inner membrane a living layer in which the resistance to diffusion is high. When this layer is killed the rate of diffusion across the whole membrane increases considerably. The structure of the seed coat is described, and its bearing on the problem under consideration is discussed."

**The salt relations of plant tissues.—I, The absorption of potassium salts by storage tissue,** W. STILES and A. D. SKELDING (*Ann. Bot. [London], n. ser., 4 (1940), No. 14, pp. 329-363, figs. 11*).—Absorption by carrot root tissue of both ions of a number of K salts (chloride, bromide, nitrate, dihydrogen phosphate, and sulfate) was followed for 4-5 days by determining the fall in concentration of the external solution, use being made of adsorption indicators, the polarograph, and the Spekker absorptiometer. From all the salts except sulfate, absorption of both ions proceeded rapidly. The rate of intake of  $K_2SO_4$  ions, although notably less than for other salts examined, was nevertheless quite definite in younger carrots. At the end of the storage season, however, it may be negligible. Apart from any initial exosmosis the absorption of all ions examined followed a two-phase course. The first phase was characterized by more rapid initial absorption, which fell off with time. The second phase, becoming evident after 2-3 days, was characterized by an increased absorption rate, and the falling off of this rate was conditioned by exhaustion of the external solution in respect to the ion concerned. The two-phase course of absorption can be explained as due either to an increase in permeability of cell membranes as a result of exposure to a solution of the salt employed, or to absorption being of two kinds. It is held that present evidence is inadequate to decide which view is correct. The two ions of a salt are absorbed unequally, but as such unequal absorption involves exosmosis of ions from the tissue, the degree of unequal absorption depends on the extent to which exosmosis of ions is possible. Hence, the departure from equality in absorption rate of cations and anions is more marked with dilute than with stronger solutions, since the concentration of ions available for exosmosis will be relatively less in relation to the amounts of ions absorbed the higher the concentration of the external solution. There are 31 references.

**Bibliography of references to the literature on the minor elements and their relation to plant and animal nutrition,** compiled by L. G. WILLIS (*New York: Chilean Nitrate Ed. Bur., Inc., 1940, 3. ed., Sup. 1, pp. 82*).—A supplement to the third edition (E. S. R., 81, p. 186).

**Botanical index to the third edition of bibliography of references to the literature on the minor elements and their relation to plant and animal nutrition** (*[New York]: Chilean Nitrate Ed. Bur., Inc., 1940, pp. 24*).—See above.

**Distribution of selenium in *Astragalus bisulcatus* and seleniferous soils,** L. R. WILLIAMS (*Thesis, Univ. Ill., Urbana, 1939, pp. [2]+4*).—An abstract of a thesis.

**The effect of low concentrations of selenium upon the growth of grain,** G. W. STANFORD and O. E. OLSON. (S. Dak. State Col.). (*S. Dak. Acad. Sci. Proc., 19 (1939), pp. 25-31*).—Examination of relative growth values and comparative dry weights of tops and roots of wheat seedlings indicated a possible stimulation to growth from additions of selenium in the form of  $Na_2SeO_3$ , low concentrations of Se (0.01-0.05 p. p. m.) appearing to cause root elongation. Increases in the length of leaves in corn without added Se were more rapid than in those receiving it, but the average dry weights of roots indicated that root development was stimulated by adding low concentrations (below 0.05 p. p. m.). Dry weights of tops indicated no inhibition or stimulation of growth in corn by Se. The average dry weights of oat roots and tops failed to show growth effects from Se, but growth values indicated an increase in the rate of change in height of plants from low concentrations. Sorghum growth was apparently stimulated somewhat by adding small amounts of Se to culture solutions.

Some effects of treatment of non-dormant seeds with certain growth substances, L. V. BARTON (*Contrib. Boyce Thompson Inst.*, 11 (1940), No. 3, pp. 181-205, figs. 4).—Seeds of various plants were treated with growth substances in the form of vapors, liquids, or dusts, and their effects on germination and further growth noted. Soaking in solutions of potassium  $\alpha$ -naphthaleneacetate at 320, 106.6, 35.5, 11.8, 3.7, and 1.2 mg./l. failed to increase the rate or percentage of germination, and injury resulted from the higher concentrations. Powder treatments with Auxan, Rootone, or Merck preparations (containing indolebutyric acid at 2, 5, 8, or 12 mg./gm.) also failed to stimulate, and similar treatments of 6-year-old tomato seeds revealed no advantages in germination. Measurements of very young seedlings from treated seeds of nine different varieties indicated increased seedling length following certain treatments of eggplant, radish, and stock, these differences being apparent only when the seeds were germinated on moist filter paper. Stunting effects followed treatment of all nine types of seeds with one or more of the higher concentrations. In tomatoes grown to maturity from treated seeds, no stimulation was noted, but some stunting effects persisted. Treated and control seed lots of meadow fescue, perennial ryegrass, Kentucky bluegrass, oats, spring rye, and wheat produced plants having the same growth rates and times of maturity. Studies of the flowering in larkspur, marigold, nasturtium, snapdragon, stock, and zinnia plants from treated seeds revealed no significant differences from controls, either in number of plants producing flowers or in number of flowers appearing. In many radish taproots from seeds treated with the higher concentrations, a constricted region was produced after the root started to enlarge, and below this constriction a second enlargement developed, giving the appearance of a double root. There are 23 references.

Seed treatments with talc and root-inducing substances, W. J. YODEN (*Contrib. Boyce Thompson Inst.*, 11 (1940), No. 3, pp. 207-218, figs. 2).—Seeds of wheat and soybeans were treated in the dry state with indoleacetic, indolebutyric, and naphthaleneacetic acids, talc, and Rootone and grown in sand and soil in the greenhouse and field. The concentration of the organic compounds in the talc preparations, as well as the proportion of powder to seeds, was adjusted to cover the range 0.5-240 p. p. m. of active substance by weight of seeds. In 10 experiments, observations of the germination, seedling height, wet weight of tops, grain yield, and root systems yielded no significant case in which the germination and growth of the treated seeds exceeded the controls. On the contrary, the evidence in the aggregate pointed to slightly lower values for the treated lots, and indicated that they had resulted from the presence of the talc. Of 19 contrasts of talc-treated seeds with controls, there were 15 cases in which the latter were superior and 1 case was a tie. The excess weight of the control plants averaged  $\pm 5$  percent.

Some effects of treatment of seeds with growth substances on dormancy, L. V. BARTON (*Contrib. Boyce Thompson Inst.*, 11 (1940), No. 3, pp. 229-240, figs. 4).—Treatment of dry, dormant seeds of the domestic apple (*Pyrus* sp.) and *P. malus niedzwetskyana* (= *Malus niedzwetskyana*) with growth substances in concentrations of 3.7 to 320 mg./l. had no effect on their subsequent production of seedlings. On the other hand, seeds of *Ulmus americana*, which did not require a pretreatment period at low temperature for germination but which showed improved germination capacity with such treatment, seemed to benefit by the application of solutions of 35.5, 11.8, or 3.7 mg./l. of potassium  $\alpha$ -naphthaleneacetate. This benefit was relatively small, however, so that growth-substance treatment of these seeds could not be used as a substitute for either low-temperature pretreatment or soaking in water under a light source as a means of speeding up the germination. The germination of seeds of *Cornus florida*, *C. stolonifera*,

*Pyrus* sp., and *P. malus niedzwetskyana* which had been afterripened by a period at 5° C. was inhibited by treatment with growth substances. This inhibiting effect was partially removed by a second period at 5°, but abnormalities often appeared in the seedlings so produced. Growth-substance treatment of germinated seeds of *Lilium auratum*, *Paeonia suffruticosa*, and *Viburnum* sp. failed to initiate growth of the dormant epicotyls.

**Effects of two preparations of naphthylacetic acid on the germination and early growth of wheat seed damaged by formaldehyde**, N. H. GRACE (*Canad. Jour. Res.*, 18 (1940), No. 6, Sect. C, pp. 215-218).—Seed of two wheat varieties was sprinkled with solutions of formaldehyde and naphthylacetic acid to give treatments of 1 and 10 parts of the latter to a million parts of seed by weight. In both varieties, formaldehyde reduced the germination rate, final count, and air-dry weight of stems and roots at 29 days after planting. Some reduction in root suppression resulted from the 1 p. p. m. concentration of growth substance, while the higher level had no observable effect. The study involved two preparations of the acid, differing only in respect to a trace of halogen in one which had no effect on final germination or stem and root weights, but increased the germination rate. The trace of halogen had the more marked effect at the higher concentration, and the Marquis variety was more affected than the Reward.

**Adventitious shoots and roots induced by natural influences and synthetic growth substances**, P. W. ZIMMERMAN and A. E. HITCHCOCK (*Contrib. Boyce Thompson Inst.*, 11 (1940), No. 2, pp. 127-141, figs. 5).—Althea cuttings produced numerous adventitious shoots along the disbudded stem in contrast to cuttings with normal buds. Most of these new buds were initiated from the upper end of cuttings, the lower end producing adventitious roots. There was a relatively narrow transition zone between the regions producing shoots and those producing roots. The new organs were usually associated with proliferating lenticel tissue or on the callus formed at scars. Apparently the potential meristematic tissue was first stimulated into activity and then regulated chemically. The well-known root-inducing substances prevented initiation of shoots, inducing roots from the same tissues instead. When disbudded althea cuttings were treated with vapors of naphthalene and indole substances, root production was induced from upper, middle, and lower regions, thus disturbing the normal polarity. By separating bark from wood and otherwise mutilating cuttings, it was found that wood kept humid produced callus and then adventitious shoots from this new tissue, but not roots. Extracts of bark contained both growth-accelerating and growth-inhibiting substances. Extracts of wood induced leaf epinasty and root formation when applied to tomato plant tissue. In contrast to althea, disbudded *Populus* and *Elaeagnus* cuttings produced adventitious shoots only at the apical cut surface or at scars where buds had been removed. Althea cuttings exposed a few days to high concentrations of CO<sub>2</sub> or traces of ethylene gas and then stored in a moist chamber produced more adventitious buds than controls. It is suggested that these gases interfered with the normal metabolism and brought about a condition favoring initiation of adventitious organs. There are 19 references.

**Effects obtained with mixtures of root-inducing and other substances**, A. E. HITCHCOCK and P. W. ZIMMERMAN (*Contrib. Boyce Thompson Inst.*, 11 (1940), No. 2, pp. 143-160, figs. 4).—Using many plant species and water or talc as carriers, mixtures of two or more substances were in many but not all cases more effective on cuttings than any of the individual substances alone. This greater than additive effect was characterized by increased numbers of roots, higher percentages of rooted cuttings, more uniform rooting, and other effects typical of higher concentrations of root-inducing substances. These effects were obtained with substances differing in root-inducing activity but not with those of

about equal activity. Not all genera or species of cuttings responded equally well to a given mixture. Certain mixtures of indolebutyric and  $\alpha$ -naphthaleneacetic acids were effective on indolebutyric- and  $\alpha$ -naphthaleneacetic-sensitive cuttings. Depending on the kind of cutting and test conditions, the following functioned as activators: Indoleacetic, indolebutyric,  $\alpha$ -naphthaleneacetic, and phenylacetic acids, vitamins B<sub>1</sub> and B<sub>6</sub>, and ethylene. Only a few of the possible combinations were tried with respect to number and kind of substances, relative proportions, and total concentration. A mixture of equal parts of two substances proved as effective (or more so) as 3- and 4-substance mixtures. In the tests reported, vitamins B<sub>1</sub> and B<sub>6</sub> functioned as activators for root formation in cuttings but not as root growth factors. Parallel tests with established plants also failed to indicate favorable effects of vitamin B<sub>1</sub> as a root growth factor, and deferred treatments were not effective on cuttings of tomato, *Taxus*, *Celastrus*, *Actinidia*, and *Hibiscus*, regardless of whether or not they had been given an initial treatment with a root-inducing substance. It is concluded that before any general practical use of vitamin B<sub>1</sub> can be recommended for soil amendment, more substantial data are needed.

**A study of the effects of different forms of colchicine on the roots of *Vicia faba* L.,** P. N. BHADURI (*Jour. Roy. Micros. Soc.*, 59 (1939), No. 4, pp. 245-276, pls. 2, figs. 30).—The forms tested were the chemically pure alkaloid, colchicine salicylate, and crude corm and seed powder of *Colchicum autumnale*. Although the general effects were the same, the roots revived better from the action of the third form. All forms induced collapse of the spindle mechanism. After some time the blocked metaphase split chromosomes reorganized a nucleus containing the double chromosome number. Also, a large number of tetraploid nuclei were formed by fusion of two groups of chromosomes caught in early anaphase. These nuclei appeared normal with four equal-sized nucleoli, and each had a membrane. Colchicine also temporarily arrested chromosome division at the attachment constriction region. The chromosomes straightened and shortened markedly due to the action of colchicine, and their constrictions became very distinct. Cell-plate formation was stopped, even after normal anaphasic separation of the chromosomes. The resting nucleus was most resistant to colchicine action, and the resting polyploid nuclei formed after treatment had no nuclear membrane. The chromosome-nucleolus relation seemed to remain unaffected, as did the growth and division of the chromosomes, but the fluidity of the nucleolar substance increased.

Extension of the zone of vascular tissue farther toward the root tip and premature differentiation of some of the vascular tissues were common in treated roots. Early cell-wall thickening rendered the tissues more tough and leathery. Branching of the root tip at time of recovery was a peculiar feature. Linear root growth progressively slowed down during treatment. The treated cells lost their polarity and grew uniformly in all directions. Seeds beginning to germinate revived very poorly from treatment, seedling treatment, therefore, being preferable for induction of polyploids. The minimum time for producing a positive effect was 5 min. for both the pure alkaloid and the salicylate. Although there was a minimum threshold of concentration, roots reacted very differently in this respect, as did also different cells of the same root.

It is suggested that colchicine induces definite chemical reactions as a result of which a change in the colloidal state of the chromosomes and the supporting medium occurs, which inhibits spindle formation. The other changes are considered to be of secondary nature. Colchicine seems to play the role of a catalyst in this chemical reaction, which is reversible and proceeds until it attains equilibrium. For this reason increase in concentration above the mini-

mum produces but little change. The root revives if the drug is removed. When its concentration becomes lower than the threshold of strength, the cells start normal division. The erratic behavior of roots at the time of recovery is said to be due to a shock effect, causing the dividing and resting cells to remain dormant for varying periods after treatment.

**Proceedings of local branches of the Society of American Bacteriologists** (*Jour. Bact.*, 39 (1940), No. 6, p. 757).—Abstracts of the following papers presented are of interest to agricultural botany: Factors Influencing the Production of Acetyl-methyl-carbinol by the Aerobic Spore-formers [*Bacillus* spp.], by N. R. Smith; and The Possible Utilization of Bacteriophage in the Classification of the Aerobic Spore-formers [*Bacillus* spp.], by R. E. Gordon (both U. S. D. A.).

**Micro-organisms and fermentation**, A. JØRGENSEN, rev. by A. HANSEN, A. LUND, and C. A. MITCHELL (*London: Charles Griffin and Co., 1939, 6. ed., rev., pp. XII+416, pls. 40, figs. 20*).—In this edition of the textbook (*E. S. R.*, 27, p. 204), the original plan is left essentially unchanged, but throughout the mode of presentation has been brought up to date, with expansion of the discussions of some subjects and restriction in the treatment of others. The chapter headings are historical introduction, general features of the morphology and physiology of fermentation organisms, laboratory equipment, nutrient media, sterilization and disinfection, technic, molds, yeasts, bacteria, and micro-organisms in water and air. The appendix contains data on nutrient media, stains, and reagents. The word concludes with a two-page bibliography and author and subject indexes.

**Nuclei in Actinomyces**, E. H. NEWCOMER and G. KENKNIGHT. (*Mich. Expt. Sta.*). (*Mich. Acad. Sci., Arts, and Letters, Papers, 25 (1939), pp. 85-87*).—Discrete intramyceial inclusions of nuclear morphology, which gave a positive reaction to the Feulgen technic and were interpreted as nuclei by the authors, are reported as observed in *A. viridis* and in six isolates of *Actinomyces*. Two of these isolates were from soil and three from *Actinomyces* scab lesions on potato tubers, while the sixth was from a scab lesion on a turnip root.

**The oxyhydrogen reaction in green algae and the reduction of carbon dioxide in the dark**, H. GAFFRON (*Science, 91 (1940), No. 2370, pp. 529, 530*).—The experimental data presented led to the conclusion that in these algae the oxyhydrogen reaction promotes the reduction of CO<sub>2</sub> in the dark. This means that all three types of CO<sub>2</sub> assimilation observed in organisms—chemical reduction in the dark, photochemical reduction with H donors in the light, and photosynthesis as specified by the liberation of O<sub>2</sub>—may occur in the same plant cell. Decomposition of CO<sub>2</sub> in plants is generally believed to be intimately linked with and dependent on the effect of light on chlorophyll. However, the results here reported suggest that the photochemical process and reduction of CO<sub>2</sub> are more widely separated reactions than has hitherto been assumed.

**An ecological effect of the New England hurricane**, M. D. ROGICK (*Ohio Jour. Sci., 40 (1940), No. 3, pp. 163-167, pl. 1, fig. 1*).—Following the hurricane of September 21, 1938, an unusually high tidewater struck the general region of Woods Hole, Mass. As a result the usual collecting sites showed changes in the quantity and kinds of organisms available during the previous summers. Moreover, some of the fresh-water ponds in the lowlands near the coast became salty or brackish from flooding by sea water. Detailed data concerning the resulting changes in fauna in one of these ponds are given, particularly with regard to the replacement of fresh-water with salt- or brackish-water species of *Bryozoa*.

**Nomina generica conservanda: Contributions from the Nomenclature Committee of the British Mycological Society, II** (*Brit. Mycol. Soc. Trans., 23 (1939), pt. 3, pp. 281-292*).—This contribution includes statements concern-

ing a further 13 of the names which were proposed for conservation in the lists published as a supplement to the International Rules, 1935 (E. S. R., 75, p. 753).

**Records for the Gramineae of the Douglas Lake region, Michigan, L. H. HARVEY** (*Mich. Acad. Sci., Arts, and Letters, Papers, 25 (1939), pp. 43-46*).—Collections of grasses by the author and J. H. Ehlers have added 15 species to the region, 3 of which seem to be previously unreported from the State.

**A revision of the genus *Lycopersicon*, C. H. MULLER** (*U. S. Dept. Agr., Misc. Pub. 382 (1940), pp. 29, pls. 10*).—It is stated that 29 specific names have been applied to 5 species of the genus, most of which are here reduced to synonyms, with a few maintained as subspecific entities. New names and combinations are as follows: *Eulycopersicon* n. subgen., based on *L. esculentum* as type—*L. esculentum* f. *pyriforme* n. comb., based on *L. pyriforme*; *Eriopersicon* n. subgen., based on *L. peruvianum* as type—*L. cheesmanii* f. *minor* n. comb., based on *L. esculentum minor*; *L. glandulosm* n. sp.; *L. hirsutum* f. *glabratum* n. f.; *E. peruvianum humifusum* n. var. The genus, except for *L. cheesmanii* of the Galápagos Islands, is apparently native only in the Andean region of South America, although *L. esculentum*, *L. esculentum cerasiforme*, and *L. pimpinellifolium* are widely distributed in the tropics of both North and South America as well as to some extent in the Old World. These are the more edible forms of the genus. They have been widely cultivated and have frequently escaped.

**Six thistles recently introduced into Texas, V. L. CORY**. (*Tex. Expt. Sta.*). (*Madroño, 5 (1940), No. 6, pp. 200-202*).—Includes species of *Centaurea*, *Silybum*, *Carduus*, and *Onopordum* (= *Onopordon*).

## GENETICS

**Biological symposia, edited by J. CATTELL** (*Lancaster, Pa.: Jaques Cattell Press, 1940, pp. VII+238, figs. [39]*).—Papers are presented by many of the leading authorities at the symposia on The Cell Theory, Its Past, Present, and Future; Mating Types and Their Interactions in the Ciliate Infusoria; and Chromosome Structure.

**Abstracts of papers presented at the 1939 meetings of the Genetics Society of America, Columbus, Ohio, December 28-30, 1939** (*Genetics, 25 (1940), No. 1, pp. 116, 117, 131, 132, 136, 140*).—The following are of interest to agricultural botany: Effects of Colchicine Upon the Nuclear and Cytoplasmic Phases of Cell Division in the Pollen Tube, by O. J. Eigsti; Karyotaxonomy of *Erythronium*, I, Preliminary Survey of Chromosomal Number, Morphology, and Structure of Developing Microgametophyte of [*E.*] *americanum*, by H. M. Phillips; The Developmental Basis of Inherited Size Differences in Plant Organs, by E. W. Sinnott and W. G. Whaley; and Changes in Chromosome Sensitivity to X-rays, by G. B. Wilson and B. R. Nebel (N. Y. State Expt. Sta.).

**The relation of genetics to geographical distribution and speciation; speciation, I, II** (*Amer. Nat., 74 (1940), Nos. 752, pp. 193-278, figs. 12; 753, pp. 289-321*).—The following papers on speciation and the relation of genetics to geographical distribution, presented before the joint sections of the American Association for the Advancement of Science, showed that speciation is no aimless wandering of genes through the organic world but rather is an orderly adjustment under the rigid control of environment. The papers are as follows: Introduction, by L. J. Cole (pp. 193-197) (Univ. Wis.); Speciation of Fishes, by C. L. Hubbs (pp. 198-211); Ecologic and Genetic Variability Within Species of *Peromyscus*, by I. R. Dice (pp. 212-221); Speciation From the Point of View of Genetics, by M. R. Irwin and R. W. Cumley (pp. 222-231) (Wis. Expt. Sta.);

Breeding Structure of Populations in Relation to Speciation, by S. Wright (pp. 232-248); Speciation Phenomena in Birds, by E. Mayr (pp. 249-278); Speciation in *Peromyscus*, by L. R. Dice (pp. 289-298); Levels of Divergence in *Drosophila* Speciation, by W. P. Spencer (pp. 299-311); and Speciation as a Stage in Evolutionary Divergence, by T. Dobzhansky (pp. 312-321).

Plant breeding in agronomy section outlined; several crops discussed, D. W. ROBERTSON. (Partly coop. U. S. D. A.). (*Colo. Farm Bul. [Colorado Sta.]*, 2 (1940), No. 3, pp. 6-8).—Problems, current objectives, and methods in crop improvement are discussed for wheat, oats, barley, corn, alfalfa, sugar beets, sorghums, and Sudan grass.

Genetic and cytologic studies of a brachytic mutation in barley, S. P. SWENSON. (Minn. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 60 (1940), No. 10, pp. 687-713, figs. 11).—Further studies on the inheritance of the brachytic habit of growth, carried on earlier by Powers (E. S. R., 80, p. 174), are reported, with considerations of linkage relationships of the gene for brachytic (*br*), the cytological nature of the mutation, and the nature of the action of *br* with respect to plant and organ size, cell size and number, growth rate, and frequency of cell division.

The gene for brachytic habit of growth behaves as a simple Mendelian recessive to the gene for normal growth habit, and *Br br* was found to be independent of the first six linkage groups and definitely associated with *F<sub>c</sub> f<sub>c</sub>* (chlorina) in the seventh group. The linkage intensity between these two pairs was determined from repulsion data. The cross-over value from *F<sub>2</sub>* data, considered more reliable than that from *F<sub>3</sub>*, was  $9.27 \pm 0.90$  percent. Chromosomes in Brachytic were as regular in appearance, behavior, and number as in the normal Himalaya and B4 barleys. The character was not associated with any observable change in chromosome structure, more likely being the result of gene mutation.

Brachytic grows about two-thirds as tall as Himalaya, from which it mutated, has leaf sheaths about two-thirds as long, awns about one-half as long, and a similar number of seeds per plant, although Brachytic seeds are about 85 percent as heavy.

Length of cells in comparable field-grown plants was found similar in the two strains, number of cells being proportional to length of plant and its parts. Epidermal cells were longer and narrower in the tip than in the middle and basal regions of the leaves and in older than in younger leaves. Plumules and primary roots of Himalaya were about twice as long as those of Brachytic, yet no significant differences were obtained for cell size in comparable parts. Primary roots of Brachytic were larger in diameter than those of Himalaya, the difference being associated with number rather than with width of cells. The cells in primary leaves and roots increased progressively in size at increasing distances from the meristematic region. Brachytic grew 65.19 percent as tall as Himalaya, with the difference in daily amounts of growth remaining fairly constant. Factors for differentiation and maturity appeared to act independently of that for growth rate. Himalaya had a longer and narrower meristematic region in sections of root tips, but the total area per section was similar in both varieties. Indications were that Himalaya has a higher frequency of mitosis per section of meristematic region and number of mitoses per square millimeter. The rate of cell division and elongation might be expected to be higher in Himalaya. The results indicated that cell formation is subordinate to the development of the organism as a whole.

A male sterile character in barley: A new tool for the plant breeder, C. A. SUNESON. (U. S. D. A. and Calif. Expt. Sta.). (*Jour. Hered.*, 31 (1940), No. 5, pp. 213, 214).—The type of male sterility in barley described, in which

florets contained shrunken, rudimentary anthers and normal pistillate flower parts, was shown by segregations in  $F_2$  to result from the action of a single recessive gene. It might be useful in breeding work.

**Effect of the method of combining the four inbred lines of a double cross of maize upon the yield and variability of the resulting hybrid, R. C. ECKHARDT and A. A. BRYAN.** (Iowa Expt. Sta. and U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 5, pp. 347-353).—In double crosses involving two inbreds from each of two corn varieties, combinations bringing together inbreds of the same variety in the parental single crosses were consistently the higher yielding. The highest yielding double crosses were those combining single crosses of widely different parentage. Significantly lower variances for ear height and ear length resulted from combining two inbreds from the same variety in each single cross parent. While lower variances were also found for plant height and ear weight, differences associated with method of combining were not significant.

**Chromosome aberrations in the endosperm of maize, F. J. CLARK and F. C. COPELAND.** (Conn. [New Haven] Expt. Sta. et al.). (*Amer. Jour. Bot.*, 27 (1940), No. 4, pp. 247-251, figs. 11).—Aberrant mitotic divisions were observed in endosperm tissue in stocks of corn giving high rates of mosaic formation. The frequencies of abnormal anaphases, such as single bridges and fragments, bridges alone, fragments alone, and double bridges, ranged from 2.5 to 13.2 percent in the plants used. Possible correlation of chromosomal aberrations and observed genetic variegation is discussed. The chromosomal break-fusion mechanism evidently can account for unstable types of changes in the endosperm.

**The origin of American tetraploid *Gossypium* species, J. O. BEASLEY.** (U. S. D. A.). (*Amer. Nat.*, 74 (1940), No. 752, pp. 285, 286).—The meiotic chromosome behavior and other features in hybrids between the synthesized tetraploid and natural tetraploids support Skovsted's hypothesis (E. S. R., 71, p. 457; 79, p. 31) that 26-chromosome *Gossypium* species were allotetraploids with one of the original species similar to Asiatic and the other similar to American 13-chromosome species.

**The effect of chromosome doubling on the crossability of *Solanum chacoense*, *S. jamesii*, and *S. bulbocastanum* with *S. tuberosum*, J. R. LIVERMORE and F. E. JOHNSTONE, JR.** (Cornell Univ.). (*Amer. Potato Jour.*, 17 (1940), No. 7, pp. 170-173).—When *S. jamesii* was crossed with diploids or with tetraploids, no seeds were obtained. From the crosses involving *S. bulbocastanum*, only one small seed, which may or may not be viable, was produced. With *S. chacoense*, however, a few seeds were obtained in  $2n$  crosses and many more in the  $4n$  crosses. The average in a seed ball was 1.2 for  $2n$  and 30.6 for  $4n$ . The reciprocal crosses of Earline  $\times$  *S. chacoense*  $4n$  were successful. In all three species, the percentage of viable pollen in diploids was higher than in tetraploids. In general, diploids contained more than 90 percent viable pollen, whereas tetraploids of *S. bulbocastanum* and *S. jamesii* averaged about 60 percent and those of *S. chacoense* seldom more than 10 percent. The quantity of pollen in the anthers of the tetraploids was less than in those of the diploids. See also an earlier note (E. S. R., 82, p. 318).

**Inheritance and linkage relationships of a chlorophyll mutation in rice, N. E. JODON.** (U. S. D. A. and La. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 5, pp. 342-346, figs. 2).—A recessive virescent mutation (*v*) appeared in an  $F_4$  Kameji  $\times$  Blue Rose progeny row. In the  $F_2$  of No. 2912A21 (virescent)  $\times$  C. I. 4630 (normal), virescence was found to be linked with three other recessives in the order glutinous (*gu*), colorless apiculus (*as*), virescent

(*v*), and noncluster (*cl*). A maturity factor (*fl*) appeared to be linked closely with virescent, but the relative position was not determined.

**Effect of awns on kernel weight, test weight, and yield of wheat, B. B. BAYLES and C. A. SUNESON.** (U. S. D. A. coop. 8 expt. stas.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 5, pp. 382-388).—Composited populations of homozygous awnless or awnleted and of awned plant segregates from Triplet × Oro and Baart × Onas wheat were grown in adjacent replicated nursery plats 5 and 4 yr., respectively, at several widely separated western experiment stations. Grain from the composite of awned plants surpassed that from the composite of awnless or awnleted plants in both kernel weight and test weight per bushel for each cross regardless of environment. The two composites from the winter wheat cross, Triplet × Oro, did not yield significantly different, but in the spring wheat cross, Baart × Onas, the awned composite outyielded the awnless or awnleted composite in 2 of 4 yr.

**A study of nicking in Jersey cattle, L. A. JOHNSON, J. W. BARTLETT, and L. COPELAND.** (Univ. N. H., N. J. Expt. Stas., et al.). (*Jour. Dairy Sci.*, 23 (1940), No. 8, pp. 709-718).—Analysis of the fat production records of the daughters of 17 Jersey bulls grouped according to grandsires showed that these sires nicked better with certain progeny than with others. Many factors, such as environment, also needed to be considered. Therefore, no very positive views regarding the operation of nicking could be made with the numbers of individuals furnishing the basic data and the variations found.

**Twins, but not full sisters, E. L. VIETH.** (Iowa State Col.). (*Jour. Hered.*, 31 (1940), No. 7, p. 306, fig. 1).—An account is given of a cow which produced twin calves following double mating with bulls of the Aberdeen Angus and Hereford breeds. One of the calves showed characteristics of the former and the other of the latter breed.

**Inheritance of horns and scurs in sheep, H. L. IBSEN and R. F. COX.** (Kans. Expt. Sta.). (*Jour. Hered.*, 31 (1940), No. 7, pp. 327-336, figs. 2).—A theory is presented to explain the inheritance of horns and scurs, based in part on data from Arkell (E. S. R., 28, p. 267) and from Warwick (E. S. R., 82, p. 320) and on correspondence with J. P. Willman. The operation is suggested of four pairs of genes, as follows: (1) *H* for horns and its allele *P* for polled (*HP* producing horned ♂♂ and hornless ♀♀); (2) *hm*, horn modifier, causing horned ♂♂ and hornless ♀♀; (3) *Ih* for horn inhibition, which causes skull depressions of the horn region in both sexes; and (4) *Sc* for scurs, incompletely dominant. Homozygous dominants had longer scurs than heterozygotes. There were no scurs on horned or *scsc* animals. *Ih* prevented the occurrence of scurs in heterozygous ♀♀.

**Development of the Notail sheep, J. W. WILSON** (*South Dakota Sta. Cir.* 28 (1940), pp. 22, figs. 16).—Progress is described on the development of a strain of sheep with no tails or tails sufficiently short that docking was not required. The flock originated in 1913 by mating fat-rumped rams from Siberia with purebred and grade Shropshire, Cheviot, and Hampshire ewes. In 1926, 100 western crossbred Rambouillet ewes were mated with 10 no-tail rams to improve the quality of the fleece. In the no-tail flock there was improvement in the elimination of the tail so that in 1939 most of the progeny had tails under 1.5 in. or no tails at all. None of the rams would eliminate the tails from the progeny of the first cross with other breeds and strains, but in the backcrosses only a very small proportion of the lambs needed docking.

**Wild × domestic sheep crosses, B. L. WARWICK, R. O. BERRY, and S. P. DAVIS.** (Tex. Expt. Sta.). (*Southwest. Sheep and Goat Raiser*, 10 (1940), No. 6, pp. 30, 31, figs. 6).—The authors call attention to the occurrence of short tails

among all the wild species of true sheep, but wild sheep (such as the mouflon) have no wool of commercial value. Since crosses of the mouflon with domestic sheep have produced fertile offspring, the transference of desirable genes from the wild to the domestic sheep seems possible.

[Studies on the genetics of Rhode Island Reds], F. A. HAYS and R. SANBORN (*Massachusetts Sta. Bul.* 369 (1940), pp. 89-91).—Brief reports are presented on progress in studies of the inheritance of the presence and absence of broodiness; relation of Rhode Island Red color to fecundity and early dorsal feather growth; selective breeding to reduce mortality; and improvement of fecundity through development of a line genetically pure for maturity at 180-215 days of age, elimination of winter pause, and high persistency.

The correlation of the condition of the uterine cervix to the reaction of the mares to teasing, M. M. ROBLES (*Philippine Jour. Anim. Indus.*, 7 (1940), No. 1, pp. 21-29, pl. 1, fig. 1).—Correlation between the condition of the cervix in 521 mares and their reaction to teasing showed complete agreement in those designated as highly positive or highly negative, but there was less agreement between mares designated as doubtful or uncertain by either of the tests. Differences in the response to a teaser stallion were so great as to make determination of heat by this method unreliable.

Some observations on a chemical test for pregnancy in mares, L. B. SHOLL and G. E. DERSHAM. (Mich. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 95 (1939), No. 751, pp. 507, 508).—Chemical tests for pregnancy by the method of E. Cuboni<sup>7</sup> were made on the urine of 17 mares at from 59 to 192 days after conception. Tests were negative under 80 days, but positive results were usually obtained after 90 days.

An artificial vagina for controlled-temperature studies of bull semen, G. W. SALISBURY and E. L. WILLETT. (Cornell Univ.). (*Cornell Vet.*, 30 (1940), No. 1, pp. 25-29, fig. 1).—An artificial vagina for use in semen collections for artificially inseminating dairy cattle is described. It consisted of a test tube inserted in a rubber hose and surrounded by warm water.

Observations on the oestrous cycle of the guinea-pig, P. BACSICH and G. M. WYBURN (*Roy. Soc. Edinb. Proc.*, 60 (1939-40), No. 1, pp. 33-39, figs. 3).—Study of 100 oestrous cycles in 35 virgin ♀ guinea pigs by the smear method showed the cycles to average 16 days in duration and oestrus to average 50 hr. in length. Climatic, domestic, and genetic variations are suggested in explanation of marked differences in the duration of the oestrous cycle in this animal as observed by other workers.

Experimental studies of the anterior pituitary, IV, V (*Endocrinology*, 21 (1937), No. 1, pp. 30-39, figs. 3; 26 (1940), No. 6, pp. 979-985, figs. 14).—In continuation of this series (*E. S. R.*, 69, p. 642), two papers are presented, as follows:

IV. *The replacement capacity and the noncyclic behavior of homoplastic anterior pituitary grafts*, M. Schweizer, H. A. Charipper, and H. O. Haterius.—Intraocular implants attached to the pupillary margin of the iris and extraocular implants in the lateral subconjunctival tissues became dominantly basophilic and retained their gonadotropic capacity in completely hypophysectomized guinea pigs. The ovaries became progressively more follicular until, after approximately 2 mo., a condition of constant oestrus supervened. On the basis of these observations the conclusions are advanced that the hypophyseal grafts were functional in maintaining the ovaries in the follicular phase and that the guinea pig pituitary when transplanted to a site removed from its normal anatomical position lost its cyclic character.

<sup>7</sup> *Klin. Wehnschr.*, 13 (1934), No. 8, pp. 302, 303.

V. *Functional activity of anterior pituitary grafts in the adult male guinea pig*, M. Schweizer, H. A. Charipper, and W. Kleinberg.—Anterior pituitaries from normal ♂♂ and ♀♀ were grafted into the eye chamber of hypophysectomized adult ♂ guinea pigs. The reproductive elements and interstitial cells of all the hypophysectomized animals were stimulated by the implants, and spermatogenesis was well maintained, as indicated by the electric ejaculation test. It seemed to make no difference whether the pituitary grafts were from ♂♂ or ♀♀.

**Presence of the sperm middle-piece in the fertilized egg of the mouse (*Mus musculus*)**, R. A. R. GRESSON (*Nature [London]*, 145 (1940), No. 3672, p. 425, fig. 1).—After the stage of pronucleus formation was reached, the spermatozoon middle piece was usually found detached from the sperm head. The sperm mitochondria became similar in size and staining properties to those of the egg and were distributed in approximately equal numbers in the first two blastomeres.

**The tolerance of male and female mice, respectively, to estrogens and androgens**, C. D. KOCHAKIAN (*Endocrinology*, 26 (1940), No. 1, pp. 54-60, figs. 4).—Immature mice injected daily with ♂ and ♀ hormones showed that testosterone was more injurious to ♂♂ than to ♀♀, though not fatal. The opposite result in the two sexes was found with oestrogen.

**The effects of Antuitrin-S, progesterin, and a vital dye on late pregnancy in the rat**, R. M. COCO. (La. State Univ.). (*Endocrinology*, 26 (1940), No. 6, pp. 1057-1063, figs. 4).—The effects of Antuitrin-S, progesterin, and dianil blue injected in pregnancy on parturition and the occurrence of fetal mortality were studied in rats. The results varied with the dosages and the time of injection, but, in general, Antuitrin-S on the eighteenth day of gestation resulted, in nearly all cases, in the birth of living or dead young at term without postponing parturition. Doses earlier than the nineteenth day of gestation usually resulted in the postponement of parturition and, in some instances, prolonged it from 1 to 5 days. Injections of from 75 to 100 rat units of Antuitrin-S on the eighteenth day of pregnancy caused luteinization of mature follicles, but such luteal tissues did not become functional enough to prolong gestation. Progesterin late in pregnancy did not prolong gestation. Injections of dianil blue during pregnancy proved toxic to the fetuses.

**The effect of testosterone, estrone, and estradiol applied locally to the penis of the rat**, H. S. WIGODSKY and R. R. GREENE (*Endocrinology*, 26 (1940), No. 6, pp. 1078-1080).—Administration by local application or subcutaneous injection of 7.5 $\gamma$  of testosterone for 10 days caused an increase of nearly 10 percent in the length and nearly 50 percent in the weight of the penis, as compared with the controls. Oestradiol and estrone percutaneously applied had no significant effect on the size or weight of the organ.

**Response of hypophysectomized rats to highly purified extracts of pregnant mare serum**, R. I. PENCHARZ, H. H. COLE, and H. GOSS. (Univ. Calif.). (*Soc. Expt. Biol. and Med. Proc.*, 43 (1940), No. 3, pp. 432, 433).—Two pregnant-mare serum extracts, highly purified and containing only small amounts of inert material, were found to give good follicular response and increases in the weight of the ovaries of immature, hypophysectomized ♀♀ and a very strong interstitial-cell response in the testes, seminal vesicles, and prostates of hypophysectomized ♂♂.

**Inactivation of pituitary lactogenic hormone by iodine**, C. H. LI, W. R. LYONS, M. E. SIMPSON, and H. M. EVANS. (Univ. Calif.). (*Science*, 91 (1940), No. 2370, pp. 530, 531).—Decrease in the potency of lactogenic solutions in pigeon crop-gland tests was associated with increased iodine absorption by thiosulfate.

The essentiality of both tyrosine and free amino groups for the action of the lactogenic hormone was thus demonstrated.

**The yield and composition of the milk of dairy cows and goats as influenced by thyroxine.** N. P. RALSTON, W. C. COWSBERT, A. C. RAGSDALE, H. A. HERMAN, and C. W. TURNER. (Coop. Miss. Expt. Sta.). (*Missouri Sta. Res. Bul.* 317 (1940), pp. 75, figs. 33).—Results of two series of experiments are summarized. In part 1, a total of 18 cows, including representatives of 3 dairy breeds, received injections of 15 mg. of thyroxine in alkaline solution on 3 successive days of each month of the lactation period. Average increases in milk yield, butterfat yield, and percentages of butterfat in the milk due to thyroxine administration were 13.6, 22.18, and 4.73, respectively. Milk and fat production reached a maximum 6–8 days after injection was started and gradually returned to a normal level between the twelfth and the fourteenth day. A rise in pulse rate (average increase, 7.64 beats per minute) closely paralleled the increase in milk yield. The response to thyroxine was greater during the declining phase of lactation, including the second to the eighth months, than at the peak of production. A seasonal variation in response was also observed, with smaller responses occurring in April and in October than during other months of the year. Goats in advanced stages of lactation also showed a marked response to thyroxine administration. Electrocardiographic studies of 2 cows which had received 15 mg. of thyroxine daily for 3 successive days showed no indication of heart damage, but results with goats were conflicting.

In part 2, similar investigations conducted at the Mississippi Experiment Station on 10 dairy cows are reported which confirmed the findings on the stimulating effect of thyroxine on the milk and butterfat production. The solids-not-fat content of the milk showed much variation between both experiments and between individual cows.

A review of the literature and an extensive bibliography are included.

## FIELD CROPS

**[Field crops work in Massachusetts],** W. S. EISENMENGER, K. J. KUCINSKI, R. W. DONALDSON, W. G. COLBY, and C. E. CROSS (*Massachusetts Sta. Bul.* 369 (1940), pp. 8, 14–16, 37, 38, 52, fig. 1).—Brief reports are made again (E. S. R., 81, p. 501) on field crops experiments concerned with efforts to overcome the unfavorable effects on tobacco yield and quality usually noted when old sod is plowed under preceding tobacco; planting, fertilizer, and production tests with sunflowers; trials of hay seeding mixtures and effects of potash dressings on meadows; pasture experiments, including tillage, fertilizer, reseeding, and grazing management studies; and control of weeds and shrubs of cranberry bogs.

**[Farm crops experiments in Mississippi]** (*Miss. Farm Res. [Mississippi Sta.],* 3 (1940), No. 7, pp. 1, 7, fig. 1).—Articles entitled Hay Crops Will Ripen—Little Else, by H. W. Bennett (p. 1); and Summer Legumes Plowed Under Increase Yields of Cotton, Corn in Delta Branch Station Tests, by R. Kuykendall (p. 7), report progress from farm crops studies.

**[Field crops work in Nebraska].** (Partly coop. U. S. D. A. et al.). (*Nebraska Sta. Rpt.* [1939], pp. 9–12, 13–23, 24, 25, 30, 54, 55, 58, 59, 60, 61).—Experiments with field crops (E. S. R., 81, p. 639) reported on from the station and substations included variety tests with winter and spring wheat, corn, oats, barley, grain sorghums, sorgo, alfalfa, sweetclover, soybeans, potatoes, and Jerusalem-artichokes; breeding work with corn (and hybrids), sorghum, wheat, oats, barley,

alfalfa, sweetclover, bromegrass, and potatoes; interspecific hybridization and inheritance of green cotyledon color and dwarf branching habit in sweetclover; crop rotations; response of wheat, sorghum, and spring grains to fallow and other tillage practices; the influence of manure, alfalfa, pastured sweetclover, and phosphate on yields of irrigated crops; nutrition and heat endurance studies with potatoes; drying seed corn with heated air under forced draft (E. S. R., 81, p. 778); planting tests with corn, wheat, oats, barley, sorghum, soybeans, and sweetclover; comparative forage yields of soybeans, alfalfa, and sorgo (E. S. R., 82, p. 479); studies of seed setting in alfalfa and bromegrass; a clipping test and coumarin determination with sweetclover; surface v. furrow drilling of wheat, oats, and barley; cold resistance of wheat as affected by defoliation, bunt, and variety; improvement of permanent pastures and meadows by improvement of species for reseeding, tests of forage grasses and legumes, response of grasses to intensity of clipping, and a range survey in a sand hill area; and control of bindweed by cultivation, smother crops rotations, and sodium chlorate and other chemicals.

[Field crops and pasture research in New Hampshire] (*New Hampshire Sta. Bul.* 319 (1940), pp. 19-21, 23, 26, 27).—Progress reports are made again (E. S. R., 82, p. 175), on agronomic experiments variously participated in by F. S. Prince, P. T. Blood, L. J. Higgins, T. G. Phillips, G. P. Percival, P. N. Scripture, and S. Dunn, and including tests with legumes on neglected hay lands; a dairy farm rotation in southern New Hampshire with sweet corn as cash crop; crop responses in a 3-yr. fertilized rotation of potatoes, oats, and hay; a fertilizer experiment with clover-timothy hay in the Connecticut Valley; effect of soil moisture and fertilizer placement on the vitality of the potato seed piece; a top dressing experiment on old pastures; and a study of pasture grasses and legumes pure and in mixtures.

Field-crop experiments at Las Vegas, 1937-1939, J. CARTER, JR. (*New Mexico Sta. Bul.* 271 (1940), pp. 11, figs. 8).—Varietal leaders in tests at 6,400 ft. elevation on black heavy soil under limited irrigation and their average acre yields included corn, Hays Golden 36.6 and Colorado No. 13 28 bu.; grain sorghum Early Kalo 12.6 and hegari 7.5 bu.; sorgo, Early Sumac 3.5 and Leoti Red 3.4 tons; annual hay crops, Siberian millet 1.91, field peas and oats 1.88, and Sudan grass 1.79 tons; pinto beans, strain 247 596.3 and Huddleston strain 579.4 lb.; and alfalfa, common 1.96 and Ladak 1.66 tons per acre. Silage from Colorado No. 13 corn 5.9 and Leoti Red sorgo 6.2 tons per acre was much better in quality due to advanced stage of maturity than that made from Ensilage corn, 7.1, or Atlas sorgo, 6.8 tons. Better hay was produced by field pea combinations than by any other annual hay crops. Range grasses under study are listed.

Review and discussion of literature pertinent to crop rotations for erodible soils, C. R. ENLOW (*U. S. Dept. Agr. Cir.* 559 (1939), pp. 51, figs. 14).—Information derived from the review of 158 listed publications has been compiled and discussed, with particular reference to the nature of and losses in soil organic matter, crop sequence, and the results reported from rotation experiments at State, Federal, and conservation experiment stations in the northern Great Plains, Corn Belt, and Northeastern and Southeastern States. Sections are also devoted to rotations on the contour, grass-legume mixtures, and rotations recommended for erodible soils. Merits of current practices are evaluated, with comments on needs for specific information on practices and crops in the several regions.

Effects of interplanting legumes in corn, C. K. McCLELLAND (*Arkansas Sta. Bul.* 393 (1940), pp. 29, figs. 3).—The effects of interplanting legumes in corn on the corn yields and on the yields of succeeding crops were studied, 1926-38, at the station, the Cotton Substation, and the experimental field at Scott.

As to yields of legumes, the most consistently successful method was to plant them in the row with corn at corn planting time, and the next best practice was to widen corn rows from 44 to 57 in. and plant the legumes in the middles when corn was waist high. Interplanting of legumes usually resulted in reduced corn yields—in the rows (A) an average reduction of 19.4 percent, in middles at laying-by time (B) 4.03 percent, and in middles of 57-in. corn rows (C) 7.54 percent, partly due to reduction of stand from 6,480 to 5,040 stalks per acre. The largest reduction in corn yields at Scott was with interplanted soybeans, at the Cotton Substation with velvetbeans, and at the station with mung beans.

Cotton yields at Scott increased 13.8 percent after (A), 2.7 percent following (B), and 2.5 percent after (C). Most consistent gains were obtained on cowpea plats and the least on the soybean plats, although cotton after soybeans in corn rows yielded 12 percent more than after corn alone. At the Cotton Substation, gains in cotton yields were 24.7 percent when cotton followed (A), 7.3 percent after (B), and 8.2 percent after (C). Velvet beans in the corn rows produced the highest gains, and soybeans similarly planted were second. In spite of the growing of legumes in corn, corn yields showed a downward trend, attributed to continuously clean cultivation, nonuse of cover crops, and lack of rotation with small grain, grass, or other solid planted crops, which would allow the land some rest from tillage.

At the station, oats yields following (A) were increased 5.9 percent but were reduced following the other methods. Oats yields were reduced after soybeans in wide middles of corn and on all plats after mung beans. Here too, although oats have been used in the rotation with corn and legumes, the trend of corn yields has been downward, due in part to unfavorable seasons.

Yields of dry forage from interplanted legumes varied from 0 to 2.4 tons per acre, the higher yields being made by legumes planted early and in corn rows. When the legumes were planted in middles at laying-by time, there were so many failures of stand, or such small growth, that the method was of doubtful value.

**Placement of dolomite, superphosphate, and basic slag for soybeans, Austrian winter peas, and vetch, W. B. ANDREWS.** (Miss. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 5, pp. 337-341).—Hay yields indicated that placing the 1:1 mixture of dolomite and superphosphate (400 lb. per acre) 2 in. to one side and from 2 to 3 in. below soybean and Austrian winter pea seed was superior to contact placement. Potassium chloride in contact with the seed decreased the yield. The best placement was dolomite in contact and superphosphate below and to the side of the seed. Indications were that separating the dolomite and superphosphate prevented undesirable chemical reactions and stimulated nodule bacteria. In general, the placement producing the highest yield of soybeans resulted in the highest nitrogen content, but placement had no effect on the nitrogen content of Austrian winter peas. Basic slag (400 lb. per acre) placed in contact with or below vetch seed was superior to side placements.

**Pasture top-dressing in New Hampshire, F. S. PRINCE, G. P. PERCIVAL, P. T. BLOOD, and P. N. SCRIPTURE** (*New Hampshire Sta. Bul.* 320 (1940), pp. 24, figs. 3).—Top dressing experiments (*E. S. R.*, 73, p. 773) continued on pastures near Stratham on Charlton soil and in Claremont on Sutton soil are reported on with evaluations of factors involved and suggestions on the use of fertilizers on pastures and the maintenance of soil fertility.

Response of pasture sods to fertilizers and lime seemed to be governed by moisture relationships of the soil, the lighter, drier soils responding mainly to nitrogen and the heavier, moister soils to all the nutrients and lime because

wild white clover forms a component part of the sod on such soils under proper treatment. Farmers appear to be justified in using lime and superphosphate in beginning pasture improvement on the heavier soils. After these materials improve the sod, potash should be added to the fertilizer for maximum results and also nitrogen, if there is a pasture shortage in spring as through summer and fall. The results in the Connecticut Valley in both pasture and hay production suggest that potash exerts a more beneficial effect on clover growth than any other material. Nitrogen has been consistent in producing more forage on both light and heavy soils in these tests reported. The principal response from nitrogen applied in the spring has come soon after application in spring and in early summer. Variation in response to different nitrogen carriers prevented definite recommendations. A heavy triennial application of superphosphate on the pasture near Stratham gave better returns over a period of years than a light annual treatment, with equal amounts of phosphoric acid applied, but with potash the annual light treatment was superior.

Pastures under test yielded about 1,300 lb. more dry matter per acre in the wet season of 1938 than in the dry season of 1939 with the same treatments, suggesting that moisture is an important factor in pasture production and emphasizing the need for choosing a heavy, well-watered soil for treatment. As an average, \$1 invested in fertilizers used on these pastures has brought in about \$2 worth of feed, a return apparently ample to warrant the practice.

**The chemical composition of pasture species of the northeast region as influenced by fertilizers, B. A. BROWN.** ([Conn.] Storrs Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 4, pp. 256-265, figs. 3).—In another phase of the station's pasture program (E. S. R., 81, p. 776), analyses of over 300 samples of pasturage from 17 variously fertilized permanent, grazed plats were made from 1932 to 1936. Fertilizers ranged from superphosphate alone to complete minerals (PLK) plus 84 lb. of N per acre annually. Superphosphate caused the greatest improvement in important nutritional characteristics, namely, a 25-percent increase in protein, a 5-percent decrease in fiber, and a 50-percent increase in P. In these respects, further advances were attributed to adding limestone and/or nitrogenous fertilizers with superphosphate. Superphosphate (16 percent) at 500 lb. per acre in 1924 was responsible for a 40-percent increase in the P in the pasturage in 1938. The Ca:P ratios varied from 1.4 for the PLK plus high N plats to 2.9 for the nonphosphated pastures. The Si, Fe, and Al contents of the unfertilized vegetation were each approximately double those found in the P or P+ pasturage. Mn was consistently 60 percent higher in the grasses from the unlimed plats. S, Cl, and Mg did not vary so much as the elements mentioned above, and the effects of fertilization were much less evident. Intraseasonal variations in composition of samples from the same plat were equivalent to 25 percent frequently and 40 percent occasionally of the annual means, illustrating the difficulty of obtaining fresh pasturage of uniform quality for feeding trials.

The N content of timothy, mowed June 1, was not increased by 28 lb. of N but was raised by 56 lb. of N per acre applied annually in April. In this case, early cutting was much more important than nitrogenous fertilizers. On seeded, lawn-mowed plats, the N, P, K, Ca, and Mg contents of pure stands of Kentucky bluegrass and Rhode Island bentgrass were influenced appreciably by the source of fertilizer nitrogen. Materials carrying Na increased the K in the grasses, while magnesian fertilizers had the opposite effect. On this soil (pH 5.3), the use of physiologically neutral or alkaline N carriers resulted in higher N, P, and Ca contents in the grasses.

**A comparison of yields and composition of some Illinois pasture plants, R. F. FUELLEMAN and W. L. BURLISON.** (Ill. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 4, pp. 243-255).—Yields of oven-dry forage were obtained, 1935-37, from reed canary grass, bromegrass, Kentucky bluegrass, and orchard grass pastures at Urbana, Ill. Analyses as tabulated show the protein, calcium, and phosphorus contents of these grasses when sampled as follows: A, herbage plucked or clipped under a cage placed over a representative grazed area at a previous sampling date or when cattle were turned in; C, harvested from a representative grazed area; and B, herbage harvested from beneath the cage placed on the C area on the previous sampling date.

Bromegrass has yielded more oven-dry forage and total digestible nutrients per acre than these other grasses. On the basis of percentage composition, Kentucky bluegrass usually contains more digestible nutrients per pound than the other three grasses. The considerable variability in composition found in the same species in different seasons was apparently a seasonal effect due in part to previous management, to type of livestock used, or to the physiological effects of environment, more specifically precipitation and temperature. Data on the chemical composition of these forage grasses are expressed in the form of hyperbolic curves, the reverse of the seasonal temperature curves which were in the form of parabolas. Yields as calculated by the A and B methods usually varied from each other depending on season and previous treatment. Following the season of 1936, forage yields of a bunch type, as orchard grass, showed larger differences between A and B yields than did the sod-forming bluegrass and bromegrass. See also a previous note (E. S. R., 81, p. 777).

**The influence of grazing upon certain soil and climatic conditions in farm woodlands, R. F. CHANDLER, JR.** (Cornell Univ.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 3, pp. 216-230, figs. 6).—Measurements of soil and climatic conditions in 18 paired grazed and ungrazed woodland areas in central New York revealed the higher contents of soil organic matter and soil moisture, higher moisture equivalent, and higher relative humidity on ungrazed soils, and the higher volume weight of soil, higher air and soil temperatures, and greater amount of light penetrating forest canopy on grazed soils. No significant differences were found in the pH of the surface soil.

**Effects of grazing upon bunch wheat grass, W. R. HANSON and L. A. STODART.** (Utah Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 4, pp. 278-289, figs. 4).—Bunch wheatgrass (*Agropyron inerme*) was studied on protected and heavily grazed areas on range land in Cache Valley, Utah, to compare root development, herbage and seed production, and content of sugar, starch, and hemicellulose in roots and stem bases.

The habits of growth of the roots are well adapted to its habitat and insure the species a place as dominant in the area studied. The soil mass below normal plants was thoroughly permeated from a depth about 5 cm. to as deep as 180 cm. Root weight was 13.1 times the top weight. The weight of roots per cubic decimeter of soil averaged 25.85 gm. on protected range and 4.22 gm. on heavily grazed range. Maximum depth of roots of grazed plants was reduced materially. A very marked decrease in the above ground parts accompanied overgrazing, as was shown by reduced basal area, height, and number of seed stalks. Germination tests of filled florets from protected and heavily grazed range showed no significant difference. On protected range 38.8 percent of the florets matured viable seeds and on heavily grazed range 23.9 percent matured, and the respective seed production was 630.2 and 12.2 viable seeds per square meter of ground. Stem bases and roots of protected plants contained 17.77 percent sugar and

starch, while those of plants grazed heavily contained 14.33 percent. The hemicellulose content was not significantly different. Evidently *A. inerme* could have been, and probably was formerly, dominant on much range land in Cache Valley where it is at present scarce or wanting. Sustained yield of *A. inerme* depends predominantly upon extent, intensity of ramification, and carbohydrate content of the root system.

**Inflorescence variations in buffalo grass, *Buchloe dactyloides*, L. E. WENGER.** (Kans. Expt. Sta. and U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 4, pp. 274-277, figs. 3).—A number of offtype inflorescences occurring in dioecious plants observed at Fort Hays, Kans., are described.

**Leaf pigment concentration and its relation to yield in Fairway crested wheat grass and Parkland brome grass, I. J. JOHNSON and E. S. MILLER.** (Minn. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 4, pp. 302-307).—Widely significant differences were found in percentage of total carotenoid pigments,  $\beta$ -carotene, and total chlorophyll in a study of 55 clonal lines of Fairway crested wheatgrass and 76 clonal lines of Parkland bromegrass. The strains studied also varied significantly in yield on a green weight basis. No significant relationship was noted between the concentration of chlorophyll or carotenoid pigments and yielding ability. Significant correlations were obtained between the concentration of total chlorophyll and either total carotenoids or  $\beta$ -carotene.

**Germination of seed of goosegrass, *Eleusine indica*, E. H. and V. K. TOOLE.** (U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 4, pp. 320, 321).—Test results indicated that from 20° to 30° C. or from 25° to 40° alternations seems to be the most favorable temperatures for germination. Potassium nitrate is beneficial, and light is needed if potassium nitrate is not used. Complete germination at from 20° to 35° with potassium nitrate required from 28 to 84 days, depending upon the maturity and the age of the seed.

**Effect of frequency of cutting on the growth, yield, and composition of Napier grass, C. P. WILSIE, E. K. AKAMINE, and M. TAKAHASHI.** (Hawaii Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 4, pp. 266-273, figs. 2).—Napier grass was harvested uniformly February 19, 1935, and plats were cut every 6, 8, 10, 12, and 14 weeks thereafter until November 23, 1937, 144 weeks later. An increase in the interval between harvests resulted in a higher total forage yield. Dry matter yields arranged themselves in the decreasing order 14-week cutting interval, 12-week, 10-week, 8-week, 6-week. There was some indication of a seasonal effect on forage yields. The greatest amount of palatable forage was produced by cutting every 8 weeks, and the most protein in the palatable portion was produced by grass cut at 6 and 8 weeks of age. The percentages of palatable forage and of protein and ash (including phosphorus and calcium) decreased as the plants grew older, while crude fiber percentage increased as the interval between cuttings was prolonged. Grass cut every 6 weeks was handicapped by poor recovery after each harvest, depleted stand, and greater weed competition. When yield, quality, and persistence are all considered, it appears desirable under Hawaiian conditions to cut Napier grass every 8 weeks. A 10-week cutting interval might be used to advantage during winter months when growth is slower.

**The ryegrasses, H. A. SCHOTH and M. A. HEIN.** (Coop. Oreg. Expt. Sta.). (*U. S. Dept. Agr. Leaflet 196* (1940), pp. 8, figs. 2).—The characteristics, merits, and uses of the Italian (*Lolium multiflorum*), perennial (*L. perenne*), and common ryegrasses are described briefly, with information on climatic and soil adaptations, seeding practices, management for hay and pasture, use as lawn grasses, and seed production.

**The relationship between leaf area and yield of the field bean, with a statistical study of methods for determining leaf area, J. F. DAVIS.** (Mich.

Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 5, pp. 323-329, fig. 1).—Field bean leaf areas measured with a planimeter closely approximated those estimated from use of factors obtained from length and width measurements of the center leaflets. Total leaf area =  $0.004517 L \times W$  (of center leaflet) was deemed the best of 4 equations because of time saved, since only the length and width of the center leaflet are needed. Furthermore, the leaf area of a field bean plant could be obtained without removing the leaves. Measurements of 36 leaves sufficed to arrive at a suitable factor. This method of securing leaf areas might also be used with any plant with similar leaf habits, providing a suitable factor was calculated. Plants from fertilized plats tended to have greater leaf area and higher yields than plants from untreated plats.

**Preliminary results on seed setting in red clover strains**, C. P. WILSIE and N. W. GILBERT. (Iowa Expt. Sta. and U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 3, pp. 231-234).—Studies, 1938-39, indicated both less honeybee activity and less seed production in the Zofka short corolla tube strain of red clover than in American strains. Contrary to popular expectation, length of corolla tube did not seem to be important under the conditions. Possibly abundance of pollen, or secretion, or concentration of nectar may have been more important in determining attractiveness of strains to honeybees. Data on seed setting suggested that with well-adapted American strains there might be excellent potential possibilities for high yields of seed when conditions favor abundant bee activity.

**Effect of pollination upon chemical composition of silks of certain inbred lines of maize**, I. R. HOENER and R. O. SNELLING. (Ill. Expt. Sta. and U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 3, pp. 213-215).—Pollinated silks (sampled about 72 hr. after emergence) of four inbred lines of corn appeared to be significantly higher in protein content and significantly lower in moisture content than unpollinated silks. The protein content of the silks of the inbred line L317 (Iowa) was considerably higher than that of K4 (Kansas), Ohio 51, and U. S. 540. The H-ion concentration of the juice expressed from silks of K4 and L317 was not influenced by pollination, that of inbred 51 showed an increase of 0.12 pH, and that of inbred 540 a decrease of 0.43 pH. Pollination did not appear to influence significantly the refractive index of expressed juice.

**Corn varieties in Mississippi**, C. R. OWEN (*Mississippi Sta. Bul.* 339 (1940), pp. 20, figs. 10).—Variety tests with corn at the station and substations, 1928-38, are summarized, effects of early and late plantings on yields are compared, and remarks are made on regional adaptation and characteristics of varieties and on the merits of hybrid corn.

Neal Paymaster, Jellicorse, Cocke Prolific, and College Hybrid 47 (Cocke Prolific  $\times$  Laguna) were generally outstanding, although rankings varied among stations. Other good sorts were Laguna and the two prolifics Mosby and Hastings. Early plantings, about April 1, have yielded better than late planting, about June 1. Even Laguna, the leader of the late planted group, averaged higher in the early planting.

**Effect of "clipping" or rubbing the oat grain on the weight and viability of the seed**, G. H. CUTLER. (Ind. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 3, pp. 167-175, figs. 2).—When grain of six varieties of oats was lightly and heavily rubbed to remove tips or tails of the hull and other extraneous materials, the increase in test weight averaged from 21.8 to 37.4 percent, or 7.3 to 10.2 lb. per bushel, the higher percentages occurring in the lighter samples. Germination tests in a Minnesota germinator and in soil in the greenhouse showed no indication of loss in viability traceable to rubbing or clipping. Results were consistent in all samples stored for from 4 mo. to more than 3 yr.

**Maintaining identity and pure seed of southern oat varieties, T. R. STANTON** (*U. S. Dept. Agr. Cir. 562 (1940), pp. 20, figs. 15*).—Maintenance of varietal identity and purity in southern red oats, long a perplexing problem, has been complicated further by the distribution of improved strains of the relatively few established varieties. Fulghum and Red Rustproof, old and widely distributed varieties, are still being mislabeled. Development of new varieties resembling certain old sorts in plant and grain characters has also led to confusion. Columbia, a new spring variety, is being sold as Winter Turf, and Fulgrain, a new smut-resistant variety, is being confused with Fulghum. Characters useful for differentiating these varieties are described and compared for those interested in identification. Comment is also made on efforts by State seed laboratories and crop improvement associations in making available better seed, true to variety of known breeding.

**Potato research at Cornell University, O. SMITH.** (Cornell Univ.). (*Amer. Potato Jour.*, 17 (1940), No. 2, pp. 27-37).—Research activities mentioned deal with potato rotations, fertilizers and side dressings, rate of applying potash, seed spacing and rate of fertilizer application, soil reaction and green manure, seed storage and handling methods, storage of table stock, control of dormancy, flowering response to environmental changes and chemical treatment, hollow heart, and cooking quality.

**Potato culture and storage investigations in 1938 and 1939, E. V. HARDENBURG.** (Cornell Univ.). (*Amer. Potato Jour.*, 17 (1940), No. 3, pp. 60-65).—The review covers 23 titles.

**Performance of clonal strains of Triumph potatoes, I-V, H. O. WEBNER.** (Nebr. Expt. Sta. et al.). (*Amer. Potato Jour.*, 17 (1940), Nos. 3, pp. 66-80; 4, pp. 95-99; 5, pp. 123-127; [6], pp. 153-155; 7, pp. 174-181).—Extensive field tests of five or more clonal strains of Triumph potatoes, ranging from very early to very late in maturity, conducted during the last decade in different potato-growing sections of Nebraska and in cooperation with experiment stations in several Southern and Central States, are reported in contributions entitled I, Triumph Strains on Dry Land in Western Nebraska, II, Comparison of Strains Under Irrigation Conditions in Western Nebraska, III, Comparison of Strains in Central Nebraska (at North Platte) With and Without Irrigation, IV, Comparison of Triumph Strains in Eastern Nebraska (at Lincoln) With and Without Irrigation, and V, Comparison of Triumph Strains in Various Southern States.

Where potatoes are grown as a late crop on dry land, the late strains appeared to produce the highest yields in most years and seemed less likely to produce scabby tubers. They produced, however, somewhat rougher tubers and were least productive in dry years. The earliest strains lacked in productivity in the best years and the tubers were quite scabby. Midseason strains appeared to be most desirable because they were reasonably satisfactory each year. Under irrigation in western Nebraska, the earliest strain was desirable if planted early or very late, but seemed hazardous for midseason planting because of the possibility of much scab infection. If this strain is used, plants should be spaced close together. The medium strain appeared most generally suitable. The later strains appeared to have the least scab even if planted early, but the large vine growth, large tuber size, and inferior tuber type render them of doubtful merit. In eastern and central Nebraska with or without irrigation, only the earliest strain could be considered desirable, and it seldom equaled the other early varieties, as Warba or Irish Cobbler.

In the Southern States, yields were slightly higher from the late strains, but the earlier strains, because of somewhat superior tuber type, were often most desirable. The very early strains did not seem so suitable as the second early

or midseason strains for general use in the South. Strain differences, as in time of tuberization, etc., were very much less than in the North.

**Relation of some growth characters to stoloniferous condition in seedling Irish potatoes, J. C. MILLER, F. MCGOLDRICH, and E. L. LECLERG.** (La. Expt. Sta. and U. S. D. A.). (*Amer. Potato Jour.*, 17 (1940), No. [6], pp. 140-147, fig. 1).—Study of a number of progenies from potato selfings and crosses under field conditions at Baton Rouge, La., revealed that as degree of maturity increased from early to late, tuberization decreased accordingly. The degree of tuberization, in general, decreased as the maximum plant height and as primary stolon length increased. In the crosses studied, heat sprouting increased as stolon development progressed from a tuberous to a less tuberous condition. Maximum heat sprouting occurred at a higher level of tuberization in the two selfings than that for the crosses.

To obtain high-yielding clonal lines of potatoes, it seemed desirable under Louisiana conditions to select first-year seedling segregates having tuberous to slightly stoloniferous types of stolon growth. Since the studies indicate that maximum plant height and earliness of maturity are associated closely to these types of stolon development, these two characters may serve as criteria.

**Longevity of potato seed, C. F. CLARK.** (U. S. D. A.). (*Amer. Potato Jour.*, 17 (1940), No. [6], pp. 147-152, fig. 1).—Potato seeds stored for 13 yr. in an envelope and in a bottle at room temperatures and in bottles at 40° and 32° F. were tested yearly. Cold storage was decidedly superior to storage at room temperature in maintaining viability, and the envelope was the least efficient. Seed stored at 40° showed no decline in viability after 11 yr. of storage. The 32°-storage prolonged the life of the seed to the end of 13 yr. and appeared to have a stimulating effect, since the highest germination percentages in this lot were obtained during the last 5 yr. of the test.

**Potato quality.—I, Relation of fertilizers and rotation systems to specific gravity and cooking quality, O. SMITH and L. B. NASH.** (Cornell Univ.). (*Amer. Potato Jour.*, 17 (1940), No. 7, pp. 163-169).—Specific gravity measurement, as determined in sodium chloride solutions, is considered a practical cheap method of separating the mealy from less mealy or soggy potatoes on a commercial scale. Tubers of lower specific gravity and less mealiness were produced by applications of 1,500 lb. per acre of 5-10-5 fertilizer than from lower rates of application, and by 1,000 lb. of this fertilizer on Smooth Rural tubers and 1,333 lb. on Green Mountain than of fertilizer carrying less potash. The 1,000-lb. rates of 5-10-5 fertilizer plus the quantity of nitrogen, phosphorus, and potassium in a 12-ton-per-acre application of manure also resulted in tubers of lower specific gravity and much less mealy texture than those produced with lighter applications. Soils of pH 6.36 produced tubers of lower specific gravity and less mealy texture than soils of higher and lower pH. The tubers grown in soils of pH 7.88 were highest in these respects.

Of 10 rotation systems, the most mealy tubers of the Green Mountain variety with the highest specific gravity were grown on plats where potatoes are grown every year and receive no fertilizer or cover crop. Lowest specific gravity and least mealy tubers were obtained following soybeans harvested for hay.

**Potato quality.—II, Relation of mineral nutrition and alterations in light intensity to cooking quality, L. B. NASH and O. SMITH.** (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 861-865).—Continuing the above, efforts were made to duplicate and accentuate for experimental purposes the alterations in sunlight normally occurring at Ithaca, N. Y., in late August and September. Periodic shading in every fertilizer treatment decreased the specific gravity, dry weight, and mealiness, and in plats receiving nitrogen

increased the incidence of blackening. Partial composition of tubers from various treatments and results of cooking tests are discussed briefly. Differences in the amount of sunlight and alterations therein during the tuber formation period may provide some explanation of differences in quality of potatoes grown in different regions and years.

**Cooking quality of the potato as measured by specific gravity, C. F. CLARK, P. M. LOMBARD, and E. F. WHITEMAN. (U. S. D. A.). (*Amer. Potato Jour.*, 17 (1940), No. 2, pp. 38-45, fig. 1).**—While the two methods of measuring specific gravity used in tests on 12 varieties of potatoes grown at Aroostook Farm, Maine, gave about the same results, the salt solution method is more rapid and preferred to the method of weighing in air and water. Use of salt solutions of known densities was found practical for making preliminary selections for mealiness. Studies of large populations could be facilitated greatly by this method, since it required much less time than the usual cooking method, and the material tested might be used later for planting. The highly significant interaction between seasons and mealiness indicated that a single season's test is not an adequate basis for rating the mealiness of a variety.

**Sorghum production in Nebraska, R. L. CUSHING, T. A. KIESSELBACH, and O. J. WEESTER (*Nebraska Sta. Bul.* 329 (1940), pp. 58, figs. 26).**—Sorghum, recently of special interest in Nebraska as a relatively dependable crop to meet conditions of prolonged drought, has increased in acreage harvested from 135,000 acres in 1929 to 1,324,000 in 1939. About 60 percent of the crop is used as forage and most of the remainder as grain. Information on varieties and their adaptation, cultural and field practices, and harvesting and storage methods for producing sorghum for grain and forage is set forth, with discussion of diseases and insects and their control. The recommendations are based largely on research by the station and stations in nearby States.

The superiority of Early Kalo, Sooner, Kalo, and Day for grain production has been demonstrated by yield tests at Lincoln and North Platte and on farms throughout the State. Under conditions of chinch bug infestation, Club and Western Blackhull kafir are considered more suitable in southeastern Nebraska. Atlas, Leoti, Kansas Orange, Early Sumac, and Black Amber have produced highest yields of forage. The 23 varieties currently of greatest importance in the State are described. As an average for several years, Early Kalo and other adapted varieties have yielded more than twice as much grain as corn, and, in general, superior sorgos have given forage yields double those from corn.

Cultural suggestions include early and thorough tillage and planting about 16 to 14 days later than the normal time for planting corn, i. e., in late May and early June in most of Nebraska. For grain production it usually is advisable to have stands too thin rather than too thick. More and better forage usually is obtained from closer spacings, either in rows or drilled. Plants in 40- or 42-in. rows in eastern Nebraska should be spaced for grain from 6 to 10 in. and for forage from 2 to 4 in., and in central and western Nebraska for grain from 8 to 12 in. and for forage from 4 to 6 in. Drilled for hay, about 100 lb. per acre of seed should be sown in eastern Nebraska and 75 lb. further west. The seed should generally be covered with from 1 to 1.5 in. of soil firmly packed. Sorghum may be grown successfully under irrigation and has particular merit where water is abundant only in the fall and spring. Later-maturing varieties and closer plant spacings may be used under irrigation than on dry land at the same location.

**Methods and rates of planting soybeans, C. K. McCLELLAND (*Arkansas Sta. Bul.* 390 (1940), pp. 18, fig. 1).**—Planting experiments, 1925-36, comprised seed-

ings of Laredo soybeans at rates of from 7 to 56 lb. (7-lb. increments in 36-in. rows and from 20 to 90 lb. (10-lb. increments) in 8-in. drills and broadcast, and of Mammoth Yellow from 14 to 63 lb. in rows and from 30 to 117.5 lb. (12.5-lb. increments) under the other methods. The respective average yields from the rows were for Laredo seed 11.7 bu., hay 1.91 tons, and Mammoth Yellow 10.44 and 1.8, drills 6.38, 1.41, and 5.7, 1.03, and broadcast 5.42, 1.20, and 4.86 bu., 0.96 ton. The row-cultivation method was superior, especially in droughty seasons. The number and chances of failures were much greater from the drill and broadcast methods.

Under row cultivation, the 49-lb. rate for Mammoth Yellow produced the highest seed yield and the second highest yield of hay, yet increases over the lower rates, except over 14 lb., in seed production were not significant. Hay yields from the 21-lb. rate were equally satisfactory, but higher rates produced a finer-stemmed hay. The 14-lb. rate of seeding Laredo soybeans returned the highest seed yields and within 0.05 ton as much hay as any higher rate. Yield variations due to seasonal conditions were much more marked than those due to varying seeding rates.

When drilled, Mammoth Yellow seed yields were reduced nearly one-half. The optimum acre rate for hay, 67.5 lb., was slightly less than the average of the three amounts returning highest seed production. With Laredo there were no significant differences among the seeding rates for either seed or hay yields.

Under the broadcast method, more failures resulted and yields of seed and hay of both sorts were lower than under the other two methods. The heavy rates of seeding Mammoth Yellow, from 92.5 to 117.5 lb., produced the higher seed and hay yields, but with Laredo a medium rate, 60 lb., produced the most satisfactory returns for both.

**Electricity in sweet potato plant production, J. B. EDMOND and G. H. DUNKELBERG** (*South Carolina Sta. Rpt. 1939, pp. 54-60; abs. in Amer. Soc. Hort. Sci. Proc., 36 (1939), pp. 855, 856*).—Experiments on Porto Rico sweetpotato plant production in electrically heated hotbeds in the spring of 1939 included tests with several types of hotbed covers and of insulating materials, spacing and position of the heating cable, temperatures, and regular v. crowded bedding of roots.

Covers of Sun-Ray cloth, Vito-Mesh, and glass sash varied somewhat in number of plants per root and per bushel but did not differ widely in number of kilowatts of electricity required to produce the same number of plants. Tobacco cloth in two layers was the least satisfactory cover, resulting in fewer plants and using more electricity per unit number of plants. Cinders and soil and double walls filled with glass wool conserved electricity better than did pine straw and soil and soil only. In general, the wider spacing of the heating cable resulted in fewer plants produced per root and per bushel and smaller use of electricity per unit area of bedding space. Soil temperatures usually were from 2° to 3° F. lower and less uniform throughout the bed in the 18- than in the 6- and 12-in. spacings. Roots bedded 1 in. above the heating cable produced more plants per root and per bushel and used slightly less electricity per unit area of bedding space than those bedded on the same level with the cable. The high-temperature bed (78° to 80°) produced more plants per root and per bushel and consumed more electricity per unit area than the low-temperature bed (68° to 70°) but with most profitable returns. Crowded bedding, 300 roots in about 18 sq. ft., gave more plants per unit area but fewer per root and per bushel than regular bedding,

150 roots in an equal area, and also used less electricity to produce unit number of plants.

The influence of variety, season, and green manures upon the composition of wheats, J. E. GREAVES, A. F. BRACKEN, and C. T. HIRST. (Utah Expt. Sta.). (*Jour. Nutr.*, 19 (1940), No. 2, pp. 179-186).—Spring wheat (7 varieties) grown, 1923, 1929-35, on the Nephi Substation dry farm carried greater percentages of ash, calcium, magnesium, potassium, iron, phosphorus, and sulfur than did winter wheat (17 varieties), both produced on the same deep dry-farm clay loam soil. A significant difference was found in the calcium content of different winter wheats grown on the same soil. A highly significant correlation existed among most of the mineral constituents of wheat. When wheats of different years were compared, a high variation was apparent in the various mineral constituents from year to year. Addition of green manures to a typical dry-farm soil caused a highly significant variation in ash content and a significant difference in calcium and phosphorus. Green manure increased materially the phosphorus content of wheat, probably due to increased bacterial activities which in turn increased available plant food in the soil.

**Report of the Sixth Eastern Wheat Conference** (*U. S. Dept. Agr., Bur. Plant Indus.*, 1939, pp. [2]+10).—Papers given at the conference held in Wooster, Ohio, June 16, 1939, included The Federal Soft Wheat Laboratory, by E. G. Bayfield (pp. 1, 2); Breeding for Resistance to Hessian Fly, by W. B. Cartwright (pp. 2, 3) (U. S. D. A.); Inheritance of Quality and Cold Resistance in Wheat and Their Inter-Relationship, by W. W. Worzella and G. H. Cutler (pp. 3, 4) (Purdue Univ.); Disease Resistance in the Soft Winter Wheats, by R. M. Caldwell (pp. 4-9) (Purdue Univ. and U. S. D. A.) (see p. 785); and Scab Resistance in Winter Wheat, by R. G. Shands (p. 9) (Wis. Expt. Sta. and U. S. D. A.)

[Seed research] (*Farm Res. [New York State Sta.]*, 6 (1940), No. 3, p. 9).—Seed Injury Lowers Germination, by M. T. Munn, describes mechanical injury in certain stocks of soybeans and red kidney beans which lowers germination percentage. The injury may be done by either combine or threshing machine when the crop is very dry at harvest or threshing. In every case, adjustments of speed of the machine and cylinder must be carefully made by the operator for each type of combine used if such injury is to be prevented. When the Seeder-Box "Speaks," by L. E. Everson, describes samples of home-grown seed obtained on 1,000 farms during the active clover planting season. About 39 stocks of each 100 were considered unfit for use as they were. An additional 13 percent were objectionable because of presence of certain weed seeds. Wild carrot was the most prevalent weed seed in red clover and alfalfa seed farmers had grown for their own use, night-flowering catchfly in sweetclover samples, and yellow rocket in mixtures of alsike and timothy. Nearly 86 percent of the seed stocks used had been recleaned, but the mill used apparently was not adequate or properly equipped for satisfactory work. Seed Notes accounts for sudden appearance of a profuse stand of certain weeds, as yellow rocket, the mustards, and cinquefoil, as due to cold and moist season; discusses the appearance of bindweed in stocks of dark-colored soybeans, especially Black Wilson; and mentions the possibility of farmers growing hardwood trees for seed production.

**Summary of bindweed situation and progress of eradication in 1939**, T. F. Yost (*Kans. State Bd. Agr. [Quart.] Rpt.*, 59 (1940), No. 237, pp. 74, figs. 15).—This report of the further progress (*E. S. R.*, 82, p. 42) of the program describes eradication activities in 1939, including cultivation and chemicals by farmers, work done by highways, railroads, cities, and State institutions, and also kinds of implements and equipment used; and includes results of coopera-

tive determination of effects of the weed on crop yield and soil moisture, fires and livestock losses due to use of sodium chlorate, and brief reports on other noxious weeds in Kansas.

**Russian thistle silage**, F. T. DONALDSON and K. J. GOEBING. (Mont. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 3, pp. 190-194).—Analyses showed Russian-thistles to equal alfalfa in protein and fat content and to surpass it in carbohydrate: crude fiber ratio. The thistles were high in mineral content, with the  $K_2O$  exceeding 8 percent. The high content of  $P_2O_5$  (0.78 percent) may enhance the feeding value of the thistles in areas known to produce phosphorus-deficient forages. Analyses of silages prepared by ensiling Russian-thistles in  $\frac{1}{2}$ -gal. jars indicated that good silage could be prepared with the addition of either sugar (3 percent) or  $H_3PO_4$  (1 percent) but that poor silage would probably result from untreated thistles.

## HORTICULTURE

[Horticultural studies conducted by the Massachusetts Station], K. J. KUCINSKI, W. S. EISENMENGER, H. M. YEGIAN, L. H. JONES, C. J. GILGUT, W. G. COLBY, E. BENNETT, H. F. BERGMAN, W. E. TRURAN, H. E. WHITE, C. L. THAYER, H. S. TIFFANY, W. H. LACHMAN, R. E. YOUNG, P. W. DEMPSEY, A. P. TUTTLE, J. K. SHAW, L. SOUTHWICK, A. P. FRENCH, O. C. ROBERTS, J. S. BAILEY, R. A. VAN METER, and W. H. THIES. (Partly coop. U. S. D. A. and Conn. and R. I. Expt. Stas.). (*Massachusetts Sta. Bul* 369 (1940), pp. 10, 11, 22, 25, 32, 39, 51, 53-55, 69, 70, 76-85, figs. 5).—Among projects the progress of which is discussed are winter cover crops for onion fields; onion breeding; effect of the type of container on the growth of flowering plants; factors affecting yield of onions and their shrinkage in storage; effect of storage and processing on the carbohydrates of varieties of edible onions; breeding of cranberries resistant to false blossom; flower and fruit production of cranberries; breeding of snapdragons; effect of plant nutrients, soil reaction, and light on the gardenia; forcing tests of hybrid Easter lily seedlings; culture of the freesia; physiological disorders of the carnation; quality of flower seeds retailed in packets; propagation of hybrid lilacs; factors influencing the hardiness of evergreens; shape index in the tomato; sweet corn breeding; testing of hybrid sweet corns; tomato breeding; effect of cultural practices prior to field setting on the yield and quality of peppers; varieties and culture of asparagus; growing of tomatoes on trellises; improvement of lettuce, celery, tomatoes, rutabagas, carrots, peppers, broccoli, beets, beans, etc.; clonal rootstocks for the apple; tree characters of fruit varieties; genetic composition of peaches; cultivation v. sod emulsion for the apple; cultivation v. mulching for the apple; fertilizer needs of the apple; testing of fruit varieties; fruit bud formation in the strawberry; fruit bud mutation in the apple; behavior in storage of apples affected with internal cork; nutrition of the high-bush blueberry; blueberry culture; factors affecting the premature dropping of the McIntosh apple; and methods of sun-coloring harvested apples.

[Horticultural studies by the Nebraska Station] (*Nebraska Sta. Rpt.* [1939], pp. 23, 24, 25, 26).—Included are progress statements on investigations of water requirements and irrigation of apple trees, spray materials for apple scab control, rootstocks for the apple, tomato breeding and culture, testing of sweet corn hybrids, and breeding of carrots.

[Horticultural studies by the New Hampshire Station], A. F. YEAGEE, L. P. LATIMER, W. W. SMITH, J. R. HEPLER, and H. S. CLAPP (*New Hampshire Sta. Bul.* 319 (1940), pp. 37-40).—Included are brief progress reports on investigations on the fertilization of apple trees, apple spraying, strawberry culture, effect of

boron upon apple drop and upon apple cork spot, propagation and culture of the blueberry, rootstocks for the apple, relation of the time of applying nitrogen to the time of winter injury in the apple, and vegetable breeding.

**Horticulture at the Ohio Agricultural Experiment Station, Wooster, Ohio** (*Ohio Sta. Spec. Cir. 60 (1940), pp. [2]+59, figs. 19*).—Ninth in a series (E. S. R., 80, p. 192) designed to give the reader concise information on the progress of various horticultural investigations conducted by the station, this circular discusses varietal, cultural, breeding, physiological, and other studies with various fruit, vegetable, potato, and flower crops.

**Vapor-heat treatment for fruits and vegetables grown in Hawaii, W. W. JONES** (*Hawaii Sta. Cir. 16 (1940), pp. 8*).—As a result of studies of the tolerance of different fruits and vegetables to heat treatment and of methods of subsequent handling to insure safe shipment to the mainland, practical recommendations are presented for the handling of certain Hawaiian-grown fruits and vegetables which are most likely to be shipped.

**The frozen fruit and vegetable industry, D. K. TRESSLER** (*Farm Res. [New York State Sta.], 6 (1940), No. 3, p. 15*).—Information is given as to the extent and distribution of the industry, with comments that New York State leads in the production of frozen peas, sweet corn, and Montmorency cherries.

**Asparagus: Its planting, care, and management, L. A. SOMERS** (*Illinois Sta. Cir. 507 (1940), pp. 36, figs. 12*).—General information is offered on the structure of the asparagus plant, varieties, plant production, selection of sites, planting, cultural care, causes of poor stands, harvesting, marketing, economic outlook, etc.

**Descriptions of types of principal American varieties of red garden beets, R. MAGRUDER, V. R. BOSWELL, H. A. JONES, J. C. MILLER, J. F. WOOD, L. R. HAWTHORN, M. M. PARKER, and H. H. ZIMMERLEY.** (Coop. Calif., La., Tex., and Va. Truck Expt. Stas.). (*U. S. Dept. Agr., Misc. Pub. 374 (1940), pp. 60, pls. 30*).—Sixth in the series (E. S. R., 83, p. 627), this deals with distinguishing characteristics of the principal commercial varieties of red garden beets. Special consideration is given to the effect of environmental factors, such as season, temperature, soil acidity, soil fertility, etc., on the vigor of growth, shape, color and quality of roots, and other characteristics.

**Effects of controlled calcium supply on carrots grown in colloidal clay cultures, A. W. PURDY.** (Mo. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc., 36 (1939), pp. 799-802*).—That Ca is of primary importance in the nutrition of carrots was indicated by experiments in which plants were grown in a colloidal clay culture and at a uniform pH and constant level of all nutrients except Ca. Plants without Ca lived for only 6 weeks and developed only one tiny true leaf. Successively better growth was made as the Ca increased from 2 to 6 milligram equivalents per plant. Beyond 6 m. e., there was no added increment in total growth. The highest percentage of P in the roots and leaves occurred in the 6-m. e. lot. The leaves were particularly responsive to changes in the Ca supply. With every increase in Ca there was a marked increase in Ca per unit weight of tops produced. Results suggest the practical value of liming soils low in Ca and the relative ineffectiveness of excess applications.

**Handling and shipping lettuce in New York, H. PLATENIUS** (*[New York] Cornell Sta. Bul. 732 (1940), pp. 24, figs. 7*).—The increase in the production of iceberg types of lettuce in New York State was found to be leading toward improved practices in the packaging and handling of the product. Compactness of the head and freedom from defects were found of major importance in determining the price of lettuce. Observing that New York grown lettuce has been trimmed less closely than California lettuce, the author suggests greater

attention to this detail. From a study of temperature records and observations on the appearance of lettuce at the market it is concluded that there is no significant difference between the condition of lettuce shipped by rail or by truck.

The beneficial effects of precooling have been overrated because precooling is a slow process and the lowered temperature does not continue long after removal from storage. No other handling method was equal to package-icing in effectiveness. In this treatment the temperature of the lettuce drops to less than 40° F. in 12 hr., with the result that the iced lettuce is always better than that shipped directly from the field. However, the Boston variety cannot be satisfactorily package-iced, leaving precooling as the only practical means of handling this type. The rate of reheating of iced packages was found to be slow, permitting the product to continue in good condition for some time after the lettuce reaches the markets. Package-iced New York grown lettuce of the iceberg type sold on a favorable basis with the California product. Practical suggestions are presented.

**The effect of cultivation on the yield of onions on peat soil, R. D. SWEET.** (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 807-810).—In cooperative investigations on growers' farms in the Genesee-Orleans peat area of New York it was observed that in four of seven comparisons of deep with shallow cultivation the deep tillage reduced the total yields and in no case increased yields. In the three negative comparisons it is believed that the effects of late planting, weed growth, or mineral deficiencies may have conflicted with tillage results.

**The response of onions to manganese on unproductive peat soils, J. E. KNOTT.** (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 803-806, fig. 1).—In 1937, a year of above-normal rainfall, comparisons of Mn with other minor elements in experiments in various peat areas of New York where the pH range was from 4.4 to 7.3 failed to show any benefit from the use of 50 lb. per acre of MnSO<sub>4</sub> or any of the other materials. On June 2, 1939, MnSO<sub>4</sub> and borax were applied as aqueous solutions at the rate of 100 lb. per acre of each to onions which had a yellow color and were dying at the tips. Within a week the plants receiving MnSO<sub>4</sub> alone or with borax became green and resumed vigorous growth. Similarly favorable results were secured on other unproductive areas. Since the addition of borax to MnSO<sub>4</sub> had little benefit, the author suggests that borax is not a factor in increasing growth. By far the most serious condition is that in which shallow peat is underlaid with marl. It is suggested that the use of MnSO<sub>4</sub> should be more economical than incorporating large amounts of S, and that under dry weather conditions aqueous solutions will give quick results.

**Fertilizer experiments with tomatoes, 1919-39, W. B. MACK, G. J. STOUT, and E. M. RAHN** (*Pennsylvania Sta. Bul.* 393 (1940), pp. [2]+28).—Of 30 different manurial treatments carried on over a period of years, those associated with the greatest mean yields of total fruit and of marketable fruit were as follows: "Rotted barnyard manure; complete fertilizer containing half the standard amount of nitrate of soda (supplying 30 lb. N to the acre) and the standard amounts of superphosphate and muriate of potash (supplying 100 lb. P<sub>2</sub>O<sub>5</sub> and 80 lb. K<sub>2</sub>O to the acre, respectively) broadcast before planting, together with a side dressing of nitrate of soda supplying 30 lb. N to the acre at the time of blossom set; complete fertilizer containing 50 percent more than the standard amount of superphosphate (supplying 150 lb. P<sub>2</sub>O<sub>5</sub> to the acre), in combination with the standard amounts of nitrate of soda and muriate of potash (supplying 60 lb. N and 80 lb. K<sub>2</sub>O to the acre, respectively); complete fertilizer containing the standard amounts of nitrate of soda and superphosphate and half

the standard amount of muriate of potash; twice the standard complete fertilizer with 10 tons of rotted manure to the acre. Calcium nitrate and cyanamide were not significantly different from nitrate of soda, in combination with superphosphate and muriate of potash, in their influence on yields. Ammonium sulfate, tankage, and dried blood, each in similar combination, however, were less favorable than the other three carriers just mentioned. Marketable yields were very highly correlated with total yields. The only significant differences among mean early yields were those between each of the standard carriers applied alone, and any combination of each, respectively, with one or more of the other carriers, except between superphosphate and the combination of superphosphate and muriate of potash. Early yields from single-element carriers were less than from combinations of two or more carriers.

"In an experiment conducted for 1 yr. only, differences among mean yields associated with different placements of fertilizers were insignificant. There is some evidence that dilute phosphoric acid or superphosphate solutions applied to the roots at transplanting increased the early yield of tomatoes in comparison with water alone, similarly applied. Solutions of nitrogen or potash-containing compounds, however, were not consistently favorable to yields when applied in the same manner."

**The ripening and repacking of mature-green tomatoes, R. C. WRIGHT and E. A. GORMAN, JR. (*U. S. Dept. Agr. Cir. 566 (1940), pp. 8, fig. 1*).**—Stating that the ripening and repacking of green-picked tomatoes from the Southern States has become a specialized business in several of the large cities, the authors describe the methods employed in ripening, the necessary equipment, the ethylene treatment, etc. Ultimate quality depended on proper maturity when the fruits were harvested, that is, the fruit should be in the mature-green stage when removed from the vines. Poor quality, frequently observed during the winter season, is due largely to picking of the fruits when too immature. Under average market conditions, tomatoes are usually ripened at about 68° F., 4 or 5 days being required for mature-green tomatoes, and 2 days for turning tomatoes. If the maximum quality in flavor and color is desired, a temperature close to 60° is recommended. At this temperature the finished product will be firmer, will keep longer, and will develop less decay than if ripened at higher temperatures, but the time requirement will be considerably longer. With a very active market, temperatures of from 70° to 72° may be used to give maximum speed in ripening.

**Fruit setting of watermelons, C. R. CUNNINGHAM. (*Mo. Expt. Sta.*). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 811-814, fig. 1).**—To determine the relationship of leaf area to fruit set, certain plants were defoliated partially when they reached the fruit-setting stage. Of the three types of defoliation, (1) every other leaf, (2) every third leaf, and (3) two of every three leaves, the greatest inhibition to fruit setting came with the severest treatment. When  $\text{NaNO}_2$  was applied as a side dressing, it appeared to reduce fruit setting by delaying and decreasing the fruit set. The setting of watermelon fruits tended to check terminal growth of that particular vine and to interfere with the development of fruits setting subsequently.

**New hardy fruits for the Northwest, N. E. HANSEN (*South Dakota Sta. Bul. 339 (1940), pp. 31, figs. 15*).**—Included is information as to the origin, principal characters, and uses of a large number of hardy fruits—apples, crabapples, pears, plums, cherries, and currants—originated and introduced by the station during the period 1927-40. Appended is a complete alphabetical index of all the station's horticultural introductions.

**The morphology of the apple and other pome fruits, L. H. MACDANIELS (*[New York] Cornell Sta. Mem. 230 (1940), pp. 32, figs. 16*).**—The author pre-

sents "a review of the evidence on the interpretation of the morphology of the pome flower as largely receptacular or largely appendicular in nature, and a critical study of a number of pomaceous and other rosaceous genera, [which] support the conclusion that the pome flower is appendicular in its derivation and structure. The appendicular interpretation is consistent with the comparative anatomy of the whole range of families, and with the nature of the inferior ovary generally. Phylogenetically the pome flower has arisen from the fusion, by adnation, of the fleshy rosaceous floral tube with the compound ovary. The floral tube, composed of the fused bases of the stamens, petals, and sepals, enlarges greatly as the fruit matures, and forms the larger part of the pome fruit. The so-called 'core line' of the apple is interpreted as representing the line of fusion between the floral tube and the ovary. According to the appendicular interpretation, the fruits of the apple, the pear, and the quince are described as fleshy accessory fruits, made up of a five-carpeled ovary, with cartilaginous endocarp and fleshy exocarp, united with a fleshy floral tube or disk consisting of the fused bases of the sepals, petals, and stamens. Variation in pome structure is chiefly in the following characters: In the number of carpels, which may vary from two to five; in the nature of the endocarp, which may range from bony in *Crataegus* and some other genera to cartilaginous; and in the degree of completeness with which the ovary is covered by the fleshy floral tube."

**New rootstocks for apples on trial, H. B. TUKEY** (*Farm Res. [New York State Sta.]*, 6 (1940), No. 3, pp. 8, 15, fig. 1).—Indicating the interest in apple rootstocks that will produce smaller than standard trees, the author discusses other potentially valuable characters of rootstocks, such as tolerance to unfavorable soil moisture conditions, and classifies the Malling group as to moisture tolerance. Malling VII, I, and XIII proved adaptable to a wide range of soil moisture conditions. Malling IV, XII, and II were intolerant to low moisture, and others occupied intermediate places.

**What new apple varieties are doing: A survey of growers, R. WELLINGTON and H. O. BENNETT** (*Farm Res. [New York State Sta.]*, 6 (1940), No. 3, pp. 3, 12).—This second paper in the series (E. S. R., 82, p. 774), based on analyses of growers' replies to questionnaires, presents information as to the performance of a number of McIntosh seedlings, namely, Early McIntosh, Milton, Cortland, Macoun, and Kendall.

**Experiments in orchard soil management: Fertilizers, mulches, and cover crops, R. C. COLLISON** (*New York State Sta. Bul.* 691 (1940), pp. 37).—In studies on subsurface placement of manure and fertilizers in a McIntosh orchard, data taken over a 3-yr. period indicated no better response to any method of deep placement employed than to the usual surface applications. The results suggested that the greater expense of placing fertilizers in the root zone, at least as based on the results of this particular experiment, is unjustified.

Studies of N fertilization in a well-mulched McIntosh orchard located on medium-light soil indicated that applications normally recommended for unmulched orchards may be too large for use with a heavy mulch of nonlegume material. Excessive N may result in a serious reduction in color of the fruit and an increase in dropping during the preharvest period. The differential response of apple varieties to fertilizer treatment is considered of sufficient significance to warrant more detailed study. For example, it was found that Delicious has appreciably more Ca in its leaves than did Baldwin, McIntosh, or Northern Spy and that this fact may be related to the apparent susceptibility of Delicious to acid soil conditions. Northern Spy took up the least Ca of the 4 varieties and was the least resistant to adverse nutrient conditions. Some 15 different cover crops available for temporary or permanent orchard covers

were compared from as many angles as possible, with stress on seeding, persistence, dry matter production, weed competition, self-seeding, type of cover produced, water relations, and snow retention.

**Very dilute a-naphthalene acetic acid spray and fruit drop, M. McCOWN and C. L. BURKHOLDER.** (Ind. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 429-431).—Application on September 19, 1939, of 0.0001 percent a-naphthaleneacetic acid to halves of 18-year-old Delicious trees and on September 28 to Golden Delicious, Stayman Winesap, and Rome Beauty trees had no material influence on fruit dropping, as compared with unsprayed portions of the trees. In one case, where some difference was noted, high-temperature injury to the fruit in mid-September was a disturbing factor tending to invalidate results. The authors point out, however, that only one season's results are included.

**Further observations on the pollination of the highbush blueberry, T. A. MERRILL and S. JOHNSTON.** (Mich. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 617-619, figs. 2).—Employing four technics, (1) flowers not emasculated but hand pollinated, (2) flowers emasculated and hand pollinated, (3) flowers brushed but not emasculated, and (4) open-pollinated, the authors report that the percentage of set secured from self-pollination was not significantly different from that under open-pollination. A slightly lower percentage of set of emasculated blooms is attributed to either mechanical injury during stamen removal or to lack of receptivity due to the immaturity of the pistils of some of the unopened flowers. The percentage of set when blossoms were brushed was lower than when open-pollination was used in all varieties except Concord. Berries from self-pollination matured normally and were as large as, if not slightly larger than, open-pollinated berries of the same variety.

**Sees new interest in blueberries, R. C. COLLISON** (*Farm Res. [New York State Sta.]*, 6 (1940), No. 3, pp. 2, 12).—General information is presented on the rapid development in the growing of named varieties of blueberries under systematic cultural methods. See also Circular 189 (E. S. R., 83, p. 340).

**Effect of spacing plants on yield of strawberries, H. J. SEFICK** (*N. J. State Hort. Soc. News*, 21 (1940), No. 5, p. 1247).—Fairfax strawberry plants, set from 18 to 20 in. apart in 4-ft. rows, were spaced during the summer so that the runners stood from 7 to 9 in. apart. At the end of the growing season there was an average of 2.88 and 4.36 plants per square foot in the spaced and matted rows, respectively. In the spring fruiting season the spaced plants produced 8,024 and the unspaced 6,676 qt. of berries per acre. The average size of berries was consistently larger in the spaced plats. The proper spacing distance was found to vary with varieties, depending on the length of the runners.

**Grape production in Texas, E. MORTENSEN and U. A. RANDOLPH** (*Texas Sta. Cir.* 89 (1940), pp. 26, figs. 10).—Among subjects discussed are the status of the industry, soils and sites, propagation, rootstocks, varieties and their uses, planting, pruning, culture, control of insect and disease pests, harvesting, etc.

**Grape progenies of self-pollinated vinifera varieties, E. SNYDER and F. N. HARMON.** (U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 625, 626, fig. 1).—Observations on progeny vines from self-pollination of vinifera varieties showed, in general, a striking resemblance in growth vigor and foliage characters to the parents. There was no general indication of loss of vigor in the seedlings. Despite the fact that all vinifera parents had upright stamens, there was an average of 13.1 percent of seedlings with reflex stamens. White-fruited parents produced all white-fruited seedlings. Red-fruited parents produced white and red seedlings, with an occasional black. Black-fruited parents produced mostly white and dark red. Petit Syrah produced only black seedlings. There

was sufficient variation in time of ripening in certain progenies to permit the selection of earlier-ripening varieties.

**"Synthetic" Zante currant grapes:** Breeding investigations indicate possible origin, and point way toward production of new varieties, E. SNYDER and F. N. HARMON. (U. S. D. A.). (*Jour. Hered.*, 31 (1940), No. 7, pp. 315-318, figs. 3).—An account is presented of the origin by chance mutation of a currant-type seedless grape on a 27-year-old Muscat of Alexandria vine near Fresno, Calif., and also of the development by breeding of currant-type seedless grapes. In breeding, parthenocarpic seedless types appeared more frequently in the  $F_2$  than in the  $F_1$  population.

**Preliminary observations on the refrigerated gas storage of Gros Michel bananas,** C. W. WARDLAW (*Trop. Agr. [Trinidad]*, 17 (1940), No. 6, pp. 103-105).—In the case of "heavy  $\frac{3}{4}$ -full" fruits rapidly cooled to 53° F. and held there for 20 days, gas mixtures containing 5 percent  $CO_2$  and from 7 to 12 percent  $O_2$  notably retarded ripening without injurious effects. The best results were secured at the lower  $O_2$  percentage. The gas-ripened fruit assumed a good yellow color and quality and showed no evidence of chilling. Under conditions of rapid cooling from tropical temperatures to 53° with  $CO_2$  accumulation and  $O_2$  depletion in closed containers, the respiration rate fell off rapidly from an initial value of from 35 to 40 mg. kg. hr. to from 8 to 10 mg. kg. hr. An increase in the concentration of  $CO_2$  observed in tissues under high  $CO_2$  conditions was soon lost on return of the bananas to open air. A rise in  $CO_2$  and a decrease in  $O_2$  occurred under conditions of restricted ventilation, but there was difficulty in lowering the  $O_2$  sufficiently. Mature fruits were found unsuitable for refrigerated gas storage, as is the case with ordinary storage.

**Stigma receptivity and pollen shedding in some pecan varieties,** C. L. SMITH and L. D. ROMBERG. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 60 (1940), No. 8, pp. 551-564, figs. 6).—Determinations during from 1 to 3 seasons of the receptive period of the stigmas of 16 varieties of pecan showed wide variation under Texas conditions in the length of receptive periods of different varieties in a single season and the same variety in different seasons. The variations in the lengths of the periods in the same variety are ascribed to variations in time of initiation of shoot growth and to seasonal variations. The pollen-shedding periods varied in the same way as the stigma-receptivity periods. In 12 varieties studied, all unpollinated nuts dropped in from 5.5 to 6.5 weeks after the last date of stigma receptivity. The degree of dichogamy varied widely in different varieties, with the result that in some a relatively good set of nuts was obtained from self-pollination while in others little or no self-pollination was evident. All varieties studied fall into two groups with reference to the relative time of pollen shedding and stigma receptivity. In one group (protandrous), pollen shedding occurred relatively early and stigma receptivity relatively late; and in the other group (protogynous), the relative time of flower maturity was reversed. However, the actual time at which the flowers of any tree of variety mature, as compared with another, is also dependent upon the time of growth initiation and rates of shoot and flower development. Adequate pollination in a pecan orchard may be attained by interplanting protandrous and protogynous varieties.

**Gravel and cinder culture of greenhouse flowering crops,** A. LAURIE and D. C. KIPLINGER (*Ohio Sta. Bimo. Bul.* 204 (1940), pp. 98-108, figs. 5).—"The subirrigation method of growing plants in an inert medium is gradually assuming commercial importance. Overoptimistic suggestions for the immediate success of this method are to be condemned, as much remains to be done before large-scale installations should be made. Enough has been accomplished, however, to present some facts on the method."

Diagrammatic drawings and some general directions for the construction of concrete benches, conversion of wooden benches, construction of solution tanks, arrangement of piping, valves, spreading troughs, pumps, and other details of the mechanical set-up are presented. For waterproofing, asphalt emulsions and paints were satisfactory, but tar showed itself toxic to the plants. Galvanized piping should be avoided because of possible damage from the zinc. Eaves trough used as a spreading trough is to be asphalt coated to prevent zinc injury. It is pointed out that sump pumps are easier to put in than pumps of the side-suction centrifugal type and do not require a separate compartment in the tank to keep the matter dry. The pumping equipment should be such that benches can be pumped in 30 min. and drained in 60 min. Clock control of the pumping system is recommended as insuring regular pumping.

Cinders, if used as the solid growth medium, must be leached before use. They may have too high a water-holding capacity; may contain excess boron (though this may be rendered harmless by adding 10 cc. of commercial sodium silicate solution to each 100 gal. of culture solution); may be so alkaline as to precipitate iron, manganese, and phosphates; and they may disintegrate too readily. Gravel, if calcareous, may require broadcasting of monocalcium phosphate, 5 lb. per 100 sq. ft., followed by thorough watering, to prevent too high a pH value and precipitation of iron, manganese, and phosphates. A commercial material called Haydite has thus far proved satisfactory and to cost no more than properly prepared cinders. Other materials, such as trap rock and granite chips, may be found to be equally suitable.

Directions for the preparation of a culture solution are given. The solution recommended supplies potassium, magnesium, calcium, iron, manganese, both ammonium and nitrate nitrogen, phosphate, and sulfate. Impurities in the commercial chemicals used are depended upon to furnish the trace-requirement elements not added as such. Adding compounds of boron, zinc, copper, etc., may cause injury through excess. The solution may be changed every month, but the authors used the same solution for 2 mo. without harmful effects. Testing of solutions for nutrient content, frequency of pumping, planting, and pest control are also discussed.

**Studies on the effects of additions of trace elements to the greenhouse rose, A. LAURIE and J. R. CULBERT.** (Ohio State Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 945-950).—Using a relatively inert medium (C media haydite), a combination of burned shale and clay, budded Better Times rose plants were supplied with a nutrient solution plus minute quantities of B, Zn, Cu, and ammonium sulfate. It was found that small amounts of B or Zn in concentrations below toxicity stimulated the flowering of the rose. Cu applications decreased total production and caused greater percentages of short-stemmed blooms. Apparently some ammonium was necessary for optimum rose production, particularly during periods of high carbohydrate production in the spring and fall.

**The effect of different soil media on the production of flowers of Better Times roses, E. I. WILDE.** (Pa. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 36 (1939), pp. 942-944).—Four soil media were used in greenhouse studies, viz,  $\frac{2}{3}$  sand and  $\frac{1}{3}$  manure;  $\frac{1}{3}$  sand,  $\frac{1}{3}$  Hagerstown silty clay, and  $\frac{1}{3}$  manure;  $\frac{2}{3}$  Hagerstown silty clay and  $\frac{1}{3}$  manure; and  $\frac{2}{3}$  Morrison silt loam and  $\frac{1}{3}$  manure. Plants in media containing sand produced more flowers than those in clay or loam. The 3-yr. average annual production per plat of 40 plants was 863.3, 873.3, 829.1, and 823.5 flowers, respectively. A difference of 26.5 was significant.

**Fertilization of woody ornamental plants, L. C. CHADWICK** (*Ohio Sta. Bimo. Bul.* 204 (1940), pp. 89-96).—In connection with general information on the

fertilization of woody plants, data are presented on the root distribution of Moline elms as influenced by fertilizer treatments. The use of highly concentrated fertilizers resulted in a deeper and less extended root system than was the case with less concentrated materials. In the light of observations, suggestions are given for the effective placement of fertilizers by the hole method. Based on trunk increments, fall applications of fertilizer were generally found equal to or better than spring applications. In general, complete fertilizers gave better results than incomplete, with definite evidence in favor of N and P. A fertilizer chart for various ornamental plants is presented.

**Dividing and planting bulbous ornamental plants**, F. S. BATSON (*Miss. Farm Res. [Mississippi Sta.]*, 3 (1940), No. 7, p. 2).—Largely in tabular form, information is offered as to the principal characteristics, requirements as to digging, and planting.

## FORESTRY

[Forestry investigations by the New Hampshire Station] (*New Hampshire Sta. Bul.* 319 (1940), pp. 36, 37).—Brief statements are made as to the survival of planted white pine, Scotch pine, Norway spruce, and white spruce, and results are given as to a sustained yield study conducted in the northern part of the State.

**Coniferous forest plantings in central Pennsylvania**, D. D. STEVENSON and R. A. BARTOO (*Pennsylvania Sta. Bul.* 394 (1940), pp. [2]+20, figs. 14).—In connection with a brief history of the establishment of experimental forestry plantings, the first of which were started in 1908, data are presented on the growth and behavior of various species of conifers, both native and exotic. Most of the early plantings were made with seedling stock, later resorting to transplants because of their evident superiority.

Among promising species have been red pine and Norway spruce, grown either in pure stands or as a mixture of the two. White pine was severely injured by weevils, with indications of belated recovery. Pitch pine made almost as good growth as red pine and is recommended for poor, dry sites. Jack pine made more rapid vertical growth than other species. Table mountain pine grew vigorously in early life but had little merit as a forest tree. Scotch, shortleaf, Japanese red, and Austrian pines did not grow well under the conditions existing. Larch, both European and Japanese types, showed adaptability to both upland and lowland sites.

**Forest outings**, edited by R. LORD (*U. S. Dept. Agr., Forest Serv.*, 1940, pp. [XVI]+311, pl. 1, figs. 48).—Information relating to the recreational facilities and opportunities of the national forests is presented in popular form.

## DISEASES OF PLANTS

Report of the 1940 annual meeting of the southern division of the American Phytopathological Society (*Phytopathology*, 30 (1940), No. 8, pp. 702-711).—Abstracts of the following papers are presented: A Photo-electric Method and Its Use for Determination of Fungus Growth Rates, by L. A. Adair and E. J. Moore; Infection of Cotton Seedlings in the Greenhouse by *Phymatotrichum omnivorum*, by L. M. Blank; Growth Response of *Phymatotrichum omnivorum* to Certain Inorganic Nitrogens, by L. M. Blank and P. J. Talley; Control of Sclerotiniase of Celery on Florida Muck, by A. N. Brooks; Field Results With Gravity-Graded Cotton Seed, by K. S. Chester; Résumé of Five Years Spraying With Low-Lime Bordeaux Mixture and Zinc Sulphate to Control Pecan Scab and Rosette Diseases, by J. R. Cole; Effect of Girdling and Topping of

Cotton Plants on Survival of *Phymatotrichum omnivorum* on the Roots, and Relation of Age of Cotton Plants to Susceptibility to Field Inoculations with *Phymatotrichum* Root Rot, both by W. N. Ezekial; Field Tests of the Resistance of Cotton to *Phymatotrichum omnivorum*, by G. W. Goldsmith and E. J. Moore; Effectiveness of Organic Manures in Controlling Cotton Root Rot on Various Soil Types, by C. J. King; Cotton-seed Dusting in Relation to Control of Seedling Infection of *Rhizoctonia* in the Soil, by S. G. Lehman; Microorganisms Associated With Cotton-Boll Rots in 1939, by P. R. Miller; Fusarium-Wilt Resistance of New Strains and Hybrid Cottons in Louisiana in 1939, by D. C. Neal and H. B. Brown; Experiments on the Control of Downy Mildew of Cucumbers, by A. J. Plakidas; The Relation of Nitrogen Fertilization of the Peach on the Control of *Bacterium pruni*, by R. F. Poole; Further Studies on the Control of *Cercospora* Leaf Spot of Peanuts With Various Dusts and Sprays, and Results of Four Years of Extension Work on Cotton-seed Treatment in North Carolina, both by L. Shaw; An Occurrence on Cotton of Black Root Rot Caused by *Thielaviopsis basicola*, and Pathogenicity Tests Conducted in 1939-1940 on Different Isolates of *Fusarium vasinfectum*, both by C. D. Sherbakoff; Storage Tests With Cottonseed, by D. M. Simpson; A Regional Study of the Relationship of Potash Treatments to the Development of Cotton Wilt Under Widely Varying Conditions of Soil and Environment, by A. L. Smith; Notes on the Pathogenic Action of *Phymatotrichum omnivorum*, by G. M. and M. O. Watkins; Fungi Found on Diseased Cotton Seedlings From Thirteen States Surveyed in 1939, by R. Weindling; Root Rot of Austrian Winter Peas and Vetches [and associated fungi], by J. L. Weimer (U. S. D. A. and Ga. Expt. Sta.); Some Observations on the Development of Root-Knot Nematode Diseases in Virginia, by S. B. Fenne; Some Suggestions for Quick Testing of Nematode Resistance in Plant-Breeding Programs, by G. H. Godfrey; Resistance to Root-Knot Nematode in *Nicotiana*, by E. E. Clayton; Control of Root Knot in Florida Cigar-Wrapper Tobacco Fields, by R. R. Kincaid; Comparison of Crop Rotation and Fallowing as Methods on Control for Root Knot of Cotton Under Irrigation, by C. J. King; Recent Root-Knot Damage in Potatoes, by J. T. Middleton; The Effect of Crop Rotation on the Control of *Heterodera marioni* on Norfolk Sandy Loam, by K. J. Shaw; Distribution and Relation of Meadow Nematode, *Pratylenchus pratensis*, to Fusarium Wilt of Cotton in Georgia, by A. L. Smith; On the Occurrence of the Banana Nematode (*Pratylenchus musicola*) in the United States, and The Root-Knot Nematode Attacking Stems and Leaves of Plants, both by G. Steiner; Further Observations on the Nematode-Fusarium-Wilt Experiments at Lumberton, North Carolina, by A. L. Taylor, H. D. Barker, and P. H. Kime; Suggestions Arising From an Analysis of Plants Reported Resistant or Tolerant Toward Root-Knot-Nematode Infestation, by J. Tyler; and Chemical Treatment of Soil to Control the Root-Knot Nematode, by P. A. Young.

[Abstracts of papers on phytopathology] (*Assoc. South. Agr. Workers Proc.*, 41 (1940), pp. 32-35, 155, 156, 159, 160, 178-188, 189-207).—The following are included: Recent Research in the Control of Bacterial Blight of Snapbeans, by L. H. Person and K. W. Kuitlow (pp. 32, 33) (La. Expt. Sta.); The Epidemiology and Control of Cucurbit Downy Mildew, by C. J. Nusbaum (pp. 33, 34) (S. C. Sta.); The Breeding of Wilt Resistant Watermelons in the South, by M. N. Walker (pp. 34, 35), and Minor Element Deficiency Symptoms of Tung Trees, by R. D. Dickey (pp. 155, 156) (both Fla. Sta.); A Preliminary Report of Pecan Leaf Scorch Studies, by M. B. Hardy, H. Lutz, and S. Merrill, Jr. (pp. 159, 160), and Extension Work on Diseases of Cotton and Other Southern Crops, by R. J. Haskell (pp. 178-181) (both U. S. D. A.); A Photo-Electric Method and Its Use for Determination of Fungus Growth Rates, by L. A. Adair and E. J.

Moore (p. 182); Growth Response of *Phymatotrichum omnivorum* to Certain Inorganic Nitrogens, by L. M. Blank and P. J. Tilley (p. 182) (U. S. D. A.); The Control of Sclerotinose of Celery on Florida Muck, by A. N. Brooks (pp. 182, 183) (Fla. Sta.); Infection of Cotton Seedlings in the Greenhouse by *Phymatotrichum omnivorum*, by L. M. Blank (p. 183) (U. S. D. A.); Effect of Certain Methods of Treating and Planting Cotton Seed in South Louisiana, by H. B. Brown (p. 184) (La. Sta.); Field Results With Gravity Graded Cotton Seed, by K. S. Chester (p. 185) (Okla. A. and M. Col.); Résumé of Five Years Spraying With Low-Lime Bordeaux Mixture and Zinc Sulphate To Control Pecan Scab and Rosette Diseases, by J. R. Cole and J. R. Large (p. 185) (U. S. D. A.); Effect of Girdling and Topping of Cotton Plants on Survival of *Phymatotrichum omnivorum* on the Roots (pp. 185, 186) and Relation of Age of Cotton Plants to Susceptibility to Field Inoculations With *Phymatotrichum* Root Rot (p. 186), both by W. N. Ezekiel (Tex. Sta.); Field Tests of the Resistance of Cotton to *Phymatotrichum omnivorum*, by G. W. Goldsmith and E. J. Moore (p. 186); Influence of Deep Tillage on Cotton Root Rot Infection, by D. R. Hooton (p. 187) (U. S. D. A.); A New (Virus) Disease of Snap Beans (*Phaseolus vulgaris* L.), by W. A. Jenkins (p. 187) (Ga. Sta.); Preliminary Inheritance Study of *Fusarium* Wilt, by W. H. Jenkins, D. C. Harrell, and J. O. Ware (pp. 187, 188) (U. S. D. A. and S. C. Sta.); Effectiveness of Organic Manures in Controlling Cotton Root Rot on Various Soil Types, by C. J. King (p. 189) (U. S. D. A.); Cotton Seed Dusting in Relation to Control of Seedling Infection of *Rhizoctonia* in the Soil, by S. G. Lehman (p. 189) (N. C. Sta.); Micro-Organisms Associated With Cotton Boll Rots in 1939, by P. R. Miller (pp. 189, 190) (U. S. D. A.); *Fusarium* Wilt Resistance of New Strains and Hybrid Cottons in Louisiana in 1939, by D. C. Neal and H. B. Brown (p. 190) (U. S. D. A. and La. Sta.); Chemical and Physical Studies on Soils From the Regional Cotton Wilt Plots, by L. C. Olson (pp. 190, 191) (Ga. Sta.); Distribution and Condition of Sclerotia of the *Phymatotrichum* Root Rot Fungus in Manured and Unmanured Soils, by O. Parker and C. J. King (p. 191), and A Map History of Some Cotton Root Rot Spots in Arizona, by R. B. Parker and C. J. King (pp. 191, 192) (both U. S. D. A.); Experiments on the Control of Downy Mildew of Cucumbers, by A. J. Plakidas (p. 192) (La. Sta.); The Relation of Nitrogen Fertilization of the Peach on the Control of *Bacterium pruni*, by R. F. Poole (pp. 192, 193) (N. C. Sta.); Number and Viability of Cotton Root Rot Sclerotia From Areas Cropped Continuously to Susceptible and Non-Susceptible Crops (p. 193) and Quality of Cotton Seed From Plants Killed by Cotton Root Rot at Different Dates During the Growing Season and as Affected by Varietal Characteristics (pp. 193, 194), both by C. H. Rogers (Tex. Sta.); Further Studies on the Control of *Cercospora* Leafspots of Peanuts With Various Dusts and Sprays, and Results of Four Years of Extension Work on Cotton Seed Treatment in North Carolina, both by L. Shaw (p. 194) (both N. C. Sta.); An Occurrence on Cotton of Black Root Rot Caused by *Thielaviopsis basicola*, Breeding Disease-Resistant Red Clover, and Pathogenicity Tests of Different Isolates of *Fusarium vasinfectum* During 1939-1940, all by C. D. Sherbakoff (all p. 195) (Tenn. Sta.); Storage Tests With Cotton Seed, by D. M. Simpson (pp. 195, 196), and A Regional Study of the Relationship of Potash Treatments to the Development of Cotton Wilt Under Widely Varying Conditions of Soil and Environment, by A. L. Smith (p. 196) (both U. S. D. A.); The Development of Wilt in a Wilt-Resistant and in a Wilt-Susceptible Variety of Cotton as Affected by the N-P-K Ratio in Fertilizers, by H. B. Tisdale and J. B. Dick (pp. 196, 197) (Ala. Sta. and U. S. D. A.); Notes on the Pathogenic Action of *Phymatotrichum omnivorum*, by G. M. and M. O. Watkins (p. 197) (U. S. D. A.);

Root Rot of Austrian Winter Peas and Vetches, by J. L. Wiemer (pp. 197, 198) (U. S. D. A. and Ga. Sta.); Fungi Found on Diseased Cotton Seedlings From Thirteen States Surveyed in 1939, by R. Weindling (p. 198), and Plant Nematode Council, by H. P. Barss (pp. 198, 199) (both U. S. D. A.); Inducing Uniform Soil Infestations of the Nematode *Heterodera marioni* as an Aid in Breeding for Resistance to Root Knot, by K. C. Barrons (p. 199) (Mich. State Col.); Remarks on Additions to a List of Hosts of the Root-Knot Nematode, by E. M. Buhner (pp. 199, 200), and Resistance to Root Knot Nematode in *Nicotiana*, by E. E. Clayton (p. 200) (U. S. D. A.); The Bulb Nematode (*Ditylenchus dipsaci*) in Narcissus Plantings in Western Oregon, by C. A. Cole (pp. 200, 201); Some Observations of the Development of Root-Knot Nematode Diseases in Virginia, by S. P. Fenne (p. 201) (Va. Sta.); Some Suggestions for Quick Testing of Nematode Resistance in Plant Breeding Programs, by G. H. Godfrey (p. 201) (Tex. Sta.); Controlling Root-Knot Nematodes in Potatoes in the Klamath Basin by Means of Irrigation, by A. E. Gross (p. 202) (Oreg. Sta.); Control of Root Knot in Florida Cigar-Wrapper Tobacco Fields, by R. R. Kincaid (pp. 202, 203) (Fla. Sta.); Comparison of Crop Rotation and Fallowing as Methods on Control for Root Knot of Cotton Under Irrigation, by C. J. King (p. 203) (U. S. D. A.); Recent Root Knot Damage in Potatoes, by J. T. Middleton (p. 203) (Calif. Citrus Sta.); The Effect of Crop Rotation on the Control of *Heterodera marioni* on Norfolk Sandy Loam Soil, by K. J. Shaw (pp. 203, 204) (U. S. D. A.); Recent Field Observations on Tomato and Cotton Root-Knot Nematodes, by C. D. Sherbakoff (p. 204) (Tenn. Sta.); The Distribution and Relation of the Meadow Nematode, *Pratylenchus pratensis*, to *Fusarium* Wilt of Cotton in Georgia, by A. L. Smith (p. 204) (Ga. Sta. and U. S. D. A.); On the Occurrence of the Banana Nematode [*Pratylenchus musicola*] in the United States, and The Root-Knot Nematode Attacking Stems and Leaves of Plants, both by G. Steiner, and Some Further Observations on the Nematode *Fusarium* Wilt Experiments at Lumberton, North Carolina, by A. L. Taylor, H. D. Parker, and P. H. Kime (all p. 205) (U. S. D. A.); Nematode Population and Species Determination Studies on Soils From the Regional Cotton Wilt Plots, by A. L. Taylor and A. L. Smith (p. 206) (U. S. D. A. and Ga. Sta.); Suggestions Arising From an Analysis of "Plants Reported Resistant or Tolerant Toward Root-Knot-Nematode Infestation," by J. Tyler (p. 206) (U. S. D. A.); and Chemical Treatment of Soil To Control the Root Knot Nematode, by P. A. Young (pp. 206, 207) (Tex. Sta.)

The Plant Disease Reporter, [August 1 and 15, 1940] (U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr., 24 (1940), Nos. 14, pp. 277-308; 15, pp. 309-335, figs. 2).—The following items of interest to phytopathology are included:

No. 14.—Plant disease check list revision, including *Amygdalus* spp., by F. Weiss; *Verticillium* wilt of elm, by E. G. Kelsheimer and C. May; *Sclerotinia sclerotiorum* on calceolaria, by H. H. Whetzel and A. W. Dimock; did *Botrytis* actually cause gladiolus blight in Florida? by W. B. Tisdale; bacterial ring rot of potato in the Kansas crop, by L. E. Melchers; ring rot and other potato diseases in the Hastings section of Florida in 1940, by A. H. Eddins; reports on potato late blight from New York and West Virginia; tomato diseases in northeast Texas in 1940, by G. E. Altstatt, P. A. Young, and A. L. Harrison; the 1939 tomato disease situation in Utah, by H. L. Blood and R. M. Christiansen; downy mildew and bulb nematode on onions in New York, by A. G. Newhall; garlic rust (*Puccinia porri*) in California, by M. W. Gardner; downy mildew in Massachusetts tobacco fields, by O. C. Boyd; reports on wheat scab from Pennsylvania, West Virginia, and Indiana; wheat loose smut and other cereal smuts in West Virginia, Indiana, and Kansas; crown rust (*Puccinia coronata*) of oats in Illinois, by G. H. Boewe;

reports on wheat rusts in Indiana and Kansas; *Cercosporella* foot rot of wheat in Idaho; glume blotch of wheat and anthracnose on rye in West Virginia; bacterial wilt of sweet corn in New York; peach leaf curl in Illinois, by G. H. Boewe; and brief notes on phloem necrosis destructiveness in West Virginia, bacterial spot of peach in northeast Texas, and fire blight in West Virginia.

**No. 15.**—Plant disease check list revision, including *Anacardium* through *Bertholletia*, by F. Weiss; notes on the distribution of fungi collected in the southeastern United States in 1938 and 1939, by G. G. Hedgcock; a *Meliola* on a new host genus (*Juniperus virginiana*), by J. A. Stevenson; peach leaf curl in Idaho, by E. C. Blodgett; apple rusts in the Shenandoah Valley, by P. R. Miller; outbreak of *Ascochyta* blight of cotton in Georgia, by B. B. Higgins; black shank in the Burley tobacco section of Kentucky, by W. D. Valleau; reports on potato late blight from Virginia, New York, and Wisconsin; flax diseases in the North Central States, by H. H. Flor; stem rust of oats in Illinois, and alfalfa downy mildew (*Peronospora trifoliorum*) in Illinois, both by G. H. Boewe; and brief notes on grain diseases in Wisconsin, tomato leaf blight severity in middle and southwest Virginia, and cucumber wilt in Virginia.

[**Abstracts of theses**] (*La. State Univ. Bul., n. ser., 32 (1940), No. 1, pp. 31-33, 97, 98*).—Of interest to phytopathology are Studies on Internal Breakdown of Sweet Potatoes, by T. T. Hebert (p. 31); Studies of a New Leaf Spot of Strawberry, by L. W. Lenz (pp. 31, 32); The Soil Rot Disease of Sweet Potatoes Caused by an *Actinomyces*, by W. J. Martin (pp. 32, 33); and Studies of Host-Parasite Relationship in the Red Rot Disease of Sugar Cane, by R. Y. Nesom (pp. 97, 98).

[**Studies in plant pathology by the Massachusetts Station**]. (Partly coop. U. S. D. A.). (*Massachusetts Sta. Bul. 369 (1940), 7, 8, 16-18, 22-25, 25-28, 39-41, 76*).—Brief progress reports by members of the station and U. S. Department of Agriculture staffs (W. S. Eisenmenger, K. J. Kucinski, H. F. Bergman, W. L. Doran, E. F. Guba, C. J. Kilgut, M. A. McKenzie, A. V. Osmun, C. V. Kightlinger, H. S. Tiffany, and W. E. Truran) are presented on tobacco black root rot, and overwintering of common tobacco mosaic virus in soil under natural conditions; damping-off of ornamental herbaceous plants due to soil-infesting microorganisms, with special reference to fungicidal control and to the effects of soil treatments and enviroinal modifications on seedlings and cuttings of woody plants; chemical soil surface treatments in hotbeds for control of damping-off of early forcing vegetables; control of tomato leaf mold disease due to *Cladosporium fulvum*; causes and control of decay in winter squash in storage; apple scab control; copper sprays for vegetables; the Dutch elm disease; control of crown root of dogwood; spraying tests for control of rosebloom and fruit rot of cranberries and powdery mildew on garden phlox; and blueberry wilt associated with *Phomopsis*.

[**Phytopathological studies by the Nebraska Station**] (*Nebraska Sta. Rpt. [1939], pp. 13, 26-28*).—Brief reports are included on seed treatment of winter wheat for bunt; breeding and variety tests with reference to resistance to scab and *Fusarium* wilt of potatoes; effect of dry land rotations on potato scab, *Fusarium* wilt, and *Rhizoctonia*; breeding for resistance to bacterial blights of beans; damping-off and storage rots of broadleaf nursery stock (coop, U. S. D. A.); and new disease problems, including bacterial ring rot and *Fusarium* dry rot of potatoes.

[**Plant disease investigations by the New Hampshire Station**] (*New Hampshire Sta. Bul. 319 (1940), pp. 26, 27-30*).—Brief statements of progress are included on plant injuries by lime-sulfur sprays, spraying for apple scab, effect of mulching on bitter pit development in apples, and effect of temperature, soil, and fertilization on potato mosaic and leaf roll, all by O. R. Butler; and ascospore discharge relation to the apple scab spray schedule, by S. Dunn.

**Virus diseases of plants, II**, edited by M. S. DUNIN (DOUNINE) (*Virusnye-bolezni rastenii. Moskva: Vsesoyuzn. Akad. Selsk. Khoz. Nauk Lenina, 1938, vol. 2, pp. 240, figs. [76]*).—The following collected papers appear in this volume: On the Classification of Viruses of Plants, by M. S. Dunin (Dounine) (pp. 7–28); A New Disease of Cotton in Azerbaidzhan (Azerbaijan), by D. D. Verderevskii (Verderevsky) (pp. 29–55); Physiological Changes in Cotton Plants, by L. Kara-Murza (Kara-Mourza) (pp. 56–72); A Comparative Biochemical Description of Healthy Potatoes and Potatoes Affected With Virus Diseases, by R. P. Nikolaev and S. M. Kondrat'eva (Kondratieva) (pp. 73–82); Leaf-Roll of Tomatoes in the District of Kursk and Voronezh, by N. A. Ryakhovskii (Riachovsky) (pp. 83–100); Streak of Tomatoes, by E. A. Asniťskaya (Asnitzkaya) (pp. 101–109); The Spread of Big Bud of Tomatoes in Connection With Ecological Conditions, by M. N. Medish (pp. 110–117); On the Susceptibility of Solanaceae and Convolvulaceae to Big Bud Disease, by I. K. Korachevskii (Korachevsky) and A. V. Semen'kova (pp. 118–124); Virus Diseases of the *Physalis angulata* L., by I. Tsivenko (Tzivenko) (pp. 125–132); Mosaic of Wheat in Voronezh Province, by V. K. Zazhurilo (Sajurilo) and M. Gorlenko (pp. 133–138); Virus Diseases of Fruit Trees, by N. I. Feiginson (pp. 139–180); The Virus Diseases of Cultivated Berry-Bush Plants, by O. B. Natal'ina (Nataljina) (pp. 181–196); On the Isolation of Plants for Virological Experiments, by E. V. Shatova (pp. 197–206); The Microcage for Entomovirological Experiments, by B. G. Krivin (pp. 207–215); On the Problem of the Transmission of Plant Viruses by Insects, by N. S. Sherbinovskii (Sherbinovsky) (pp. 217–219); A Study of the Insect Vector of Virus Diseases of Cotton, by V. N. Rekach (Recach) (pp. 220, 221); On the Physiology of Potato Plants Infected With Rugose Mosaic and Leaf-Roll, by V. F. Kuprevich (Kuprewitch) (p. 222); Virus Diseases of Tobacco in the U. S. S. R., by I. P. Khudyna (pp. 223–225); Virus Diseases of the Soybean, by E. D. Yakimovich (Yakimowich) (pp. 226, 227); Virus Diseases of Oil Producing Plants, by V. N. Yagodkina (Jagodkina) (pp. 228, 229); Virus Diseases of Vegetables and Leguminous Plants in the Ordzhonikidze (Orjonikidze) Region, by V. I. Kozlova (Koslova) (pp. 230, 231); The Virus Diseases of Cultivated Plants in the Saratov Region, by O. N. Vertogradova (pp. 232–237); and Virus Diseases in Cucurbitaceae and Other Plants in the Volga District and the Organization of Virological Work, by M. P. Rodigin (pp. 238, 239).

**The study of plant viruses with special reference to their insect-relationships and some comparisons with the animal viruses**, K. M. SMITH (*Roy. Soc. Trop. Med. and Hyg., Trans., 32 (1939), No. 5, pp. 557–574, pls. 4*).—This is a general discussion and critical review (14 references) centering around the symptoms of plant-virus diseases, methods of their spread, and the relationships of viruses and insects, including the question of their multiplication within insect vectors, transmission by larval forms, discontinuous ejection of virus, inheritance of virus, and viruses in relation to nonvectors.

**A design for laboratory assay of fungicides**, J. G. HORSFALL, J. W. HEUBERGER, E. G. SHARVELLE, and J. M. HAMILTON. (Conn. [New Haven], Minn., and N. Y. State Expt. Stas. et al.). (*Phytopathology, 30 (1940), No. 7, pp. 545–563, figs. 4*).—The authors present a design for measuring the spore-inhibiting aspects of a material as distinct from its tenacity to the sprayed surface, techniques for which are being published elsewhere. The problem was to apply known and reproducible deposits onto a surface. The deposit varied directly with air pressure at the nozzle, size of nozzle, length of spraying time, and velocity and dewpoint of the carrier air stream, and inversely with spraying distance and height of lifting the spray fluid. These variables were controlled by fixing the level of the spray fluid, nozzle, and target in relation to each

other, by enclosing the spray stream in a cylinder to prevent wavering and to control its velocity, by metering the spray time with a stop watch, and by the relative humidity of air sprayed through. The resistance level of spores varied with the size, concentration, age, and method of producing them. Accordingly, the standard fungus (*Macrosporium sarcinaeforme*) was grown on oat agar at 30° C. Spores at a concentration of 5,000 per cubic centimeter were germinated at 30° in distilled water without growth stimulant, to avoid the implications of an unstable balance between stimulation and toxicity. A Breed eyepiece micrometer facilitated counting. The slides to be sprayed were coated with cellulose nitrate to assure uniformity in size of drops and deposits of spores. Where the deposits contained detergents, it was necessary to measure and correct for variations in drop size. The spore response to most toxicants proved to be a function of the logarithm of the dose per spore irrespective of the dosage, number of spores, or area covered by the spore drop. Owing to insufficient control over all these variables in the indicator, there remained a residue of variance in day-to-day response. It was found that the magnitude of this variance could be cut in half by expressing the data, not as deposit to give LD50 (lethal dose for 50 percent inhibition), but as a bordeaux coefficient (LD50 of standard bordeaux/LD50 of the unknown). Since the size of both numerator and denominator varies with the resistance level, the size of the quotient varies much less than the LD50.

**A simple single-spore isolator**, S. J. P. CHILTON and C. C. WERNHAM. (U. S. D. A. and Pa. State Col.). (*Phytopathology*, 30 (1940), No. 8, pp. 695-697, figs. 2).—The authors describe and illustrate a simple device for clamping on the microscope substage condenser holder, in which a glass needle is used for isolating single spores.

**Emendations to the second edition of the list of common names of British plant diseases** (*Brit. Mycol. Soc. Trans.*, 23 (1939), pt. 3, pp. 273-280).—This supplements the work already noted (E. S. R., 74, p. 47).

**Some resupinate polypores from the region of the Great Lakes**, XI, D. V. BAXTER (*Mich. Acad. Sci., Arts, and Letters, Papers*, 25 (1939), pp. 145-170, pls. 12).—In this paper of the series (E. S. R., 83, p. 512), 10 resupinate polypores are presented, including species of *Trametes*, *Poria*, and *Polyporus* (with some new taxonomy).

**An unusual telial collection of *Puccinia graminis***, R. U. COTTER. (U. S. D. A. and Minn. Expt. Sta.). (*Phytopathology*, 30 (1940), No. 8, pp. 693-695).—Teliospores on *Agrostis* stems are reported to have produced aecia on *Berberis vulgaris*, whose aeciospores infected wheat in one trial and rye in another, but not *Agrostis*. When this rust collection was crossed with one from wheat, races of *P. graminis tritici* resulted; when crossed with one of the *secalis* variety, both the *tritici* and *secalis* varieties were obtained; and when crossed with a second collection of rust on *Agrostis*, both *tritici* and *secalis* varieties resulted. Race 161 of the *tritici* variety (a new race) appeared when the *Agrostis* collection was crossed with a race of the *secalis* variety.

**Disease resistance in the soft winter wheats**, R. M. CALDWELL. (Coop. Ind. Expt. Sta.). (In *Report of the Sixth Eastern Wheat Conference, 1939*. U. S. Dept. Agr., Bur. Plant Indus., 1939, pp. 4-9).—Resistance to leaf rust, loose smut, bunt, scab, mosaic, powdery mildew, and stem rust is discussed.

**New physiologic races of flax rust**, H. H. FLOR. (U. S. D. A. and N. Dak. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 60 (1940), No. 9, pp. 575-591).—Ten new physiologic races of *Melampsora lini*, besides the 14 previously reported, have been identified by the reaction of 30-day-old seedlings of 11 varieties of flax grown

and tested in the greenhouse during winter at Fargo, N. Dak. To differentiate the new races it was necessary to add to the list of host testers 3 varieties that had previously been considered immune to rust, viz, Argentine (C. I. 462), Bombay (C. I. 42), and Ottawa 770 B (C. I. 355). All of the 201 varieties and strains of flax selected for testing because of diverse morphologic type or rust resistance were susceptible to 1 or more of the 24 identified races. The differential varieties Argentine, Bombay, J. W. S., and Ottawa 770 B appeared to possess distinct factors conditioning immunity to specific races. Of the 201 varieties tested 48 had the reaction of Argentine, 8 the reaction of Bombay, 4 the reaction of J. W. S., and 20 the reaction of Ottawa 770 B to 16 races of *M. lini*. Varieties with the reaction of Ottawa 770 B or Argentine were immune to all North American races but susceptible to one or more of those from South America. Varieties with the reaction of Bombay or J. W. S. were immune to all South American races but susceptible to one or more of those collected in North America.

**Austrian Winter field pea diseases and their control in the South, J. L. WEIMER.** (Coop. Ga. Expt. Sta.). (*U. S. Dept. Agr. Cir. 565 (1940), pp. 16, figs. 12*).—The Austrian Winter field pea, grown as a winter cover and green manure in several Southern States, is attacked by a number of diseases, some of which have in recent years increased so much in severity that growing of the crop is restricted in certain localities. The leaf spot and black stem fungi live over from one crop season to the next, principally in the soil or in pieces of diseased stems. Since field conditions are so variable, it is impossible to estimate how long these fungi persist in the soil, but they have been found to live 2 yr. or longer. They can be brought to a field by seed, wind, water, or other agencies. The amount in the soil increases from year to year if peas are planted on it each fall. If peas are not planted on the same land oftener than 1 yr. out of 3 or 4, losses can be reduced to a minimum, but susceptible crops such as hairy vetch and the Tangier pea should not be used in the rotation. Crimson clover, bur clover, and cereals are not susceptible, and Monantha, common, and Hungarian vetches, although probably not immune, are highly resistant. No resistant varieties that can be substituted for the Austrian Winter field pea are known.

Leaf blotch kills much leaf tissue and often girdles young stems, but varies greatly in severity from season to season and in different localities. Losses can be held to a minimum by rotations. Root rot may kill the plants in certain areas and thus cause almost total losses. No satisfactory control measure is known, but low wet areas should not be used and the rotation should be as long as practicable. Powdery mildew is often prevalent, especially in the extreme southern part of the pea-growing area, and although it seldom causes much damage by the time the crop is ready to plow under, it may become important when seed-growing is attempted. Bacterial blight, downy mildew, mosaic, *Fusarium* root rot, and stem rot are found at times, but usually do little damage. Rotation should help to hold these diseases in check.

**Results of experiments in control of bacterial ring rot of potatoes in 1939, T. P. DYKSTRA** (*U. S. Dept. Agr., Bur. Plant Indus., [1940], pp. 8*).—A progress report compiled from data furnished by investigators in California, Colorado, Maine, and Wyoming on control of potato ring rot due to *Phytophthora sepedonica*.

**The resistance of progeny of Katahdin potatoes to viroses, L. K. JONES, C. L. VINCENT, and E. F. BURK.** (Wash. Expt. Sta.). (*Jour. Agr. Res. [U. S.], 60 (1940), No. 9, pp. 631-644, figs. 5*).—Field and greenhouse tests with the vein-banding, latent mosaic, tobacco mosaic, and curly top viruses on potato varieties and seedlings are reported upon in detail. A number of potato varieties, including Katahdin and its progeny, showed marked resistance to infection by the first

three viruses. No significant difference in susceptibility to the curly top virus was noted in the seedling lots observed. A variant of the latent mosaic virus causing a mosaic disease on Katahdin is reported.

**Comparative wilt induction by *Erwinia tracheiphila* and *Phytomonas stewarti*, H. A. HARRIS.** (Univ. Ill.). (*Phytopathology*, 30 (1940), No. 8, pp. 625-638, figs. 2).—In tests with *E. tracheiphila* infecting cucumber and *P. stewartii* infecting sweet corn, their filtrates from cultures in beef-extract broth solution caused wilting in cuttings of the respective host plants. Transpiration histories of infected plants showed a decrease in water losses during the initial stages of wilting in plants grown either in soil or in nutrient solution. Fluometric data exhibited a marked reduction in water flow through infected compared with noninfected stems. The transpiration and fluometric data would seem to suggest that the primary cause of wilting induced by both organisms is occasioned by a mechanical plugging of the water conduction system.

**Seasonal development, insect vectors, and host range of bacterial wilt of sweet corn, C. ELLIOTT and F. W. POOS.** (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 60 (1940), No. 10, pp. 645-686, figs. 2).—The authors report upon cooperative investigations of bacterial wilt of sweet corn in Virginia and New York for the 1934-37 seasons and discuss the results in relation to winter temperatures. Following the relatively cold winter of 1935-36 flea beetles were much less abundant early in the season in these regions and wilt was correspondingly less destructive. During the 4 yr. concerned, 28,769 insects representing 94 species and 76 genera were tested for *Aplanobacter stewartii* (= *Phytomonas stewartii*) to determine which might prove to be vectors of wilt under field conditions. Results of these isolations, which included 18,613 individuals of *Chaetocnema pulicaria*, indicated that this is the only species of importance in harboring the wilt organism over winter and also in spreading the disease during the corn-growing season. While *C. denticulata* ranks next in numbers of adults from which these bacteria have been isolated, and may possibly play some part in wilt dissemination, it is apparently not a close second in importance to *C. pulicaria*, and it is doubtful whether the wilt organism ever overwinters in adults of *C. denticulata*. None of the other species from which wilt bacteria have been isolated can be considered vectors of any importance under field conditions. During the 4-yr. period the wilt organism was isolated from *C. pulicaria* collected at Arlington Farm in every month of the year except February, and one isolation was made from beetles collected February 26, 1936, at Norfolk, Va. Early- and late-season isolations from *C. pulicaria* from other localities have shown that overwintering adults are more or less infested in all sections of the country where wilt is prevalent and isolations have been made. *Euchlaena perennis* proved susceptible to infection with the wilt organism, but *Tripsacum dactyloides*, *T. pilosum*, *T. lanceolatum*, and *T. latifolium* were immune in these experiments. Other genera and species tested failed to develop typical wilt symptoms.

**Pink-root disease constitutes a serious problem for onion growers of Colorado, W. A. KREUTZER** (*Colo. Farm Bul. [Colorado Sta.]*, 2 (1940), No. 3, pp. 13-15, fig. 1).—A brief account of the symptoms, prevalence, widespread occurrence in Colorado, and difficulties in control. No significant resistance in any commercially desirable variety has yet been found, and crop rotation cannot be recommended since it is shown that the causal fungus *Phoma terrestris* can attack the young roots of many crop plants. Since the parasite invades both living roots and dead outer scales of the onion bulbs, seed rather than set bulbs should be planted, and no plant growing in the soil of a field known to harbor the disease should be transplanted (E. S. R., 81, p. 532).

**Not easy to spot causes of pea root-rot and foot-rot, O. A. REINKING** (*Farm Res. [New York State Sta.], 6 (1940), No. 3, pp. 11, 16, fig. 1*).—Pea root rot is reported to be again in evidence. A study of records over a 15-yr. period revealed that a number of factors are involved in the large fluctuations in yield from year to year, including culture, site, planting time, and presence of disease organisms. Investigations on pea root rot and foot rot during the past 4 seasons indicate that the disease situation is complicated by the large number of different pathogenic soil organisms present. It is believed that the near-wilt fungus (*Fusarium oxysporum* f. 8), widespread in the State, accounts for much of the root rot and foot rot. This progress report gives a general picture of the complex situation and the consequent difficulty of controlling these two disease manifestations.

**The effect of growing and shipping methods on tomato plant diseases, W. D. MOORE.** (U. S. D. A.). (*Canner, 90 (1940), No. 11, p. 17*).—A brief summary of the factors found to influence disease incidence in southern-grown tomato seedlings shipped for northern planting.

**Tomato wilt resistance and its decrease by *Heterodera marioni*, P. A. YOUNG.** (Tex. Expt. Sta.). (*Phytopathology, 29 (1939), No. 10, pp. 871-879*).—"The time-weighted percentages of wilt resistance of 83 varieties including 207 selections of tomatoes were determined by growing their plants in epiphytotics of wilt caused by *Fusarium lycopersici* in the practical absence of other tomato parasites. These percentages were calculated with a new formula that was derived to time-weight 7 percentages of wilting and wilt-killed plants. Time-weighted wilt resistance of 70 percent or more is needed in commercially desirable varieties of tomatoes. These time-weighted percentages describe with mathematical precision the wilt resistance of the tomato varieties under the environmental conditions described. However, according to the general rule, the wilt resistance of tomato varieties is expected to vary in different environments that cause differences in details of cell physiology and structure of both host and parasite. Different physiologic races of the parasite also affect wilt resistance.

"Scarlet Dawn, Glovel, and Norton varieties are markedly susceptible to *F. lycopersici* in this region [eastern Texas], although they are described as being wilt-resistant elsewhere. Selections of Blair Forcing, Buckeye State, Illinois Baltimore, Louisiana Pink, Louisiana Red, Marglobe, Riverside, and Rutgers showed the most marked wilt resistance of the varieties of tomatoes tested. Of the 14 varieties in a special yield test, Pritchard, Michigan State, Break O'Day, Rutgers, Louisiana Pink, and Marglobe gave the best yields in an epiphytotic of *Fusarium* wilt. Large yields were directly correlated with marked wilt resistance. Extensive evidence showed that *H. marioni* greatly decreased the time-weighted percentages of resistance of many tomato varieties to *F. lycopersici*."

**Spraying versus dusting of canning tomatoes with early and delayed applications, J. D. WILSON** (*Ohio Sta. Bimo. Bul. 204 (1940), pp. 76-84*).—The questions raised years ago, and a few new ones, enter into this discussion of an experiment designed to test the relative effectiveness of various materials applied both as sprays and as dusts in applications begun before leaf spot appeared (July 10) and after it had gained a foothold on plants of the canning crop (August 1). The materials compared in early and delayed applications were bordeaux mixture, monohydrated copper sulfate-hydrated lime dust, Tribasic copper, copper oxychloride sulfate, Copper Compound A, Copper Hydro 40, and Cuprocides 54 and G. A. The average yield from plats treated with five applications of dust, beginning on July 10

(early dusts), was 19.8 tons per acre, and this was significantly better than that obtained with early spraying or delayed dusting or spraying. Leaf spot was definitely more severe by September 1 on those plats where dusting or spraying had been delayed until August 1 than on those treated for the first time on July 10. This relative severity was reflected in smaller final yields on October 5 from the delayed treatments. Five applications of spray or dust gave an average increase in yield over untreated plats of  $\pm 3.4$  tons per acre. With an estimated cost of \$3 per acre per application and with grade No. 1 tomatoes at \$13.50 a ton, a net return of about \$30 per acre was thus obtained by the varied disease control programs tested. No one of the six copper-containing materials used gave results significantly better than those of another when the average yields of all four treatment schedules were considered.

The excellent results with Compound A in the delayed dusting schedule suggest that only the best types of fungicides should be applied in this schedule if *Septoria* leaf spot is to be checked successfully. One of the possibilities in connection with delayed ripening is that it may be possible to lengthen the period of heavy production of ripe fruits from tomato fields suffering severe and rapid defoliation by leaf spot through proper use of a disease-control program. The use of two materials, such as Tribasic copper, with little effect on the date of fruit ripening, and Compound A, which retards ripening to some extent, in different parts of the same field might lengthen this period of peak production of ripe fruits still further. Either dusts or sprays are more effective in controlling *Septoria* leaf spot of tomatoes if applied ahead of the first infection period. Dusting with the fixed coppers may be expected to give satisfactory results if applications are properly timed and sufficient material is used during periods when atmospheric conditions are suitable for dusting.

**A destructive bud-transmissible disease of sour cherry,** G. W. KEIT and C. N. CLAYTON (*Wis. Hort.*, 30 (1940), No. 10, p. 276).—Note on the disease previously called "physiological yellow leaf" or "boarder tree," here shown to be bud-transmissible and evidently a virus malady.

**Pathological changes in the phloem and neighbouring tissues of the banana (*Musa cavendishii* Lamb.) caused by the bunchy-top virus,** C. J. P. MAGEE (*N. S. Wales Dept. Agr., Sci. Bul.* 67 (1939), pp. 32, figs. 30).—The most reliable diagnostic symptom of this disease is said to be the green streaking of the vascular traces in the lamina, midrib, and petiole of the leaves. The presence of these streaks is correlated internally with a profound modification of the structure of the phloem and surrounding tissues of the vascular bundles, details of which are described and illustrated. These abnormalities arise as a result of early aberrations in the ontogeny of the phloem and surrounding tissues during the incubation period of the disease and subsequently as each young leaf develops. The primary effects of the virus are to cause hypertrophy of cell volume and/or the nucleus of any unspecialized cell adjacent to the sieve tubes and hyperplasia of the more distant surrounding cells. The mechanism of these hypertrophies and hyperplasias is not understood, but it is suggested as possible that the virus is a growth-stimulating substance, the relative concentrations of which regulate cell responses. Phloem necrosis is considered of secondary importance to other changes. Replacement of the phloem by morbid tissues is believed responsible, by interfering with translocation, for the accumulation of starch and crystalline material in affected leaves, and ultimately for all the externally observed symptoms. The histopathology of bunchy top is compared with that of potato leaf roll and sugar beet curly top, the similarities being considered most striking.

**Texas citrus diseases, [I, II], G. H. GODFREY** (*Tex. Farming and Citric.*, 16 (1940), Nos. 11, pp. 8, 14; 12, p. 6).—General discussions are given of (1) tree diseases and (2) fruit diseases.

**Cephalosporium elm wilt in Massachusetts, M. A. MCKENZIE and E. M. JOHNSON** (*Massachusetts Sta. Bul.* 368 (1939), pp. 24, figs. 12).—This disease, becoming widespread in Massachusetts, is a typical vascular mycosis which cannot be distinguished from other vascular diseases of elm except by identification of the causal fungus from cultural studies of tissue plantings. Under experimental conditions the organism frequently reacts similarly to *Ceratostomella ulmi*, the cause of Dutch elm disease. Infection early in the growing season is apparently more destructive than late in the summer or fall. The external symptoms of the disease are typical of dieback diseases, and the internal symptoms include brown streaks in the wood. Aerial mycelium grows on infected twigs under certain conditions. The evidence at hand supports the hypothesis that the fungus may be spread by spores within the tree. Spores were germinated most readily on potato dextrose agar, in darkness, and in a moist atmosphere. The thermal death point of the fungus was placed between 75° and 80° C., and freezing exerted no influence on the viability of the spores. Sporogenesis was typical of the genus.

Inoculations were made from single-spore colonies in stems and leaves of *Ulmus americana*, *U. americana ascendens*, *U. campestris*, *U. glabra fastigiata*, *U. parvifolia*, and *U. pumila*. Infection followed inoculation of freshly wounded leaves in all cases, and all trees except *U. glabra fastigiata* were infected by twig inoculations in fresh wounds. In nature, comparable fresh injuries by insects would serve readily as infection courts if the insects themselves were the principal vectors, and reports by Becker (*E. S. R.*, 74, p. 523; 77, p. 359) of a native elm beetle invading living cambium may prove to have particular significance in connection with the spread of this *Cephalosporium*. The fact that the findings of the authors agree with previous results obtained in New England and do not agree with those obtained in Nebraska, suggests the possibility that more than one form of *Cephalosporium* may be concerned. Based on the assumption that the fungus is native to the United States, control measures should be directed toward maintaining the vigor of infected elms. Particular attention to the careful pruning out and burning of diseased parts of trees is desirable, and treatment of fresh wounds or scars should be directed toward the avoidance of reviving of latent infections.

**Oak root fungus presents serious economic problem, R. G. LA RUE** (*Citrus Leaves*, 20 (1940), No. 3, pp. 5, 6, figs. 4).—A note on the insidious spread of *Armillaria* root rot in citrus groves of San Bernardino County, Calif., with orchard records and summary of a carbon bisulfide fumigation test apparently indicating more than one treatment per year to be needed.

**Serious disease threatens the sycamore or planetree, J. M. WALTER, P. V. MOOK, and C. MAY.** (*U. S. D. A.*). (*Arborist's News*, 5 (1940), No. 7, pp. 49–55, figs. 2).—A summary of information on the new disease of sycamore trees due to *Ceratostomella* sp., including its history, distribution, losses induced, hosts, symptoms, cause, dissemination of the fungus, and control.

## ECONOMIC ZOOLOGY—ENTOMOLOGY

**Small mammals and the forest, W. J. HAMILTON, JR., and D. B. COOK.** (Cornell Univ. et al.). (*Jour. Forestry*, 38 (1940), No. 6, pp. 468–473, fig. 1).—The authors emphasize the fact that small mammals are a potent force tending to control insects in the forest, since they are nonmigratory and active throughout the year and potentially more effective than birds. Although the popula-

tions vary over wide limits, numbers are controlled by ecological factors and may be increased only by environmental improvement. Certain forest practices may be detrimental to small mammals in the forest. The contribution is presented with a list of 20 references to the literature.

**Studies on a population cycle of snowshoe hares on the Lake Alexander area.**—I, **Gross annual censuses, 1932-1939**, R. G. GREEN and C. A. EVANS, (Univ. Minn.). (*Jour. Wildlife Mangt.*, 4 (1940), No. 2, pp. 220-238, figs. 4).

**Natural restocking of muskrat-vacant habitats**, P. L. EBBINGTON. (Iowa Expt. Sta.). (*Jour. Wildlife Mangt.*, 4 (1940), No. 2, pp. 173-185).

**The summer food of minks and raccoons on the Montezuma Marsh, New York**, W. J. HAMILTON, JR. (Cornell Univ.). (*Jour. Wildlife Mangt.*, 4 (1940), No. 1, pp. 80-84).

**Internal parasites of cottontail rabbits in Connecticut**, C. F. CLANCY, E. JUNGHERR, and P. R. SIME. (Univ. Conn., U. S. D. A., et al.). (*Jour. Wildlife Mangt.*, 4 (1940), No. 2, pp. 162-168, figs. 2).—In the course of a study of the cottontail by the State Cooperative Wildlife Research Unit a survey was made with a view to determining the species, the incidence, and the seasonal and geographic distribution of parasitic helminths and coccidia of this rodent in Connecticut. "Internal parasites were found in 85 percent of 342 cottontail rabbits collected in different parts of Connecticut. The parasites found and the percentages of all rabbits positive for each parasite were as follows: *Eimeria* sp. (coccidia) 63 percent, *Obeliscoides cuniculi* (stomach worm) 40 percent, *Cittotaenia variabilis* (tapeworm) 32 percent, *Cysticercus pisiformis* (tapeworm cyst) 28 percent, and *Passalurus ambiguus* (pinworm) 6 percent. These parasites appear to occur fairly uniformly in the eastern cottontail (*Sylvilagus floridanus mallurus*) as well as in the New England cottontail (*S. transitionalis*) throughout the State, with the exception of *P. ambiguus*, which was found exclusively in the New England cottontail, and primarily in eastern Connecticut. *Obeliscoides* parasitism was lowest in the winter months."

**A survey of the parasites of the Iowa cottontail (*Sylvilagus floridanus mearnsi*)**, B. B. MORGAN and E. F. WALLER. (Iowa State Col.). (*Jour. Wildlife Mangt.*, 4 (1940), No. 1, pp. 21-26).—During the year 1938-39 210 cottontail rabbit carcasses submitted to the laboratory for examination were examined for parasites. All harbored from 1 to 7 species of coccidia, 3 of which had not previously been reported from North American rabbits. "Heavy infestations of the protozoan *Sarcocystis cuniculi* were found in 20 individuals. Three species of fleas, *Cediopsylla simplex*, *Hoplopyllus affinis*, and *Ctenocephalides canis*, and 1 species of tick, *Haemaphysalis leporis-palustris*, were identified. The tapeworm *Cittotaenia variabilis* was found in 76 of the animals necropsied. Eighty-seven cottontails were infested with the larval stage of *Taenia pisiformis*. The trematode *Hasstilesia tricolor* was found in 11 rabbits. Four species of nematodes were recorded, namely, *Trichuris leporis*, *Trichostrongylus calcaratus*, *Obeliscoides cuniculi*, and *Nematodirus leporis*."

A list is given of 15 references to the literature.

**A field method of analyzing game bird foods**, V. E. DAVISON. (U. S. D. A.). (*Jour. Wildlife Mangt.*, 4 (1940), No. 2, pp. 105-116).

**The food habits of the ring-necked pheasant in Minnesota**, L. A. FRIED. (Minn. Expt. Sta.). (*Jour. Wildlife Mangt.*, 4 (1940), No. 1, pp. 27-36, fig. 1).—The results of examinations of 515 ring-necked pheasants collected from June 1935 to July 1938, 106 of which were picked up dead during unusually severe weather in January, February, and March of 1936, are reported. It is said that in Minnesota the ring-necked pheasant is chiefly a granivorous bird, preferring cultivated grains at all times of the year. Corn is taken more often

and in greater quantity than any other single kind of food and is the most important item in the pheasant's diet. Damage to newly planted and growing corn by the pheasant has been greatly exaggerated. Less than 1 percent of the corn eaten is sprouted. In May and June, when pheasants are believed to do their greatest damage to corn, the amount of mutilated and silage corn together exceeded by 24.4 percent the amount of perfect corn. While winter feeding probably saved many pheasants from starvation, the high mortality during the winter of 1936 was due more to lack of good cover than to want of food. Proper shelter is at least as important a factor in saving birds during periods of severe weather as is food, and in some cases it is the decisive factor. Pheasants consume a large number of weed seeds, but the effect upon the next year's crop of weeds is probably small. Green and yellow foxtails, common ragweed, and wild buckwheat made up 78.7 percent of all weed seeds eaten. Grasshoppers were eaten more often and in greater numbers than any other kind of animal food. The largest proportions of these insects were taken in April and in July when they were in the egg and nymphal stages, respectively. Thus, pheasants may act as a check not only on the immediate damage to growing crops but also on future grasshopper populations.

**Sex and age ratios in survival of the California quail, J. T. EMLER, JR.** (Univ. Calif.). (*Jour. Wildlife Mangt.*, 4 (1940), No. 1, pp. 92-99, figs. 3).—A total of 17,632 sex and age records on California quail (*Lophortyx californica*) that were taken from various parts of California are summarized and analyzed.

**Economic status of the English sparrow in the United States, E. R. KALMBACH** (*U. S. Dept. Agr., Tech. Bul.* 711 (1940), pp. 66, pls. 3, figs. 7).—The changed agricultural practices, extension of crop areas, phenomenal growth of metropolitan sections, and successive inroads of various new insect pests upon which the bird can prey since the extensive report of Barrows on the economic status of this sparrow in the United States (*E. S. R.*, 1, p. 108) led to the investigation here reported. A total of 8,004 stomachs were examined, this being a larger number than ever before employed in a study of the food habits of a single species of bird. The information thus gained has been analyzed and deductions drawn. "Of the annual food of the adult English sparrow, about one-fifth (19.64 percent) represents services beneficial to man, about one-fourth (24.78 percent) those neutral in effect, and the remainder, a little over half (55.58 percent), those injurious. The feeding on noxious insects (2.67 percent) and weed seeds (16.97 percent) represents the adult bird's meritorious work, whereas its harmful proclivities are centered largely in its consumption of chicken feed, grain of various kinds, and garden truck. In marked contrast to the food of the adult is that of the nestling. Nearly three-fifths (59.38 percent) of its food reflects feeding habits beneficial to man, about an eighth (12.33 percent) those neutral in effect, and the remainder, well over a fourth (28.29 percent), those injurious. Practically all the nestling's beneficial work involves the destruction of injurious insects. Its harmful tendencies include its feeding on chicken feed, grain, and a few useful insects. Despite the commendable food habits of the nestlings, however, and the fact that they outnumber the adults during the breeding season, their influence lasts individually for but a brief span of 10 or 12 days. In the final analysis the benefits accruing from the food habits of the nestlings do not appear to counterbalance the real and potential harm with which the adults must be charged.

"This conclusion concerning food habits is applicable to those situations or conditions that may be considered average in character. There are circumstances and environments in which such an appraisal is too severe, and

again there may be those in which the English sparrow, through excessive numbers, deserves even more emphatic condemnation and becomes a fit subject for control."

A list of 42 references to the literature is included.

**Chemistry in pest control**, R. C. ROARK. (U. S. D. A.). (*Soap and Sanit. Chem.*, 15 (1939), No. 11, pp. 93, 95, 97, 123).

**The incorporation of direct with protective insecticides and fungicides.—IV, The evaluation of the wetting and spreading properties of spray fluids**, H. MARTIN (*Jour. Pomol. and Hort. Sci.*, 18 (1940), No. 1, pp. 34-51).—A continuation of this series of studies (E. S. R., 80, p. 512), which has resulted in the devising of a laboratory method suitable for the assessment of the wetting and spreading properties of spray fluids.

**Test methods for recording moribund kill**, H. E. WHITMIRE (*Soap and Sanit. Chem.*, 15 (1939), No. 11, pp. 99, 101, 103, 123, fig. 1).

**Some preliminary experiments with  $\beta$ -butoxy- $\beta'$ -thiocyanodiethylether as an industrial insecticide**, C. POTTER and A. J. MUSGRAVE (*Ann. Appl. Biol.*, 27 (1940), No. 1, pp. 110-121).—Report is made of preliminary experiments aimed at the determination of the toxicity of  $\beta$ -butoxy- $\beta'$ -thiocyanodiethylether (normal butylcarbitolthiocyanate) to some industrial and household insect pests. "The insecticide was found to be toxic as a spray and had a marked effect in its vapor phase (except on *Tenebrio molitor* L.); under suitable conditions it could also be made to form a toxic film on wooden surfaces. The thiocyanate appeared to be particularly toxic to the eggs of the bedbug (*Cimex lectularius* L.). The following were used as test insects: *Sitophilus granarius* L., *S. oryzae* L., *Caulophilus latinasus* Say, *Lasioderma serricorne* F., *Oryzaephilus surinamensis* L., *Tribolium castaneum* Hbst., *Plodia interpunctella* Hb., *Ephestia kuehniella* Z., *Cimex lectularius* L., *Tenebrio molitor* L., *Dermestes vulpinus* F., and *Ephestia elutella* Hb. Of these insects all, except *D. vulpinus* and *T. molitor*, which were used only in experiments on the toxicity of the vapor, were susceptible in varying degrees to the thiocyanate in one form or another. The thiocyanate appears therefore to have considerable promise as an industrial insecticide either alone or mixed with other toxic substances, e. g., pyrethrum or derris."

**Preliminary selection experiments with Derris**, C. D. V. GEORGI, J. LAMBOURNE, and G. L. TEIK (*Malayan Agr. Jour.*, 24 (1936), No. 8, pp. 374-389).—The results of a survey of the principal species of *Derris* being grown in Malaya, undertaken to determine the variations in toxic content as shown by chemical analysis between roots of individual plants, are reported, the details being given in 15 tables. The species of *Derris* examined included *D. malac-*

*censis sarawakensis*, *D. elliptica* (Sarawak creeping), *D. elliptica* (Serdang type), *D. polyantha*?, *D. elliptica* (Singapore type), and *D. malaccensis* (Kinta type).

**Variations in toxicity of some races of *Derris elliptica***, C. D. V. GEORGI, J. LAMBOURNE, and G. L. TEIK (*Malayan Agr. Jour.*, 25 (1937), No. 5, pp. 187-200, pl. 1).—The results of further experiments (see above) aimed at the isolation of high rotenone content strains of *D. elliptica* are reported, the details being given in 10 tables.

**Further experiments with selected plants of *Derris elliptica***, Changi No. 3, C. D. V. GEORGI and G. L. TEIK (*Malayan Agr. Jour.*, 28 (1940), No. 2, pp. 44-68).—In continuation of the above, cuttings from certain outstanding plants were propagated as individual clones with a view to studying intra- and inter-clonal variations. The results, the details of which are given in 21 tables, are summarized under the headings of yield of root, ether extract of root, rotenone content of root, and correlation between rotenone and ether extract.

**Factors influencing the use of some common insecticide-dispersing agents**, L. H. DAWSEY (*U. S. Dept. Agr. Cir.* 568 (1940), pp. 10).—Report is made of a laboratory investigation of the dispersing efficiency, cost, stability against water hardness, heat, and bacteria, and versatility in dispersing different kinds of material of 14 commonly used agents. These dispersing agents were tested with refined petroleum oil, phenothiazine, menhaden fish oil, rosin residue, and paraffin. Only 4 out of the 14 agents, ammonium caseinate, glue, arabic gum, and whole-milk powder, were capable of dispersing all the materials. The best all-around agent was arabic gum. In the unstable class, blood albumin, egg albumin, ammonium caseinate, glue, and whole-milk powder were the most efficient, in the order named. Their chief usefulness appeared to lie in the preparation of insecticidal sprays which are to be used within 24 hr. after mixing. In the emulsification of refined petroleum oil, blood albumin was the best agent in the unstable class and arabic gum in the stable class. For menhaden fish oil, bentonite clay was the best agent regardless of class. For rosin residue, whole-milk powder was the best agent in the unstable class and arabic gum in the stable class. In the dispersion of paraffin, ammonium caseinate was the best agent in the unstable class and arabic gum in the stable class. For phenothiazine, whole-wheat flour was the best agent in the unstable class and arabic gum in the stable class. No correlation of practical value was found between the dispersing efficiency of the agents and their tendency to foam.

**Insect pests of cabbage present perplexing problems**, G. E. R. HERVEY (*Farm Res. [New York State Sta.]*, 6 (1940), No. 3, pp. 5, 6, fig. 1).—A practical discussion of control measures for cabbage insects, including spray and dust formulas and methods of application.

**Control of the major pests of the Satsuma orange in south Alabama**, L. L. ENGLISH and G. F. TURNIPSEED (*Alabama Sta. Bul.* 248 (1940), pp. 48, figs. 17).—The details of the seasonal history and control work with insect pests and sour scab disease of the Satsuma orange, which have been conducted at the Spring Hill Field Station since 1928, are presented in tables and charts. Of the several insects, including purple scale, citrus rust mite, citrus whitefly, and citrus red mite, the first mentioned is said to be of greatest importance. If uncontrolled the purple scale may cause from 75 to 80 percent of the fruit to be classed as culls, and trees may be seriously devitalized or even killed. Its development is almost continuous but is retarded by cold weather. The shortest life cycles and the greatest hatch of eggs take place during the warm summer months.

Spring applications of bordeaux-oil and bordeaux-sulfur aid in controlling the purple scale, but the opportune time to use an oil spray is in July. Only one oil spray per year is required for commercial control. Frequent use of sulfur sprays gives only partial control of scale. The citrus rust mite, in the absence of control measures, may russet young fruits in the early summer, but more serious damage is caused by the late summer or early fall infestation, when, if uncontrolled, from 50 to 70 percent of the fruit may be russeted. It is readily controlled by sulfur sprays or dusts, the dust being preferable. Bordeaux-oil mixture has been found effective against the citrus whitefly, the optimum time of application being just before the adults begin to emerge. Oil sprays have been found effective against the citrus red mite. If applied in July they will keep trees relatively free from mites for several months and if applied every year, control is easily maintained. The sour scab disease, which causes bumpy fruit, is best controlled by the regular use of bordeaux mixture or sulfur fungicides twice a year, one application before growth of the trees commences in the spring and the other after petal fall.

"Oil sprays prepared from highly refined white oils are much more desirable for use on Satsumas than those prepared from unrefined oils. This is especially so when the trees are subjected to critical climatic conditions. Spray programs containing applications of oil in July and September seriously delay maturity and reduce the yield of Satsumas after the first year. However, a refined white oil with a viscosity of 78-80 sec. (Saybolt) was applied at a concentration 1.5 percent in July for 4 successive years without material effect on the maturity or yield of the fruit. Although liquid lime-sulfur was conducive to early maturity of the fruit, the occasional severe injury caused by this spray makes its use unwise. Sulfur applications should be confined to dust and to wettable sulfur. Spray schedules for effective and economical control of sour scab and the arthropod pests of Satsumas are given."

[Contributions on fruit and nut insects] (*Oreg. State Hort. Soc. Ann. Rpt.*, 31 (1939), pp. 37-45, 57-64, 67-72, 119-124, 136-140, figs. 4).—Contributions relating to economic insects presented at the annual meeting of the Oregon State Horticultural Society and the Western Nut Growers Association held in December 1939 include The Pear Psylla—an Important Pear Pest, by L. G. Gentner (pp. 37-39), and Pear Psylla a Threat to the Northwest Pear Industry (pp. 41, 43-45) and Oil Sprays and Their Effects in Hood River (pp. 57-63), both by L. Childs (all *Oreg. Expt. Sta.*); Cherry Fruit Fly Situation, Hood River County, by A. L. Marble (pp. 67, 68); Observations and Experiments on the Removal of Spray Residues in the Yakima Valley, by A. L. Ryall (pp. 68-72) (*U. S. D. A.*); Injury to the Tree and Fruit From Different Sprays Applied in 1939, by F. L. Overley, E. L. Overholser, and D. F. Allmendinger (pp. 119-124) (*Wash. Sta.*); and Progress Report on Filbert Insect Investigations, by B. G. Thompson (pp. 136-139) (*Oreg. State Col.*).

The detection of wood-boring insects by means of X-rays, R. C. FISHER and H. S. TASKER (*Ann. Appl. Biol.*, 27 (1940), No. 1, pp. 92-100, pls. 2, fig. 1).—The investigation reported led to the conclusion that the "general condition of a sample of wood can readily be determined by X-ray examination. For example, the presence of insect tunnels and the extent of disintegration within a sample can be detected with ease, even when not apparent from its external appearance. In favorable cases the presence or absence of insects can be ascertained, but for the results of the examination to be conclusive the sample must not be too thick, and above all, must not be severely disintegrated and powdered. It is not possible to state definitely the limits of thickness through

which various insects can be detected; this depends primarily upon the state of the wood and, secondly, on the stage and size of the insects and the amount of frass in the tunnels in their immediate neighborhood. When insects can be detected their movements can be followed by taking radiographs at successive intervals of time. The method might prove of value in laboratory studies of wood-boring insects when the progress of development cannot usually be determined without destructive examination of the infested samples. It appears that the practical application of X-rays for the detection of wood-boring insects will be confined to timber of small dimensions, e. g., small articles of furniture, picture panels and frames, plywood, etc., and, where cost allows, could be used for determining the efficacy of methods of control by insecticide or fumigation treatments applied to such material. The examination of structural timbers in situ in buildings for the detection of the death-watch beetle [*Xestobium rufovillosum* De G.] is in general impracticable. Such timbers are usually of large dimensions, and while it is reasonably certain that larvae favorably situated would be detected, a negative result would be inconclusive and beetles would generally not be located. The X-ray equipment best suited to the radiography of wood is one with a high power output operating in the voltage range 10-40 kv. power. A Grenz-ray tube or an X-ray tube having a very thin window is essential if kilovoltages below 20-25 are to be used."

[Work in entomology by the Massachusetts Station] (*Massachusetts Sta. Bul.* 369 (1940), pp. 33-37, 45-48, 49, 57-66, pl. 1).—The work of the year reported upon (E. S. R., 81, p. 540) relates to injurious and beneficial insects affecting the cranberry, including the fire beetle *Cryptocephalus incertus*, cranberry weevil, cranberry spittle insect *Clastoptera saint-cyri*, rootworm *Colaspis brunnea costipennis*, hill fireworm *Tlascala finitella* Walk., Atlantic cutworm *Polia atlantica*, gypsy moth, cranberry root grub *Amphicomma vulpina*, cranberry fruitworm, black-headed fireworm *Rhopobota* sp., and the blunt-nosed leafhopper *Ophiola* sp., by H. J. Franklin; investigations of materials of promising value in insect control (particularly oil sprays for dormant applications, dormant sprays for control of bud moth, and summer sprays for apples) and apple maggot control, both by A. I. Bourne and W. D. Whitcomb; control of striped cucumber beetle, cabbage maggot, squash vine borer, biology and control of the apple leaf curling midge *Dasyneura mali* Kieff., control of plum curculio in apples, and liberation of parasites of the European earwig, all by Whitcomb; control of onion thrips, the spray residue problem, insecticides for the control of European corn borer, potato spraying experiments, and introduction of parasites of oriental fruit moth in peach orchards, all by Bourne; naphthalene and similar compounds as greenhouse fumigants, by Whitcomb and W. Garland; control of the common red spider on greenhouse plants, by Whitcomb, Garland, and W. E. Tomlinson, Jr.; biology and control of the grape plume moth and grape cane girdler *Ampelogypter ater* Lec., by Whitcomb and Tomlinson; and insects concerned in the dispersal of Dutch elm disease and the effects of solar heat on the subcortical development of the native elm bark beetle, both by W. B. Becker.

[Work with insects by the Nebraska Station] (*Nebraska Sta. Rpt.* [1939], pp. 30-32).—The work of the year reported upon (E. S. R., 81, p. 672) includes reference to the hessian fly, chinch bug, and grasshopper control.

[Work in entomology by the New Hampshire Station]. (Partly coop. U. S. D. A.). (*New Hampshire Sta. Bul.* 319 (1940), pp. 34-36).—Brief reference is made (E. S. R., 82, p. 217) to a study of the penetration of contact insecticides, by W. C. O'Kane, J. G. Conklin, L. C. Glover, and R. L. Blickle, and of ovicides, by O'Kane, Blickle, and Glover; and the occurrence of the European corn borer, gypsy moth, and European spruce sawfly, by O'Kane.

**Insect and other pests of 1939**, A. E. CAMERON (*Highland and Agr. Soc. Scot. Trans.*, 5. ser., 52 (1940), pp. 91-115, figs. 8).—A continuation of the annual reports on the economic insects of Scotland (E. S. R., 81, p. 809).

**A key to the Acrididae (Orthoptera) of northeastern Texas with ecological notes**, H. KNUTSON (*Field and Lab.*, 8 (1940), No. 2, pp. 33-58, figs. 3).

**The hairworm *Gordius robustus* Leidy as a parasite of the Mormon cricket (*Anabrus simplex* Haldeman)**, G. THORNE. (U. S. D. A.). (*Jour. Wash. Acad. Sci.*, 30 (1940), No. 5, pp. 219-231, figs. 7).—The nematode *G. robustus* was first observed as an important parasite of the Mormon cricket in 1935 in the vicinity of Arrowrock Reservoir, Idaho. In certain localities of this area there are favorable breeding grounds for this nematode along small mountain streams and in pools or swamps, and it should be of economic importance in the control of ordinary populations of this pest. "However, during heavy outbreaks of crickets, such as occurred in 1935 to 1937, the percentage of parasitism was too small to be of economic importance, although in some instances it reached 25 to 50 percent of the crickets. Similar parasitism was also observed near Augusta and Cutbank, Mont., where in certain small areas 50 to 99 percent of the crickets contained *Gordii*. Parasitized crickets rarely produce eggs. They live normally until the mature *Gordius* breaks through the abdominal wall and enters water or wet soil. Here the *Gordii* mate and later hibernate in moist places under sticks and stones or among roots and rubbish. Some eggs are deposited in fall but more generally in spring, when the females emerge from hibernation and deposit them along the shores of streams, ponds, or swampy areas. Here the minute larvae hatch and probably are picked up by the young crickets when drinking water or eating aquatic vegetation. Upon reaching the intestine of the cricket they apparently bore through the wall and enter the body cavity, remaining there until maturity. Under present erosion conditions in breeding areas of the *Gordius* most of them are carried away by floods." A list of 11 references to the literature is included.

**Evidence for the identity of the yellow-spot virus with the spotted-wilt virus: Experiments with the vector, *Thrips tabaci***, K. SAKIMURA. (Hawaii. Pineapple Prod. Expt. Sta.). (*Phytopathology*, 30 (1940), No. 4, pp. 281-299, figs. 4).—In the work reported the yellow spot virus was recovered by the onion thrips from field-infected tomatoes. This virus was transmitted by the onion thrips to and recovered from spinach, broadbean, celery, potato, eggplant, bell pepper, tomato, tobacco, *Nicotiana glutinosa*, *Datura stramonium*, petunia, chicory, endive, and lettuce, which are known also to be susceptible to the spotted wilt virus. A list of 49 references to the literature cited is included.

**Hydroxyl-ion concentration of the saliva of partly desiccated beet leaf hoppers**, J. M. FIFE. (U. S. D. A.). (*Phytopathology*, 30 (1940), No. 5, pp. 433-437, fig. 1).—In the study reported the saliva of beet leafhoppers that had been kept without food or water for from 18 to 24 hr. was found to contain a high concentration of hydroxyl ions. Measurements and calculations show that the pH of normal leafhoppers' saliva is greater than 10 and may reach approximately 11 in the saliva of desiccated leafhoppers.

**An undescribed *Corythucha* (Tingitidae-Hemip.) from Colorado [C. tuthilli]**, C. J. DRAKE. (Iowa State Col.). (*Ent. News*, 51 (1940), No. 6, p. 172).

**The toxicity of sulphur dioxide to the bed-bug (*Cimex lectularius* L.)**, H. C. GOUGH (*Ann. Appl. Biol.*, 27 (1940), No. 1, pp. 101-109, figs. 3).—Experiments reported have shown that the egg of the bedbug is more resistant to sulfur dioxide than is any other stage. "This resistance is greatest during the first half of the incubation period and then gradually decreases. Nymphs are more resistant than adults. Starved nymphs and adults appear to be more

resistant than recently fed ones. From preliminary experiments it appears that resistance of nymphs starved for long period may be nearly as high as that of eggs."

A list of 21 references to the literature is included.

**The mealybug makes a discovery**, W. J. SCHOENE and G. M. SHEAR (*Va. Fruit*, 28 (1940), No. 5, pp. 18, 19).—This is a discussion of the factors responsible for the greater injury caused by the mealybug in well sprayed and fertilized orchards than in partially sprayed and unfertilized orchards.

**Resistance of corn strains to the leaf aphid**, *Aphis maidis* Fitch, R. O. SNELLING, R. A. BLANCHARD, and J. H. BIGGER. (Ill. Expt. Sta., U. S. D. A., et al.). (*Jour. Amer. Soc. Agron.*, 32 (1940), No. 5, pp. 371-381, fig. 1).—The studies here reported indicate a possibility of reducing injury caused by the corn leaf aphid through host resistance. The prevention of its injury is a problem of special importance in the production of certain foundation seed stocks used in the production of commercial hybrid seed corn. Its infestation was determined by an examination of recently emerged tassels for the presence of the aphids. "Although the severity of the infestations was measured by classifying all infested plants in one of three infestation classes, in general the total percentage of infestation was considered as a reliable indicator of the relative resistance or susceptibility. Data are presented from many yellow and white inbred lines as well as from a sufficient number of single crosses to indicate that resistance to this insect is a heritable character." The contribution includes a list of 31 references to the literature cited.

**Nicotine sulphate dust for control of cotton aphids**, A. L. HAMNER (*Miss. Farm. Res. [Mississippi Sta.]*, 3 (1940), No. 7, p. 1).—Attention is called to the importance of cotton aphid infestations of fruiting cotton, often overlooked by cotton planters. The best control for such infestations has been found to be a 5 percent nicotine sulfate dust (2 percent free nicotine) applied at the rate of 10 lb. per acre on cotton of average height.

**The biology of the Rubus aphides**, G. H. L. DICKER (*Jour. Pomol. and Hort. Sci.*, 18 (1940), No. 1, pp. 1-33, pl. 1, figs. 2).—An account is given of the biology of *Macrosiphum rubiellum* Theo., *M. rubifolium* Theo., *Amphorophora rubi* (Kalt.), and *Aphis idaei* Van der Goot, and notes on an unidentified species and on six other species recorded from *Rubus* in Great Britain, followed by information on the parasites and predators and statistical investigation of the sampling methods used to obtain population data. A list of 23 references to the literature is included.

**Notes on some Ohio aphids**, C. F. SMITH. (N. C. Expt. Sta.). (*Ohio Jour. Sci.*, 40 (1940), No. 3, pp. 139-142).—The species *Aphis acritus* taken on *Sedum* and *Capitophorus ohioensis* from the underside of leaves of *Helianthus* sp. are described as new. Notes are given on the occurrence of 20 other species.

**The walnut caterpillar**, L. HASEMAN (*Missouri Sta. Bul.* 418 (1940), pp. 14, figs. 11).—A practical account is given of the walnut caterpillar, which is a source of injury to black walnut, hickory, and pecan trees in Missouri. Of its several natural enemies, two small hymenopterous egg parasites, *Telenomus ichthyurae* Ashm. and *Trichogramma minutum*, were found to be the most important. When control measures are necessary, either poison spray or hand destruction of the colonies of caterpillars is effective.

**The length of development of the greater wax moth**, M. H. HAYDAK. (Univ. Minn.). (*Science*, 91 (1940), No. 2370, p. 525).—Reference is made to the rearing of 35 generations of healthy wax moths on the special food formula previously described (E. S. R., 76, p. 357).

**Life history and effective control of asparagus fern caterpillar**, J. W. WILSON. (Fla Expt. Sta.). (*South. Florist and Nurseryman*, 49 (1940), No. 10,

pp. 9, 23, 24).—The author reports having found arsenate of lead dust to be effective against the asparagus fern caterpillar. Eight different species of parasites and two predators have been found feeding on this pest in ferneries, with four secondary parasites attacking the primary parasites. Of the eight species, *Chelonus texanus* Cress. was the most abundant, closely followed by *Euplectrus platyhyphenae* How. Two predators were observed, namely, the large wasp *Polistes fuscatus rubiginosus* Lep. and the spined soldier bug.

**Observations on *Stenomoma mistrella* Busck (Stenomidae, Lepidoptera),** H. D. O. MILLER. (Kans. Expt. Sta.). (*Jour. Kans. Ent. Soc.*, 13 (1940), No. 1, pp. 1-3, figs. 7).

**Fighting codling moth with chemically treated bands,** A. H. TESKE (*Va. Fruit*, 28 (1940), No. 5, pp. 16, 17).—It is concluded that the codling moth bands treated with  $\beta$ -naphthol when applied at the proper time and in the proper manner can be expected to "catch from 60 to 70 percent of the worms of the first brood that leave the fruit. Estimating that on the average these bands will catch 50 out of every 100 worms that leave the fruit, and that 50 percent of these worms will develop into female moths and that an average single female will lay 100 eggs, it can be readily seen that bands would reduce the late worm population very materially and that bands should be one of the best investments that a grower could make."

**The importance of local mosquito surveys in Minnesota,** W. A. RILEY. (Univ. Minn.). (*Minn. Acad. Sci. Proc.*, 7 (1939), pp. 7-10).

**The biology of the chrysanthemum midge in England,** H. F. BARNES (*Ann. Appl. Biol.*, 27 (1940), No. 1, pp. 71-91, pl. 1, figs. 5).—A report is made upon a study of the life history of the chrysanthemum midge at the Rothamsted Experimental Station under both laboratory and unheated glasshouse conditions. Field observations have shown that the midge behaves in commercial nurseries in much the same way as in the experiments conducted in the unheated glasshouse throughout the year. "For total eradication it is shown that fumigation and spraying are not economical. Dipping the cuttings in nicotine-soft soap solution greatly reduced the numbers of developing midges. The most hopeful method of eradicating the pest seems to be cutting down the entire plant, then isolating the cut down stools, and subsequently using the new growth for cuttings."

**New and little-known Utah Dolichopodidae (Diptera),** F. C. HARMSTON and G. F. KNOWLTON. (Utah Expt. Sta.). (*Ent. News*, 51 (1940), No. 5, pp. 129-134, figs. 2).—The species *Dolichopus vernaee* and *Syntormon uintaensis*, both from Utah, are described as new to science, and descriptions are given of two additional species (*Polymedon castus* Wheeler and *Parasyntormon hendersoni* H. & K.).

**Toxicity tests with the Queensland fruit fly *Strumeta* (Chaetodacus) tryoni** Froggatt, S. L. ALLMAN (*Jour. Austral. Inst. Agr. Sci.*, 6 (1940), No. 1, pp. 40-44).

**Biology of the seed-corn maggot in the Coastal Plain of the South Atlantic States,** W. J. REID, JR. (*U. S. Dept. Agr., Tech. Bul.* 723 (1940), pp. 44, figs. 7).—Report is made of studies of the biology of the seed-corn maggot, which attacks a wide range of food plants, including several important vegetable crops, namely, potatoes, beans, spinach, cabbage, melons, and peas, conducted from 1925 to 1935, inclusive, in eastern portions of North Carolina and South Carolina, with a view to devising a means of preventing its injury to potato seed pieces and spinach seedlings. It was found that mating in captivity was rare, but otherwise the insect could be reared without great difficulty in the cages described. Immature stages live in the soil. The incubation period of the egg varied from 1 to 8.5 days at mean temperatures ranging from 83.7° to 42.5° F., respectively. Eggs hatched at mean temperatures as low as 40°-45° and as high as 95°, but

not at 100°. The larval stage lasted from 5 to 78 days at mean temperatures of from 100° to 40°-45°, with a range of from 7 to 26 days during the period that seed potatoes are attacked. The pupal stage lasted from 7 to 26 days at mean temperatures from 83.7° to 54.1° and as long as 126 days at 40°-45°. Mated females lived an average of 34 days in confinement and laid an average of 97.25 eggs; mated males lived an average of 29 days. Sprouting beans, potato seed pieces with poorly healed or decaying cut surfaces, and such organic fertilizer materials as cottonseed meal were favorite larval foods. Immature stages were present in the fields from late in September through April, with peaks of larval abundance in November and in March. Only adults, chiefly females, were found in the fields during the summer months.

**Kentucky white grubs**, P. O. RITCHER (*Kentucky Sta. Bul. 401 (1940)*, pp. 71-157, pls. 6, figs. 40).—The results of early observations and work under way continuously from April 1936 relating to the biology and control of white grubs in Kentucky are reported. Studies of species belonging principally to the genus *Phyllophaga*, 36 of which are recorded from the State, have shown them to be widespread and of great potential importance. The life history studies indicate that these species have 2-, 2- and 3-, or 3-yr. life cycles. The life cycles of *P. hirticula*, usually a 3-yr. species, and *P. ephillida*, a 2-yr. species, are charted. It is concluded that the May beetles spend at least the first part of the winter in their pupal cells, some species beginning to burrow toward the surface in January or February. A detailed account is given of the sequence of emergence, seasonal abundance, and feeding preferences of many species of May beetles for a number of the State's physical divisions. Most of the stripping of oaks in May in the Inner Bluegrass region of the State is done by *P. hirticula*, the dominant species. A study of light traps showed the common 100-w., white, frosted bulb to be a more efficient lure than similar 60- or 200-w. bulbs. Individual May beetles were found to lay approximately 50 eggs which hatched in from 15 to 29 days, depending upon the species and the soil temperature.

Their larval life in the soil and food preferences are considered at length, and a key is included, by means of which the larvae of 23 species may be distinguished. *P. ephillida* was found to differ from most other grubs in its hibernation habits of overwintering only 3 in. deep in the soil. The time of pupation and the length of the pupal stage are discussed, and evidence is presented to show that some species, such as *P. hirticula*, pupate deep in the soil, while such species as *P. inversa* and *P. ephillida* pupate at shallow depths. The life histories of *Cyclocephala immaculata*, *Anomala innuba*, *A. nigropicta*, and *A. flavipennis* are discussed, and mention is made of *C. borealis*, *A. binotata*, and the green June beetle, all of which have 1-yr. life cycles. A number of natural enemies were found attacking white grubs in various stages of their life cycles. *Diognites discolor* Loew is recorded as a common parasite of May beetle pupae. The methods used in the course of this study are considered.

A bibliography of 40 references is included.

**Notes on Texas Phyllophaga, with description of one new species (Coleoptera, Scarabaeidae)**, H. J. REINHARD. (*Tex. Expt. Sta.*). (*Jour. Kans. Ent. Soc.*, 13 (1940), No. 1, pp. 4, 5).—The May beetle *P. sodalis* from Texas is described as new, and the name *P. pleroma* is proposed for *P. plena*, which is unavailable due to prior use. A note on *P. renodis* Reinhard is included.

**Continued culture of a nematode parasitic in the Japanese beetle**, R. W. GLASER (*Jour. Expt. Zool.*, 84 (1940), No. 1, pp. 1-12).—The author has found that the sterility of females which results from prolonged culture of the parasitic nematode *Neoapectana glaseri* on a standard medium may be prevented by (1) host passage, (2) use of desiccated material from the host, and (3) by use

of desiccated, bovine, ovarian substance. "After a number of generations in the host or in the presence of the desiccated materials, the parasites again usually developed on the standard medium for a large number of generations. The results indicated that some growth factor initially stored within the tissues was diluted with each generation until depletion occurred. This growth factor was restored to the parasite tissues by proper treatment over many generations. By testing various materials, it was found that, under culture conditions, living yeast, host substance, and especially bovine ovarian substance, were necessary to the prolonged normal development of the nematodes. When living yeast and one of these substances were combined, the character of the growth and survival was greatly improved. A variation in the growth and survival of certain strains was observed. The prevention of extinction of *Neoaplectana* cultures by the use of ovarian substance has proved valuable during the course of some economic work conducted jointly by the State of New Jersey and the Federal Government. Tests with certain sex hormones and other glandular preparations alone and in conjunction with various proteins failed to throw light on the nature of the stimulating factor or factors present in bovine ovarian substance."

**The milky disease vs. the Japanese beetle**, E. N. CORY (*Sci. Mo.*, 50 (1940), No. 6, pp. 574-576, figs. 2).—This contribution relates to the application of the so-called milky disease of the Japanese beetle in the retardation work under way with this pest in Maryland, recent reports of which disease by White and by White and Dutky have been noted (E. S. R., 83, pp. 374, 375).

**White grubs and their control in eastern Canada**, G. H. HAMMOND (*Canada Dept. Agr. Pub.* 668 (1940), pp. 18, figs. 12).

**Parasites of the elm leaf beetle**, S. E. FLANDERS. (Calif. Citrus Expt. Sta.). (*Trees Mag.*, 3 (1940), No. 2, p. 14).

**The clerid *Thanasimus lecontei* (Wolc.) as a factor in the control of the western pine beetle**, H. L. PERSON. (U. S. D. A.). (*Jour. Forestry*, 38 (1940), No. 5, pp. 390-396, fig. 1).—The author finds that artificial methods of control of the western pine beetle are only moderately successful at best and always expensive; that biological methods hold considerable promise. The black-bellied clerid *T. lecontei* was found to be the most effective of the predators of this beetle, and methods are given by which the clerid population may be increased.

**Blister beetles and their control**, G. I. GILBERTSON and W. R. HORSFALL (*South Dakota Sta. Bul.* 340 (1940), pp. 23, figs. 11).—This nontechnical account, which includes life histories, descriptions, damage done by, and control of blister beetles common to South Dakota, treats particularly of the immaculate blister beetle *Macrobasis immaculata* (Say), a striped blister beetle *Epicauta lemniscata* F., the spotted blister beetle, ash-gray blister beetle, shiny black blister beetle *M. murina* Lec., squash blister beetle *Henous confertus* (Say), white-segmented blister beetle *M. segmentata* (Say), and sunflower blister beetle *E. callosa* Lec. They are of importance in the State because of their destructiveness to a wide range of field, garden, and ornamental plants, and because certain species often occur in great hordes overrunning vast acreages. Many of the approximately 35 species found in the State have a wide variety of host plants and are often scattered more or less uniformly over whole sections, while others are limited or have preferred hosts and therefore are concentrated or localized.

A survey of the insect enemies attacking grasshopper egg pods in an 80-acre field in Hand county in 1938 resulted in the finding of 23.7 percent damage by blister beetle larvae, 35.6 by bee fly larvae, 1.7 by hymenopterous parasite *Scelio calopteni* Riley, and 17.8 percent unknown, or a total of 78.8 percent.

The blister beetles are difficult to control since they appear suddenly and often do a large amount of damage before being detected. Although they are not readily

poisoned with ordinary stomach poisons, fluosilicate dusts have been used to advantage, barium fluosilicate being the safest for the crops. A number of proprietary spray compounds are said to have given fair results when applied thoroughly with sufficient pressure.

**The biology and control of the round-headed apple-tree borer (*Saperda candida* Fabricius),** A. D. HESS (*New York State Sta. Bul.* 688 (1940), pp. 93, figs. 36).—Studies of the roundheaded apple tree borer in the Champlain Valley and the region of Ithaca, N. Y. extending over a 4-yr. period, are reported in 2 parts, accompanied by 30 references to the literature cited. Part 1 (pp. 6–67) reports upon biological work, the details being given in 13 tables and many charts. The emergence of adults occurs mainly during June, followed by a preoviposition period of less than a week. “Egg laying occurs from the last part of June until the last part of August, reaching a peak around the middle of July. Each female usually deposits 30 to 40 eggs. Eggs hatch in about 2 weeks, the period varying from 10 to 25 days. All eggs have hatched by the middle of September. Most larvae complete their life cycle in 3 yr. Some complete their development in 2 yr., and a few require 4 yr. The length of the pupal period varies with the season from 19 to 30 days. Pupation begins during the last part of April, and most mature larvae have pupated by the end of May. Adults remain in the pupal chamber about 11 days before emerging.” Control work is reported upon in part 2 (pp. 67–91) with the details presented in 11 tables and 2 charts. In this work many materials and methods of control were experimented with, 30 chemicals being tested for their injuriousness to apple trees. Among the least injurious were paradichlorobenzene, pyrethrum extract in alcohol, dichloroethyl ether, and a solution of paradichlorobenzene in carbon disulfide. Among the most injurious were ethyl acetate, orthodichlorobenzene, and carbon disulfide.

The investigations have shown that the practice of clean culture greatly facilitates control. The eradication of wild host plants from the vicinity of the orchard is advised. It is recommended that sprays of lead arsenate or cryolite be applied to the foliage of young orchards during June and the first part of July, following the same schedule and spray formula which is applied to older trees. Such sprays gave as high as 95-percent control in experimental orchards. Heavier applications gave as high as 100-percent control.

A new type of injection gun is recommended as the best means of treating trees infested with borers. Dichloroethyl ether, pyrethrum extract in alcohol, rotenone extracts, and a solution of paradichlorobenzene in carbon disulfide are recommended for use in this gun. A paint of calcium cyanide and raw linseed oil is also recommended as giving satisfactory results.

**The influence of temperature, moisture, and food upon the development and survival of the saw-toothed grain beetle,** E. L. THOMAS and H. H. SHEPARD. (*Minn. Expt. Sta.*). (*Jour. Agr. Res.* [U. S.], 60 (1940), No. 9, pp. 605–615, figs. 2).—In order to secure more definite information on the life history of the saw-toothed grain beetle over a considerable range of controlled conditions relating to temperature, food, and atmospheric moisture, development of all stages of the pest was investigated. “Rearings were made or attempted at temperatures of 15°, 20°, 25°, 30°, 35°, and 40° C., at saturation deficiencies of 5, 12.5, and 22.5 mm., and with rolled oats, English walnuts, and raisins as food. At 5 mm. saturation deficit and on rolled oats as food, the total life cycle from egg to adult requires 69.06 days at 20°, 30.31 days at 25°, 20.67 days at 30°, and 18 days at 35°. With rolled oats as food the developmental optimum appears at 35°, while with walnuts the developmental optimum occurs between 30° and 35°. Eggs and larvae failed to develop at 15° and 40°.

In general, development is more rapid at the higher humidities. The egg and pupal stages appear to be little affected by atmospheric moisture conditions. On the basis of the rate of development, rolled oats are superior to either walnuts or raisins as a food for the saw-toothed grain beetle. Adults of the saw-toothed grain beetle and the confused flour beetle were exposed to high temperatures. At 44° and 30-percent relative humidity 50 percent of the flour beetles were killed in a little over 4 hr., while at 46° and 50-percent relative humidity about 40 min. were required. At 42° 50 percent of the adult saw-toothed grain beetles were killed in 34 hr., while at 44° the exposure periods were approximately 4.5 and 5.7 hr. at 30- and 75-percent relative humidities, respectively. Adult saw-toothed grain beetles exposed at 10° and 2° gave 50-percent mortality values at 30 days and 105 hr., respectively."

A list is given of 16 references to the literature cited.

**Weevils from eggs in raw materials**, D. COSTA (*Macaroni Jour.*, 22 (1940), No. 2, pp. 12, 31, figs. 3).

**Respiratory metabolism during larval and pupal development of the female honeybee (*Apis mellifica* L.)**, R. M. MELAMPY and E. R. WILLIS. (U. S. D. A. and La. State Univ.). (*Physiol. Zool.*, 12 (1939), No. 3, pp. 302-311, figs. 5).—The results of studies conducted, presented in tables and graphs, are accompanied by a list of 18 references to the literature cited. In this work measurements of oxygen consumption and carbon dioxide production were made on individual queen and worker bees throughout their larval and pupal development. It was found that "the respiratory rates rise per individual insect during the larval period, fall to a minimum during pupation, and finally rise before emergence. The queen or reproductive caste is characterized by a higher metabolic rate, which is associated with the more rapid growth rate of this caste. Respiratory quotients greater than unity indicate a synthesis of lipid from carbohydrate for both castes during the larval stages. The respiratory quotient for the queen ranges between 0.96 and 0.83 during the pupal stage, whereas that for the worker ranges between 1.05 and 0.94. The average respiratory quotient for the queen during the pupal stage is 0.87, whereas that for the worker is 0.96."

**A comparison of wintering bees versus destroying them in the fall and restocking the hives with package bees in the spring**, J. A. MUNRO (*North Dakota Sta. Bimo. Bul.*, 2 (1940), No. 6, pp. 12-16, figs. 4).—The information presented has led to the conclusion that destruction of the bee colonies in the fall is justified only when it is not possible to provide satisfactory wintering conditions for the bees.

**Wintering bees in Wyoming**, C. H. GILBERT (*Wyoming Sta. Bul.* 238 (1940), pp. 15, figs. 5).—A description is given of the methods of wintering tested, and the findings are outlined and briefly discussed. The experiments conducted show that (1) wintering in yards with protected hives gives better results than wintering in cellars, (2) excellent low cost protection is given by tar paper packing, and (3) individual celotex cases, though more expensive, are very convenient and gave the best results during the 4 yr. of tests.

**The two-queen hive and commercial honey production**, C. H. GILBERT (*Wyoming Sta. Bul.* 239 (1940), pp. 15, figs. 5).—In work at the station, various modifications of the two-queen system were tested, all of which gave increased honey production as compared to single-queen hives. It is pointed out that the increased skilled labor and attention required for manipulation will add to the costs and probably restrict its use in large commercial apiaries.

**Problems encountered in the management of package bees**, W. E. DUNHAM (*Ohio Sta. Bimo. Bul.* 204 (1940), pp. 73-75).—Information gathered on 984

package bee colonies during a 3-yr. survey of their performance is brought together under the headings of size of package and time of installing, supplying combs or foundation and food, queen losses, and productiveness of package bees v. overwintered colonies. It is concluded that such colonies cannot be depended upon to produce a maximum crop in areas where the bulk of the honey is harvested from alsike clover. In the sweetclover areas of the State, in which the honey flow is late, package bees will produce crops of honey equal to or larger than those produced by overwintered colonies.

**Laying workers**, M. H. HAYDAK. (Minn. Expt. Sta.). (*Amer. Bee Jour.*, 80 (1940), No. 4, p. 163).—A contribution in apiculture.

**A contribution to the knowledge of the Eucharidae (Hymenoptera: Chalcidoidea)**, A. B. GAHAN (*U. S. Nat. Mus. Proc.*, 88 (1940), No. 3086, pp. 425-458).—Descriptions of 13 new species of Eucharidae, all forms of which family are parasites of Formicoidea, are given, accompanied by notes.

**A new species of Encopognathus from California (Hymenoptera: Sphecoidea)**, P. H. TIMBERLAKE. (Calif. Citrus Expt. Sta.). (*Ent. News*, 51 (1940), No. 6, pp. 167, 168).—*E. (Rhectognathus) rufiventris*, collected on flowers of *Phacelia distans* near Victorville, is described as new.

**New genera and species of ichneumon-flies, with taxonomic notes**, R. A. CUSHMAN (*U. S. Natl. Mus. Proc.*, 88 (1940), No. 3083, pp. 355-372, figs. 2).—Two new genera, *Apotemnus* and *Brachyscleroma*, are erected and nine species are described as new.

**The ichneumon-flies of the subfamily Neorhacodinae, with descriptions of a new genus and three new species**, R. A. CUSHMAN (*U. S. Natl. Mus. Proc.*, 88 (1940), No. 3088, pp. 523-527, fig. 1).—A new genus, *Romaniella*, is erected, of which *R. exsulcatus* n. sp., reared from an old cotton boll at Campinas, São Paulo, Brazil, is the type species, and *Neorhacodes enslini* (Ruschka), *N. longicauda* n. sp. from Colorado, and *N. brevicauda* n. sp. from Arizona are described.

**Telenomus ovivorus (Ashmead), an egg-parasite of the false chinch bug**, F. M. WADLEY. (U. S. D. A.). (*Jour. Kans. Ent. Soc.*, 13 (1940), No. 1, pp. 6, 7).—Notes are given on *T. ovivorus*, described in 1893 from material reared from eggs of a hemipterous insect collected near Washington, D. C. First observed by the author in 1914, at which time it was reared from the eggs of the false chinch bug at Garden City, Kans., it is concluded that this parasite might be at times a definite check on the increase of the false chinch bug in this region.

**Spiders and insects found associated with sweet corn, with notes on the food and habits of some species.—V, Homoptera and summary**, R. T. EVERLY (*Ohio Jour. Sci.*, 40 (1940), No. 3, pp. 143-146).—This contribution dealing with the Homoptera is the last of a series (*E. S. R.*, 81, p. 674), and presents a list of species of insects and spiders collected within the limits of a 4-acre field of sweet corn at Holmesville, Ohio.

**Bacterium tularense: Its persistence in the tissues of the argasid ticks, Ornithodoros turicata and O. parkeri**, G. E. DAVIS (*Pub. Health Rpts. [U. S.]*, 55 (1940), No. 16, pp. 676-680).—It is shown that this organism may survive for at least "674 and 701 days, respectively, in the tissues of *O. turicata* and *O. parkeri*, but is not transmitted during feeding. The virulence of the organism was not adversely affected by the long period of residence in these ticks nor by the failure of the ticks to receive a blood meal."

**A new species of Taenia from a coyote [T. laruei]**, P. C. HAMILTON. (Okla. A. and M. Col.). (*Amer. Micros. Soc. Trans.*, 59 (1940), No. 1, pp. 64-69, figs. 5).

## ANIMAL PRODUCTION

[Livestock investigations in Mississippi] (*Miss. Farm Res. [Mississippi Sta.]*, 3 (1940), No. 7, pp. 1, 2, 7, 8).—Results of experiments with livestock are presented in articles entitled Grass Silage and Stack Silos Seem Worthy of Trial, by W. C. Cowsert (pp. 1, 2); Cottonseed Cake Fairly Satisfactory When Used as Principal Concentrate in Ration for Finishing Beef Calves, by A. E. Cullison (pp. 7, 8); Mowing Doubles Palatability, Adds to Protein Content, by H. W. Bennett and R. H. Means (p. 8)); and Blackstrap Molasses About Equals Corn in Livestock Ration, by W. C. Cowsert (p. 8).

[Livestock investigations in Nebraska] (*Nebraska Sta. Rpt. [1939]*, pp. 33-37, 42-44, 56, 57, 59).—Experiments for which results are briefly reported include sorghum grain v. corn for fattening cattle; comparisons of alfalfa hay, prairie hay, and silage, of rye and corn, and of cottonseed meal and soybean oil meal in winter rations for steer calves; a comparison of protein concentrates in the winter ration of heifer calves; the influence of sorghum grains upon beef quality and upon the quality and palatability of pork; hybrid v. open-pollinated corn for fattening pigs; sorghum grains v. corn for pigs in dry lot and on Sudan grass pasture; soybean oil meal alone v. mixtures of soybean oil meal and tankage or cottonseed meal and tankage as protein supplements for pigs on Sudan grass pasture; the value of sorghum grain, silage, and fodder as feeds for lambs; and sorghum fodder v. native wild hay as a roughage for growing colts.

From experiments with poultry, results are noted on the antirachitic value of ultraviolet irradiation for laying hens; the utilization of protein from various sources by laying hens and by growing poults; a comparison of pulverized oats, feeding-grade oatmeal, and germinated oats in chick rations; the field feeding of grain sorghums to turkeys; and a recommended system of feeding turkeys during the final 6 weeks' finishing period.

[Livestock investigations in New Hampshire], E. G. RITZMAN, R. C. DURGIN, T. B. CHARLES, A. E. TEPPER, S. R. SHIMER, H. A. DAVIS, P. A. WILCOX, C. L. MARTIN, M. S. COVER, C. A. BOTTORFF, W. T. ACKERMAN, G. M. FOULKROD and B. J. FRENCH (*New Hampshire Sta. Bul. 319 (1940)*, pp. 25, 26, 40, 41, 42, 43, 44).—Progress reports (E. S. R., 82, p. 228) are presented for investigations on the energy expended by the horse during work, the effect of adding wheat-germ oil to the ration of breeding sheep on the frequency of twinning, the protein requirements of chickens, selective breeding as a control of ruptured egg yolk, the efficiency of gas-burning brooders, controlling moisture in poultry litter, and the relation of vitamin C in the diet to the incidence of ulcerated gizzards in chicks.

The nutritive values of some forage crops of Puerto Rico.—III, Grasses, legumes, and mixtures, J. H. AXTMAYER, G. RIVERA HERNÁNDEZ, D. H. COOK, ET AL. (*Jour. Agr. Univ. Puerto Rico [Col. Sta.]*, 24 (1940), No. 1, pp. 3-31).—In a further report of this series of investigations (E. S. R., 81, p. 255), data are presented on the results of 17 digestion trials with sheep, measuring the digestibility and the biological value of the protein when fed as a sole ration of cowpeas (three stages of maturity), Merker grass, yaragua grass, alfalfa hay, and malojilla grass; mixtures of Merker grass and pigeon-pea and of malojilla grass and pigeonpeas; and a low-protein synthetic diet plus Merker grass straw. In general, the biological value of proteins was higher for the grasses than for the legumes. The grasses ranked in order of descending net-protein values as follows: Guinea, Merker, Para, elephant, Guatemala, and yaragua, the last-named having a very wide nutritive ratio due

to its low digestible-protein content. The biological value of the protein in cowpeas progressively increased as the plant passed from the blooming stage to the full-pod stage. Alfalfa yielded more total digestible nutrients than any of the other legumes studied. Samples of the various herbages dried in the laboratory varied in vitamin A content from 33 Sherman units per gram in yaragua grass to 200 units per gram for immature velvetbeans or soybeans.

**Chemical analyses of grasses, J. H. AXTMAYER, G. RIVERA HERNÁNDEZ, D. H. COOK, ET AL.** (*Jour. Agr. Univ. Puerto Rico [Col. Sta.]*, 24 (1940), No. 1, pp. 32-39).—Data are presented on the chemical composition of 83 grasses calculated on the wet and dry basis and the results discussed from the nutritional point of view.

**Legumes, grasses, and cereal crops for silage, A. C. RAGSDALE and H. A. HERMAN** (*Missouri Sta. Cir.* 209 (1940), pp. 10, figs. 3).—The discussion deals with the advantages of legumes, grasses, and cereal crops for silage; crops suitable for grass silage purposes; proper stage for harvesting; methods of harvesting and ensiling; the use of preservatives, including molasses, the A. I. V. method, and phosphoric acid; and the feeding of such silages.

**Biochemical and nutritional studies of dehydrated sweet potato, E. J. LEASE and J. H. MITCHELL** (*South Carolina Sta. Bul.* 329 (1940), pp. 15, figs. 2).—Raw sweetpotatoes (68 percent moisture) were found to contain an average of 40  $\mu\text{g}$ . of carotene per gram, while sweetpotato flour contained 130  $\mu\text{g}$ . On a dry-matter basis the sweetpotatoes contained an average of 4.3 percent crude protein and 91.21 percent nitrogen-free extract.

In a feeding experiment, dairy cows maintained on a vitamin A-deficient ration until their milk contained very little carotene or vitamin A were then changed to a ration containing 25 percent sweetpotato meal as a substitute for white corn in the concentrate mixture. Under this feeding regime the carotene content of the milk steadily increased. The sweetpotato meal also proved palatable and nutritious for dairy calves. When fed to one calf as the only source of vitamin A and administered in skim milk, the calf grew well and stored vitamin A in its liver.

When laying hens received a ration containing 25 percent of the meal after having been on a vitamin A-low diet for 6 weeks, the vitamin A potency of the egg yolks increased from 8 to 42 blue units per gram. Day-old chicks receiving a vitamin A-low basal ration plus 50 percent sweetpotato flour stored more vitamin A in their livers than control birds receiving 1 percent cod-liver oil as a supplement to the basal diet.

Suggestions are offered regarding the use of sweetpotato flour in recipes for human use, devised by E. Mishler. Analyses of the carotene content of the flour and in baked products prepared from it are included.

**Prevention of nutritional muscular dystrophy in suckling E-low rats with alpha-tocopherol and related substances, H. M. EVANS and G. A. EMERSON.** (*Univ. Calif. et al.*). (*Soc. Expt. Biol. and Med. Proc.*, 44 (1940), No. 2, pp. 636-639).—Muscular dystrophy consistently developed in suckling young rats when the mothers were maintained on a vitamin E-low diet throughout the gestation and lactation periods. The administration of 6 mg. of  $\alpha$ -tocopherol to the mothers on the day of littering largely prevented the onset of this disorder, and 10 mg. entirely prevented it. Also direct administration of 1 mg. daily of  $\alpha$ -tocopherol to the young rat after the tenth day or 3 mg. daily after the fifteenth day prevented this disorder, but the young receiving  $\alpha$ -tocopherol after the eighteenth day were not protected. Four compounds related chemically to  $\alpha$ -tocopherol were tested for antidystrophic activity and found to be inactive.

The plane of intake of beef muscle protein as affecting the energy and the nitrogen metabolism of the mature albino rat, E. B. FORBES, A. BLACK, E. J. THACKER, and R. W. SWIFT. (Pa. Expt. Sta.). (*Jour. Nutr.*, 20 (1940), No. 1, pp. 47-58).—Continuing this line of investigation (E. S. R., 82, p. 229), mature rats were fed equicaloric diets containing 10, 25, and 45 percent protein, respectively, over 70-day balance experiments. Practical equilibrium of live weight and nitrogen content of the body was maintained. The digestibility of the dietary protein increased in the order of the increase in protein of the diets. Digested nitrogen and urinary nitrogen were similar in value. The metabolizable energy and also heat production diminished in the order of increasing protein contents of the diets, the diminishing heat production being equivalent to a slightly increasing heat production in relation to the metabolizable energy. Urinary nitrogen per calorie of urinary energy increased as the level of dietary protein increased.

H ion concentration of various fluids of the genital tract of the cow, H. A. LARDY, W. D. POUNDEN, and P. H. PHILLIPS. (Univ. Wis.). (*Soc. Expt. Biol. and Med. Proc.*, 44 (1940), No. 2, pp. 517-519).—The following pH values were found to exist for genital secretions of the cow: Vaginal fluid (anoestrous) 6.4, cervical fluid 8.33, uterine fluid 6.8, amniotic fluid from calf fetus 7.12, and follicular fluid 7.6.

Studies on the bovine electrocardiogram, I, II. (Mich. Expt. Sta.) (*Soc. Expt. Biol. and Med. Proc.*, 43 (1940), No. 3, pp. 575-584, figs. 3).—Two reports of this study are noted.

I. *Electrocardiographic changes in calves on low potassium rations*, J. F. Sykes and B. V. Alfredson (pp. 575-579).—Four experimental calves used in this study were placed on a semipurified diet containing from 0.1 to 0.12 percent potassium at 160 days of age. After extended periods on this ration the serum potassium values declined to approximately one-half normal levels in all cases. Increasing the potassium intake resulted in restoration of normal serum potassium levels which were then retained despite later reduction of potassium intake. Electrocardiograms made at frequent intervals revealed marked changes in three of the experimental animals, characterized chiefly by a pronounced increase in the duration of the QRS complex and accompanied by striking changes in its contour and voltage. The intervals were approximately twice as long as those displayed by the electrocardiograms of control calves and of other normal animals. This condition persisted among the experimental calves despite the restoration of serum potassium values to normal levels.

II. *Bundle branch block*, B. V. Alfredson and J. F. Sykes (pp. 580-584).—Employing an operative technic as described, section of right and left branches of the His bundle to produce bundle branch block was successfully carried out in 14 calves and 10 dogs. Electrocardiograms of these animals revealed that changes in duration and form of QRS after bundle branch block are much less pronounced in calves than in dogs. The difference between these two species is attributed to differences in the distribution of the intraventricular conducting system.

The utilization of certain feeding stuffs by cattle, E. B. FORBES, J. W. BRATZLER, and C. E. FRENCH (*Pennsylvania Sta. Bul.* 391 (1940), pp. [2]+14).—In trials with steers involving 18-day experimental periods for the collection of urine and feces, determinations were made of the digestibility and metabolizable energy for the following feedstuffs: Silages from alfalfa, soybean herbage, and clover-timothy mixture, each preserved with molasses and with phosphoric acid; finely cut corn stover; gluten feed; and soybean oil meal made by the hydraulic, solvent, and expeller processes. Calcium and phosphorus balances

were also determined on the silage rations. The digestible crude protein values were higher for the acid than for the molasses silages, but the total digestible nutrient and metabolizable energy values of the molasses silages were materially higher than the corresponding values for the phosphoric acid lots. The digestibility of corn stover, especially its crude protein and ether extract, was much lower than as compiled by Morrison, as were the dry matter, ether extract, and crude fiber of gluten feed. The three soybean oil meals were similar in digestibility, the solvent-processed meal having slightly higher crude protein and lower total digestible nutrients and metabolizable energy values than the other two. Calcium and phosphorus balances on the silage rations were generally positive.

**Rations for fattening cattle in Arizona, E. B. STANLEY and A. H. WALKER** (*Arizona Sta. Bul. 170 (1940), pp. [2]+135-155*).—A summary of the results of a series of feeding trials with good-quality range-raised yearling steers is presented. The variety of rations included in these trials afforded an opportunity to compare the value of numerous feeding stuffs for steer fattening. No. 2 alfalfa hay proved to be practically equal to No. 1 alfalfa and worth only slightly more than No. 3 alfalfa. No advantage in grinding alfalfa was apparent. When hegari silage was evaluated at \$3.50 per ton, hegari fodder and cottonseed hulls were worth \$9.75 and \$5.73 per ton, respectively, when supplemented with cottonseed meal. When fed without silage whole cottonseed was equal to cottonseed meal, but with silage the seed proved somewhat inferior to the meal. When fed in combination with alfalfa hay, barley, and cottonseed meal, hegari silage was worth approximately 50 percent the value of alfalfa hay. Ground barley was worth as much as cottonseed meal when replacing part of the meal in alfalfa hay-hegari silage ration. Cottonseed meal was equal in value to meat or fish meal when fed at the same protein level as supplements to hay, silage, and barley. Calves made somewhat more efficient gains than yearlings, but yearlings utilized a larger percentage of roughage in their ration than calves.

**Beef cattle feeding trials in Hawaii, A. L. HENKE, S. H. WORK, and A. W. BURT** (*Hawaii Sta. Bul. 85 (1940), pp. 37, pls. 6*).—In addition to presenting a brief history of the beef cattle industry in Hawaii, the authors summarize results of eight beef cattle fattening trials. A single fattening trial with Aberdeen Angus steers showed that over a period of 126 days a ration of cane molasses, pigeonpea meal, and corn-cob-and-husk meal supported average daily gains of 2.46 lb., with an average requirement of 10.2 lb. of the mixture per pound of gain. Similarly, steers fed a mixture of pineapple bran, cane molasses, cane bagasse, and soybean-oil-cake meal for 133 days made average daily gains of 1.39 lb. and required 15.2 lb. of concentrate per pound of gain. The ration composed of pineapple bran and cane molasses in 5:3, 4:4, and 3:5 ratios, supplemented with 20 percent soybean-oil-cake meal in each instance, promoted satisfactory gains in steers (4:4 mixture most effective) but was less economical than pasturing steers on koa haole with supplementary cane molasses. Two experiments gave evidence that pigeonpea pasture was superior to improved grass pasture for fattening steers, both from the standpoint of average daily gain and quantity of beef produced per unit area. Supplementing either type of pasture with cane molasses increased the rate of gain and improved the carcass quality. Molasses had a calculated value of about \$13 per ton as a supplement to pigeonpea pasture and from \$8.90 to \$10.77 per ton as a supplement to grass pasture. Similarly, in three trials it was found that molasses was a desirable supplement to koa-haole pastures, having a calculated average value of \$12.57 per ton.

**Lamb feeding tests, designed for study of urinary calculi, also compare rations, I. WATSON** (*Colo. Farm Bul. [Colorado Sta.], 2 (1940), No. 3, pp. 16,*

17).—Twenty different rations were compared in feeding tests of 125–140 days' duration with 25 lambs on each ration. Alfalfa was fed as a roughage in 5 of the rations, cane fodder in 14, and beet tops in 1. Corn proved somewhat more efficient as a supplement to alfalfa than wheat, barley, millet, or milo, although similar gains were made on all 5 rations. Barley and milo were much inferior to the other 3 grains when fed with bran and cane fodder. The addition of small amounts of lime or of bonemeal to the cane fodder rations proved desirable. The cheapest and most efficient gains were secured on a ration of white corn, "C" beet molasses, and beet tops. The total gains obtained on this ration were only slightly below those on the alfalfa-grain rations.

**Soybean oilmeal for growing lambs, T. B. KEITH, R. C. MILLER, and W. L. HENNING** (*Pennsylvania Sta. Bul. 397 (1940), pp. [2]+18, figs. 3*).—Using red clover or mixed timothy-clover hays, corn, and soybean oil meal as basic feed-stuffs, the authors conducted 6 experiments involving 66 pairs of lambs to determine the optimum amount of soybean oil meal for feeding growing lambs. In 3 experiments in which the ratio of concentrate to hay was not controlled but averaged 1:1.3, a supplement of 5 percent soybean oil meal increased the rate and efficiency of gain over that on corn alone when red clover hay was fed, but with mixed timothy-clover hay neither 5 nor 10 percent soybean oil meal in the ration gave significantly better results than corn alone. In the three later experiments lambs received concentrates and red clover hay in the definite ratios of 3:2, 1:1, and 2:3, respectively, with 35 percent and 10 percent soybean oil meal being fed at each concentrate-to-hay ratio. All lambs receiving 35 parts soybean oil meal and 64 parts corn gained 15 percent more rapidly and required 13 percent less feed per unit of gain than those receiving 10 parts soybean oil meal and 89 parts corn. All lambs fed at the 3:2 concentrate-to-hay ratio required 19 and 74 percent less feed per unit of gain than those fed at the 1:1 and 2:3 ratios, respectively. The ration composed of soybean oil meal and corn (35:64) and fed at the concentrate-to-hay ratio of 3:2 (total ration, 17 percent protein) promoted the most economical gains in lambs regardless of feed prices. Those receiving the above concentrate mixture and red clover hay made the most economical gains regardless of the concentrate-to-hay ratio.

**Purebred and crossbred pigs: Comparison of rate of growth and economy of gains, F. B. HEADLEY.** (Coop. U. S. D. A.). (*Nevada Sta. Bul. 153 (1940), pp 9, figs. 2*).—Based on the results of four feeding experiments, each comparing the rate and efficiency of gain of purebred Duroc-Jersey pigs and crossbred (Duroc-Jersey male × Poland China female) pigs, it was found that the crossbred pigs on the average made 100 lb. gain in 4 days less time and on 22 lb. less of the concentrate mixture than the purebred pigs. The results were essentially the same in experiments I and III, in which individual feeding was practiced, and II and IV, in which the pigs were fed as groups.

**Protein and vitamin supplements for growing and fattening pigs, J. P. WILLMAN and F. B. MORRISON** ([*New York*] *Cornell Sta. Bul. 730 (1940), pp. 45*).—The results of four series of experiments are summarized. Six trials comparing tankage, menhaden fish meal, and whitefish meal as supplements to shelled corn, linseed meal, ground alfalfa hay, and minerals for fall pigs in dry lot gave for these supplements average daily gains of 1.53, 1.6, and 1.57 lb., and feed required per 100 lb. of gain, 371.5, 376.8, and 369.4 lb., respectively. In a seventh trial, not included in the average, in which pigs had free choice of corn and the trial mixture, the whitefish meal gave very unsatisfactory results. In four trials comparing tankage and fish meals as supplements for pigs having access to rape and oats pasture and in which pigs had free choice of corn and supplement mixture, the following average results were obtained: Average daily gains,

1.23, 1.34, 1.42, and 1.33 lb.; and feed required per 100 lb. of gain, 357.4, 336.1, 331.8, and 336.5 lb. for tankage and linseed meal, menhaden fish meal and linseed meal, whitefish meal and linseed meal, and menhaden fish meal alone, respectively. Results of three trials gave evidence that the inclusion of either 1 or 2.5 percent cereal yeast fed as a supplement to ground corn and the trial mixture for pigs in dry lot did not influence materially either the rate of gain or feed required per unit of gain. Likewise, the inclusion of 0.5 lb. of cod-liver oil or 0.125 lb. of fortified cod-liver oil per 100 lb. of the basal concentrate mixture did not significantly influence the rate of gain of pigs in dry lot. The cod-liver oil supplements increased the cost of gain and hence were not economical.

**The nutrition of the bacon pig.—V, The minimum level of protein intake consistent with quick growth and satisfactory carcass quality, H. E. WOODMAN and R. E. EVANS** (*Jour. Agr. Sci. [England]*, 30 (1940), No. 1, pp. 83–97).—Continuing this series of investigations (E. S. R., 82, p. 524), an experiment was conducted similar to that described in part 3, except that whitefish meal replaced the mixture of protein concentrates in the ration until the pigs weighed 150 lb., after which soybean oil meal was substituted. The high-protein group received 12, 10, and 5 percent protein and the low-protein group 5, 4, and 3 percent protein during growth stages (1) up to 90 lb., (2) 90–150 lb., and (3) 150–200 lb., respectively. A third group of pigs allowed the lower levels of protein received the protein concentrate mixture used in the former trial. The conclusions of the previous trial were completely confirmed by this experiment. The biological efficiency of the protein in the fish meal was at least as high as that of the combined proteins in the concentrate mixture. However, when fed at the upper level it exerted a slight softening effect on the carcass fat.

**An investigation on the alleged toxicity of cod-liver oil for pigs, N. J. SCORGIE and W. C. MILLER** (*Empire Jour. Expt. Agr.*, 7 (1939), No. 28, pp. 357–368).—To secure information on the possible toxicity of cod-liver oil for pigs experiments were conducted in which 10 pigs received high, medium, and low grades of cod-liver oil in excessive amounts ranging from 2 to 8.3 percent of the ration. Four control pigs received no oil and two pigs an equivalent amount of olive oil. All pigs made similar live weight gains, and those receiving cod-liver oil appeared fully as healthy as the control animals. Post-mortem examinations revealed that the livers, heart, and kidneys of pigs fed cod-liver oil were normal in appearance and weight, indicating that cod-liver oil is not a factor in the causation of toxic liver dystrophy, even when fed in excessive amounts.

**The calcium, inorganic phosphorus, and magnesium content of the blood serum of young horses, C. T. BLUNN, C. E. HOWELL, and R. W. CALDWELL.** (Univ. Calif.). (*Jour. Nutr.*, 20 (1940), No. 1, pp. 1–6).—Calcium, inorganic phosphorus, and magnesium determinations on the blood serum of foals ranging from birth to 23 mo. of age indicated that the calcium and magnesium contents in the blood of young colts were essentially the same as those reported for adult animals. The inorganic phosphorus content of the foal's serum at birth was higher than that of the dam. A rapid rise in inorganic phosphorus to 2 weeks of age was noted, followed by a further increase to a maximum at about 10 weeks of age. After this age inorganic phosphorus gradually declined as the animals became older.

**Relief of hypochromic anemia in dogs with synthetic vitamin B<sub>6</sub>: Influence of "filtrate factors," H. J. BORSON and S. R. METTIER.** (Univ. Calif.). (*Soc. Expt. Biol. and Med. Proc.*, 43 (1940), No. 3, pp. 429–432).—Dogs maintained on a purified diet of washed casein, sucrose, cottonseed oil, lard, cod-liver oil, bone ash, and salt mixture, and supplemented with known members of the vitamin B complex other than vitamin B<sub>6</sub>, consistently developed hypochromic

microcytic anemia. The administration of either natural or synthetic vitamin B<sub>6</sub> at the rate of 60  $\mu$ g. per kilogram live weight daily alleviated the anemia. An adequate supply of the nonadsorbable filtrate factors in the diet was found to be necessary for the complete disappearance of this anemia.

**Studies on the metabolism of fowls.—II, The effect of activity on metabolism, T. DEIGHTON and J. C. D. HUTCHINSON** (*Jour. Agr. Sci. [England]*, 30 (1940), No. 1, pp. 141–157, figs. 3).—Continuing this series of reports (E. S. R., 82, p. 807), results of a series of metabolism tests with Light Sussex cockerels are presented. When the results were reduced to a basis of zero activity by a system of "point scores" as described, a diurnal rhythm in metabolism during fasting was found to occur, morning observations averaging about 9 percent higher than evening observations. The metabolism in the standing position averaged about 40–45 percent above that in the sitting position, while at the moment of rising the heat production may be trebled. The application of these findings to the estimation of food requirements of fowls is discussed.

**Observations on the mineral metabolism of pullets, IV, R. H. COMMON** (*Jour. Agr. Sci. [England]*, 30 (1940), No. 1, pp. 113–131).—Continuing these investigations (E. S. R., 80, p. 671), experiments were conducted to determine the nature of the calcium and phosphorus combinations present in the droppings of pullets and the extent to which phytic acid present in the ration may be recovered from the droppings. It appeared that phytic acid in rations based on cereals was incompletely hydrolyzed during its passage through the digestive tract, since a considerable portion was recovered in the droppings even when the ration contained no calcium supplement. The supplements of calcium carbonate or tricalcium phosphate, particularly the former, greatly increased the percentage recovery of phytic acid in the droppings. Recovery of phytic acid was higher in laying birds than in nonlaying birds. The relationship of these findings to those of Knowles et al. (E. S. R., 71, p. 86) is discussed.

**Studies of calcium and phosphorus metabolism in relation to the chemical structure of bone.—I, Experiments with laying birds, C. TYLER** (*Biochem. Jour.*, 34 (1940), No. 2, pp. 202–212, figs. 3).—Continuous calcium and phosphorus trials were conducted over 35-day periods with laying pullets which received in addition to a low-calcium basal diet supplements of either calcium carbonate, calcium sulfate, or calcium gluconate. From data obtained in the balance studies values for the calcium as calcium phosphate and as residual calcium of the bone gained or lost each day were calculated. It appeared that the residual calcium was chiefly concerned in egg laying, since there was generally quite a large gain in residual calcium on nonlaying days and quite large losses on laying days. The calcium as calcium phosphate fluctuated slightly from day to day, but showed a trend toward a loss over the entire period. A highly significant reciprocal relationship was found to exist between the calcium of calcium phosphate and the residual calcium of the bone. The implications of this relationship are discussed.

**Micromelia in adult fowl caused by manganese deficiency during embryonic development, C. D. CASKEY and L. C. NORRIS.** (Cornell Univ.). (*Soc. Expt. Biol. and Med. Proc.*, 44 (1940), No. 2, pp. 332–335, fig. 1).—A group of chicks, hatched from eggs of hens fed a low-manganese diet, which were ataxic and most of which were also micromelic were reared on well-balanced diets adequately supplemented with manganese. Most of the birds attained maturity and were continued on experiment to about 16 mo. of age. Chicks which were micromelic at the time of hatching failed to show any apparent recovery from this condition. Comparative measurements of six normal

and six micromelic mature females of approximately the same age and weight showed that in micromelia the sternum was not affected and the metacarpus only slightly shortened, but that the femur, tibia, humerus, ulna, radius, and tarsometatarsus were significantly shorter. Also the consumption of a diet adequate in manganese did not promote recovery from the brachycephalism.

**Identification of the rice factor.** (Univ. Calif. et al.). (*Jour. Biol. Chem.*, 134 (1940), No. 1, pp. 213-216; 465, 466; 135 (1940), No. 1, pp. 355, 356).—Efforts by H. J. Almquist, E. L. R. Stokstad, E. Mecchi, and P. D. V. Manning to identify the principle in polished rice not present in dried yeast which has a growth-promoting effect on chicks revealed that the rice factor can be identified with, or at least replaced by, a mixture of glycine and chondroitin. Each proved to be a distinct growth factor for chicks. A casein basal diet low in both glycine and chondroitin permitted little or no increase of growth when either was added alone, but when sources of both were added growth was markedly accelerated.

Studies by Almquist, Mecchi, Stokstad, and Manning on the role of chondroitin indicated that its glucuronic acid component is similarly growth-promoting, while its galactosamine component appeared to be unessential, if not detrimental. Other substances, including sodium alginate, gum arabic, and certain pentoses, also possessed growth-promoting qualities, indicating that several substances related to glucuronic acid may also be active.

Studies by Almquist and Mecchi on the essential nature of glycine for the chick gave evidence that the presence of creatine in the ration is even more effective than glycine in promoting growth. Likewise, sodium or ammonium acetate successfully replaced glycine in the basal diet, but glycolic acid, betaine, guanidine,  $\beta$ -alanine, and choline proved to be ineffective or detrimental supplements. It is suggested that glycine or the acetates are used in the synthesis of creatine or that insufficient supplies result in creatine deficiency of sufficient magnitude to retard chick growth.

**Generalized edema in chicks prevented by d,l-alpha tocopherol,** H. R. BIRD and T. G. CULTON. (Md. Expt. Sta.). (*Soc. Expt. Biol. and Med. Proc.*, 44 (1940), No. 2, pp. 543-547, fig. 1).—In experiments to determine the nutritive completeness of different samples of dried skim milk for chicks, it was observed that a large percentage of chicks fed a simplified diet of dried skim milk, dextrinized cornstarch, cod-liver oil, and mineral mixture developed a generalized edema resulting in death. The most consistent post-mortem condition was edema of the heart and pericardium. This disorder, which was never observed in chicks fed a practical ration, was prevented by the administration in cod-liver oil of *dl*- $\alpha$ -tocopherol.

**Investigations of the cause and prevention of perosis,** R. PENQUITE, V. G. HELLER, and R. B. THOMPSON (*Oklahoma Sta. Bul.* 243 (1940), pp. 18, figs. 4).—When a basal ration consisting of yellow corn (66 percent by weight), wheat gray shorts (5), alfalfa leaf meal (3), dried buttermilk (15), meat and bone scraps (5), bone meal (5), cod-liver oil (0.25), and common salt (0.75 percent) was fed to young chicks, perosis developed in from 76 to 100 percent of the cases. The addition of ether, alcohol, and water extracts of the basal ration or water extracts of wheat bran, wheat shorts, wheat embryo, and alfalfa to the basal ration did not prevent the incidence of perosis. However, a drinking solution consisting of a water extract of rice bran was highly effective in preventing this disorder, as was the addition of the ash of 70 lb. of rice bran to 100 lb. of the basic ration. The growth of chicks receiving rice bran extract was above normal, indicating that rapidly growing chicks are not necessarily more susceptible to perosis than more slowly growing ones. Numerous other supplements

were added to the basal ration, with varying degrees of success. The addition of small amounts of manganese salts was highly effective, and a correlation appeared to exist between the manganese content of other supplements and their protective properties. However, the addition of an excessive amount of manganese in the form of 1 percent manganese carbonate in the diet decreased viability and growth of the chicks. Substituting casein for meat and bone scraps and bone meal in the basal diet practically eliminated the incidence of perosis, although the manganese contents of the two diets were similar. The manganese required to prevent perosis was shown to vary markedly with the breed of chicks and with the amount of other minerals in the diet. The administration of phosphorus subcutaneously was just as productive of perosis as when given orally. The addition of a calcium supplement markedly reduced the inorganic phosphorus content of the blood of chicks.

**Prevention of perosis by choline**, T. H. JUKES. (Univ. Calif.). (*Jour. Biol. Chem.*, 134 (1940), No. 2, pp. 789, 790).—When a basal diet of yellow corn meal, dried skim milk, washed casein, alfalfa meal, mineral mixture, and fish-oil blend was fed to baby turkeys perosis occurred in a high percentage of cases, even in the presence of a manganese supplement. The addition of thiamin, riboflavin, or nicotinic acid to the diet had little effect in retarding the incidence of perosis, but the addition of choline chloride to the diet entirely prevented the occurrence of this disorder. The addition of 0.3 percent of choline to a simplified perosis-producing diet also was effective in preventing perosis in turkeys. Choline also promoted growth on the simplified diet.

**An improved ration for starting ring-necked pheasants**, W. C. SKOGLUND (*Pennsylvania Sta. Bul.* 389 (1940), pp. [2]+22, figs. 4).—Ten starting rations varying mainly with respect to the protein content of the meat scrap used and the levels of meat scrap, white fish meal, and soybean oil meal incorporated in the mixture were compared. A group of 100 ring-necked pheasant chicks was reared in colony brooder houses on each of the experimental rations, and, in addition, 8 check lots of 25 chicks each were reared in electric battery brooders. Variations in the levels of animal protein and soybean oil meal resulted in a rather wide range of calcium and phosphorus contents and calcium: phosphorus ratios in these rations. Data are presented on the growth rate, mortality, and occurrence of perosis on the different rations. A mixture containing about 11 percent meat scrap (50 percent protein), 2.7 percent white fish meal, and 19.5 percent soybean oil meal in addition to the basic ingredients, corn, wheat bran, wheat flour middlings, ground oats, dried skim milk, alfalfa leaf meal, salt, and cod-liver oil, gave the most satisfactory results both from the biological standpoint and on the basis of economy. The incidence of perosis was markedly higher on those rations containing relatively high levels of animal protein and little or no soybean oil meal than on the ration described above.

## DAIRY FARMING—DAIRYING

[Experiments with dairy cattle and dairy products in Massachusetts] (*Massachusetts Sta. Bul.* 369 (1940), pp. 18, 19, 42-44, 75).—Reports of animal nutrition investigations, by J. G. Archibald, C. H. Parsons, C. R. Fellers, K. G. Shea, and W. B. Esselen, include the effect of complex mineral and vitamin mixtures on milk production, general health, and reproductive efficiency in dairy cattle; the effect of supplemental iron in the dairy ration on the iron content of milk; the preparation and utilization of legume and grass silage; and the vitamin D and riboflavin activity of cacao shell meal.

From studies with dairy products by W. S. Mueller, M. J. Mack, J. H. Frandsen, M. Glickstein, and M. A. Widland, results are noted on the value of various antioxidants in improving the flavor and keeping quality of milk and some of its products, the effect of aging treatments on gelatin and other ice cream stabilizers, the use of egg solids in ice cream, sodium alginate as a stabilizer for ice cream, the utilization of whey byproducts, and the efficiency and practicability of the paper milk bottle.

[Investigations with dairy cattle and their products in Nebraska]. (Partly coop. N. J. Expt. Stas. et al.). (*Nebraska Sta. Rpt.* [1939], pp. 38, 39, 40-42).—Included are brief reports on the value of sorghum grain as a substitute for corn in the ration of milking cows, hormones of the pituitary gland and their relation to milk secretion, the semen and spermatozoa characteristics of individual dairy bulls, certain factors involved in the spread of mastitis infection, and the preparation and preservation of condensed skim milks and their use in ice cream manufacture.

[Investigations with dairy cattle and dairy products in New Hampshire], E. G. RITZMAN, J. W. M. BUNKER, M. O. LEE, H. C. MOORE, and K. S. MORROW (*New Hampshire Sta. Bul.* 319 (1940), pp. 24, 25, 31-33).—Progress reports (E. S. R., 82, p. 239) are presented for studies dealing with the metabolism of dairy cattle during growth, dry-feed systems of raising dairy calves, and factors affecting the variability in milk solids-not-fat.

Does sprouting increase the nutritional value of grain? S. BARTLETT (*Empire Jour. Expt. Agr.*, 7 (1939), No. 27, pp. 244-250).—Experiments at the National Institute for Research in Dairying comparing sprouted corn and dried corn grain for milking cows and growing dairy heifers indicated that sprouting does not improve the nutritive properties of corn. A brief résumé of the literature is included.

Bone meal versus no bone meal: Results of a long-time feeding experiment with a dairy ration consisting of timothy hay, corn silage, and concentrates, S. I. BECHDEL, P. S. WILLIAMS, J. F. SHIGLEY, and A. A. BORLAND (*Pennsylvania Sta. Bul.* 395 (1940), pp. [2]+12, fig. 1).—In a test extending from December 1930 to July 1933, the basal ration was compared with the same ration plus 2 percent bone meal. All animals in the experiment had access to good pasture in season. Thirty-three animals used in this trial completed a total of 117 lactation periods, with 23 of the cows completing 1 or more of the lactations on each of the rations. The average daily milk production for those animals completing lactations on each ration was identical on the 2 rations, and the total milk production for the bone meal group was only slightly higher than the control lot. Records on weight and health of calves and number of services required per conception showed only a slight advantage in favor of the bone meal-fed group. Blood calcium and phosphorus values were normal on all cows, although averaging slightly higher for the bone meal group. It is concluded that no outstanding deficiency of minerals resulted under the prevailing conditions when no bone meal was fed.

The carotene content of several herbage during the growing season, W. W. SNYDER and L. A. MOORE. (Mich. Expt. Sta.). (*Jour. Dairy Sci.*, 23 (1940), No. 5, pp. 363-371).—Data are presented on the carotene content of seven herbage, including alfalfa, bromegrass, corn leaves, the oat plant, the soybean plant, Sudan grass, and sweetclover, at intervals throughout the growing season. An enormous range in carotene values is recorded, extending from 646.1  $\mu\text{g}$ . of carotene per gram of dry matter in green corn leaves to 7.9  $\mu\text{g}$ . in dry soybean stalks. In general, the carotene content was much greater during the early growth stages than at the stage of maturity at which the plants are usually

harvested. The decline tended to occur at a progressive rate as the plants approached maturity. The importance of harvesting plants at an early stage of maturity in order to obtain the greatest carotene content is stressed.

**The effect of feeding pea vine silage on the carotene and vitamin A content of milk**, B. C. JOHNSON and W. H. PETERSON. (Wis. Expt. Sta.). (*Jour. Dairy Sci.*, 23 (1940), No. 5, pp. 385-389, fig. 1).—A study of the milk production and the vitamin A potency of the butterfat of a herd of cows alternately receiving a ration including 25 lb. of pea vine silage preserved with phosphoric acid and a dry ration in which alfalfa hay replaced the pea vine silage gave evidence that the milk produced on the silage ration was markedly higher in carotene and vitamin A than that produced on the dry ration. The level of milk production was also maintained more satisfactorily on the silage than on the dry ration. The vitamin A potency of the milk dropped rapidly when silage was omitted from the ration. After the restoration of silage feeding the vitamin A potency increased to approximately the same level as that of milk from cows fed the silage continuously.

**Improvement in milk production thru breeding**, A. C. DAHLBERG (*Farm Res. [New York State Sta.]*, 6 (1940), No. 3, pp. 14, 16, fig. 1).—A report of the improvement in the type and milk-producing ability of a Holstein herd brought about by the continuous use of good sires on mediocre foundation animals.

**Reproductive efficiency in dairy cattle**, F. E. HULL, W. W. DIMOCK, F. ELY, and H. B. MORRISON (*Kentucky Sta. Bul.* 402 (1940), pp. 159-188).—A summary of the breeding record of the station dairy herd from 1900 to 1940. Considering a 12-mo. calving interval as ideal, that is, 100 percent breeding efficiency, over a 28-yr. period (1900 to 1928) when no organized program of disease control except for tuberculosis was in effect, the average reproductive efficiency was found to be 69.8 percent. By the continuous application of intensive health measures, a carefully planned mating program, and added attention to nutritional and genetic influences, this herd has been freed from disease so that in 1939 the breeding efficiency was 94.5 percent.

**Extreme rarity of cancer in the cow's udder: A negative finding of vital interest to the dairy industry and to the consumer**, W. W. SWETT, C. A. MATTHEWS, and R. R. GRAVES. (U. S. D. A.). (*Jour. Dairy Sci.*, 23 (1940), No. 5, pp. 437-446, figs. 4).—A detailed examination of gross sections of the udders of 313 cows of lactating age and of 105 heifers and freemartins failed to reveal a single case of cancerous growth. This paper describes unusual lesions of the udder encountered in the course of this study. A brief review of the literature confirms the findings that cows are rarely susceptible to mammary cancer.

**The coagulation temperature of milk as affected by pH, salts, evaporation, and previous heat treatment**, P. G. MILLER and H. H. SOMMER. (Univ. Wis.). (*Jour. Dairy Sci.*, 23 (1940), No. 5, pp. 405-421, figs. 8).—The method employed for measuring coagulation consisted in sealing the milk in small glass tubes and subjecting them to a rocking motion in an oil bath. The milk came up to the temperature of the bath in less than 2 min., and coagulation time could be detected by noting the flow of the milk. For each sample a series of subsamples ranging from pH 5.0-6.8 was studied. The coagulation of normal skim milk was very sensitive to pH changes within two pH zones from approximately pH 6.4-6.2, and to a lesser extent between pH 5.4-5.2. Maximum coagulation temperature of milk at the higher pH levels was above 152° C. The presence of phosphate displaced the curve into the more stable regions at pH values below 6.4, whereas calcium had the opposite effect. The effect of added salts at pH above 6.4 depended upon the milk in question. Concentrating and preheating milks displaced the coagulation curve in the same general manner, although concentrat-

ing had a much greater effect than heating alone. Added salts affected heated and concentrated milks in much the same manner as the original milk. The pH of milk tended to decrease with increased temperatures. The presence of calcium increased and that of phosphate decreased the effect of temperature changes.

**The dissolved gases in milk and dye reduction, J. M. FRAYER (Vermont Sta. Bul. 461 (1940), pp. 32).**—Employing a modified Van Slyke-Neill method for quantitatively measuring the carbon dioxide, oxygen, and residual gases in milk, a study was made of the dissolved gases in milk as affected by sunlight, metabolic activity, evacuation, and processing in an effort to determine the relationship of these factors to the reduction of methylene blue and resazurin in milk. Milk as drawn from the udder contained some oxygen and on exposure to air gained in oxygen and nitrogen while losing carbon dioxide. As bacterial growth increased, both oxygen content and the reduction time of the milk decreased. The point at which fading of methylene blue was first observed correlated closely with that at which reduction of resazurin to full pink occurred. Both occurred when oxygen was low, usually below 0.045 volume percentage, although this level was usually reached some little time before reduction was observed. A marked increase in carbon dioxide and a less increase in nitrogen occurred during this period. Exposure of milk to sunlight resulted in rapid dissipation of oxygen, and dye in milk could be reduced by sunlight without evidence of metabolic activity. An inhibitive effect of sunlight toward bacterial growth was frequently observed. Partial depletion of all gases in milk by evacuation resulted in greatly decreased reduction time, but augmentation of the oxygen content had little effect on subsequent reduction time. Data are also presented on the quantitative nature of gaseous rearrangements occurring during pasteurization, cooling, and handling of milk. It is suggested that reduction of either dye may occur in two steps, (1) oxygen exhaustion to a minimum level, and (2) mobilization and transference of hydrogen to the dye molecule.

**The relation of iodine and peroxide numbers to oxidized flavor of milk, D. H. NELSON and C. D. DAHLE. (Pa. Expt. Sta.). (Jour. Dairy Sci., 23 (1940), No. 5, pp. 391-398).**—Samples of milk and cream obtained from cows known to produce spontaneous oxidized flavor were subdivided and subjected to (1) 80° C. for 10 min., (2) 62° for 30 min., and (3) no heat treatment. All samples were then stored in the dark at 4.5° until examined and analyzed. Samples of both milk and cream known to be resistant to spontaneous oxidized flavor were treated in a similar manner except that copper was added after pasteurization to those samples heated to 62°. Analyses made of the purified butterfat from the fresh samples and again when pronounced oxidized flavor had developed showed that no significant changes in either iodine number or peroxide number occurred even when a strong oxidized flavor had developed. Marked changes in these values did not occur until after the color of the butterfat was affected.

**Ascorbic acid and oxidized flavor in milk.—II, The effect of various heat treatments of milk upon the stability of ascorbic acid and upon the development of the oxidized flavor, E. C. GJESSING and G. M. TROUT. (Mich. Expt. Sta.). (Jour. Dairy Sci., 23 (1940), No. 5, pp. 373-384, figs. 5).**—Continuing these investigations (E. S. R., 81, p. 565), individual samples of milk from 20 cows were pasteurized for 30 min. at 145.4° and 167° F., with and without the addition of copper to the milk. In general, the ascorbic acid was quite unstable in the milk processed at the lower temperature with copper added after pasteurization, and such milk was prone to the development of oxidized flavor after 3 days' storage. In milk pasteurized at the higher temperature, the ascorbic acid was relatively stable, and no oxidized flavor developed after 3 days regardless of the presence or absence of copper. The milk of some cows ex-

hibited a natural stability for ascorbic acid regardless of processing methods. With flash pasteurization of individual cow and also mixed herd samples, the critical temperature for promoting ascorbic acid stability was between 167° and 185°, a temperature of about 176° generally giving the greatest stabilizing effect. The addition of copper before heat treatment had a greater destructive effect on ascorbic acid, even at the optimum protective temperature, than when copper was added after pasteurization. Conversely, the addition of copper after heating induced more intense oxidized flavor development than when added before heat treatment. Below the critical temperature "pure" oxidized flavor usually occurred, while above this temperature "pure" cooked flavor was apparent, suggesting that the formation of reducing substances at the higher temperatures may play an important role in the ascorbic acid titration values and in the development of oxidized flavor.

**Classification in dairy bacteriology**, J. G. DAVIS (*Dairy Indus.*, 5 (1940), Nos. 2, pp. 41-44; 3, pp. 72-74; 4, pp. 99-103).—This contribution from the National Institute for Research in Dairying presents a simple scheme of identification and classification of bacteria for dairy scientists. Part 1 deals with fundamental considerations in classifying bacteria and includes a general scheme for grouping various types of organisms. Later discussion deals with methods of identification, part 2 covering characteristics of importance in determining the genus of an organism and part 3 describing the identification of types and species.

**Hemolytic streptococci in raw market milk**, J. B. GUNNISON, M. P. LUXEN, M. S. MARSHALL, and B. Q. ENGLE. (Univ. Calif. et al.). (*Jour. Dairy Sci.*, 23 (1940), No. 5, pp. 447-455).—An examination of raw market milk samples (mixed herd milk) from 444 dairy farms revealed the presence of hemolytic streptococci in 134 of the samples, of which only 4 contained streptococci which could not be assigned to a group. The distribution of the organisms among the Lancefield serologic groups was as follows: Group A, 3; group B, 125; group C of animal type, 1; group C of human type, 2; group E, 2; group G, 6; and group H, 1. Of 19 samples of cream tested 5 were found to contain group-B streptococci. Double zones of hemolysis in rabbit blood agar were produced by about one-half of the group-B organisms.

**Study of dairy cleaning problems, I, II**, J. J. JOHNSON and C. T. ROLAND (*Jour. Dairy Sci.*, 23 (1940), No. 5, pp. 457-469, figs. 2).—Two reports are noted.

I. *Films and deposits on hot-milk equipment* (pp. 457-461).—A simple apparatus for studying the formation of heat-deposited milk film is described. The results of seven trials involving a series of variable conditions gave evidence that two definite types of films occur, one of cheeselike consistency resulting from superheating and partial dehydration of milk around gas bubbles at the heat-transfer surface, the other a thin metalliclike film which may occur independently or concomitantly with the former type. Accumulation of the latter type is considered the primary cause of milkstone formation on hot-milk equipment.

II. *Effectiveness of alkalis in removing heat-deposited milk solids and butterfat films* (pp. 463-469).—In experiments dealing with heat-deposited milk solids it was found that the approximate minimum concentrations of alkalis effective in their removal were trisodium phosphate 0.3 percent, sodium metasilicate 0.2, sodium carbonate 0.2, and sodium hydroxide 0.04 percent. The minimum effective pH values were sodium carbonate 11.2, trisodium phosphate 11.8, and sodium metasilicate and sodium hydroxide 12. A study of the removal of butterfat from glass indicated that sodium hydroxide was not effective at any concentration between 0.05 and 2 percent, whereas sodium carbonate, sodium metasilicate, and

trisodium phosphate were all fairly effective at concentrations above 0.1 percent. A combination of sodium hydroxide with either sodium metasilicate or trisodium phosphate was more effective in removing fat than the hydroxide and carbonate. A surface-active organic detergent used either alone or in combination with sodium hydroxide was effective in fat removal, although it did not produce emulsification when used alone.

**The butter industry**, O. F. HUNZIKER (*LaGrange, Ill.: Author, 1940, 3. ed., rewritten and enl., pp. [8]+821, figs. 136*).—The third edition of this well-known textbook (E. S. R., 57, p. 769) has been completely rewritten and enlarged.

**Acid values and acid ratios as related to the keeping quality of salted butter**, H. A. BENDIXEN. (Wash. Expt. Sta.). (*Jour. Dairy Sci., 23 (1940), No. 4, pp. 275-284*).—Acid values were determined on both the butter and the purified butterfat from 28 samples of sweet cream butter, 51 samples of neutralized cream butter, and 8 samples of neutralized cream butter with butter culture, the samples being obtained from the fresh butter and also after 1 week's storage at 21° C. and after 1 mo. at 0°-5°. Average values for the sweet cream butter were 0.096, 0.109, and 0.103 and for the neutralized cream butter 0.122, 0.14, and 0.132 percent for the fresh, week-old, and month-old samples, respectively. Certain trends were observed which appear to have significance in predicting the keeping quality of the butter. High increases in the acid values after storage at either temperature showed a fairly high correlation with reduced keeping quality, particularly of the sweet cream butter. Also an increase in the acid ratio (fat acidity: butter acidity) during the storage periods seemed to be closely related to poor keeping quality, particularly for sweet cream butter. The average acid ratios were higher after 1 mo. at 0°-5° than after 1 week at 21°.

**The keeping quality of butter**, C. M. SORENSEN (*Jour. Dairy Sci., 23 (1940), No. 5, pp. 423-436*).—This is a summary of the common defects observed in commercial butters based on the examination of over 22,000 samples. Putrid and cheesy-type flavor development was most frequently encountered, and the major cause of this difficulty was traced to contamination of creamery water supplies by spoilage types of bacteria. Rancid flavor development was also a common defect. Comparatively few cases of mold, staleness, or tallowy flavor development were encountered.

**"Just salt" is obsolete in the cheese industry**, J. C. MARQUARD (*From Res. [New York State Sta.], 6 (1940), No. 3, p. 10, figs. 3*).—A brief discussion of modern methods of salt production and the relation of salt to quality and means of preventing salt and quality losses in cheese.

**Packaging sliced Cheddar and Swiss cheese in cans for sandwich dispensers**, H. L. WILSON (*U. S. Dept. Agr., Misc. Pub. 386 (1940), pp. 8, figs. 7*).—Directions are presented for preparing loaves of Cheddar cheese curd of desirable shape and size, slicing and wrapping the loaf, and packing in valved cans for curing and merchandising. The same package has been successfully used for cured Swiss cheese by cutting desirably shaped loaves from large wheels of cheese, slicing, wrapping, and packaging. The chief advantage of this method of merchandising is that slices of natural cheese of uniform shape, size, and thickness and without waste are made available for the sandwich trade. Adaptation of the method to various-sized packages is described.

**Report of committee on ice cream sanitation**, F. W. FABIAN ET AL. (*Jour. Milk Technol., 3 (1940), No. 2, pp. 72-74*).—A further report of this committee (E. S. R., 82, p. 248), covering suggested standards for ice cream ingredients and various problems confronting ice cream control agencies in the United States and Canada.

**Examination of ice cream with the Burri smear culture technic, H. F. LONG and B. W. HAMMER.** (Iowa Expt. Sta.). (*Iowa State Col. Jour. Sci.*, 14 (1940), No. 2, pp. 163-177, pls. 3).—An adaptation of the Burri smear culture technic to the examination of ice cream is described, and the results of a large number of samplings of both the surface and the interior of ice creams are presented. The method proved useful in studying the distribution of bacteria in ice cream, particularly when comparing the numbers of organisms in the interior and at the surface of dipped ice creams. Difficulty was encountered in picking uniform weight samples. Counts with the Burri smear technic tended to be higher than plate counts, which is in opposition to that encountered in butter (E. S. R., 80, p. 678).

**Egg solids, M. A. WIDLAND and M. J. MACK.** (Mass. State Col.). (*Ice Cream Trade Jour.*, 35 (1939), No. 10, pp. 21, 48, 56, fig. 1).—Data are presented on the composition, including the percentage of yolk solids, of seven samples of powdered egg yolk and egg powder blends, also on the effect of adding 0.3 percent of these egg products to ice cream mixes on the quality of the resulting ice cream. Whipping ability, melting properties, and texture of ice cream were generally improved by the addition of egg yolk solids. The value of the various products was therefore in proportion to the yolk solid content. Old or stale egg products detracted from the flavor of ice cream even when added at 0.3 percent levels.

## VETERINARY MEDICINE

[Contributions on animal pathology and parasitology] (3. *Internatl. Cong. Microbiol.*, New York, 1939, Rpt. Proc., pp. 283, 284, 287-292, 293, 300-309, 310, 311, 318, 323-326, 334-345, 346, 347, 360-365, 388, 389, 390-394, 413-416, 418, 419, 421, 422, 428, 429-438, 443-445, 454-471, 472-482, 523, 524, 525, 526, 527, 528, 581, 582-589, 594-596, 596, 597, 598-611, 612, 613, 614, 620, 621, 622, 623, 625, 628-631, 632-634, 634-643, 647, 664-668, 669-678, 832-840).—Contributions presented at the Third International Congress for Microbiology held at New York City in September 1939, and here reported, include: The Nature of Viruses, by J. McIntosh (p. 283); The Essence of the Ultravirus Based on Recent Researches, by J. v. Darányi (pp. 283, 284); Use of the Ultracentrifuge in the Study of Yellow Fever Virus, by J. H. Bauer and E. G. Pickels (pp. 287, 288); Comparative Studies on Ultracentrifugation and Serological Reactions of Bacteriophages, Plant Viruses, and Insect Viruses, by A. Gratia (pp. 288, 289); Experiments on Immunity to Fowl-Pox, Especially by Means of Skin Grafts on the Chorio-Allantois of Chick Embryos, by E. W. Goodpasture and K. Anderson (pp. 289, 290); Passive Immunity to Newcastle Disease Virus in the Chick Embryo, by E. V. Keogh (p. 290); Susceptibility of Mammalian Fetuses to Viruses, by N. P. Hudson and O. C. Woollpert (pp. 291, 292); Comparative Investigations on the Cultivability of Viruses by Different Methods of Tissue Culture [trans. title], by E. Haagen (pp. 292, 293); Mosquito Transmission of Equine Encephalomyelitis, by R. A. Kelsner (p. 300); Transmission of Equine Encephalomyelitis, by C. TenBroeck (pp. 300, 301); Human Encephalitis Caused by the Virus of Equine Encephalomyelitis, by L. D. Fothergill (pp. 301, 302); Equine Encephalomyelitis—Its Relationship to Man and Animals in California, by B. F. Howitt (pp. 302, 303); Neutralization Tests With the Sera of Pheasants Surviving an Outbreak of Equine Encephalomyelitis, by F. R. Beaudette (pp. 303, 304); Immunological Studies on the Virus of Equine Encephalomyelitis, by P. K. Olitsky and I. M. Morgan (pp. 304, 305); Changes of the Central Nervous System in Equine Infectious Anemia and Their Differentiation From Those of Other Virus Diseases of the Horse [trans. title], by O. Seifried (p. 307); The Comparison of Concentrations of the Virus

of Japanese Encephalitis in Blood, Cerebro-Spinal Fluid, and Brain Tissue From Encephalitis Patients, Monkeys, and Mice, by R. Kobayashi (p. 308); The Immunity of the Mouse to Lymphocytic Choriomeningitis [trans. title], by E. Traub (pp. 308, 309); A Soluble Antigen of Lymphocytic Choriomeningitis, by J. E. Smadel and T. M. Rivers (pp. 310, 311); The Forms and Types of X-Bodies Formed by Different Viruses Within the Same Host, by F. P. McWhorter (p. 318); In Vitro Culture of Rabies Virus, by K. Kanazawa (p. 323); The Cultivation of Fixed Rabies Virus and the Immunizing Properties of Culture Virus, by I. J. Kligler and H. Meyer (pp. 675, 676); Active Immunization Against Plague, by H. L. Schutze (pp. 676, 677); *Bacterium tularensis*, by E. Francis (pp. 677, 678); and Report of the Subcommittee of the Nomenclature Committee of the International Association of Microbiologists on the Genus *Salmonella* (pp. 832-840).

[Work in animal pathology by the Massachusetts Station] (*Massachusetts Sta. Bul.* 369 (1940), pp. 92-96).—The work of the year briefly reported upon (E. S. R., 81, p. 569) relates to pullorum disease eradication, diagnosis, *Pasteurella* and *Pasteurella*-like cultures (avian origin), avian encephalomyelitis, equine encephalomyelitis virus (eastern type), viability of *Salmonella pullorum*, and pullorum disease in turkeys, all by H. Van Roekel, K. L. Bullis, O. S. Flint, and M. K. Clarke; and studies of neoplastic and neoplasticlike diseases of poultry, by C. Olson, Jr.

[Work in animal pathology by the New Hampshire Station] (*New Hampshire Sta. Bul.* 319 (1940), pp. 30, 31, 43, 44, 45).—The work of the year briefly reported upon (E. S. R., 82, p. 249) includes studies of bovine mastitis, by L. W. Slanetz; paralysis in chickens, by C. L. Martin and M. S. Cover; control of coccidiosis in poultry, by Martin, Cover, T. B. Charles, and R. C. Durgin; methods of administering medicine to sheep, by Martin; pullorum eradication; and poultry autopsies, by C. A. Bottorff, Martin, and Cover.

Myocardial lesions resulting from dietary deficiency, R. M. THOMAS, E. MYLON, and M. C. WINTERNITZ (*Yale Jour. Biol. and Med.*, 12 (1940), No. 4, pp. 345-360, pls. 4, figs. 2).—Investigations have shown that rats and hogs develop severe myocardial lesions, characterized by necrosis of muscle fibers and marked cellular infiltration, when they are fed a diet deficient in potassium and in vitamin B.

Brucellosis or Bang's disease of farm animals, C. P. FITCH and W. L. BOYD (*Minnesota Sta. Bul.* 348 (1940), pp. 32, figs. 12).—A practical summary of the present status of Bang's disease of farm animals is presented. It is pointed out that the agglutination test of the blood is an invaluable aid in the diagnosis of the disease and at the present time is the best method for its control. The present Federal-State Bang's disease program is considered to be an economical method for ridding a herd of this infection.

Ineffectiveness of proprietary remedies and other drugs in the control of Bang's disease, with special reference to "3-V Tonic" and "Bowman's," A. B. CRAWFORD and B. A. BEACH. (U. S. D. A. and Wis. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 60 (1940), No. 8, pp. 565-574).—Report is made of a study, conducted under special Congressional authority, which consisted of carefully controlled tests of two widely used, alleged remedies for Bang's disease, namely, 3-V Tonic and Bowman's. The details of the work are given in tables. Thus far no drug or therapeutic chemical of a large number tested by qualified investigators under controlled conditions has proved to be effective in the prevention or cure of Bang's disease. The animals treated with these two products, 60 and 40 head, respectively, both before and after exposure to virulent *Brucella* organisms, became chronically affected with Bang's disease in the same manner and to about the same degree as the untreated control animals in the experiments.

A survey of the types of *Cl. welchii* present in soil and in the intestinal contents of animals and man, A. W. TAYLOR and W. S. GORDON (*Jour. Pathol.*

and *Bact.*, 50 (1940), No. 2, pp. 271-277).—In an attempt to determine the significance of the toxin of *Clostridium welchii* type D in, and the isolation of the associated organism from, the intestinal contents of a few acute cases of grass sickness in horses, a survey was made of the types of *C. welchii* normally present in farm soil and in the intestinal contents of man and several animal species. "Of 196 strains of *C. welchii* isolated from 43 samples of farm soil, 7 were of type D and the remainder of type A. Of 1,147 strains isolated from the intestinal contents of man and of several species of animals, 1,134 were of type A, 3 of type B, and 10 of type D. The type B strains were isolated from a wild rabbit. Of the D strains, 1 was isolated from a sheep, 2 from a bovine, and 7 from a domesticated rabbit. Of 174 filtrates prepared from intestinal contents, the toxin of *C. welchii* was detected in only 1, a sample from a rabbit which died after an acute illness. This was of type D, and the animal probably died of enterotoxemia."

**Antigenic variation in a strain of *Cl. welchii* type C (B[acillus] paludis),** A. W. TAYLOR (*Jour. Compar. Pathol. and Ther.*, 53 (1940), No. 1, pp. 50-54).—In the studies reported the gradual loss of ability over a period of years by cultures of *Clostridium welchii* type C, and by cultures of the same strain obtained from different sources, to produce C toxin (Z factor of Wilsdon, beta toxin of Glenny) were demonstrated. This is said to confirm the findings of Dalling and Ross (*E. S. R.*, 80, p. 826) that a culture of *C. welchii* type C on occasion fails to produce C toxin.

**Cyanosis in chickens and mice induced by sulfanilamide,** A. P. RICHARDSON (*Bul. Johns Hopkins Hosp.*, 65 (1939), No. 6, pp. 445-455).—A description is given of methods of inducing sulfanilamide cyanosis in chickens and mice. In chickens the cyanosis is explained by the formation of methemoglobin, while in mice the presence of cyanosis is accounted for by the presence of sulfhemoglobin. Under the conditions described, sulfanilamide will convert hemoglobin into methemoglobin *in vitro*. Methylene blue exerts a beneficial effect on the sulfanilamide cyanosis in chickens but not on the mouse cyanosis.

**Further studies on the effect of sulfanilamide on experimental tuberculosis,** R. H. FOLLIS, JR., and A. R. RICH (*Bul. Johns Hopkins Hosp.*, 65 (1939), No. 6, pp. 466-488, pls. 3).—The study of the effect of sulfanilamide on experimental tuberculosis in the rabbit here reported is said to confirm the results of the authors' earlier study on the guinea pig,<sup>8</sup> demonstrating that adequate dosage of the drug, properly administered, has a definite inhibitory effect upon the development of tuberculosis. Individual rabbits exhibit marked differences in the degree to which they acetylate the drug and in their ability to attain and maintain a high concentration in the blood following the administration of a given dosage. These differences undoubtedly play a role in determining the degree to which a given dosage will exert a beneficial effect upon the progress of the infection in different animals.

**The relation between skin measurements and the character of the swelling in eleven hundred double intradermal tuberculin tests,** J. R. RIDER (*Vet. Jour.*, 96 (1940), No. 4, pp. 154-159).—A study made of 1,100 tuberculin tests has shown that the increase in the thickness of the skin can be correlated with the character of the swelling. "The increase in skin thickness bears no relation to the age or the sex of the animal. In over 90 percent of the cattle exhibiting swellings of the accepted negative character the increase in skin thickness does not exceed 2 mm. at the forty-eighth hour, and the total increase does not exceed 3 mm. In 90 percent of the cattle exhibiting swellings of the accepted positive character the increase exceeds 3 mm. at the forty-eighth hour,

<sup>8</sup> *Bul. Johns Hopkins Hosp.*, 62 (1938), No. 1, pp. 77-84.

and the total increase exceeds 5 mm. An atypical group exists showing total increases between 3 mm. and 5 mm. This group contains animals which may react after an interval of 2 to 3 mo."

**Pulmonary tuberculosis in cattle: The location and type of lesions in naturally acquired tuberculosis, E. M. MEDLAR** (*Amer. Rev. Tuberc.*, 41 (1940), No. 3, pp. 283-306, figs. 4).—Report is made of the results of a statistical analysis as to type and location of 2,005 lesions from 520 pairs of tuberculous bovine lungs. The findings indicate that the infection is air-borne. The greater frequency, per unit volume, of tuberculous foci in certain specified areas of the lung parenchyma in comparison with other areas cannot be satisfactorily explained on a basis of the mechanics of respiration. A comparison of the predominant location of cavitating lesions in cattle and in man suggests that the difference between the two species cannot be explained on a basis of air-borne distribution or on a basis of the mechanics of respiration. The dominance of progressive tuberculosis in the more elevated portions of the parenchyma of lobes of lung tissue in both species can best be explained on the hypothesis that posture influences the condition within the lung parenchyma. What alterations may be induced by posture remain to be determined. From this study it is also evident that calcification is not a common occurrence in bovine pulmonary tuberculosis in the less advanced stages of the disease. Endobronchial tuberculosis in cattle is a corollary to cavitation of a parenchymatous focus. This should be borne in mind when endobronchial tuberculosis in man is observed.

**Factors affecting reproduction in the dairy herd (Nebraska Sta. Rpt. [1939], p. 40).**—Brief report is made of studies of methods and practices for the elimination of trichomoniasis.

**The experience of nearly six years with calfhood vaccination, L. J. TOMPKINS** (*Cornell Vet.*, 30 (1940), No. 2, pp. 178-192, figs. 3).—Work carried on in New Jersey, and extending over a period of 6 yr., has shown that all individuals after vaccination give a pronounced agglutination response. "The time required to return to a negative blood status varies widely with individuals. A few individuals carry a high titer, without any recession, at least through their first lactation period. Some individuals carry a low titer for months, with a strong tendency to become negative in time. Calfhood vaccination eliminates the danger of vaccinating adult or pregnant animals. The general behavior of the reactions following calfhood vaccination is such that they are not too confusing when interpreting the subsequent herd tests. The administration of a vaccine, prepared from *Br[ucella] abortus* strains with the low virulence of strain 19, seems to be practically free of danger when used on from 5- to 7-month-old calves. Clinical abortions and retained placentae do occur in animals vaccinated at calfhood, but apparently from other causes than *B. abortus*, when we accept the agglutination blood test as an indicator of *B. abortus* infection. Vaccination with strain 19 at the proper age seems to take off the 'edge in susceptibility' and act as good insurance against Bang's infection. With cleaner herds each year, natural exposure to calves will be gradually eliminated even though of questionable value, so artificial vaccination may produce this protection."

**Methods of controlling the liver fluke of cattle in Hawaii, J. E. ALICATA, L. E. SWANSON, and G. W. H. Goo** (*Hawaii Sta. Circ. 15* (1940), pp. 23, figs. 5).—It is concluded that the liver fluke of cattle (*Fasciola gigantica*) in Hawaii may be best combated through control of the snail carrier *Fossaria ollula*, a common inhabitant of fresh-water streams and swamps. This includes the prevention of grazing in swamps or the feeding on grass cut from these areas and treatment of infected animals. "The snail may be controlled (1) by broadcasting copper sulfate at the rate of 20 lb. per acre, using 1 part of the chemical to 4 parts of a carrier such

as sand; (2) by application of copper sulfate in streams at the rate of 1 to 200,000 or 1 to 300,000 parts of water; or (3) by drainage of swampy areas. Cattle may be protected from infection by fencing off areas where drainage is not practical and allowing the cattle to feed only on vegetation from dry areas. Distol and kamala have been found effective in most instances in the removal of flukes in cattle. Experimental treatment was chiefly with steers and dairy cows which were non-lactating or near the end of their lactation period. Distol was found effective in most cases when given at the rate of 1 capsule to 70 lb. of body weight over a period of 2 or 3 successive days. Kamala was effective at the rate of 10 gm. of drug to 60 lb. of body weight, administered over a period of 4 days, but produced considerable diarrhea and loss of appetite lasting from a few days to about 2 weeks, and resulted in death in two instances. Additional studies are being conducted to determine the efficacy and safety of other drugs available in the United States. For the present . . . Distol is considered superior to kamala because it is safer and requires less time to administer. Kamala has the advantage of costing about one-third as much as Distol, and it may be obtained in local markets. It is suggested that Distol be used for dairy cows and kamala for beef cattle and possibly for less productive dairy cows."

**An analysis of environmental and genetic factors influencing stomach-worm infestation in sheep**, P. W. GREGORY, R. F. MILLER, and M. A. STEWART. (Univ. Calif.). (*Jour. Genet.*, 39 (1940), No. 3, pp. 391-400, figs. 3).—In the work reported, fecal examination for trichostrongyle eggs of ewes of known ages sired by two different rams were made weekly over a period of 2 mo. from September to November 1937. "All data on the egg counts were quantitative. Though the numbers of ewes studied were somewhat limited, the results were consistent and indicate that at least three different factors influence the degree of stomach-worm infestation. The season of the year is the first variable. Age of the ewe is the second, although, in these data, age beyond 2 yr. 8 mo. ceased to be important. The third and most important variable influencing stomach-worm infestation is genetic constitution for resistance and susceptibility. Judging from these results, genetic selection should effectively change the degree of resistance or susceptibility in populations of sheep."

**Chronic copper poisoning in sheep**, I. B. BOUGHTON. (Tex. Expt. Sta.). (*Southwest. Sheep and Goat Raiser*, 10 (1940), No. 8, p. 19).—A brief report is made of investigations which have led to the finding that the large losses of range sheep that had been licking so-called medicated salt mixtures were due to chronic copper poisoning. The percentage of copper sulfate in the medicated mixtures varied from approximately 2 to 6, and the symptoms of the disease appeared within from 5 mo. to 2 yr. after the mixtures were placed before the sheep. Stomach worms, which the mixtures were supposed to control, were found alive and unaffected in many animals.

**Botulism in equines due to contaminated drinking water and hay**, J. M. FOURIE and P. S. SNYMAN (*Jour. So. African Vet. Med. Assoc.*, 10 (1939), No. 3, pp. 132-135, figs. 4).—Observations made in the course of outbreaks of botulism in horses, mules, and donkeys have led to the diagnosis of botulism due to contamination of the hay with carcass material.

**The isolation and typing of equine encephalomyelitis virus**, M. S. SHAHAN, L. T. GILTNER, and O. L. OSTEN. (U. S. D. A.). (*Cornell Vet.*, 30 (1940), No. 2, pp. 151-160).—This is a report of work conducted since 1932, during which time 65 strains from various parts of the United States have been recovered from field specimens and typed by the authors and their associates in the U. S. D. A. Bureau of Animal Industry. Case selection, technic of procuring specimens, methods of handling specimens in the field and in transit to the laboratory, and technic in the laboratory are considered in connection with the recovery of

viruses from field cases. The differential diagnosis on a pathological basis is considered, and the failure to demonstrate virus in field material is discussed. Of 267 specimens listed during the 7-yr. period, 66 yielded virus, which, with 68 others, displayed typical pathology. A discussion of the technic employed by the authors for classification of viruses as eastern or western type is included, as is a list of 16 references.

**Equine encephalomyelitis, R. GRAHAM and H. R. HESTER. (Univ. Ill.). (Ill. State Acad. Sci. Trans., 32 (1939), No. 2, pp. 205-207).**

**Natural infection of fleas with the dog heartworm *Dirofilaria immitis*, H. W. BROWN and A. J. SHELDON. (Univ. N. C.). (North Amer. Vet., 21 (1940), No. 4, pp. 230, 231).**—The findings reported indicate that the dog flea is a potential vector of *D. immitis*, which suggests that it may play a role in the transmission of this parasite, especially throughout portions of the South.

**Can hares and rabbits act as hosts of sheep and goat bankrupt (*Trichostrongylus* spp.) worms in South Africa? R. J. ORTLEPP (Jour. So. African Vet. Med. Assoc., 10 (1939), No. 4, pp. 166-169, figs. 2).**—The author found that *T. colubriformis* larvae recovered from sheep readily set up an infection in rabbits, and that they easily grow to maturity in this host and are able to produce eggs whose larvae are capable of setting up an infection in sheep.

**Sub-clinical coccidial infection in chickens, P. P. LEVINE (Cornell Vet., 30 (1940), No. 2, pp. 127-132).**—In studies reported, 39 examinations of intestinal tracts of White Leghorn pullets largely received alive from 33 premises in New York State were made for the presence of coccidia. "Ninety-two percent of the birds had no gross lesions of coccidiosis. The coccidial species were identified by observing the time of first appearance and size of oocysts discharged by test birds fed suspected material. *E[imeria] tenella* and *E. necatrix* were identified by the gross lesions these species produce in the ceca and intestine, respectively. The incidence of the various species found were as follows: *E. praecox* 13 times (33 percent), *E. acervulina* and *E. mitis* (considered as a single category) 21 times (53 percent), *E. maxima* 11 times (28 percent); *E. necatrix* 15 times (38 percent), [and] *E. tenella* 9 times (23 percent). The finding of such a high percentage of subclinical infections with *E. necatrix* and *E. tenella* was especially surprising."

**Phenothiazine for the removal of *Heterakis gallinae* from chickens, E. C. McCULLOCH and L. G. NICHOLSON. (Wash. Expt. Sta.). (Vet. Med., 35 (1940), No. 7, pp. 398-400, fig. 1).**—The authors report tests in which phenothiazine was administered to Single-Comb White Leghorn chickens suffering from a natural heavy infestation of cecal worms. *H. gallinae*, a common parasite of chickens, served as a vector for *Histomonas meleagridis*, the cause of enterohepatitis. The drug was given either in the feed or in hard gelatine capsules, both single and repeated doses being tested. "Between 0.05 and 0.5 gm. was found to be a satisfactory individual dose. Repeated doses and administration of the drug in individual capsules were found to be slightly more satisfactory, although flock medication appears to be practical. The average effectiveness was between 95 to 100 percent, both from the standpoint of cecal worms expelled and killed. Enormous doses, up to 500 times the smallest amount therapeutically effective, had no apparent harmful effect on the birds; such massive doses also had no anti-heterakid effect. Individual capsule medication of 0.5 gm. had no appreciable effect on a flock in egg production. Neither massive nor therapeutic doses had any effect upon the flavor of the meat. The administration of phenothiazine was not followed by enteritis or other digestive disturbances, except for a slight softening of the feces 24 hr. following treatment. The use of phenothiazine as an anthelmintic for the removal of heterakids is recommended, even though the most desirable dosage has not been definitely determined."

## AGRICULTURAL ENGINEERING

[Agricultural engineering investigations by the Massachusetts Station] (*Massachusetts Sta. Bul.* 369 (1940), p. 45).—These have included cranberry storage investigations, by C. I. Gunness, H. J. Franklin, and C. R. Fellers; work on frost protection on cranberry bogs (use of a wind machine), by Gunness; and poultry-house investigations (electric brooders in insulated and noninsulated colony houses), by Gunness and W. C. Sanctuary.

[Agricultural engineering investigations by the Nebraska Station] (*Nebraska Sta. Rpt.* [1939], pp. 46-49).—These have included work on performance characteristics of rubber tires on tractors, adaptation of small electric motors to farm use (coop. U. S. D. A.), automatic electrical water systems, electrical water heating for livestock, methods of cooling milk on the farm and their effect on quality, the adaptability of electric hotbeds to farm use, adaptation of insulated electric brooders in uninsulated poultry houses, and mechanical equipment for the eradication of bindweed.

Surface water supply of the United States, 1938, parts 5, 8 (*U. S. Geol. Survey, Water-Supply Papers* 855 (1940), pp. IX+350, pl. 1; 858, pp. VII+355, pl. 1).—These papers record measurements of stream flow for the year ended September 30, 1938, No. 855 covering the Hudson Bay and upper Mississippi River basins, and No. 858 the western Gulf of Mexico basins.

The effect of several chemicals on the swelling and the crushing strength of wood, H. D. ERICKSON and L. W. REES. (Minn. Expt. Sta.). (*Jour. Agr. Res.* [U. S.], 60 (1940), No. 9, pp. 593-603, figs. 2).—The degree of swelling of test blocks of *Pinus resinosa* (red pine) produced by concentrated solutions of certain inorganic salts, and of chloral hydrate, tannic acid, urea, pyrogallol, and resorcinol, as well as by certain of the lower aliphatic alcohols, ethylene glycol, and acetone, were determined, together with the effect of these reagents upon the maximum crushing strength of the wood. In the test with each liquid, 10 blocks, approximately 1 by 1 by 2 in. when green, were used. The blocks were dried slowly to a uniform 2 percent moisture content before treatment. Adequate penetration was obtained by forced submergence and intermittent application of a high vacuum, except that high vapor pressure of the liquid prevented attaining a high vacuum over some of the organic liquids. In the strength test a uniform rate of compression strain, approximately 0.035 in. per minute, was used.

An inverse relationship between maximum crushing strength and swelling caused by the organic liquids was indicated. At the same degree of swelling, the organic liquids swelled and weakened the wood less than water did. Swelling and loss of strength decreased with increasing carbon number of the alcohols. Benzene had no appreciable effect on wood. Nearly complete swelling of wood in *n*-butyl alcohol required 120 days. The solutions of potassium sulfate and of lithium, sodium, potassium, magnesium, calcium, and manganese chlorides increased the crushing strength as compared with that of water-treated wood.

Potassium bromide very slightly increased the strength. Potassium thiocyanate and potassium iodide distinctly decreased the strength. In the organic group, urea, resorcinol, and pyrogallol, which caused a relatively high degree of swelling, markedly decreased the crushing strength, whereas chloral hydrate, which also swelled the wood strongly, and tannic acid, which caused little swelling, increased the strength decidedly.

Electric motors for the farm (single phase), H. H. BEATY and W. A. THOMAS (*Iowa Sta. Bul.* P13, n. ser. (1940), pp. 361-390, figs. 17).—This bulletin deals only with A. C. (single phase) motors, except for brief mention of the

universal type, and discusses the smaller motors, from  $\frac{1}{6}$  to  $7\frac{1}{2}$  hp., which may be operated on such current.

As a guide to the selection of a motor suitable for the work to be done, attention is called to the differences in starting torque, in the percentage of overload which can be brought up to speed, and in the percentage of overload carried without stalling, the common types being listed in order of increasing starting torque as split phase, capacitor start-induction run, capacitor run, repulsion start-induction run, and repulsion induction. Two portable motors, the one of from  $\frac{1}{4}$  to  $\frac{1}{2}$  hp., the other of from 3 to  $7\frac{1}{2}$  hp., are recommended for machines used seasonally, these being considered capable of operating practically all farm machines not supplied with an attached motor. Individual motors are recommended for machines used daily, such as water pumps, cream separators, milking machines, etc.

To promote efficiency and to prolong motor life, line-shaft drives are to be avoided, pliable belts are to be preferred to stiff or heavy belts, attention should be given to belt speed so that speeds greater than 4,000 ft. per minute will not be used, and special fuses (delayed action to permit momentary heavy starting currents) or cut-outs are to be used for preventing excessive overload. Lubrication and the need for keeping the motor clean and dry are also dealt with, together with the importance of a current supply not more than 10 percent higher or lower in voltage than that for which the motor is designed.

The general advantages of electric motors over manual operation or other sources of power are pointed out.

**Remodeling used machinery for tractor farming, L. F. LARSEN** (*South Dakota Sta. Cir. 30 (1940), pp. 15, figs. 12*).—Several adaptations of machines designed to be horse-drawn to permit their use with tractors are described and illustrated by diagrams and photographs.

Using a stub tongue to attach the first of two binders directly to the tractor drawbar and a tongue truck on the second binder, the operator can hitch the two machines to work in combination by means of two chains or cables. The longer of these chains or cables must be passed through two slip joints under the front binder (an ordinary clevis can be so attached as to serve this purpose), and the evener bracket on the second binder must be removed, lengthened to about 32 in., and replaced inverted, bringing the end nearer the ground.

To provide for windrowing and drying in the windrow before using a combine, the author rebuilt an old binder into a right-hand windrower, suitable for preparing the grain for a combine having right-hand pick-up. It is also pointed out that any farmer who has an old header available will find that it makes a very good windrower for a right-hand combine by merely removing the elevator.

**Cotton-tillage studies on Red Bay sandy loam, J. W. RANDOLPH, I. F. REED, and E. D. GORDON.** (Coop. Ala. and Miss. Expt. Stas.). (*U. S. Dept. Agr. Cir. 540 (1940), pp. 55, figs. 34*).—Seedbed preparation experiments, planter tests, cultivation experiments, and a study of the relation between apparent specific gravity and crop yield are separately dealt with.

With respect to seedbed preparation, the desirable physical condition at planting time for Red Bay sandy loam was found to be that of a relatively low apparent specific gravity with about one-third of the top 8 in. of soil in soft clods embedded in settled, finely granulated soil. The structure should be such that the soil will not settle to a high apparent specific gravity by fall. With seed, fertilizer, and methods of planting and cultivation kept constant, the 6-yr. average yields varied, due to seedbed preparation methods, from 1,038 to 1,324 lb. of seed cotton per acre. Plats receiving no seedbed preparation produced an average of 1,100 lb. per acre.

Preparation of the seedbed by plowing or breaking the row and then the middle in winter not only produced the best yields but released labor in the spring for handling feed and food crops. Excessive tillage in seedbed preparation did not increase the yield per acre much above that obtained when there was no seedbed preparation. A loose, overpulverized, structureless condition was produced in the surface soil, which consolidated rapidly after the normal spring rains. These operations tended also to pack the subsoil, producing an impervious layer which prevented development of a normal root system, slowed up drainage, and increased erosion. Maximum yields per acre and returns per man were obtained by use of a few properly executed, well-timed operations. The tillage work under the row was found to be more beneficial than work done in the middles if the soil is not overpulverized. Yield increased with the depth of work under the row down to 8 in. Subsoiling did not increase the yields. Deep plowing gave the best control of weeds. Shallow working or ridging the soil did not cover weed seed deep enough to prevent their germination. Tillage methods that increased the moisture-holding capacity of the soil tended to increase yields.

The planter tests showed that the machine must have weight, strength, and contact with the ground sufficient to hold the opener to the desired depths in the soil, and that a sweep mounted on the front of the planter to cut the bed to the desired height improved the yield of seed cotton, removed weeds and trash from the row, and made possible a better first cultivation. The variable-depth method of planting practically insured a stand of cotton on the first planting even under the very unfavorable conditions often encountered in early spring, giving better stands where soil crusts formed than did planting at constant depth because conditions favorable for development of crusts caused seed planted shallow to germinate and emerge before the crust was fully formed. The seed press wheel helped to insure a quick stand, but tended to reduce yields. It is not recommended for the conditions encountered in this experiment. A surface press wheel should be used throughout the season. The open-type wheel gave best results when the soil was inclined to crust, but the closed or solid-tire type was best under certain dry conditions. The covering spoons or disks should be arranged to throw a uniform amount of soil onto the row.

The cultivation experiments showed that cultivation should be shallow and only frequent enough to control weeds. Cross-row cultivation with drag harrow, spring-tooth weeder, or rotary hoe controlled the weeds, removed weak plants, and lengthened the chopping period, allowing hoe hands to select the better plants to leave for stand. Cross-row cultivation can be done economically as the equipment used handles a relatively wide strip and has light draft. It may be destructive to cotton planted on very loose beds or in a furrow. The same three tools were found very effective for breaking soil crusts to allow cotton seedlings to come up. The rotary hoe seemed most satisfactory. Cross-row cultivation before and during chopping time followed by enough shallow-row cultivations to keep down the weeds produced the maximum yield of seed cotton and was efficient in the use of labor.

Apparent specific gravity, measured by drying and weighing fixed portions of a core sample taken with a thin-walled steel tube and determining the required figure from the weight per unit volume, showed that the type, number, and time of the seedbed-preparation operations substantially altered the compactness at certain depths. The data indicate close correlation between yield and apparent specific gravity for certain ranges of depth in the row area, especially between 4 and 8 in. in the top 2 in., because of cultivation. The average apparent specific gravity of the soil in the cotton row was found to be less after harvest than

in the period immediately following planting. This loosening is attributed in part to the permeation by roots and in part to the alternate wetting and drying of the soil through the growing season.

**Cotton picking machinery:** A short list of references, E. L. DAY (*U. S. Dept. Agr., Bur. Agr. Econ., Econ. Libr. List 9 (1940), pp. 19*).—This reference list, superseding three previous typewritten lists, was compiled mainly from *Agricultural Economics Literature* (vol. 1, 1927, to vol. 13, 1939) and *Cotton Literature* (vol. 1, 1931, to vol. 9, 1939). A brief indication of the nature of each article cited is given.

**Sources of heat for cotton drying,** C. A. BENNETT, V. L. STEDBRONSKY, and W. J. MARTIN (*U. S. Dept. Agr., Misc. Pub. 385 (1940), pp. 23, figs. 19*).—The advantages to both producer and ginner derivable from drying cotton before ginning are briefly summarized, and figures showing the increasing use of driers (800, handling nearly 1,000,000 bales in 1938, as against only 15 driers handling about 25,000 bales in 1931) are stated.

Of the 3 heat sources now used, a survey made in 1938–39 showed 73 percent of the driers reported upon using steam heat, 20 percent using air-heating furnaces, and 7 percent using waste heat from engines. The nature of the equipment needed for the use of these 3 sources of drier heat is discussed, and cost per bale, advantages and disadvantages in operation, and other characteristics are indicated for each method. Fuel for drying by steam heat is estimated to average a little over 16 ct. per bale, for an air-heating furnace about 12 ct., and for engine waste heat, both that from the engine cooling water and that from the exhaust gases being utilized, slightly less than 6 ct. per bale. In connection with the last-named source of heat, however, it is noted that there will often be need for a supplementary source of heat. Combinations of engine heat with other air-heating equipment are described and illustrated by photographs, diagrams, and, in part, by dimensioned drawings. Numerous experimental observations and recommendations with respect to economical and efficient set-up and operation are given in connection with the various forms of drier equipment dealt with.

**Dehydrated and sun-cured hay,** S. I. BECHDEL, A. W. CLYDE, C. O. CROMER, and P. S. WILLIAMS (*Pennsylvania Sta. Bul. 396 (1940), pp. [2]+24, figs. 8*).—For artificial drying of hay, both rotary drums and conveyor machines were tested. To accelerate field drying, experimental crushers, cracking stems by passing the freshly cut hay between rolls, were tried with encouraging results. The bulletin also reports results of feeding experiments with dairy cattle showing the superiority of artificially dehydrated hays over field-cured or silage products.

The drum drier used feeds the chopped hay material into a current of hot gases and heated air drawn from the furnace into the innermost of three concentric drums, to pass backward between the innermost and the second drum and forward again between the second and outer drum to the outlet of the exhaust fan. This machine evaporated, at its rated capacity, 1 ton of water per hour, producing  $\frac{3}{8}$  ton of dried hay (about 12 percent moisture content) from freshly cut alfalfa of 75 percent moisture content or  $\frac{3}{4}$  ton from partially dried material of 60 percent moisture content. The exhaust fan could be operated successfully at somewhat less than 1,100 r. p. m. instead of the recommended speed of 1,350 r. p. m. with a decrease in exhaust-heat loss and in exhaust-fan power consumption. Fairly complete data from a 7½-hr. run are tabulated. The conveyor drier, of the countercurrent type, passes the furnace gases first through a long tunnel under the drier and through a screen to prevent sparks from reaching the hay, and then back against the motion of the conveyor, baffles

causing the gases to pass alternately upward and downward through the mat of hay. The freshly cut material for this drier is chopped at 1½ in. and distributed in a layer of uniform thickness by a mat-forming device. The thermal efficiencies of the conveyor machines were 63 percent for the smaller and 65 percent for the larger, as against 67 percent found for the concentric drum type.

It is believed that the cost of dehydration, including all overhead, will vary between \$5 and \$10 per ton. Fuel oil can be burned with better efficiency and automatic control but the local coal production makes coal usually the cheaper fuel in Pennsylvania. It is concluded that large initial investment, the lack of small movable driers compelling cooperative ownership, and the necessary haulage of green forage and hay render the total cost too high to permit dehydrated hay to compete with sun-cured hay in dairy feeding. Dehydrated alfalfa, however, even at a cost much higher than sun-cured alfalfa, is much in demand for poultry rations. The supply of dehydrated alfalfa has never exceeded the demand in this country.

The experimental crusher described passes the cut forage material between rolls, cracking the stems lengthwise with very little effect on leaves, and drops the crushed hay to the ground for natural drying. Hay so treated dried enough for storage in about 1 day less than the usual curing time. The crushed hay dried no faster in the artificial driers than the untreated material, but the crushing treatment is considered to have some advantage when partial field drying is to precede artificial dehydration. Crushing soybean hay reduced the field drying time from 17 to 5 days and resulted in a better product. It is expected that a practical crusher will be on the market soon.

**The effect of position in the bin and temperature differentials on loss of weight of potatoes in storage** (*New Hampshire Sta. Bul. 319 (1940), p. 30*).—Data are reported from a study of three types of air intake for the ventilation of potato bins, by O. R. Butler and P. T. Blood.

**Experiments with new electric devices for pasteurizing soils**, A. G. NEWHALL ([*New York*] *Cornell Sta. Bul. 731 (1940), pp. 38, figs. 21*).—Consideration of the thermal death points of more than 120 plant-pathogenic microorganisms, coupled with practical soil tests, led to the conclusion that a final soil temperature of 65° C. (149° F.) is a sufficient pasteurization to kill all important plant pathogens and most weed seeds.

Ordinary soil-heating cable failed to withstand the temperature required for soil-pasteurization work. An induction type of electric pipe grid was found too costly, both in material and labor. Soil in greenhouse benches and ground beds was brought up to pasteurizing temperatures with a series of buried portable pipe-type heaters, of 0.75-in. galvanized pipe, having a rating of approximately 100 w. per linear foot and spaced to give from 220 to 400 w. per cubic foot of soil. These, however, must be buried, dug up, and reset at frequent intervals, and attention was turned to the possibility of generating steam with electric heating units close to the soil but not buried in it. A portable, electrically operated, inverted steam pan, with which pasteurizing temperatures in bench and ground-bed soil were obtained to a depth of from 7 to 10 in. in 2 hr. with the expenditure of approximately 1.5 kw.-hr. per square foot of soil, appeared to have promise as a means of treating coldframe, hotbed, cutting-bench, seedbed, and slat-house soil while in place.

Successful use was made of the new Nixon electric dairy-utensil steamer for pasteurization of soil in flats, or trays. In a series of more than 250 test runs it was shown that pasteurizing temperatures could be obtained in from 2 to 3 hr. at an expenditure of approximately 1.37 kw.-hr. per cubic foot of soil treated. No appreciable pressure of the steam generated is necessary for adequate soil

treatment. A continuous or semiflash type of electric soil pasteurizer was tested. In this device the soil is placed in a hopper at one end and discharged 5 min. later from the other end, having attained a temperature of from 65° to 80° C. on its way through at an expenditure of 1.5 kw.-hr. per cubic foot of soil treated.

**Poultry equipment, H. H. ALP.** (Coop. U. S. D. A.). (*Illinois Sta. Cir. 506 (1940), pp. 20, figs. 32*).—In this revision and extension of Circular 333 (E. S. R., 60, p. 882), suggestions for the construction of the following devices are accompanied by dimensioned drawings: Simple chick feeders, indoor hen feeders, weatherproof range feeder, open nests, and roosts and droppings board or pit. Other equipment, discussed and shown in photographs or in drawings without dimensional detail, comprises chick roosts and brooder, outdoor wire pens, movable roosting shelters, shade shelters, catching crate, egg storage cellars, trap nests, range watering device, range watering system, heater for water trough, electric water heater, broody coop, and screen platform. The circular deals with models and types of equipment that are simple to construct and have proved their worth in everyday use on poultry farms in Illinois.

**Equipment for burning sulfur in empty greenhouses and in mushroom houses for the destruction of mites and insects, O. K. HEDDEN and C. R. NEISWANDER.** (Coop. U. S. D. A.). (*Ohio Sta. Bimo. Bul. 204 (1940), pp. 63-72, figs. 8*).—The authors describe apparatus which can be constructed from steel barrels, the simpler of the two devices being a natural-draft burner which must be placed inside the building to be fumigated. Sulfur trays with suitable perforated bottoms are set one above and one below a charcoal-burning grate in which briquets are used. Placing two or three burning briquets in each of the two sulfur trays was found desirable to insure prompt ignition of the sulfur. A 50-lb. sulfur charge was found to be best burned when 35 lb. were placed in the upper and 15 lb. in the lower tray. Such a burner required a metal shield between it and any nearby woodwork to obviate fire hazard.

A forced-draft burner of similar construction could be supplied with sufficient air (a fan delivering about 250 cu. ft. per minute being recommended) by a ½-hp. gasoline engine or electric motor. This device gave better control, lessened fire risk by placing the combustion chamber entirely outside of the building, and permitted adding more sulfur through a funnel fitted into the top of the burner. The sulfur dioxide from this burner was blown into the building through a suitable length of 6-in. stovepipe ending in a T with screen-covered openings. It was necessary to provide a movable baffle plate capable of being turned in front of the air inlet after the sulfur began burning rapidly, since exposing the burning sulfur to the direct draft burned or melted the metal trays. Construction of the forced-draft burner necessarily involves some welding. Drawings adequate for the construction of both types of burner are included.

The build-up of sulfur dioxide concentration was determined at the upper and lower bench levels in two experiments and at two points nearly at the same level in a third experiment, the data being presented in three graphs. Concentrations lethal to red spiders and their eggs were secured at all points where test leaves infested with these pests were placed, but the chemical determination of the concentrations attained and of the rates at which the concentration rose and fell indicated a necessity for the very careful closing of all openings, especially those in the upper part of the building. Despite the fact that sulfur dioxide is heavier than air, it was shown to be more difficult to secure high concentrations of the gas in the lower than in the upper part of the structure under fumigation. It was concluded that 3 lb. of sulfur per 1,000 cu. ft. should produce a concentration of sulfur dioxide amply sufficient to kill all forms of mite and insect life.

**Plans of farm buildings for Southern States.** (Coop. land-grant colleges of Ala., Ark., Fla., Ga., La., Miss., N. C., Okla., S. C., Tenn., Tex., and Va.). (*U. S. Dept. Agr., Misc. Pub. 360 (1940), pp. 123, figs. 124*).—Dwelling houses, barns, and shelter, storage, and work buildings are covered. The plan, a section, and a sketch of the completed structure are accompanied in each instance by a brief description and a reference number to be given in ordering the working drawings through the county agricultural extension agent or the extension agricultural engineer at the cooperative land-grant college or university.

## AGRICULTURAL ECONOMICS

[Papers and notes on agricultural economics] (*Jour. Farm Econ., 22 (1940), No. 2, pp. 411-497, figs. 5*).—Included are the following papers: Training and Recruitment of Agricultural Economic Personnel—I, A General View, by H. C. Taylor (pp. 411-414), II, The Civil Servant, by F. V. Waugh (pp. 415-417) (U. S. D. A.), and III, The South, by R. J. Saville (pp. 418-420) (La. State Univ.); Agricultural Labor and the Fair Labor Standards Act of 1938, by H. W. Hannah (pp. 421-429) (Univ. Ill.); A Desirable Foreign Trade Policy for American Agriculture, by J. S. Davis (pp. 430-439); An Application of Analysis of Covariance to Price-Quality Relationships of Eggs, by L. E. Cron (pp. 440-445) (Univ. Md.); Export-Dumping Plans, by F. L. Thomsen (pp. 446-459), and Role of Soil Depletion in Land Valuation, by D. B. Ibach (pp. 460-472) (both U. S. D. A.); County Planning for Land-Use Adjustment, by J. G. Crawford and G. Lange (pp. 473-483); and On Agricultural Policy, by R. R. Renne (pp. 484-492) (Mont. State Col.). Notes are included as follows: Federal-State Relationships in Agriculture, by O. B. Jesness (pp. 493-495) (Univ. Minn.); and Memory Errors as They Affect Survey Data, by O. Brownlee (pp. 495-497), and Market-Sharing in the Packing Industry—A Correction, by W. H. Nicholls (p. 497) (E. S. R., 83, p. 405) (both Iowa State Col.).

[Economic Library Lists 5-8, 10-12] (*U. S. Dept. Agr., Bur. Agr. Econ., Econ. Libr. Lists 5 (1939), pp. 8; 6, pp. 13; 7, pp. 3; 8, pp. 13; 10 (1940), pp. 11; 11, pp. 58; 12, pp. 4*).—No. 5, Acts Administered by Agricultural Marketing Service, by M. E. Wheeler, is a list of acts administered by the Agricultural Marketing Service of the Department.

No. 6, Periodicals Relating to Shipping, by E. M. Colvin and N. G. Larson, includes 57 references to periodicals containing information on foreign, coastal and intercoastal shipping, and commerce of the United States, Canada, Argentina, Brazil, India, Australia, and South Africa.

No. 7, Electrical Properties of Cotton—Some References to the Literature, January 1931-October 1939, by E. L. Day, includes 7 references.

No. 8, Sea Island Cotton—Selected References, by E. L. Day, includes 92 selected references covering the United States, the West Indies, and other countries.

No. 10, The Tomato Industry in Puerto Rico and Cuba—A Short List of References, by H. E. Hennefrund, includes 47 selected references.

No. 11, The Dairy Industry in the United States—Selected References on the Economic Aspects of the Industry, by L. O. Bercau, includes 323 selected references on the economic aspects of the dairy industry in the United States, mainly issued from January 1939 through June 1940.

No. 12, Planning for the Farmer—A Short Reading List of Free and Inexpensive Material, is a list of 25 free or inexpensive bulletins, articles, etc., on the farm, community, county, State, and nation.

[Investigations in agricultural economics by the Massachusetts Station] (*Massachusetts Sta. Bul. 369 (1940), pp. 5, 6, 44, 45*).—Results of studies not

previously noted are reported as follows: (1) Receipts and labor income on dairy farms, by C. R. Creek and E. Rauchenstein, (2) cost of production and labor used per acre in producing set onions on 25 farms in 1938, by Creek and C. Bokina, (3) man-hours used in packing celery on 15 market-garden farms, by Creek and R. Elliott, and (4) findings as to the land uses in Worcester County, by D. Rozman.

[Investigations in agricultural economics by the Nebraska Station, 1939] (*Nebraska Sta. Rpt. [1939], pp. 49-52, 56*).—In addition to results previously noted, brief statements are included as to the average cost per 100 lb. 1930-35 for shipping hogs to Omaha, and the cost in 1939 of pumping water for irrigation at the North Platte Substation, the cost of irrigating, and the increased yields of potatoes, corn, and Atlas sorgo.

[Investigations in agricultural economics by the New Hampshire Station, 1939] (*New Hampshire Sta. Bul. 319 (1940), pp. 12-18*).—In addition to results previously noted, statements of findings are included on (1) the ownership and use of lands in Grafton County, (2) results and costs of clearing pasture plats by burning, pulling, and cutting brush, and (3) practices, economies available and utilized, and possible adjustments in purchases by farmers.

[Investigations in agricultural economics by the Ohio Station] (*Ohio Sta. Bimo. Bul. 204 (1940), pp. 85-88, 96-98, 112*).—Included are articles on Operating Costs of Portable Sprayers, by C. W. Ellenwood, analyzing the cost of spraying with three different portable sprayers used by the station during the period 1925-39, and on Difficulties Faced By Cooperatives in Marketing Poultry and Eggs, by C. G. McBride and R. L. Baker, based on a survey of poultry and egg cooperatives. The table of index numbers of production, price, and income, by J. I. Falconer (*E. S. R.*, 83, p. 257), is brought down through March 1940.

An economic background for agricultural research in Puerto Rico, E. B. HILL and S. L. DESCARTES (*Puerto Rico Col. Sta. Bul. 51 (1939), pp. [4]+61, figs. 10*).—This is a description and discussion of the general economy of the island, with particular reference to agriculture and its problems. The several sections deal with exports; imports; industrial employment; physical, social, and economic factors; land use; commercial cash crops; food supply, and the creation of small farms. English and Spanish summaries are included.

Land use planning under way (*U. S. Dept. Agr., 1940, pp. III+48, figs. 10*).—The Mount Weather agreement of 1938 between the Department and the State land-grant colleges to sponsor land planning by farmers, the organization and functioning of the State, county, and community committees, and some of the results of county land planning in different States are described.

Tailoring conservation research to fit the needs of farm planning, N. W. JOHNSON (*U. S. Dept. Agr., Bur. Agr. Econ., 1940, F. M. 9, pp. [1]+11*).—This is a brief discussion of the planning and presentation of the results of research in conservation for use in farm planning.

Agricultural land-use planning in the Territory of Hawaii, 1940, J. W. COULTER (*Hawaii Univ., Agr. Ext. Bul. 36 (1940), pp. 124, figs. 33*).—This monograph is a partial revision of the bulletin previously noted (*E. S. R.*, 70, p. 850). The background of the problem of land planning in the Islands, the major aspects of land utilization for agricultural purposes, and the important phases of land-use planning are discussed.

Planning minimum sized farms for the Beadle County area in central South Dakota, J. L. PASCHAL, A. G. NELSON, and O. ROGENESS. (*Coop. U. S. D. A.*). (*South Dakota Sta. Bul. 341 (1940), pp. 63, figs. 5*).—Some of the more important problems and means of increasing the stability of the agricultural economy of the area are analyzed with a view to determining a type and minimum size of farm that will support an average family over a period of years and to

suggesting policies that will assist farm operators, landlords, and public agencies in developing and maintaining a desirable type of agriculture. The topography, soils, climate, crop production, etc., of the area and the development of Beadle County are described. The planning and operation of farms in the area are discussed. The situation in Vernon and Richmond townships in 1937—number, tenure, mobility, financial status, age, etc., of farm operators, family situation, land ownership and use, future land use, farm organization and equipment, etc.—is described.

**The place which agricultural economics should occupy in a program of development for the South** (*Conf. Agr. Econ., Chattanooga, 1939, Proc., pp. [5]+69, fig. 1*).—Included are the discussions at a conference of deans, directors, members of the staffs in agricultural economics, etc., of the southern State agricultural colleges, the General Education Board, and others held at Chattanooga, Tenn., June 8–13, 1939, on content of courses for training in agricultural economics; considerations in outlining a program of research in agricultural economics; allocation of work; faculty development and recruiting; graduate student selection, preparation, time, and amount of aid; and institutional cooperation for a program of development in agricultural economics.

**Production responses of dairy farmers in east-central Minnesota**, E. G. STRAND and E. HOLE. (Coop. Minn. Expt. Sta.). (*U. S. Dept. Agr., Bur. Agr. Econ., Farm Mangt. Rpt. 6 (1940), pp. 71, figs. 10*).—The physical characteristics, agricultural development, and type of farming in the area are described. The annual variations in certain physical and economic factors and their effects on crop, livestock, and butterfat production are discussed. A detailed analysis is made of the production responses of 54 representative dairy farmers during the period 1927–37.

**The cutover region of Wisconsin** (*Wis. State Planning Bd. Bul. 7 (1939), pp. [11]+146, pls. 13*).—This is a report on conditions in the area, with recommendations for rehabilitation. It deals with general conditions; property tax base, county zoning ordinances, public land ownership, and tax delinquency; agriculture; forestry, recreation, and wildlife; mineral resources, industry, and water power; schools and school administration; local government, taxation, and grants in aid; unemployment and relief; the measures proposed for rehabilitation, operating agencies, problems, etc.; and the organization and membership of the Northern Lakes States Regional Committee.

**Philippine agriculture, a problem of adjustment**, O. L. DAWSON (*U. S. Dept. Agr., Off. Foreign Agr. Relat., Foreign Agr., 4 (1940), No. 7, pp. 381–456, figs. 20*).—Part 1, Resources and Historical Development—Problems of Future Economy, summarizes the resources, historical development, and problems of future economy, and part 2, Commodity Studies, discusses the present position of different agricultural commodities with regard to future prospects.

**Tobacco trade with Latin America**, J. B. GIBBS (*U. S. Dept. Agr., Off. Foreign Agr. Relat., 1940, F. S. 82, pp. 9*).—The production, consumption, exports, and imports of tobacco and tobacco products by Mexico and the countries of Central America, South America, and the West Indies, and the United States' exports to and imports from these countries are discussed.

**Cost of production and price margins for Long Island potatoes, 1939**, R. L. MARGOLIN (*N. Y. City Dept. Invest., Studies Munic. Prob., No. 2 [1940], pp. [1]+VIII+39*).—Analysis is made of marketing through regular wholesale channels and through the farmers' section of the Wallabout market, New York City, July 1, 1939, to January 15, 1940. The average cost of production was 95 ct. per 100 lb.; the margins in selling through wholesale channels were farmer 26 ct., country dealer 37 ct., wholesaler 12 ct., and retailer 90 ct.; and through the farmers' market 60 ct. and retailer \$1.05.

**Ten-year cost study, production of fluid milk, region of Montreal, R. LECUYER** (*Quebec: Dept. Agr., pp. [1]+22*).—This study, made by the survey method, covers the period 1929–38, inclusive, and had for its purpose the determination of the items and total costs and their variations for different herds, the relation of different factors to total costs, etc.

**Cost of transporting milk and cream to Boston, L. T. SONLEY.** (Coop. U. S. D. A. et al.). (*Vermont Sta. Bul. 462 (1940), pp. 56, figs. 20*).—The evolution of transportation facilities and rate structures for milk, the trends in methods of transportation of milk, 1930–39, the variations in service included at different rates, and the costs of such services and other factors affecting costs of transportation are discussed. A comparison is made of truck and rail rates in effect September 1, 1939.

Rail rates were increased approximately 75 percent from 1916 to 1932. Since 1932 reductions totaling approximately 75 percent of the previous increases have been made. During the last decade the principal changes in the transportation in the Boston milkshed were an increase in receipts of cream from midwestern points from 16 to 32 percent of the total receipts, the practical disappearance of less than carlot shipments, a marked shift from rail to truck shipments, and a great increase in the use of tank cars. It is estimated that in 1939 45 percent of the milk and 26 percent of the cream were transported by truck, and that 86 percent of the rail shipments and 21 percent of the truck shipments were handled in tanks.

**Short-term credit for agricultural production in South Carolina, W. T. FERRIER** (*South Carolina Sta. Bul. 327 (1940), pp. 40, figs. 4*).—In cooperation with the Farm Credit Administration approximately 842 farm operators were interviewed and additional information obtained from 500 cash-borrowing owners, part-owners, and tenants, 62 sharecroppers, 17 banks, 8 other lending agencies, and 12 merchants in 5 counties of the State. The records included 14 from Negro operators. In addition records of cash borrowing of 108 Negro farmers obtained by the South Carolina Agricultural and Mechanical College for Negroes and 36 records of white users of short-term credit in undesignated counties were used. The extent and size of short-term loans, the amount of loans and sources, the purpose for which the credit was used, amounts of merchant credit, installment purchasing, cash on hand at the beginning of the crop season, seasonality of credit needs, length of loans, interest charges and amount of budgetary loans, and security requirements are analyzed. The comparative costs of bank and production credit association credit, splitting the line of credit, adequacy of production credit, the coordination of credit activities, and the existing credit facilities are discussed. Comparisons are made with the findings in the study made in 1926 (*E. S. R., 67, p. 615*).

Approximately 60 percent of the farmers borrowed for crop or livestock production, about \$13,000,000 being borrowed in 1937. Credit supplied by merchants decreased from 31.6 percent in 1926 to less than 10 percent for white operators in 1937. Installment purchases constituted 4.1 percent of all purchases. Approximately 88 percent of the production credit was used for cash payments for fertilizers and farm operating expenses. Of the 500 cash borrowers, 25 percent had no cash on hand at the beginning of the crop season. The average cash reserves were owners \$277, part owners \$361, and tenants \$114. The greatest number of loans were made from March 1 to 15, and were paid between October 1 and 15, the average term being 7.1 mo. The average rates of interest were production credit associations 4 percent, Farm Security Administration 5 percent, banks 7 percent, and individuals from 4 to 20 percent. Slightly over one-third of the loans of production credit associations were on the budget plan. Livestock and crop security was most often pledged, but most production credit

associations required all farm equipment also. The percentage of bank loans secured by crops or livestock increased from 34 percent in 1926 to 78.1 percent in 1937. Due to the service charges of the associations, loans of \$300 or less were usually obtained more cheaply from banks than from production credit associations. There were adequate loanable funds and credit facilities for farmers who could meet the security requirements of banks and production credit associations.

"The existence of three Federal or Federally supervised short-term agricultural credit agencies confuses many farmer borrowers and their separate operation leads to some duplication of field and office activities. Since crop and feed loan offices, production credit association, and Farm Security Administration offices are all under the administration of the Secretary of Agriculture, a more efficient coordination of their lending activities should be possible."

**Sharecroppers and wage laborers on selected farms in two counties in South Carolina, E. J. HOLCOMB and G. H. AULL. (Coop. U. S. D. A.). (*South Carolina Sta. Bul. 328 (1940), pp. 70, figs. 4*).**—This study was made to ascertain the amount of shift in tenure status between sharecroppers and wage laborers, the effects of such shift, the factors associated with the shifts, and prospective shifts. The two counties, Laurens and Florence, were selected as typical of the upper Piedmont cotton area and the lower Coastal Plain tobacco and cotton area, respectively. The analysis is based chiefly on the records obtained by personal interviews with 105 farm operators, 70 sharecroppers, 31 wage families, and 10 single wage hands in Laurens County, and 61 operators, 79 sharecroppers, 44 wage families, and 14 single wage hands in Florence County selected at random irrespective of cooperation with the soil conservation and domestic allotment program. The historical development of the sharecropper and wage-labor systems, the advantages of each to the laborers and the farm operators, the effects of soil conservation and domestic allotment programs, and farm organization on the farms surveyed are described. An analysis is made for each county of the income of sharecroppers and wage laborers in relation to family composition and days worked, home-use goods and perquisites, income by income groups, seasonal distribution of employment, credit arrangements (croppers only), trends in economic status, mobility, preference between the systems, etc. Sharecropper land use, economic advantage of each type of labor, and means of improving income of each type of labor are discussed.

Some of the findings and conclusions were: From 1933 to 1937 the net changes in the numbers or tenure status in both counties were insignificant, and those that occurred were closely related in direction but not in magnitude with the program of the Agricultural Adjustment Administration. The economic status of both classes was more closely related to size of family and its working force than to tenure status insofar as cash income is concerned. A change from sharecropping to wage labor results in a rather sharp decline in the family income from home-used goods and perquisites. The income of both groups could be increased greatly by increased production of home-used goods. A very marked change in wage rates in relation to prices of cotton and tobacco will be necessary before the income of wage families, including home-used goods and perquisites, will equal that of sharecroppers.

"Until the technology of cotton and tobacco production is greatly improved, farmers in these areas will find little encouragement to make complete shifts to the use of wage laborers in lieu of sharecroppers."

**American cooperation, 1939 (*Washington, D. C.: Amer. Inst. Coop., [1939], pp. XII+695, figs. [6]*).**—Included are the papers presented at the fifteenth summer session of the American Institute of Cooperation held August 7-11, 1939,

on cooperation and Federal policy in the national economy, intergroup cooperation, education in cooperation, public relations and publicity, and cooperative marketing of dairy products, grain, livestock, poultry and eggs, and fruits and vegetables, and cooperative purchasing of farm supplies.

**Development of cooperative cotton ginning**, O. W. HERRMANN (*Farm Credit Admin.* [U. S.], *Coop. Res. and Serv. Div.*, *Cir. C-112* (1939), pp. [2]+11+68, *figs. 11*).—The development of local cooperative gins in Oklahoma, southeast Missouri, Texas, New Mexico, Arizona, Mississippi, and California, the organization structure and operating policies and the gin programs of such associations, and the associations of local cooperative gins in Oklahoma and Texas are described and discussed.

**Cooperative marketing of livestock at Cincinnati by the Producers Cooperative Commission Association**, H. H. HULBERT (*Farm Credit Admin.* [U. S.], *Coop. Res. and Serv. Div.*, *Bul. 34* (1939), pp. VI+130, *figs. 24*).—The development and structure of the association, the major trends in receipts, the field services and educational activities, the handling of complaints, sales policies, branch operations, etc., of the association, and the significance of transportation to cooperative marketing of livestock are discussed. An appendix includes statistical data.

**Livestock auction sales in the United States**, C. G. RANDELL and L. B. MANN (*Farm Credit Admin.* [U. S.], *Coop. Res. and Serv. Div.*, *Bul. 35* (1939), pp. VIII+116, *figs. 28*).—The development of livestock auctions in the United States, the plant equipment, operating methods, financial responsibility, statutes and regulations governing such auctions, and the viewpoints of producers and others toward these auctions are discussed, and an appraisal of the advantages and disadvantages, etc., is made. Appendixes include copies of operating forms in use and a brief summary of the reorganization and regulation of livestock markets in the British Isles.

**Base allotment or quota plans used by farmers' cooperative milk associations**, W. C. WELDEN and L. F. HERRMANN (*U. S. Dept. Agr.*, *Farm Credit Admin.*, *Coop. Res. and Serv. Div.*, *Misc. Rpt. 23* (1940), pp. [3]+41).—"This report deals briefly with experiences in selected milk markets in the use of allotment or quota plans." The historical development of base or quota plans, the variations between markets, types used in selected markets, and the operating results of base plans are described and discussed.

**Butter marketing by cooperative creameries in the Middle West**, P. E. QUINTUS and T. G. STITTS (*Farm Credit Admin.* [U. S.], *Coop. Res. and Serv. Div.*, *Bul. 36* (1939), pp. VI+66, *figs. 12*).—The importance of cooperative creameries, the market outlets for butter, sales to patrons, local sales, outlets for shipped butter, direct sales to central markets, sales through country concentration plants, the special services of cooperative regional sales agencies, packaging and transportation of shipped butter, and the selection of marketing outlets and selling arrangements are described and discussed.

**Financial results of the operations of farmers' elevators in Illinois in 1938 and 1939**, L. J. NORTON and G. W. FREEMYER (*Illinois Sta.*, 1940, *AE-1445*, pp. [1]+30, *figs. 2*).—This publication supplements that previously noted (*E. S. R.*, 78, p. 269). Records of 83 companies in 1938 and 106 companies in 1939 were studied.

The average rate of earning on total assets was 8 percent in 1938 and 11 percent in 1939. The earnings per bushel for companies with more than 90 percent of their business made up of grain were corn 1.9 ct., oats 3 ct., and soybeans and wheat 3.8 ct. The average gross earnings on merchandise were 13.8 percent in 1939 and 12.4 percent in 1938. In both years the average cost of handling grain,

including 6 percent on net worth of business, was 1.7 ct. per bushel. The average net return in 1939 was 0.55 ct. In 1939, 66 companies paid or authorized dividends on stock and 28 paid patronage dividends.

**North Dakota farm prices, W. L. ETESVOLD** (*North Dakota Sta. Bimo. Bul.*, 2 (1940), No. 6, pp. 18, 19).—This series (E. S. R., 83, p. 553) is continued for May and June 1940.

**Reasons for differences in the price of apples received by Ulster County [New York] growers, 1937 crop, F. A. HARPER** (*Cornell Univ., Dept. Agr. Econ. and Farm Mangt.*, 1939, AE-263, pp. 58, figs. 27).—An analysis is made of the effects of variety, grade, size, time of sale, type of market outlet, by whom sales were made, kind of storage, and type of container on prices received, and of how growers marketed their crops.

**Statistical analysis of the annual average f. o. b. prices of canned apricots, 1926-27 to 1939-40, H. R. WELLMAN and R. S. BYLIN** (*California Sta. Mimeog. Rpt.* 72 (1940), pp. [1]+9, fig. 1).—The average relationship between f. o. b. prices of canned apricots and the three factors studied were (1) a change of a million cases in domestic shipments was accompanied by a change of 40 ct. per case in the price in the opposite direction, (2) a change of 10 points in the index of nonagricultural income payments in the United States was accompanied by a 43 ct. change in price in the same direction, and (3) a change of 10 points in the adjusted price of competing fruits was accompanied by a 26 ct. change in price in the same direction.

**Statistical analysis of the annual average f. o. b. prices of Pacific Coast canned Bartlett pears, 1926-27 to 1939-40, H. R. WELLMAN and R. S. BYLIN** (*California Sta. Mimeog. Rpt.* 73 (1940), pp. [1]+9, fig. 1).—Using  $X_1$ =annual average f. o. b. price per case of canned Bartlett pears,  $X_2$ =domestic shipment of Pacific coast canned Bartlett pears in millions of cases,  $X_3$ =index of nonagricultural income payments in the United States in percentage points, and  $X_4$ =adjusted index of prices of competing canned fruits in percentage points, the multiple linear regression equations fitted by least squares were:  $X_1 = -3.41687 - 0.30491X_2 + 0.05000X_3 + 0.03478X_4$  and  $X_2 = -2.49468 - 1.61200X_1 + 0.07455X_3 + 0.04312X_4$ . The standard errors of estimate were  $\bar{S}_{1,234} = \$0.201$  per case and  $\bar{S}_{2,134} = 463,000$  cases, and the adjusted coefficients of multiple correlation were  $\bar{R}_{1,234} = 0.968$  and  $\bar{R}_{2,134} = 0.652$ . The linear relation between f. o. b. prices and each of the three factors are presented graphically, and show that if the other two factors are held constant on an average (1) a change of a million cases in domestic shipments was accompanied by a change of 30 ct. per case in the price in the opposite direction, (2) a change of 10 points in the index of nonagricultural income was accompanied by a change of 50 ct. in price in the same direction, and (3) a change of 10 points in the adjusted index of prices of competing canned fruits was accompanied by a change of 35 ct. in the price in the same direction.

## RURAL SOCIOLOGY

**Cooperative rural research, C. E. LIVELY.** (Univ. Mo.). (*Social Forces*, 18 (1939), No. 2, pp. 200-210).—The author discusses the historical development of cooperative rural sociological research in the United States.

**Natural increase in the population of New York State, W. A. ANDERSON** ([*New York*] *Cornell Sta. Bul.* 733 (1940), pp. 22, figs. 8).—The index of natural reproduction in New York State is 88, or 12 points below the index necessary for replacement. However, the total rural population of the State has a reproduction index of 120. The rural farm population is reproduced at the rate of 139 and the rural nonfarm population at the rate of 113.

It is concluded that New York will continue to be an area of absorption for excess population produced elsewhere. In 1930, 37.8 percent of its inhabitants were born outside the State. Mobility within the State is also likely to increase. As of 1930, only 97 men to every 100 women came to New York, while of those leaving New York State for other areas there were 103 men to every 100 women. The population moving into New York State is chiefly adult. The migration of excess population from the rural areas of population overproduction to the urban areas of underproduction means that the rural areas bear the cost of rearing and educating these persons for their productive use by the urban regions. Institutions and organizations in the rural areas, especially those of a voluntary type such as the church, suffer particularly from this migration, for the young people migrate just when they could begin to contribute support and leadership.

**Preliminary report on development of economic opportunities in Montana for migratory and stranded families** (*Helena: Mont. State Planning Bd., 1939, pp. [109, pls. 17]*).—This is an attempt to indicate the scope of the problem of migratory and stranded families in the State, its principal causes, its social and economic consequences, the adjustments which have been made to date, a statement of resettlement opportunities for migratory and stranded farm families in the State, and some recommendations and suggestions for the future. The report contains data on the number of migratory and stranded families in the State, an estimate of the number of opportunities of re-establishing such families on irrigated tracts, and the approximate cost of such rehabilitation.

**Migratory farm labor in the Western States**, P. H. LANDIS (*Wash. State Col. Res. Studies, 8 (1940), No. 1, pp. 45, 46*).—"The disorganizing forces of a transitional age have made their disrupting influences felt on the agricultural labor situation. Included among farm laborers are castaways of mechanized farming areas and of urban industrial centers; former farm owners, tenants, and sharecroppers who have been forced downward on the agricultural ladder; and youth, both those hoping some day to farm independently and those unable to find other employment. . . . The migratory farm worker exists because there is a seasonal demand for his services in intensive crop areas where the supply of local labor is insufficient. The situation in the Yakima Valley, Wash., is typical. Some 4,000 to 6,000 farm workers reside in the valley, yet 35,000 full-time workers are needed for the hop harvest during the second week in September; within 2 weeks the harvest is completed. A month later 12,000 workers are required for the apple harvest. By midwinter a total of only 500 workers is needed. Adding to the seasonal migratory labor problems has been the stream of migrants from the drought States in quest of employment. . . .

"Farm laborers as a group have benefited from few of the social protections which have been extended urban industrial workers through social legislation and welfare programs. . . . Government is beginning to take steps to improve the lot of farm workers in appreciation of the fact that this is a social rather than an individual problem."

**Forces influencing rural life: A study of a central Pennsylvania community**, M. E. JOHN (*Pennsylvania Sta. Bul. 388 (1940), pp. [2]+28, figs. 11*).—Howard community in Centre County was selected for study. Three periods are compared—1770–1875, 1875–1910, and 1910 to the present—economically and socially. A number of recommendations are made for more effective use of local resources and for social evolution.

**Composition and characteristics of the population of rural relief households in South Carolina**, B. O. WILLIAMS and W. S. CRAWFORD (*South Carolina*

*Sta. Bul. 326 (1940), pp. 32, figs. 13*).—This bulletin deals with the relief situation in South Carolina during 1935, presenting an analysis of the composition and characteristics of the population in rural households which received aid from the Federal Emergency Relief Administration. Included in the study were 3,430 rural relief households, containing 14,098 persons. Of the heads of these households, 41.4 percent were white and 58.6 percent were Negro; 59.4 percent were male. Among the whites, about 1 in every 7 of the heads had received no formal schooling, and 70.1 percent had attained not more than the seventh grade in school. Of the Negro heads of households, 46.9 percent had received no formal schooling, and three-fourths had attained less than fourth grade. Of all the heads, 65.2 percent were engaged in agriculture and 34.8 percent in nonagricultural occupations. Fifty-three percent of the heads had received direct relief, 38.2 percent work relief, and 8.8 percent both direct and work relief. Loss of employment was given as the reason why the largest number of cases went on relief. The study indicates that relief is tied up with the general social and economic conditions.

**Problems of rural youth in selected areas of North Dakota, D. G. HAY, J. P. GREENLAW, and L. E. BOYLE. (Coop. U. S. D. A.). (North Dakota Sta. Bul. 293 (1940), pp. 67, figs. 14).**—This survey indicated that the total numbers and the proportion of youth in the population of North Dakota have reached an all-time high in a period when there is no longer any free land, when depression and drought have greatly reduced the agricultural income of the State, and when there is a scarcity of opportunities elsewhere. In an endeavor to improve their situation, somewhat less than half of the older youth left home, but most of those who left remained nearby where opportunities were probably little better than at home. Most of those who remained at home found employment scarce and wages low. Approximately half of all youth and more than half of farm youth had only eighth grade schooling or less. A majority of those who had discontinued their schooling reported that financial difficulties were the cause. School and church organizations were those most frequently attended by youth, but lesser percentages attended meetings of other organizations operative in the State.

**What problems face the rural youth of North Dakota? J. P. GREENLAW (North Dakota Sta. Bimo. Bul., 2 (1940), No. 6, pp. 7-12, figs. 3).**—A digest of Bulletin 293, noted above.

**Rural community organization, D. SANDERSON and R. A. POLSON (New York: John Wiley & Sons; London: Chapman & Hall, 1939, pp. IX+448, figs. 13).**—This is a textbook for mature students.

**The church in rural life, D. E. LINDSTROM (Champaign, Ill.: Garrard Press, 1939, pp. XIV+145).**—This book is intended to present the way to new and enlarged opportunities for service among rural churches.

**How should the permanent school fund be managed? O. A. HOLM (South Dakota Sta. Cir. 29 (1940), pp. 19, figs. 2).**—The origin, growth, investment, etc., of the permanent school fund of the State are described. House Joint Resolution No. 10 of the 1939 State legislature proposing a constitutional amendment permitting changes in the handling of the fund, is analyzed, with suggestions and recommendations.

**The nature of news, C. F. REUSS (Wash. State Col. Res. Studies, 8 (1940), No. 1, pp. 26-32).**—The author concludes that "news is a medium of communication across space, making man aware of events in his transperceptual environment and bringing one person or group into contact with another at some remote point—in another part of the city, continent, or the world."

## FOODS—HUMAN NUTRITION

[Food and nutrition studies of the Massachusetts Station] (*Massachusetts Sta. Bul.* 369 (1940), pp. 19, 20, 29-31, 41, 42, 71-73, 74, 75).—Included in this progress report are summaries of studies, several of which represent a continuation of earlier work (E. S. R., 81, p. 591), by J. E. Fuller and W. B. Esselen, Jr., on iodine in the ration with reference to the coli : acidophilus ratio in the stools of white rats, Fuller on indol production by *Escherichia coli*, and Fuller and E. R. Higgins on the relationship of onion juice to bacterial growth (pp. 19, 20); by M. E. Freeman and W. S. Ritchie on chemical changes in the cooking of potatoes and the preservation of spinach by canning and freezing (pp. 29-31); by W. S. Mueller and N. L. Keyock on the nutritive value of chocolate milk, Mueller and L. D. Lipman on the effect of cocoa upon the digestibility of milk proteins, and Mueller on the nutritive value of milk flavored with a water extract of cocoa (pp. 41, 42); by H. S. Mitchell, G. M. Cook, O. A. Merriam, and A. W. Wertz, with the assistance of G. J. Hadro and M. D. Henderson, on the cause and control of nutritional cataract (E. S. R., 82, p. 848), Mitchell and Hadro on the comparative effects of kelp, kelp ash, and a synthetic salt mixture on cholesterol-induced atherosclerosis in rabbits, and Mitchell, Merriam, and E. Miller on the adaptometer as an instrument for detecting vitamin A deficiency (pp. 71-73); and by C. R. Fellers and J. A. Clague on canned apple slices in sirup, Fellers, C. F. Dunker, and L. R. Parkinson on vitamin D bio-assays, Fellers, K. G. Shea, and Esselen on cocoa shell meal as a source of vitamin D for rats, Fellers and K. T. Farrell on factors influencing the nutritive value of snap beans, and Fellers and W. H. Hastings on the availability of iron in certain foods as affected by freezing (pp. 74, 75).

**Improper mixing is cause for failure of sponge cakes at higher altitudes**, W. E. PYKE and G. JOHNSON (*Colo. Farm Bul.* [*Colorado Sta.*], 2 (1940), No. 3, pp. 9-12, figs. 2).—In explaining to the housewife in the Rocky Mountain West the directions given in Technical Bulletin 27 (E. S. R., 83, p. 268) for preparing and baking whole-egg and egg-yolk sponge cakes at high altitudes, the authors state that the reason difficulty has often been experienced in the use of sponge cake recipes adjusted for altitude is that the leavening air which is whipped into the meringue during the batter mixing has been added almost entirely by chance. The method of controlling the amount of air, as developed by the authors, is described, with the tabulated formulas for whole-egg and yolk sponge cake and correct weights of one cup of batter for proper leavening at different altitudes.

**Formulas and methods for preparation of better fresh cherry juice products**, W. E. PYKE and G. JOHNSON (*Colo. Farm Bul.* [*Colorado Sta.*], 2 (1940), No. 3, pp. 4, 5).—Practical directions are given for the home preparation and pasteurization of cherry juice, with three formulas for cherry cocktails. It is noted that cold pressing yields a juice that retains the fresh cherry flavor better than hot pressing, but hot pressing yields a more highly colored juice. Cold pressed juice of the cherries of the English Morello variety is more highly colored than juices from Early Richmond or Montmorency varieties. Although there is little difference in the acidity of apple and sour cherry juice, and apple juice contains only a little more sugar than cherry juice, the latter is from four to six times more astringent. For this reason cherry juice should be diluted and sweetened to bring out its best flavor. The three cocktail formulas illustrate (1) the blending of hot processed juice and cold processed juice of a single variety of Montmorency, (2) the blending of cold and hot pressed English

Morello and cold pressed Montmorency, and (3) a straight cold pressed blend, all with appropriate amounts of 18 or 15 percent sugar sirup.

**Effectiveness of heat penetration in the canning of meat in the home by the pressure cooker both in tins and glass jars,** C. I. NELSON (*North Dakota Sta. Bimo. Bul.*, 2 (1940), No. 6, pp. 5-7).—In this brief article, prepared particularly for farm housewives in the State, studies covering the work with tin cans (E. S. R., 82, p. 556) are summarized, with recommendations for safe practices in home canning by the pressure cooker method of meat, both in tin cans and in glass jars.

**The physiological and economic bases of nutrition, I-III,** J. B. ORE (*Jour. Roy. Inst. Pub. Health and Hyg.*, 2 (1939), No. 12, pp. 661-676; 3 (1940), Nos. 1, pp. 9-24; 2, pp. 37-51).—The three Harben lectures for 1939, delivered at the Royal Institute of Public Health and Hygiene, Great Britain, were given under the following topics:

I. *Dietary standards.*—In this lecture the author discussed methods of determining the requirements for calories, protein, fat, minerals, and vitamins and factors affecting these requirements, and presented as dietary standards those of the British Medical Association, Stiebeling, and the League of Nations. Attention was called to the rather close agreement among these standards, although the first is at minimum cost, the second at moderate cost, and the third an optimum standard with no reference to cost.

II. *The assessment of the state of nutrition.*—Methods which have been used in assessing the state of nutrition were discussed under the groupings somatometric body measurements, clinical examination, and physiological tests, with the conclusion that the subject is still in the experimental stage and that what is needed most at present is a closer linking up of laboratory research and clinical observation. "The laboratory research worker is apt to overemphasize the importance of the tests he is using and may fall into grievous error unless results are controlled by expert clinical examination, which takes account of the state of health of the individual as a whole. On the other hand, clinicians trained too exclusively to deal with pathological conditions which are so gross that the layman has recognized the need for calling in the doctor are apt to pay too little attention to the all important effects of the earlier deviations from health caused by minor degrees of dietary deficiencies." It was pointed out, however, that the final and conclusive test is the resulting improvement in health and physical fitness in the individual child following improvement of faulty diet.

III. *The economic basis of nutrition.*—The economic problems raised by the newer knowledge of nutrition were discussed, with particular emphasis on food in wartime. A national food policy for the war was proposed, the general principle of which is to increase home-production of milk, potatoes, and vegetables, and in the case of imported foods to give priority first to wheat and fats and next to valuable foods which occupy small shipping space per unit value, such as dried milk and cheese. Literature references are appended.

**Food values at a glance and how to plan a healthy diet,** V. G. PLIMMER (*London and New York: Longmans, Green and Co.*, [1939, 2. ed.], pp. 190, pls. 27, figs. 9).—The present revision of this book does not differ appreciably from the earlier edition (E. S. R., 75, p. 420) in the general plan of presentation. The text has been revised and brought up to date with regard to the essential facts about food requirements and food values, and a number of charts and numerical tables have been added to show at a glance the vitamin content of many of the common foods. The values given are averages derived from a number of sources that are cited. The book has been written looking toward the

demand for practical information on foods that would be necessitated by war conditions.

**The synthesis of fat from protein by the albino rat, R. HOAGLAND and G. G. SNIDER.** (U. S. D. A.). (*Jour. Nutr.*, 18 (1939), No. 5, pp. 435-440).—A pair of rats was selected from each of seven litters at the age of 20-25 days. One rat from each pair was sacrificed for determinations of the content of total fatty acids. The other was maintained for 60 days on a diet consisting chiefly of casein and then killed for similar analysis. The difference between the values at the beginning (estimated from litter mate analyses) and end ranged from 1.17 to 10.12 gm., with an average of 6.85 gm. The percentage gains ranged from 38 to 358, with an average of 257 percent.

**Choline metabolism.—I, The occurrence and prevention of hemorrhagic degeneration in young rats on a low choline diet, W. H. GRIFFITH and N. J. WADE** (*Jour. Biol. Chem.*, 131 (1939), No. 2, pp. 567-577, fig. 1).—This report deals with the production of fatty livers in young rats on a choline-deficient diet, as noted in a preliminary report (*E. S. R.*, 81, p. 869), and the production of a hitherto unrecognized effect of choline deficiency "characterized by an extreme toxic state in which there is a marked hemorrhagic enlargement and degeneration of the kidneys, a regression of the thymus, and an enlargement of the spleen." This pathological condition was prevented in a group of young rats by the addition of 0.4 mg. of choline chloride per gram of food, but the livers of the protected animals had 8.8 times the normal fat content, and 2 mg. of choline chloride per gram of food was required to prevent this lipotropic action. A greater requirement for choline by young than by older rats was shown by the fact that while 40-gm. rats developed fatty livers on diets only moderately low in choline, rats weighing 124 gm. failed to develop fatty livers on the same diet.

**The mineral and nitrogen metabolism of college women (Nebraska Sta. Rpt. [1939], pp. 52, 53).**—Progress is reported on studies of the calcium, phosphorus, iron, copper, and nitrogen metabolism (*E. S. R.*, 81, p. 739).

**Mineral metabolism, A. T. SHOHL** (*New York: Reinhold Pub. Corp.*, 1939, pp. X+384, figs. 13).—This monograph presents a connected account of the role of minerals in the structure and function of the human body. An extensive bibliography is presented, although the review makes no pretense at being exhaustive. The following topics are given consideration: Mineral composition of the body: secretions and excretions; internal secretions; total base, chloride, ammonium, and bicarbonate; calcium and magnesium; phosphorus; sulphur; iron; iodine; trace elements; water metabolism; anion-cation relationships; and mineral intakes, balances, and requirements. The chapters on iron and iodine are credited to F. C. Bing, and an author and subject index are included.

**On the approximation of the calculated to determined calcium content of human dietaries, A. B. GUTMAN and M. LOW** (*Jour. Nutr.*, 18 (1939), No. 3, pp. 257-263).—The calcium contents of 16 low-calcium and 12 intermediate- and high-calcium diets, as determined by chemical analysis, were compared with the calculated values based on Sherman's figures for the raw foodstuffs. Variations in determined values reflect variations in the calcium content of raw foodstuffs plus errors due to sampling, cooking losses, and chemical analysis. The range of variation attributable to these causes is shown in the tabulated results of analyses of diets in consecutive 5-day periods. In these diets the variations were minimized as far as possible by careful weighing and sampling of the raw material, which was purchased in quantities sufficient for the entire diet period, by preparation of the cooked foods in the diet kitchen under con-

ditions designed to minimize leaching out of minerals and to promote conservation of the cooking juices, and by careful sampling and analysis of the cooked foods.

Calculated estimates exceeded the determined values in 14 out of 16 observations on the low-calcium diets and in 8 out of 12 observations on the high- and intermediate-calcium diets; in the former group the percentage deviations of the calculated values (based on Sherman's 1937 figures) ranged from +16 to -49 percent as compared with +13 to -24 percent in the latter group. For the majority of the diets, estimates based on Sherman's 1937 tables were in closer agreement with the determined values than estimates made from the 1926 tables.

It is emphasized that calculated estimates of the calcium content of diets should not be used when conducting calcium balances for clinical or metabolic studies.

**Adaptation to a low calcium intake in reference to the calcium requirements of a tropical population,** L. NICHOLLS and A. NIMALASURIYA) *Jour. Nutr.*, 18 (1939), No. 6, pp. 563-577, fig. 1).—The standard allowances for the daily intake of calcium for children and adults, as given by authorities in America (H. C. Sherman) and in Europe (I. Leitch), are considered too high for the Ceylonese population. Children at 5 yr. receive as a rule as little as 0.2-0.4 gm. of calcium daily and many adults never receive more than 0.3-0.6 gm. per day. Most of the children grow to adults, however, and the population shows a racial metabolic adaptation to these low levels.

As evidence of this metabolic adaptation, data are presented showing an average of 0.0041 gm. per 100 cc. in urines of 62 boys of the laboring classes as compared with 0.0096 gm. in urines of a similar number of upper class boys receiving about 1 gm. of calcium daily. Results of calcium balance studies are also presented showing retentions in children varying from 34 to 89 percent on daily intakes of approximately 0.2 gm.

Tables are presented showing, for Ceylonese males and females in each of two social classes, the yearly increase in the calcium content of the body from the fifth through the seventeenth year of age. The body content of calcium was estimated from data obtained at autopsy on skeletal weights (dry basis) of 35 individuals. Skeletal calcium, considered an approximate measure of total body calcium, was estimated in children as 25 percent of the dry skeletal weight; in adults (12-17 yr.), it was calculated from the average of analyses of 10 femurs.

Daily retentions for the lower class males ranged from 0.06 gm. between the ages of 5 and 6 yr. to 0.254 gm. between the ages of 15 and 16 yr. In the upper class males this retention ranged from 0.079 gm. between the ages of 6 and 7 yr. to 0.416 gm. between the ages of 13 and 14 yr. The retention rates of the females were somewhat lower.

Adult calcium requirements, considered to give generous allowances, were calculated by the formula—grams of calcium retained  $\times 2 + 10$  mg. per kilogram body weight; the weights used in these calculations were taken from standard age-weight tables for Ceylonese children and adolescents of the various social classes.<sup>9</sup> Standard allowances convenient for practical use are also recommended on the basis of these calculated values for the children of the upper social status (children of the poorer classes compared unfavorably in height and weight with those of the upper classes). These recommendations are for 0.5 gm., 0.75, and 1.00 gm. of calcium, respectively, for children from 1 to 7 and from 7 to 12 yr. and for adolescents from 12 to 20 yr. A standard

<sup>9</sup> Ceylon Jour. Sci., Sect. D, Med. Sci., 4 (1936), No. 1, pp. 70, pl. 1, figs. 14.

allowance of 0.5 gm. of calcium daily is considered sufficient for Ceylonese adults excluding lactating women.

**The calcium content of white bread,** W. W. PROUTY and W. H. CATHCART (*Jour. Nutr.*, 18 (1939), No. 3, pp. 217-226).—Moisture, ash, and calcium are reported for control loaves of bread made on a small commercial scale, with 0.25 percent (on the basis of flour 100 percent) of Arkady yeast food in each dough and with various percentages of dry skim or dry whole milk. With no milk, the loaf on a 38 percent moisture basis averaged 1.75 percent ash and 0.025 percent Ca; with 2, 4, 6, 8, and 10 percent of dry skim milk the loaves on this same moisture basis averaged 2.07, 2.07, 2.14, 2.29, and 2.31 percent of ash and 0.039, 0.052, 0.063, 0.081, and 0.097 percent of Ca, respectively; with the same proportions of dry whole milk corresponding values of 2.20, 2.10, 2.64, 2.21, and 2.46 percent were obtained for ash and 0.041, 0.042, 0.047, 0.060, and 0.074 percent for Ca.

Moisture, ash, and Ca are also reported for 39 commercial loaves of white bread obtained from 33 bakeries. These loaves were made with different types of milk variously used in amounts ranging from 2 to 15 percent on the basis of flour 100 percent. The values obtained for Ca ranged from 0.048 to 0.145 percent, averaging 0.080 percent (calculated on a 38 percent moisture basis); ash values averaged 1.86 percent on this same basis. It is pointed out that white breads made with milk solids and with the use of yeast foods, which may contain relatively large quantities of calcium salts, are richer in Ca than some of the older figures on this constituent in bread would indicate.

**The effect of apples and cranberries on calcium retention,** A. MINDELL, W. B. ESSELEN, JR., and C. R. FELLERS. (Mass. Expt. Sta.). (*Amer. Jour. Digest. Diseases*, 6 (1939), No. 2, pp. 116-119).—Calcium retention, estimated as the difference between calcium intake and calcium excretion (fecal), was determined (after preliminary adjustment to the dietary regime) for 3-day experimental periods in individual rats receiving either the control basal diet or this diet supplemented with 20 percent of cranberries or apples. The basal diet, with the calcium chiefly in the form of the carbonate, furnished 11.40 mg. of calcium per gram of food; the apples and cranberries contained, respectively, 0.209 and 0.587 mg. of calcium per gram (moist basis). The findings indicated that the animals receiving the apple supplements retained 50.5 percent of the ingested calcium, while the corresponding control group retained on an average 39.6 percent. Corresponding averages for the test animals receiving cranberries and the control group were 49.8 and 41.5 percent.

In the femur ash little difference was noted between controls and test animals when apples constituted the supplement. When cranberries were added to the basal diet the femur ash of the 10 test animals averaged  $1.8 \pm 0.4$  percent higher than that of the 10 controls.

**Normal hematologic standards in the aged,** I. MILLER (*Jour. Lab. and Clin. Med.*, 24 (1939), No. 11, pp. 1172-1176).—The results of a hematologic study of 160 men over 60 yr. of age are presented. Average results by 5-yr. groups in the 160 men are reported, as well as averages for the entire group. The latter are compared with standards in males 14-30 yr. of age. This comparison indicated that the red blood cells per cubic millimeter of blood are diminished in old age, the average red blood cell count being 4,460,000 as compared with an average of 5,400,000 in the younger subjects. It is considered that chronic low grade infection, nephrosclerosis, and decreased cellularity of the red bone marrow in old age may be causative factors. No increase in red blood cells was found associated with hypertension. The hemoglobin per 100 cc. of blood (determined with the Hellige wedge hemometer) averaged 14.3 gm. in the

aged group as compared with an average of 15.8 gm. in the younger group. The decrease in hemoglobin is proportional to the decrease in red blood cells.

**The rat growth factors of the filtrate fraction of liver extracts, G. H. HITCHINGS and Y. SUBBAROW** (*Jour. Nutr.*, 18 (1939), No. 3, pp. 265-276, fig. 1).—A 95 percent alcohol extract of liver, which served as the starting material, was treated with fuller's earth, adsorbate and filtrate fractions thus being obtained. The filtrate fraction was subjected to further study in an attempt to concentrate the rat growth factor. Various preparations were tested for their activity by feeding them as supplements to young rats on a basal diet essentially free of B vitamins but supplemented with adequate amounts of pure thiamin and riboflavin and by the fuller's earth adsorbate fraction from the liver extract. This adsorbate fraction was included as a supplement to the basal diet, since preliminary studies had shown that the filtrate fraction did not give the full activity of the liver extract except as fed with the adsorbate fraction, which also was relatively inactive when fed separately.

The growth-promoting substances of the fuller's earth filtrate could be concentrated by a series of steps involving extraction with amyl alcohol, followed by extraction of the alcoholic solution with aqueous NaOH, adsorption on charcoal from this aqueous solution, elution from the charcoal with 60 percent aqueous ethanol, evaporation to remove the alcohol, taking up the residue in water, acidifying, and finally submitting the acid aqueous solution to continuous ether extraction. Part of the activity, however, appeared to remain in the aqueous phase, this portion being more stable to acid hydrolysis than the portion in the ether phase. The activity of the ether extract could be concentrated further by fractionation of the brucine and calcium salts; some evidence was obtained to indicate that the active substance in this final preparation might be pantothenic acid.

**Fruits and vegetables contain many vitamins, D. K. TRESSLER** (*Farm Res. [New York State Sta.]*, 6 (1940), No. 3, p. 8).—Recent studies by the station on the vitamin content of New York State fruits and vegetables are noted briefly, and a table based upon these studies is given of a number of vegetables and fruits classified as excellent, very good, good, and fair sources of vitamin C.

**The effects of vitamin deficiency on the gastro-intestinal tract, D. L. WILBUR** (*Amer. Jour. Digest. Diseases*, 6 (1939), No. 9, pp. 610-617).—The material included in this review has been grouped in sections dealing with the effects of deficiency of vitamins A, the B complex, C, D, E, K, and the anti-gizzard erosion factor, with the first three sections subdivided into pathologic changes in animals and man, physiologic changes in animals and man, and symptomatic changes. A list of 64 literature references is appended.

**Biophotometer test as index of nutritional status for vitamin A, G. STEINGER and L. J. ROBERTS** (*Arch. Int. Med.*, 64 (1939), No. 6, pp. 1170-1186, figs. 4).—For the purpose of determining the reliability of the biophotometer test and its validity as a measure of vitamin A stores, over 2,000 tests, following the technic of Jeans et al (*E. S. R.*, 77, p. 886), were made on 194 adults and 265 children. Data used in determining the reliability of the test were obtained from 6 adults given from 16 to 20 tests each, 50 children given 6 tests each, and 283 subjects (48 adults and 235 children) given 2 to 3 tests each. From these tests the authors conclude that "single tests of a subject are unreliable, as the readings may vary so widely on successive tests, even with a constant dietary regimen, as to change his classification to or from the normal or the subnormal zone. The general trend, however, of the readings for the same subject is fairly constant, and the test, therefore, can be used to determine the level for a person or for a group if a sufficient number of readings are

obtained to determine their variability. This procedure is time consuming and practically rules out the test, even if it were valid, for routine clinical use."

Evidence concerning the validity of the test as a measure of vitamin A stores was obtained along 3 lines. (1) A group of 100 children of high socioeconomic class was compared with 160 from a very low socioeconomic group in mean biophotometer readings and in the percentage of children in each group classed from the readings as normal, borderline, and subnormal. The biophotometer readings were significantly higher for the children in the high than in the low socioeconomic group, but even in the superior group only 26 percent of the children could be classed as normal according to the Jeans standard. (2) A daily supplement of 10,000 units of vitamin A in the form of carotene for 6 weeks and 20,000 for a subsequent 2 weeks given to 50 children with low original readings caused no significant difference in the mean values of the group as a whole as compared with those of a matched group of controls, but in 14 of 16 pairs in which a real difference was evident the odds were in favor of the child who received the supplement. (3) Six women subsisted on a constant weighed diet with a calculated vitamin A content of less than 100 units per day for 25, 30, and 44 days in the case of 3 and 123 days for the other 3 subjects who each received a supplement of 1,000 units of vitamin A on the sixty-fifth, seventy-second, and seventy-sixth day. A significant change in the biophotometer readings occurred in only 2 of the 6 subjects, and these were not among the 3 subsisting on the diet for 4 mo. The response of the various subjects was not consistent with either their original biophotometer readings or their dietary histories.

"These results make it evident that, although some relation exists between the biophotometer readings and vitamin A nutrition, the relation is not close enough to warrant the use of the test as a means of diagnosing subclinical vitamin A deficiency. The basic idea, however, of the use of measurements of dark adaptation for determining deficiencies of vitamin A seems promising and worthy of further experimentation."

**Vitamin A requirements in infancy as determined by dark adaptation,** J. M. LEWIS and C. HAIG (*Jour. Ped.*, 15 (1939), No. 6, pp. 812-823, figs. 3).—Using the procedure noted previously (*E. S. R.*, 83, p. 564), the authors have determined the minimum light thresholds after complete dark adaptation in 53 normal institution infants from 1½ to 13 mo. of age. One group of 26 received the average diet recommended in private practice for infants but without vitamin A supplements. A second group of 9 had been for 4 mo. on a similar diet, but fortified with 15 drops daily of halibut-liver oil furnishing approximately 17,000 units. A third group of 4 was placed at 2 or 3 mo. of age on a special diet containing approximately one-fourth as much vitamin A as the ordinary diet, and a fourth group of 14 on a diet even more restricted in vitamin A, furnishing about one-twelfth that of the ordinary diet. Both of these groups were tested at intervals for periods varying from 8 to 10 mo.

The results of the dark adaptation tests were within the arbitrarily assigned normal limits in all four groups, and the infants on the diets furnishing only 135-200 vitamin A units daily showed as good weight gains and freedom from susceptibility to infection as those receiving 17,000 units daily. Three infants who, because of eczema, received in place of milk a proprietary preparation containing soybean, starch, and olive oil and almost devoid of vitamin A showed poor dark adaptation in from 3 to 4 weeks. The addition of 120 units daily of vitamin A in the form of cod-liver oil brought the values back to normal in 2 of these infants. This dosage amounted to from 18 to 20 units per kilogram of body weight, respectively. A single dose of 30,000-50,000

units of vitamin A administered to 2 other infants who had shown poor dark adaptation on the soybean diet resulted in return to normal dark adaptation values in 40 and 65 min., respectively. The authors conclude that, since the average diet of infants contains approximately 12 times as many units of vitamin A as were contained in the low vitamin A diet tested, it would seem unnecessary to supplement the average diet of infants with special vitamin A preparations.

**Effect of anoxemia on the dark adaptation of the normal and of the vitamin A-deficient subject,** R. McDONALD and F. H. ADLER (*Arch. Ophthalmol.*, 22 (1939), No. 6, pp. 980-988, figs. 5).—This study was conducted with the Hecht apparatus on a healthy adult male who had been a subject for dark adaptation experiments for several months. After the normal dark adaptation curve for rods and cones had been obtained, the amount of oxygen in the circulating blood was reduced by breathing a mixture of air and nitrogen containing only about half as much oxygen as normal air and the readings were repeated. During the period of anoxemia there was a temporary but significant upward displacement of the thresholds for both rods and cones by a factor of 2.5 ( $\log I=0.4$ ). The subject was then placed on a vitamin A-deficient diet calculated to supply from 250 to 350 Sherman units per day. A rise in the threshold values was first noted on the fourth day and continued until about the fifth week, after which the levels remained practically constant until the end of the experiment in the ninth week. Curves plotted at the fourth and sixth weeks showed an unequal rise in the two plateaus, the rods showing the greater rise. A second anoxemia test resulted in a similar rise in threshold values for rods and cones. The unlike changes produced by anoxemia and vitamin A deficiency are considered to suggest that two different processes in the visual response are involved.

**Riboflavin deficiency in man,** N. JOLLIFFE, H. D. FEIN, and L. A. ROSENBLUM (*New England Jour. Med.*, 221 (1939), No. 24, pp. 921-926, figs. 4).—Lesions similar to, though more advanced than, those produced experimentally by Sebrell and Butler through riboflavin deficiency (E. S. R. 83, p. 134) are described for 15 patients, with detailed case reports and accompanying photographs for 4. "These lesions consist of filiform, seborrheic excrescences distributed most often in the nasolabial folds but frequently involving the alae nasi and less often the bridge of the nose and the forehead, superimposed on a skin which has a fine, scaly, greasy desquamation in the same locations, and cheilosis, characterized by maceration and fissures at the angles of the mouth and degeneration of the epithelium of the lips, especially the lower. These lesions, like those produced experimentally, improve following the administration of natural or synthetic riboflavin, but fail to respond to diets poor in the vitamin B complex or to nicotinic acid. We, therefore, feel justified in attributing them to riboflavin deficiency."

It is considered of interest that 9 (60 percent) of the 15 patients with riboflavin deficiency were women, whereas only 26 percent of the pellagrins routinely admitted to the service (Bellevue Hospital, New York City) are women. Attention is also called to the fact that the cases of riboflavin deficiency reported by Sebrell and his associates were from the South where pellagra is endemic, while the cases here reported were from New York City. The average of 1 case a month among a total of 272 admissions at Bellevue Hospital indicates that the disease may not be uncommon in the Northeastern States.

**The synthesis of vitamin B<sub>1</sub> from the pyrimidine and thiazole portions by animal tissues** [trans. title], E. and R. ABDERHALDEN (*Pflüger's Arch. Physiol.*, 243 (1939), No. 1, pp. 85-93).—The synthesis of aneurin from 2-methyl-4-amino-5-

bromomethyl-pyrimidinehydrobromide and 4-methyl-5-hydroxy-ethyl-thiazole was accomplished in the presence of blood plasma or serum or extracts of organs (liver, muscle, heart, brain, and kidneys of rabbits, liver, muscle, and heart of pigeons, and liver and muscle of the rat). The reaction was carried out in physiological saline at 37° C. and a pH optimum between 6 and 7. The extracts were prepared by treating freshly excised and finely comminuted tissue with 0.9 percent NaCl (2-3 cc. per gram of tissue), grinding the mixture with sand, and centrifuging for 10-15 min.

Pigeons which had been kept on a vitamin B<sub>1</sub>-free ration for 1 mo. were restored to health by parenteral administration of 12 mg. of 2-methyl-4-amino-5-bromomethyl-pyrimidinehydrobromide and 6 mg. of 4-methyl-5-hydroxy-ethyl-thiazole on each of two successive days. There was a decrease in body weight and a fall in temperature upon this treatment, but such behavior was also observed in vitamin B<sub>1</sub>-deficient pigeons similarly injected with 10 $\gamma$  of aneurin. Vitamin B<sub>1</sub> avitaminosis in pigeons was not cured, however, by the injection of relatively large doses of 4-amino-5-chloromethyl-6-methylpyrimidine or 4-amino-5-bromomethyl-pyrimidinehydrobromide or 2-ethyl-4-amino-5-bromomethyl-pyrimidinehydrobromide+4-methyl-5-hydroxy-ethyl-thiazole; nor were the organ extracts or blood serum or plasma able to synthesize the vitamin *in vitro* in the presence of these compounds.

**Methods for assessing the level of nutrition: A carbohydrate tolerance test for vitamin B<sub>1</sub>.**—I, Experiments with rats, G. G. BANERJI and L. J. HARRIS (*Biochem. Jour.*, 33 (1939), No. 8, pp. 1346-1355, figs. 8).—The possibility of assessing degrees of vitamin B<sub>1</sub> deficiency by the measurement of latent defects in carbohydrate metabolism was investigated in exploratory work on rats. In the first of three series of tests the excretion of bisulfite-binding substances (B. B. S.) was determined over long periods of time in rats receiving adequate amounts of vitamin B<sub>1</sub> as compared with others receiving no vitamin or only suboptimal amounts. It was found that the excretion of B. B. S. increased slightly with the degree of deficiency of the vitamin. A related intermediate metabolite, sodium lactate, given to the animals in tests similar in other respects to those of the first series, caused an increase in the excretion of B. B. S., thus making minor deficiencies more apparent. In the third series the administration of a single dose of vitamin B<sub>1</sub> caused a temporary check in the excretion of B. B. S., its magnitude as determined by the time elapsing before the B. B. S. returned to normal being found to be proportional to the dose given.

The method is thought to be applicable in rat tests for the assay of vitamin B<sub>1</sub> in foods and in tests with human subjects to assess the nutritional status of the subject with respect to vitamin B<sub>1</sub> as an alternative to measurements of B<sub>1</sub> in the urine. "Preliminary tests on human subjects indicate that an increase in B. B. S. can be produced experimentally by a diet low in vitamin B<sub>1</sub>, and that high values frequently accompany subnormal excretion of vitamin B<sub>1</sub> (e. g., during pregnancy). Further work is needed, however, to define quantitatively the most accurate conditions for applying the carbohydrate tolerance test to human beings so as to control other variables, e. g., basal diet, exercise. The results have always to be checked by giving vitamin B<sub>1</sub> to prove whether the abnormal carbohydrate tolerance is the result of a specific vitamin B<sub>1</sub> deficiency."

**Methods for assessing the level of nutrition of the human subject: Estimation of vitamin B<sub>1</sub> in urine by the thiochrome test,** Y. L. WANG and L. J. HARRIS (*Biochem. Jour.*, 33 (1939), No. 8, pp. 1356-1369, figs. 4).—Detailed examination of the thiochrome method for the determination of vitamin B<sub>1</sub> in the urine is reported, with working details for a modified technic and data

obtained by the modified method in the examination of the urines of 11 normal subjects and a number of patients and in a comparison of the method with the bradycardia method as applied by Harris and Leong (E. S. R., 76, p. 425).

The most important sources of error in the thiochrome method as ordinarily used were found to be incomplete removal of the vitamin in the adsorption; interference from nonspecific fluorescing substances, other reducing substances, and pigments in the urine; and fluorescence caused by the use of impure reagents. The principal features of the technic as developed to overcome these difficulties include omission of the preliminary adsorption to avoid loss of the vitamin and overconcentration of interfering substances, preliminary washing with isobutanol to remove preformed thiochrome or other pigments, regulation of the amount of  $K_3Fe(CN)_6$  used, treatment of the filter paper and reagents to remove fluorescing substances, further removal of interfering substances by washing the final isobutanol solution of thiochrome with water, and direct comparison of the blue fluorescence.

The usual range in vitamin  $B_1$  excreted by normal subjects not receiving special sources of vitamin  $B_1$  was from about 50 to 80 International Units daily, with minimum and maximum values of 33 and 160 I. U. (the latter from a subject receiving marmite). Attention is called to the fact that the minimum values are considerably higher than the earlier estimates by the bradycardia method. Low values were obtained in pregnancy and in conditioned deficiencies attributed to anorexia or faulty nutrition. Responses to test doses were consistent with the state of nutrition of the subject, two normal subjects showing a marked increase after the first dose and a subject known to be deficient showing but little increase until the second dose. A satisfactory parallelism was found between the results of chemical and biological tests. Percentage recoveries of added vitamin  $B_1$  ranged from 94 to 108 percent.

**The thiochrome test for aneurin (vitamin  $B_1$ ) in urine as an index of nutritional level,** G. M. HILLS (*Biochem. Jour.*, 33 (1939), No. 12, pp. 1966-1979, *figs.* 3).—A simplified procedure for the determination of aneurin (thiamin) in urine by the thiochrome test in which photoelectric measurement of fluorescence is employed and rendered more specific for thiochrome is described in considerable detail, and data are reported on the application of the method to the determination of thiamin excretion in normal subjects and in hospitalized neurological patients. Values are given for 24-hr. excretions and for 3-hr. excretions following a test dose of 1 mg. of thiamin given with a breakfast low in thiamin.

In the discussion of the method particular consideration is given to the collection of the specimens, the question of the advisability of using the adsorption technic recommended by some and not by others, sources of error in the blank test, calibration, the use of one concentration of oxidizing agent, and the use of wet isobutanol as solvent. Concerning adsorption, the author considers that the direct oxidation technic, as recommended by Wang and Harris in the paper noted above, is best adapted for use in concentrated urines of high thiamin content, but for greater accuracy with urines of low thiamin content adsorption as adopted in the present study is preferable. On the same samples, thiamin values by the adsorption method were on an average 30 percent lower than by the Wang and Harris method. Six normal subjects, five male and one female, excreted from 50 to 170, with a mean of 100  $\mu g.$ , of thiamin in 24 hr.; and from 26 to 110, with a mean of 65  $\mu g.$ , in 3 hr. following a 1-mg. test dose. The results for the 24-hr. excretion were roughly parallel to those obtained after the test dose, but with sufficient variation to warrant recommendation of the 3-hr. excretion after the test dose, without correction for the excretion during the previous control period, as the best index of nutritional

level, with the further precaution of having the test period preceded by a few hours of low thiamin intake to avoid errors due to retention of the concentrated urine of the previous night. Of the nine neurological cases, five gave a lower 24-hr. excretion and six a lower excretion after the test dose than the lowest normal case. In an attempt to saturate some of the hospital subjects by continued treatment of thiamin in quantities of 1-3 mg. daily by mouth or 10 mg. by intravenous injection, the thiamin excretion increased considerably in all patients except a case of thyrotoxicosis. Saturation appeared to be reached at a level of about 500  $\mu\text{g.}$  per day, with an excretion of 200  $\mu\text{g.}$  in 3 hr. after the 1-mg. test dose.

**A quantitative chemical study of the urinary excretion of thiamine by normal individuals,** D. MELNICK, H. FIELD, JR., and W. D. ROBINSON (*Jour. Nutr.*, 18 (1939), No. 6, pp. 593-610, figs. 7).—Analyses of six consecutive 4-hr. urine collections from three normal male subjects on adequate diets of calculated thiamin intake showed lower values in the morning than in the afternoon and evening specimens, indicating an appreciable lag in the excretion of ingested thiamin. The response in increased thiamin excretion of the same subjects to 5-mg. test doses administered in different ways was the most prompt and extensive following intravenous injection, with the greater part of the total amount excreted (representing over 30 percent of the intake) occurring in the first 4 hr. The response was somewhat slower and less complete following subcutaneous and intramuscular injections, and even more gradual and less complete following oral administration. However, the authors recommend oral rather than parenteral administration of single test doses because the flooding effect of the latter tends to mask the differences in excretion of normal and vitamin B<sub>1</sub>-deficient subjects. The thiamin excretion of three subjects on the same oral dose of thiamin was much less when the thiamin was taken fasting 12 hr. after the preceding meal than when taken with a meal. "Apparently a considerable part of the vitamin taken into the fasting stomach is destroyed prior to absorption."

The 24-hr. thiamin excretion of a group of 15 men and 10 women from 25 to 30 yr. of age on their customary diets ranged from 90 to 350, with an average of 198  $\mu\text{g.}$ , for the men, and from 61 to 146, with an average of 93  $\mu\text{g.}$ , for the women. The thiamin content of the diets, calculated from the tables of Williams and Spies (*E. S. R.*, 80, p. 710), averaged 960  $\mu\text{g.}$  for the men and 710  $\mu\text{g.}$  for the women, and the thiamin nonfat-calorie ratios 0.8 and 0.9, respectively. Recoveries following test doses of 5 mg. of thiamin taken immediately after the largest meal of the day ranged from 8 to 19 percent for both men and women, with averages of 14 and 12 percent, respectively. During a period of 8 mo. two male subjects gave thiamin excretion values ranging from 120 to 200  $\mu\text{g.}$  and 120 to 260  $\mu\text{g.}$ , respectively. The variations on different diets approached uniformity for the same subject on a constant diet. During the production of thiamin deficiency in a single subject on a diet furnishing only 260  $\mu\text{g.}$  daily of thiamin, the thiamin excretion dropped rapidly to very low levels, which were maintained with slight fluctuations during the 22 days in which no supplement was fed and showed a very slow response to increased intake of thiamin. Evidence is also presented, showing that the response to an oral test dose of thiamin is governed by the nutritional status of the individual rather than by the adequacy in thiamin of the diet consumed at the time of the test, and that subsequent to flooding the organism with thiamin (as is the case with thiamin therapy) a period of 2 weeks may elapse before the urinary values return to the normal basal levels.

**Vitamin C studies in the rat: The effect of copper and various organic substances,** J. L. SVIRBELY (*Jour. Biol. Chem.*, 131 (1939), No. 1, pp. 233-241).—

This paper represents a continuation of earlier studies (E. S. R., 78, p. 136) of the effect on the vitamin C content of rat organs and tissues of the administration of substances which interfere with the normal metabolic activities of the organs.

Appreciable quantities of vitamin C were found in the organs of rats maintained on diets of varying composition and fed copper as copper sulfate or various organic compounds, including indophenol blue, methylene blue, and bromobenzene. Injections of organic substances such as pyridine, menthol, borneol, thymol, camphor, or phenylacetic acid to fasting rats or the feeding of amidopyrine and antipyrine to rats on the stock diet did not decrease, but in some instances increased, the reducing capacity (vitamin C content) of the liver and gut. A decrease in reducing power of both organs followed the injection of toluenediamine, and a greater increase in reducing power of the gut than the liver followed phlorhizin injection. Marked decreases in the reducing power of the adrenals followed the feeding of acetanilide, acetophenetidin, and to a smaller extent amidopyrine and injections of camphor, borneol, toluenediamine, and hydrazine.

In the tabulated data corrections are made in the vitamin C values as expressed by reducing power for variations in the weights of the liver and gut resulting from the administration of the foreign substances. These corrections are based on observations on the control animals and the relative weights of the organs per 100 gm. of final body weight.

**The relationship of acidity to the vitamin C content of tomatoes, M. YARBROUGH and G. H. SATTERFIELD.** (Univ. N. C.). (*Ztschr. Vitaminforsch.*, 9 (1939), No. 3, pp. 209-212; *Ger., Fr., abs.*, p. 212).—Simultaneous determinations of the ascorbic acid content and acidity (by titration with N/10 KOH) of 12 or 13 samples each of 3 varieties of tomatoes grown on experimental farms in North Carolina showed no relationship between acidity and vitamin C content or between the size of tomatoes of uniform ripeness and their vitamin C content. The range in ascorbic acid values for the 3 varieties was 0.165-0.290 mg. per gram for Louisiana Pink, 0.148-0.258 for Pritchard, and 0.179-0.309 mg. per gram for Marglobe. The acidity values, expressed as cubic centimeters N/10 KOH per gram of tomato for the individual samples giving the above values, were 1.009 and 0.879, 0.991 and 1.298, and 1.272 and 1.055.

**The effect of vitamin C on lead poisoning, H. N. HOLMES, K. CAMPBELL, and E. J. AMBERG** (*Jour. Lab. and Clin. Med.*, 24 (1939), No. 11, pp. 1119-1127, figs. 3).—From a large number of workmen in an industrial plant where the lead hazard was great, 34 patients were selected with chronic lead poisoning as judged by the basophilic aggregation, abnormal stippling of the red blood cells, and clinical symptoms which were observed to be similar to those in subclinical scurvy. Accordingly, ascorbic acid therapy was instituted, the dosages amounting to 100 mg. per man per day. Half of the men received ascorbic acid alone, at least 2 mo. after discontinuing calcium salt injections which had previously been given as routine therapy, while the other half continued the calcium therapy and at the same time received ascorbic acid. In the former group there was a marked gain in vigor, cheerfulness, color of skin, and blood picture, the improvement beginning in less than a week of therapy. In the 17 patients given ascorbic acid with calcium, the gain was less marked and rather irregular. The improvement due to ascorbic acid treatment in these industrial cases was confirmed by observations on a number of house painters, chronic lead absorption patients, who were given 200 mg. of ascorbic acid daily. In these patients analytical determinations of lead and ascorbic acid in the urine indicated that the ascorbic acid decidedly lowered

the urinary excretion of lead. This fact, together with the observation that men actually suffering with lead absorption excreted less ascorbic acid than the average man, suggested that the toxic lead compounds react with vitamin C to form a poorly ionized salt or a complex salt which yields a very low concentration of simple lead ions.

**The plasma ascorbic acid of infants and children, C. E. SNELLING** (*Jour. Ped.*, 15 (1939), No. 6, pp. 824-830, figs. 6).—Plasma ascorbic acid measurements by the technic described by Jackson (*E. S. R.*, 81, p. 744) were made on 158 infants and 77 older children shortly after admission to the hospital and are reported in scatter diagrams plotted against age and in tables.

In 31 breast-fed infants, 8 of whom received orange juice regularly, there was no essential difference in the plasma ascorbic acid between those receiving or not receiving orange juice. The average for the group was 0.76 mg. per 100 cc. In 127 artificially fed infants the average value was 0.23 mg. per 100 cc. In the 79 infants in this group who received 2 oz. or more of orange juice daily, the average value was 0.30 mg. per 100 cc., with about one-third of these having values as low as 0.1 mg. or less per 100 cc. The 48 artificially fed infants receiving no orange juice gave an average value of 0.12 mg. per 100 cc., with two-thirds having values of 0.1 mg. or less. Three in this group had scurvy. Of the entire number of artificially fed infants, 32 showed no evidence and 95 evidence of infection. The average values for these two groups were 0.18 and 0.23 mg. per 100 cc. In 77 children from 2 to 14 yr. of age on admission to the hospital, the average value was 0.75 mg. per 100 cc., with a range of from 0.55 mg. per 100 cc. for 24 with respirator infection to 0.96 mg. per 100 cc. for 8 with diabetes.

The effect of giving ascorbic acid by mouth was tested on 39 infants with low initial values. After one dose of 100, 500, or 1,000 mg., 15 of the 24 infants showed a definite increase in plasma ascorbic acid, and after 2 or 3 days on 500 mg., 8 of 11 showed an increase. Four others, including one mild case of scurvy, required a longer time to bring the plasma ascorbic acid back to normal.

The author concludes that "low plasma ascorbic acid measurements by themselves do not give one the picture of the general ascorbic acid nutrition of the individual and cannot be used as a standard for the diagnosis of scurvy."

**Factors preventing oxidation of ascorbic acid in blood serum, E. M. MYSTKOWSKI and D. LASOCKA** (*Biochem. Jour.*, 33 (1939), No. 9, pp. 1460-1464).—Experiments on the action of proteins, amino acids, and salts on the oxidation of ascorbic acid *in vitro* are described, with the conclusion that proteins have an inhibiting action on the oxidation of ascorbic acid which may be offset to some extent by the presence of copper, the binding of which with protein does not entirely abolish catalytic activity. The amino acids also inhibit the oxidation of ascorbic acid, and are not affected by the presence of copper. Of various salts tested, only chlorides exerted a retarding effect on the oxidation.

**Studies on the possible carrier rôle of ascorbic acid in animal tissues, M. O. SCHULTZE, C. J. HARRER, and C. G. KING** (*Jour. Biol. Chem.*, 131 (1939), No. 1, pp. 5-12, figs. 2).—Evidence from the literature in support of the concept that ascorbic acid may function in animal tissues as a reversible oxidation-reduction carrier is noted briefly, as well as earlier work from the authors' laboratory indicating that the evidence thus far does not favor the theory that ascorbic acid functions as a major respiratory carrier in animal tissues. This view is strengthened by the demonstration reported in this paper of the failure of ascorbic acid to function *in vitro* as a hydrogen transfer agent in a system containing, in addition to ascorbic acid, nicotine, hemochromogen, coenzyme, glucose dehydrogenase, and glucose. The presence of glutathione, either as a

substitute for or in addition to ascorbic acid, did not alter the hydrogen transfer results, although both reagents in the presence of the hemochromogen were oxidized aerobically. Dehydroascorbic acid, either in pure solution or in the presence of dialyzing suspensions of rat liver or muscle, was not reduced by reduced cozymase *in vitro*, at pH 7.2.

**The effect of phosphorus on the biological estimation of vitamin D activity,** B. O'BRIEN and K. MORGAREIDGE (*Jour. Nutr.*, 18 (1939), No. 3, pp. 277-284, figs. 2).—Young rats from a standardized D-assay colony were placed on the 2965 rachitogenic diet of Steenbock and Black. After a 21-day depletion period in which satisfactory rickets developed, as evidenced by radiographic examination, the rats were divided into groups which were given for 8 days supplements of varying amounts of vitamin D dispersed in 4 cc. of a 5 percent gelatin solution. The vitamin D (Drisdol) used was a crystalline vitamin D<sub>2</sub> in propylene glycol, and it was dispersed in the gelatin as a protective colloid to simulate the aqueous protein medium of milk. Standardized against the international standard vitamin D solution in corn oil, the vitamin D preparation was found to have a potency of 6.7 International Units per milligram when fed dispersed in gelatin. The experiments were repeated with the modification that a daily supplement of 4 mg. of phosphorus (as sodium glycerophosphate) was added to the gelatin-vitamin D supplement. The response of the rats in this test was such as to indicate an apparent potency of the vitamin preparation of 22.7 I. U. per milligram. This enhancement effect due to the added phosphorus was represented by the factor 3.4. Similar experiments with 2 and 1 mg. of phosphorus, respectively, gave lower enhancement factors, but in all cases in which the phosphorus was supplied by sodium glycerophosphate the factor could be represented by the formula  $1.0 + 0.58 P$ . Other phosphorus compounds possessed different enhancement factors. Since the total antirachitic activity of the mixture depended not only on the phosphorus level but on the amount of vitamin D present, the observed vitamin D activity, A, was expressed as  $(1.0 + 0.58 P) D$ , where P equaled the number of milligrams of phosphorus (from glycerophosphate) and D the number of units of vitamin D. The significance of this relationship in the determination of the vitamin D potency of phosphorus-containing foods, such as milk, is pointed out.

**Vitamins D<sub>2</sub> and D<sub>3</sub> in infantile rickets: A comparison of their therapeutic efficiency,** N. MORRIS and M. M. STEVENSON (*Lancet [London]*, 1939, II, No. 27, pp. 876-879, figs. 5).—Twelve infants and children with active rickets were placed on a standard milk mixture consisting of two-thirds milk, one-third water, and sugar and oat flour in amounts suitable for the age of each patient and were observed for a preliminary 3-week period, during which the subjects were kept on the same side of the ward out of direct sunlight. There being no evidence of spontaneous healing of the rickets at the end of the period, the patients were divided into two groups fairly well paired as to the age distribution of the patients and the expected growth responses. The one group was given vitamin D<sub>2</sub> and the other vitamin D<sub>3</sub> in amounts per patient equivalent to 2,000 International Units daily. The course of the healing of the active rickets was then followed by serial radiography of the wrists and by the estimation of the plasma phosphatase. "The results revealed no significant difference between the therapeutic effects of these two vitamins on rachitic infants and children."

**Vitamin K** (*Lancet [London]*, 1939, II, No. 23, pp. 1178, 1179).—This editorial gives a brief outline of the research on vitamin K, considering in chronological order its discovery and the naming of the compound, the perfection of a biological technic for testing it, the Dam unit of potency, the preparation of rich concentrates, the isolation of vitamin K, tests leading to the elucidation of its chemical structure,

clinical application of compounds with vitamin K activity, and dietary deficiencies of the vitamin. Seventeen references are cited.

**Vitamin K potencies of synthetic compounds**, S. A. THAYER, S. B. BINKLEY, D. W. MACCORQUODALE, E. A. DOISY, A. D. EMMETT, R. A. BROWN, and O. D. BIRD (*Jour. Amer. Chem. Soc.*, 61 (1939), No. 9, p. 2563).—Of the various compounds that could be administered intravenously in aqueous solution, the most active one found was 1,4-dihydroxy-2-methylnaphthalene, which was found to have a potency of approximately 1,000 Thayer-Doisy units per milligram. It is suggested that this compound, which is easily prepared by reduction of 2-methyl-1,4-naphthoquinone, may prove important for intravenous vitamin K therapy.

Several quinones previously studied (E. S. R., 83, p. 16) were re-assayed, and the earlier results were confirmed except in the case of 2-methyl-1,4-naphthoquinone. In the present tests this compound, assayed by the Thayer-Doisy method (E. S. R., 81, p. 406), had a potency of 1,000 Thayer-Doisy units per milligram; this agrees with the value previously assigned to the natural vitamin K<sub>1</sub> (E. S. R., 82, p. 89), and confirms the results of Ansbacher and Fernholz (E. S. R., 83, p. 14). It is suggested that 2-methyl-1,4-naphthoquinone should be adopted as a basic standard for the assay of vitamin K, since it is readily obtained in the pure state, has a definite melting point, and is relatively stable. The unit could be defined as the specific vitamin K activity of 1  $\mu$ g of the pure compound.

**Vitamin P**, H. SCARBOROUGH (*Biochem. Jour.*, 33 (1939), No. 9, pp. 1400-1407, figs. 7).—The conflicting evidence concerning the existence of a capillary fragility control factor, vitamin P, as first announced by Szent-Györgyi and coworkers, is reviewed, with the conclusion that "the reality of such a vitamin cannot be maintained on the basis of the published work." However, new evidence from clinical material is presented, demonstrating the existence of such a factor. Seven case reports are given as typical examples from a larger number showing abnormal capillary fragility, as determined by either the positive or negative pressure method, which responded to treatment with one or another of three different extracts containing flavanones from certain fruit sources but not ascorbic acid. The nature of the material producing this effect has not been determined, but it has been shown to be active when given by mouth, by intravenous injection, or through the rectum.

**The V-factor content and oxygen consumption of tissues of the normal and blacktongue dog**, H. I. KOHN, J. R. KLEIN, and W. J. DANN (*Biochem. Jour.*, 33 (1939), No. 9, pp. 1432-1442, figs. 2).—To determine whether or not there is any connection between the two functions of nicotinic acid (1) to act as a vitamin for a number of species of mammals and bacteria and (2) as nicotinamide to be a part of two coenzymes, the authors have determined the content of the V-factor (E. S. R., 82, p. 710), which is used as a measure of coenzyme, in the tissues of normal dogs and dogs suffering from acute deficiency of nicotinic acid (blacktongue) and have measured in vitro the O<sub>2</sub> consumption of some of these tissues in the presence of suitable substrates.

In dogs with acute blacktongue the concentration of coenzymelike substances was 70 percent lower in the liver and 35 percent lower in striated muscle than in dogs receiving liberal or large amounts of nicotinic acid. In dogs just cured of blacktongue the liver and muscles were 45 and 25 percent lower, respectively. No difference was found in the other tissues examined, which included brain, heart, kidney, pancreas, and blood. The decreased coenzyme content in the liver in blacktongue dogs was accompanied by an increase of 35 percent in O<sub>2</sub> consumption. In the kidneys, although the coenzyme content was unchanged, the ability

to oxidize lactate was decreased by 50 percent. The percentage of coenzyme in the reduced form was increased in most tissues except the brain and kidney.

These results are considered to afford no evidence that blacktongue results from a generalized decrease of coenzyme levels in the tissues. Two possibilities in explanation of the definite reduction in level of coenzyme in striated muscle and liver and changes in the oxidative metabolism of liver, muscle, and kidney are suggested. "When the V-factor level of the liver is reduced below a certain limit, some reaction upon which the maintenance of health depends is impaired because sufficient coenzyme is not available. Nicotinic acid enters the metabolism in essential ways as yet unknown." It is pointed out that these results contrast sharply with those reported for vitamin B<sub>1</sub> deficiency where the level falls very markedly in brain, heart, muscle, and liver and is accompanied by a decrease in the activity of the coenzyme formed from this vitamin.

**The synthesis of cozymase and of factor V from nicotinic acid by the human erythrocyte in vitro and in vivo, H. I. KOHN and J. R. KLEIN (*Jour. Biol. Chem.*, 130 (1939), No. 1, pp. 1-11, figs. 2).**—In these experiments the content of factor V in the erythrocytes was determined by the method of Kohn (E. S. R., 82, p. 710). Since lactate oxidation is mediated by cozymase and glucose oxidation by coenzyme II, the content of these two enzymes was determined by measuring in the Warburg apparatus the rate of oxidation of added lactate and glucose by the washed corpuscles in the presence of methylene blue which served as an autoxidizable carrier. A correction was applied for the oxygen consumed in the formation of methemoglobin, and due allowance was made for the oxidation rate of the blank. (This was appreciable, since the washing of the corpuscles was not sufficient to remove all of the glucose).

The administration of nicotinic acid to two subjects, one normal, the other a pellagrin, was followed in each case by an increase in factor V, by an increased rate of oxidation of lactate, indicating an increase of cozymase in the erythrocytes, and by no change in the rate of oxidation of the glucose. Similarly, when fresh defibrinated blood was incubated under sterile conditions with nicotinic acid, there was an increase in the factor V content of the erythrocytes and the rate of oxidation of lactate, although the glucose oxidation was not affected by the nicotinic acid. These experiments indicated that the human erythrocyte can synthesize factor V from nicotinic acid in vitro as well as in vivo.

The relation between factor V and the rate of oxidation of lactate was not entirely simple, however, either in vivo or in vitro. In the former case the lactate oxidation rate failed to follow the factor V level when the latter was above 130 cozymase equivalents; in the in vitro experiments the synthetic reactions depended on the initial level of factor V. Synthesis, when the level was normal, occurred but not when it was high, probably because nicotinic acid was no longer the limiting factor, other materials for the synthesis having been exhausted.

**Synthesis of coenzymes I and II, S. P. and R. W. VILTER and T. D. SPIES (*Nature [London]*, 144 (1939), No. 3657, p. 943).**—In the experiments reported briefly 1 cc. of venous blood (from normal or leukemic persons) or its hematocrit equivalent of red blood cells (obtained by repeated washing to separate these cells, the white blood cells, and the serum) was incubated for 18 hr. with an equal volume of saline containing 0.25 mg. of nicotinic acid amide per cubic centimeter. Control tubes with no nicotinic acid amide were similarly incubated with an equal volume of saline. The concentrations of coenzymes I and II were found to be doubled in the blood after incubation with the nicotinic acid amide, but in the case of the red blood cells suspended in saline or serum

no increase was observed in the coenzyme concentration. In a suspension of white cells (from the blood of patients with leukemia) similarly incubated with nicotinic acid amide there was a decided increase in the concentration of coenzymes I and II. These results are considered to suggest that nucleated cells are essential for the synthesis of these enzymes. This view is in contrast to that of Kohn and Klein noted above, who concluded from their findings that red blood cells synthesized the coenzymes.

**Nicotinic acid in the cure of pellagra** [trans. title], F. MANCINI, M. DELLA CORTE, and V. LEONE (*Quad. Nutr.*, 6 (1939), No. 4, pp. 374-393, figs. 14).—Case reports are presented and summarized for 50 pellagrins; 27 were treated with nicotinic acid in physiological saline or water injected intravenously or intramuscularly at the rate of 50 mg. daily (some received as much as 300 mg. daily); 23 were given oral doses varying from 100 mg. to as much as 900 mg. daily. In those receiving nicotinic acid by injection the lesions of the mucous membrane, when present, healed upon the second or third injection and with this the asthenia and anorexia also vanished. The nervous manifestations lessened in both cases having such symptoms. Erythema subsided in 4-5 days; desquamation was eliminated in 15-20 days. Weight increased in 20 cases and was not changed in 7. Patients to whom the nicotinic acid was administered orally responded less satisfactorily. Of those having oral mucous lesions, 1 received no benefit and in the other 2 alleviation of the symptoms began only after 10 days of treatment. Asthenia and anorexia, when present, did not vanish until amelioration of the cutaneous symptoms. The muscular atrophy of the 1 patient was not modified; delirium on the other hand vanished in 2 days and the skin lesions cleared up in 10-20 days; 2 patients had relapses, the one during treatment and the other 45 days after treatment. It is recommended, therefore, that nicotinic acid in therapeutic use be administered by injection and that oral administration be reserved for preventive treatment over long periods.

**The nature of nutritional diseases occurring in the South**, W. H. SEBRELL (*Milbank Mem. Fund Quart.*, 17 (1939), No. 4, pp. 358-366).—This report deals chiefly with the pellagra problems in the South along the same lines as in the paper noted below.

**Public health implications of recent research in pellagra and ariboflavinosis**, W. H. SEBRELL (*Jour. Home Econ.*, 31 (1939), No. 8, pp. 530-536).—Following a brief review of the history of the etiology and treatment of pellagra from the original discovery of the disease in Spain 200 yr. ago to Goldberger's proof of the vitamin deficiency nature of the disease, the author discusses the present status of the relation of the members of the vitamin B complex to pellagra with the differentiation of the symptoms due to lack of nicotinic acid from those due to lack of riboflavin, and calls attention to current problems concerning endemic pellagra in the South. Health education and crop diversification are considered the most important factors in the reduction of pellagra incidence, with the use of dried yeast and nicotinic acid as palliatives.

## TEXTILES AND CLOTHING

**Progress in textile research from the consumer point of view**, P. B. MACK. (Pa. State Col.). (*Amer. Dyestuff Rptr.*, 28 (1939), No. 24, pp. P696-P699).—This discussion, presented as an address, is concerned with the research studies on textiles that have been planned and carried out distinctly from the consumer point of view. The lines of investigation have dealt with (1) accuracy of sales information secured by the ultimate consumer on the retail market, (2) performance of fabrics secured on the retail market as judged by laboratory and wearing

tests, and (3) technical studies on the relationship of fabric performance to fabric construction, including fiber composition, fabric construction, and chemical composition of the dye. A survey of such studies, as carried on in various colleges, universities, the U. S. D. A. Bureau of Home Economics, and the U. S. Bureau of Standards, is presented, together with brief indications as to the findings.

**Textile testing: Physical, chemical, and microscopical**, J. H. SKINKLE (*New York: Chem. Pub. Co., Inc., 1940, pp. IX+267+[4], figs. 63*).—This is essentially a book of methods. Under physical testing, methods are described for moisture determination, various fiber, yarn, and fabric tests, and strength and stretch testing of fibers, yarns, and fabrics. Chemical methods are given for testing for inorganic and organic extraneous matters, fiber mixtures, and swelling and damage in cellulose fibers, wool, and silk. Microscopical tests are described for identifying starches and fibers, for determining quality and damage, and for quantitatively analyzing fiber blends. Where several methods are available, the one considered best is given in detail, and other methods are given in less detail or are merely noted. A list of references is given at the end of each test.

**Identification of the newer textile fibers**, J. H. SKINKLE (*Amer. Dyestuff Rptr., 28 (1939), No. 24, pp. P694, P695*).—Based on differences in general chemical behavior and microscopic appearance, a scheme is presented for the separation and identification of glass fiber, casein wool, mixtures of viscose and casein of the cisalfa type, nylon, and vinyl resin type fibers. The 11 tests employed in this separation involve burning, solubility, and dyeing tests and microscopic examination.

**Pectic substance in cotton and its relation to the properties of the fiber**, R. L. WHISTLER, A. R. MARTIN, and M. HARRIS (*Jour. Res. Natl. Bur. Standards [U. S.], 24 (1940), No. 5, pp. 555-565, fig. 1*).—Evidence presented indicated that a pectin-cellulose compound does not exist in native cotton fibers and that the pectic substance is present as the insoluble salt of polyvalent ions. Replacement of these ions by sodium or ammonium renders the pectic substance soluble. Cotton freed of pectic substance with alkali showed no significant change in tensile strength or in viscosity, whereas treatment of the fibers with acids, which removed only a small proportion of the pectic substance, produced an appreciable lowering of these two properties. When dewaxed fibers were dispersed in cuprammonium hydroxide solutions, a small portion remained insoluble, and it consisted practically entirely of pectic substance. The conclusion that pectic substance does not contribute to the viscosity of cuprammonium dispersions of cotton was substantiated by determinations of the viscosities of cuprammonium solutions receiving added pectic material from different sources.

**Recent developments in methods for shrinkproofing wool**, B. A. HAROLD (*Amer. Dyestuff Rptr., 28 (1939), No. 24, pp. 683-685, 704*).—This is a brief review of various methods that have been tried, with indications as to the effectiveness for shrinkproofing and the suitability from the standpoint of damage to fiber. A short bibliography is given.

**Technical evaluation of textile finishing treatments: Flexibility and drape as measurable properties of fabric**, L. J. WINN and E. R. SCHWARZ (*Amer. Dyestuff Rptr., 28 (1939), No. 24, pp. P688-P694, figs. 6*).—In this study a series of 10 fabrics ranging from organdie through tracing cloth to a stiff-finished cotton material and varying in weight from 5 to 45 mg. per square centimeter were compared for bending length, rigidity, bending modulus, bending torque, chord length, and radius of curvature. These tests were made by means of the drape tester, the hanging loop, the Gurley stiffness tester, and the Schiefer flexometer. A brief summary of the testing methods and the re-

sults by each method are given. In making the comparisons between the various materials in the series, the Spearman rating system was used. This system, discussed and illustrated with the present data, takes the form of calculating the correlation coefficient for a series of ranked observations. It is pointed out that the various technics employed measure in each case differences in flexibility which are difficult to determine in any ordinary way. The results obtained indicate that the drape test method was the most sensitive of the series, being the only method which would satisfactorily and consistently distinguish between bending of the fabric with face toward the concave and the convex sides, respectively.

## HOME MANAGEMENT AND EQUIPMENT

What the farm woman can do to improve the economic status of her family, D. DICKINS (*Mississippi Sta. Bul. 346 (1940), pp. 18, figs. 5; also in Miss. Farm Res. [Mississippi Sta.], 3 (1940), No. 7, pp. 3-6, figs. 5*).—Five means whereby farm women in Mississippi can help (and in many instances are helping) improve the economic status of their families are discussed, with illustrations from the author's research publications (E. S. R., 66, p. 694; 78, p. 128; 79, p. 142) and unpublished work of good and poor practices along lines of the suggestions made. These include using time and money efficiently, improving the family health, acting in the capacity of partner in the farm business, engaging in nonagricultural pursuits, and guiding sons and daughters in such a way that they will make a valuable economic contribution in the future.

**Family income and expenditures: Middle Atlantic and North Central Region and New England Region.**—I, **Family income**, D. MONROE, E. PHELPS, and I. G. SWISHER (*U. S. Dept. Agr., Misc. Pub. 370 (1940), pp. IV+447, figs. 12*).—This report, the fourth in the series on family income and expenditures (E. S. R., 83, p. 286), is the third in the urban and village series. It is based on a survey of small city and village families in selected communities in the Middle Atlantic, North Central, and New England regions, and presents information similar to that previously reported for similar groups in the Pacific (E. S. R., 81, p. 603) and the Plains and Mountain regions (E. S. R., 82, p. 287). Part 1 reports data on income and composition of the native-white unbroken families studied, while part 2 deals with the distribution of total family expenditures and the relationship between family income, expenditures, and net worth.

**The economic status of 436 families of Missouri clerical workers and wage earners**, J. V. COLES and L. HIESER (*Missouri Sta. Res. Bul. 318 (1940), pp. 80, figs. 11*).—This study is based on the data obtained from schedules secured by the U. S. D. A. Bureau of Home Economics for the consumer purchases study noted above, and included families of 279 wage earners and 157 clerical workers selected at random in Moberly and Columbia, Mo. These towns, the latter primarily an educational center and the other an industrialized community, were selected as representative small cities of less than 15,000 population located in a predominantly agricultural area typical of the State and having close relationship with families living on farms. The findings summarized from the family and expenditure schedules obtained by the interview method are discussed at length, each factor in relation to the others.

Of particular interest is the section devoted to implications of the data to families and to educators. Here it is pointed out that plans for the future welfare of families must be made within the limits of their particular incomes, the majority of which are below \$1,500, with many under \$1,000. Supplementing these small incomes with nonmoney income through wise use of home skills and energy thus becomes important. Future plans, it is further indicated, must give

special attention to the larger families where increase in income is seldom commensurate with increase in size; must recognize that expense for food is the most important item at all low-income levels, that household operation is not a minor item and should be studied for effective expenditures, and that goods received should give the maximum of satisfaction for the money expended, this being a particular problem in the matter of clothing. The necessity for evaluating expenditures for different groups of commodities and services and the necessity for budgeting effectively and purchasing wisely become very important when incomes are low. Home ownership, medical care, life insurance, mortgages on future income, credit, emergencies, and small savings are also considered with reference to low incomes.

[Household equipment research by the Nebraska Station] (*Nebraska Sta. Rpt.* [1939], p. 52).—Progress reports are given on an investigation of the efficiency of top burners and ovens of gasoline stoves and on the adaptation of an electric food mixer controlled by a centrifugal switch to different types of beaters.

Storage facilities for personal belongings in the home management house, M. WILSON and R. MORRISON. (Oreg. State Col.). (*Jour. Home Econ.*, 32 (1940), No. 5, pp. 321-329, figs. 3).—Recommendations for storage space desirable in a home management house for the personal possessions of the students, as based on lists submitted by home economics students of garments and personal belongings customarily taken to the house and on observations made by a student supervisor are given, with dimensional diagrams for bedroom and central closets, dressers, and study tables and inside depths and lengths of dresser drawers. Tables are also given of dimensions of garments and accessories as arranged for storage and frequency distribution of students with varying requirements.

Farm freezing cabinets now available, C. W. DuBois (*Farm Res.* [New York State Sta.], 6 (1940), No. 3, pp. 1, 2, figs. 3).—This brief article notes the rapid increase in frozen locker storage plants throughout the country and the development as an outgrowth of the locker idea of individual farm freezing and storage units. Attention is called to Bulletin 690 (E. S. R., 83, p. 701).

## MISCELLANEOUS

The land grant college movement, F. B. MUMFORD (*Missouri Sta. Bul.* 419 (1940), pp. 140).—This bulletin is discussed editorially on page 721.

Report on the agricultural experiment stations, 1939, J. T. JARDINE, F. D. FROMME, ET AL. (*U. S. Dept. Agr., Off. Expt. Stas., Rpt. Agr. Expt. Stas.*, 1939, pp. 265).—This report has been discussed editorially (E. S. R., 83, p. 145).

Annual Report of the Massachusetts Agricultural Experiment Station, 1939, F. J. SIEVERS ET AL. (*Massachusetts Sta. Bul.* 369 (1940), pp. 104, figs. 10).—The experimental work not previously referred to is for the most part noted elsewhere in this issue. Abstracts are also included on Cranberry Juice: Properties and Manufacture, by C. C. Rice, C. R. Fellers, and J. A. Clague (p. 99); Effect of Particle Size on the Solubility of Magnesium in Dolomite and Magnesian Limestone in 4 Percent Citric Acid Solution Adjusted to pH 4.0 With Ammonium Hydroxide, by J. W. Kuzmeski (pp. 100, 101); Factors To Be Considered in Selecting Chocolate-Flavored Milk, by W. S. Mueller (p. 101); New and Easy Ways to Prevent Damping-Off of Seedlings, by W. L. Doran (p. 102); and Report on Zinc, by E. B. Holland and W. S. Ritchie (p. 102).

Fifty-third Annual Report of [Nebraska Station, 1939], W. W. BURR (*Nebraska Sta. Rpt.* [1939], pp. 68).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

**Agricultural research in New Hampshire: Annual report of the director of New Hampshire Agricultural Experiment Station for the year 1939, M. G. EASTMAN** (*New Hampshire Sta. Bul. 319 (1940), pp. 46*).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

**Colorado Farm Bulletin, [July–September 1940]** (*Colo. Farm Bul. [Colorado Sta.], 2 (1940), No. 3, pp. 20, figs. 4*).—In addition to several articles noted elsewhere in this issue and the customary announcements and news notes, this number includes Claims Regarding Wheat-Wild Rye Hybrid Grass Found To Be Without Foundation, by R. M. Weihing and D. W. Robertson (p. 3); Study Shows Trend in Agricultural Population (p. 12); Another Check on Potato Ring Rot Found (p. 18); and Table Provides Short Cut in Calculation of Irrigation Costs, Examples Are Cited, by R. T. Burdick (p. 19).

**Bimonthly Bulletin, [July 1940]**, edited by W. C. PALMER (*North Dakota Sta. Bimo. Bul., 2 (1940), No. 6, pp. 23, figs. 9*).—In addition to several articles noted elsewhere in this issue, there are included North Dakota Plants of the Carrot Family, by O. A. Stevens (pp. 4, 5); When Is Sudan Grass Safe as a Feed for Livestock? by F. W. Christensen (p. 19); and the customary abstracts.

**Abstracts of Bulletins 567–580, Circulars 83–85, and other publications during 1939, A. D. JACKSON** (*Texas Sta. Cir. 88 (1940), pp. 47*).—In addition to abstracts of the station's own publications as indicated, this circular contains abstracts of articles contributed by members of the staff for publication elsewhere. Some of these have been previously abstracted or are noted elsewhere in this issue, but there are also abstracts of the following: A Technique for Making Photomicrographic Prints in Color, by H. A. Smith (pp. 26, 27); Notes on Texas Plants, by V. L. Cory (p. 28); and Observations on Chromosome Elimination in the Germ Cells of *Sciara ocellaris*, by R. O. Berry (p. 28).

**Citations to literature in the Journal of Agricultural Research, technical bulletins, circulars, and miscellaneous publications (other than bibliographies), C. WHITLOCK** (*U. S. Dept. Agr., [1940], pp. 17*).—Directions and examples are given.

## NOTES

---

**Arkansas University and Station.**—Martin Nelson, associated with the agronomic work of the institution since 1908, dean and director from 1913 to 1920, and subsequently head of the department of agronomy and vice dean, has retired. The resignations are noted of Dr. Lincoln Opper, assistant professor and assistant in agricultural chemistry; Olivia Smenner, instructor in home economics and assistant in home economics research; J. V. Highfill, assistant to the dean and director; Claude J. Byrd, assistant director in charge of the Cotton Substation; and Dr. Albert Miller, instructor in entomology and plant pathology. New staff members include Helen Cannon and Ruth A. Allen as assistant professor and instructor in home economics, respectively; Dr. T. J. Claydon, Dr. C. H. Anthony, and F. H. Vogel, instructors in dairy manufacturing, veterinary science, and forestry, respectively; Max A. Jeter, assistant to the dean and director; and J. E. Walker, assistant director in charge of the Cotton Substation.

**Connecticut Stations.**—Dr. Roger B. Friend, State entomologist and chief of the department of entomology, has been appointed assistant director of the State Station and will serve as acting director in the State and Storrs Stations during the leave of absence of Director W. L. Slate. Dr. C. I. Bliss has been appointed biometrician in the State Station.

**Maryland University and Station.**—C. E. Temple, professor of plant pathology and plant pathologist, retired October 1 and has been succeeded by Dr. R. A. Jehle, associate in plant pathology.

**Massachusetts Station.**—Recent appointments include Dr. Dale H. Sieling, assistant professor of agricultural chemistry in Purdue University as research professor in chemistry; Sargent Russell, research assistant in agricultural economics; and Mabelle Booth as laboratory assistant in agricultural economics.

**Montana College and Station.**—Appointments effective September 1 include Layton S. Thompson as instructor and assistant in agricultural economics and G. Curtis Hughes as instructor and assistant in animal industry.

**New Hampshire University and Station.**—Arval L. Erikson has been appointed assistant to the director of the station, assistant agricultural economist, and assistant professor of agricultural economics. Other appointments include Dr. James H. Gillespie as instructor in poultry husbandry in the university and assistant poultry pathologist in the station and Dr. Jan Kazimierz Strzemienski of the Jagellonian University of Kraków, Poland, for temporary analytical work on the chemical composition of grasses.

**New Mexico Station.**—D. E. Wasson, assistant in agricultural economics, resigned October 1 to accept a position with the U. S. D. A. Farm Security Administration.

**Pennsylvania College and Station.**—Dr. Frederick P. Weaver, associated with the institution since 1910 and professor of agricultural economics since 1925, died September 5, aged 68 years. He was a native of Pennsylvania, graduating from the college in 1914 and receiving the M. S. and Ph. D. degrees from Cornell University in 1923 and 1930.

The first part of the history is devoted to a description of the country and its inhabitants. The author describes the various tribes and their customs, and the different parts of the country. He also mentions the various wars and battles that have taken place in the country.

The second part of the history is devoted to a description of the government and the laws of the country. The author describes the different forms of government that have been used in the country, and the various laws that have been enacted.

The third part of the history is devoted to a description of the commerce and industry of the country. The author describes the different trades and professions that are carried on in the country, and the various commodities that are produced and exported.

The fourth part of the history is devoted to a description of the religion and the manners of the country. The author describes the different religions that are practiced in the country, and the various customs and manners that are observed.

The fifth part of the history is devoted to a description of the military and naval forces of the country. The author describes the different armies and navies that have been raised in the country, and the various battles and sea-fights that have taken place.

The sixth part of the history is devoted to a description of the arts and sciences of the country. The author describes the different arts and sciences that are practiced in the country, and the various inventions and discoveries that have been made.

The seventh part of the history is devoted to a description of the state of the country at the present time. The author describes the different parts of the country, and the various improvements that have been made since the time of the first settlement.

## INDEX OF SUBJECTS

NOTE.—The abbreviations "Ala.", "Conn.[New Haven]", "Mass.", etc., after entries refer to the publications of the respective State experiment stations; "Hawaii" and "P.R." to those of the experiment stations in Hawaii and Puerto Rico; "Can." to those of the experiment stations in Canada; and "U.S.D.A." to those of this Department.

- Abaca bacterial wilt, nature, and pathogenicity tests, 351.
- Abies* spp., diseases of, revised check list, U.S.D.A. 201.
- Abortion—*see also* *Brucella abortus*.  
control from standpoint of animal breeder, 677.  
control in experimental herd of range cattle, 246.  
control in Western States, problems in, 677.  
Federal-State program, status, 677.  
field immunization experiments with vaccine from strain 45, 106.  
in army stud farm, role of mineral deficiency in, 250.  
in ewes, Wyo. 541.  
in sheep, excretion of *Brucella melitensis* following, 105.  
report of committee on, 677.  
tests for determining in dairy cattle, N.J. 677.  
transmission from swine to cattle, Mo. 242.  
tube agglutination and plate tests on low reacting serums in, comparison, Mo. 242.  
vaccinated heifers in an infected herd, report, 542.  
virus, in mares, Ky. 540.  
virus, of mares, diagnosis, 399.
- Abutilon* through *Aleurites*, host-parasite check list revision, 635.
- Acacia*, species, histogenesis and morphology of phyllode in, 170.
- Acanthocephala, relations of, 821.
- Acediopsylla*, new subgenera, erection, 525.
- Acer* section of revised plant disease check list, U.S.D.A. 500.
- Acetic acid, antiseptic action, Mass. 725.
- Acetonemia in swine, 684.
- Achromotrichia—  
in piebald rats, fractionation of factor preventing, 382.  
nutritional, 567.
- Achyla ambisexualis*, sex hormones in, 318.
- Acid phosphate, *see* Superphosphates.
- Acids—  
amino, *see* Amino acids.  
fatty, *see* Fatty acids.
- Acmaeodera*—  
*palmarum* n.sp., description, 93.  
*perlanosa* n.sp., description, 93.
- Acorduleceros megacephalus*—  
n.sp., description, 228.  
notes, 228.
- Acrididae—  
geographic distribution, in northern Oklahoma, 523.  
of northeastern Texas, key, 797.
- Acridine derivatives, mode of action, 822.
- Acrobasis caryae*, *see* Pecan nut casebearer.
- Acrospermoides*, new genus erection, 40.
- Acorotellium* genus, new taxonomy for, 201.
- Actinomyces*—  
and allied organisms, classification basis, 467.  
cause of sweetpotato soil rot, 783.  
*cellulosae* inoculated into sterilized soil, survival, 27.  
nuclei in, 752.  
population of soils, N.J. 593.  
*scabies*, races, variation in tolerance to pH, 642.  
taxonomic notes, 607.  
thermophilic autolysis of, 28.
- Actinomycetales, structure, development, and classification, 467.
- Actinomycetes, classification, 467, 606.
- Adelopus gaumanni*, cause of needle-cast of Douglas fir, 647.
- Adenylic acid and nicotinamide as substitute for yeast filtrate or yeast eluate factors, 711.
- Adrenal—  
cortex hormones, role in lactation in guinea pigs, Mo. 182.  
glands, hemorrhagic necrosis in rats on deficient diets, 139.
- Aecidium* new species, 636.
- Aedes thibaulti*, studies, Ark. 84.
- Aeolus*—  
*dorsalis*, notes, Ky. 518.  
*mellillus*, injurious to tobacco, Ky. 376.

- Aenasius paulistus*, parasite of *Pseudococcus maritimus*, 83.
- Aeolothrips melaleucus*, seasonal history on hops, 85.
- Aerobacter aerogenes*, acetylmethylcarbinol enzyme-system of, 608.
- Aerobacter* spp., preparation of an active juice from, 607.
- Aglossa cupralis*, new pest of tobacco, N.J. 651.
- Agnathia, new type in an Ayrshire calf, 183.
- Agouti, golden-rumped, unrecorded form of nematode from, 522.
- Agricultural—
- Adjustment Administration, Division of Marketing and Marketing Agreements, report, U.S.D.A. 122.
  - and home economics education, papers, 698.
  - census, first world, 694.
  - census of 1940, 405.
  - colleges—*see also specific colleges.*
    - organization lists, U.S.D.A. 559.
  - Commodities Act, Perishable, digest of decisions of Secretary of Agriculture under, U.S.D.A. 122.
  - conservation—
    - and efficient production, measures needed to achieve, 115.
    - programs in Illinois, operation, U.S.D.A. 690.
    - program in Licking County and surrounding counties, Ohio 551.
  - control, wartime, in Germany, U.S.D.A. 263.
  - cooperation, inter-American, U.S.D.A. 555.
  - cooperation, yearbook, 407.
  - credit—
    - conditions in Aroostook County, Me. 405.
    - from production credit associations and commercial banks, cost of, S.C. 551.
    - short-term, in South Carolina, S.C. 837.
    - short-time, used by plantation operators, owners, and tenants in cotton area, Ark. 116.
  - economic personnel, training and recruitment of, 834.
  - economics—
    - early history, 404.
    - levels of training for service in, La. 689.
    - personnel training and recruitment in, 404.
    - place in program of development for the South, 836.
    - training for work in, nature and scope, 404.
  - economist, theoretical equipment, needed additions to, 404.
  - education and research, closer inter-American relations in, editorial, 289.
- Agricultural—Continued.
- education, vocational, organization and administration, 698.
  - experiment stations, *see* Experiment stations.
  - extension, *see* Extension.
  - journals, changes in, 720.
  - labor—
    - and Fair Labor Standards Act of 1938, 834.
    - impact of industrial, labor, and agricultural control policies, 124.
    - migratory in Western States, 841.
    - requirements and supply of Kern County, Calif. 691.
    - sharecroppers and wage laborers, shift in tenure status of, S.C. 838.
    - since 1920, 115.
    - supply and demand, Ohio 689.
  - legislation, international yearbook, 552.
  - machinery for pea weevil control, Idaho 549.
  - machinery, rubber-tiring, Iowa 549.
  - marketing service, acts administered by, U.S.D.A. 834.
  - measures, wartime, of Canada, U.S.D.A. 555.
  - planning, county project, 405.
  - policy, 834.
  - policy, foreign, recent developments in, U.S.D.A. 120.
  - policy, national, changes needed for the South, 405.
  - policy, place of farmers, economists, and administrators in developing, 404.
  - policy of Canada, wartime, U.S.D.A. 120.
  - population, trend in, Colo. 863.
  - press, international directory, 430.
  - price statistics in United States and abroad, 115.
  - prices, control, in United Kingdom, U.S.D.A. 555.
  - production—
    - and types of farming in Minnesota, Minn. 689.
    - and types of farming, statistical supplement, Minn. 690.
    - plans, changes in and reason, Wis. 117.
  - products—
    - cost of production, *see specific crops.*
    - gross cash income from and Government payments, 406, Ohio 6.9.
    - indexes of prices, demand deposits, and purchasing power, Okla. 405.
    - marketing, *see* Marketing
    - prices, of North Dakota, N.Dak. 553.
    - regional prices received for, in Tennessee and United States, Tenn. 553.
    - State laws limiting competition in, 405.

- Agricultural—Continued.  
 products—continued.  
   transportation in United States, U.S.D.A. 263.  
   world trade in, growth, crisis, and new policies, 695.  
 relief, *see* Relief.  
 research—*see also* Research.  
   in Puerto Rico, economic background for, P.R.Col. 835.  
   quantitative spectrographic methods for development, Fla. 581.  
 sampling, new developments in, 405.  
 situation, Okla. 405, 689.  
 situation, world, 694.  
 statistics—  
   century of, 115.  
   development, close-up view, 115.  
   development in Bureau of Census, 115.  
   future improvement in, 115.  
   progress in world, 115.  
 surpluses and nutritional deficits, 405, 693.  
 surpluses, programs for use to reduce malnutrition and to benefit farmers, 405.  
 surveys, experiment in design of, 115.  
 tenancy, *see* Farm tenancy and Farm tenure.
- Agriculture—  
 American, war adjustments for, 405, and its problems in Chosen, U.S.D.A. 120.  
 Department of, *see* United States Department of Agriculture.  
 electricity in, *see* Electricity.  
 Federal-State relations, 834  
 history of, in Europe and America, 559.  
 how to be financed? 404.  
 in Denmark, as affected by war, U.S.D.A. 555.  
 in Finland, U.S.D.A. 263.  
 in Haiti, U.S.D.A. 120.  
 in Norway, U.S.D.A. 120.  
 in Turkey, changing agro-economic policy, U.S.D.A. 263.  
 in United States, 1839 and 1939, 404.  
 income parity for, U.S.D.A. 692.  
 permanent aspects of supply and price adjustment in, 115.  
 Philippine, a problem of adjustment, U.S.D.A. 836.  
 poverty in, problem, 404.  
 State legislation dealing with, Ohio 551.  
 use of normal value concept as stabilizing influence, 405.
- Agrilus communis rubicola*, control, 226.
- Agropyron*—  
*inermis* for erosion control, Wash. 160.  
*inermis*, notes, Wash. 229.  
 Iowa species, 745.  
 spp., transpiration ratio, 169.
- Aircraft insect problem, 793.
- Alabama argillacea*, *see* Cotton leaf worm.
- Albumin, egg—  
 crystalline, denaturation, effect on nitrogen content, 587.  
 injury, histological changes in tissues and nerve cells from, Wis. 126.  
 protein, efficiency in forming serum albumin, 128.  
 quality relation to pH and cloudiness, 534.  
 toxicity, relation to certain proteins, Wis. 126.  
 watery, Wash. 229.
- Alcaligenes* spp., taxonomic relations to soil saprophytes and plant parasites, 40.
- Alcohol production and use by plant tissues, 37.
- Alcohols, sugar, quantitative estimation, rapid micromethod for, 725.

*Apotennus* n.g. and n.sp., description, 804.

Apparatus—  
 continuous liquid-extraction, mechani-  
 cally operated, 438.  
 for determining riboflavin in foods, 152.  
 for fixing and dehydration, 464.  
 for holding a vial or test tube, 588.  
 for measurement of rigidity of starch  
 paste, 150.  
 for measuring turgor pressure of large  
 cells; 35.  
 for seed treatment against grain loose  
 smut, Okla. 74.  
 glass needle used for isolating single  
 spores, 785.  
 melting point, electric, 588.  
 precipitate dryer, description, 8.  
 psychrometer, motor-ventilated, descrip-  
 tion, 738.  
 to prevent bumping and promote boil-  
 ing, 588.

Apple—  
 anthracnose, control, Me. 344.  
 aphid—  
 green, tests with insecticides for,  
 Wis. 364.  
 rosy, control, 218, Ky. 518.  
 rosy, control, experimental spray-  
 ing for, Pa. 367.  
 rosy, newer dormant sprays for,  
 367.  
 rosy, studies, Me. 363.  
 studies, Me. 363.  
 woolly, soil fumigants for, 221.  
 woolly, studies, Me. 363.

aphids, control experiments, technic in,  
 656.

bitter pit development, effect of mulch-  
 ing, N.H. 783.

bitter rot, copper sprays for control,  
 Del. 68.

boron-deficiency disease, 355.

dieback in California, 79.

diseases in Massachusetts, U.S.D.A. 500.

drop and apple cork spot, effect of boron,  
 N.H. 772.

fire blight, report of conference on,  
 U.S.D.A. 356.

flowers, pollen germination on stigmas  
 treated with fungicides, 492.

fruit set, effect of tar oil spray for pre-  
 vention, 629.

fruitfly, studies, Me. 363.

grain aphid, studies, Ky. 518, Me. 363.

insect outlook for 1940, in Illinois, 523.

insects, control, 522.

insects, test of insecticides against,  
 N.Y.State 217.

internal cork, control by boron, 355.

juice, galacturonic acid from, Wash. 150.

juice, making table sirup from, Wash.  
 150.

juice, studies, Wash. 150.

layers, root forming ability, 491.

## Apple—Continued.

  - notes, U.S.D.A. 344.
  - spray schedule, ascospore discharge relation to, N.H. 783.
  - spraying for, N.H. 783.
- season of 1939, climatic conditions, relation to production, 338.
- slices, canned in sirup, Mass. 843.
- soft rot caused by *Trichoseptoria fructigena*, 213.
- sprays, tests, Conn.[New Haven] 651.
- stocks, hardy, methods of propagating, Wash. 190.
- styles, pollen tube growth after inter-varietal cross-pollination, 492.
- thinnings, availability as source of pectin, Wash. 150.
- tree borer, roundheaded—
  - biology and control, N.Y.State 802.
  - control, Ohio 518.
- trees—
  - Blaxtayman and Gallia Beauty, Malling understocks for, Del. 57.
  - calcium cyanamide as source of nitrogen for, Mo. 189.
  - complete fertilization, Mo. 189.

## Apple—Continued.

- trees—continued.
  - delayed dormant spray for, replacing cresylic acid with tar oil, 653.
  - fertilization, N.H. 771.
  - in sand culture and in commercial orchards, magnesium deficiency of, 508.
  - pruned and unpruned, effect of seedling- and own-rooted understocks on growth, Del. 57.
  - pruning, Ark. 56.
  - pruning experiments on young stock, Mo. 194.
  - receiving nitrogen treatments, carbohydrate-nitrogen relations, Del. 57.
  - summer spraying, semirefined oils for, 366.
  - 3-year-old, root development on Coastal Plain soil, N.J. 628.
  - water requirements and irrigation, Nebr. 771.
  - young, growth and assimilation, effects of nitrogen, potassium, and phosphorus, 492.
  - young, importance of soil pore space to, N.Y.State 194.
  - white root rot, due to *Corticium galactinum*, So.
- Apples—
  - affected with internal cork, behavior in storage, Mass. 771.
  - breeding, 59, N.J. 628.
  - clonal rootstock for, Mass. 771.
  - Comstock's mealybug as orchard pest, 221.
  - consumers and restaurants buying, and quantities and price paid, Del. 116.
  - crab, *see* Crab apples.
  - cultivation v. mulching for, Mass. 771.
  - effect on calcium retention, 847.
  - embryo growth and development, Mo. 189.
  - fertilizer requirements, Mass. 771.
  - foliage and fruit injury from spray materials, 509.
  - fruit bud mutation in, Mass. 771.
  - fruit set following daily exposure of flowers to insects, Ohio 195.
  - Granny Smith, superficial scald in, 61.
  - Gravenstein, calyx end structure in, 195.
  - harvested, methods of sun-coloring, Mass. 771.
  - Hibernal and Northwestern Greening, chromosome numbers, 491.
  - injury from use of standard spray schedules, Del. 85.
  - Jonathan and Grimes Golden, maturity studies, 60.
  - Jonathan, soft scald in, physiological study, 509.
  - lead-arsenate-sprayed, noninjurious to swine in moderate amounts, 684.
  - losses from plant diseases, U.S.D.A. 201.

## Apples—Continued.

## McIntosh—

- comparison of solid blush and striped strains, Me. 335.
- preharvest drop, affected by nitrogen-carrying fertilizers, 629.
- premature dropping, Mass. 771.
- spur nitrogen and preharvest drop, 629.

morphology of flower, [N.Y.]Cornell 774.  
new hardy for Northwest, S.Dak. 774.

new rootstocks for, tests, N.Y.State 775.  
pollination, 194.

potential production, relation to growth status, N.J. 628.

premature dropping, relation to curculio injury, Del. 57.

preventing excessive abscission by spraying with growth substances, 629.

price differences received by Ulster County, New York, growers, reasons for, 840.

production of ethylene in ripening process, Minn. 339.

pruning, Iowa 491. N.J. 628.

quality, spray schedules for, Miss. 193.  
rate of ripening, effect of type of storage, Ohio 488.

red strains, effective date for picking, Ohio 488.

rootstocks for, N.H. 772, Nebr. 771.

size, effect of artificial drought on, Ohio 488.

spray residue studies, N.J. 625.

spray schedule for 1940, 509.

spraying, N.H. 771.

storage troubles, 500.

sun coloring, in Delaware. 195.

thin wood pruning, Mich. 60.

thinning, 339.

thinning an essential to quality and yield, Miss. 491.

time of winter injury, relation to time of applying nitrogen, N.H. 772.

total yields, on young trees, 628.

varietal susceptibility to rust organisms, 646.

varieties, effect of Malling II and IX rootstocks on, 491.

varieties, new, survey of growers on performance, N.Y.State 775.

vitamin C in, 715.

yields, costs, prices, markets, etc., N.J. 688.

## Apricot—

brown-spotting, a boron-deficiency disease, 356.

gum-spot disease in South Africa, 356.

trees, unthinned, fruit size, relation to crop and season, 492.

## Apricots—

canned, annual average f. o. b. prices. statistical analysis, Calif. 840.

dried, color and SO<sub>2</sub> retention, effect of drying and storage conditions, 156.

*Aptilopsylla carlsbadensis*, n.g. and n.sp. from an unknown host, 525.

*Arabis* genus in Iowa, 745.

Arborvitae, oriental, blight caused by *Corynum berckmanii*, 647.

*Arctostaphylos elegans*, status, 324.

*Argyrotaenia velutinana*, see Leaf roller, red-banded.

Arkansas Station, notes, 288, 864.

Arkansas Station, report, 143.

Arkansas University, notes, 288, 864.

*Armillaria* root rot in citrus groves, 790.

## Armyworm—

beet, studies, U.S.D.A. 84.

control, Mo. 217.

fall, Fla., 651.

fall, relation to European corn borer situation, Me. 363.

notes, Tenn. 519.

response to lights, Ohio 518.

southern, studies, U.S.D.A. 84.

Arrowgrass, dangerous because of hydrocyanic acid, Wyo. 541.

Arsenic, effectiveness in preventing selenium poisoning, 531.

## Arsenical—

spray residues—see also Spray residue and specific fruits and vegetables.

elimination from soils, N.J. 592.

sprays, accumulations in orchard soils, Wash. 160.

sprays, substitutes for, Mo. 217, Wis. 364.

Arspenamines, antispasmodic action in vitro, 822.

Arteriosclerosis, experimental, relations to aging, Ark. 127.

Arthritis in swine, Wash. 242.

## Artichoke plume moth—

larvae, methyl bromide as fumigant for, 90.

new *Angitia* parasitic on, 91.

*Ascaridia lineata*, food of, 254.

*Ascaris*—

*equorum* infestation in Philippine horses, 251.

*lumbricoides*, hematin in intestines of, 686.

*suum*, saline requirements of larvae, 395.

*Ascia rapae*, see Cabbageworm, imported.

*Ascochyta* blight of cotton, outbreak, U.S.D.A. 783.

*Ascogaster carpocapsae*, notes, 658.

## Ascomycetes—

from Minas Geraes, Brazil, 596.

new taxonomic data, 456.

## Ascorbic acid—see also Vitamin C.

as substrate in oxidase measurements, 445.

biological synthesis, role of manganese in, 422.

concentration in endocrines and organs, effect of Walker carcinosarcoma, Ark. 127.

destruction in rumen of dairy cow, 670.

effect on calcium retention, 570.

effect on poliomyelitis virus, 139.

excretion, relation to saturation and utilization, 137.

- Ascorbic acid—Continued.  
 in animal tissues, possible carrier role of, 855.  
 in bananas, variations in, 136.  
 in blood and urine after oral administration of vitamin C, 422.  
 in blood serum, factors preventing oxidation, 855.  
 in certified milk, effect of pasteurization, 282.  
 in feces, determination, 569.  
 in milk, effect of heat treatments, 816.  
 in orange juice, fresh, effect of refrigeration, 136.  
 in tomato juice, effect of refrigeration, 136.  
 in tomatoes, effect of home canning and subsequent storage, 136.  
 oxidation, effect of bacteria, 137.  
 plasma, of infants and children, 855.
- Ash analysis and microincineration, 726.
- Ash, green, growth of seedlings, relation to subsoil acidity and fertility, 342.
- Asparagine metabolism, 230.
- Asparagus—  
 beetle control, S.C. 519.  
 breeding, N.J. 625.  
 butts, digestibility, Calif. 532.  
 cooked in fat, calcium and phosphorus in, 273.  
 crown-grading experiments, Calif. 191.  
 deep soil treatment essential for, 336.  
 depth of planting, Tenn. 489.  
 fern caterpillar, life history and control, 798.  
 fertilizer requirements, Ga.Coastal Plain 625, Wash. 190.  
 home-canned green, nature of yellow deposit in jars, 134.  
 manure experiments with, Ark. 626.  
 nutrient deficiencies, effect of root temperatures on development, N.J. 625.  
 planting, care, and management, Ill. 772.  
 production in California, effect of spacing, 626.  
 quality, tenderometer readings as an index, 626.  
 studies, P.R.Col. 625.  
 varieties and culture, Mass. 771.  
 waste as source of asparagin, Wash. 150.  
 yield and size of spears, S.C. 488.  
 yields, effect of spacing and length of harvesting period, Iowa 191.
- Aspartic acid metabolism, 230.
- Aspergillus*—  
 and *Penicillium* and their nitrate metabolism, classification, 467.  
 and *Penicillium* relations, 467.  
*niger*, carbon nutrition relation to trace-element and accessory requirements, 38, 468.  
*niger*, growth, effect of nitrogen compounds and trace elements, 38.  
 spp. extracts, vitamin C in, 598.  
 spp., genetic changes in, chemical induction, 177.
- Aspergillus*—Continued.  
 spp., mutations and reversions in, 456.  
*sydowi*, enzyme-resistant protein of, 467.  
*sydowi*, isolation of nitrogenous compounds from, 437.  
 variations in, 467.
- Aspidiotus ancyclus*, see Putnam's scale.

- Autoserica castanea*, see Garden beetle, Asiatic.
- Auxin—  
 formation in plants, relation to boron, 172.  
 in *Avena* coleoptiles, light stability of, 172.  
 production, in isolated roots growing in vitro, 461.
- Auxins, chemical structure and biological activity, relation, 455.
- Avitaminosis in diabetic patients under insulin therapy, 714.
- Avocado—  
 diseases, control, Fla. 635.  
 fruit spots, control, 357.  
 leaf symptoms for deficiencies in solution cultures, 62.  
 meal, digestibility, Calif. 532.

## Avocado—Continued.

- seedlings, growth and transportation, effect of artificial winds of low intensity, 62.
- seedlings, growth, effect of pH, 62.
- seedlings, growth, effect of root temperature, 62.

## Avocados—

- anatomy, 35.
- culture, Fla. 625.
- studies, P.R.Col. 625.
- use in swine rations, Hawaii 528.

## Azalea—

- disease affecting flowers, 80.
- flower spot in Texas, U.S.D.A. 635.
- insect pests, control, Ala. 519.
- lacebug, notes, Ala. 519.
- leaf miner, notes, Ala. 519.
- Monilinia* causing brown rot and blight, 514.
- twig and bud blight, due to *Sporocybe azaleae*, new stages of, 513.

## Azaleas, resistance to fumigation with methyl bromide, 214.

*Azolla filiculoides*, sporangium development in, cytology, 606.*Azotobacter*—

- activity, relation to surface soil acidity, N.Dak. 742.
- chroococcum* inoculated into sterilized soil, survival, 27.
- chroococcum*, synthesis of coenzyme R by, 463.
- distribution and activity in range and cultivated soils, Ariz. 164.
- fixation of atmospheric nitrogen by, colloidal clay as basic medium, 29.
- nutrition, molybdenum and calcium in, 468.

## Baby beef, see Cattle, baby beef.

## Bacilli, mesophilic, taxonomy, 467.

*Bacillus*—

- abortus*, see Abortion and *Brucella abortus*.
- coli*, variations, relation to bacterial inhibitory agents, 822.
- enteritidis*, see *Salmonella enteritidis*.
- genus, description of dextro-lactic acid forming organism of, 607.
- genus, relation between temperature growth range and size in, 607.
- krzemieniewski*, bacteriological studies, 28.
- krzemieniewski* n.sp., nature and properties of polysaccharide produced by, 28.
- larvae*, nitrite nitrogen test for, 378.
- larvae*, thermal resistance, 378.
- mallei*, artificial infections of goat, sheep, and dogs with, 678.
- megatherium* inoculated into sterilized soil, survival, 27.
- radicola*—see also Legumes, inoculation, and Nodule bacteria.
- spp., aerobic spore-formers, production of acetyl-methyl-carbinol by, 752.

## Bacon, Wiltshire, bacteriology, quantitative analysis of curing pickle, 533.

## Bacteria—

- acidfast, staining method, 105.
- action of radioactive radiations on, 467.
- adsorption by, 456.
- aerobic and anaerobic, proteases of, 467.
- aerobic, nonspecific growth factors of, 468.
- air-borne device for sampling, 240.
- anaerobic, see Anaerobes.
- classification, effect of variation on, 466.
- counting by microscopic method, 468.
- development from single cell, motion pictures of, 466.
- enzymatic cellular divergencies, 467.
- estimating numbers, evaluation of errors by plating method, 469.
- fermentation of sugar acids by, 469.
- growth, and glutamine, 468.
- growth factors for, 460.
- in Hawaii, and hosts, check list, U.S.D.A. 345.
- in lactic and butyric groups, growth factor requirements, 468.
- in milk and soil, see Milk and Soil.
- morphogenesis and formation of colonies, 466.
- non-spore-forming, heat resistance of, determination, 155.
- nutritive conditions, dependence on oxygen optimum, 467.
- oxidase, and other reactions, relation to dairy products, 537.
- phytopathogenic, relations, 345.
- preparation of an active juice from, 607.
- primitive forms, in milk and milk products, 100.
- production of tryptophanase by, 467.
- purple, carbon dioxide reduction with molecular hydrogen in, 467.
- respiratory systems in, 467.
- thermoduric, resistance to chlorine disinfection, 673.
- toxicity of basic fuchsin for, 456.
- toxicity of cerium compounds for, 745.
- utilization of CO<sub>2</sub> by, 467.

## Bacterial—

- antagonism, 745.
- cell nucleus, problem of, 467.
- cells, living, effect of ultrashort electric waves on, 467.
- cells, radiant energy from, new factor in symbiotic phenomena, P.R.Col. 581.
- chemotherapy, nonsulfur compounds of interest in, 822.
- characters, independent variation in, 467.
- condition of foods, resazurin reduction rates and bacterial plate counts as indices, 301.
- counts, making by rolltube method, suitability, 391.
- cultures, detection of hydrogen sulfide in, by salts of cobalt and nickel, 456.
- cultures, oxygen demand and oxygen supply, 467.

- Bacterial—Continued.  
 development, effect of electric field of atmosphere, 467.  
 infections, chemotherapy of, status, 821.  
 metabolism, luminescence and respiration in, 467.  
 photosynthesis and oxygen, 467.  
 pigment, new type, 467.  
 population, serological analysis of, 466.  
 studies, errors of plate method, 468.  
 toxins, effect of sulfanilamide and related compounds, 822.  
 type transformation, 467.
- Bacteriological—  
 nomenclature, code, 466.  
 studies, sterile transfer chamber for, 595.
- Bacteriology—  
 dairy, classification in, 817.  
 determinative, Bergey manual, changes in outline of classification, 466.  
 mathematics in, 323.  
 pathogenic, and immunity for domestic animals, 394.  
 significance of conceptions genotypus and phaenotypus to, 466.  
 textbook, 677.
- Bacteriophage—  
 effects of ultraviolet radiation and X-rays, 467.  
 factor in disease resistance, Ohio 501.  
 in classification of aerobic spore-formers, *Bacillus* spp., possible utilization, 752.  
 method for concentration and purification, 467.  
 precursor of, 467.  
 purified, 467.
- Bacteriophages—  
 and viruses, ultracentrifugation and serological reactions, comparison, 345.  
 plant and insect viruses, comparative studies on ultracentrifugation and serological reactions, 819.
- Bacteriophagey, research on and problem of virus, 345.
- Bacterium*—  
*coli*, see *Escherichia coli*.  
*neurophorum* in chronic ulcerative colitis, 823.  
*phytophthorum*, cause of potato blackleg, 353.  
*pruni* canker of cherries, Mo. 201.  
*pruni* on peach, relation of nitrogen fertilization to control, 781.  
*pruni* on peach, relation to nitrogen fertilization, 780.  
*pseudotsugae*, galls on *Pseudotsuga macrocarpa* induced by, 647.  
*pullorum*, see *Salmonella pullorum* and Pullorum disease.  
*radioicola*, see Legumes, inoculation, and Nodule bacteria.  
*stewartii*, mutation in, Iowa 68.  
*translucens* v. *undulosum*, studies, 41.  
*tularensis*, persistence in tissues of argasid ticks, 804.  
*tularensis*, studies, 823.
- Bacus californicus* life history, notes, 665.
- Baking—  
 maltose fermentation activators affecting, 441.  
 oven, experimental, uniform temperature maintenance, 296.
- Balloons, radio-sounding, improvement in, 18.
- Balsam fir needle blight due to *Rehmiellopsis bohemica*, U.S.D.A. 500.
- Banana—  
 black end and anthracnose, cause, 510.  
 diseases, P.R.Col. 635.  
 leaf spot, P.R.Col. 635.  
 phloem and neighboring tissues, pathological changes in, 789.  
 products of variety Giuba, chemical composition, 700.  
 variety, Giuba, chemical composition, 700.
- Bananas—  
 ascorbic acid in, variations in, 136.  
 Gros Michel, refrigerated gas storage of, 777.  
 production of ethylene in ripening process, Minn. 339.
- Barberry eradication, 207, N.Dak. 503, U.S.D.A. 68.
- Barium—  
 determination, colorimetric method for, 581.  
 soils high in, fertility, 166.
- Bark beetles—  
 and borers, control with chemicals, 516.  
 damage to plantation pine, Conn.[New Haven] 652.  
 isolation of *Ceratostomella ulmi* from, 648.
- Barley—  
 as supplement to alfalfa for range ewes and lambs, Nev. 529.  
 brachytic mutation in, genetic and cytologic studies, 754.  
 breeding, Mo. 185, N.J. 617, N.Mex. 48, Nebr. 759, Tenn. 481, Wash. 185.  
 breeding, methods in, U.S.D.A. 470.  
 bulbous, processing seed of, U.S.D.A. 618.  
 covered smut, seed disinfection tests, irregular results in, 350.  
 culture experiments, Wyo. 481.  
 disease-resistant breeding stocks, location and testing, Wis. 345.  
 diseases, control, Mo. 201.  
 fertilizer experiments, Ark. 48, Wyo. 481.  
 improvement, Colo. 754.  
 loose smut, control by vacuum treatment, 346.  
 loose smut, machine for control, Okla. 74.  
 losses from plant diseases, U.S.D.A. 201.  
 male sterile character in, new tool for plant breeder, 754.  
 outstanding varieties, N.Dak. 49.  
 phosphorylation and respiration in, 34.  
 planting tests, Nebr. 760.

## Barley—Continued.

- respiration, effect of cyanide on, 319.
- roots, accumulation of salt by and pH effects, relation to metabolism, 319.
- seed treatments, Ark. 637.
- surface v. furrow drilling, Nebr. 760.
- tests for yield, cultural requirements, and malting quality, Wis. 333.
- v. corn for fattening pigs on pasture, Tenn. 529.
- varieties recommended, Nebr. 618.
- varieties registered, 49.
- variety tests, Ark. 48, Del. 48, Me. 333, Mo. 185, N.J. 617, N.Mex. 48, Nebr. 618, 759, Tenn. 481, Wash. 185, Wyo. 481.
- western Canadian, feeding value for bacon hogs, 384, 385.
- winter, for swine, adaptability and value, Mo. 229.
- yields and other data, Nebr. 618.
- yields, effect of time of seeding, Wis. 49.

Base exchange capacity, electrometric determination, Hawaii 448.

## Basidiomycetes—

- new taxonomic data, 456.
- sexuality in, 468.

*Basisporium gallarum*, pathogenicity to corn, Iowa 68.

Bat, female, longevity of sperm in, 615.

*Bathyplectes curculionis*, larval parasite of alfalfa weevil, Calif. 664.

## Bats—

- New England, migrations, 215.
- parasite of, 364.

## Bean—

- bacterial blight, control, 780.
- bacterial blights, breeding for resistance, Nebr. 783.
- beetle, Mexican—
  - notes, Tenn. 519.
  - paris green toxicity and repellency to, relation to particle size, 661.
  - studies, U.S.D.A. 84.
  - tachinid parasite of, U.S.D.A. 373.
- black root, new virus disease of snap beans, 511, 781.
- blight, common and halo, varietal reactions and control tests, Wyo. 502.
- blights, relation to temperature, 75.
- disease, hitherto unreported due to aerial species of *Rhizoctonia*, Fla. 634.
- flour, principle with progesterone-like activity obtained from, 613.
- halo blight in Florida, Fla. 634, U.S.D.A. 500.
- jassid, control, Fla. 650.
- leaf area, determination, and relation to yield, U.S.D.A. 764.
- mosaic resistant and nonresistant Green Refugee variety, disease in, 211.
- nodules, ether extracts of, coleoptile assay, 172.
- pod borer, larvae destruction, methyl bromide fumigation for, 89.
- pod borer, studies, Hawaii 517.

## Bean—Continued.

- root knot resistance, 75.
  - rust, control, N.J. 635.
  - rust, etiology and control, Wash. 202.
  - rust, notes, Fla. 634, Hawaii 501.
  - seedlings, radiophosphorus in, absorption and movement, 174.
  - weevil, experimental population, destruction by *Pediculoides ventricosus*, 652.
- Beans—*see also* Soybeans and Velvetbeans.
- breeding, Me. 335, P.R.Col. 617, Tenn. 489.
  - breeding for quality and resistance to rust and powdery mildew, Fla. 634.
  - bush, arsenic toxicity to, Hawaii 501.
  - carbohydrate and nitrogenous compounds in, effect of  $\alpha$ -naphthaleneacetamide and  $\alpha$ -naphthaleneacetic acid, 319.
  - disease-free canning, excel in quality, Wis. 345.
  - dried, iron availability in, 274.
  - Duluth snap, origin and distinguishing characters, 336.
  - fertilizer experiments, P.R.Col. 617.
  - Green Refugee, mosaic resistant and nonresistant types, disease in, 211.
  - green snap, fresh and frozen, carotene in, 456.
  - home canning, Wyo. 562.
  - improvement, Mass. 771.
  - inheritance of resistance to alfalfa mosaic virus 1 and stringiness in, 178.
  - lima—
    - bud drop in the fall, Fla. 634.
    - bush, yields, S.C. 488.
    - culture experiments, Ga.Coastal Plain 625.
    - culture on special soils, West.Wash. 190.
    - fertilizer experiments, Ga.Coastal Plain 625.
    - natural crossing in, 489.
    - production of seed on nutrient-deficient plants, N.J. 625.
    - production, relation to fertilizer placement and seed spacing, 58.
    - spacing, West.Wash. 190.
    - variety tests, Ga.Coastal Plain 625.
  - losses from plant diseases, U.S.D.A. 201.
  - pinto—
    - breeding, N. Mex. 48.
    - flavin and vitamin B<sub>6</sub> in, effect of cooking, N.Mex. 126.
    - improvement, N.Mex. 619.
    - riboflavin and vitamin B<sub>6</sub> in, effect of cooking, 422, N.Mex. 421.
    - yields of varietal leaders, N.Mex. 760.
  - planting rates, Me. 335.
  - pole, preparation for hot weather yields, Miss. 287.
  - response to calcium deficiency, 173.
  - rust-resistant snap, development and selection, Hawaii 488.

## Beans—Continued.

## snap—

- irrigation, Ark. 56.
- N and P needs of, Ky. 488.
- new virus disease of, 511, 781.
- nutritive value, factors affecting, Mass. 843.
- quality, reliability of retail prices as guides to, Ohio 116.
- resistant to root and leaf diseases and nematodes, breeding, Ga. Coastal Plain 625.
- vitamin C in, 135.
- string, frozen, enzyme activity in, 154.
- studies, P.R.Col. 625.
- varieties for commercial canning, N.Y. State 191.
- variety tests, 337, N.Mex. 48, P.R.Col. 617, West.Wash. 190.

## Bedbug—

- evaluating liquid insecticides against, 520.
- toxicity of sulfur dioxide to, 797.

## Bedding materials for livestock, absorptive capacity, 535.

## Bedroom space inadequate in most Utah homes, Utah 559.

## Bee—

- bread and soybean flour as pollen substitutes for bees, 378.
- foods, vitamins in, 378.
- stings, serious reactions to, 363.

## Beech—

- bleeding canker, U.S.D.A. 201.
- root system and mycorrhizal relations in woodland soils, 604.

## Beef—see also Cattle, beef.

- amount of drip, relation to time of freezing after slaughter, 381.
- amount of fat consumers want, 380.
- flavor and juiciness, factors affecting, 381.

## Government grade-stamped and packer-branded, consumer attitudes, 381.

## production—

- and quality, relation to method of feeding supplements, U.S.D.A. 233.

## in California, 532.

- on bluegrass, alfalfa, and clover pastures, economy of, Tenn. 529.
- per acre of variously fertilized pastures, Ky. 528.

## quality, effect of sorghum grains, Nebr. 805.

## roasts and steaks, storing in freezer lockers, 381.

## steaks, broiling methods, standardization, Mo. 269.

## steers on pasture, effect of winter weight changes on gains, 381.

## weight produced per animal unit and per section on ranches, N.Mex. 116.

## Beekeeping—

- as means of diversifying farming, Wis. 364.
- laying workers in, 804.

## Bees—

- as pollinators, value, 516.
- breeding, nutrition, and pollination, U.S.D.A. 84.
- foulbrood, see Foulbrood.
- lethal effects of insecticides, U.S.D.A. 84.
- losses in Utah, 363.
- mind of, 227.
- outside wintering, Wyo. 519.
- package, factors affecting, 94.
- Package, management problems, Ohio, 803.
- queen and worker, respiratory metabolism during larval and pupal development, 803.
- studies, N.J. 651.
- trees and shrubs of Michigan furnishing nectar and pollen to, Mich. 93.
- two-queen colonies, Wyo. 519, 803.
- wintering in Wyoming, Wyo. 803.
- wintering v. destroying and restocking hives with package bees in spring, N.Dak. 803.

## Beeswax—

- characteristics, contaminants, processing, and uses, U.S.D.A. 217.
- physical and chemical properties, U.S.D.A. 303.

## Beet—

- internal black spot, borax for control, 352.

## leafhopper—

- control in Idaho, 354.
- on tomatoes, repellency of pyrethrin dusts to, 368.
- partly desiccated, hydroxyl-ion concentration of saliva, 351, 797.
- resistance of Chilean tomatoes to, 78.
- studies, 354.

## pulp v. sunflower silage, as supplement to native hay for dairy heifers, Wyo. 535.

## soil, borax treatment for, Wis. 345.

## sugar, stored, survival of thermophilic food-spoilage organisms in, 155.

## Beetles—

- bark and timber, of North America, north of Mexico, 226.
- brood provision and rearing instincts, 522.

## Beets—

- canning, boron requirement, Mich. 489.
- improvement, Mass. 771.
- premature seeding studies, 489.
- red garden, principal American varieties, types, U.S.D.A. 772.
- reproduction in, physiology, effects of temperature, Mo. 189.
- role of aphids as virus vectors on, 507.
- sugar, see Sugar beet(s).
- table, fertilizer requirements, Wis. 336.

*Bembecia marginata*, see Raspberry root borer.

## Bentgrass scald, Wis. 334.

## Bentonite suspensions, properties, effect of iron on, 167.

- Benzol and related compounds, principles involved in their use, 72.
- Berberi—  
acute, pathology of, 425.  
control, relation to new chemistry of vitamin B<sub>1</sub>, 425.  
patients, urinary excretion of vitamin B<sub>1</sub> by, 279.
- Bermuda grass—  
constituents, relation to nitrogen, phosphoric acid, and lime in, 743.  
pastures, rotational v. continuous grazing, S.C. 535.  
sod, seedings of small grains and legumes on, Tenn. 481.

## Birds—Continued.

- yield of weed crops and waste grain as food for, Wis. 83.
- Bismuth, antiprotozoal action in vitro, 822.
- Bittacidae, North American, biology and morphology, 524.
- Black Hills beetle, studies, U.S.D.A. 84.
- Black hunter, most common predaceous thrips in North America, 655.
- Black scale—
  - eggs, toxicity of hydrocyanic acid to, 89.
  - frequency distribution, 83.
  - winter mortality on oranges in California, 657.
- Black vine weevil control, Wash. 217.
- Blackberries—
  - Brainerd, in central Illinois, 495.
  - breeding, 59, N.J. 628, West.Wash. 190.
  - tartaric acid determination in, 269.
  - varieties, Fla. 624.
  - variety tests, West.Wash. 190.
- Blackhead in turkeys, control, 401, Mo. 242.
- Blackleg—
  - and associated conditions of cattle, 823.
  - in Sao Paulo, etiological agents, 396.
- Bladder, human, recovery of vitamin C from, 569.
- Blatella germanica*, see Cockroach, German.
- Blissus—
  - hirtus*, see Chinch bug, hairy.
  - leucopterus*, see Chinch bug.
- Blister beetle—
  - ash-gray, control, S.Dak. 801.
  - spotted, control, S.Dak. 801.
- Blister beetles, control, S.Dak. 801.
- Bloat—
  - in cattle, factors relating to, 674.
  - in dairy cattle, 536, S.Dak. 246.
- Blood—
  - and anemia studies, Hawaii 562.
  - and blood-forming organs, symposium, 242.
  - ascorbic acid in after oral administration of vitamin C, 422.
  - cell volume, capillary hematocrit method of determining, Hawaii 562.
  - clotting disturbance in obstructive jaundice and its elimination by vitamin K therapy, 285.
  - coagulation problem, status, 243.
  - coccarboxylase in, 419, 420.
  - constituents, cellular, of guinea pig, effects of vitamin C deficiency and diphtheria toxin, 570.
  - constituents of nonlactating Red Scindia cows, quantitative data, 233.
  - fat procedure, Allen, modification of, 674.
  - human, coccarboxylase content, 439.
  - neutral fat glycerol in, determination with periodate, 301.
  - nicotinamide and cozymase in, 714.
  - of cattle, use of cellular antigens for determining parentage, 608.

## Blood—Continued.

- of newly hatched chick, lipid content and changes during first month of life, 390.
  - oxalated, use for cytological studies, 541.
  - picture in hemorrhagic anemia, Minn. 140.
  - picture of horse, 250.
  - pyruvate levels in animals and man, 133.
  - pyruvate, relation to cardiac changes, 133.
  - regeneration, see Hemoglobin.
  - review of literature, 413.
  - values, survey, of young men and women, Hawaii 562.
  - vitamin A and carotinoid in, determination, 297.
- Blowfly populations, winter, and activity relation to carcass temperatures, 92.
- Blueberries—
  - breeding, fruitfulness, and use of growth substances, Me. 335.
  - cultivated, inheritance of characters in, 631.
  - culture, Mass. 771, Wash. 190.
  - fertilization, N.J. 628.
  - frozen, behavior of micro-organisms in, 154.
  - high-bush, improved varieties, culture, N.Y.State 340.
  - high-bush, nutrition, Mass. 771.
  - high-bush, pollination, 776.
  - irrigation and frost control, Wash. 190.
  - low-bush, pruning, 630.
  - mulching v. cultivation for, N.J. 628.
  - new interest in, N.Y.State 776.
  - propagation and culture, N.H. 772.
  - pruning and spacing, N.J. 628.
  - varieties, Ga.Coastal Plain 625, N.J. 628.
  - variety tests, West.Wash. 190.
- Blueberry—
  - cuttings, rooting, effect of growth substances, 631.
  - diseases, studies, N.J. 635.
  - fertilizer distributor, mechanical, N.J. 687.
  - insects, N.J. 651.
  - maggot, studies, Me. 364.
  - thrips, studies, Me. 364.
  - twig blight fungus, development of perfect stage, 357.
  - wilt, associated with *Phomopsis*, Mass. 783.
- Bluegrass—
  - breeding, Ky. 479.
  - in mixtures, effects of legumes on, Ky. 479.
  - parthenogenesis in, cytology, 472.
  - pasture v. rye for breeding ewes, Ky. 528.
  - pastures, continuous v. rotational grazing, Ky. 528.
  - pastures, white grubs in, 55.

- Bluegrass—Continued.  
soil, density and productivity, factors affecting, Mo. 185.
- Bluestem grasses, constituents, relation to nitrogen, phosphoric acid, and lime in, 743.
- Bobwhite, *see* Quail.
- Body louse control, 524.
- Boletus elegans* in pure culture, studies, 323.
- Bollweevil—  
control on upland and sea-island cotton, Ga.Coastal Plain 654.  
studies, S.C. 518, U.S.D.A. 84.
- Bollworm—  
injury, important period of, Ark. 84.  
pink, P.R.Col. 651.  
pink, larval diapause, in Trinidad, 223.  
pink, primary external parasite of, biology, 379.  
pink, studies, U.S.D.A. 84.  
studies, U.S.D.A. 84.

- maggot, timing experiment leading to control program for, 364.
- manure experiments with, Ark. 626.
- response to superphosphate, 57.
- Sclerotinia* on, U.S.D.A. 68.
- strains, new, work progressing on, N.Y.State 191.
- varieties for disease resistance and fertilizer needs, Mo. 190.
- varieties, new, tests, 191.
- variety tests, Ga.Coastal Plain 625, Ohio 488.
- vitamins in, effect of winter storage, Mont. 276.
- white butterfly, migrations, 222.
- yellows-resistant varieties, suitable for New York State, N.Y.State 626.

## Cabbageworm, imported—

- biological control, Hawaii 517.
- insecticide tests for, Ohio 518.
- studies, U.S.D.A. 84.
- toxicity of nicotine to, 653.

Cabbageworms, control by derris-nicotine dust, Wis. 364.

## Cacao—

- shell meal, vitamin D and riboflavin activity of, Mass. 813.
- swollen shoot disease transmission, 358.

## Cacoecia—

- cerasivorana*, see Ugly-nest caterpillar.
- fumiferana*, see Spruce budworm.

Caddice fly and its hymenopterous parasite, rearing, 228.

Cadmium poisoning, experimental chronic, 426.

## Cakes—

- sponge, effect of dry milk solids on keeping quality and batter stability, Minn. 411.
- sponge, failure at higher altitudes, improper mixing as cause, Colo. 843.
- test, standardization of scoring 411.

## Cakes—Continued.

yellow sponge, preparing and baking at different altitudes, Colo. 268.

Calciferol, ultraviolet absorption of, 437.

Calcium—*see also* Lime.

and phosphorus, metabolism, 562.

arsenate, preparation for use as orchard insecticide, 86.

balance in preschool children, 273.

blood, in dogs, variations with age, 669.

citrate uroliths on low phosphorus diet, 129.

content of white bread, 847.

cyanamide, decomposition on soil surface, Mo. 189.

deficiency, effect on pea roots, 644.

fate after intravenous administration to adults, 414.

in blood of young colts, 810.

in human diet, approximation of calculated to determined values, 845.

in serum of ruminants, physicochemical state, 232.

in vegetables cooked in fat, 273.

in very small amounts of biological materials, spectrochemical analysis for, 437.

requirements of tropical population, adaptation to low calcium intake, 846.

resorption in intestine of rats under action of fats, 415.

retention, by rat in presence and in absence of vitamin C, 570.

California Station, notes, 144.

California University, notes, 144.

*Calliephialtes dimorphus*, biology, 379.

*Calomycterus setarius*, notes, Conn.[New Haven] 652.

## Calves—

beef, and yearlings, comparison of silages for wintering, Fla. 666.

beef, molasses as substitute for corn for, Mo. 229.

beef, silage crops for, yield and palatability, Del. 94.

beef, wintering, test of various rations, Wyo. 530.

blood picture in health and under parasitism, 109.

blood plasma magnesium in, seasonal variations, 239.

changes in pH and in bacterial count of milks sham fed to, 675.

creep-fed, feeder, and lot-fattened, relative merits of producing, W.Va. 233.

dairy, dry-feed systems of raising, N.H. 814.

dairy, fed only alfalfa hay and milk, rate of development, Mo. 238.

dairy, ration for inducing rapid growth in, Mo. 238.

fed different levels of milk proteins, physiological responses, 238.

growth rate on different rations, U.S.D.A. 676.

## Calves—Continued.

heifer, grain in pellet form v. meal for, Ohio 535.

heifer, raising on limited whole milk, Ohio 535.

identical twin, description, Wis. 42.

milk for, open-pail v. nipple-pail methods of feeding, S.C. 535.

on low potassium rations, electrocardiographic changes in, 807.

purified diet studies with, 675.

steer, finishing in dry lot, Iowa 96.

veal, feeding milk fat substitutes to, Ohio 535.

wheat bran v. alfalfa hay v. cottonseed meal as protein supplements to silage in winter rations, 384.

wintering, feed requirements, Ga.Coastal Plain 666, Nebr. 805.

*Camassia esculenta*, disappearance following burning over of its prairie-meadow habitat, 168.

## Camellia—

flower blight, 80.

insect pests, control, Ala. 519.

scale, notes, Ala. 519.

Camera, inexpensive microphotographic, 746.

*Campeloma* sp., life cycle and other aspects, 522.

Canary pox, treatment, new and effective method, 113.

Cancer in cow's udder, extreme rarity, 815.

Cancer of mammary gland in mice, 183.

Cane fodder and alfalfa hay, relative net energy values, 382.

Cankerworm, spring, control, Mo. 90.

Canned food reference manual, 701.

Cantaloup. *see* Muskmelon(s).

*Capillaria perforans*, redescription and new hosts, 400.

*Capitophorus*—

*fragaefolii*, *see* Strawberry aphid.

*ohioensis* n.sp., description, 798.

Capons, production, N.Dak. 99, S.Dak. 533.

## Carbohydrates—

in plant material, methods of determination, comparison, Mo. 153.

indigestible, of feeds, 231.

## Carbon—

activated, as catalyst in oxidation-reduction reactions, 8.

dioxide assimilation, light and temperature retardation in, 33.

dioxide assimilation, nature of light and temperature optima in, 32.

dioxide gas, method for supplying to culture tubes, 678.

disulfide as soil fumigant for woolly apple aphid, 221.

in soils under different treatment, Mo. 159.

monoxide poisoning of chicks and poults in poorly ventilated brooders, 253.

tetrachloride emulsion, anthelmintic action, 678.

- Carborundum for plant virus inoculations, 72.
- Carmine, effect on gastrointestinal motility of children, 128.
- Carnation cuttings, *Alternaria* branch rot on, effect of treatments, 214.
- Carnations—  
greenhouse, onion thrips on, Wash. 217.  
physiological disorders, Mass. 771.  
subirrigation method of supplying nutrients to, N.J. 631.
- Carotene—  
and vitamin A in milk, determination, 668.  
and vitamin A, relation to serum lipids, 564.  
and vitamin C in forage crops, 745.  
determination with photoelectric colorimeter, 729.  
effect of sweetpotato carbohydrates on determination, S.C. 439.  
for chickens, sweetpotato flour as source, S.C. 529.  
in forage crops during growing season, 814.  
in fresh and frosted peas, 277.  
in fresh and frozen vegetables, determination, 455.  
in green and mature soybeans and cowpeas, 130.  
in milk, effect of feeding pea vine silage, 815.  
in nutrition of dairy cattle, 99.  
in Oklahoma feeds, Okla. 668.  
in plant tissue, determination, Mich. 438.  
 $\beta$ -, in raw and cooked vegetables, 707.  
photocolorimetric determination in human plasma, 708.  
picture in serum, pathogenic and diagnostic significance, 709.  
production in plants, seasonal variations in, 317.  
use, as affected by dietary factors and variations in light exposure, 707.  
utilization, effect of certain fats, 668.
- Carotinoid in blood, determination, 297.
- Carpet beetle control, traps and flypaper for, Wis. 364.
- Carpet grass—  
fertilizer experiments, Fla. 616.  
yield and composition, relation to fertilizers, Fla. 49.
- Carpocapsa pomonella*, see Codling moth.
- Carpocapsa pomonella simpsonii*, notes, 652.
- Carpophilus hemipterus*, see Dried-fruit beetle.
- Carposina adreptella*, morphology, life history, and habits, 222.
- Carrot—  
family, North Dakota plants of, N.Dak. 863.  
*Macrosporium* leaf blight, a menacing disease, Wis. 345.  
yellows, a menacing disease, Wis. 345.
- Carrots—  
breeding, Nebr. 771.  
Chantenay, vitamin A values, Tenn. 564.
- Carrots—Continued.  
grown in colloidal clay, effects of controlled calcium supply on, U.S.D.A. 772.  
grown in sand cultures under glass, effects of deficiency of essential elements, 336.  
improvement, Mass. 771.  
orange-fleshed, descriptions of types of American varieties, U.S.D.A. 627.
- Carts, rubber tired, home-made, S.Dak. 403.
- Casein—  
manufacture, continuous-process method, 241.  
proteins, biological value, 530.
- Cassava—  
bread, P.R.Col. 581.  
fertilizer experiments, P.R.Col. 617.
- Castor-beans—  
culture, S.C. 488.  
production, Miss. 58.  
variety tests, S.C. 480.
- Castration, effect on body weight and length of male rats, 330.
- Catalase, crystalline, studies, 297.
- Cataract—  
nutritional, cause and control, Mass. 843.  
production in rats, relation to skim milk feeding, 283.
- Catalysts, catalyst-modifiers, life and specificity of vital processes, 462.
- Cats—  
immature female, effect of male urine extract, 328.  
induction of mating and ovulation with pregnancy urine and serum extracts, 328.  
prenatal growth, weights of organs, relation to adult weight, 47.
- Cattle—see also Calves, Cows, Heifers, Livestock, and Steers.  
baby beef, enterprise in southern Iowa, Iowa 552.  
basal energy metabolism, diurnal variations in, Mo. 238.
- beef—  
accuracy of scoring certain characters in, 381.  
feeding experiments, Hawaii 808, Kans. 384.  
improvement of herds through use of purebred sires, Fla. 666.  
industry in Florida, history, 669.  
pasture fattening, value of cane molasses for, Hawaii 528.  
breeding, giving impetus to, 475.  
consistently giving low titer reactions to Bang agglutination test, Mo. 242.  
crosses between Holstein-Friesian and Brown Swiss, color genes in, 609.  
dairy—see also Cows.  
bone meal v. no bone meal for, Pa. 814.  
breeding efficiency, factors affecting, 608.  
developing strain for high production, Mo. 238.

## Cattle—Continued.

## dairy—continued.

- differences in production level, Wis. 42.
- effect of complex mineral and vitamin mixtures, Mass. 813.
- effects of inbreeding, 608.
- in Philippines, 392.
- inbreeding, line-breeding, and outbreeding, Wis. 42.
- increase in serum magnesium during midsummer drought, 239.
- inheritance of solids-not-fat percentage in, 608.
- metabolism during growth, N.H. 814.
- nicking in, 179, 756.
- nutrition, carotene and vitamin A in, 99.
- pregnancy urine extract for treatment of sterility in, 613.
- production at different levels of producing ability, effect of age and dry period, 391.
- purebred v. grade in dairy farming in future, 391.
- reproduction in, factors affecting, Nebr. 825.
- reproductive efficiency in, Ky. 815.
- roughage as sole rations, Wyo. 676.
- vitamin A requirements for growth, 391.
- vitamin C in nutrition of, 675.
- diseases, *see specific diseases*.
- diminished reproductive activity, and lowered resistance to disease in, cause. Nev. 540.
- effect of climate, 96.
- external parasites of, U.S.D.A. 84.
- fattening in Arizona, rations for, Ariz. 808.
- feeding, comparison of rotation pastures with cultivated crops for, Mo. 185.
- feeding experiments, S.C. 535, Wyo. 535.
- fever tick, tropical variety, complicates tick eradication in Florida, 396.
- fluky, treatment with Distol and kamala, Hawaii 517.
- fly sprays, possibilities in India, 218.
- foot rot in, Zephiran in treatment, 543.
- growth in linear size and body weight, interrelations, Mo. 238.
- grub, bionomics in India, 224.
- grub larva, digestive enzymes of, 224.
- grubs, studies, U.S.D.A. 84.
- Guernsey, color pigmentation in skin and milk, and effect of feeds on, N.J. 676.
- Holstein, results of continued inbreeding, N.J. 676.
- methane production by, estimation, 669.
- minimum lethal dose of selenium as sodium selenite, 543.
- nicotinic acid and grass juice factor requirements, 382.
- parasites of, P.R.Col. 677.
- poisoning, *see* Livestock poisoning, Plants, poisonous, and *specific plants*.

## Cattle—Continued.

- range, calcium and inorganic phosphorus in blood, N.Mex. 95.
- rations, mineral deficiencies in, Fla. 666.
- sold for slaughter, costs and returns, N.Mex. 116.
- ticks, *see* Ticks.
- tuberculosis in man as source of infection, 108.
- utilization of feeding stuffs by, Pa. 807.
- vitamin B<sub>1</sub> deficiency in, blood picture and symptoms, 669.
- welfare on Florida pastures, 234.
- Cedar rust, *see* Apple rusts.
- Cedar, southern white, in New Jersey, growth studies, 499.
- Cediopsylla simplex* parasite of cottontail rabbit, 791.
- Celery—
  - diseases, control, Fla. 634.
  - early, response to fertilizer ingredients, 58.
  - greenhouse fertilizer studies, 192.
  - growth at different fertility levels, Fla. 625.
  - growth, relation to irrigation water, N.J. 625.
  - improvement, Mass. 771.
  - leaf tier, studies, U.S.D.A. 84.
  - mosaic, western, control, 500.
  - overliming injury to, N.J. 625.
  - packing, man-hours used in, Mass. 835.
  - sclerotinose, control on Florida muck, 779, 781.
  - varieties, susceptibility to *Fusarium* yellows, Ohio 75.
- Cell—*see also* Plant cell(s).
  - division in pollen tube, effect of colchicine, 753.
  - division, mechanism and morphological bases of cytology, 170.
  - theory, past, present, and future, 753.
  - wall constituents of forage plants, development, 314.
  - walls, studies, 605.
- Cellulose—
  - decomposing organisms, changes produced in bleached cotton duck by, U.S.D.A. 428.
  - in wood, fermentation, 468.
  - industry in Puerto Rico, prospects on establishment, P.R.Col. 581.
  - membranes from various parts of plants, 35.
- Cellulosic materials, thermophilic fermentation, products and micro-organisms involved in, 456.
- Centipede grass pastures, value, Fla. 616.
- Cephalin, highly unsaturated, tissue content in C-avitaminosis, 570.
- Cephalosporium*—
  - elm wilt in Massachusetts, Mass. 790.
  - sp., description, 649.
- Cephalothecium roseum* extracts, vitamin C in, 598.

- Cephus pygmaeus*, see Sawfly, European wheat stem.
- Cerataphis lantaniae* on yellow dwarf coconut, P.R.Col. 651.
- Ceratophyllum*—  
*demersum*, fruits and seedlings of, 606.  
*echinatum*, seedlings and fruits of, 606.
- Ceratostomella*—  
 sp., cause of new disease of sycamore trees, 790.  
 sp. on plane tree, 513.  
 sycamore (plane tree) disease, new locations for, U.S.D.A. 500.  
*ulmi*, attempts to isolate from stored elm wood, 81.  
*ulmi*, host-parasite relations, 346.  
*ulmi*, isolation from *Scolytus multi-striatus* stored at different temperatures, 648.  
*ulmi* transmission by *Scolytus* spp., 215.
- Cercaria*—  
 apharyngeal brevifurcate, new species, description, 244.  
*wardlei*, revised description, 244.
- Cercospora*—  
*apii* in pure culture, inducing spore production by, 645.  
*beticola*, effect on composition and carbon assimilation of sugar beets, 641.  
*cardiostegiae* n.sp., description, 202.  
*cercidicola*, notes, 214.  
*laburni* n.sp. from Oklahoma, description, 348.  
 leaf-spot disease of *Nandina*, U.S.D.A. 201.  
 leaf spot of peanuts, control, 780, 781.  
 leaf spot of zinnia, control, Fla. 634.  
*musae*, notes, P.R.Col. 635.  
 on beets, control by spray and dust, 354.
- Cercosporiella*—  
 foot rot of wheat, U.S.D.A. 783.  
*herpotrichoides* in Pacific Northwest, U.S.D.A. 350.
- Cereal—  
 black stem rust, relation to barberry host, N.Dak. 503.  
 browning root rot, studies, 640.  
 crops as winter pastures for swine, comparison, Ark. 94.  
 crops suitable for silage, Mo. 806.  
 diseases for Georgia, U.S.D.A. 635.  
 diseases in Virginia and Texas, U.S.D.A. 500.  
 germinating seed and young seedlings, morphological-developmental stages of, 605.  
 grasses, fresh extracts of, nutritive factors in, Mo. 229.  
 root rots, 502.  
 rusts—see also Rust(s) and specific hosts.  
 in southern Plains States, U.S.D.A. 635.  
 in Texas, U.S.D.A. 344.  
 seed treatment, see Seed treatment.
- Cereal—Continued.  
 smuts—see also Smut and specific hosts. notes, U.S.D.A. 782.  
 stem rust, summary, 350.
- Cereals—see also Grain and specific grains.  
 African, proximate constituents and composition of ash, 699.  
 and cereal products, nicotinic acid in, 713.  
 available iron in, 704.  
 in fattening ration of poultry, 386.  
 rickets-producing action, effect of phytin, 425, 426.  
 snow molds of, caused by *Typhula* spp., 73.  
 use of commercial fertilizers for, Nebr. 741.  
 vitamin B<sub>1</sub> assays, 132.
- Cerebrospinal fluid pressure and vitamin A deficiency, 675.
- Ceuthorrhynchus assimilis*, biology and control, 218.
- Cevitamic acid, see Ascorbic acid.
- Chaetocnema pulicaria*, see Corn flea beetle.
- Chaetodacus tryoni*, toxicity tests, 799.
- Chaetomium globosum*, changes produced in bleached cotton duck by, U.S.D.A. 428.
- Chaff scale on camellia, Ala. 519.
- Chagas' disease, susceptibility of natural vectors to experimental development of, 820.
- Changa—  
 of Puerto Rico, parasite of, 83.  
 specific parasite of, establishment in Puerto Rico, P.R.Col. 651.
- Chaparral shrubs, stem anatomy of, 606.
- Cheese—  
 and butter industry symposium, 102.  
 blue, effect of salting curd for, 104.  
 brick, changes during manufacture, 673.  
 brick, starter combinations for, Wis. 101.
- Cheddar—  
 bitter flavor development in, relation to salt, 674.  
 curing, changes for study, 674.  
 pasteurized milk in manufacture, 103.  
 ripening, effect of lipolytic enzymes, 674.
- cottage—  
 effect of standardizing acidity, 674.  
 homogenized milk in manufacture, 674.  
 quality improvement, Mo. 238.
- flavor, body, and texture, factors affecting, 103.
- foreign, studies, 103.
- foreign varieties, manufacture, ripening, and development, Wash. 238.
- grading, points observed in, N.Y.State 241.
- hard, new types, development, 103.
- industry, "just salt" obsolete in, N.Y. State 818.
- Italian, industry growing in New York State, N.Y.State 241.

## Cheese—Continued.

- making, 104.
- making, laboratory tests necessary, 103.
- making, producing milk for, 103.
- production, consumption, exports, and imports, U.S.D.A. 556.
- quality, means of improving, 103.
- score value and serving properties, effect of temperature, 674.
- skipper, primary parasite of, biology, 227.
- sliced Cheddar and Swiss, packaging in cans for sandwich dispensers, U.S.D.A. 818.
- soft, fat, moisture, and salt in, determination, 301.
- Swiss—
  - activity of starters, effect of heat-treatment of milk, 673.
  - control of fat content, Wis. 101.
  - fat in, standardization and relation to quality, 674.
  - manufacture, control of abnormal bacterial fermentations in, 673.
  - quality improvement, 674.
  - starters, preparing, storing, and using, Wis. 101.
  - types, making, tests of milk for, Wis. 117.
  - types, suitability for frozen-pack methods of storage, Wash. 238.

*Chelonus texanus*, notes, 799.

Chemical calculations, elementary, mathematics of, Minn. 293.

## Cherries—

- brining, cracking problem in, 155.
- factors limiting production in Missouri, Mo. 189.
- losses from plant diseases, U.S.D.A. 201.
- Montmorency, effect of sprays on size, color, and per cent solids of fruit, 493.
- Montmorency, frozen, industry, N.Y.State 772.
- new hardy for Northwest, S.Dak. 774.
- pollination, 194.
- pruning, Iowa 491.
- quality, reliability of retail prices as guides to, Ohio 116.
- rootstocks for, Ark. 57.
- sour, destructive bud-transmissible disease called physiological yellow leaf, 789.
- vitamin C in, 715.

## Cherry—

- aphid, black, tests with insecticides for, Wis. 364.
- canker, studies, Mo. 201.
- casebearer, tests with insecticides for, Wis. 364.
- fruitfly, black, control, spray residue and substitutes for lead arsenate in, 660.
- fruitfly control, spray residue and substitutes for lead arsenate in, 659.
- fruitfly situation, Hood River County, Oregon, 795.
- fruitworm, life history and control, Wash. 217, West.Wash. 217.

## Cherry—Continued.

- fruitworm on blueberries, N.J. 651.
- juice products, improved, formulas and methods for preparation, Colo. 843.
- leaf spot, bordeaux best remedy, Wis. 345.
- leaf spot, fungicidal control, N.J. 635.
- sour, boarder tree or physiological yellow leaf of, Wis. 345.
- trees, young, importance of soil pore space to, N.Y.State 194.

## Chess—

- downy, hazard of basing permanent grazing capacity on, 50.
- or cheat control, Mich. 50.

## Chestnut—

- blight eradication, 500.
- blight, relation to principle of disease resistance, 215.
- seeds, viability, effect of storage conditions and other treatments, Ark. 65.

## Chick—

- antidermatitis factor, 667.
- embryo development, effect of temperature shock, 386.
- embryo, unincubated, development, relation to hatchability of egg, 386.
- embryo vaccine, reactions in horses following inoculation, 680.
- embryos, Cornish lethal and creeper compared with normal sibs, glutathione values, 44.
- losses due to faulty ventilation, 253.

## Chicken—

- dressed, precooling, freezing, and storage, 388.
- meat, market quality, factors affecting, 533.
- meat production, efficiency in, N.J. 390.
- mite, notes, 400.
- palatability, effect of drawing before freezing, 388.
- squab, preparing and serving, 388.
- Chickens—*See also* Chicks, Cockerels, Fowls, Hens, Poultry, and Pullets.
  - broiler, development of economical rations, Ark. 94.
  - broiler industry, economic study, Ind. 263.
  - broiler production, cottonseed meal and shrimp meal as protein sources, Miss. 666.
  - broiler production, cross-breeding for, Ark. 94.
  - broiler production, early, liberal amounts of animal protein for, Wis. 382.
  - broilers, optimum protein levels in rations, Del. 95.
  - coryza in, vaccination for, Wyo. 541.
  - holding prior to evisceration and freezing, problems arising during, 388.
  - squab, outlet for excess cockerels, 387.
  - squab production, improved, breeding and feeding for, N.J. 671.
  - table, creation of reserves in, purpose and technic, 387.
  - undrawn, quality, effect of time and temperature of holding, 388.

## Chicks—

- additional factors required by, 667.
- alcoholic precipitate factor required by, complex nature, 668.
- and laying hens, protein requirements, Wash. 229.
- body weight and feather growth in, effect of whole wheat, bran, and shorts, Nebr. 533.
- carbon monoxide poisoning due to poorly ventilated brooders, 253.
- care and management, N.J. 390.
- day-old, sex determination, 611.
- day-old, vaccination for control of fowl pox, Hawaii 518.
- deformity called crooked toes in, cause, 534.
- electric brooding of, Mo. 255.
- embryonic development, effect of riboflavin deficiency in hen, 390.
- fat requirements, 672.
- feather development, effect of protein level in ration, Del. 95.
- fed simplified diets, growth, effect of yeast extract and other supplements, 383.
- feed requirements for development of gizzard lining, 386.
- free-choice feeding v. all-mash feeding for, Ky. 528.
- growth and yolk absorption, effect of cold drinking water, 533.
- growth rate, Mo. 229.
- injected with testosterone propionate, follicle and comb development in, 332.
- injury by boric acid, Wis. 382.
- new growth factor requirement, essential nature, 533.
- newly hatched, lipid in blood, liver, and yolk sac and changes in first month, 390.
- protein requirements, 386.
- relation of gain in weight to gain in energy, 98.
- slipped tendon in, cause and prevention, Okla. 812.
- slipped tendon in, use of manganese by, Wis. 95.
- ulcerated gizzards in, relation to vitamin C in diet, N.H. 805.
- vitamin A requirements when fed as carotene, Tex. 390.
- year-round hatching, practicability, N.J. 671.

## Children—see also Boys, Girls, and Infants.

- Chinese, basal metabolism, 412.
- dependent, in South Dakota, S.Dak. 410.
- gastrointestinal motility, effect of carmine, 128.
- in selected communities, food habits and nutritional status, Me. 410.
- preschool, calcium, phosphorous, and nitrogen balances, 273.
- preschool, hemoglobin and blood cell levels, Hawaii 562.
- school, importance of dairy products in diet, 412.

## Chilies—see also Peppers.

- mutation in, 491.
- variety tests, N.Mex. 57.
- Chimeras, induced periclinal, use in determining constitution of organs and origin from germ layers in *Datura*, 456.
- Chinch bug—
  - bionomics and control, Iowa 85.
  - control, Mo. 217, Nebr. 87.
  - false, egg parasite of, 804.
  - hairy, control, 87.
  - losses, prevention, Ill. 656.
  - resistance of  $F_1$  sorghum hybrids to, 220.
  - studies, Nebr. 796.

*Chionaspis furfura*, see Scurfy scale.

- Chlamydomonas*, new growth factors, 468.
- Chlorazol black E as aceto-carmine auxiliary stain, 465.

*Chlorella*—

- rate of photosynthesis, effect of magnesium deficiency, chlorophyll concentration, and heat treatments, 175.
- vulgaris*, growth in freshly prepared medium, effect of size of inoculum, 39.
- Chlorine, available, rapid multiple color test for approximation of, 536.
- Chlorophyll—
  - as prosthetic group of a protein in green leaf, 34.
  - in plant tissue, determination, Mich. 438.
- Chloropirin in soil solution, effect on plant growth, 173.
- Chloroplast, structure, and location of chlorophyll in ferns, 602.
- Chloroplasts, studies, 34.
- Chlorosis—
  - control, N.Mex. 69.
  - in corn, Fla. 616.
  - in corn and other field crops, Fla. 634.
  - in cottonwood trees, ferric phosphate control, Wyo. 502.
  - of baldcypress, control, effect of ferric chloride, 513.
  - of Concord grapes controlled by grafting, Utah 357.

*Choanotaenia infundibulum* of poultry, intermediate hosts, 255.

- Chocolate milks, physical characteristics, factors affecting, 104.
- Chokecherry leaf curl, new disease, U.S.D.A. 500.

## Cholesterol—

- determination, 725.
- feeding to guinea pigs, blood and tissue changes produced by, nature, 668.
- Cholic acid in dogs, intravenous fat not a precursor, 667.

## Choline metabolism, 845.

## Choriomeningitis, lymphocytic—

- immunity of mouse to, 820.
- soluble antigen of, 820.
- Chromosome sensitivity to X-rays, changes in, 753.

## Chromosomes—

- cleavage, synthesis of, 326.
- in buffalo, studies, 326.

## Chromosomes—Continued.

- in mammals, smear method of counting, Mo. 182.
- numbers in species of British plants, 606.
- of fowls, linkage map for, 609.
- sex, in fowls, linkage data, 181.
- structure, symposium on, 753.

## Chrysanthemum—

- foliar nematode, inefficacy of methyl bromide fumigation, 649.
- gall midge in England, biology, 799.
- leaf blight, status of, causative agent, 214.
- Verticillium* wilt, roguing and selection for control, Ohio 501.

## Chrysanthemums—

- fumigation injury, 649.
- made to bloom earlier or later, Miss. 496.
- novel species, 168.
- testing, N.Mex. 57.

*Chrysomphalus*—

- aonidum*, see Red scale, Florida.
- aurantii*, see Red scale, California.

*Chrysomya ruffacies*, life history and bionomics in India, 373.

## Church in rural life, treatise, 842.

*Chusquea* new species, 597.

## Chytridiales, sexuality in, 468.

## Cider preservation experiments, Ohio 439.

*Cimex lectularius*, see Bedbug.*Cirphis unipuncta*, see Armyworm.*Citrobacter freundii*, preparation of an active juice from, 607.*Citromyces ramosus* extracts, vitamin C in, 598.

## Citrus—

- areolate leaf spot, cause, 80.
- byproducts, utilization for poultry, Fla. 666.
- canker eradication, U.S.D.A. 68.
- cold storage, Fla. 624.
- culture, Fla. 625.
- culture in California, 630.
- dieback and scab, control, Fla. 634.
- diseases of Texas, 790.
- exchange system of Florida, Fla. 121.
- fruit set, effect of spring soil moisture on drop, 495.
- fruits—see also Lemon(s), Orange(s) etc.
  - melanose and stem-end rots of, Fla 634.
  - studies, P.R.Col. 625.
  - varieties, Ga.Coastal Plain 625.
  - yield and composition, effect of type and treatment of soils, Fla. 592.
- gummosis and psorosis, Fla. 634.
- juice and pulp, preservation, Fla. 624.
- meal for poultry, 386.
- meal, use as swine feed, Fla. 666.
- nutritional requirements, Fla. 625.
- physiology of maturity processes in, Fla. 624.
- psorosis, 500.
- psorosis, nature and cause, 358.

## Citrus—Continued.

- pulp as carrier for molasses in preserving grass silage, N.J. 676.
- red mite on Satsuma orange, control, Ala. 794.
- root rot, control, Fla. 634.
- rootstocks for, Fla. 625.
- rust mite, cost of control measures, 379.
- rust mite on Satsuma orange, control, Ala. 794.
- scab disease, effect of climatic factors, 358.
- soil fertility studies with, Fla. 625.
- soils of Florida, chemical studies, Fla. 309.
- soils, studies, Fla. 592.
- thrips control, field studies, 523.
- thrips on lemon and oranges, field studies on control, 219.
- thrips on lemons, control, U.S.D.A. 83.
- thrips on lemons, tartar emetic for control, 219.
- trees, effect of manganese applications, 63.
- trees, spraying, rating thoroughness of application in, 89.
- variety testing and breeding, Fla. 625.
- whitefly, see Whitefly, citrus.
- Cittotaenia variabilis* parasite of cottontail rabbit, 791.
- Cladosporium*—
  - fulvum*, control, Mass. 783.
  - paconiae*, cause of peony stem spot, 359.
- Clastoptera saint-cyri*, studies, Mass. 796.
- Clausenia purpurea*, parasite of Comstock's mealybug, 657.
- Clay—
  - samples, natural and homoionic, properties, 453.
  - saturated, permeability of, 453.
  - soils, *Azotobacter* activity, relation to surface soil acidity, N.Dak. 742.
- Climate—see also Meteorology.
  - and health, quantitative physical data useful in, 739.
  - world, problem of, 739.
- Climatological—
  - data, Ohio 446, U.S.D.A. 156, 446, 590.
  - data of Colorado, 21.
  - survey for Ohio and Wooster, Ohio 740.
- Climatology, comparative applications to Mexico, 306.
- Clitocybe tabescens* root rot of citrus and other woody plants, Fla. 634.
- Clostridium*—
  - butylicum*, preparation of an active juice from, 607.
  - pasteurianum*, notes, 155.
  - welchii* type C, antigenic variation in a strain, 824.
  - welchii*, types A, C, and D, blood changes and post-mortem findings following inoculation of sheep with, 681.
  - welchii* types in soil and in intestines of animals and man, 823.

- Clothes moth larvae, minimum size of openings through which they pass, 652.
- Clothes moths control, traps and flypaper for, Wis. 364.
- Clothing costs of different sized and different age groups, Ark. 142.
- Cloud—  
bases, form and relative humidity gradient, 738.  
forms and states of the sky, codes for, International system, U.S.D.A. 158.
- Clover—  
alfalfa-timothy seedings, mixed, productiveness, Ohio 480.  
alsike, cultural and fertilizer practices on peat land, Wis. 333.  
fertilizer experiments, Fla. 616.  
foreign, failure in 1938, Ohio 480.  
Ladino, fertilizer and cultural requirements, Me. 333.  
mite in dwellings, Conn.[New Haven] 652.  
Persian, advantage for early pasture, Miss, 617.
- red—  
adapted and nonadapted, resistance to pea aphid injury, Ky. 518.  
breeding, Ky. 479, N.J. 617.  
breeding for disease resistance, 781 Tenn. 501.  
cultural and fertilizer practices on peat land, Wis. 333.  
cuttings, development, effect of plant hormones, 172.  
seed, pubescent characteristic, relation to determination of origin, 50.  
strains, seed setting in, 765.  
varieties, adaptation in northern and southern Ohio, Ohio 480.  
variety tests, Ky. 479, N.J. 617, Wash. 185.  
seed crop, harvesting, Miss. 479.  
seeds, red, alsike, and white, relations of color to germination and other characters, 50.  
sweet, *see* Sweetclover.  
timothy hay, fertilizer experiment, N.H. 760.  
variety tests, Fla. 616, Tenn. 481, Wyo. 481.
- white—  
breeding, N.J. 617.  
in pasture as affected by management, Ohio 480.  
Ladino a promising strain, Ohio 480.  
strain tests, Fla., 616.  
variability in, relation to pasture improvement, N.J. 619.  
variety tests, N.J. 617.
- Cocarboxylase—  
action, mechanism, 731.  
and vitamin B<sub>1</sub> in organs, determination, 712.  
in blood, 419, 420.
- Cocarboxylase—Continued.  
in blood and tissues, quantitative determination by thiochrome procedure, 440.  
in human blood, 439.  
ultraviolet absorption spectra and their reduction products, 731.
- Coccidial oocyst output in feeder lambs, effect of copper sulfate-ferric sulfate mixture, 248.
- Coccidiosis—  
control, in wire-floored batteries and houses, Hawaii 518.  
in chickens, physiological effects, Wis. 105.  
in chickens without gross lesions, 827.  
in feeder lambs, 545.  
in litter of pigs, 398.  
in poultry, 547, N.H. 823, Wyo. 541.
- Coccinellidae, predaceous, toxicity of calcium arsenate to, S.C. 518.
- Coccus, Gram-positive—  
in birds positive to serum plate test for pullorum disease, 254.  
isolation from birds in serological tests, Wash. 242.
- Coccus hesperidum*, *see* Scale, soft.
- Cochliomyia americana*, *see* Screwworm.
- Cockerels—  
excess outlet for as squab chickens, 387.  
New Hampshire, sexual behavior, 476.  
surplus White Leghorn, marketing, N.Dak. 236.  
White Leghorn, interrelation of lipids in blood plasma, 236.
- Cockroach—  
auditory perception in, 523.  
German, control, N.J. 651.  
German, evaluating liquid insecticides against, 520.  
German, rate of regeneration in, 219.
- Cockroaches, toxicity of phosphorus to, 86.
- Cocoa—  
effect on digestibility of milk proteins, 674.  
shell meal as source of vitamin D for rats, Mass. 843.
- Coconut—  
industrial utilization, P.R.Col. 581.  
oil meal for pigs, desirability of limiting, Ohio 529.  
yellow dwarf, flower buds, aphids attacking, P.R.Col. 651.
- Cod roe, canned, vitamin D potency, 717.
- Codling moth—  
activity of adults, 90.  
activity, variation with locality, Wis. 364.  
baits, 367.  
baits and insecticides, N.Mex. 85.  
biological control, 658, N.J. 651.  
bionomics and control, Del. 85.  
control, 366, Ky. 518, Mo. 217.  
control by electric and other traps, 524.  
control, fundamentals, 518.  
control, group action in, 367.

## Codling moth—Continued.

- control, how to use nicotine and oil for, 367.
- control, practical supplementary<sup>1</sup> measures, 524.
- control, studies, U.S.D.A. 83.
- control with chemically treated bands, 799.
- control with pyrethrum, 90.
- end of hatching period, Ark. 84.
- flight habits, effect on results of experiments, 658.
- flights, effect of variety, Wis. 364.
- golden, 652.
- habits, newly discovered, 83.
- in Indiana, status, 524.
- in fruit regions of France, papers on, 223.
- infestation, relation to temperature and rainfall, N.Y.State 223.
- insecticides, testing, laboratory-field method, U.S.D.A. 216.
- larvae, migration from one apple to another, 524.
- larval attractants, studies, 370.
- nonresidue sprays for, 370.
- problem, extension aspects, 518.
- scraping and banding as supplementary control, 367.
- tolerance to toxic action of insecticides, Mo. 217.

## Cod-liver oil—

- feeding, effect on goaty and oxidized flavors, and vitamin C in milk, 673.
- toxicity for pigs, 810.

*Coenurus glomeratus*, studies, 686.Coenzyme R, synthesis by *Rhizobia* and by *Azotobacter chroococcum*, 463.

## Coenzymes I and II, synthesis, 858.

## Coffee—

- Columnaris* and Puerto Rican varieties, comparison, P.R.Col. 625.
- farms, earnings on, P.R.Col. 689.
- fertilizer requirements, Hawaii 488.
- leaf miner, studies, P.R.Col. 651.
- plant, fertilizer needs and light requirements, P.R.Col. 625.
- plant, growth, relation to yield, Hawaii 488.
- plant, lime requirements, P.R.Col. 625.
- plant, root studies, P.R.Col. 625.
- plantations, analysis of production practices, P.R.Col. 625.
- prices, P.R.Col. 689.
- tree seeds, Kentucky, viability, effect of storage conditions and other treatments, Ark. 65.

*Cohnistrepthorix*, taxonomic notes, 607.*Colaspis*—

- brunnea costipennis*, studies, Mass. 796.
- favosa*, notes, Ala. 519.

## Colchicine—

- different forms, effect on roots of *Vicia faba*, 751.
- effect on nuclear and cytoplasmic phases of cell division in pollen tube, 753.

## Colchicine—Continued.

- treatment of petunias, variations induced by, 473.
- treatment of *Salvia splendens*, variations induced by, 473.

Cold, *see* Temperature, low.

## Cold storage—

- locker plants in Wisconsin, data, Wis. 117.
- studies, Wash. 256.

*Coleophora pruniella*, *see* Cherry casebearer.

## Coleoptera, hymenopterous parasites in Great Britain, 379.

## Coli-aerogenes intermediates, dissimilation of glycerol by, 725.

## Coliform—

- group in ice cream, 673.
- test, critical discussion, 240.

Colitis, chronic ulcerative, *Bacterium necrophorum* in, 823.*Collabismodes cubae*, notes, Fla. 650.

## College men, basal metabolism of, Wyo. 562.

Colleges, *see* Agricultural colleges.

## Collembola, North American, geographical distribution, 219.

*Colletotrichum*—

- fruit rot of papaya, 358.
- leaf spot of *Nephtytis*, Fla. 634.
- sp. on ornamentals, N.J. 635.

## Colloidal—

- behavior of soils, laws, 23.
- suspensions, chemical preparation in non-aqueous solvents, 6.

## Colloids, soil—

- effect on toxicities of sodium selenate and sodium selenite for millet, 166.
- hydrolysis effects, 165.
- identification of minerals in, 593.
- inorganic, break-down, relation to plant growth, 165.

*Collyricium faba* infestation in purple finch, 255.

## Colonization project of Sicily, U.S.D.A. 555.

## Color genes in Holstein-Friesian by Brown Swiss crosses, 609.

## Colorado—

- College, notes, 575.
- Farm Bulletin, notes, 863.
- Station, notes, 575.

## Coloration, adaptive, in animals, treatise, 514.

## Colts—

- calcium, inorganic phosphorus, and magnesium in blood serum, 810.
- draft, growth, Mo. 229.
- roughage for, Nebr. 805.

Communities—*see also* Rural community.

- town-country, in Lansing region, mapping of areas as to services, Mich. 409.

## Community—

- life, American, rebuilding, 696.
- organization and life, trends in, 698.

## Compass, Brunton, use in Saskatchewan soil survey, 449.

## Concentrates, in various combinations, feeding value for lambs, Wyo. 530.

## Conifers—

- damping-off of and causative fungi, effects of H-ion and Al-ion concentrations, 646.
- northern, successful direct seeding on shallow-water-table areas, 499.
- Rocky-Mountain, water requirements, 65.
- scale insects on, use of oil sprays for control, 516.
- vegetative propagation, 199.
- wind-thrown, fungi causing decay in, 361.

*Coniothyrium fuckeli* on rose leaves, 360.

## Connecticut—

- State Station, notes, 288.
- Stations, notes, 864.
- Storrs Station, notes, 431.
- University, notes, 431.

*Conoderes*—

- auritus*, notes, Ky. 518.
- spp., injurious to tobacco, Ky. 376.

*Conopia exitiosa*, see Peach borer.

*Conotrachelus nenuphar*, see Plum curculio.

*Contraecacum spiculigerum*, life cycle studies, 821.

Convolvulaceae, susceptibility to big bud disease, 784.

Cooperation—see also Agricultural cooperation.

- American, papers on, 838.

## Cooperative—

- associations, farmers', in Florida, Fla. 121.
- creamery accounting, 695.
- egg and poultry auction associations, 695.
- elevators, salaries of managers in, Okla. 689.
- exchanges, amounts and cost of credit extended by, Mo. 259.
- extension work in agriculture and home economics, U.S.D.A. 698.
- purchasing by Indiana farmers, 695.

Cooperatives, Oklahoma farm, causes of failure, Okla. 406.

*Cooperia* spp., efficacy of nonconditioned phenothiazine against, 543.

## Copper—

- as trace element, 599.
- compounds, fixed, injury to vegetables, Ohio 210.
- compounds, toxicity for nematode parasites, 245.
- feeding to pregnant ewes, effect on sway-back in progeny, 234.
- fixed, role in stone fruit spraying, 356.
- fungicides, cause of injury by, principles underlying, N.J. 635.
- fungicides, fixed, new weapon against vegetable diseases, 511.
- in blood stream, fate of, 243.
- in butter, determination, 673.
- in human organs at various ages, 562.
- in spray residues, small amounts, determination, 584.
- poisoning, acute and chronic, in animals, 681.

## Copper—Continued.

- poisoning, chronic, in sheep, 826.
- sprays for vegetables, Mass. 783.
- sulfate as anthelmintic, critic on efficacy, 678.
- value in utilization of iron, Wis. 126.

Corbett, L. C., necrology notes, 576.

*Corbulopsora* n.g. and n.spp., 636.

Cormorant, nematode from, life cycle studies, 821.

## Corn—

- acres reduced, compensation by growing superior hybrids and putting larger proportion in the silo, Ohio 480.
- and legumes, interplanting, effect on yields of succeeding crops, Ark. 48
- and lespedeza hay v. cottonseed meal for fattening steers, S.C. 529.
- and velvetbeans, ground v. unground mixtures, with and without molasses, for fattening steers, Fla. 666.
- and wheat acreages, response to changes in ratio of corn price to wheat price, Iowa 116.

Argentinian, sterility in, 471.

Argentinian varieties, duplications of embryos in, 471.

average yields per acre in Ohio, Ohio 257.

## bacterial wilt—

- resistance and genetic host-parasite interactions in, 502.
- resistance in, genetics, Iowa 68.
- symptomless host plants, after inoculation by corn flea beetle, 211.

## borer, European—

- effect on potato yield, Conn.[New Haven] 652.
- insecticides for control, Conn.[New Haven] 652, Mass. 796.
- nutritive requirements, 524.
- studies, Del. 85, N.H. 796, N.J. 651, U.S.D.A. 84.

bran, energy value, 382.

breeding, Ark. 48, Fla. 616, Ga.Coastal Plain 617, Ky. 479, Mo. 185, N.J. 617, Nebr. 759, P.R.Col. 617, Tenn. 481, Wash. 185.

breeding for stronger roots, Ohio 480.

carotenoid pigments, 456.

characteristics, relation to industrial utilization, Iowa 6.

check-planted, hill spacing, Iowa 113.

chromosome aberrations in endosperm, 755.

chromosome rearrangement, growth changes resulting, 456.

cost of irrigating, and increased yields, Nebr. 835.

cribs, fumigation to prevent weevil damage, Miss. 287.

cultivation, weed killing v. mulching, Wis. 333.

culture experiments, Ark. 48, Tenn. 481, Wyo. 481.

damage by insects, fumigation surest preventive, Miss. 143.

## Corn—Continued.

- Diplodia zeae* dry rot of, Iowa 68.  
 diploid and tetraploid, relation between carotenoid content and number of genes per cell, 176.  
 disease resistance in and nature and methods of measuring, Iowa 68.  
 double crosses, effect of method of combining four inbred lines of on yield and variability, 755.  
 dried grains, distillers', and tankage v. cottonseed meal as protein supplements for fattening steers, Ky. 528.  
 dried grains, distillers', v. cottonseed meal for pregnant and nursing beef cows, Ky. 528.  
 ear rot fungi, prevalence and geographic distribution, U.S.D.A. 500.  
 earworm—  
   attack, resistance of plants to. West.Wash. 217.  
   control, N.Y.State 659.  
   control, dichloroethyl ether in mineral oil for, 652.  
   control in sweet corn by fumigation, U.S.D.A. 216.  
   effect of temperature and moisture on overwintering pupae in North-eastern States, 91.  
   metabolism, 371.  
   notes, N.J. 651, Tenn. 519.  
   on lima beans, studies, U.S.D.A. 84.  
   relation to European corn borer situation, Me. 363.  
   response to lights, Ohio 518.  
   studies, 85, Del. 85, U.S.D.A. 84.  
 endosperms, growth hormones in, extraction methods, 726.  
 fertilizer experiments, Fla. 616, Ga. Coastal Plain 617, Tenn. 481, Wash. 185.  
 flea beetle, inoculation of symptomless host plants with bacterial wilt, 211.  
 flea beetle vector of bacterial wilt, 787.  
 for fattening pigs, hybrid v. open-pollinated, Nebr. 805.  
 genetic malformation in, histology, 745.  
 genetic studies, Mo. 185.  
 gluten meal proteins, biological value, 530.  
 growing, with and without soybeans in drill, S.C. 481.  
 harvested and fed in various forms, costs and profitability of acre-beef yields from, Tenn. 529.  
 hogging off, returns from, Ga.Coastal Plain 666.  
 hybrid, adaptation trials, Wyo. 334.  
 hybrid, increased yields from, Colo. 186.  
 hybrid, planting rates, Wis. 333.  
 hybrid, production, and commercial hybrid seed, La. 187.  
 hybrid program expansion, Ohio 480.  
 hybrid strains for silage production, Wis. 333.  
 hybrid, tests and classification, Mich. 52.

## Corn—Continued.

- hybrid v. open-pollinated, for swine, Ohio 529.  
 hybrids and varieties, yield tests, Del. 48.  
 hybrids, growth rate, Ohio 480.  
 improvement, Colo. 754.  
 in various forms, for winter finishing of baby beeves, Tenn. 529.  
 inbred lines—  
   composition of silks, effect of pollination, 765.  
   damage by southern corn rootworm, Ohio 518.  
   relative resistance to *Diplodia zeae*, Iowa 69.  
 internal grain infection and kernel rot, 352.  
 interplanting with—  
   legumes, effects, Ark. 760.  
   velvetbeans at various spacings, effect, Fla. 616.  
 Iowa, yield test, Iowa 51.  
 irrigation experiments, P.R.Col. 617.  
 Kansas, tests, Kans. 51.  
 kernel, amino acids in, 9.  
 leaf aphid, reducing injury through host resistance, 798.  
 linkage studies, 325.  
 losses from plant diseases, U.S.D.A. 201.  
 maturity, Mich. 483.  
 merits as emergency forage crop, N.Dak. 481.  
 Napier grass, sugarcane, and sorghum, ensiled, comparison of loss of nutrients, Fla. 666.  
 nutrition studies, nutrient ion concentration and carbohydrate and nitrogen in tissue, relation, 460.  
 on Everglade peat and muck soils, response to less common elements, Fla. 616.  
 open-pollinated v. hybrid, for pigs, Ohio 96.  
 outstanding varieties, N.Dak. 49.  
 pickers, efficiency, Iowa 113.  
 planters and listers, adjusting for sorghums, Nebr. 550.  
 planting, basin method on representative soil areas, Iowa 113.  
 planting tests, Nebr. 760.  
 plants and pathogens response to chemical treatments of seed, Iowa 68.  
 production in alluvial section, La. 187.  
 production in Delta, Miss. 479.  
 production of genetic variations by radiation of pollen with ultraviolet rays, Mo. 185.  
 production on hill lands, La. 187.  
 protein, fractionation and characterization, Iowa 6.  
 quality, reliability of retail prices as guides to, Ohio 116.  
 quick-frozen, keeping quality after thawing and storing, Wis. 126.  
 research in Iowa, Iowa 50.

## Corn—Continued.

- root and scutellum rots, microflora of, Mo. 201.
- root webworm, studies, U.S.D.A. 84.
- roots, absorption of soil moisture by, 747.
- rootworm, southern, damage to inbred lines of corn from, Ohio 518.
- rotation experiments under Everglades conditions, Fla. 616.
- seed drying with heated air under forced draft, Nebr. 760.
- seed treatments, Ark. 637.
- seed treatments, effect on stand and yield, Mo. 201.
- seedbed preparation, production methods and equipment, Iowa 113.
- seedlings, absorption of phosphorus and sodium, radioactive isotope study, 174.
- seedlings, resistance to high temperatures in laboratory tests, 52.
- selfed lines, origin, relation to value in hybrid combination, Minn. 325.
- silage, *see* Silage.
- sirup, high conversion, use in ice cream and ices, 672.
- sirups and sugar for frozen desserts, 672.
- smut promycelia, delayed reduction of diploid nucleus in, 638.
- smut resistance and semisterility in, linkage relations, 41.
- spacing for green manure, 52.
- sprouted v. dried for milking cows and growing heifers, 814.
- stalk and ear rot resistant lines, inbred, development, Iowa 68.
- Stewart's disease, *see* Corn bacterial wilt.
- sweet, *see* Sweet corn.
- uncontrolled vegetative development in, 37.
- v. barley for fattening pigs on pasture, Tenn. 529.
- v. blackstrap molasses in livestock ration, Miss. 805.
- v. milo as main portion of lamb ration, Colo. 235.
- v. sorghum grain for fattening cattle, Nebr. 805.
- varieties, Miss. 185.
- variety tests, Ark. 48, Fla. 616, Ga. Coastal Plain, 617, Ky. 479, Me. 333, Miss. 765, Mo. 185, N.J. 617, N.Mex. 48, Nebr. 759, S.C. 480, Tenn. 481, Wash. 185, Wyo. 481.
- wheat, and hay in rotation, residual effects of limestone, Ky. 479.
- whole, proteins, biological value, 530.
- winter cover and green manure crops for, Ga.Coastal Plain 617.
- winter grazing, returns from, Ga.Coastal Plain 666.
- yellow, odor, compounds responsible for, identification, Iowa 6.
- yield increase and profits from better varieties and fertilizers, Miss. 48.

## Corn—Continued.

- yields—
- effect of kernel size and shape, Wis. 333.
- effect of rainfall and evaporation, 159.
- effect of shelterbelt, Wyo. 481.
- of varietal leaders, N.Mex. 760.
- residual effect of *Sericea* on, Tenn. 481.
- segregation of genes affecting, 177.
- suggestions for increasing, La. 187.
- Cornercrib pressures, Ohio 548.
- Cornell University, notes, 288.
- Cornstalks and straw, use in soil building, Mo. 159.
- Cornstarch—
- oxidation, Iowa 6.
- production, laboratory control technics for, Iowa 6.
- Correlation, mathematical theory, principles, 430.
- Corticium*—
- album* n.sp., on orange stem, 358.
- areolatum*, cause of citrus leaf spot, 80.
- fusciforme*, notes, U.S.D.A. 344.
- gelactinum* on apple trees, 80.
- solani*, use of name, U.S.D.A. 636.
- Corydalis caseana*, studies, Nev. 540.
- Corymbites aeripennis destructor*, control, relation to summer-fallow, N.Dak. 226.
- Corynebacterium*—
- equi*, serological classification, 251.
- infections in swine, 112.
- ovis* infection, agglutination reaction in, 111.
- taxonomic notes, 607.
- Coryneum*—
- beijerinckii*, notes, 356.
- berckmanii* n.sp., description, 647.
- cardinale* canker on cypress, 513.
- carophilum* n.comb., proposed name, 646.
- Corythucha tuthilli*, undescribed, from Colorado, 797.
- Coryza in chickens, vaccination for, Wyo. 541.
- Cost of production, *see specific crops*.
- Cotinis nitida*, *see* June beetle, green.
- Cotton—
- American-Egyptian, utilization, supplies, and prices, Ariz. 260.
- angular leaf spot infection, winter carry-over in Arizona fields, 642.
- aphid, nicotine sulfate dust for control, Miss. 798.
- aphid on camellia, Ala. 519.
- Ascochyta* blight, outbreak, U.S.D.A. 783.
- black root rot caused by *Thielaviopsis basicola*, 780, 781.
- boll rots, micro-organisms associated with, 780, 781.
- breeding, Ark. 48, Ga.Coastal Plain 617, N.Mex. 48, P.R.Col. 617, S.C. 480, Tenn. 481.
- breeding, hormone treated cuttings and special type grafts in, 745.

## Cotton—Continued.

- crosses, hybrid vigor in, S.C. 480.  
 culture experiments, Ark. 48.  
 disease, new, in Azerbaïdzhân (Azerbaijan) 784.  
 disease survey, S.C. 501.  
 diseases, extension work on, 780.  
 diseases virus, insect vectors, 784.  
 drying, sources of heat for, U.S.D.A. 831.  
 duck, bleached, changes produced in by cellulose-decomposing organisms, U.S.D.A. 428.  
 effect of fertilizer neutralized with dolomite limestone, Miss. 48.  
 effect of fertilizers on fiber quality and on fruiting parts, Ark. 48.  
 effect of girdling and topping on survival of *Phymatotrichum omnivorum* on roots, 780, 781.  
 effect of preceding corn interplanted with legumes, Ark. 48.  
 electrical properties, references to, U.S.D.A. 834.  
 fabrics, quality in, determined by research, 717.  
 fertilizer and nutrition studies, S.C. 480.  
 fertilizer experiments, Ark. 48, Miss. 479, N.Mex. 48.  
 fertilizer placement, Ga.Coastal Plain 617.  
 fertilizers, neutral v. acid, Miss. 48.  
 fiber, developing, studies, 456.  
 fiber development, relation to the other boll constituents, 456, 605.  
 fiber, measuring length and fineness, technic for, Tenn. 481.  
 fiber methylation with ethereal diazomethane, 35.  
 fibers, cellulose membranes in, lamellate structure, 605.  
 flea hopper, studies, U.S.D.A. 84.  
 flea hopper, variations in abundance due to variations in preferred host plants, 656.  
 formulas and carriers of N, P, and K, Ga.Coastal Plain 617.  
*Fusarium* wilt—  
   inheritance, S.C. 480.  
   relation to meadow nematode, 780, 782.  
   resistance, breeding for, Tenn. 501.  
 genetic studies, S.C. 480.  
 ginning, cooperative, development, 839.  
 ginning equipment and practices, Tenn. 256.  
 gins, numbers operated by cooperative gin associations and bales ginned by each, N.Mex. 116.  
 grade and staple estimates, N.Mex. 48.  
 grade, staple length, and tenderness in United States, U.S.D.A. 693.  
 hybridization of American 26-chromosome and Asiatic 13-chromosome species, 472.  
 hybrids and new strains, *Fusarium* wilt resistance of, 780, 781.

## Cotton—Continued.

- inbreeding, effect on staple length and lint percentage, Ark. 187.  
 insect pests in Philippines, 519.  
 insects, miscellaneous, studies, S.C. 518.  
 insects, summer months draw attention to, Miss. 652.  
 irrigation, duty of water in, N.Mex. 114.  
 irrigation experiments, N.Mex. 48.  
 land, and people, problem of, 405.  
 leaf worm, studies, U.S.D.A. 84.  
 losses from plant diseases, U.S.D.A. 201.  
 maximum yields with four-ton manure application, Miss. 479.  
 nitrogen and potassium top dressings for, Ga.Coastal Plain 617.  
 pectic substance in, relation to fiber properties, 860.  
 picking machinery, U.S.D.A. 831.  
 plantations, trends in land use, labor organization, and mechanization on, Ark. 115.  
 plants, age, relation to susceptibility to field inoculations with *Phymatotrichum*, 781.  
 plants, nitrogen and carbohydrate metabolism, effect of boron, N.J. 597.  
 plants, physiological changes in, 784.  
 production, legume nitrogen for, Miss. 617.  
 production, value of cover crops, manure or their combination, S.C. 480.  
 quality of 1939-40 crop, Okla. 689.  
 questions and answers on adoption of net-weight trading and standards for tare, U.S.D.A. 693.  
 resistance to *Phymatotrichum omnivorum*, 780, 781.  
 root aphid, studies, U.S.D.A. 84.  
 root aphids, control, S.C. 519.  
 root knot, under irrigation, crop rotation v. fallowing for control, 780, 782.  
 root rot—  
   infection, effect of deep tillage on, 781.  
   infection of seedlings in greenhouse, 781.  
   on soil types, effectiveness of organic manures in control, 780, 781.  
   sclerotia, number and viability from areas cropped continuously to susceptible and nonsusceptible crops, 781.  
   serological studies, 76.  
   spots in Arizona, map history, 781.  
 rotation experiments under Everglades conditions, Fla. 616.  
 S × P, comparison with Pima, U.S.D.A. 484.  
 sea-island—  
   development of production, Ga. Coastal Plain 617.  
   fertilizer experiments, Fla. 616.  
   selected references, 834.  
 secondary nutrient elements for, Ga. Coastal Plain 617.

## Cotton—Continued.

- seed, *see* Cottonseed.  
 seedbed, winter preparation most profitable, Miss. 48.  
 seedling diseases in 1940, and fungi associated with them, U.S.D.A. 636.  
 seedling diseases, seed treatment for, S.C. 501.  
 seedlings, diseased, fungi found on, 780.  
 seedlings in greenhouse, infection by *Phymatotrichum omnivorum*, 781.  
 severely injured by weeks of unseasonable rainfall, Miss. 740.  
 staple lengths, produced in South Carolina in 1928-38, percentage distribution, S.C. 551.  
 tillage studies on Red Bay sandy loam, U.S.D.A. 829.  
 varietal selection for wilt resistance and fiber quality, S.C. 501.  
 varieties for Missouri, Mo. 188.  
 varieties, improved, registration, 53.  
 varieties, nutritional studies, and measurement of fibers, Ark. 48.  
 variety tests, Ark. 48, Ga. 187, Ga. Coastal Plain 617, Miss. 48, 479, Mo. 185, N.Mex. 48, Okla. 188, S.C. 480.  
 wilt development in resistant and in susceptible varieties, relation to N-P-K ratio in fertilizers, 781.  
 wilt development, relation to potash treatments, 780, 781.  
 wilt fungi, biological strains, Ark. 68.  
 wilt organism, variation in pathogenicity and cultural characteristics, 504.  
 wilt plats, chemical and physical studies on soils from, 781.  
 wilt plats, regional, nematode population and species determination on soils from, 782.  
 wilt resistance of wilt-susceptible and wilt-resistant varieties, and mineral nutrition, S.C. 501.  
 wilt-resistant lines, variation in fiber characters, S.C. 480.  
 wilt-resistant varieties, breeding, Ark. 68.  
 wilt, rust, and drought injury greatly reduced by potash, 352.  
 wilt variety tests, S.C. 501.  
 winter cover and green manure crops for, Ga.Coastal Plain 617.  
 winter cover crops on, comparison, Tenn. 481.  
 yield increase and profits from better varieties and fertilizers, Miss. 48.  
 yields, effect of skips of different lengths, Ark. 48.

## Cottonseed—

- and cottonseed products, processing, Tenn. 436.  
 anthracnose spore load on, U.S.D.A. 68.  
 cake in ration for finishing beef calves, value, Miss. 805.  
 dusting, relation to control of *Rhizoctonia* infection of seedlings, 780, 781.  
 effect of methods of treating and planting, 781.

## Cottonseed—Continued.

- germination, relation to fertilizer placements, S.C. 480.  
 gravity graded, field results with, 779, 781.  
 hulls, hemicelluloses from, 585.  
 hulls, hydrolytic treatment, 153.  
 meal, alone v. mixtures of protein concentrates as supplements to silage for fattening steers, Tenn. 529.  
 meal, analyses, Ariz. 233.  
 meal and hulls v. corn and lespedeza hay for fattening steers, S.C. 529.  
 meal, effectiveness in preventing ricketts-like nutritional disorder in cattle on pasture, Fla. 666.  
 meal for pregnant and lactating sows, Ark. 94.  
 meal, iron-treated, as partial source of protein for pigs, Ohio 529.  
 meal, nutritive value, 668.  
 meal v. alfalfa hay v. wheat bran as protein supplements to silage in winter rations for calves, 384.  
 meal v. distillers' corn dried grains and tankage as protein supplements for fattening steers, Ky. 528.  
 meal v. distillers' corn dried grains for pregnant and nursing beef cows, Ky. 528.  
 meal v. soybean oil meal as protein supplements for milking cows, Hawaii 528.  
 oil, gossypol in, 585.  
 quality from plants killed by cotton root rot, 781.  
 soaking in boric acid, effect, 334.  
 storage tests, 780, 781.  
 treatment, effectiveness, U.S.D.A. 500.  
 treatment, extension work on, 780, 781.  
 treatments, N.Mex. 48, Okla. 207, U.S.D.A. 207.

## Cottonwood—

- cuttings, rooting, growth-promoting substances for, Ark. 65.  
 plantations, establishing with seed and cuttings, Ark. 65.  
 seeds, viability, effect of storage conditions and other treatments, Ark. 65.  
 stands, thinning, Ark. 65.

Cottony-cushion scale predator, maintenance of supply, P.R.Col. 651.

Country, *see* Rural.

County government of rural New York. receipts and expenditures, [N.Y.]Cornell 692.

## Cover crops—

- variety tests, Fla. 616.  
 winter, culture experiments, Ga.Coastal Plain 617.  
 winter, residual effects on cotton and corn, Ark. 48.  
 winter, variety tests, Ga.Coastal Plain 617.

## Cow—

- double mating with bulls of two breeds, twins from, 756.  
 manure, nitrogen content, effect of lime, Vt. 593.  
 tester's manual, U.S.D.A. 239.

- Cowpea *curculio*, studies, S.C. 518.
- Cowpeas—  
 green and mature, carotene in, 130.  
 variety tests, Ark. 48, Fla. 616, Ga. Coastal Plain 617, N.Mex. 48.  
 vitamin A and vitamin B<sub>1</sub> in, 531.
- Cows—*see also* Cattle and Heifers.  
 barley feeding v. sole roughage ration for economy of, Wyo. 535.  
 beef, winter ration for, Ga.Coastal Plain 666.  
 dairy, length of gestation in, Mo. 238.  
 dairy, on different planes of feeding, milk and butterfat production by, U.S.D.A. 536.  
 dairy, sweetpotatoes in rations, Miss. 666.  
 deterioration of udder in absence of streptococci, 538.  
 effect of anterior pituitary extracts on milk volume and fat production, 100.  
 genital tract of, H-ion concentration of various fluids, 807.  
 Holstein, live weight and milk-energy yield in, 392.  
 iodized, blood iodine values for, 239.  
 Jersey, milk yield, effect of carotene consumption on, 675.  
 lactating, home-grown hay and silage v. alfalfa hay for, nutritive values, West. Wash. 238.  
 lactating, roughage as sole ration, Mo. 238.  
 milk production, *see* Milk production.  
 milking, all-roughage ration v. roughage and grain feeding for, Tenn. 535.  
 milking, comparison of winter pasture v. silage for, Tenn. 535.  
 ovulation in, time of, Wis. 42.  
 Red Seindi nonlactating, blood constituents of, quantitative data, 233.  
 shy breeders, production of oestrus and stimulation of ovulation in, Wis. 42.  
 thyroxine injections during declining stages of lactation, Mo. 182.  
 udders, *see* Udders.
- Cozymase—  
 and factor V from nicotinic acid, synthesis by human erythrocyte, 858.  
 and nicotinamide in blood, 714.
- Crab apples, new hardy for Northwest, S.Dak. 774.
- Crab louse control, 524.
- Crambus caliginosellus*, *see* Corn root webworm.
- Cranberries—  
 effect on calcium retention, 847.  
 fertilization, N.J. 628.  
 flower and fruit production, Mass. 771.  
 harvesting methods, 196, N.J. 628.  
 irrigation and frost control, Wash. 190.
- Cranberry—  
 blossom blast, 357.  
 bogs, control of weeds and shrubs in, Mass. 759.  
 bogs, frost protection on, Mass. 828.  
 bogs, rebuilt, effect of weeding and sanding, N.J. 628.
- Cranberry—Continued.  
 bogs, use of chemicals for killing weeds in, N.J. 628.  
 bogs, use of honeybees in, 379.  
 false blossom—  
 breeding for resistant varieties, 214, Mass. 771.  
 virus-induced, N.J., 635.  
 fruitworm on blueberries, N.J. 651.  
 fruitworm, studies, Mass. 796.  
 insects, injurious and beneficial, Mass. 796.  
 juice, properties and manufacture, Mass. 862.  
 leafhopper, N.J. 651.  
 leafhopper, spread of false blossom by, 214.  
 root grub, studies, Mass. 796.  
 rosebloom and fruit rot, spraying tests for, Mass. 783.  
 spittle insect, Mass. 796.  
 storage and byproducts research, Mass. 725.  
 storage, studies, Mass. 828.  
 weevil, studies, Mass. 796.
- Crassulaceae, studies, 169.
- Crawfish control, time to poison burrows for, Miss. 143.
- Crazy ant, notes, Conn.[New Haven] 652.
- Cream—  
 acidity, effect of salt on microflora, 102.  
 cooling and storing for butter manufacture on Oregon dairy farms, 391.  
 cost of transporting to Boston, Vt. 837.  
 for butter making, vacation of, 391.  
 for manufacturing purposes, annatto as tracer in, and its detection, 538.  
 frozen, prevention of oxidized flavor in, 673.  
 hydrolysis of fat in, effect of lactic acid, 537.  
 keeping quality, effect of salt on, 673.  
 keeping quality, effect of temperature, 391.  
 pasteurization efficiency, determining, Wis. 101.  
 pasteurization, high-temperature, for butter making, 536.  
 quality from creameries in southern Michigan, Mich. 102.  
 removal of French weed flavor from, 102.  
 sales, seasonal variation in, Me. 405.  
 tests, materials read as fat, density at 140° F. 538.  
 viscosity of, increasing, 241.
- Creameries, Minnesota, competitive problems among, 102.
- Creamery accounting, cooperative, 695.
- Creatine in animal tissues, glycoyamine and methionine as precursors, 667.
- Cricket—  
 house, Conn.[New Haven] 652.  
 mole, studies, U.S.D.A. 84.  
 Mormon, nematode as important parasite, 797.

- Cricket—Continued.  
 Mormon, studies, U.S.D.A. 84.  
 Puerto Rican mole, parasite of, methods of collecting and shipping, 525.
- Crioceris asparagi*, see Asparagus beetle.
- Crop—  
 and livestock reporting, developments in since 1920, 115.  
 diseases of South, extension work on, 780.  
 insect pests in Hawaii, notes, Hawaii 517.  
 insects, control, chart for, 519.  
 reporting and forecasting, government entry into field of, 115.  
 reports, U.S.D.A. 122, 267, 556, 694.  
 residues, use for soil and moisture conservation, 29.  
 rotations, see Rotation of crops.  
 yields, effect of organic matter on, N.J. 592.
- Croplands, abandoned, restoring, Colo. 618.
- Crops—see also Forage crops and specific kinds.  
 acreages, yield per acre, and production, Ohio 688.  
 average monthly prices received by farmers for, Ohio 689.  
 chemical composition, Tenn. 436.  
 composition, Iowa 22.  
 effects of preceding crops, Fla., 616.  
 interception of rainfall by, 590.  
 irrigated, yields, factors affecting, Nebr. 760.  
 management, relation to wind erosion and duststorm hazards, U.S.D.A. 165.  
 minor, retail agencies selling, P.R.Col. 689.  
 organic composition, relation to growth and maturity, Fla. 592.  
 plantation, tropical and subtropical, vegetative propagation, 625.  
 severely injured by weeks of unseasonable rainfall, Miss. 740.  
 sodium chlorate injury, comparative susceptibility, U.S.D.A. 72.  
 variety tests, N.Dak. 49.  
 yield and composition, effect of type and treatment of soils, Fla. 592.
- Crossopora* new species, 636.
- Crotalaria—  
 culture experiments, Ga.Coastal Plain 617.  
 rotation experiments under Everglades conditions, Fla. 616.  
 variety tests, Ga.Coastal Plain 617.
- Croton monanthogynus* as bank cover, 168.
- Crown gall—  
 bacteria, chemical attenuation, 346.  
 behavior and pathogenicity of causal bacteria, Wis. 344.  
 growth, effect of animal hormones and vitamins, 346.  
 relation to growth substances, 346.  
 studies, 70.  
 susceptibility of Cupressaceae species to, 81.
- Crucifer—  
 clubroot, N.J. 635.  
 mosaic disease prevalent in China, 209.
- Cryolite—  
 effect on soils and plant growth, S.C. 518.  
 injury of fruit, magnesium oxide as corrective for, Tenn. 519.  
 place in fruit pest control, 218.  
*Cryptocephalus incertus*, studies, Mass. 796.  
*Cryptodiaporthe* and related conidial forms, fungi associated with, 348.  
*Cryptomycina pteridis*, life history, notes, 202.  
*Cryptotermes brevis*, notes, P.R.Col. 651.  
*Ctenocephalus canis*, see Dog flea.  
*Ctenocephalus inaequalis*, notes, 525.
- Cucumber—  
 beetle, striped, control, Fla. 650, Mass. 796.  
 beetle, western spotted, damage to pole beans, 84.  
 diseases, epidemiology and control, S.C. 501.  
 downy mildew—  
 control, 780, 781.  
 dusting for, Fla. 634.  
 resistance, breeding for, P.R.Col. 625.  
 resistant variety, Fla. 634.  
 varietal tests with, S.C. 501.  
 fermentations, effect of sugar addition to brines, 436.  
 fermentations, yeasts in, 436.  
 insects, control, derris dust for, Miss. 520.  
 mock, seeds, dormancy and germination, 316.  
 mosaic in New Zealand, 348.  
 pickle, fresh, bacteriological methods of examination, 436.  
 pickles, fermentation under southern conditions, 468.  
 root knot, N.J. 635.  
 seeds, rest period in, Ark. 57.  
 virus in lilies, 71.  
 virus 1, strains of, effects in lily and tulip, 71.  
 wilt in Virginia, U.S.D.A. 783.
- Cucumbers—  
 breeding, Ark. 56, Miss. 490.  
 experimental work on, Miss. 490.  
 fertilization, Ill. 336.  
 frequency of bordeaux injury on, P.R.Col. 635.  
 greenhouse, production, Mo. 190.  
 inheritance in, 474.  
 manure experiments with, Ark. 626.  
 Midget, new bush variety, 58.  
 response to superphosphate, 57.  
 studies, P.R.Col. 625.  
 variety tests, S.C. 488.  
 vitamin C in, 715.  
 waxing, effect on loss of weight following harvest, S.C. 488.  
 yields under irrigation, Okla. 190.
- Cucurbit—  
 diseases, control, Ohio 501.  
 downy mildew, epidemiology and control, 780.

- Cucurbitaceae, virus diseases in, 784.  
 Cull caliper, construction and use, 632.  
*Cunninghamella blakesleeana*, growth, effect of forms of nitrogen and phosphorus, 312.  
 Cupressaceae, susceptibility of species to crown gall, 81.  
 Curly top in Pacific Northwest, U.S.D.A. 201.  
 Currant, black, sirup, vitamin C in, photochemical decomposition, 715.  
 Currants—  
   black, breeding, 59.  
   culture, Mo. 631.  
   new hardy for Northwest, S.Dak. 774.  
   vitamin C in, 715.  
 Currents, Pacific Ocean, relation to climates of the coasts, 19.  
 Curtain fabrics, rayon glass and cotton, selection and care, Ohio 573.  
*Curvularia lunata*, notes, Tex. 206.  
 Cuterebrine larvae, taxonomic characters, 244.  
 Cut-over lands of Wisconsin, 836.  
 Cutworm—  
   Atlantic, studies, Mass. 796.  
   injury, controlled by poisoned bait, Miss. 525.  
   variegated, control by thorough turning under and delayed planting after winter crops, Miss. 223.  
 Cutworms—  
   rearing for laboratory toxicological studies, 659.  
   studies, U.S.D.A. 84.  
 Cyanide compounds used as insecticides, bibliography, U.S.D.A. 217.  
 Cyanosis in chickens and mice, induced by sulfanilamide, 824.  
 Cyclamen mite, N.J. 651.  
*Cycocephala immaculata*—  
   life history, Ky. 800.  
   studies, Ark. 84.  
 Cyclones, speed over North America, 306.  
*Cylas formicarius*, see Sweetpotato weevil.  
*Cylindrosporium*—  
   *chrysanthemi* synonymy, 214.  
   in Indo-China, new taxonomy, 596.  
 Cypress, chlorotic, 513.  
 Cypress, *Coryneum* canker, 500.  
 Cypress, Monterey and columnar Italian, threatened by spread of canker in California, 513.  
*Cyrtopeltis varians*, ecology, Hawaii 517.  
 Cysteine, effect on gonadotrophins, 184.  
*Cysticercus*—  
   *fasciolaris*, rats infested with, and normal rats, tissue reactions against injected *Cystercercus* material, 821.  
   *pisiformis* parasite of cottontail rabbit, 791.  
 Cystine—  
   a possible deficiency in ration of alfalfa hay for milk production, 675.  
   and methionine for growth and lactation, 669.  
   as dietary lactagogue, 667.  
   in aqueous solution, decomposition, 587.  
 Cystoamylase (cytoamylase?) in potato, variation, 598.  
 Cytology, experimental, monograph, 606.  
*Cytospora chrysosperma*, biology, 513.  
 Dacinae of China, key to genera, 224.  
 Dairy—  
   breeds, fusion of two Swedish, results, 43.  
   bull associations, cooperative, U.S.D.A. 238.  
   cattle and dairy cows, see Cattle and Cows.  
   equipment, cleaning problems, 817.  
   equipment, sterilization by irradiation, N.J. 676.  
   farm organizations in Barron Co., Wisconsin, forces causing changes in, U.S.D.A. 552.

    - native, effects of solar heat on sub-cortical development, Mass. 796.
    - smaller European, control, 662.
    - smaller European, notes, Conn.[New Haven] 652.

## Elm—Continued.

bark beetles, feeding period, generations, and habits, 215.

*Cephalosporium* wilt in Massachusetts, Mass. 790.

disease, Dutch—

control, 215, 662.

detecting by trunk sampling, 512.

eradication, U.S.D.A. 68.

insect vectors, Mass. 796, U.S.D.A. 84.

*Scolytus sulcatus* as vector under controlled conditions, 377.

spread, factors affecting, 215.

studies, Mass. 783, Me. 344.

leaf beetle, parasites of, 801.

leaf beetle, rotenone-bearing insecticides for control, 376.

trees, virus phloem necrosis of, Ohio 501.

trees, young, importance of soil pore space to, N.Y.State 194.

*Verticillium* disease, control, Ohio 501.

*Verticillium* wilt, U.S.D.A. 782.

wood, stored, attempts to isolate *Ceratomyxa ulmi* from, 81.

Elsinoe new species and variations in fructifications, 346.

Emmer, outstanding varieties, N.Dak. 49.

*Empoasca fabae*, see Potato leafhopper.

## Encephalitis—

acute specific, infectious, of sheep, cattle, and goats, 545.

fox, and canine distemper, differentiation of viruses, 546.

human, caused by virus of equine encephalomyelitis, 819.

Japanese, comparison of concentrations of virus in blood, cerebrospinal fluid, and brain tissue of different subjects, 820.

St. Louis, susceptibility of wild mice to virus, 394.

## Encephalomyelitis—

avian, Mass. 823.

avian, infectious, cultivation of virus, 400.

equine—

clinical manifestations, 516.

human encephalitis caused by virus. 819.

in avian hosts, 678.

in Iowa during 1939, studies, 541.

Intradermal method of vaccination against, 541.

mosquito transmission of, 819.

pheasants surviving outbreak, neutralization tests with sera of, 819.

possible avian reservoir sources, 107.

relation to man and animals in California, 819.

studies, 677, 827, Nev. 540.

susceptibility of guinea pigs to virus inoculated through various routes, 244.

transmission, 819.

## Encephalomyelitis—Continued.

equine—continued.

vaccination of man against virus, 251.

vaccine, reactions following administration, 680.

virus, eastern type, Mass. 823.

virus, immunological studies, 819.

virus, isolation and typing, 826.

virus protein, purification procedure, 399.

western type and botulism, differential diagnosis, 251.

infectious, of cattle, 396.

*Encopognathus*, new species from California, 804.

## Endocrine—

imbalance induced experimentally, effects in female mice, 329.

literature of 1939, 616.

system and plumage types in fowls, 610.

Endocrines, histopathology in avitaminoses A and B<sub>1</sub> of rats, Ark. 127.

*Endophylloides* new species, 636.

Engineer, agricultural, and micro-climate, 740.

## Enteritis—

necrotic, in pigs, relation to nutrition, Mich. 97.

syndrome in swine, 546.

Enterohepatitis, infectious, see Blackhead.

## Entomological—

conditions in 1939, 519,

usage of subspecific names, 793.

Entomologists, Connecticut, program of annual conference Conn. [New Haven] 651.

Entomology—see also Insects.

at Dartmouth College, bequest for, 144.

Economic, American Association of, fifty years of work, 83.

laboratory guide in, 216.

Entozon, highly lethal to *Streptococcus agalactiae*, 679.

## Enzymes—

adaptive production by bacteria, 607.

in milk, effect of added iodine and hydrogen peroxide to, 673.

*Ephestia figulilella*, see Raisin moth.

*Epicauta*—

*maculata*, see Blister beetle, spotted.

spp., control, S.Dak. 801.

*Epilachna varivestris*, see Bean beetle, Mexican.

Epinasty, production, by emanations from fruits and from *Penicillium digitatum*, 510.

*Epitrix*—

*cucumeris*, see Potato flea beetle.

*parvula*, see Tobacco flea beetle.

Ergosterol, production by *Penicillium carmino-violaceum*, 464.

*Eriococcus azaleae*, notes, Ala. 519.

*Eriopersicon*, n.subgen., notes, U.S.D.A., 753.

Eriophyid studies, new species, 528.

*Eriosoma lanigerum*, see Apple aphid, woolly.

Erosion, see Soil erosion.

- Erycinia tracheiphila* and *Phytomonas Stewartii*, wilt induction by, comparison, 787.
- Erysipelas in turkeys, West. Wash. 253.
- Erysipelothrix rhusiopathiae*—  
infection of peacock, followed by case of human erysipeloid, 107.  
isolation from swine, Ky. 540.  
phenol tolerance of, 249.  
studies, 683.
- Erysiphe cichoracearum* spp. on ornamental plants, 360.
- Erythroneura comes*, see Grape leafhopper.
- Erythronium*, karyotaxonomy of, 753.
- Escherichia coli*—  
indol production by, Mass. 843.  
preparation of an active juice from, 607.  
sensitivity to cold-shock during the logarithmic growth phase, 607.
- Eskimos, basal metabolism, 127.
- Ethyl mercury iodide as fungicide and nematocide, 205.
- Ethylene production—  
by ripening McIntosh apples, quantitative study, 339.  
by ripening papaya fruit, Hawaii 488.  
during ripening of apple and banana, Minn. 339.
- Eucharidae new species, descriptions, 804.
- Euchlaena-Zea* hybrids, inheritance of intergeneric differences in, 42.
- Euethoia rugiceps*, see Sugarcane beetle.
- Euhoplopsyllus*, new subgenera, erection, 525.
- Eulycopersicon* n. subgen., notes, U.S.D.A. 753.
- Euphasiopteryx australis*, parasite of Puerto Rican Changa, 83.
- Euplectrus platyhypenae*, notes, 799.
- Euproctis terminalis*, biology and control, 222.
- Eurosta solidoginis*, autecology, 224.
- Euschistus variolarius* on tomatoes, control, 368.
- Euscirpus* subgenus, redefined, 169.
- Euspinolia*, systematic revision of genus, Minn. 379.
- Eutettix tenellus*, see Beet leafhopper.
- Evaporation experiments, present trend in, 304.
- Evergreens, hardiness, factors affecting, Mass. 771.
- Evolutionary divergence, speciation as stage in, 754.
- Ewes—see also Sheep.  
and lambs, barley as supplement to alfalfa for, Nev. 529.  
breeding, feeding experiments, Ky. 528.  
breeding, value of grain feeding for, Tenn. 529.  
periodicity of oestrus in, 183.  
range Rambouillet, selection, 178.  
sperm survival in different portions of vagina and uterus, Mo. 182.  
sterility in, treatment, Wis. 42.  
sway-back in, control by copper feeding, 234.
- Exanthema, vesicular, of swine, 820.
- Experiment station at Clarinda, Iowa, history, and description of watersheds, U.S.D.A. 590.

  - in peach orchards, introduction of parasites, Mass. 796.
  - mass liberation of parasites, 371.
  - parasite project, 1939, 517.
  - parasites, Ky. 518.
  - situation, 515, 516.
  - studies, S.C. 518.
- products, soft, utilization, Wash. 150.
- season of 1939, climatic conditions, relation to production, 338.
- set and size, effect of branch ringing, 59.
- set in Washington orchards, factors affecting, Wash. 190.
- tree buds, internal temperatures, 628.
- tree diseases, virus, 346, 784.
- trees, pollination, 194.
- trees, pruning, Iowa 491.
- trees, winter injury, relation to soil temperatures, Wash. 190.

## Fruitflies—

- of north China, 224.
- of south China, 224.

## Fruitfly—

- infested products, treatments for entry into United States, U.S.D.A. 93.
- Mexican, control, U.S.D.A. 84.
- Queensland, toxicity tests, 799.

## Fruits—see also Orchards, Apples, Peaches, etc.

- breeding, 59.
- canned, quality, reliability of retail prices as guides to, Ohio 116.
- citrus, see Citrus.
- culture experiments, Can. 336.
- dried, spoilage due to sugar tolerant yeast, 346.
- Florida, composition of ash, Fla. 581.
- freezing preservation, research project, Utah 412.
- frozen, commercial packs, microbiological studies, 154.
- frozen, industry, N.Y.State 772.
- frozen, use in ice cream, Utah 540.
- grown in British Columbia, chemical constituents, 194.
- Hawaiian-grown, vapor-heat treatment for, Hawaii 772.
- Indian, cold storage, 494.
- marketing regulation in South Africa, U.S.D.A. 120.
- minor, Fla. 625.
- mutant, produced by radiation, N.Y.State 193.
- new hardy, for Northwest, S.Dak. 774.
- nicotinic acid in, 713.

## Fruits—Continued.

- North Dakota grown, sharp freezing for cold storage lockers, N.Dak. 560.
- of Florida, vitamin C content, Fla. 699.
- of ornamental shrubs, vitamin C in, 715.
- phenological investigations, N.Mex. 57.
- pollination, Can. 336.
- pome, morphology of flower, [N.Y.]Cornell 774.
- preparation, freezing, and storage, N.Y. State 701.
- production, climatic factors in, N.J. 628.
- propagation, Can. 336.
- responses from irrigation, Wash. 190.
- ripening, hexose sugars in, Wash. 190.
- ripening, pectic changes in, effect of ethylene, 61.
- seedless, development by synthetic growth substances, 455.
- selection of genetic strains high in minerals and vitamins, Me. 411.
- small, virus diseases of, 784.
- statistics, Calif. 267.
- stone—
  - brown rot of, control, West.Wash. 202.
  - Coryneum* disease in Argentina, 646.
  - gum-spot disease in South Africa, 356.
  - list of virus diseases, U.S.D.A. 201.
  - role of fixed copper sprays for, 356.
  - virus diseases of, U.S.D.A. 68.
- storage and handling, Wash. 190.
- studies, Ohio 772.
- tests in toxic orchard soils, 628.
- thinning, 492.
- thinning an essential to quality and yield, Miss. 491.
- utilization, Tenn. 436.
- varieties, Fla. 624.
- varieties, tree characters, Mass. 771.
- variety tests, Ark. 56, Can. 336, Mass. 771, Tenn. 489, Wash. 190, West.Wash. 190, Wyo. 489.
- vitamin B<sub>1</sub> assays, 132.
- vitamins in, N.Y.State 848.
- Fruitworm control, Wash. 217.
- Fuchsin, basic, toxicity for bacteria, 456.
- Fumigants—
  - for control of insect pests, U.S.D.A. 84.
  - greenhouse, naphthalene and similar compounds as, Mass. 796.
- Fumigation—
  - of quarantined products, methyl bromide dispenser for use in, U.S.D.A. 83.
  - ship, chloropicrin as a prewarning gas in, 86.
  - studies, U.S.D.A. 84.
- Fumigator, low-cost water seal, U.S.D.A. 83.
- Fungi—
  - and plants, symbiosis, selective action in, 346.
  - causing decay in wind-thrown conifers, 361.

- Fungi—Continued.
- chytridiaceous, relation to disease in flowering plants, 346.
  - collected in southeastern United States, distribution, U.S.D.A. 783.
  - cytoplasmic structures in basidium revealed by silver impregnation, 745.
  - ecology, seasonal frequency in grassland, 603.
  - fleshy, of Crawford County, Kansas, 168.
  - flesh on diseased cotton seedlings from thirteen States, 782.
  - genetics of, problems, 466.
  - growth substance demand of, 468.
  - imperfecti, new taxonomic data, 456.
  - imperfecti, taxonomic monograph, 596.
  - in Hawaii, and hosts, check list, U.S.D.A. 345.
  - lower, biochemistry, 745.
  - mycorrhiza-forming, effect on pine seedling growth, 463.
  - nutrition, 38.
  - of Florida, additions to list, 202.
  - outline and keys, 202.
  - phylogeny, significance of chitin and cellulose in, 468.
  - production of organic acids by, N.J. 593.
  - simple single-spore isolator for study, 785.
  - surviving exposure to radiation and high temperature, growth and other physiological characteristics, 468.
  - taxonomic problems in, 595.
  - thiamin-requiring, factors affecting yield, 468.
  - unusual chytridiaceous, 502.
  - variation of, 468.
  - wood-inhabiting, from region of Great Lakes, 512.
  - wood-rotting, biochemistry, 362.
  - yeastlike, anascosporus, taxonomy, 467.
  - yeastlike, dissociation, 467.
- Fungicides—*see also* Sprays and specific kinds.
- analyses, N.J. 193.
  - copper, *see* Copper.
  - design for laboratory assay, 784.
  - development and use, 72.
  - eradicator, 509.
  - use on ornamentals and shade trees, 360.
  - volatile, principles involved in their use, 72.
- Fungus—
- diseases in Hawaii, seasonal list, Hawaii 501.
  - flora of Nevada, U.S.D.A. 68.
  - growth rates, determination method, 779, 780.
  - spores, bombarded in vacuum with cathode ray beams, death rate of, 457.
  - spores, insects as disseminators of, 364.
- Fur animals—
- diseases of, Wis. 105.
  - nutritive requirements, Wis. 95.
  - reproduction in, application to breeding practices, 183.
- Fur trade, glossary of terms used in, Iowa 215.
- Furs, care and handling and traps and trappings, Iowa 215.
- Fusarium*—
- culmorum* inoculated into sterilized soil, survival, 27.
  - genus, biochemistry, 467.
  - in Indo-China, new taxonomy, 596.
  - lycopersici*, notes, Mo. 201.
  - moniliforme* on *Sansevieria*, 514.
  - niveum* wilt of watermelons, control, Fla. 634.
  - oxysporum*, cause of potato seed piece rot, 77.
  - solani*, notes, 77.
  - species concept in, 203.
  - spp. on banana, 511.
  - strains from cotton and Burley tobacco, cross-inoculation experiments, S.C. 501.
  - vasinfectum* isolates, pathogenicity tests, 780, 781.
  - vasinfectum*, variation in pathogenicity and cultural characteristics, 504.
  - wilt, inheritance study of, 781.
  - wilt isolations from tomatoes, differences in growth characters and pathogenicity, U.S.D.A. 212.
  - wilt of potato, effect of dry land rotations on, Nebr. 783.
  - wilt resistance of cotton new strains and hybrids, 781.
  - yellows of celery, varietal susceptibility, Ohio, 75.
- Fusicladium dendriticum*, *see* Apple scab.
- Galactose, *d*-, final solubility in water, 394.
- Galacturonic acid, making from apple juice, Wash. 150.
- Galerucella xanthomelaena*, *see* Elm leaf beetle.
- Gall midge, new species, predacious on mealybugs, 223.
- Gall midges, economic aspects in West Indies, 224.
- Galleria mellonella*, *see* Wax moth.
- Galls, casual complex of, role of dysauxony in, 346.
- Game—
- big, North American, review, 215.
  - mammals of Iowa, Iowa 215.
  - preparation, freezing, and storage, N.Y. State 701.
- Gapeworms—
- new intermediary vectors for, 401.
  - sex difference in infection rate of birds with, 401.
- Garden—
- beetle, Asiatic, damage in field of sweet corn, Conn.[New Haven] 652.
  - insects, studies, U.S.D.A. 84.
  - pests, control, 793.
- Gardenia—
- canker control, 359, 500.
  - diseases, control, N.J. 649.
  - leaf spot due to *Rhizoctonia*, 649.

- Gardenias—  
 bud abscission, factors related to, Wash. 190.  
 effect of plant nutrients, soil reaction, and light, Mass. 771.  
 effects of soil temperature, Mass. 745.
- Garlic rust in California, U.S.D.A. 782.
- Gas gangrene anaerobes, toxin production by, 822.
- Gases—  
 dissolved, in milk and dye reduction, Vt. 816.  
 in dense subsoils, method of sampling, advantages and limitations, 160.
- Gastrointestinal motility, effect of nicotinic acid, 567.
- Gastrophilus nasalis*, see Botfly, throat.
- Gelasinospora*, nuclear migration in, 468.
- Gelatin—  
 effect of aging treatments, Mass. 814.  
 protein, efficiency in forming serum albumin, 128.  
 stabilizing action, effect of drawing temperature and body and texture of ice cream, 673.
- Genetics—  
 Congress, reports from, 176.  
 in the Soviet Union, present views, 324.  
 International Congress of, activities of sections, 176.  
 mammalian, 608.
- Genus, concept of, papers on, 596.
- Geocoris decoratus*, notes, 363.
- Georgia Coastal Plain Station, report, 718.
- Georgia Station, notes, 431, 719.
- Georgia University, notes, 431.
- Geotrichum* sp. from pink-stained southern yellow pine lumber, 513.
- Geraniol samples used in Japanese beetle baits, properties, 374.
- Geranium leaf crinkle, U.S.D.A. 201.
- Giardomyia rhododendri*, notes, N.J. 651.
- Girls—  
 from birth to age of 5 years, progressive skeletal development, scale for rating, 275.  
 growth during adolescence, relation to change in basal metabolism, 270.
- Gladiolus—  
 blight in Florida, role of *Botrytis* in, U.S.D.A. 782  
*Botrytis* blight in Florida, epiphytotic of, U.S.D.A. 344.  
 bulb diseases, control, West.Wash. 202.  
 cormel germination experiments, 198.  
 corms, *Botrytis* dry rot of, U.S.D.A. 68.  
 culture in Iowa, Iowa 496.  
 seed production, effects of time of pollination and light intensity, 198.  
 thrips, Fla. 650.  
 thrips control,  $\beta,\beta'$ -dichloroethyl ether for, 363.  
 thrips control on corms during storage, U.S.D.A. 216.  
 thrips, control through winter and summer treatment, Minn. 368.
- Gladiolus—Continued.  
 thrips, studies, U.S.D.A. 84.  
 thrips, field control, 655.  
 yellows disease, effect on germinating ability of corms, 359.  
 yellows problem solved by clean soil for clean corms, 648.
- Glass-container research, Mass. 725.
- Glaucoma-colpidium group of ciliates, antigenic properties, 821.
- Gloeosporium*—  
*fructigenum* on peony, 359.  
*musarum*, monographic study, 510.  
 spp. on ornamentals, N.J. 635.
- Glomerella glycines*, notes, 209.
- Glutamic acid, *DL*-, crystalline anhydrous and monohydrated, 297.
- Glutamine, and growth of bacteria, 468.
- Gluten—  
 protein fractionation from sodium salicylate solution, 581.  
 wheat, proteins, biological value, 530.
- Glycerol—  
 fermentation, studies, 725.  
 neutral fat, in blood, determination with periodate, 301.
- Glycine, effect on *Rhizobium*, 456.
- Glycogen in liver of vitamin B<sub>1</sub>-deficient rats, 712.
- Glypta rufiscutellaris* parasite or oriental fruit moth, 371.
- Gnomoniella*, new taxonomy, 40.
- Gnorimoschema lycopersicella*, see Tomato pinworm.
- Goats—  
 dairy, improvement, N.Mex. 100.  
 external parasites of, U.S.D.A. 84.  
 Kirghiz, genetics of color and spotting in, 609.  
 parasites of, P.R.Col. 677.  
 poisoning by sacahuiste buds and blooms, Tex. 544.
- Goldenrod gall fly, autecology, 224.
- Golgi material in plant cells, 37.
- Gonadotropic—  
 hormone, see Hormone.  
 substance, International Standard, graded doses, comparative action on infantile male and female rats, 479.  
 substances, comparative assay on rats, mice, and chicks, 612.
- Gooseberries—  
 culture, Mo. 631.  
 vitamin C in, 715.
- Goosegrass, seed germination, 764.
- Gopher, pocket, control, Kans. 363.
- Gordius robustus* as parasite of Mormon cricket, 797.
- Gossypium* species, American tetraploid, origin, 755.
- Gossypol, toxicity, for pigs and guinea pigs, Ohio 529.
- Gracilaria azaleella*, notes, Ala. 519.
- Grain beetle—  
 flat, in stored grain, fumigation with chloropierin, 654.

## Grain beetle—Continued.

saw-toothed, development and survival, factors affecting, 802.

saw-toothed, flight habits and seasonal abundance, 86.

Grain borer, lesser, in stored grain, fumigation with chloropierin, 654.

Grain—*see also* Cereals and Oats, Rye, Wheat, *etc.*

diseases, U.S.D.A. 500.

diseases in Wisconsin, U.S.D.A. 783.

farms, organization and crop production practices in Great Plains, U.S.D.A. 691.

foot rot in Pacific Northwest, U.S.D.A. 350.

foot rots and root rots in Oregon, Oreg. 74.

heap in the open, temperature, 517.

moth breeding rooms for parasite production, description, 658.

sacked, fumigation with chloropierin, 653.

small, spring, changes in acreage, Nebr. 618.

smut, *see* Cereal smuts, Smut, and specific grains.

spring, response to fallow and other tillage practices, Nebr. 760.

sprouting, effect on nutritional value, 814.

stored, insects in, fumigation, U.S.D.A. 84.

stored, pests, control, Nebr. 519.

treated, effect of storage, N.Y.State 207.

weight, effect of potash, N.J. 592.

windrowing before combining, Wis. 114.

Grama grass, side-oats, disease of, 504

Gramineae of Douglas Lake region, Michigan, records for, 753.

## Granary—

ever-normal, and insects, 516.

weevil, death-feints of, 227.

weevil in stored grain, fumigation with chloropierin, 654.

## Grape—

berry moth control, spraying for, Mich. 524.

berry moth, studies, U.S.D.A. 83.

boring plume moth, bionomics, 222.

cane girdler, biology and control, Mass. 796.

disease, resembling formerly prominent California vine disease, 500.

fruit rots, Fla. 634.

leafhopper, studies, U.S.D.A. 83.

plume moth, biology and control, Mass. 796.

plume moth in Boston area, 370.

## Grapefruit—

pulp, dried, for milk production, 675.

refuse, dried, feeding value, Fla. 666.

## Grapes—

Arkansas varieties, composition, Ark. 126.

causes of uneven ripening, Ark. 57.

## Grapes—Continued.

Concord, chlorosis of, controlled by grafting, Utah 357.

Concord, nutrition, Mo. 189.

culture, in California, 630.

currant-type seedless, development, 777.

losses from plant diseases, U.S.D.A. 201.

muscadine, potash requirements, Miss. 198.

Ontario, and seedlings as parents, 495.

production in Texas, Tex. 776.

quality, spray schedules for, Miss. 193.

rootstocks for, Ark. 57.

self-pollinated vinifera varieties, progenies, 776.

studies, P.R.Col. 625.

training and pruning, Iowa 197.

varieties, Fla. 624, Ga.Coastal Plain 625.

varieties, evaluation in Northeast, 341.

varieties, new, promising, N.Y.State 198.

variety tests, N.Mex. 57, West.Wash. 190.

vinifera, on phylloxera-resistant rootstocks, testing, U.S.D.A. 62.

*Grapholitha*—

*molesta*, *see* Fruit moth, oriental.

*packardi*, *see* Cherry fruitworm.

## Grass—

artificially dried v. naturally cured hay, Del. 95.

as remedy for small gullies, Wis. 306.

crops, Everglades, yield and composition, relation to fertilizers, Fla. 49.

diseases in Pullman nurseries, U.S.D.A. 68.

juice vitamin, nature and sources, Wis. 95.

methods for ensiling, Wis. 95.

mite, proposed name, 228.

mixtures and alfalfa in rotation for 2 years or longer, benefits, Ohio 480.

new for Kansas, 168.

seeds, germination experiments, Hawaii, 479.

sickness in horses, 399.

species, cytological studies, Ark. 48.

stripe smut, studies, 73.

Grasses—*see also* Lawns, Meadows, Pastures, *etc.*

adaptation studies, Hawaii, 479.

chemical analyses, P.R.Col. 806.

cytotaxonomic studies, 472.

durability of, studies, N.J. 617.

effect of burning on maintenance and establishment of improved types, Fla. 616.

ensiling with and without molasses, Fla. 616.

ensiling with phosphoric acid, losses from, 675.

erosion-controlling, Wash. 160.

forage, breeding, Wash. 185.

forage, comparative palatability, Hawaii 528.

forage, diseases, Wash. 202.

forage of east Texas timber country, composition, Tex. 232.

forage, tests, Nebr. 760.

## Grasses—Continued.

- forage, variety tests, Wyo. 481.  
 improvement, Fla. 616.  
 large, grown for silage, comparative production, Fla. 616.  
 new American, 597.  
 of Puerto Rico, nutritive values, P.R.Col. 805.  
 on typical sandhill range land, Nebr. 186.  
 pasture, breeding, Ga.Coastal Plain, 617.  
 pasture, variety tests, Ga.Coastal Plain 617, S.C. 480.  
 prairie, interception of rainfall by, 590.  
 processing seed of, U.S.D.A. 618.  
 range and browse, composition at varying stages of maturity, N.Mex. 95.  
 range, digestibility, 232.  
 range, growth behavior and relative composition as affected by burning, Fla. 616.  
 range, studies, N.Mex. 760.  
 response to intensity of clipping, Nebr. 760.  
 science and practice of conservation, 233.  
 snow molds of, caused by *Typhula* spp., 73.  
 suitable for silage, Mo. 806.  
 variety tests, Fla. 616, Tenn. 481, Wash. 185.  
 variously fertilized, forage production or, P.R.Col. 617.  
 western, water relations, 169.

## Grasshopper—

- baits no hazard to pheasants, Wis. 364.  
 control research, papers, 516.  
 eastern lubber, life history, food preferences, distribution, and control, Fla. 650.  
 egg pods, insect enemies attacking, S.Dak. 801.  
 parasites and natural enemies, new facts on biology, 515.  
 poison bait and turkey poult mortality, 685.  
 poisons, arsenical, effect on pheasants, 655.  
 variegated, notes, 219.

## Grasshoppers—

- control, Mo. 217, Nebr. 796.  
 control, poison bran bait recommended for, Miss. 523.  
 factor in soil erosion in Michigan, 654.  
 mid-western, identification of eggs, Kans. 367.  
 studies, Ark. 84, U.S.D.A. 84.

## Grazing—see also Range.

- all-season, experiment, Ohio 480.  
 crops for fattening feeder pigs, comparison, Fla. 666.  
 management, 381.

## Green aphid, control, 218.

## Green manure—

- fertilizer experiment, S.C. 481.  
 v. sodium nitrate for small grains, N.J. 618.

## Greenhouse—

- studies, experimental designs to increase accuracy, 746.  
 thrips, notes, Ala. 519.  
 thrips, studies, U.S.D.A. 84.  
 Greenhouses, empty, equipment for burning sulfur in, Ohio 833.  
 Grocery buying habits in independent and chain stores, Wis. 142.  
 Growth, nuclear changes affecting, 324.  
 Growth substances, see Plant growth substances.  
 Grubs, white, see White grubs.  
*Gryllus domesticus*, see Cricket, house.  
 Guamá leaf miner, P.R.Col. 651.  
 Guavas, studies, P.R.Col. 625.  
*Guignardia*, new taxonomy, 40.  
 Guinea pigs—  
 coat color, study of genic effect on, 180.  
 hair and skin color in, physiological genetics, 180.  
 internal organ differences in, inheritance, 180.  
 lactation, role of hormones of adrenal cortex in, Mo. 182.  
 oestrous cycle of, 757.  
 pigment production in, 329.  
 reproductive system in male, postnatal development, and relation to testis hormone secretion, 478.  
 vaccination against *Brucella melitensis*, 822.  
 Gull, Franklin's—  
 feeding habits, N.Dak. 515.  
 fluke in, 363.  
 Gully control structures, behavior of models of, 403.  
*Gymnosporangium juniperi-virginianae*, varietal susceptibility of apples to, 646.  
 Gypsy moth—  
 as it approaches the barrier zone, 218.  
 control, Conn.[New Haven] 651.  
 control and extermination, value to uninfested States, 657.  
 in Nanking, 519.  
 insecticides and spreaders for, 367.  
 notes, N.H. 796.  
 studies, Mass. 796, Me. 363, U.S.D.A. 84.  
*Haemaphysalis cerealellae* in grain moth breeding rooms, combating, 658.  
 Haddock muscle, progressive decomposition, Mass. 735.  
*Haemaphysalis leporis-palustris*, see Rabbit tick.  
*Haemonchus contortus*—  
 efficacy of nonconditioned phenothiazine against, 543.  
 in sheep, anthelmintics for, 678.  
 resistance to various medicaments, 682.  
 Hailstorm of August 4, notes, Conn.[New Haven] 446.  
 Hair, anti-gray, vitamin, 667.  
 Hair pigmentation, loss of in rats, vitamin B complex factor concerned in, 567.  
 Hairy root, noninfectious, 355.

- Halisdota caryae*, see Tussock moth, Hickory.
- Hamadryas antiopa*, see Mourning-cloak butterfly.
- Hanseniella agilis*, embryology and affinities, 523.
- Haplostegus epimelas*, notes, 228.
- Haptoglossa heterospora* n.g. and n.sp., description, 649.
- Hares, snowshoe, population cycle on Lake Alexander, 791.
- Harlequin bug, studies, Hawaii 517.
- Harmolita*—  
*grandis*, see Wheat strawworm.  
*tritici*, see Wheat jointworm.
- Hasstilesia tricolor* parasite of cottontail rabbit, 791.
- Hatchery industry, commercial, in United States, 387.
- Hawaii Station, report, 574.
- Hawks—  
in the hand, treatise, 514.  
sparrow, food habits in Utah, 652.
- Hawthorn and cherry leaf miner, N.J. 651.
- Hay—see also *specific kinds*.  
average yields per acre in Ohio, Ohio 257.  
better, from improved curing methods, Miss. 48.  
chopping for cattle, Wis. 382.  
corn and wheat in rotation, residual effects of limestone, Ky. 479.  
crop response in a 3-year fertilized rotation, N.H. 760.
- crops—  
annual, variety tests, N.Mex. 48.  
annual, yields of varietal leaders, N.Mex. 760.  
cultural and fertilizer practices on peat land, Wis. 333.  
of Upper Peninsula, improvement, Mich. 484.  
ripening, Miss. 759.  
silage from, 381.  
spring-sown, combination for, N.J. 617.
- dehydrated and sun-cured, Pa. 831.  
drying systems for small farms, 391.  
first-, second-, and third-cutting, comparative values for steers, Nev. 529  
moisture determination in, Ohio 535.  
naturally cured v. artificially dried grass, Del. 95.  
requirements on dairy farms, area in meadows for, Ohio 480.  
seeding mixtures, tests, Mass. 759.  
shed drying by forced draft, West.Wash. 186.  
stack curing with chimney ventilation, West.Wash. 186.
- Hazelnuts, vitamins A and B<sub>1</sub> in, 707.
- Health and climate, quantitative physical data useful in, 739.
- Heat—see also Temperature.
- Hegari in lamb fattening rations, amount of cottonseed meal necessary to supplement, N.Mex. 95.
- Heifers—see also Cows.  
dairy, dried beet pulp v. sunflower silage as supplement to native hay for, Wyo. 535.  
dairy, factors responsible for delayed conception and sterility in, Ky. 535.  
dairy, growth rate on sole roughage ration, N.J. 676.  
dairy, urea as protein supplement replacement for, 382.  
effect of phosphorus and protein deficiency on ovulation, oestrous and reproduction, 675.  
growth rate on different rations, U.S.D.A. 676.  
twin-born with bulls, early recognition of freemartin condition in, 608.
- Helianthus* test, indicator of growth stimulation, 173.
- Heliothis*—  
*obsoleta*, see Bollworm, Corn earworm, and Tomato fruitworm.  
*virescens*, see Tobacco budworm.
- Heliothrips*—  
*fasciatus*, see Bean thrips.  
*haemorrhoidalis*, see Greenhouse thrips.
- Hellula undalis*, see Cabbage webworm.
- Helminth parasites—  
and parasitic diseases of sheep in Canada, 248.  
in lambs on Scottish border farm, 397.  
of Australia, bibliography of, 395.  
of ducks, host-parasite catalogue, 401.  
of poultry, treatment and control, 254.
- Helminthology—  
human, manual, 218.  
studies, 254.

household, evaluating liquid insecticides against, 520.  
in coffee groves, P.R.Col. 651.  
in their cocoons, method for study, U.S.D.A. 83.  
injurious stages, identification key in Manitoba, 519.  
injurious to crops, *see special crops*.

## Insects—Continued.

interception at port of New York, plant inspections for, 363.  
olfactory responses, 521.  
orchard, *see* Orchard insects and Fruit insects.  
oviposition, temperature coefficients for, 522.  
physiology of, U.S.D.A. 84.  
role in hybridization of lima beans, 489.  
scale, *see* Scale insects.  
soil, identification by burrow characteristics, 217.  
soil-infesting, N.J. 651.  
test methods for recording moribund kill, 793.  
toxicity of nicotine administered internally to, 653.  
undesirable aliens, 85.  
wood-boring, detection by X-rays, 795.

## Insemination, artificial—

conference on, 178.  
cooperative, of dairy cows, lessons from 178.  
electrical method of ejaculation in foxes for, Wis. 42.  
methods, 184.  
of dairy cattle, S.C. 535.  
of dairy cows, efficiency, 178.  
results from, Mich. 479.

## Insulation—

fill-type, moisture accumulation in, relation to wall construction, Iowa 550.  
not always what it seems, 793.

## Intersexuality, experimental, 46, 477.

## Intestinal protozoan parasitism, reciprocal effect of avitaminosis A and C, 425.

## Iodine—

and peroxide number in milk, relation to oxidized flavor, 816.  
content of Texas soils, 450.  
feeding, increased, effect on a dairy herd, 239.  
in animal nutrition, 669.  
in city waters and vegetables in Texas, 275.  
in iodized salt, stabilizing, Wis. 126.  
in ration with reference to coli:acidophilus ratio in stools of rats, Mass. 843.  
in soils, plant material, and waters, estimation, 300.

## Iodine-starch complexes, absorption spectra, Iowa 6.

## Ion equivalent, fundamental minimum lethal, 456.

## Ions, surface migration and contact exchange, 6.

## Iowa Station, report, 143.

## Iron—

and manganese concretions in Dayton soils, 451.  
availability in certain foods affected by freezing, Mass. 843.  
availability in dried peas and beans, 274.

- Iron—Continued.  
 determinations, colorimetric, use of hydrogen peroxide as oxidizing agent, 436.  
 effect on blood-forming organs of anemic animals, Hawaii 562.  
 excretion by gastrointestinal tract of dog, 414.  
 in human organs at various ages, 562.  
 in milk, effect of supplemental iron in dairy ration, Mass. 813.  
 in vegetables, Fla. 699.  
 metabolism in infancy, 705.  
 total and available, in vegetable foods, 704.
- Irrigation—  
 and drainage research, Utah 548.  
 cost in 1939 of pumping water for, Nebr. 835.  
 costs, calculation, short cut in, Colo. 863.  
 experiments, *see special crops*.  
 practice, evaporation-index meter for use in, Ohio 20.  
 quantity of water used, time and methods, Wash. 256.  
 sprinkler, in humid sections of Oregon, 114.  
 system, small, Wis. 114.  
 water, duty of, N.Mex. 114.  
 water, saline, effect on soils, 26.  
 wells for, putting down and developing, U.S.D.A. 548.
- Iseropus*—  
*brunneifrons septentrionalis* n.sp., description, 227.  
*californiensis* n.sp., description, 227.  
 Nearctic species, 227.
- Isovaleric acid, effect on hemoglobin production in anemia, 572.
- Jacks—  
 enrollment in Indiana, Ind. 670.  
 feeding and care, Miss. 97.  
 sperm production, effects of feed on, 178.
- Japanese beetle—  
 adult, control, tests of tergitol 7 penetrant for, 527.  
 and parasites, relation of ants to, 226.  
 as shade tree pest, control, 218.  
 control, U.S.D.A. 84.  
 control in Virginia, 226.  
 control, methyl bromide fumigation for, 526.  
 control, value of traps in, 374.  
 diseases of, N.J. 651.  
 feeding habits of adult, U.S.D.A. 660.  
 grubs, control in lawns and putting greens, Wis. 334.  
 insecticides and spreaders for, 367.  
 larvae populations, effect of introduction of milky diseases, 375.  
 larvae type A milky disease, survival under adverse conditions, 374.  
 larvae, vertical migration, 526.  
 milky disease, relation to control work, 801.
- Japanese beetle—Continued.  
 studies, Conn. [New Haven] 651, Del. 85, Ky. 518.  
 traps, color, relation to effectiveness, 374.  
 traps, inexpensive, 373.
- Jasminums, neglected, 168.
- Jaundice, obstructive—  
 clinical use of 2-methyl-1,4-naphthoquinone in, 284.  
 prothrombin deficiency in, control by vitamin K, 424.  
 prolonged bleeding in, relation to prothrombin deficiency, 285.

  - by nonleguminous plants, radioactive nitrogen in study, 604.
  - from cyanamide and dried blood in soils, Del. 22.
  - symbiotic, respiratory enzyme systems in, 40.

## free extract, from plant-physiological viewpoint, 455.

## free extract of foods and feeding stuffs, symposium on, 231.

## in soils under different treatment, Mo. 159.

## mineralizable, in soils, Hawaii 448.

## of various compounds, retention by soils shown by subsequent plant response, 743.

## sources, effect on pH of soil of cotton plats, S.C. 480.

## storage in children, effect of irradiated milk, 282.

*Nodonota puncticollis*, see Rose leaf beetle.

## Nodule—

- bacteria—see also Legumes, inoculation. and legumes, noneffective associations of, 463.
- new growth factor for cultures of, Wis. 6.

formation, relation to nitrogen-fixing efficiency of *Rhizobium meliloti*, 456.Nodules and roots of bean, soybean, and pea, *Avena* coleoptile assay of ether extracts, 171.*Nolina texana* buds and blooms, poisonous to livestock, Tex. 544.

## Nomenclature—

- biological, philosophy of, 215.
- of cultivated plants, 595.
- problem under present-day conditions, 57.
- stability in, 595.

## North Carolina—

- College, notes, 575.
- State College of Agriculture and Engineering, history, 559.
- Station, notes, 575.

## North Dakota Station, notes, 719.

*Notocelia uddmanniana*, morphology and biology, 222.*Notolophus antiqua badia* and *Hemerocampa pseudotsugata*, attempts to hybridize, 364.

## Nurseries, observational, for herbaceous and woody species, Wash. 160.

## Nursery—

- implement, important, hammer mill as, 632.
- inspection, Conn.[New Haven] 651.
- soils and application of potash fertilizers, base exchange properties, 633.
- stock, broadleaf, damping-off and storage rots, Nebr. 783.
- stock fumigation, Fla. 650.
- stock production, Wash, 160.

## Nut casebearer, Fla. 650.

## Nutrition—see also Diet.

- animal, see Animal nutrition.
- bacterial, 466.
- diseases of, 425.
- human and animal, relation to minerals of wheat, Utah 273.
- human and animal, trace elements in, 129.
- human, vitamin B<sub>6</sub> requirement in, 281.
- level, assessing by carbohydrate tolerance test for vitamin B<sub>1</sub>, 851.
- level of human subjects, assessing by estimation of vitamin B<sub>1</sub> in urine, 851, 852.
- physiological and economic bases, 844.
- plant, see Plant nutrition.
- scientific, seven centuries of, 127.

## Nutritional diseases—

- extent among children and adults, Fla. 699.
- in South, nature of, 859.

## Nuts—

- nicotinic acid in, 713.
- phenological investigations, N.Mex. 57.

## Nuts—Continued.

varieties, Fla. 624.

varieties and propagation, Mo. 189.

*Nygmia phaeorrhoea*, see Brown-tail moth.

*Nymphalis antiopa*, seasonal history on hops, 85.

## Oak—

Alvord, habit, 324.

and hickory stands, defects reducing quality and yield, Iowa, 66.

forest, evergreen, in vicinity of New Orleans, 603.

girdler, Arizona, notes, 662.

root fungus, serious economic problem in citrus groves, 790.

seeds, viability, effect of storage conditions and other treatments, Ark. 65.

trees, dormant buds in, origin and growth, 200.

trees, standing, girdling experiments, 527.

trees, young, importance of soil pore space to, N.Y.State 194.

white, stave bolts, use of cull caliper in scaling, 632.

## Oat—

blast, studies, 504.

crosses, reaction to mixed inoculum of smuts and rusts, 74.

crown rust—

biology and control, Ark. 68.

genetics of resistance to, Ark. 68.

in Illinois, U.S.D.A. 782.

longevity of urediospores, Ark. 639.

diseases and winter injury, Ark. 68.

flour, finely milled, antioxidative action on milk, 101.

grain, effect of clipping or rubbing on weight and viability of seed, 765.

hulls, fraction preventing cannibalistic tendencies in chickens, 534.

leaves, reddening in Oregon, Oreg. 351.

smuts, new races, Wash. 202.

smuts, physiologic races, 206.

smuts, races and resistance to, 351.

stem rust in Illinois, U.S.D.A. 783.

stem rust, physiologic races, crossing and selfing studies, 326.

straw, whole and cut, as bedding material, absorptive capacity, 535.

Oatgrass, tall, processing seed of, U.S.D.A. 618.

## Oats—

average yields per acre in Ohio, Ohio 257.

breeding, Ark. 48, Fla. 616, Ga.Coastal Plain 617, Mo. 185, Nebr. 759, Tenn. 481, Wash. 185.

crop response in a 3-year fertilized rotation, N.H. 760.

culture experiments, Ark. 48, Ga.Coastal Plain 617, Wyo. 481.

effect of preceding corn interplanted with legumes, Ark. 48.

fertilizer experiments, Fla. 616, Ga.Coastal Plain 617.

## Oats—Continued.

forms in chick rations, Nebr. 805.

growing on peat land, Wis. 333.

hybridizing to combine growth for winter pasture, hardiness, and rust and smut resistance, 53.

improvement, Colo. 754.

in poultry rations, S.Dak. 671.

losses from plant diseases, U.S.D.A. 201.

mechanically dehulled, poor germination of, Tenn. 621.

merits as emergency forage crop, N.Dak. 481.

nurseries for winter hardiness studies, West.Wash. 186.

outstanding varieties, N.Dak. 49.

planting tests, Nebr. 760.

seed treatments, Ark. 637.

surface v. furrow drilling, Nebr. 760.

varieties and strains, registration, 53.

varieties recommended, Nebr. 618.

varieties, southern, maintaining identity and pure seed, U.S.D.A. 766.

variety, Huron, new for Michigan, Mich. 53.

variety tests, Ark. 48, Fla. 616, Ga. Coastal Plain 617, Me. 333, Mo. 185,

Nebr. 618, 759, S.C. 480, Tenn. 481, Wash. 185, Wyo. 481.

Vieland, tests, Wis. 333.

winter hardiness, including refrigeration, experiments, Ark. 48.

yield increase and profits from better varieties and fertilizers, Miss. 48.

yield increase by fertilizers, Miss. 48.

yields and other data, Nebr. 618.

yields, effect of seed treatments for smut, Mo. 201.

yields, effect of time of seeding, Wis. 49.

yields of varietal leaders, N.Mex. 760.

*Obeliscoides cuniculi* parasite of cottontail rabbit, 791.

*Ocellaria* studies, 468.

*Oesophagostomum*—

genus, division and creation of new genus, 684.

*radiatum*, efficacy of nonconditioned phenothiazine against, 543.

Oestradiol—

applied locally to penis of rat, effect, 758.

effect of liver and uterus on, 331.

effect on secretion of gonadotropic hormones in parabiotic rats, 330.

Oestriol—

effect of liver and uterus on, 331.

effect on secretion of gonadotropic hormones in parabiotic rats, 331.

Oestrogen—

administration, pituitary mitotic changes after, 331.

and progesterone induction of mating responses in spayed female rat, 331.

and testosterone, tolerance of male and female mice to, 758.

- Oestrogen—Continued.  
 in ovaries and follicles of laying hens, 332.  
 in urine of mares, pregnancy diagnosis by, 613.
- Oestrogens—  
 metabolism of, effect of liver and uterus on, 331.  
 paradoxical effect on sexual development of female rat, 46.
- Oestrone—  
 action on sexual organs of immature male cats, 45.  
 and prolactin interactions, relation to pigeon crop-gland response, 46.  
 applied locally to penis of rat, effect, 758.  
 effect of liver and uterus on, 331.  
 effect on secretion of gonadotropic hormones in parabiotic rats, 331.  
 v. diethylstilboestrol in causing oestrus and inducing sexual receptivity in spayed animals, 45.
- Oestrous cycle—  
 of mares, 179.  
 of rats, inhibition, 613.
- Office of Experiment Stations, notes, 432.
- Ohio State University, notes, 575.
- Ohio Station, report, 574.
- Oidium* mildew of papaya, 358.
- Oil sprays—  
 atomized, effect on truck crops, Wis. 364.  
 chemistry, Wash. 217.  
 effects in Hood River, 795.  
 mineral, selection for insecticides, Wash. 217.  
 studies, Mass. 796.  
 use on coniferous trees for control of scale insects, 516.
- Oils—*see also* Fats and specific oils.  
 lubricating, Mass. 725.  
 mineral, deposits on plant surfaces, determination, 86.  
 mineral, ingestion, effect on animal nutrition, Ariz. 561.  
 nut, refractive index, N.Mex. 126.  
 used in spray program, photosynthetic studies, Wash. 217.
- Oleander witches' broom, *Sphaeropsis*-induced, Fla. 634.
- Olfactometer, construction and use for muscoid flies, 521.
- Olives and olive products, production and trade, 695.
- Olsen, N. A., necrology notes, 576.
- Omorgus mutabilis*, notes, 222.
- Oncideres*—  
*cingulatus*, *see* Twig girdler.  
 spp., notes, 662.
- Onion—  
 downy mildew in New York, U.S.D.A. 782.  
 eelworm rot or bloat due to bulb nematode, 355, 649.  
 fields, winter cover crops for, Mass. 771.
- Onion—Continued.  
 juice, relation to bacterial growth, Mass. 843.  
 maggot, timing experiment leading to control program for, 364.  
 mildew, U.S.D.A. 344.  
 pink-root disease, serious problem, Colo. 787.  
 plasmolysis form in, effect of potassium ion upon it, 460.  
 sets, fertilization, Ill. 336.  
 thrips—  
 control, 368, Mass. 796.  
 on greenhouse carnations, Wash. 217.  
 seasonal history on hops, 85.  
 studies, Fla. 650, U.S.D.A. 84.  
 transmission of yellow-spot virus by, 797.  
 vector of yellow-spot virus and spotted-wilt virus, 205.  
 yellow dwarf, notes, U.S.D.A. 344.
- Onions—  
 breeding, Mass. 771.  
 carbohydrates of edible varieties, effect of storage and processing, Mass. 771.  
 Early Grano, growth and yield, effect of seedling treatments, 59.  
 grown in sand cultures under glass, effects of deficiency of essential elements, 336.  
 produced for seed, diseases of, factors affecting, N.Mex. 69.  
 response to manganese on unproductive peat soils, 773.  
 sets, cost of production and labor used per acre in producing, Mass. 835.  
 studies, P.R.Col. 625.  
 vitamins in, effect of winter storage, Mont. 276.  
 White Grano, growth and yield, effect of irrigation, N.Mex. 57  
 White Grano, selection in, N.Mex. 57.  
 yield, and their shrinkage in storage, Mass. 771.  
 yield on peat soil, effect of cultivation, 773.
- Ophiodothella*, new taxonomy, 40.
- Ophiola*—  
*striatula*, notes, N.J. 651.  
 studies, Mass. 796.

management, Mass. 759.

old, top dressing experiment, N.H. 760.

permanent, comparison of treatments, N.J. 482.

permanent, establishing under various conditions, Fla. 616.

permanent v. rotation for meat production, 380.

rapidity of development, effect of heavy initial fertilizer treatments, S.C. 481.

studies, 381, Ark. 48, Mo. 185, Wyo. 481.

studies on peat and muck soils of Everglades, Fla. 616.

timbered and clear, relative carrying capacity for grazing, Wis. 382.

top dressing experiments, N.H. 761.

treatments, comparison, and palatability tests, N.J. 617.

yield in terms of known feed equivalents, 380.

## Pea—

## aphid—

control, 516.

control by natural enemies and old rotenone dusts, Wis. 364.

control experiments in Oregon, 88.

control in Maryland during 1939, 656.

damage to plant, relation to its physiological age, 523.

derris dusts effective against, Wis. 364.

injury, resistance of adapted and nonadapted red clover to, Ky. 518.

injury to pea vines, 87.

not a factor in spread of potato virus diseases, Me. 364.

## Pea—Continued.

## aphid—continued.

on canning peas, effect of alfalfa plantings, 87, Wash. 217.

predators, resistance to rotenone, Wis. 364.

rate of reproduction on alfalfa plants, 656.

studies, Me. 363, N.J. 651, U.S.D.A. 84.

timing experiment leading to control program for, 364.

cannery refuse, nutritive value and vitamin A activity, West.Wash. 238.

combinations, best annual hay crop, N.Mex. 760.

diseases of Austrian winter field variety, control, U.S.D.A. 786.

diseases, virus, Wash. 202.

insect control, 516.

marsh spot, relation to manganese distribution in seed, 212.

mosaic, three previously undescribed viruses, 645.

near-wilt fungus, site of invasion and mode of advance, 511.

near-wilt, new disease, U.S.D.A. 500.

nodules, ether extracts of, coleoptile assay, 172.

plant, physiological age, effect on recovery from aphid damage, 523.

plants, effects of aphids on, Wis. 364.

plants, injury from horse-drawn dusters, Wis. 364.

proteins, replacement value for those of eggs, Wis. 126.

root rot and foot rot, complex situation and difficulty of control, N.Y.State 788.

root rot of Austrian Winter variety, 782.  
root rot, studies, N.J. 635.

roots, effect of calcium deficiency, 644.

roots, isolated, cultured in vitro, auxin products in, 461.

seed treatment beneficial under some conditions, Wis. 345.

seed treatment to prevent rotting in soil, West.Wash. 202.

seed treatment with red copper oxide, S.C. 488.

vine, red-stemmed, toxicity to cattle, sheep, and goats, 680.

vine silage, effect of feeding on carotene and vitamin A in milk, 815.

weevil control, mechanized dusting equipment for, Idaho 549.

weevil, studies, U.S.D.A. 84.

## Peach—

aphid, black, control, 83.

bacterial leaf spot, Del 68.

bacterial spot in northeast Texas, U.S.D.A. 783.

borer, studies, U.S.D.A. 83.

buds, late winter injury to, Ark. 57.

buds, varietal resistance to cold injury in 1939, S.C. 488.

## Peach—Continued.

- crown gall in the nursery, 356.
- diseases in Massachusetts, U.S.D.A. 500.
- diseases, virus, 510.
- fruits, thinning, Ark. 56.
- gum-spot disease in South Africa, 356.
- insects, studies, 523.
- leaf-casting yellows, graft-transmissible, 213.
- leaf curl—
  - control, 201.
  - in Idaho, U.S.D.A. 783.
  - in Illinois, U.S.D.A. 783.
  - notes, U.S.D.A. 344.
- little disease, control, Del. 68.
- little-leaf, relation to zinc deficiency, Fla. 357.
- mosaic control, U.S.D.A. 67.
- mosaic, survey and eradication in California, 500.
- orchards, effects of soil covers as conservation practices in, 630.
- parasite project, 517.
- pests, Ohio, present status, 518.
- phony disease, control, U.S.D.A. 68.
- phony disease eradication, Ky. 501.
- season of 1939, climatic conditions, relation to production, 338.
- shoots, secondary and lateral, productivity, 61, 493.
- trees from embryos grown in sterile media, growth of, N.J. 628.
- trees, magnesium requirements, Del. 57.
- trees, mounding, following ethylene dichloride emulsion and paradichlorobenzene treatment, 83.
- trees, winter injury in New York, U.S.D.A. 344.
- trees, young, importance of soil pore space to, N.Y.State 194.
- trees, young, pruning, Ark. 56.
- X disease in Northeastern States, 201.
- X disease, summary, 214.
- yellows, causes, dissemination, and control, Del. 68.

## Peaches—

- breeding and distribution, N.J. 628.
- canned clingstone, annual average f. o. b. prices, statistical analysis, Calif. 692.
- dried, on the ranch, fumigation and shade cloth for protection, U.S.D.A. 83.
- Elberta, blooming data, N.J. 628.
- fertilizers for, Ark. 56.
- freestone, harvesting and handling for canning, 630.
- fruit and tree growth, effect of nitrogen fertilizers, 339.
- genetic composition, Mass. 771.
- injury from use of standard spray schedules, Del. 85.
- losses from plant diseases, U.S.D.A. 201.
- maturity studies, Wash. 190.

## Peaches—Continued.

- new, for Western States, U.S.D.A. 196.
- nitrogen fertilization, relation to control of *Bacterium pruni*, 781.
- nutrient-deficiency symptoms in, N.J. 628.
- premature dropping, relation to curculio injury, Del. 57.
- pruning, Iowa 491.
- quality, spray schedules for, Miss. 193.
- saucer fruit shape and other characters, genetic study, 474.
- thinning an essential to quality and yield, Miss. 491.
- trends in South Carolina, 340.
- varieties, Fla. 624, Ga.Coastal Plain 625.
- varieties, catechol tannin content, N.J. 628.
- varieties, testing for resistance to low temperatures, Ky. 488.
- variety tests, S.C. 488, West.Wash. 190.
- Peanut—
  - Cercospora* leaf spots, control, 780, 781.
  - meal, substitution for animal protein in poultry ration, effects, N.C. 389.
- Peanuts—
  - as feed for swine, deficiencies of, Fla. 666.
  - breeding, Fla. 616, Ga.Coastal Plain 617, N.C. 188.
  - culture experiments, Fla. 616, Ga.Coastal Plain 617.
  - deficiencies as feed for swine, 381.
  - dusting for pest control, 519.
  - fertilizer experiments, Fla. 616, Ga. Coastal Plain 617.
  - rotation experiments under Everglades conditions, Fla. 616.
  - runner, hogging off, returns from, Ga. Coastal Plain 666.
  - runner, sulfur dusting on, Fla. 616.
  - variety tests, Ark. 48, Fla. 616, Ga. Coastal Plain 617, N.C. 188.
  - vitamins A and B<sub>1</sub> in, 707.
- Pear—
  - bitter pit and related diseases, Wash. 202.
  - fire blight control, growth restriction as aid, 510.
  - fire blight, report of conference on, 356.
  - fire blight resistance, breeding for, Tenn. 489.
  - psylla, an important pear pest, 795.
  - psylla, discovery in Washington, Wash. 217.
  - psylla survey, 367.
  - rots, studies, Wash. 202.
  - thrips in prune orchards, West.Wash. 217.
  - thrips on prunes, studies, U.S.D.A. 83.
  - trees, dwarfing by quince roots, 196.
  - trees, young, importance of soil pore space to, N.Y.State 194.

## Pears—

Bartlett, respiration and emanation of volatiles from, 61.  
breeding, 59.  
canned Bartlett, annual average f.o.b. prices, statistical analysis, Calif. 840.  
D'Anjou, vitamin C in, Wash. 268.  
losses from plant diseases, U.S.D.A. 201.  
new hardy for Northwest, S.Dak. 774.  
pollination, 194.  
pruning, Iowa 491.  
quality, spray schedules for, Miss. 193.  
varieties, Ga.Coastal Plain 625.  
vitamin C in, 715.

## Peas—

Alaska, protein values for poultry, Wash. 229.  
Austrian Winter—  
breeding for disease resistance, 76.  
placement of dolomite, superphosphate, and basic slag for, 761.  
root rot and associated fungi, 780.  
rotation experiments under Everglades conditions, Fla. 616.  
stem scald and leaf spot of, *Septoria viciae* as cause, 641.  
breeding, West.Wash. 190.  
breeding stocks show resistance to near-wilt, Wis. 345.  
canning, contracts and effects on net returns to farmers, Wis. 117.  
canning, fertilizer requirements, Wis. 336.  
canning, variety tests, Wis. 336.  
cooked in fat, calcium and phosphorus in, 273.  
dried, iron availability in, 274.  
English, failure of pods to fill properly, Fla. 634.  
flat, variety tests, West.Wash. 185.  
freezing, culture on special soils, West. Wash. 190.  
freezing, fertilizers for, West.Wash. 190.  
fresh and frosted, corotene in, 277.  
frozen and canned, relative quantities purchased, Wis. 142.  
frozen, industry, N.Y.State 772.  
frozen-pack, quality, Utah 412, Wash. 268.  
frozen-pack, vitamin C in, factors affecting, Wash. 268.  
grade, determination from raw product, 627.  
losses from plant diseases, U.S.D.A. 201.  
Michigan, production and marketing, Mich. 53.  
quality, reliability of retail prices as guides to, Ohio 116.  
rate of seeding, West.Wash. 190, Wis. 336.  
studies, P.R.Col. 625.  
testing for resistance to aphids, improved method, Wis. 364.  
varieties, yields, relation to disease control treatments, Wyo. 502.

## Peas—Continued.

variety tests, West.Wash. 190, Wyo. 481.  
winter, breeding, Tenn. 481.  
yields of varietal leaders, N.Mex. 760.  
Peasant household, Russian, under Mir and collective farm system, U.S.D.A. 263.  
Peat—  
bogs in British Columbia, paleoecology, 324.  
for soil improvement in Connecticut, Conn.[New Haven] 594.  
Pébrine characteristic symptoms in fall web-worm parasitized by *Nosema bombycis*, 525.  
Pecan—  
diseases, U.S.D.A. 510.  
insect enemies, summary, U.S.D.A. 519.  
leaf scorch studies, 780.  
leaves, photosynthetic activity, effect of foliar conditions, 745.  
nut casebearer in Texas, insecticide tests, 370.  
nut casebearer, studies, U.S.D.A. 83.  
scab and rosette diseases, spraying for, 779, 781.  
trees, effect of size on subsequent growth and yield, 63.  
Pecans—  
fertilizer and cover crop tests with, Fla. 624.  
food storage, growth, and reproduction in, relation to N absorption, Fla. 624.  
fumigation, Fla. 650.  
grafting methods and waxes, U.S.D.A. 496.  
grown under irrigation, composition, N.Mex. 126.  
stigma receptivity and pollen shedding in, 777.  
varieties, Fla. 624, Ga.Coastal Plain 625.  
variety tests, N.Mex. 57.  
yields, factors affecting, 341.  
Pectic enzymes, studies, 296.  
Pectin-methoxylase activity, determination, 296.  
*Pectinophora gossypiella*, see Bollworm, pink.  
*Pediculooides ventricosus*, destruction of an experimental population of bean weevils by, 652.  
*Pediculus humanus corporis*, see Body louse.  
*Peganum harmala*, poisonous in southwest, 396.  
Pellagra—  
prevention by nicotinic acid entering into cozymase, Wis. 126.  
recent research in, public health implications, 859.  
role of nicotinic acid in, 425, 859.  
Penicillium—  
and *Aspergillus* and their nitrate metabolism, classification, 467.  
and *Aspergillus*, relations, 467.  
*carmino-violaceum*, coloring matters of, 464.  
*digitatum*, production of epinasty by emanations from, 510.

- Penicillium*—Continued.  
*expansum* spores, toxicity of chemicals in aqueous solutions to, 636.  
 spp., pigments of, 467.
- Penitentiary, Louisiana State, composition of population, 410.
- Pennsylvania College, notes, 432, 864.  
 Pennsylvania Station, notes, 432, 864.
- Pentatomids attacking tomatoes, control, 368.
- Peonies, studies, Ind. 632.
- Peony—  
 anthracnose and *Cladosporium* stem spot, 359.  
 Lemoine disease and nematodes, 360.  
 scale on azalea, Ala. 519.  
 scale on camellia, Ala. 519.
- Pepper—  
 downy mildew resistance, breeding for, P.R.Col. 625.  
 mosaic, N.J. 635.  
 mosaic disease resistance, breeding for, P.R.Col. 625.  
 stem weevil, Fla. 650.  
 weevil, Fla. 650.
- Peppergrass, perennial, distribution and characteristics, N.Dak. 623.
- Peppers—  
 improvement, Mass. 771.  
 manure experiments with, Ark. 626.  
 yield and quality, effect of cultural practices prior to field setting, Mass. 771.
- Peridermium strobii*, see White pine blister rust.
- Perilla, variety tests, Ga.Coastal Plain 617.
- Perimegatomia vespulae*, new parthenogenetic species, 226.
- Permeability—  
 and porosity, relation, 453.  
 of soil, relation to noncapillary porosity, 162.
- Peromyscus*—  
 ecologic and genetic variability within species, 753.  
 speciation in, 754.
- Peronospora tabacina*—  
 control, 506, Conn.[New Haven] 505.  
 sporangial proliferation in, 70.
- Perosis—see also Chicks, slipped tendon in. in poult, prevention by choline, 813.
- Persimmon—  
*Cephalosporium* wilt, known range, U.S.D.A. 344.  
 oriental, culture, marketing, and uses, U.S.D.A. 630.  
 trees, girdling to reduce fruit drop in, 64.
- Pest control, chemistry in, 793.
- Pestalotia* spp. on ornamentals, N.J. 635.
- Petunia, colchicine-induced variations in, 473.
- Pezicula* studies, 468.
- Pezizella lythri* on peony, 359.
- Phaseolus lunatus* and relatives, 168.
- Pheasant, ring-necked—  
 curtailment of egg production due to oviduct fluke, 515.
- Pheasant, ring-necked—Continued.  
 feeding habits in fall and winter, N.Dak. 216.  
 food habits in Minnesota, 791.  
 improved ration for starting, Pa. 813.  
 nesting habits and causes of nest mortality, 515.
- Pheasants—  
 abundance, time and cause, 363.  
 effect of arsenical grasshopper poisons, 655.  
 non-injury from grasshopper baits, Wis. 364.  
 sex invert or intersex, 183.  
 surviving outbreak of equine encephalomyelitis, test with sera of, 819.  
 yield of weed crops and waste grain as food for, Wis. 83.
- Phenothiazine—  
 as anthelmintic for pigs, 250.  
 unconditioned, for removal of intestinal worms of cattle, 543.
- Phenylarsenoxides, antispirochetal action in vitro, 822.
- Philonthus quisquiliarius*, life history, 526.
- Phloem necrosis destructiveness in West Virginia, U.S.D.A. 783.
- Phlox—  
 irregular flowers in, 341.  
 powdery mildew, Mass. 783.
- Phoma*—  
*betae*, behavior in presence of boron, 641.  
*terrestris*, notes, Colo. 787.
- Phomopsis*—  
 canker and bacterial leaf spot of gardenias, N.J. 635.  
*gardeniae*, notes, 359.  
*vaccinii*, development of perfect stage, 357.
- Phormia regina*—  
 response to stimulations of tarsal chemoreceptors, 224  
 studies, U.S.D.A. 84.
- Phorodon humuli*, see Hop aphid.
- Phosphatase values of butter, factors affecting, 673.
- Phosphatases, bacterial, 467.
- Phosphate—  
 colloidal, scant increases shown in tests of, Miss. 185.  
 migration of, Tenn. 448.  
 wastepond, Fla. 616.
- Phosphates—  
 availability, studies, Ky. 455.  
 comparison, West.Wash. 160.  
 effect on crops, Mont. 167.  
 organic and inorganic, ability to penetrate soils, Nev. 448.
- Phospholipoids, extraction from soybean oil meal, Del. 6.
- Phosphorus—  
 absorption by corn seedlings, radioactive isotope study, 174.  
 absorption by wheat, effect of lime and phosphorus applications, 173.

## Phosphorus—Continued.

- and calcium, metabolism, 562.
- assimilation by mixed soil population and by pure cultures of soil fungi, 28.
- balance in preschool children, 273.
- deficiency, effect in ration of beef heifers, Wyo. 530.
- deficient rations, effect on ovulation, oestrus, and reproduction in dairy heifers, 675.
- in phytic acid, availability, effect of calcium in diet, Wis. 126.
- in southern soils, effect on crop yields, 30.
- in vegetables cooked in fat, 273.
- inorganic, in blood of young colts, 810.
- inorganic, in dogs, variations with age, 699.
- metabolic behavior, 704.
- metabolism in normal and rachitic chickens, 386.
- organic, in soils, nature of, Hawaii 448.
- oxidation to pentavalent form by carbon dioxide, 7.
- radioactive, in soils, Hawaii 448.
- soil organic, nature of, 455.
- soil, solubility, Nebr. 741.
- total and phytic acid in foods, 426.
- transformation during decomposition of plant materials, 313.
- uptake by crops, effect of liming, Ky. 455.

Photomicrographic prints in color, technic for making, Tex. 863.

Photomicrography, color, technic for, 456.

## Photoperiodic induction—

- interrelation of light and darkness in, 175.
- relation to photoperiodic inhibition, Mo. 189.

## Photoperiodism—

- and enzyme activity, Mo. 189.
- in plant kingdom, 603.

## Photosynthesis—

- bacterial, and oxygen, 467.
- capacity for, relation to quantity of chlorophyll, 317.
- in plants, mechanism, 602.
- light-mass absorption during, 317.
- mechanism of, effect of light intensity on development, 317.
- of *Chlorella*, rate, effect of magnesium deficiency, chlorophyll concentration, and heat treatments, 175.

Phthiocol, antihemorrhagic activity, 14, 15.

*Phthirus pubis*, see Crab louse.

## Phycomyces—

- blakesleeanus*, growth test for vitamin B<sub>1</sub> in blood, 280.
- gametic reproduction by and growth substances, 461.
- metabolism of vitamin B<sub>1</sub> by, 468.

*Phyllocoptes oleivorus*, see Citrus rust mite.

*Phyllophaga*—

- crinita*, life history, 660.
- ephillida*, life cycle, Ky. 518.
- lanceolata*, life history, 660.

*Phyllophaga*—Continued.

- of Texas, 800.
- pleroma*, name proposed for *P. plena*, 800.
- renodis*, notes, 800.
- sodalis* n.sp., description, 800.
- sp., notes, 516.
- spp. of Kentucky, biology and control, Ky. 800.

## Phylloquinone—

- $\alpha$ -, blue alkali salt of, 734.
- $\alpha$ -, isolation and history of its discovery, 733.
- nor- $\alpha$ -, and related compounds, 735.

*Phyllosticta nyssae*, notes, 648.

*Phymatotrichum*—*omnivorum*—

- cotton resistance to, tests, 780.
- growth response to inorganic nitrogens, 779, 781.
- infection of cotton seedlings in greenhouse by, 779.
- pathogenic action, 352, 780, 781.
- survival on cotton roots, effect of girdling and topping plants, 780, 781.

## root rot—

- chemistry of resistance of plants to, 203, 502.
- experimental, of retama and corn, 502.
- fungus, distribution and condition of Sclerotia in manured and unmanured soils, 781.
- relation of age of cotton plants to susceptibility to field inoculations with, 780.

*Physalis angulata* virus diseases, 784.

*Physoderma* species, relation to disease in flowering plants, 346.

Phytin, isolation from soil, 452.

*Phytomonas*—

- lespedezae* n.sp., notes, U.S.D.A. 76.
- sepedonica*, control, U.S.D.A. 786.
- sepedonica* distribution in different parts of potato plant, significance, 352.

*stewartii*—

- and *Erwinia tracheiphila*, wilt induction by, comparison, 787.
- bacteriophage lytic to, data, 645.
- mutation in, Iowa 68.
- production and rate of mutation in by X-radiation, 471.
- sectoring in colonies, 69.
- strains, invasion of sweet corn plants of different ages by, 75.

*tumefaciens*, notes, 356.

*Phytophaga destructor*, see Hessian fly.

*Phytophthora*—*cactorum*—

- bleeding canker on Norway maple, 360.
- cause of sweetclover root rot, 641.
- notes, U.S.D.A. 201.
- on maple, 513.

*cambivora* canker on Norway maple, 360.

*Phytophthora*—Continued.

- capsici*, causing rot of Winter Queen watermelon, 512.
- infestans*—see also Potato blight, late origin, 70.
- role of peroxidase in immunity against, 507.

## Pickles—

- and related products, use of lactic acid in, Mich. 16.
- dill, prevention of softening, Wis. 6.
- processing and finishing, Mich. 17.

## Pickleworm—

- control, S.C. 519.
- notes, Fla. 650.

## Pigeon crop-gland response to prolactin, sex difference in, 46.

## Pigeons—

- effect of restricting cereal diet to corn and wheat, 388.
- hyphysectomy of, technic, 332.
- parasites of, P.R.Col. 677.
- somatic mosaics in, 475.

## Pigment, bacterial, new type, 467.

## Pigment production in guinea pigs, 329.

## Pigmentation of frozen rabbits' skin, 475.

## Pigs—see also Sows and Swine.

- bacon, nutrition of, 810.
- blood studies, 682.
- coconut oil meal for, desirability of limiting, Ohio 529.
- cod-liver oil toxicity of, 810.
- composition of blood, 105.
- cross-breeding tests, Ohio 529.
- experimental liver damage associated with hematologic changes, 682.

## fattening—

- and growing, protein and vitamin supplements for, [N.Y.]Cornell 809.
- economy of gain, factors, affecting, S.C. 529.
- grazing crops for, Fla. 666.
- hybrid v. open-pollinated corn for, Nebr. 805.
- on corn and tankage, alfalfa pasture v. dry lot for, Wyo. 530.
- on rye pasture, protein supplements for, S.C. 529.
- protein supplements for, comparison, Del. 95.

## finishing, corn and tankage for, Miss. 666.

## group feeding experiments, 381.

## hard liver disease in, Wash. 242.

## hybrid and open-pollinated corn for, Ohio 96.

## in dry lot and on Sudan grass pasture, sorghum grains v. corn for, Nebr. 805.

## iron-treated cottonseed meal as partial source of protein for, Ohio 529.

## litters farrowed by months, and pigs saved per litter, Wis. 117.

## mineral requirements, 381, Wis. 382.

## morphologic changes in blood associated with vitamin deficiency, 96.

## Pigs—Continued.

## myocardial lesions from dietary deficiency, 823.

## of different weights, percentage of protein in ration for growing and fattening, 381.

## on pasture, value of concentrate supplements for, Mo. 229.

## on rations containing low protein tankage, meeting protein requirements, 667.

## on Sudan grass pasture, protein supplements for, Nebr. 805.

## parasites of, P.R.Col. 677.

## prices, differences in several markets, Mo. 257.

## prices, differences in spread, Wis. 117.

## purebred and crossbred, comparative performance, Mo. 229, Nev. 529, 809, S.C. 529.

## selling by carcass weight and grade, problems of, Iowa 120.

## shipping costs, Nebr. 835.

## streamlined, new legless mutation, 609.

## transmissible diseases, 678.

## type of leg weakness induced by nerve degeneration, relation to diet, 382.

## types, factual basis for changing, 381.

## unbred gilts, low agglutination reactions in, Mo. 242.

## weanling—

- comparison of protein concentrates as supplements to corn, Mo. 229.
- nutritional requirements, 381.
- protein requirements, 381, 384.
- vitamin requirements, 381.
- wheat shorts for, Miss. 529.
- young, protein requirements, 381.
- young, value of sugar beet molasses in ration, Utah 385.

## Pigweeds and relatives in North Dakota, N.Dak. 488.

## Pimelic acid as substitute for yeast filtrate factor, 711.

## Pimiento plant, chlorophyll deficient, description, 627.

## Pine—see also White pine.

## beetle—

- mountain, destructive infestation in lodgepole pine stands, 526.
- mountain, studies, U.S.D.A. 84.
- southern, factors in natural control, 662.

western, control, *Thanasimus lecontei* as factor in, 801.

## western, studies, U.S.D.A. 84.

## beetles in Great Britain, ecology and control, 226.

## blister rust, see White pine blister rust.

## brown tail moth, biology and control, 222.

cankers, *Atropellis* species from, 647.

## jack, crowns, lateral growth of, 499.

## jack, successful direct seeding on shallow-water-table areas, 499.

## loblolly, root and shoot growth, relation to environment, 343.

## Pine—Continued.

- lodgepole, destructive infestation by mountain pine beetle, 526.
- longleaf, direct seeding as practical method of reforestation, 342.
- nursery, seedlings, raising, 632.
- plantation, bark beetle damage to, Conn. [New Haven] 652.
- plantations on bottom lands, management, Ark. 65.
- ponderosa—
  - damage by logging and slash disposal, 343.
  - growth and mortality, relation to site of trees and cutting method, 633.
  - index of seed maturity, significance and applicability, 199.
  - longevity, 499.
  - racial strains, 65.
- sapwood substitution for malt agar in culturing test fungi, 69.
- Scotch, size of cones, relation to seed size and yield, 199.
- seedlings, effect of nutrient deficiencies, 746.
- shoot moth, European, notes, 218.
- shortleaf, root and shoot growth, relation to environment, 343.
- Sphaeropsis* dieback and needle blights, 215.
- twig blight, types affected by, Wis. 344.
- Virginia, witches'-broom on, 215.
- white and Scotch, survival of planted trees, N.H. 779.

## Pineapple—

- bran, use in swine rations, Hawaii 528.
- diseases, P.R.Col. 635.
- plants, uncombined hexosamine in, distribution, 584.
- sister shoots, exposed and covered, distribution of nitrogenous and carbohydrate fractions in, 322.
- yellow-spot virus and spotted-wilt virus, identity, 205, 213.
- yellow-spot virus on tomatoes, 205, 213
- Hawaii 501.

## Pineapples, studies, P.R.Col. 625.

Pingue on grazed and protected areas, rate of increase or decrease, N.Mex. 95.

Piñon nuts, grown under irrigation, composition, N.Mex. 126.

Pinworm in poultry, life cycle, Hawaii 518.

*Piophilica cascii*, see Cheese skipper.

## Pituitaries—

- from cows in different stages of pregnancy, gonadotropic activity, 179.
- of chicks, signet-ring cells in, 614.

## Pituitary—

- anterior—
  - changes in vitamin A-deficient rats, Ohio 184.
  - experimental studies, 757.
  - gland hormones of cattle, effects in guinea pig of formalin treatment, 477.

## Pituitary—Continued.

- anterior—continued.
  - hormone for treatment of ketosis in cows, 543.
  - mammary growth hormone of, 179.
  - mamrogenic lobule-alveolar factor of, 608.
- extract-treated sheep, progonadotropic sera of, 45.
- gland hormones, relation to milk secretion, Nebr. 814.
- glands of cattle, assay for gonadotropic hormones, Wis. 42.
- gonadotropic activity of, action of progesterone on, 613.
- hormone, specific activity, essentiality of primary amino groups for, 184.
- lactogenic hormone—
  - action of ketene on, 10.
  - electrophoretic study, 184.
  - inactivation by iodine, 758.
- substance of sheep, gonadotropic principles in, 45.
- Plagioderma metallica*, injury to Governor plum in Philippines, 526.
- Plagiorchis potanini* in Franklin's gull, 363.
- Plague, active immunization against, 823.
- Planetree—
  - blight, London, due to *Ceratostomella* sp., 513.
  - disease, new locations for, U.S.D.A. 500.
  - serious disease threatening, 790.

## Plant—

- acids, biochemical formation from hexoses, 467.
- biology applied to agriculture, 636.
- breeding—see also *Heredity and specific plants*.
  - programs, quick testing of nematode resistance in, 782.
  - studies, Colo. 754.
- cell membranes, microscopic structure, relation to micellar hypothesis, 35.
- cell wall structure revealed by infrared photomicrography, 466.
- cell walls, structure and delignified and cellulosan-free cellulose examination, 466.
- cells, Golgi material in, 37.
- cells, mature, division induced by wounding, 456.
- cells, turgor pressure in, determination, 35.
- cells, vacuolate, cytoplasmic behavior during division, 606.
- chromosomes, see Chromosomes.
- composition, effect of fertilizers and soil type, Wash. 160.
- cuttings, adventitious shoots and roots induced by natural influences and synthetic growth substances, 750.
- cuttings, effect of mixtures of root-inducing and other substances on, 750.
- cuttings, rooting, value of root-inducing substances in, Fla. 624.
- disease survey, Iowa 69, Wash. 202.

## Plant—Continued.

- diseases—*see also* Fungi and different host plants.  
 and pests, control, 218, 360, Can. 336.  
 British, common names, emendations to second edition, 785.  
 check list revision, U.S.D.A. 201, 500, 635, 636, 783.  
 crop losses from in United States, U.S.D.A. 201.  
 etiology and pathogenesis, 346.  
 fungus, distribution in Caribbean region, 347.  
 in Kiangsu Province, 69.  
 insect transmission, 516.  
 miscellaneous, identification, Mo. 202.  
 notes, U.S.D.A. 635, 636.  
 of ornamentals, 218, 360, Fla. 635, N.J. 635, U.S.D.A. 500.  
 on specimens received, laboratory diagnoses and summary of causes, 500.  
 parasitic, morbid anatomy and causes, 636.  
 virus, chemical studies, Mo. 202.  
 virus, in eastern Asia, host index, U.S.D.A. 347.  
 virus, in Saratov region, 784.  
 virus, in Volga district and organization of virological work, 784.  
 virus, microcage for entomovirological experiments, 784.  
 virus transmission by patch grafting or contact, 346.
- fibers, phloem, fine structure of, 170.  
 food developments, 30.  
 foods, extra, no need for. Ohio 448.  
 growth, abnormal, relation to vitamins, hormones, and irradiations, 346.  
 growth and aeration in wet soils, 316.  
 growth and break-down of inorganic soil colloids, 165.  
 growth, effect of—  
 aeration on, N.J. 597.  
 alkali salts, 37.  
 arsenious oxide, arsenic oxide, and antimony oxide, Mass. 740.  
 boron and indoleacetic acid on, interrelations, 172.  
 chloropicrin in soil solution, 173.  
 cryolite, S.C. 518.  
 growth factors, 36, 455.  
 minor elements on, N.J. 592.  
 oxidation-reduction potential, 24.  
 Zn and other unusual mineral supplements, Fla. 625.
- growth-factor-oxidizing substance in *Phaseolus* seedlings, thermolabile, 597.  
 growth regions of United States, map and check list revision, U.S.D.A. 636.  
 growth, relation to minute amounts of chemical elements, 450, 456, 599.  
 growth, response to addition of vitamin B<sub>1</sub>, 462.

## Plant—Continued.

- growth responses induced by naphthalene acetamide and naphthalene acetic acid, comparison, 461.  
 growth substances—  
 adventitious shoots and roots induced by, 750.  
 effect on development of cuttings of red clover and alfalfa, 172.  
 mixtures of, effect, 750.  
 new interpretation of significance for life-processes, 597.  
 physiologically active, and responses of plants to, 455.  
 relation to crown gall, 346.  
 relation to mechanism of action of radiation on plants, 461.  
 review, 460.  
 survey, 467.
- growth, vitamin B<sub>1</sub> as regulating substance, N.J. 597.  
 hormones, *see* Plant growth substances.  
 identification service, N.Dak. 287.  
 injuries by lime-sulfur sprays, N.H. 783.  
 insects, control by poison supplied through roots, Ohio 518.  
 inspections for insect interception at port of New York, 363.  
 introductions, recording, Hawaii 488.  
 leaves and stems, attacked by root knot nematode, 780, 782.  
 material, extraction of hemicelluloses from, 10.  
 material introduced for testing, U.S.D.A. 324, 594.  
 material, iodine determination in, 300.  
 microtechnic, treatise, 464.  
 nutrients, leaching through soil, effect of cropping systems, Wash. 160.  
 nutrition, physiological phases, Fla. 634.  
 organs, inherited size differences in, developmental basis, 753.  
 pathogens in eastern Asia, host index, U.S.D.A. 347.  
 pathogens, seed-borne, laboratory techniques for detecting, Iowa 68.  
 pathogens, wind dissemination, 345.  
 physiology, elements of, treatise, 597.  
 pigments, seasonal variations in production, 317.  
 pigments, studies, 745.  
 products, quarantined, methyl bromide for treatment, U.S.D.A. 216.  
 root diseases, losses to world agriculture through, 69.  
 sections, use of translongitome in making and interpreting, 32.  
 succession in central Iowa, secondary, early weed stage, 745.  
 taxonomy, ecological aspects, 595.  
 taxonomy, experimental and synthetic, 595.  
 tissue reactions, 346.  
 tissues, alcohol production and use by, 37.

## Plant—Continued.

- tissues, parasitized, staining vacuolar system of living mycelia in, 346.
- tissues, storage, absorption of potassium salts by, 748.
- tumors, colchicine in inhibition and death of, 346.
- tumors, killing by colchicine, cytological basis, 502.
- virus inhibitors, 345.
- virus inoculations, carborundum powder used in, 72.
- virus preparations, size and structure, X-ray evidence on, 345.
- viruses—
  - classification, 784.
  - insect relations and comparison with animal viruses, 784.
  - insect transmission of, manner, 345.
  - purified preparations, properties, 345, 346.
  - thermal inactivation rates, 347.
  - transmission by insects, 784.
- world, adaptation and origin in, 32.

*Plantago lanceolata* leaf galls, structure, 69.

## Plantain—

- diseases, P.R.Col. 635.
- studies, P.R.Col. 625.

## Plants—see also Flora and Vegetation.

- absorption of minerals, relation to lignin, Mass. 725.
- aluminum in, 599.
- and animals, defense mechanisms in, symposium, 346.
- and fungi, symbiosis, selective action in, 346.
- and minerals in soil and health of domestic animals, relation, Wyo. 511.
- at low temperatures, decreased water absorption by, cause, 316.
- at temperatures above freezing point, cold injuries to, 600.
- availability of fixed potassium to, 313.
- British, chromosome numbers in, 606.
- bulbous ornamental, dividing and planting, Miss. 779.
- calciphile and calciphobe, relative intake of elements on soils at varying pH, Mass. 740.
- calcium content, relation to boron concentration of nutrient substrate, N.J. 597.
- chromosome alterations in and atypical growths, 346.
- cold resistance in, bibliography, 600.
- cultivated, new systematics, 596.
- cultivated, nomenclature, 595.
- cultivated, origin and behavior, 596.
- culture, construction and operation of gravel experimental plats, Ohio 198.
- culture in hormonal media during whole life cycle, 595.
- culture, use of chemical stimulants, hormones, and vitamins in, 460.
- cyclic aging and rejuvenation in ontogenesis, theory, 468.

## Plants—Continued.

- dangerous because of hydrocyanic acid, Wyo. 541.
- desert, see Desert.
- economic, recent investigations, 595.
- effects of carcinogenic substances on, 502.
- experimental, photography, 32.
- flowering—
  - distribution of self-sterility in, 595.
  - effect of deficiency of minor elements, Ohio 488.
  - growth, effect of type of container, Mass. 771.
  - in greenhouse, deficiency symptoms, Ohio 37.
  - of, possible relation to plant hormones, 455.
  - of Saline County, Kansas, 168.
  - time, 316.
- food, absorption of chemical elements important in human nutrition, Mass. 740.
- foundation stock, seed increase, Wash. 160.
- glasshouse, diseases, Wash. 202.
- growing, fluorescent lamps as source of light for, 176.
- growing in water culture, seedling support for, N.H. 32.
- growing without soil by solution culture methods, papers, 173.
- honey and pollen, of United States, U.S.D.A. 227.
- inorganic metabolism in, 745.
- insecticidal, chemical investigations, U.S.D.A. 84.
- intake of elements applied to soil in pairs and singly, Mass. 740.
- isolation for virological experiments, 784.
- magnesium requirements of, Mass. 740.
- mechanism of action of radiation on, relation to growth substances, 461.
- mitochondria in, 171.
- new to Iowa, 745.
- observational field plantings, Wash. 160.
- of Arizona, new species, varieties, and combinations, 596.
- of Iowa, catalogue, supplement, 596.
- of Kansas, annotated list, Kans. 596.
- of New Mexico, 597.
- of sand mounds of Iowa, preliminary list, 745.
- of Texas, Tex. 863.
- oil-producing, important pests of, biology and control, 218.
- oil-producing, virus diseases of, 784.
- organic acids of, 745.
- ornamental—
  - culture experiments, Can. 336.
  - cuttings, synthetic growth substances for rooting, Ohio 488.
  - damping-off of, Mass. 783.
  - for landscape uses, culture experiments and variety tests, Ark. 57.
  - fungicides for, 360.

## Plants—Continued.

- ornamental—continued.  
 imported, testing, Tenn. 489.  
 perennial, adaptation to eastern Washington, Wash. 190.  
 powdery mildew of, U.S.D.A. 360.  
 propagation, Can. 336.  
 varietal and propagation tests, Fla. 624.  
 phosphate availability to, Nev. 448.  
 photosynthesis, *see* Photosynthesis.  
 poisonous—*see also* Livestock poisoning and *specific plants*.  
 of India, 396.  
 range, Nev. 540.  
 studies, Wyo. 541.  
 to livestock in Florida, Fla. 677.  
 to man and farm animals, descriptions and drawings, 396.  
 respiration, *see* Respiration.  
 response to carcinogenic agents and growth substances, 70, 346.  
 role of potassium in, 598.  
 seed, modifications induced by growth substances, 468.  
 translocation in, 599.  
 transpiration, *see* Transpiration.  
 transverse reactions of, treatise, 597.  
 twining, klinostat studies in, 318.  
 types, nature of cold resistance, Nebr. 740.  
 upward movement of salt in, 456.  
 vegetative growth, relation to photoperiod, 318.  
 vegetative reproduction in by treatments with hormones and heteroauxin, 497.  
 virus infected, intranuclear inclusions in, 205.  
 wild, transplanting experiments, 457.  
 woody, *see* Woody.
- Plasmiodiophora brassicae*, *see* Cabbage clubroot.  
 Plasmodiophorales, zoosporengia and zoospores of, 468.  
 Plasmodium—  
*knowlesi*, action of immune serum in vitro, 821.  
*praecox*, development, 821.  
 Plasters for rammed earth walls, S.Dak. 589.  
*Platynota flavedana* on roses, control, 369.  
*Platyptilia carduidactyla*, *see* Artichoke plume moth.  
*Plodia interpunctella*, *see* Indian-meal moth.  
 Plowing as aid in soil and water conservation, Ark. 22.  
 Plum—  
 curculio—  
 in apples, control, Mass. 796.  
 life history and habits, in Georgia peach belt, 662.  
 on peach in Illinois, control, 662.  
 studies, Tenn. 519, U.S.D.A. 83.  
 sawfly control, 527.  
 trees, young, importance of soil pore space to, N.Y.State 194.

## Plums—

- breeding, 59.  
 cool storage, 494.  
 grown under hillculture conditions, response to modifications in cultural treatment, 196.  
 Hungarian, chemical composition of important varieties, 561.  
 hybrid, cross-pollination requirements, Wis. 336.  
 new hardy for Northwest, S.Dak. 774.  
 pollination, 194.  
 pollination on Vancouver Island, 340.  
 pruning, Iowa 491.  
 quality, spray schedules for, Miss. 193.  
 variety, new, for Western States, U.S.D.A. 196.  
 vitamin C in, 715.  
*Plutella maculipennis*, *see* Diamondback moth.  
 Pneumoenteritis of dairy calves, Fla. 677, 680.  
 Pneumonia—  
 contagious hog, etiology, 397.  
 contagious hog, virus, histological alterations of lungs produced by, 398.  
 in foals, serological classification of etiologic agent, 251.  
*Pneumonyssus caninum* n.sp. from frontal sinus of dog, 252.  
*Poa ampla* for erosion control, Wash. 160.  
*Poa* cross, uniform drought- and heat-resistant F<sub>2</sub> of, Mo. 185.  
*Poa* new species, 597.  
*Podisus maculiventris*, *see* Soldier bug, spined.  
*Poecilomyces* sp. extracts, vitamin C in, 598.  
 Poinsettia blossoms, nectar secretion in, 379.  
 Poisonous plants, *see* Livestock poisoning, Plants, poisonous, and *specific plants*.  
*Polia atlantica*, studies, Mass. 796.  
 Pollomyelitis—  
 experimental, vitamin C therapy in, 139.  
 virus, Lansing strain, transfer from cotton rat to white mouse, 107.  
*Polistes fuscatus rubiginosus*, notes, 799.  
 Pollen—  
 and pollen substitutes, comparative value for bees, 378.  
 substitutes, possibilities of, 516.  
 tube technic, use of acenaphthene in, 464.  
 Polyarthritis of swine, and experimental *Erysipelothrix* infection, 633.  
*Polychrosis viteana*, *see* Grape berry moth.  
 Polycythemia, studies, 243.  
 Polydactyly in an inbred strain of mice, 327.  
*Polymedon castus*, description, 799.  
 Polyploidy in papaya, induced by colchicine, Hawaii 488.  
 Polypores, resupinate, from region of Great Lakes, 512, 785.  
 Polyporus—  
*anceps*, isolates from widely separated forest regions, 512.  
*ellisianus*, isolates from widely separated forest regions, 512.  
 spp., from region of Great Lakes, 785.

- Ponds, fresh-water, changes in fauna resulting from flooding by sea water, 752.
- Popcorn, variety tests, West.Wash. 185.
- Popillia japonica*, see Japanese beetle.
- Poplar—
- borer, in Parkland regions of Canada, 516.
  - canker and heart rot resistance, selection for, Wis. 344.
- Population—
- migration and natural increase, Ky. 557.
  - of Louisiana State penitentiary, composition, 410.
  - of New York State, natural increase in, [N.Y.]Cornell 840.
  - rural and urban, percentages by census periods from 1880 to 1930, N.Mex. 116.
  - rural, density in southern Appalachians, U.S.D.A. 407.
  - southern, gainful employment for, 405.
  - trends and adjustments in Arkansas, Ark. 123, 557.
- Poria*—
- species new or little known, 324.
  - spp., from region of Great Lakes, 785.
- Pork—
- chops, cooking methods, standardization, Mo. 269.
  - chops, frozen, keeping qualities, factors affecting, 381, Mich. 560.
  - economical, production, Miss. 528.
  - quality and palatability, effect of sorghum grains, Nebr. 805.
- Porphyrins—
- and diseases of the blood, 242.
  - formation by yeast-cells and by enzymes from yeast, 467.
- Porthetria dispar*, see Gypsy moth.
- Portulaca oleracea*, macrosporogenesis and embryology, 604.
- Postharmostomum*—
- commutatatum* in intestine of fowls, morphology, 401.
  - gallinum*, life cycle, 401, Hawaii 518.
- Posts, preservation, Ark. 113.
- Potash—
- as plant nutrient, bibliography, 744.
  - fixation in soils, effects of drying, Ohio 448.
  - in cotton soils, effect, 352.
  - level, replaceable, of soil, Ky. 455.
  - manure as carrier, effectiveness, Ky. 455.
- Potassium—
- deficiency in ammonium- and nitrate-fed tomato plants, 193.
  - determination of small amounts, 726.
  - fixation and release on Coastal Plain soils, 30.
  - fixed, availability to plants, 313.
  - in bentonite clay, availability for tomato growth, N.J. 597.
  - in honey, 411.
  - in plants, role, 174, 598.
- Potassium—Continued.
- in very small amounts of biological materials, spectrochemical analysis for, 437.
  - release from nonreplaceable forms in Illinois soils, 167.
  - salts, absorption by storage plant tissues, 748.
- Potato—
- bacterial ring rot—
    - and wilt, eradication method, 208.
    - in Arkansas, first report, U.S.D.A. 635.
    - in Kansas, U.S.D.A. 782.
    - in North Dakota, U.S.D.A. 201.
    - in Utah, a menacing disease, U.S.D.A. 500, Utah 507.
    - in Virginia, first report, U.S.D.A. 635.
    - in Washington State, U.S.D.A. 68.
    - new problems, Nebr. 783.
    - studies, N.Dak. 77, U.S.D.A. 77.
  - beetle, Colorado—
    - food preferences, 225.
    - studies, U.S.D.A. 84.
    - toxicity of nicotine to, 653.
  - bins, types of air intake for ventilation, N.H. 832.
  - blackleg, dissemination, role of insects in, 77.
  - blackleg, identity of *Bacterium* causing, 353.
  - blight, early, Fla. 634, Hawaii 501.
  - blight, late—
    - notes, U.S.D.A. 782.
    - organism, role of peroxidase in immunity against, 507.
    - relation to copper content of Long Island soils, 353.
    - reports on, U.S.D.A. 783.
    - tuber decay by organism, Me. 344.
  - brown rot, Fla. 634.
  - byproducts research, Me. 302.
  - calico and alfalfa mosaic viruses, relation, 347.
  - discs, metabolic process under conditions conducive to salt accumulation, 320.
  - disease resistant varieties in Maryland, 201.
  - diseases—
    - control, 507, Fla. 634, Wyo. 502.
    - due to *Rhizoctonia*, control, Fla. 634.
    - in Dade County, control, Fla. 635.
    - in Hastings section of Florida, U.S.D.A. 782.
    - in Louisiana, new or unusual, U.S.D.A. 635.
    - in Maine, Me. 344.
    - new and unusual, committee to coordinate research on, report, 352.
    - of seed pieces, 500.
    - studies, N.J. 635, West.Wash. 202.
    - virus, 205, 346, Wash. 202
    - virus, prevalence, Wis. 345.

## Potato—Continued.

- diseases—continued.  
 virus, transmission by insects, Me. 364.  
 flea beetle—  
 biology and control, 652.  
 in Nebraska, Nebr. 662.  
 notes, Conn.[New Haven] 517.  
 foliage, mercury absorption by, Me. 344.  
*Fusarium* dry rot, new problems, Nebr. 783.  
*Fusarium* wilt resistance, breeding and variety tests for, 353, Nebr. 783.  
 insects, dusting and spraying for, N.Mex. 365.  
 leafhopper, control, Ohio 518.  
 leafhopper on citrus, whitewash for control, 87.  
 leafhopper spraying and dusting experiments, 521.  
 mosaic and leaf roll, effect of temperature, soil, and fertilization, N.H. 783.  
 nematode, field experiments, 362.  
 nematodes, 501, Hawaii 501.  
 nematodes, control in Klamath Basin by irrigation, 782.  
 psyllid in Nebraska, Nebr. 662.  
 psyllid yellows, control, Wyo. 501.  
 psyllids and psyllid yellows in Montana, U.S.D.A. 344.  
 ring rot, another check on, Colo. 863.  
 ring rot control, Colo. 209, U.S.D.A. 786.  
 ring rot in Hastings section of Florida, U.S.D.A. 782.  
 ring rot in Wisconsin, Wis. 345.  
 root knot damage, 780.  
 root rots in Montana, U.S.D.A. 344.  
 rugose mosaic and leaf roll, physiology of plants infected with, 784.  
 scab, effect of dry land rotations on, Nebr. 783.  
 scab, effect of sources of nitrogen on, 353.  
 scab resistance, breeding and variety tests for, Nebr. 783.  
 scab resistance, variety tests, Wis. 333.  
 scab, studies, N.J. 635.  
 seed, longevity, 767.  
 sprays and spraying programs, improvement, Wis. 345.  
 stems, dry rot of, 77.  
 tissue, introduction of liquids into, 456.  
 tissue, simulation of cooking by chemical agents, 269.  
 tuber net necrosis and stem end browning, 208.  
 tubers, cut surface of, control of bud growth and initiation of roots at, 36.  
 tubers, respiration, effect of substances produced by fungi, 207.  
 vines, spray and dust treatments, N.J. 635.  
 virus Y, suspected variant of, 642.  
 viruses, Y-group, studies, 352.  
 yellow dwarf damage to late crops in 1939, Wis. 345.

## Potatoes—

- anaerobic respiration of tubers, 747.  
 as feed for laying hens, 386.  
 ascorbic acid in, effect of storage, Wyo. 562.  
 average yields per acre in Ohio, Ohio 257.  
 blackening after cooking, relation to mineral elements, 456.  
 blackening when cooked, test of varieties, Wis. 333.  
 breeding, Hawaii 479, Nebr. 760, S.C. 480, Wash. 185.  
 breeding for *Fusarium* resistance, 353, Nebr. 783.  
 breeding for scab resistance, Nebr. 783, Wis. 333.  
 breeding hosts of tobacco flea beetle, 661.  
 certification work, Wyo. 481.  
 chemical changes in cooking, Mass. 843.  
 cooking quality as measured by specific gravity, 767, 768.  
 cooking quality, relation to mineral nutrition and alterations in light intensity, 767.  
 cost of growing, harvesting, storing, and selling, Me. 405.  
 cost of irrigating, and increased yields, Nebr. 835.  
 crop response in a 3-year fertilized rotation, N.H. 760.  
 culture and storage, 766.  
 culture experiments, Fla. 616, Hawaii 479, N.Mex. 48, Tenn. 481, Wyo. 481.  
 cystoamylase in, variation, 598.  
 deep fat frying at high altitudes, Wyo. 411.  
 dormancy studies, Hawaii 479.  
 fertilizer experiments, Fla. 616, Me. 333, Mo. 185, N.J. 617, S.C. 480, Tenn. 481, Wash. 185, Wyo. 481.  
 field stands, effects of improper storage, Wash. 185.  
 for starch, optimum yields in Jones County area, Miss. 688.  
 healthy and with virus diseases, comparative biochemical description, 784.  
 in Boston market, consumer preferences for, 693.  
 Katahdin, resistance of progeny to viroses, 786.  
 Long Island, cost of production and price margins, 836.  
 losses from plant diseases, U.S.D.A. 201.  
 manure experiments with, Ark. 626.  
 Nebraska, outyielding others at Crystal Springs, Miss. 48.  
 nutrition and heat endurance studies, Nebr. 760.  
 origin, 177.  
 production in Western States, U.S.D.A. 334.  
 production on Long Island, sources of nitrogen for, 57.  
 quality, effect of fertilizers and rotative systems, 767.

## Potatoes—Continued.

- quality, reliability of retail prices as guides to, Ohio 116.  
 research at Cornell University, 766.  
 role of aphids as virus vectors on, 507.  
 root knot damage in, 782.  
 seed, dips for, and soil treatments, N.J. 635.  
 seed, internal discoloration and net necrosis, U.S.D.A. 344.  
 seed, maintaining foundation stocks, Me. 344.  
 seed-piece decay, Fla. 634.  
 seed-piece decay, role of insects in, 77.  
 seed-piece rot due to *Fusarium oxysporum*, 77.  
 seed-piece vitality, effect of soil moisture and fertilizer placement, N.H. 760.  
 seed pieces, prevention of damage by seed-corn maggot, U.S.D.A. 225.  
 seed, roguing service for producers, Me. 333.  
 seed, strength of mercuric chloride solutions in treating, Me. 344.  
 seedling, stoloniferous condition in, relation to growth characters, 767.  
 shallow v. deep planting, effect on yield and on *Rhizoctonia* and unmarketable tubers, Me. 344.  
 spraying and dusting, and comparison of spray fungicides, Me. 344.  
 spraying experiments, Mass. 796.  
 spring-grown, treatments to break dormancy, Mo. 185.  
 storage, bulk v. box, Me. 333.  
 studies, Ohio 772.  
 Triumph, free from sprain, Wis. 345.  
 Triumph, performance of clonal strains, 766.  
 urea as source of nitrogen for, 54.  
 varieties, scab-resistant bud mutant, Wis. 333.  
 variety tests, Fla. 616, 634, Hawaii 479, Mo. 185, N.J. 617, N.Mex. 48, Nebr. 759, S.C. 480, Tenn. 481, Wash. 185, Wis. 333, Wyo. 481.  
 vitamin C in, 715.  
 wireworm injury to, Conn.[New Haven] 652.  
 yield, effect of fertilizers, S.C. 480.  
 yield increase by special rotations, Ohio 480.  
 yields, effect of sources of nitrogen on, 353.  
 yields on land long in grass, Ohio 480.
- Poultry—*see also* Chickens, Chicks, Cockerels, Ducks, Fowls, Hens, *etc.*  
 and egg industries, economic services provided by government and private agencies, 387.  
 and egg industries, mercantile exchanges in, 387.  
 and egg situation in Canada, 386.  
 and eggs, international trade in, trends, 387.  
 autopsies, N.H. 823.

## Poultry—Continued.

- breeding—  
 for disease resistance in, West. Wash. 236.  
 for high viability, Del. 95.  
 for meat and egg production, 388.  
 in Hungary, improvement, governmental proceedings, 387.  
 organization and control, 387.  
 selection, use of short-time trapping in, 476.  
 studies, Fla. 666.  
 use of stud mating in, N.J. 389.
- brooders—  
 electric, in insulated and noninsulated colony houses, Mass. 828.  
 electric, inexpensive, Wis. 114.  
 electric, insulated, in uninsulated poultry houses, adaptation, Nebr. 828.  
 gas-burning, efficiency, N.H. 805.  
 calcium and phosphorus metabolism, relation to chemical structure of bone, 811.  
 cannibalism in, effect of types of fiber and bulk, West. Wash. 236.  
 cannibalism preventing properties of fiber fraction of oat hulls, 534.  
 cecal fluke, life cycle, 401.  
 disease resistance and susceptibility, expression of, 387.  
 diseases—*see also specific diseases.*  
 and parasites, treatment and control, 253.  
 control by veterinarian, 678.  
 effect of environment, Nebr. 546.  
 dressed, federal inspection, 387.  
 effect of thyroxin injections to normal, caponized, and thyroidectomized caponized birds, 610.  
 egg production, hatchability, and livability of chicks, effect of substituting peanut meal for animal protein, N.C. 389.  
 energy and gaseous metabolism, investigations in Bureau of Animal Industry, 386.  
 enterprise, place in Corn Belt farm business, 386.  
 equipment, Ill. 833.  
 evisceration and quick freezing in United States, 387.  
 existence in America before its discovery and conquest, 387.  
 farming, breeding arrangements for in Netherlands, 387.  
 farms, profits, factors affecting, 386.  
 fat requirements, 98.  
 fat requirements and metabolism, N.J. 671.  
 fecundity in, behavior of persistency in individual hens, 609.  
 feed, energy value, 386.  
 feed, legume silage as, Tenn. 530.  
 feeding, U.S.D.A. 97.  
 feeding, improved, in Bulgaria, 386.

## Poultry—Continued.

- feeding, substitute for dried milk in, Miss. 529.
- Health Service in Germany, organization and accomplishments, 387.
- helminth parasites, treatment and control, 254.
- houses, construction, relation to egg production, Mo. 229.
- houses, effect of types, Wyo. 530.
- houses, insulation and protective covering for insulating material, N.J. 687.
- husbandry, effect of variations in sectional economic maturity, 386.
- husbandry, health control measures in, 253.
- improvement plan, national, 387, 677.
- in Rumania and southeastern Europe. frizzle plumage in, 610.
- indoor-hen-battery mortality, 253.
- industry, advancing, 387.
- industry in Denmark, 387.
- industry in Estonia, 387.
- industry in Great Britain, women's part in, 387.
- industry, papers on, 386.
- inherited longevity tendency in, economic significance, N.J. 671.
- Iowa, marketing methods and costs, 387.
- irradiated yeast for, Wis. 382.
- keeping, small-scale, advisory system for, in Germany, 387.
- lice control, effectiveness of nicotine, Ky. 518.
- litter, controlling moisture in, N.H. 805.
- marketing, cooperative, in Ohio, 557.
- marketing, cooperative, in United States, economic analysis, 387.
- marketing, difficulties faced by cooperatives in, Ohio 835.
- meat, market quality, factors affecting, 388.
- metabolism, effect of activity on, 811.
- mixing rations for, N.J. 671.
- neoplastic and neoplasticlike diseases of, Mass. 823.
- New Hampshire, rate and efficiency of gain, Hawaii 528
- nutrition, progress in, 385.
- nutrition, role of manganese in, 386.
- operating problems and scientific approach to their solution, 388.
- parasites in São Paulo, 400.
- parasites, studies, Hawaii 517, P.R.Col. 677.
- preparation, freezing, and storage, N.Y.State 701.
- Producers' Marketing Associations, services to by Farm Credit Administration, 387.
- products, flavor, effect of cod-liver oil and fish meal on, 388.
- progeny performance, prediction by production of ancestors and relatives, 327.
- protein requirements, N.H. 805.

## Poultry—Continued.

- protein values of Alaska peas for, Wash. 229.
- rations, white corn v. yellow corn in, Miss. 236.
- rations, fiber and bulk in, effect on growth and on prevention of feather picking and cannibalism, 386.
- rations, role of xanthophylls in, 667.
- rearing in Norway, organization and marketing, 387.
- Regional Research Laboratory dedication, 44.
- Rhode Island Red, genetics of, Mass. 757.
- riboflavin requirements and sources, Ohio 529.
- statistics, national and international, improvement, 387.
- statistics of United States, characteristics, 405.
- stud-mating system, merits, N.J. 671.
- sulfur feeding unsafe in winter, Wis. 382.
- sweetpotato flour as source of carotene, S.C. 529.
- transmissible diseases, report of committee on, 678.
- vitamin A requirements, 385.
- vitamin requirements, 236.
- vitamins in breeding rations, Wis. 382.
- White Leghorn, development of strain suited to individual cage management, N.J. 671.
- White Wyandotte, relation between breed characteristics and poor reproduction in, 181.
- young, scientific fattening, 388.
- Poverty grass, seed germination, 54.
- Powdery mildew—  
flora of Pennsylvania, additions to, 203.  
of ornamental hosts, U.S.D.A. 360.
- Prairie chickens, tree buds as winter food for, Wis. 82.
- Prairie dog, control, Kans. 363.
- Prairies, bunchgrass, of southeastern Washington, plant succession due to overgrazing in, 169.
- Pratylenchus*—  
*musicola* in United States, 780, 782.  
*pratensis*, distribution and relation to *Fusarium* wilt of cotton, 780, 782.  
*pratensis*, parasite of, 649.
- Precipitation—see also Rainfall, Snow, etc.  
and evaporation in New Mexico, N.Mex. 590.  
and tree growth in Harney Basin, Oregon, 402.  
at Ohio station, tabulations, Ohio 446.  
data, published, interpretation, advantages in nonuniform hour of observation, U.S.D.A. 591.
- Pregnancy—  
diagnosis in mares by colorimetric estimation of oestrogens, 613.  
electrolyte and nitrogen metabolism in, 413.

## Pregnancy—Continued.

urine extract for treatment of sterility in dairy cattle, 613.

Pressure differences, diurnal, in regions of high pressure, 738.

Price policy, British, and price developments in wartime, U.S.D.A. 120.

## Prices—

local market, estimating since 1920, 115. received by farmers, Ohio 689.

*Proactinomyces* taxonomic notes, 607.

*Prodenia eridania*, see Armyworm, southern.

*Profenusa collaris*, notes, N.J. 651.

## Progesterone—

action on gonadotropic activity of pituitary, 613.

and oestrogen induction of mating responses in spayed female rat, 331.

and testosterone propionate, relative effects on ovipositor lengthening of female bitterling, 328.

assay technic for, 329.

effect on mouse ovary as influenced by gestation, 45.

Progesterin, effect on late pregnancy in rats, 758.

## Prolactin—

and oestrone interactions, relation to pigeon crop-gland response, 46.

response of crop sacs of pigeons to, factors in, 478.

sex difference in response of pigeon crop gland to, 46.

*Propionibacterium pentosaceum*, fixation of CO<sub>2</sub> by cell suspension, 469.

Proso, outstanding varieties, N.Dak. 49.

*Prospodium*—

genus, monograph, 456.

new species, 636.

*Prosthogonimus macrorchis*, notes, 515.

## Protein—

and fat problem in German agricultural-chemical investigation, 603.

concentrates, gross values, Wash. 229.

deficient rations, effect on ovulation, oestrus, and reproduction in dairy heifers, 675.

from various sources, use by laying hens and by poults, Nebr. 805.

intake, effect on energy, and nitrogen metabolism of rats, 807.

nutrition, recent advances in, 382.

plastics from soybean products, 17.

poisoning in feeding of swine 678.

supplements, comparative values in winter rations for stock cattle, Kans. 384.

supplements for pigs on rye pasture, comparison, S.C. 529.

Proteinase in wheat flour, 441.

## Proteins—

biological value, determination methods, 530.

denaturation, changes of nitrogen content brought about by, 587.

dietary, and regeneration of serum albumin, 128.

## Proteins—Continued.

effect of different percentages in diet of six generations of rats, 703.

sensitization to, animal disease conditions possibly associated with, 686.

storage, with low-caloric diets, 272.

Proteolytic enzymes, activation by metals. Wis. 6.

## Prothrombin—

deficiency in obstructive jaundice, control by vitamin K, 424.

levels of bile fistula rats, effect of choleic acid of vitamin K, 572.

plasma, in newborn infant, factors affecting, 424.

*Protoparce*—

*quinquemaculata*, see Tobacco worm.

*sexta*, see Tomato worm.

Protozoa, chemotherapy of infections with, 821.

Provitamin A in Oklahoma feeds, Okla. 668.

Prune leaf spot of Italian variety perpetuated in budded stock, 214.

## Prunes—

ground, digestibility, Calif. 532.

Italian, harvesting, maturity indices for, 494.

pear thrips affecting, West.Wash. 217.

Pruning club, Hebo, description, 497.

*Prunus* crosses, plant characteristics of second generation progeny, 493.

*Psallus seriatus*, see Cotton flea hopper.

*Pseudaonidia paeoniae*, notes, Ala. 519.

Pseuderanthemums and notes on nomenclature, 168.

*Pseudococcus*—

*adonidum*, see Mealybug, long-tailed.

*comstocki*, see Mealybug, Comstock's.

*maritimus*, Brazilian parasite of, 83.

*Pseudolpidium*, sexuality in, 468.

*Pseudomonas*—

*citri*, see Citrus canker.

*fragi*, distribution, 674.

infection in turkeys, 255

*tumefaciens*, active immunity of plants against, 204

*tumefaciens*, pathological changes in host tissue due to, 346.

*Pseudoperonospora*—

species and recorded hosts, U.S.D.A. 344.

spp., nomenclatorial note, 71.

Pseudorabies, see Paralysis, infectious bulbar.

Pseudotuberculosis in a blackbird, 685.

*Pseudovalsa*—

and related conidial forms, fungi associated with, 348.

cultural histories, 596.

Psychrometer, motor-ventilated for station use, description, 738.

*Psyllia pyricola*, see Pear psylla.

Public health facilities, increasing in importance, S.Dak. 558.

*Puccinia*—

*coronata avenae*, life history, Ark. 68.

genus, new taxonomy for, 204.

**Puccinia**—Continued.*graminis*—

- flexuous hyphae of, 346.
- tritici*, physiologic races in Italian East Africa, 350.
- tritici*, studies, 41.
- unusual telial collection, 785.
- variation and hybridization in, 346.
- new species, 636.

*Pucciniopsis caricae* leaf blight of papaya, 358.

**Puerto Rico**—

- College Station, report, 718.
- Station, notes, 432.
- University and College Station, notes, 432.

**Pullets**—*see also* Fowls and Poultry.

- blood calcium level in, Wis. 95.
- Japanese Shamo Game, egg production, Hawaii, 528.
- laying, battery cages v. pen management, N.Mex. 95.
- laying, feeding methods, Ky. 528.
- laying, increased returns from artificial lighting, Del. 95.
- laying ration, carrots, Greenmelk, and dehydrated alfalfa leaf meal, compared, Mich. 98.
- livability and egg production cause, effect of previous management, Ohio 529.
- mineral metabolism of, 811.
- mortality and economic significance, 387.
- raising, relative cost in sexed and unsexed groups, Wyo. 530.
- response to androgens, 46.
- sexual maturity in, use of median age as measure, 475.
- White Leghorn, effects of slow, medium, and fast growth in, N.J. 671.
- White Leghorn, nutritional requirements, Mo. 229.

**Pullorum disease**—*see also* *Salmonella pullorum*.

- agglutination blood testing for, Mo. 242.
- birds positive to serum plate test for, Gram-positive coccus from, 254.
- control, national plan for, 678.
- control program, coordinated breeding for in United States, 387.
- eradication, Mass. 823, N.H. 823.
- in poults threat to growers, Colo. 255.
- in turkeys, Mass. 823.
- of turkeys, whole blood tests for, 112.
- transmission, West.Wash. 253.
- value of repeated testing for, 685.
- whole blood test, effect of *Salmonella* species on, 254.

**Pumpkin**—

- crop, variations in fruit of, 474.
- seed-coat membranes, permeability to gases, 747.

Pumpkins, yields under irrigation, Okla. 190.  
Purdue University, notes, 431.

**Purple scale**—

- control with lime-sulfur, Fla. 650.
- on Satsuma orange, control, Ala. 794.
- studies, U.S.D.A. 84.

Putnam's scale on blueberries, N.J. 651.

*Pyrausta nubilalis*, *see* Corn borer, European.

Pyrenomyces of Georgia, 40.

**Pyrethrum**—

- as an ascaricide, 396.
- as crop for western Washington, West. Wash. 217.
- constituents, chemical investigations, U.S.D.A. 84.
- improvement, Tenn. 489.

Pyridine, germicidal mercury derivatives of, 243.

Pyridoxin, suggested term for vitamin B<sub>6</sub>, 713.

Pyruvic acid metabolism in normal and vitamin B<sub>1</sub>-deficient states, 133.

*Pythium* spp., associated with root rots, 71.

Quackgrass control, Wash. 185, Wyo. 481.

**Quail**—

- bobwhite, studies, Ark. 84.
- California, sex and age ratios in survival, 792.
- yield of weed crops and waste grain as food for, Wis. 83.

Quinhydrone electrode, salt error, effect of pH on, 456.

**Quinones**—

- synthesis, 15.
- synthesis, relation to vitamins K<sub>1</sub> and K<sub>2</sub>, 299.
- vitamin K potency, 16.
- with vitamin K activity, 15.

**Rabbit**—

- fibroma virus, effect, relation to age of host, 820.
- milk, composition, stimulated by lactogenic hormone, Mo. 182.
- myxomatosis, infectious, review, 820.
- papilloma, chemical studies on active agent of, 820.
- tick, parasite of cottontail rabbit, 791.
- virus, Shope papilloma, relation to cancer causation, 820.

**Rabbits**—

- blood value, breed, age, and sex variations in, 611.
- cottontail, parasites of, 791.
- cottontail, range within a year, Wis. 83.
- feed requirements, 388.
- feeding in Germany, 388.
- parthenogenetic activation of ova, 182.
- Russian, cold blackening in, physiology of, 475.
- unilateral castration, effect on spermatogenesis, 183.
- yield of weed crops and waste grain as food for, Wis. 83.

**Rabies**—

- cultivation of fixed virus and immunizing properties, 820.

## Rabies—Continued.

- human, virus distribution and pathology, 820.
- papers on, 677.
- vaccines, immunizing potency, 820.
- virus. *in vitro* culture, 820.

## Raccoon-dogs, toxoplasmosis in, 105.

## Raccoons, summer food on Montezuma Marsh, New York, 791.

Radiation—*see also* Solar radiation.

- effect on psychrometric readings, 305.
- sky, intensity, simple recorder for, 305.

## Radiophosphorus in bean seedlings, absorption and movement, 174.

## Radiosonde, short cycle, description, 18.

## Radish plants, growth, availability of boron for, effect of pH, N.J. 597.

## Radishes—

- grown in sand cultures under glass, effects of deficiency of essential elements, 336.
- vitamin C in, 715.

*Raillietina* spp. of poultry, intermediate hosts, 255.Rainfall—*see also* Precipitation.

- and discharge records for northern Iowa drainage districts, 256.
- and run-off from watersheds, U.S.D.A. 21, 590, 738.
- characteristics, relation to soil erosion, U.S.D.A. 20.
- conduction by plant stems in tropical rain forest, 304.
- distribution for 1939, Conn. [New Haven] 446.
- ground, under various crop canopies, measurement, 303.
- intensities, Ark. 22.
- interception by vegetation, 590.
- tabulated data, Ga. Coastal Plain, 589.
- unseasonable, and flooded fertile cotton areas, Miss. 740.

## Rains, erosive, in Ohio, frequency and seasonal distribution, Ohio 20.

## Raisin moth, flight habits and seasonal abundance, 85.

## Ram, heavily parasitized, effect of commercial phenothiazine on, 545.

## Ram semen, characteristics, effect of method of collection, 178.

## Ramie—

- fertilizer experiments, Fla. 616.
- production tests, Fla. 616.

*Ramularia* blight of parsnips, U.S.D.A. 344.

## Rancidity prevention, 268.

## Range—

- forage utilization, 381.
- grasses, *see* Grasses.
- mixtures fed alone and with supplements, 232.
- pastures, Great Plains, restoring, Colo. 618.
- plants, nutritive value, Wash. 229.
- plants, poisonous, *see* Plants, poisonous, Livestock poisoning, and specific plants.

## Range—Continued.

- resources of Rich County, Utah 258.
- typical sand hill, vegetative survey, Nebr. 186.
- vegetation injury from early grazing, Utah 430.

## Ranges—

- carrying capacity, N.Mex. 95.
- depleted mountain, restoring, Colo. 618.
- restoration by natural and artificial re-vegetation, N.Mex. 49.
- well-managed, depleted by drought since 1931, Colo. 186.

*Ranunculus*—

- new combinations in Arizona, 324.
- oresterus*, new collection of, 324.

## Rape mosaic disease prevalent in China, 209.

## Raspberries—

- breeding, 59, Tenn. 481, Wash. 190, West.Wash. 190, 202.
- Cuthbert, profitable in coastal British Columbia under proper treatment, 197.
- fertilizer requirements, 197.
- frozen, vitamin C in, varietal differences, Wash. 268.
- mulching, pruning, and fertilizer tests, Ky. 488.
- resistant to mosaics and aphids, breeding, West.Wash. 202.
- retarding decay in by use of CO<sub>2</sub>, 495.
- soil management for, N.J. 628.
- spraying studies, Ky. 488.
- Sunrise, new variety, characteristics, N.J. 197.
- varieties for freezing storage, 495.
- vitamin C in, 715.

## Raspberry—

- budmoth, morphology, life history, and habits, 222.
- crown borer, control, N.J. 651.
- fruitworm, studies, U.S.D.A. 84.
- Indian Summer red, testing, Ohio 488.
- root borer, studies, U.S.D.A. 84.
- spur blight, control, N.J. 635.

Rats—*see also* Rodents.

- Albany, prolonged vaginal bleeding and fetal resorption in, 47.
- control, Kans. 363.
- female, effect of antenatal androgens on sexual development, 477.
- hypophysectomized, response to highly purified extracts of pregnant mare serum, 758.
- myocardial lesions from dietary deficiency, 823.
- Norway, blue mutation in and blue-black mosaic, 611.

## Rattlesnakes, nomenclature, distribution, and variation, 516.

## Raven, northern, life and habits, 514.

## Rayon—

- fiber, structure, 573.
- viscose, stress-strain properties, effect of specimen length, 573.

- Real estate—  
 foreclosed, best methods of servicing and handling, 405.  
 tax rates, tax delinquency, and total tax collections 1938, Ark. 115.
- Red char, salted, vitamin D. potency, 717.
- Red mite—  
 citrus, control by insecticides, U.S.D.A. 83.  
 European, control, 366, 380, Pa. 367. notes, Ala. 519.
- Red scale—  
 California—  
 control by fumigation and insecticides, U.S.D.A. 83.  
 oil sprays for, increasing effectiveness, 88.  
 control, toxicants and solids in oil for, 524.  
 Florida, on camellia, Ala. 519.  
 Florida, studies, U.S.D.A. 84.
- Red spider—  
 control on greenhouse plants, Mass. 796.  
 control on sorghum in greenhouse, sterilized soil for, 73, 365.  
 greenhouse, N.J. 651.  
 on apple, studies, U.S.D.A. 83.  
 seasonal history on hops, 85.  
 species affecting fruit trees in irrigated regions, Wash. 217.  
 studies, U.S.D.A. 84.  
 tartar emetic sprays for, 652.
- Redbud *Cercospora* leaf spot, developmental cycle, 214.
- Redtop—  
 fertilizer experiments, Fla. 616.  
 nutritive value, 381, 383.
- Reed canary grass—  
 competition as means of control of weeds, Nev. 481.  
 cultural and fertilizer practices on peat land, Wis. 333.
- Reforestation studies, Fla. 625.
- Refractive index measurements in qualitative organic microanalysis, 152.
- Refrigerated locker plants, development and lay-out, Mich. 126.
- Refrigerator, general purpose farm, construction, 115.
- Rhmiellopsis bohémica* needle blight of balsam fir, U.S.D.A. 500.
- Relapsing fever—  
 argasid tick as vector, 107.  
*Ornithodoros hermsi* as vector, 244.  
 spirochetes in *Ornithodoros hermsi*, relation to feeding and molting habits, 228.
- Relief—  
 families, characteristics, 123.  
 measures relating to raising of farm prices, U.S.D.A. 553.  
 rural, population, composition and characteristics, S.C. 841.
- Rennin, purification, 674.
- Research—*see also* Agricultural research.  
 in agriculture at Missouri Station, Mo. 287.  
 in New England, appraisal and evaluation, 693.  
 refuge, Patuxent, flora of, 597.
- Respiration—  
 effects of photoperiod on, Mo. 189.  
 of barley, effect of cyanide on, 319.  
 relation to phosphate in barley, 34.
- Reticulitermes flavipes*, notes, N.J. 651.
- Reticulo-endothelial system, 243.
- Reticulo-endotheliosis in cattle, case of, 247.
- Retithrips syriacus*, biology and ecology, 523.
- Rhabdocnemis obscura*, *see* Sugarcane weevil, New Guinea.
- Rhagoletis*—  
*cingulata*, *see* Cherry fruitfly.  
*fausta*, *see* Cherry fruitfly, black.  
*pomonella*, *see* Apple maggot and Blueberry maggot.
- Rhectognathus rufiventris* n.sp. from California, 804.
- Rhipicephalus sanguineus*, *see* Dog tick, brown.
- Rhizobium*—  
 effect of glycine on, 456.  
 from legume nodules and laboratory cultures, respiration, 40.  
 growth factor problem in, 467.  
*meliloti* nodule formation, relation to nitrogen-fixing efficiency, 456.  
 spp., growth rates, effect of temperature, 463.  
 strains, synthesis of coenzyme R by, 463.  
*trifolii*, growth stimulating factors, nature of, 468.
- Rhizoctonia*—  
 aerial species, hitherto unreported disease of beans due to, Fla. 634.  
 control with home-made yellow oxide of mercury on bentonite, 73.  
 damping-off of papaya, 358.  
 diseases on potatoes, N.J. 635.  
 infection of potato, effect of dry land rotations on, Nebr. 783.  
 leaf spot of gardenias, 649.  
*solani* inoculated into sterilized soil, survival, 27.  
*solani* on strawberries in transit, U.S.D.A. 500.  
*solani* on sugar beets, 209.  
*tuliparum*, notes, U.S.D.A. 500.
- Rhizopertha dominica*, notes, 654.
- Rhizopus*—  
 fumaric acid formation by, 467.  
*oryzae*, spore germination, early growth, and fermentation, 467.
- Rhode Island College, notes, 432.
- Rhode Island Station, notes, 432.
- Rhodes grass v. Sudan grass for dairy cows, Hawaii 528.
- Rhododendron—  
 midge, N.J. 651.  
 twig and bud blight, due to *Sporocybe azaleae*, new stages of, 513.

*Rhopalosiphum*—*prunifoliae*, see Apple grain aphid.*pseudobrassicae*, see Turnip aphid.*Rhopobota naevana*, see Fireworm, black-headed.

## Rhubarb—

breeding and forcing, West.Wash. 190.  
 organic acids of, behavior during culture  
 of exised leaves, 584.  
 vitamin C in, 715.

*Rhyacionia buoliana*, see Pine shoot moth, European.*Ribes* eradication, chemical and mechanical methods in Western States, U.S.D.A. 82.

Riboflavin—see also Lactoflavin.

activity of cacao shell meal, Mass. 813.  
 as preventive of curled toe paralysis in  
 chicks, Wis. 95.  
 assay, bacteriological method, Wis. 95.  
 deficiency—

and lack of nicotinic acid, differen-  
 tiation of symptoms, 859.

in dogs, production, 531.

in hens, effect on embryonic devel-  
 opment in chicks, 390.

in man, 850.

in man, experimental production,  
 134.

reduction of *d*-amino-acid oxidase in  
 rat tissues, 712.  
 treatment, 134.

determination, fluorometric and biologi-  
 cal method, 445.

determination in natural products, 444.  
 in dried milk products, determination,  
 152.

in foods, fluorometric method for deter-  
 mining, 151.

in pinto beans, effect of cooking, 422.  
 N.Mex. 421.

requirement of chickens, and sources.  
 Ohio 529.

review of literature, 421.

## Rice—

and byproducts, nutritive value, Ark.  
 127.

and rice products for fattening lambs,  
 532.

black kernel and white tip, Tex. 206.  
 bran, energy value, 382.

chlorophyll mutation in, inheritance and  
 linkage relations, 755.

eater's diet, deficiencies of, 425.

effect of nutrient amendment, and other  
 elements, Ark. 48.

fertilizer experiments, Ark. 48, Calif.  
 484.

irrigation, water resources for, Ark. 113.  
 leaf spot, control, by resistant varieties,  
 641.

polish, energy value, 382.

polished, identification of factor with  
 growth-promoting effect on chicks,  
 812.

prices by varieties, Ark. 116.

## Rice—Continued.

rough, farm storage and marketing, Ark.  
 116.

seedling blights, Ark. 68.

stem rot, studies, Ark. 68.

stem rot, varietal resistance, irrigation  
 methods, and treatment, 641.

weevil, death-feints of, 227.

weevil in stored grain, fumigation with  
 chloropicrin, 654.

white tip, effects of Mg:Ca ratio and  
 irrigation methods, 641.

wild, botany and history, 597.

winter cover crops for, Ark. 48.

yield and growth, effect of fertilizers,  
 Ark. 48.

*Ricinus communis*, shoot, size of nuclei in,  
 170.

## Ricketts—

experimental, in rats, effect of A. T. 10,  
 571.

in chickens, etiology and treatment,  
 385.

in fowls, pathology, 400.

production by cereal diet, effect of phytin  
 and of fats, 425, 426.

*Rickettsia diaporica*—

cultivation in tissue culture and in  
 tissues of developing chick embryos,  
 107.

proposed name, 107.

recovery of three strains from *Dermacen-  
 tor andersoni*, 108.

*Rickettsia*, pathogenic, from Gulf coast tick,  
 820.*Rickettsial*—

diseases, relation to boutenneuse fever,  
 820.

infection in rodents, papers on, 820.

*Rickettsioses*, infectious agents of, preserva-  
 tion, 395.River measurement, see Stream flow measure-  
 ments.*Rivoltasia bifurcata* in fowls, 400.

## Roach—

control with sodium fluoride, Miss. 523.  
 powder, Mass. 725.

Roads of different types, mileage, Me. 405.

Rocky Mountain spotted fever tick, rickettsia-  
 like agent from, causing infection in man,  
 107.

## Rodents—see also Mice and Rats.

control, 517, Conn.[New Haven] 651,  
 Kans. 363.

control in orchard and vegetable garden,  
 523.

control in orchards and in cold storage,  
 518.

under field and village conditions, prev-  
 alence and control, Fla. 651.

*Rodolia cardinalis*, see Vedula.

Roentgen rays, see X-ray.

*Romalca microptera*, see Grasshopper, eastern  
 lubber.*Romaniella casulcatus* n.g. and n.sp., descrip-  
 tion, 804.

- Root knot nematode—  
 additions to list of hosts of, 782.  
 attacking stems and leaves of plants, 780, 782.  
 control and active migration, Ga.Coastal Plain 635.  
 control by chemical treatment of soil, 780, 782.  
 control on vegetable crops, Fla. 634.  
 decrease of tomato wilt resistance by, 788.  
 diseases in Virginia, development, 780, 782.  
 effect of crop rotation on control, 780.  
 host specialization in, Tenn. 501.  
 in *Nicotiana*, resistance to, 780, 782.  
 in the U. S. S. R., 362.  
 infestation, analysis of plants reported resistant or tolerant toward, 780, 782.  
 on tomato and cotton, 782.
- Root nodules, *see* Nodule bacteria.
- Root pathology and development, miniature observation box for microscopic study, 205.
- Root tips, handling in paraffin method, card mounts for, 465.

- Rubber tires—  
 on tractors, performance characteristics, Nebr. 828.  
 v. steel for farm vehicles, 256.
- Rubus* aphids in Great Britain, biology, 798.
- Rue, Syrian or African, poisonous in Southwest, 396.
- Rum—  
 aroma, natural, P.R.Col. 581.  
 manufacture, Birectifier in, P.R.Col. 581.  
 types modified through variations in fermentation technic, P.R.Col. 581.
- Rumen—  
 contents, nutritive value for chickens, 386.  
 digestion studies, 382.
- Ruminants—  
 and nematode problem, view of, 246.  
 digestibility studies, 383.  
 respiratory and fermentation gases, Mo. 238.
- Run-off—  
 and erosion from different soil types, S.C. 448.  
 and erosion from New Hampshire upland soils, determination, N.H. 742.  
 of Humboldt River, forecasting, Nev. 446.
- Rural—*see also* Community.  
 community organization, textbook, 842.  
 credit, *see* Agricultural credit.  
 culture, role of folk schools in, 410.  
 housing, floor finishes and cost reduction in, Ark. 113.  
 labor, *see* Agricultural labor.  
 life, forces influencing, Pa. 841.  
 living, improvement, U.S.D.A. 698.  
 regions of the United States, 689.  
 rehabilitation and relief, suggestions for national program, 115.  
 rehabilitation progress in Stearns County, Minnesota, U.S.D.A. 690.  
 schools, *see* School.  
 sociological research, cooperative, 840.  
 youth in selected areas of North Dakota, problems, N.Dak. 842.  
 youth of Minnesota, migration, 558.  
 youth, out-of-school, enter farming, Pa. 124.
- Rust—*see also* Cereal rusts and specific hosts.  
 fungi, flexuous hyphae of, 346.  
 fungi of Alaska, 349.  
 fungus, physiologic races, host selection by, 503.

## Rust—Continued.

- species, new, of Minas Geraes, Brazil, 636.
- Rusts, tropical, descriptions, 204.
- Rutabagas, *see* Swedes.
- Rye—
- anthracnose in West Virginia, U.S.D.A. 783.
  - breeding, Wash. 185.
  - culture experiments, Tenn. 481.
  - flour, energy value, 382.
  - for turkeys, value, Wyo. 530.
  - losses from plant diseases, U.S.D.A. 201.
  - outstanding varieties, N.Dak. 49.
  - soybeans as green manure v. sodium nitrate as top dressing for, N.J. 618.
  - stillage, feeding value for dairy cows, 675.
  - straw, whole and cut, as bedding material, absorptive capacity, 535.
  - v. bluegrass pasture for breeding ewes, Ky. 528.
  - variety tests, Ark. 48, Ga.Coastal Plain 617, Tenn. 481, Wash. 185.
  - vitamin B<sub>1</sub> and plant hormones for, N.Y.State 188.
  - wild, and wheat hybrid grass, claims regarding, without foundation. Colo. 863.
  - wild varieties, processing seed of, U.S.D.A. 618.
- Ryegrass as cover crop, tests, Del. 48.
- Ryegrasses, characteristics, merits, and uses, U.S.D.A. 764.
- Sacahuiste buds and blooms, poisonous to livestock, Tex. 544.
- Saccharomyces*—
- cerevisiae*, minerals in, spectroscopic analysis, 726.
  - ellipsoideus*, effects of carcinogenic substances on, 468.
  - sp., development, 468.
- Safflower, outstanding varieties, N.Dak. 49.
- Safranine, for staining plant materials, 465.
- Saissetia oleae*, *see* Black scale.
- Saliva of hens, studies, 388.
- Salmon meal, vitamin D content, effect of methods of preparation and storage, Wash. 229.
- Salmonella*—
- aertrycke*, virulence and immunizing properties, rough and smooth strains, 822.
  - ballerup*, new type with Vi-antigen, 395.
  - cholerae-suis kuzendorf* strains, from pigs in New South Wales, O antigens of, 397.
  - diagnosis, serological, 822.
  - enteritidis gaertner* in ducks and ducklings, 684.
  - enteritidis*, mouse populations infected with, role of inborn resistance factors in, 476.
  - genus, nomenclature committee report on, 823.

*Salmonella*—Continued.

- group, swarming phenomenon in, 822.
  - pullorum*—*see also* Pullorum disease.
    - viability, Mass. 823.
  - species from domestic animals, antigenic analysis, 822.
  - strain from camels in Palestine, 685.
  - typhimurium binns*, notes, N.C. 401.
  - typhimurium*, biological characteristics of types, Ky. 547.
  - typhimurium* in ducks and ducklings, 684.
- Salometer, use in pickle manufacture, Mich. 17.
- Salt—
- iodized, stabilizing iodine in, Wis. 126.
  - taste threshold of humans, 129.
  - upward movement in plants, 456.
  - water injury to turf and lawn soils, Wis. 334.
  - water spray on foliage, effect, Conn. [New Haven] 651.
- Salts in soil or spray waters, chemical effect on lead arsenate, 520.
- Salvia*—
- lanceolata*, poisonous to livestock, Wyo. 541.
  - splendens*, colchicine-induced variations in, 473.
- Sand—
- dune area, Dalhart, soil and erosion changes on, 687.
  - dune control and wind erosion, list of references, U.S.D.A. 549.
  - hill area, range survey in, Nebr. 760.
  - hill range land, vegetative composition and grazing capacity, Nebr. 186.
- Sands, saturated, permeability of, 453.
- Sandy loam, Ruston fine, productivity, Ark. 22.
- Sandy soils, infiltration and capillary rise in, 308.
- Sansevieria*, *Fusarium* leaf spot, 514.
- Saperda*—
- calcarata*, *see* Poplar borer.
  - candida*, *see* Apple tree borer, round-headed.
- Saprophytes, filtrable, new group of, 456.
- Sapwood and sapwood products, blue stain in, control, U.S.D.A. 361.
- Sarcocystis cuniculi* parasite of cottontail rabbit, 791.
- Sarcoma—
- and leucosis, viruses and related substances producing, characteristics, 820.
  - and leukemia of fowls, chemical aspects of agents, 820.
  - chicken, virus, effect, relation to age of host, 820.
- Sarcoma, avian, filtrable agents of, and serological experiments, 820.
- Sardines, sild, vitamin D potency, 717.
- Sauerkraut—
- bacteriology, 436.
  - kitchenette, bacteriology, Wis. 126.

- Sauerkraut—Continued.  
 kitchenette, causes of discoloration and destruction of vitamin on cooking, Wis. 126.  
 pink color in, development, 156.  
 quality, reliability of retail prices as guides to, Ohio 116.
- Sawdust as bedding material, absorptive capacity, 535.
- Sawflies—  
 studies, Del. 85.  
 three species attacking guava in Brazil, 228.
- Sawfly—  
 European wheat stem, and parasite, distribution, 228.  
 gregarious guava, biology, 228.  
 guava, biology, 228.  
 guava shoot-boring, biology, 228.
- Sawmills, portable—  
 efficiency of labor in, Ark. 64.  
 slack stave, operation in cut-over bottom-land hardwoods, Ark. 64.
- Scale insects—*see also* Black scale, Purple scale, and Red scale.  
 infection by *Septobasidium*, 821.  
 on conifers, use of oil sprays for control, 516.
- Scale—  
 male, injurious to olives, 83.  
 soft, infesting holly on Vancouver Island, 364.  
 soft, on camellia, Ala. 519.
- Scapteriscus*—  
 spp., studies, U.S.D.A. 84.  
*vicinus*, *see* Changa.
- Scelio calopteni*, notes, S.Dak. 801.
- Schistosoma* spp., hematin in intestines of, 686.
- Schizomycetes, species-concept among, bearing of dissociative variation of, 466.
- Schizotrypanum cruzi*, susceptibility of natural vectors to experimental development of, 820.
- School—  
 area, rural, in central South Carolina, income, expenditures, and educational facilities, S.C. 408.  
 fund, permanent, of the State, origin, growth, investment, etc., S.Dak. 842.  
 population and school services in open-country school districts, Ark. 115.
- Schools, folk, as means of rural culture, 410.
- Sciara ocellaris*, chromosome elimination in germ cells, Tex. 863.
- Scirpus*, genus, delimitation of subgenera *Euscirpus* and *Aphyloides*, 169.
- Scirtothrips citri*, *see* Citrus thrips.
- Sclerotinia*—  
 and *Botrytis*, connection of, 468.  
*camelliae* n.sp., description, 80.  
 on cabbage, U.S.D.A. 68.  
*sclerotiorum* on calceolaria, U.S.D.A. 782.  
*sclerotiorum* pink rot of celery, control, Fla. 634.
- Sclerotinia*—Continued.  
 spp. on stone fruits, control, West. Wash. 202.
- Sclerotium rolfsii*, host relations and growth and parasitism, Fla. 634.
- Scolopendra*, sp., vector of gapeworm, 401.
- Scolytoidea, keys to families, genera, and species, 226.
- Scolytus*—  
*multistriatus*, *see* Elm bark beetle, smaller European.  
*quadrispinosus*, *see* Hickory bark beetle.  
*sulcatus*, vector of Dutch elm disease fungus under controlled conditions, 377.
- Scopella* genus, new taxonomy for, 204.
- Scorpion flies, biology and morphology, 524.
- Scorzonera tau-saghyz*, nematode disease of 362.
- Serapie studies, 682, 820.
- Screwworm—  
 outbreaks in territory beyond winter survival, 516.  
 response to stimulations of tarsal chemoreceptors, 224.
- Screwworms, studies, U.S.D.A. 84.
- Scurfy scale, control, 218.
- Scymnus flavifrons*, introduced into California, 83.
- Sedimentation principles, treatise, 161.
- Seed—  
 and seedlings, causes of failure in various Florida soils, Fla. 634.  
 introductions, recording, Hawaii 488.  
 plants of Sedgwick County, Kansas, 168.  
 propagation of plant material for conservation planting, U.S.D.A. 454.  
 research, N.Y.State 770.  
 treatment, studies, Fla. 616.  
 treatment with growth substances, effect on dormancy, 749.  
 treatments with talc and root-inducing substances, 749.
- Seedbed preparation—  
 methods, Wyo. 481.  
 studies, Mo. 256.
- Seed-corn maggot—  
 biology in South Atlantic States, U.S. D.A. 799.  
 damage to potato seed pieces, prevention, U.S.D.A. 225.  
 role in dissemination of potato diseases, 77.
- Seed-potato maggot, role in dissemination of potato diseases, 77.
- Seeds—  
 and seedlings, response to treatment with indoleacetic acid, 318.  
 buried viable, in series of old field and forest soils, 171.  
 detection and identification of disease organisms, technics, 82.  
 disinfection, dry, 511.  
 fumigation, Fla. 650.  
 inspection, Ind. 189, Mass. 335, N.J. 189.

## Seeds—Continued.

nondormant, effects of treatment with growth substances, 749.  
storage, Fla. 616.  
used in producing area, percentages of Wisconsin-produced, Wis. 117.  
viability as affected by siloing process, 383.

weed, *see* Weed seed.

Seedstock, improved, maintenance, Miss. 185.  
Selenium—

chronic toxicity, effect of diet, 141.  
compounds, absorption by crop and converter plants, 455.  
compounds, toxicity, effect of soil colloids, 166.  
cystine and other organic selenium compounds, toxicity, 680.  
in *Astragalus bisulcatus* and seleniferous soils, distribution, 748.  
in wheat of Saskatchewan, 727.  
introduction into plant tissues as toxicant for insects and mites, 654.  
low concentrations, effect on growth of grain, 748.  
minimum lethal dose for horses, mules, cattle, and swine, 543.  
poisoning, 243.  
poisoning, effectiveness of arsenic in preventing, 531.  
relation to creeper fowl malformations, 475.  
relation to sulfur and nitrogen deposition in cereals, 599.  
retention and excretion after administration of sodium selenite to rats, 706.

*Selenophoma* on grasses, 641.

## Semen—

bovine, fresh and stored, fecundity and other characteristics, 608.  
evaluation, methods for, 178.  
physiological properties, 178.

Seminal ejaculation, artificial production of, 615.

*Sepsis impunctata*, life history, 525.

*Septobasidium* infection of scale insects by, 821.

*Septoria*—

*bromigena* and *S. donacis*, transfer to genus *Selenophoma*, 641.  
*chrysanthemi* synonymy, 214.  
*viciae* of vetch and peas in Oregon, 641.

*Sericea*—

hay, improved quality by early harvesting, Miss. 48.  
residual effect on corn yields, Tenn. 481.

Serum albumin, regeneration, efficiency of food proteins in, 128.

*Sesbania* for green manure, tests, N.Mex. 48.

Settlements—*see also* Land settlement.

isolated in cut-over area of Minnesota, private and public costs, 697.

## Sewage—

disposal problems, 102.  
treatment, studies, N.J. 687.

Sex control in animals, 615.

Sex hormones, *see* Hormones.

Shark-liver oil, vitamin content, Fla. 666.

Shavings as bedding material, absorptive capacity, 535.

Sheep—*see also* Ewes and Lambs.

breeding, effect of adding wheat-germ oil to ration on frequency of twinning, N.H. 805.

breeding for adaptability to local conditions, 178.

chronic copper poisoning in, 826.

crossbred, wool- and mutton-producing qualities, Wyo. 530.

crosses, wild with domestic, 756.

diseases, 397.

external parasites of, U.S.D.A. 84.

Hampshire, genetic history, 179.

inheritance of horns and scurs in, 756.

Karakul, breeding experiments at Beltsville, 96.

Karakul, difference in blood value, correlation with organic constitution, 326.  
manganese requirements, Ark. 94.

methods of administering medicine to, N.H. 823.

native, grade Columbia, and purebred Columbia, progeny performance, comparison, Fla. 666.

Navajo, improvement, 326.

nicotinic acid and grass juice factor requirements, 382.

oestrus in, relation to extra-seasonal production of lambs, 179.

parasites—

and parasitic diseases in Canada, 248.

portable dipping vat for control, 650.

studies, Mo. 242.

poisoning, *see* Livestock poisoning,  
Plants, poisonous, and specific plants.  
by sacahuiste buds and blooms, Tex. 544.

with lead arsenate on foliage beneath sprayed apple trees, 248.

Rambouillet, clean wool production in, dam-daughter correlation, 178.

range, production in northeastern Nevada, Nev. 118.

range, reproduction in, 179.

range, rotation paddock system of grazing on irrigated meadows, Nev. 481.

range, wool and lamb production, effect of crossbred matings, N.Mex. 95.

record of performance for, 179.

removal of gastrointestinal parasites from, efficacy of crude unconditioned phenothiazine, 397.

soybean lecithin as supplement to hay and barley for, Wyo. 530.

soybean phospholipids for, 381.

toxicity of lead arsenate and lead arsenate spray residues to, 544.

vaccination against *Brucella melitensis*, 822.

## Sheep—Continued.

with gastrointestinal nematodes, reinfection, 821.

with no tails, development, S.Dak. 756.

Shellfish preparation, freezing, and storage, N.Y.State 701.

Shelterbelt plantations, insect problem in, 516.

Sherbet, consumer acceptance, effect of serving temperature, Mo. 238.

Shipping, periodicals relating to, U.S.D.A. 834.

Shrimp, vitamin D potency, 717.

Shrub root rot, N.Mex. 69.

## Shrubs—

hardy in North America, manual, 497.  
injured by cold weather, treatment, Miss. 64.

newly planted, importance of soil pore space to, N.Y.State 194.

of Michigan for bee pasturage, Mich. 93.  
ornamental, care of, U.S.D.A. 199.

seed propagation for conservation planting, U.S.D.A. 454.

varietal and propagation tests, Fla. 624.

## Silage—

alfalfa, fermentation studies, 675.

## corn—

carotene content, 675.

feeding value for lambs, Wyo. 530.

soybean and sorghum-soybean, relative quality and feeding value, S.C. 535.

varietal quality, N.Mex. 760.

weight of, effect of depth of corn in silo, 675.

crimson clover, quality and palatability for cows, Tenn. 535.

crops, yields and relative palatability and nutritive value for beef calves, Ark. 94.

from hay crops, 381

## grass—

and legume, phosphoric acid as preserving agent for, 239.

citrus pulp as carrier for molasses in preserving, N.J. 676.

effect on nutritive value of milk, Wis. 95.

phosphoric acid as preservative and other aspects, N.J. 676.

temperatures in, and preservatives necessary, N.J. 687.

v. corn, lateral pressure exerted by, N.J. 687.

worthy of trial, Miss. 805.

in various types of silos, quality and carotene in, Ohio 535.

legume, as feed for poultry, Tenn. 530.  
legume-grass—

effect of feeding various lots to dairy cattle, Mich. 536.

moisture, protein, soluble carbohydrate, and carotene in, Mich. 95.  
on Ohio farms, 552.

preparation and utilization, Mass. 813.

## Silage—Continued.

legume, studies, Tenn. 436.

legumes, grasses, and cereal crops for, Mo. 806.

*Lespedeza sericea*, alfalfa and corn for dairy cows, comparison, 675.

making problems, Minn. 303.

prepared by phosphoric acid and molasses methods, fermentation studies, 100.  
role in dairy program, Miss. 528.

Russian thistle, composition, 233.

sorgo, varietal quality, N.Mex. 760.

stack, effect of type of construction on losses and nutritive value, Wash. 238.

stack, worthy of trial, Miss. 805.

sugarcane, digestibility, Fla. 666.

sugarcane, shocked sugarcane, and pasture, comparative value for wintering beef cattle, Fla. 666.

v. alfalfa hay for fattening yearling steers, Tenn. 529.

Silages, corn, red clover, and alfalfa, comparative analyses, Ky. 528.

Silk, artificial, *see* Rayon.

Silkworm, toxicity of nicotine to, 653.

## Silos—

and grass silage, N.J. 687.

temporary v. permanent, S.C. 548.

Silverfish, in a new role, 517.

Siphonaptera, new North American, 525.

Siphonaptera, new records for British Columbia, 364.

Sires—*see also* Bulls.

dairy, proving, Wash. 238.

proved, and sons of proved sires, utilization, 608.

proved, nation-wide, D. H. I. A. program, 608.

purebred, improvement of beef cattle herds through use of, Fla. 666.

reliability of average records of daughters, factors in, 43.

sterile or partially sterile, vitamin C for, 674.

*Sitella*, new genus segregated from *Waltheria*, 168.

*Sitophilus*—

*granarius*, *see* Granary weevil.

*oryzae*, *see* Rice weevil.

## Skim milk—

as feed for laying hens, 386.

condensed, preparation and preservation, Nebr. 814.

dried, value for young pigs, Ohio 529.

feeding, relation to cataract production in rats, 283.

fresh and frozen plain, superheated, and sweetened condensed, for ice cream, 672.

powder, base exchange treated, characteristics, in ice cream, 672.

value, for pigs, Wyo. 530.

## Skin—

lesions in rats, types of, relation to vitamin B<sub>6</sub> deficiency, 713.

wounds, experimentally produced, action of vitamin A on, 425.

- Sky radiation intensity, simple recorder for, 305.
- Slugs, studies, U.S.D.A. 84.
- Sminthurus viridis*, vector of gapeworm, 401.
- Smut—*see also* Cereal smuts and specific hosts.

## Soil—Continued.

## fertility—

determination, quick methods for, Fla. 592.

need of organic matter high in nitrogen, Miss. 452.

studies, Wash. 160.

## moisture—

and tillage, studies, Wash. 185.

calculations from capillary tension records, 163.

capillary tube hypothesis of, 307.

conservation, Nebr. 741.

continuous field measurement, electrical resistance method, Mich. 307.

determination at sticky point, 25.

energy relations, determination by centrifugation, 162.

fluctuation under a lawn, 454.

heat conductivity as index, 25.

holding capacity and its determination, 454.

monoliths, method for taking, 448.

nitrogen, effects of cropping systems, Ky. 479.

nutrients, determination, chemical methods for, La. 7.

parent materials, nature of in southern British Columbia, 449.

population, effect of plants, 468.

profile, ingredients in, N.J. 592.

profile, lateritic, from Puerto Rico, nature of laterization, P.R.Col. 593.

profile, soil constituents and water movement in, N.J. 592.

reaction, determination, comparison of methods, 299.

samples, natural and homoionic, properties, 453.

selenized, for aphid control on sorghum in greenhouse, 365.

separates, mineralogical subdivision by heavy liquid specific gravity separations, 161.

structure, attempts at quantitative characterization, 161.

structure, measurement, Mo. 159.

## survey in—

Iowa, Cerro Gordo Co., U.S.D.A. 160.

Iowa, Davis Co., U.S.D.A. 593.

Iowa, Osceola Co., U.S.D.A. 593.

New York, Cattaraugus Co., U.S.D.A. 448.

New York, Otsego Co., U.S.D.A. 306.

North Carolina, Stokes Co., U.S.D.A. 306.

Ohio, Scioto Co., U.S.D.A. 160.

Oklahoma, Major Co., U.S.D.A. 306.

Saskatchewan, use of Brunton compass for, 449.

Virginia, Albemarle Co., U.S.D.A. 306.

survey, progress of, Ohio 448.

## Soil—Continued.

surveys, relation to land classification in Alberta, 449.

testing, operation, interpretation, and application, Pa. 742.

testing technic, rapid, standardization, 448.

tests, Me. 309, N.J. 592.

tests, rapid, relation to crop yields in United States, 742.

treatments, effect on bacterial activity in, Mo. 159.

water, *see* Soil moisture.

## Soils—

acid—*see also* Soil acidity.

exchangeable-base level, primary minerals of silt fraction as contributors to, 308.

alkali, *see* Alkali.

alluvial, source and nature of erosional damage on, Mass. 741.

amphoteric points, pH. and Donnan equilibrium, 23.

and fertilizers, Tenn. 448.

base-exchange complex, effect of alternate drying and wetting, 166.

base exchange in, 24, N.J. 592.

base-exchange properties, determination, triethanolamine acetate-barium hydroxide buffer for, 300.

biological activity in Sanborn Field after fifty years of treatment, 164.

boron behavior in, U.S.D.A. 314.

brown loam, response to winter legumes, Miss. 479.

buckshot, cultural methods for, Miss. 185.

calcium in, relation to acidity, Mo. 159.

composition, effect of green manure, Fla. 592.

composition, effect of organic matter on, N.J. 592.

Dayton, of Oregon, iron-manganese concretions in, 451.

dry, of great soil groups, thermal conductivity, 162.

effect of arsenious oxide, arsenic oxide, and antimony oxide, Mass. 740.

effect of cryolite, S.C. 518.

eroded, rebuilding, Ohio 448.

erodible, review of literature pertinent to crop rotations, U.S.D.A. 760.

greenhouse, fertility studies, Wash. 160.

heavy, physical properties, effects of cropping and manure, 163.

infertile, relation to barium, 166.

infiltration capacity, measuring, North Fork infiltrometer for, 497.

iodine determination in, 300.

lake, available plant nutrients in, Mich. 449.

lime requirements, determination, buffer for, 300.

loess pampaneo, consistency and physicochemical data, 453.

magnesium in, quantitative determination, 300.

## Soils—Continued.

- management and fertilization, Mo. 159.  
 mechanical analysis, chaino-hydrometer for, 306.  
 microbiological action in and cropping systems, interrelations, Fla. 592.  
 mineral composition, Fla. 699.  
 minor elements in, occurrence and behavior, Fla. 592.  
 muck, *see* Muck.  
 neutral salt effect and amphoteric points, 23.  
 nitrogen content, *see* Nitrogen.  
 of Brazil, studies, 22.  
 of central Florida, distribution of macro and micro elements in, Fla. 450.  
 of Florida citrus groves, chemical studies, Fla. 309.  
 of Florida, classification and mapping, Fla. 592.  
 of Hawaii, organic base-exchange properties, Hawaii, 448.  
 of humid and arid areas, chemical comparison, P.R.Col. 593.  
 of Iowa, plant-food content and lime requirements, Iowa 22.  
 of Mississippi, additional fertilizer nitrogen requirement, Miss. 455.  
 of Morrow plats, changes in during long-continued cropping, 163.  
 of Morrow plats, microbiological aspects 164.  
 of Palestine, 449.  
 of Saskatchewan, index rating, 449.  
 of Texas, composition, Tex. 22.  
 of Texas, iodine content, 450.  
 Okanagan, boron in, 451.  
 orchard, accumulations of arsenical sprays in, Wash. 160.  
 organic matter in, *see* Organic matter.  
 oxidation-reduction potentials, relation to soil characteristics and plant growth, 163.  
 Palouse, leaching of plant nutrients through, effect of cropping systems, Wash. 160.  
 pasteurizing, new electric devices for, [N.Y.]Cornell 832.  
 peat, *see* Peat.  
 permeability to water, Nebr. 741.  
 pH of, effect of exchangeable ions and neutral salts, 24.  
 pH of, factors affecting, 453.  
 physical characteristics. 306.  
 physical characteristics, relation to earth structures, 452.  
 physicochemical properties, relation to vegetation, Mass. 741.  
 Piedmont, in South Carolina, deposits of organic matter under 20 ft. of soil, U.S.D.A. 593.  
 Podzol, of Massachusetts, Mass. 741.  
 pore-size distribution in, determination, 452.  
 range and cultivated, *Azotobacter* distribution and activity in, Ariz. 164.

## Soils—Continued.

- saturated, permeability of, 453.  
 selenized for aphids and red spiders on sorghum in greenhouse, 73.  
 single-base, heat of wetting values, 306.  
 slick spots in, studies, 31.  
 sterilized, survival of micro-organisms inoculated into, 27.  
 structure and pore space in, revised method for microscopic examination, 307.  
 studies, Fla. 592, N.J. 617.  
 surface, sampler for, 23.  
 water percolation in, mean effective pore size and clay migration during, 162.  
 wet, aeration and plant growth in, 316.  
 wind-blown, physical and chemical properties, Mass. 741.  
 Sol concentration, effect on flocculation values, 7.  
 Solanaceae, susceptibility to big bud disease, 784.  
*Solanum*—  
   spp., crossability, effect on chromosome doubling on, 755.  
   virus 2, suspected variant of, 642.  
 Solar radiation—  
   relation to biophysics and problem of climate and health, 739.  
   variations in, relation to weather, 447.  
 Soldier bug, spined, notes, 799.  
*Solenopsis geminata*, *see* Fire ant.  
 Soremouth of sheep, vaccination for, Wyo. 541.  
 Sorghum—  
   adjusting corn planters and listers for, Nebr. 550.  
   breeding, Nebr. 759.  
   characteristics, relation to industrial utilization, Iowa 6.  
   culture and use for forage, U.S.D.A. 485.  
   D Rs P linkage group in, 42.  
   fertilizer experiments, Fla. 616.  
   fodder v. native wild hay as roughage for colts, Nebr. 805.  
   germination of treated and untreated lots, field studies for comparing, Iowa 68.  
   grain as corn substitute in ration of milking cows, Nebr. 814.  
   grain, field feeding to turkeys, Nebr. 805.  
   grain, outstanding varieties, N.Dak. 49.  
   grain, silage, and fodder as feeds for lambs, Nebr. 805.  
   grain v. corn for fattening cattle, Nebr. 805.  
   grain, variety tests, Ark. 48, Ga.Coastal Plain 617, N.Mex. 48, Nebr. 759, S.C. 480, Wash. 185, Wyo. 481.  
   grain, yields of varietal leaders, N.Mex. 760.  
   hybrids, inheritance of chinch bug resistance in, 220.  
   improvement, Colo. 754.

## Sorghum—Continued.

Napier grass, corn, and sugarcane, ensiled, comparison of loss of nutrients, Fla. 666.

planting tests, Nebr. 760.

production in Nebraska, Nebr. 768.

response to fallow and other tillage practices, Nebr. 760.

varieties, tall growing best for silage, Miss. 479.

## Sorgo—

alfalfa, and soybeans, comparative forage yields, Nebr. 760.

Atlas, cost of irrigating, and increased yields, Nebr. 835.

fertilizer experiments, Tenn. 481.

merits as emergency forage crop, N.Dak. 481.

outstanding varieties, N.Dak. 49.

sirup, composition and quality, factors affecting, 583.

sirup, studies, Tenn. 436.

varieties, Ga. 189.

variety tests, Ark. 48, Ga.Coastal Plain 617, N.Mex. 48, Nebr. 759, S.C. 480 Tenn. 481, Wyo. 481.

yields of varietal leaders, N.Mex. 760.

South Carolina Station, report, 574.

South Dakota College, notes, 575.

South Dakota Station, notes, 575.

Sows, brood—*see also* Pigs and Swine.

and their litters, management, Fla. 666. Ga.Coastal Plain 666.

nutritive requirements, Mo. 229.

## Soybean—

amylase concentration and characterization, 583.

diseases, virus, 784.

flour and bee bread as pollen substitutes for bees, 378.

flour as pollen supplement to increase honey yield, Wis. 364.

lecithin, as supplement to hay and barley for sheep, Wyo. 530.

meal as grass fertilizer, value, Ohio 480.

meal, constituents, solubility in alcohol-water solutions, 443.

meal, solvent-extracted, proteins, biological value, 530.

nodules, ether extracts of, coleoptile assay, 172.

oil meal, extraction of phospholipoids from, Del. 6.

oil meal for lambs, Pa. 809.

oil meal rations for chicks, animal proteins as supplements, Wis. 95.

oil meal v. cottonseed meal as protein supplements for milking cows, Hawaii 528.

oil meal v. roasted soybeans v. fish meal as protein supplements for swine, Hawaii 528.

plants, yellowing and dying of leaves in, relation to day length, 603.

proteins, effect of different heat treatments on availability or digestibility, Wis. 126.

## Soybean—Continued.

proteins, plastics from, 17.

root temperature effects in nutrient solution, Mass. 745.

seedling stem blight, 209.

## Soybeans—

advisability of extensive introduction, Utah 334.

alfalfa, and sorgo, comparative forage yields, Nebr. 760.

Biloxi, floral initiation, effect of age and position of leaf receiving photoperiodic treatment, 746.

Biloxi, growth responses to variations of N and P in nutrient solution, 174.

breeding, Ga.Coastal Plain 617, Mo. 185, Tenn. 481.

combined, lower wheat yields following, Ohio 480.

conservation of nutrients as silage and as hay, Vt. 667.

culture experiments, Fla. 616, Ga. Coastal Plain 617, Tenn. 481.

edible varieties, cooking tests, Miss. 562. fertilizer experiments, S.C. 480.

green and mature, carotene in, 130.

high yields, early planting essential to, Miss. 479.

late varieties, higher yields from, Ohio 480.

photoperiodic responses of varieties, 457. placement of dolomite, superphosphate, and basic slag for, 761.

planting methods and rates, Ark. 768.

planting tests, Nebr. 760.

roasted, v. fish meal v. soybean oil meal as protein supplements for swine, Hawaii 528.

small response to fertilizers, Ohio 480.

unprofitable on irrigated farms, Colo. 189.

varieties for hay and grain, R.I. 334.

varieties, oil contents, Ark. 48.

variety tests, Ark. 48, Colo. 189, Fla. 616, Ga.Coastal Plain 617, Mo. 185,

N.J. 617, N.Mex. 48, Nebr. 759, P.R. Col. 617, S.C. 480, Tenn. 481, Wash.

185, West.Wash. 185, Wyo. 481.

vitamin A and vitamin B<sub>1</sub> in, 531.

## Sparrow, English—

economic status in United States, U.S. D.A. 792.

effect of theelin administration on reproductive system, 478.

gonad-hypophyseal relations and cyclic osseous changes, 44.

*Spartina*, cytotoxic studies, 472.

## Speciation—

and geographical distribution, relation of genetics to, 753.

from genetic point of view, 753.

Specimen-envelope folder, description, 176.

Spectrograph, role in analysis of agricultural materials, 437.

Sperm middle-piece, presence in fertilized egg of mouse, 758.

- Spermatogenesis—  
effect of unilateral castration, 183.  
in rats, 330.
- Spermatozoa—  
of dairy bulls, morphological variations  
in, 608.  
of dairy bulls, storage, 608.  
preservation, 178.
- Sphaeridium scarabaeoides*, life history, 526.
- Sphaerognomonina*, new taxonomy, 40.
- Sphaerophragmium* new species, 636.
- Sphaeropsis*—  
dieback and needle blights of pines, new  
information on, 215.  
*ellisi* on conifers, N.J. 635.  
induced witches' broom of oleander, Fla.  
634.
- Spider beetle, white marked, notes, 363.
- Spider, black widow—  
effects of ingestion with canned food,  
665.  
egg parasite, life history, 665.  
unusual infestation of a ship with, 228.
- Spider lily, seed of, 606.
- Spider mite, see Red spider.
- Spiders—  
associated with sweet corn, 804. .  
red, see Red spider.
- Spilonota ocellana*, see Budmoth, eye-  
spotted.
- Spinach—  
downy mildew, U.S.D.A. 344, 500.  
manure experiments with, Ark. 626.  
preservation by canning and freezing,  
Mass. 843.  
production on Long Island, sources of  
nitrogen for, 57.  
response to length of day, effect of so-  
dium nitrate, 338.
- Spirochaeta cytophaga*, changes produced in  
bleached cotton duck by, U.S.D.A. 428.
- Sporocybe azaleae*, new stages of, 513.
- Spotted fever—  
relation to ticks, 541.  
tick, hereditary survival of *Anaplasma*  
*marginale* in eggs or larvae, 395.  
tick-transmitted, discussion, N.J. 228.
- Spotted-wilt virus and pineapple yellow-spot  
virus, identity, 205, 213.
- Spray—  
deposits, chemical evaluation, field  
method, U.S.D.A. 216.  
fluids, wetting and spreading properties,  
evaluation, 793.  
materials, foliage and fruit injury from,  
509.  
mixtures, standard, stickers for, Conn.  
[New Haven] 652.  
program, nonwash, essentials and non-  
essentials in, 518.  
programs, emergency, 522.  
residue tolerances, bibliography of, 219.  
residues and their removal, Mass. 796,  
U.S.D.A. 84, Wash. 190.
- Spray—Continued.  
residues, copper in, determination in  
small amounts, 584.  
residues in Yakima Valley, removal, 795.
- Sprayers—  
portable, operating costs, Ohio 835.  
spraying, spray schedules for azalea and  
camellia, Ala. 519.
- Sprays—see also Fungicides, Insecticides,  
and specific forms.  
and dusts for florists and gardeners,  
U.S.D.A. 511.  
copper, see Copper.  
dinitro and related types, experiments  
with, 218.  
dormant, tests, Wash. 217.  
early spring, 219.  
for codling moth control, Wash. 217.  
impact and movement of individual  
drops upon a surface, photographic  
apparatus for study, 86.  
in potato insect control, 521.  
injury to tree and fruit from, 367, 795,  
Wash. 190.  
oil, see Oil sprays.  
studies, Mass. 796.  
use in orchard test plats, 523.
- Spruce—  
black, role of forest fires in reproduc-  
tion, 633.  
budworm in Minnesota, Minn. 657.  
Norway and white, survival of planted  
trees, N.H. 779.  
Norway, cuttings, rooting, effect of  
growth-promoting substances, 199.  
Norway, vegetative propagation, 499.  
sawfly, European, studies, 218, 516, N.H.  
796, U.S.D.A. 84.  
type, southern Appalachian, plantation  
success, relation to vegetative com-  
petition, 66.
- Spurge, leafy, control, Wis. 333.
- Squash bug—  
control by calcium cyanide, 655.  
parasitism by *Trichopoda pennipes*, ef-  
fect on reproduction, 373.
- Squash insects, control, Conn.[New Haven]  
652.
- Squash vine borer, control, Mass. 796.
- Squashes—  
studies, P.R.Col. 625.  
winter, in storage, causes and control  
of decay in, Mass. 783.  
yields under irrigation, Okla. 190.
- Squirrel—  
Piute ground, life history notes, 514.  
red, life history, in New York, 514.
- Squirreltail, processing seed of, U.S.D.A. 618.
- Staining—  
plant materials, chlorazol black E as  
aceto-carmine auxiliary stain, 465.  
plant materials, Delafield's hematoxylin  
and safranin for, 465.  
use of Feulgen nuclear stain and effect  
of fixatives, 465.

- Stallion—  
 laws in other States. Ind. 670.  
 semen, studies, 178.
- Stallions—  
 enrollment in Indiana, Ind. 670.  
 feeding and care, Miss. 97.  
 sperm production, effects of feed on, 178.
- Standards of living in six Virginia counties, U.S.D.A. 408.
- Staphylococci of bovine origin, studies, 100.
- Starch—  
 degradation by enzyme, characterization of products, Iowa 6.  
 elasticity and viscosity as characteristics, Iowa 6.  
 electrodialyzer for, requirements, 150.  
 from potatoes, production, Me. 302.  
 iodine complexes, absorption spectra, Iowa 6.  
 pastes, rigidity of, 150.  
 wheat, amylopectin and amylose content, 9.
- Starlings—  
 family life and behaviors, 216.  
 spring development of gonads, 44.
- Starks—  
 of high quality, essential steps in making, 103.  
 preparation and care, 103.  
 slow, problem of, 241.
- Steers—*see also* Cattle, beef.  
 beef, fattening, test of various rations. Wyo. 530.  
 fattening—  
 alfalfa hay v. alfalfa-molasses silage as roughage, 381.  
 cottonseed meal and hulls v. corn and lespedeza hay for, S.C. 529.  
 effect of decreasing corn and increasing hay in rations, Ohio 529.  
 experiments, Fla. 666, Ga.Coastal Plain 666.  
 tests of various rations, Ky. 528.  
 2-year-olds on pasture, feed requirements, Tenn. 529.  
 use of cracked cull peas in combination with cereal grains, Wash. 229.  
 use of limited grain ration for, Mo. 229.  
 feeding experiment in Rice Belt, 234.  
 grazing tests of summer and winter pastures, Ga.Coastal Plain 666.  
 Hereford, of selected blood lines, rate and economy of gain, Wyo. 530.  
 on pasture, feeding concentrates to, 381.  
 shorthorn, plane of nutrition and digestibility of hay-oil cake ration, 383.  
 stocker, wintering, rye pasture v. sorghum silage for, S.C. 529.  
 yearling, fattening, blackstrap molasses in rations, Mo. 229.
- Stemphylium*, pathogenicity and taxonomy, Fla. 634.
- Stenoma mistrella*, studies, 799.
- Stephanitis pyrioides*, notes, Ala. 519.
- Stereum gausapatum*, carbon and nitrogen metabolism, 636.
- Sterility—  
 in corn in Argentina, 471.  
 in dairy cattle, treatment with pregnancy urine extract, 613.  
 in ewes, treatment, Wis. 42.
- Stinkbug—  
 predaceous, notes, 517.  
 southern green, Fla. 650.
- Stipa* new species, 597.
- Stock, *see* Livestock.
- Stock foods, *see* Feeding stuffs.
- Stomach worm—  
 in sheep, anthelmintics for, 678, 682.  
 in sheep, factors affecting infestation, 826.  
 red, experimental infection of swine with, 398.
- Storage facilities for personal belongings in home management house, 862.
- Storm damage in Vermont and forest tent caterpillar, 218.
- Stoves, gasoline, top burners and ovens of, efficiency, Nebr. 862.
- Straw and cornstalks, use in soil building, Mo. 159.
- Strawberries—  
 Blakemore, mulching, Ark. 56.  
 breeding, 59, Ark. 56, N.J. 628, Wash. 190, West.Wash. 190.  
 culture, N.H. 771.  
 fertilizer applications and plant development, 197.  
 fertilizers for, Ark. 56.  
 fruit bud formation in, Mass. 771.  
 in transit, *Botrytis* sp. on, U.S.D.A. 500.  
 in transit, *Rhizoctonia solani* on, U.S.D.A. 500.  
 losses from plant diseases, U.S.D.A. 201.  
 manure experiments with, Ark. 626.  
 nitrogen and phosphorus fertilization, 61.  
 response to MgSO<sub>4</sub>, Fla. 625.  
 retarding decay in by use of CO<sub>2</sub>, 495.  
 sex expression, effect of environmental factors on, Ark. 57.  
 soil reaction requirements, Ark. 57.  
 value of barnyard manure for, Ark. 56.  
 varieties, Ga.Coastal Plain 625.  
 varieties for freezing storage, 495.  
 varieties, growth standards for, N.J. 628.  
 vitamin C in, 715.  
 winter protection for, 340.  
 yield, effect of spacing plants on, 776.
- Strawberry—  
 aphid, field sampling for comparison of crop infestations, 519.  
 black root resistance, testing of hybrids and segregates for, Tenn. 501.  
 crown borer, control, Ky. 518.  
 diseases, spraying for, Ark. 68.  
 dwarf, notes. U.S.D.A. 500.  
 fruitworm on hops, seasonal history, 85.  
 insects, control, Mo. 217.

## Strawberry—Continued.

- leaf roller, American, new control measures for, 222.
- leaf roller, western, life history and control, 90.
- leaf spot, new, 783.
- leaf spot resistance, Tenn. 489.
- red stele root rot, 201.
- root weevil, West.Wash. 217.
- weevil, studies, Del. 85, U.S.D.A. 84.

## Stream—

- and valley sedimentation, accelerated principles of, U.S.D.A. 741.
- flow forecasting on tributaries of upper Mississippi, problems of, 738.
- flow measurements, 828.
- pollution and water treatment, N.J. 687.

## Streptococci—

- hemolytic, in raw market milk, 817.
- in experimentally infected animals, localization, 822.
- of mastitis, examination of milk for, 109.

*Streptococcus*—

- agalactiae* as an entity and definite agent in bovine mastitis, 822.
- agalactiae* in naturally infected milk, germicidal action of antiseptic dyes, Mo. 238.
- cremoris*, variation within pure cultures, 102.
- infections in mice, effectiveness in relation to blood concentration of sulfanilamide and related drugs, 822.
- lactis*, serological integrity, 674.

## Strip-cropping project, Tenn. 448.

## Strongyloid larvae—

- biometrics, and epizootology of helminthiasis of grazing animals, 821.
- pasture infestation by, technic for estimation, 396.

*Strongyloides*—

- agoutii* n.sp., studies, 522.
- papillosus*, efficacy of nonconditioned phenothiazine against, 543.
- ratti*, indirect mode of larval reproduction in, 821.
- validity of species, experimental studies, 821.

## Strongyloidiasis, proof of internal autoinfection in, 821.

*Strongylus*—

- spp., hematin in intestines of, 686.
- spp. infestation in Philippine horses, 251.
- spp. removal from horses, effectiveness of crude, unconditioned phenothiazine for, 399.
- vulgaris*, studies, 244.

## Strontium, fate after intravenous administration to adults, 415.

## Substance—B, Nielson's so-called, properties, 746.

*Subutura brumpti* in poultry, life cycle, Hawaii 518.

## Sucrose—

C. P. grade, impurities significant for nutrition of excised tomato roots in, 321.

synthesis by sugarcane excised leaf blades, 603.

v. dextrose as carbohydrate source for excised tomato roots, 321.

## Sudan grass—

arsenic toxicity to, Hawaii 501.

culture experiments, Wash. 185.

development and deterioration of roots, relation to growth under different treatments, Fla. 616.

hay, feeding value for lambs, Wyo. 530.

*Helminthosporium turcicum* in seed and glumes, 504.

hydrocyanic acid in, variation in different areas, Wis. 333.

improvement, Colo. 754.

merits as emergency forage crop, N.Dak. 481.

seed production under Michigan conditions, Mich. 54.

v. Rhodes grass for dairy cows, Hawaii 528.

when safe as feed for livestock? N.Dak. 863.

yields of varietal leaders, N.Mex. 760.

## Sugar acids, fermentation by bacteria, 469.

Sugar beet—*see also* Beet(s)

blight control, dusting or spraying for, 209.

blight-resistant strains, tests, 78.

byproducts, feeding value for lambs, Wyo. 530.

curly top and plant ecology, 354.

curly-top epidemiology, studies, 354.

curly-top resistance, inheritance, 354.

diseases, etiology and control, Wash. 202.

downy mildew, effect on size, sucrose percentage, and purity, 354.

heart rot, relation to boron, 507.

leafhopper, *see* Beet leafhopper.

nematodes, notes, 362, 500.

nematodes, varietal resistance to, 354.

root rot, status of disease with list of hosts, 209.

root rots, 354.

seed, annual production, relation to fertilizer, N.Mex. 48.

## Sugar beets—

breeding, N.Mex. 48.

composition and carbon assimilation, effect of *Cercospora beticola* on, 641.

culture experiments, Wyo. 481.

dusting and spraying, 78.

fertilizer experiments, N.Mex. 48, Wash. 185, Wyo. 481.

improvement, Colo. 754.

irrigation water requirements, Wyo. 481.

losses from plant diseases, U.S.D.A. 201.

soil structure required for, Ohio. 480.

variety tests, Mo. 185, N.Mex. 48.

- Sugar—*see also* Sugars, Dextrose, Lactose, Sucrose, *etc.*  
 Division, report of chief, U.S.D.A. 693.  
 mills, financial results of operation, La. 262.  
 raw, prices, P.R.Col. 689.
- Sugarcane—  
 as fresh forage, shocked fodder, and silage, composition and value, 675.  
 beetle, studies, Ark. 84.  
 borer, biological control, P.R.Col. 651.  
 borer, studies, U.S.D.A. 84.  
 borer under field and village conditions, prevalence and control, Fla. 651.  
 breeding, Fla., 616, P.R.Col. 617.  
 buds, germination experiments, Hawaii 479.  
 characteristics, related to forms of nitrogen used on, 621.  
 chlorotic streak disease, relation to intracellular chytrid fungus, 505.  
 disease resistance tests and seedling selections in 1938 and 1939, 505.  
 diseases, foreign, 501.  
 diseases in Hawaii, 501.  
 effects of minor elements, 485.  
 excised blades, synthesis of sucrose by, 603.  
 farms, large, financial results of operation, La. 261.  
 fertilizer experiments, Fla. 616, P.R.Col. 617.  
 fertilizer experiments, reducing border effect as source of error, 485.  
 for sirup, disease-resistant varieties, Miss. 48.  
 germination, factors affecting, 621.  
 irrigation and green manuring tests, P.R.Col. 617.  
 irrigation interval control as aid in lowering production costs, 552.  
 juice, Kjeldahl digestion of, 301.  
 Napier grass, corn, and sorghum, ensiled, comparison of loss of nutrients, Fla. 666.  
 nitrogen application for, proper proportioning and timing, 485.  
 production on small farms, costs, returns, and physical units involved in La. 259.  
 quarantine, plantation inspection, and consultation services, 501.  
 red rot disease, host-parasite relations, 783.  
 value for forage and other purposes, composition factors affecting, Fla. 616.  
 variety tests, Fla. 616, P.R.Col. 617.  
 vegetative organs, morphology, 746.  
 water requirements, Fla. 616.  
 weevil, New Guinea, field movement, 525.
- Sulfanilamide—  
 and azo dye derivatives, activity in vivo and in vitro, 821.
- Sulfanilamide—Continued.  
 anti-catalase property of, relation to mechanism of bacteriostatic effect, 822.  
 mode of action, 821, 822.  
 solubility, stability, specifications, *etc.*, 686.  
 therapeutic activity in experimental brucellosis of mice, 244.
- Sulfapyridine—  
 in small animal practice, clinical studies, 396.  
 mode of action, 822.
- Sulfonamide series of drugs, disturbances in pigment metabolism following administration, 822.
- Sulfur—  
 burning in empty greenhouses and in mushroom houses, equipment for, Ohio 833.  
 compounds, fungistatic and fungicidal action, 72.  
 dioxide, effect on plants and animals, 456.  
 flotation, Mass. 725.  
 forms, tests with cotton, N.Mex. 48.  
 mixtures, *see* Lime-sulfur.
- Sunflowers, planting, fertilizer, and production tests, Mass. 759.
- Sunlight, *see* Light.
- Sunspot—  
 frequency for 1749–1938, tables, 158.  
 periodicity, relation to precipitation, temperature, and crop yields in Canada, 18.
- Superphosphates, ammoniated and limed, of low fluorine content, absence of reversion in, 594.
- Survey data, memory errors affecting, 834.
- Swamp fever, *see* Anemia, equine infectious.
- Swayback in lambs—  
 prevention by adding copper supplements to diet of ewes during gestation, 681.  
 with affinities to Schilder's encephalitis in man, 681.
- Swedes—  
 dark centers in, borax for prevention, Mass. 725.  
 improvement, Mass. 771.  
 vitamin A values, Tenn. 564.
- Sweet corn—*see also* Corn.  
 as cash crop in a dairy farm rotation, N.H. 760.  
 bacterial wilt, N.J. 635, U.S.D.A. 635.  
 experimental forecast of incidence, U.S.D.A. 201.  
 in New York, U.S.D.A. 783.  
 seasonal development, insect vectors, and host range, 787.  
 breeding, Fla. 616, Iowa 58, Mass. 771.  
 breeding, spacing, and fertilization, Me. 335.  
 damage by Asiatic garden beetle, Conn. [New Haven] 652.  
 fertilization, Ill. 336.

## Sweet corn—Continued.

- fertilizer requirements, Hawaii 488, Wis. 335.
- freezing, fertilizers for, West.Wash. 190.
- fresh and frozen, carotene in, 456.
- frozen, industry, N.Y.State 772.
- hybrids, new Illinois, Ill. 627.
- hybrids, testing, Mass. 771, Nebr. 771.
- pericarp, characteristics, relation to toughness, Iowa 6.
- response to superphosphate, 57.
- spiders and insects associated with, 804.
- staminate and pistillate inflorescences, development, 192.
- variety and canning tests, 192.
- variety tests, Ga.Coastal Plain 625, West.Wash. 190.
- wilt, severity, and winter temperature indexes, N.J. 645.
- wilt tests, N.J. 76.
- young and more mature, invasion by *Phytomonas stewartii*, 75.

## Sweet peas, testing, N.Mex. 57.

## Sweetclover—

- as probable host of tobacco streak virus, 354.
- breeding, Nebr. 760, Wash. 185.
- clipping test and coumarin determination with, Nebr. 760.
- disease in cattle, and treatment, Wis 105.
- disease-resistant varieties, Ohio 480.
- growing in permanent bluegrass pastures, Ohio 480.
- hay, nutritive value, Wash. 229.
- interspecific hybridization and inheritance of character, Nebr. 760.
- new insect pest, U.S.D.A. 84.
- planting tests, Nebr. 760.
- root rot, *Phytophthora cactorum* as cause, 641.
- variety tests, Nebr. 759, Wash. 185.

## Sweetpotato—

- carbohydrates, effect on determination of carotene, S.C. 439.
- diseases, control, Del. 68.
- flour as source of carotene for chickens, S.C. 529.
- plant production beds, electrically heated, S.C. 548.
- pox, effect of soil reaction, N.J. 635.
- scurf, mercurial dips for, N.J. 635.
- soil rot disease, caused by an *Actinomyces*, 783.
- starch, use in baking, 702.
- surface rot, U.S.D.A. 344.
- weevil, studies, U.S.D.A. 84.

## Sweetpotatoes—

- as feed for dairy cows, value, Miss. 666.
- breeding, Tenn. 481.
- date of planting and plant bed experiments, N.Mex. 48.
- dehydrated, biochemical and nutritional studies, S.C. 806.
- dips for enhancing color and preventing rots, N.J. 635.

## Sweetpotatoes—Continued.

- fertilizer experiments, Mo. 185, S.C. 480, Tenn. 481.
  - formulas and carriers of N, P, and K, Ga.Coastal Plain 617.
  - hogging off, returns from, Ga.Coastal Plain 666.
  - internal break-down, 783.
  - losses from plant diseases, U.S.D.A. 201.
  - manure experiments with, Ark. 626.
  - nitrogen and potassium top dressings for, Ga.Coastal Plain 617.
  - nutrient absorption as affected by fertilizer placement, Del. 48.
  - Porto Rico, vitamin A values, Tenn. 564.
  - production don'ts, Miss. 48.
  - production in electrically heated hotbeds, S.C. 769.
  - ratios of organic: nonorganic nitrogen with, Ga.Coastal Plain 617.
  - storage and slip production, electricity as source of heat for, Tenn. 481.
  - value of close spacing, Miss. 185.
  - varieties for starch, Miss. 48.
  - variety tests, Ga.Coastal Plain 617, Hawaii 479, Mo. 185, P.R.Col. 617, Tenn. 481.
- Swine—see also Pigs.
- cross, hybrid vigor in, 43.
  - enteritis, papers on, 678.
  - erysipelas—
    - acute, outbreak, 542.
    - bacterium in hog cholera virus blood, phenol tolerance of, 249.
    - isolation of causative organism, Ky. 540.
    - notes, Wash. 242.
  - influenza virus, intermediate host between epizootics, 821.
  - manganese requirements, Ark. 94.
  - minimum lethal dose of selenium as sodium selenite, 543.
  - semen, storage, 178.
  - tonsillar tissue, acidfast bacterium in, 398.
- Sycamore trees, serious disease threatening, 790.
- Sylvatic plague, latent, 823.
- Symphyla*, embryology and affinities, 523.
- Symptomatic anthrax. see Blackleg.
- Syngamus trachea*—
  - hematin in intestines of, 686.
  - new intermediary vectors for, 401.
  - sex difference in infection rate of birds with, 401.
- Synovitis, tuberculous, in bovines resulting from intravenous injection of avian tubercle bacilli, 247.
- Syntormon uintaensis* n.sp., description, 799.
- Syphilis, protective antibodies in, 822.
- Syrphidae of Minnesota, Minn. 92.
- Taenia*—
  - n.sp., from coyote, 804.
  - pisiformis* parasite of cottontail rabbit, 791.

- Taeniothrips*—  
*inconspuens*, see Pear thrips.  
*simplex*, see Gladiolus thrips.  
*xanthii*, studies, U.S.D.A. 84.
- Tankage v. mixture of tankage and soybean oil meal, for swine, Ky. 528.
- Tapeworm—  
 cysticeroid of, 363.  
 genus *Hymenolepis*, compendium, Okla. 650.  
 infestation, effect on condition of sheep, 111.
- Tapeworms—  
 of poultry, intermediate hosts in Kansas, 255.  
 of poultry, relation to nutrition, Hawaii 517.  
 of sheep, Wyo. 541.
- Taphrina*—  
*dearnessii*, new host for, 648.  
 group on North American maples, distribution, 648.  
*lethifera* on mountain maple, distribution, 648.  
*macrophylla* n.sp. on alder, 214.
- Taro—  
 fertilizer experiments, Hawaii 479.  
 variety tests, Hawaii 479.
- Tarsonemus pallidus*, see Cyclamen mite.
- Tartar emetic—  
 on leaf and fruit surfaces, analysis, using iodine-starch paper, 533.  
 sprays for red spider, 652.
- Tax—  
 delinquency on farm real estate, S.C. 551.  
 legislation, graduated land, Oklahoma's experience with, Okla. 689.  
 revenues in towns in Aroostock County, Me. 405.  
 trends of Michigan as related to agriculture, Mich. 119.
- Taxes, rural property, problems in the State, Ala. 691.
- Taxonomy and floristics of the Americas, 596.
- Tea scale on camellia, Ala. 519.
- Teeth—  
 mottled enamel, production halted by change in water supply, 141.  
 pathology of, effects of darkness and controlled radiation, 427
- Telenomus*—  
*ichthyurac*, notes, Mo. 798  
*ovivorus*, egg parasite of false chinch bug, description, 804.
- Telephone facilities on farms, Me. 405.
- Temperature—see also Climate.  
 climate of Sweden, 21.  
 conservatism of equivalent potential and wet-bulb potential, 157.  
 low, damage to fall grains and legumes, Miss. 19.  
 low, mechanism of injury and death by, 600.  
 low, resistance in crop plants, nature of, Nebr. 740.
- Temperature—Continued.  
 subzero, home-made device for maintaining, 363.  
 wet-bulb potential, distribution in four selected cyclones, 157.
- Tenant-landlord relations in Ohio, legal aspects, 406.
- Tenebroides mauritanicus*, intermediate host of chicken cestode, 255.
- Tennessee Station, report, 574.
- Tenodera angustipennis*, egg content and nymphal production and emergence in oothecae, 219.
- Tent caterpillar—  
 eastern, insecticides and spreaders for, 367.  
 forest, and storm damage in Vermont, 218.  
 forest, ecological aspects in national forests in Minnesota, 515.  
 forest, studies, 515.
- Teosinte, uncontrolled vegetative development in, 37.
- Tephritinae of China, key to genera, 224.
- Tephrosia virginiana*, extracts of roots, toxicity tests, 520.
- Tergitol 7 penetrant, insecticidal properties for adult Japanese beetle, 527.
- Termite, dry-wood, studies, P.R.Col. 651.
- Termites—  
 control, N.J. 651.  
 control, new developments in, 516.  
 subterranean, diphenylamine as soil poison against, 523.
- Test tube, modified to prevent bumping and promote boiling, 588.
- Testosterone—  
 and oestrogen, tolerance of male and female mice to, 758.  
 and theelin, comparison of effects on immature female rats, 46.  
 applied locally to penis of rat, effect, 758.
- propionate—  
 action on female genital tracts, 329.  
 action on structure of anterior pituitary of female rat, 46.  
 and progesterone, relative effects on ovipositor lengthening of female bitterling, 328.
- propionate, effect on—  
 black-crowned night heron, 615  
 development of reproductive ducts in female sparrow hawk, 478.  
 immature female rat and guinea pig, 476.  
 ovariectomized rat, 331.  
 pregnancy and on passage of ova through oviducts, 612.  
 sexual differentiation in genetic female mice, 329.  
 thyroid and parathyroid glands of rats, 615.
- propionate injections, precocious copulatory activity induced in male rats by, 477.

- Tetranychus*—  
 sp., notes, Ala. 519.  
*tetarius*, see Red spider.
- Tetraploidy, colchicine-induced, in *Lilium*, 598.
- Texas Station, notes, 575.
- Texas Station publications, abstracts, Tex. 863.
- Textile—  
 fabrics, adequacy of labeling with regard to fiber content, 142.  
 fibers, newer, identification, 860.  
 finishing treatments, technical evaluation, flexibility and drape as measurable properties, 860.  
 materials, capacitance in relation to moisture content, Minn. 427.  
 research from consumer point of view, progress in, 859.
- Textiles—see also Fabrics.  
 consumer specifications for, 286.  
 household, place in farm budget, Miss. 142.  
 household, provision and use by farm families, S.C. 574.  
 testing, physical, chemical, and microscopical, 860.
- Thallium toxicity and tobacco frenching, differentiation, 209, 506.
- Thanasimus lecontei* factor in control of western pine beetle, 801.
- Theelin—  
 administration, effect on reproductive system of female English sparrow, 478.  
 and testosterone, comparison of effects on immature female rats, 46.
- Thelazia californiensis*—  
 from a mature buck deer in Sequoia National Park, 249.  
 normally a parasite of herbivorous mammals, 249.
- Thelaziasis, ovine, studies, 249.
- Thiamin—see also Vitamin B<sub>1</sub>.  
 administration in vitamin B<sub>1</sub> deficiency, fatty livers resulting from, 132.  
 chemical reagent for, 10.  
 in urine as index of nutritional level, thiochrome test for, 851, 852.  
 in urine, chemical determination, stability, and form, 731.  
 ultramicrodetermination by fermentation method, 444.  
 ultraviolet absorption spectra and their reduction products, 731.  
 urinary excretion of, by normal individuals, 853.
- Thielaviopsis basicola*, notes, 780, 781.
- Thiol compounds, effect on gonadotropins, 184.
- Thistle, Russian—  
 hay, feeding value for lambs, Wyo. 530.  
 silage, composition, 233.
- Thistles recently introduced into Texas, 753.
- Thompsonella*, genus, history and status, 169.
- Thrips—  
 collecting, modified Berlese funnel for, U.S.D.A. 83.  
 injurious, distribution in United States, 86.  
 new species from Mojave Desert, 86.  
 on stone fruits, control, West. Wash. 202.
- Thrips tabaci*, see Onion thrips.
- Thurberia weevil, studies, U.S.D.A. 84.
- Thyroid—  
 activity and vitamin B<sub>1</sub> requirements, 280.  
 effect on egg production, Mo. 672.  
 gland and lactoflavin, relation, 713.  
 glands of immature rats, effect of testosterone propionate, 615.
- Thyrolactin—  
 assay method, 608.  
 new source of thyroxine for dairy cattle, 608.
- Thyroxine—  
 effect on yield and composition of milk of dairy cows and goats, Mo. 759.  
 for dairy cattle, thyrolactin new source of, 608.  
 injections, effect on physiological processes of dairy cattle, 608.
- Thysanoptera of Kauai, host plant list, 220.
- Thysanosoma actinioides*, studies, 249.
- Thysanus*—  
*elongatus*, parasite of Comstock's mealybug, 657.  
*nigra*, parasite of Comstock's mealybug, 657.
- Tick—  
 argasid, burrowing owl as host, 216.  
 fever, Colorado, 820.  
 fever, studies, 820.  
 fowl, problem of acquired immunity to, 254.  
 Gulf coast—  
 in southern Georgia, 94.  
 pathogenic rickettsia from, 820.  
 testing repellents of, U.S.D.A. 83.  
 problem of New Jersey, N.J. 228.  
 tropical horse, hereditary transmission of anaplasmosis by, 106.
- Ticks—see also Cattle ticks.  
 and disease, 541.  
 eradication in Florida, complicated by tropical variety, 396.  
 eradication, report of committee on, 678.  
 filter-passing infectious agent isolated from, 107, 820.  
 in Arizona bat caves, 528.  
 in Manchoukuo, studies, 678.
- Tierzucht Congress, topics receiving most attention, 178.
- Tillage and soil moisture, studies, Wash. 185.
- Tilletia* spp., new races, Wash. 202.
- Timber—see also Lumber and Wood.  
 and snow, studies, Nev. 446.  
 depletion of starch from, relation to attack by *Lyctus* beetles, 527.

## Timber—Continued.

farms in upper Ozark region, Ark. 115.  
marketing problems in central hardwood region, 201.

## Timothy—

alfalfa-clover seedings, mixed, productiveness, Ohio 480.  
alfalfa seedings, improvement by use of cultipacker, Wis. 333.  
clover hay, fertilizer experiment, N.H. 760.  
conservation of nutrients as silage and as hay, Vt. 667.  
cultural and fertilizer practices on peat land, Wis. 333.  
hay, adequacy in calcium for growth of dairy heifers, 675.  
high-protein, production, N.J. 517.

*Timulla*, systematic revision of genus, Minn. 379.

*Tipula* sp., vector of gapeworm, 401.

## Tires—

pneumatic tractor, for use of North Dakota farmers, N.Dak. 256.  
rubber, for agricultural machinery, Iowa 550.  
rubber, for home-made carts and trailers, S.Dak. 403.

Tissues, introduction of liquids into, 456.

*Tlascata finitella*, studies, Mass. 796.

## Tobacco—

analyses, Ky. 436.  
angular leaf spot in plant beds, Ky. 501.  
bacterial leaf spots in Kentucky. U.S.D.A. 500.  
black root rot, Mass. 783.  
black shank in Burley section of Kentucky, U.S.D.A. 783.  
black shank spread by drainage water, Ky. 501.  
blackfire, control, Ky. 354.  
brown root rot and black root rot, in Canada, prevention, 506.  
brown root rot, relation to weather, Wis. 345.  
Burley, *Fusarium* wilt-resistant, Ky. 501.  
Burley, prices and sales, changes in seasonal movements, Ky. 551.  
cigar, fertilizer tests, Wis. 333.  
cigar-leaf, harvesting, chemical and fermentation studies, Conn.[New Haven] 486.  
constituents, chemical investigations, U.S.D.A. 84.  
curing experiments, Ky. 479.  
curing methods, S.C. 481.  
curly top virus, passive immunization from, 643.  
disease-resistant varieties, Fla. 635.  
diseases—  
and decays in Connecticut, Conn. [New Haven] 354.  
in Canada, 505:  
in Kentucky, U.S.D.A. 635.

## Tobacco—Continued.

diseases—continued.

losses from, U.S.D.A. 201.  
relation to weather, Fla. 634.  
virus, 784.

downy mildew control, Conn.[New Haven] 505, Fla. 78, 635, S.C. 501.

downy mildew, control demonstrations, Fla. 634.

downy mildew, control, toxicity of paradichlorobenzene in relation to, 506.

downy mildew in Massachusetts, U.S.D.A. 782.

downy mildew, relation to weather conditions, history, 643.

downy mildew, studies, Ky. 501, U.S.D.A. 500.

effect of various rotations, S.C. 481.

farms, receipts, expenses, farm and labor incomes, etc., P.R.Col. 689.

fertilizer experiments, Ga.Coastal Plain 617, Ky. 479, S.C. 481, Tenn. 481.

fertilizer formulas, Ga.Coastal Plain 617.  
fertilizer placement, Ga.Coastal Plain 617.

## flea beetle—

control in tobacco plant beds, S.C. 519.

host plants, 661.

migration, 661.

studies, U.S.D.A. 84.

flue-cured, diseases, control, Ga.Coastal Plain 635.

flue-cured, general recommendations for, Ga.Coastal Plain 617.

frenching, distinguished from thallium toxicity, 209, 506.

*Fusarium* wilt resistance, breeding for, Tenn. 501.

growth and level of replaceable potassium, Ky. 479.

growth, in solution cultures, effect of algae, 601.

hornworm control, Tenn. 519.

in principal producing countries of far east, U.S.D.A. 555.

injury from wireworms, control, Ky. 518.

leaf spot diseases, low soil fertility predisposing to, Ky. 501.

leaves, infection by *Bacterium tabacum*, relation to stomata, 77.

mosaic control, Wis. 78.

mosaic, cytological research, 346.

mosaic damage and resistant varieties, Ky. 501.

mosaic dissemination in the field, 210.

## mosaic virus—

electro-optical effect in, 346.

formation of plate and needle crystals in cells affected with, 346.

in liquids over 14 years old, infectivity of, 643.

in living cells, reversible inhibition with molar sodium cyanide, 210.

inhibition, Wis. 345.

## Tobacco—Continued.

- mosaic virus—continued.
- movement, relation to food translocation, 642.
- new views in, 205.
- overwintering in soil under natural conditions, Mass. 783.
- protein, break-down of, 345.
- protein, thixotropic character, 346, 643.
- thermal denaturation, 210.
- type-1, attempt to propagate in chorioallantoic membrane of chick embryo, 71.
- type-1, causing tomato fruit stripe, 644.
- new insect pest, N.J. 651.
- plant bed fertilization, Fla. 616.
- production and consumption in Netherlands Indies, U.S.D.A. 406.
- quality following weed fallow, 54.
- red rot, U.S.D.A. 500.
- root knot in Florida cigar-wrapper fields, control, 780, 782.
- rotations for, Tenn. 481.
- secondary nutrient elements for, Ga. Coastal Plain 617.
- seed, germination after 7 yr. in different types of storage, Fla. 616.
- seed production, Ga.Coastal Plain 617.
- seedbeds, damping off in, U.S.D.A. 68.
- seedbeds, use of paradichlorobenzene in, to control tobacco downy mildew, 506.
- shade diseases, Ga.Coastal Plain 635.
- soils, relative rate of nitrification of nitrogen materials, Mass. 740.
- streak, relation to similar virus disease in sweetclover, Ky. 501.
- streak virus, sweetclover as probable host, 354.
- thrips, notes, Conn.[New Haven] 517.
- trade with Latin America, U.S.D.A. 836.
- variety tests, N.Mex. 48, Tenn. 481, Wis. 334.
- wildfire relation to stomata, Ky. 501.
- wildfire, studies, U.S.D.A. 500.
- worm, studies, U.S.D.A. 84.
- worm, toxicity of nicotine to, 653.
- yield and quality, control of injury from old sod plowed under preceding tobacco, Mass. 759.
- yield and quality, effect of soil nitrate level, Ky. 479.
- yards on land long in grass, Ohio 480.

## Tocopherol—see also Vitamin E.

- $\alpha$ , preventive effect in nutritional muscular dystrophy, 382.

Tocoquinone.  $\alpha$ , vitamin E activity of, 284.

## Tomato—

- big bud spread in connection with ecological conditions, 784.
- blight diseases, spraying for, Wis. 345.
- blight, early, effect of rainfall and humidity, Ga.Coastal Plain 635.
- blight, spray program against, Miss. 79.
- bug, ecology, Hawaii 517.
- curly top, notes, U.S.D.A. 635.

## Tomato—Continued.

- curly top, resistance of Chilean tomatoes to, 78.
- disease in Hawaii due to pineapple yellow spot virus, 213.
- diseases—
- control, Fla., 635. Ohio 501.
- effect of growing and shipping methods, 788.
- in New Jersey, 212.
- in northeast Texas, U.S.D.A. 782.
- losses from, U.S.D.A. 201.
- seasonal occurrence in Florida, Fla. 644.
- situation in Utah, U.S.D.A. 782.
- fields in Cumberland County, survey, N.J. 625.
- fruit pox in Arkansas, U.S.D.A. 344.
- fruit pox in Texas, 213.
- fruit stripe, caused by tobacco type-1 virus, 644.
- fruitworm—
- control, 91, U.S.D.A. 216.
- control, effects of alfalfa on abundance, Wash. 217.
- poison tests with, S.C. 518.
- response to lights, Ohio 518.
- studies, U.S.D.A. 84.
- Fusarium* wilt—
- control, Fla. 634.
- resistance, breeding for, Tenn. 501.
- resistant varieties, Mo. 78.
- industry in Puerto Rico and Cuba, list of references, 834.
- juice, ascorbic acid in, effect of refrigeration, 136.
- juice, canned, vitamin C in, effect of presence of iron and tin, Ark. 126.
- juice, commercially canned, vitamin A in, 416.
- juice, home-canned, standardization, Fla. 699.
- leaf blight severity in Virginia, U.S.D.A. 783.
- leaf mold disease, control, Mass. 783.
- leaf roll in District of Kursk and Voronezh, 784.
- leaf spot in hotbeds, adequate ventilation as control, Ohio 488.
- leaf spot resistance, Tenn. 489.
- leaves, rolling of, U.S.D.A. 500.
- mosaic, virus strain of aucuba-type, 511.
- pectin-methoxylase, heat, inactivation, 296.
- pinworm, studies, U.S.D.A. 84.
- plants, ammonium- and nitrate-fed, potassium deficiency in, 175.
- plants, growth status and metabolism, effect of varying amounts of potassium, 174.
- plants, nematodes in, 362.
- pomace, feeding value, 530.
- roots, effect of zinc deficiency on, 644.
- roots, excised, growth, effect of impurities of C. P. grade sucrose, 321.

## Tomato—Continued.

- roots, excised, sucrose v. dextrose as carbohydrate source for, 321.
- seed treatments and sprays, Ga.Coastal Plain 635.
- seed, X-ray treatment, white flower character from, 177.
- seedling disease, studies, 212.
- seedlings, ammonium- and nitrate-fed, potassium deficiency in, 193.
- shoots, excised, metabolism of nicotine monohydrochloride in, 321.
- streak, 784.
- wilt resistance and its decrease by *Heterodera marioni*, 788.
- wilt, studies, Mo. 201.
- worm, response to lights, Ohio 518.
- worm, studies, U.S.D.A. 84.

## Tomatoes—

- acidity in, factors affecting, Ohio 488.
- ascorbic acid in, effect of home canning and subsequent storage, 136.
- availability of potassium in bentonite clay for, N.J. 597.
- breeding, Ark. 56, Mass. 771, N.J. 625.
- breeding and culture, Nebr. 771.
- breeding for *Septoria* and early blight control, Wis. 345.
- canning commercially, use of calcium in, N.Y.State 302.
- canning factory, economic considerations in growing, Ind. 262.
- canning, scoring system for, 193.
- canning, spraying v. dusting, Ohio 788.
- Chilean, resistant to curly top, 78.
- culture experiments, Ga.Coastal Plain 625.
- disease resistant, breeding and selection, Del. 68.
- fertilizer experiments, Ga.Coastal Plain 625, Mo. 190, Pa. 773.
- fertilizer placement methods, N.J. 625.
- greenhouse-grown, pollination studies, Mich. 490, Mo. 189.
- growing on trellises, Mass. 771.
- home-canned, standardization, Fla. 699.
- improvement, Mass. 771.
- improvement through selection of new hybrids, Fla. 625.
- induction of parthenocarpic fruiting in, Ark. 56.
- irrigation, Ark. 56.
- leaf anatomy and starch content, effect of pruning, Ark. 56.
- manure experiments with, Ark. 626.
- maturation, Fla. 625.
- mature-green, ripening and repacking, U.S.D.A. 774.
- Mingold, origin and distinguishing characters, 336.
- mulching materials for, N.J. 625
- N and P nutrition of, Ky. 488.
- pectic enzymes of, 296.
- phosphoric acid requirements, N.J. 625.
- planting date, Me. 335.
- production, factors affecting costs, prices, and profits from, N.J. 688.

## Tomatoes—Continued.

- pruning and staking, Fla. 625.
- puffing disorder of, Fla. 634.
- quality, reliability of retail prices as guides to, Ohio 116.
- resistant to *Septoria* leaf spot, testing, Ark. 56.
- response to superphosphate, 57.
- Rutgers, yield, factors affecting, N.J. 625.
- shape index in, Mass. 771.
- shipping conditions, Ga.Coastal Plain 635.
- spray residue studies, N.J. 625.
- spraying, Fla. 634.
- staked, spacing, 193.
- starter solutions for, N.Y.State 193.
- stem morphogenesis, cell size and number in, 315.
- varieties, *Fusarium* wilt isolation from, differences in growth characters and pathogenicity, U.S.D.A. 212.
- variety tests, Fla. 625, Ga.Coastal Plain 625, Ky. 488, Mo. 190, N.Mex. 57, Ohio 488, West.Wash. 190.
- vitamin C in, 715, Ohio 488, Utah 412.
- vitamin C in, relation to acidity, 854.
- yields under irrigation, Okla. 190.
- Tonsils, vitamin C in, and relation to their protective function, 422.
- Toxemia in sheep, Mo. 242.
- Toxocara* spp., hematin in intestines of, 686.
- Tractor farming, remodeling used machinery for, S.Dak. 829.
- Tractors—
  - rubber tires on, performance characteristics, Nebr. 828.
  - tests, Nebr. 114.
- Trade—
  - agreement, Venezuelan, agriculture in, U.S.D.A. 120.
  - agreements, reciprocal, analysis of terms pertaining to, Okla. 406.
  - policy, foreign, desirable for American agriculture, 834.
- Trailers, rubber tired, home-made, S.Dak. 403.
- Trametes* spp., from region of Great Lakes, 785.
- Transpiration stream in leaves of cereals, 599.
- Tree—
  - area ratio and its applications, 632.
  - buds as winter food for prairie chickens, Wis. 82.
  - cankers in Iowa, fungi associated with, 348.
  - diseases, control, Ohio 501.
  - diseases of shade and ornamental species, U.S.D.A. 343.
  - diseases, studies, 215.
  - girdlers, important economic species in United States, 662.
  - growth, soil factors affecting, 450.
  - leaves, rate of decomposition relation to acid-base balance and other chemical properties, 25.

## Tree—Continued.

losses in mid-west United States during 1933-39, 66.

ring analysis, bibliography, 740.

ring chronology, estimated, of western Pueblo area. 150-1934 A. D., 740.

root rot, N.Mex. 69.

seedlings, distribution for shelterbelt and other uses, Wyo. 489.

Treehoppers, effect of lime-sulfur and of oil sprays on eggs, and emergence, 652.

## Trees—

coniferous, *see* Conifers.

drought injury, in Nebraska, U.S.D.A. 500.

evergreen, *see* Evergreens.

forest and fruit, studies, Fla. 625.

forest, growth and survival, relation to ground water level, Wis. 342.

forest, high temperature tolerance, Minn. 65.

forest, of Michigan for bee pasturage, Mich. 93.

growth, and precipitation in Harney Basin, Oregon, 402.

growth as related to soil morphology, [N.Y.]Cornell 497.

hardwood, effective utilization, Ohio 497.

hardwood, growth, effect of root pruning after digging, 498.

hardwood, growth rates, Ark. 65.

hardy in North America, manual, 497.

injury from sulfur dioxide fumes of electric refrigerators, 72.

newly planted, importance of soil pore space to, N.Y.State 194.

on prairie soils, causes of failure, Wis. 342.

ornamental, care of, U.S.D.A. 199.

resistance to defoliation by, 516.

responses from irrigation, Wash. 190.

Rocky Mountain, handbook with plates and distribution maps, 457.

seed propagation for conservation planting, U.S.D.A. 454.

shade, fungicides for, 360.

shade, insecticides and spreaders for, 367.

shelterbelt, *see* Shelterbelt.

## Trematodes—

avian, from India, morphology and classification, 254.

gut contents, hematological studies, 686.

morphology, in intestine of fowls, 401.

*Triatoma* spp. in Tucson area of Arizona, 220.

*Tribolium castaneum*, *see* Flour beetle, red.

*Trichinella spiralis*—

development, effect of short electric wave radiation on, 395.

in swine in United States, 821.

Trichiniasis in rats, immunity to, 821

Trichinosis—

in an American badger, 395.

in Canada, incidence in garbage-fed hogs, 250.

*Trichoderma*, use for biological control, need of reinvestigation, 204.

*Trichogramma minutum*—

artificially reared for sugarcane borer control, P.R.Col. 651.

experimental work, 658.

notes, Mo. 798.

*Trichomonas*—

*foetus*, cultivation, 245.

*foetus*, cultural diagnosis, simple medium for, 397.

spp. in domestic animals, biology and pathogenicity, 820.

vaginitis, pathology and vaginal implants with *Trichomonas vaginalis* and *T. intestinalis*, 820.

Trichomoniasis—

bovine, S.C. 540.

in Utah Experiment Station dairy herd, 110.

of cattle, experimental transmission, 110.

*Trichonema* spp. infestation in Philippine horses, 251.

*Trichopoda pennipes*—

notes, Fla. 650.

parasitic castration of *Anasa tristis* by, effect on reproduction, 373.

*Trichopria*—

*angustipennis*, notes, 525.

*paludis*, notes, 525.

*Trichostrongylus*—

*axei*, efficacy of nonconditioned phenothiazine against, 543.

*calcaratus* parasite of cottontail rabbit, 791.

*colubriformis* from sheep, rabbits as host, 827.

*Trichuris*—

*leporis* parasite of cottontail rabbit, 791.

sp., efficacy of nonconditioned phenothiazine against, 543.

*Trifidaphis phaseoli*, studies, U.S.D.A. 84.

*Triticum monococcum*, genetic analysis, Mo. 185.

Trout, insect food of, 650.

Truck crop insects, studies, U.S.D.A. 84.

Truck crops—

effect of atomized oil sprays on, Wis. 364.

fertilizer experiments, Fla. 624, Wash. 190.

fertilizer requirements, Wash. 190.

selection and breeding, Wash. 190.

soil fertility studies with, Fla. 625.

variety tests, Wash. 190.

Truck farming in Copiah County, receipts, expenses, prices, etc., Miss. 262.

*Trypanosoma*—

*equiperdum*, growth in developing chick embryo, 108.

*equiperdum*, method for preserving, 542.

*rhodesiense*, rabbits cured of, protracted immunity in, 821.

*theileri* and turning sickness of cattle, 397.

- Trypanosomes—  
 antigenic composition and immunizing properties, 821.  
 cultivation in developing chick embryo, 108.  
 nature of blepharoplasts of, 820.
- Trypanosomiases, experimental, mechanism of resistance to, 821.
- Trypetinae of China, key to genera, 224.
- Trypodendron* spp.—  
 and associated fungi, 378.  
 on aspen and paper birch and associated ambrosia fungi, 81.
- Tubercle bacilli—  
 avian bovine type, nature of dissociation of, 822.  
 avian, pathogenicity for cattle, 677.  
 bactericidal effect of serum from the tuberculous on, 822.  
 in hen's eggs, 108.
- Tuberculin—  
 reactions in cattle, due to human type of tubercle bacillus, 679.  
 tests, double intradermal, relation between skin measurements and character of swelling, 824.
- Tuberculosis—  
 anacoresis in, 822.  
 and tuberculin intoxication, effect of vitamin C on, 822.  
 avian, in poultry and swine, field control and eradication, 677.  
 bovine and human strains, differentiation, 679.  
 experimental, effect of sulfanilamide on, 824.  
 immunity induced in calves by B. C. G., duration of, 247.  
 immuno-serological test for, value, 822.  
 in elk, 685.  
 in guinea pig, sulfonamide treatment, 822.  
 in man as source of infection for cattle, 108.  
 in sheep, 544.  
 naturally acquired, location and type of pulmonary lesions in cattle with, 822.  
 pathology and pathogenesis in domesticated animals v. man, 395.  
 pulmonary, in cattle, location and type of lesions, 825.  
 reaccreditation of modified accredited counties in New York, 677.  
 situation, general, 677.
- Tuberose root knot, bulb treatments for, 500.
- Tularemia—  
 in beaver in Montana, 246.  
 in beaver in Wyoming, and transmission to man, 246.  
 relation to ticks, 541.  
 tick-transmitted, discussion, N.J. 228.
- Tulip—  
 beds, microclimate and growth in, 447.  
*Botrytis* blight, U.S.D.A. 500.  
 bulb diseases, control, West.Wash. 202
- Tulip—Continued.  
 failures due to fungi, U.S.D.A. 635.  
 gray bulb rot, U.S.D.A. 500.  
 virus in lilies, 71.
- Tumor grafts, resistance to in offspring of immunized rats, 43.
- Tumors—  
 avian, incidence and classification, 112.  
 benign intestinal, problem of virus etiology, 820.  
 chicken, nature of, 820.  
 infective and noninfective, differentiation between and response to radium treatment, 820.  
 mammalian, viral origin, 820.  
 mammary, in rabbits, breeding history of two types, 476.
- Tuna fish, ventral and dorsal parts, vitamin D potency, 717.
- Tung trees—  
 flowering, fruiting, yield, and growth habits, Fla. 341.  
 minor element deficiency symptoms, 780.  
 propagation, planting, and fertilizer tests, Fla. 624.  
 studies, P.R.Col. 625.  
 varieties, Ga.Coastal Plain 625.
- Tupelo leaf spot, 648.
- Turf—  
 dusting, new machine for, 87.  
 fine, establishing and maintaining, N.J. 617.  
 making, R.I. 333.
- Turkey—  
 carcasses, predicting quality, use of body measurements, Ky. 528.  
 disease control, in commercial flocks, 678.  
 eggs, size and shape, Mo. 229.  
 eggs, turning during incubation, Ky. 528.  
 meat, flavor, effect of cod-liver oil and fish meal on, 388.  
 poult mortality due to grasshopper-poison bait, 685.  
 poults, brooding, N.J. 237.  
 poults, carbon monoxide poisoning due to poorly ventilated brooders, 253.  
 poults, perosis prevention by choline, 813.  
 poults, use of proteins from different sources, Nebr. 805.
- Turkeys—  
 bone deformity of leg joints, relation to blood mineral ratios, Utah 391.  
 egg production, effect of all-night lighting, Mo. 229.  
 feeding and management, Ohio 237.  
 feeding system during finishing period, Nebr. 805.  
 field feeding of grain sorghums to, Nebr. 805.  
 four strains, variations in earliness of maturity and size and quality, Nev. 529.  
 growth and quality, effect of different cereals, Wyo. 530.

## Turkeys—Continued.

- holding for spring market, merits of, Miss. 529.
- mineral requirements, Wash. 229.
- production in Utah, Utah 535.
- raising in confinement to prevent parasitic diseases, 547.
- raising, vegetable protein concentrates for, Mo. 99.
- recessive slate plumage color of, 611.
- value of rye for, Wyo. 530.
- vitamin D requirements, Wash. 229.
- with bone deformity, percentage of calcium and inorganic phosphorus in blood serum, 534.

Turning sickness of cattle and *Trypanosoma theileri*, 397.

## Turnip—

- aphid, studies, U.S.D.A. 84.
- clubroot resistant varieties, 79.
- greens, mineral composition, comparison under various environmental conditions, S.C. 439.

Turnips, Amber Globe, vitamin A values, Tenn. 564.

Tussock moth, hickory, toxicity of nicotine to, 653.

## Twig girdler—

- notes, 662.
- Texas, notes, 662.

Twins, but not full sisters, 756.

*Tyloderma fragariae*, see Strawberry crown borer.

Typhoid, avian, see Fowl typhoid.

*Typhula* spp. associated with snow molds of cereals and grasses, 73.

Tyrosine metabolism, 230.

Udders, extreme rarity of cancerous growths in, 674.

Ugly-nest caterpillar, toxicity of nicotine to, 653.

Ultravirus, essence of, 345, 819.

## U. S. Department of Agriculture—

- Appropriation Act, 1941, 577.
- Bureau of Agricultural Economics, see Bureau of Agricultural Economics.
- Office of Experiment Stations, see Office of Experiment Stations.
- organization directory and field activities, U.S.D.A. 267.
- publications, citations to literature in, U.S.D.A. 863.

## University—

- of the Philippines, notes, 720.
- relations to forest influences research, 125.

## Urea—

- as protein supplement replacement for dairy heifers, 382.
- hydrolysis in soils by thermolabile catalysis, 312.
- ingestion, effect on nitrogen balance and energy metabolism of rats, 231.
- nitrogen, use by cattle and by swine, Hawaii 528.
- nitrogen, use by chickens, Hawaii 528.

## Urea—Continued.

- utilization by ruminants and its stability in feeds, Wis. 95.

Uredinales of New Guinea, 636.

## Uredo—

- genus, new taxonomy for, 204.
- new species, 636.

Uric acid in mixed excrements of birds, determination, 153.

## Urinary calculi—

- formation on low phosphorus diet, 129.
- in lambs, feeding experiments for study, Colo. 808.
- in wethers, failure of dietary magnesium imbalance to produce, 545.

Urinary excretion of vitamin B<sub>1</sub> by normal individuals and beriberi patients, 279.

## Urine—

- androgens excreted in by bulls, 588.
- ascorbic acid in after oral administration of vitamin C, 422.
- gelding, effect on reproductive system of rats, 614.
- thiamin in, chemical determination, stability, and form, 731.
- vitamin C in, determination, 730.

## Urocystis—

- oculta* in culture, spore germination and growth, 637.
- status of generic name, 502.

## Uromyces—

- appendiculatus*, notes, Wash. 202.
- caladii*, variations in systemic infections, 204.
- graminis*, host selection by, 503.
- new species, 636.

Uropygial gland in chickens and turkeys, characteristics of oil, Ky. 528.

Ustilaginales, additions and corrections to, 204.

## Ustilago—

- bullata*, haplolethal deficiency preventing saprophytic development, 471.
- hordei*, physiologic races in Alberta, 74.
- spp., new races, Wash. 202.
- striaeformis*, new race, studies, 73.
- vallantii* on *Bellevalia*, U.S.D.A. 201.
- zeae*, cultural and genetic studies, 348.
- zeae*, resistance of corn strains to, Iowa 68.

Utah College, notes, 288.

Utah Station, notes, 288.

## Uterus—

- effect on corpus luteum, 330.
- physical conditions governing duration of pregnancy, 47.

Vagina, artificial, for use in semen collections for artificially inseminating dairy cattle, 757.

Vaginal bleeding, prolonged and fetal resorption in Albany strain of rats, 47.

Valine, effect on hemoglobin production in anemia, 572.

*Valsa sordida*, biology, 513.

Veal production, profitability, Ga.Coastal Plain 666.

Vedalia, maintenance of supply, P.R.Col. 651.

Vegetable—

- disease-resistant varieties, progress in development, 511.
- diseases—
  - and pests, 210.
  - control, N.J. 635, Ohio 501.
  - due to *Rhizoctonia*, control, Fla. 634.
  - fixed copper fungicides for control, 511.
  - newly reported in Oregon, U.S.D.A. 344.
  - on New York market, U.S.D.A. 343.
  - seed- and soil-borne, Fla. 634.
  - virus, in Ordzhonikidze Region, 784.
- leaf blights, Fla. 634.
- seeds, deterioration and methods for prevention, U.S.D.A. 487.
- seeds, germination of treated and untreated lots, field studies for comparing, Iowa 68.
- seeds, production, N.Mex. 57.
- weevil may survive January temperature, Miss. 143.
- weevil, studies, Hawaii 517.

Vegetables—

- available iron in, 704.
- cooked in fat, calcium and phosphorus in, 273.
- copper sprays for, Mass. 783.
- cover crops for, Ark. 56.
- culture experiments, Can. 336.
- damping-off of early forcing varieties, control, Mass. 783.
- fertilizer placement methods, Fla. 625.
- fertilizers for, Ark. 56.
- Florida, composition of ash, Fla. 581.
- for panhandle area, Okla. 190.
- freezing, West.Wash. 190.
- freezing preservation, research project, Utah 412.
- frozen, bacteriological flora during spoilage, 346.
- frozen, commercial packs, microbiological studies, 154.
- frozen, enzyme activity in, 154.
- frozen, industry, N.Y.State 772.
- growth and yield, relation to soil reaction, Fla., 624.
- growth, yield, and quality, effect of green manure, Fla. 624.
- Hawaiian-grown, analyses, Hawaii 562.
- Hawaiian-grown, vapor-heat treatment for, Hawaii 772.
- importance of minor elements in, 599.
- iron and other minerals in, Fla. 581.
- irrigation, Tenn. 489.
- manure experiments with, Ark. 626.
- methods of application of fertilizer and sources of N for, Ark. 56.
- mineral constituents, effect of cooking and canning, 701.
- mineral content, Fla. 699.
- minor, Fla. 625.
- nicotinic acid in, 713.

## Vegetables—Continued.

- North Dakota-grown, sharp freezing for cold storage lockers, N.Dak. 560.
- nutrition studies, 490.
- of Florida, vitamin C content, Fla. 699.
- of Texas, iodine in, 275.
- preparation, freezing, and storage, N.Y.State 701.
- protection by wax emulsion, Tenn. 489.
- quality, relation to fertilizers high in potash, Mo. 189.
- quality, reliability of retail prices as guides to, Ohio 116.
- raw and cooked, carotenoids in, 707.
- response to phosphate fertilizer, 57.
- root knot nematode control on, Fla. 634.
- selection of genetic strains high in minerals and vitamins, Me. 411.
- spraying with fixed coppers, injurious effects, Ohio 210.
- studies, Ohio 772.
- tests in toxic orchard soils, 628.
- uptake of nutrients by, effect of soil reaction, Ark. 57.
- value of barnyard manure for, Ark. 56.

Varieties—

- adaptability, effect of mineral deficiencies, Fla. 624.
- and strains adapted to commercial use, development, Fla. 624.
- for Colorado conditions, Colo. 190.
- for peat soils, Wis. 336.
- variety tests, Can. 336, Fla. 625, Ga.Coastal Plain 625, Hawaii 488, Me. 335, Mo. 189, N.H. 772, S.C. 488, West.Wash. 190, Wyo. 489.
- vitamin B<sub>1</sub> assays, 132.
- vitamin C in, 135.
- vitamins in, N.Y.State 848.
- yields, relation to K, N.J. 625.

Vegetation—see also Flora and Plants.

- in Wah Wah Valley in Utah, effect of unrestricted grazing, 483.
- of southwestern Puerto Rico, 745.
- types in Escalante Valley, Utah, as indicators of soil conditions, U.S.D.A. 743.

Velvet ants, Neotropical genera, revision, Minn. 379.

Velvetbeans—

- after corn, winter grazing, returns from, Ga. Coastal Plain 666.
- and corn, ground v. unground mixtures, with and without molasses, for fattening steers, Fla. 666.
- culture experiments, Ga.Coastal Plain 617.
- variety tests, Ga.Coastal Plain 617.

Venturia—

- inaequalis*, variability and inheritance in, 349.
- pirina*, heterothallism in, 349.

Vernalization—see also specific crops.

- and growth-phase concept, 35.

*Verticillium*—

- disease on elm and maple, control, Ohio 501.
- isolations in Illinois, U.S.D.A. 201.
- wilt of elm, U.S.D.A. 782.

*Vespula arenaria*, new parthenogenetic dermestid beetle taken from nest of, 226.

## Vetch—

- as cover crop for apple orchards, Ark. 56.
- bruchid control by fumigation of seed, U.S.D.A. 216, 227.
- bruchid, studies, U.S.D.A. 84.
- downy mildew in Oregon, U.S.D.A. 344.
- nodule bacteria, longevity, factors affecting, 55.
- placement of dolomite, superphosphate, and basic slag for, 761.
- root rot and associated fungi, 780.
- root rot, notes, 782.
- seed, fumigation for vetch bruchid, U.S.D.A. 216, 227.
- stem scald and leaf spot, 641.

Veterinary—*see also* Animal diseases.

- medicine, experiment station research in, editorial, 433.

Vial holder, description, 588.

*Vibrio fetus* recovery from aborted bovine fetuses and role in abortion, 678.

*Villadia*—

- elongata* n.comb., notes, 169.
- history and status of genus, 169.

Villages, agricultural, changes in social organization, 124.

## Virginia—

- Polytechnic Institute, notes, 575.
- Station, notes, 575.

Virgins-bower, processing seed of, U.S.D.A. 618.

## Virus—

- action, nature and mechanism, 345.
- and insect vectors, relations, 345.
- disease research, new views in, 205.
- diseases with cultivated plants, 205.
- forms as primitive stages in bacterial life cycles, comparative morphology, 345.
- mutant relations, acquired-immunity test and limitations for establishing, 345.
- mutants, studies, 345.

## Viruses—

- and bacteriophages, ultracentrifugation and serological reactions, comparison, 345.
- and carcinogenic chemicals, 820.
- and nonvector insects, 345.
- biochemistry, 745.
- cultivability by different methods of tissue culture, 345, 819.
- different within same host, forms and types of X-bodies formed by, 346, 820.
- fibroma-myxoma spectrum of, 820.
- in Hawaii, and hosts, check list, U.S.D.A. 345.
- nature of, 345, 394, 819.
- neoplastic, as conditioned by age of host, effect, 820.

## Viruses—Continued.

- phytopathogenic, nomenclature and classification, 345.
- properties of, 345.
- recent advances in study, 204.

## Vitamin A—

- absorption by dogs, 667.
- accumulation in egg yolk and in liver of chick, 416.
- action on experimentally produced skin wounds, 425.
- activity in pea cannery refuse, West. Wash. 238.
- and A<sub>2</sub>, comparison by distillation, 729.
- and butter color, 102.
- and carotene in milk, determination, 668.
- and carotene, relation to serum lipids, 564.
- and dehydrated alfalfa hay, relative efficiency, 675.
- crystalline esters of, preparation, properties, and potency, 297.
- deficiency—
  - and cerebrospinal fluid pressure, 675.
  - detecting, adaptometer as instrument for, Mass. 843.
  - effect on gastrointestinal tract, 848.
  - effect on structure of gonads and pituitary gland, Ohio 535.
  - effect on vitamin C in the bovine, 675.
  - effect on young bulls, 675.
  - in dogs and rabbits, hematology of, 685.
  - in normal and tuberculous persons, biophotometer test, 417.
  - reliability of dark-adaptation test for, 277.
- deficient rats, changes in pituitary glands of, Ohio 184.
- determination by destructive irradiation, 728.
- determination with photoelectric colorimeter, 729.
- determinations by rat growth tests, 416.
- effect on thrombocytes and bone marrow, 709.
- effect on urea clearance in rat, 565.
- in blood, determination, 297.
- in blood during fever, 417.
- in blood of normal adults, effect of depletion diet, 708.
- in liver oil of snapper shark, 130.
- in livers of healthy dogs, 530.
- in milk, effect of feeding pea vine silage, 815.
- in nutrition of dairy cattle, 99.
- in nuts, 707.
- in soybeans and cowpeas, 531.
- in tomato juice commercially canned, 416.
- nutritional status for, biophotometer test as index, 848.
- photocolorimetric determination in human plasma, 708.

## Vitamin A—Continued.

picture in serum, pathogenic and diagnostic significance, 709.  
 potency, effect of treated fats on, 131.  
 preparations, purity and activity of, 728.  
 recent research in, 415.

## requirements—

for growth of dairy cattle, 391.  
 in infancy, as determined by dark adaptation, 849.  
 of adults, 278, 707.  
 of chickens when fed as carotene, Tex. 390.  
 of dairy cows for high vitamin A value of butter, 675.  
 of poultry, 385.

rich concentrate from butter, preparation and determination in Pulfrich photometer, 727.  
 values of foods, effects of cooking and storage, Tenn. 564.

Vitamin A<sub>2</sub> cyclization, 730.

## Vitamin—

antihemorrhagic *see* Vitamin K.  
 antineuritic, *see* Vitamin B<sub>1</sub>.  
 antirachitic, *see* Vitamin D.

Vitamin B<sub>1</sub>—*see also* Thiamin.

action in animal experiments, 418.  
 and cocarboxylase in organs, determination, 712.  
 and manganese, metabolic interdependence, 565.  
 as growth regulating substance for green plants, N.J. 597.  
 complex nature of, Wis. 126.  
 complex, significance in human pathology, 425.  
 deficiencies, clinical neurologic aspects, 711.  
 deficiency in animals and man, blood picture and symptoms, 668.  
 deficient rats, glycogen in liver of, 712.  
 determination, 11.  
 determination in pure preparations, food, and urine, 279.  
 diphosphate in blood, 419, 420.  
 from pyrimidine and thiazole portions by animal tissues, synthesis, 850.  
 in cerebrospinal fluid, estimation, 420.  
 in foods, bradycardia method of determining, 419.  
 in nuts, 707.  
 in royal jelly and bee bread, 378.  
 in soybeans and cowpeas, 531.  
 in wheat, flour, and bread, 417.  
 injection studies, 566.  
 metabolism, 279.  
 metabolism in rats studied by *Drosophila* sterile culture method, 418.  
 metabolism, usefulness of thiochrome procedure for study, 566.  
 need for addition to staple American foods, 711.  
 new chemistry of, and control of beriberi, 425.  
 new color reaction for, 443.

Vitamin B<sub>1</sub>—Continued.

of blood in health and disease, 280.  
 of foods in terms of crystalline thiamin, U.S.D.A. 131.  
 requirement, 425.  
 requirements and thyroid activity, 280.  
 therapeutic uses, 417.  
 utilization, endogenous disturbance in, 419.

Vitamin B<sub>2</sub> complex, yeast eluate factor, 711.Vitamin B<sub>6</sub>—*see also* Pyridoxin.

and factor U, relation, 383.  
 and skin lesions in rats, 713.  
 and unsaturated fatty acids, supplementary relations, 668.  
 deficiency in rat, histopathology of, 568.  
 importance in nutrition of dogs, 236.  
 in New Mexico pinto beans, effect of cooking, 422, N.Mex. 126, 421.  
 isolation and synthesis, 422.  
 preparation from natural sources, 730.  
 requirement by chicks for maintenance and growth, 534.  
 requirement in human nutrition, 281.  
 studies, Wis. 126.

## Vitamin B complex—

components, requirements for lactation, Ark. 127.  
 deficiency, effect on gastrointestinal tract, 848.  
 deficient rats, carbohydrate, fat, and protein appetite, 132.  
 factors concerned with gastrointestinal function, 567.  
 factors, importance in nutrition of dogs, 236.  
 factors in meat and meat products, 276.  
 in rumen of cow, synthesis of members, 668.  
 new anti-gray factor of, 667.  
 recent research in, 415.  
 relation to animal nutrition, 383.  
 relation to nutrition of chick and pigeon, 385.  
 requirements of rats, 280.  
 role in weight restoration in pigeon, 667.

Vitamin C—*see also* Ascorbic acid.

and aging eyes, 138.  
 and carotene in forage crops, 745.  
 consumption, effect of increase in vitamins B<sub>1</sub> and B<sub>2</sub>, 135.  
 content of Florida fruits and vegetables, Fla. 699.  
 deficiency, effect on gastrointestinal tract, 848.  
 deficiency, relation to nutritional anemia, 138.  
 destruction in kitchenette sauerkraut on cooking, Wis. 126.  
 effect on lead poisoning, 854.  
 for sterile or partially sterile sires, 674.  
 free diet of a man for 160 days, effects, 715.  
 in apples, effect of light, 423.  
 in black currant sirup, photochemical decomposition, 715.

## Vitamin C—Continued.

- in blood and fever metabolism, relation, 570.
  - in blood, on diets rich and poor in vitamin C, 716.
  - in canned tomato juice, effect of presence of iron and tin, Ark. 126.
  - in D'Anjou pears, Wash. 268.
  - in frozen-pack peas, factors affecting, Wash. 268.
  - in frozen raspberries, varietal differences, Wash. 268.
  - in fruits and fruit products, vegetables, and other plants, 715.
  - in fruits and vegetables, N.Y.State 848.
  - in fungus extracts, 598.
  - in milk, effect of feeding cod-liver oil, 673.
  - in nutrition of dairy cattle, 675.
  - in rats, effect of copper and various organic substances, 853.
  - in tomatoes, relation to acidity, 854.
  - in tonsils, and relation to their protective function, 422.
  - in urine, determination, 730.
  - in vegetables, 135.
  - metabolism, effect of nicotine on, 716.
  - minimum requirement by normal person, Utah, 569.
  - nutrition, determination by skin test, 569.
  - recent research in, 415.
  - recovery from human bladder, 569.
  - requirement, 425.
  - requirements of college women, Wash. 268.
  - synthesis and excretion, acceleration by feeding known organic compounds to rats, 281.
  - synthesis and excretion by rats, 281.
- Vitamin, chick antidermatitis, identity, Wis. 95.
- Vitamin D—*see also* Vitamin, antirachitic.
- activity, biological estimation, effect of phosphorus on, 856.
  - activity of cacao shell meal, Mass. 813.
  - and radioactive phosphorus, fed to rachitic rats, 284.
  - bio-assays, 571, Mass. 843.
  - deficiency, effect on gastrointestinal tract, 848.
  - deficiency of dairy cattle, relation to blood plasma magnesium, 675.
  - for rats, cocoa shell meal as source, Mass. 843.
  - in liver oil of snapper shark, 130.
  - in salmon meal, effect of methods of preparation and storage, Wash. 229.
  - potency of fish and fish products, 717.
  - quantitative estimation with growing chicks, 385.
  - recent research in, 415.
  - requirements of turkeys, Wash. 229.
  - synthesis of, studies, 585.
- Vitamin D<sub>2</sub> and D<sub>3</sub> in infantile rickets, comparison of therapeutic efficiency, 856.

## Vitamin E—

- activity of  $\alpha$ -tocoquinone, 284.
  - bibliography, 423.
  - deficiency, effect on gastrointestinal tract, 848.
  - deficiency, prolonged in rats, effect, 231.
  - injections for difficult breeding in dairy cows, 391.
  - potency of feeds, 675.
  - prevention of muscular dystrophy in guinea pigs with, 669.
  - recent research in, 415.
- Vitamin G. *see* Riboflavin.
- Vitamin K—
- activity—
- in benzoquinone series, 736.
  - in simple compounds, 14.
  - of naphthoquinones, 14, 585.
  - of quinones, 15, 16.
  - of 2-methyl-1,4-naphthoquinone, 284.
  - biological assay, 12.
  - biological assay, and application to several quinone compounds, 423.
  - choleic acid of, effect on prothrombin levels of bile fistula rats, 572.
  - clinical and experimental studies, 423.
  - concentrates, color reactions in, 14.
  - control of prothrombin deficiency in obstructive jaundice by, 424.
  - deficiency, effect on gastrointestinal tract, 848.
  - deficiency in normal and sick infants, 285.
  - feeding for low infant prothrombin levels, 424.
  - from alfalfa, 298.
  - isolation from alfalfa, and history of its discovery, 733.
  - nutritional deficiency of, in man, 285.
  - outline of research on, 856.
  - physicochemical concentration, 445.
  - potencies of synthetic compounds, 857.
  - progress in research of, 284.
  - properties, 386.
  - recent research in, 415.
  - therapy in obstructive jaundice, 285.
- Vitamin K<sub>1</sub>—
- and 2-methyl-3-phytyl-1,4-naphthoquinone, identity, 586, 587.
  - blue alkali salt of, 734.
  - constitution and synthesis, 586, 734.
  - derivatives of, 13, 735.
  - identification, 734.
  - isolation, 13, 733.
  - K<sub>2</sub>, and related compounds, ultraviolet absorption, 736.
  - natural and synthetic, 139.
  - nor-, and related compounds, 735.
  - preparations and 2-methyl-1,4-naphthoquinone, antihemorrhagic activity, comparison, 736.
  - structure, 15.
  - synthesis, 735.
  - synthetic approach to, 586.

- Vitamin K<sub>2</sub>—  
 derivatives of, 13.  
 isolation, 13.  
 isolation from commercial sardine meal, 787.
- Vitamin nutrition, advances in, 95, 382.
- Vitamin P, a capillary fragility control factor, 857.
- Vitamin studies, development of highly purified diets for use in, Mo. 229.
- Vitamins—  
 and related substances in yeast, 707.  
 deficiency of, *see* Avitaminosis and specific vitamins.  
 effect on growth of crown gall, 346.  
 in animal organs, Wis. 126.  
 in cabbage and onions, effect of winter storage, Mont. 276.  
 in wheat, 707.  
 recent research in, 415.  
 water-soluble, site of action of, 711.
- Vitis*, species and hybrids, characterization, 169.
- Vitula edmundsii* in honeybee combs, 94.
- Wall construction, relation to moisture accumulation in fill-type insulation, Iowa 550.
- Walnut—  
 caterpillar and its natural enemies, Mo. 798.  
 caterpillar, toxicity of nicotine to, 653.  
 growth, effect of root temperature, 62.  
 trees, lumber and nut production, Ark. 65.  
 trees, young, importance of soil pore space to, N.Y.State 194.
- Walnuts—  
 black, judging schedule for, 631.  
 black varieties, shuck : nut ratio in, 631.  
 variety tests, N.Mex. 57.  
 vitamins A and B<sub>1</sub> in, 707.
- Warblers of New Jersey, transient, N.J. 650.
- Wartime profits, Uruguay imposes tax on, U.S.D.A. 120.
- Washington College, notes, 432, 719.
- Washington Station, notes, 144, 432, 719.
- Washington Station, report, 287.
- Wasp, small pteromalid, biology, 227.
- Wasps, Neotropical mutillid, revision of genera, Minn. 379.
- Water—  
 absorption, decreased, by plants in poorly aerated media, causes, 600.  
 city, of Texas areas, iodine in, 275.  
 conservation, contour farming for, Iowa 549.  
 control, studies, Fla. 687.  
 culture, *see* Plants, culture.  
 duty of, *see* Irrigation water.  
 filtration by oysters, N.J. 651.  
 heating for livestock, electrical, Nebr. 828.  
 iodine determination in, 300.  
 irrigation, *see* Irrigation water.  
 mineral composition, Fla. 699.  
 movement in soil, N.J. 592.  
 of Big Horn River, Wyo. 454.
- Water—Continued.  
 pasture, studies, Fla. 616.  
 resources and geology of Harney Basin, Oregon, 402.  
 resources of Colorado, 21.  
 resources of river basins in Nevada, inventory and history, Nev. 548.  
 shortage predicted unless abundance of precipitation before May 1, Utah 304.  
 supply of United States, Pacific slope basins in Washington and upper Columbia River Basin, 402.  
 systems, automatic electrical, Nebr. 828.
- Waterfowl, danger of lead shot to, 515.
- Watering trough, electrically heated automatic, description, 114.
- Watermelon—  
 diseases, control, Fla. 634.  
 wilt-resistant varieties, breeding, 780, Ga.Coastal Plain 625.
- Watermelons—  
 culture experiments, Ga.Coastal Plain 625.  
 fertilizer experiments, Ga.Coastal Plain 625.  
 fruit setting, 774.  
 manure experiments with, Ark. 626.  
 thinning of fruits, Ark. 57.  
 total soluble solids and sugars in varieties, Calif. 337.  
 varieties, Mo. 190.  
 variety tests, Ga.Coastal Plain 625, S.C. 488.  
 Winter Queen, rot caused by *Phytophthora capsici*, 512.
- Watershed protection, U.S.D.A. 497.
- Wax moth—  
 length of development, 798.  
 proxate, methyl bromide, and chlorosol as fumigants for, tests, 222.
- Weather—*see also* Meteorological observations and Meteorology.  
 changes, relation to sunspot changes, 447.  
 conditions for 1937, summary, Ohio 446.  
 data, Ga.Coastal Plain 589.  
 factors, relation to wheat yields, U.S.D.A. 591.  
 forecast and frost warning service of Florida Station, Fla. 589.  
 forecasting, long-range, recent Australian papers on, 738.  
 station, unmanned, radio equipment for, 738.  
 ten years of large-scale studies, 738.
- Webworm—  
 fall, easily parasitized by *Nosema bombycis*, 525.  
 fall, insecticides and spreaders for, 367.  
 Hawaiian beetle, control, Va.Truck 369.
- Webworms, sod—  
 control in lawns and putting greens, Wis. 334.  
 in pasture and cultivated fields, Iowa 85.
- Weed problem of Upper Peninsula, Mich. 487.

Weed seed in soil, chloropicrin for killing.

Ohio 480.

Weeds—

control, Nev. 481, Wis. 333.

control activities and accomplishments under State program, Utah 335.

control by cultivation, Miss. 617.

control in hayfields, Wis. 333.

control in lawns, tests of Sinox for, Ohio 480.

control, new selective spray for, Calif. 55.

duration of effects of renovation in control of, 55.

eradication in lawns, Tenn. 481.

eradication in tame pastures, Fla. 616.

interception of rainfall by, 590.

of cranberry bogs, control, Wash. 185, of United States, descriptions, 623.

Weevils from eggs in raw materials, 803.

Western Washington Station, report, 287.

Wheat—

and corn acreages, response to changes in ratio of corn price to wheat price, Iowa 116.

and wild rye hybrid grass, claims regarding, without foundation, Colo. 863.

as nurse crop with crested wheatgrass, Wash. 185.

average yields per acre in Ohio, Ohio 257.

bran v. alfalfa hay v. cottonseed meal as protein supplements to silage in winter rations for calves, 384.

breeding, Mo. 185, Nebr. 759, Wash. 185.

breeding for disease resistance, Tenn. 501.

bulk, handling in Australia, 695.

bunt, *see* Wheat smut, stinking.

*Cercospora* foot rot of, U.S.D.A. 783.

cold resistance, factors affecting, Nebr. 760.

composition, effect of variety, season, and green manures, 770.

corn and hay in rotation, residual effects of limestone, Ky. 479.

culture experiments, Ga.Coastal Plain 617, Wash. 185.

decomposition, transformation of phosphorus during, 313.

diseases, losses from, U.S.D.A. 201.

diseases, problems, 503.

effect of acreage on returns on dry farms, Wyo. 552.

effect of awns on kernal weight, test weight, and yield, 756.

fertilizer experiments, Del. 48, Wash. 185, Wyo. 481.

flag smut, seed disinfection tests, irregular results in, 350.

flour, *see* Flour.

from Saskatchewan, selenium in, 727.

germ oil injections for difficult breeding in dairy cows, 391.

germ oils, preventive effect in nutritional muscular dystrophy, 382.

Wheat—Continued.

glume blotch in West Virginia, U.S.D.A. 783.

gluten thermal fractionation, amino acid in proteins resulting from, 293.

hard red spring varieties, comparative data, 702.

Hope, origin and history, 335.

improvement, Colo. 754.

in farm storages, ventilation methods, U.S.D.A. 687.

laboratory, Federal, U.S.D.A. 770.

leaf rust, studies, 503.

loose smut—

control by vacuum treatment, 346.

infection, reaction of winter varieties to, U.S.D.A. 503.

machine for control, Okla. 74.

notes, U.S.D.A. 782.

spores, dissemination, 503.

meal-time-fermentation test, 295.

mills, Allis-Chalmers and Buhler automatic, comparison, 295.

mineral constituents and vitamins, 707.

minerals of, relation to human and animal nutrition, Utah 273.

mosaic in Voronezh Province, 784.

New Zealand aims at self-sufficiency in, U.S.D.A. 120.

offgrade, in Oklahoma, causes, Okla 486.

phosphorus absorption by, effect of lime and phosphorus applications, 173.

planting tests, Nebr. 760.

*Pythium* root rot, effects of soil amendments, 640.

quality and cold resistance in, inheritance and interrelations, U.S.D.A. 770.

response to fallow and other tillage practices, Nebr. 760.

rusts—*see also* Cereal rusts, Rusts, Wheat leaf rust, and Wheat stem rust, in Indiana and Kansas, U.S.D.A. 783.

sagging of grain heads and straw breakage, Ohio 548.

scab, reports on, U.S.D.A. 782.

scab, studies, 503.

seed damaged by formaldehyde, germination and early growth, effect of naphthylacetic acid on, 750.

seed treatment, 503.

seedlings, growth, effect of low concentrations of selenium, 748.

shorts for feeding pigs, Miss. 529.

smut, stinking—

from Afghanistan, U.S.D.A. 201.

Great Plains uniform nursery, summary of data, U.S.D.A. 503.

infection, effects of soil type, soil sterilization, and soil reaction, 350.

inheritance of resistance to, Wash. 202.

initiation of infection by, 639.

losses from in United States, 350.

## Wheat—Continued.

- smut, stinking—continued.
  - on winter wheat, seed treatment, Nebr. 783.
  - uniform nurseries in western region in 1939, results from, U.S.D.A. 503.
  - uniform nursery, 503.
- smuts, new races, Wash. 202.
- soybeans as green manure v. sodium nitrate as top dressing for, N.J. 618.
- spring—
  - culture experiments, Wyo. 481.
  - outstanding varieties, N.Dak. 49.
  - varieties recommended, Nebr. 618.
  - variety tests, Nebr. 618, 759, Wash. 185, Wyo. 481.
  - yield, relation to depth of soil moisture at seeding time, U.S.D.A. 622.
  - yields and other data, Nebr. 618.
  - yields, effect of rainfall and evaporation, 159.
- spring-sown, variety tests, N.Mex. 48.
- starch, studies, 9.
- stem rust—
  - epidemiology in Mexico, 206.
  - immune varieties, 207.
  - in crosses involving Iumillo, relation between seedling and mature plant reaction to, 639.
  - in Texas, U.S.D.A. 344.
  - physiologic strains, distribution and importance, 503.
  - resistance and reaction to black chaff, genetic study, 41.
  - severe, in California, U.S.D.A. 635.
  - unseasonable germination of teliospores, 640.
- straw, whole and cut, as bedding material, absorptive capacity, 535.
- surface v. furrow drilling, Nebr. 760.
- Thorne, merits, Ohio 480.
- top dressing, effects of weather on returns, Ohio 480.
- varieties, hard red spring, comparative performance, N.Dak. 55.
- varieties, improved, registration, 55.
- varieties, new, production at Phyto-technical Institute of Santa Catalina, 472.
- variety tests, Ark. 48, Ga.Coastal Plain 617 Me. 333, Mo. 185, N.J. 617, S.C. 480, Tenn. 481.
- vitamin B<sub>1</sub> in, 417.
- whole, proteins, biological value, 530.
- winter—
  - culture experiments, Wyo. 481.
  - nematodes injuring, 362.
  - outstanding varieties, N.Dak. 49.
  - scab destructive in Atlantic Coast States, U.S.D.A. 635.
  - scab resistance in, U.S.D.A. 770.
  - soft, disease resistance in, 785, U.S.D.A. 770.

## Wheat—Continued.

- winter—continued.
  - varieties in Nebraska, Nebr. 622.
  - variety tests, Nebr. 759, Wash. 185, Wyo. 481.
  - winter-sown, variety tests, N.Mex. 48.
  - yields, relation to weather factors, U.S.D.A. 591.
- Wheatgrass—
  - Bluebunch, processing seed of, U.S.D.A. 618.
  - bunch, effect of grazing, 763.
  - crested—
    - culture experiments, Wash. 185, Wyo. 481.
    - Fairway, leaf pigment concentration, relation to yield in, 764.
    - nutritive value, Wash. 229.
    - seed responses, effect of maturity at time of harvest, 53.
    - yield, effect of shelterbelt, Wyo. 481.

## Whey—

- byproducts, utilization, Mass. 814.
- dried, feeding value, 639.
- from casein manufacture, utilization, 241.
- mixtures which dry satisfactorily on atmospheric drum drier, properties, 674.
- soluble proteins, denaturation by heat, 241.

White ants, *see* Termites.

## White grubs—

- biology and control, Ky. 800.
- control in lawns and putting greens, Wis. 334.
- distribution, Ky. 518.
- identification, 516.
- in bluegrass pastures, 55.
- in eastern Canada, control, 801.
- in forest nurseries of the Carolinas, U.S.D.A. 216.
- problem of, papers, 516.
- studies, Iowa 85.

White pine blister rust—*see also* Ribes eradication.

- cankers, mycelial extent beyond visible canker margins, 647.
- control, Ohio 501, U.S.D.A. 68.
- resistance, selection for, Wis. 344.
- studies, 360, 500.

## White pine, western, current season's shoots resistant to blister rust infection, 361.

## Whiteflies, control with lime-sulfur, Fla. 650.

## Whitefly—

- azalea, notes, Ala. 519.
- citrus, on Satsuma orange, control, Ala. 794.

## White-fringed beetle—

- adult activities, 83.
- and natural enemies, survey in South America, U.S.D.A. 216.
- control with methyl bromide, 663.
- studies, Ky. 518, U.S.D.A. 84.

- Whitetop—  
 control, Nev. 481.  
 seed, spread in droppings of grazing cattle, Nev. 189.
- Whitewash as repellent for potato leafhoppers on citrus, 87.
- Wild life area, insect abundance, 517.
- Williams, V. R., prizes in memory of, 720.
- Wind—  
 direction recorder, portable, description, U.S.D.A. 18, 83.  
 erosion and sand dune control, list of references, U.S.D.A. 549.  
 on southern Great Plains, relation to crops, U.S.D.A. 165.
- Windbreaks, *see* Shelterbelt.
- Winery pomace, digestibility, Calif. 532.
- Wireworm—  
 eastern field, Conn.[New Haven] 517.  
 Pacific coast, studies, U.S.D.A. 84.  
 prairie grain, control, relation to summer-fallow, N.Dak. 226.  
 sugar beet, studies, U.S.D.A. 84.
- Wireworms—  
 control with dichloroethyl ether, 377.  
 injury to potatoes, Conn.[New Haven] 652.  
 injury to tobacco from, control, 376, Ky. 518.  
 studies, Fla. 651, Wash. 217.
- Wisconsin Station, notes, 719.
- Wisconsin Station, report, 143, 430.
- Wisconsin University, notes, 144, 719.
- Witches'-broom on Virginia pine, 215.
- Women—  
 college, mineral and nitrogen metabolism, Nebr. 845.  
 college students, diets of, 270.  
 college, vitamin C requirements, Wash. 268.  
 farm, means of improving economic status of family, Miss. 861.  
 Indiana University, basal metabolism, 127.
- Wood—*see also* Lumber and Timber.  
 and wood products, mechanical properties and structural uses, list of publications, U.S.D.A. 403.  
 lignin distribution in, methods for demonstrating, 605.  
 pink stain, caused by *Geotrichum* sp., 513.  
 plastics, adhesion in, origin and mechanism, 303.  
 pulp, simultaneous production with alcohols, oils, and resins by conversion of noncellulosic constituents of wood, U.S.D.A. 737.  
 swelling and crushing strength, effect of chemicals on, 828.
- Woodcocks, banding, on Pennsylvania singing grounds, 793.
- Woodlands, farm, effect of grazing on soil and climatic conditions, 200.
- Woody—  
 ornamental plants, fertilization, Ohio 778.  
 plants of Iowa, keys, 169.  
 plants, seedlings and cuttings, control of damping-off of, Mass. 783.  
 plants, virus diseases in, methods requisite for proving, 346.  
 tissues, isolated, oxygen consumption, 601.
- Wool—  
 and lamb production, costs and returns from, Ky. 551.  
 black fibers in, inheritance, Ark. 43.  
 fibers, fineness, estimating accuracy of two methods compared, 573.  
 fibers from five breeds of sheep, diameter relations, 717.  
 fineness and cross-sectional variability, estimating, U.S.D.A. 141.  
 raw, compressed volume as indicator of yield, 381.  
 sampling methods, factors affecting, Wyo. 530.  
 shrinkage, factors affecting, Wyo. 530.  
 shrinkproofing, developments in methods, 860.  
 value, based on grease weights unreliable, Utah 532.
- Woolen mill, quality control in, 717.
- Woolly aphid, *see* Apple aphid, woolly.
- Worms, removing from alimentary canal of cattle, efficiency of nonconditioned phenothiazine against, 543.
- Wound hormones—  
 intercellular, produced by toxic effect of heteroauxin, 172.  
 of plants, structure and synthesis of traumatin, 172.
- Wyoming Station, notes, 719.
- Wyoming Station, report, 574.
- Xanthophyll—  
 leaf, chemistry and functions, 601.  
 production in plants, seasonal variations in, 317.  
 role in poultry ration, 667.
- Xordies indicatorius*, parasitic on *Leiopus nebulosus*, 379.
- X-ray diffraction analysis and application to study of plant constituents, 598.
- Xylose as a cataractogenic agent, 573.
- Yam diseases, control, P.R.Col. 635.
- Yams, staking test, P.R.Col. 617.
- Yautias—  
 fertilizer experiments, P.R.Col. 617.  
 seed piece test, P.R.Col. 617.
- Yeast—  
 baker's, effect of saturated fatty acids on, 470.  
 cells, development, 468.  
 cells, time lapse motion photomicrographic studies, 468.  
 compressed, for bread making, preservation by freezing, Wyo. 562.

## Yeast—Continued.

- fermentation rate, factors affecting, 468.
  - irradiated, for poultry, Wis. 382.
  - minerals in, spectroscopic analysis, 726.
  - peptidase, chemically pure, 467.
  - role in fermentation of tobacco, 486.
  - vitamins and related substances in, 707.
- Yeasts—
- asporogenous, forming a pseudomycelium, taxonomy, 467.
  - film-forming, studies, 39.
  - sexuality, developmental cycle, and phylogeny, 39.
- Yellow-fever virus, use of ultracentrifuge in study, 819.
- Yellow mite, notes, Ala. 519.
- Yellow-spot virus, identity with spotted-wilt virus, 797.
- Yolk sac of newly hatched chick, lipid content and changes during first month of life, 390.

Youngberry culture, Hawaii 488.

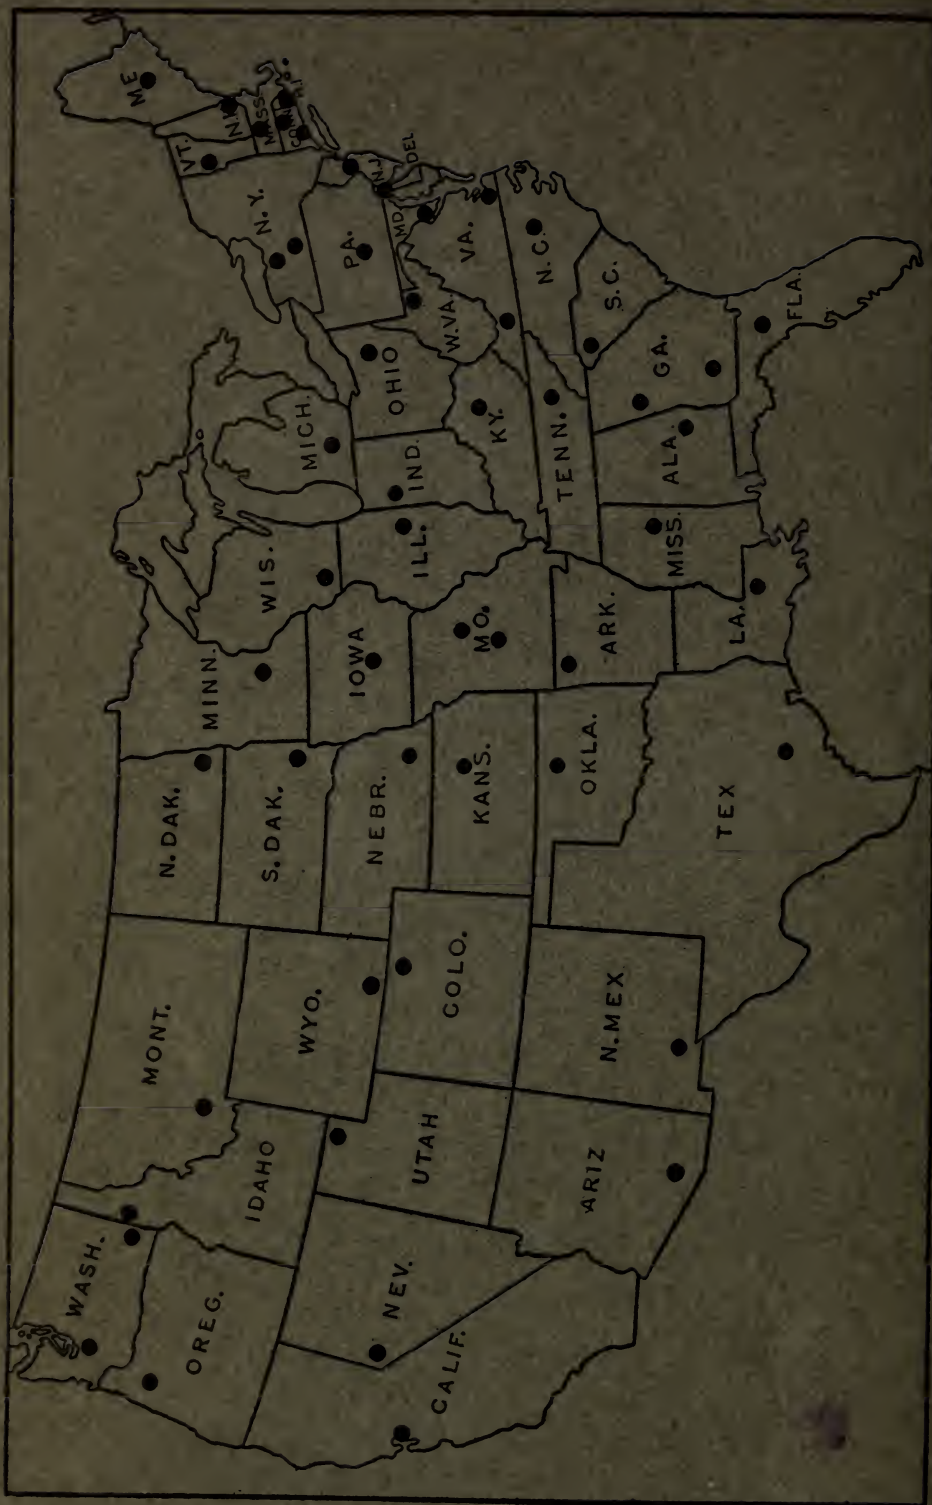

- Zea-Euchlaena* hybrids, inheritance of intergeneric differences in, 42.
- Zebra caterpillar, studies, U.S.D.A. 84.
- Zein hydrolysates, nutritive value, 667.
- Zephiran for treatment of foot rot in cattle, 543.
- Zinc—
- availability in soils, effect of pH, 166.
  - chemical status in soil with methods of analysis, Calif. 31.
  - deficiency, effect on tomato roots, 644.
  - in foods, determination methods, Mass. 725.
  - report on, Mass. 862.
  - role in animal nutrition, Wis. 95.
- Zinnia powdery mildew, control, Fla. 634.
- Zinnias, types, characteristics, Pa. 64.
- Zizania aquatica*, botany and history, 597.
- Zonocerus variegatus*, notes, 219.

HEADQUARTERS OF STATE AGRICULTURAL EXPERIMENT STATIONS
