for  
**MONTANA & NORTHERN WYOMING**

UNITED STATES DEPARTMENT of AGRICULTURE...SOIL CONSERVATION SERVICE,  
and  
MONTANA AGRICULTURAL EXPERIMENT STATION

Data included in this report were obtained by the agencies named above in cooperation with the Bureau of Reclamation, U.S. Forest Service, U.S. Geological Survey, National Park Service, State Engineers of Montana and Wyoming and other Federal, State, and private organizations.

AS OF  
**FEB. 1, 1962**

# UNITED STATES DEPARTMENT OF AGRICULTURE - SOIL CONSERVATION SERVICE

## *To Recipients of Cooperative Snow Survey and Water Supply Forecast Reports:*

The climate of the cultivated and populated areas of the West is characterized by relatively dry summer months. Such precipitation as occurs falls mostly in the winter and early spring months when it is of little immediate benefit to growing crops. Fortunately, most of this precipitation falls as mountain snow which stays on the ground for months, melting later to sustain streamflow during the period of greatest demand during late spring and summer. Thus, nature provides in mountain snow an imposing water storage facility.

The amount of water stored in mountain snow varies from place to place as well as from year to year and accordingly, so does the runoff of the streams. The best seasonal management of variable western water supplies results from fore-knowledge of the runoff.

A snow survey consists of a series of about ten samples taken with specially designed snow sampling equipment along a permanently marked line, about 1000 feet in length, called a snow course. The use of snow sampling equipment provides snow depth and water equivalent values for each sampling point. The average of these values is reported as the snow survey measurement for a snow course.

Snow surveys are made monthly or semi-monthly beginning in January or February and continue through the snow season until April, May or June. Currently more than 1400 western snow courses are measured each year. These measurements furnish the key data for water supply forecasts.

By relating snow survey measurements taken over a period of years to spring-summer runoff during the same period, relationships have been developed which make it possible to forecast seasonal runoff several months in advance of occurrence. In order to make a forecast, once a forecast relationship has been developed, the maximum snow water content at previously selected key snow courses is usually entered in the forecast relationship. More accurate forecasts are often obtained when other factors such as soil moisture, base flow and spring precipitation are considered and included in the forecast relationships.

Listed below are the Federal-State-Private Cooperative Snow Survey and Water Supply Forecast reports available for the West which contain detailed information on snow survey measurements, streamflow forecasts, reservoir storage, soil moisture and other guide data to water management and conservation decisions.

MONTANA  
WATER SUPPLY OUTLOOK  
as of  
February 1, 1962

\* \* \* \* \*  
\* The water supply outlook for the coming \*  
\* irrigation season is much better than \*  
\* last year and is near to slightly above \*  
\* the 15-year average. \*  
\* \* \* \* \*

The present snowpack on the headwaters of the Yellowstone, Madison and Jefferson rivers is almost twice that of last February 1 and 15 to 20 percent above the 1943-57 average. In the Gallatin drainage, the snowpack is 90 percent greater than on February 1 last year and 140 percent of the 15-year average.

Two snow courses measured in the Bitterroot drainage are 40 percent above last year and 5 percent below average.

The snowpack on headwaters of the Flathead and Clark Fork drainage is 70 to 80 percent greater than last year and 15 to 20 percent above average.

The Kootenai drainage in Canada has a snowpack almost equal to last year's and is very near average.

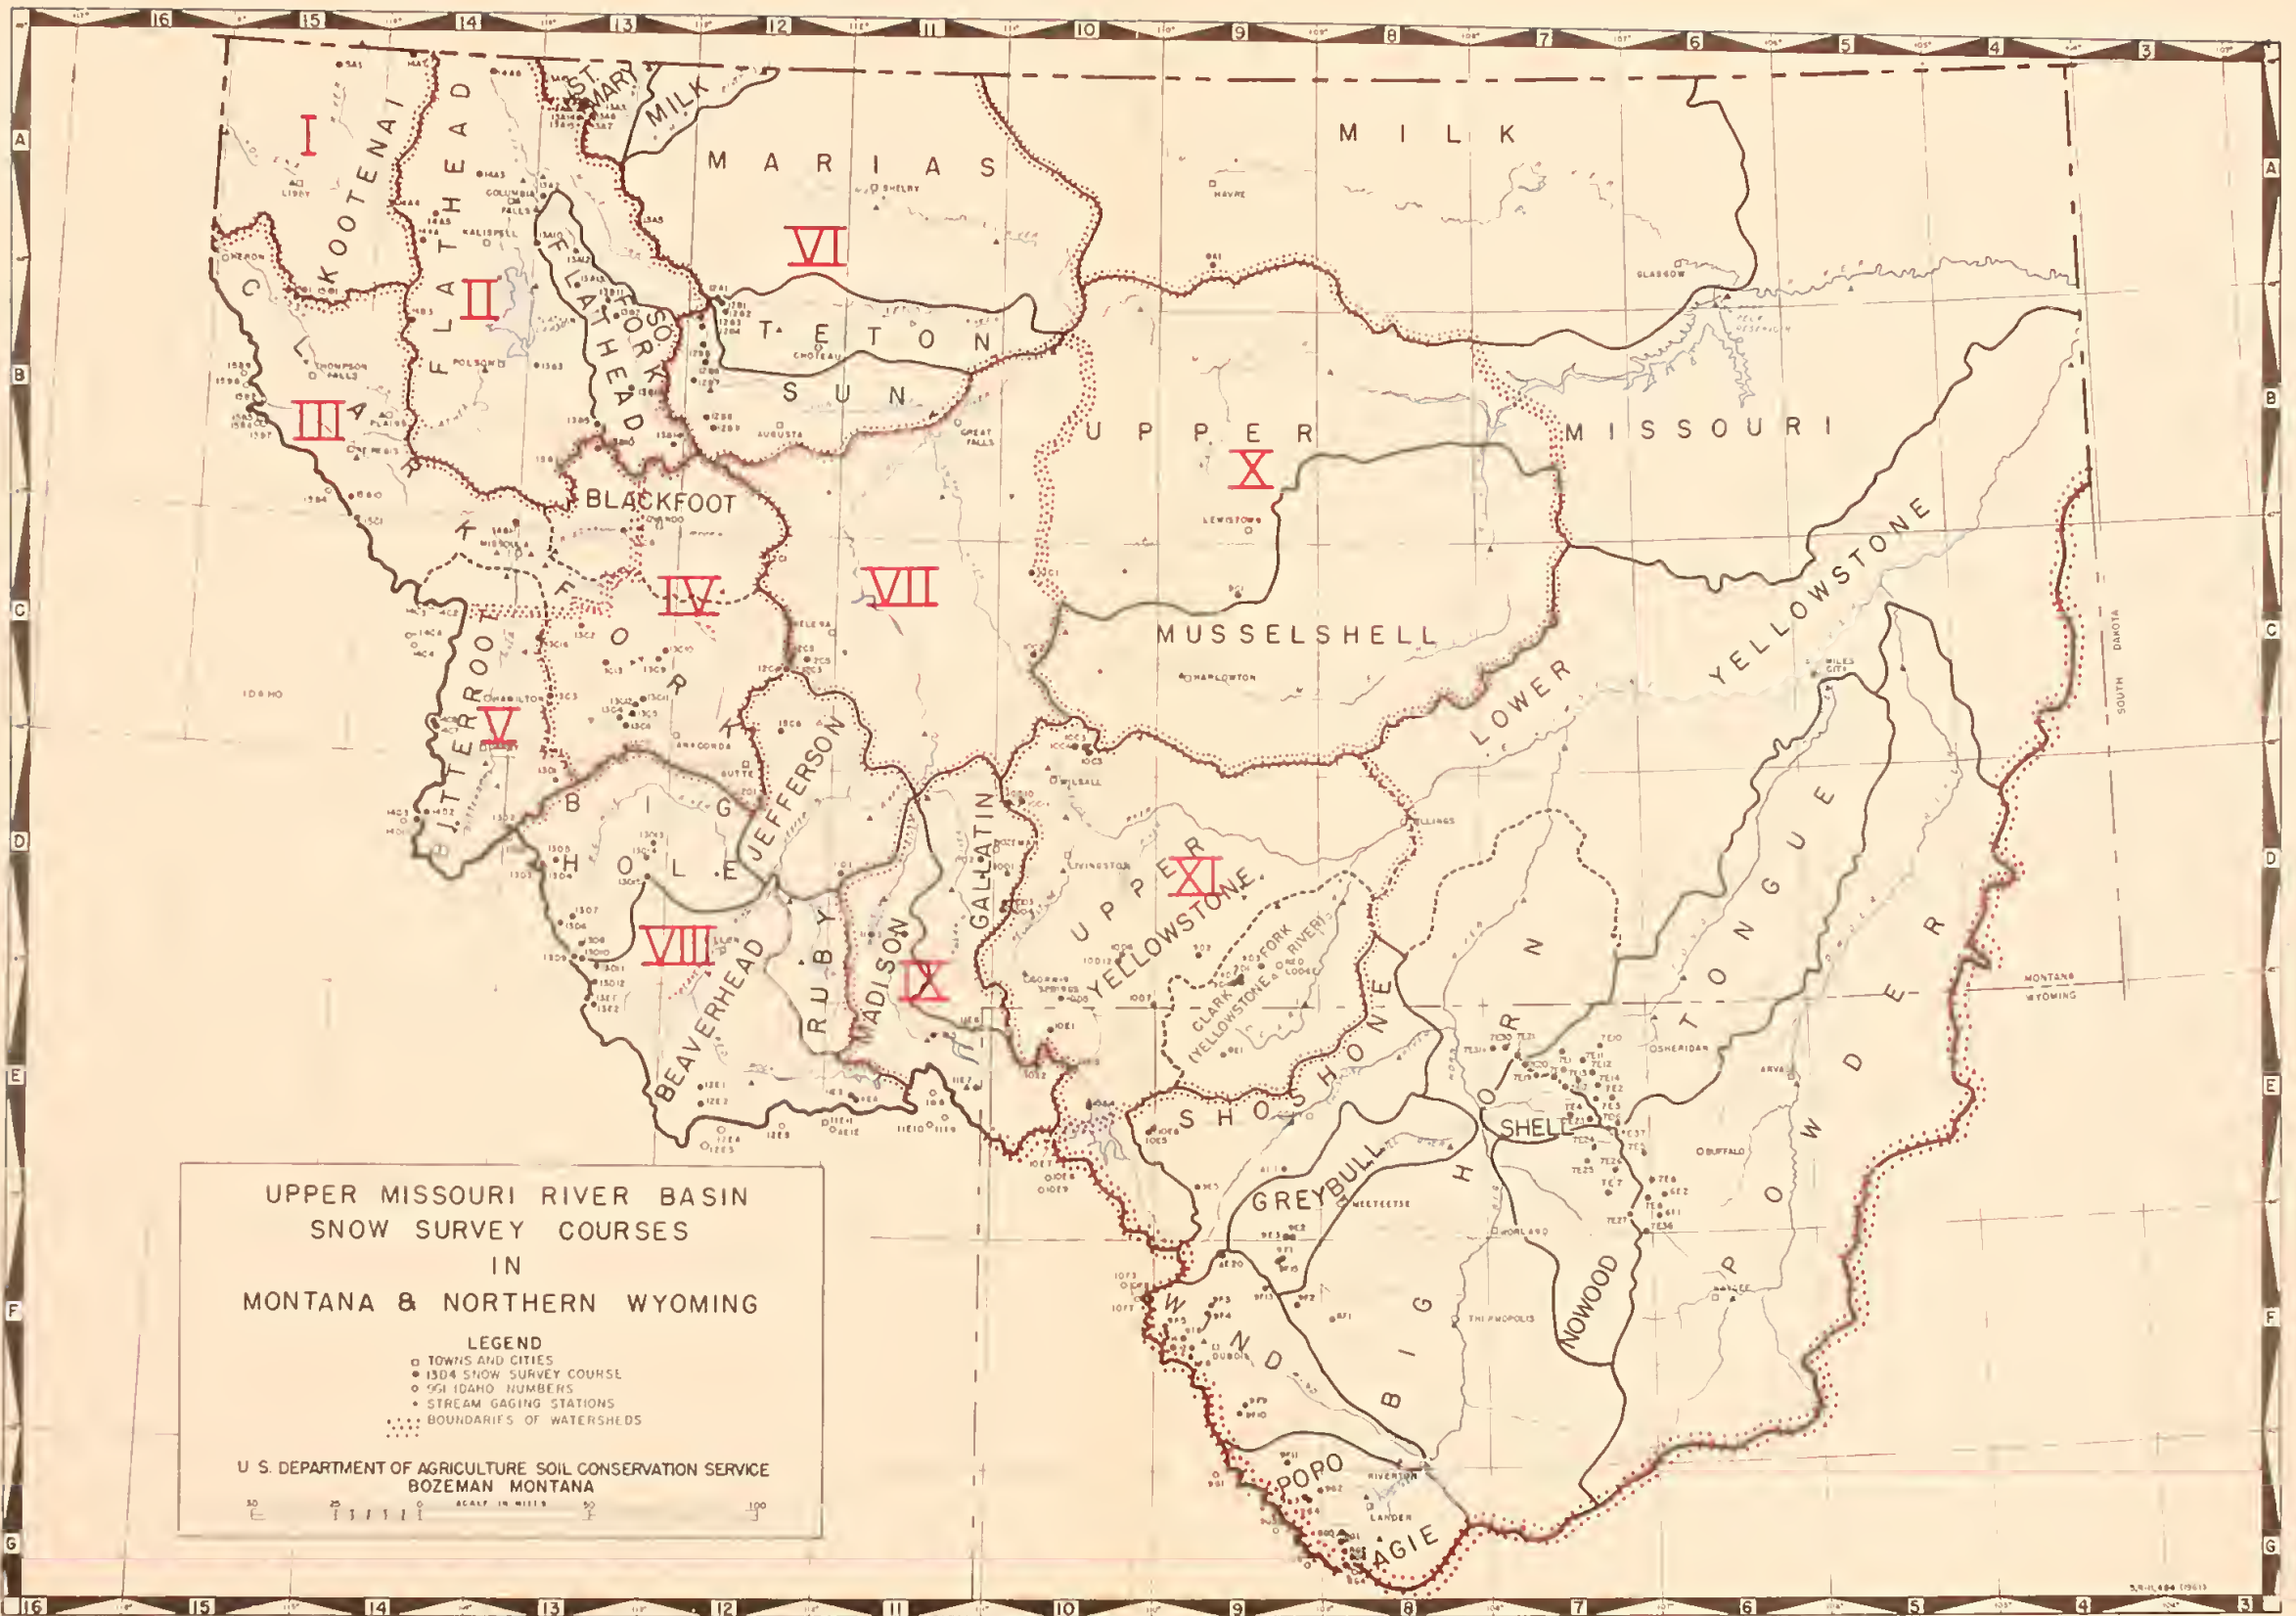

Soil moisture is above average in the southern portion of the state with other areas near to slightly above average. One exception is the headwaters of the Clark Fork river above Missoula, where soils underlying the snowpack are generally dry.

Storage in irrigation reservoirs is generally below average; however, prospects for reservoirs to fill during the spring runoff are good.
