- BEEVES, very fine ones slaughtered in Baltimore by Mr. Elmore 16.
- BEESELY, THOMAS, on the Hessian fly 165.
- BELLINGER, DR. G. sends three kinds of peas 48
- BENE PLANT, Dr. James Smith, on the medical uses of 331.—the oil of its seed highly recommended as not inferior to sweet oil, by J. F. Smith 388.
- BERRY, HENRY, his conditional acceptance of challenge to shew Herefords against short horns 2 7.
- BIOGRAPHICAL Dictionary, by T. I. Rogers, highly recommended by H. Niles 55.
- BLACK, Doctor S., called on for a statement of the effects of his system of improvement 359.—enquiries after the practical result of his theories by Ephraim Buck 47.
- BONNET, made of grass, account of a remarkable one 279.
- BONNETS, extensive manufacture of in Mass. 367.
- BOTT'S, in horses, remarks on by J. Haslam 103—remarks on by a subscriber 166—in horses, how best cured, by Nimrod Owings, Esq. 214—angular cure for 208.
- BOTANICAL Garden, in New York 28.
- BOYLE, JAMES, communicates extracts from English laws respecting the tanning of leather 312.
- BRACEY, DR. on the rot in cotton 15, 16, 26.
- BRANDY, Apple and peach, on the distilling of, by Joseph Cooper 94.
- BREWERY, Barclay's in England description of, by Professor Griscom 222.
- BRIGGS'S, ISAAC, on canals and internal improvements, to the citizens of Maryland 123.
- BROWN, Dr. George on the use of the waters of the sweet springs 152.
- BRUSH, description of one to destroy caterpillar's nests, by the Hon. T. Pickering 85.
- BUCK, Ephraim, enquires after the result of doctor Thuck's experiments 47.
- BUCKNER, R. B. favours the opinion that wheat turns to cheat, and recommends how to avoid cheat 332.
- BUDGING, interesting remarks on, by C. Harrison 383.

- BUEL**, Judge J. of Albany, makes a valuable communication on the culture and comparative value of various grasses 289, 297—entertains a more favorable opinion of Fiorin grass, and why 316—on the preservation, time and manner of sowing various seeds 394—on the application of stable manures 219—letter respecting a large breed of sheep, and manufacturing worsted 72.
- BULL**, presented by Admiral Coffin to the Mass. Agricultural Society 195.
- C.
- CABBAGE** made into sour crout and exported 53—perennial, notice of 182—on the preservation of 2, 9.
- CALHOUN**, the Hon. J. C. sends tobacco seed from the Rocky Mountains 167—his report on internal improvements 172.
- CALIGRAPHY**, or improvement in the art of writing described 398.
- CALVERT** County, remarks on the agriculture and general appearance of by the editor 160.
- CALVES**, on the best mode of raising 132—on the rearing and management of 172.
- CANADENSIS** Bromus or Cheat, origin of 22.
- CANAL** across the Isthmus of Darien 7—the Maritan 7—Susquehanna 113, 121, 129, 145, 161—on the importance of 89, 105—remarks on 61—remarks on by W. Kenworthy 73, 81, 153.
- From Baltimore to Conewago, reports of Commissioners 393, 299.
- Chesapeake and Delaware, 25, 105—remarks on 44—progress of 55.
- Hudson and Delaware 43.
- Route recommended for one from Potowmac to Baltimore by J. Hughes 81.
- Union 103.
- To join from Potowmac and Susquehanna 161.
- CANALS** and Roads, report on by J. C. Calhoun 281
- Remarks on by Isaac Briggs 122.
- Union of Potowmac and Susquehanna 169.
- CANDLES** not so cheap as oil, proved by experiment 343.
- CARDS**, playing, origin of 413.
- CARPENTER**, H. A. his experience of improved short horns as milkers 115.
- CARROTS**, sample of and letter on the culture of from T. Harris 295.
- CASTRATION**, when best performed on domestic animals 167.
- CATERPILLARS**, a brush to destroy them described and recommended by the Hon. T. Pickering 85
- CATTLE**, Importation of suggested 18—vermin on, how to destroy 30—observations on fattening 218—diseases of in Talbot county 245—editorial remarks on 245—are certain disorders of occasioned by eating turnip tops 263—various breeds of and accounts of large oxen 337—remarks on various breeds 353—disorders of in Kentucky 357—number of and of sheep killed in the Smithfield market from 1789 to 1824, and average price of wheat for same time 358—the “rubbing disorder” in, as observed in the State of Missouri, by John Hardeman 389—disorders of in Ohio, observed and described by S. P. Hildreth 401.
- And Horses, remarks on certain diseases of by S. B. D. 359.
- Herefords and Short Horns compared with others, and terms of agreement to shew them against each other, between the Duke of Bedford and the Right Hon. Charles Arbutnot 221.
- Improved short Horns, their properties and qualities 74—their qualities as milkers 115—account of remarkable ones 333.
- Improved Durham Short Horns, some remarks on Mr. Champion's and on the qualities of that race in general, by J. H. Powell 394.
- North Devon, price of in England 20.
- Norfolk polled recommended and wanted 28—brindle colour much esteemed 28.
- Tuscan, some account of Mr Middleton's 303, 367.
- CATTLE SHOW** of Maryland Agricultural Society, notice of next on the western shore 56—No. 4
- 222—rules and regulations for the government of 255—remarks on the one to be held in Nov. 1825, with remarks on the evidence to be given by claimants 240—account of with all the reports 273.
- One of Fredericksburgh Agricultural Society 370
- First annual one of Pennsylvania Ag. So. 313.
- CATTLE SHOW**, Brief account of an interesting one at Washington, Penn. 340.
- Of Alleghany county, Penn. 77.
- At Hillsborough, report of committee on working cattle 253.
- CHALLENGE** of Mr. Smythies to show Herefords against Short Horns 200—accepted 207.
- CHARCOAL** used and recommended as a cathartic 316
- CHEAT**, on the origin of 22, 82—remarks on 114—remarks on by S. V. S. 131—experiments recommended to ascertain its origin 167—remarks on by B. C. 189—do. by W. M. Barton 208—do. by R. B. Buckner 332.
- CHESAPEAKE** and Delaware Canal, remarks on 44
- CHESNUTS**, French, specimens of large ones 15.
- CHICORY**, best substitute for coffee 3—directions for using 4.
- CHILDERS**, Flying, his performance 127.
- CIDER**, premium offered for 34—remarks on the best modes of making by Agricola 124—how best made 174.
- CISTERNS** to receive and keep rain or other water, 85—description of by J. R. Gowan 86.
- GLARKE**, James, describes a very complete bee house 362.
- CLAY** land, how affected by frost 2.
- Burning 45—remarks on by T. Pickering 98.
- Or argil defined as connected with soils 380.

by corn and potatoes 30—ringing the bark of experiment in by Joseph Sabine 309.

G.

GARDEN, Botanical one ought to be at Washington 28.—Plough, cut and explanation of one 389.

GARDINER, Lyceum, address of the Trustees on the objects of the institution 217.

GARLIC, valuable communication on the extirpation of 381—contrivances for separating from small grain 382—use of suggested as a preventative of fall fevers 128—first sowed by the Swedes on the Delaware 28.

GARNETT, J. M., his address to the Fredericksburgh Agricultural society 325.

GELDING heifers, swine, &c. how performed 298.

GEOGRAPHY of plants, remarks on 86.

GIBBS, W. S. remarks on the culture of the grape vine 12.—George, valuable observations on various grape vines at Sunswick in New York 241.

GLANDERS in horses, description and how distinguishable from other disorders 308—symptoms described, and cure suggested by Joseph Kersey 333.

GOATS, Cashmere premium of \$100 offered for their introduction by the Mass. Ag. society 399.

GOODSELLS'S Machine for dressing flax 46—his machine for dressing hemp and flax 91—trial of his flax dresser in Pennsylvania 126.

GOWAN, J. R. describes a well or cistern for holding rain water 86.

G. R. interesting letter from, communicated by J. M. 65.

GRAFTING, remarks on by S. Preston 195.—And Budding, interesting experiments in 351.

GRAIN, how to preserve from mice 109—experiments in cutting earlier than usual 311.

GRAPES, how to preserve from rotting 144.

GRASS Bonnet, statement of Miss Julia Harrison's 279.—Dub, remarks on by T. Spalding 212.—Florin, how valued by J. Buel 316.—and Garden seed, how best imputed 29.—Guinea, experiments with and results 59—remarks on, by R. Lowry 212.—Meadow or perpetual rye grass 183.—Perpetual rye, some ordered from England 189.

GRASSES, valuable communication from J. Buel, on 289, 297—remarks on various kinds of, by John Welles 134.

GRAVEL, cure for 88.

GRIFFITH, Thos. W. on the plantation of timber 141.

GRIPES, or cholic in horses, how cured 38.

GUINEA Corn 47.

G. W. on plaster and slacked ashes 46.

GYPSUM, acts as a stimulis 59—remarks on the use of 59.

H.

HAINES, Reuben, on the selection of dairy cows 69

HALE, Benjamin, Principal of the Gardiner Lyceum, his address 225.

HAMILTON on the Tariff 284—on domestic manufactures 292.

HAMS cured by pyroigneous acid 367.

HARDEMAN, John, on the extraordinary productions of the west 5—on the "rubbing disorder" in cattle in the State of Missouri 387.

HARDIN, Mark, on the emasculation of squirrels 318

HARRICOTS or French beans 30.

HARRIS, T. sends samples of immense carrots and mangel wurtzel, with letter on the culture of 295

HARRISON, J. on budding 383.—James C. challenges Eclipse 128.

HAR, Nathaniel, on the culture of hemp 53.

HASLAM, John, on botts in horses 03.

HAY, expeditious method of moving 46.

HEDGECOCKS and appoplexy, probable causes of 88

HEDGE, the crab tree recommended for by Robert Barnard 189—live ones not suited to our country 243.

HEDGLING, remarks on by Caleb Kirk 171, 179.

HELME, Dr. R. H. extracts from his address 201.
MEMP, on the culture of 53—importation of from Russia into the U. S. in 1821, 53—natural history of by Philips 83—remarks of S. Swartwout on the culture and dressing of 90—proper soil, seed, harvesting, wretting and dressing 99.
 —And Flax, how cultivated and treated in Flanders 147—report 170.
HEREFORD cattle, challenge to show against short horns 200.
 —And short horns compared 414.
HEROD, Thomas, on the best method of storing mangel wurtzel 358.
MESSIAN Fly 113—remarks on by "a Virginian" 123—do. by a Farmer of Buck's county 134—do. by S. 139—do. by "a Farmer" 139—do. by a Subscriber 140—do. by J. H. Cocke 241.
HINDE, T. S. on the cotton of Illinois 79.
HOG, large one slaughtered 40.
HOGS, (see Swine, and Piggery.) Scorching off the hair recommended in lieu of scalding 357.
HOLLOW HORN, the disease and its cure 124.
HONEY, how secured 45—how to take 72—remarks on saving of 102.
HOOPING Cough, cure for 112.
HOP Beer, how to make 71.
HOPS, on the culture of 10, 114—further remarks on the culture and management of by Israel Thordike 172—on the culture of by W. Blanchard 210.
HORSE, how to know his age 250.
 —Power, what it is, and the application of 365—what does it mean, and what the best mode of applying it 342.
HORSES, the celebrated hunter Emperor 8—on the management of 27, 35, 50—various diseases of and how cured 37, 38—how to know a good eye or a bad one 50—worms in the stomach 50—wounds on the skin of how cured 50—how to distinguish between two sorts of choleric or gripes 50—how to judge the best colt 50—cure for sore backs 50—when not to be carried 50—not to be littered in day time 50—lotion for blows and bruises of 50—speed of celebrated ones 103—on the salivation of 159, 214—remarks on by Albion to his son 152—remarks on the choice of by Albion 190—on the expense of keeping them 181—of the genuine racing blood, their high value maintained and importance of attending to *inculcated by Philip* 213—on the bots in 214—association to improve the breed of in Maryland 222—on the appellatives, qualities, habits and defects of 265, 341, 345, 355, 365, 372—ointment and medicine recommended for 279—on the glanders in 398—forces of working ones and manner of feeding of in Flanders 402.
 —And Cattle, remarks on certain diseases of 359—
 —And Cows, how fed in different districts of Flanders 410.
 —And Dogs, on the management of 93.
 —And Sheep, comparative view of expense of raising 298.
HORTICULTURE, on a succession of garden crops 347
HORTICULTURAL Society of New-York, notice of meeting of 55.
HOUSEWIVES, great convenience for 56.
H. T. on the price of Devon cattle 20.
HUDSON, canal from to the Delaware proposed 43
HUGHES, John, recommends a route for canal from Potomac to Baltimore 81.
HYDRAULICKS, on procuring water by boring 162
HYDROPHOBIA, strange case of in sheep 5.
 —Singular effect of 349—remedy for 350—instances of with symptoms 375.

I.

ICE, oak leaves recommended as covering for 286.
 —and Ice Houses, on the use and construction of 184—remarks on by Cresina 242.
 —And Ice houses, valuable remarks of P. E. T. construction of Ice Houses, and the storing of ice 332—on the construction of 189—with closets attached, described by cuts 253.

IMPORTS, may exceed exports consistently with individual and national prosperity 51.
IMPORTATIONS, ruinous in amount 18.
IMPROVEMENTS, Internal, in New York, New Jersey, Pennsylvania, Delaware and Maryland proposed 43—tunnel across the Thames 305.
INDIAN Corn, in Tuscany 30—account of large crop, and its culture 347.
INDUSTRY, Domestic, protected every where except in Holland and America 18.
INFIRMARY, Clinical, plan of one established in Baltimore 176.
INGERSOL, Nathaniel account of his Piggery 321.
INVENTIONS, sailing carriages 55.
IRRIGATOR, cut of one for watering high lands, communicated by C. E. Rowand 173.
IRRIGATION, remarks on by Albion 12.

J.

JAMES, John, President of the Agricultural society of Williamsburgh, N. C. his address published at the request of the society 49.
 —Edward sends tobacco seed from the Missouri 167.
J. D. C. on the power of men and horses, the meaning of, and how best ascertained and applied 357—on the meaning and application of horse power 365.
JEFFERSON, Thomas, letter to Major Adlum on his wines 63.
J. M. communicates an interesting letter for publication on the agriculture of Spain and Portugal 65.
JOHNSON, W. R. challenges Eclipse—challenge declined 127.
JONES, Calvin, on the native fertility of the western lands 315.
 —R. J. recommends an economical paint for houses 335.

K.

KALE, Sea, on the culture of 202.
KENWORTHY, William, on canals 62, 73, 81, 89, 105, 113, 122, 129, 145, 153, 181.
KERCHEVAL, Dr. describes an extraordinary disorder in the cattle of Kentucky 357.
KERSEY, Joseph, describes the symptoms of, and prescribes a cure for glanders in horses 333.
KINLOCK, Cleland, on the rot in cotton 23.
KIP, Henry, on the culture and dressing of hemp 100
KIRK, Caleb, on hedging 171, 179—relates several instances of hydrophobia, with symptoms and effects 375.
KNIGHT, T. A. letter from to the Hon. J. Lowell on various interesting topics 383.

L.

LABOUR, daily, of negroes estimated 319.
LADIES, news for 52.
LAMB, account of a singular biped one 102.
LANDRUM, Abner, on grafting and budding 351.
LAW, Thomas, on burning sod 29, 45.
LEAF, on the phenomena of the fall of 308.
LETTERS, an interesting one from G. R. 65.
LIFE, probable duration of at different ages 411.
LIGHT from oil more economical than candles 343.
LIME, definition of and remarks on its application 59—opinion of Sir H. Davy on its operation quoted 97—do. of Agricola quoted and preferred by P. Pickering 97—remarks on the use and application of by T. Pickering 97.
 —Or calcareous earth, remarks on in connexion with soils 380.
LINCOLN, Levi, recommends ruta бага highly 39.
LITHOGRAPHY, or stone engraving, how executed 224
LIVINGSTON, Robert R. on the comparative agricultural advantages and disadvantages of England and the United States 413.
LOCUST Trees, how to procure a nursery of young ones 15—natural history of 374—remarks on the raising of 396.
LONGEVITY, cases of 95.
LOWELL, J. on the culture of sea kale 133—account of fruits received from Mr. Knight, Pre-

sident of the Horticultural Society of London 209—communicates an interesting letter from A. Knight, Esq. President of the Horticultural Society 343.
LOWRY, R. remarks on Guinea grass 212.
LUCERNE, remarks on the culture of 214.
L. W. sends water melon seed 30.

M.

MACAULY, Dr. P. on the supposed emasculation of squirrels 317
MACHINES, Pope's for threshing 21—one for dressing flax 46—one for dressing flax, adverted to by the Editor 80—representation of one for dressing hemp and flax 91.
MACHINE for boring posts, drawing and description of 54—cut of one for mowing 199.
MACHINERY, how best moved by horse power 342.
MACKALL, B. F. details experiments with fish as a manure 241.
MADISON, James, letter to Major Adlum on his wines 64.
MAGNESIA, as connected with soils 381.
MAGNOLIA Grandiflora, natural history of 404.
MOGOTHY Bay Bean, paper on the value and use of 333.
MANGE, cure of in dogs 69.
MANGEL WURTZEL, extraordinary produce of 14—on feeding of to sheep 174—on the culture and keeping of 181—on feeding with 200—very large ones, with letter on the culture of, by T. Harris 295—on storing of 358—great crop of made by J. H. Powel 409.
MAN Power, how best ascertained and comparison of with that of horses 357.
MANUFACTURES, American, memorial in behalf of 17—at Patterson, account of 43—encouragement of 228—on the policy of encouraging 245—Hamilton on the policy of encouraging 284, 292.—Domestic how far to be encouraged by government 262—Ruris Consultus against further encouragement of 369—Ruris Consultus against further protection of 377—Ruris Consultus 393—Memorial of Agriculturists of Pennsylvania, in favor of further protection of 399—ought to be encouraged 406.
MANUFACTURERS, Board of Pennsylvania society, their memorial 17.
MANUFACTORY at Steubenville, account of 302.
MANURE, remarks on the application of 200—salt recommended 259.
MANURES, soap ashes when and how to be used 41—remarks on the nature and application of, by the Editor of the Emporium of Arts and Sciences 57—remarks on the accumulation and use of, by T. Pickering 99—remarks on by W. Plumer, Jr. 194—Of the stable, on the application of 219.
MANURING, how to calculate distribution of 53.
MARLE, on the effects and value of in Maryland 387.
MARSH LAND, letter on the reclamation of by C. E. Rowand 92.
MARTEN, Samuel, deprecates war 47—communicates a singular cure for the bots 398.
MEAD, Cowles, his trials of lupens, &c. various grasses in Miss. 167.
MEAT, how best preserved in war a weather 410.
MELON, Water, superior kind 30.
MEMORIAL, from board of Manufacturers of the Pennsylvania society 17.
MERCHANTS, amply protected by Congress 17—their honesty asserted 19—ought to instruct their captains to bring seeds, plants, &c. 23.
MICE, to preserve grain from 109.
MIDDLETON, J. letter respecting his Tuscany cattle 367.
MIGRATION of Birds, interesting explanation of 340.—Periodical of Birds, explained 348.
MILDEWED Wheat 229.
MILL, Tread, improved one 15.
MILLET, how to manage 24—answers to enquiry about, by Curwen 270.
MILLS, Robert, the

MITCHEL, Henry, sale of his pippins in England 47.
 MONOPOLY, dangers of by Manufacturers 18.
 MOROCCO, on the manufacture of 279.
 MUSE, Joseph E. on the Hessian fly 114—on the culture of rice, and the reclamation of marsh lands in Maryland 220.

N.

NATURAL HISTORY—changes in the colour of the clothing of animals 261, 267—emasculation of the squirrel only apparent and accounted for 317, 318, 350—periodical migration explained 342, 340, 354—of the acacia or locust tree 374—torpidity of animals 388—food of animals 404.
 NEWELL, J. R. describes and recommends wool and cotton spinner 47.
 NEW-YORK, its exports in four different years 25—her tonnage at different periods 25—owns botanical garden 28—Board of Agriculture, editorial remarks on its publications 135.
 NORTH Devon, on the management of calves 172.
 NURSERY, how to make one of locusts 15.

O.

OAKS, on the raising of from the acorn 141.
 OIL of pumpkin seed 13—extracted from cotton seed 245—cheaper than candles proved by experiment 343.
 OLIVER, R. Esq. his kit for sod burning 32.
 OLIVES, American, specimen of received from Georgia 223.
 ONIONS, ground suitable for 5—selection of seed of 5.
 OPIUM, some remarks on the culture of 96, 182.
 ORCHARDS, on the planting and cultivation of 403
 ORCHARD GRASS, remarks on by J. H. Powel 270—do. on the properties and value of 402.
 ORNITHOLOGY, specimens of presented by J. Hume to a society in Charleston 71.
 OWINGS, Nimrod, on the botts in horses 214.
 OXEN, best form and premium offered for 35.
 OYSTERS, medical qualities of in consumptions and fevers 391.

P.

PABULUM of plants, in what does it consist? 58.
 PAINT, a cheap species of recommended 335.
 PARING and burning, view of, at Mr. Oliver's farm 32
 PARKIN, W. on the culture and use of rape 395.
 PATERSON, Manufactories at, account of 48.
 PIA, Angola 15.
 PEAS, on the culture of 15, 84—different kinds sent to the editor 71.
 —Georgia or tory peas recommended by a North Carolina correspondent in lieu of clover, and as excellent food for hogs 39.
 PEACHES, notice of peculiar Chinese ones 182.
 PEACH Trees, on the calamities to which they are subject 118—enquiries respecting 173.
 PEARS, 150 varieties in the nurseries of Paris only esteemed good 28.
 PEDESTRIANISM, extraordinary case of 8.
 PEDIGREE of J. H. Powel's stock 390.
 PERKINS' Steam Engine, notice of 118—cut and description of 204.
 PETERS, Richard, on the diseases of peach trees 118—on fattening swine 372.
 PHILADELPHIA, her exports in 1793, 1800, 1818 and 1820, 25.

NOTICE TO SUBSCRIBERS.

Those who continue their subscription to the *Farmer*, are respectfully reminded that the *best proof* they can give of their approbation of our labours, will be a prompt compliance with the stipulated terms of subscription, which will remain, as heretofore, to wit:

To those who take the risk of all casualties, \$4 per annum, payable *in advance*—but those who prefer, as we hope most of them will, to pay \$5 in advance, will be entitled to have each paper supplied, which may happen from any cause, *not to reach them in good order*, and an agricultural almanack, in the bargain. The almanack, besides the contents of common almanacks, will have recipes, short essays, &c. connected with the farmer's and the *housewife's* duties and business. Those who prefer the payment of four dollars, are assured that the *Farmer* is *regularly put up* and sent off in *at least as good condition*, and with as much security for its safe arrival, as any paper in the United States, excepting always that invaluable work, Niles' Weekly Register.

The money, whether four or five dollars, to be remitted, in all cases, directly **BY MAIL**, at the Editor's risk—he, requiring only the word of the subscriber that the money was deposited in the neighbouring post office. The difficulty arising from the impracticability of getting \$4 notes, in many places, may be obviated in this way.—Let the subscriber send a \$5 note, with a request that the odd dollar be passed to his credit for three months of the succeeding year, and it will be done: but where \$5 are received, without any such *wish expressed* by the subscriber, it will be taken for granted, that his desire is to be considered as a *guaranteed* subscriber, and entitled to an Agricultural Almanack, and he will be so entered on the books. Lastly, the Editor assures his friends, that from the variety and value of materials on hand, the regularity of his supply from abroad, of such publications as afford matter adapted to this journal, and above all, from the number, zeal, intelligence and generous publick spirit of his correspondents in all the states of our own blessed country, with her infinitely diversified soil and climate, and unexplored resources of Agriculture and Natural History, he can promise, *without fear of failure*, that the *Farmer* will continue to be at least as *well worthy* of their patronage as heretofore; to say nothing of *improvements* in the plan and substance of the work, which ought to be expected from greater experience and facilities, and undiminished fondness for the subject.

The most inattentive observer, must have perceived the progress of publick opinion, within the last few years, in attaching more respectability, and a higher moral consideration to the business and character of the *Farmer*, embellished as it now is, with researches and acquirements in Natural History, Botany, and other liberal studies, and guided by the results of modern discoveries, in physiology, chemistry, &c. No longer is the practice of agriculture, associated with the idea of mere *brute force*, and all its results, considered as ending solely in calculations of profit and loss. Its votaries are expected to combine the polish and the pleasures of reading, with *better judgment*, in directing the labours of the field—and hence it is, that we witness the just pride, which is now felt, in selecting the cultivation of the soil, in all its alluring varieties, as their regular profession, by young men of the first consideration and talents: and how much more useful and honorable to seek, where "all the grateful country breathes delight," the invigorating toils of the field, and the never tiring studies of nature, renouncing the unmanly and enervating pleasures and pursuits of the town, of which, if ever, it may now be truly said

"Where news and politicks divide mankind,
"And schemes of state involve th' uneasy mind,
"Faction embroils the world; and every tongue
"Is mov'd by flattery, or with scandal hung:
"Each rival Machiavel with envy burns,
"And honesty forsakes them all by turns;
"While calumny upon each party's thrown,
"Which both promote, and both alike disown."

It is from reflections like these, and not from the vanity, which is the growth of overweening partiality, for our own offspring, that we anticipate the time, when every tiller of the soil will patronise the "*AMERICAN FARMER*." To the intelligence and the liberality of our correspondents, we owe unspeakable gratitude, for enabling us to say with confidence to *every farmer*, that in its pages, his wife may find the most valuable recipes, and instructions in every branch of household industry—that his children may find in them, amusement and edification, and that to himself, they will furnish the results of experiments and practical directions, applicable to the whole circle of agricultural operations—finally, we ask the favour of all those, who think its usefulness not overrated, not only to consider themselves as agents to receive subscriptions, but that the Editor will feel himself under particular obligations to *all* those, who by sending him a *single* subscriber, so far enable him to continue, the *first American Journal*, devoted exclusively to the instruction and benefit of the agriculturists of America. To promote their interests, to defend their rights, to deserve *their* esteem, and to exalt and embellish their vocation in the estimation of themselves, and of mankind, is the greatest pride, and the highest ambition of their humble servant,

J. S. SKINNER, EDITOR.

AMERICAN FARMER.

RURAL ECONOMY, INTERNAL IMPROVEMENTS, PRICE CURRENT.

"O fortunatos nimium sua si bona norint
"Agricolos." VIRG.

Vol. V.

BALTIMORE, FRIDAY, MARCH 28, 1823.

No. 1.

IMPROVEMENTS IN THE BARSHARE, SUBSTRATUM, AND SHOVEL PLOUGHS;
AND MANNER OF USING THEM EXPLAINED.

Remarks on Ploughing, Planting and Tillage; with some observations on the Drill Husbandry. Prepared by GIDEON DAVIS, Manufacturer, Georgetown, D. C. for the "AMERICAN FARMER."

The present time is one of much inquiry, research and practical experiment, in Agricultural and Manufacturing affairs, which forebodes vast results. We are told, that in the Eastern, as well as this Western World, many men of the highest attainments and greatest refinement, are not only turning their attention to the promotion of Agriculture, Manufacturing, and Internal Improvements; but are endeavouring to adapt their habits to a rural life; with a view, to systematise the art of husbandry, and render it more pleasant, profitable, and honourable.—Hence it is, that science having united her powers to effect the plan—research must go its faithful rounds, and explore every part. With the knowledge of chemistry, much has been explained already; and by the knowledge of Arts, every process is scrutinized with accuracy so just, that habits in husbandry, no matter how ancient, or how much revered must yield to plans more perfect.—And implements or machines, no matter what their structure, or how much celebrated they may hitherto have been, they must all give place to such as are found to be better adapted to their respective purposes.

Under these impressions, I am quite aware that the time is coming, (perhaps it is near at hand) when implements of husbandry will be valued by their merits only, and not by their appearance, or price, or the recommendation of whoever may take a fancy to that particular form. Therefore, having applied the word *improvement* to those implements which I make; the object of this communication is, to convince those interested in their use, of the fact;—and

also, to caution all persons whomsoever, against making and using, or vending those improvements without my consent.

STRUCTURE. In order to give a better idea of the structure of those implements, I have obtained drawings to assist me.—Although the plough has been the most material implement of husbandry, for thousands of years, I have not learned that there has ever been much attention given to its structure until within a few years past. But since it has become a subject of attention, many very interesting men have undertaken to advance its improvement, and a great many forms have been made, and tested.—Having come at a knowledge of what others have done, together with the use of the Dynamometer, by which I could with certainty test each result; has afforded me an opportunity of realizing facts respecting improvements in the plough, which I believe will justify me in recommending those which I have made.

The first drawing exhibits a figure of the Barshare plough, taken perspective, so as to delineate the most material parts. By which it will be seen that the shear, (or cutting edge) is made of wrought iron; and so shaped, as to be easiest made, strongest, and easiest kept in repair. It is fastened to the plough with two screwbolts, one passing through the mouldboard and wing of the shear; the other through the heel of the shear and handle of the plough. I believe the point and edge of this share to be the most natural and perfect shape.

The next is the moulding part, or mouldboard. The shaping of the face of which, is found to be the most material part in the structure of the

plough; and I believe, one of the most difficult processes in mechanics.—Not being able to find a rule to work by, which would produce the desired shape; I determined upon trying experiments by testing, or realizing such shapes as fancy might dictate; in the course of which I have (besides the number I have seen of other's make) made sixteen different patterns for the mouldboard of the plough. And whether the present is the perfect shape, futurity will tell us. But that which I have found to be most complete, is partly a section of a cylinder, whose radius is about equal to the width of the furrow the plough is intended to turn; but made so that the fore and rising part is considerably concave and the lower part behind rather convex.—The mouldboard is made of cast iron. (This is a great improvement in the structure of ploughs because, if we can once attain the perfect shape we can always retain it.) The top of my mouldboard extends up to the beam, and is attached to it by a strong screwbolt, which passes through an iron brace that extends from the top of the mouldboard down to the heel of the shear and handle of the plough.

THE COULTER.—I have made some ploughs to work without any coulter at all, and where there is no tussicks, or a stiff sward to cut, I believe they are quite as well, and many say much the best without in all such as clover stock, or stubble land, and some use them in a blue grass sod. I have made many ploughs with the common sward coulter, but applied to the side of the beam, instead of passing through it. The advantage of applying the coulter in this way is, that it stands plum, and cuts the sod so that all the after part of the plough except the land side, runs clear of the edge of the furrow and that it may be used with or without the coulter at pleasure; and as there is no coulter mortice through the beam, it is stronger, and less apt to be abused. Very recently, I have applied a horizontal coulter. This I believe to be entirely a new structure of the coulter, and so far as it has been noticed, is much admired; it may be made of cast or wrought iron, or steel has an edge at each end, that when one is worn dull, the other can be applied. It is so constructed as to answer every purpose in cutting the sward or sod, and still preserves the broad circular throat of the plough, which is so constructed as to prevent the plough from clogging; this is an advantage that those will know how to compute, who have been in the habit of turning in large growths of clover, weeds, stubble, &c. its form may be seen by referring to the drawing. Each end of the coulter is seen, one in its proper position just forward of the fore part of the mouldboard, the other end resting against the outside of the left hand handle.

STOCKING. My ploughs are put together without mortice or tenon, but with iron screwbolts, the beam being fastened to the top of the mouldboard with a single screwbolt, from a swive by which they can be so constructed as to adjust so as to work after two or three horses abreast which is effected by fixing a block between the handle and the end of the beam, when the block is in it is then set to work after three horses; it is also necessary to have a brace to extend iron screw outside of the beam to the hand'

fastened with a screw bolt; this brace prevents that end of the beam from drawing down by the operation of the team. When the block is out, and the beam drawn up to the handle, there is no need of the brace; the plough is then set to work after two horses abreast; or two or more oxen. I fasten an iron brace on top of the beam to the main screwbolt, and to the right hand handle which answers two purposes—one is to support the handle, the other for the plough line to lie on, and prevents it from being caught under the furrow.—In constructing this plough, I have endeavoured to retain, and add every thing necessary to make it perfect, and to avoid every thing that could be done without. The timber is worked as nearly straight as possible, in order to avoid working it across the grain.

When those ploughs are first put to work, in some situations, it will be necessary to rub the mouldboard with a brick, or sandstone, in order to make it scour, and be sure to remember, that the plough will never work to perfection, until the mouldboard does scour completely smooth. They are calculated to run deep or shallow by altering at the clevis, and backbands. If the team should walk wide, so that the plough would incline to take rather too much land; put a piece of leather between the handle and beam. If the team should crowd to the furrow, so that the plough does not take land enough, take a little off of the beam, and so repeat the process until the plough runs exactly to suit the team.

SUBSTRATUM PLOUGH. The 2d figure, is made much in the form of the common shovel plough, except the leg, the lower part of which is made of a strong bar of wrought iron with the edge forward, bent in a suitable shape and attached to the beam with a screw bolt, and to the wooden part of the leg, by means of two strong straps, rivited to the iron, and screwed to the wood; thus constructed it is simple, and very strong considering its weight. The cutting edge or substratum shovel may be made of wrought iron or steel, and of any shape, square, round or oval; the present are made of cast iron, and round, so constructed that both sides are exactly the same shape, a countersink on each side, whilst one forms a rest for the toe of the leg iron, the other protects the burr of the screw, by which it is fastened on, from wearing. When the shovel is worn to a bevil on the under side (in front) so that it don't stick properly to its work, loosen the screw and turn it until a sharp part is brought forward, and so repeat the process until it is worn to a bevil all round, then take it off, and turn it upside down; this will place the bevil on the top, and render the shovel completely sharp, and so proceed as before. Price for the substratum plough \$8. Those ploughs are designed (in part) to work after the Barshare Plough, in the same furrow, in order to produce a deep tilth, without burying the soil or mixing the under stratum with it; this they will do with the power of two horses, or a yoke of good oxen in common land, to the depth of from 6 to 10 inches, and to the greatest perfection. Also to be used in the drill husbandry, in the cultivation of small grain, corn, potatoes, &c whenever it is desired to cultivate the land deeply without mixing the under stratum with the soil. They will pulverise the ground to any depth, without casting a furrow so as to cover the smallest vegetable, and by enlarging the shovel (or cutting edge) and altering its shape, this plough may be adapted to working land foul with weeds, and what is termed scraping tobacco.

Figure 3. **ADJUSTING SHOVEL PLOUGH.** The stock of which is made much in the form of the common shovel plough. There is a cast-iron fastened to the lower end of the leg with a

strong screw bolt, which we term the leg-iron; to this the shovel, whether round or square (see figure 4) is fastened with a single screw pin. The plough can be adjusted, that is set to work, deep or shallow, by putting a bit of wood or leather between the leg iron and the leg above or below the screw bolt, as may be required—and when one part, or corner of the shovel wears dull, loosen the screw and turn down another, and repeat that process until the shovel is worn all round. The shovel may be made of wrought iron or sheet iron; the present are made of cast-iron which are found to be much the cheapest; and most uniform; they are made concave, and work with the concave part forward, by which means they work deeper, pulverise the ground finer, and leave it much even on the surface, than the common shovel plough does. Those ploughs are well calculated to work in a deep soil, sand, or loam.

I have reason to believe, that the shovel plough is not known (or at least used) at all in some parts of the country. They are certainly a very useful implement; but to those not accustomed to use them, they are at first quite unpleasant to operate with; this is owing to their standing on a single point, of course would incline to run any other way as soon as the right one, therefore, need strict attention. But a few days practice will render them quite pleasant to work with, and it will be found that they will pulverise the ground to greater perfection, than any other implement.—One difficulty in operating with the shovel plough is, the management of the horse: the ploughman must hold the plough with both hands, then if the horse is awkward, or wild, he is to manage also. Take double lines, and make them just so long that the ploughman can stand, or walk at ease, with the line over one shoulder, and round his back, and under the other arm; thus it will be found, a little practice with some skill, will enable the ploughman to manage the most refractory horse if he will only pull, and without saying but very little to him. By twisting the body a little he can incline the horse to the right or left, and by holding back regulate his speed or stop him at any time.

PLOUGHING. Many very interesting farmers, have taken up the idea, that deep ploughing is an improvement in the art of husbandry; that—in fact, the deeper they plough their ground, the deeper they make the soil; and of course the richer the land. With whom this notion originated I have not learned, and it mat-

ters not: as it is entirely incorrect. As for making land rich, merely by deep ploughing, it is just as absurd, as to attempt to satisfy hunger by drinking more water.—The case is very plain. In deep ploughing, where there is but a thin soil, it is either buried so deep as to be of little or no use to vegetation; or is mixed with so much clay, (or under strata) that it is all made poor, and of quite as little use.—Deep ploughing qualifies the ground to receive more moisture, and will afford an opportunity for the roots of vegetation to run deeper. Hence it is, that where farmers plough their land deep, their crops suffer less with drought; and will sometimes yield a better increase. But the land is not any the richer, for the deep ploughing.—Deep ploughing done in the common way, is very injurious in the production of troublesome weeds, and all such growths as the husbandman wish to keep clear of. The reason is because the seeds are buried at every depth from the surface to the bottom of the ploughing, and at every operation in tillage, which brings them within the influence of the atmosphere, they vegetate and grow; thus it is, that the farmers are so much beset with these unwelcome growths. My idea with respect to a preventive is, to work so shallow with the barshare plough, that all the seeds that are turned under, will be within the influence of the atmosphere, where they will vegetate and grow, and when they get to a suitable size, turn them under with a plough, or cut them off at a proper depth, with some suitable implement, and they will perish. By an attention to such a process, as this proposed, I believe the farmers might get clear of many very troublesome weeds, which it is almost impossible to get rid of, whilst they plough their land deep at one operation.

In that portion of the country, best adapted to the growing of wheat, with which I am most acquainted, if the soil is found to be 3 inches deep, the land is said to be very good.—Then, suppose it to be a clover lay, and that it be ploughed 7 inches deep; that there be 4 inches of clay thrown on top of the soil; that it be sown with wheat, and harrowed in (I have seen this process practised in some neighborhoods, and produce tolerable crops of grain.) But some very unfavourable effects must result.—The first hard rain that falls on land in that situation, (especially if the clay has been made very fine by harrowing) it will become soft, and run, or cement together like mortar; and form a coat or crust, which when wet, water will hardly penetrate; of course, instead of soaking into the ground, much will run off, which, besides washing the land; the crop needs the moisture.—And, when that coat or crust becomes dry, it is very hard and unfavourable to the growth of vegetation.—Again, when the surface of a field is composed of clay, the atmosphere operating on it—it becomes very fine and compact, so that it holds too great a portion of water, at or near the surface; it is the water, that the frost operates on,—frost has no effect on the clay when dry; hence it is, that a clay surface with its thin coat of verdure will freeze to a considerable depth in a situation where a rich soil with its thick coat of verdure would not freeze at all; and this is the reason why winter grain is so much affected by the frost when sown on clay, and clover so much drawn out of the ground during the winter season.—When clay has been operated on by the frost, and is thawing, the particles become so extremely fine, that they will float a running water to a great distance; thus it is, that fields, the surface of which are composed of clay, wash so much.

The great art in husbandry, is to assist nature, which we see has fixed the soil on the surface,

universally, in the growing of every thing, from the most tender plant, to the most solid oak. It is the soil that contains the principal part of the vegetable matter, which must be decomposed, and also in solution, (that is mixed with water,) before it is qualified for vegetable food; if so, the soil should be kept on the surface; because, there the atmosphere has the greatest influence on all matter. If this is admitted as the fact; see how contrary to the nature of those things, most of the husbandmen act. Yet so it is.—When the soil is kept on the surface, it decomposes or rots the fastest. Its particles, though they may become as fine, or even much finer than those of clay, yet they have not that adhesive quality, which would make them run, or cement together, like mortar, as the clay does.—And when rain falls on the soil, it soaks through so long as the broken strata underneath will retain it, and even if the water runs off, a surface composed of soil, does not wash as much, as when composed of clay. And when dry, it is not too hard, it never bakes, it is so qualified as to be exactly right. Besides this, it is known, that dark colours attract a greater portion of heat from the atmosphere, than light colours do, and I presume that it is the heat of the atmosphere, that renders vegetation active, and enables it to perform offices necessary to its life and growth; this assures us, that the soil should be kept on the surface. Again when the soil is buried 3 or 4 inches under the natural stratum, the atmosphere has but very little influence on it; and even if it had, it is a considerable time before the roots of vegetation, (which is planted or sown on the surface) run deep enough to derive any benefit from it; this also would teach us, that the soil should be kept on the top.

The 1st section in this drawing is intended to exhibit a view of deep ploughing, done in the common way—a shews an open furrow,—cut 7 inches deep, and 14 inches wide, in land where the soil is only 3 inches deep; b, the furrow slice turned over on the bottom of the preceding furrow, with the soil down, and 4 inches of clay on the top of it; c, a plant of corn with its roots first in the clay, entirely above the soil; d, the unbroken stratum, on the left hand, and under the tillage.

The 2d section, will exhibit ploughing, done at two operations: an open furrow (is seen) cut only 3 inches deep, 10 inches wide; and that the furrow slices, including the soil only, are turned over on a bed of substratum, pulverised to the depth of 9 inches, (this is done with the substratum plough,) a plant of corn is seen with its roots fixed in the soil. On the left hand and underneath is seen the unbroken stratum.

(To be continued.)

FROM THE NATIONAL GAZETTE.
CHICORY THE BEST SUBSTITUTE FOR
WEST INDIA COFFEE.

Several specimens of Germanic, formerly called Westphalia Coffee, have been placed in my hands by an importing commercial house of this city, with a request that after a sufficient number of trials of the beverage it yields, I would give some account of the plant from the root of which it is obtained, together with an opinion of its dietetic properties and effects.

A quantity of this prepared substitute for coffee, having been introduced from the manufactories in Germany into this city, which I understood from the importers is intended to be offered for sale, it appears to me proper that the citizens who may be disposed to try, or habitually use the beverage made from it, should be acquainted with the information requested. I have, therefore, subjoined an account of the plant from

which this succedaneum is prepared, after having frequently used in my family the beverage made from the specimens sent me, both alone and combined with coffee.

Germanic or Westphalia Coffee is manufactured from the root of the *Cichorium Intybus*,* Succory, Cychory or wild succory.† This plant is not a native, but has been introduced into the United States, probably with grass seeds, and has become naturalized, being frequently met with along the margins of cultivated fields, and by road sides, among rubbish. In the neighbourhood of this city it is quite common, and particularly abundant on the Ridge Road near town, and on the Frankford and Germantown roads. It is sometimes, but not frequently met with in the Neck, on the Lancaster Turnpike Road and other highways. The root is perennial, shaped like a carrot or raddish root. The stem is about two feet high, erect and branched, its branches straggling, garnished with a few short leaves, those of the lower part of the stem and those proceeding from the root, being much longer, and resembling the leaves of dandelion. The flowers are bright blue, sometimes white, about the size and form of those of dandelion. The endive or winter curled sallad, of our markets (*scarole* or *scariole* of the French) is a species of the same genus to which the *Cichorium Intybus* belongs, and by Poiret is conjectured to be the identical plant, varied by culture, though the endive is more generally supposed to be a distinct species originally from the East Indies.

Every part of the wild succory root has a fresh and bitter taste; and in a greater degree in the wild plant, than in that subjected to cultivation. On breaking it a milky saponaceous juice exudes, which is bitter and slightly styptic—this juice seems to contain the peculiar virtues of the plant. These are said to be stomachic, stimulating, refreshing, aperient, demulcent, resolvent, deobstruent, &c. Geoffery asserts that the mild bitterness of the succory invigorates the stomach, excites the appetite, aids digestion, and frequently promotes perspiration and expectoration. Murray is inclined to think it useful in emaciations, melancholy, hypochondria and consumptions, and in diseases of the throat and breast. Van Swieten declares that the root of succory has had extraordinary effects in visceral obstructions and the disorders which they produce. Several writers of great respectability say that hysterical females have been cured by the use of the juice of this plant, and that the decoction either with or without milk has been serviceable to melancholy hypochondriacs. Some authors pretend that the powder of the dry leaves acts beneficially in diseases of the skin, in gout and rheumatism. The expressed juice has been medicinally employed, and it is said, often successfully in catarrhal engorgements of the lungs and in visceral derangement. United with ammoniac and other stimulating articles, it has frequently been used in intermittent fevers: but it cannot be doubted that in most cases which it is believed to have cured, the good effects were derived principally from the associated medicine. This opinion is supported by Alibert, who remarks, in opposition to the extravagant encomiums on the virtues of succory, that they are at least problematical as regards the removal of obstructions and cure of intermittent fevers; and that

he sees no good reason to assign to the plant any peculiar efficacy against certain diseases.

Chaumeton, Chamberet, and Poiret state that succory root is very much used in the north of Europe, and in France, as a surrogate for coffee, and that it is used in the latter country to adulterate the coffee which is sold in powder or ground, in the shops: and I learn from the importers of the prepared substitute, who have requested this account, that immense magazines or factories are established in Germany, for the sole purpose of its preparation. The manufacturers collect the root towards the end of autumn, it is then cut in slices, dried, afterward torrifed and pulverised or ground. The French authors say, "it is used in infusion or decoction with water, to make a drink which has all the appearance and bitterness of coffee, without possessing the other precious qualities of that useful beverage. But that it is nevertheless applied to the same uses, either alone or mixed with milk or cream." They state that it is necessary to take great precaution in keeping it, since, in large masses, it is liable to spontaneous combustion. Murray states that five houses in Augsburg, were consumed by a fire which had originated in a magazine, in the midst of a great quantity of this substance.

The Egyptians consumed immense quantities of succory, and the Greeks also used it. In Europe it is continually cultivated for economical and pharmaceutical purposes. Cattle eat the leaves during scarcity of pasture, and they never at any time show dislike to them. It thrives in any kind of soil, and any exposure, resisting droughts, deluges of rain, hail, or cold. It grows speedily, and forms an excellent forage for cattle in the spring. Under cultivation, it is bleached, like celery, by screening it from air and light, and in this state, forms an excellent and healthful sallad. Geoffrey says that intermittent fevers, which had resisted other means, had been cured by a free use of succory sallad.

To return to the root, as a substitute for coffee. From the preceding accounts of the properties of succory, it will be evident that it is, comparatively with coffee, an inert, or at least an inactive plant. And it is doubtless destitute of the subtle, heating and very stimulating effect of the favourite beverage made from coffee seeds. The empyreuma, on which the fine flavour and exhilarating powers and much of the peculiar effects of coffee depends, is wanting in the succory—it can therefore never be made to possess the delicate and grateful taste of coffee, while it will certainly be incapable of producing the same injurious effect. From the trials I have made of it, I believe, as a dietetic article of family use, it is more healthful than rye coffee, and has a softer and more agreeable taste; it is less injurious to delicate constitutions than coffee—it is less heating, more perspirative, less stimulating than coffee; and, though far inferior, as every substitute must be, to genuine coffee taken in moderation, I yet believe the health of the community, the female part of it especially (to whom there can be no doubt coffee is peculiarly injurious,) would be benefited by using a moiety or two thirds of this article, mixed with one half or one third of genuine coffee. That it is preferable to torrifed rye as a succedaneum, I fully believe. And this opinion is supported by the sensible properties of succory root, and those preserved in the prepared surrogate. Under these impressions, and influenced by the opinion that rye coffee is, to most constitutions hurtful, to some extremely prejudicial, I feel no hesitation in recommending to my fellow citizens the use of succory coffee; and so favourable is my opinion of its healthfulness and economy, that it is my intention to propos

* An inaugural dissertation on this plant by Rodolphe Jacques Camerarius, was published at Tubingen, to which the curious are referred.

† *Chicoree*, *chicoree sauvage*, French; *zichorien*, *wægwardt*, *himlæuft*, German; *cicoria*, *cicorea*, *radichio*, Italian; *achichoria*, *chicoria*, Spanish; *wægwarda*, Swedish.

the honourable the Secretary of the Navy, that it be introduced into the diet of sailors on ship-board, and soldiers in marine posts. The opinion just stated of the unhealthfulness of rye coffee, demand a word or two in its justification, since it is so palpably opposed to the prejudice and interest of a large proportion of our population. It is grounded on the observations I have made in my professional practice for some years past. I have found numerous instances of distressing choleric and flatulence in delicate constitutions and sedentary persons, traceable to no other source, which have appeared a short time after the free use of rye coffee; and which continued until I interdicted its use as a daily beverage. But I have seen other more distressing affections, attended, particularly in females, with violent habitual spasms—produced, as I believed, by small portions of spurred rye or ergot, which had been mixed with the pure grain. In such cases, I have only succeeded in procuring relief, by interdicting the use of the beverage. My suspicion of the presence of ergot has arisen from an actual detection of elongated grain in masses of unground torrified rye, which grain appeared to be nothing more than the incipient state of the spurred or poisonous seed. The same thing I have observed in examining the heads of rye in the rye fields, during botanical excursions. While I am sensible that great care is taken by the manufacturers of rye-coffee to cleanse the grain of extraneous substances, I still believe that the cockle seed and half-spurred grains will elude detection. I subjoin a translation of the remarks and directions printed in German on the papers in which the succory coffee is enveloped, with this single remark that it should be made either mixed with coffee or by itself, by pouring boiling water on it through a bag or strainer.

WILLIAM P. C. BARTON.

Use and qualities of this Surrogate of West India Coffee.

This elegant Surrogate of coffee is very conducive to health, does not heat the blood—is not injurious to the eyes—nor does it affect the nerves, but assists digestion.

It may be drunk without any addition or with a small proportion of coffee, agreeably to the taste of the persons using it; it is prepared in the usual manner of coffee.

Directions for using the Germanic, formerly called Westphalia Coffee.

To one portion of 3 cups take of this coffee 1-4 Loth, this would be according to our weight only the eighth part of an ounce, and appears to me a great deal too little; and if you wish to have it quite similar in taste to real coffee, add 3 or 4 beans, and prepare it as usual. But even without this addition, it will be found an agreeable beverage, as in its preparation the greatest cleanliness is observed, and its component parts consist only of such things as are conducive to health, by no means injurious; and may be submitted to any medical examination.

Professor Barton's remarks will prove interesting to our readers, so far as they explain the medical qualities and effects of Chicory and of Rye, when used instead of coffee—but those who have been subscribers from the commencement of this work, will recollect that several communications, commencing with one from Judge Holmes, of Winchester, in the first volume, have been published, to show, that of all substitutes for imported coffee, the root of this plant affords the best; and that it is, perhaps, yet more deserving the attention of Farmers, as food for their stock. Mr. Bellinger, recommends it as

being little affected by the winter in South Carolina, and as yielding the best early pasture for sheep. For a very satisfactory paper, in relation to the uses, mode of planting, and yield of Chicory, the reader is referred, especially, to the American Farmer, vol. 3, page 65.—*Edit. Am. Farmer.*

FROM THE NATIONAL INTELLIGENCER.

NATURAL PRODUCTIONS OF MISSOURI.

SENATE CHAMBER, MARCH 3, 1823.

Messrs. Gales and Seaton:

Gentlemen—I wish you to publish the enclosed letter. The facts stated in it, relative to the vegetable productions of Missouri, will give correct data for forming opinions about the soil and climate of that country. The writer is a gentleman of science, character, and fortune, greatly attached to the pursuits of agriculture, and entitled to an implicit confidence in all his statements.

Yours, respectfully,
THOMAS H. BENTON.

Franklin Missouri, Nov. 24th, 1822.

SIR—Agreeably to your request, I have forwarded to you some of the largest specimens of plants which have been reared in my garden this year, with a few others of two years growth.—You will bear in mind, that I have not travelled for these samples out of my own garden, which was laid out on the poorest part of my land, and on which there has not a particle of manure been spread. It is a rich sandy loam; contains, for vines and other small fruits, &c. eleven acres, and has too great a portion of sand in my own estimation, but in the opinion of my neighbours, a great deal too much.

Perhaps it may afford some satisfaction to know, I live on the north bank of the Missouri River, about 180 miles above its mouth, in latitude 39, and in a bottom whose greatest extent, from East to West, is about 25 or 26 miles, and whose average breadth is about 2 miles. I know of no part less than one, nor many above 3 miles in width. At Boon's Lick, the bottom is about its medium breadth. That our country is incomparably rich in its products of corn, wheat, and such articles as are generally raised in the Western countries, I believe has never yet been disputed, and I need not particularise them.

It is known to most, that an individual of any species of plant may accidentally attain to great size, even on a poor soil; and that some soils abound with salts peculiarly adapted to the nurture of particular species of plants; and that, consequently, the whole species will be reared to great perfection on them. But, it is not known by any farmer, that a great variety of plants can be raised, to great perfection, for a series of years in succession, unless the soil and climate be both rich and warm. Let me not theorise, but leave it for others to conjecture the causes of the great fertility of our country: facts are all I vouch for; and these not conjectural, but such as I have determined by the trial.

By the by, these theories, or conjectural causes, though a source of much error, have yet afforded me much occasional amusement, and I seldom go to Tennessee without experiencing its exhilarating influence. My acquaintance meets me, and exclaims, "Ah! my old friend, are you alive yet, and just come from that cold country?" *Hardeman.* "I am alive, you see, and I left the Missouri but ten days ago." "Well, what are the times there? I suppose you came down to purchase your old plantation again: or perhaps to buy cotton?" *H.* "I am content to live in

Missouri; and, as for cotton, I raise what I want." *H.* "Come, come, my friend, that will not do—for cotton to grow in the Missouri, is out of the question." "Why so?" "Because it lies too far north; and because it is so much elevated; for you know that high mountains, even in low latitudes, are covered in the summer time with snow; therefore, a high latitude, and a high country conjoined, must produce the most extreme cold." Generally, here, I yield to my acquaintance; and answered his conclusion, by stating the advantages we derive from this cold: That it is the only spot of earth which civilized nations allow to be inhabited by civilized people—that is, free from the visitations of the Devil: that, in fact, he once came here, piping hot, and was immediately seized with such a chill, that he ran back, swearing he would never visit so cold a place again. Thus I break with those whose idle dreams prevent them from observing useful facts. But, the cotton: I raised about 1,200 lbs. in the seed, per acre, this year. I say about, for I was away from the State in September and part of October, when a part was picked out, and put up without being weighed; but, from what was gathered before I left home, and since my return, I am satisfied there is no great error.

It is the opinion of some men, that a certain number of days is necessary to perfect a vegetable, in any soil or situation, and that cotton, being a native of a southern country, where the seasons are long, in which this plant grows, it cannot be brought to maturity in ours. Here is another sort of theory, about which I shall not detain you so long as I did with the other, but simply say: I planted my cotton about the 28th of April: a drought was then prevailing here, and it continued until the 30th of May, at which time a rain fell. In a few of the first days of June, my cotton came up; on the 6th July, I saw blooms; on the 16th August, it began to open; and the field was picked over on the last days of August. Our old friend, Dr. John Sappington, who lives a neighbour to me, says his cotton came up from the 8th to 10th June, the seed having laid in the ground something more than five weeks; and he raised this year, by actual measurement of the ground, and weight of the cotton: To say, 10½ acres of ground, picked out before the 15th instant, 10,272 lbs. of clean dry, white cotton, of fine staple. His letter to me this day, and now lying before me, informs me of this; and, further, that there is now open in his field from 1,800 to 2,000 lbs. to be gathered.

In order to test this theory a little better than Obadiah did his, by his wife and cow, I planted some Indian corn on the first day of May.—On the 9th June, it was in silk; on the 15th July it was ripe. I planted some of the new corn, which was then ripe enough for the purpose, on the 10th July; on the 11th August it was in silk; on the 10th September it was ripe; being the second crop, or two generations in 4 months and 10 days. I planted some other new corn on the first of August; and on the 1st September it was in silk; on the 1st October it was ripe. Thus, in 61 days I have perfected a generation of Mandan corn.

The timber is not generally tall in our country, particularly near the prairies, where it is thinly set; the bodies are low, with large spreading tops, even in our richest lands. In the bottoms it is otherwise; for there it is thickly set, and tall. Gen. T. A. Smith has had several cut into rail lengths, 11 feet long, and 7 cuts to the tree, which would require a body of 84 feet of straight timber. Mr. Hater cut one, a few days ago, in this bottom, from which he got 8 rail lengths, of 11 feet each. Allow, then, as is really done, for the stump and half the gap made in cutting the

logs off, it must have taken a tree of 95 feet to produce these rail lengths. A hollow sycamore tree, which stands about half a mile from me, I measured, and found it required 43 feet to compass it. This is the largest that I ever saw.

Lately, I measured some trees which I am rearing for shade, and their girths were, Catalpa 2 years old, 37½ inches round, proportional height—Black locust, 13 round—Balm of Gilead, 13 5-8 round—Catalpa one year's growth 7½ inches round—White Mulberry, 6 inches round—Sweet Cherry, 5½ round—Tulip poplar, 6 round—Sycamore one year old, from a stump in the garden, 10½ inches round—Grape vine, one year also, 3 inches round, 20 feet long. Annual plants—Black mustard, 9 feet high, 4½ inches round; this is the evangelical mustard that the fowls of the air roosted upon. White do. 4 feet 5 inches across the leaves—Ruffle do. 4 feet 3 inches across the leaves; Palma Christi, 14½ inches round, and supported me standing erect at the main fork, 4 feet above the ground, and 13 branches being below, most of which were 8 feet in length. Asparagus stalk, 3 inches round, 8 feet 3 inches high, the root being only two years old. Salmon Radish, 19½ inches round, 26½ long; another 18½ round, 36½ long. White summer, do 23 inches round, 16 inches long, and broken off by drawing up, the point 2 inches thick. Hemp stalk, 15 inches round, its branches 9 feet long. My hemp raised for seed grew in length from 12 to 15 feet. One stalk, raised by my neighbour, measured in length, 18 feet 7 inches. Turnips now growing, one measured on the 9th inst. 30 inches round. Yesterday I drew up three, which grew about a foot apart, and their measures were 27, 28, 28½ inches round. I raised this year on two vines, they were so blended I could not separate them, 4468 cymlins, or squashes. On one vine I raised 96 citron melons; one, taken as a medium size, weighed 7 lbs. then 96×by 7=672 lbs. I had three days ago dug from one hill, one bushel and a half and one quart of Jerusalem artichokes; these were raised without any cultivation, except the planting of 3 or 4 small bulbs in the hill last spring. This plant I have seen growing spontaneously in the prairie near St. Louis.

On the 16th instant I killed a steer 5½ years old, which was raised and fattened in the bottom without being fed, except 15 days to prevent his falling off before the weather would change—neat beef, 884 pounds, tallow, 181 pounds. He was inferior to several others of the same age.

I cannot forbear saying something more about my asparagus. I have 12 square rods set with it, not one particle of manure. The roots planted in the native soil, 18 inches apart, and 6 inches deep. Since I sat down to write, one bunch has been counted, and it contains 81 stalks. This abundance is from one root in two years time.

My vineyard contains from 6 to 800 plants, mostly of European kinds; and they grow luxuriantly, as you will perceive from the specimen above stated; it was the Bordeaux. Our native bunch grape is acknowledged, by all who have tasted them, to surpass any other indigenous grape in the United States. I shall transplant 1 or 200 next spring, to see if cultivation can improve them.

In the fore part of this week, in getting timber to build a cabin, I found about a peck of bees-comb, hanging to a limb. The negroes, after I left them, got it down, and stated, on inquiry, that it contained a quantity of good honey. This fact I mentioned to two other persons severally, and they each told me of something similar, which fell under their own observation. One said he was hunting for deer last fall, and found a large quantity of comb depending from a limb—he had

3 others with him, and they shot through the comb, and cut off with their rifle balls as much honey as they all could eat, and left the remainder for the next fortunate hunter. The other man to whom I related my story, believing it not to be a new case, said, that, in the summer, he went with 4 others to a prairie, about a mile off, and in the bottom, to run a race, and while they were getting their switches to ride with, they found as much honey as they could all eat, suspended from a limb not longer than a chainpost. Thus, having mentioned my case to but two others, and they both knew something better, I concluded it was a case so common as not to merit the relation; therefore, I left the story at rest, except my sending it thus to you.

Respectfully yours,
JOHN HARDEMAN.

Col. BENTON.

TO THE EDITOR OF THE AMERICAN FARMER.

HYDROPHOBIA IN SHEEP.

Springdale, Va. 18th March, 1823.

DEAR SIR,

The effects of hydrophobia were singularly exhibited a few years since, on a flock of sheep belonging to the plantation of my father, in this county. As the facts were at the time perfectly novel to me, and may still be interesting to others, I have thought them not wholly unworthy of a place in your excellent paper.

In the month of February, 1810, while it was intensely cold, and a very deep snow covered the ground, the flock of sheep were confined in a small enclosure surrounding a fodder house, which served the double purpose of supplying them with food and protecting them from the inclemency of the weather. In this situation they were visited by a dog belonging to one of my neighbours, which, although there had been something rather extraordinary in his appearance and conduct, had evinced no very marked symptoms of hydrophobia. About daylight in the morning he was discovered by the negroes, in pursuit of the sheep in their inclosure; but on seeing them, and being menaced with a stick, he ran off, but instead of going immediately home he took the direction to a neighbouring village, where he bit two cows, and disclosed other marks of unusual ferocity and ill nature. These circumstances at length excited suspicion of the true nature of his malady, and on his return home, he was shot. Upon examining the sheep, it was found that 15 or 20 had been bitten, most of them so slightly that in one instance, only, was it thought that death would probably ensue, merely from the wounds. The peculiar manner in which the animals were bitten, and the number injured, showed that the dog was actuated more by a strange and malignant propensity to mischief, than from the mere desire of food. Instead of killing them immediately, he appeared to have attacked them merely for the purpose of teasing them; and the impressions of his teeth were barely visible, on their ears and faces, and not unfrequently on their legs.—In every case however, he succeeded in bringing blood; most of the female sheep were in their last stage of pregnancy, and so trifling was the injury they sustained, that they bore their lambs as usual, without exception; and before the lapse of a fortnight, their wounds were entirely healed. About this period hydrophobia first made its appearance. Two of the flock were found sick, and unable to stand, before they were known to be affected. In a few days the disease was observed in several others, and in this manner three or four in each week, disclosed the symptoms,

and six weeks had elapsed before the whole number bitten, had been affected.

There was a peculiarity attending the early symptoms, which soon marked the individual destined shortly to become a victim to the dreadful malady. It first attracted attention by pursuing and tormenting its associates, by almost incessant libidinous actions. The diseased were all females, and several with lambs at their sides; yet their veneral inclinations were so powerful, that they exhibited in a most astonishing degree, the manners and actions of the other sex. In this manner did some of them, with persevering industry, tease and torment a companion, for twenty or thirty minutes, until the fugitive would find shelter by mingling with the flock—a second would then be attacked in the same manner, and have to run the same vexatious round; sometimes the fugitive would turn upon its pursuer, and by an effectual resistance obtain relief. This paroxysm would intermit occasionally, and the infected sheep, would feed peaceably, with the others, if not disturbed; but upon approaching the flock, it could readily be recognized by its bold countenance, staring or glassy eyes, and an advance to make battle. In this state of the disease they would attack a man with much resolution, and beat him with their heads. In some instances I recollect seeing them advance from fifty to one hundred yards, from the flock, and attack persons so furiously, that they were obliged to defend themselves with sticks. After discovering more than common strength and vigor for a short time, an instantaneous debility appeared to come on, and their limbs refused to do their office. I have seen them in the very act of advancing vigorously to battle, fall as suddenly, as if shot by a ball from a gun. In a few minutes their strength would return, and they would rise again, to renew the combat. This I think might generally have been considered the second stage of the disease; yet in this situation their amorous propensities continued, for I have seen them fall, while pursuing other sheep of the flock. These paroxysms, or falling fits at last, became more and more frequent—the animal refused to take food, and became too feeble to follow the flock.—But even in this state of excessive debility, and while apparently suffering the most excruciating pain, the inclinations which predominated throughout the disease would still manifest themselves, until a complete exhaustion would terminate the struggle. The lambs which had continued to suck during the lives of their dams, were now fed by hand, and if I recollect aright were without an exception raised. The wool was invariably saved after the death of the sheep, without any inconvenience whatever; indeed as a proof that the blood of the infected animal cannot be injurious, unless commingled with that flowing in the veins of the living; the skins were taken from several hogs, which died of hydrophobia, the same time, and the bodies frequently eaten by the others, with entire impunity.—It was a remarkable circumstance, that with the infected animals, putrefaction ensued almost immediately after death.

Very respectfully,
WILLIAM M. BARTON.

ONIONS—POTATOES—GROUND SUITABLE FOR—SELECTION OF SEED, &c. &c. &c.

In vol. 4, page 374, a communication was published from a gentleman of the first respectability in New York, communicating an important fact, respecting the preservation of vines from the ravages of the bug, and stating also, "should you desire it, I can send you some seed of

"Onion of very superior quality, a large flat white Onion—a kind we have raised in our garden for more than twenty years in the same beds, without finding any necessity for change of seed."—Accordingly he has had the kindness to send some of the Onion seed, and with them, the following hints, which may prove useful.—*Edit. Am. Farmer.*

Bedford, 7th March, 1823.

SIR—I have received your polite letter, and agreeably to your request, now forward to you by mail some onion seed, and some more melon seed. The ground should be highly manured for the onions; and the young plants not suffered to stand too thick. It is not necessary to change the ground—we have raised them now, for nearly twenty years—year after year, in the same beds, and we perceive no symptoms of degeneracy. Our melons are likewise planted every year in the same place. The great secret of preventing your vegetables from degenerating, is keeping your ground rich, and observing very great care in selecting your seed. When we take up our onions, they are spread in the garden walks, and one or two dozen of the largest and flattest, are immediately selected from the whole quantity for seed. A few years since, in the spring, being scant of seed potatoes, we unwisely planted the screenings, that is, the potatoes which were too small for the table; and the crop was hardly worth gathering. This lesson, has taught us to select the largest potatoes for seed. I take the liberty of sending you the list of premiums offered by our Agricultural Society; and when more at leisure than at present, may trouble you with some statements relative to our premium crops.

I am, Sir,

Your obedient servant.

A southern, or even a middle state farmer, would be surprised to see a list of all the articles sold from a New England farm—instead of relying on one, or two, or three, they cultivate something of every thing, to suit, and to fill up all times and seasons, and though the sum received for any one may be trifling, the aggregate is considerable. He sells from a small farm, *cider* enough to pay for his groceries—beans to pay for his leather—hops to pay for his children's schooling, and so forth—reserving unbroken the proceeds from his chief products, to accumulate for his children—for old age, or a "rainy day."—*Edit. Am. Farmer.*

AGRICULTURAL SCHOOLS.

On the policy and advantages of Professorships for teaching young people, who intend to pursue farming for a livelihood, how to conduct their agricultural operations on scientific principles, Mr. Madison's address to the Farmers of Virginia, and the report to the Legislature of New York by Judge Buel, are so able and satisfactory, that nothing more need be said on that view of the subject; but there is yet room and necessity, for collecting details, to make known the history, and the practical effects of such establishments in Europe, with a view to the better organization of such, as may, and we hope will soon be instituted in America. The following remarks from the Editor of the New York Commercial Advertiser, present interesting general views, and prove that could the writer give, more time to the consideration of the subject, he might afford yet stronger and more ample illustrations.

Edit. Am. Farmer.

With these among other views that might be stated, we beg leave to second the recommendation of the committee for the establishment of a LITERARY AND AGRICULTURAL SEMINARY. We shall not attempt to state minutely what would be its peculiar organization, but merely give some hints as to a general plan that might perhaps be adopted. Let a suitable farm for the various purposes of agriculture, of two, three, or four hundred acres to be selected—to be placed under the immediate superintendance of an accomplished theoretical and practical farmer. Let a suitable building, or buildings, be erected upon it for an Academy; and let able instructors of the English, Latin, and Greek languages, a professor of Natural Philosophy, of Mathematics, and of Chemistry, particularly agricultural chemistry, be provided. Here let all farmers who are able, send one or more of their sons, unless specially designed for the before named professions; and even then, if our ideas are correct, two or three years spent in such an institution, would be of great advantage.—Let the said farm then be properly divided for the various purposes of agriculture; and let it be cultivated in the best manner, by the students; who should have their time appointed between hours for study, for labor, and for recreation. In this way a competent knowledge of all the important branches of education taught in our Colleges, might be acquired; and in addition, when the pupil had completed his course of instruction he might return home a thorough bred theoretical and practical farmer. We would also have an experienced Horticulturist attached to the institution; and a large garden cultivated. This might be divided into parcels of various dimensions, suited to the age and capacity of the scholars selected from time to time for this department. As an inducement to labor, and an incitement to superior excellence, premiums might be awarded for the greatest skill, or the most labor performed in a given time; and the whole produce of the farm, garden, &c. should be applied towards defraying the expenses of the institution. This would greatly lessen the expenses, which would otherwise be incurred by the students, and would enable many farmers to educate their sons in the institution, who, in common cases, would be obliged to content themselves with giving them nothing more than a common school education. The farm should also be well stocked; and in winter, each scholar should have the care of a certain number of animals. He might also perform other work, such as threshing, cutting wood, &c. &c.

It does appear to us, that institutions upon this or a similar plan, would be of incalculable benefit to our country. By acquiring an education in this way, the pupil would be in no danger of getting a sickly constitution, so frequently the effect of sedentary habits. Their activity would be increased by exercise, and their nerves braced and strengthened by labour. Instead of the pale and ghastly countenances frequently brought from College rooms, we should see the rosy cheeks of health—bodies strong and athletic, and eyes sparkling with vivacity—but we have not room to pursue the subject. The public have our general ideas, thrown hastily together; and this must suffice for the present. We may resume the subject

From the National Intelligencer.

CULTIVATION OF THE VINE, &c.

A small work has lately issued from the press of the enterprising booksellers, Davis & Force, of this city, entitled "A Memoir on the Cultivation of the Native Grape, and the best mode of making Wine," by Maj. Adlum. This is one

of those works that have been long required in this country, and that, I conceive, must and will circulate extensively, from the value and importance of the information it contains. The cultivation of the grape, considered as a branch of agriculture, is of much greater importance than it has hitherto been supposed to be. It has been estimated, from correct data, by the author, that an acre of ground would yield 15,000 lbs. of grapes, which, at 6½ cents per lb. would make

700 gallons of wine, at \$1 per gallon,	\$937 50
	700 00
	1,637 50
Expenses, labor, capital, &c.	500 00

Profit, \$1,137 50

If such be the profit of a single acre of ground planted in vines, it must be obvious that scarcely any other branch of agriculture could be more productive. And as this, too, can be carried on in connexion with other crops, it is a matter of astonishment that it has been so long neglected in our country. In a political point of view, also, its importance cannot be too highly appreciated. "We pay, annually," says a writer quoted by the author, "to foreign nations a sum of money for wines, spirits, and materials for making spirits, and for fresh and dried grapes, as great as our whole specie medium." If, then, the demand of our country for wines and grapes, could be met without resorting to foreign nations for a supply, this immense sum would be retained in the country, and applied to other objects of industry and national wealth. These are subjects, however, at which I can but barely glance. Time will not allow me to enlarge upon them. The indigenous vines are very numerous throughout the United States; in almost every latitude and soil they are to be found springing up, and spreading out in the richest profusion. The most of these, says our author, "are capable, by proper cultivation, of yielding a wine superior to the best cider, as a wholesome beverage, and equal to most imported wines." But these, he very correctly asserts, are diminishing daily, from the progress of improvement and the rapid increase of population; and, if not attended to in time, will become altogether extinct." To avert this evil, which might ultimately be deeply lamented Maj. Adlum has, I understand, devoted a considerable portion of his life to the propagation of the native grape, and the fabrication of native wine. This wine I have drank, and, with many others, have no hesitation in saying, that it is not at all inferior to most of the foreign wines we receive, and that the grapes themselves are excellent for the table.

The object of the present little work is to diffuse a knowledge of the mode of cultivating the grape and of making wine; the want of which, it is presumed, has been the cause why so little attention has been paid to this very valuable production of the vegetable kingdom. This information, which the author has condensed and embodied in a few pages, will be found highly useful to all who wish to add to their wealth or their gratification, and will, I sincerely hope, be the means of extending the cultivation of this very valuable production of our country. To those who have gardens, as well as those who have farms, or country seats, it must be delightful to have their vacant ground bespread with vine-covered arbors, and to be able to regale their friends with the luscious fruit, and the not less luscious juice, of the grape. It would be, indeed, to realise the delicious picture of beautiful France, and to make this country still more lovely, more independent, and more happy.

VETIS.

INTERNAL IMPROVEMENTS.

FROM THE UNITED STATES MAGAZINE.

CANAL THROUGH THE ISTHMUS OF DARIEN.

Ingenious men have been much occupied with the idea of a communication between the Atlantic and Pacific Oceans, through what is termed the Isthmus of Darien. The late changes in the political institutions of this part of the globe, have given to this subject an additional interest; and we hope that the desired communication will rank among the first public acts of our sister republic of Colombia. But a few years have passed since a canal of the extent, was considered only to be the parallel of an Egyptian pyramid, requiring the wealth of an absolute monarch, and the labor and skill to be wielded by such power alone. Now, a single member of our young republic, constructs canals of many hundred miles in extent in the short space of four years, with an expense comparatively insignificant; and overcomes obstacles hitherto deemed insurmountable.

Our attention is now called to this subject by a MS. map of part of the Isthmus of Darien, with an accompanying memoir in Spanish, which have lately been put into our hands by our distinguished townsman, Dr. Mitchell. The map appears to be genuine, and is constructed as late as 1821, by W. E. Cortin. It embraces that portion of the Colombian republic, through which flow the rivers Atrato and St. Juan, between the latitudes of six and ten degrees north.

Humboldt, the most accurate and indefatigable traveller of ancient or modern times, has enumerated no less than nine different points of communication between the Atlantic and Pacific oceans, the most northerly being at the river Columbia, and the most southerly a conjectural passage in Patagonia. The mountainous range of the Andes opposes an irremovable barrier to a free water communication, at all these points but two; and it is to these two points we beg leave at present to direct the attention of our readers.

In latitude 80 deg. 12 min. north is the mouth of the river Atrato, called Baracoa, emptying into the Bay of Candelaria at the bottom of the gulf of Darien. This bay is sufficiently large for all the ships in the world; it has good anchorage from fifteen to twenty fathoms, and sheltered from all winds. There is a bar of 200 varas in breadth, with five feet at low water, across the mouth of the Atrato, consisting of hard sand. The Atrato, in the memoir above referred to, is estimated at 530 miles in length, to its source, and is navigable for steam boats drawing six feet water, about 400 miles, to its junction with the Quito. It strongly resembles our Mississippi, in its inundations, its numerous windings and bayous, and in being filled with logs, sawyers, and other impediments to a safe navigation. These obstacles will be removed, as the country becomes settled and cultivated. Pursuing the course of the Quito, by a very shoal navigation, to nearly its source, we have only to cross the Ravine de la Raspadura, a distance of four and a half miles, and we arrive at the bank of the river St. Juan, which empties into the bay of Charrambira, in the Pacific.

We are indebted to Humboldt for the knowledge of the fact, that as early as the year 1788, an enterprising monk, caused a canal to be made, connecting these two rivers: by means of which, in rainy seasons, loaded canoes have passed from the waters of the Atlantic, to those of the Pacific. It is not, however, our intention, at present to examine this particular route, as another

presents itself, less tedious and dangerous, and which seems to us far preferable.

Following the course of the Atrato from its mouth, a distance of about 150 miles, we come to a tributary stream, entering from the north, called the Naippi. This river presents no great obstacles to navigation, for a distance of 45 miles, from which point, a portage of six miles brings us to the bay of Cupica, opening to the Pacific. This portage is level and well adapted to a canal; and Cupica bay is safe, and sheltered from all winds. It is here, we think, that the only advantageous junction of the two oceans must be undertaken.

The shoal and rapid course of the Quito, clearly exhibits such an elevation of the country, as would prevent the construction of a useful canal in that direction—presenting the objection of numerous locks, and perhaps a deficiency of water at the summit level. The little cut made in 1788, will remain more an object of curiosity than of utility.

By the river Naippi, on the contrary, with a level portage, and perhaps assistance from the river Nasique that discharges itself into Cupica bay, a canal can easily be made, which would give facility to the transportation of merchandise from one sea to the other. We are not however, of the number of those who think that this channel would for centuries, be widened by natural causes sufficiently for sea vessels. From the most exact barometrical experiments the difference of level between the two seas cannot be but few feet—which difference may readily be ascribed to the want of minute accuracy attending this mode of measurement. From geological appearances, we are warranted in concluding, that the whole sea of Antilles has at a distant period been land, of which the numerous islands, are the remains. Hence, the gradual operations of the sea may, in the course of ages, make a passage through the isthmus; but there never will, we imagine, be effected by human agency, a free water communication for the largest ships. Humboldt has enumerated the many and important consequences that would ensue, if the two continents were disjoined; and the lynx-eyed jealousy of our English brethren, has already anticipated the serious results of this disruption, affecting the stability of her eastern empire.*

The countries watered by the rivers Atrato and Naippi are represented as fertile, and occupied by numerous hordes of hostile Indians, by which it is rendered necessary for boats on these rivers to be well armed. These hordes, under better political institutions, will be harmless, or disappear; and we consider it a matter of congratulation, that the spot designated for this important work falls within the limits of our sister republic, Colombia.

* *A canal across the isthmus would facilitate the subjection of Japan, by giving the western shore of the continent, the advantages of the superior resources of the eastern shore. America may be looked upon as a stepping stone to the European strife, which has in view to reach eastern Africa. It is the nursery of the race of men who are to conquer and civilize Asia.—Vide Crawford's History of the Indian Archipelago, vol. 8 p. 337, et seq.*

RARITAN CANAL.

The Trenton True American has reason to believe that the expense of completing the Raritan and Delaware Canal will not exceed \$250,000.—It would be cheap at a million, calculating the immense advantages which the three states would derive from it. The tolls would in a short time

be \$50,000 per annum, taking into consideration the commerce and travelling which would result on this great post rout. The steam boats would leave Philadelphia early in the morning, send the passengers in the canal boats at Lambertton, dine in the steam boat at Brunswick, and arrive at the Battery by sunset without difficulty or fatigue.—No time should be lost in commencing the project.

CURE OF THE DYSENTERY.

A physician at St. Clairsville, Ohio, states that "during the autumn of 1821 and 1822, the dysentery was very prevalent in the eastern section of the state, and in the latter season peculiarly obstinate. The various remedies recommended for that loathsome and distressing disorder, were prescribed with but little advantage, for the disease seemed to bid defiance to our utmost skill, and rendered all our remedies impotent and ineffectual. Thus baffled by a disease we could not remove, and the excruciating sufferings of our patients demanding immediate relief, we were compelled to resort to some other than the usual mode of practice. And accordingly, I prescribed to a young woman of strong constitution (but at the time laboring under a violent attack of the dysentery,) ten grains of the prussiate of iron, (in milk,) every two hours, and the effect was so immediate, salutary and complete, as at once to astonish the patient, the nurse, the friends and myself; since which I have used it in a great number of cases, with the most happy effects, and believe it to be a most valuable and entirely safe medicine. (in the hands of the skilful physician.) Since the publication of Dr. Zollikoffer's book, I have used it in some cases of bilious remittent fever, with great advantage, but in larger portions than he recommends, say from eight to fifteen grains in a dose, and repeated every six hours.

"I am indebted to Dr. Wright, of Baltimore, for the knowledge I have of this remedy, as it was from a paper published by that learned gentleman, some years ago, that I received the first hint of making use of the prussiate of iron as a medicine."—*Salem Messenger.*

AMERICAN PORCELAIN.

The editors, a few days since, when they published an article from North Carolina, on the subject of *Porcelain Clay*, did not recollect the manufactory of porcelains or *American China* which has been established at Corlaer's Hook, by Dr. Mead, and in a state of operation for many years past. Specimens of this manufacture, of unquestionable beauty and fineness, were exhibited during the late war. On the return of peace, with its influx of foreign imports, this business declined. But the last time I was at the establishment, some time last fall, it contained upwards of ten thousand pieces ready for baking. The doctor is at present absent from the city, or he would doubtless give a full and satisfactory account of this interesting branch of our domestic manufactures.—*N. Y. paper.*

DONT SCALD YOUR POULTRY.

A writer in the Connecticut paper remarks upon scalding poultry, as follows: Scalded fowls are ill looking and will not sell for so much as those that are picked, and soon spoil, often before market; otherwise the feathers although not of the first quality will amply pay for plucking. By scalding, poultry is deprived of its delicious flavour, is made insipid, often producing what is termed rising on the stomach.

FROM THE MAYSVILLE EAGLE.

John Wilson, better known as "Walking Wilson," commenced trading to New-Orleans, in the spring of 1800; completed his forty eighth voyage during the last summer, averaging nearly two and a half trips per season; and during that period has travelled by land and water one hundred and twenty eight thousand miles, in the prosecution of trade, as will appear from the following exhibit.

48 trips to New Orleans, 1600 miles	78,000
Walked 20 trips through the wilderness returning, 800 each	16,600
12 do. on horseback, do.	9,600
16 do. in steam boats, 1600 do.	25,000
	128,000

Wilson has more than once beaten the United States' mail whilst walking; man could never keep side and side with him; has never been overtaken by man on foot or horseback; is about forty years of age; possesses a constitution apparently unimpaired; has amassed a portion of "earthly goods," and is now in the "full tide of successful experiment," making his forty ninth trip. Wilson is a native of Mason county, Kentucky.

A PARODY

On Moore's favourite song of the Woodpecker. I knew by the post that so gaily display'd

The sign of a bear, that a tavern was near,
And I said if a cask of good gin was e'er made,
The man that was thirsty might hope for it here.

It was noon, in the mud puddles scatter'd around,
In silence repos'd the voluptuous hog;
Every leaf was at rest, and I heard not a sound,
Save the innkeeper flogging a mischievous dog

And here in this lone little spot, I exclaimed,
With a pipe in my mouth and a drop in my eye,
With a cask of good liquor, old rye coffee nam'd,
How blest could I live and how calm could I LIE.

By the side of yon oak, where an old toper sips
His glass of gin toddy, how sweet to recline,
And to know that the liquor I raised to my lips,
Had never been tasted by any but mine.

THE FARMER.

BALTIMORE, FRIDAY, MARCH 28, 1823.

Those who receive this, the first number, will be considered subscribers to the fifth volume of the American Farmer. They will accordingly remit the amount of a year's subscription, forthwith, by mail at the risk of the Editor, and be pleased to accept his sincere thanks, for their continued patronage, and his assurances, that no pains shall be spared to give to this volume, such variety and value, as will make it worthy of being recommended by its present patrons, to the notice of their neighbours and friends.

Commodore Porter's squadron, has arrived at St. Thomas. The steam-boat Sea Gull, being the first vessel of that sort ever seen there, "astonished the natives." Hearing of continued depredations on American commerce, by Porto Rico privateers, the commodore made—steam immediately to correct the procedure.

LATER NEWS.—Later intelligence, by a few days, is received from France by the brig Oak, Capt. Weeks, at Boston. War was considered inevitable, though it was not expected that any formal declaration would be made; the King's speech being sufficiently intelligible. Troops were

leaving Paris to join the main army on the Frontiers, preparatory to their march upon the Spanish Capital.—The Spanish Amdassador had left Paris for London, on his way home. England has taken no part—merely fanning the embers—it is easier to kindle than to extinguish war—like the wood cutter's fire which gets abroad in the mountains. *Produce of all kinds had risen in price.*

Letters received from Havre of the 2d February, state as follows.

"War is all the talk here at present; and it is the general belief that *England will make common cause with Spain.* Cotton rose yesterday three cents per lb. and all in market was bought up. It is now 26 sous per lb."—The following is a postscript to a letter from a very respectable French house at Havre, of the same date.

"A house of this city, yesterday received, by express, from Paris, orders to purchase all cotton remaining in market, for account of a house in Paris, which is very intimate with our prime minister, M. de Villele. We are assured the minister is interested in the speculation.—If it be so, you may consider it certain that" war will take place between France and Spain.

Another says,

"There has been a great rise in every article of produce in our Market, tobacco excepted. Cottons have risen 3 or 4 sous.—Georgia may be quoted at 26 sous, and as the demand is great will no doubt go higher.—Thirty sous have been refused for Louisiana. St. Domingo coffee has sold at 42 sous. French sugars at 110 per cent. profit, although they have fallen a little in Paris. All kinds of dye woods have risen very much, and rice is worth 42 francs—some even ask 45. In any event, the French cannot make war before the first of April, and great caution should prevail on your side not to give too high prices, counting on the certainty of war, for I cannot yet think, as many do, that it is inevitable. I will write to you by the Montano, to sail in a few days. The Hector is in the roads."

PRICES CURRENT.—CORRECTED WEEKLY.

Flour, best white wheat, \$7 50—Howard st. Superfine, \$7 25—fine do. \$6 75—Wharf, do. \$7—Wheat white, \$1 50 to 1 55—Red do, 75 to 80 cts—Rye, 75 to 78 cents—Corn, 59 cents.—country Oats, 43 cents—Beef, 8 cents per pound—Live Cattle, \$6 to \$6 50 per cwt.—Bacon, round, 8 to 9 cents—Pork \$4 50 to 5 50 per c. lb.—6 to 8 cts. per lb.—Mutton, 5 to 6 cts. per lb.—Beans, \$1 37½ to 1 50—Peas, black eyed, 55 to 60 cts.—Red Clover Seed, \$7 50 to 7—Orchard Grass do. \$3—Herds' Grass do. \$3—Timothy do. \$5—Millet, \$2—Flax Seed, 75 to 80 cts.—Whiskey, from the wagons, 32 to 35 cts. per gal.—Apple brandy, 30 to 52 cts.—Peach do., 65 to 70 cts.—Shad, none in market—Herrings, No. 1, \$3 62½ per bbl.—No. 2, \$3 37½—Fine salt 80 to 90 cts. per bush.—Coarse, do. 75—Butter, 20 to 25 per lb.—Eggs, 18½ cts. per doz.—Turkeys, 75 cts. to \$1—Geese, 37½ to 50 cts.—Chickens, \$2 per doz.—Straw, \$17 per ton—Hay, \$10.

WHEAT.—Several cargoes of Wheat were sold yesterday at 155, 156, 157 and 158 cents per bushel.

MARYLAND TOBACCO.—Fine yellow, from \$25 to 30—Yellow, 16 to 20—Fine red, 10 to 14—Common red, 4 to 7.

Prices of Seed at Philadelphia.—Herd's Grass of the best quality, \$1 per bushel—Orchard Grass, \$2—Timothy, \$3—Clover, \$6—Millet Hay at \$18 per ton.

THE CELEBRATED HUNTER EMPEROR.

Imported four years ago, by Messrs. Tabb and Smith of Virginia, for the purpose of improving the breed of horses in our country, has been obtained by the subscriber, for the present season. This noble animal is a fine bay—with black legs, mane and tail—handsomely marked in the face, and possessed of all the points which constitute perfection in the most useful horse, viz. size, beauty, strength, activity, and spirit. It is, indeed, a rare thing, to see a horse of such ample proportions—and at the same time, so active and light in his movements.

Emperor will cover at \$12 the spring's chance, \$5 the single leap, and \$20 to insure. The Groom will be entitled to 50 cents in each case.—It is indispensable, that the money be paid by the 10th of September, for every mare not insured—otherwise double the amount will be forfeited. The most satisfactory proofs have been received by the subscriber; which will be exhibited to any person having a desire to see them; that this horse is not only remarkably sure to get foals, but that they are superior, both for size and beauty. It is believed, that so favourable an opportunity to improve our stock of horses, in this state, will not again speedily occur—and gentlemen from the adjacent counties, and the Western Shore, will be accommodated with good pasturage, on moderate terms. Those who intend to breed from Emperor, will consult their own interests by applying in time—because he will be limited as to the number of mares, and to two stands, viz. at the stable of the subscriber, and at the town of Easton. It is a fact, that the excess to which this thing is carried—superadded to incessant travelling about, is two often attended with disappointment—frequent failures being the inevitable consequence.

N. GOLDSBOROUGH.

Orwell, Talbot County, March 22.

N. B. No mare will be considered insured, without a written agreement to that effect. If an insured mare be sold, or transferred, the insured price must be paid.

WANTS A SITUATION.

As an Overseer, a man who has a small family. He is acquainted with all the branches of Agriculture, as practised in England. Respectable references will be given. A line left at the Post Office directed to A. B. will be attended to.

AGENTS FOR THE AMERICAN FARMER.

Complete sets of the first, second and third vols. of the "AMERICAN FARMER," new and corrected Editions, can be had of the following persons; price of which, bound, \$5 per vol. or \$4 in Sheets:—

M. CAREY & SONS and E. LITTELL, Philadelphia.

W. A. COLMAN, New-York.

WELLS & LILLEY, Boston.

WM. F. GRAY, Frederickburg.

PETER COTTOM, Richmond, Va.

RICHARD COTTOM, Petersburg.

E. THAYER, Charleston, S. C.

JOSEPH GALES, Raleigh, N. C.

W. F. REDDING, special agent, now journeying through the Southern States.

The fourth volume, now publishing, can be forwarded to any part of the United States, on application being made, by letter or otherwise, to J. S. SKINNER, Baltimore.

Printed every Friday at \$4 per annum, for JOHN S. SKINNER, Editor, by JOSEPH ROBINSON, on the North West corner of Market and Belvidere streets, Baltimore; where every description of Book and Job Printing is executed with neatness and dispatch—Orders from a distance for Printing or Binding, with proper directions promptly attended to, addressed to J. Robinson, Baltimore.

AGRICULTURAL.

Remarks on Ploughing, Planting, and Tillage; with some observations on the Drill Husbandry. Prepared by GIDEON DAVIS, Manufacturer, Georgetown, D. C. for the "AMERICAN FARMER."

[CONCLUDED.]

PLANTING.—Say of corn, as being the most familiar. It is a practice with many, in laying off for corn, (or making the furrow to plant in) to plough tolerably deep, with a view, that the corn when planted down in that situation, will send forth its roots deeper, (than if planted shallow, or nearer the surface) that it will sustain a drought better, that it will derive more benefit in the course of its tillage, and that it will be less liable to be blown down by a storm. But if the husbandmen would make themselves acquainted with the nature of the case, they would find, that it matters not, whether they plant deep or shallow, the roots will run to their proper depth, and no deeper. That it is the heat, or influence of the atmosphere, that enables the seed to vegetate and grow; that if the seed is planted too deep, it will not vegetate at all, but rot in the ground, as much does; that when planted in a deep furrow, it is commonly covered with a poor clay, (or other stratum,) in which there is but very little vegetable food: of course it cannot produce a strong growth; and again, that this kind of clay or stratum, by the action of heat and moisture, is liable to adhere together, and bake or form a crust; through which, sometimes, the plant cannot force its way; and mostly, very unfavourable to the growth of the plant. They would become convinced, that in laying off for corn, it is best to make the furrow very shallow, and also, to cover the seed shallow, and above all to be particularly careful to cover the seed with the richest soil that can be obtained. That if covered with a rich soil, it will not bake, nor form a crust over it, that will hinder its coming up, or be unfavourable to the growth of the plant.

TILLAGE.—On this process there is much difference of opinion; some break their land deep, and cultivate the crop shallow; some break their land shallow, and cultivate the crop deep; some both break and cultivate deep, and others shallow. Formerly, in the cultivation of corn especially, it was considered, (by many, or perhaps most,) absolutely necessary to hill the plant. And as it is said, "that whatsoever the son seeth the father do, that he doeth," so in the present case, the hilling system still has many advocates. But they that will examine the case, will find objections to hilling in the tillage of corn, potatoes, &c. The first is, that when the plant sends forth its roots, they are fixed at a proper depth, and of course, if the plant is hilled, that set of roots will be covered too deep; they will cease to grow; and the plant must send forth another set of roots to obtain food necessary to its support, which, if the husbandman through kindness should hill the plant again, will cease to grow also, and the plant must send forth another set at a proper depth; thus at every process in hilling we hinder the growth of that set of roots then in operation; and no doubt, injure the growth of the plant. Another reason is, that when the ground is thrown into hills and hollows, in time of rains, the pulverised part being hilled up lays so much inclined, that the water cannot so well soak in, and the middle being an open furrow on hard earth, the water would incline to run off; so much so, that I be-

lieve, often times, there is complaint at drought when there had been moisture plenty, if the land had been so prepared and worked as to have retained it. Another objection to the hilling system is, that it leaves the ground very unpleasant in consequence of the hills and hollows. I believe, in the most perfect system, in the cultivation of summer crops, the first care should be, to keep the soil as completely on the surface as possible, and (in broken or hilly land) to keep the surface as even, or level as possible; and till the ground as deep as possible. I would say twelve inches deep; and even more than that if it could be done. When the soil is kept on the surface, though it is not more than one inch deep, it will prevent the ground from baking; in time of rain the water will soak through it, and by having the stratum underneath broke to sufficient depth, the land will absorb all the moisture, and entirely prevent washing; and, I believe, since my memory, would very nearly have prevented any complaint of drought. I conceive this to be a subject deserving of much attention, because it is an expensive operation.

DRILL HUSBANDRY.—It is said the drill husbandry originated, (or at least was found) with the North American Indians, in their manner of cultivating corn.—Tull, by some is called the father of it: he introduced the practise first in England.—Perhaps the celebrated Cooke, has profited most by it, because he has pursued it to the greatest extent. To that portion of the agricultural community, who have, and are turning their attention to the cultivation of small grain, this is a subject deserving much attention. It has been fully ascertained, that to raise the most perfect and profitable crop of small grain, (especially winter grain) it is just as absolutely necessary to cultivate it, as it is to cultivate maize corn, or other plants in order to ensure the most perfect and profitable crops of them. I believe that in the common mode of tillage, so far as I have been acquainted, land does not produce more than from one third to half as much wheat, as it will of corn; that if there was as much attention and labour bestowed in the tillage of wheat (and other small grain) as there is in the tillage of corn, land would produce quite as much wheat, as it will of corn—I saw an experiment made last year which convinced me fully, that with a suitable tillage it is possible, to make land of common quality yield from two to three times as much wheat as it will with the common management.

In the present process in cultivating wheat, there are several objections, manifest to every one that will examine the case; one is, that lands having but a thin soil, are commonly broke up too deep, the consequence is, that the soil is either buried too deep, or there is too much clay or other stratum mixed with it; in fact, the surface is too poor to mature a crop equal to the strength of the land. When wheat is sown on a surface of clay or other poor stratum, though it may come up quick and handsome, yet there cannot be a strong growth; such a result, it is not in the nature of things to expect to produce a strong growth of wheat; the surface must be composed of soil, (or a rich earth) let the understratum be what it may. If the surface is composed of clay or other poor stratum, during winter the frost will draw the bulb of the root of wheat out of the ground, and the stool (or plant) will only be sustained by the small roots or fibres that will extend from it. Some seasons the wheat will remain a considerable time, much in the same situation, before it will become vigorous enough to send forth other roots, or shoots to assist in gaining the necessary food to

support the plant; and especially, if the plant has a large family of the Hessian fly to maintain, because in that situation the fly (or rather the nit) would consume the sap about as fast as the roots could procure it, and sometimes faster, in which case the plant must perish, as we see many do. Perhaps much light may be thrown on this subject by explaining a circumstance, that I presume has not generally been taken notice of. The nit of the fly is found in the stool of wheat on the ground, but so near to the surface, that it may be said, they live between wind and water; and that it is their element exactly, because the greatest influence of the atmosphere is to be found there, and as the wheat grows they are raised up from the surface of the ground; or the probability is, that the heat would become so intense that they could not sustain it, and of course would perish. The fly being considered the greatest enemy to the growing of wheat, it is certainly a matter of much importance to find out some plan which would restrain their ravages. Now I believe it possible to pursue a process in the cultivation of wheat, that will prevent the depredations of the fly, perhaps entirely. We know that they live in the vegetable on the ground; that if they are put under the ground they must perish; because that is not their element; there they cannot exist: Then the secret is, bury them; this deserves the more to be recommended because it can be done, not only materially to the destruction of the fly, but greatly to the benefit of the wheat, and well worth the attention of the farmer when his wheat crop is not at all affected with the fly.

The 3d drawing is intended to exhibit a view of the drill husbandry; *a. a. a.* are the rows of wheat (or other grain) sown in drills at a suitable distance a part, (I suppose about nineteen inches, in land broke at two operations; *b.* the soil of three inches depth turned over with a bar-share plough, and kept on the surface; *c.* the understratum broke nine inches deeper with a substratum plough; *d.* the unbroken stratum underneath. Lines are seen between the rows, which represent the tracks of the harrow teeth; *e. e.* shew a track, or operation of the substratum plough in the tillage of wheat, for which use this plough is designed to be perfectly adapted; *f.* the leg of the plough in operation.

Now to effect this mode of tillage, I will propose what is certainly practical in the very worst case; say a stiff blue grass field; one man, one boy and three horses to perform the work. That whether for corn, or wheat, or any other grain, the first operation should be to apply the whole team of three horses to a very heavy strong harrow of about 32 inches in width, having nine very strong teeth, the harrow to be loaded so as to be a heavy draft for the team; then set to and harrow that very stiffest blue

grass field, and cross harrow it; harrow it again, and then cross harrow it, until the blue grass and sod are both torn all to pieces, which will be found to be a cheap way of subduing blue grass, especially if the weather is very dry. Then put one horse to a small barshare plough and turn the soil, thus pulverised, completely over; this will bury the vegetable matter at a suitable depth for it to decompose most to the advantage of the soil, because the soil will receive and retain the vegetable matter as it is decomposed; if it is suffered to lie on top of the ground, much of it would be carried off by evaporation. This operation should be performed by the boy, because it would be the easiest; and there should be a strict watch kept over him that he should not plough but very little deeper than the soil, whether three inches, or only one in depth, this is a matter of very much importance. Then the man should take the two horses and substratum plough, follow the barshare in the same furrow, and use his endeavours to work the ground as deep as the team were able, which would vary very much according to the quality of the stratum for a crop of wheat; this may be done after harvest. Then harrow the ground lightly with a large harrow. Then with a small (or one horse) barshare plough lay off furrows very shallow at about nineteen inches distant, from centre to centre; this will lay the land completely in lists (or ridges)—then as soon as possible after the 20th of the 9th month, September, sow the wheat broad cast, $1\frac{1}{2}$ bushels to the acre, and harrow it in lengthways with the laying-off; the wheat will come up completely in drills, also in the hollows, having higher ground on either side, which, by the operation of the winter, will in some measure keep hilling the wheat; this will tend much towards keeping the bulb of the root under ground, in which situation the plants will be much more vigorous, than if that part is drawn out; and also destroy much of the fly by burying it. As soon as the ground has become settled in the spring, harrow it, either length or crosswise, as may seem best; and whenever it has become dry enough to be in suitable order, plough one furrow in each row with the substratum plough as deep as possible. And as it is seen that another operation with the harrow or plough would be of use to the crop, apply it. If tolerable wheat land was treated thus, there would be little or no complaint of the fly—of the hard winter—of the washing rain, or of drought—and above all, of the light crop. Land of common quality, treated in this way, would yield quite as many bushels of wheat per acre, it is believed, as it would of corn with the best tillage. For clover or other grass, so uncertain by the common mode of sowing the seed on a surface composed of clay, in the spring of the year, and among a crop of small grain, what could reasonably be expected? but that it would spring up, in the first moist growing weather, as it commonly does. And again, that as the season becomes dry and hot, and besides this, the ground sapped by the growing crop of grain, surely those tender plants of grass must be poorly provided for; of course they dwindle, they die; the consequence is, that the seed and labour of sowing it, are both lost, and most of the husbandmen still wonder why they cannot succeed in raising clover and other grass quite as tender when young; it is no wonder at all to me. Though I look back, and see that I have tread in those very same steps over and over again, and very much to my loss. But after having pursued the mode of preparing the land and cultivating the grain just described, the husbandman will go on, and after harvest, when his field is gleaned by stock, turn in with his one

horse plough and turn the soil over again, and follow after with his substratum plough urged by two horses, using his endeavours to pulverise the under stratum as deep as possible.—Then in the 8th month, August, sow about one bushel of oats or one peck of buckwheat per acre, and harrow it in, then sow the clover or other grass seed on the surface, thus treated, and harrow it again. Then look at the result. The land worked to a great depth, with the soil at the surface having the stubble and other vegetable matter, (if any) mixed with it, so as to render it as loose as it can be made, well adapted to the nursing of tender roots. That when the clover or grass comes up, the oats, or buckwheat will come up also, and during hot weather protect it from the sun, and when frost comes, it will prostrate itself and protect the grass from the frost. In the ensuing spring we may expect to see that field make a rich appearance indeed. But it will be said, this costs a great deal of labour; but without this labour we cannot expect to reap a plentiful harvest. This is my present belief, resulting from experience, and observation, which is submitted—with again urging the use of the small, strong, heavy harrow, in destroying the blue grass sod, that powerful enemy to the growth of wheat and clover; this harrow will be found just as much preferable to the scarifier, as it is stronger and cheaper.

At the request of my friend Gideon Davis, and for the use of the Agricultural part of the community: This is to certify, that in breaking my land for corn last spring, (about 60 acres) I followed the barshare plough, with a substratum plough, until I had broke about 25 acres.—I believe the average depth of my ploughing with the barshare was about five inches. That the substratum plough worked about seven inches deeper, in the same furrow; making the whole depth twelve inches. That otherwise, in the planting and tillage, the management was just the same, and the land of about equal quality throughout the field. That, the corn on that part where the substratum plough was used, grew about twelve inches taller, kept its colour through the season; and produced at least fifty per cent. more corn. That the corn on the other part of the field, suffered very much with the drought; and fired considerably.

JOSEPH DELAPLANE.

Montgomery County, Md. }

FROM NICHOLSON'S ENCYCLOPEDIA. CULTIVATION OF HOPS.

The hop planters esteem the richest and strongest ground, the most proper; and if it is rocky within two or three feet of the surface, the hops will prosper well; but they will by no means thrive on a stiff clay or spongy wet land. Hops require to be planted in a situation so open as that the air may freely pass round and between them, to dry up and dissipate the moisture, whereby they will not be so subject to fire blasts, which often destroy the middle of large plantations, while the outsides remain unhurt. The hills should be eight or nine feet asunder, that the air may pass freely through them. If the ground is intended to be ploughed with horses between the hills, it will be best to plant them

* If some spongy wet land is laid dry by either open or hollow drains it will bear the best hops.

† Many hops are planted in Kent and Sussex, at six and a half feet each way, with five sets to a hill as described—and four poles are used to each hill.

in squares, chequerwise; but if the ground is so small, that it may be done with the breast-plough or spade, the holes should be ranged in a quincus form. Which way soever you make use of, a stake should be stuck down at all the places where the hills are to be made. Persons ought to be very curious in the choice of the plants as to the kind of hop; for if the hop-garden is planted with a mixture of several sorts of hops, that ripen at several times, it will cause a great deal of trouble, and be a great detriment to the owner.

The two best sorts are the white, and the grey bind, the latter is a large square hop, more hardy, and is the more plentiful bearer, and ripens later than the former.

There is another sort of the white bind, which ripens a week or ten days before the common, but this is tenderer and a less plentiful bearer, but it has this advantage, that it comes first to market. If there is a sort of hop you value, and would increase plants and sets from, the superfluous binds may be laid down, when the hops are tied, cutting off the tops, and burying them in the hill; or when the hops are dressed, all the cuttings may be saved, for almost every part will grow and become a good set the next spring. As to the manner of planting the sets, there should be five good sets planted in every hill, one in the middle, and the rest round about sloping. Let these be pressed close with the hand, and covered with fine earth, and a stick should be placed on each side the hill to secure it. When the hop ground is dug in January or February, the earth about the hills, and very near them, ought to be taken away with a spade, that you may come the more conveniently at the stock to cut it. About the end of February, if the hops were planted the spring before, or if the ground is weak, they ought to be dressed, in dry weather; but else, if the ground is strong and in perfection, the middle of March will be a good time; and the latter end of March, if it is apt to produce over rank binds; or the beginning of April, may be soon enough. Then having with an iron picker, cleared away all the earth out of the hills, so as to clear the stock, to the principal roots, with a sharp knife you must cut off all the shoots which grow up with the bind the last year; and also all the young suckers, that none be left to run in the alley and weaken the hill. It will be proper to cut one part of the stock lower than the other, and also to cut that part low, that was left highest the preceding year. In dressing those hops, that have been planted the year before, you ought to cut off both the dead tops, and the young suckers which have sprung up from the sets, and also to cover the stocks with fine earth, a finger's length in thickness. About the middle of April the hops are to be poled, when the shoots begin to sprout up; the poles must be set to the hills deep into the ground, with a square iron picker or crow, that they may the better endure the winds—three poles are sufficient for one hill. These should be placed as near the hill as may be, with their bending tops turned outwards from the hill, to prevent the

‡ There are a number of different sorts, known by the following names in Kent and Sussex.

1st. The Golden.—They are productive and early, if planted on a fine dry deep mellow soil.

2d. Early Grape.—Answers on a loamy soil, they are hardy and productive.

3d. Backward do.—Suit a stronger soil, they are hardy and productive.

4th. Ruffer.—Are a coarse sort, are early and answer on strong land.

5th. Old Canterbury.—Require land similar to the Golden.

FOR THE AMERICAN FARMER.

NAKED BARLEY.

Long Meadow, March 14th, 1823.

JOHN S. SKINNER, ESQ.

I procured from a friend in 1821, a few grains of Naked Barley,* which I have carefully cultivated, and intended to enquire its value, through the medium of the Farmer, but on the receipt of No. 46, Vol. 4, I got the information desired.

Mine was a small experiment; in 1821, I planted 50 grains, on the 15th April, and made 5 gills. In 1822, I made from those 5 gills, one bushel and three quarts, weighing 63 lbs. per bushel. It was planted 13th April, (too late,) and cut 28th June. I think it is a very early productive grain, and will give the small quantity I have, a fair trial this season, sown broad cast.

This is a trifling affair to trouble you with, and by many it may be thought unworthy of attention, but it is by this kind of attention, that we acquire a knowledge of the value of any plant.

Farmers are frequently imposed on, by those who first offer rare seeds for sale, and I generally make experiments on a small scale; if I find the article not valuable, or curious, I discard it; for instance, the Helligoland bean was puffed off, as a very valuable field bean, producing very abundantly. I procured two pints, which cost me two dollars, (at the rate of sixty-four dollars per bushel.) I planted them carefully, in good ground, expecting to make enough to plant an acre or two, but was disappointed; I planted them two years, and concluded I had been imposed on. It is not necessary to give the character of this bean, as I believe all who have planted it, have discarded it; I think it is worthless in the extreme, but I speak only from my own knowledge; it may have succeeded better with others. I could name a number of other seeds, I have planted, and discarded as unprofitable. But when experiments are made on a small scale, the expense is trifling, and although we may be frequently disappointed, we are sometimes gratified in the result; but it does not appear, that the properties of the Naked Barley, has been ascertained here, and it may possibly turn out to be a valuable grain to cultivate.†

Although the large class of Farmers, the renters of land, are not generally experimenters, there are a great number of intelligent, wealthy persevering agriculturists, excited by the spirit now prevailing, who are making direct attacks upon old prejudices and systems, which may result in lasting benefits to the country. And it is by the exertions of those aided in their communications, by the agricultural societies, and the periodical agricultural publications, that the

* The Barley mentioned by our correspondent A, is of the same kind, with that we noticed in No. 46, Vol. 4, as having been cultivated by Captain Hall, of Harford county, Md. some of which has since been brought to Baltimore for sale as per advertisement, on the last page of No. 48. We believe that this variety of Barley, will be found more profitable to the farmer, than the kinds usually cultivated, and very probably be more desirable than these to our brewers.—*Edit. Am. Farmer.*

† It is perhaps more incumbent on us to report when the result is unfavourable, than when it is promising—where is the benefit of experiments, if the result be not made known? What would we say of the Pilot, who being wrecked upon an unknown shoal or rock, would refuse to anchor a buoy as a signal of danger to his brother mariner? Yet we fear it is too much the fashion to suppress a knowledge of failures in cases of new and unsuccessful processes.—*Edit. Am. Farmer.*

spirit of improvement will increase—your paper, as a vehicle of communication, is doing its full part.

But, sir, improvement will be gradual. It is almost impossible to persuade, or drive the old three field farmers of Maryland, from their rotation of crops, which have been pursued by their ancestors for many generations.

I have been farming twenty-four years, and have sometimes made pretty good crops; for instance, I have had 25 bushels of wheat per acre, for a field; this was the greatest quantity of straw I ever saw, on so much ground; but it was, in spots, very much injured by the rust, or the quantity of grain would have been greater, I have had 85 bushels of wheat off two acres.—I have had six stacks of Lawler wheat off six acres, which were generally estimated to be large enough for 40 or 45 bushels per stack, but the straw was very long, and it is a kind of wheat that does not yield well from the stack, and I had but 23 bushels per stack. I have had 50 bushels of oats per acre, and as good crops of corn as my neighbours, say sometimes 30 bushels per acre; I have had 30 bushels of corn, 33 cart loads of pumpkins, and five loads of cymbelins, off five acres planted in rows, alternately: I have had three tons of herd grass hay per acre, and very frequently, very fine crops of clover; I have never weighed the produce of an acre of clover, when cured, but I one year, secured 627 cart loads. I have had upwards of 300 lbs. flax per acre; barley has never succeeded with me, ruta бага and potatoes, I have cultivated with great attention, but I have never made a great crop of either, and although I have made tolerable crops of all those articles, I have sometimes made very indifferent ones. But when I compare those products, (and some of them are pretty good,) with the eastern crops, as published in the Farmer, say 72 bushels winter, 44 bushels spring wheat, 84 bushels oats, 130 bushels corn, upwards of 600 lbs. flax, 60 bushels barley, 48 bushels rye, from 6 to 800 bushels ruta бага, potatoes, and mangle wurtzel, &c. per acre, I am astonished at the difference, and am willing to acknowledge myself a novice at the business.

The crops I notice, as having made myself, are not to be considered as the general produce of my land. Far from it; they are parts of the best crops I have ever made, and compared with my general crops, and those of my neighbours, of two barrels of corn, per thousand hills, and from six to ten bushels of wheat, for one sown, proves that our lands are capable of much higher improvement, and although I am considerably advanced in years, I hope yet to improve by the examples set before me, and the information derived from the experience of others.

A.

FOR THE AMERICAN FARMER.

ALBION'S 4th LETTER TO HIS SON.

*The country wins me still;
I never fram'd a wish, or form'd a plan,
That fix'd me with hopes of earthly bliss,
But there I laid the scene.*

In the 3d letter I gave you some hints respecting sheep, and now I propose giving you a description of the Albion farm—from the plan which you have had of this farm, it may be seen, that numbers one to ten inclusive, being one half part of the same, was arable land, cultivated on a regular and an unchangeable system of cropping, and the remaining half part, was old pasture and meadow ground, which had not been

bands from entangling; and a space between two poles ought to be left open to the south to admit the sun beams.

As to the tying of hops, the buds that do not clasp of themselves to the nearest pole when they are grown to three or four feet high, must be guided to it by the hand, turning them to the sun, whose course they will always follow. They must be bound with withered rushes, but not so close as to prevent them from climbing up the pole. This you must continue to do till all the poles are furnished with binds, of which two or three are enough for a pole, and all the sprouts, and binds that you have no occasion for, are to be plucked up, but if the ground is young, then none of those useless binds should be plucked up, but should be wrapped up together in the middle of the hill. About the beginning of July, the hops begin to blow, and will be ready to gather about Bartholomew tide. A judgment may be made of their ripeness by their strong scent, their hardness, and the brownish colour of their seed. When by these tokens they appear to be ripe, they must be picked with all the expedition possible; for if at this time a storm of wind should come, it would do them great damage, by breaking the branches, and bruising and discolouring the hops; and it is well known that hops, being picked green and bright, will sell for one-third more than those that are discoloured and brown.

The most convenient way of picking them, is into a large square frame of wood, called a bin, with a cloth hanging on tenter hooks, within it, to receive the hops as they are picked. The best method of drying hops, is with charcoal on an oast or kiln, covered with hair cloth, of the same form and fashion that is used for drying malt.—The hops must be spread even upon the oast, a foot thick or more, if the depth of the curb will allow it; but care is to be taken not to overload the oast if the hops are green or wet. The oast ought to be first warmed with a fire before the hops are laid on, and then an even steady fire must be kept under them; it must not be too fierce at first, lest it scorch the hops; nor must it be suffered to sink or slacken, but rather be increased till the hops are nearly dried, lest the moisture or sweat, which the fire has raised, fall back and discolour them. § When they have lain about nine hours, they must be turned, and in two or three hours more, they may be taken off the oast. It may be known when they are well dried, by the brittleness of the stalks, and the easy falling off of the hop leaves. ¶ As soon as the hops are taken off the kiln, lay them in a room for three weeks or a month to cool, give and toughen; for if they are bagged immediately they will powder, but if they lie a while (and the longer they lie, the better, provided they are covered close with blankets to secure them from the air,) they may be bagged with more safety, as not being liable to be broken to powder in treading, the better and the harder they are trodden, the better they will keep.

§ After the hops have been put upon the oast about half an hour, rolls of Brimstone are put upon the fire—quantity in proportion to the colour of the hops, from half a pound to a pound and a half.

¶ As soon as they are taken off the oast they ought to be sifted through a sieve, with openings about an inch square, to take out the stalks and the hops, that are not sufficiently dried.

§ They are generally bagged sooner in the above counties than recommended in this account, viz. in less than 48 hours, if thoroughly cool.

ploughed for, at least, a century: indeed, to plough this ground, and particularly that part in pasture, would reduce its value at least one half, as it would require another century to recover the mischief done by the plough.

Through the centre of the farm, from north to south, ran, with a gradual fall, a stream of water, sufficiently large to turn a small mill, and the east and west sides of the farm had a gentle fall into this stream, so that the whole farm formed a valley, looking towards the south.

When this property was first inclosed into fields, the proprietor had in view the present system of management, and divided the arable part accordingly into ten fields of 30 acres each, so that by following a ten-field system, no field had two kinds of cropping in it at the same time—each field, on the whole farm was inclosed by a white thorn hedge, and a ditch three feet deep, and three and a half feet wide at the top, on the side of the fence most exposed to the stock, or else on the side where it would the more readily take off the superfluous water; these fences were kept good at so little expense, by plashing and scouring out the ditches, that they were a source of profit to the tenant, as they furnished him with—faggots for farm yard shelters, wattled fences, and fire wood.

The highest ends of the arable fields, were, originally, of a brown, loose, sandy soil, intermixed with some small flint stones, and the lower ends of them were of much the same kind of soil, but very wet, occasioned by the understrata of all the arable fields, which lay from nine to twelve inches below the surface, being a very solid white clay, similar in appearance to pipe clay, but in some parts it was of the nature of marl, which might be ascertained by putting it into strong vinegar, when it would ferment like yeast—but by sough or under draining all the wet parts of these fields, and ploughing the whole of them in autumn, with a very strong plough, and four huge horses, some of the white clay was turned up, and where this could not be effected by the plough, the mattock and shovel were employed, until the whole surface was well covered with the under strata, which occasioned a vast improvement.

The grass ground was one half part of the farm, and had a surface of brown sandy clay, resting on an under strata of dark lead coloured clay, particularly greasy and tough, and quite impervious to wet; this ground was originally too wet, but by sough or under draining the wet parts, and sinking the ditches round the pastures, the whole was made sufficiently dry, and became very valuable ground for breeding and feeding stock, being covered with a herbage consisting of rough stalked meadow, or orchard grass, smooth stalked meadow, sheeps fescue, sweet vernal, meadow catstail, or timothy, rib grass, white clover, cow grass, and a vast number of other grasses, which altogether formed a most beautiful smooth verdure, and particularly so in the autumn, winter, and spring—a short time after the sward dresser had been passed over it—one hundred and twenty acres of this grass ground, could be, at any season of the year, covered with water, one half of which was meadowed, and the other half pastured alternately.

By turning to the plan, you may see the directions of the artificial water courses, which were made to convey water to these grounds—these cuts were exactly on a level, from one end of them to the other, and had no outfall at the south end; and all the soil, taken out in forming them, was placed on the top side, next the arable land, so that when a pair of draw gates were let down, they were placed at the top end of the original

water course, all the water was forced into the artificial cuts, and having no other way to escape, flowed regularly over their level sides into the meadow, from one end to the other, covering the surface two or three inches deep—where the water was interrupted by small cuts, running nearly parallel with the main feeders, and like them exactly level; these cuts were repeated, so often as the water appeared inclined to collect together, in order that it might be carried regularly over the whole surface of each piece of ground, when it fell into the original water course, where it turned a mill, that thrashed and ground all the grain, and at the same time cut all the hay and straw eaten by all the stock on the farm.

The buildings on the farm, were all of brick, and covered with welch slate; the barn adjoined the mill, the stables, sheds and other buildings adjoined the barn; and the thrashing machine was turned by water.

The house was three stories high, and had two sitting rooms 14 by 16 feet—servant's hall, kitchen and back kitchen each, 14 by 20 feet—in the latter was a complete set of brewing utensils, where two hogsheads of ale, and an equal quantity of beer could be made at a brewing, and water was conveyed by lead pipes into the kitchens, stables, sheds and foldyards, the whole being planned with a view to save manual labour as much as possible.

ALBION.

FROM THE WINYAW INTELLIGENCER.

Stateburgh, S. C. Jun. 1823.

Sir,—I enclose you some further observations and experiments made by Dr. Bracey upon the rot in cotton the last year, which taken with those made by him in 1821,* will, I think, settle the question so long agitated about its origin. A committee of the CLAREMONT AGRICULTURAL SOCIETY, appointed to select such pieces for publication as are presented to it, and thought to be the most interesting and worthy of public notice, have requested me to send you Dr. BRACEY'S for insertion in your useful paper.

With sentiments of respect, I am, Sir, your's, &c.

* See *Winyaw Intelligencer* of January, 2d, 1822.

EXPERIMENTS ON THE ROT.

BY DR. XENOPHON J. BRACEY.

In a small detached field of about 15 acres, I had the stalks and trash of the preceding year's cotton collected and burned. The seed were then soaked 24 hours in a strong solution of salt and water, and carefully rolled in fresh wood ashes, and planted in beds in the usual manner. In another field, I had the fibres of cotton burned off the seed by setting fire to the heap, stirring it briskly, so as to destroy effectually all eggs &c. these were also soaked in brine, and rolled in lime. These preparatory steps gave me a good stand, and vigorous growth when young—but early in the month of August, the rot had made a formidable appearance in both these fields, the cotton was very forward on account of the seed, having been procured from the extreme part of North Carolina, bordering on Tennessee. I enveloped several plants, with gauze entirely, first clearing away every appearance of larva, egg, or insect; I then covered several limbs, containing many pods on them, in all about a dozen, under three of the gauze sacks, I placed

some insects* and rendered them, as well as all the others, inaccessible by close tying around the body of the plant. The envelope remained until nearly the whole of the pods opened, or about the last of September,—in the course of which time, much of the adjoining cotton rotted, the season having been uncommonly wet. Notwithstanding, I could not discover a puncture, or even the slightest appearance of rot on any one of the pods so protected, except the three plants which had insects placed within the covering, nearly every pod rotted on those, or were materially injured by frequent punctures—I am certain that the whole would have rotted had not a few days dry weather intervened, which saved 14 pods out of 52, the aggregate number on the three plants. There were about 170 pods on the other plants enveloped, which looked larger than those around, and were entirely free from the black specks observable on all unprotected cotton—and I am fully impressed with the belief, that they yielded more cotton, though I did not weigh them to test the fact. One of the insects under one of the coverings produced about 40 young ones in the latter part of August, and they were able to produce rot about 6 days after. This circumstance induced me to collect about a dozen insects, and place them under three tumblers, dividing them equally. I fed them daily with fresh pods of green seed cotton, for a week; they all appeared healthy, and punctured the pod, about every two hours for sustenance, during the night as well as day—I then fed those under one of the tumblers with black seed pods, and continued the green seed to the others; at the end of another week, all under the glass fed with black seed cotton died, the others continued healthy, and seemed to feed rather oftener than at first. In the course of a few days after, I found, upon changing the pods, that one of them which had been under the glass 24 hours, had a number of eggs on it, which I carefully preserved, by returning it under the covering, and placed a cotton leaf under the other glass. Two days after I found the leaf almost covered with eggs, which hatched in four days. I then had an innumerable brood of small black insects which collected in groups on different parts of the pod, giving them an ulcerated appearance. I was obliged to sweep them off carefully with a feather in order to renew their daily food. In the course of two or three days, they began to assume a greenish cast, and gradually developed all the appearances, which has been described on a former occasion.

I wish therefore to correct conjectures formed the last year in regard to their manner of propagation. The egg certainly brings forth the insect, and it speedily matures, without undergoing any change except in size and colour. How often they multiply their species in the course of the year, I am unable to say, but believe it to be more than once?—The matured insect probably undergoes a change at the approach of winter, but as yet I have not been enabled to detect it. It is not material whether it does undergo a change or not; the object of this research has been directed, in ascertaining fully the cause of rot, by which means we might be enabled to come also at the remedy—but so far as my researches go, the remedy seems removed, if possible, to a greater distance; such as have been heretofore recommended, are at least, perfectly ineffectual—and the only one which now holds out to be really successful, is planting together alternate rows of black and green seed cotton. This plan has succeeded in

* Genus, *Cimex* Linn. Species, *Velox*, as it is believed.

two fields in which it was planted this year; perhaps from the dislike the insects have to the black seed the intermixture deceives and confuses them—by which means they are driven from the field.

From the Farmers' Messenger.

SIGNS OF A POOR FARMER.

He grazes his mowing land late in the fall, and his pastures early in the spring, and consequently ruins both. Some of his cows are much past their prime. He neglects to keep the dung and the ground from the sills of his buildings; and it costs him twenty dollars to make repairs when one dollar's worth of work would have been sufficient if performed at leisure time ten years before. He sows and plants his land until it is exhausted before he thinks of manuring. He has generally too much stock, and many of them unruly. He is almost sure to have a good deal of stake and pole fence. He says that he cannot arm it for want of money: this is frequently the case with good farmers, but you may know a sloven by his inattention to little things—his children's shoes are spoiled for want of shoe strings to tie them, or for want of a little tallow to supple them—his door hinge comes off for want of a nail, and the door is destroyed for want of a hinge, and his mow is trampled on and cattered for want of a door; and all this loss is occasioned by not timely driving and clenching a single nail. Nothing is in order—he has a place for nothing, and nothing in its place. If he wants a gimblet, a chissel, or a hammer, he hunts up chamber, out at the barn and corn-house, in the cupboard, and lastly when he has spent more time in pursuit than it takes him to do the job, he finds it down cellar. He keeps no stock of the smallest things: if a button or a bail to a pail gives way, or a key to a yoke, or a pin to a sled, or a helve to an axe, a string or a swingle to a flail, or even a tooth to a rake, he has none to replace them. He seldom does any thing in stormy weather, or in an evening, and is sure to keep no memorandum of little jobs that are to be done. You will perhaps hear of his groaning about the hardness of the times frequently in a bar room. Death and the tax-gatherer he knows must come; yet he makes no provisions for either of them. Although he has been on a piece of good land for twenty years, ask him for a grafted apple, and he will tell you that he could not raise them for he never had no luck. His indolence and carelessness subject him to many accidents.—He loses soap or cider for want of a hoop—in the midst of his busy ploughing, his plough breaks because it was not housed; and when he is reaping away from home his hogs break into his garden for want of an additional board. He does not take the advantage of his business by driving it when he can, and consequently he is like the old woman's son, "so busy that he never does any thing;" or at least he seldom finishes one thing before he begins another, and therefore brings little to pass, and is often to be seen in a great hurry. He is seldom neat in his person, and will sit down to table without combing his hair, and suffer his children to do so without washing their hands and faces. He frequently drives his cattle with a club, and is generally late to public worship. His children are also apt to be late to school, and their books are torn and dirty. He is careless; his children and domestics are so too. As he has no enterprise, so he is sure to have no money. If he must have money, he frequently makes great sacrifices to get it; and as he is slack in his payments, and buys altogether on credit, he pays through the nose for every thing. His want of forethought, economy,

and exertion makes him poor, and his poverty tendeth to poverty. You will generally see the smoke begin to come out of his chimney long after day light in winter. His horse stable is not daily cleaned out, or his horse littered and curried.—Boards, shingles, and clapboards are to be seen off his buildings month after month, without being re-placed. He feeds his hogs with whole grain and suffers them to be much injured for want of a warm bed and warm pen; he seems to live without thinking; if his lambs die, or the wool comes off his sheep, he does not seem to think that it is for want of care and food. He is generally a troublesome borrower, and frequently forgets to return the thing which he has borrowed.

In a word, a poor farmer in the strict sense of the word; is a poor creature—he is a poor husband, a poor father, a poor neighbour and a poor citizen. A good farmer may be poor, but a poor farmer cannot act his part well: in other words, he cannot be good as a man or as a christian.

A.

PUMPKIN SEED OIL.

To the President of the Hampshire, Franklin and Hampden Agricultural Society.

DEAR SIR—As a member of your Society, I deem it to be my duty to communicate to you the result of an experiment that I have made on Pumpkin seeds, in the Linseed Oil Mill.

A number of my neighbors furnished me this year with seeds, which, together with my own, made about nine bushels, and on making the experiment, I found that they produced about six gallons of oil, and probably when the experiment is tried upon a large scale, they will produce more. I tried the oil on the screw of the Oil Press, and find that it answers an equal purpose, to prevent friction as sweet oil, and of course it will be good to use on the axletrees of carriages that are made of iron, either alone, or mixed with tar, to prevent friction. I have also tried it in the lamp, and find it to be as inflammable as lamp oil, and without the offensive smell of that oil; and the light emitted from it is of a greenish yellow tinge and is easier to the eyes, and, especially, when reflected from white paper, than the weak glimmering light of a candle, and of course the light is easier to read or write by, and especially to weak eyes.

I have been informed by gentlemen of medical skill, that the seeds of pumpkins have so great a tendency to promote urine in animals, as to render them unfavourable to their health; and a neighbor of mine informed me that his geese became so relaxed as to be unable to go, by eating pumpkin seeds.—These circumstances induced me this season to cut open my pumpkins, and take out the seeds before I gave them to my cattle, and I found by the experiment last fall, and the beginning of winter, that my horned cattle, sheep, and swine derived the greatest benefit with the least expense to myself of any thing that ever I tried in the agricultural line. And from the little experience that I have had as a farmer, I am induced to think, that there is no one article that is cultivated, from which so much advantage can be obtained, by so little labour, as from the cultivation, and right use of the pumpkin. It is probable that the oil of pumpkin seeds may be made a complete substitute for tallow; and when it is once introduced into use it will probably be worth at least \$1.50 per gallon. Children can with the greatest ease take out the seeds when the pumpkin is cut open, with a spoon or their hands, and spread them on a floor where they will soon dry; and it is proper that they should be preserved clean, and

without being suffered to mould. In the United States, where there is such an unbounded region of land, and labour above the price of produce, the main object of the farmer ought not to be the obtaining of the greatest quantity of produce, from the best piece of land, as in many places in old countries which are so crowded with population as almost to be in a state of starvation, and labor of no consequence; but the obtaining of the greatest quantity from the least labor and expense, taken together. I have no idea that fields appropriated exclusively to pumpkins would be profitable like those of corn and pumpkins planted together; for if they be planted too thick they are an inconsiderable damage to each other. There ought not probably to be more than one pumpkin suffered to grow to twenty hills of corn, otherwise they are apt to choke the growth of the corn, and not produce so many or so good pumpkins either. It costs scarce any more labor to raise corn and pumpkins in the same field than it does to cultivate it exclusively for corn, and perhaps the crop is worth a third more. On the whole, I am inclined to think that this subject is worth your notice.

I am yours, &c.

Respectfully,
JOSIAH WHITE.

Northampton, March 17, 1820.

NAVAL OFFICERS.

The attention of the officers of our navy to the arts, sciences, improvements, valuable products and curiosities of the different parts of the world which they visit, has often been mentioned with the approbation that it deserves. It seems as if they generally felt themselves bound to bring home something that might gratify or benefit their fellow citizens. A late instance is thus noticed in our Baltimore papers—

"Captain C. G. Ridgely has presented to the University of Maryland, for the museum, a collection of minerals, formed during his late visit to South America, and which includes several of the most interesting productions of Peru and Chili, principally from their gold and silver mines. Capt. R. has also presented, with other general curiosities, a couple of specimens of earthen ware, found near the tombs of the Incas, which shew that considerable skill in the art of pottery existed among the ancient Peruvians. These specimens, when compared with the fragments of similar works found in the western states, may, possibly, throw some light on the probable history of the civilized tribes who appear once to have inhabited that portion of our continent."

We may add, that capt. Spence, of the navy, has forwarded to us "a sketch of Spanish continental America," showing the various establishments therein, up to the year 1810, the epocha of the revolution. It makes three folio pages, of elegant penmanship, displayed in the most pleasing manner, with the judgment of an experienced statistical writer. We cannot copy this into the REGISTER so as to do justice to the original; and, from the great changes that have taken place, it would not afford much of that sort of information about those regions which the people are most interested just now in obtaining; but we are not the less thankful, on that account, to capt. Spence for his interesting compliment.

Niles' Register.

An English publication observes, that "seeds when not sufficiently ripe, will swim, but when arrived at full maturity, they will be found uniformly to fall to the bottom; a fact that is said to hold equally true of all seeds."

Number of hhd. Maryland Tobacco shipped from 1st January to 31st December, 1822. 27092

To which add what remained in the state on the 1st January, 1823, viz:
 In the Warehouses in Baltimore, 8456
 On board of four vessels then loading, 924
 In the Warehouses on the Potomac, including Bladensburg—estimated number, 2250
 In the Warehouses on the Patuxent and Bay-side up to the Severn—estimated number, 1750—13380
 40472

Deduct what remained in the state the 1st January, 1822, viz:
 In the Warehouses in Baltimore, 5070
 On Board the ship Athens, loaded in December, 1821, & not cleared on the 1st of the following month, 728
 In the Warehouses on Potomac including Bladensburg, as ascertained to be, 1240
 In the Warehouses on Patuxent and Bay-side up to the Severn—estimated number, 1200—8238

Which makes the Crop of Maryland Tobacco, the growth of 1821, to be hhd. 32234

PHILADELPHIA SOCIETY FOR PROMOTING AGRICULTURE.

November 19.—Stated Meeting. The President in the Chair.

A Communication was read from Mr. James Williams of Philadelphia County, dated November 18, accompanied by several specimens of Ruta Baga Turnip, Mangel Wurzel, Table Beet, and Carrots all of a very large size. The Mangel Wurzel of his crop averaged four pounds each; several weighed 8 or 9 lbs. some 10 lbs and measuring 16 to 22 inches in circumference. Some of the Table Beet measured nearly as much as the Mangel Wurzel. Many of the Carrots weighed between 2 and 3 lbs. and several measured near the crown from 9 to 11 inches round, and averaged about one pound. One quarter of an acre produced 87 bushels, equal to about 10 tons per acre. The Mangel Wurzel yielded at the rate of 400 bushels, or 12 tons per acre. The soil was not favourable to the cultivation of tap roots. These valuable crops were cultivated with the horse hoe-plough, invented by Mr. Williams, and tried before several members of the Agricultural Society at their exhibition in June last, to their decided approbation, as stated in the Report. He thinks that with it, and in a proper soil, 20 tons of either of the roots mentioned may be obtained, or 50 bushels of Indian corn with the same labour, could be gathered. Considering the extremely dry weather during the last season, the size of the roots and the quantity yielded by the land of Mr. Williams was considerable, and shows the good effects of good cultivation with a proper tool, even under unfavourable circumstances.

avourable circumstances of soil and season.—Crops, equally good, if not superior to that of Mr. Williams, were raised this year, by Mr. Walker, Washington Village, Philadelphia County; and by Mr. Joshua Gilpin, on a very elevated spot of ground back of Wilmington, Delaware. The drill system was pursued in both instances, and the land properly prepared. The uncommon fine and late autumn, enabled Mr. Gilpin to put in a crop of wheat after his turnips were pulled.

Mr. James Vaux attended the society, and exhibited a stem of a young apple tree perforated in various places above ground, but not extending to the branches, nor descending to the roots. The stem being sawn into blocks, and connected by a wire running through their centres, showed the depredations of the insect fully. Several hundred apple trees in the orchards in Philadelphia County, from which this specimen came, have been killed by these insects. Farmers should examine their young trees frequently, and with an awl or other pointed tool, or iron ware, destroy the insects by perforating the puncture made by them. The holes ought to be filled with thick lime wash, to keep out the rain and prevent future attacks in the same places.

Specimens of very large French Chesnuts, in the burrs, the growth of the present year, from Mr. Shallcross, of Hope Farm, near Wilmington, Delaware, were shown. The roots producing the tree from which they were taken, was planted in the year 1806, and bore fruit for the first time in the year 1816. The nuts came from France. In 1820, one nut selected from a burr containing two others, weighed 20 dwt. 6 grs.—The other two were of a large size. No fruit-bearing tree offers greater inducements to the farmer to plant than these large Chesnuts. In the south of France, in Spain and Italy they constitute the principal part of the diet of the labouring class of people in the country. The trees may be obtained from some of the American Nurserymen.

In the third volume of the Memoirs of the Philadelphia Society for promoting Agriculture, may be seen a paper on the engrafting of the Chesnut tree, by a mode pursued in France, called "pipe or ring grafting," and on the profit of an orchard of these trees.—*Union*.

FROM THE ALBANY ARGUS.

ON THE CULTURE OF PEAS.

The pea is a native of the southern parts of Europe, and is found growing spontaneously in the western parts of our own continent. The family is a large one, containing several species; but of these the *field pea* alone comes within the scope of our present purpose. Of this, there are two varieties, denominated from their colour, the grey and the green; both productive, and (when separated from the skin that surrounds them) a food of excellent quality for man; wholesome, nutritive and pleasant; and for cattle, whether in a dry or green state, much to be recommended. Sheep, cows and horses are particularly fond of them; and hogs are more promptly and economically fattened on a mixture of pea and barley meal, in a state of acetous fermentation, than by any other food.

The structure of the roots would indicate, that peas are an exhausting crop; and it is on this evidence, that in Europe they are admitted only in long, or six years rotations; but if we examine the leaves, in regard to both number and form, we will probably find reason to modify this opinion, and allow, that by stifling weeds, by checking evaporation, and eventually by their

own fall, they meliorate the soil and render it more favourable to subsequent crops.

Following turnips, the preparatory labour for a pea crop, is not great. One, or at most two ploughings, will be sufficient. Sowing, as a general rule, ought to follow ploughing, without loss of time; and care should be taken, that the seed be not laid too deeply. The two methods, row and broad cast sowing, may be indifferently pursued. By the former, the seed is economised, the product increased, and the soil better tilled; but not, as some have supposed with such decided advantage as to outweigh the saving, in time and labour, of the latter.

The length and feebleness of the stems of peas and the little tendrils they throw out for support, indicate the advantage of mixing with them other plants of more erect growth, which may prevent the peas from falling and lodging. For this purpose, rye, oats and beans have been selected, and with great advantage.

This crop is employed either in a dry or in a green state; between which every farmer will select, according to circumstances. If the market for peas be brisk and high, he will in harvest, thresh and sell the grain; if, on the other hand, peas are low and pork high, the moment the pods fill, he will turn in his hogs upon them, and with the following advantages: 1st, the hogs feed and fatten themselves, without any additional interposition of his labour; 2d, no particle of their manure is lost; 3d, the *debris* of the crop, refused by the hogs, is given back to the soil; and 4th, the rooting of these animals, which in other cases is an injury, is in this a benefit.

INVENTION OF AN IMPROVED TREAD MILL.

Mr. Richmond, who is engineer to the gas works here, and whose mechanical inventions so evidently point out his just ideas of the principles of mechanics, lately exhibited through the medium of Mr. Hopper, the County Surveyor, to the magistrates assembled at the Shire-hall, the model of an improved Tread Wheel. It was desirable that the motion of the tread wheel should be accelerated at pleasure, without the necessity of the connexion of the flour mill; and that it should likewise be made applicable to the punishment of any lesser or greater number of prisoners. Another object was also sought, that of making it more or less laborious, so as to apportion it to the delinquency and sentences of the parties put to work. The mills already erected are generally upon the principle of revolving 120 times in an hour, or twice in a minute. The present improvement will enable the governor of a prison to regulate the velocity to his own desires; to make the labour easy or oppressive, and all this without the necessity of connecting the works with machinery for grinding; or it may be converted to any such use, at discretion. The model itself must have required much time, as it is finished in the most complete manner. This improved mill moves with a triangular action; having levers and weights; the balls attached to which regulate the opening and shutting of flyers which are attached, so as to increase or decrease the weight upon the centre, and by that means render the labour greater or less. The simplicity of the movements will tend much to protect it from a probability of frequent defect. The Bench were much pleased with the production, and expressed their approbation in very flattering terms to Mr. Richmond for the ingenuity of his invention, and the peculiarly clear manner in which he had illustrated it by his model. We have heard some observations as to the propriety of

the speculation which the county has been driven into in order to afford labour; and whether it produced loss or gain was not a consideration; the quantity of flour manufactured, the complainants say, is thrown into the market, and has its weight in the depression of the article; whilst a capital is necessarily employed out of the county purse; it will therefore be accomplishing a most important object as regards the public, and give infinite satisfaction to the magistrates of counties, if labour can be found, even without profit, as such was never the object so much sought; the prevention of loss being the grand desideratum. Mr. Richmond's improvements promise to produce such results, and we sincerely hope he will reap his merited reward. As a proof of the manner in which the project was received, a tread mill, with such improvements, was directed to be put up, without loss of time, in Halsted Bridewell. The idea of the tread mill is of Chinese origin, in which country they are used for drawing water, &c. An index, or sort of clock, nick named a *tell-tale*, is proposed to be affixed to the new mill, by which the Governor can ascertain the number of revolutions in a given time, whether he may be present or not.—*Chelmsford Chronicle*.

Editorial Correspondence.

ANGOLA PEA.

SIR—The Abbe Raynal, in his 11th book,* speaks of an Angola Pea. It grows to the height of four feet, lives four years, and its fruit (a Pea,) is highly nourishing. It is useful in Medicine and Surgery; and grows in the most barren parts of the West Indies. Will any of your readers give us an idea on the subject, as it is probable it may be highly useful in the Southern States.

A SOUTH CAROLINIAN.

* Raynal, London edition, 8vo. 1778, p. 475.

HOW TO PROCURE A NURSERY OF YOUNG LOCUSTS.

Hills, Ohio County, Va. March 22, 1823.

I have had great success in raising the Black Locust tree, (*Robinia pseud acacia*,) from the seed, for many years, until last spring, when I nearly met with a total failure. A knowledge of the circumstances under which this happened, may be of service to some of your readers.

On the 29th of March, I, as usual, placed my seeds into a small vessel, and poured boiling water upon them. Those that floated were thrown away. When the temperature of the water had descended to that of the atmosphere, I poured it off of the seed, and dropped them into a drill, made by drawing the end of the handle of a rake, along the prepared ground, with a little pressure. The earth, thus pushed out of the drill, was brought back over the seed, which covered them from three-fourths to an inch deep.

The morning was fine and warm, for the season, but it became cold in the afternoon, and continued so through the night. Next morning, the surface of the ground, nearly, if not quite down to the seed, was frozen.

On the 26th of April, the young plants began to appear. I think, about a fifth of the seed did not vegetate. This was a much greater loss than I had ever before experienced. Indeed, in all my former trials, I believe that every seed put into the ground germinated,

Some time in May, about the 20th I think, we had a slight frost, which killed all my young locusts, except about a half dozen. I lost from 140 to 150.

It would seem from this, that the seed ought either to be sown later, or the young plants protected, on frosty nights.

Receive my good wishes,

LAW. A. WASHINGTON.

MR. JOHN S. SKINNER.

A QUESTION.

Said Lady Bab, to Lady Sue;

"I wish I were as blessed as you—

Your husband is polite and kind,

Of gentle manners—generous mind—

Obliging, gay—in friendship warm,

With every quality to charm."

"Pray Lady Bab," cried Lady Sue,

"How came my husband—entre nous,

"So intimately known to you."

THE FARMER.

BALTIMORE, FRIDAY, APRIL 4, 1823.

FINE BEEF.

In the stall of Mr. James Elmore on Saturday last, we had the satisfaction to see a display of beef, which for its quality, and the neatness with which it was dressed and handled, has never been excelled in any country. This superb lot of cattle, reflected credit on the breeder, the grazer, and the victualler; and, for one, we can say, from trial, afforded particular pleasure to—the consumers.

It is to be regretted, that the particulars, as to live and dead weight, comparative weight of offal, tallow and nett butcher's meat, were not more minutely ascertained, because after all, it is in a comparison of these particulars, and the age, that we arrive at what is called the "proof" and profitableness of the animal.

The weight as ascertained were—the Bakewell bullock, bred by Gen. Ridgely, and fattened by Mr. Barney, of Port Penn—1306 pounds, at five years old—he was extremely fat, for that age, and would have attained great weight, in two years more. The bullock, of Gen. Ridgely's celebrated Dutch stock, also fattened by Mr. Barney, weighed 1405. Mr. Isaac Clements' Teeswater bullock, 1351—his Holstein bullock, 1230, and his cow of the Porter breed, 914. The fine Maryland bullock, bred and fed by Mr. Pearce, rising six years, weighed 1541—and a spayed heifer, in beautiful condition, gave 643 pounds.

We have much pleasure in adding, that our citizens appreciated properly, the policy of giving prompt encouragement to the taste, skill and labour, of those who, with Mr. Elmore, thus contributed to the credit of our market, for, we understand, that the whole lot, making 8390 pounds, was sold at very liberal prices, at an early hour of the day, on which it was exhibited.

SEED RECEIVED FOR DISTRIBUTION, SINCE LAST NOTICE.

Warley Peas—Seawright Peas—Dea's Peas—from Dr. John S. Bellinger, Barnwell district, South Carolina.

Guinea Corn—and Snap Bean for table use—from J. Dozier, Summerville, South Carolina.

Millet seed, from Wm. Cox, Burlington, N. J. Varinas, or Spanish Tobacco seed, from V. Maxy, Esq. Annapolis, Md.

Corn raised in Ohio, by the Waugh-paugh-connetta tribe of Indians, presented to the Editor, by Thomas Ellicott, Jr. with the following

"Herewith you will receive an ear of Indian Squaw Corn, the seed of which I obtained whilst in the State of Ohio, and was raised by the Waugh-paugh-connetta Tribe.

"The above seed I had planted, and it proved to be very superior for Roasting ears, and about four weeks earlier than such as is in common use, and generally bearing from five to seven ears on each stock.

"N. B. They yield about 50 per cent. more than any other.

WAR—and its effects on the price of produce.

Since our last the prospect of war in Europe increases. The King of England in his speech to parliament, says—"Faithful to the principles which his Majesty has promulgated to the world, as constituting the rule of his conduct, his Majesty declined being party to any proceedings at Verona, which could be deemed an interference in the internal concerns of Spain on the part of Foreign Powers. And his Majesty has since used, and continues to use, his most anxious endeavours and good offices to allay the irritation unhappily subsisting between the French and Spanish Governments; and to avert, if possible the calamity of war between France and Spain."

The French House of Deputies in reply to the King, say amongst other things *equally true*, and honorable—"By concerting with the Holy See measures which are about to restore to the churches the pastors of whom the revolution had deprived them, your Majesty has provided for the *first want of your people*, and consolidated social order on its long convulsed basis.

"Sire, to preserve Spain from imminent ruin, the consequences of which would be fatal to our own tranquility, you have summoned to arms 100,000 Frenchmen; at their head marches a prince of your family; of that august family *always prodigal of its blood, when its glory, and ours are at stake*. [A good one!] Such an army is worthy of having for its chief a prince of tried valor; his virtues form the true pledge which your Majesty presents to the *people* whom you wish to deliver; to the people whom it is offered a salutary support, to assist them in finally escaping from the anarchy which devours them, in guaranteeing, at the same time their own happiness and the repose of nations, under the protection of institutions freely emanating from the *legitimate authority*. [Meaning the King.]

"It belonged to your Majesty alone to determine on the greatest questions of war and peace. This function of the high prerogative confided to you by Providence, you have exercised with that deliberation which such grave circumstances demand."

THE KING OF THE DONS SAYS TO HIS CORTES.

"*Messieurs Deputies*—I have received with lively satisfaction the message which the Extraordinary Cortes addressed to me on the 11th inst. and, perceiving in it the conformity of their sentiments with my own, I, anew, congratulated myself upon being placed at the head of a nation which so many qualities distinguish. The sentiments of honour and national independence, so profoundly rooted in the hearts of Spaniards, offer me the securest guarantee that the existing political institutions, the object of their predictions will continue unalterable, notwithstanding the efforts of their most violent enemies. How, in this respect, can I entertain the slightest doubt, when I am witness of the effusion of the patriotic sentiments and generous resolutions which will render the sitting of the Congress on the 9th and 11th of this month eternally memorable? Those days have shown gentlemen; what a nation is capable of when the conformity of elevated sentiments gives so generous an impul-

sion to confidence. They are the most positive and most eloquent answers to the calumnious imputation with which the communications of foreign cabinets are filled, and which have excited the surprise and indignation of the Extraordinary Cortes. Nations will at once see the free manifestation of my sentiments and principles, they will be convinced that the constitutional King of the Spains enjoys the free exercise of all the rights vested in him by the fundamental code, they will form an exact idea of the true origin of the disorders which afflict the country. The sacrifices which, under these circumstances, the honour and independence of the state require will be cheerfully made, for nothing is considered too great a sacrifice by a nation habituated to suffer, and to hear no other cry than that of liberty and honour. For myself, convinced more and more of the imperious necessity, that all the children of this great family should assemble round the constitutional throne, I will steadily follow the route which my duty prescribes to me; and, if the spectacle of a nation destined to defend her independence and laws do not restrain those who meditate to invade her, I will place myself at her head, certain of victory in the most just of causes, which is at the same time that of all the free nations of the earth."

(Signed)

"FERDINAND.

"At the Palace, Jan. 11, 1823."

PRICES CURRENT.—CORRECTED WEEKLY.

Flour, best white wheat, \$7 50—Howard st. Superfine, \$7 25—fine do. \$6 75—Wharf, do. \$7 to 7 12½—Wheat white, \$1 55 to 1 60—Red do., \$1 50 to 1 55—Rye, 75 to 78 cts.—Corn, 56 to 57 cts.—country Oats, 43 cents—Beef, 8 cents per pound—Live Cattle, \$6 to \$6 50 per cwt.—Bacon, round, 8 to 9 cents per lb.—Pork \$4 50 to 5 50 per c. lb.—6 to 8 cts. per pound—Mutton, 5 to 6 cts. per lb.—Beans, \$1 37½ to 1 50—Peas, black eyed, 55 to 60 cts.—Red Clover Seed, \$6—Orchard Grass do. \$3—Herds' Grass do. \$3—Timothy do. \$5—Millet, \$3 to 4 50—Flax Seed, 75 to 80 cts.—Whiskey, from the wagons, 32 to 35 cts. per gal.—Apple brandy, 30 to 32 cts.—Peach do., 65 to 70 cts.—Shad, none in market—Herrings, No. 1, \$3 62½ per bbl.—No. 2, \$3 37½—Fine salt 80 to 90 cts. per bush.—Coarse, do. 75—Butter, 20 to 25 per lb.—Eggs, 18½ cts. per doz.—Turkeys, 75 cts. to \$1—Geese, 37½ to 50 cts. Chickens, \$2 per doz.—Hay, \$17 per ton—Straw, \$10.

MARYLAND TOBACCO.—Fine yellow, from \$25 to 30—Yellow, 16 to 20—Fine red, 10 to 14—Common red, 4 to 7.

AGENTS FOR THE AMERICAN FARMER.

Complete sets of the first, second, third and fourth vols. of the "AMERICAN FARMER," new and corrected Editions, can be had of the following persons; price of which, bound, \$5 per vol. or \$4 in Sheets:—

M. CAREY & SONS and E. LITTELL, Philadelphia.

W. A. COLMAN, New-York.

WELLS & LILLEY, Boston.

WM. F. GRAY, Frederickburg.

PETER COTTOM, Richmond, Va.

RICHARD COTTOM, Petersburg.

E. THAYER, Charleston, S. C.

JOSEPH GALES, Raleigh, N. C.

W. F. REDDING, special agent, now journeying through the Southern States.

The fifth volume, now publishing, can be forwarded to any part of the United States, on application being made, by letter or otherwise, to

J. S. SKINNER, Baltimore.

MANUFACTURES.

[COMMUNICATED FOR PUBLICATION IN THE
AMERICAN FARMER.]

To the Honourable the Senate and House of Representatives of the United States in Congress assembled.

THE MEMORIAL

Of the Board of Manufactures of the Pennsylvania Society for the encouragement of American Manufactures.

RESPECTFULLY SHEWETH,

That it is with extreme reluctance we feel constrained by a sense of duty to ourselves and to our common country, to undertake to prove, that the existing tariff of the United States is unjust, oppressive, partial, and impolitic; and loudly calls for a radical revision and correction.

I. We believe it unjust and oppressive—

Because it taxes necessities of life most exorbitantly high, some of them used exclusively by the poor, and admits at low duties, comforts, conveniences, and luxuries, used chiefly and some of them exclusively by the rich.

If this be proved, as we hope will be the case, we fondly flatter ourselves, that enlightened citizens of all classes, paying due regard to their own honour, and that of their country, will not only not oppose a revision and correction of it, but unite in the accomplishment of that object.

The duty on molasses is about 42 per cent.—on bohea tea, 120—on souchong, 150—on brown sugar, 100—and on salt about 180. These are all necessities of life. Three of them are used exclusively by the poor, and, according to the practice of wise nations, and the dictates of reason, common sense, and justice, ought to be admitted at low duties. The rich, deriving far more advantage than the poor, from the protection of government, and being able to contribute incomparably more in proportion to their means, ought to be taxed accordingly. It would therefore be unjust, even were the duties equal on both. What decision then must be passed on a system which taxes the poor ten, fifteen, and twenty fold higher than the rich, as will appear clear as the noon-day sun from the following detail? Gold and silver plate, jewels, lace, lace veils, watches, &c. pay but 7½ per cent. duty—cloaks, silks, satins, cambric linens, bombazets, tartan plaids, gauzes, and Canton crapes, but 15—china, elegant cutlery, girandoles, and bistres, but 20—and plated ware, fine muslins, calicoes, kerseymere, broad cloth, Cashmere and merino shawls, Brussels carpets, &c. &c. but 25.

We respectfully solicit your most serious consideration to this exhibit—being persuaded that the tariff of no nation in the civilized world affords a more striking picture of oppression of the poor—partiality to the rich—or violation of the fundamental principles of sound legislation. It appears that 100 dollars worth of salt pays as much duty as 720 dollars worth of Brussels carpets—500 dollars worth of girandoles or porcelain—or 2400 dollars worth of plate!

II. The tariff is partial in the extreme.

A wealthy sugar planter, with an annual income of 3, 4, 5, or 10,000 dollars, is, as appears above, protected in his bulky staple, of which the freight is very high, by a duty of 100 per cent.—the tobacco planter by duties all but prohibitory—the cotton planter by a duty of 37½ per cent.—and the farmer by a duty of 33 per cent. on hemp—150 per cent. on cheese—and by duties averaging about 100 per cent. on foreign spirits, to protect him in the market for his grain for distillation, and in the sale of his rye and apple whis-

key and peach brandy—while all manufactures of flax are admitted at 15 per cent.—the great mass of those of iron, steel, brass, lead, tin, pewter, china, pottery, and stone at 20 per cent.—and manufactures of cotton, (at or above 25 cents per square yard,) wool, and copper at 25 per cent.

We respectfully invite your attention to the preceding view—and feel confident that the extreme partiality of these features of the tariff will not be controverted.

III. The tariff is manifestly impolitic.

It is a maxim in political economy, consonant with the practice of the wisest statesmen, to admit raw materials, whereon the industry of a nation may be employed, and whereby its wealth and prosperity may be promoted, either absolutely duty free, or on easy terms. This maxim we have ourselves adopted in parts of our tariff, witness hides, furs, block-tin, &c. imported duty free. But in other cases, the duty on the cumbersome raw material is equal and in some nearly double that of the manufactured article.—Flax falls under the first description—cotton and hemp, under the second. Flax, which, from its bulk, is subject to considerable freight, pays 15 per cent. Linens of every kind, fine and coarse, Russia diapers, damasks, thread stockings, and all other articles made of flax, as above stated pay only the same duty. Cotton pays 37½ per cent. duty. Whereas cotton stockings pay but 20—and fine manufactures of cotton 25. Hemp pays a duty equal to 33 per cent. But hempen cloth, (except Russia and German linens, Russia and Holland duck,) pays only 20—Russia duck 16—and Ravensduck 25 per cent. To this part of our system, there are two equally strong objections. It is as partial as impolitic.

We now proceed to notice some of the objections to an alteration of the tariff.

I. Extortion.

The clamour raised, and the hostility and other angry passions excited against the manufacturers, in 1816, for alleged extortion during the war, which was the principal cause of their being abandoned in the succeeding years to the ruin in which they were overwhelmed, requires serious consideration, as the same feelings and prejudices still prevail in certain quarters, generating jealousy and alienation between fellow citizens, who having one common interest, ought to regard each other with kindly sentiments.—We hope to prove the accusation undeserving of notice. We single out, (as has been frequently done heretofore in vain,) the article of superfine broad cloth, which is a fair example. Other articles will stand or fall with it. That species of cloth was sold before the war for seven or eight dollars—and was raised during the war to twelve, thirteen and fourteen. This was regarded as an instance of base extortion, and was the grand foundation of the obloquy then cast on manufacturers. But the fact was never brought into notice, that Merino wool was sold previously to the war at 75 cents per lb.—and raised in 1814 to three and four dollars! The extortion, if any, was therefore on the part of the sellers of the wool—and not on that of the manufacturers of the cloth—as it is susceptible of complete demonstration, that the per centage of profit was less on the high than on the low priced cloth.

But this accusation could not come with the least propriety from any other class of society—as at that period they all enhanced their prices in proportion as the demand rose. The merchants, on the declaration of war, raised the prices of foreign articles, in many cases, 60, 70, and 100 per cent. In the year 1816, when, as we have,

stated, this clamour was excited, and when its operation was so severely felt, agricultural products underwent a great rise. In 1814, cotton was 13 cents per lb.—in 1816, it rose to 27—In 1815, wheat was 125 cents per bushel—in 1816, it rose to 175. But the case of tobacco is far more strong and striking, and entitled to more weight, from the consideration that among the most ardent accusers of the manufacturers, were to be found some prominent citizens almost wholly engaged in tobacco planting. Tobacco in 1815 according to the treasury returns, was only 396 per hhd. whereas it rose in 1816 to \$185. This is a rise, which, under no circumstances, has ever taken place with manufactures, and must settle the question for ever in the mind of every honorable member of society.

II. "Trade will regulate itself." "Let us alone." "It is wrong for government to interfere with private pursuits or capital." "Capital will always find its most beneficial mode of employment."

Whenever application has been made to congress for an increase of the duties on imported merchandise, Chambers of Commerce in different cities have used great exertions to prevent success—and have presented petitions, memorials and remonstrances against the measure, on the ground that "trade would regulate itself"—that "it ought to be let alone." This course, we are sorry to say, for the honour of our country, was pursued with great zeal and ardour even in the years 1817, 18, and 19, when desolation and destruction pursued the manufacturers, who were in vain struggling under all the disadvantages of inexperience, want of skill, and slender capitals—and when nothing was wanting but the powerful protection of the government, to foster their establishments to a maturity of strength which would bid defiance to foreign rivalship.—Yet by a strange inconsistency, these very Chambers of Commerce were seen, sometimes in the same session, praying for counteractions, restrictions, and exclusions of foreign tonnage, as well as for special favours for "the regulation of trade." Our statute book abounds with acts of the most exclusive and restrictive character in favour of our merchants—always sought for when in any way necessary—and always granted when sought for. The second act passed by congress at its first session had this object in view—and it has never been lost sight of since. We are therefore warranted in saying, that "let-us-alone," in the mercantile language, strictly means to let the merchants import and export whatever may suit their purposes how pernicious soever it may be to the general welfare, or to the industry or happiness of any class of their fellow citizens. But when their interests require it, the "let-us-alone policy" is laid aside—and the government is loudly called on to interfere for their protection. We instance, from the great mass of laws of this description, the law respecting plaster of Paris—and those to counteract the colonial laws of Great Britain, and the navigation laws of France. We would ask, and it would be found difficult, without condemning this policy, to give a satisfactory reply—Why the importation of ships should not be allowed at low duties, to destroy the art of ship building, and blast the fortunes of the shipowners, as well as that of cottons or woollens, to ruin the proprietors of cotton and woollen manufactories? With what propriety or consistency did the same Chambers of Commerce that solicited the government to force Great Britain to relax her colonial system for their advantage, use all their efforts to debar their fellow citizens from a small addition to the duty on goods of which the importation was effecting their destruction? Why, in or

should one species of industry and one class of citizens be protected by every kind of restriction that can be devised, and another species and class be subjected to the overwhelming competition of foreign rivals?

We beg leave briefly to state, that every nation in the civilized world, except Holland and the United States, imposes heavy duties on, or actually prohibits, such articles as interfere with or destroy the domestic industry of the country.—The four greatest nations in Europe, Great Britain, France, Russia, and Austria, have systems abounding with various restrictions. France prohibits manufactures of steel, brass, copper, woolen cloths, wove cotton goods, cotton yarn, watches, clocks, &c. &c. The prohibitions in the Russian tariff amount to three hundred and ten articles, embracing the important manufactures of iron, brass, steel, copper, wool, leather, silver, glass, flax, hemp, and cotton. England prohibits altogether a variety of articles, and imposes a duty of 172 per cent. on printed linens—104 on linen sails—80 on glass—75 on china, earthen ware, and manufactures of leather, skins and furs. Seventy or eighty enumerated articles, and all that are not enumerated pay 50 per cent. Spain, Portugal, Prussia, Denmark, Sardinia, Sweden, Mexico, and Peru, pursue the same system. The latter subjects to double duties, "*such articles as directly prejudice the industry of the country—such as ready made clothes, white and coloured leather, boots, shoes, chairs, sofas, tables, commodes, coaches, culushes, saddles, and other manufactures of harness, ironmongery, wax, spermaciti, and tallow candles.*"

It cannot possibly be supposed that we possess more wisdom, and have devised a more perfect system than the oldest and most prosperous nations in the world.

But if we refuse to profit by the salutary lessons and examples of the rest of the civilized world, it would be unwise not to profit by our own melancholy experience. We wish to recal to your recollection the awful scenes of 1784, 5, 6, 7, and 8, when intense suffering and distress stalked through the land—when tender, and appraisalment, and stop laws disgraced and dishonoured the statute books of one-half the states in the union—when civil war raised its bold front in Massachusetts—and when our citizens were disposed to doubt whether all the boasted blessings of the revolution, were not likely to vanish "*like the baseless fabric of a vision.*"

To what was this shocking state of things owing? To extravagant importations of foreign goods alone, whereby we were drained of our specie, a general paralysis produced, and property of every kind was sacrificed at one-half, one-third, or one-fourth of its former value. The merchants who were then, as now, in favour of the "*let-us-alone policy,*" suffered in the general wreck with the rest of the community.

If from that dreadful period, we direct our eyes to the disastrous years 1816, 1817, 1818, and 1819, when so much distress pervaded the land, we find the same causes and the same effects.—We find that to the extravagant importations of 1815 and 1816, nearly the whole of the sufferings of the country may be as fairly traced as any effect whatever to its proximate cause. Those importations exceeded our means of payment by our natural productions. The balance was paid in specie. The banks were drained—all of them obliged to press on their customers—and no small number to suspend specie payments altogether—and thus bankruptcy and ruin swallowed up thousands of our citizens, particularly in 1819. In this case, as in the former, the mercantile class largely shared in the general disasters.

To the consequences of the enormous importations of the present year, we look with the most serious apprehension. They so far exceed the amount of the export of our productions, that although we have remitted of government and United States' bank stock, exclusive of stocks of various other kind, within the year above \$4,500,000—and exported 6 or 7,000,000 of specie more than we imported—we still have not by some millions met the demands of Europe on us for the fiscal year recently closed.

It is an important truth, demanding the most serious and solemn consideration, that by those extravagant importations, we hold specie payments, so vitally important to the character, the morals, the happiness, and the prosperity of the country, by a very precarious tenure.—Whenever importation greatly exceeds exportation, the balance must be paid in specie: and when that payment goes to the extent it reached in 1784, and 5, and in 1815, 16, 17, and 18, the consequences in all future times, as in times past, must necessarily be tremendous.

To our fatal experience of the ruinous consequences of extravagant importations, and the necessity of controlling them by legislative interposition, we can add that of Russia and Holland, which ought at once to preclude all controversy on this subject, and to settle the question without appeal. Russia, which had prospered for a series of years, under the restrictive system, made a total change early in 1820, abrogating its prohibitions and greatly reducing its duties. The consequence—during 1820 and 1821, were fatal to its industry, happiness, wealth and prosperity, which were most dreadfully impaired. The limits of a memorial prohibit entering into detail—and we shall only quote the pithy statement of the Russian government, dated March 23, 1822, when the "*let-us-alone policy*" was wholly renounced—"*Agriculture without a market—industry without protection—languished and declined. Specie was exported. And the most solid commercial houses were shaken.*" The whole invaluable document may be seen in our gazettes.

The facts of this case are immensely important—and ought never for a moment to be disregarded by our statesmen. Narrow and illiberal views of this grand subject, have assumed an hostility between the different classes of society, and supposed that the promotion of the prosperity of manufactures, by protecting duties, would be pernicious to agriculture and commerce. Nothing can possibly be more foreign from the truth. Their interests are identified. It is impossible that so great a national branch of industry, as that of the manufacturing class, can prosper or decay, without the other branches enjoying a portion of the prosperity or suffering a portion of the decay. In confirmation of this plain theory, Russia found, as we have found by our own fatal experience, that although by opening the flood-gates to foreign merchandise, and *buying goods where they could be had cheapest*, manufactures and manufacturers may be the first to suffer, yet agriculture and commerce ultimately partake equally in the disastrous consequences.

Holland is at present writhing under the consequences of the "*let-us-alone policy.*" Her tariff bears the same date as ours, 1816. It imposes very light duties. Since its operation commenced, her finances have failed—her industry is paralyzed—real estate has fallen throughout the kingdom, (except at the Hague and in Brussels,) one-third—and one-ninth part of the population of the most industrious country in the world is actually dependent on public support for a living.

In every other science, but political economy, when a theory is broached, it is according to the

dictates of reason and common sense, subjected to the test of experiment—and if it cannot pass this ordeal, it is abandoned. It is melancholy to reflect, that in the grand science of promoting the happiness and prosperity of nations, this sound procedure is wholly abandoned; and that so many of our most estimable citizens, yielding themselves to plausible but delusive theories, shut their eyes to the deleterious consequences produced in Spain, Portugal, Ireland, Poland, Russia, and the United States, by the "*let-us-alone policy*"—as well as to the incalculable benefits derived by Great Britain and France, and the vast additions to their "*wealth, power and resources*" from the restrictive system.

III. *The injustice of taxing the many for the benefit of the few.*

This phrase has been so often reiterated, that many of our citizens are impressed with an opinion that the manufacturers are but a "*few,*" and form a very "*insignificant*" part of the community. In an address recently delivered by a member of an agricultural society, which has memorialized congress against the applications of the manufacturers, they have been styled "*the most insignificant and inconsiderable interest in this nation!*" We deeply regret the use of such harsh language, so wholly unlooked for, so wholly unfounded, and so well calculated to excite irritation and retaliation. The orator must have been ignorant of the fact, that this "*most insignificant and inconsiderable interest*" actually comprises, in the eleven old states, from Maine to Maryland inclusive 1,064,742 souls, being 22 per cent. of 4,839,738, the total population of those states; and about 1,349,000 in the whole union, being about one-seventh of its aggregate population. The manufacturers "*purchase from their agricultural fellow citizens all the animal food—all the bread stuffs—four-fifths of the drinks—all the timber, except mahogany—one-third of the sugar—and ninety-nine parts in one hundred of the tobacco, which they consume. Moreover, all the flax, all the hemp, all the wool, all the hides, all the skins, and all the furs furnished by our fields and forests, find a ready market in the workshops*" of this "*insignificant interest,*" who are thus ignominiously held up to the contempt of their fellow citizens. In one word, the market this "*caste*" affords its agricultural brethren, is six fold greater than the markets of all the world besides, and not subject to the destructive fluctuations of foreign markets.

IV. *The dangers of monopoly.*

It is asserted that protecting duties will afford the manufacturers a monopoly—and enable and induce them to impose on the public by charging exorbitant prices. There cannot be any monopoly in this country. There is no power to grant one. Every species of industry, of whatever kind it may be, is open to every citizen without exception. It has been conclusively observed on this subject by one of our greatest statesmen—"*When a domestic manufacture has attained to perfection, and has engaged in the prosecution of it a competent number of persons, it invariably becomes cheaper [than the foreign article.] The internal competition which takes place, soon does away every thing like a monopoly, and by degrees reduces the price of the article to the minimum of a reasonable profit on the capital employed.*" But we are not to depend on the theory. We have the most satisfactory experience on the subject. The objection is set at rest by the experience of the duties on yarn, coarse cottons and nails. These duties are very nearly prohibitory—and, so far from realizing the gloomy

anticipations of the consequences of prohibitory duties—those articles are furnished of better quality and cheaper than they were when foreign rivals enjoyed the market.

V. *It will destroy the revenue.*
Our demands for the productions of Europe will increase with our population and our prosperity—and the tariff may, without difficulty, be so far modified, that the increased duties on the articles which we must continue to import, will amply compensate for any deficiencies that may arise from the diminution of other articles, for which our citizens will provide substitutes.—Silks and linens, neither of which are at present manufactured here to any extent, would afford an addition to our revenues, of probably one million of dollars. A variety of other articles might be pointed out, which would admit of additional duties. For a long time we cannot supply ourselves fully with cottons or woollens. It cannot be doubted that an addition to the existing duties of 12½ or 15 per cent. on what we must continue to import, would amply compensate for the defalcation of the amount resulting from an increase of the domestic production.

VI. *The danger of smuggling.*
On this point very few observations will suffice. We impose 80, 90, 100, and 150 per cent. on teas, sugar, wines, and spirits, without any apprehension of smuggling. It is, therefore, highly incorrect, to magnify the danger of smuggling, to deter congress from imposing duties of 30, 35, or 40 per cent. on manufactures. There is no body of merchants in the world more fair or honourable than ours—and it is a libel on them to suppose the existence of this danger.

Most of the observations we have hitherto offered, partake of a local or sectional character, merely to meet and obviate sectional prejudices. But it does the subject great and manifest injustice, not to consider it on a grand national scale, so far as it affects the interests of a rising empire. We will now present one feature of our policy, predicated on the national importance of this subject.

We have probably exported this year 135,000,000 lbs. of upland cotton. At 8 pence sterling per lb. which is the average of the year in Liverpool, it amounted to £4,500,000 or about \$20,000,000.—Had we manufactured 35,000,000 lbs. additional—and the increase in value by the manufacture been but four-fold,* it would amount to about \$20,000,000, the actual amount of the whole crop, leaving a national gain of about \$15,000,000 for rent, wear and tear of materials, wages of labour, and profit of capital. And from the luminous circular letter of Cropper, Benson & Co. recently published, and the actual state of the production of cotton in all the countries where it is cultivated, as well as the great increase of consumption, there is no doubt that the residue would have produced as much as the whole has done. The price abroad has fallen by excess of exportation.† Nothing but a decrease is likely

* *Very recent accounts from Great Britain warrant the belief that the increase is 7 or 8 fold. The exports of cotton goods from Great Britain this year are about £23,000,000 or above \$100,000,000.*

† *The average price in Liverpool in 1819 was 15½ pence sterling. That year there were only 205,000 bales imported from this country. The next year the importation was 300,000 bales, and the price fell to 13d. In 1821, the importation continued at 300,000 bales—and the price fell to 11d. This year the quantity increased considerably, and the price has fallen to an average of 8d. These are facts which cannot be too seriously considered by our statesmen.*

to raise it. And nothing but extending the domestic consumption can produce this decrease.—The interests therefore of the cotton planter and cotton manufacturer are indissolubly identified—and the general prosperity, wealth, power, and resources of the nation materially depend on the regulation of our policy with a steady eye to this identity. Cropper, Benson & Co. expressly state that by a decrease of the exportation, our planters "*might sell their cotton at any price.*"—What an important field for reflexion on the immense advantages presented to us by bounteous nature, which we lavish for the support of foreign industry and foreign governments! These considerations might be advantageously extended to various other branches of our industry.

We could make large additions to this memorial—but we hope we have adduced sufficient reasons to prove, as we stated, that the tariff is unjust, oppressive, partial, and impolitic—and requires complete correction.

All which is respectfully submitted.

Philadelphia, December 30th, 1822.

Signed by order of the board,

WILLIAM TILGHMAN,

President of the Pennsylvania Society for the encouragement of American Manufactures.

Attest.

HENRY HORN, Sec. pro tem.

ANECDOTES OF DRESS IN THE LAST CENTURY.

The love of *novelty*, it has been truly observed, is the parent of Fashion. As the fancy sickens, says a writer on this subject, with one image, it longs for another. This is the cause of the continual revolutions of habit and behaviour, and why we rose so industrious in pursuing the change; this makes fashion universally followed, and is the true reason why the awkwardest people are as fond of this folly as the genteel. This passion for novelty, particularly in the article of dress, seems for ages to have been a predominant feature in the English character, and with the exception of our neighbours, the French, may be said to be almost peculiar to it. Most of our early writers make some allusions to it in their works, and Dr. Andrew Borde, in a satirical tract published by him in the reign of Henry VIII., to show the then excess of the folly, has prefixed, in a rude wood-cut, the figure of a naked Englishman with a piece of cloth and a pair of sheers, debating on the fashion he shall have his clothes made in. Purposing in the few slight notices which follow, to confine our observations merely to the costume of the last century, we shall pass over the fashions of those which preceded it, with only quoting some general remarks:—

"The party-coloured coat," says the author of a Treatise on Dress, published in 1761, "was first worn in England in the time of Henry I. Chaplets, or wreaths of artificial flowers, in the time of Edward III.; hoods and short coats without sleeves, called tabarts in the time of Henry IV.; hats in the time of Henry VII.; ruffs in the reign of Edward VI.; and wrought caps and bonnets in the time of Queen Elizabeth. Judge Finch introduced the band in the reign of James I.; French hoods, bibs, and gorgets were discontinued by the Queen of Charles I.; the commode, or cover, was introduced in the year 1687; shoes of the then fashion, in 1633; breeches instead of trunk hose, in 1634; and perukes were first worn after the Restoration.

About the year 1700, the ladies wore Holland petticoats embroidered in figures, with different coloured silks and gold, with broad orrices at the bottom. Muffs were at this period in use,

but very different in shape and materials from those of the present day, being in general very small, and frequently made of leopard skin. Diamond stomachers adorned the ladies' bosoms, which were composed of that valuable stone set in silver, in a variety of figures, upon black silk, and which must be admitted to have been a brilliant, if not elegant ornament. Satin gowns were lined with Persian silk; and handkerchiefs, and Spanish leather-shoes, lined with gold, were common with persons of respectability. To these different articles the ladies added bare necks, with gold and other crosses suspended from them. Those odd little circular pieces of black silk, called *patches*, prevailed also at this period to a most extravagant degree. These were stuck on different parts of the female face, and varied in size. Frequent allusions are made to these fancied "beauty spots," by early comic writers.

In 1709, a lady's dress is that described in an advertisement to recover one that was lost: "A black silk petticoat, with a red and white calico border; cherry-coloured stays, trimmed with blue and silver; a red and dove-coloured damask gown, flowered with large trees; a yellow satin apron, trimmed with white Persian; muslin head clothes, with crows-foot edging; double ruffles, with fine edging; "a black silk furbelowed scarf, and a spotted hood." In 1711, a lady's riding dress is advertised for sale, in the *Spectator*, of blue cambiet, well laced with silver; being a coat, waistcoat, petticoat, hat, and feathers. And another advertisement, 1712, mentions an *Isabella* coloured *Kincob* gown, flowered with green and gold; and a dark coloured cloth gown and petticoat, with two silver orrices; a purple and gold *atlas* gown; a scarlet and gold *atlas* petticoat, edged with silver; a wrought *under* petticoat, edged with gold; a black velvet petticoat; *allegah* petticoat, striped with green, gold, and white; and a blue and silver silk gown and petticoat; a blue and gold *atlas* gown and petticoat, and clogs, laced with silver. A Mrs. Beale, at the same period, advertises her loss of a green silk knit waistcoat, with gold and silver flowers *all over it*, and about fourteen yards of gold and silver thick lace on it; with a petticoat of rich strong flowered satin red and white, all in great flowers or leaves, and scarlet flowers with *black specks* brocaded in, raised high, like velvet or shag.

The ladies wore hooped petticoats, scarlet cloaks, and masks, when walking. The hoops were fair game for the wits, and they spare them not:—

"An elderly lady, whose bulky squat figure, By hoops, and white damask, was render'd much bigger,

Without hood, and bare neck'd, to the Park did repair,

To show her new clothes, and to take the fresh air:

Her shape, her attire, rais'd a shout and loud laughter;

Away waddles madam—the mob hurries after.

Quoth a wag, thus observing the noisy crowd follow,

As she came with a hoop, she's gone off with a hollow!"

An advertisement, in 1703, gives a whole-length portrait of a youth in middle life. Such a figure would attract much wonder in the streets of London at present. "He is of a fair complexion, light brown lank hair, having on a dark brown frieze coat, double breasted on each side, with black buttons and button-holes; a light dregget waistcoat, red shag breeches, striped with stripes, and black stockings."

The ridiculous long wigs of 1710 were very expensive. One was advertised as stolen that year, said to be worth five guineas. This however, was a trifle; for Drumver's "fair wig," in the *Tatler*, cost "forty guineas." But, lest it should be supposed that the gentlemen only were expensive in decorating the head, take the prices from the Lace Chamber on Ludgate-hill: "One Brussel's Head, at £40; one Ground Brussel's Head, at £30; one looped Brussel's Head, at £30." Wigs maintained their ground, though not so enormously large in 1720; at which period white hair for them was all the fashion, and bore a monstrous price. They were still a more important article of dress in 1734; but the favourite colour had then changed—those of "right grey human hair" were four guineas each; light grizzle ties three guineas; right grey human hair "cue perukes," from two guineas to fifteen shillings each, which was the price of dark ones; and right grey bob perukes from two guineas and a half to fifteen shillings, the price only of dark bobs; those mixed with horse hair were much lower. It will be observed, from the gradations in price, that right grey hair was most in vogue, and dark hair of no estimation.

A lady, corresponding with her friend, whimsically describes the dress of the box-lobby loungers of 1738; from which it will be seen, whatever we may think of them, that our ancestors were by no means behind hand with us in folly. "Some of them," she says, "wore those loose kind of great coats which the vulgar call 'wrapsals;' with gold-laced hats slouched, in humble imitation of coachmen; others aspired at being grooms, and had dirty boots and spurs, with black caps on long whips; and a third sort wore light scanty frocks, little shabby hats, put on one side, and clubs in their hands."

In 1760, the ladies are stated to have worn the following species of caps:—The French night cap; the Ranelagh mob; the Mary Queen of Scots cap, and the fly cap. The latter we may suppose was the most esteemed, as the late Queen Charlotte, when she landed in England in 1761, was, in compliance with the English costume, habited in "a gold-brocade, with a white ground; had a stomacher ornamented with diamonds, and wore a fly-cap, with richly-laced lappets."

The *London Chronicle* for 1762, enumerates the following articles of male attire, on which it indulges several witty remarks. Of hats, there were, the Kevenhuller; the sailors, described as uniformly tacked down to the Crown, and laughably said to look as if they carried a triangular apple party upon their heads; the Quaker's hat which is said to spread over their heads like a pent-house, darkened the outward man, to signify they have the inward light. Some are described as wearing their hats (with the corner that should come over their foreheads in a direct line) pointed in the air. These were called "Gawkies." Others are said to not above half cover their heads, but between beaver and eye brows, to expose a piece of blank forehead, that looks like a sandy road in a surveyor's plan. Of wigs then in use, are satirized, among others, "the 'prentice minor bob, or hair cap; the citizens sundry buckle, or bob major; the apothecary's bush; the physical and chirurgical tye; the scratch, or the blood's scull covering, and the John's jemy or white and all white, in little curls like a fine fleece on a lamb's back. This last is the species of wig now frequently worn by a gentleman's coach-men."

Taking the fashion generally within the last 40 or 50, we find the ladies heads covered with cushion, as it was termed, generally formed of horse hair, and something like a porter's knot set

upon the ends; over this the hair was combed straight, the sides curled, and the back turned up, and the whole powdered; diminutive caps of gauze adorned with ribbands, and miniature hats generally of black silk, trimmed, were stuck on the tower of hair with long pins. The waist was covered by a large-bodied gown, drawn exceedingly close over stays laced still closer; the hips sometimes supported a bell hoop; the shoulders alternately small cloaks and cardinals; the former of muslin and silk, and the latter almost always of black silk, richly laced.

This description of dress altered by degrees to the present fashion. The head insensibly lowered; the horse-hair first gave place to large natural curls spread over the face and ears; the cap enlarged to an enormous size, and the bonnet swelled in proportion. Silks became unfashionable, and printed calicoes, and the finest white muslins were substituted. Hoops were entirely discontinued, except at Court. These were all improvements; but it is only of late years that the ladies—much to their honour, have thrown aside most of the hateful attempts to supply nature's deficiencies, and now appear in that native grace and proportion which distinguishes an English woman. The hair cleansed from all extraneous matter, shines in beautiful lustre carelessly turned round the head, in the manner adopted by the most eminent Grecian sculptors; and the form appears through their snow-white draperies in that fascinating manner, which excludes the least thought of impropriety. Their hats and bonnets of straw, chip and beaver, if somewhat less would be extremely becoming; and their velvet pelisses, shawls, and silk spencers, are contrived to improve, rather than injure the form.

The male dress, like the female, changed almost insensibly from formality to ease. This was effected merely by altering the cut of the clothes; the materials are the same as they were a 100 years ago; the colours however, are more grave. Instead of "Claret-coloured clothes, Pompadours, light blue, with silver button-holes, &c., deep blue, dark browns, mixtures, and blacks, are now worn by the sedate and the gay, the young and the old. In point of shape, there is, and always will be, a continued variation. The hat has as many different forms and denominations as it had in the times we have been speaking of, though not of the same kind. The modern neck-cloth should not be omitted, especially as it has been more ridiculed than other parts of the male dress. It is enough to say, though some have considerably reformed it in this particular, that it has been compared to a towel tied under the chin.

Too much praise cannot be given to the abolition of the unnatural custom of wearing hair-powder. The appearance of this, in a young person at least, though only discontinued a few years, is becoming now quite Gothic.—*Albion*.

NORTH DEVON CATTLE—THEIR PRICES IN ENGLAND.

Many gentlemen express surprise at the prices asked for cattle of improved breed, from imported stock, without reflecting sufficiently on the causes, which go to shew the justice and reasonableness of such prices. The breeds in highest estimation now in England, are the Improved short horns, the Herefords, and the North Devon cattle. These several breeds, in the perfection they now exhibit for the various purposes, for which neat cattle are reared, have been brought to their present condition, by immense expense, by great skill in the selection of the progenitors, and unwearied attention to every particular, for

more than half a century. Is it then reasonable to expect, that they should be sold for any thing near the prices of common cattle? As well might we expect to purchase a fine full grown tree, bearing abundantly the high flavoured pippin, for the price we should have to give for the scion of a common redstreak. We have ascertained by actual purchase, the cost of the improved short horns, when procured under the most favourable circumstances, and from one of the very best breeders of that stock in England—and we have already stated at different times, the prices of the Herefords purchased by Mr. Clay, and others in Kentucky; but the North Devons of full blood, which have fallen under our notice, were a free and spontaneous offering, to their present owners, by that enlightened and generous English farmer, Mr. Coke of Norfolk. His opinion of their superior qualities, has already been published in the *Farmer*, but we knew not what would be the cost of such cattle in England. Having heard that a gentleman who owns a cow of this breed, had sent to England to procure some heifers, we solicited such information, as he might have received, as to the prices at which they are selling, to which he has politely replied by the following note.—*Edü. Am. Farmer*.

Baltimore County, 11th February, 1823.

MR. JOHN S. SKINNER,

Dear Sir,—In answer to your enquiry respecting an order sent to England, for Devon Cattle, I take pleasure in communicating the result.

Last May I wrote to Messrs. Wm. and Jas. Brown & Co. of Liverpool, to purchase and ship to me, by a vessel in which I had previously engaged accommodation for them, three full bred Devonshire Heifers, provided their cost did not exceed \$70 or 80 each, and on the 4th July, they wrote as follows:

"We should be very glad to carry your wishes into effect, as respects the stock you want; but we are sure it is quite impossible at the prices you quote. The Earl of Sefton is the only person in this neighbourhood who has any Devon Cattle, and he bought them at Mr. Child's September sales, at two or three times the price you mention, and none of his Lordship's are to be sold."

If I mistake not, you are in possession of the prices obtained by Mr. Child, at his last September sale for Devon cattle, and which I think will confirm the above letter.

Your's very respectfully,
H. T.

THE UNNATURAL SON.

A certain farmer in Connecticut, possessing a small estate, was persuaded by his only son, (who was married, and lived with his father,) to give him a deed of the property. It was accordingly executed. Soon the father began to find himself neglected—next removed from the common table, to a block in the chimney corner, to take the morsel of food reluctantly given him—at last, one day the unnatural son resolved to try once more to break the heart of his sire. He procured a block, and began to hollow it. While at work, he was questioned by one of his children what he was doing. "I am making a trough for your grandfather to eat out of," was the reply. "Ah," says the child, "and when you are as old as grandfather, shall I have to make a trough for you to eat out of?" The instrument he was using fell from his hand—the block was cast on the fire—the old man's forgiveness asked, and he was restored to the situation his age and worth entitled him.

POPE'S THRESHING MACHINE.

In the fourth volume, page 253, we published the "REPORT ON INVENTIONS," made to the Massachusetts Agricultural Society, by their Committee, Messrs. Josiah Quincey, Cyrus Alger, and Paul Moody. In that report these gentlemen speak of Mr. Pope's Threshing Machine as follows:—

"The machine which most attracted the attention of your Committee, was one presented by Joseph Pope, Esq. of Boston, a gentleman long known by the public by his inventions and mechanical ingenuity. This machine is patented—intended to work by hand, in its present model, but easily capable of being enlarged and applied to a horse power.

The material to be threshed, passes through opposite sets of surfaces placed transversely in a frame. They are respectively moving rods—and constitute a threshing power on an open floor composed of stationary rods.

It was stated to your Committee that it threshed fifty bushels of grain in 12 hours—and four bushels and 12 quarts of oats in one hour—and that a common sized sheaf passes through it and is completely threshed in one minute. The labour is done by two hands, one destined to turn it, the other to feed it, or one man and two boys are sufficient for the same purpose.

In the experiment made before the committee, it threshed the grain out perfectly. And it is obvious that with a very small expense, it may be converted into a machine for cutting straw without any injury to its threshing power.

Owing to an accident, for which the owner of the machine is not responsible, it was not duly entered, although it was brought to Brighton and deposited in the society's room in proper season for that purpose.

As your Committee consider the machine as likely to be very useful, and as Mr. Pope has been at great expense and trouble for the purpose of bringing it to Brighton, your committee appre-

hend that some notice ought to be taken of it, and they therefore recommend that he should have a premium of \$20, he producing the requisite certificates of its being used and approved by a practical farmer."

Since that time, frequent inquiries have been made by our correspondents for more precise information, as to the construction, power and capacity of the machine—we have endeavoured "as in duty bound," to gratify these inquiries, and now spread before them the result of these endeavours, and if they prove not satisfactory, it will be our misfortune—not our fault.—We begin with the engraving and description of the machine itself, and these are followed by the certificates of members of the Pennsylvania Agricultural Society—all of them practical farmers, and many of them known to us, and extensively known through the country, as gentlemen in whose word and judgment every reliance may be placed.—*Edit. Am. Farmer.*

EXPLANATION.

- a The revolving Beater, the rods of which strike the grain 2000 times in a minute.
- b The parallel fluted Rollers, that assist in conducting the straw forward to the Beater.
- c The circular or endless cloth, an which is spread the material to be threshed, and which conducts the straw to the rollers (b).
- d The shears worked by a small crank at the end of the axle of the wheel (f).

- e The curved floor, consisting of slats, on which the grain is beaten out.
- f The wheel turned by hand.

CERTIFICATES.
Philadelphia, March 6th, 1823.

JOHN S. SKINNER, Esq.
Sir,—According to your request, I forward you the enclosed documents relative to a thrashing machine, invented by my father, that you may,

should it be your pleasure, give them publicity in your paper, the American Farmer.

This is the same machine that obtained the premium at the last Brighton Cattle Show. A description of it is fully contained in the Schedule, annexed to the patent, a copy of which I herewith hand you—attended with several certificates, testifying its capacity, both as a hand, and horse machine. The power of a man exercised at the lever, to which the horse is attached,

being sufficient to move the hand machine, with the greatest ease, it appears obvious to all those who have witnessed this effect, that a horse possesses ample power to work with light labour, a machine of larger dimensions, and of much greater capacity than the hand machine in its present form. You will perceive by the certificates accompanying this, that the machine with hand power, is capable of thrashing five dozen sheaves of wheat in an hour, and that the same machine, with the application of horse power, thrashes ten dozen* an hour—this it performs without the use of the shears.—The shears indeed, should not be considered as a necessary appendage to the hand machine, and are only advantageous when the straw is long—for by removing with them the thick ends or butts of the straw, the labour at the wheel is thereby much reduced, and a more considerable quantity of grain, may be beaten out, than can be thrashed in the same time from the straw if whole—I forward you a certificate by which you will perceive how much thrashing by hand is accelerated, with the assistance of the shears.

The hand machine can be constructed at little expense, the materials, including the shears, cost \$13, and it can be made by a good workman, (say a joiner or a carpenter) in 12 days.

The extra expense of the wheels for the application of horse power, does not exceed \$20.

I am sir, respectfully,

Your very obedient servant,
JOSEPH POPE, Jr.

* Ten dozen sheaves of wheat here yield five bushels of grain.—*Edit. Am. Farmer.*

(The following Certificate will prove what advantage is gained by using the shears.)

This is to certify, that we the subscribers, witnessed the operation of Mr. Jos. Pope's newly invented patent hand thrashing machine, in Mr. Joshua Coolidge's barn in Watertown, and it beat out clear, forty sheaves of winter rye, that yielded three bushels of grain, in twenty four minutes.

(Signed) JOSHUA COOLIDGE,
ISAAC STONE,
JOSHUA COOLIDGE, Jr.
SAMUEL SYMONDS,
WILLIAM JOHNSON.

Watertown, Massachusetts, }
November 1, 1822, }

The thrashing machine constructed by Mr. Joseph Pope, agreeably to his patent, has been fixed up at my farm for about two weeks past, for the inspection of the public, and has been in operation most of that time, thrashing of wheat. It has well and clearly thrashed, in twenty-five minutes, sixty sheaves of wheat, requiring one man to feed the machine, and a man or boy to take away the straw. This is a small machine constructed for hand power. A horse was used to try its operation, although, the force required, was not more than any common man could easily exert.—It is fully my opinion that a large machine (such as the power of any horse would be adequate to keep in operation) would easily thrash twenty dozen sheaves of wheat per hour—and from the simplicity, power and cheapness of the machine, I think it will become highly beneficial to all practical farmers who may use it.

(Signed) MANUEL EYRE.
Philadelphia, Feb. 25, 1823.

Delaware County, Pontreading Farm, }
March 1, 1823. }

Mr. Jos. POPE,

Sir,—I have seen in operation with a horse, your small thrashing machine, intended for hand

use, with pleasure; I am well satisfied with its principles, it appears to me to be better adapted to thrashing, than any machine I have seen or heard of; it thrashes much cleaner and more expeditiously, than is usually done by the flail or by horses, and without the objections to the latter method.

This machine should always be made to work by a horse, when it can be attended by infirm men, or small boys, who could make but little way with a flail; the same power may be at the same time carried to the fan for cleaning the grain.

Although I did not ascertain the quantity thrashed in a given time, yet I am perfectly satisfied, it is the interest of every farmer to have one.

I am, with due respect, your's &c.
(Signed) JOSHUA HUMPHREYS.

Delaware County, Penn. 5th March, 1823.
Mr. J. POPE,

Sir,—We with pleasure reply to your request to have our opinion of your thrashing machine, as we have witnessed the operation of it, first by hand, and subsequently by horse power; and are decidedly of opinion (from its execution, simplicity and little liability to get out of order) that it is fully entitled to the patronage of the practical farmer. We think a machine of the size of the one you exhibit, operated upon by the power of a man, would be quite sufficient to do all the thrashing required on the smaller sized farms in the neighbourhood of Philadelphia—and that one equal to the power of one horse, would with facility thrash all the grain grown on the largest farms we are acquainted with. We are also of opinion from the trials we saw made, that it will thrash cleaner than is usual with the flail, whilst the straw not broken but bruised and softened, is left in the most favourable state for fodder.

Very respectfully, &c.

(Signed) THOS. SMITH.
AARON CLEMENT.

Powelton, Philadelphia County, }
March 5, 1823. }

JOHN S. SKINNER, ESQ.

Dear Sir,—I can reply to your inquiries, about Pope's thrashing machine, from close examination of its construction, and attention to its performance, both here and at Brighton. It was exhibited to our society—tried by their committee, and has been again in operation before several of our directors, and many other farmers, (not "Dilletanti," nor "Book farmers,") who are not less satisfied than myself, that since it has been adapted to the power of one horse, it is by its simplicity, cheapness, strength, and force, better suited to our purposes, than any thrashing machine which we have seen. It costs fifty dollars, occupies not more room than a fan, thrashes 120 sheaves per hour, and can be carried in a cart, or taken to pieces at will.

I am, dear sir,

Your's truly,
JOHN HARE POWEL,
Corresponding Secretary of the Penn.
Agricultural Society.

TO THE EDITOR OF THE AMERICAN FARMER.

BROMUS CANADENSIS—(CHEAT.)

DEAR SIR—You are not unacquainted with the propriety and advantage of proper names, and good definitions. By fixing these, disputes are often settled. Indeed provincial names are a high road to error—for it is no uncommon thing for five different names to be affixed to one vegetable, and again the same name to be applied to five different vegetables. The subject of this

essay, is an instance where the same provincial name is given to two distinct articles.—*Bromus Canadensis* as above, is called Cheat, and so is *Lolium Temulentum*.* They are both objects of great superstition—the former in this country, and the latter in England—not only among the illiterate, but I find it adhering to the better informed, like a paralytic plant, without a foundation. It is to these I address myself.—A few questions will be proposed, to bring this article to a solitary standing, which alone would render it very suspicious, and cause it to yield in the balance, to one grain of reason, in counterbalance.

I ask the credulist, in the first place, if he ever knew (the article in question, to be excepted for the present,) any one vegetable to become another genera? And has not the vegetable family been as constant to produce after its own kind, as the animal race? 2d. Did he ever know any one animal, to change to another genera, by metamorphosis, or by procreation, viz. a dog become a cat; an ox, turn to an ass; or even a mouse grow to a rat? 3d. Did he ever know of a vegetable changing to an animal; even an orchis become a butterfly, or a gnat? which they so much resemble, in some of their species.

4th. Did he ever know the converse of the above, i. e. an animal become a vegetable, viz. a polypus become a sensitive plant, or a tabularia become a honeysuckle? For these are as nearly approaching, as any thing I have seen in the two kingdoms. To some of these questions, methinks, I hear a good old farmer, (who has by some mistaken whim, resolved to protect his son from hard hands, and brow sweats,) reply that his Tommy has read at the college of some lovers, that were changed to mulberry trees; and that he had found a book that told how to turn a dead heifer, into a swarm of bees. Well, my good old father, I can only say, that your polished son, will surely outdo all that you have ever done. He has only to read Gulliver to finish his education; where he will hear of some talking horses, that will take his orders, and supercede his overlooking, whilst he may stretch his dandy limbs, and floating trowsers, beneath the oak, and there in soft luxuriant idleness, enjoy the breeze; or read of Cadmus, Ajax, and Proteus too.

I will warrant that he will soon see a genuine metamorphosis on his farm, and his wheat will assuredly become cheat. But remember, my good friend, all these odd things happened in old times; I want some proof in things of later date—in our day, when substances are acted upon, more by physical powers, than by fiction. But the authority of Virgil, or even Ovid, is very unfavourable to your theory in this article—for they both mention the famous cheat, without any idea of its being either a natural child of wheat or a metamorphosis.†

It is granted, that there are changes in vegetables—but what are they? Are they not mongrels? i. e. two hermaphrodite plants, mixing their pollen and ligmatic irritability produce a third, varying from both; thus our common tobacco, mixing with another species of tobacco, produces a half blood; and this new species, or rather variety, being impregnated again, with our common tobacco, will produce a three-fourth blood—in this way, they may be carried on and re-

* This difference of opinion in the two countries, is enough to overact their assertion.

† *Intenque nitentia culta infelix lolium et steriles dominenter avenae.*—VIRGIL.

Lolium tribulique fatigant

Triticæ messes et inexphugnabile gramen.

OVID.

duced back again, as was tried by Mr. Kolrother, and so of animals. But where is the other plant, that is to be the mother or father, of cheat? Even supposing it to be a mongrel, none can be shown. It certainly is not rye—and yet it is remarkable that there are no hybrids, from these two grains, so often grown together. But you may ask, whence comes this seed of cheat, and why peculiar to wheat grounds. Answer me first, whence comes the white clover, when we dress a piece of low ground with ashes. If you cannot answer this, I will. It comes from that great stock of seeds, that is buried below the point where exposed to air, they would rot, or vegetate—some perhaps 1000 years past. When the ground is put in that order, that admits them to rise, and a manure that is a peculiar stimulus to them is applied, they come forth in a hard soil, and without this stimulus, they sleep. But in cultivated ground, a reigning crop keeps them under, if the weather and tillage suit. When ground is too wet for wheat, the cheat seed springs. The time and all other circumstances favouring it; and so of other articles innumerable. S. V. S.

† Cobbet, to shew that he did not understand every thing he writes about, denies the effects of what is called the sexuality of plants, and at the same time, absurdly supposes the bulbs of potatoes under ground, to have a secret contaminating influence!

FROM THE WINYAW INTELLIGENCER.

CLAREMONT AGRICULTURAL SOCIETY

Mr. Cleland Kinloch's report on Rot in Cotton.

The great agricultural interests of our country, the cotton crops, have suffered, of late, so much from what is commonly called the rot, that any enquiries into the subject are supposed to be not uninteresting to this Society; and it will now be attempted to be shewn, that some palliative, at least, of this great evil may reasonably be expected, from a careful destruction of all the dead stalks, leaves, pods, &c. that are usually left in the cotton fields, during winter, and from keeping for more than a year, all cotton seed, reserved for the purposes of manuring, or of planting.

It is well known, that many of the insect tribes, which prey upon vegetables, deposit their eggs on some part of the plant preyed upon; so that the succeeding generation finds its proper food, within its reach, while it is yet too feeble, to go far in search of subsistence; in some cases, the eggs are supposed to be deposited on the seed of the favorite plant; thus, whenever the seeds of a plant, called the silk plant, have been imported into this country from Portugal, a new, and remarkable insect has always appeared on these plants; when the species of this plant has been lost among us, the insects has disappeared; and upon a new importation of the same seed, the same insect has again made its appearance: a similar circumstance has occurred, too, with regard to the black seed cotton; which, when first cultivated in this country, some 70 or 80 years ago, was entirely free from the attacks of an insect, called the chenille; but, upon a renewal of this cultivation, after an interval of many years with seed from the West Indies, the chenille (at that time the great scourge of the West Indies) soon made its appearance among us, and, in some parts of the country, were not less destructive, than the present rot in the green seed: The presumption then is, that in those too cases, the eggs of each insect have been brought hither with the seed, that the race of the one has perish-

ed, from a want of its proper food, and that our climate has, happily proved too severe for the other.

In the West Indies (when the green seed cotton grew to such a height, as occasionally to require the use of ladders, in gathering in the crop, and when its cultivation was repressed, only by the want of the saw gin) the rot was unknown, nor, was it known in this country, until after the introduction of the green seed among us, from the southward and westward of our own continent; it existed also, in a most ruinous degree, to the southward and westward, long before it was much known, or much noticed among us; and among us, it had become almost general while yet unnoticed, or unknown in North Carolina; whereas it has now extended to the neighbourhood of Halifax Court House, and even to the south mountains in Virginia; where this particular species of cotton had been partially cultivated for the greater part of a century, without any suspicion of the rot, until the present times. The presumption then is, that the eggs of the insect were brought into this country, with the seed, from the southward and westward of our own continent; that the difference of climate between its ancient, and its present places of abode, may not be sufficient for its complete destruction; and that it has gradually spread over the whole extent of the cotton country, either by an interchange of seed; or from the prevailing wind of the summer season, wafting the insects before it; or from flight of the insect itself, when in its winged state.

Some of the planters of this neighbourhood have, formerly, procured cotton seed from parts of North Carolina, where the rot had never made its appearance; and when this northern seed has been planted on lands, newly cleared, and at a distance from other cotton fields, the crop is said to have suffered less from the rot, than other crops; but when these precautions have not been attended to, there is said to have been no perceptible difference, between the produce of this northern seed, and of our own; from which it may be presumed, that the northern seed was probably free, from the accompaniment of the eggs of the insect; but that it suffered from being brought into bad company.

Lastly it has been found, that considerable benefit was derived, from opening, at the commencement of winter, the cotton trenches, destined for the next crop, and strewing therein, the necessary seed at once, leaving it uncovered, until the usual season for planting; these seeds were thus exposed to all the inclemencies of the weather, and many of the eggs, deposited upon them may have perished for such exposure.

It has indeed been confidently asserted and upon very high authority, that the rot is a disease of the plant, from a well known cause of disease, among plants, a superabundance of sap; and that superabundance of sap may be a predisposing cause of the evil, is probable; but if it or if any thing else, common to the whole plant, were the primary cause, we might expect, that all the pods of the same plant would be similarly affected, which every cotton planter knows, not to be the case: in this neighbourhood, there is a species of the pear, the fruit of which becomes rotten at the heart first, about the period of inceptant maturation; but every pear of every tree of this species (so far as it is known) is every year affected in the same manner; a similar instance of a particular species of the apple occurs, at a well known orchard in North Carolina; while no single solitary instance is known, of such desultory, and capricious distinction, as by the rot in cotton, whenever destruction may, fairly, be traced to a disease of the plant.

It has also been said, that if the rot were occasioned by an insect, that insect would be seen; and, there is no doubt, but that it would be seen, if the cotton planters could be roused to the same skilful, and patient investigation, by which Linneus is said to have preserved all the timber, of the navy yards, in Sweden.

The last objection which occurs is, that if the rot were occasioned by a winged insect, the eggs of this insect (according to the usual economy of all the insect tribes, which, during some period of their existence, are winged) would become worms, and would, occasionally, be found in the cotton pods as the worm in the peach, and other stone fruits, &c. but in this instance, there is a clear misapprehension of the theory of some of those, who impute the rot to an insect, even a winged insect: they do not impute the evil to a worm, the produce of an egg, deposited by a winged insect itself, puncturing the pods, to draw its nourishment from them, and thereby superinducing upon them an incurable malady; while it, the winged insect, may continue its species, by depositing its eggs, on some part or other of the plant preyed upon, or on the pods; so that, if every part of the plant, usually left in the fields during winter, could be destroyed, perhaps by fire, the eggs deposited on such parts might share their fate; and if all the seed, reserved for use, could be kept for more than a year, the eggs deposited on this seed might be hatched, while in such keeping; and their produce might perish from a want of the usual supply of food: thus in the West-Indies, when the ravages of the chenille became intolerable, the cultivation of the black seed cotton was abandoned, throughout whole districts; and when, after an interval of one or two years, this cultivation was resumed, the chenille was first scarcely known, and its ravages, for several seasons together, were inconsiderable; until wafted about by winds, or spreading themselves by flight, they again increased to their former destructive numbers; upon every return to this cultivation, the eggs deposited on any parts of the plant, or on the seed, must, it is presumed, have been hatched, and their produce must have perished, and an entirely new generation must have arrived, from some of the neighbouring districts.

At any rate, if the rot should be a disease of the plant, the use of seed, more than a year old, may still be advantageous; for as it is well known that the flour of some vegetables is in some cases affected by the age of the seed, the age of the seed may possibly, have some effect on their health; and among the experiments, which this interesting subject seems to demand, from every agriculturist, we may, it is thought, be justified, in recommending one, that holds out a double chance of success.

The experiment indeed was made, and fairly made, the last season, by a member of this society; seed more than a year old, was planted on land newly cleared, and at a distance from all other cotton fields, but unfortunately the whole was destroyed, by the freshets.

Editorial Correspondence.

Richmond, Feb. 11, 1823.

VIRGINIA UNIVERSITY—EXTRACT TO THE EDITOR, FROM A MEMBER OF THE VIRGINIA LEGISLATURE.

The prospects of our University are improving. We have obtained a third loan of \$60,000 to complete the buildings. The original annuity of \$15,000, set apart from the income of our literary fund, for our University, is now charged with the interest of \$180,000; that is, to

the amount of \$10,800, leaving only \$4,200, of free income. Yesterday and to day, we have made an effort to get the debts of the University extinguished; but have failed. It cannot be done till next session of Assembly. Should it be then effected, measures may forthwith thereafter be taken, to engage professors, with the view of opening the institution in the fall of 1825. Delay is the price we pay for unanimity. But unanimity will come. The opposition diminishes, and the institution is gaining ground. We shall in a few years, have all Virginia with us; and headed by the admired sage of Monticello, I trust we shall accomplish a work that will be a lasting blessing to the Union. I think you may calculate pretty confidently, that our University will open in two years from this time, which I hope will be in time for your sons.

MILLET.

Burlington, March 28, 1823.

DEAR SIR,

I observe in your 52d number, just received, mention is made of white millet seed, received from Col. Pickering. I am desirous of ascertaining whether this is the same kind, which I have cultivated for several years, of which I send for your inspection a small sample.* In 1821, I had about 11 tons from 5 acres, and last year about the same product, from another lot of about 5 acres. I cradled it as wheat, bound it in large sheaves, brought it in the following day—threshed the sheaves at the end of several months, without unbinding them, and obtained about 17 bushels of seed per acre; returned them to the mow for the use of my horses, who ate it as greedily as the best timothy hay. This mode of managing the millet saves much room, as it is very bulky; more seed is saved, than when cut with the scythe as hay—I calculated the product at about 20 bushels per acre, including the seed remaining in the unbound sheaves. In 1821 I had about 30 bushels, weighing 55 lbs. each, ground for my hogs, who ate it as eagerly as Indian meal, given to them at the same time.—Both crops were sowed about the 6th June, and gathered in the middle of August—they were sown after Indian corn—one year with one ploughing, and the other with two, and harrowed in, without any perceptible difference—the quantity of seed, half a bushel per acre—the averaged length of the straw, about 5 feet. I have this year sold it at one dollar per bushel for seed, which is much in demand.

Very respectfully, your's,
WM. COXE.

JOHN S. SKINNER, Eso.

* The millet sent by Mr. Coxe, is of the common kind, and that which is generally referred to in communications which relate to that grain. That from Col. Pickering, was very different, being somewhat larger, rounder, and whiter grain.—*Edit. Am. Farmer.*

BY T. G. FESSENDEN.

RURAL PEACE AND INDEPENDENCE

That man is fortunate, who, timely wise,
Life's peaceful blessings can discern and prize,
Who ne'er his talents, wealth nor time employs,
In quest of costly and tumultuous joys;
Nor churlishly refuses to partake
Of God's good things, created for his sake,—
Spurning the gifts of Deity design'd
To cheer and bless the lot of human-kind—
With some good books, some good companions
blest,
"Health in his veins, and quiet in his breast,"

Aloof from scenes of riot, noise and strife,
Enjoys the comforts of a rural life.
Him no anxiety, no fears appal;
He ne'er submits to "low ambition's" thrall,
Ne'er condescends a falsehood to impart,
But makes his tongue the herald of his heart—
Ne'er stoops to high, nor spurns at low degree,
His manners still from affectation free,
He never masks grim malice with a smile,
Nor makes hypocrisy the guise of guile.
Though sometimes blunt, he always is sincere,
And what he is, is willing to appear.
Though no rich labors of a foreign loom,
Nor costly paintings decorate his room,
Light, but sound slumber, softly seals his eyes,
That boon of innocence and exercise,
Which monarchs covet, but cannot enjoy,
Sweetly rewards his every day's employ.
Health tempers all his cups, and at his board
Reign the cheap luxuries his fields afford.
Seen from the eylet-holes of his retreat,
High Life appears a bubble and a cheat;
He marks the many who to ruin run,
Knaves who undo, and fools who are undone,
Some by a sordid thirst of gain control'd,
Starve in full stores, and cheat themselves for gold.

Others devour ambition's glittering bait,
Striving to gain the dignities of state,
Much harder, and more dirty work go through
Than farmers can be call'd upon to do;—
Beholding these, is thankful that his lot
Gives peace and freedom in a country cot.

TO PRODUCE A YELLOW ROSE, WITHOUT A THORN.

Take the genistella, or sweet broom; cut it down to within a few inches of the ground, engraft upon the centre stems, slips from the white rose bush, and if the process is properly managed, you will produce the rose without a thorn and of colour as yellow as the most brilliant jonquil.

THE FARMER.

BALTIMORE, FRIDAY, APRIL 11, 1823.

FOREIGN NEWS.

Since the last number was issued, later dates have been received from England, by the way of New York. France and Spain are preparing for war, but the blow had not yet been struck. It is yet impossible to say, what will be the precise course taken by England. It is known that we do not speculate in great matters of state, except to draw conclusions, as to the probable effect of political movements on the prices of the commodities, which constitute the staple products of those who patronise the Farmer. From the best view we have been able to take of the latest news, it appears to us, first, as to England—that she is waiting to see how the Spaniards will meet the first shock—should they preserve harmless, the person of the King, and make resistance worthy of their cause, the English will probably, after a few months aid them, with her fleet and her money—she may reckon also, on the hearty co-operation of Portugal—but

Spain herself, seems to be in a most critical situation.—On the one hand, it appears certain, that the King is secretly in the views of France, and the danger is, that his treachery will provoke them to dethrone and decapitate him; in which case, the cry of revolution and bloodshed, will be raised against her, and she will lose not only the actual assistance of the government of England, but the moral force of public opinion, in her behalf.—Of France—it is said that disaffection has been manifested, in the ranks of the French army on the frontiers, and so great was

the riot and uproar in the House of Deputies, that it was found impossible to proceed with business.—Thus it appears that the Spaniards have more to hope from opposition to the war in France itself, than from any other resource—but another month may demonstrate the short-sightedness of all these conjectures—we have carefully noted all changes which have taken place in the prices, they will be seen however to vary very little, from our last quotations.

Prices Current at London, March 5.

Ashes, U. S. pearl, per cwt. 52s. cotton, S. isl- and, fine, good and middling, per lb. (duty paid) 11d. a is. 8d; stained and ordinary 7 a 10d; N. Orleans 8 a 10d; Georgia bowed 7 a 9d; Carolina rice, new, per cwt. 41 a 44s; old 37 a 40s; tar, Carolina, per bbl. 15s; Virginia, 17s; tobacco Maryland, cargoes (in bond) per 100 lbs. 27 a 30s; fine yellow, per lb. 16½ a 21½d; fine colour, 13½ a 14½d; light brown, 6 a 9d; 8 ord. and scrubs, 2½ a 5½d; Virg. ord. and dry, 3 a 4d; part faded, with flavor 4 1-8 a 4½d; middling do. 4½ a 5½d; part black 5½ a 7d, fine black and sweet scent, 7 a 7½d; stemmed 4 a 6½d; do. very fine 6½ a 7½d; Kentucky leaf 3 a 4d; stemmed 4 a 5d; cargoes per 100 lbs 23 a 23 5d; turpentine, rough, per cwt. 16s 6d a 17s.

The demand for cotton has been considerable, and the advance of ¼ per lb. on the East India sale has been readily obtained. The purchases since our last are chiefly on speculation—the sales consist of 2400 bags, &c. viz. in bond, 300 bowed 7½d fair, to 8½ good; 200 Madras, 5 7-8d and 6d good and fair; 500 Surats, 5 5-8d fair, to 6d good fair; 1300 Bengals, 5 1-8d and 5 1-4 ordinary, 5 3-8 a 5 3-4, middling to good fair, and 6d good. Also, 75 Grenadas fair 9½d duty paid, and 80 fine Demerara 11d.

Prices Current at Liverpool, March 6.

Cotton Georgia bowed, 6½ a 8½d; Sea Island, 7 a 10½d; N. Orleans 7½ a 10½d; Tennessee, 6½ a 7½d—Tobacco, James River, leaf fd. 2½ a 2½d; ord. sound, 3 a 4½d; middling, 5 a 5½d; good and fine, 6 a 7½d; stemmed, 3 1-2 a 7 1-2d; Rappahannock, leaf, 2 1-4 a 4 1-4d; do. stemmed, 3 a 5d—Ashes, N. Y. 1st pot, 58s; Boston, 58s; Am. pearl, 55 a 58s—Rice Carolina, in bond, 20 a 23s—Tar, Am. 13 a 16s—Quercitron bark, N. Y. 12 a 14; Philad. 13 a 16s—Turpentine, rough, 12 a 14s. 6d.

BALTIMORE MARKET.

PRICES CURRENT.—CORRECTED WEEKLY.

Flour, best white wheat, \$7 50—Howard st. Superfine, \$7 25—fine do. \$6 75—Wharf, do. \$7 to 7 12½—Wheat white, \$1 55 to 1 60—Red do., \$1 50 to 1 55—Rye, 75 to 78 cts.—Corn, 61 to 63 cts.—country Oats, 55 to 62½ cts.—Beef, 8 cts. per lb.—Live Cattle, \$6 to \$6 50 per cwt.—Bacon, round, 8 to 9 cents per lb.—Pork \$4 50 to 5 50 per c. lb.—6 to 8 cts. per pound—Mutton, 5 to 6 cts. per lb.—Beans, \$1 37½ to 1 50—Peas, black eyed, 55 to 60 cts.—Red Clover Seed, \$6—Orchard Grass do. \$3—Herds' Grass do. \$3—Timothy do. \$4 50—Millet, \$3—Flax Seed, 75 to 80 cts.—Whiskey, from the wagons, 32 to 35 cts. per gal.—Apple brandy, 30 to 32 cts.—Peach do., 65 to 70 cts.—Shad, none in market—Herrings, No. 1, \$3 62½ per bbl.—No. 2, \$3 37½—Fine salt 80 to 90 cts. per bush.—Coarse, do. 75—Butter, 20 to 25 per lb.—Eggs, 18½ cts. per doz.—Hay, \$17 per ton—Straw, \$10.

MARYLAND TOBACCO.—Ten hogsheads of fine red tobacco, the crop of Mr. B. M. Hodges, from Patuxent, sold this day at 4½ a 11½ per hundred. This parcel was greatly enhanced in value, from the very judicious manner in which it was assorted, and its general excellent condition.

INTERNAL IMPROVEMENT.

DELAWARE CANAL.

TO THE CITIZENS OF PHILADELPHIA.
Friends and Fellow Citizens—We submit to your most serious reflection a subject of more importance to your vital interests, to the prosperity of our capital, and to the general welfare, than any that has been under consideration for years, which, we regret to state, has not hitherto attracted that degree of attention, which it ought to command. We mean the completion of the Chesapeake and Delaware Canal, which, for fifty or sixty years past, has been at various times presented to the public view—but, by a most extraordinary and unaccountable fatality, has hitherto mocked the sanguine hopes and anxious expectations of our public-spirited citizens, and remains a reflection either on our want of good sense to discern, or of public spirit to promote our true interests.

To the unfortunate result, we should readily reconcile ourselves, were the difficulties of the undertaking insuperable, or the expenses so great as to be beyond our ordinary resources. In that case, such an issue as has taken place, would be perfectly natural. But when we consider the immense disparity between the sum required for, and the boundless advantages that would accrue, from the completion of this object—and further, when we reflect on the wealth, the great resources, and the increasing population of our capital, we are truly humbled and mortified that such a magnificent undertaking, so easy of accomplishment, should have so long lingered in the execution—that so little progress has been made in it, and that even now, without some extraordinary exertions, its completion seems almost as remote as it appeared twenty years ago.

The object of the present address is to produce those exertions, and to convince you, fellow citizens, how intimately connected in this case are private interest and public spirit—and that in following the expanded and liberal dictates of the latter, you will as fully promote the former, as if you were solely actuated by mere views of personal advantage.

We shall now state the actual situation of the funds of the Canal Company, the deficit which is requisite to be supplied, in order to complete the work, and propose a simple plan for accomplishing that object:

Of the original subscriptions, there are about 700 on which the instalments recently called for have been paid, the balance on which, of course, may be safely calculated on. This balance is 95 dollars per share, equal to \$66,500
There are 306 shares, on which there have been 100 dollars each paid, and the same due, equal to \$30,600—of which suppose about two-thirds to be collected \$20,000
There are 82 shares, on each of which 60 dollars have been paid—and 140 dollars due—99, on which 30 dollars have been paid, and 170 dollars due, leaving a balance on the whole 181 shares, of 28,000 dollars; we will suppose one-half may be collected, equal to \$14,000
There are 344 shares, on some of which only 5, and on others 15 dollars have been paid, leaving a balance of 66,700 dollars—but as few of these will probably be completed, we make no calculation on them.
50 new shares \$12,000
Subscription from the Philadelphia Bank 100,000

Subscription from the State of Maryland 50,000
State of Delaware 25,000

Funds actually secured \$287,500

The recent estimate by Mr. Strickland, of the expense of a canal for sloop navigation, sixty feet wide at the surface, nine feet deep, and 14 miles long from Newhold's landing, opposite the Pea Patch, to Black creek, is \$700,000

It therefore follows, that the deficit is only about 412,500 dollars, and that 2000 shares, at 200 dollars each, would very nearly suffice to complete this great work, a main link in the chain of internal water communication from Boston to South Carolina.

And surely, there cannot be any difficulty in procuring, by proper exertions, in the city and liberties of Philadelphia, containing 130,000 inhabitants, and about 22,000 houses, individual subscriptions to this amount.

Gentlemen acquainted with the feelings and views on this subject, of the citizens of Delaware and Maryland, assure us, that we may safely calculate on considerable aid from thence, particularly from the eastern shore of Maryland. But we lay no stress on this aid, as the object can be accomplished by Philadelphia alone.

There is not in the United States, perhaps not in the world, a situation for the location of a canal, which would produce more advantage than the proposed one would insure to Philadelphia. To the shores washed by, and adjacent to, the Chesapeake and the Susquehanna, the Potomac and the Rappahannock, and partly the James's river, Philadelphia would through this canal afford the most natural and advantageous market. At present three fourths, perhaps more, of the produce of those rich countries, are absorbed by New York and Baltimore, which furnish in return the same proportion of the foreign and domestic merchandise consumed there. In seeking the former market, vessels from that quarter are exposed to the risk and loss of time attendant on doubling the capes of Virginia. Were the proposed communication opened, can it be for a moment doubted, that most of the sloops which navigate the Chesapeake, would almost as naturally seek this market, as those which shall navigate Lake Erie will seek the Albany and New York markets as soon as the great western canal is completed?

Should Philadelphia acquire by this canal, even but one half of the increased trade, on which we may confidently calculate, the real estate in the city, and the industry and talents of its citizens, would be enhanced in value from 10 to 20 per cent. This consideration comes home to the "business and bosom" of every individual in the community, without exception. And it is a truth susceptible of demonstration, that it would amply repay our citizens, if the whole present balance of the subscription were raised, without any expectation of interest. Indeed it is not an extravagant calculation to assume that the advantage which would accrue even to those who support themselves by the labour of their hands, would compensate them for the expenditure, were it to devolve on them alone. To illustrate this position, which would otherwise appear paradoxical, we submit the following striking view of the subject to your calm consideration.

The shares are 200 dollars each. And as the completion of the canal will probably require three years, the subscriptions might be arranged as follows:—20 dollars when the requisite number of subscriptions is procured—60 at the end of the first year—60 at the end of the second—and 60 at the end of the third. Thus 2000 in-

dividuals, paying merely at the rate of about one dollar and a quarter weekly, (a sum which could be afforded, by those who work for six or seven dollars per week,) would in three years complete a work, the want of which, during the last war, cost the government and individuals, in the extra expense of transportation, probably 750,000 dollars; individuals probably half as much in the amount of captures; and a third in the circumstance of trade—and the want of which has long been a subject of reproach to the nation, and of regret to every citizen who has any regard for the public welfare. Has the world then ever witnessed a much more extraordinary delay than has taken place in this case, with so practicable and useful an undertaking? We believe not.

But fortunately, however light the sacrifice would be, to subscribe without expectation of interest, there is no occasion for such a sacrifice; for there cannot be a doubt that the stock of this canal would be as productive as almost any other stock in the U. States, probably yielding from 8 to 12 per cent. per annum.

There is one point to which we earnestly request your particular attention. Different routes have been proposed by different gentlemen, each supported by plausible arguments. Hence opposition has been excited. To this diversity of opinion may the delay of the great work be in some degree ascribed: for we lament to say, that many gentlemen, some of them of great public spirit, have resolved to afford no support to the canal, unless the particular route to which they give a preference is adopted!! This spirit is truly unfortunate—is greatly to be deprecated—and we hope will be for ever abandoned. The paramount object is to cut a canal so as to open a communication between the great waters of the Chesapeake and the Delaware. The particular location is altogether a secondary consideration.—There have been three, four or five routes proposed, any one of which would completely subserve the interests of Philadelphia.—Let us, therefore, lay aside all controversy on the subject of the route—exert our energies to raise a sufficient sum to complete the grand work—and then let the site be determined by the board of managers, under the advisement of experienced engineers from New York, who have no undue bias for any particular location.

The following statements of the exports and tonnage of the three ports of New York, Philadelphia, and Baltimore, will show the decline, speaking comparatively, of Philadelphia, and the necessity of making every exertion to regain, as far as possible, the rank from which she has fallen. In 1796, Pennsylvania was the first exporting state in the union—Her exports were above a fourth part of the whole of those of the nation at large—whereas, in 1820, she sunk to the seventh grade—and her exports were not a tenth part of the whole. Her domestic exports in the latter year were not a seventeenth part of the exports of that description; for the total domestic exports for 1820, were \$51,683,640—whereas those of Pennsylvania, were only \$2,948,879.

Total Exports Foreign and Domestic.

	1793.	1802.	1818.	1820

New York,	217,538
Philadelphia,	78,049
Baltimore,	56,837

After recommending these tables to your sober and attentive consideration, we conclude, with the fond hope, as the subscription is so small, and the terms of payment are so very easy, that no citizen, but those whose circumstances will not justify them in incurring the expense, will hesitate to subscribe towards this grand undertaking as far as his means will allow. We shall receive with equal thankfulness subscriptions for single shares as for five or ten, when the former are regulated by that regard to the means of the subscriber, which prudence and common sense dictate.

Resolved that a committee of five members for each ward in the city, Northern Liberties and Southwark—and two for Moyamensing and Passyunk, be authorized and empowered to procure subscriptions for the completion of the Chesapeake and Delaware canal on the terms herein stated:—

Form of Subscription.

The subscribers hereby pledge themselves to pay the subscriptions annexed to their names respectively, in the following manner:—

20 dollars per share as soon as _____ shares are subscribed.

60 dollars on the 1st of May, 1824.

60 dollars on the 1st of May, 1825.

60 dollars on the 1st of May, 1826.

But this subscription is not to be binding unless _____ shares are subscribed within three months from this 10th of April, 1823.

FROM THE WINYAW INTELLIGENCER.

CLAREMONT AGRICULTURAL SOCIETY.

The following extracts, are taken from a Communication made by Dr. Bracey to the Hon. W. D. James, Chairman of the committee on Rot in Cotton.

"On a spot of luxuriant cotton, which I had observed to rot rather worse than the rest of the field, I was induced to try various experiments, such as taking away the bed, twisting the branches, wounding the stalk, breaking the limbs, &c. I found when vegetation was by any means interrupted, the rot was uniformly checked, and the wounded pod, either healed up, or spread no farther. I had marked several pods, by binding a thread around them, to observe minutely, the changes, in the various stages of rot, as well as effects, of lessening the circulation of the juices. The rot becomes manifest, first, by a spot of deeper green, about one twelfth of an inch in diameter which ultimately mortifies, and destroys the whole, or a great part of the pod. I found the rot to vary in its destructive tendency, depending on the state of luxuriance, its situation, and the weather, as in wet weather, the plant was tender, and abounded with redundant juices, consequently more easily punctured, and more disposed to mortification. In dry weather the exterior of the pod is tough, and very little of the fluid of the plant in circulation. These circumstances combined, evince the great difference, which may have been remarked by every planter, in the progress, and cessation so often manifested, during the season of rot. In attentively watching the changes, which resulted from my experiments, in the modes of interruption of vegetation, the least likely to injure the plant, and at the same time arrest the progress of rot—I observe on one of the marked pods, a *Small Insect*, busily engaged puncturing it, in which it succeeded; it remained with its

proboscis in the pod about two minutes, apparently extracting the juices, increasing during that time greatly in size, from the quantity of fluid taken in, I suppose, as nourishment; it then withdrew its proboscis, laying it up along the breast, quickly hiding itself, among the leaves of the plant. As I had long discarded the belief that the rot was owing to an insect, and so different was this from the insect said heretofore to depredate the fields in the night, I was about to turn my attention to something else, and think no more of it; when, shortly after, I saw another emerge from its hiding place, on an adjoining plant, and with great readiness, reached a pod, which it soon penetrated, and remained nearly the same length of time the first did, and retired in a similar manner. My attention was now awakened, and I began diligently to search for them, success soon gave me an opportunity of properly identifying them by close examination. I left this spot, and went to a part of the field, where no impression had been made on vegetation and quietly concealed myself in a place, where there was much fresh rot around me; so soon as all was quiet, (as it seems to be particularly necessary to be still some time, before they move about) I observed on one pod, two of these insects, both having entered their proboscis before I discovered them, and were extracting the juices from the pod. As soon as they retired, I tied a thread around the pod, and examined it attentively, but observed no change as yet; I soon had another and a third opportunity of marking pods, which I saw the insect puncture. About two hours after, I visited these pods again and observed the perforations had changed to a deep green, exactly on the part of the pod, I had seen the insects bore. The day after I visited them again, and discovered two out of the four, had turned dark and beginning to enlarge, the others seemed less, and healing. I suppose I had by this time seen about fifteen insects in all. I caught two or three, carried them home, and the day after, having kept them about fifteen hours without food, I placed them under a tumbler, with a fresh pod of Cotton, and it was indeed remarkable to see the quickness they manifested in piercing it. No injurious or destructive change takes place in punctured pods, which have been detached from the plant, or where vegetation is even properly checked. In my succeeding visits to the pods marked in the field, most of them rotted exactly as I had observed the rot to progress before I knew any thing of the insects, some of them healed up, as I have remarked many do, which I did not see punctured, both before and since the discovery of the insects. I therefore discard the erroneous doctrine of the disease existing in the plant itself, finding that I had mistaken effect for cause and had been heretofore, obliged to reconcile diseased plants looking vigorous, producing healthy pods, and sound cotton, and many other contradictory circumstances, which have all become consistent, and natural so soon as the insects were discovered.

It is a well known fact, that every plant has some insect, which feeds, almost exclusively on it, cotton affords many insects nourishment, as the cut worm, various caterpillars, and two branches of the family of the hemiptera-tribe, class cimex, one kind large resembling the blood sucker, and nearly as large as the arctic bug, of these there are very few in number, but their puncture which is generally about the foot stalk, is very destructive. The other is very small, and numerous, and would scarcely attract notice, from its harmless appearance, but in truth is the great and formidable enemy, in the destruction of our cotton crops. This

small insect, makes a puncture in a pod of cotton which resembles exactly the puncture made with a small needle, yet the puncture made with a needle, never deranges the contents of the pod, because it takes out nothing; but a plethoric state of the plant, which is a predisposing, and not a primary cause, (as is alleged by some,) becomes instrumental in its destructive tendency, only when a portion of the fluid of the pod, has been taken out, though ever so small in quantity. This fact I proved, among many other experiments, in the following manner: I constructed an instrument, with an extremely small and delicate end, which I introduced in a puncture first made with a needle, and drew out by the action of a piston, a small portion of the fluid of the pod—rot uniformly followed, every instance, in which I used this instrument on a plant, in a state of repletion; yet it never occurred, from a puncture made, with a needle alone. Therefore it seems that the nutriment extracted by the insect deranges the circulation of the fluid in the pod, and mortification ensues, by such an abundant supply from the plant, restoring the loss, that the powers of the pod, are unable to assimilate it.

Rather more than half the punctured pods, rot in wet weather, or on moist situations, but in dry weather, when the plant does not abound in juices, not more than one in twenty is destroyed, the rest sustaining very little injury. This insect seems to extract nourishment from no other substance, as I have kept them until they were nearly starved and could never yet get them to puncture any other substance, than pods of cotton, though they were repeatedly offered, many kinds of wheat and vegetables.

It may perhaps be asked, why the green seed cotton should rot and the black seed when fresh from the Islands be exempt from it? I can only recommend to such as find a difficulty on that head, to taste a pod of each, and the evidence will be such as requires no great powers of epicureanism, either in man or insect, to select the sweet agreeable taste of the one, from the disagreeable bitter of the other.

Naturalists assert that immense numbers, of various insects, perish every year in the midst of vegetation; merely because they are unable to find the exact food to suit their taste;—it is on this ground that Louisiana has been freed from the rot; as the planters ceased getting supplies of green seed from abroad, and their own stock of seed become changed to black seed (as it soon does) by successive planting, and the influence of climate and soil, the insects perished for want of their proper food, consequently the rot ceased.

The eggs of the insect are deposited on different parts of the plant in October; we bed in the undecayed leaves and parts of the stalk in spring, consequently we literally plant the insect in the egg state, which becomes a worm, by the influence of the summer's sun; which worms, in due time, becomes this insect, having its proper food within its reach, these changes take place, in the latter part of July and beginning of August. At first they are small and green, and would at this time attract no notice, on account of its harmless appearance; they are at this age to be found in very great numbers, and notwithstanding their apparent insignificance we begin to see punctures and rot; soon they change to a brick dust colour, being at this age much less than the lady bug, of an oval form, flat, without wings, six legs, run very fast, with a pair of horns or feelers, and carries its proboscis, drawn close under, along the chest; they remain but a few days in this state, before the body lengthens, and they acquire wings, having attained when fully matured, the size, and something of the appearance of the

fire fly, possessing great activity, and vigilance; they fly off at the approach of any thing, and are not now to be seen in such numbers, but are rather difficult to find at this age. They feed very often in the course of the day, which accounts for the great destruction of cotton from this heretofore invisible enemy. They emigrate Eastwardly at the rate of from ten to twenty miles annually, and appear in that respect alone analogous to the Hessian fly.

I cannot omit this opportunity, of suggesting a few hints on the important point of prevention, and remedies. I have often heard that the burning of brimstone in cotton fields, has entirely stopped and prevented further losses from rot; as yet, I have had no experience on the subject, but from the well known pernicious effects of brimstone on insects, I am strongly disposed to credit it, but the advantages in its application would be just after the insects had changed from the worm, until their maturation, as at this period they are without wings, and could not escape.—Checking the growth of the plant, by taking away the bed of earth about it, either with hoes, or ploughs, twisting the stalk of the plant &c. an excellent remedy—the pod by being deprived of the redundant juices, sustains little or no injury from the puncture.

I think however, that the burning of the undecayed leaves and stalks would be a much more effectual remedy; originally they were burned, and I question if that plan was still pursued, generally, but the rot would be greatly lessened, if not entirely prevented, as it would be the most favourable time to destroy their eggs."

Cotton.—A Mr. Dunham, of Long Island, has ascertained by experiment, that cotton can be raised in the Northern States without fear of injury from the frost. He planted the seeds in the early part of May; the plants began to flower in August, and continued to grow until the first frost which checked all further vegetation. There had been one picking before the frost; and after the frost there were other pickings, viz. on the 1st and 20th November; on the 5th, 14th, and 25th December; on the 14th January; and a few more pods were expected to be gathered about the 1st February. It appears that after the frost has stopped the progress of vegetation, there is so much nourishment left in the plant that every pod of any size matures, expands, opens, and yields as good cotton as that which is produced before the frost. Mr. D. planted and hoed his cotton in the same manner as corn is commonly cultivated.—*Hamp. Gaz.*

ON THE MANAGEMENT OF HORSES AND DOGS—BY AN EXPERIENCED SPORTSMAN.

I shall begin by making known the most useful medicine for horses that I am acquainted with. I have constantly used it for above thirty years, and, may in truth say, I have given it one hundred times. I shall relate how I first proved its surprising efficacy. About thirty years ago, when I was confederate on the turf with my friend Mr. Robert Pigott, when his celebrated horse **SHARK** was at his best,—Mr. Pigott trusting the whole conduct of his stables to me, I came, some days before the meetings, to try his horses and my own, and to see his horse **SHARK** take his last sweat, before he ran with Lord Abingdon's **Leviathan**, for a very large sum of money we both had depending on that race.

SHARK went through his sweat, at the dawn of day, very well, and to my perfect satisfaction; after which he was taken home, fed, and locked up, till twelve o'clock at noon. At twelve o'clock, when the trainer, Thomas Price, and myself came into his stable, we found all his legs

swelled, his hind legs very much indeed, quite up to the hocks, and his fore legs considerably. I was much alarmed, and told Tom Price to keep the door locked, that none of the boys might see the condition he was in, and that I would send a servant to Mr. Pigott, to inform him, that he might get his money off.

Price said, "Sir, you are alarmed at that which is of no consequence whatever. Horses' legs, after sweating, frequently fly, and, I assure you, I have had many horses more swelled than **SHARK** is. Provided his legs are not fine by to-morrow night, I will suffer death; and, to prove to you my sincerity, I will, if you will allow me, stand every shilling you have on the race; and I know you have a very large sum depending. I will give him something which, by to-morrow night, shall make his legs as fine as they were yesterday." "You shall give him nothing," said I, "unless you tell me what the medicine is composed of." "It is the most simple and innocent of medicines, sir: I will write it down for you, and you shall go yourself to the apothecary's and have it made up, and see it given to him yourself. It is this: ONE POUND OF NITRE, AND HALF A POUND OF SULPHUR, (*flower of brimstone,*) MIXED UP INTO A MASS WITH MOLASSES." For **SHARK**, I had it made up with honey, being so valuable a horse; but I never have given it to any other horse, except made up with molasses—and I look both on the honey and molasses, as only vehicles to give the nitre and sulphur. Before one o'clock at noon, I gave **SHARK** a ball of it, as large as a good-sized hen's egg; at night another; the next morning, another; and, in the evening, about five o'clock, another. At night, when we shut the stable up, we could scarcely perceive that his legs were at all swelled; and, at day-break the next morning, his legs were as fine as they ever had been. He had *two balls* given him the first two days, but only one every day after, until the day he started for the match, which was seven days after he had taken his sweat. His exercise was stopped only two days, during which time he was only walked, which, I am convinced, benefited him, for he was a delicate horse. All running horses and hunters, must be well purged; if they are not, they will never stand their work, without *flying to pieces*, as the grooms vulgarly call it.

It is not necessary to purge draft horses, or hackneys. I have not physicked one for above thirty years. You need only give them one ball, as big as a hen's egg, every day, until they have taken the whole mass which I have prescribed. Give this in the spring; and, provided you find their legs swell again, from work, or that they look unkind in their coats, give it them again,—for you need never stop their work.

Farmers, who are fond of having their cart-horses look well in their coats, when they go to market, are in the habit of giving antimony and other noxious drugs to their horses; this medicine will answer every purpose, and is most innocent and simple, and very efficacious.

Ignorant John Groom, and the farrier, equally ignorant, whenever a horse looks unkind in his coat, and most particularly when his legs in the least swell, give him, for two or three successive days, a strong diuretic ball; which makes the horse stale profusely, weakens him, and is detrimental to his constitution. Diuretic balls are composed of rosin, juniper-berries, and other violent, strong diuretics, violent in their operations, and noxious to the animal. The medicine I recommend is perfectly innocent, and so mild and gentle in its operation, that it acts insensibly on him, and is not to be perceived, but by the cure.

The first horse, after **SHARK**, I gave this medicine to, was a most valuable brown horse, a hunter, presented to me by my worthy and old friend,

Lord Egmont. The man who sold him to my friend, had deceived him, by telling him, that the horse had been properly physicked before the season. I had not rode him much above a fortnight, ere he flew all to pieces.

My groom came in one morning, and desired I would look at my horse. I found his coat extremely rough, staring, and unkind to the feel, and his legs very much swelled. I gave him, the first day, two balls; the second day two balls; and every day after only one ball, until he had taken the whole mass. I hunted him on the fifth day, his legs being nearly as fine as they had been, and his coat every day looking better and kinder to the feel. Since that time I have given it to some hundreds of horses.

I gave this receipt to a horse dealer in London, an old acquaintance of mine, who was accustomed, whenever he had purchased a lot of horses in the country, when any of them flew at the heels, their legs swelled, or looked unkind in their coats, to put them under a regular course of physic; by which method he lost the sale of his horses for six weeks. He has assured me that, ever since I gave him my receipt, his horses have, in ten days, been fit to shew to any gentleman.

I do not assert that this medicine will cure a confirmed grease in horses' heels, but it will cure an incipient disorder. Be sure never to apply any grease or ointment to the horses' heels, nothing but a turnip poultice. If the grease be obstinate, nothing but mercury will cure him, thus administered: Give the horse TWO DRACHMS OF CALOMEL OVER-NIGHT, AND THE NEXT MORN A COMMON ALOETIC PURGE. This must be repeated three times, stopping one or two days between each dose; after which give him the nitre and sulphur balls. This process will cleanse him thoroughly.

When horses come in from hunting and perfectly empty in the stomach, when you give them a double feed of corn, before they have eaten one half, you sometimes will observe them leave off feeding for a time, turn their heads back and look at their flanks; sometimes they will even lie down for a minute or two, then get up and finish their corn. Wise John Groom says directly, to a master as wise as himself, "Sir, your honour's horse has got the gripes; I will give him a comfortable drink, which will soon relieve him." John Groom might just as well rub the horse's, or his own shins with a brickbat. This proceeds from the horse having worms. The worms, as hungry as the horse, begin to feed; and, by moving about in the body of the horse, make the horse, for a time, sick.

Two drachms of calomel, given over-night, tying his head up to the rack, so that he cannot eat any thing, and half a dose of the common aloetic physic the next morning, three times repeated, will kill the worms, and bring them from the horse. (*To be continued.*)

TO THE EDITOR OF THE AMERICAN FARMER.

Sir,—There is not a country upon our globe, which possesses greater facilities for agricultural improvement, than the United States of America, nor any one which offers so great advantage, to the industrious and prudent experimentalist.

Our ships, national and private, visit every clime, we have the unfettered, uncontrolled disposal of the produce of our labour, and for which we obtain higher prices, than any other nation.—I do not confine my views to the great staples of our country, grain, tobacco, cotton, and sugar; for the grazier, the orchardist, the gardener and ornamental planter, have yet a wide field for improvement, and much to learn from the thousand years experience of Europe, Asia, and Africa.

In France, and more so in England, it is rare that a vessel returns from a foreign voyage

out bringing to a beloved wife, to a father, a mother, a relative, friend, or perhaps public institutions, some rare or valuable animal, superior domestic poultry, birds for their voice or beauty, seeds of delicious culinary vegetables, trees deciduous or evergreen, shrubs and plants useful or ornamental, &c. &c.

From my earliest recollection, I have been much devoted to rural improvements, and may now boast, that my collection of hardy fruits, of every kind, of trees and shrubs, both useful and ornamental, most of which have been collected and propagated by my personal labour, cannot well be excelled by any farm in our country.—My collection has not been expensive, but has been made by steady industry, through more than forty years, yet strange to tell, but true as strange, that with the exception of one cork tree, and one Sicilian chesnut, I cannot point to a tree, or shrub, of foreign growth, presented by a travelled friend or acquaintance.

I am not disposed to impeach the taste, patriotism, intelligence, or industry, of my fellow citizens; I rather think that the neglect which I complain of, arises as much from indifference in our farmers, who live near to, and have frequent intercourse with our great commercial cities, as from inattention in our travellers. There has not been a clear understanding between these classes—perhaps I should, with more propriety, go to the fountain head, and impeach our national legislature, with a shameful disregard to the subject upon which I am treating.

The public land at Washington is so extensive, that thirty acres might be apportioned for a garden, in which to collect the various trees, shrubs, and plants, of our own, and every other country. The members of congress, coming from every section of our country, would not only most cheerfully assist to make a collection, but they would take home with them, the various seeds and plants, which a well managed institution would supply. Even now, do we not stand indebted to early enterprise for all our grains, for our cotton and sugar, for every good fruit, and for all our culinary vegetables? Are we not indebted to foreign nations for our horses, cattle sheep, &c. and can we be so vain, as to suppose that we have arrived at that state of perfection, which does not require further improvement?—In fruits we are extremely deficient, we have yet to find that apple, pear, peach, cherry, and grape, which is most perfect in the particular section of the country in which we reside. It is a fact indisputable, that the apple, (and no doubt other fruits,) which may be most valuable in one district, is good for but little in another.

The redstreak so highly esteemed in the neighbourhood of Baltimore, both for cider, and keeping, is with me a most worthless fruit. I have two fine healthy trees, which produce abundantly, their beautiful fruit, yet I have never been able to make a gallon of cider from them, or keep an apple to the last of November. It is the same with the cataline, and maiden's blush, they produce well, but rot immediately.—On the other hand, my newtown pippins are nearly double the size, keep equally well, and are thought to be much higher flavoured, than the pippin grown upon Long Island, where it originated.

If our ministers and consuls abroad, are wanting in taste and patriotism, they should be instructed to forward to the national garden, every production of the earth, which can benefit their fellow man; but fruits and forest trees, the seeds of grain, grass, and culinary vegetables, should be the first object. The improvement of our live stock, must be left to the enterprise of our merchants. For the horse, you already have opinion, but with regard to the cow, I fear

that we are carried away by mistaken prejudice, in favour of high prices. I have lately seen one, recently imported by Mr. John Riddle of New Castle, Delaware, at a very trifling expense; yet her size, form, and disposition to yield milk and meat, is quite equal to any thing, which I have seen—she is from some part of Germany.

Young cattle, from one to two years old, can be picked up in various parts of Europe at a trifling cost, and the expense of importation, (if owners, commanders, and supercargoes are so disposed,) will on a return voyage be trifling.

The purchaser for his guide, will have to judge from the general appearance of the stock, with which the animal is associated, and in every sea port town of Europe, the cattle kept for the use of that town, are always the best, which the neighbouring country can produce, and possessing a specific (not an imaginary) value, for the dairy or shambles, they can always be purchased at that value, and it only requires judgment to select.

We yet want the celebrated Norfolk polled or hornless cattle, valued as hardy, and great milkers; they no doubt could be procured at fair prices. These polled cattle, would prove an acquisition, where many young horses are kept; in my time, I have lost a most valuable brood mare, and three fine young colts, by the goeing of cows.

I am partial to the deep brindled colour. At very distant periods of my life, I have recorded four beeves, decidedly superior to all others killed by me, both for proportionate weight, fineness and tenderness of grain, and mixture of fat; and when I find they were all brindles, in no wise related, and without having received more than my usual care in feeding, I am disposed to think there is something in colour. The opinion of your city victuallers, would perhaps be conclusive.

We want that variety of sheep, which produces the fine combing wool. It is reported that at the Texel, there is a breed celebrated for their great size, for their wool, and vast increase; and we have never yet seen among us, the immense sheep of Lincolnshire, England.

Of forest trees, we have many yet to procure, both useful and ornamental, and the everlasting teak tree of India, will immortalize the man, who will first introduce it in our country. A perusal of the remarks of Pering and Money, to be found in the Analectic Magazine, Vol 1, p. 263, will satisfy the reader, that there is a ship timber, of yet more value than the live oak of the south; but in the south, this invaluable tree must no doubt be planted.* Let it not be said, that many foreign trees will not suit our climate, we have climates for all trees, and they may be naturalized to colder and hotter climates than from whence they are procured. A cork tree, which in its wild state, is only to be found in hot climates, grows quite as well as an oak on my farm. The sweet gum or liquid amber, the holly, white, red and black oak, hickory, sassafras, black walnut, magnolia, &c. &c. grow from Maine to Florida. I have eat of the pickled fruit from olive trees, which grew upon Cumberland Island, in Georgia, quite equal to any we import; the tree is large, healthy and beautiful.

I trust that the day is not far distant, when Congress will pass a law, for the improvement of a public garden at Washington, and for planting several thousand acres in Florida, with live oak, and teak. We are earnestly engaged in clearing our lands, and in a country where land can scarcely be called real property, (it so often

* Respecting the live oak of Florida—see the description of Florida by Mr. Vignoles.

changes owners,) we must not expect the same care and attention to plantations of wood which is customary in Europe. In England, it is thought so important, that liberal bounties are given for planting private property.

Timber land for national use, should have the nation for owner, it will then be unchangeable.—A forest need not as in Europe, be converted into a sinecure, or princely establishment. If a ranger is appointed, let his reward depend upon the number of growing trees planted; let him work, or at his own cost, have work done for his living; his account should show but one item, the number of trees actually growing.

New York, as in many other things, has set an example to all the states, by establishing a botanic garden. This example should be followed by every state in our union, with ground sufficient to plant out the varieties of fruits, and trees, and shrubs, and plants, which industry and taste can collect, and for a nursery to propagate all approved articles. The use of the ground, under proper restrictions, with a very moderate salary, would invite a skilful manager.

For the great commercial states, there cannot be any excuse, and I trust that Baltimore will not any longer neglect a scheme of such general utility, and of so little expense. Every merchant should instruct his captain or supercargo, to bring back with him, trees, shrubs, plants and seeds, nay animals, if they show superiority.

By this method, a few years of care, would establish a splendid garden, worthy the public notice and of general benefit.

Wheat, our great staple, has in general been imported from the south of Europe. I have been always more successful, when I have procured my seed wheat, from the north, than from the south; but not so with Indian corn, having never succeeded with northern corn, and more than once, have seriously suffered by the experiment. We do not want any better corn, than such as has been well proved in every state, and we do know, that with a little care, we may have it of any colour, flinty or mealy, long or short ears, many or few rows, and by careful selection, we may have an earlier or later variety.

But varieties of seed wheat, from the north of Europe, is extremely desirable, as well as fruit trees, vines, grasses, shrubs and vegetables.

Out of the one hundred and fifty varieties of pears, which the nurseries of Paris contain, sixty only are esteemed fine, but believing that soil, and climate, may change the quality of fruit, we should possess every variety which their nurseries afford, and you well know, that charging cost, freight, commission and insurance, they will come cheaper to you, than from an American nursery. In preference, let every thing of the kind, come by the fall vessels. Grapes in all their varieties, can be had for the trouble of bringing in.

Apples I do not think an object, because our native varieties are already immense, and are annually increasing; there is not a state or country in the union, which cannot claim its own variety of apple—I am endeavouring to make hedges from the apple pomace, and already discover new varieties of fair apples—peaches are desirable, fine as we have them. Within a few years, I have seen some from France, of uncommon size, beauty and rich flavour.

Of vegetables, we have many yet to procure, but at the same time we should use great caution to ascertain their properties, before they are too generally distributed. The star and blue bottle hyacinths, first planted in our gardens as ornamental bulbs, have become a destructive nuisance on many farms.

Wild garlic was first sowed by the Swedes, on

the Delaware, for early pasture, and the late Judge James Tilghman, about 1790, imported by the name of sheep's fescue, two bushels of the hateful ripple grass, as a superior food for sheep, who, we now know, will not eat it.

All trees, shrubs and plants should be carefully packed and wrapped with matting or coarse canvass, during the voyage; should be protected from salt water, placed in that part of the ship which is neither very dry, nor very damp, and when they arrive in port, and are planted, should be protected from too much light; and I recommend that pine or cedar bushes should for two or three weeks be stuck around them.

Grass and garden seeds must have air, but as dry as possible, the more delicate kinds placed in brown paper bags, and hung up in the cabin, the more hardy kinds put up in common biscuit kegs; nuts, such as the large thin shelled walnut of France, the great chesnut, and fine hazlenut of Italy, the acorns of the cork tree of Portugal and Spain, and of the evergreen oak of England, may be mixed with earth in barrels, kegs, or boxes, and immediately planted on their arrival. The almond tree is equally hardy with the peach, and to insure fruit, should be planted to the coldest exposure we can command, to retard the bloom; but it is known that with us the shell is much harder than that of the imported fruit, and that nineteen times out of twenty, the kernel is bitter; budded trees of this fine fruit brought from the Mediterranean, would sell to great advantage, and benefit our country.

I am sir,
Your obedient servant,
F.

March 26th, 1823.

FOR THE AMERICAN FARMER.
BURNING SOD.

That agriculture in Maryland, has not proved profitable generally, is demonstrated by the desertion of many from our lands, and by the poverty of cultivators, although taxation is very light, and the owners possess slaves, and although almost every farm is near a navigable stream. What reason can be assigned for this, but that our land being worn out, will no longer yield as formerly. Corn and tobacco, have been our principal crops, and these require four ploughings, to bring them to maturity. Our rains fall very heavily, and the oftener the ground is turned over, the more of the fine particles of mould, are of course washed away—few farmers keep up their cattle, and of course little manure is made.

For many years, we have been leaving out old fields, cutting down our woods, and cultivating virgin soils, but these being now exhausted, families have been compelled to emigrate.

Mr. Beatson's pamphlet on clay or sod burning, has come most apropos, and promises to restore our lands cheaply, and expeditiously—I commenced his practice last year, and all my neighbours remarked, what benefit my corn received, by only putting one or two handfuls of burnt sod in every corn hill, before I put in the corn. I take up my pen now to inform you, of one experiment which has afforded me great encouragement, and which has determined me to devote the labour of two hands, exclusively, to clay or sod burning.—On a very poor spot, I perceived the corn only about two feet high, whilst the adjoining corn, was five feet; having been told, that manure, when placed between the corn rows, would improve the crop, as the roots would shoot into it when the corn began to tassel, I run a furrow between each row, and put in, and covered over the burnt sod—the result was, that this poor

corn, became as good as all the rest. In the fall I ploughed in my wheat, and now the wheat where I put in the burnt sod, is so verdant and luxuriant, that you may distinguish it from the rest of the field, half a mile off—my neighbours have been surprised at the great difference, and calculate that it will yield twice or thrice as much as the adjoining wheat, although the soil last year was evidently richer.

The average of corn crops last year, on unmanured, and commonly cultivated fields, did not amount I fear to more than ten or twelve bushels to the acre, the cost of four ploughings and planting, cannot I think be estimated at less than seven dollars; if the price of corn, be three and a half dollars per barrel, the cultivator is nearly repaid for his labour, and nothing remains for wear of animals, and of implements, and for contingencies.

I calculate that two hands can make 140 bushels of burnt sod in two days, which are the most that can be advantageously put upon an acre—say that these 140 bushels, only double crops of corn, wheat, clover, &c. for only six years, and then consider the profit to make it clear, I will put down the expense and profit in an account.

ESTATE	Dr.	ESTATE	Cr.
Tot two hands for two days,	4	1st year, two barrels more corn,	7
Scattering the burnt sod, and hauling stumps and sticks.	3	2d year, ten bushels more wheat,	10
	—	3d year clover,	10
Days 7		Add the three following years,	30
			Dollars 57

Let every one buy Mr. Beatson's book, and he will see, that my calculation is very moderate, and that it might be doubled on the credit side.

When I consider how many stumps and sticks, are left to rot in the woods, and to be washed into our rivers by rain, which might be converted into ashes, and to useful sod burning, I sigh at the loss of riches by ignorance—of this mode of making manure.

Three or four free negroes, who have used it on tobacco, and in their gardens by my advice, tell me that it has astonished them—my neighbour an excellent English farmer, has long practised it with success, and in gardening, he had last year several stalks of corn, in his garden, with six or seven ears. Think how by restoring worn out soils, we can support more cattle, &c.—and thus make stable manure, and then estimate the profit to landholders throughout Maryland.

When I cut down my wheat, I will give you a statement of the produce from the land manured with burnt sod in the rows, and from that adjoining not so manured. I hope that emigration will henceforth cease, till we are over populous, and that our lands will rise in value, and that prosperity will be exhibited by comforts and cheerfulness, instead of long faces, and complaints and sickness, which are now produced by bad harvests.—Your's respectfully,

THOMAS LAW.

P. S. I have not a fixed kiln, but carry my stumps and sticks to the place where I plough up the clay, to cover the stumps and sticks with it, and after setting fire to the sticks, I continue throwing on clods wherever the smoke comes out. The clods ought to be dry.

Diodorus Siculus says, that among the ancient Egyptians, one of the articles or conditions of their marriage contracts was, "the husband should be obedient to the wife."—We have often heard of Egyptian bondage, but never knew that it had been carried so far as this before.

AGRICULTURE OF TUSCANY.

EXTRACT FROM SINOND'S TABLEAU.

[Translated for the American Farmer, by a friend in South Carolina.]

XI. SECTION. On the *Assolemens*.

The *assolement*, or regular rotation of crops, forms one of the most interesting parts of the agriculture of Tuscany; this rotation continues either during three years, and then the ground is planted five times; or four years, when it is planted seven times without ever being left in fallow.—The three year's course is as follows: 1st. Wheat followed by lupins in the Autuma. 2d. Wheat followed in Autumn by turnips, or any other forage crop. 3d. Indian corn, millet or sagine, (*Holcus Sorgum*, Linn.) The four year's course consists of—1st. Wheat succeeded by French beans, (*Haricots*) intermixed with Indian corn. 2d. Wheat with lupins in Autumn. 3d. Wheat with forage in Autumn. 4th. Indian corn followed by millet or sagine.

XIV. SECTION.

On turning in lupins as a manure. As soon as the wheat harvest is finished, the ridges into which the land had been previously thrown are divided into two parts, and a small harrow which is called by the inhabitants *Splanuccio*, is drawn over each second ridge, while the other remains untouched until the whole field is passed over. The lupin *lupinus albus*, (Linn.) which is sown on the fields thus prepared, is a leguminous annual plant, which grows to the height of two or three feet, and requires no support; on the contrary, although its stalk puts forth a great number of branches, each is hard, strong, and of a very woody fibre; the flowers, which are of the size, form and nearly of the colour of those of the bean, are gathered together in large clusters at the end of each branch—and the long pods which succeed them contains the lupins, resembling large peas flattened. The lupins are planted in the month of August or September, on such of the ridges as have been harrowed, and are covered in with the hoe. The ordinary moisture of the plane is sufficient to make them germinate and grow; they are however, commonly refreshed by seasonable rains which assist their vegetation. The lupin is generally well grown by the month of October, which is the seed time for wheat, for which it is intended to prepare the land. When it has grown to the height of 15 inches, it is ploughed in, and left to rot in the land, possessing more than any other plant yet known, the property of fertilizing by the decomposition of its leaves. The same operation of the plough, which buried the lupin, prepares the ridge for the seeding of the corn, which is then covered with a hoe; this operation of burning the lupin to fertilize the earth is what is called by the Italians the *sovercù* or *rovescù*; it shows great knowledge of the best principles of Agriculture and succeeds wonderfully in fertilizing the earth. The peasants sow sometimes different plants for the same purpose, among others, they sow beans, but none rot so thoroughly or so fast as the lupin, nor possesses the power of fertilizing in so high a degree. When it is heated in an oven or large kettle, so as to destroy its vegetation, it becomes the most powerful of all manures: it is said that three or four pounds of these lupins, buried at the foot of an olive tree, or a fruit tree that is decaying, will restore it to all its health and vigor. Careful gardeners use it, but always in very small quantities, to manure their orange trees, instead of horse manure—and produce from it surprising effects.

XV. SECTION.

Harricots, or French Beans.

Sometimes instead of lupins which enrich the earth, such farmers as have an abundance of manure, sow after the 1st year, French beans which impoverish it. They are intermixed with some grains of Indian corn to support them, instead of sticks and branches. The kind of beans which bears the drought best, and is alone proper to be planted after the harvest, is marked with an eye about the germ, from which it is called *faggiuole dall occhio*. When these are planted, the course of cropping continues four years, because it is not until the year following, that in which the beans are planted, that the farmer can sow the lupin for fertilizing the earth, by burying which, is conceived by all to be absolutely necessary.

Second year. Fourrages.

After wheat harvest of the second year, the land is turned up afresh, in the months of July and August, and the forage crop is planted in September. The two kinds of forage crops most in use, are a mixture of lupins, flax, turnips, and the annual trefoil, or lupinella; it may appear strange to observe flax ranked among the forage crops, but its grain is very abundant, and easily gathered, the plant endures the winter extremely well, grows quickly, and furnishes an abundance of leaves, of which the cattle are fond. As the lupin grows much faster than the flax or the turnip, it is pulled up towards the end of Autumn. When it is well grown, and after being washed, it is given to the cattle who are fond of it—notwithstanding its bitterness. The flax and the turnips, which are choked by its growth, prosper as soon as it is taken away; during the winter, these last are drawn as they are wanted. The flax is mowed in the spring, and towards the middle or end of May, all has disappeared. Among the turnips that are planted, not one half ripen, being relied upon, more for their leaves, than for their roots, in the nourishment of cattle. There are many varieties in Lucca; those that are cultivated are large and long, and of a yellow skin, such as the turnips, which are called English turnips. In the planes of Pescia, they are large, flat, and coloured red and rose, the produce of the seed removed from one place to another, does not resemble the plant from which the seed was taken.

In Parma and Milan, more turnips are planted, than in Tuscany; in the two provinces, with the exception of the rice fields, the assolemen is for two years, and consists of wheat, turnips, and Indian corn; or if it is prolonged to 3 years, it is in order to plant beans or turnips, twice in the course of the third year, for the purpose of burying them in the nature of the severcio. The prodigious quantity of turnips, which covers these rich provinces, must have been very agreeable to Arthur Young, when he travelled over them. The lupinella, or annual trefoil, (*trifolium incarnatum*, Linnæi,) is one of the most beautiful plants, which is cultivated as a forage crop; its beautiful carnation oblong flowers, the deep colour of its foliage, and the vigour of its vegetation, make it the ornament of the fields; it is planted in September, and mowed between the middle of April, and the middle of May, sometimes it is intermixed with lupins, which are taken up in Autumn, its forage is more abundant than that of the flax, but it is mowed only once.

Third year. Indian Corn.

After the forage crop is gathered in, the ground is completely turned up with the spade; this work is commenced about the middle of April and is continued during the month of May; the preparation of the ground with the spade, al-

ways precedes the planting of Indian corn, which constitutes the crop for the 3d year. It is planted during the three months of April, May and June, although it is sometimes planted as late as July, on moist spots, but there it is of a particular variety, which grows more quickly but produces less, and is called *sessantino*, because it ripens in sixty days. Indian corn planted in the plane, about the end of April, suffers little from drought provided it has rain about the beginning of July, which most commonly happens. The corn is planted on large ridges with hoes, and although it is scattered with a great deal of economy, more is nevertheless put in, than is suffered to remain—this is done to provide against the attacks of insects, which often destroy it, as soon as it begins to sprout—when it is out of harms way, the superfluous plants are taken out, and each plant is removed from the other about 10 or 11 inches on the rows, but each row is distant about 20 inches or 2 feet—it is moulded up twice during its growth; while it is growing it furnishes an abundant and excellent forage, of which the cattle are very fond. The Indian corn is a great resource to the people, and furnishes an excellent aliment. Mixed with wheat in bread, it gives the bread a redish yellow appearance, but does not injure the taste. The peasantry live chiefly on Indian corn, either in the shape of *farinata*, or *pollenta*. To make *farinata*, the meal is thrown into a kettle or porridge pot, containing boiling water, and seasoned with butter, oil, or broth, (couillon,) and salt; it is then stirred for 5 or 6 minutes, when the fire is withdrawn. It is served up as a soup, or thick couilli; the *pollenta* is made like the *farinata*, but without grease, and is more thick, so that in withdrawing it from the fire, it should be of a solid consistency; it is then cut with a thread, and placed on a gridiron over burning coals for some minutes. These two modes of using the Indian meal, have the advantage of rendering very little bread necessary; for this substance, without having too much taste, has nevertheless enough to render it palatable, without any other accompanying food. It is probable that it would be more nourishing, if it was better cooked, for the labouring people complain, that it fills them without strengthening them, while on the other hand count Rumford remarks that Indian corn, *well prepared*, is the most wholesome and nourishing of all grains.

Editorial Correspondence.

RYE AND OATS DESTRUCTIVE TO YOUNG FRUIT TREES—CORN AND POTATOES BENEFICIAL—HOW TO DESTROY VERMIN ON CATTLE, &c. &c.

Sir—I have lately read the extracts from Cobbett on gardening, published in the American Farmer, which afford much useful information on that subject.

Although he is generally correct, yet, in some few instances, I think him erroneous; which errors ought to be timely corrected. For instance, he recommends, amongst other crops to be grown in an orchard, rye, as one—but, in my opinion, no crop ever raised in an orchard (especially a young one,) was so pernicious as rye. Two or three crops of rye, grown successively in a young orchard, is almost as fatal as an axe would be to the roots.

When the rye is in blossom, a certain rank effluvia arises from it, which poisons the trees.

Oats is a bad crop, from the injurious effect it has on the soil.

Cobbett says, that ploughing or digging between young fruit trees, should only be done in the fall; but the fact is, that planting a young orchard with

corn, and keeping the ground well cultivated, will bring on the trees more rapidly than any other plan; nothing will more promote the growth of a young orchard, than to plant it with corn or potatoes for seven years in succession, and have the ground annually cultivated, manuring round the roots of the trees yearly.

Gentle oxen is the best kind of team for ploughing an orchard: with a horse team, the ends of the swingle-trees are apt to bark the trees, unless they are well guarded by strong stakes.

Cobbett asserts, that the stones of fruit, never produce the same kind as the original, except by mere accident: in this opinion, I think he is not correct, notwithstanding it has been ascertained, by experiment, that if a dozen seeds, taken from one apple or pear, when planted and grown, will produce as many different kinds, and none like the original,—yet it is not so with stone fruit—if the pits [stones] of peaches, plums or cherries are planted, they will generally produce the kind from which they originated.

Cobbett ridicules the idea of any mixture or communication of vegetables or grain, without exception, from the farina; however, there are certainly exceptions to his rule on that subject—for instance, the mixture of Indian corn does proceed from the farina; as far as it blows and falls on the silk projecting from the shoot, so far you will find different kinds to mix. The fact is, that if a hill of corn be planted by itself, a sufficient distance from any other corn to prevent any of the fine farina, which forms on the tassels, from blowing on the silk, and the tassel of the hill is cut off before the frey or farina is formed, no grains or corn will grow on the cob.*

A N. CAROLINA FARMER.

*The attention of a correspondent at Kingston, Tennessee, is requested to this, and if facts to the contrary have come under his knowledge, we should be glad to have them under the sanction of his name—with “A North Carolina Farmer” we are not acquainted.—*Edit. Am. Farmer.*

TO REMOVE VERMIN FROM CATTLE.

I have found that a strong decoction of tobacco, washed over a beast infected with vermin, will generally drive them away; it sometimes will make the beast very sick for a short time.

But a better remedy is to mix plenty of strong Scotch snuff, in train oil, and rub the back and neck of the creature with it, which will effectually kill or drive away all vermin from a quadruped.

Sir, if you think the foregoing, or any part of it, worth a place in your useful paper, you are at liberty to publish the same.

MIDDLESEX.

FROM A FRIEND IN VIRGINIA.

Saturday, 29th March, 1823.

I have, for some years past, raised a variety of water-melon, of a very superior quality indeed. I have distributed its seed very widely, through this neighborhood, and find it the opinion of every person, with whom I have conversed, who has tasted it, that it is *vastly superior* to any they have ever met with.

I obtained the seed of this melon about the year 1815, at which time I lived on the bank of the Great Kanawha river. It was sent to one of my neighbours there, by a friend in Richmond, who called it the “ice-rind melon.”

I should have sent you some of its seed, a year or two ago, had I not taken it for granted that so excellent a fruit could not be raised more than a year or two in the vicinity of Richmond, before its reputation would be known at Baltimore, and its culture eagerly attended to by the agriculturists.

of that quarter. Upon reflection, however, I have thought this consideration ought no longer to prevent my sending you some of its seed, because if you have this melon amongst you already, the receipt of a small parcel of its seed from hence, can do no harm; but should it be that you have it not, I feel assured that any lover of fine melons, who obtains the seed, will consider it an invaluable acquisition.

It is a southern melon, and requires a long continuance of warm weather to bring it to perfection. I would, therefore, advise its being sown earlier than common, and protected by small boxes, covered with old muslin, as is recommended by your New York correspondent.

L. W.

P. S. My melons have degenerated a little, by other varieties being cultivated too near them. The purest seed are those without spots on their sides, having *only* a dark brown spot on *each* side of the *scar*, or what we farmers generally call the *eye* of the seed. Be so good as to request those who feel disposed to give them a trial, to sow them at a distance from any other melons, which will prevent their admixture.

GEOGRAPHICAL.

We have an hundred times laughed at the scheme of the British to build brigs of a 'peculiar construction' to ascend the cataract of Niagara, and so obtain the mastery of the upper lakes—than which a voyage to the moon in a coal wagon, was not less impracticable. The power of man, it is true, might convey a brig round the cataract; but that of all the men who ever lived, with the wealth of the whole world at command, could not cause a vessel to *ascend* it: yet we see that, (in a very interesting manual of New York, compiled by Mr. *Goodenow*), during the late war, a vessel on lake *Ontario*, was directed to proceed to *Onondaga Hollow*, there to receive a parcel of cannon balls, and thence convey them to *Rome*, where the cargo was to be discharged! We are not told by whom this wise order was issued—but, as the fact is gravely related, we have ceased to laugh at the idea of *sailing up* the cataract of Niagara!—the American exhibition of ignorance being less excusable than the British.

Now, this was only about, or less than ten years ago. What was then a wilderness in New York, has 2 or 300,000 inhabitants—and the lands wrested from the forest are cover with flocks of sheep and herds of cattle. In parts where the wolf, at that time, had his home, and the wild deer bounded as on his own soil, one thousand men, fit for battle, may be called together by the spirit stirring sound of a drum. The voyage from the city of New York to the city of Detroit, is now enjoyed as a pleasurable excursion, and Michilimackinac is visited by those who have a few days' leisure and an inclination to 'see the world.' The great lakes *Ontario*, *Erie*, and *Michigan*, have become familiar, like the Chesapeake bay; *Huron* is already pressed with the burthen of commerce, and *Superior*—

"the pool,

"In which we might souse Britain's island, whole." will soon have her packets for the transport of men and goods. The wilderness is conquered, and the busy hum of industry has succeeded the whoop of the wild inhabitant of the woods. By the power of steam, the city of New Orleans seems as if in the neighbourhood of the Falls of St. Anthony, and the Saut de St. Marie is about to be within the common range of the trade of New York! The Rocky mountains are as if in view at St. Louis; and St. Louis, that seemed as the uttermost point west, now in free communication with Baltimore, has opened a trade

with the internal provinces of Mexico! A settlement at the mouth of the *Columbia* has been seriously advocated in congress, and will soon be made under the sanction of government; and, in a few years, we may expect that some persons *here*, feeling themselves too much crowded, like, 'Leather Stocking' in the 'Pioneers,' will seek a country more *west*—Japan, perhaps, if good hunting could be expected therein! The history of the famous col. Boone is the history of thousands of his countrymen. The no less celebrated gov. Shelby, of Kentucky, the venerable and the brave, has, and yet lives on, a most elegant estate which he discovered when in chase of a buffalo, after he had arrived at manhood. The progress of the state of *Ohio* is even more extraordinary—she has outstripped all calculation, and stands the fourth in representative power.—*Niles' Register*.

It is said to be a specific for the Rheumatism, to apply a cabbage-leaf to the part affected.—Choose a perfect leaf, cut off the protuberant stalk on the back, and place it on the part with a bandage of flannel on going to bed. It will produce a local perspiration, and in two or three repetitions a cure will be effected.

PUBLISHED IN THE AMERICAN FARMER, BY ORDER OF THE STATE.

Baltimore, April 7th 1823.

A report of the tobacco inspected at, and delivered from Calhoun's Inspection Warehouse, during the quarter, ending on the seventh day of April, in the year of eighteen hundred and twenty-three.

THE FOUR P'S.

M. Pontac, a French magistrate of great abilities, but extremely indolent, having retired to his country seat, to divert himself during the summer season, a suitor went to him to solicit a final determination of a cause which had been many years protracted. He arrived just as the President was going to mount for the chase. M. Pontac being of a facetious disposition, bade him stay till he came back, and in the meantime to amuse himself with finding out the meaning of the letters that were over his gate, namely—four P's.—When M. Pontac came back from the chase, he found his dangle suitor. "Well, my friend," says the Judge, "Have you made out the inscription?" "Yes, my Lord, that I have." "Aye, well, what is it?" It is *plauvre plaideur, prenez patience*.—(Poor pleader, pray have patience.)—The real signification of the letters was *Peter Pontac, Premier President*; but M. Pontac was so pleased with the new turn ingeniously given to them, and so admonished by the reproof it conveyed, that the cause was decided next day.

FOR THE AMERICAN FARMER.

AGRICULTURAL ENQUIRIES.

Warrenton, N. C. April 8.

Would you be good enough to make enquiry through the Farmer, for the best mode of preparing mustard for table use, from the seed—the process of cleaning it from the husk—as that which comes for sale, is so much adulterated, as to be useless—such information I doubt not, would be highly acceptable to many of your country subscribers. G. A.

MR. SKINNER,

Be good enough to correct an error in my communication, as published in the Farmer, No. 2, vol. 5. For "I have had 30 bushels corn, 33 cart loads pumpkins and 5 loads of cymbins, off five acres, &c." read "30 barrels corn, &c." A.

THE FARMER.

BALTIMORE, FRIDAY, APRIL 18, 1823.

The Printer assures us, that we may confidently promise the Index to the fourth volume, to go along with the sixth number—and we trust it will be found ample and satisfactory.

Note on Mr. Law's communication on burnt sod.—We should suppose that for this purpose a permanent kiln might be constructed at a very trifling expense—such as has been in use for several years at Harewood, Mr. Oliver's estate in back river neck. This contrivance is highly worthy of the attention of thousands of farmers on our river shores, where immense masses of oyster shells have been lying in heaps and rotting, since their contents were devoured by the rude native lords of the soil, some hundred years ago. This kiln is dug out on the side of a hill—the shells and brush wood, old rotten trees, fence logs, &c. are brought, and with the shells, deposited in the kiln from the upper side of the hill, and are withdrawn and carted off from the bottom of the kiln on the lower side. The kiln is of the shape of a common copper kettle or boiler—was dug out by an Englishman, for ten dollars—has neither brick or stone work about it, and will burn one thousand bushels of shells at a time; supposing that from the side of a copper kettle, a narrow slip to be cut out perpendicularly, and you have the shape of the kiln, the sides of which bake harder and harder, the oftener it is used—a little caution is used at the beginning, to preserve a vacuum under the

bottom of the kiln to promote the burning, and the whole operation is conducted by the farm hands, at an inconceivably small expense of time and labour. This simple and yet highly important manure-manufactory, is of Mr. Oliver's own suggestion, and would of itself, entitle him to the thanks of thousands, who might avail themselves of it, to restore the fertility of immense tracts of river shore lands, which being the first settled is the soonest exhausted.

The entirely new and beautiful aspect given to Harewood estate within a few years, would exceed the belief of those who knew it only in the wild, wasteful and barbarous condition in which it was when purchased by the present proprietor; and it is obvious that its melioration is the work of new and spirited plans of improvement, struck out and practised by him, and is not attributable alone to his ample means.

It is there alone, and on a large scale, that we have seen the operation of *paring and burning* actually and advantageously going on—whereof we read so much in, but get only an idea from the English books. Our calculation on the spot was, that in the manner in which paring and burning is there conducted, with a *rapidity* that surprised us—each acre afforded as much manure as would dress four acres well for turnips.—We should be glad to describe the process as we have witnessed it, but we are, just now, pressed for time and space.

SEED RECEIVED FOR DISTRIBUTION, SINCE LAST NOTICE.

Variety of the best muskmelon seed, from C. E. Rowan, Esq. Charleston, S. C.
Ice-rind water-melon seed, from L. A. Washington, Esq. Winchester, Va.
Early golden corn, from Brazil, from Mr. Brown—Baltimore.

LATEST NEWS.

FROM FRANCE—DIRECT.

New York, April 15, noon.

The elegant fast sailing ship HOWARD, captain Holdrege, arrived yesterday morning, from Havre, having sailed on the 14th ult.

PARIS, March 9.—The Duke of Reggio has this day taken his leave of the King, and sets off to-morrow to take the command of the first corps of the Army of the Pyrenees at Bayonne.

A vast number of young men from La Vendee, yesterday waited upon their Deputy, M. Manual, who had been expelled, and forcibly dragged from the Chamber of Deputies—who appeared deeply affected at this mark of their attachment.

Extracts of letters from Havre, March 12.

"Many people not believing that this government really intend going to war with Spain, speculation has become quite cool of late, and the market in consequence dull, the holders of produce not being disposed to give way.

Prices are about the same as at our last dates, except for cotton, which coming in freely from your ports, has been sold in some instances at a reduction of five centimes—and one lot has been sold this week at 30 which the brokers say was worth 32 some time ago. Our imports in February were heavy. The arrivals this month are four vessels from New Orleans with 3143 bales.—Our present stock may be stated at 17000 bales, chiefly American."

We learn verbally by the Howard, that so strong was the expectation of war between France and Spain, that insurance on French vessels from the West Indies could not be effected in France, and that the French merchants were

paying 25 per cent. at Lloyd's, on their homeward bound West India trade.

We also learn, that all the French men of war are fitting out as fast as possible, and that immediately on the arrival of a French merchant vessel, the seamen are sent on board the men of war. A squadron was fitting out at Rochfort, to cruise on the coast of Spain, which was expected to be ready for sea about the 1st of April.

Capt. Holdrege has brought dispatches for Government, from Mr. Gallatin, our Minister at Paris, which were stated to be important.

BALTIMORE MARKET.

Superfine, \$7 25—fine do. \$6 75—Wharf, do. \$7 10 7 12½—Wheat white, \$1 55 to 1 60—Red do., \$1 50 to \$1 55—Rye, 80 cents—Corn, 60 to 63 cents—country Oats, 50 to 55 cents—Beef, 8 cts. per lb.—Live Cattle, \$6 to \$6 50 per cwt.—Bacon, round, 8 to 9 cents per lb.—Pork \$4 50 to 5 50 per c. lb.—6 to 8 cts. per pound—Mutton, 5 to 6 cts. per lb.—Beans, \$1 37½ to 1 50—Peas, black eyed, 55 to 60 cts.—Red Clover Seed, \$6—Orchard Grass do. \$3 to 3 50—Herds' Grass do. \$3—Timothy do. \$4 50—Millet, \$3—Flax Seed, 75 to 80 cts.—Whiskey, from the wagons, 32 to 35 cts. per gal.—Apple brandy, 30 to 32 cts.—Peach do., 65 to 70 cts.—Shad, none in market—Herrings, No. 1, \$3 62½ per bbl.—No. 2, \$3 37½—Fine salt 80 to 90 cts. per bush.—Coarse, do. 75—Butter, 20 to 25 per lb.—Eggs, 18½ cts. per doz.—Hay, \$18 per ton—Straw, \$11 to 12.

MARYLAND TOBACCO.—In demand; fine yellow 20 to 35—Good do. 16 to 18—Fine spangled 16 to 18—Fine red, 8 to 12—Good do. 5 to 7—Common do. 3 to 4½—Second, 1½ to 5.

TO THE FARMERS OF MARYLAND AND VIRGINIA.

CASTOR BEANS, OR PALMA CHRISTI.

A large quantity will be wanted at this place, as soon as they can be gathered, for which \$2 50 per bushel, (each bushel to weigh 45 lbs.) will be paid in cash. The crop to be delivered monthly, or semi-monthly. Letters to J. D. Rogers, will be duly attended to.

Washington City, April 10th, 1823.

AGENTS FOR THE AMERICAN FARMER.

Complete sets of the first, second, third and fourth vols. of the "AMERICAN FARMER," new and corrected Editions, can be had of the following persons; price of which, bound, \$5 per vol. or \$4 in Sheets:—

M. CAREY & SONS and E. LITTELL, Philadelphia.

W. A. COLMAN, New-York.

WELLS & LILLEY, Boston.

WM. F. GRAY, Fredericksburg.

PETER COTTOM, Richmond, Va.

RICHARD COTTOM, Petersburg.

E. THAYER, Charleston, S. C.

JOSEPH GALES, Raleigh, N. C.

W. F. REDDING, special agent, now journeying through the Southern States.

The fifth volume, now publishing, can be forwarded to any part of the United States, on application being made, by letter or otherwise, to

J. S. SKINNER, Baltimore.

Printed every Friday at \$4 per annum, for JOHN S. SKINNER, Editor, by JOSEPH ROBINSON, on the North West corner of Market and Belvidere streets, Baltimore; where every description of Book and Job Printing is executed with neatness and despatch.—Orders from a distance for Printing or Binding, with proper directions, promptly attended to, addressed to J. Robinson, Baltimore.

AGRICULTURE.

FROM THE NEW ENGLAND FARMER.

PREMIUMS

Offered by the Essex Agricultural Society, in 1823.

The committee of the trustees appointed to propose objects for premiums, adverting to the original design of the institution—the improvement of the general husbandry of the county—have thought it advisable, at this time, to depart materially from what seems to have been a leading principle in all the agricultural societies of the country—that of offering premiums chiefly for certain specific articles of husbandry, instead of the combined improvements of entire farms.

Since the formation of the Essex Society, specific premiums have produced valuable effects; by demonstrating, that with high manuring, and good culture, some former usual crops may be doubled, trebled, and even quadrupled. But the important question is—*not what small lots in or near market towns, and abundantly supplied with manures, may be made to yield; but how the productive powers of farms can be essentially increased—and this can be effected only by a better management in all articles of husbandry.*—With this in view, the committee propose to extend the encouragement heretofore given for general improvements; and offer the following premiums:

I.—MANAGEMENT OF A FARM.

For the management of a farm, in its tillage, mowing, orcharding and pasturage: the quantity of land appropriated to each—their cultivation—the means and the manner of making, increasing, preserving and applying manures—their quantities—the respective crops and products—the quantity and management of the live stock—and the quantity of labour employed—to be detailed.

For the best - - - - -	\$30
For the second best - - - - -	25
For the third best - - - - -	20
For the fourth best - - - - -	15

II.—DAIRY STOCK-SOILING.

For experiments in feeding milch cows on green crops, from the middle of June to the middle of October, by supplying them to the full with those crops, in their stables, without turning them to pasture. Feeding cattle in this manner is called *soiling*.

For the best - - - - -	\$20
For the second best - - - - -	15
For the third best - - - - -	10

The whole process to be detailed.

REMARKS.

The green crops may be rye (sown the preceding year) oats, barley, millet, Indian corn, clover and various grasses. Any sorts of grain sown to produce fodder for soiling, after being harrowed in, should be rolled, to make the surface and the ground smooth for mowing. The clover and upland meadow grounds, destined for soiling, will be better for rolling, with a heavy roller, to make a smooth bottom, without which the mowing cannot be close; and if not close shaven, the thickest part of the grass will remain uncut.

If the soil be rich and the surface smooth, the grass may be cut when only three or four inches high, and will then yield a good swarth. Such ground well set with the grasses which produce what is known among us as English hay, and inclined to moisture, may in this manner be mown three or four times in a season. The cutting of the rye, oats, barley and millet

should commence as soon as they will yield a good swarth, and be finished before they have passed the flowering state. If mown before they flower, they will shoot again; and if the growth be rich, yield second crops.

Indian corn will be well grown for soiling by the 10th or 15th of July; and will continue green, and in full sap until the last of August. And in order to continue a supply of this rich, green food—to which probably no other vegetable of our country is equal, especially for milch cows—pieces of land may be planted in succession, so that some may be in full sap to the last of September, when, in Essex, frosts usually strike the blades, and greatly lessen their value.

If there be a piece of rich mowing land in the farm, its second or third crop will furnish green fodder to the middle or last of October. Perhaps late sown oats, hardier plants than Indian corn, may supply the place of grass. Pumpkins, also, during this month and the next, will furnish a most valuable food.

All the sorts of fodder above mentioned, like the young grasses of the spring, naturally dispose cattle to a degree of looseness, though probably without injuring them. But if any of them operate to an excess, a little good hay will furnish a useful corrective.

After November, potatoes, mangel wurtzel and carrots, added plentifully to their dry fodder, even if this be only barley, or oat straw, or wet or low ground meadow hay, will doubtless keep cows in milch till within a few weeks of their calving.* Cows, during the time of their going dry, and other stock at all times, fully supplied with ruta baga, or common turnips, with the same poor dry fodder, may be kept in high condition. In England, cattle intended for beef are often fattened on wheat straw and turnips, giving of the latter as many as they will eat. They commence feeding in this manner in autumn, and by the spring the cattle are fat for the market. The cattle thus fattened, and in so short a time, are of moderate sizes.

Rye, oats, barley and millet, when destined for soiling, should be sown twice as thick as when intended to ripen their seeds. In like manner, Indian corn may be planted in continued rows only so far apart as to admit a small plough in its culture, and with the plants only four or five inches apart in the rows. The surface of the ground should be smooth in the rows, so as to admit of mowing the corn.

The farmer who shall pasture some of his cows, and soil the others, will add to the value of the experiment, by keeping their milch separate, and noting their relative quantities from cows of equal goodness, and the quantity and quality of the butter made from each set.

III.—THE DAIRY.

For the greatest quantity of good butter, in proportion to the number of cows producing it, (not fewer than four) made on any farm, from the 20th of May, to the 20th of November, twenty-six weeks, and the quantity of butter averaging not less than seven pounds per week for each cow, - - - - - \$20
For the second greatest - - - - - 15
For the third greatest - - - - - 10

* An observing farmer, long ago expressed to me the opinion, that cows should go dry five or six weeks before calving, to give time for the milk vessels to be distended, and the bag enlarged; in the language of farmers, for the springing of the bag. It was his opinion that the greater increase of milk after calving, would amply compensate the loss of going dry so long.

The kinds of food and the management of it to be detailed.

REMARKS.

The object of agricultural institutions, as already observed, is *improvement*; and in Essex, none seems to be more wanted than in *milch cows*. If the society were to continue their premiums, during any length of time, merely for the greatest quantity of butter, they would not enforce any improvement in the quality of those animals. Seven pounds of butter a week, for each cow, is less than half what the Oakes cow of Danvers produced, in the same time. The seven pounds a week, therefore, are very attainable by every farmer who will improve his breed of cows, and feed them to the full with juicy and highly nourishing food. The committee trust they do not entertain a groundless hope, that the premiums here offered will have claimants; and that in some future years, the trustees will be justified in confining these premiums to cows yielding ten, twelve, and fourteen pounds of butter a week, for twenty-six weeks in the year.

IV.—TURNING IN GREEN CROPS AS A MANURE.

For the best experiment of turning in green crops as a manure, on not less than one acre - - - - -	\$15
For the second best - - - - -	10
For the third best - - - - -	5

REMARKS.

The claimants must give a particular account of their respective processes, and the results.—The object aimed at is to ascertain whether land can be manifestly improved by turning under green crops, and to what degree enriched. Each experimenter will follow his own judgment in his process; but the following intimations may merit his attention.

The turning in of green crops is a very ancient, though not a very general practice. Its utility has lately been called in question. Hence the desire to bring it to the test of fair experiment.

Take an acre of land, so far exhausted at the last crop as to render it inexpedient to introduce another without a good manuring. Plough it in the spring, and sow it with oats, barley, buck-wheat, or millet—and not be sparing of the seed. When the crop shall be full grown, but still in blossom, plough it in, and sow it again. When this second crop shall be full grown, plough it in. The next year repeat this process—again ploughing in two crops; the last by the beginning of October. It may then be sown with winter rye, to produce a crop of grain at the next harvest—sowing five or six pecks, because sown so late. Or it may lie till the ensuing May, and then be planted with Indian corn. The product, compared with the last of the same acre, prior to the commencement of the experiment, especially if a crop of the same kind, will show the value of the green crop ploughed in.

ANOTHER MODE.

The acre being divided lengthways into two equal parts, plough the whole uniformly in the spring. Sow on one part two bushels of oats or barley, or a bushel of buck-wheat, or three or four half pecks of millet; and harrow the whole acre alike, and so as duly to cover the seed which has been sown. When the crop has attained its full growth, but is still in blossom, plough it in; ploughing the vacant half acre at the same time, and to the same depth. Sow the first half acre again immediately, and harrow in the seed, harrowing the other half in the same manner. The next year repeat the same process. Then the whole acre may be sown with winter rye (3 pecks on each

or the land may lie (as in the process first proposed) to be planted with Indian corn the ensuing spring. In the third year, the crop put in must stand to ripen. The produce of each half acre, (both being sown or planted, and cultivated in the same manner,) must be kept by itself, and accurately measured. The difference between them will show the value of the green crops ploughed in.

Every experimenter will perceive that no manure whatever is to be used—the crops sown, and the weeds ploughed under, excepted.

Until ploughs constructed for the purpose of completely turning in green crops shall be introduced, it will be necessary to roll flat the green crop before ploughing, or it cannot be duly covered. Perhaps a small roller, or what is called a *foot*, only of a large size, may be attached to the fore end of the plough beam, to press down the crop to the ground, and thus cause it to be effectually covered. Such a roller, or foot, will serve as a gauge for the depth of the furrow in which the crop shall be buried.

V.—CIDER.

For the best cider, the pure juice of the apple, which shall be made in the present year, not less than eight barrels - - - \$10
For the second best - - - - - 5

The greater part of the cider may be sold, if the owner please, only reserving one cask, of which a sample is to be produced at the Society's public exhibition in 1824; with good evidence that the casks sold were equal to that reserved. If sold, the claimant will state when, to whom, and at what prices; and describe his whole process in collecting, sorting and keeping the apples, in making the cider, conducting the fermentation and fining, if any artificial fining be used, and in preserving the cider in the cask.

For some information of an eligible process in making and managing cider, the committee refer to the intimations contained in the explanatory observations subjoined to the list of premiums for 1821.

VI.—FOREST TREES.

The same premiums that were offered in 1821 and 1822; to which intended claimants are referred. And they are desired to give notice of their proposed claims to the secretary, John W. Proctor, Esq. in Danvers, before the first of July next.

VII.—POTATOES.

Numerous experiments have been made, to increase the products of this root, and premiums have been awarded for the greatest; but no measures for improving their *qualities* have fallen under the observation of the committee. It is well known that the seeds in the *apples* or *green balls*, which grow on the tops of potato stalks, will produce potatoes, which, planted for one year, and their produce a second year, will yield well sized potatoes. It is from these small seeds that all the varieties of potatoes have been produced. It was in this way that a distinguished farmer in Ireland—a country so famous for the culture of potatoes—obtained excellent kinds. From the numerous seeds in every ball, a variety of potatoes may be expected; some early, some late in ripening—some yielding small, and others abundant products—some watery, and others mealy and well flavored.

Expectations have often been formed of raising potatoes of the best qualities, by planting those brought from the British isles; but disappointment is the common result—the products of the first year have scarcely borne a resemblance to the fine originals. It is very possible, and not improbable, that some sorts superior to any in

cultivation among us, may be obtained from the small seeds found in the green balls. To encourage the necessary experiments, the following premiums are offered:

For the best and most valuable potatoes, taking them for all in all, raised from the seed of the apples or green balls, samples of which shall be produced at the society's public exhibition in 1825 - - - \$10
For the second best - - - - - 7
For the third best - - - - - 5

The claimants are to detail their whole processes, and state the results.

REMARKS.

Some sorts may be of superior excellence for their mealiness and flavor, but moderate in their product; some not so well flavored, may be very abundant in quantity, and highly valuable for feeding live stock; some very early ripe; some growing compactly, and so expeditiously harvested. The sorts which, combining most of these good qualities, shall be judged the most valuable, will be preferably entitled to the premiums, without excluding claims for potatoes of highly superior goodness, although less productive. To facilitate the execution of these novel experiments, the committee offer the following

DIRECTIONS.

The experimenter, having determined with what sorts of potatoes he will make his trials, will gather the balls when the stalks, by their drying, indicate a ripeness in the seeds; and if they are not quite soft, so that the seeds will easily separate from the pulp, they may be laid by (out of the way of frost) until the pulp becomes soft. Then mash them with the hand, and with the aid of water, separate and wash the seeds clean. These, being dried, may be preserved like garden seeds, until the ensuing spring. Then sow them in rows, in a bed of rich garden earth, just as small garden seeds are sown. The rows may be ten inches apart; and the plants, when grown enough to be thinned, may stand four or five inches asunder.—Keep them clear of weeds, and stir the earth between the rows. The supernumerary plants arising from the thinnings, may be transplanted if needed, to another bed.

In autumn, or when the stalks become so far dried that the roots cease to grow, dig these up carefully, so that the potatoes growing on the same plant may be saved by themselves; for it may happen that each distinct plant may produce a sort different from the rest. The bulbs, or roots, of the first year, will be very small. In the next spring, choosing a piece of rich ground, plant each sort in a hill by itself. The product of this year will furnish bulbs big enough to be boiled. And this will be the time for selecting the best. Many sorts may not deserve any further attention; but some may be of excellent qualities, as to time of ripening, texture, flavour and productiveness. Their several qualities should be carefully noted; and again be separately preserved and planted another year; when they will probably have attained all the perfection of which their natures admit.

Lancashire, a western county of England, as well as Ireland, is distinguished for producing good potatoes. Ireland is remarkable for the moisture of its climate; and the western is more moist than the eastern coast of England. Both are many degrees farther north than Massachusetts, and are exempt from the burning heats and droughts of our summers. These circumstances suggest the propriety of our planting potatoes on moist and cool grounds; thus assimilated, in some measure, to the soils of Ireland and Lancashire.

VIII.—PLOUGHS AND PLOUGHING.

Some ploughs are of easier draught and make better work than others; and some oxen draw or plough extremely well without a driver. The design of ploughing matches, is to attain all possible perfection in both. The premiums, therefore, under this head, will be confined to efficient ploughs of easiest draught, drawn each by one yoke of oxen without a driver, ploughing one quarter of an acre, and turning the best furrow, at least five inches deep, and in the shortest time compatible with the continuance of the labor to complete the ploughing of an acre, if that, were required.

For the best plough, team and work - - \$15
For the second best - - - - - 12
For the third best - - - - - 8

IX.—SUMAC.

The premium for this article is continued of course, as the claim is to be presented the ensuing autumn.

GENERAL REMARK.

The committee repeat—and desire it may be remembered—that premiums claimed are not to be awarded, unless the subjects of the claims are decidedly meritorious. That is, the respective experiments must be so conducted as to exhibit results worthy of encouragement and imitation—or decisive of a question of which the solution is sought.

Where a premium has heretofore been awarded to any person, he is not to receive another for the same object. And where any plough has obtained a premium, another is not to be awarded for the same plough, nor for one of the same mould. Some important improvement can alone justify an appropriation of the society's funds, in cases of this nature.

To allow time for enterprising farmers to make preparations for becoming competitors for the premiums now offered, the committee are of opinion that there should be no public exhibition in the present year. The disposable funds of the society will thereby be increased, to reward successful candidates for premiums the year following. But whether there shall, or shall not be a public exhibition in the present year, the society, at their approaching annual meeting, will determine. As, however, some claims were to be made in the present year, these may be sent to the secretary of the society, to be laid before the trustees, for their decision thereon.

The committee propose no premium for the greatest quantity of any kind of crops. The experiments already made, have demonstrated what is practicable; and if those known examples of success are insufficient to stimulate general exertions, the usual premiums must prove ineffectual.

Essex, not being a county for grazing and fattening cattle much beyond the farmer's own wants, this article also is discontinued in the list of premiums.

As to the usual live-stock—working oxen, milch cows, young cattle, sheep and swine—they are to be considered as comprehended in the management of a farm, additionally to the provisions under the heads No. III, and No. VIII, relating to the dairy and ploughing matches; and to the following article.

X.—FOR IMPROVING OUR NATIVE BREED OF NEAT CATTLE.

The first most celebrated breeder of live stock in England, was the late Robert Bakewell; to whom, Mr. Arthur Young says, that country is indebted for *just principles of breeding*. And a later eminent breeder says, that 'before Mr. Bakewell's days, we had no criterion but size:

nothing would please but elephants and giants." And he declares "that Bakewell enabled those who followed his ideas, to produce two pounds of mutton, where only one was produced before." The following were the points to which Bakewell specially attended: "fine forms, small bones, and a true disposition to make ready-fat: which, indeed, is inseparable from small bones, or rather fine bones and fine forms, or true symmetry of the parts."

But Bakewell's prime object, in improving cattle and sheep, was to render his animals most profitable in beef and mutton. And he succeeded in obtaining forms indicating strength of constitution—a disposition to fatten, and at an early age—weightiness in the most valuable parts—with lightness of offals. If there was deficiency in any point, he would cross his animal with one that was amply supplied in that part; and if any point of his animal was too heavy, by an opposite cross he would reduce the superfluity. By such management, diligently pursued, he, at length, gave to his stock the shape and qualities he desired.

So far as we breed domestic animals in this country—and the observation will apply to our whole state, and generally to all New England, we must extend our views beyond beef and mutton—and with the former combine milk, butter and cheese, and a fitness for labor—and together with mutton, aim at the greatest quantity of the most useful wool.

If Bakewell could alter the shape of his cattle, and lay flesh and fat on the most valuable joints—as was the fact,—can it be doubted that, by similar attention, the quantity and quality of the milk of our cows may be increased and enriched? But to obtain this improvement, calves should be raised from such cows only as excel in these two particulars.

It seems to be the best opinion, that of the different breeds of live stock, those of the largest size are not the most profitable. The breed of cattle, however, should be such as to produce oxen, a single pair of which, at their full growth, should have strength sufficient, on proper tillage land, with well formed ploughs, to open a furrow to the depth of five, or even of six inches. As to the form of the different kinds of live stock, an eminent naturalist and farmer in England has thus expressed his opinion: "The more deep and capacious the chest, and the shorter and lower any animal is, relative to its weight, the better adapted it will be to live and fatten on little food, the more labor it will go through; and I have always found the most short-legged oxen to be the best laborers."

The foregoing rules of breeding, and description of good live stock, being the result of the experience of eminent English farmers and breeders, merit the particular attention of all who shall attempt to improve upon our present races of domestic animals; and are here introduced to furnish them with useful information. And in the hope and expectation that such improvements will be undertaken, the following premiums are offered:

To the person who shall produce at the public exhibition of the society, in the year 1828, any number of milch cows, not less than four, of our native breeds, showing manifest improvements therein, by an important increase in the quantity, and maintaining, at least, if not improving, the good quality of milk—the latter to be tested by the quantities of butter made in the six months next preceding the exhibition—

For the best - - - - - \$30
 For the next best - - - - - 25
 For the third best - - - - - 20

For the best pair of working oxen, or well

trained steers, improved on the principles above stated, and exhibited at the same time—

For the best pair - - - - - \$20
 For the second best - - - - - 15
 For the third best - - - - - 10

It will readily be admitted that our live stock demand great improvements; and no one will question whether such improvements are practicable. They ought then to be attempted. It will avail little to bestow premiums merely for the best that shall be produced; for such premiums might be given for a century, without effecting any real improvements; and thus, as to live stock, defeat the object for which the society was formed. The known excellency of some oxen and cows, of our native breed, give assurance to judicious and enterprising farmers, that their numbers may be multiplied by observing the well-tried rules of breeding. The Oakes cow has probably not been surpassed in any country. By some she was judged to be under the size of our common cows. Her short legs probably gave rise to that opinion. There are, however, many larger cows in the county.

The best bulls and cows do not always produce a progeny equal to the parents; but experience has shown, that from such only the highest improvements may be expected. The same observation applies to all other kinds of live stock.

Farmers who shall effect great improvements in live stock, while they render a lasting benefit to their country, will lay a foundation for advancing their own interest, in the demand, and consequently increased prices, of their improved breeds.

Reflecting farmers, who shall become candidates for premiums, will be aware, that if their exertions should not obtain the honor of a prize, they will not pass unrewarded; as all the improvements they make will either give them immediate profits, or add to the value of their farms. The direct object of premiums is not to excite merely trials of skill, but to add to the solid interests of farming; and he, who shall show how we may add most to that solid interest, will obtain the highest prize.

In behalf and by order of the committee,
 T. PICKERING.

Salem, Jan. 22, 1823.

TO THE EDITOR OF THE AMERICAN FARMER.

ON THE WATER CULTURE OF RICE.

Poplar Grove, 13 miles from Charleston.

DEAR SIR,

You will no doubt be pleased to receive the enclosed from the pen of Gen. Thomas Pinckney, on the subject of rice planting, the most important staple of South Carolina. The system of water culture, as explained in the essay, is one highly approved, and extensively pursued by some of the best planters in the state; particularly, and successfully, by your friend, C. E. Rowan, Esq. from whom I received the pamphlet for transmission.

Your's,
 WM. F. REDDING.

A letter from THOMAS PINCKNEY, ESQ. to the Agricultural Society of South Carolina, on the WATER CULTURE OF RICE.

Charleston, 12th December, 1810.

DEAR SIR,

Having last year made an experiment, on a small scale, of cultivating rice, in a manner which I believe, has not heretofore been practised in the United States, and having this year repeated the experiment, much more extensively, with such a degree of success, as, in my opinion, to warrant further trial, I am induced to request

the favour of you to lay before the society the following account of the method pursued, with its result.

I have taken pains, for a considerable time past, to obtain correct information concerning the production of this grain, in countries where, in consequence of its long establishment and extensive use, I was induced to believe that experience must have suggested the most advantageous mode of culture; and I observed in the course of this investigation, that the practice of those countries differed considerably from our own; particularly in the application of water: for I found that in them, rice was generally sown and grew to maturity in land continually inundated to a greater or less depth; except during the short intervals necessary for occasional shifting the water. I, therefore, determined to endeavour to ascertain what advantage that method might possess over the practice which generally prevails among us of keeping our rice-fields dry for a considerable portion of the first half of its growth.

Various accidents, to which the state of agriculture in this country renders us peculiarly liable, prevented me from obtaining the result of my first experiments with such accuracy, as to enable me to lay them before the society; they were, however, sufficiently satisfactory to myself to induce me to persevere; and, on Friday the 5th day of May, 1809, I directed five bushels of seed rice to be sprouted, which was effected by putting it into a rice-tierce filled with water, which gradually leaked out after the rice had been well soaked; and on the Monday following, the grains being fully swollen and some of it having protruded the germ, it was spread out, some slaked lime sifted over it, to facilitate the distribution, and was immediately sown in a little more than two acres of ground:—this small field had been planted with rice several preceding years, and had then been prepared, by the stubble having been hoed off and burned, and the soil turned and made fine by the hoe: part of it was sown in drills at the distance of about sixteen inches from centre to centre, and the remainder broad-cast: the seed was not covered, but the water very gradually brought over it, covering the land six inches deep on the general level, but being ten inches deep on the lower parts of the field, and scarcely two inches over the highest: directions were given to retain the water constantly, as nearly as could be, at that height, keeping it sweet and cool, by occasionally admitting fresh tide-water, and by turning through it a small drain from the highland. The rice grew through the water, and in about a fortnight the points of the leaves were seen floating on the surface. In those parts where the water had covered the land six or more inches, no weeds or grass appeared, except a few leaves of the wampee and some rushes. In the higher parts especially, near the edges, some water grasses appeared; all these, however, were effectually removed, being picked by hand out of the water, by the application of labour equal to the work of three labourers for one day. This rice, when ripe, was separately harvested and yielded one hundred and fifteen bushels and one peck of clean heavy grain; the drilled appeared better than the broad cast, but no accurate account of their relative product was kept; and, in fact, the whole experiment is deficient in accuracy, because the land being a small detached piece of very irregular shape, it was difficult to ascertain its precise contents. Its product, however, certainly exceeded the average of the whole plantation that year, and the comparative experiment was so far satisfactory, that this product also considerably exceeded the crops of the two preceding years made from the same land.

neither of which crops exceeded ninety bushels. It was also proved, satisfactorily, by this trial that rice would germinate, grow through and tiller, or branch out, well in land constantly covered with from six to ten inches of water.

In the present year I have cultivated, in this mode, twenty-two acres at my upper plantation on Santee river, and forty-eight acres of my lower place. A field of twenty-two acres at the plantation of my mother-in-law, Mrs. Motte, has been subjected to the same process; and my son-in-law, Mr. John Middleton, has cultivated, in the same way a small field containing seven and an half acres, at the plantation whereon he resides. The whole of these are tide-lands, and as the method used in all of them was nearly similar, I will not trespass on the patience of the society, by the details of more than one of them, and will select for that purpose the comparative experiment made at my upper place, because it was made on two fields so similar in quantity, quality of soil, previous treatment, and indeed, in every respect, that a fairer test of the merit of each mode, could scarcely be made in one year.

Each of these fields contain twenty-two acres of our usual plantation measure, (210 feet square to the acre,) they are precisely of the same shape; the soil in both is a light black mould, on a blue clay foundation; the clay, however, lies too low to affect the quality of the upper stratum which is too light, they both have been cultivated upwards of twenty-years successively, in rice, and are only divided from each other by a bank: the drains and ditches in both were clean, the remains of the last year's stubble by burnt off, and the ground prepared, by being once ploughed and harrowed, and assisted by the hoe in low places where the plough could not do good work; the whole was then ploughed with what we call a trenching plough, into drills, being, on an average, nearly eighty in number on each quarter of an acre (105 feet square) and the seed having been put to soak in water the day before, (No. 1 being the field intended for the common culture) was sown at the rate of two bushels an acre, (heaped measure) on the 28th day of March: the seed was not covered but was suffered to lie in the open trench during the night after it was sown, that it might better adhere to the soil, and not be displaced on the introduction of the water, which was slowly brought over it the succeeding morning:—this water continued over the land five days, when finding, on examination, that some of the grains began to sprout, the field was dried and continued so until the rice was old enough to admit of being hoed, when that operation was well executed, and the land still kept dry, until the growth of the rice and the appearance of some grass among it called for a second weeding, which was well executed by hoeing the intervals, and picking by hand, all the grass from the rows of the rice; it then received what is commonly called the long flowing, the water being thrown on the land, to the depth of six or eight inches on the general level, where it was retained sixteen days, only occasionally shifting a little of it to keep it pure. The water was then gradually withdrawn, and as soon as the land was sufficiently dry, a third hoeing was given, stirring the ground well and picking out all the grass and weeds from among the rice: it was then kept dry until it had formed a joint, when the water was again introduced and continued, with occasional freshening, until it was let off to dry the field for harvest; but during this flowing the grass and weeds which had come forward since the third hoeing were pulled out by hand. It was begun to be cut down on the 1st day of September, and when thrashed and

winnowed yielded nine hundred and ninety bushels of rough rice, weighing forty-six pounds per bushel.

I have so minutely described the method used in this field, that the society might be enabled to judge how far this part of the experiment was properly conducted.

The field, No. 2, intended for the water culture, was treated exactly in the same manner with No. 1, until after it was sown, except that the seed prepared for it, was longer soaked and approached nearer to germination; and that one half acre was sown with seed that had not been previously wet. This field was sown on the 2d and the water introduced on the 3d of April, and was kept as nearly as could be flowed to the depth of six inches, on the general level, until the 21st of May; the ground, however, was so uneven, that I measured several plants of rice which had just appeared above the surface, and found that they had grown through 17 inches of water, while some high parts of the field were not covered 3 inches deep. On the 21st of May, the rice now standing up firmly, the whole of the water was turned off and some hands sent in to pull out the weeds, and on the 22d the water was re-admitted and retained until the 30th of June, when it was again completely shifted; immediately after which the field was again flowed, until the 14th of July, when it was once more emptied and renewed the succeeding day; and in addition to these total changes the water was partially freshened as often as circumstances would admit. Immediately after the 14th of July, the rice began to put out the ear, and was ready for the sickle on the 22d day of August, but on account of rainy weather, on that and the two succeeding days, it was not begun to be cut until the 25th of that month.

Some wampee and rushes appeared early in this field, and the washing of the loose earth from the banks covered the seed in the adjoining rows so deep that the rice did not come through it, and some labour was bestowed in transplanting into those rows.

The quantity of labour expended on this field, between sowing and harvest, was as follows:

May 17th Eight labourers picking out weeds, etc. half a day each,	4 days work
21st 22 labourers the whole day, Nine transplanting on margin,	22
24th One raking off green scum,	1
25th One ditto ditto	1
June 30th Twenty-two hands picking rushes, wampee, etc.	22
Total days work,	59

The product of this field when thrashed and winnowed, was 1069 bushels of rough-rice, weighing 46 pounds per bushel.

This field must have suffered some injury from my having left home about a week after it was sown, without having given sufficient directions concerning the shifting of the water, at an early period of its growth. I was absent near three weeks, and on my return found a considerable quantity of green scum among it, which gave it a very unpromising appearance; the rice was then in that state that it would have been thrown down if the water had been altogether withdrawn, it was, therefore, only freshened partially, and the water was not totally changed until the 21st of May; and as I am of opinion that pure water is as essential to keep rice in a flourishing condition, as pure air is to the health of animals, I have no doubt but that this field would have yielded more grain but for this neglect. The half acre, whereof the seed was not soaked, grew equally well through the water, was as early

ripe, and to all appearance as good as the rest of the field.

One field of twelve and another of fourteen acres were sown at my lower plantation, on Santee river, on the 25th of April, and treated in the same manner; they were both harvested soon after the storm in September—the twelve acres yielded five hundred and ten bushels, and the fourteen acres six hundred and thirty-two bushels of rice, weighing forty-five pounds to the bushel.—A violent gust of wind passed through the plantation while this rice was growing through the water, being then six or seven inches long, and the agitation of the waves drew up a considerable quantity of the plants by the roots, from the 14 acre field, this left the rice, as we then thought, too thin in that field. The twelve acre field was not so much affected by the storm, and stood very regular and thick, and it proved at harvest that it was too thick, for the ears were much smaller than those of the fourteen acre, and it yielded only at the rate of forty-two and an half bushels per acre, while the other gave at the rate of forty-five.

Another field of twenty-two and a quarter of an acre, very much broken by a large creek, was sown on the 10th of May, and subjected to the same treatment: It yielded one thousand and twelve bushels, or nearly, at the rate of forty-six bushels per acre, of rice weighing forty-seven pound per bushel. The rice in this field also, stood too thick, and one rood which had been sowed broad cast, injudiciously, scarcely produced any grain.—One hundred and forty-four days labour was applied between sowing and harvest to these three fields, containing, together, forty-eight acres and a quarter, being precisely three days labour of one hand bestowed on each acre.

The field of twenty-two acres, cultivated at Mrs. Motte's plantation, was so very much polluted with rushes, wampee, and the species of jointed conch grass, called here blanket grass, that the labour bestowed on it was very considerable, and the product bad, nor was this product so accurately separated from the rest of the crop as to enable me to state the amount. I was not present when it was harvested, but on walking over the field, and examining the stubble, I found many patches where the rice appeared to have been totally destroyed by the weeds, but where that was not the case, the rice appeared to have grown perfectly well, the ears of what I was shown as part of the crop was certainly fine, but the deficiencies were so great that I should not estimate the product at more than a barrel and an half, or thirty bushels per acre. One observation was, however, afforded by this trial, which is, that the accumulation of green scum or water moss, was prevented by twice shifting the water completely, during the night before the rice had progressed beyond the point or needle state: and another hint of some importance may be collected from it, namely, not to attempt this mode of culture in fields so foul with water grasses.

The field of about seven acres, cultivated according to this plan, by Mr. John Middleton, was sown on the 18th of April and reaped on the 3d of September, and yielded thirty five bushels per acre, weighing forty-five pound per bushel; the labour bestowed on it was equal to the labour of one hand for eleven days. This field also, was not in good order, and the rice evidently stood much too thick in it, except on the margins, which failed almost entirely, owing, I presume, to the same cause as mentioned in the first experiment. It was remarkable that this field, which was sown on the 18th April, was reaped on the same day with another field, which had been sown on the 28th of March, making a difference of twen-

one days; and this acceleration of maturity attended all the fields thus watered, though not in so great a degree:—I think, however, the trials I have made will authorize me to promise, that rice, cultivated in this mode, will be fit for harvest at least ten days before that treated in the usual manner.

My object, in troubling the society with the above tedious detail, being to induce some of our members to give this method a fair trial; I hope to be excused if I trespass a little longer on their patience, by explaining the reasons why I consider it worthy of their attention.

I think it is evident, in the first place, that to pursue this system, much less intelligence will be required in the cultivators, than the mode usually adopted; and, when we consider the general want of information in the agents commonly employed, this must appear a considerable advantage. Every practical planter knows that to understand the proper periods when the water should be admitted; to what depth the land should be flowed; how long the water should be retained, and how often the irrigation should be repeated, requires experience, judgment and attention. In the method I recommend, the watering process is certainly more simple, nothing being required but to admit the water from the first to a certain height over the land, and to retain it steadily through the whole growth at that height, the only skill and attention necessary to this part of the business being to keep the water pure and sweet, by changing it partially, or altogether, as often as is necessary for that purpose, and as circumstances will permit.

Of the advantages this method possesses over the common mode as it respects the saving of labour, the comparative statement, exhibited above, furnishes abundant proof; and when the disadvantages arising from want of experience are considered, little doubt can, I think, be entertained, but that a few years practice, would enable us to diminish even the small portion of labour applied in these trials, and the application of the labour, so saved, to other useful purposes would certainly be peculiarly beneficial to the land holders of the lower country, where many persons possessing more land than they can cultivate, it must be of the utmost importance to them to have more than three-fourths of their labourers relieved from their present occupations for one-third of the year, and ready to be employed in bringing into cultivation valuable land now lying useless, or of more highly improving that now in use. Many planters also, who have not now the leisure to prepare materials for building and to erect dams sufficient to enable them to use water-mills, and other machinery for manufacturing their crops would no longer be prevented from enjoying that benefit. Such also, as have good highland near their swamps, would be enabled to plant cotton or other valuable products in addition to their rice crops; and they whose highlands are of inferior quality, might improve them by manures, which, in our lower country, are every where at hand; for the worst of what is called pine barren, abounds in weeds and plants which grow luxuriantly in summer; and every part of vegetable as well as animal substances, may be converted into good manure. It is not therefore, the scarcity of that article, but the want of labour necessary to collect, prepare, and transport it, that occasions this great improvement to be so little used among us.—Lime, which is known to act so beneficially as a manure on the texture of sandy soils, might, during this season of leisure, be burnt from the shells, with which our sea-coast abounds, within the reach of most of our rice-planters, and either applied to the melioration of the soil, or

sold to considerable profit at market; and, where timber abounds, sawing for market would prove a beneficial resource. But in no respect would this system, if successfully pursued, afford such permanent advantage and satisfaction as in the improved health of the persons actively employed in the cultivation; for it must be evident that the exhalation from the water frequently shifted and kept in a state as pure as is here recommended, would be far less deleterious, than that arising from the mud of the swamps after the water is withdrawn. Any person who has passed near a rice-field within a few days after the water has been let off from it must be convinced of the truth of this observation. But a further improvement in the health of our labourers may reasonably be expected to result from the experience which, of late years, has amply proved, that our pine-barrens, removed but a small distance from the swamps, and especially where a barrier or screen of trees is kept between them, afford residences infinitely more healthful than the immediate vicinity of rice-fields. If then, we shall find our labourers no longer bound to reside near the rice-fields by the attention and work necessary to be performed in them, according to the present plan, is it unreasonable to hope, that we shall, by degrees, and as circumstances may admit, remove our settlements to convenient distances in the higher lands, where our people might be employed to advantage, and enjoy better health? A few persons, in this case, must necessarily be left to attend to the watering process; and when the rice approaches to maturity the water should be withdrawn a few days earlier than is now customary, which would not injure the crop, but would suffer the first and greatest exhalations to pass off before the attendance of the labourers would be necessary in the field.

Before I conclude I will mention one more advantage that may possibly attend this mode, without entering into any detail concerning it, which is, that this mode of culture seems calculated to admit with advantage the practice of transplanting rice, whereby we may be enabled to obtain two crops in one year, from a considerable portion of our land;—this, I find, is a practice generally pursued in Egypt, in China, in Indostan, in the Phillipine Islands, and in Spain; and I hope next year, to have it in my power to offer to the society the result of an experiment I have begun, with the hope of ascertaining whether this practice may be beneficially adopted in the culture of our rice lands.

It may have the appearance of presumption in a person having so little experience in this mode of culture, and who, it is evident, from the above detail, committed several errors in his former trials, to offer instructions on the subject; but, hoping that such of my friends as may be induced to try this mode, may profit by my mistakes, I will venture to recommend to them to keep their land dry all the winter, and to plough and harrow, or turn and break the soil, with the hoe, as well and as often as circumstances will admit, and for this purpose the land should be enclosed with good banks and well drained; by this the growth of the roots and seeds of aquatic plants, which alone are to be feared in this culture, will be much checked if not destroyed. Until further experiments shall have ascertained it to be unnecessary, I would advise that the seed should be steeped in water for, at least, twenty-four hours before sowing, and then sown as usual in drills, (that in case the experiment should so far fail as to render hoeing necessary, that operation might be performed) as in this mode of sowing nearly every grain sown germinates. I believe from one and an half to one and three quarters of a bushel of seed to the acre, will be found suffi-

cient, giving the largest quantity to those parts of the field which are lowest. The seed should by no means be covered by earth, but the water admitted slowly in the morning of the day after sowing, and increased gradually to as great depth as the supply of water and situation of the banks will admit, whereby all the loose stubble and trash in the field will float and be driven by the prevailing wind to one side or corner of it; this trash should be removed, and, immediately after the water reduced to six inches over the general level of the field. In the afternoon of the fifth day after sowing, water should be entirely withdrawn from the field, and readmitted with the next tide, or early in the morning of the next day. In five or six days more this complete change of water should be repeated, taking care to effect it while the rice is still in the needle state, and consequently not liable to be thrown down. After this the water must be kept on steadily until the rice shall have grown through it and stands firmly; observing only to freshen it occasionally, by drawing off one or two inches and raising it again with the next tide to its standard. As soon as the rice stands up strongly, the water should be again entirely changed, and that process repeated two or three times (or often if it be necessary to keep the water quite pure and fresh) before it is finally taken off to dry the field for harvest.

I remain, with the utmost respect,

Dear Sir,

Your faithful and obedient servant,

THOMAS PINCKNEY.

JOHN CHAMPNEYS, Esq.

President of the Agricultural }
Society of South Carolina. }

ON THE MANAGEMENT OF HORSES AND DOGS—BY AN EXPERIENCED SPORTSMAN.

(Continued from page 27, vol. 5.)

I shall now speak concerning inflammatory fevers. They are not difficult to cure. First, the horse's pulse should be felt to ascertain the height of the fever; a horse's pulse is to be felt by applying the palm of your hand, pressing hard, just behind the elbow of the left fore-leg. A horse's pulse, in good health, should beat about forty or forty-two pulsations in one minute. I have known a horse's pulse to beat above 80; but then the fever was very violent, and the horse must be plentifully bled; and he must be bled again the second day, provided the fever is not abated.—To this one horse I now speak of, I gave four ounces of nitre every day—but, in general, three ounces is sufficient, unless the fever be very high. As the horse will not eat corn, in which the nitre may be given, you must make the nitre into a ball, and give it him; and be sure to drench him plentifully with water gruel.

When a horse is much reduced by illness, but has recovered his appetite, the best thing to nourish him, I know, is malt. Put the malt into a stable bucket, and just cover it over with boiling water; throw a cloth over the pail, and let it steam for about half an hour. A person I knew well, who used to prepare the physic for his horses himself, put a certain quantity of calomel to a certain quantity of aloes and other ingredients, into an earthen pot, and boiled them together. From not stirring the ingredients constantly, until they were quite cold and stiff, the calomel all settled at the bottom of the pot. The first year he physicked his race-horses, they did well; but the second year, coming to the bottom of the pot for the physic, he killed two or three of his young racing colts, and materially injured some of the aged horses.

To obviate this danger, when it be judged ne-

cessary to give a horse *calomel*, let *two drachms* be given over-night, and the aloetic purge the next morning. To a young colt, of two or three years old, you must not give above half the quantity of calomel.

For the gripes, or cholick in horses, the very best thing you can give them, is a WHOLE BOTTLE OF DAFFY'S ELIXIR, MIXED IN ABOUT HALF A PINT OF WARM ALE, AND A LITTLE GRATED GINGER.

When I kept a stable of horses, I never was without three or four bottles in the stable. It is an expensive medicine, I acknowledge; but what of that?—purging must be promoted, not checked. We all know that Daffy's elixir is made of a decoction of senna and warm spices. The senna purges gently, and the warm spices comfort and warm the horse's stomach. You will find a horse sometimes shew that he is in considerable pain, endeavoring frequently to stale, and cannot. This is frequently taken for the gripes; but it is not the gripes: it proceeds from costiveness in the horse, and the dung-bag being so full as to press hard upon the bladder, which prevents the horse from staling. Let a boy, with a small hand, well oiled, rake him: the horse will stale directly.

To ease pain in a horse's foot, or to make a dry, hard, brittle, or contracted foot supple and expand, I know nothing equal to boiled linseed, applied warm to the foot.

When the foot be wounded by picking up a nail, cut by glass, or by some other accident, in which case gravel may have got into the foot, it will be necessary to apply a common poultice with Venice turpentine, to draw the gravel out.

Never, on any account, grease a horse's hoof, which all-wise John Grooms do, as they say, to supple it: and keep it from cracking; grease has a contrary effect. Take your horses out from the clean straw and dab their hoofs well, morning and evening, with stale chamber ley.

Take a dry hoof of a horse, cut it in half, steep one half for several days in a pot of chamber ley, and the other in a pot of grease; take them out, wash them both clean, and lay them aside. In a short time you will find the one steeped in chamber ley tough, genial and pliant; the other, steeped in grease, will be hard and brittle; this has been tried. You may anoint the coronet of the foot with a little fresh grease, but no other part of the foot.

Provided a splint lies on the bone of the leg, so as not to impede the action of the sinew, I recommend by all means to let it alone, and do nothing to it; but if it lies near the sinew, it must be taken away. The best method I am acquainted with, is to rub it with a round stick, till it feels somewhat soft, then prick it in many places with a bodkin or packing-needle, moderately hot; be sure to make two or three holes quite at the bottom. A gentle blister will then reduce it.

With spavins and ring-bones I will have nothing to do. Send for a skilful veterinary surgeon. It requires skill and practice to operate on the vein in blood spavins, and I believe bone-spavins generally incurable; at least the horse will not have the free use again of his joint; and ring-bones are very bad maladies.

Corns should be clean cut out, and a wide wash extended from the shoe, in the form of three-fourths of a circle, and about two inches broad, over the part where the corn was, to guard it from sharp stones, gravel, &c. I do not approve of a bar shoe, it confines the dirt in the foot too much.

It is dangerous to attempt to dry up running thrushes, unless the horse be put under a course of strong physic; for, if, by sharp washes alone, you attempt to dry them up, the disorder fre-

quently flies to the eyes, when, for a time, you nearly blind the horse. I look on running thrushes as a discharge of nature, much the same a sweaty feet in man: dry them up, and I imagine the disease will fly to some other part of his body. I am certain it always will in a horse. The only safe method of treating them is, to WASH THEM CONSTANTLY WITH STALE CHAMBER LEY. I would also particularly recommend giving a FEW OF THE NITRE AND SULPHUR BALLS, provided the thrushes run abundantly, and smell very foetid.

A horse cannot easily be lamed in the shoulder, except from a fall, a blow, or from running against some hard substance. But wise John Groom, and the farrier, provided they know not where the lameness really lies, swear the horse is lame in the shoulder; whereas the lameness is in their heads, and not in the horse's shoulder.

I will give you an infallible method to know whether a horse be lame or not in the shoulder. When you trot the horse, if he be lame in the shoulder, the muscles are affected, so as to prevent his extending that leg, or stepping out so far with it, as he will with the other leg; he will step considerably shorter with that leg. When the lameness lies below, he will extend the lame leg as far as the other; but, when he puts the foot to the ground, will shew lameness. If the cause of lameness be not very visible to the eye, you may rest assured it lies in the foot or fetlock joint: in this case send for a veterinary surgeon; for, to cure it, great skill and practice is necessary, and a thorough knowledge of the anatomy of the foot and fetlock joint. I have known several horses totally spoiled by lameness in the feet, and never fit for any other use but to draw a cart or wagon, where they never are forced beyond a walk.

The best method of treating gun-shot wounds in horses, is, to inject spirit of wine; if that cannot be procured, use brandy, which will do extremely well; if that be not at hand, use rum.—It is wonderful how speedily horses recover from gun-shot wounds, provided they are not shot in the bowels or other dangerous parts of the body. Yet I once had a horse shot directly through the centre of the body, about five inches above the bottom of his belly, and he was very well in a short time: and another horse of mine (it was singular,) had a ball absolutely flattened on the bone of the hind leg, just above the fetlock, which I cut out in the afternoon with a common pen-knife; the side of the ball next the bone was quite flat, and as broad as a shilling: it lamed him for some time. I saw a horse belonging to a captain in our regiment, in a very few months shot once through the neck, and the second time through both buttocks. In about five weeks after each wound, his master rode him; so very quick does the flesh of horses heal.

Ointments should seldom be used to any lacerated part, and never to gun-shot wounds; but when absolutely necessary. The following is the best, as there is very little grease in it.

TAKE OF LINIMENTUM ARCAEI (ARCAEUS LINIMENT.) ONE OUNCE; OIL OF TURPENTINE, TWO DRACHMS; VERDIGRIS, A SUFFICIENT QUANTITY TO TURN IT TO A DARKISH GREEN COLOUR. This is an excellent healing ointment; BUT SIMPLE OIL OF TURPENTINE WILL DO WONDERS.

I have not made any observations relative to the shoeing of horses for several years at Newmarket: formerly they were scandalously ill shod. It is to be hoped that since skilful veterinary surgeons have resided there, the method of shoeing has been altered. I have seen many horses' feet so narrowed at the heels by bad shoeing, that the points of the fore shoes have nearly touched at the heel. I am certain this has been the cause of laming numbers, and would have lamed many

more, were it not from the fine soft turf they are exercised on.

I have frequently bought strong boney horses, with feet infinitely contracted. In four or five times shoeing, I have widened their feet above one inch, and, in time, brought them to have a good foot, broad and open at the heel. To accomplish this, the shoe must be made quite straight, from the centre to the heel, not in the smallest degree turned in at the points; pare the contracted points away, and let the point of the heels rest on the shoe. The heel, thus rested on the shoe, will naturally expand. Some people may say this method of shoeing may make the horse cut; I deny it; the horse never cuts with the heels of his shoes; nay, even in the speedy cut, he strikes his leg with the centre of the shoe.

When a running horse is badly let down, as it is termed, in the back sinews, the best way is to turn him to the stud; for I am certain he will never stand a severe race; and whatever you do to him, if you hunt him, he is ever liable to break down in deep ground. However, in case you are determined to try him, the leg must be reduced first as much as it is possible, and then he must be blistered and fired; but, above all, he must have long rest given him, and the whole winter's run, in a very dry paddock, wherein there is no marshy nor wet ground.—The winter's frost and cold air, will, I believe, perform the greater part of the cure, together with long rest.

I own the following is a fancy of my own, and that I never have tried it; but, in my poor opinion, I think it stands to reason. On the former lame leg, the shoe should be made full half an inch thicker at the heel than the shoe on the other foot, to give the injured sinew some additional relief. Indeed, I once had a capital cantering hackney fired in both fore-legs. I always shod him at the heel of both feet, much thicker than any other horse; but then I never cantered him at above the rate of ten miles in the hour. He went so completely on his haunches, that but little strain laid on his fore-legs. This is the great perfection in all horses' actions. All of them go from their hinder parts, but very few go completely on their hinder parts—no hunter can go through deep ground, unless he does; and no horse, which goes differently, can be used on the road with safety to your neck.

(To be continued.)

Doyle's Town, 19th Nov. 1822.

A writer says, "tobacco exhausts those juices so essentially necessary to further digestion; it creates thirst and nausea; it destroys appetite; the complexion becomes cadaverous; finally, the chewer and smoker becomes a poor, miserable, attenuated, atrophic, walking skeleton, smoking away his few remaining ideas, and spitting up his lungs, until death releases him from all his sufferings." The truth, we believe, is, that to many constitutions tobacco is hurtful—to others innocent; and the true course is for those who find it injurious, to abstain from its use.—That it is pernicious to young people generally, is past doubt, and therefore its use by them ought to be forbidden or discouraged.

THE CHRISTIAN ÆRA.

The most ancient author whom we find using the modern mode of date, *Anno Domini*, is the venerable Bede, who published his Ecclesiastical History in 731. It was adopted in France under King Pepin, and fully established in the reign of Charlemagne. The custom of beginning the year on 1st of January, commenced in France in 1564.

RUTA BAGA.

HAVE MORE NUMEROUS AND PARTICULAR EXPERIMENTS PROVED IT TO BE A PROFITABLE CROP? DOUBTED, AND REASONS GIVEN.

Mr. Skinner—

It is important to the agricultural interest of our country, that the merit of any new product or mode of cultivation, should be tested by careful and accurately recorded experiments, in order that its fitness to our climate and the habits of our people, should be well understood.

Several years have elapsed since the public attention was called to the subject of ruta бага, by the publication of Cobbett's books, and the experiments of many of our intelligent and enterprising cultivators. Time has been allowed for testing the value of this root as a food for stock. I have seen no recent communications in your paper on the subject, and judging from my own experience, and my observation of the agriculture of my own neighborhood, I am apprehensive that it has not proved so profitable a product, as was anticipated by our zealous and enterprising agriculturists. It is very certain that the great product stated by Mr. Cobbett and other English writers, to be so common in their country, very far exceeds any well authenticated account of the product of any experiment in this country. I have received an account, which I have no doubt is correct, of a crop of 335 bushels on half an acre, raised by Mr. Samuel Sayre, of Sussex county, in this state, for which he received the premium offered by the agricultural society of New Brunswick. This, however, is a solitary instance, as far as I have been informed, of a great crop in this state, and falls very far behind the ordinary crops of England, according to Mr. Cobbett.—The result of many careful experiments, made by farmers in my own neighborhood, is by no means so favorable. I have pursued the object diligently, and anxiously, for four years, and in no instance, with the most careful management, have I obtained more than 250 bushels from an acre.—Whether the failure is to be ascribed to our climate, or to the dry seasons which have prevailed since the commencement of my course of experiments, I am unable to decide. That in some, at least two of my experiments, I have used good seed, I am perfectly satisfied; and that, in no instance, have I omitted the closest attention to time and good cultivation, I can venture to assert. A summary of my management will probably satisfy you on these points.

In 1819, I prepared an acre of fine sandy loam, by twice ploughing; 32 cart loads of well rotted compost were placed in the furrows, and covered to 4 feet ridges. The seed was drilled on the 26th of June. Such was the severity of the drought that all the seed perished, except on the sites of two compost heaps, where they came to perfection. These few roots made about sixteen bushels, and were large, fair, well coloured and finely flavoured. An attempt to replant was rendered abortive by the continuance of the drought, too long to admit of the plants attaining any size. In 1820, I drilled 3 acres of a sandy loam, capable of producing 5 bushels of corn per acre—about 22 loads of well burnt ashes, from rushes and hassocks, were spread broad cast on each acre—the ground was sown into 4 feet ridges,—the time 26th June.—Nothing could exceed the beauty of the crop when growing—the leaves frequently met in the street spaces. The best acre was measured, and produced only 250 bushels—their quality was excellent, their appearance perfectly fair. In 1821, 20 acres of stronger ground were prepared by two ploughings, after a crop of corn 35 bushels per acre—about 25 cart loads of well rotted barn manure were applied—the seed drilled 26th June. The crop was kept in high cultivation—it

was much admired by those who passed it. Five hundred bushels per acre was the expected crop—when pretty well advanced, the tops assumed the appearance of cabbages, with necks three and four inches long—when gathered, the roots were hard, fibrous and tough, of a pale yellow colour, and unfit for the table, although greedily eaten by my hogs—the produce did not exceed 160 bushels per acre. The quality of the ground may be fairly estimated, by the crop of oats which followed the ruta бага, being 51 bushels per acre.

In 1822, I was induced, by the success of Mr. Sayre beforementioned, to plant earlier than recommended by Cobbett. His best roots were sowed in his garden on the 22d and 23d of May, and transplanted on the 20th of July. I drilled this crop about the 1st June, on a very fine piece of sandy loam, manured with about 40 cart loads of stable dung per acre. The crop was beautifully regular and vigorous in the early part of the season. I was confident of obtaining 500 bushels per acre. In the latter part of their growth the drought became extremely severe, and was afterwards so destructive, that the lower leaves perished, and the growth of the roots was completely checked. I did not gather more than 150 bushels per acre of hard, fibrous, bad coloured, and almost tasteless roots. They were not eatable in my family, but were relished by my hogs, who have lived on them through the winter, up to this time. They had the same cabbage-like appearance as the preceding crop. This same appearance was exhibited by a row raised from the seed sent by Mr. Christopher Hughes, Jr. from Sweden, and which you kindly sent me a sample of—and was equally visible in two rows from English seed, sent to me by Dr. Mease, of Philadelphia. I observed the same defect in the plants from seed sowed broad cast on the 26th of June. My seed this year was bought of Mr. McMahan, and warranted as true yellow ruta бага.

I believe, from the best information I have been able to obtain, that the ruta бага, when sowed before the end of June, loses much of its excellence as food both for man and beast. I have raised them for my table for twenty years, broad cast, sown in July, of a good size and quality. I suspect much of the seed used at this time is spoiled by mixture with the cabbage—this I have known by personal observation.

As the produce of the ruta бага is so much less here than in England, I have long suspected the climate of America to be less adapted to it than that of England. It is well known that the potatoe, with the best management, yields much less in this country than in England, and very much less than in the Eastern states and in the British provinces. It is possible that the same effect may be produced in the two roots from one and the same cause.

I have, for many years, found the benefit of raising green vegetable food for my stock. Potatoes and pumpkins I have raised in large quantities for this purpose—but having found my hogs particularly fond of the ruta бага, on which they will thrive through the winter without grain, and even without water, I have felt extremely desirous of convincing my mind that they were a profitable crop. On this point, from my own experience, and from my observation of the practice of others, I am compelled to doubt. I wish the subject to be examined by sensible and practical men—with this view, I ask of you an insertion in your very useful paper, of the loose thoughts I have thrown together. I shall rejoice if better informed men shall convince me that I am in an error, on a subject that is interesting to every cultivator of the soil. My present impression is, that I should have raised fifty bushels of corn on every acre which I have applied to the cultiva-

tion of the ruta бага, which would have afforded a far greater quantity of nourishing food, and in a more convenient and economical shape for winter use. A NEW-JERSEY SUBSCRIBER.

April 2, 1823.

Editorial Correspondence.

PEA CULTURE.

Extract of a letter dated Scotland Neck, N. C. 3d April, 1823.

"I saw in the farmer a few weeks past, that a gentleman was about to send you from this state, some *Georgia* or *Tory peas*—should you receive them by the 20th April—if your land is kind for peas, I want you to plant a few in ground that was tended last year, and not cultivate them at all—I have for the last two years planted a considerable quantity in the following manner.—About the last of April or first of May, I lay off rows by the side of the old corn hill; the peadroppers follow and drop from 8 to 10 against the hill, and cover them with their feet. I do nothing more to them, and have had as luxuriant a growth as I ever have seen grown in fields cultivated in the fall. I turn my hogs in on them, in their green state, which fattens them very fast, and will not injure them. On land that really suits, I think them far preferable to clover for us, as we have the vine, leaf and hulls—and nearly or quite as many weeds, as if nothing were planted in the ground."

RUTA BAGA.

Worcester, (Mass.) April 1st, 1823.

"In reference to the ruta бага, I regret to say, that I am almost alone in this part of the country, in its cultivation. The well established fact, that it communicates an unpleasant flavour to milk, when fed to cows, has brought it into general disesteem. Still I regard it as the most valuable root for husbandry culture. It has been particularly useful to me, in the keeping of swine; and added to my own observation, I have the authority of my farmer for the assurance, that it is equal to one half of their keeping in summer, with the most inconsiderable expense only of labour. My course is to sow the seed thick, and as soon as the plants are of the usual size to set, to begin thinning them out, and giving the green plants, which are pulled, to the swine. The field may thus be gone over several times during the season, leaving the plants at last as thick as they will well ripen by harvest time. The swine being thus fed at first, became fond of the roots, and will continue to eat them greedily through the winter. Within a few days I have witnessed a large basket of them from the cellar thrown into the pen, and apparently as readily devoured, as would have been so much corn. The hogs are in good condition, and these turnips have been their principal food. My sheep also are much improved by them, especially about the time of weaning. These facts are the rather stated, as proof that the seed which you kindly sent, will be appreciated by at least one individual, and with the thanks of the society for your attention, I pray you to accept mine for the value of the present.

With much respect,

I am your obedient servant,
LEVI LINCOLN,
Cor. Sec'y W. Ag. Society."

AN EXTRAORDINARY CHARACTER.

We learn from our Penzance correspondent, that on Thursday, the 9th Jan. died suddenly at Tra-sza, in the parish of Ludgyan, Mr. James Hosken, a farmer, possessed of some proper

and said to be a very honest man, but of singular opinions and eccentric conduct. Some years since he parted from his wife, in a fit of jealousy, occasioned by her allowing a relative who was taking leave on going abroad to salute her. The quarrel was never made up, and he afterwards lived with another woman. He evinced little respect for the forms of religion, and in consequence of dispute with the clergyman of the parish, respecting a charge for the erection of a tombstone at the grave of his two daughters, declared that he never would be interred in the church-yard. In consequence of this determination, he fixed on a spot in his own land as the resting place of his mortal remains, on a hill near the ruins of an ancient tower called Castle Dennis, said to be built by the Druids, from which there is a view of both channels. Here a few years since he enclosed a small space with a wall, and at each end fixed a tablet. On the one is engraved "Custom is the Idol of Fools;" on the other, "Virtue only consecrates the Ground." In this spot his remains were deposited on Monday last, agreeably to the directions in his will.—A concourse of between 5 and 6,000 persons attended, to whom the Rev. G. O. Smith, of Penzance, delivered a suitable discourse on the occasion.—*Cornwall Gazette.*

THE FARMER.

BALTIMORE, FRIDAY, APRIL 25, 1823.

CATTLE SHOWS.

Every week lately has brought us hand-bills setting forth the premiums to be distributed the ensuing autumn by the Eastern agricultural societies. From these there appears to be no abatement of their zeal, and great improvement in the application of it. In this paper we have copied the list of premiums offered by the Essex Agricultural Society, signed and probably prepared by the venerable PICKERING—because it "departs materially from what seems to have been the leading principle in all the agricultural societies of the country—that of offering premiums chiefly for certain specific articles of husbandry, instead of the combined improvements of entire farms."—It will be conceded that we ought not to publish all these lists—for, like constitutions, they are very much alike, and contain generally little that is new and important; not so, however, with the one in question—and we have therefore inserted it for the consideration of the Maryland, and other Agricultural Societies.—Moreover, the reasons given for drawing attention, and for offering their highest rewards, to new objects, serve at the same time to convey practical information which must prove acceptable to most farmers. There is, however, one thing in this scheme of premiums we regret—and that is, that they are offered in—*money* instead of pieces of plate, in some specific form for domestic ornament or use. There seems to us to be all imaginable difference in the sentiment which must accompany the two forms of reward—with the idea of mere *money*, "filthy lucre," it is difficult to associate that of generous and patriotic pure spirited rivalry, which conquers without force or aggression, and defeats without inflicting a wound. Money, is the common boon of vulgar competition in the lowest grades of human exertion and strife.—The common stimulus proclaimed for the apprehension of the runaway slave and the house breaker is "twenty dollars reward"—whereas, when the premium is given in the shape of a can or a goblet, a spoon or a tumbler, it may be placed on the sideboard or the mantle, and becomes an object for exhibi-

tion and harmless boasting to our friends—and goes down, from one generation to another, as a sort of heir-loom in the family—a mark of affection in family bequests—some simple inscription serving to chronicle the merits or the enterprize for which it was originally bestowed.—For ourselves, we confess that we never feel more self-satisfaction than when we are displaying to our agricultural friends, the little silver waiters, standing on cow's feet—"Presented to J. S. S. by the Maryland Agricultural Society, for importing Shepherdes and White Rose: June, 1823"—and the silver pitcher, with a well engraved likeness of Champion on its front—ten times the cost of them in money would be valueless in comparison. For every premium, however small, some appropriate symbol may be devised, combining permanence with utility—and we take occasion to repeat the offer of our services to have them prepared by Mr. Warner, who has heretofore supplied, on the most reasonable terms, appropriate pieces of plate, by order of several societies to whom his work has given entire satisfaction.—All we desire is to experience the pleasure of aiding in giving the best direction to the bounty of those who wisely patronize agricultural emulation. It should be remembered that all Orders for premiums in this shape should be given several months before hand, to give time for their preparation.

BAKEWELL, OR DISHLEY SHEEP.

A number of very superior sheep were slaughtered and sold in this market, early in this month, by Mr. Curtin and Mr. Elliott.

The lot, consisting of forty, yielded 3834 pounds of mutton, and 588 pounds of rough fat. These sheep sold, we understand, for 13 dollars each, for mutton to the victualler, and some of them cut full four inches of clear fat across the ribs. What was remarkable in this case, was the fact that they were generally only year olds past, or two years this spring. Every one acquainted with the difference of sheep, however, knows that the Dishley are chiefly remarkable for the fineness of their bone, and their great disposition to fatten at a very early age. This lot of sheep, were from the same gentleman, and are of the same breed, as those exhibited at the Maryland cattle show in June last, of which the society made such favorable mention, and which were afterwards sold to a gentleman at Wheeling.

➤ LARGE HOG.—Along with the sheep, Mr. Barney brought a hog, two years old last fall, of General Ridgely's Parkinson stock, which weighed:—

Nett weight of carcase, - 751
Leaf fat, - - - - - 88

Mr. Barney took the precaution to *measure* the bullocks on the hoof, an account of which we published in No. 2, vol. 5—to prove the accuracy of the mode given by Mr. Wright, in No. 24, volume 4—for ascertaining the *nett weight* by the *measurement* of *living* animals. The result was, that the ox of General Ridgely's Dutch breed, measured to weigh 1415 pounds, and actually weighed 1405. It is probable that a little experience would enable graziers to come by measurement, near enough to the real weight for all practical purposes.

New-York, April 22.

FROM CADIZ.

We learn from Captain Packard, of the brig Walter, arrived yesterday from Cadiz, that the king and royal family were hourly expected at Seville; and when coming out he heard a firing in that direction, which was supposed to be the

signal of their arrival. Accounts of hostilities having commenced were daily expected.

Captain Packard is the bearer of dispatches from Mr. Forsyth, our Ambassador at the court of Spain.

It was reported at Cadiz on the 16th, that 15,000 French troops had entered Spain, which increased the probability of war. A Spanish fleet, which had been driven from Madeira with loss of anchors and cables, had arrived at Cadiz.

It was reported at Madrid on the 4th, that the 23d French regiment, which had been sent to construct a bridge at Sidache, had deserted with all the plans in their possession, and had declared themselves in favour of a free constitution.

Philadelphia, April 23.

THREE DAYS LATER.

The new packet ship Montezuma, capt. Potts, arrived here yesterday from Liverpool, bringing Liverpool dates three days later than those heretofore received. The Paris dates are not so late as those received at New York.

The intelligence from Bayonne, which is to the 2d of March, is decidedly warlike. The army collecting in the Lower Pyrenees is estimated at 35,000—the artillery at 160 light, and 24 heavy guns—the number of wagons is 500.—The army of the Faith, in Navarre, the three provinces and Arragon, amounted to 15,000 men, to which must be added an equal number enrolled in the provinces, who wait only for arms and ammunition. O'Donnell is to command in Navarre, 12,000 muskets, 12 pieces of artillery, and a pretty large sum of money have been placed at the disposal of O'Donnell and Quesada.

The Paris correspondents of the London papers mention, that the French journals give the idea of the state of public feeling on the important question of the expulsion of Manuel, and that the alarm in the upper circles of Ultramar was excessive.

It is affirmed under the Brussels head of March 5th, that the English officers on half pay, who are on the continent, have received orders to return to England, where they will be employed in actual service.

Private letters of the 14th state, that the King and Cortes had left Madrid for Seville, which is confirmed by accounts from the latter place.—The first detachment was to have left Madrid on the 10th, and it was supposed that the King would attach himself to the centre party.

PRICES CURRENT.—CORRECTED WEEKLY.

Flour, best white wheat, \$7 50—Howard's Superfine, \$7 25—fine do. \$6 75—Wharf, do. \$7 7 1/2—Wheat white, \$1 55 to 1 60—Red do., \$1 50 to \$1 55—Rye, 80 cents—Corn, 60 to 63 cents—country Oats, 50 to 55 cents—Beef, 8 cts. per lb.—Live Cattle, \$6 to \$6 50 per cwt.— Bacon, round, 8 to 9 cents per lb.—Pork \$4 50 to \$5 50 per c. lb.—6 to 8 cts. per pound—Mutton, 6 to 6 cts. per lb.—Beans, \$1 37 1/2 to 1 50—Peas, black eyed, 55 to 60 cts.—Red Clover Seed, \$3—Orchard Grass do. \$3 50—Herds' Grass do. \$3—Timothy do. \$4 50—Millet, \$3—Flax Seed, 75 to 80 cts.—Whiskey, from the wagons, 32 to 35 cts. per gal.—Apple brandy, 30 to 32 cts.—Peach 65 to 70 cts.—Shad, none in market—Herring, No. 1, \$3 62 1/2 per bbl.—No. 2, \$3 37 1/2—Fish salt 80 to 90 cts. per bush.—Coarse, do. 75—Butter, 20 to 25 per lb.—Eggs, 18 1/2 cts. per doz.—Hay, \$18 per ton—Straw, \$11 to 12.

MARYLAND TOBACCO.—Grown by C. S. Ridgely, Anne Arundel county \$25 a 30—by George Edelin, Anne Arundel county 23—by J. Ridgely, Baltimore county 26 50—by George Thomas, St. Mary's county 13 50—by Dr. James Thomas, St. Mary's county 17 a 19.

AGRICULTURE.

From the Archives of Useful Knowledge.

AN ESSAY ON SOAP-ASHES, AS A MANURE.

It has been found, that the produce of soap-ashes in London, and its immediate neighbourhood alone, amounts to above 20,000 tons annually and is likely to increase, more especially from the use of *kelp* having been lately introduced into the London markets. The Board of Agriculture having been convinced, from the most accurate information, and from experience, that this quantity of valuable manure if brought into more general use, would be an object of very considerable importance to the national agriculture, ordered an abstract of their report, on this subject, to be printed and circulated; being desirous of giving all the publicity possible, to a circumstance so well deserving the attention of farmers, gardeners, *hop-planters*, *nursery-men*, and others employed in the cultivation of the soil, more especially those in the vicinity of the metropolis, and on the borders of navigations therewith connected.

This abstract of the report of the board of agriculture, published about four years since, having been widely circulated, and much considered, has deservedly attracted the notice of agriculturists in general, and has induced them to make a variety of experiments with soap-ashes, on different soils, and for different crops. Many highly interesting communications, on this subject, having been made to us, we conceive it to be a public duty to render them more permanently useful, by publishing in a condensed, but popular form, the important facts which they contain.

This is the object of the present essay. We shall consider the subject under the following heads:—

1. The nature of soap-ashes.
2. Analysis.
3. The soils on which soap-ashes may be used with advantage.
4. The quantity per acre.
5. The crops for which soap-ashes are used, and the manner of applying them.
6. The price.
7. The effect of soap-ashes on grass and arable lands, in parks, gardens, &c.

SECT. I.—NATURE OF SOAP-ASHES.

Soap-ashes differ very materially in quality, according to the sort of alkaline salt which is used by the soap-boiler. When *kelp* and *barilla* are the materials, the ashes are found to possess twice the strength and effect of the refuse of common potash. Much *kelp* being now used by the soap-manufacturers in London, their ashes are greatly improved as a manure; as they contain a larger quantity of neutral salt, sulphur, and carbon, than when *barilla* only was employed. To this circumstance, we must attribute not only the different quantities per acre that are recommended, but also the different results which have attended the use of this dressing, in various parts of the kingdom.

Soap-ashes afford a much cleaner manure than dung. A dung-hill, after laying for some time, is covered with weeds; and, in using dung, the farmer generally introduces almost every sort of weed into the ground. A heap of soap-ashes is never covered with weeds, but with a fine sweet grass.

Some ill-founded prejudices having been formed against the use of soap-ashes, on account of their supposed burning quality, a statement of the following fact, will, we think, completely eradicate them. When a piece of ground has been covered, for a length of time, with soap-ashes and

dung, the verdure is naturally destroyed. Those parts of the ground on which soap-ashes have been laid, recovered their verdure first, and bring up sweet grass and white clover.

In *East Lothian*, in North Britain, the farmers are very careful in collecting all the *kelp weed* which is cast ashore during the winter, and which they lay in heaps, upon their lands. This is using soap-ashes in another way. In the neighbourhood of *Dunbar*, where the farmers use soap-ashes, as well as the *kelp weed*, they pay as high a rent as seven pounds per English acre, for very considerable tracts of land; which are principally cultivated with wheat.

SECT. II.—ANALYSIS.

Soap-ashes contain lime partly saturated by carbonic acid from the *barilla* or *kelp*; a portion of alkali; neutral salt; sulphur; carbon; siliceous matter; and calx; each, separately, of the utmost importance to land. According to the more minute analysis of *Dr. Davy*, the ashes from *barilla* contain 91 parts in 100 of carbonate of lime, and quick-lime; and carbonate of soda. The ashes from *kelp* contain calcareous matter, in the same state as that from *barilla*; gypsum; and soluble saline matter, containing, apparently, nearly the same proportions of carbonate of soda, and of common salt, as in the former instance.

It is obvious then, from the chemical nature of soap-ashes, that they will be applicable wherever calcareous matter is wanted in lands, and that they will serve the purposes of liming.—Soap-ashes are, indeed, much superior to quick-lime as a manure.

A very respectable farmer in *Holderness*, *Yorkshire*, has affirmed, that he found ground chalk very superior to quick lime; this however, from the expense of grinding it, he was obliged to relinquish. The soap-ashes and the chalk holding carbonic acid, and the lime being deprived of it, afford a convincing proof of the superiority of soap-ashes as a manure. The alkaline salt and gypsum that they contain, will render them much better than common calcareous matter, as a top-dressing to every kind of grass.

SECT. III.—THE SOILS ON WHICH SOAP-ASHES MAY BE USED WITH ADVANTAGE.

Upon all strong and cold soils, soap-ashes will prove of infinite service, whether applied to the wheat crop or to cold wet pastures, particularly in *Surrey*. Upon the lighter loams, it is an excellent manure mixed, and in a moist season, its effects are quickly visible and permanent.* Of all the manures tried on *peat-moss*, soap-ashes answered the best.†

Soap-ashes used in cold, wet, spongy, meadow-land, have apparently dried it, and the salts they contain, made it produce much greater crops of grass than before.‡

They are found very good and durable, in *Lancashire*, on dry pastures.§

On a clayey loam, somewhat brashy, and particularly on cold wet pastures, soap-ashes have been used with great success.¶

Poor clay land. Soap-ashes laid on this soil, will form a marle.

Some of the worst land of this sort, has been rendered rich and productive, by the use of this manure.

* *Malcolm's Compendium of Mod. Husb. vol. iii. p. 177.*

† *Wight's Husb. Scot. vol. iii. p. 184.*

‡ *Bath papers, vol. i. p. 133.*

§ *Lancashire Report, p. 127.*

¶ *Communications to the Board of Agriculture, vol. vi. pp. 324, 325.*

On thin, sandy, and hot, and gravelly soils. It is no less remarkable than true, that soap-ashes used in these soils, will make them more firm, enrich them, and will be found to answer much better than stable-dung. Those who have never used soap ashes have erroneously supposed, that they are not fit for dry and hot soils. This, however, is a sad mistake. Soap-ashes, like lime or salt, are, in their nature, a very cold manure, but a very rich one in production. The effects of this manure will be seen by the farmer for seven years after it has been laid on the ground, if used in the same quantity as dung; while the latter would be more exhausted in three years than the former would be in seven.

Soap-ashes applied to light sandy land, operate as a binder, on account of the quantity of lime which they contain. Lime descending considerably below the surface of the earth, in consequence of the repeated rains, a bottom is formed, and other manures are better retained. Several liberal dressings with soap-ashes will be required to form a good bottom; and, indeed, some time also, as most farmers use them and dung alternately.

In addition to these numerous testimonies, may be adduced the authority of that experienced mineralogist and chemist, *Mr. Kirwan*, who considers soap-ashes to be an excellent manure.*

These ashes will prove highly beneficial to soils abounding with undecomposed vegetable substances; as, upon these, the alkaline salt will act powerfully. A confirmation of this fact may be found in the advantage resulting to peat-moss, and low spongy meadows, from the use of soap-ashes.

SECT. IV.—QUANTITY PER ACRE.

From one hundred, to one hundred and sixty bushels.†

Mortimer, in his husbandry, directs eight cubic yards per acre.

Mr. Arthur Young recommends sixty bushels per acre, to be harrowed in with turnip-seed.‡

Six loads per acre, on wet grass land.§

Seven loads per acre, on wet lands,¶ the immediate effect wonderful.

Ten loads on poor loamy land, the effect very great.¶

One hundred and fifty bushels per acre, on arable land, ploughed in with seed.**

It is not surprising that there should be some slight variation in these quantities; it is not more than occurs every day in the accounts we receive of other manures. There must of necessity, be a variation, in proportion to many circumstances, particularly the quantity of the ashes used; but above all others, the difference in the soils upon which they are spread, must occasion a diversity in the quantities established by practice. Great attention should be paid to the age of the ashes, as some farmers have kept them a year, and some have used them immediately. The London ashes being mostly of the same quality, a certain quantity per acre might soon be established.

SECT. V.—CROPS FOR WHICH SOAP-ASHES ARE USED, AND THE MANNER OF APPLYING THEM.

Wheat.—*Mr. Mortimer*, in his husbandry, says, that six crops of wheat running, have been taken,

* *Essay on Manures, p. 18. Seventh edition.*

 ¶ *Ibid. pp. 324, 325.*
 ¶ *Memoir of M. L'Hommiedieu, in the transactions of the agr. society of New-York, vol. ii. p. 324.*
 ** *Memoirs of the Phil. agr. so. vol. ii. p. 324.*

after eight cubical yards of soap-ashes per acre, have been laid on.

By the assistance of this manure, the ground will not only yield a large crop, but may be sown constantly, without fallowing for many years together.*

Soap-ashes are frequently employed as a *top-dressing* to wheat, in smaller quantities than when applied to pasture, and to great advantage. They are very frequently used in Berkshire.†

In the memoirs of the Philadelphia agricultural society,‡ it is stated, that soap-ashes answer best for clover and Indian corn, for *wheat* and *rye*. They are used in an open fallow, put on a the time of seeding, and ploughed in with the seed; and have been put on after the grain has been sown with very great success, but the other method is preferred.

Barley.—When soap-ashes were harrowed in with barley-seed, the benefit was plainly visible.§

Grass land and clover.—One half of a field of clover was top-dressed with soap-ashes—the dressed part of the field produced double the quantity of *hay* obtained from the other.¶

In Gloucestershire, they are much approved for low meadows over-run with aquatic weeds. They improve the herbage, and produce abundance of white clover.¶

Dr. Cogan, formerly of Bath, observes,** that many persons use soap-ashes in a compost, and that in various quantities. One farmer tells me, that it is often used with *road earth*, in the proportion of eighteen loads of the ashes to thirty of the earth per acre, laid on *pasture land* in the spring; but the following very interesting account will evince that the *above precaution is not necessary nor advantageous*. It was transmitted to me by a plain, sensible farmer. I shall state his practice in his own words:—

"My experience of soapers' ashes is confined to the application of it as a top-dressing on pasture land. About twelve years ago, I agreed with a soap boiler for 1,500 tons of soapers' ashes; I then agreed with an hallier, to deliver it on my farm. I used to apply about twenty wagon loads per acre, and a single bushing would let the whole in. I was laughed at and abused by every body for my folly—those wisecracks, alleging that my land would be *burnt up for years*, and totally ruined, &c. &c.; all which I disregarded, and applied my soapers' ashes EVERY DAY IN THE YEAR, Sundays excepted, reeking from the vat, without any mixture whatever.

"I tried a small quantity, (say six acres,) mixed up with earth; but I found it was only DOING THINGS BY HALVES, a practice I never could adopt.

"In defiance of all these prophecies my land NEVER BURNED; but from the moment of the application, became of a dark green colour, bordering upon black, and has given me sometimes more, but never less, than two tons per acre, ever since, upon being *hayned*, (*kept up*,) 42 days, viz. in May and June. The ground I so dressed was twenty-four acres; and I have had one hundred and twenty sheep (hogs of the new Leicester breed) in the ground from August last to this day, (March 2,) but I always allowed them plenty of hay. And although they were culled in August, as the *worst* I had, out of seven hundred

lambs, and selected for *this* ground, on purpose to *rush* them, they are now as good as the best I have."

In the communications to the board of agriculture,* it is stated, that in Berkshire, soap-ashes are applied to coarse, wet, grass land, in the quantity of six loads per acre, UNMIXED, with astonishing effect. The value of this manure is well known in the county of Berkshire.†

Turnips.—When soap-ashes were harrowed in, at the rate of *sixty bushels* per acre, with turnip-seed, the use of them was extremely apparent; the turnips were much better than where no manure was laid.‡

This important fact is further confirmed by the practice of R. Moate, Esquire, near Watford, who found precisely similar effects to result from the use of soap-ashes.

We do not hesitate to affirm that a better manure cannot be used for turnip-ground, as nothing so much promotes their growth. Soap ashes are an effectual preventive for the *black fly* which devours all before it, and which attacks the turnips in dry weather, while they are coming up.—When rain falls, this manure forces the growth of the turnips. If the ground be sown with wheat after the turnips are eaten or drawn off, an abundant crop will be produced. If turnip seed be steeped in the liquor in which soap-ashes have been infused, it will be an effectual remedy for the *fly*.§

In August last, (1811,) a gentleman in Hertfordshire, sowed a close of seven acres with turnip-seed, six acres of which he had previously manured with soap-ashes. Although the seed was put into the ground in a bad time, the six acres produced an excellent crop of turnips; while the single acre which was NOT manured with soap-ashes, afforded no turnips that came to maturity: the few that did come up, were soon destroyed by the black fly and wire-worm.

Potatoes.—Mr. Townly, of Lancashire, tried soap ashes as a manure for potatoes, and found the effect very great. Ground which had NOT been manured, produced one hundred and thirty-four pounds; that which HAD been manured with soap-ashes, yielded *three hundred and eighty-three pounds*.¶

Mixed ashes.—Notwithstanding what has been said respecting the use of soap-ashes UNMIXED, some farmers who are in the habit of making composts, may think proper to use these ashes as a material in forming these heaps, and so far as earth is concerned, there can be no objection to the practice. When these ashes are applied to *arable* crops, it seems advisable to sow and harrow them in, previously to sowing the seed, which will prevent the action of any caustic quality on the germination of the young plant. The same circumstance will point out the *autumn* as the proper season for applying them on grass lands, though experiments may be tried with them early in *spring*.

Soap-ashes are eagerly sought after at Liverpool, Hull, &c.; where they are usually mixed with pond, ditch, and river mud, and used in about four months afterwards. This, also, was the method pursued by Robert Thornton, Esq. of Clapham, who used ashes for several years, and thereby greatly improve a very *sour pasture*.

In Cheshire, soap-ashes are usually *ploughed into the land*.

The following is the quantity of *mixed* ashes per acre, used in Surrey.*

Upon strong loams for *wheat*, ten to twelve cart loads.

Upon light loams for ditto, eight to ten ditto.

Ditto ditto *barley*, six to eight and ten ditto.

Ditto ditto *turnips*, six to eight ditto.

SECT. VI.—PRICE.

The price of soap-ashes, when introduced from Flanders about two hundred years since, was as high as *three or four shillings* a load.

About thirty years since, soap-ashes were imported into Liverpool from Dublin; but such is now the increasing value and extensive use of this article, that they are all used in Ireland.

In the year 1777, the Essex farmers would readily give from *twelve shillings to a guinea* for a wagon load, and fetch it five or six miles, and find their account in so doing.†

At Hull, ten years since, the soap-makers *paid for having their ashes taken away*; they are now sold for *twenty four shillings* per cart load.

At Ipswich, *twenty-five shillings* per cart load, besides carriage.

In Suffolk, where the soap-makers are farmers, they will never sell any.

SECT. VII.—EFFECTS. See also, SECT. V. CROPS.

The various effects on different crops, will be noticed in the following order:

Wheat.—Mr. Thorne and Mr. Knivett, two principal farmers near Ealing have used soap-ashes on *arable* land, with great success and advantage. They have taken the produce of one large soap house between them for several years. These ashes produce clean crops, with neither smut nor weeds; and not only effectually destroy, but also prevent, the approach of the *wire-worm* and *slug*, which are so injurious to wheat.

From *thirty five to forty* bushels of corn, per acre, have been taken off land that had been ashed, and had produced a crop of wheat, and two crops of clover; and, that without any other help than a *single dressing of soap ashes*. The land was so poor before, it could not have produced five bushels per acre.‡

M. L'Hommiedieu, in a memoir, presented to the agricultural society of New-York, states, that *ten loads* of soap-ashes on poor loamy land, will, in general, produce *twenty five* bushels of wheat, per acre, which defrays the expense of raising the crop by more than one half. The land is then left in a state for yielding a crop of hay, containing from one and a half, to two tons of hay, per acre, for several successive years.

Grass and clover.—Mr. Sherwood of Abbott's Langley, has used soap-ashes with very great success, when mixed with composts.

Mr. Mansfield, near Epping, had a poor sour pasture, that would not mow, nor would stock eat it; a total change was effected by the use of soap-ashes. The soil was strong, wet, and heavy.§

Lord Suffolk, a member of the board of Agriculture, possesses a grass field in Wiltshire, which was manured with soap-ashes nearly twenty years since, and the improvement was very great, and has continued so ever since. A line may be now drawn where the soap-ashes were used.

Robert Thornton, Esq. of Clapham, in some experiments on very sour, bad pasture, amounting to seven acres, found that these ashes added one load of hay, per acre, to the crops. It pro-

duced a sweet pasture bottom, with white clover.

Mr. Packman, of Rainham, in Kent, had a sour and coarse pasture; the sheep would not eat, and always had the rot. This pasture having been well manured with soap-ashes, produced good and sweet herbage; and the sheep became as healthy as any in the county.

In Berkshire, Mr. Billingsly says,* he has applied soap-ashes on very coarse, wet, grass lands, in the quantity of six loads per acre, unmixed, with an astonishing effect. The rushes disappeared, and gave place to a luxuriant crop of trefoil; and the benefit was so obvious, three or four years after the application, that the eye could trace the line of separation. He pronounces these ashes to be much superior, in such cases, to every other manure.

Another gentleman says,† "on pasture ground inclined to be wet, though not sufficiently so as to require under-draining, I have seen the effect to be very striking, particularly in the second year. I am convinced that wet lands are preferable from the following fact. I once covered four acres of upland with these ashes, about seven loads per acre. The immediate effect was wonderful. The grass grew famously, and I cut, certainly, thirty-five hundred weight of hay, per acre; the grass came on equally well. The best time of hauling out is, evidently, when the ground is open, and the rain does not fall in such torrents as to wash it away."

A Gloucestershire correspondent, in the *Farmer's Journal* for March 30th, 1812, narrates some interesting facts respecting the use of soap-ashes on old, worn-out pasture land which are a strong confirmation of the circumstance related in pp. 289-90. This correspondent observes that it is now sixteen years since he completed the dressing, and that this piece of land is, at the present moment, the best in the parish. He also advises the draining of the land before the soap-ashes are laid on. This, of course, applies only to such lands as by their excessive moisture, require the operation. The correspondent was rewarded in the year 1797, by the *Bath and West of England Society* with a pair of silver goblets.

Soap-ashes used on *sour pasture land*, will produce more hay or pasture than any other manure; and are equally good for dressing upland grass. If laid on in winter, this manure will produce a large crop of hay in the following summer, and will afford a greater quantity in a subsequent year. It will also destroy the COUCH GRASS, rendering it easy for the farmer to throw out the roots.

A better article than soap-ashes cannot be laid on clover, in winter, and early in spring. This manure is double the value of coal-ashes, and will not cost half the money. Coal ashes are not only very dear, but much inferior in quality, compared with what they were formerly. This arises, in some measure, from the immense quantity of bricks made in the vicinity of London. All the coal-ashes that can be procured, are sent to the brick makers, who pay a great price for them, and the farmer gets mere sand and dirt. If the farmer would once use soap-ashes, he would buy no more coal-ashes; for the former will not only improve his crop of clover, but greatly increase the wheat crop after the clover.

It should be particularly remembered, that the effects of soap-ashes will not be so evident in the first, as in the subsequent years; and that these beneficial effects are not sudden and temporary, but certain and lasting.

Kitchen Garden.—No gentleman or gardener,

who wishes to see his plants flourish, should be without soap-ashes, if he can obtain them.—Where they have been freely used, they will destroy all vermin, and prevent moles from turning up the ground. These ashes will entirely eradicate the grub, which gets into the root of young cabbages, and occasions the CLUB ROOT,* or large botches and warts. This destructive evil, which greatly impedes the growth of cabbages, cauliflowers, brocoli, &c. is never seen where soap-ashes have been used in proper quantities. They prevent weeds, and improve the vegetables in flavor.

Peas and beans, in fields and gardens, will be completely protected from the devastations of rats and mice, by the liberal use of soap-ashes.

Worms and slugs.—In gardens where dung is profusely employed to force crops of lettuces, radishes, onions, and the like, those crops are very often destroyed by grubs and wire-worms. Were the gardener to lay up his dung in a heap, and cover it over with an equal quantity of soap-ashes, and let it remain for a month or six weeks, mixing it well together, he would have lettuces early, and of a large size, which would not be injured by worms and slugs.

Snails.—A gentleman at Fulham, who had taken great pains in cultivating a large kitchen garden, was greatly pestered with snails; so much so, that he had collected a bushel in a morning, and could not keep them under. This evil was to be attributed, in some measure, to a quick-set-hedge, which separated his land from some adjoining grounds belonging to a market-gardener. Soap-ashes were spread on a strawberry border, next the hedge; and, in twenty-four hours, there was not a snail to be seen on the border, or in the hedge. These enemies to vegetation did not return that summer or autumn; and, by occasionally using the soap-ashes, the ground is now entirely freed from snails in the most wet and hot seasons.

Wall Fruit.—If the snails are carefully picked off the wall fruit, and a quantity of soap-ashes spread on the border, under the wall, the snails will never travel over them. At the same time, an excellent manure will be provided for the borders. The truth of this statement may be easily ascertained. Place a snail upon a few of the soap-ashes; it will immediately quit its shell, and perish.

Plants.—Limed soap-ashes have a strong attraction for carbonic acid, which they separate from the atmosphere, and thus render an important service to plants. These ashes also absorb, with avidity, the night dew in hot weather, and furnish moisture for vegetation during the day.—The following singular instance will illustrate this remark. At Marble Hall, (Surrey) some soap-ashes were, accidentally, placed round the trunk of a poplar tree, to the height of four feet, and remained in that situation, for the space of three years; on removing the soap-ashes, it was discovered, that seven new roots had struck into them, from the trunk of the tree.

Gravel walks.—Soap-ashes laid three or four inches in depth previously to putting on the gravel, will bind the walk, render it hard and firm, and effectually prevent the worm from working through.

* Prefixed to the pamphlet are two coloured plates of Brocoli roots; one taken from one-half of a bed well dressed with prepared soap-ashes; and which had produced fine healthy plants, with very few weeds. Another plate representing a root from the other half of the bed, dressed with dung: four out of five plants were affected by the club root, and thrown away; being in a fungous state. The bed was also full of weeds.—Editor.

Parks, Inclosures, &c.—Soap-ashes have been used with much success in parks and meadows.—For lawns they are excellent, as they produce a close, thick, clover bottom. Steeped in water, they will destroy the worm in lawns. Manure being so very scarce, they are particularly applicable to new inclosures.

Conclusion.—What an advantage would it be, if, instead of being sparing of manure, farmers would endeavour to increase their number, and to render them more beneficial, by employing them in a more effectual manner. Were this part of rural economy better attended to, and more carefully considered, we should see many places in a state of cultivation, which, on account of the bad quality of their soil, have, hitherto, resisted all our labours to render them fertile.

The expense of rent and taxes to the farmer, is always the same, whether his crops be large or small. How important, then, is manure! but, infinitely of more consequence is it, to possess a manure, which will last for a long time and be reasonable in price. If the farmer obtain this manure, (and by using soap-ashes he will obtain it,) both expense and time are saved; and crops that would scarcely pay their own charges, are made abundant and profitable.

A good dressing of soap-ashes will last in the land, three times as long as a dressing of dung.

REMARKS.

The editor is indebted for the above essay to the author, an attentive correspondent in London. The utility of leached ashes as a manure is well known in New Jersey and on Long Island, and by a few farmers in the vicinity of Philadelphia.—The price of a single horse cart load at the soap-boilers is two-thirds of a dollar; it is then carted to the wharf (if destined for New Jersey,) and put on board sloops and flats, and taken to the landings up and down the Delaware, and thence hauled as far as seven miles by the farmers.—Great quantities are also taken to Long Island every winter, and much of the improvement there in the lands, and in those of New Jersey, has arisen from the use of this article. Three years since, the editor was informed by Mr. A. Taylor, of Buck's county, of the good effects of the ashes in destroying worms and other insects, a fact strongly proved in the preceding essay.—Knowing the value of this manure, he could not but see last summer, with astonishment and regret, TONS of it not used, near several pot-ash manufactories in Saratoga county, New York, although it might have been had free of cost, and the lands were in great want of it: twelve and fifteen bushels of wheat having been stated to him as the common product per acre!—Editor.

The present price at the soap factories in Baltimore is 5 cents per bushel.—Ed. Am. Farmer.

INTERNAL IMPROVEMENTS,

In which the states of New York, New Jersey, Pennsylvania, Delaware, and Maryland, are more immediately interested.

HUDSON AND DELAWARE CANAL.

State of New York,

In Senate, April 22, 1823. §

Whereas the legislature of the state of New Jersey has ordered the survey of an inland navigation, to connect the rivers Hudson and Delaware, a communication that cannot fail to produce the most beneficial effects upon the agriculture, manufactures and general industry, not only of that, but of this state.

And whereas the legislature of New York, is desirous of giving a public testimonial of

* *Conn. mun. Board of Agr. vol. vi. p. 323.*

† *Ibid. pp. 324, 325.*

probation of this branch of the great system of internal improvement:

Resolved, (if the Assembly concur) That the canal commissioners shall send to the line of the above mentioned contemplated canal one of the Engineers in the employment of this state, (if in the opinion of the commissioners one can be spared,) for the purpose of making a survey and estimate thereof, under the direction of the commissioners appointed by the state of New Jersey, to whom he shall report, as also to the canal commissioners of this state.

Ordered, that the Clerk deliver a copy of said resolution to the Assembly.

(Signed) JOHN F. BACON, Clerk.
State of New York,

In Assembly, April 22d 1823. }

Resolved, That this House do concur with the Senate in their said resolution.

By order.

(Signed) E. LIVINGSTON,
Clerk of the Assembly.

CHESAPEAKE AND DELAWARE CANAL.

As the public attention has been drawn to the Chesapeake and Delaware canal, the following information may not be unacceptable.

In 1801, a company of gentlemen were incorporated for the purpose of making a canal to connect the tide waters of the Chesapeake, with those of the Delaware bay.

In 1803 and 1804, Benjamin H. Latrobe, Cornelius Howard and John Thompson, surveyed almost every part of the peninsula which appeared suitable for canalling, and maps, plans and estimates were made of various routes for this canal; which being laid before the board of directors, they decided in favour of a route, which commencing at Welch Point on Elk River, about six miles below Elkton, crossed the peninsula obliquely in a north easterly direction, to Mendenhall's landing on Christiana creek, about four miles above Wilmington, from whence to the Delaware, a distance of six or seven miles, this creek has a depth of 10 or 12 feet of water at high tide. A canal along this route would be about 21½ miles in length, have a summit level of about 13 miles in length, and would require 20 locks, including the two tide locks. In 1822, Wm. Strickland, of Philadelphia, surveyed a route for this canal, which commencing on the Delaware, about 40 miles below Philadelphia, at a place about half a mile above Fort Delaware, erected on Pea Patch Island, crossed the peninsula nearly at right angles, and arrived at Welch Point on Elk river, by a route 17¼ miles in length, three miles of which would be through Back creek, where the water is from 8 to 24 feet deep at low tide; a canal following this route would have a summit level five miles in length, and requires 18 locks, including the tide locks.

In 1823, John Randel, jun. of Albany, surveyed a route for this canal, which commenced and terminated near the same points with that laid out by Mr. Strickland, would have the same length, but its summit level would be one mile in length, and 16 locks would be needed, including the two tide locks.

Each of these plans depended for their supply of water upon Elk river and White Clay creek, both of which could be carried to the canal as laid out by Mr. Latrobe, by two feeders, which, together, would amount to a length of 17 miles; to the route laid out by Mr. Strickland, by 20 miles of feeder, and to the route laid out by Mr. Randel, by 22 miles of feeder.

In 1804, Mr. Latrobe estimated the supply of water which could be derived to the canal from the river, at 190 locks full per day, which would be sufficient for the passage of about 38 vessels

across the summit. In 1807, he estimated the daily supply at 144 locks full, which would pass 29 vessels daily. In 1823, Mr. Randel measured this stream, and found its averaged daily supply for the whole year, amount to only 79 locks full, which would pass 16 vessels across the summit; but that in the months of July, August, September and October, the daily supply was only 30 locks full, and would be competent for the passage of 6 vessels across the summit, or 3 each way the whole length of the canal. The supply of water from White Clay creek will be about equal to that from Elk river.

The route recommended by Mr. Randel is located at a place where the tide of the two bays have originally approached within 4½ miles of each other, and were separated by a hill consisting apparently of gravelly loam, having an averaged height of only 35 feet above the level of the tide. By the plan last mentioned, this canal was to have been carried upon the level of the tide, from which it would receive its supply of water to the east and west foot of this hill, and the locks which were required to surmount this hill, were to be fed from the beforementioned streams.

The plan which he recommends as the most eligible for this route, is to cut down this hill to the depth of the canal below the level of flood tide; to have a tide lock at each bay, which would make still water, and prevent a current in the canal, and to feed the canal from the Delaware, having the ocean for its reservoir. Should this plan be adopted the extra cost of deep cutting would, Mr. Randel thinks, be more than balanced by the saving in making 17 miles of feeder, 18 locks, 100 acres of reservoir, purchasing from 7 to 10 water-rights, together with aqueducts, culverts, &c. with the cost and disastrous contingencies to which they are liable, even though no account be made of the abundance in the supply of water. And should the deep cutting prove to be, as its external surface indicates, a canal for ships can be made to connect the two bays, at a cost not exceeding that of one for sloops, if carried across the hill by locks, and fed by the above-mentioned streams.

Shafts have not yet been sunk to test the kind of earth to be removed from the deep cut. This Mr. Randel is to do as early in the season as his other engagements will permit.

Benjamin Wright, of Rome, is also appointed to explore this peninsula, and report for this canal the route which he may think most eligible. Should this latter plan be adopted and vigorously pursued, in four years time ships might pass from Philadelphia to sea by the way of the Chesapeake. The water communication between Philadelphia and Baltimore would be shortened about three hundred miles; and the produce from the Susquehanna, when at Havre de Grace, would, by this route, be within about twenty miles as near to Philadelphia as to Baltimore.

When this canal shall be completed, there will only remain the New Jersey canal to be made, to give an inland water communication from the Capes of Virginia to Rhode Island, which in time of war would be invaluable.—This canal was laid out by Mr. Randel in 1816, (twenty-nine miles in length, and sixty-eight feet above the tide,) under commissioners appointed by the legislature of New Jersey. It was intended for the passage of sloops, but could be made of dimensions competent for the passage of ships, at a cost not exceeding about 25 or 30 per centum above that of constructing the Chesapeake and Delaware canal, and would shorten the water communication between the cities of Philadelphia and New-York about one hundred and eighty miles.

If in addition to these canals, the ship canal projected by E. C. Genet, Esq. and laid out by

Mr. Randel in 1819, under commissioners appointed by the legislature of New-York, be made from Albany, a distance of thirteen miles, to the deep water at New-Baltimore, (which would not exceed about half of the cost of the Chesapeake and Delaware canal,) then the termination of the Erie and Champlain canals at Albany would be accessible by ships as well as coasting vessels, by an inland communication from any port between Virginia and Rhode Island.

It will at once be perceived, that as the water communication between Virginia and Lake Champlain would be nearly in a northerly direction, every mile you advanced along it would give a change of latitude, and a consequent change in the productions of the earth, as well as in the wants of the inhabitants. The advantages which would result from canals giving such facilities for the exchange of the products of different climates, and of friendly intercourse between the citizens of different states, could not fail to be productive of the most salutary consequences, both in a pecuniary as well as moral and political point of view.

[Albany Daily Advertiser.]

In one of the papers of the Spectator, upon the miseries arising from the gloomy forebodings of dreams, and sombre thoughts of death, known to be written by the celebrated Mr. Addison, is the following:—

"I know but one way of fortifying my soul against these gloomy presages and terrors of mind, and that is by securing to myself the friendship and protection of that Being who disposes of events and governs futurity. When I lay me down to sleep, I recommend myself to his care; when I awake, I give myself up to his direction. Amidst all the evils that threaten me, I will look up to him for help, and question not but that he will either avert them, or turn them to my advantage. Though I know neither the time nor the manner of the death I am to die, I am not at all solicitous about it; because I am sure that he knows them both, and that he will not fail to comfort and support me under them."

These were the sentiments of that eminent man, who so much instructed, amused, and improved the age in which he lived, and whose name is handed down to posterity. The quotation I have made is in the commencement of the Spectator, and I find, on reviewing his numbers for Saturday, that they contain so fervent a strain of piety, and so beautiful a system of good morals, and are conveyed in so impressive and agreeable a manner, that I cannot but believe they would, if more generally read by young persons, greatly tend to their advantage.

The mind of one not estimating the importance of a life of piety, and under the anxieties of a life of the opposite course, would, I should think, receive some salutary impressions upon the subject, when he comes to see how exactly the death of Mr. Addison accorded with his opinions while living; for we read, and the fact is universally acknowledged, that this great man, who, in 1710, penned these sentiments for the edification of the public, did, in 1719, upon his death bed, attest the truth of them: for, on that solemn occasion, he directed the young Earl of Warwick, his stepson, to be called to him, who, desiring with great tenderness to hear his last injunctions, was answered—it is to shew you how a Christian can die! and then closed his eyes forever.

What reflections ought we to draw from this lesson? I think we ought to ask ourselves seriously if we are in this state of serenity. If we are not, we ought to endeavour to attain it. It may be obtained by following the precepts of Him who loved us more than we love ourselves, and it will in the end be of more value to us, than all other acquisitions.

IMPROVEMENT IN THE CONSTRUCTION OF BEE HIVES.

Newburyport, March 3d, 1823.

JOHN S. SKINNER, Esq.

Dear Sir—I observed in your paper, No. 48, Vol. 4th, an extract from the National Gazette, recommending the method practised in Germany, of gathering honey, as being easier than that of India, and more merciful than that of this country, which induces me to think that Blake's patent bee hive, had never been examined by the writer—as honey can be taken from a hive of that kind, and if too much be taken the bees

can be furnished without using in one case, herbs, gloves, cap and mask; and in the other lifting the hive to feed them from a saucer—and besides it is well known, that most of the white comb is put in the top, therefore in taking out a box, as described by the plate, and replacing it by another, the bread, &c. of the bees is not disturbed. I enclose you a drawing of the hives, a copy of the schedule referred to in his letters patent, and making part of the same, containing Mr. Blake's description of his improvement, in the construction of the bee hive.

“This improvement consists in the construction of a hive, so that any quantity of honey, from a very small portion, to nearly one-third part of the whole, may be extracted at any time from the hive, without any serious injury to the bees, or without the destruction of any of the lives of those valuable little animals, and so that whenever there is a deficiency of honey for the support of the bees, or no more than is necessary for the purpose, it may be supplied or taken away at pleasure. Let a square box, of the size of the common hive, or any other convenient size, be made of pine, or any other suitable wood.—Let a number of bars be placed horizontally, at about one-third part of the distance, from the top of the hive, so that the space between each bar shall be about two-fifths of an inch. Let any number of separate boxes, say nine or more, or less, be so made, that they shall fill up the whole

space above the bars mentioned, with any convenient thing inserted in the tops of the boxes, for the purpose of extending them at pleasure, and let there be a cover to be placed over the whole, in such a manner, as may be thought most convenient.”

(Signed) EDWARD BLAKE.

I would also observe, that I have several of those hives preparing, and am confident, they will answer a valuable purpose—the cost is very trifling, and those who purchase the rights of vending to the several states and counties, charge only about \$2, to each farm or individual for the privilege. Mr. Blake's residence is in the town of Hartford, County of Oxford, state of Maine, unless he has removed within a few months.

Respectfully, your obedient,
BENJAMIN POOR.

From the National Gazette.
BEEES.

I have seen on the great heath of Lunenburg in the Hanoverian dominions, hundreds of hives that were carried there from distant places in the spring of the year, for the bees to pasture on the heath flowers: herdsmen attend them, and in the autumn they are taken home again.

The mode of securing the honey is this: early in the fall the bee father (as the person who cultivates bees is called,) protects himself with gloves and a kind of cap long enough to hang over his neck and shoulders, and which has a wire mask—and in dark rainy weather, or early in the morning or late in the evening, when all the bees are at a home, he turns the hives upside down—a match made of dry herbs, such as rue wrapped in tow and linen, which burns without flame and makes a great smoke, is lighted and the smoke blown upon the hive, and gives him an opportunity of taking what quantity of honey he thinks they can spare, leaving a sufficiency for provision. Should it happen that the bee father takes too large a tribute, or that an early winter

prevents the bees from replenishing their stock as expected—they then are regularly fed with a composition consisting of sugar, honey, wine and water, boiled together, which is put in a saucer under the hive.

TO DESTROY THE BEE MILLER.

This troublesome insect is making great ravages among the bees in this vicinity. A subscriber has requested us to state that he had discovered an effectual method of destroying them, which is as follows: To a pint of sweetened water (sweetened with sugar or honey,) add half a gill of vinegar; set this in an open vessel on the top of the hive, and at night, when the miller comes to his work of destruction, he will prefer this composition, and diving into it, will immediately drown. This simple method, our correspondent assures us, is certain success. At all events, it is worthy of attention; and we would recommend to the owners of bees to make a trial of it.—*Lake George paper.*

TO THE EDITOR OF THE AMERICAN FARMER.

Dear Sir—Since I wrote you upon clay and sod burning, I have perused the book you kindly sent me, published by Mr. Gresenthwaite, entitled “Theory of agriculture,” in which sod burning is condemned, “because every hundredth part so burnt, is reduced to ten, and consequently ninety parts are lost—paring and burning have been approved, from the supposed value of ashes, left after such an operation, but the approbation will be very much diminished, when it is remembered that burning adds nothing to those ashes. That it removes all the oxygen, hydrogen, and ninety nine parts out of every hundred of carbon, and the saline bodies discovered before—existed before in the entire vegetable.” I know not to what chemical work he can refer, to prove, that a decayed vegetable will leave a salt. We plough our land, to destroy blue grass, as it is termed by frequent exposure of its roots; do they leave any thing like burnt roots, turned to ashes? this must be proved, before his conclusions can be verified—in my woods I find stumps and sticks, which would all decay, and be washed by heavy rains into the Potomac—by burning these I surely gain; on my farm, there is the remains of a brick kiln, where the vegetation is always luxuriant, on this spot bricks were made 20 years ago—I can only attribute the great luxuriance of vegetation there, to the bricks absorbing the moisture of the nocturnal dews, and giving them out every day—if you weigh a salmon brick, in the summer, after it has been exposed to the sun, and weigh it again early next morning, and you will find that it has increased very much in weight—I think Sir Humphrey Davey, (his work I cannot now refer) says that a good soil may be ascertained by a thermometer, for if it heats quickly, and cools quickly, it is a good soil. That alkaline salts attract moisture, is ascertained by taking the stopper out of a bottle, in which it is contained, for the salt will soon be all dissolved—how the ashes operate upon the substances in the soil I know not. Mr. Beaton has published his facts, and on perusing his work, having followed his practice, and having experienced its good effects, I communicated them to you—facts must supersede theories—my neighbour had ears of corn on one stalk, where he applied burnt clay and ashes—stable manure causes weeds, and also soon evaporates during our hot summers, and under repeated ploughings for a corn crop, it also frequently burns—whereas, burnt clay or burnt sod and ashes, do not. My neighbor, a superior practical farmer, informs me, that the last mentioned manure operates more favorably here than in England or Ireland. I have written these suggestions, lest the reader of the “Theory of Agriculture” above referred to, should deter them from making experiments to confirm or invalidate Mr. Beaton's plan.

Let me avail myself of this occasion, to return my thanks for the various seed you have sent me; these attentions are a proof of your zeal to benefit your country, by disseminating whatever promises to be useful. The congress has 200 acres in Washington city, which have remained a waste—if a scientific gardener had been placed on this ground after it was enclosed, what useful experiments might have been made—what plants and seeds might have been brought by our patriotic captains of ships, and what supplies your activity would have afforded. Thirty years have elapsed and these acres remain a waste. Pardon this digression—my heart dictated and my hand obeyed. My neighbor says, that he finds burnt sod or clay preferable to the best stable manure.

THOMAS LAW.

FOR THE AMERICAN FARMER.

FLAX DRESSING MACHINE.

To WM. M. BARTON, ESQ.

Dear Sir,—I beg your acceptance of a sample of flax for the inspection of the "Valley Society of Virginia." The bleached sample is from flax that was water-rotted, the dew-rotting being found not to answer for that process. Of the dew rotted parcel, I must remark, that the quality of the flax is not considered to be the first—all of this year's crop being very inferior, and all of that which is dew-rotted, at any time, whatever the quality may have been previously, sustaining so much injury from the process as not to entitle it to first rate, however well cleaned it may be. I cannot, therefore, present this as very fine in quality, but beg your attention to the dressing of it. This was done by a machine of small dimensions, simple construction, and exceeding durability, invented by Mr. Rodman Goodsell, of Oneida county, New York. With this machine, driven by one horse, a man will break, hatchel, and dress clean enough for the distaff, 100 lbs. per day—and with the same thresh 100 bushels of grain per day, the latter without one cent extra expense. As your county is celebrated for its wheat culture, Mr. Goodsell and myself have determined to send one of them to you in the course of a month. Should it arrive in time for your March meeting, please to do us the favor to call the attention of the gentlemen of the society to its performance, and drop me a line of the impression it produces. The price of each machine is \$100—that is, we furnish the machine and give the right to use it for that price, the purchaser paying, of course, the expenses attending the erection of the same, together with such incidental charges as may attend its transportation from the place where it may be manufactured.

I am, with great respect,

Your obed't humble serv't,

SAM'L SWARTWOUT.

New York, 6th Feb. 1823.

The Flax Machine may be driven either by water or horse power.

One horse is sufficient to turn one or more of these cylinders. The cylinder for dressing or threshing requires to be driven at the rate of about 160 or 170 revolutions in a minute. Any millwright will make the calculations for the size of the large wheel, when intended for water power. For horse power, our large horizontal wheel attached to the horse shaft, is 12 feet diameter—around this we put a strap, 5 or 6 inches broad, of harness leather—this strap runs round the shaft or axis of the second large wheel, upon a whirl 18 inches diameter. There is a wheel for a strap or band upon one end of this axis 6 feet diameter, over which another strap of the same breadth and thickness, as that which runs over the large wheel, descending into the room below, and is attached to and runs over a small whirl fixed upon the axis of the cylinder. This latter whirl is 8 inches diameter. The above calculations are made upon the supposition that the horse walks three times round his path in a minute—the diameter of his walk being 24 feet.

AN EXPEDITIOUS METHOD OF MOVING HAY.

Culpepper County, Va. July 7th, 1821.

MR. SKINNER,

In the last number of your American Farmer, one of your correspondents has described an expeditious mode of drawing hay to stacks, in use in Hardy county, Va. The same method was formerly adopted by some farmers in this county ;

but that now most generally used here, seems to be so much more easy and expeditious, that, perhaps, a description of the mode may deserve a place in your useful paper. So slow is the progress of even small improvements in agriculture, and labor saving operations, that it is probable many of your readers have never seen this-practised.

The hay being cocked, and the stacking about to be commenced, a hickory pole ten or twelve feet long, is procured, and the knots all well trimmed off. The larger end of the pole should have a hole bored in it, to admit a clivis pin, and to which the swingle tree of the horse in gear, is to be attached by means of the clivis. The smaller end of the pole should be brought to a smooth point, so as to admit its being run under the cocks of hay, and a leading line should be attached to the large end, about where the clivis goes through. A boy, holding this pole in one hand, thus fixed to the horse, and guiding the horse with the other, comes to the cock of hay. The pole is immediately disengaged, by taking out the clivis pin—the boy then runs the pole under the cock, till the sharp end has passed a little distance, say two or three feet on the other side: he then throws the line attached to the large end of the pole, across the top of the cock, and by a slight bow knot fastens it to the pole on the other side, taking care to have the rope placed exactly over the middle of the cock—the horse is then attached to the pole by fixing in the clivis; just as the horse sets off, it is necessary to take hold of the pole just behind the place where the rope is tied to it, to prevent its slipping, until the cock moves, when there is no longer any danger. After getting with the cock to the stack, without its being necessary even for the horse to stop, the knot is slipped, and the horse goes on with the pole, leaving the cock in nearly as good a situation as when it was first touched. There is less work for the hand-rake after the cocks thus drawn, than in the mode described by your correspondent, and the draft is much less. One horse will draw, with ease, cocks of three hundred weight, and as fast as two can pitch up to one stacker. The draft is less, in consequence of the hay next the horse being somewhat raised from the ground, and the friction against the ground greatly reduced.

Your constant reader,

A YOUNG FARMER.

The date of the preceding shews, that though we may, for a time, overlook good suggestions, we do not altogether lose sight of them.

Ed. Am. Farm.

TO THE EDITOR OF THE AMERICAN FARMER.

Dear Sir,

A farmer in Anne Arundle county, (a friend of mine) said to me a few days ago, he wished I would again say something to you about the use of plaster and slacked ashes in planting corn. I told him I had already said enough on that subject, and if farmers would practice it agreeably to my method, I was convinced they would be benefited by the experiment, and be corn-sellers instead of corn-purchasers; and lest it may have escaped the notice of some, I will again at his request repeat my practice, which if you think proper, you may notice in your most useful paper.

Last fall twelve months, I had my corn ground ploughed as deep as it could be turned by two horses, and left it exposed during winter to frost and rain; in the spring, it was as light as an ash heap. I again gave it a deep ploughing, then listed and planted my corn, (as early as it was prudent to do so,) planting a large handful of plaster

and slacked ashes mixed; one-third of the former and two thirds of the latter, which was dropped on the seed and covered up together. The early spring showers of rain were absorbed by the loose ground, and the plaster and ashes brought soon into action upon the young plants, which grew off finely, and my corn was made before the dry weather in July and August could affect it, and from twenty-five acres of ground, I made 120 barrels of corn, measured and lofted; from which I was able to sell fifty barrels from the loft, and had sufficient for the year's use. I don't know of any farmer within ten miles of me that made corn sufficient for their families, owing to the great draught last summer, and am convinced, had they practiced the same method, the same success would have attended them. G. W.

STRAWBERRIES.

Frederick County, (Va.) June, 1821.

Sir,—On the subject of that delicious fruit called the strawberry, I wish to solicit through the medium of your journal, some information. My vines are thick and luxuriant; they blossom well, and then blight. This has been the case, for the three last years: how can the blight be prevented? I hope that some of your numerous readers will be able to give me the required information.

Very respectfully yours,

R. K. M.

UNIVERSITY OF MARYLAND.

It is with feelings of pride and exultation that we observe not only the annual increase of her students, but also the appearance and conduct of the young gentlemen, which demand the warmest approbation of our citizens. We were delighted to remark during last session that the fact of being "a student of the University" was considered by our best society, as a sufficient passport to their houses and hospitality. The Commencement took place on the 5th instant, and we were much pleased to find the chemical hall fitted up very handsomely for the occasion, and crowded at an early hour by a highly respectable audience, made infinitely more interesting by much of the youth and beauty of the city and neighbourhood, the gay decorations of whose dresses relieved the sombre solemnity of the scene and produced a charm and an interest which the society and approbation of women alone can impart.

The procession entered the hall at eleven o'clock, and took possession of the seats allotted to them. First, the Graduates, two and two—the Dean of the Faculty of Divinity, followed by the Professors, two and two. The Dean of the Faculty of Law, followed by Professors in the same manner. The Dean of the Faculty of Arts and Sciences attended in the same way. Then the Dean of the Faculty of Physic. On Professor DAVIDGE (the father of the institution) and Professor PATTISON making their appearance, they were received with three distinct bursts of applause by the whole assembly. The Rev'd Provoost followed the Professors, and the Regent closed the procession.

The Professors having taken their chairs with their respected Dean (Dr. De Butts) at the head of the table, Dr. De Butts read the "mandamus," and the Right Rev. Bishop followed by prayer. The young gentlemen were then asked a few questions by the learned body, touching the subject of the different thesis: and having received their degrees, the commencement concluded with solemnity. We cannot close this article without adverting to the complete realization of the sanguine expectations which we have all along entertained in regard to the rapid growth

most flourishing institution; and we are glad to observe the pride—the well grounded pride, which the whole population of our state place in this their school, which is not second to any in our country, nor perhaps in the world. I shall only add—"Palmar qui meruit firat." Our readers will be able to judge of the rise of the school by the following list taken from the books of the University:—

In 1820—21, the number of the students	115
In 1821—22, - - - - -	247
In 1822—23, - - - - -	503

[American.]

Editorial Correspondence.

GUINEA CORN—BEANS, &c.

Dr. Skinner—Accompanying this you will receive a head of guinea corn, and a small parcel of the snap bean for table use, both of which Mr. R. informed me he did not recollect to have seen before.

The guinea corn is extremely productive—it is, as you will perceive, very white and compact in the ear. It is very good for table use in lieu of the small hominy, and is the best food for poultry. It is also valuable food for horses. It branches from the root, and every stem will bear an ear on the top—it suckers from almost every joint, which also bears an ear on the top, and is, in all seasons, perennial. In the year 1821, in the course of my travelling through the state of Alabama, I met with the beans. They are planted in the rich lands of that country, in the corn hills, and run up the stalk. I think, however, they are superior to the corn—the weight of vines and leaves are apt to break down the corn. The beans are very tender until the hull becomes yellow, and the strings are much easier separated from the bean than any other kind that has come within my knowledge. I planted them in my garden and set up poles for them to run on—they are very prolific, and if not known in your neighborhood, will be a great acquisition to the kitchen garden.

The beans and corn have been distributed.—*Ed. Am. Farmer.*

Bridgeton, W. N. Jersey, April 21, 1823.

Sir,—It would give me pleasure (and I have no doubt but many others would participate with me,) to see from the pen of Samuel Black, of Delaware, the writer of an essay published in the second volume of the Farmer, a description of his experiments in farming for the last four years, with a statement of the result both with respect to his crops, and the improvement of his farm land. If his theory, as stated in that essay, will stand the test of experiment fairly conducted, he must have by this time eight inches of good soil and that not only without expense, but with a handsome profit. Now if his former calculations are established by experience, it will add new vigour to the exertions of enterprising improvers and make them look forward to Mr. Black's third course, which is to produce twelve inches of good soil, as an object not altogether beyond their reach. If Mr. Black will practically show that twelve or even eight inches depth of soil, naturally sandy, can be made good soil, and that without expense, he will perform a service to his country which ought never to be forgotten.

That twelve inches of soil and even more, can be made in some soils, I know very well; but as fearful it will not be easily accomplished in a sandy soil. I paid a visit last week to the seat of John Hare Powel, Esq. near Philadelphia, where

I saw a plough drawn by two pair of fine large oxen running to the depth of seventeen inches, which I ascertained by actual measurement in different places; this was in an elevated situation, and Mr. Powel informed me that the soil was not naturally deep, but had been made by himself—this however was not a sandy soil.

In an editorial note on the essay of Mr. Black's, you state that much of the soil in the vicinity of Baltimore, requires large supplies of manure annually repeated; or in the language of farmers, it will not hold manure. Can you inform me, whether the capacity of this soil to retain manure has been increased by the application of lime, which from another note, I learn has been very bountifully applied by some of your farmers. I feel much interested in receiving experimental information respecting the application and effects of lime on sandy soils.

Your's respectfully,
EPHRAIM BUCK.

ON THE EFFECT OF WAR AND HIGH PRICES.

Kingston, (Tenn.) 30th March, 1823.

Sir,—In the Farmer of the 14th inst. you rather appear to hope that the war approaching in Europe, may eventually be the cause of increasing the value of the products of the United States, and that it might be beneficial to the farmer. I have never yet seen what general good was produced by high prices, but think it has brought more misery on the farming class, than any thing else that ever happened to them; I therefore hope war may not take place, and if it does, I hope it may not raise the price of the staple products of the country—to entail such misery as is sure to follow; a few might and would be benefited by it, but misery would follow to twenty where one would be benefited, and the manufactures of the country would suffer by it.

SAMUEL MARTIN.

ENQUIRY ABOUT FAMILY WOOL AND COTTON SPINNER—ANSWERED.

Sir—I notice, in your paper of the 14th inst. a query—if a wool-spinning machine, invented by a Mr. Brown, (of which I am the owner, in part, of the patent right,) will spin cotton as well as wool? The principles of the machine are precisely those of the common spinning wheel, which we know is used for both purposes; I have no doubt that this machine is as well adapted to cotton as wool—and from the little experiment I have made since I noticed your communication on the subject, I am more fully confirmed in my conjecture. But as the spinning of cotton by hand machine, cannot be an object of consequence to us in this part of the country, we have never given it our attention.

The machine, for the purpose intended, is a most perfect and useful domestic implement, and a thing which gives general satisfaction to every one who has used it—its cost here is from 18 to \$30 according to the finish: one should be delivered in Charlestown, in good order, with suitable directions for its use, free of freight, for 30 dollars. Have the goodness to give this communication to your correspondent as soon as convenient—and oblige yours,

J. R. NEWELL.

Any communication on the subject, addressed as above, will be duly attended to.
Boston, 31st March, 1823.

LONG ISLAND PIPPINS.

We are informed that Mr. Henry Mitchel, of Flushing, Queen's county, gathered last fall from one tree, eight barrels of apples, six barrels

of which were sent to Liverpool by one of the line of packets as an adventure. The captain was requested to return him the proceeds in British sovereigns, thirty of which, amounting to \$133 33, were lately paid over to Mr. Mitchell, exclusive of freight and commissions. Such is the celebrity of Long Island pippins throughout the world, and so important is the cultivation of good fruit.

PUBLISHED IN THE AMERICAN FARMER, BY ORDER OF THE STATE.

Baltimore, April 7th, 1823.

A report of the tobacco inspected at, and delivered from Dugan's Inspection Warehouse, during the quarter, commencing on the first Monday in January, and ending the first Monday in April, in the year of eighteen hundred and twenty-three.

PATERSON MANUFACTORIES.

Rejoicing in every circumstance which has a tendency to render our country independent of the rest of the world, and to develop its enterprise, ingenuity, wealth and resources, we cannot but hail with delight such intelligence as the following, let it come from what quarter it may; but we must, in candor, confess we enjoy it with a peculiar zest when it relates to a portion of our native state, to whose prosperity and honor we are, from affection and gratitude, most heartily devoted. But to the information:

The "Voice of Passaic," published at Paterson, (New Jersey,) enumerates the following manufacturing establishments in that town:

Ten cotton factories, having now in operation twenty thousand spindles.

New factories erected, which, in about three months, will put in motion twenty thousand spindles more.

Making 40,000 spindles employed in spinning cotton.

Three extensive woollen factories.

Two large duck factories, supplying, in a great measure, our navy with canvass, and working up more than a ton of flax per day.

Three manufactories of machinery, one of which is stated to be the most extensive and complete in the United States.

Three very extensive bleach greens.

Two brass and iron founderies.

Besides paper, grist, saw, rolling, and slitting mills, &c. &c.

With the great natural advantages which Paterson possesses, and the prospect it has of deriving, at no very distant day, immense benefits from the contemplated canal from the Delaware to the Hudson, we may venture to predict that it will soon attain to a degree of usefulness and importance of which every Jerseyman may well be proud.—*True Am.*

SIGN OF FLODDEN WELL.

A Scotch innkeeper, who had determined on adopting the sign of Flodden Well, was much puzzled for a suitable inscription. At length he waited on Walter Scott, and asked aid, observing, that "as he had written so much about it, he might ken something that would do for an inscription." The worthy poet immediately replied, "why, man, I think ye cannot do better than take a verse from the poem itself." The innkeeper was very willing to do this, when Mr. Scott said to him, "Why, then, you have just nothing to do, but to leave out one letter, and put for a motto—

Drink, weary traveller—drink and PAY!
instead of *pray*, which you might not attend to so punctually.—*Dumfries Courier.*

THE FARMER.

BALTIMORE, FRIDAY, MAY 2, 1823.

THE MARYLAND AGRICULTURAL SOCIETY.

At a special meeting of the Maryland Agricultural Society, held agreeably to public notice, in the city of Baltimore on Monday last, the 28th day of April, Robert Smith, President, having taken the chair, James W. M'Culloh was, in the absence of the Secretary, appointed Secretary pro tem.

The attention of the meeting was then called by preliminary and appropriate remarks, to the consideration of several important resolutions, that were submitted by Lloyd N. Rogers, and which, with slight modifications, were severally

adopted by the meeting, after a free interchange of opinion among the members.

1st.—*Be it Resolved*, That it is expedient in the opinion of this meeting to form "the Maryland Agricultural Society," into two independent societies—one for the Eastern, and the other for the Western Shore of this state.

2dly.—*Resolved*, That a Committee, consisting of John S. Skinner, Benedict W. Hall, Lloyd N. Rogers, and James W. M'Culloh, be appointed to frame a constitution to be submitted on Monday, the 23d day of June next, to the members of this society, for their consideration and adoption; and that said committee be instructed to provide therein for the annual election of a board of Trustees to watch over the affairs of the society—and further, that they be especially instructed to insert an article in said constitution, conferring honorary membership on all members of the society, who reside upon the Eastern Shore, and on all those who may hereafter become members of the new society on that shore, should an independent society be organized there in pursuance of the above resolution—and said committee are hereby further instructed to provide for the continuance of the right now enjoyed by all persons residing in that section of the state, to compete on equal grounds, for all premiums at our future exhibitions.

3dly.—*Resolved*, That the next cattle show of this society, on the Western Shore, shall be held in the autumn of the present year; and that the former committee of arrangement be, and they are hereby authorised and requested to publish a list of premiums, amounting in all to \$500, to be awarded at the aforesaid show, as soon as they can conveniently designate the objects for which they may deem it most proper to offer rewards.

4thly.—*Resolved*, That the committee charged by this meeting, with the formation of a constitution, be instructed to transmit a copy of this and the foregoing resolutions, to the Hon. Edward Lloyd, Vice President of the Maryland Agricultural Society, and to ask his assistance to obtain for them a special conference, with a committee to be appointed by the members resident on the Eastern Shore, upon topics connected with the interests and objects of our association.

The society having adopted the above resolutions, they elected Robert Sinclair, a member of the committee of arrangements for this shore, *vice* Dr. James Stewart, who had previously resigned.

ROBERT SMITH, *President.*
JAMES W. M'CULLOH, *Sec'y pro tem.*

The following extract from Dr. JOHN S. BELLINGER, ought to have accompanied the distribution of the Peas—the receipt whereof was noticed in No. 2, vol. 5:

"I thank you for the peas and the millet seed—I send you three parcels of early peas—of each kind two crops can be obtained in our state. No. 1, (Warley peas) presented me by Capt. Warley, of Colleton district. No. 2, (Deas' peas) by T. H. Deas, Esq. of Charleston; and No. 3, (Searight peas) by Mr. Searight, who keeps a public house in Lexington district, on the road to Columbia—who informs me he found great benefit from their cultivation, with an early and late crop of them. I shall be pleased if all or either of them prove, on trial, worthy the notice of the farmers of your state."

COMMERCIAL.

A letter from Liverpool, of the 14th March, after stating an increased demand for tobacco, and that sales since the 1st of the month amount to about 800 hhd. the letter proceeds—"The

prospect of war has created great activity in bread stuffs. Wheat has advanced within the last week 1s. per bushel in almost every part of England, and from the lowest point, six weeks ago, the general advance may be fairly put down at 40 per cent. English Flour has advanced about the same degree. A pause took place in the last London market, which has caused to-day a partial reduction of 3d per bushel in this market."

There has been another arrival at New York, but it brings nothing new.

BALTIMORE MARKET.

PRICES CURRENT.—CORRECTED WEEKLY.

Flour, best white wheat, \$7 50—Howard's Superfine, \$7 25—fine do. \$6 75—Wharf, do. \$6 50

—Wheat white, \$1 55 to 1 60—Red do., \$1 50 to \$1 55—Rye, 80 cents—Corn, 60 to 63 cents—Country Oats, 50 to 55 cents—Beef, 8 cts. per lb.

—Live Cattle, \$6 to \$6 50 per cwt.—Hacon, round, 8 to 9 cents per lb.—Pork \$4 50 to 5 50 per c. lb.—6 to 8 cts. per pound—Mutton, 5 to 6 cts. per lb.—Beans, \$1 37½ to 1 50—Peas,

black eyed, 55 to 60 cts.—Red Clover Seed, \$5—Orchard Grass do. \$3 50—Herds' Grass do. \$3—Timothy do. \$4 50—Millet, \$3—Flax Seed, 75 to 80 cts.—Whiskey, from the wagons, 32 to 35 cts. per gal.—Apple brandy, 30 to 32 cts.—Peach do. 65 to 70 cts.—Shad, none in market—Herrings, No. 1, \$3 62½ per bbl.—No. 2, \$3 37½—Fine salt 80 to 90 cts. per bush.—Coarse, do. 75—Butter, 20 to 25 per lb.—Eggs, 18½ cts. per doz.

—Hay, \$18 per ton—Straw, \$11 to 12.

MARYLAND TOBACCO.—Fine yellow \$20 a \$25—good do. 13 a 18—fine spangled 16 a 20—fine red 8 a 13—good do. 5 a 7—dull do. 2½ a 4—plenty, no demand—Seconds, 1½ a 6.

One hhd. raised by Francis X. Boorman, near Benedict, Charles county, Maryland, on old ground, sold at \$20—three hhd. raised by Thomas Chaney, Anne Arundel county, near Friendship, on old ground, sold, 1 at \$20—1 at \$13—and 1 second at \$8—One hhd. very fine, sold by Mr. Cephas Simmons for \$35.

PRINCE REGENT.

This justly celebrated and well known horse is a dark bay, full sixteen hands high, of fine form, figure, and great bone—he walks, paces, trots and canters remarkably light, and well. He is in strength, form and figure, what may be conceived in the description of a first rate English coach horse or Hunter, his eye is a large clear hazle, his movements graceful and grand, and his colts where he has stood the last three years, are much admired for their size, action and beauty.

He will stand this season, from the 1st of May, from Saturday till Wednesday morning in each week at Govan's Town, under the direction of Mr. John Wooden; and from Wednesday till Saturday mornings, each week, at the Maryland tavern, four miles from this city, on the Frederick turnpike road, under the direction of Mr. John Wattson—at the rate of EIGHT DOLLARS the season, for each mare, and 50 cents for the groom, the money to be sent with the mares or a note given for the amount, payable on the first day of August next.

Baltimore, April 29, 1823.

N. B. Pasturage may be had at each place for mares, if required.

Printed every Friday at \$4 per annum, for JOHN S. SKINNER, Editor, by JOSEPH ROBINSON on the North West corner of Market and Belvidere streets, Baltimore; where every description of Book and Job Printing is executed with neatness and dispatch—Orders from a distance for Printing or Binding, with proper directions promptly attended to, addressed to J. Robinson, Baltimore.

AGRICULTURE.

WILLIAMSBURGH AGRICULTURAL SOCIETY.

At a meeting of the Williamsburgh Agricultural Society, S. C. on the second Monday in October last, the president, Capt. John James, delivered the following practical address, which was ordered, by unanimous vote of the society, to be forwarded to the American Farmer for publication.

J. DOZIER, Cor. Sec.

March 21st, 1823.

ADDRESS.

GENTLEMEN,

In the district of Williamsburgh where we are locally situated, the soil is like the adjacent country in many places low, flat, and broken with swamps, ponds, and what we term bays; that is, large ponds grown over with bay-trees, which at times are overflowed with water. The swamps have natural vents by creeks, so that the waters run off, if no impediments are in the way. But the ponds and bays, are shaped in the form of a basin, brimmed round the edges to hold it in, and thereby it becomes putrid and unwholesome, and destroys vegetation, unless very soon removed. Yet this soil when made dry is found to be prolific, and amply rewards the cultivator for his trouble, and expense of draining it.

These things considered, with many others that could be enumerated, would it not then be wisdom in us all particularly to attend to it, so as to lead off those poisonous waters out of our fields, and in those other places adjacent: if generally done by each person, who possesses or occupies such soil in the district, the advantage herefrom resulting to ourselves, and the community would be incalculable. In the first place, we would most assuredly enjoy better health; our fields would produce more abundantly—we would save much of the money that is spent by travelling in a certain season of the year for health, to more salubrious parts; and much of that which it now takes to pay our Doctor's bills.

To my knowledge many of you have in some measure been thus engaged, and have gotten your fields partially drained; but I have to remark that the drains I have seen generally indicate to be their incapacity to lead off the water in due time, before its bad effects are produced in the plants, which is soonest done in their young and tender state, and if injured then, I find it impracticable to restore them to their native vigor again, I therefore recommend to planters to have their business executed if possible, before the seed is sown or planted on the soil. A great deal of labour may be saved in laying out the drains to the best advantage, so as to have the least quantity of earth to remove—water itself is the best muller and director, and if well observed, will lead to some running stream, by which it can be carried away, and the most suitable time to discover this, is when the basin is full to overflowing; our fields cannot be said to be ready for the plough, nor to receive the seed until it is sufficiently freed from water.

Indian corn, with us, is generally the first sown crop in the spring season, and as early as the months of March and April, for most generally the earliest planted, produces the heaviest, and heaviest grain: but for me to attempt to give this society any thing new on the culture of that grain, after what has been so ably written by Colonel Taylor of Virginia, in his "ARABIAN," and in many numbers of the "AMERICAN FARMER," might appear to you presumptuous:—I therefore refer the inexperienced in that art, to the more experienced guides; only with their

permission, I will recommend to the inexperienced planters of the south, to make suitable allowance for the difference of seasons; ours being earlier, and requires sooner planting than theirs: our soil is generally thinner and lighter in this district than theirs, and will not admit of such deep ploughing, without greatly injuring it. In this I judge from experience.

Of the ploughs in use amongst us—I consider the most of them to be very defective as to their model, but am happy to observe we are beginning to find out their defects, and new modeling them, or purchasing the patent kind. The plough of late years, in my opinion, in this district, has been too much used in tending the crops after they are planted; we plough, and cross plough again, and again, and turn the manure that was laid on the soil at first, over and over, until its good effects become thereby destroyed by exposure to the sun and air, and suffering it to evaporate. But some planters will enquire how then are we to destroy the grass and weeds amongst it, without making great use of the plough for that purpose? I answer, that we must do it by the hoe and harrow principally.—For it is a well known fact, that a heavy clod or furrow, laid on the seed of grass, and suffered to remain there, will prevent it from germinating; but removed by frequent cross ploughing, and raised up again near the surface, it will unquestionably sprout, and grow if done in that season; then the consequence must be, that every time that it is done, it will produce more grass to be killed. In my recollection, the farmers of half a century past, ploughed their fields once in the season, and they produced more and better corn, than we do now with all our ploughing; but, man is prone to run from one extreme to the other, and this we find to be the case in the use of the plough.

Our soil if well cultivated, will produce abundantly of red, or cow peas; they are an excellent substitute for Indian corn to fatten horses, being both grain and fodder, cattle also will get very fat on them, and give much rich milk; which makes butter of an excellent flavour. The grain when scalded in boiling water, or well steeped in cold water, and given to hogs, make them good and palatable bacon for our tables; more especially with a little mixture of Indian corn, to harden their fat. A lively sandy soil is most productive, and they bear best if planted by themselves on ridges, or beds, elevated or made with the plough; but good crops have been frequently made by planting them in the field with Indian corn; by putting in a bunch of them between every two hills of corn so as they can vine up the corn stalks, which support them—some cotton planters object to having a pea and cotton crop both on hand at once to harvest; and say that time is not to be found for them. I acknowledge this might sometimes be the case, but if it should, has not the cultivator a choice which of them to choose, and which to refuse? and if the peas are left in the field, he can turn in his stock to gather them, and they will not be lost—for the vines ploughed in, will make manure to good advantage.

Sweet potatoes, our soil will produce, and they are a profitable crop to the cultivator, being a substitute for bread, and a good wholesome food for our labourers; children are uncommonly fond of them, and it is a food that agrees with them: they are good for all our domestic animals, and poultry, and also fattening; but especially for hogs—the value of this root is so great, and well known, that it might be well considered an insult on your good sense, should I attempt to advise you to continue the culture of it.

The method most generally used to prepare

the soil to receive the seed, is by raising it, either by the plough or hand hoe, into round hills or ridges, to the height of about eighteen inches, upon a base of about four feet six inches square, if for hills; or if ridges are preferred by the cultivator, the same width of surface in the base, continued on in a straight line by the plough, will be sufficient to form them on; the slip, or seed, is deposited in the top, so as to be buried about an inch under the soil, that the roots may run down through the soft earth, to the hard bottom left there, where they stop descending and then thicken in their growth.—To destroy the grass, and weeds, that will arise amongst the vines in their young stage, that is before they descend to the bottom of the hills, or ridges, and to keep the soil loose for the potato to grow, I plough the earth amongst them, by turning the bar of the plough into the potatoes on the top, the share out, and slice off a part of the hill or ridge; throwing the dirt into the water furrows below, and this on each side of them, only observing to take care to leave a sufficiency of the centre untouched to support the plants, then extirpate what grass, or weeds, that may be left remaining amongst the plants, and in three or four days afterwards, when the sun has had time to warm the soil, reverse the plough, and throw back the earth that was first taken away from the hills or ridges, and dress them up again into their former shapes, and let them remain so until digging time.

The best manure for sweet potatoes that I have yet experienced, is first, cowpen; second, cotton seed, the sprout or bud of which must first be killed by steeping it in water; or lastly, unrotted straw laid or placed in the bottom of the hills or ridges; when they are first drawn up, it keeps the soil loose, and suffers the heat of the sun to penetrate, which is of great advantage.

Cotton.—Every member of this society is, or has been a cotton planter; we differ somewhat in our methods of planting, and the after cultivation of this most valuable plant; but our general plan is nearly the same. I will therefore only give the inexperienced a few hints of my own method, leaving it to their own discretion to improve thereon. In the winter season I endeavour to have the soil well broken up and pulverised, more especially if it be recently cleared of its timber, and brought into cultivation, or has been lying waste, or uncultivated, for some time previous. When the season of planting is near, I have it laid off by the plough into beds at a proper distance; that is, from three to four feet apart: which I find to be sufficiently wide, for the most of my fields; but in a strong rich mould it would be necessary to have them one or two feet wider; so that the branches when at full growth will but just meet; for if they interlock it will be injurious, or if they cannot meet, it will be a loss of space. I lay three furrows together to form the basis of my beds to sow my seed on, and I leave the remainder of the soil, if any, to be turned up afterwards to mould the plants with, and raise the beds higher, which at last will be from six to eight inches high. At planting time, split the beds, or these three furrows, laid together lengthways, with a small trenching plough, or the corner of a hand hoe, to receive the seed, by drilling it in; one bushel to an acre will be fully sufficient if the ground is loose and mellow; or if foul and full of clods, it may require two bushels or more; then cover the seed lightly with the earth, that the plough threw up in forming those trenches; use a hand rake for that purpose, taking care to remove from it all trash, or heavy clods of earth that might cover and smother the sprout. If the cultivator prefers his cotton to grow in bunches in a straight

line for the plough to attend, he can checker it crossways of those three furrows, or beds, which was first laid off at any given distance he may prefer, and thereby it will be in square spaces to form flat hills; then in the centre of them, open a trench, or hole, and throw a small bunch of seed in, and cover them over with the soil. If the field has been planted in cotton the year previous, I reverse the beds, and form the new beds, on the old water furrows. When the seed has sprouted, and well risen above the ground, and grown so as to have four or five leaves on the stalks, it is then time to weed it, and lay fresh mould to its roots; soon afterwards plough up the middle spaces that were at first left between the rows of cotton, and throw an equal part of it to the row on one side, and as much on the opposite side, so as to preserve an equal distance between them; great care must be taken in this performance, that the plants be not covered with the soil thrown over by the plough. Then give the plants another dressing over with the hoes, and at every dressing add more soil to the roots, to keep it growing, unless you find it about to overgrow itself; then to check it, and make it pod, in place of adding soil to the roots, have some of what you had formerly laid on, scraped and removed from them. As soon as your plants are high enough to get hold of them with the finger, it will be time to thin them out, by leaving them single at their proper distances, by taking away the most useless ones, and leaving the most healthy to grow. The distance to leave them standing must be judged from the quality of the soil; on lean soil six inches may not be too close in the rows on which they stand; but on very rich soil, four feet or more may not be too much; the air and rays of the sun must have room to pass between the branches, or the shapes, and pods, will rot.* The safest way of thinning it, to insure a good stand, is to do it at two different times; but be cautious it be not delayed too long at any of the times, or it will certainly suffer an injury. The cotton plant requires careful nursing, more particularly when young; to subdue our *crab grass*, or more properly speaking *croft grass*, from amongst it, more especially if it is at first neglected, and suffered to remain until it has passed the plant leaf, is an arduous undertaking; to accomplish this, I run my cutter plough lengthways of the rows, so near the cotton as not to injure, or bury it, the bar in, and the share out from it, and throw the soil between the rows, taking care to leave a sufficiency of soil to support the plants, to keep them from falling; then hoe, or pitch out the grass left in the cotton, then plough back the soil to it, and cover that grass, dress up the beds with the hoe, and soil the plants; but this work should be performed before the horizontal roots have extended far out, or it will impede the growth of the plants, and is to be performed as a second dressing if possible. To give a minute detail of every particular circumstance respecting the cultivation of this plant and to prepare the cotton for market, would far exceed the limits of an address; and before gentlemen of your experience I consider it unnecessary.

Gentlemen spectators: we thank you for the honour you have done us in attending this day's meeting of this society; we are a small band endeavouring to do great good to ourselves, and the community at large; that is, in promoting and advancing agriculture: which is the true interest of every nation and clime. We need, and require more assistance from you individually.—

* I do not mean the rot, a fatal disease that has come of late years in our cotton: but the rot produced by an obstruction of air and light.

We are acquainted with, and appreciate your theoretical and practical knowledge in the business, and are aware how much it would serve us, to be aided at our board by such practical husbandmen?—Our interest in agriculture is one and the same; why not then associate and assist each other in promoting its best interests, by establishing and encouraging societies, which has been a practice in different states and kingdoms, from times immemorial, and they are in our day accumulating faster than ever in the United States of America; we wish them much success, and every individual person who devotes their time and talents to so laudable a purpose.

This agricultural society of Williamsburgh district, South Carolina, has existed nearly four years; our soil is generally thin and light, and considerably exhausted; but capable of being improved when the proper methods are taken.—This and similar purposes we profess to be the great design of this society; and the cause why we so constantly call in your assistance to help us; for we of ourselves can do but little of the much we wish to do. Therefore we solicit your help, by your counsels and your experience; and the generations to come will bless you for it.

JOHN JAMES, *President.*

Delivered 16th November, 1822.

ON THE MANAGEMENT OF HORSES AND DOGS—BY AN EXPERIENCED SPORTSMAN.

(Continued from page 38, vol. 5.)

Of nicking Horses.

I once knew a most valuable horse killed by nicking his tail; it mortified. The surest method is to give him a dose of physic the morning before the operation is performed, and at least one dose more the third day.

Of sore backs in a Regiment of Cavalry.

All our cavalry, on service, should have a blanket, eight times doubled, under the saddle. It is of great utility; for, with care, you never will have a horse with a sore back; and, at night, the man may draw it from under the saddle, and cover himself with it; thus he will have two blankets to cover himself. But road-horses, and wagon-horses too, frequently have sore backs.

A cure for sore backs.

The best method of curing sore backs, and I have frequently experienced the efficacy of it, is to DISSOLVE HALF AN OUNCE OF BLUE VITRIOL IN A PINT OF WATER, and dab the injured parts with it four or five times a day. The best captain of cavalry, I know, is not he who only fights his troop well in action; but he who has his horses in the best condition, and has the fewest sore backs in his troop. What a laudable example the German hussars, and other cavalry, shew us, in the care of their horses. The attention they pay to their horses is wonderfully meritorious.

No Horse, out in all weathers, and standing still in the streets, should be curried or brushed.

I never allow a horse of mine, which is out in all weather, and frequently stands for hours in the street, and very often in rain, to be curried, or brushed: currying and brushing thins their coats, and makes them more liable to catch cold. Nor do I ever allow them to be covered in the stable with a cloth. They are rubbed well with a whisp of straw, and then with a course hair-cloth; this makes the blood circulate, and it is fully sufficient. I am thoroughly persuaded, no cavalry horse, on service, at the picket cord, should ever be curried or brushed: indeed, a couple of curry-combs may be kept in each troop, in case a horse may have some hard dirt caked on, which cannot otherwise be rubbed off.

No horse should stand on litter in the day time.

I never allow a horse to stand on litter in the day-time in the stable. I speak not of running-horses or hunters. Provided the straw be not perfectly dry and clean, it perishes the feet.—Look to horses which stand upon half-perished litter, as one half of them do at the livery-stables; you will find their feet full of dirty, half perished litter. This materially injures the feet.

An infallible lotion for blows, bruises and

For the present, I have nearly done with the treatment of horses; but will give you one receipt more, which, of all the medicines in the world, is the most efficacious. It is as beneficial to man and woman, as it is both to horses and dogs. You should never be without a bottle of it in the house. It is infallible in its cure of all bruises, blows, and gentle strains, which horses and dogs receive in the field. I do not mean to say that it will cure a horse, which is absolutely let down in the sinews; but, in every other respect, it is a sovereign remedy. I have had, in the course of time, four or five servants who have slipped down stairs, and have terribly bruised their legs, and sprained their ancles. I have also given it to numbers who have received injuries in their limbs from falls, blows or bruises, and I never have known it to fail. It was given to me by an old huntsman, thirty years ago. It may even be used when the skin is broken, or rubbed off; not absolutely on the wound itself, because it will occasion great pain; but it may be rubbed in well all round the wound. TAKE OF SPIRIT OF WINE, EIGHT OUNCES; DISSOLVE ONE OUNCE OF CAMPHOR FIRST, IN THE SPIRITS OF WINE, THEN ADD ONE OUNCE OF OIL OF TURPENTINE, ONE OUNCE OF SPIRIT OF SAL AMMONIAC; OIL OF ORIGANUM HALF AN OUNCE, AND ONE LARGE TABLE SPOON FULL OF LIQUID LAUDANUM. It must be well rubbed in with the hand, for full a quarter of an hour, every time it is used; which must be four times each day, you will be astonished at its efficacy when you try it.

With certainty how to know a strong and good eye from a weak one.

I will now inform you how for certain, you may know whether a horse has a strong and good eye, or a weak eye, and likely to go blind. People in general turn a horse's head to a bright light to examine his eyes. You can know very little, by this method, what sort of an eye the horse has, unless it be a very defective one. You must examine the eye first, when the horse stands with his head to the manger. Look carefully at the pupil of the eye in a horse; it is of an oblong form—carry the size of the pupil in your mind, then turn the horse about, bring him to a bright light, and if, in the bright light, the pupil of the eye contracts, and appears much smaller than it was in the darker light, then you may be sure the horse has a strong, good eye—but, provided the pupil remains nearly of the same size as it appeared in the darker light, the horse has a weak eye; therefore, have nothing to do with him. There are contracting and dilating muscles in the eye, which will plainly shew you, provided you follow my instructions, in what state the eye is, whether it be a strong or a weak one.

Many horses are attacked in their eyes when coming five years old. This is vulgarly called moon-blindness. It is a periodical blindness, which comes and goes, sometimes three or four times; but, if it ever comes above once, I imagine his eye to be in great danger.

Of Worms being in a horse's stomach.

I have often read, in farrier's works, and those of veterinary surgeons, of worms in

horse's stomach—for my own part, I cannot credit it; for the peristaltic motion of the stomach is so powerful, and the heat so great, when the horse is alive, that I am of opinion that worms may as well live between two mill-stones, when at work, or in a hot baker's oven, as in a horse's stomach—and this I have a right to say, that, when the motion of the stomach ceases, which it does with the life of the animal, in half a minute, worms may move from their former quarters into the stomach, particularly if the stomach be replete with food. Certain we are, that no person has ever seen the stomach of a horse when alive; therefore I am justified in saying, that I imagine it must be conjecture, and that I give a good reason for my opinion: however, I will not assert, or be positive in an opinion which may be contrary to that of more experienced men.

Wounds in the skin of horses.

Wounds in the skin of horses will generally be cured by LINT DIPPED IN FRIAR'S BALSAM. I have already mentioned the great benefit of it in inflammatory fevers. Osmer relates a story of a horse, which he asserts to be a fact:—that a horse, with the mad staggers on him, broke out of the stable at a powder-mill, and got into a cistern of water in which a large quantity of nitre-petre had been dissolved. He drank plentifully of it, after which he became immediately well, without any thing else being given him. I mention this, to shew the good effect of nitre in fevers.

Duffy's Elixir be too expensive, give Philonium Romanum.

I have already mentioned, that a BOTTLE OF DUFFY'S ELIXIR is the best medicine I ever used for a horse taken with the cholick, or gripes, and drinking cold water, &c. &c. But, as Duffy's Elixir is expensive, you may give him ONE OUNCE OF PHILONIUM ROMANUM—repeat the dose in one hour, if the horse be not relieved. *Two sorts of Cholick and Gripes; how to distinguish them, and to cure both.*

You must be particularly careful to distinguish, whether there are two sorts of cholick, or gripes; the one proceeds from the horse being chilled by cold water, &c.; the other proceeds from costiveness and inflammation of the bowels. In the former disorder you must be guided by feeling the horse's pulse, to ascertain whether it be attended with any degree of fever. I have told you already how to feel a horse's pulse, and how often, in a minute, a horse's pulse, free from fever, should beat. In this latter disorder, the dung must be constantly raked away, as it falls into the dung-heap. Give the horse sweet oil inwardly, to relax the intestines, and to supple the hard excrement, which, from dryness, may be lodged in the gut, which is frequently the cause of this complaint. Give him, every four hours, one ounce of the common purging salts. In this case, nitre is not to be given, as it acts mortally as a diuretic. If the horse be in considerable pain, he should be bled, and, if the pain be very violent, bleeding should be repeated, because the inflammation will be increased.

How to judge whether or not that you have the best Colt of the year.

I do not believe there ever was a better horse than Mr. Robert Pigott's Shark, excepting those, which was a very uncommon horse. I will tell you what Shark could do, by which you may give a tolerably good guess whether you have nearly the best horse of his year. Run five or six of your young colts together, one mile: if they all come in well together, you may be sure that not one of them is worthy to be kept in the stable, excepting you have one amongst them, which is an uncommonly large sized colt, large

limbed and loose made. It is possible that, when he comes to his strength, and fills up, he may turn out a good horse. If you have one colt, which, in the trial, runs clear away from all the rest, you may expect that he will turn out a good runner. Take him, about a fortnight after, run him with two of the others which were the two first of those beaten; for you must not run him with the worst or last of the lot. Let him give them both twenty-one pounds. If he does not beat them cleverly, you have no right to expect that he is the best, or nearly the best horse of his year.

(To be continued.)

BALANCE OF TRADE.

The subject of the following essay, is one of such very general concern, and yet one which has been so mystified, by writers on political economy, that we concluded on reading it, that our friends, plain farmers, would be pleased to see a matter generally considered so abstruse, thus simplified and brought home to every one's understanding—with essays like these, we apprehend we may diversify the columns of the Farmer occasionally, without any dereliction of promise or duty. Farmer's sons may read them to advantage, gaining thereby a knowledge of elementary principles of importance, applicable to the operations and dealings of neighbours and of nations. If, however, our impression in this respect be not well founded, we shall regret the indulgence of it, and only wish that we had some way of taking the vote of our numerous and generous patrons, whose will ought to be our law.—*Edit. Am. Far.*

FROM THE PORTSMOUTH JOURNAL.

In the science of political economy, there are no errors so inveterate, as those relating to foreign commerce. It is but a few years, since it was the fashion to regard the books of the custom-house as the only standard by which the prosperity of the nation could be measured. If the imports exceeded the exports, it was said that the balance of trade was against us; that we were running in debt to foreign nations; and that poverty and ruin were overtaking us. As the balance of trade, in this sense, has always been against the United States, it would seem to be difficult to reconcile our acknowledged prosperity with the correctness of the principle. But though better opinions begin to prevail, they are not universally received. We still hear predictions of ruin, because our imports are greater than our exports. It may be worth while to examine the reasons for this apprehension.

In the case of an individual, nothing can be plainer than that his imports should exceed his exports. How can a man become rich, but by receiving more than he parts with? It is the same with a nation. If the United States, by exporting sixty millions annually, can import sixty-four millions, it is apparent that nearly the whole difference has been profit.

The error has arisen from estimating the value both of imports and exports at our own custom house, instead of estimating their value in the foreign country where the exchange is actually made. An inquirer learns at the custom house that sixty-four millions have been received, and that only sixty millions have been sent to pay for it; and he naturally asks how the difference is to be supplied. If he is not acquainted with the course of trade, he naturally supposes that a debt of four millions has been incurred; and he shudders at the thought of having all the gold and silver drawn from the United States to pay it.

Yet a slight attention to the course of domestic trade would shew him that his apprehensions were groundless. In some of our distant settlements corn is fifty cents a bushel, and salt is one hundred. If a Farmer from one of these settlements were to come to market with thirty bushels of corn, he might sell it for sufficient to purchase thirty-seven bushels of salt. If the value of these articles is to be estimated at his own door, he has exported fifteen dollars, and imported thirty-seven dollars. But unless the expenses of his journey have exceeded twenty-two dollars, he has made a profit by the exchange.—Now the Custom-House returns give just as correct a view of the trade of the nation, as an account kept at a Farmer's door of his out-goings, and in-comings, would give of the state of his business. These returns are valuable and necessary—but for a very different purpose.

The great fallacy of arguments drawn from the custom-house returns, will be apparent from considering only one branch of the trade of this town, namely the freighting business. In the course of the last year, we have had twenty-seven Ships and twelve Brigs employed in this trade; several of which have made two voyages. It will therefore be perfectly within the truth, to make a calculation upon forty voyages in the year. These vessels generally took with them hay and lumber sufficient to pay their port charges in the Southern States, say \$1000 each, or \$40,000 for the year. They receive upon an average £1000 sterling each, in Europe; or \$177,600. Deducting from this sum, their port charges in Europe, there are brought home in salt and iron, or left behind to be brought home by others \$150,000. The whole of this sum appears on the books of the custom-house as imports, without one cent of exports to balance it.—But as from this sum, the Merchant keeps his ship in repair, pays his seamen, and purchases the outfits of the voyage, it consists of interest and reimbursement of capital, wages of labour, and profit in the same manner as the price, which the Manufacturer receives for a piece of Broad cloth, consists of interest and reimbursement of capital, wages of labour, and profit.

A merchant sending his ship to sea, must charge against his voyage not only the first cost of his cargo, but all the outfits, provisions, and wages advanced to the seamen: his own or agents services, and the premiums of insurance. On the return of the vessel, he must again charge the adventure, with the seamen's wages, and all the expenses attending the landing and sale of the goods. In order to know then whether the balance of trade is for or against the Country, the imports of the merchant must be placed against all these charges, and if it exceed the aggregate amount we may conclude that his business can be continued with profit to himself and benefit to the country. The exports of this part of the country are bulky and of small value; in many cases not constituting one half the consideration that produces the imports—yet this is all that appears on the books of the Custom-House.

Another error, still more inveterate, is the opinion that the exportation of specie is injurious to the country. Almost the whole of our specie currency is Spanish coin.—We received it in foreign ports in exchange for the products of our labour. It was received and brought home, because it was more advantageous at the time to receive it, than to barter our merchandise for that of the foreign country. We export it for the same reason; because it is more advantageous at the time, to make our purchases with it, than to send merchandise to be bartered. Apply the principle once more to an individual. He becomes richer or poorer, by the terms of the contract

makes, and not by the mere fact of bartering, or of buying and selling for money. If he sells to A for money, and employs that money to purchase of B, he is not necessarily poorer than if he exchanged his merchandise, at once, with B. If it would be profitable to the United States to export the products of agricultural industry—grain, provisions and lumber—to the East Indies and China, and then to exchange them for sugars and teas, it does not necessarily follow that the trade is ruinous, because the merchandise is sent to the West Indies, there exchanged for dollars, and the dollars are afterwards sent to China. The only difference is the expense of the intermediate voyage, which may, or may not be repaid by the profit of the first adventure, or by that of the final shipment.

Principles are best tried by familiar examples. A Hatter, who pays his Shoemaker with money, is an *exporter* of specie. He must previously have *imported* it by the sale of hats. Whether he gains or loses by the mode of payment, depends upon the fact of his getting better shoes or not, by paying in money, instead of paying in hats. If he gains by purchasing with money, he will generally be anxious to sell for money, that he may employ it in his purchases. That is, he will import specie, that he may afterwards export it. The case is precisely the same with a nation. If money is not exported, it is perfectly certain, it will not be imported. In this, as in every thing else, it is the demand that produces the supply.

Again,—the quantity of money in a country is no certain mark of its prosperity.—We do not estimate the wealth of an individual, by the number of silver dollars actually in his pocket, but by the command he possesses over the products of labour. In like manner the wealth of a nation does not consist in its circulating medium, but in that, which the circulating medium represents—the products of labour. If all the precious metals in England were at once destroyed, she would still be a wealthy nation; for she would still possess her fertile soil, her roads and canals and bridges, her buildings and manufactories, her ships and merchandise. So far from the quantity of money being the standard of wealth, it is found that money is always scarce in enterprising and thriving communities when it can be profitably employed; and is always plenty, when from any cause, it will not pay the usual rate of interest.

We should feel almost ashamed of stating anew and defending such plain principles, if every week did not bring us papers, in which they are misunderstood or perverted.

NEWS FOR THE LADIES.

French Female Parliament—Paris, Nov. 20, 1822.

CHAMBER OF PEERESSES.—A committee of the whole chamber sat, for the purpose of taking into consideration the necessary steps for re-establishing female conjugal authority in its pristine form.

Madame la duchesse Haute Voix drew a very eloquent picture of the degeneracy of husbands in these times, and the wanton infringements which they were daily making upon the conjugal prerogatives of wives. "She would not," she said, "take up the time of the chamber by insisting upon the necessity there was to take immediate steps for arresting the progress of this evil, because she was sure that every one of the noble members would agree with her, that there was no time to lose in suppressing an abuse of such magnitude. The only question was, what measures ought to be adopted? whether the chamber would think it most expedient for wives to act in an amicable or in a warlike manner? that is to say, to try the effect of flattery and insinuation on their domestic tyrants, or at once to assert

their rights, and set the usurped authority of their husbands at open defiance? For her part, she was, after much consideration, of opinion that this last measure would be the most efficient, as she trusted she should satisfactorily prove from the documents she held in her hand."

The noble lady then read several petitions, the substance of which was as follows: that, upon diligent enquiry in all parts of the kingdom of France, it appears that the spirit of matrimonial insubordination has spread very much during the last eight years; that owing, as it is supposed, in a great measure, to the intercourse France has had with England, the married men in the former country have in general imbibed the false and dangerous opinion, that a husband has actually and *bona fide* a right to be master in his own house; and in consequence the authority of wives has been circumscribed in several points, upon which, till the above-mentioned period of time, it was always undisputed. Several instances of this were given in the different petitions which the *duchesse* read, and from which we select the most prominent.

The marquise de — had been compelled by her arbitrary husband to wear her gown half an inch higher in the bosom than the precise height fixed by the fashion (Cries of 'too bad!' 'shameful indeed!' from several members.) Monsieur de T —, on finding that his wife had broken her solemn promise made to him when he last paid her debts of honour, never to game again, had hurried her down to his country seat, where she had now remained three months in durance, and without hope of liberation. (Exclamations of 'shocking!' 'insupportable!' from the majority of the members.) Madame de C — had been forced to diminish the expenses of her toilet during the last year nearly one half. (Violent murmurs of indignation.) "Yes, ladies," continued the *duchesse* energetically, "you may well murmur—these are grievances; but what will you say to the one I am now about to state? an atrocious act of tyranny hitherto unexampled in French annals. Monsieur L — took it into his head to be jealous, without the least reason, of his wife's most intimate friend, comte —, and positively forbade her to receive any more visits from that gentleman. It chanced that he returned home suddenly, at a time when she supposed he was in the country, and found her *tete-a-tete* with the *comte*—and notwithstanding she condescended to declare that it was by mere accident he had been let in, Monsieur L — had the audacity to express himself in terms of the highest indignation, and even to threaten a separation." (At these words the members seemed absolutely electrified.) "Yes, ladies," continued the *duchesse*—"you may well be mute with horror and astonishment; this is, indeed, an outrage, of which, in former times, no French husband would have dared to be guilty; but such is the consequence of innovation. We have, by weak concessions, been ourselves the cause of these disorders; and it is only by vigorous measures, and a determined assertion of our rights, that we can replace things upon their ancient footing.

Madame la comtesse Tres-Doucement begged leave to differ from the noble *duchesse*—she was certain that coercive measures would only precipitate the downfall of female authority, which she thought, by good policy, might still be preserved. The question was, which was most desirable, the reality, or the reputation of power? (Several voices, 'the reality, to be sure.')

"If this is your opinion, ladies, I think I can convince you that mild methods are most likely to procure it."

The noble speaker then entered on the subject at great length, and in a very able manner. She

quoted several examples, to prove that smiles, tears and caresses were the natural weapons of women; and who, she asked, could wield these weapons with more certain effect than French women, whom nature had gifted with the most seducing powers of persuasion? It had been asserted that this spirit of innovation was fostered by intercourse with the English. This assertion was perfectly false: she was no partizan of the English; on the contrary, she regarded them as natural enemies; but she could not refuse justice even to an enemy. She had been in England, had seen much of society there, and she could assure the chamber, that there was no country in Europe in which the wives exercise a more despotic sway. It is true, there is a certain restiveness of character, if she might so express it, in the men, which prompted them, occasionally, to oppose the measures of their wives, merely and solely that they might enjoy the reputation of being masters; but this opposition was a mere gasconade, which never went further than words, and was rarely to be found but among the little gentry of the provinces. The nature of it has been happily described by one of their poets in the following lines:—

"The surly 'squire at noon resolves to rule;
And half the day, zounds! madam is a fool:
O'ercome at night, the vanquish'd victor says,
'Ah! Kate, you women have such coaxing ways!'"

If, then, English women, in spite of their native pride and timidity, can by their blandishments subjugate their husbands, what may not Frenchwomen hope to effect?" The noble speaker then sat down amidst great applause.

Madame la marquise le Sage, thought that neither of the noble members had looked at the matter in all its various bearings. The evil was, in fact, of so complicated a nature, that it was not possible to apply a general remedy: for if forcible measures might be improper in some cases, lenient ones would in others be equally so; and she had many reasons to believe, that there were circumstances under which a mixture of both might be necessary.

After considerable discussion, the business was referred to a private committee of twelve experienced matrons, who were appointed to investigate the various petitions presented to the chamber, and to draw up a matrimonial code, by which provision should be made for all possible difficulties which wives might have to encounter in the government of refractory husbands.

Madame la vicomtesse du Fard, begged leave to call the attention of the chamber to the necessity of bestowing some mark of approbation on a person who, though in an humble rank of life, had shown that he knew how to support the character which the French have always maintained for politeness. "This person," continued the *vicomtesse*, "is Monsieur Cosmetique, a perfumer, who, with a delicacy worthy of imitation, offers his renovating bloom to ladies who fancy themselves troubled with wrinkles. Observe with what delicacy the word *fancy* is introduced!" (A burst of laughter from some of the juvenile members.) "Ladies may laugh, but I maintain that an affair of this kind is no joking matter. We all know that age is not the only enemy to female charms: hot rooms, the vigils of the card-table, and other causes, may accelerate their decline; but what woman of delicate feelings could bear the thought of applying to a coarse tradesman, who should inform the public, that he had invented a wash to take away wrinkles? It is only by looking at the matter in this point of view, that we can estimate the exquisitely beautiful mixture of sentiment and politeness observable in the advertisement of Monsieur Cosmetique, for which I move

that he be rewarded by a vote of thanks from the Chamber."

After a short debate, the motion was carried by a considerable majority, and the sitting closed at three o'clock.

TRIBUTE TO MERIT.

Translation of a letter from Monsieur de Dombelle, President of the Central Agricultural Society of Nancy, to the Right. Hon. Sir John Sinclair, Bart. dated Nancy, 7th November 1821.

"SIR,—I have the honour to inform you, that on the 3d of this month, the Central Society of Agriculture of Nancy, has inscribed your name on the list of its Foreign Correspondents. The Diploma shall be transmitted to you without delay. I hope that you will not refuse the lustre which your name would procure it, to a Society now in its infancy

"I beg leave here to express, all the satisfaction which I experience, in a choice so honourable to the Society; and to add, how much I am personally flattered, with the sort of brotherhood, which this gives me, with the person, whom I consider to be the first agriculturist in Europe.

"I have been occupied, Sir, for some time, in translating your excellent "Code of Agriculture." If any thing can contribute to raise Agriculture in France, to the rank of a science, which we could not till now pretend to do, it will certainly be the publication of this work in French, being the most systematic, the most concise, and, in my opinion, the most perfect, which has hitherto been written in any language.

"In the course of this work, which is already well advanced, I have perceived more than once, that I should require information, respecting some particulars. If you would have the extreme kindness, to permit me to apply to you, to obtain such information, it would be a motive for gratitude, which I would well know how to value; and in which all the French Agriculturists, who know how to appreciate your useful lessons, would participate with me.

"I have already met with some words of which I do not well know the meaning; for instance, I do not know what is the insect called *wire worm*. I have not been able to ascertain it, nor even to approximate what it can be, as it does not extend its ravages with us, to grain sown on clover, when ploughed up, as is the case in England. I do not know either, what is the plant called "*rib-grass*," of which I have not yet seen the botanical name given. Perhaps, indeed, it may have escaped me while reading, and I may find it out in the continuation of the translation.

"This work, to which, notwithstanding its importance, I am only able to devote a short time every day, will still require three or four months; but I hope it will be published about that time.

I beg that you will accept the expression of the respectful sentiments, with which I have the honour to be,

Sir,

Your very humble and obedient servant,
(Signed) MATTHIEU DE DOMBELLE *ainé*."

A NEW ARTICLE OF EXPORT.

We know the fact, that Mr. H. Traphagen, a respectable farmer at Horsimus, N. Jersey, near the city of Jersey, raised last summer about 20,000 heads of Cabbage for the New York market; but he was unable to dispose of more than one half of them in the fall from his wagons—The other half of this valuable vegetable he made into *Sour Krout*, which he now sells at from 8 to 10 dollars a barrel for exportation to India &c. On Saturday we saw a wagon load of barrels of *Krout* going on ship board.—*A. Y. Gaz.*

FROM THE FARMERS' JOURNAL.

SIR—

You probably know that farmers are in the habit of Manuring land by the eye, and in that way are liable to mistakes—I have found, in the Complete Grazier, a valuable table, and presuming the calculation to be accurate, I think its publication may be very useful.

I remain, your's, &c.

East Greenwich, March 27.

The following table for manuring land is extracted from an English work entitled the Complete Grazier:—

No. of heaps to load.	No. of loads per acre.							
	1	2	3	4	5	6	7	8
At 5 yards distance.	193	96	64	48	38	32	27	24
At 5½ do. do.	160	80	53	40	32	26	23	20
At 6 do. do.	134	67	44	33	26	22	19	16
At 6½ do. do.	114	57	38	28	22	19	16	14
At 7 do. do.	98	49	32	24	19	16	14	12
At 7½ do. do.	86	43	28	21	17	14	12	10
At 8 do. do.	75	37	25	18	15	12	10	9

Explanation of the first two rows of figures in the preceding table.

The number of heaps, consisting of one load each, laid at five yards distance, is 193 to cover one acre; at two heaps to a load 96; at three heaps, 64; at four heaps, 48; and so to the end—each of the following rows is to be read in a similar manner.

FROM THE REPORTER.

HEMP.

The sample of hemp accompanying the following letter, can be seen at our office. It has been examined by a competent judge who does not hesitate to pronounce it equal to the best Russia. The thanks of the public are due to the worthy gentleman, for communicating a fact of so much importance, which he has fully established by repeated experiments.

Springhill, February 8, 1823.

DEAR SIR,

I send you for the inspection of the farmers of Fayette and the adjoining counties, a sample of hemp, the produce of my farm. The only difference in the management of it from the ordinary mode, is in *ricking* it away, and letting it remain a year. The parcel from which this sample was taken, was laid down the middle of November and taken up the last of January. You will observe it has a red tinge, which was produced by spreading it too thick, and the wet warm weather milled it. It is however of such a quality that I have no hesitation in saying, that if all growers of hemp in the western country would join and raise such, we should soon banish the Russian hemp from our ports. I observe a writer in Niles' Register of the 25th ultimo, estimates the importation to the U. States from Russia in 1821 as follows: Duck and Sheeting \$818,850, Cordage \$28,281, Hemp \$441,114. Our exports in the same year of domestic articles, to Russia, amounted to \$127,939, composed of Oak bark, Rice, Cotton, Hops, Spirits, &c. leaving a balance of \$1,160,306 against the United States. This writer very justly observes "that if those articles now exported from Russia were made at home, then there would be an additional market for at least \$1,160,306 more of domestic materials, labour and subsistence, which are now useless, unemployed and unsaleable. It would give a new aspect to Kentucky and Missouri, if these states could supply the hemp, cordage and duck which we buy from Russia. This sum distributed

among the farmers, ropemakers and weavers, of the west, would indeed cause the wilderness to blossom like the rose. Yet for the sake of the paltry revenue derived from those articles, the country is deprived of the profits of raising, manufacturing, and distributing such articles." But can or ought we to ask those favours of the United States, until we first produce the hemp of a quality suitable? That can only be done by water rotting or preserving it a year. The latter is in the power of every grower of hemp, and certainly much the largest number of them can by an exertion lay one year out of the proceeds of their hemp, when the quality will be so much improved, and the price greatly enhanced. The sample sent is inferior to any of several experiments I have known made, and there are many farmers in the country who can testify to the uniform result. Your friend and humble servant,

NATH'L HART

We feel under an obligation to our friendly correspondent, for the opportunity he has afforded us of giving such early publicity to the interesting event noticed below.

[Harper's Ferry Free Press.]
TOTAL ECLIPSE OF THE SUN.

On the 27th of June, 1824, at 34 minutes past 4 o'clock in the afternoon, will end the present Chaldean period, and leave us for the space of two hours and fifty minutes in sublime and pleasing astonishment, as night will be realized and the stars visible, if our atmosphere should be free from clouds. The writer of this article has undertaken the agreeable task of making calculations relative to the different phases and aspects of this great Eclipse: they are made for the meridian of Harper's Ferry, in latitude 39 deg. 29 min. N. longitude 77 deg. 5 min. W. of Greenwich, and are as follows:

Beginning of the eclipse,	4 h. 34 m. afternoon.
Total darkness,	5 56
End,	7 24
Duration,	2 50

The return of this Phenomenon being variable in consequence of the retrocession of the lunar nodes, which is 19 degrees and 20 minutes every year. By means of this variation, it is seldom seen in any country more than twice in an age.—It will not be visible in Europe, but will to the American continents, and part of the Atlantic and Indian Oceans.

In this instance of Eclipse, the Moon's inhabitants on the side next the Earth (if any such there be) will see her shadow, like a dark spot, travelling over the Earth's surface about twice as fast as her equatorial part moves from West to East, for the space of about five thousand miles, the breadth varying according to the Sun's obliquity.

P. S. Since the above was written, the calculation has been pursued, and the following results obtained:

The next total eclipse will occur on the 9th of July, 1842, at 16 minutes 44 seconds past 11 in the morning. It will be invisible to us, of course.

The succeeding total eclipse, however, will be visible in the United States, and will happen on the 20th day of July, 1860, at 59 minutes 28 seconds past 7 o'clock in the forenoon.

Washington Co. Md. March 17, 1823.

SPORTS OF THE TURF.

The races to be held in May over the Union Course, Long Island, promise more sport than has ever before been offered on a similar occasion in any part of this country. They commence on Monday, the 26th, when a sweepstakes will be run for, by five or six three year old colts, and

which are, a full sister to Eclipse, a full brother to Sir Walter, and other high bred colts. On Tuesday, the great match race will take place between Eclipse and the horse that may be produced by the Virginia sportsmen, for 20,000 dollars. On Wednesday, the first day's purse, for 1000 dollars, will be run for, and among the horses to contend for it "Cock of the Rock," the brother to Eclipse, and second (as is here thought,) only to him in speed and bottom, is already on the ground.—The second day's purse is for 600 and the third for \$300. We understand that the Virginia sportsmen who accepted the challenge of Eclipse, have a stable of six of the best southern horses to bring on, and from Maryland, Pennsylvania, and New Jersey, several fine horses are to be produced.—The number of superior animals that will be on the ground, leaves no question that the competition between them will afford more gratification than the sportsmen of this country have yet enjoyed.

N. Y. American.

A DRAWING OF A MACHINE FOR BORING POSTS, WITH EXPLANATIONS OF ITS DIFFERENT PARTS.

A. A. A. is a frame made of oak timber 6 inches by 3, tenanted together, the long pieces 5 feet in length, and the short 2 feet, with snatch-box notches in the centre to wedge the posts before boring, as at A. A. B. B. are two upright pieces of timber 2½ inches square and of different length to clear the spire of the auger D when fixed in its conductors C C, to be tenanted in the pieces b b of 2½ inches square, and long enough to travel over the centre of the notches at A A in the short space of the frame, so as to keep the upright pieces B B perpendicular.

C C are two pieces of inch plank 2½ inches wide, of suitable length to extend across the frame lengthwise, with notches to correspond with the size of the shank of the auger D, and at such distances apart as the holes intended to be bored in the posts require; the straight piece C to be nailed on the upper ends of the pieces B B, the other piece C with corresponding notches to be kept loose, except when the auger is fixed for boring, and then it is placed upon the upper part of the nailed piece C and confined by bars or nails that may be taken out and put in with the fingers, at each end of the nailed piece, which fixing is done in an instant. The pieces thus fixed form an unerring conductor to the auger which cannot deviate from its course in turning.

D is a large auger 2½ inches, fixed to turn with a lever, which makes the labour of turning so easy that children of 5 or 6 years old can work it, and consider it as an amusing play for them. I have had all my posts bored this winter by two small boys 6 years old, one of them my own son. The auger for this mode of boring, is fixed in the following manner, take two pieces of timber not liable to crack or split, 9 inches long, 4 inches by 2 in width, bore holes with an auger 1½ inch,

the widest way of each piece so as to clear 1½ inch from one end of each, with the large auger intended to bore the posts, bore holes the same distance from the other end of each piece. These pieces then are to be fixed on the handle of the auger at each end by the small holes, not as represented in the drawing at E E, this being above the handle, the only way to be done on paper, but horizontally on one side of the handle. Thus fixed, the lever F which is a common pole, is put through the large holes of the pieces E E, and the auger turned with great facility by holding the other end of the pole in one hand and walking around the frame. This way of boring I perform altogether by children. But there is another way more expeditious but with an equal saving of labour, to be done by an able hand with a short lever about 4 feet long. In this case the borer stands in the same place on one side of the frame, and turns the auger with the short lever with as much ease as he could bore with any other auger in the usual way.

I am Sir your's with great respect,
JAMES RINGGOLD.
Rock Hall, 8th March, 1823.

Editorial Correspondence.

DRAINING MARSH LAND—RICE, POTATOES, &c.

Poplar Grove, S. C. }
13 miles from Charleston. }

DEAR SIR,

I am still at the plantation, enjoying the liberal hospitality of your excellent friend Charles Elliott Rowand, Esq. where I have been for the last seven days: I find him so very generous that he will not even suffer me to speak to him in any terms of acknowledgment.—To an honest mind, such attentions ought to be, as they are, a pain—because there is no probability of my ever being able to return them.

I wish you could be here to take a view of the beautiful Cherokee hedge fence, extending eight or ten miles around Poplar Grove plantation:—The description which you have published in the American Farmer of this "non descript," is certainly a modest one. When nature is in her desolation, we are here presented with the lively and cheerful prospect of a gay and beautiful garden, flourishing even in the rigour of winter.

Mr. Rowand is, unquestionably, and he has the reputation, of being one of the best Planters in South Carolina. He is now about 51 years of age—is the descendant of a Scotsman—has two plantations—the one where I now am, consists of 1000 acres, 500 of which is cultivated in rice—100 in corn and potatoes—all the rice, corn and potato land is reclaimed marsh, situated on Stone River, and which yields him immense crops. His method of draining land originated with himself—the particulars of which he has published in the American Farmer, and a model of his trunk, gate, &c. was also communicated.*

The trunk used by Mr. Rowand, without deviation, has been found to answer every possible service for the last thirty years—and one is now in operation flooding his rice-fields to-day, which was put in the ground in March, 1795.—I am persuaded that the publication of a drawing from the model which he sent you, with a few lines of explanation which can be made from his communication, would be very useful information to all future reclaimers of marsh land.

Mr. Rowand is amongst the most zealous friends to Agricultural improvement in this country—some part of every day is devoted to strangers in

* And loaned by the Editor to some good friend who never returned it.

answering enquiries which are made of him. I enclose you a list of names of persons to whom he has gratuitously sent boxes of the Rose Cuttings. It will give you an idea of the public spirit, the disinterestedness—the genuine *amor patriæ* which actuates such men—and will show how much may be done by a single individual, acting under such dispositions. Several boxes of different roots are now waiting the return of his boat from Charleston, to be sent to different parts of the United States.

Your's respectfully,

WM. F. REDDING.

The above extract is from a private letter on business, and was not intended for publication—but it seemed a fit occasion to make public acknowledgment of Mr. Rowand's liberality and useful services to the good cause, and to congratulate the publick on the increasing prevalence of a disposition amongst farmers, for the interchange of good offices in this way.

Edit. Am. Far.

† The list gives the names of fifty-one of the most eminent citizens and practical agriculturists in the states of Maryland, Massachusetts, Virginia, the Carolinas, Pennsylvania, Georgia, Delaware, Louisiana, and that of Lemuel Taylor, Esq. Matanzas, and Sir John Sinclair, Scotland.

Edit. Am. Far.

AGRICULTURAL PROSPECTS.

Extract to the Editor from Frederick County, Virginia, April 23, 1823.

It is with pleasure I inform you that our crops of small grain are unusually fine, and promise an abundant harvest. They are much superior to any crop since 1819, and with the exception of that memorable year, I think I have never seen them better.

TO THE EDITOR OF THE AMERICAN FARMER.

Poolsville, Md, May 2d, 1823.

"The crops of wheat and rye in this section of country and opposite this, in the limestone lands in Virginia, have a pleasing appearance, and the present scarcity of grain, together with rye straw is great—as great a scarcity was never witnessed by the oldest settler among us. The crops may be pitched, and great crops aimed at, if they should get through, but it will be (in the general phrase) a tight rub.

Corn and rye is selling in Virginia, at one dollar per bushel. Grass seems to put up slowly, and vegetation has been much checked by the very severe frost of Friday morning 25th ultimo."

With respect,

THOMAS WHEELER.

PUBLISHED IN THE AMERICAN FARMER, BY ORDER OF THE STATE.

B. HARWOOD, Tr. W. S. Md.

HORTICULTURAL SOCIETY.

The inspecting committee of this society, will meet on Tuesday evening the 6th inst. at Mr. Brantingham's Tavern, in Broadway near Art-street at 6 o'clock P. M. to receive all such vegetables, flowers, and fruit, as may be brought for prize competition, and will continue to meet there every Tuesday evening (except on the last Tuesday in each month, being the regular monthly meetings at Broadway House) until further notice.

COMMITTEE.

*Martin Hoffman, John R. Murray,
William Curr, John McNab,
Thomas Hogg, James McBrair,
Peter Hatrick, James Dick,*

From the specimens of skill already exhibited, a very handsome display is expected on Tuesday evening, particularly of choice Spring flowers.—The early cucumbers produced before the society on the 29th of April, raised by Mr. William Wilson of this city, and Mr. Arril, in the gardens of S. Van Renselaer, Esq. of Albany, do these gentlemen much credit. Mr. Arril's cucumber was 10 inches in length, and 8 inches in circumference, and in as fine perfection as could be raised in the middle of summer. The bunches of sea kail, by Mr. Floy, will probably be the means of introducing into general culture, this choice vegetable so much extolled in Europe; it seems to suit this climate well, and the cultivation is very simple.—*N. Y. paper.*

LITERARY.

Proposals, for publishing by subscription, A COLLECTION OF FUGITIVE POEMS, moral, sentimental and satirical—by Selleck Osborn.

The author of the articles which are to compose this volume, never wrote with a view to fame or profit; he merely obeyed the impulse of the moment. Of those which were sent to the press he seldom retained copies, and they were usually forgotten by him, until recalled to his mind by the public prints, which have often gratified him by flattering notice, but have also frequently annoyed him by mutilations which were extremely mortifying. This last circumstance (besides private solicitations and other motives,) has induced him to collect, with considerable pains, his scattered effusions, and to add some unpublished pieces; which, altogether, will at least have the merit of being genuine—and perhaps that of inculcating, to the best of the author's capacity, good principles and amiable sentiments—excluding all matters relative to party politics.

Disinterestedness is not pretended: It is confessed that a liberal patronage would be very acceptable, on various accounts. The author confides in the tried zeal of his friends throughout the Union, for the promotion of his interest in this case.

The volume will be neatly printed in a duodecimo form, of 200 pages, on handsome paper, with type entirely new, and well bound in boards, at \$1, payable on delivery. A commission of twelve per cent. will be allowed to agents on all returns made.

Gentlemen holding subscription papers, will please return them by the first of June next, or as soon as reasonable efforts have been made to obtain subscribers.

All communications to be addressed to the author, at Merchants' Hall, Boston, Mass.
Boston, March 24, 1823.

A subscription paper may be seen in the office of the American Farmer, and the editor of this paper will be happy to receive the names of gentlemen who may be disposed to subscribe—believing, as he does, that patronage would be, in

this case, well and judiciously bestowed, in reference both to the poems and their amiable and benevolent-hearted author.

BIOGRAPHICAL DICTIONARY:

By T. J. ROGERS, ESQ.

This work, commemorative of the actions and virtues of the heroes and statesmen of the American revolution is likely to receive a very extensive patronage, and to be enriched by biographies from the pens of some of the most learned and eminent men in the country. We have observed with great pleasure the names of several distinguished living Americans on the subscription list, and have seen one or two letters from others of equal distinction, enclosing biographical sketches to the Editor of the work.

GEOGRAPHICAL.

To the Editors of the National Intelligencer.

GENTLEMEN: It is probable that the late session of Congress has terminated without any definitive measures in relation to firm and permanent establishments on the coast of the Pacific Ocean.

As a good map of the country, from that ocean to our present Western States and Territories, would tend greatly to enlighten the public mind, now awakened to that quarter, I subjoin the south western boundary of the United States, with those of Louisiana and Arkanzaw.

The latitude of the northwest point of the Lake of the Woods has been ascertained, by a British Engineer, to be 49 degrees, 27 minutes. This gives 7 degrees, 27 minutes from the south boundary on the Pacific to the parallel of the northwest point of the Lake of the Woods. These make a meridian line of the length of 517 miles, and 77 hundredths; of which the half will be about 259 miles. If this be assumed for the length of the east and west sides, and 300 miles, as before proposed, for the north and south, they would give a double tier of Territories and States containing each about 77,700 square miles, with the exception of those on the coast.

However it may, eventually, be necessary to control the boundaries of States by mountains and rivers, the country is, at present, too imperfectly known for that purpose.

A. B. WOODWARD.

City of Detroit, March 13, 1823.

CHESAPEAKE AND DELAWARE CANAL.

The subscriptions for this important undertaking proceed with a degree of success equal to the most sanguine expectations. The amount subscribed within the last eight or nine days is above \$80,000. The Schuylkill bank yesterday subscribed \$10,000, and the Hand-in-Hand Insurance Company \$5,000. The subscriptions in one block of buildings in Chesnut ward amount to \$5,800.—*American Sentinel.*

The following remarkable instance of the sagacity of a Dog is copied from the Canadian Times of April 11, printed at Montreal:

"On Saturday, 29th ult. Mr. Dunn, formerly of this city, in attempting to go from Lapraire to his mills, a few miles distance, on the ice of the St. Lawrence, the horse and sleigh sunk through the surface, and the former immediately disappeared. By his struggling in the water the horse became disengaged from the sleigh, which floated—by this, Mr. Dunn, who had fallen through the ice when he sprung from it, supported himself for some time. During his stay in this perilous situation, a strange dog who had seen the accident, came from the shore and endeavoured to rescue him from drowning, by laying hold of the collar of his coat, and using violent exertions to drag

him to the shore. So great were the exertions of this noble animal, that he very nearly shared a fate from which he was endeavouring to save a human being. While the dog was exercising, by influence of instinct, a degree of generosity that is often found wanting in many of our race, Mr. Wood of St. Johns, succeeded in reaching to Mr. Dunn a pole, by which, after considerable exertion the latter was rescued from his dangerous situation. The above facts were related to us by a person who had them from one of the parties concerned."

SAILING CARRIAGES.

A machine, invented by a gentleman of Christ College, Cambridge, was lately tried at New Market. In shape, it is nearly that of an isosceles triangle, and it moves with the broad end forward, on four wheels. It has a boom thirty-two feet long, and an exceeding high mast. It will carry twelve persons at the rate of thirty miles an hour. To the axle of the hinder wheels is fixed a rudder. It can go on a wind, and tack as a vessel at sea, and is capable of being so correctly guided, that the pilot, at pleasure, can run the wheels over a stone.—*London Mag.*

The King of England has presented to the nation the Library of his father. The following is his letter to Lord Liverpool, announcing the donation. The trustees of the British Museum are to have the disposition of his Majesty's gift.

Dear Lord Liverpool—The King, my late revered and excellent father, having formed, during a long series of years, a most valuable and extensive library, consisting of about one hundred and twenty thousand volumes, I have resolved to present this collection to the British Nation.

Whilst I have the satisfaction, by this means of advancing the literature of my country, I also feel that I am paying a just tribute to the memory of a parent, whose life was adorned with every public and private virtue.

I desire to add, that I have great pleasure, my lord, in making this communication through you. Believe me, with great regard, your sincere friend.

(Signed)

G. R.

*Pavilion, Brighton, Jan. 15, 1823.

The Lord saw good, I was lopping off wood,
And down fell from the tree;
I met with a check, and I broke my neck,
And so death lopp'd off me.

At Selby, in Yorkshire.

Here lies the body of poor Frank Row,
Parish clerk and gravestone cutter;
And this is writ to let you know,
What Frank for others used to do,
Is now for Frank done by another.

At Northallerton.

Hic jacet Walter Gun,
Some time landlord of the Sun.
Sic transit gloria mundi!
He drank hard upon Friday,
That being a high day,
Then took to his bed, and died upon Sunday.
In the old church of All Saints, in Newcastle.
Here lies poor Wallace,
The prince of good fellows,
Clerk of Allhallows,
And maker of bellows.
He bellows did make 'till the day of his death;
But he that made bellows could never make breath

AXIOMS IN FARMING.

The following maxims are by Thomas Cooper, Esq.

1. Two crops of grain should not succeed each other: they should be separated by potatoes, clover, grass, turnips, beets or carrots for stall feeding.

2. Good agriculture requires no naked fallows: fallow crops [any hoed crops] that compel you to keep the ground clean while they are growing, answer the purpose.

3. Manure once in four years.

New-England Farmer.

THE FARMER.

BALTIMORE, FRIDAY, MAY 9, 1823.

The committee of arrangement have decided, that the next Maryland Cattle Show, shall be held at the Maryland Tavern on the Frederick Road, in the month of October next—the day will be announced, after consultation has been held with the society on the Eastern Shore. In the mean time the premiums to be awarded, have been agreed upon, and will be proclaimed in the next Farmer—when it appears, we hope the Editors in this State, and the District of Columbia, will copy it into their respective papers.

A GREAT CONVENIENCE FOR GOOD HOUSEWIVES.

Daniel Richardson, an ingenious and respectable mechanic, has brought to great perfection, the REFRIGERATOR or Portable Ice House.—Good housewives only can calculate the many useful and economical purposes to which this contrivance may be applied. The improvements made by Mr. Richardson, have so far perfected the Refrigerator, that it may now be fully relied upon, for keeping butter, milk, meat, eggs, fruit, vegetables, or any article of household consumption, perfectly cool, fresh and pure. All the above named articles, may be preserved in these machines, as long as desirable, perfectly sweet, clean and free from taint. The Refrigerator may be deposited in the cellar, in the garret, in any part of the house, or even in the open sun, without any perceptible injury to the contents; it does not require to be replenished with ice, more than once in three days, during the hottest season; and it is attended with another advantage—complete security against every species of vermin, to which it is totally inaccessible, and in winter, it will keep any article from freezing, that is deposited in it. Every family ought to have one—the price is from \$15 to \$25, according to size—and the manufactory is in East-street, opposite Mr. Nevins' Church.

We have succeeded in obtaining some very interesting information, respecting the preparation of flax, which will be given to our readers, in the next farmer, if, in the mean time, we obtain the necessary engravings of the machinery. The result of this information is, that all attempts to dress it, without wretting, have been unavailing for practical and common use—and that of the two modes of wretting, by dew and water—the latter is the more expeditious, and in other respects, the preferable one.

LATEST FROM ENGLAND.

The ship *Minerva*, Capt. Wilson, in 28 days from Liverpool, has brought papers of that place of the 5th April, from which it appears that no accounts had been received of the commencement of hostilities on the Spanish frontier. The

Duke of Angouleme had arrived at head quarters, and it is naturally to be inferred from this circumstance, that Spain would be forthwith invaded, if his royal highness did not receive counter orders in a few days from Paris.

The King of Spain, accompanied by six thousand troops, left Madrid on the 20th March, for Seville, as previously settled by the Cortes.

The Traveller of the 31st announces that intelligence had been received by a rapid conveyance from the head quarters of the French army of the eastern Pyrenees, informing of the arrival there of the Duke d'Angouleme, on the 22d March. It had been reported that strong dissatisfaction had been manifested in that division of the French army, (about 32,000 men;) but nothing was said of it in letter by this conveyance. There was a report that Mina entered the French territory on the 17th, but it appears to have been without foundation. Mina was at Perthus on the 18th.

A new Poem by Lord Byron, called "*The Age of Bronze*," was published in London, on the 1st of April.

LIVERPOOL, March 28.

The animation which our cotton market showed last week, subsided on Saturday.

The Liverpool Mercury contains an account of the shipwreck of one of the packets from Dublin for Liverpool. Upwards of one hundred passengers perished.

Accounts, it is said, have been received from Admiral Krusanstern, that a Russian officer had accomplished the extraordinary journey of 50 days on the polar ice, and had arrived at an entirely open polar sea.

April 4. Our cotton market generally has been in a very dull and declining state throughout the past month. Some speculative purchases had the effect of producing a temporary improvement, but, not being followed up to any extent, the demand again subsided, and during the present week the market has been quite as dull and depressed as in any preceding one this year. Our quotations are fully $\frac{1}{4}$ d. per lb. lower in New Orleans, and $\frac{1}{4}$ d. per lb. in every other description, than on the 1st ultimo.

The total sales of the month amount to 48,000 bags, of which 5,000, chiefly new Upland, have been taken on speculation, and 2,000 exported; besides which about 5,000 bags chiefly American, were forwarded into the country unsold.

BALTIMORE MARKET.

Flour, best white wheat, \$8—Howard street Superfine, \$7 25—fine do. \$6 75—Wharf, do. \$7 to 7 12 $\frac{1}{2}$ —Wheat white, \$1 55 to 1 60—Red do. \$1 53 to \$1 57—Rye, 80 cents—Corn, 60 to 63 cents—country Oats, 50 to 55 cents—Beef, 8 cts. per lb.—Live Cattle, \$6 to \$6 50 per cwt.—Bacon, round, 8 to 9 cents per lb.—Pork \$4 50 to 5 50 per c. lb.—6 to 8 cts. per pound—Mutton, 5 to 6 cts. per lb.—Beans, \$1 37 $\frac{1}{2}$ to 1 50—Peas, black eyed, 55 to 60 cts.—Red Clover seed, \$6—Orchard Grass do. \$3 50—Herds' Grass do. \$3—Timothy do. \$4 50—Millet, \$3—Flax Seed, 75 to 80 cts.—Whiskey, from the wagons, 32 to 35 cts. per gal.—Apple brandy, 30 to 32 cts.—Peach do., 65 to 70 cts.—Shad, none in market—Herrings, No. 1, \$2 50 per bbl.—No. 2, \$2 25—Fine salt 80 to 90 cts. per bush.—Coarse, do. 75—Butter, 20 to 25 per lb.—Eggs, 18 $\frac{1}{2}$ cts. per doz.—Hay, \$18 per ton—Straw, \$11 to 12.

MARYLAND TOBACCO.—Same as last report.

Three hds. raised by Col. C. S. Ridgley, sold, one at \$30—one at \$22—and one at \$10 50.—two hds. from Pennsylvania, Westmoreland county, sold at \$14 50.

BELLFOUNDER,

The wonderful Norfolk Trotter, imported July, 1822, from England, to Cover this season, 1823, at twenty dollars, and one dollar the Groom—the money to be paid to the Groom at Covering.

This celebrated horse, is a bright bay, with black legs, standing 15 hands high; his superior blood, symmetry, and action, excel those of every other trotting Stallion. He is allowed by the best judges in Norfolk, to be the fastest and best bred horse ever sent out of that county. He has proved himself a sure foal getter, and his stock for size and substance are not to be surpassed—they are selling at the highest prices of any horses in Norfolk.

BELLFOUNDER was got by that well known, fast and high formed trotter, Old Bellfounder, out of Velocity, which trotted on the Norwich road in 1806, sixteen miles in one hour, and though she broke fifteen times into a gallop, and as often turned round, won her match. In 1808, she trotted twenty-eight miles in one hour and forty-seven minutes, and has also done many other great performances against time.

Bellfounder, at five years old, trotted two miles in six minutes, and in the following year was matched for two hundred guineas to trot nine miles in thirty minutes, and he won, easily by twenty-two seconds. His owner, shortly after challenged to perform with him seventeen miles and a half in one hour, but it was not accepted. He has since never been saddled or matched.

Old Bellfounder, was a true descendant from the original blood of the Fireaways, which breed of horses stands unrivalled, either in this or any other nation. Bellfounder is strongly recommended to the public by the subscriber, as combining more useful properties than any other horse in America, and will stand during the season, at his stable in Charlestown, where all inquiries, post paid, will be attended to.

SAMUEL JAQUES, Jr.

Charlestown, (Mass.) April 22, 1823.

FOR SALE,

A fine bull calf, eight months old, three-fourth Alderney, and one fourth of General Ridgely's famous Dutch stock—price \$50, enquire of the Editor.

PRINCE REGENT.

This justly celebrated and well known horse, is a dark bay, full sixteen hands high, of fine form, figure, and great bone—he walks, paces, trots and canters remarkably light, and well. He is in strength, form and figure, what may be conceived in the description of a first rate English coach horse or Hunter, his eye is a large clear hazle, his movements graceful and grand, and his colts where he has stood the last three years, are much admired for their size, action and beauty.

He will stand this season, from the 1st of May, from Saturday till Wednesday morning, in each week at Govan's Town, under the direction of Mr. John Wooden; and from Wednesday till Saturday mornings, each week, at the Maryland tavern, four miles from this city, on the Frederick turnpike road, under the direction of Mr. John Wattson—at the rate of EIGHT DOLLARS the season, for each mare, and 50 cents for the groom, the money to be sent with the mares or a note given for the amount, payable on the first day of August next.

Baltimore, April 29, 1823.

N. B. Pasturage may be had at each place for mares, if required.

AGRICULTURE.

SOME OBSERVATIONS ON VEGETATION, AND MANURES, BY THE EDITOR OF THE EMPORIUM OF ARTS AND SCIENCES.

Agriculture. The art of selecting and raising to the best advantage, those vegetable substances that serve for the use of man.

It is not my intention to enter at large into the extensive theory of this first of arts, or to give a detailed account of practices adopted or recommended by the numerous writers on this prolific subject: but a few general observations hitherto seldom noticed in the connection now presented to the reader may furnish more accurate ideas than commonly prevail.

The theory of agriculture relates to I. the properties of the plant itself. II. of the climate and soil in which it is placed. III. the mode of accelerating its growth and increasing its size.

Writers on agriculture, ignorant for the most part of the physiology of animals as well as vegetables, have usually considered and treated of plants as inanimate beings: they are not so.

Every plant is the production of an organized seed endowed with the property of vegetable life, and of being acted upon by appropriate stimuli. This vegetable life is originally excited and subsequently continued by the application of what may be called *natural* stimuli, much in the same manner as in animals. Thus the pollen of the pointal received by the chive, and thence propagated to the seed vessel, impregnates the seed, and excites the action of the living fibre, which afterwards proceeds according to the laws of organization peculiar to each plant. This action is continually renewed by the application of vegetable food by means of which the germ is dilated till the plant arrives at its full growth. All this is perfectly analogous to the impregnation of the animal germ in the ovarium, and its subsequent growth to full age and size.

In animals, the muscular fibres have the property of contracting on being irritated. *Irritability* as it is called. So have vegetable fibres.—The sensitive plant, the *hedysrum*, the *dionæa muscipula* of Carolina, the phenomena of plants growing in a dark place and turning to the light, are proofs of this, if not of voluntariness. The separated twigs of *hedysrum*, are irritable, like a separated muscle. Mr. Howard has lately discovered the same property in the pollen, on the application of alcohol. (Trans. Linn. Society of London.)

Animals have feeling, perception, or *sensibility*, and the power of voluntary motion. So have plants.

The facts adduced by Percival, Smith, and Darwin, and the whole class of phenomena relating to their search of food, and the propagation of their species seems to put this beyond reasonable doubt. To which may be added the habits and customs of the parasitic plants.

Animals though perfect in all their parts, may be stunted in their growth by too small a quantity of food, and by other means; and this diminution will affect the size of their offspring. The case is precisely the same with plants. By plenty of food and favourable situations, animals may be increased in size. So may vegetables. By breeding from selected couples of a large size, the size of the animal offspring is increased.—Hereon was founded the successful practice of the greatest cattle breeder in England, Mr. Bakewell of Ditchley; and the same set of experiments has been repeated with equal success on plants by Mr. Cooper of New Jersey. Mr. Bakewell increased the flesh on particular bones of his cattle, and propagated this propensity.—Mr. Cooper has in like manner propagated not

merely increase of size, but increase of size in particular parts of the plant, and propensities to earlier vegetation.

In animals, appetite may be provoked, and digestion assisted, by the artificial stimuli, of what physicians call *Condiments*, salt, pepper, wine, acids, bitters, &c. Such also is the property of vegetables. Their hands, mouth, and stomach, are in the soil; and by the application of artificial stimuli, such as lime, common salt, alkalies, plaster of Paris, &c. their roots may be excited to want, to seek, to take in, and to digest more nutriment than they would otherwise use.

Animals may be surfeited with too much nourishment. So a plant will die if set in a mere dung-heap. Animals may be poisoned. So may plants. Every metallic combination for instance, except oxygenated and carbonated iron, and calx of manganese (and lead?) in small quantities, being poisons to the vegetable.

By the artificial stimuli of condiments, animals may be excited too much, and indirect debility will ensue. So is it with plants. In like manner, excess of these artificial stimuli will take away their beneficial effects, as half a pint of wine may assist, when a bottle will injure digestion. Thus, from the experiments of Sir John Pringle, and Dr. Watson, (Bishop of Landaff) it appears that a small quantity of common salt is a septic to the animal fibre, and a manure to vegetables, while a large quantity, is the domestic antiseptic of cookery, and destroys vegetation altogether. So in the experiments of Judge Peters, two bushels of gypsum will produce a luxuriant crop; 6 or 8 will prevent it.

In animals, when parts of muscular or other fibres, are weak, diseased and dying, artificial stimuli can be applied to excite an action in the living and healthy parts, by which the dead are separated and sloughed off. So in plants, the artificial stimulus of those substances which are not manures in the sense of affording nourishment to the plants, but only as exciting a stronger and more healthy action in the living fibre, will kill the weak and diseased roots, while they invigorate the more healthy. This is the mode of action (in part) of lime, gypsum, salt, &c. usually classed among manures, but which do not enter into the composition of the plant itself.*

Animals are resolveable into gasses, lime and phosphoric acid. There is no peculiar animal earth. The phenomena of marine animals, the experiments of Vauquelin on the production of lime in the hen, and some other facts, make it probable, that the lime of the bones, as well as their phosphoric acid, is the product of animalization.

Vegetables are resolveable into gasses and fixed alkali by fire: by putrefaction their alkali is either decomposed, or escapes, for no fixed alkali is found on the incineration of vegetables which have undergone completely the putrefactive process. Both vegetables and animals contain in their fluids accidentally, unessential quantities of iron, manganese, and neutral salts. Thus the blood contains iron, albumen, mucilage, the serum, urine, uric and phosphoric acids, with bases of lime, soda, volatile alkali. So in plants, nitre is found in borage, in nettles, &c. and oxalates in some. Hence it appears, that the essentially component parts of animals and vegetables consist chiefly of two or three gasses.

Again. Animal fibres are made from plants. So true is the scripture exclamation that all flesh is grass! An ox and a sheep are made up of vegetables, and so are we who devour them. Nothing is nourishment to an animal, but what was

originally a vegetable. In like manner nothing is nourishment to a vegetable but what enters into the permanent composition of a vegetable. We find large plants grow in pure sand (Vanhelmont,) in sand and clay, in common clay, in limestone, in limestone and sand, limestone and clay, and in all the combinations of these common earths, nay even in sulphur, in shot, in pounded glass, but we do not find that these earths or either of them, are any permanent and essential parts of the composition of a plant any more than of an animal. In a human body of 200lb. weight, we may find about the fourth or fifth of an oz. of common salt, and we may perhaps find in clover the same proportion of gypsum, but these are accidental parts of the composition.

More accurately. When a vegetable is decomposed by means of fire, in close vessels, we procure, 1st. a considerable quantity of water.—2dly. Pyroligneous acid or an empyreumatic vinegar. 3dly. On the top of these and mixed with them, is a quantity of strong oily matter, that smells of tar and smoke. 4thly. A great quantity of carburetted hydrogen gas, to wit, about 50 quarts to the lb. avoirdupois of fine saw dust. All woods, and (I believe) all vegetables, furnish it in some proportion. 5thly. A 5th or 6th in weight of charcoal, and nearly equal in bulk to the vegetable itself; of this about 90 parts in 100 are frequently pure carbon, when well burnt and freshly made and weighed. 6thly. Alkali: inland plants furnish the alkali of potash; marine plants generally furnish the alkali of soda. The alkali of potash obtainable from the green woods usually employed for the purpose, does not exceed one part in 16 or 1800 parts. 7thly. earthy salts and iron in minute and accidental proportions.

Now, The water, is hydrogen and oxygen.

The pyroligneous vinegar, is carbon, hydrogen and oxygen.

The oily matter is carbon and hydrogen. The carburetted hydrogen, is carbon and hydrogen.

The charcoal is nearly pure carbon.

The alkali, is an oxyd of a metal.

The iron, or manganese may be accidental, but one or other is almost always found, though in minute proportions.

Some vegetables, as the farinaceous that contain gluten, and the succulent tetradynamious plants that contain albuminous matter, furnish also azot. So do mushrooms, truffles, and morels, which on distillation give out volatile alkali, the base of which is azot. But the vegetables that furnish azot, are exceptions to a general rule. Lime also in very small quantities, is frequently found in vegetables, but nothing tends to induce us to regard it, as other than an accidental substance.

The result is the same, when vegetable matter is decomposed in the moist way. Thus: let us take the case of a Distillery, and consider the process that goes on there. The bruised grain is mixed with water: then yeast, (that is, carbonic acid gas enveloped in mucilage) is put to it.—The gas acts upon the grain, and decomposition, and new compositions take place. Great quantities of carbonic acid gas are evolved: alcohol is formed: then vinegar, which is alcohol united to oxygen. What do these products amount to, but carbon and hydrogen, and the oxygen imbibed from the atmosphere? For every drop of vinegar is made at the expense of a particle of alcohol united to a particle of oxygen.

In the case of the decomposition of animal substances, whether in the dry, or the moist way, no acid appears: we get azot, a fetid animal oil, swimming at the top of a volatile alkaline li-

* Vide Sir Humphrey Davy, *contra*.

and sometimes concrete volatile alkali, or carbonate of ammonia comes over. The retort contains an animal charcoal, consisting of azot, carbon loosely combined, the base of the prussic acid, and if bones be used, phosphat of lime.

In this case, the azot, the lime, and the phosphorus, seem to be new combinations, the result of animal organization modifying chemical affinity. There are many districts of Pennsylvania, perhaps the best pasture land in it, that do not contain a particle of limestone. Such for instance as a great part of the county of Luzerne and the beech country comprehended between the north east branch of Susquehanna, the New York state line, and the Delaware. There is no finer grass country; but limestone is rare throughout the greatest part of this space. A calf bred up there, will have *bones*, that is phosphat of lime: his flesh will yield *azot*, either by distillation, or by the nitric acid. Where does he get it? The soil contains none; the grass on which he feeds contains none, but the ox is chiefly composed of azot and phosphat of lime!

Hence it appears that about 99 parts out of a hundred of vegetable matter, consist of carbon and hydrogen of which the carbon far exceeds in quantity.

Hence also, the pabulum or food of vegetables, can only be carbon and hydrogen, or those substances which are easily decomposeable into carbon and hydrogen.

Hence animal matter is the best of manures, because, the carbon it contains is more easily disengaged, and the substance more easily decomposed than even putrescent vegetable matter. Hence it is that in steel furnaces and in case-hardening, animal charcoal is thought to aid the operation; the carbon of animal, being more easily separated, than the carbon of vegetable charcoal.

Hence we learn to distinguish, manures of *nourishment*, from manures of *stimulus*, and from *mechanical* manures; and we are taught that every vegetable and every animal substance when decomposed, furnishes pabulum to vegetables; and that every such substance so decomposed is a manure of nourishment, and that nothing else is or can be. It may be taken for an axiom, that from man to a cabbage or a lichen, nothing can be converted into nutriment for the living fibre, but what has been a permanently component part of living fibre before.

Other properties of vegetables there are, *similar* (rather than analogous) to those of animals, which the necessary brevity of a short essay, will not permit to be detailed at length. It may be observed however, that plants like animals may be transplanted from one climate and soil to another, provided the difference be not very great, and care be taken to accustom them gradually to the change. Indeed, vegetables like animals will accustom *themselves* to the change in a generation or two, provided the difference be not above 8 or 10 degrees of latitude or of mean temperature. The range is not yet ascertained.

On the preceding properties of vegetables, and their analogies to animals, may all the agricultural doctrine of manures be well founded.—These analogies have been remarked by others, but their application in this respect has not been heretofore sufficiently observed.

Animals *differ* from vegetables in having a more extended sphere of locomotion. The animal (cases nearly zoophytical, excepted) can move the whole of his body from one place to another—a plant can only move its root-fibres and its branches. The *convolvuli*, and other parasite plants, are in some degree exceptions; but the general rule is, that the immoveable centre of a plant's situation is the place where the

germ falls, or the seed or plant is set with intent that it should remain. Hence the use of that kind of manuring which consists in the admixture of soils of various depths and adhesion, for the mechanical purpose of keeping the plant steady.

II. Of the climate and soil.

No experiments have been made to ascertain with precision the bounds of latitude or temperature which prohibit the naturalization of exotic plants. In France, YOUNG has marked the lines of the maize and the vine culture. In this country maize grows tolerably well from lat. 42, and beyond it to Georgia. Wheat is not so good and productive south of Virginia, as in the middle states. The latitudes of cotton and rice, are not yet exactly ascertained. Coffee has not yet had a fair trial in our southern states, nor the sugar cane. Much indeed yet remains to be done in this respect, and much is doing by the British government in the West Indies.

Agriculturists have many vague denominations of soil, such as clay, loamy, marly, sandy, limestone, limestone gravel, sandy gravel, stoney, poor light soil, rich black soil. These are tolerably descriptive in a general way; but as the theory of the art improves, we shall need more accuracy. Of the primitive earths, none need be noticed under this section, but siliceous sand; argil or clay; and calx or lime. The others have never been yet found in sufficient quantity to produce any notable effect, except in the hurtful quality of magnesia when combined with lime, as 2 to 3 first noticed by Mr. TENNANT. It is evident that for the mechanical purpose of increasing or lessening adhesion, supporting the plant, and admitting its fibres to shoot more freely, clay, sand, and limestone are mutually manures to each other; acting mechanically by their mixture. Thus in Cheshire and Norfolk, in England, the clay and marl pits furnish an excellent and permanent manure to the sandy soil above; and assist moreover in retaining manure and imbibing moisture.

But it is not merely the mechanical mixture of soils that may be useful; for the experiments of M. D'ARCEY and M. FABRONI have shewn us, that in the temperature of 100° of FAHR. different earths have different capacities for retaining moisture; so that by judicious admixtures, this valuable property in soils may be increased or diminished; and as none of the earths are found perfectly pure in soils, (clay, for instance, retaining 66 per cent. of sand without losing its distinctive character) a field is opened for ascertaining this property in different admixtures and combinations. For Mr. WEDGWOOD discovered that earths would chemically combine in the moist way.

Besides the tenacity of soils, and their capability of retaining moisture, their *depth* is also to be considered by the cultivator. Some plants have long tap-roots, such as rhubarb, liquorice, carrots, parsnips, madder, &c. These are evidently unfit for any soils, but of loose adhesion and of considerable depth. Equally preposterous would it be to use a soil like the Genesee flats of 20 feet deep of light, rich mould, for grasses that spread upon the surface. Again, where soils are naturally sandy, dry, and arid and the climate warm, plants should be selected, whose roots penetrate deep and beyond the influence of atmospheric evaporation. Thus, in this country as in the south of France, Lucerne, (*medica*) and chicory (*chicorium intubus*) would be luxuriant where no other grass would grow.

III. I come now to consider the mode of accelerating the growth and increasing the size of plants.

This is done by *manures*. Hitherto, every substance added to soil, or to the plant while growing, which effected, or was meant to effect these purposes, was called a manure. But, from what has been said, manure ought to be considered in at least four divisions. 1. Manures of nourishment. 2. Manures of stimulus. 3. Manures of moisture. 4. Mechanical manures.

Manures of nourishment. Five different theories have been started on this subject, the pabulum of vegetables.

1. Practical men have for ages discovered the use of dung in agriculture, and hence the common and oldest theory was, that the juices of decomposed animal and vegetable substances in the gross, were the chief pabulum of plants.

2. VANHELMONT's experiment suggested *water* as the pabulum, but although some plants will live, none will flourish in mere water. The French experiment of the decomposition of water, and the discovery of the excretion of oxygen, give countenance to the opinion that water, though not *the* pabulum, is decomposeable, and is a pabulum; furnishing hydrogen: and it is also a component part of the plant even as water. The curious experiments of M. Braconnot add strength to this opinion. It is not yet known whether plants can decompose azot, but I am strongly inclined to suspect this substance to be a compound, for we have no fact to shew that animals absorb it from the atmosphere.

3. Dr. HUNTER, of York, in his *Georgical Essays*, persuaded the world for some time, that oil was the pabulum of vegetables. But neither his theory nor his practice succeeded.

4. Dr. PRIESTLY, who had more right to form theories and conjectures than any man living, (because he furnished more facts of extensive application in chemical philosophy than any other man,) suggested that *phlogiston* was the pabulum. Some experiments of ARTHUR YOUNG, made in consequence of this supposition, tend to support it. But though in all probability *inflammable gas* may be converted into nutriment to vegetables, yet it is far from being true, that this is the only gas which can. The gasses that escape from a dung-hill contain much carbon, azot, and ammonia, as well as various stimulating saline compounds. We know too, that electricity, and the galvanic fluid, seem to aid vegetation to a certain degree: but the action of these fluids is more satisfactorily accounted for, on the doctrine of stimulus, than of pabulum.—That oxygen is not nutriment, is clear, from its being an excretion of plants in a healthy state, and in vigorous action, under the influence of the sun, as Dr. PRIESTLEY, and afterwards M. INGENHOUS discovered. Hence, although fluid manures may contain the elements of phlogiston, or the combinations of phlogiston, this latter can not of itself be taken as the only food of plants. Both plants and animals are resolveable into gasses of which phlogiston may be a part, but there is something else which feeds and dilates the muscles of animals, and the leaves of trees, for they furnish something else.

5. Dissatisfied with former theories, Mr. KIRWAN, has proposed *carbon* or charcoal as the food of plants; and declares his opinion that it charcoal could be rendered soluble in water it would be the most efficacious manure. It is true, that charcoal and carburetted hydrogen, are found in the incineration of all undecomposed vegetables, but they contain also alkali, oxygen, and nitrogen, &c; nor is there any fact to prove that charcoal (or the oxyde of carbon) is either soluble in any liquid, or taken up as charcoal by any vegetable, or decomposed by any natural process; soot as a top dressing is a tolerable manure in England, but its use may be accounted

or from the saline substances it contains. From every fact hitherto known, the pabulum of vegetables, appears to be exhibited to plants generally in the form of a *liquid*. Hence, whatever theory of ingenious speculators be adopted as the simple and homogeneous pabulum of vegetable bodies in a living state, the old theory and the old practice must, and ought to prevail, namely, that the only manure of nourishment to be depended on, is dung, (*i. e.*) *decomposed animal vegetable substances*; which contains within itself every substance that theory has hitherto assigned as the food of plants, ready to be afforded gradually, by the continual decomposition of the various compounds which the dung contains: and although it may be of use by dung-heaps to aid this decomposition, yet even in an undecomposed, or partially decomposed state, this gradual decomposition amounts in the end to the same thing. This is applicable to ground bone, woolen rags, horn shavings, &c. All the difference is that *time is gained* by the artificial and complete decomposition of these substances.

Manures of stimulus. Whatever accelerates the growth, or increases the size of plants, and does not actually enter into the composition and substance of the vegetable, can only be considered as a manure, by stimulating the healthy fibre of the plant, by destroying the dead and decaying fibres, and by assisting the decomposition of undecomposed animal and vegetable substances dispersed through the soil. It is thus that *gypsum* or plaster of Paris acts, being the most citracious septic among the neutral saline substances. Of these manures of stimulus, none are as yet in common use, but lime, gypsum, and common salt.

Lime, is limestone deprived of its water and carbonic acid amounting to 44 per cent. by fire.—In this state, its stimulating powers are obviously much greater, than in its natural and neutral state of limestone. But even pounded limestone is a promoter of vegetation mechanically, on clayey and sandy lands; and this earth appears to be a specific stimulus to white clover, and perhaps to the potato. Hereto may be referred the rubbish of old buildings, and marl, which is clay about one half of limestone.

Common Salt. This, until the duty of two thousand per cent. in England, was a very common manure in Cheshire; the facts relating to it, in this point of view, are collected in *WATSON'S chemical essays*. In this country, Gypsum is much cheaper.

Gypsum, plaster of Paris, *vitriolated lime*, or *sulphat* of lime. This has not been certainly found in any plant, but by M. MODEL, accidentally, in rhubarb, (*Journ. de phys.* vol. 6. p. 14.) even this I suspect to be a fallacy; for the characters of gypsum were not then well ascertained. About two bushels per acre to clover or corn seem to be a full quantity. It attracts the moisture from the air, and dissolves gradually when srewed on the ground. It is brought here from France and the bay of Fundy, and has also been lately found in New-Hampshire, and on lake Erie. There is also some in Maryland on the Chesapeake, about one hundred miles below Baltimore, and throughout the Genesee country, and on the waters of the Chippawa. As it is not a component part of any plant, either in whole, or in its own component parts, it cannot act upon healthy vegetables but as a stimulus, and upon diseased and dead ones, by its septic power. Experiments remain to be tried as to other manures of this description.

Gypsum particularly deserves attention, considering that it has effected almost a complete revolution in the agriculture of Pennsylvania.—

Many thousand acres of land hitherto barren, have been converted into excellent pasture ground, by its surprising influence. Even the products of land, tolerably good, have been in some instances doubled by using it. The theory of its action was not understood. Judge PETERS of Philadelphia, who first collected the opinions of our farmers, on the subject of the gypsum as a manure, ventured to suggest, that the vitriolic acid was the fertilizing principle of this manure; But Mr. Priestly of Northumberland, has given this opinion a fair trial, both by means of sulphur and of sulphuric acid, in all proportions, without the slightest appearance of success. We shall have therefore as I think, to recur to the theory first advanced by myself in the year 1793, that it acts as a septic to dead fibres, and as a stimulus to living ones.

Manures of moisture, and Mechanical manures. Their action in giving *depth* by new addition; in giving *tenacity* by mixture, as clay with sand, or *vice versa*—in giving *capacity to retain moisture*, on the principles suggested by the experiments of FABRONI and D'ARCEY, is too obvious to require further elucidation.

Such are the ideas that occur to me as throwing some light on the theory of this complicated and most important subject, and suggesting the *rationale* of the application of manures, in cases not hitherto well understood. T. C.

GUINEA GRASS.

The following article is of the first importance to the agriculturist. It has been handed to us by a gentleman of this town, who has himself imported a small parcel of the seed, with a view to test its utility by experiment; and who has requested its publication in our paper, that others interested in the promotion of agriculture, may be induced to follow his example.

We recommend to our readers the perusal of the following communication. There can be no doubt of the correctness of the statement. Its importance, especially to this section of the country, must be self-evident.

[*Cape-Fear Recorder.*]

MR. SMITH—I am so much convinced of the immense importance of introducing the culture and propagation of the *Guinea Grass*, and of the highly beneficial consequences that will reward those, who will take the little trouble of trying faithfully, an experiment, that I cannot resist the temptation of making one more effort to bring it into notice. The paper you published was too long for the attention of many readers, and the facts too scattering to obtain their particular notice and recollection. I therefore afford you an opportunity of essentially serving your customers and country, by sending you a short but distinct view of the important subject from the former publication, and an account of my own success.

If it be found to succeed in North Carolina, it will be more valuable than the discovery of a gold mine.

Sir Bryan Edwards—In Jamaica, it is considered next in importance to the sugar cane. Most of the grazing farms throughout the Island, were originally created, and are still supported, chiefly by means of this valuable herbage. Hence the plenty of horned cattle for the butcher and planter; which is such, that few markets in Europe can furnish beef at a cheaper rate, or of a better quality, than Jamaica.

It yields a quantity of grass almost exceeding belief.

From not more than six plants, a pint of seed was given to one person. No doubt but a small proportion of the product.

In the East Indies it grows to the height of seven feet—admits of being frequently cut—makes excellent hay. Cattle eat it both in a fresh and dry state, with great avidity.

Col. Laurens, formerly President of Congress, Ambassador, &c. sowed one-fourth of an acre, of very indifferent land, in drills. Seed sprung, and soon covered the ground with grass four feet high and upwards. In August, he divided one of the roots into twenty-eight parts, which were immediately replanted. Every part took root and grew finely.

Dr. Brown sowed the seed, in the city of Natchez in the month of April, in holes two feet apart: When the plants attained a proper size, he took them up, and dividing the roots, set them out when the soil was wet, filling up the ground he had appropriated for the experiment. Began to cut the grass on the 16th July. 164 stalks from 6 to 7 feet high, growing from one root, weighed together 30 pounds—the number of stalks were 184, some of which measured ten feet eleven inches in length. Some part of the lot very poor soil—grass there 6 and 7 feet high.

One acre will more than support five horses most abundantly the year round.—One-eighth of an acre, of very fertile land, near Fort Adams, from plants set out the first and second week in May, without any trouble except cutting down the first growth of grass on the 20th June, say in five or six weeks, allowed cutting for plough horses and mules, and supplied them with as much as they could eat during the whole summer. On the 25th September it had been cut 4 times, and in two weeks would be cut the fifth.

From twenty roots, the fourth cutting yielded 250 lbs. of green grass.

No kind of grass supports the heat of the sun better—and from the first of July until killed by the frost, it will afford a constant and abundant supply of green food.

The seed should be sown as early in the spring as the danger from frost is over, and the plants set out when two or three inches high. They will readily take root. A basket or two of the young plants will be sufficient for an acre.

One hundred plants would enable a poor family to keep a cow in town, or supply a dray horse with food, all the summer.

EXPERIENCE.

About the 20th of May, Mr. A. S. Allen having kindly brought me some seed, which Mr. Gales obligingly sent me, I sowed part of it in a bed 52 feet long by 5 feet wide, in three drills.—From it I have planted out at Smitville, 187 roots in a bed 23 feet square. I have planted an irregular piece at home, with 200 roots; and from the same bed many more roots can and ought to be taken, it having been sown, by an unskilful hand, irregularly and too thick. This, with a little difference of the soil at one end of the bed from the other, occasions the grass to be uneven. Some of it actually measures a little upwards of 6 feet 6 inches. I should have began to cut this this day, [July 5.]—but observing that Dr. Brown, who sowed as early as April at Natchez, began only the 16th of July, I think I shall defer it till that day. Besides the above bed, which I shall call my experiment bed, I have sown a much larger space of ground, from which I shall have it in my power to give liberally, to any persons, without distinction, disposed to give it due attention, and will leave their names with you.

COLUMELL.

FROM THE HARTFORD COURANT.

CANADA THISTLE.

A few days since I called on a member of the Litchfield County Agricultural Society, who showed me a piece of ground from which he had easily and effectually eradicated the Canada thistle. As this subject is becoming very interesting to this portion of the county, I trust an account of the process by which this object was effected will not be unacceptable to your agricultural readers.

The secret consists in cutting off the plant near the ground at the change of the moon, or in the new moon, as near the change as possible, in June or July. This, my informant says, will generally destroy all the plants in the first year, but should any shoots sprout the next year, let the same course be pursued, and in two or three years there will not a root remain.

This process of course is better adapted to cases where the evil has but just commenced.—This is the third year from the commencement of the operation on the small piece I was shown, say from two to four rods square; and at this time not a Canada thistle is to be found there; although three years since they constituted the principal growth. That the circumstances attending this case were correctly detailed, was confirmed to me by a neighbour of my informant who was present and who had witnessed the whole process. He informed me that he derived his information from a farmer in Dutchess county, by whom and in whose vicinity this course has been extensively pursued, and with uniform success. The discovery was first made, as I am informed, through the same channel, by an observing farmer in Troy, N. Y. Some years since, being much infested with these troublesome weeds, he cut down a quantity of them in the vicinity of his house, and was surprised to find the next year that those he had thus served did not shoot up again. Upon recurring to dates, found they had been cut exactly at the change of the moon in June. This induced the same result, but subsequent and more extensive experiments have determined the best time for cutting these noxious weeds to be as I have before stated.

A FARMER.

Natural History.

PART FIRST.—ON THE CONDITION OF ANIMALS.

Chap. 1.—On the Duration of Animals.

Each species of animal is destined, in the absence of disease and accidents, to enjoy existence during a particular period. In no species, however, is this term absolutely limited, as we find some individuals outliving others, by a considerable fraction of their whole life. In order to find the ordinary duration of life of any species, therefore, we must take the average of the lives of a number of individuals, and rest satisfied with the approximation to truth which can thus be obtained.

There is but little resemblance, in respect to longevity, between the different classes, or even species of animals. There is no peculiar structure, by which long-lived species may be distinguished from those which are short-lived. Many species, whose structure is complicated, live but for a few years, as the rabbit, while some of the testaceous mollusca, with more simple organization, have a more extended existence. If longevity is not influenced by structure, neither is it modified by the size of the species. While the horse, greatly larger than the dog, lives to twice its age, man enjoys an existence three times longer than the former.

The circumstances which regulate the term of existence in different species, exhibit so many peculiarities, corresponding to each, that it is difficult to offer any general observations on the subject. Health is precarious, and the origin of diseases generally involved in obscurity. The condition of the organs of respiration and digestion, however, appears so intimately connected with the comfortable continuance of life, and the attainment of old age, that existence may be said to depend on the due exercise of the functions which they perform.

Whether animals have their blood aerated by means of lungs or gills, they require a regular supply of oxygen gas. But as this gas is extensively consumed in the processes of combustion, putrefaction, vegetation and respiration, there is occasionally a deficiency in particular places for the supply of animal life. But, in general, where there is a deficiency of oxygen, there is also a quantity of carbonic acid or carburetted hydrogen present. These gasses not only injure the system by occupying the place of the oxygen which is required, but exercise on many species a deleterious influence. To these circumstances may be referred the difficulty of preserving many fishes and aquatic mollusca in glass jars or small ponds; as a great deal of the oxygen in the air contained in the water, is necessarily consumed by the germination and growth of the aquatic cryptogamia, and the respiration of the infusory animalcula. In all cases, when the air of the atmosphere, or that which the water contains, is impregnated with noxious particles, many individuals of a particular species, living in the same district, suffer at the same time. The disease, which is thus at first endemic or local, may, by being contagious, extend its ravages to other districts.

The endemical and epidemical diseases which attack horses, sheep and cows, obtain in this country the name of *murrain*, sometimes also *the distemper*. The general term, however, for the pestilential diseases with which these and other animals are infected, is epizooty, (from *επι* upon, and *ζωον* an animal.)

The ravages which have been committed among the domesticated animals, at various times, in Europe, by epizooties, have been detailed by a variety of authors. Horses, sheep, cows, swine, poultry, fish, have all been subject to such attacks; and it has frequently happened, that the circumstances which have produced the disease in one species have likewise exercised a similar influence over others.

That these diseases arise from the deranged functions of the respiratory organs, is rendered probable by the circumstance, that numerous individuals, and even species, are affected at the same time; and this opinion is strengthened, when the rapidity with which they spread, is taken into consideration.

Many diseases, which greatly contribute to shorten life, take their rise from circumstances connected with the organs of digestion. Noxious food is frequently consumed by mistake, particularly by domesticated animals. When cows, which have been confined to the house, during the winter season, and fed with straw, are turned out to the pastures in the spring, they eat indiscriminately every green plant presented to them, and frequently fall victims to their imprudence. It is otherwise with animals in a wild state, whose instincts guard them from the common noxious substances of their ordinary situation.

The shortening of life, in consequence of the derangement of the digestive organs, is chiefly produced by a scarcity of food. When the supply is not sufficient to nourish the body, it becomes lean, the fat being absorbed to supply the

deficiency,—feebleness is speedily exhibited,—the cutaneous and intestinal animals rapidly multiply, and, in conjunction, accelerate the downfall of the system.

The power of fasting, or of surviving without food, possessed by some animals, is astonishingly great. An eagle has been known to live without food five weeks,—a badger a month,—a dog thirty-six days,—a toad fourteen months, and a beetle three years. This power of outliving scarcity for a time, is of signal use to many animals, whose food cannot be readily obtained; as is the case with beasts of prey, and rapacious birds.—But this faculty does not belong to such exclusively. Wild pigeons have survived twelve days, an antelope twenty days, and a land tortoise eighteen months. Such fasting, however, is detrimental to the system, and can only be considered as one of those singular resources which may be employed in cases where, without it, life would speedily be extinguished.

In situations where animals are deprived of their accustomed food, they frequently avoid the effects of starvation, by devouring substances to which their digestive organs are not adapted.—Pigeons can be brought to feed on flesh, and hawks on bread. Sheep, when covered with snow, have been known to eat the wool off each other's backs.

The various diseases to which animals are subject, tend greatly to shorten the period of their existence. With the methods of cure employed by different species, we are but little acquainted. Few accurate observations appear to have been made on the subject. Dogs frequently effect a cure of their sores, by licking them. They eat grass to excite vomiting; and probably to cleanse their intestines from obstructions, or worms, by its mechanical effects. Many land animals promote their health by bathing, others by rolling themselves in the dust. By the last operation, they probably get rid of the parasitical insects with which they are infected.

But, independent of scarcity, or disease, comparatively few animals live to the ordinary term of natural death. There is a wasteful war every where raging in the animal kingdom.—Tribe is divided against tribe, and species against species, and neutrality is nowhere respected.—Those which are preyed upon, have certain means which they employ to avoid the foe; but the rapacious are likewise qualified for the pursuit. The exercise of the feelings of benevolence may induce us to confine our attention to the former, and adore that goodness which gives shelter to the defenceless, and protection to the weak, while we may be disposed to turn, precipitately, from viewing the latter; lest we discover marks of cruelty, where we wished to contemplate nothing but kindness. These feelings are usually the companions of circumscribed and partial observation, and fall far short of the object at which they aim.

It would be impious in us to inquire why the waster has been created to destroy. It is enough if we know that rapacious animals occupy a station in the scale of being. And, while we eagerly explore the various methods employed by the defenceless, to secure themselves from danger, and evade the threatened death; it is suitable for us likewise to contemplate the various means employed by carnivorous animals to gain the means of their subsistence. When we see a hawk in pursuit of a lark, we are apt to admire exclusively, the dexterity of the latter in avoiding destruction, and to triumph when it has obtained the requisite protection in a thicket. We seem to forget that the digestive organs of the hawk are fitted only for carrion; and we lose sight of the benevolence and wisdom exhibited, in giving

to its wings a power of inflicting a deadly blow, and rendering the claws suited for grasping, and the bill for tearing in pieces the quarry. We are not, therefore, to take confined views of the animal kingdom, if we wish to read the lessons concerning the providence of God which it teaches. He that causeth the grass to grow for the cattle, and herb for the service of man, likewise giveth meat in due season for the young lions which roar after their prey; and feedeth the ravens, though they neither sow nor reap. We see rapacious and defenceless animals existing, yet we do not observe the former successful in extirpating the latter. Limits are assigned to the ravages of this universal war. The excess only of the population is cut off,—and this excess, on whose production so many animals depend for subsistence, is as uniform as the means used to restrain its limits.

These various circumstances which we have now enumerated as limiting the duration of animals, preserve the balance of life, restrain within suitable bounds the numbers of the individuals of a species, and give stability to that system, the wise arrangements of which can only be discovered by a close examination of the whole.

Chap. 2.—On the distribution of animals.

In examining the zoological productions of different countries, we observe, that the species which are commonly met with in one district, are rare, or not to be detected, in the others. If we confine our attention to any one species, we shall observe, that there is some particular country where the individuals are most numerous, and where the energies of life are exerted with the greatest activity. As we recede from this district, the individuals become less numerous, their increase goes on at a slower rate, and those which are produced are rather of dwarfish stature: at length, we reach the limits beyond which they do not extend. The geographical distribution of each species, therefore, may be represented by a circle, towards the centre of which, existence can be comfortably maintained; but as we approach the circumference, restraints multiply, and life, at last, becomes impracticable. Each species has a range peculiar to itself, so that the circles of different species intersect one another in every possible relation.

The extent of the earth's surface over which the individuals of a species are dispersed, can only be ascertained after a long series of observations, conducted by naturalists in different countries. Hitherto the geographical limits of but few species have been satisfactorily determined. These chiefly belong to the larger species of quadrupeds, as the African and Asiatic elephants, the ass and the quagga, the lion, the hippopotamus, and the polar bear. In the tribes of the less perfect animals, the species of which have been investigated by few, the extent of their GEOGRAPHICAL DISTRIBUTION has been very imperfectly determined.

Before proceeding to the examination of the laws which regulate the geographical distribution of any one species, it is expedient that we previously make ourselves acquainted with the range of country it inhabits, the situations in which it has been observed, and the peculiar characters it exhibits in these different situations. But while this minute and varied information is requisite for the purpose of investigating fully the physical history of any one species, it is enough, for ordinary investigations, that we ascertain those districts and situations where the individuals are most healthy and most prolific, and those where they do not exist. By comparing the physical circumstances of the former with those of the latter, it will be no difficult matter to disco-

ver those conditions which promote the vigour of life in the one, and restrain or destroy its energies in the other. What, then, are those conditions which limit the geographical distribution of species? They appear to be limited to circumstances connected with temperature, food, situation, and foes.

I. TEMPERATURE.

We have already stated, that the degree of heat at the equatorial regions appears to be most favourable for the increase of living beings, and that they diminish in numbers as we approach the poles. There is no latitude, however, which the perseverance of man has yet reached, where living beings have not been observed. The icy shores of the arctic regions are peopled as well as the arid plains or shaded forests of tropical climates. When, however, an inhabitant of the colder regions is transported to a warmer district, the increased temperature is painful, the functions become deranged, and disease and death ensue. The inhabitants of the warmer regions, when transported to the colder districts, experience inconvenience from the change of temperature, equally hurtful to the system, and fatal to its continuance. The polar bear appears to be accommodated to live in a region, whose mean annual temperature is below the freezing point. In the summer temperature of Edinburgh, however well supplied with food, he appears to languish in misery. Cold spring-water poured upon him seems to revive him for a little; but all relief is temporary, the climate is too hot for the enjoyment of life. Destined to live in a climate where the system is required to secrete heat chiefly, it seems incapable of generating the cold requisite to counteract the effects of even a temperate climate. The inhabitants of the torrid regions, on the other hand, seem capable of generating cold chiefly, all their organs being adapted for resisting high temperatures; and hence, when brought to cold districts, they are incapable of generating the requisite degree of heat.

In those districts where the individuals of a species are most vigorous and prolific, the temperature most suitable for existence prevails.—The native country of the horse is probably Arabia. There he exists in a wild state in the greatest numbers. In the Zetland Islands, where he is nearly in a state of nature, he is approaching the polar limits of his distribution. He has become a dwarf. He does not reach maturity until his fourth year, seldom continues in vigour beyond his twelfth, and the female is never pregnant above once in two years. At the line where the energies of the horse terminate, however, the rein-deer becomes a useful substitute. Its equatorial limits do not reach the shores of the Baltic.

The variations of the seasons, which bring along with them corresponding changes of heat and cold, exercise a powerful influence on the distribution of animals, in reference to temperature. Some species appear to possess a considerable range of temperature, within which life can be easily preserved, and all its functions regularly performed. We do not mean to intimate, that there is any animal which can live in our climate, for example, and remain uninfluenced by a difference of temperature of upwards of twenty degrees between summer and winter. The constitutional arrangement suited to the one season, would be prejudicial during the continuance of the other. But there are many animals which live in the same district both in summer and winter, and even in districts differing considerably in their mean annual temperature. What, then, are the means employed by these species to preserve life in the midst of such vicissitudes? The power of producing heat or cold, is a property ob-

viously possessed by the warm-blooded animal and probably in an inferior degree by those which are termed cold-blooded. But in all the efforts made by the system, to secrete extraordinary degrees of either heat or cold, there is so great a portion of vital energy expended, that exhaustion and death follow its long continuance. In all cases where the influence of the seasons are to be resisted by efforts of this kind, it would be requisite to continue them uninterrupted for many months. These efforts, however, are diminished in extent and duration by a variety of the most wonderful arrangements, exhibiting the infinite resources of that Wisdom which planned the constitution and continuance of the animal kingdom. To the chief of these compensating or counteracting circumstances, we shall now briefly advert.

(To be continued.)

Internal Improvement.

ON THE PARAMOUNT IMPORTANCE, TO MARYLAND, OF A CANAL TO THE SUSQUEHANNA.

Of two or more evils, a wise choice will always select the least; but of two or more benefits, the greatest.

In attending to the different objects of internal improvements which have lately been proposed, as being of superior importance in promoting the interests and future prosperity of Maryland, I have noticed sundry canals: one, for example, from above the obstructions in the Susquehanna river to the city of Baltimore; the Potomac canal, from the town of Cumberland, upon that river, down to tide water in the District of Columbia; the cross-cut canal, as it has been called, from the said tide water to Baltimore; also a canal to issue out of that of the Potomac, at the highest eligible point of separation, and from thence to pursue the most eligible route to Baltimore—which, for distinction I shall designate by the name of the junction canal; because, in my opinion, its most advantageous location would be to form a junction between the Susquehanna and Potomac canals; and the Chesapeake and Delaware canal, to open a more direct water communication between the cities of Baltimore and Philadelphia.

That these are all objects of great importance, I am disposed, most readily, to grant; but I presume it will by no means follow, that they are all so equally poised in the interest of Maryland, as for neither to be entitled to a preference. By a late writer in the Federal Gazette, who has particularly recognized all the abovementioned canals except the junction, we are told, that *the true means to effect one, is to secure the accomplishment of all*; and in the plenitude of his ardour, after supposing the Maryland canals to cost five, or even six millions of dollars, he has enquired, *whether that amount can be an obstacle, taking into view the extended benefits of the work and the immense patronage that it must and ought to receive?*

Were it only a well established fact, that we were in possession of the necessary funds, or that the patronage in favour of the undertaking would, doubtless, be adequate to furnish the money to the amount required, I would willingly admit, *there was then no obstacle*—and to me it would be extremely gratifying to know, that either of these facts certainly existed. But as this animated inquirer has, in this respect, offered no other proof than his own implied assertion, I confess, that to me some better assurance appears to be indispensable, before we could with safety commence our operations to secure the accomplishment of all

the amount of so many millions of dollars. We ought, at least, to have some distinct knowledge where, and by what means, the money could be obtained to discharge the amount expended.

Let it be understood, that it is by no means my intention, upon the present occasion, to interpose the least discouragement to our undertaking *all*, to the utmost extent that may *rationaly* be within our power to accomplish, to *advantage*. On the contrary, this is a business in which I am decidedly in favour of our doing all we can do. It is a business in which I am particularly anxious that all may be willing to display the most laudable liberality; because I am convinced there is no other way in which it is at all possible for us to be liberal with equal benefit, either to ourselves or to the community at large. Hence it is, with me, an ardent desire that we may act wisely; that we may be careful to adopt no plan that may be calculated, ultimately, to defeat the very important object in view; that we may not place ourselves even in a situation *abundantly worse* than the inexperienced boy, who, after having introduced his empty hand into a narrow mouthed jar, grasped it as full as it could hold of filberts, and was then in exquisite distress, in consequence of his being unable to get any out, until an old man, out of pity, advised him to let go the part that he had seized too much, and that *then* he might easily succeed with the rest. But it is evident that our dilemma would, in fact, be abundantly worse, were we *unadvisedly* to undertake too much, and exhaust the *whole* of our funds before any part of the work should be completed. We would not then have it in our power to release from our grasp the part that we had seized too much. We should be completely unable to proceed with the rest. All would *then* be gone. All would *then* be lost. Our labour and expense would both be entirely useless, by reason of nothing being in a situation to make us the least compensation for either.

The writer before mentioned, after having recognized the New York canal, as a *work justly eulogized and admired by all the world, which already begins to enrich and reward, with ample profits, those who have wisely as well as patriotically loaned their money to it*, has affected, with emphasis, to enquire,—*can Maryland hesitate at this example? Does not the canal in New-York teach a practical lesson and stimulate to exertion?* That the canal of New York presents an example *highly laudable, and worthy of imitation*, to the utmost practicable extent, I am disposed most willingly to admit; and it is further my candid opinion, that with an equal capacity to accomplish an undertaking of such incalculable utility and importance, it would be very improper were Maryland even to hesitate. But where is the evidence, permit me to ask, of the real existence of this capacity? It is true, the same writer has positively asserted, that, *what has been done there, can be done here*. It is conclusively evident, however, that this is by no means, neither possibly *can be*, the fact,—unless it were also the fact that the state of Maryland were equally as large, or at least as populous, or otherwise as wealthy, as the state of New York.

The palpable error into which the author in question, has very unhappily fallen, may thus be explained from his own words. He says, *it is now ascertained that the canal of New York, will not cost more than seven millions and a half of dollars*. Upon reference being had to the late edition of Morse's Universal Gazetteer, published in 1821, the population of that state, according to the last census, appears to be nearly 1400 thousand, for 46 thousand square miles of country, whereas our population at the same time, was only about 407 thousand, for a few square miles less than 14 thousand; and owing to one

fifth of that extent being understood to be water, we have of land, but very little more than ten thousand square miles. Hence it follows that to do us equal justice, our liberality and our enterprise would be *on a par* with what has been so highly extolled in the citizens of New York, were our population to furnish two millions of dollars, or the extent of our soil one million and a half with a small fraction over in both instances. The correctness of these sums may readily be verified by two small operations in the rule of three, thus—a population of 1,400,000 : is to 407,000 :: as 7,500,000 of dollars : are to 2,000,000, and a fraction equivalent to eighteen hundredths; and 46,000 square miles of country : are to 10,000 :: as 7,500,000 : are to 1,500,000 dollars, and a fraction equivalent to thirteen hundredths.

From the preceding calculations it is evident, that if we are now to be called upon for money to a greater amount than the sums above stated, then are we not called upon to *imitate*, but to *transcend*, the celebrated example of New York; and that *in form* nearly a three, to nearly a four fold ratio, should the sum be 6,000,000. Again, had the cost of the New York canal exceeded its present cost, in the same proportion that their population, or the extent of their soil and ours, upwards of 25,000,000 in the former case, and in the latter, upwards of 34,000,000 of dollars, would have been required for, as our population, 407,000 : is to theirs, 1,400,000 :: so are seven and a half : to 25,000,000; and as our 10,000 square miles of soil : are to their 46,000 :: so are seven and a half : to 34,000,000 of dollars, rejecting both fractions.

These calculations, founded as they are, upon the certainty of geographical evidence, except in relation to the cost of the New York canal, must, themselves, be too certain to be doubted; and I have also been thus particular in my explanations, that every one, capable of performing a small operation in the rule of three, may, if he pleases, ascertain the correctness of the whole, to his own satisfaction; totally independent of any statement of mine. From these premises, which if scrutinized to the very utmost, I trust, will be found to be substantially certain, I am now prepared to draw the following conclusions, equally certain: 1. To every rational understanding, it must doubtless be evident, that the enormous sum of 25 or 34,000,000, would have been entirely too heavy, *even* for the state of New York—and by parity of reason 6,000,000 are equally too heavy for Maryland. 2. The actual fact being now ascertained, that 7,500,000 are in a fair way to be managed, to very great advantage, by New York, it follows, from absolute calculation, that with superior local advantages, to stimulate to exertion, Maryland ought, with equal facility to manage the raising of 1,500,000 or 2,000,000.—3. But as it is understood that 6,000,000 would be required to open the *whole* of the Maryland canals, instead of attempting *all* at once, we are *here* forewarned, out of two or more benefits, wisely to choose the greatest, for which our means may be competent; and, in this way, I am persuaded, we shall have it completely in our power, as I hope *hereafter* more fully to explain, to outstrip New York, and derive from our one and a half, or 2,000,000, far greater benefits, in proportion, than can reasonably be anticipated from their 7,500,000, that is from an expenditure of three and a half, or five times the amount of ours.

WM. KENWORTHY.

Political Economy.

FROM THE PORTSMOUTH ORACLE. BALANCE OF TRADE.

The remarks which we made in the Journal, a few weeks ago, on the balance of trade, have had

the fortune to attract some attention in different parts of the Union. In general, they appear to have produced conviction; though we claim for them no other merit than that of stating plain principles in plain language. As the subject is important, and as several answers to our arguments have been attempted, we shall be pardoned for offering a few additional remarks.

What is called the balance of trade, is the difference between the value of the imports and exports of a country. We attempted to show that when the balance of trade is said to be against a country—that is, when she imports more than she exports—so far from its being a sign of decay and ruin, it is rather a mark of prosperity. When a fisherman carries out with him 50 hogheads of salt, worth \$200, and brings home 450 quintals of fish, worth \$1100, he would smile to hear us say, that he was ruining either himself, or his country. He would reply, that he had made a profitable voyage;—his imports exceeded his exports.—When a farmer goes to market with a load of pork which has cost him \$50 to raise, and returns with a load of salt and iron worth \$75, which he has purchased with the proceeds, besides paying his expenses, he would wonder a little at that political arithmetic which would teach him that he had made a losing journey.

The principal difficulty attending this subject, has arisen from the high rate of exchange. It has been said that when merchants have to give, for many successive months, 10 or 12 per cent. advance for bills of exchange, it is conclusive evidence that the country is getting in debt; that there are not goods enough sent to Europe to pay for those which we bring home, and of course that a high rate of interest is paid for money there. We hope to show, by a plain example, that the whole of this reasoning is fallacious.

Exchange, in its technical sense, is the sum given in one country for the transfer of a debt due in another. When the price given is the same sum as that which is to be received, exchange is said to be *at par*—when it is more than that which is to be received, exchange is in *advance*, or at a premium. Now, as the design of the purchaser of exchange is to employ the money in the foreign country, where the debt is due, it is obvious that he will never give more advance for exchange, than the sum it would cost him to transport specie to the same place. That is, exchange can never be higher than the freight, insurance, and commission charged upon the transportation of money. For why should A. give 10 per cent. for one hundred dollars payable in England, when he can send one hundred silver dollars to England for about one and a half per cent.

But it may be said that exchange is at present actually 10 per cent. advance; and yet where are the dollars in the country! The apparent difficulty may be removed by a single example.

A. owes a debts in England of \$482, which he wishes to pay. He purchases of B. a bill of exchange for £100 sterling, for which he gives a premium of 10 per cent. When he remits it, his account stands thus—

£100 sterling, at par,	\$444	- -	\$444
10 per cent. advance	- - - -	- -	44
			\$488

He, therefore, has paid here \$488 88 for £100 sterling in London. Now what is the value of these one hundred pounds in London? How much of his debt will be paid by it?

By the last advices, dollars were worth in England, 4s. 9½d. per oz. or 4s. 1½d a piece. A. therefore, receives in England \$482 41 in the place of \$488 88 paid here. He has really given the

only \$6 47, or one per cent. and forty-one hundredths for exchange, instead of 10 per cent.

Now, what would have been the result, if he had shipped specie, instead of buying a bill of exchange? He owes \$482 in England; he would therefore ship that sum—

	\$482 00
Premium given here for Spanish dollars,	
1 per cent. - - - - -	4 82
Freight, half per cent. - - - - -	2 41
Insurance, one percent. - - - - -	4 82

\$494 05

It would have cost him then \$12 05, or more than two and a half per cent. to have shipped specie. Even if we deduct the premium given for dollars, there will remain \$7 23, or one and a half per cent. as the cost of remittance; or one cent in the hundred dollars more than the price of exchange. Bills of exchange, therefore, are, at this moment, sold for less than their true value. And if they are any criterion of the state of trade, England is in debt to the United States, instead of the United States being in debt to England.

This result will doubtless surprise those, who consider the rate of exchange as a sure standard by which to ascertain the balance of trade. But we have other facts equally conclusive. For many years past, exchange has been from 15 to 20 per cent. in favor of England and Spain, and from 8 to 12 per cent. in favor of the United States against the island of Cuba. Is that island, with all its great and valuable exports, on the verge of ruin? Is she getting in debt from 10 to 20 per cent. a year to Spain, to England, to the United States? We believe there will scarcely be found an advocate for the old doctrine of the balance of trade, that will venture to assert it.

The truth is, the rate of exchange with any particular country, depends more upon the actual valuation of money, than upon any supposed balance of trade. In the United States, dollars are, by law, a fixed value. In England, the price of them fluctuates like that of any article of commerce. If, instead of being worth in England, as they now are, only 4s. 13d each, they could rise, as in 1810, to 4s. 7d, it is evident that 474 here would again purchase £100 sterling in England. But would such a rise in the value of dollars alter the balance of trade? Would it make our imports less, our exports greater?—Could it be, in itself, any evidence that this country was more or less indebted to England?

In Cuba, doubloons pass for seventeen dollars, while here they are worth but fifteen. Spanish dollars are therefore always worth in Cuba from 8 to 8 per cent. advance, when payment is made in doubloons. This single fact shows the whole operation of the principle. Bills on the United States are always above par, because dollars can be obtained for them; and because dollars, when obtained, can be sold above par for doubloons.—The whole difference in the rate of exchange, therefore, arises from the fact, that the nominal price of commodities is regulated there by doubloons, and here by dollars. As soon as doubloons are directly exchanged for dollars, an advance is made upon dollars, and the difference vanishes. In the same manner, the whole difference in the rate of exchange between this country and England arises from the difference of the legal standard of money. The price of commodities here is fixed in dollars; in England, by pounds sterling—representing guineas. When dollars are exchanged for dollars, we have already shown, the difference is in our favour.

Editorial Correspondence.

17—We are truly sorry to learn that the flattering prospect of a great wheat crop is already greatly impaired by the ravages of the fly. Some plants of wheat thus affected, with a view of the insect, in its larva state, may be seen at the Editor's office.

Vineyard, near Georgetown, D. C. }
April 27th, 1823. }

J. S. SKINNER, ESQ.
Dear Sir,—I send for your acceptance by the schooner Stag, I. Nevitt, master, ten bottles of wine, in a box, and one book; the other book please to send to the honourable Robert Smith, with my respects,—not as president of the Agricultural Society of Maryland,—but as from an old acquaintance and friend. As a society, they appear to be, as yet, too much engaged in attending to Bakewell rams, short-horned bulls, rampant stallions, pigs, &c. to condescend to take into view, or even a glimpse, of so trifling a subject as the cultivation of the vine, and making wine—a thing, which, no doubt, will add (before the end of the present century,) one hundred millions of dollars, annually, to the agricultural products of the United States.

Two bottles of the wine marked "Champaign," was made from the Munier, or Miller Burgundy grape, just as they were turning to ripen. I was obliged to pull them then, as they began to crack and burst, and the bees were also making great havock among them. This wine had 60 lbs. of sugar to the barrel of 32 gallons; the grapes, though not ripe, were tolerably sweet. The corks of this wine ought not to be drawn until some time in the month of June, when I expect it will sparkle.

Two bottles, marked "Tokay."—This wine was made of a grape I found at Mrs. Scholl's, at Clarksburg, Montgomery county, Md., and also at J. Johnston, Esq's. Frederick county. I could not trace where the grape originally came from; but a German priest, who saw them ripe, said they were the true Tokay, such as he had seen growing in Hungary. They are a beautiful grape to the eye, and tolerable to eat—but from their manner of growth, &c. I am strongly inclined to think they are a native of this country.

Two bottles, marked "Burgundy," are made from the Schuykill Muscadell and Constantia grapes. None of these three wines have any brandy, or other spirit in them.

Two bottles, marked "D. M. 1821," are made from the Bland Madeira grape, a native of Virginia, and has at the rate of ten per cent. of spirit in it.

Two bottles, marked "D. M. 1822," had four gallons of spirit in a half pipe, say 55 gallons.—These last four kinds had from 25 lbs. to 30 lbs. of sugar to the barrel. That marked champaign was made the first week in August last—the others in September, except that marked 1821. The tokay appears to have undergone a very complete fermentation, and scarcely a particle of the saccharine quality in it left undecomposed.—The burgundy ought to be one year older to complete its fermentation; or, probably, its saccharine quality might be decomposed and become alcohol by next August. But I shall not have an opportunity of knowing, as the quarter cask is out, and not one dozen of the wine left. I have two barrels of wine made from the same grapes, but they are not so good as this cask was,—one having more flavour, and the other is meagre, owing to the different stages of perfection in which the grapes were gathered.

I feel myself under great obligations to you for the interest and trouble you have taken in recommending the cultivation of the vine, &c. In consequence of which, I have sold this season about 7,000 cuttings, and gave to gentlemen who have sent me cuttings, &c. near 2,000 more—and they have been sent as far as Boston, north-eastward, and to beyond Savannah, in Georgia, south. But the Virginians have taken a decided lead, and from the number of correspondents I had from thence, and the beginning they have made, (although at the beginning it may appear small,) I have no doubt but that in thirty years from the present time, it will be a considerable article of export from that state; without, in the smallest degree, interfering with their other agricultural pursuits, or products. New York comes next, and from the gentlemen who have got cuttings from me, there will be a fair trial of the cultivation of the grape as far north as Albany;—and a gentleman who lives 80 miles in the country from Savannah, in Georgia, got as many cuttings as any one person, with the intention of making wine.

I am, dear sir, very respectfully,
Your most obedient servant,
JOHN ADLUM.

Monticello, April 11, 1823.

DEAR SIR,—I received, successively, the two bottles of wine you were so kind as to send me. The first, called tokay, is truly a fine wine, of high flavor, and, as you assure me there was not a drop of brandy or other spirit in it, I may say it is a wine of a good body of its own. The second bottle, a red wine, I tried when I had good judges at the table. We agreed it was a wine one might always drink with satisfaction, but of no peculiar excellence. Of your book on the culture of the vine; it would be presumption in me to give any opinion, because it is a culture of which I have no knowledge, either from practice or reading. Wishing you, very sincerely, complete success, in this your laudable undertaking, I assure you of my great esteem and respect.

TH: JEFFERSON.

Montpellier, April 12, 1823.

SIR,—I received, some days ago, the two copies of your memoir on the cultivation of the vine, with a bottle of your tokay; and I have since read your letter, enforcing the importance of making the vineyard an appurtenance to American farms.

The memoir merits well the public attention, to which it is offered. It is so long since I tasted the celebrated wine whose name you have adopted, that my memory cannot compare its flavor with that of your specimen from an American grape. I am safe, I believe, in saying that the latter has an affinity to the general character of the good Hungarian wines, and that it can scarcely fail to recommend itself to discriminating palates.

The practicability and national economy of substituting, to a great extent at least, for the foreign wines, on which so large a sum is expended, those which can be produced at home, without withdrawing labour from objects better rewarding it, is strongly illustrated by your experiments and statements. The introduction of a native wine, is not a little recommended, moreover, by its tendency to substitute a beverage favourable to temperate habits, for the ardent liquors so destructive to the morals, the health, and the social happiness of the American people; and it may be added, which is so expensive to them also: for besides the actual cost of the intoxicating draughts, the value of the time and strength consumed by them is of not less amount.

I shall forward one of the copies of the memoir, as you desire, to the Agricultural Society of Albe-marle; to which your letter will also be communicated, that the members may have the benefit of the suggestions and remarks which it contains. Nothing seems to be wanting to the addition of a desirable article to our productions, but decisive efforts, to which the patronage of the agricultural societies may contribute a seasonable stimulus. With friendly respects,

JAMES MADISON.

J. ADLUM, Esq.

STRAWBERRIES.

MR. SKINNER,

In reply to an enquiry of your correspondent R. K. M. in your 6th number of vol. 5, relative to the failure of strawberries which have apparently blossomed vigorously, I would suggest, as the cause, the undue proportion of male and female plants. These can be discovered by their blossoms. I have been, for some time, in the habit of paying attention to this point, with a view to promoting the fruitfulness of my plants. A neighbor of mine, remarkable for his knowledge and skill in gardening, showed me a most beautiful bed in full blossom last spring, from which he did not gather a gill of strawberries, and which he afterwards dug up. In the 2d volume of the Transactions of the Horticultural Society of London, p. 393, August 5, 1817, is a letter to the secretary of the society, from Mr. Michael Keens, gardener of Isleworth, from which the following are extracts, in answer to a letter requesting a detail of his practice in raising strawberries:

"There are many different sorts of hautboys; one has the male and female organs in the same blossom, and bears very freely. But that which I most approve, is the one which contains the male organs in one blossom and the female in another. In selecting these plants, care must be taken that there are not too many male plants amongst them; for as these bear no fruit they are apt to make more runners than the females. I consider one male to ten females the proper proportion for an abundant crop. I learned the necessity of mixing the male plants with the others by experience, in 1809. I had before that period selected female plants only for my beds, and was entirely disappointed in my expectations of a crop."

These remarks apply to all other varieties, with some difference in the extent of their operation. It may be easily discovered by the stamens, which are the male blossoms. It is a matter perfectly understood by our best practical gardeners, that an attention to the selection of their plants, is well rewarded by an increased quantity of fruit.

A NEW-JERSEY SUBSCRIBER.

May 8th, 1823.

THE FARMER.

BALTIMORE, FRIDAY, MAY 16, 1823.

Messrs. S. V. Merrick, & Co. Philadelphia, have invested with the privilege of making and selling Mr. Pope's newly invented thrashing machines, in any State south of New-York—all persons desirous of knowing any thing more about them, will please therefore address themselves directly, to the above named firm.

The above privilege will cease for any county or state, when the exclusive right for such county or state may be sold.

LIVERPOOL MARKETS—7th April.

From Myers' Price Current.

Montreal Pots have declined considerably, 90 bls. by auction having been sold at 6s. 9d. and

subsequently 150 bls. at 6s. 6d. to 6s. 6d.—Pearls have also been sold at a considerable reduction, 56s. having been accepted for 10 bls. by auction, and 20 to 30 have since been sold at 5s. per cwt. The market has however, since become more firm.

Nothing worthy of notice has occurred this week in Flaxseed, and the market has become languid.

Our Grain market this week, upon the whole, has been rather heavy; yet some considerable transactions have taken place between the speculators in wheat, at some trifling reduction; but which, however, has not tended to any general depression, and our quotations remain nearly the same as last week.

50 bags Pimento have been sold at 9½d. per lb. 100 casks new Carolina Rice of a mixed quality, have been sold in bond at 23s. 9d. to 24s. per cwt.

500 bbls. Am. Tar have been sold at 14s. per cwt. The sales in Turpentine consist of 500 bbls. at 14s. 3d. being a decline of 6d. per cwt.

Very little has been done in Tobacco, the sales for home consumption and for Ireland this week having been very limited, and only 30 hhd. of Kentucky leaf at 2½d per lb. have been purchased for shipment.

Ashes—Pots, N. York and Boston, £3 8s. a £3 10s.—Pearls, 2 16 a 2 17—Pots, Montreal, 3 6 a 3 7—Pearls 2 15 a 2 16. Flaxseed, £2 11s. a £3. Flour—new in bond, £1 6s. a £1 8s. Rice, Carolina, in bond, £1 a £1 5s.

BALTIMORE MARKET.

PRICES CURRENT.—CORRECTED WEEKLY.

Flour, best white wheat, \$8—Howard street Superfine, \$7 25—fine do. \$6 75—Wharf, do. \$7 25 sales—White wheat, \$1 60 to 1 64—Red do., \$1 57 to \$1 60—Rye, 85 cents—Corn, 56 to 58 cents—country Oats, 50 to 55 cents—Beef, 8 cts. per lb.—Live Cattle, \$6 to \$6 50 per cwt.—Bacon, round, 8 to 9 cents per lb.—Pork \$4 50 to 5 50 per c. lb.—6 to 8 cts. per pound—Mutton, 5 to 6 cts. per lb.—Beans, \$1 37½ to 1 50—Peas, black eyed, 55 to 60 cts.—Red Clover Seed, \$5 50 to 6—Orchard Grass do. \$3—Herds' Grass do. \$3—Timothy do. \$4 50—Millet, \$3—Flax Seed, 75 to 80 cts.—Whiskey, from the wagons, 32 to 35 cts. per gal.—Apple brandy, 30 to 32 cts.—Peach do., 65 to 70 cts.—Shad, none in market—Herrings, No. 1, \$2 50 per bbl.—No. 2, \$2 25—Fine salt 80 to 90 cts. per bush.—Coarse, do. 75—Butter, 20 to 25 per lb.—Eggs, 12½ cts. per doz.—Hay, \$18 per ton—Straw, \$11 to 12.

MARYLAND TOBACCO.—Fine yellow, \$27 to 35 scarce—good do. \$20 to 25 do.—inferior do. \$15 to 18 do.—spangled \$15 to 18 do.—fine red \$10 to 14—good do, \$6 to 8—common do. \$4 to 6, plenty—dark \$3 to 4 do.—seconds \$1½ to 6 do.

Mr. John Kilgour of St. Clement's bay, St. Mary's county, Maryland, sold 12 hogsheads on Monday last, 8 crop and 4 seconds, for 6 and 4 dollars—the same quality it is said, would not now sell so well by \$1 per hundred at least.

There may be seen in the office of the American Farmer, and we invite planters to look at them, several samples of tobacco, extraordinary by every circumstance connected with them, amongst others, there are

Some bundles of tobacco, from the estate of Governor Goldsborough, on the Eastern Shore of Maryland—of beautiful texture, and very bright nutmeg colour—exceeding in these respects any thing we have seen from that section of the state, whence we seldom see any but of the *dullest quality*. There are also some bundles from *Siding Hill*, in Somerset county, Pennsylvania, which

came down the Juniata and Susquehanna, to this market.

This sample excels in the *brilliancy of its yellow colour*, even any thing we have yet seen, and certainly gives to the cultivator, W. C. Dorsey, a right to the highest rank amongst planters—the more so, as we presume the cultivation of tobacco must have been very recently undertaken in that part of the country. It further establishes the fact of the peculiar adaptation of the soil there to the production of tobacco of the first quality. We hope that \$35 12½, the price obtained in this case, has rewarded Mr. Dorsey for his enterprise and trouble. We understood that Mr. Goldsborough's tobacco would, when left with us, have commanded \$20 per hundred. It is probable it was produced on land in Dorsey county of lighter quality than the generality of Eastern Shore land,—but it proves that Mr. Goldsborough has made himself thoroughly acquainted with the most approved mode of cultivating and handling that commodity.

PRINCE REGENT.

This justly celebrated and well known horse is a dark bay, full sixteen hands high, of fine form, figure, and great bone—he walks, paces, trots and canters remarkably light, and well. He is in strength, form and figure, what may be conceived in the description of a first rate English coach horse or Hunter, his eye is a large clear hazle, his movements graceful and grand, and his colts where he has stood the last three years, are much admired for their size, action and beauty.

He will stand this season, from the 1st of May, from Saturday till Wednesday morning, in each week at Govan's Town, under the direction of Mr. John Wooden; and from Wednesday till Saturday mornings, each week, at the Maryland tavern, four miles from this city, on the Frederick turnpike road, under the direction of Mr. John Watson—at the rate of EIGHT DOLLARS the season, for each mare, and 50 cents for the groom, the money to be sent with the mares or a note given for the amount, payable on the first day of August next.

Baltimore, April 29, 1823.

N. B. Pasturage may be had at each place for mares, if required.

AGENTS FOR THE AMERICAN FARMER

Complete sets of the first, second, third and fourth vols. of the "AMERICAN FARMER," new and corrected Editions, can be had of the following persons; price of which, bound, \$5 per vol. or \$4 in Sheets:—

M. CAREY & SONS and E. LITTELL, Philadelphia.

W. A. COLMAN, New-York.

WELLS & LILLEY, Boston.

W. M. F. GRAY, Fredericksburg.

PETER COTTOM, Richmond, Va.

RICHARD COTTOM, Petersburg.

E. THAYER, Charleston, S. C.

JOSEPH GALES, Raleigh, N. C.

W. F. REDDING, special agent, now journeying through the Southern States.

The fifth volume, now publishing, can be forwarded to any part of the United States, application being made, by letter or otherwise,

J. S. SKINNER, Baltimore.

Printed every Friday at \$4 per annum, for JOHN S. SKINNER, by JOSEPH ROBINSON, on the North West corner of Bond and Belvidere streets, Baltimore; where every description of Job Printing is executed with neatness and dispatch—From a distance for Printing or Binding, with proper directions promptly attended to, addressed to J. Robinson, Baltimore.

AGRICULTURE.

FOR THE AMERICAN FARMER.

SIR,

I have great pleasure in sending to you for insertion in the "American Farmer," extracts of two letters, which I received from a young gentleman of Philadelphia, while on his travels in Europe. From the interesting nature of their contents, I solicited permission of the writer, who has returned to this city, to publish them; and he having consented, I cannot withhold them any longer from your readers; who, I am sure will, like myself, derive both amusement and useful information from them.

With my best wishes for the extended circulation of your excellent journal, I am very respectfully,

J. M.

Philadelphia, May 7, 1823.

Liverpool, December 9, 1821.

MY DEAR SIR,

When in Munich last spring, I had the good fortune to make the acquaintance of a gentleman,* who takes great interest in the advancement of agriculture in Bavaria, and he was so kind as to present me with a number of Pamphlets, treating on the agriculture of Germany, and illustrative of the intentions of the Royal Agricultural Society of Bavaria, of which he is secretary; he also gave me some grass seed. With the view of opening an intercourse between the Philadelphia Agricultural Society and that of Bavaria, I took the liberty of proposing to present these articles in his name as Secretary of the Bavarian Society, as they would be the commencement of an interchange of good offices, that might be highly beneficial to both institutions. The idea pleased him very much, and he requested me to do so, and also addressed the enclosed communication to the Philadelphia Agricultural Society, and desired me to express verbally to the members of it, the great pleasure his society would have in communicating any thing useful to American agriculture, and the satisfaction he and his associates would feel in being in correspondence and amity with an institution that has effected so much good as the Philadelphia Agricultural Society, of whose respectability and utility he appeared to be well informed. The grass seed is called "esparcette" in German, it grows luxuriantly on the miserable gravelly plains round Munich, and attains to the height of our Timothy, [a] and grows much thicker; in

* Count Hazzi, Counsellor of State to the King of Bavaria.

[a] As there are two plants cultivated in the United States, under the name of "timothy grass," it may be proper to state, that the one here referred to, is the "Phleum Pratense." Lin.

The "esparcette" seed arrived safely. It is the saintfoin, (*hedysarum onobrychis*, Linn.) and much cultivated on the Continent and in England. In the latter country, it is uniformly sown on soils having a substratum of chalk, to prevent the plants wasting themselves by the descent of their roots. In the United States, as we have no chalk, a soil must be chosen having a hard pan or bed of clay. The only objection to this grass is, that it does not bear drought well, and in this respect, is not to be compared to Lucerne, which if sown in a deep soil, as I have long since seen, will flourish when clover, green grass and all other plants are dead from heat and want of moisture. I had an opportunity of testing the comparative merits of these two grasses last summer, in the vicinity of Philadelphia. A full opportunity of testing the saintfoin, will be had in Pennsylvania,

short, it flourishes where nothing else will exist, and has the excellent quality of great durability. I was shown some that had been sown seven years, it appeared in good condition and likely to continue yet several years: I saw some saintfoin at Holkam this summer, that had been sown fifteen years. Two years ago Mr. Coke plastered it, and he thinks it will attain the age of twenty years before he will deem it necessary to turn it in. Mr. Coke, from the experiments he has made at Holkam, where the sea air has great influence, is of opinion, that plaster will answer very well on the sea coast: I myself have seen it used on the sea coast of France. To return from this digression; the esparcette must be sown at the same time that our common red clover is sown.

I have to express my obligations to you for your kind letter of introduction to Dr. Rigby, of Norwich, which procured me the acquaintance of a man eminently distinguished in his profession, and for numerous acquisitions in several sciences. Dr. Rigby treated me with the most hospitable kindness, and among numerous other favours introduced me to Mr. Coke, at whose princely establishment, I spent my time in the most agreeable and instructive way. The wonders effected at Holkam, by the skill, industry and capital of Mr. Coke, can only be properly appreciated by a minute personal inspection of them. Whilst at Holkam, I had in my possession a piece cut out of an American newspaper, a communication from Judge Peters, to the Philadelphia Agricultural Society, relative to an apparatus used under the direction of Miss Coke, for dressing flax and hemp. If you recollect, the judge mentions that application had been made to Lord Castlereagh for permission to send one to America, for the Philadelphia Agricultural Society, which was refused; when Mr. Coke read it, he and Miss Coke laughed heartily at the serious importance attached by his lordship to a thing of such comparative insignificance, and regretted that he should wish to prevent such an instrument from becoming generally useful. I have observed sea-sand used as a manure in Wales, Ireland and in Northumberland county, England. When it is placed, particularly that which contains small shells, on cold, wet or clayey tenacious soils, it has been found useful in counteracting those bad qualities. I do not know if it has been used in that way, in our country. [b]

Oporto, August 25, 1822.

I received your favour of the 15th May, which came to hand just as I was mounting my mule to take an extensive tour to the north of Portugal, and through the celebrated wine district of the Douro. I returned two days ago, after an absence of twenty-two days from this city. As I suppose you have not much acquaintance with this remarkable country, I presume some memoranda of what I have seen, will not be uninteresting to you.

I left Oporto in company with a young English gentleman, of amiable manners and good education, and attended by a man on a mule to carry our baggage, &c. On the 4th instant, we passed through the beautifully hilly environs of this city, which are very well cultivated, almost exclusively in maize; numerous country seats are also situated on fine sites: oak and many other kinds of trees have vines planted at their roots, and now cover them with a luxuriant growth of grapes, which hang down over your head, and of which you may take as many as you wish, by extending your hand, as you ride along the road. After passing through eighteen miles of this fine country, we arrived at the celebrated mineral springs of *Caldas de St. Miguel*, which are very much frequented by persons afflicted with rheumatism, gout, cutaneous disorders, &c. There were two hundred and eighty patients; and frequently as many as five hundred persons here, for relief by these sulphur baths, which are more powerful than those of *Aix la Chapelle*, *Bath*, *Baden*, or indeed of any I have visited, excepting those of *Banos*, near *Salamanca*. The springs are five in number, and vary in temperature: the least warm, has 101° of Fahrenheit; the warmest bath has 125° Fahrenheit: it is an oblong well, three feet and a half deep, twenty-five feet long by fourteen broad. All the baths are free to those who choose to take advantage of them. The village is very rural; the principal part of it is built round a square, which is planted with trees and shrubbery, and is ornamented with statues, fountains, seats, &c. Two of the baths are situated at one end of the square, one on each side of the gate by which you enter. The valley in which this village is situated, is extremely beautiful; it is five miles long, and varies in breadth from one to three miles; there are lofty hills on each side, on which are large detached rocks and stones, so whimsically placed by nature, as to resemble castles, villages, monuments of druids, &c. The whole valley is cultivated in the most beautiful manner: the maize is of the finest and largest growth; the vines entwine themselves among the trees, and frequently rise up to their tops; every where there is shade and an agreeable freshness of the air; the cottages of the peasants are scattered every where. This on the continent is quite a curiosity, for the agricultural population is generally collected in towns and villages. A fine stream of water runs between gardens, and thickly planted trees and shrubs, and in some small meadows, I saw some white and red clover for the first time since I have been in Portugal; This stream is turned to such good account, that it not only moves many mill wheels, but is so conducted, as to irrigate the greater part of the valley, which without its assistance, would not in this dry climate, grow one twentieth part of the maize we saw. We left with regret this delightful valley, the residence of an honest, industrious and rich peasantry; and after a journey of three hours arrived just before dark, at *Guimaraens*, a large ancient city of fourteen thousand people which has figured considerably in the history of Portugal. It has an industrious population, engaged in agriculture, and in the manufacture of cutlery, and linen from Russian flax, and from some little of their own growth. The country round, is an extensive plain or valley of a circular form, surrounded by mountains: it is altogether covered with oak trees with vines growing on them, and maize, like the fine vale of *Caldas* just described. Next morning, after seeing every thing remarkable, we continued our journey, passing over a high mountain thickly covered with oak trees, and live oak, and about noon, arrived in the ancient and celebrated city of *Braga*, the *Augusta Bracharorum* of the Romans. It was formerly much more considerable than at present, but it is still the capital of

[b] Sea-sand is very commonly used as a manure on the sea coast of *Monmouth county*, *New Jersey*. M.

wealthy province of "Entre Minho e Douro," the residence of an indolent archbishop, whose salary amounts to seventy-two thousand dollars per annum. Notwithstanding this is an arch-episcopal town, and has nine monasteries and two convents, the hot beds of vice and ignorance, its population of fourteen thousand souls, is remarkably industrious, and manufacturing: making a great quantity of hats, which supply the poor people of Spain, and the greater part of Portugal. They also manufacture a good deal of cutlery, and shawls made of wool, which in England and in the United States, are known under the name of "*Braganza shawls*." The environs of Braga, like those of Caldas and Guimaraens, consist of a valley surrounded by mountains, for this province is entirely composed of mountains and valleys.

The cultivation of Braga is the same as that above described: the people are remarkably industrious. You see the peasant women and girls go to market with great loads on their heads, with the distaff in their hands, which is the common instrument for spinning throughout the Peninsula. The young children and old men are employed in the same manner; and no one appears to be idle, *excepting those connected with the religious houses*, which unfortunately abound in this country. How different is this province from those in the south of Portugal, Estremadura, Alemtejo and Algarve. Here every inch of ground capable of producing any thing is cultivated with the greatest care. Cork, olive, chestnut, oak and elm trees are every where seen, with the vine entwined round their branches, which add to the beauty of the country and produce moisture, so necessary in this dry climate. The population is extremely thick, and is scattered in small villages and in cottages over the country. The people are gay and industrious, and in short, every thing bears the appearance of a flourishing country and a happy people. In the south, on the contrary, you see thousands of acres of land, the greater part of which would bear excellent wheat, and produce oil and wine in the greatest abundance, entirely uncultivated: no trees, few villages of the most miserable appearance; every thing is parched and burnt up by the excessive heat of the sun; not moderated by trees and streams of water as in the north; the people also are serious, gloomy, listless and indolent; badly clothed, and every thing about them indicates misery. Many persons impute this wonderful difference to the influence of climate, but I think with little reason: I would rather ascribe it to political causes, for I have remarked that the neighbourhoods of the seats of arbitrary and impolitic governments are uncultivated and extremely miserable, whilst the districts of the same country that are further removed from the metropolis, though they do not possess such natural advantages, are more prosperous, and have a more independent and spirited population: this remark is strikingly illustrated by two or three examples that I will instance. The environs of Madrid are a barren wilderness, whilst the extremities of the kingdom are perfect gardens, Biscay, Cataluna, Valencia and Murcia. The neighbourhood of Rome, which was formerly teeming with a wealthy and happy people, is now a sickly deserted meadow; whilst the districts, that are removed from the blasting influence of priestcraft, are among the most flourishing countries of the world. Bologna, Ancona, &c. the countries dependent upon Lisbon, are just such as you might expect a bad, despotic and suicidal government would make them; whilst the provinces of the north, where the government has been more a name than a reality, are well cultivated and extremely rich, and inhabited by

a respectable and comparatively enlightened people. But to return to our journey. From Braga we made a pilgrimage to a beautiful church and convent, called "*Bom Jesus*," (good Jesus,) situated on the summit of a high mountain, which is resorted to by thousands of the ignorant, bigoted people. From this elevated place, we had a splendid landscape of great extent and beauty. At the distance of fifteen miles, is the ocean, in the intermediate space the valley of Braga cultivated in the beautiful manner peculiar to this province, and abounding in towns, villages and the country seats of wealthy proprietors. To the north, the lofty mountains which separate Spain from Portugal, are the principal objects comprised in the view. From this place, we traversed one hundred and twenty miles of mountainous country, abounding in fertile vallies, which are cultivated by an industrious people, and arrived at the city of Braganza, which like Braga, was a place of more note in former times than at present. This was the residence of the ancestors of the present royal family of Portugal previous to their elevation to the throne: it is now only important for the vast trade it carries on illicitly in British goods; particularly cottons and woollens, with Spain. When we were there, no less than one million six hundred thousand dollars worth of goods were in store, all intended to be smuggled into Spain. This place has but one thousand eight hundred inhabitants, but is rather increasing in consequence of the large trade with their neighbours. From Braganza to Miranda, thirty-five miles, there is nothing remarkable except the rude method of thrashing out the wheat, which is the only produce of this district. A frame, like a sled without runners is drawn by two oxen, which are goaded forward by a little girl, who sits on the sled to add to its weight; underneath the sled, are rows of sharp flints, the size of those used in musquets, which are intended to cut up the straw to about an inch in length, which is kept for the fodder of the cattle; there being no hay, nor any other food but this, for them. In Spain, and in other parts of Portugal, this operation is performed with horses, oxen or mules, and shod in such a manner as to cut the straw to the proper size. In the interior of Spain, grass is nearly, and hay is entirely unknown. In Madrid, I do not believe there is a cwt. of the latter used in the course of the year: straw supplies its place altogether. At Miranda, where we were obliged to go through the ordeal of a custom-house examination, previous to going out of Portugal into Spain, we were treated in the most shameful manner. The chief of the office, threw every difficulty in our way, and embarrassed us as much as he could, hoping to get a considerable bribe from us; we finally adjusted all difficulties by leaving in deposit the value of the duty, (ten per cent.) charged on carrying our mules out of one kingdom into the other. We crossed the river Douro, and entered Spain, at the custom-house of Villerino. Here we expected to be treated with the same harshness as on the other side; but we experienced all the liberality and gentlemanlike accommodation, that I am happy to say, I have frequently received from the Spaniards on former occasions. From the frontier to Salamanca, one hundred miles, the country is for the most part mountainous and extremely favourable for sheep, which are in this province, (the kingdom of Leon,) very numerous, and are decidedly the best in the peninsula for their wool. At Bilboa and Seville, (the export towns for Spanish wool,) the Leonese wool sells for, from nine to twelve rials per pound; whilst the Arragon, Asturias, and other good wool is not worth more than six to eight rials per pound. The reason of the great difference in the qualities of this wool is,

that the Leonese sheep travel a great deal, (which every one says improves the wool) they being driven in the autumn to Andalusia and the southern part of Estremadura for *pasture during the winter*;* and driven back to their homes, after the 25th of March, where the pasture is more abundant in the summer than in the south. Previous to arriving at Salamanca, we passed through *Los Banos*, a place well known for the efficacy of its hot sulphur baths. The water has the temperature of one hundred and thirty-two degrees of Fahrenheit: the physician appointed by government to watch over the Baths, to see there is no improper use made of these waters, would hardly permit us to bathe in them, without examining us, to see what our maladies were. He could scarcely believe that our only object in trying them was curiosity; he consented at length, when I told him that I had tried those of Aix la Chapelle, Bath, Baden, Caldas in Portugal, &c. without being injured by them; but he required us to promise that we would not remain in more than seven minutes and a half, which was quite unnecessary, for we found the water so very hot, that we could not stay even one minute in it. The physician told me that miracles are effected by the use of these waters, for rheumatisms of long standing, gout, &c. &c. It not being the proper season, which is September, there were not more than one hundred patients using them. At Salamanca we were so fortunate as to meet the Rector of the Irish College of that place, whose acquaintance I had made four months before in Madrid. This old gentleman treated us with the frank hospitality and kindness for which his nation is remarkable. This splendid seat of literature and science is a mere shadow of what it was twenty years ago, previous to the devastations it experienced from the English, French, Spanish and Portuguese armies, by whom it was taken and retaken three times by storm; from these conflicts it has suffered extremely. Out of one hundred and thirty public buildings, such as convents, colleges and churches, not more than seventy-three now remain; nine only are now attached to the University. Still there is enough remaining in this city, to make it one of the most interesting places for its size, (it only has sixteen thousand inhabitants,) in Europe. The *Ayuntamiento*, † *Plaza de constitution*, the gothic cathedral, the university, library, the *Irish college*, the *Jesuits college*, the *Duke of Alva's palace*, and many other noble and chaste buildings which it contains, would do honour to Petersburg, Paris or Dublin: formerly, fifteen thousand students attended here for instruction, which is entirely gratuitous: now there is not quite one thousand students.

The people of this city have a noble enthusiasm for liberty; six hundred of the most respectable of the male population left it whilst we were there, to march as volunteers against their brethren of Navarre and Cataluna, who have been incited to rebellion, and to the destruction of the present order of things by the French government, and by the disaffected nobles and clergy of the country. The citizen soldiers went out of town singing Riego's hymn, and other patriotic songs, and were accompanied by the great mass of the inhabitants a considerable distance. There are forty-two thousand of these militiamen to march from all the provinces of Spain to the same destinations. I sincerely hope these energetic measures will put down the "*facciosos*" of the north, but I have some fears, that they have been resorted to too late, for the

* The supply of food, not the change of climate is the secret. M.

† The Town house.

insurgents, owing to the dilatory proceedings of the former ministries, have acquired such a force and consistency, that it will require much blood and treasure on the part of the liberals to destroy. Unfortunately for the country, there has not been a ministry since the revolution, until the present, that has acted with firmness and patriotism; indeed they have winked at, and secretly encouraged rebellion: but the present ministers are all known patriots and clever men, all of them are companions of Riego, and are determined to do all in their power to carry liberty forward triumphantly. After staying in Salamanca seven days, we left it with regret, and turned our faces again towards Portugal. We passed through no towns of importance. Ciudad Rodrigo, which, though it has great celebrity from the victory gained by the allied army over the French, is a small town, and situated in an uninteresting, dry and half uncultivated country. I have frequently thought it a pity, that in the dry, parched countries of Spain and Portugal, they do not know the value of gypsum, which is so admirably calculated to serve as a succedaneum for moisture: it abounds in many parts of the peninsula. I have seen between Toledo and Madrid, on the banks of the Tagus, immense hills of this valuable mineral, which might be floated down the river, and thus supply the greater part of the peninsula with a manure that is peculiarly adapted to its dry soil. I have told several sensible men in both countries of the regenerating effect of gypsum on our worn out soil, at which they were surprised, not appearing to know any thing about its excellent qualities. Our distinguished townsman, Mr. McClure, who is now in Madrid, told me that in the course of his extensive tours over Spain, he never heard of its being used. In entering Portugal, we crossed a small river, and after traversing thirty miles of interesting country which is thickly covered with almond, olive, and cork trees, we came to St. Joas de Pesqueira, a village situated on the river Douro, and within the celebrated wine district, where all the port wine is manufactured. At this village there are eight noble and wealthy families living, who own the largest vineyards in the district; to one of the wealthiest and most intelligent of these families, we had recommendations, and staid some days at their house. We went over the vineyards with persons competent to explain every thing we saw, so that we got a great deal of information respecting this interesting subject.

The process of making wine is simple. The grapes being perfectly ripe, are cut and carried in baskets on men's shoulders, and put immediately into the press, which is a reservoir of a square figure, three feet deep made of stone or wood: the grapes are trampled upon by the labourers feet as long as any juice can be expressed from them. The juice runs into a vessel on one side of the reservoir, through a hole over which is placed a basket by way of a sieve, to prevent the husks, seeds or stalks from escaping. After the first pressure or treading, the mashed grapes are collected into a heap; this being surrounded by a cord in close circles, and having boards and pieces of wood laid over it, is then pressed by the lever, which is sunk upon it, and allowed to remain in that situation till the liquor ceases to flow. The lever is then raised; the boards and cords being taken off, the mass is broken by hoes, and is made to undergo a second treading, and again it is subjected to the pressure of the lever. This process is repeated a third time, for the purpose of procuring the "Agua Pe," a kind of beer resembling very much, lively spruce beer. In the last process, however, the mass when broken up, is as dry as a chip; and therefore previous to pressing it, a

quantity of water must be added to it in the proportion of two barrels of water to a pipe that has been obtained of juice. The mass remains under pressure a long time, generally all night, when this infusion is drawn off and put into casks for immediate use of the workmen, and is sold extremely cheap to the lower class of people. The lever is a large beam of wood, which goes across the reservoir, extending five or six feet beyond it, and is connected at its furthest end, with the spindle, where is a female screw: at the upper end of the spindle, is a male screw, while its other end is fastened by means of an iron hook to a ring fixed on a large stone, the size of which is proportioned to that of the press. This method of making wine, is general throughout the peninsula, excepting at probably a half dozen vineyards whose owners use the press, (like our cider press,) which is employed in France and on the Rhine. Intelligent persons tell me, that the French system is more economical, and every way preferable to the Portuguese, and will be adopted when the people become more enlightened and better informed. The best vineyards are on the northern side of the Douro with a southern aspect: the river runs through a deep glen from the east to the west, so that the vines are sheltered from the cold north winds. The best wine is produced in the lowest part of the glen near the river, where there is no circulation of air, and an insupportable heat prevails in summer. This "wine district," properly speaking, for the whole north of Portugal produces wine in the greatest abundance, is only twenty-seven miles long by from two to five miles broad, extending on both sides of the river; no wine but that which is grown in this district, is permitted to be sent to England, therefore it is called "factory wine," and even all the wine produced here cannot go to England; but only that which has been tasted by the "Porto Royal Wine Company's" servants, and which is accompanied by a "billete" or permit, can be sent to that country. For this "billete" you pay twenty dollars per pipe, so that the English cannot get wine as cheap as the people of the United States, or of any other nation which is not obliged to take factory wines; but any one who has bad wine which he cannot sell for the Brazil, American, or home market can immediately by purchasing a "billete" from the corrupt wine-tasters, have it sent to England, so that the object of the institution which was to prevent any but the best wine, (factory,) from going to England, is entirely defeated in this manner; and now the worst wine can easily be metamorphosed into the best by the "billete." Last year, no less than twenty-three thousand seven hundred pipes went to Great Britain, which, at the average of £32 sterling per pipe, is seven hundred and fifty-eight thousand four hundred pounds sterling, or, three millions four hundred and twelve thousand eight hundred dollars: but in the year 1812, the exportation to Great Britain, amounted to upwards of thirty thousand pipes, and the average price was forty pounds. The highest price ever given for a pipe of wine was in those days of extravagance three hundred pounds sterling. The whole product of the "wine district," is generally seventy thousand pipes per annum. This year it will fall short of that amount; but last year, it far exceeded it: that which remains after the English supply, is consumed at home, or sent to Brazil, to the north of Europe, and to our country. Six thousand, two hundred pipes were last year distilled into brandy, at five pipes, on the average of wine to one pipe of brandy. The white wine is preferred for distillation, because it is stronger as they say here; but this is an odd reason, for every one knows that in France, only the weak-

and most worthless wines are converted into brandy, and they are much better than strong wines for this object. The cultivation of the vine is here more expensive than in any other part of Europe, for the vineyards are all on the acclivities of the mountains, so that to keep the soil from being washed down, it is necessary to build terraces, which is done at great expense, of stones, so that there is a vast inequality of value between cultivated land and uncultivated: the first in a good exposure, is worth from one thousand eight hundred dollars, to two thousand two hundred dollars per acre, whilst the latter will only bring one dollar or two dollars. The vines are kept cut close, none longer than three or four feet; they produce the second year under favourable circumstances, but the fruit is not much valued till the third year: they go on in a progressive course of amelioration until sixty or seventy years old; but whilst the quality of the produce is improving, the quantity is diminishing. The French have a proverb, which is more true in this country than even in France, for the vines last much longer here than there. "*La maison de votre pere, la vigne de votre grand-pere, et l'Olivier de vos aïeux.*" Usually five thousand vines are necessary for a pipe of wine; however, there are instances of fifteen hundred young vigorous vines producing that quantity. All the wine is made by "Gallegos," Spaniards from Galicia. A man with one hundred pipes per annum is considered rich. The gentleman with whom we sojourned, has three hundred and twenty per annum, and in the course of five years, he expects it will reach to five hundred pipes, for the greater part of his estates have been planted only three years. A convent of Franciscan friars has two estates, which last year yielded the enormous quantity of six hundred pipes: the cultivation is increasing rapidly. The Douro furnishes a cheap, though not very safe means of conveyance to market for the produce of this wealthy country: the rapids in the river, require the greatest care on the part of the boatmen to prevent accidents, which in dry seasons, are by no means uncommon. Our host who has just been elected member of the Cortes, is determined to do his utmost to annul the privileges of the Royal Wine Company, which are of very great injury to this country; inasmuch as they depress industry by withdrawing competition. Among other impolitic rights they possess, the most injurious is, the monopoly of brandy, by which all distillers are obliged to sell to them the surplus of what they do not require for their own consumption, the Wine Company always fixing the price! In consequence of this, not one fourth of the brandy that would be made but for this monopoly is distilled, and it is necessary to import a considerable quantity annually from France and Cataluna. Our friend is also desirous that the commerce between the United States and Portugal, should be augmented: we only import of this wine, about one thousand five hundred pipes annually: it is much cheaper than Madeira or Bordeaux, and Portugal requires a great many articles from our country, which if we had a free trade, would render the connexion reciprocally advantageous. We might export to the north of Portugal, an immense quantity of rice and tobacco, staves, and occasionally some flour. We descended the river Douro to Oporto in a boat, in company with fifteen other persons, and sent our mules down by land. It is impossible to imagine scenery combining so many natural beauties, aided and embellished by human industry, as these sixty miles of this river presented. The first twenty miles, there is nothing to be seen but mountains towering over mountains on both sides of the covered to their very tops with vineyard

here and there a neatly whitewashed wine press-house or country seat: lower down the shores, are more rugged and romantic; the rocks in many places become perpendicular, and the cultivation is entirely changed; the vineyards cease, but the more beautiful method of growing grapes, that of entwining the vines round the boughs of trees, commences. Maize is cultivated in great abundance; every commanding site is appropriated to some church, or convent, or gentleman's seat; and innumerable villages line the shores, which with the great number of large boats passing up and down the stream, give a cheerful and bustling appearance. They reminded me of the life and activity which is seldom seen except in Great Britain, or on some of our own rivers. We arrived at Porto at dusk, just in time to see all the beauties of its rich environs, after an absence of twenty two days, highly pleased with our tour, and very grateful to the simple, good natured, but ignorant people of the country for their hospitality and kindness. We travelled about four hundred and eighty miles.

I observe by some Philadelphia gazettes, that an aloe* has been exhibited in flower. In this country and in the south of Spain, it is the most common plant that grows; I have seen many millions of them in full bloom: they form the common hedges of the fields, they are very solid, but have the disadvantage of spreading themselves too much. In this country, they multiply by shoots or suckers, and augment consequently without cultivation: they do not as is generally believed by the English and Americans, produce a flower but once in a hundred years, and then die; but usually in from six to eight or nine years, when 'tis true they die, but shoots spring out from the roots, and succeed those that perish. The Professor of Botany of the University of Coimbra told me this, and it has been since confirmed by scores of other persons. In the southern province Algarve, where it grows to the greatest perfection, the leaves of the aloe, are cut up and given to cows for want of better fodder; they are also made into baskets, which are handsomely wrought, and sent to all parts of the kingdom. Ropes, &c. are made from the threads of the leaf; but they decay in water, so that it will never be of much utility; the threads however might serve for many kinds of instruments. But oranges and lemons are the most valuable productions of the country as regards profit. At Mr. O'Niell's, (American consul at St. Ubes,) country seat, two miles from St. Ubes, where I staid six days, I got very interesting particulars on this subject. Mr. O'Niell's garden consists of twenty-one acres, principally planted with oranges and some few lemon trees; the latter do not succeed so well. From these two objects alone, he had a clear revenue last year of five thousand dollars, and it would have been six or seven more, but for a misfortune that occurred to his lemon trees in the autumn of 1819, when he lost by frost, no less than one thousand two hundred trees, which is an annual loss of three thousand dollars, until the injury can be repaired by other trees. But he has given up the cultivation of lemons, which are a precarious crop in his garden, owing to its exposure, and pays a great deal of attention to oranges, which are quite sure, and never fail. The best orange trees are from twenty-five years old and upwards; he has one sixty-three years old, which produced last year, six thousand eight hundred oranges, all fit to be shipped. I saw an orange tree at Cintra, two hundred years old, full of fruit. Engrafted trees produce earlier and more, but natural trees produce finer and better fruit. The first is profita-

ble at six years of age, whilst the latter is not so till ten years; and even then, it may produce much or little fruit. The garden is watered artificially by means of wells, from which the water is raised by oxen; for seven months of the year, they work sixteen hours per day; without this, the trees would die, for they require a great quantity of moisture. Every fifteen days, they must receive this salutary nourishment; as there is no rain excepting for about forty days of the year. Mr. O'Niell has no less than five wells, four of which are at work for the above mentioned period, which makes this cultivation expensive. In five years, the oranges and lemons will alone yield fourteen thousand five hundred dollars per annum: for he has replaced the dead lemon trees with orange trees, which will be clear profit, because the lavender, wines, corn, fruit, &c. which he grows, will pay the whole expense of cultivation. Twenty-one acres producing fourteen thousand five hundred dollars, is equal to six hundred and ninety dollars per acre per annum!! This subject should interest our Georgia, Florida and other southern neighbours. My dear Sir, with very great regard,

Your obliged friend and servant,
G. R.

Political Economy.

FROM THE PORTSMOUTH (N. H.) JOURNAL.

BALANCE OF TRADE.

We find the following letter in the last New York Statesman. It is a good omen for an opponent to begin to lose his temper.

"To the Great 'Oracle' at Portsmouth.

"SIR: You have already told the people, with becoming dignity, what every body admits, that, if a man who has exported one barrel of flour, which has cost eight, and will sell for ten dollars, has received any commodity in return for that flour of the value of 50 dollars, his profit is 42 dollars, and that he and the country are becoming rich.

"Be so good as to throw some light on the following question: If a man export a barrel of flour for which he has paid eight, and which will yield ten dollars, and also export 38 dollars in silver, for which commodities he receives in return 50 dollars worth of foreign fabrics, pray, my dear Oracle, what are the profits of his adventure to himself and to the country?"

"AN OBSERVER.

"The above query is induced by the perpetual repetition that the excess of importation is so much clear gain, whereas it is dearly paid for by our precious metals, stocks, public security, &c."

If we understand the question above proposed, it is a very simple one, and admits of a ready answer. The exporter has parted with 46 dollars, and has received 50. His gross profit, therefore, is 4 dollars. The amount of his net profit depends upon circumstances not stated in the question. If we suppose the voyage to be made to England, the charges will be about 3 per cent. upon the dollar, for

Freight and insurance, equal to	\$1 14
And upon the flour, for freight and insurance	1 02

Leaving \$1 84 as nett profit to the shipper. If we suppose the shipment to have been made in an American vessel, the ship owner has received \$1 66 for freight; and the whole profit to the country has been three dollars and fifty cents; the remaining fifty cents being the compensation for the risk incurred in transportation.

We never asserted, and never have heard it

asserted, that the whole excess of importation is "clear gain." We only contended that the whole excess of importation was not clear loss, an assertion that will be found every week in one-half of the newspapers of the United States.

But from an expression in the last paragraph of the New York writer, it is apparent that his difficulty does not arise wholly from misapprehension of our argument. The cause lies deeper.—Like many of our good citizens who attempt to reason upon the subject, he seems possessed with a superstitious reverence for gold and silver.—"The excess of importation," he says, "is dearly paid for by our precious metals," &c. How came we to have the precious metals? Or to take his own example, how came the flour merchant to have thirty-eight silver dollars, as well as a barrel of flour to send to England to exchange for hardware and broadcloth? Certainly, by having sold other barrels of flour for silver.—And what difference does it make to the country whether he exchanges his flour directly with an Englishman for cutlery, or whether he first exchanges it with a Spaniard for silver, and then exchanges the silver with the Englishman?

All trade is effected by barter, and where there is no fraud, it is an exchange of equal values.—The fair profits of trade arise from the additional value which a man is able to give his merchandise. The merchant in Charleston, who sends a bale of cotton to Providence, confers upon it, by its transportation, an additional value. It is worth more at Providence than at Charleston, and is therefore bartered for a greater quantity of merchandise, whether that merchandise be checks and gingham, or ounces of silver. The only reason that the price of silver and gold does not vary as much as that of cotton, is, that, being more durable in their nature, they are not effected by crops and seasons, and being easy of transportation, it is not possible to give them a great additional value by carrying them from one country to another. The price is therefore settled by an average of the demand of all nations that have a commercial intercourse with one another.

Much of the confusion on this subject has arisen from the attempt made by every nation to settle the relative value of its coins. When congress enacted that every dollar should contain 416 grains of silver—and every cent 208 grains of copper—and that one hundred cents should be equal to a dollar, it fixed the relative value of silver to copper as 50 to 1. They might as well have enacted that one pound of pig iron should always be worth two cents and no more, in every part of the country. A Spanish milled dollar has not unfrequently been exchanged for 106 cents; and yet the statute declares that 100 cents are just equal to a dollar. On the other hand, when there has been a want of small coin, we have known a silver dollar exchanged for 97 cents; the act of Congress notwithstanding. Whenever there is a demand for merchantable silver—such as Spanish dollars for the East India market—the price, compared with that of gold and copper, rises; when there is no such demand the price falls. When merchantable silver can be profitably exchanged for foreign commodities, as in the East Indies and China, dollars are exported; when merchandise of other kinds can be profitably exchanged for silver, as in the West Indies, dollars are imported. Just as wheat is sometimes carried from New York to Liverpool; and sometimes brought from Liverpool to New York.

The quantity of gold and silver in a country is no more a standard of its wealth, than the quantity of iron or wood. So far as it has exchangeable value, it constitutes a part of the national wealth, but no more. A merchant does not reck-

* *Agave Americana*. M.

on his property by the number of dollars in his drawer. On the contrary, as soon as he receives money, he endeavours to part with it, by laying it out in the purchase of other merchandise. He cannot add sufficient value to silver dollars, to make a profit by keeping them. A farmer who exchanges his only dollar with a neighbour for a load of manure, has not become poorer by the exchange—though he has “exported all his precious metals.” We should think the neighbour who sold his manure for money much nearer to ruin. The purchaser, by a judicious use of the manure, may add to its value, and ensure a large profit at harvest; while the seller, if he did not himself export his dollar, could add nothing to its value; and, in autumn, would have only the consolation of having “kept his precious metals at home.”

With regard to the transfer of stock and public securities to England—so pathetically alluded to by the writer in the Statesman—a very satisfactory account can be given. It is well known that money can be borrowed in England at 4 per cent. upon a pledge of United States Stock. If then, capital can be advantageously employed in this country, it is certainly desirable that the greater part of our public debt should be transferred to England upon such terms. We have in this neighbourhood a very extensive manufactory—the one at Dover, so well described by the editor of the Statesman last summer—and we have another just commenced at Sommersworth, which will be of nearly equal importance. If the proprietors of these establishments should happen to be owners of public stock to the amount of \$100,000, and should want to expend that sum in their manufactories, it would surely be better for them to borrow it in England, than to sell their stock here. It could not certainly be a very ruinous transaction for themselves or the country, if they enjoyed the use of the money, and received for interest \$2,000 a year more than they paid.

The great fall in the price of Exchange during the last fortnight, illustrates very strongly the remarks upon exchange, which we offered a few weeks ago. But we have already exceeded our limits and fear that we have trespassed too much upon the patience of our readers. At some future time we shall resume the subject.

ON THE MANAGEMENT OF HORSES AND DOGS—BY AN EXPERIENCED SPORTSMAN.

(Continued from page 51, vol. 5.)

The distemper in dogs.

Now to the diseases of dogs.—I am acquainted with two, which are most fatal to them, namely, the distemper, and a violent bilious fever, which they are very subject to, from hunting in hot weather; particularly if they have not been thoroughly purged before the season. I never as yet have found any medicine which can be relied on as a cure for the distemper in dogs. I have given Doctor James's powders, and many other medicines. Some have died, some have lived. The most efficacious I know of, is one which I have frequently tried for above eighteen years, and never gave any other. It is not always to be relied on; but it is by far more certain than any other. I cured two dogs last year, 1813, which were both very bad, so much so, that I despaired of their lives. The medicine is as follows: TURBITH MINERAL, TWELVE GRAINS, MADE INTO A BALL, WITH ANY SYRUP. Give one dose every day, for three or four days in succession. This is the quantity for a full-grown pointer: give a young puppy, three or four months old, five grains; one of seven months

I have observed that dogs, in the distemper, absolutely die for want of nourishment: for, if very bad, they refuse all food. I am convinced that I have saved the lives of several, by drenching them, three or four times a day, with strong beef or horse broth, with a little meal in it; making it a thin gruel.

I have found the turbith mineral, in the distemper, by many degrees the most efficacious; and I can with truth say, it does not often fail when given in the early stage of the disorder. Although this medicine is not a certain cure in the distemper, yet, in a violent and fatal disorder, which dogs are very subject to, *I never knew it fail*, if given when the dog was first taken ill.

The violent Bilious Fever which dogs are very subject to.

The disorder I shall next speak of, is a violent bilious fever, which kills a dog in three days, provided he be not relieved. The symptoms are as follow: first he feeds very sparingly; shortly after that, he loses that fine, florid, flesh colour, in his mouth and gums, which begin to assume a pale cast: in a very few hours after, he will turn as yellow as a guinea in the mouth and eyes. The moment he looks dull and heavy, refuses his food, and begins to look pale in the mouth, before he turns, in any considerable degree, yellow, you must give him the medicine, or I will not be answerable for his cure. The quantity is TWELVE GRAINS OF TURBITH MINERAL MADE INTO A BALL, WITH ANY SYRUP, the same as in the distemper. Give this three or four days following: on the fourth day, he will either be totally out of danger or dead. You must by no means bleed him in this disorder: if you do, you will kill him. In a very few years, I have had six or seven dogs taken with this disorder; and, upon my word, I never lost but one, and that by my own negligence; which I will prove to you.

An old gamekeeper and huntsman, who was my servant, said to me, just as I was at breakfast: “One of your dogs, sir, did not feed last night well; you observed that, and told me to look to the dog, and examine him the very first thing in the morning. I let him, sir, out of the stable, to run about; but I observed him to be rather dull, and not in such good spirits or so gay as the others. I wish, sir, you would come and look at him.”

I went directly, and examined him; looked into his mouth, and examined his eyes. I did not observe that he was even faint-coloured in the mouth; but I left him at home that day, intending to return about five o'clock; desiring the ostler to feed and take care of him. I went that day above twelve miles distant, and, finding a great deal of game, I stopped at a village contiguous, sported there the next morning, and shot my way home to where I had left my dog. On my arrival, I found him very bad indeed; he was as yellow as a guinea in his mouth, and lay stretched out and extended on his side. I gave him the above medicine, but he died the next evening. Had I returned home the first evening, I should have saved my dog: the most early attention and relief is necessary in this disorder, as well as in most others.

Of the Mange in Dogs; how best to cure it.

I will now inform you how I have, for above twenty years, treated dogs which have had the mange. About that time I was very much employed in the recruiting service, and could not give up much time to my dogs; so I sent for an old man, who made a good livelihood by curing dogs. My dog had the mange; not very bad, but something much worse with it; he had eight or ten large blotches on his body, as big as large hazle-nuts. The old man took a bottle out of his pocket, and first dabbed the blotches with a bit of

about five minutes, for that to dry in and penetrate; after which he took a pot of ointment, and rubbed the dog in well, for at least ten minutes, under the fore legs, and on the belly, but *particularly on the back bone*. He then desired me not to wash the dog, or let him go into the water; telling me, that he would call in about five days. When he called, the dog was apparently well; so much so, that he said he did not think it necessary to rub the dog again; however, I made him dab the blotches again, and rub once more in.—When he called to be paid, I told him that, upon my honour, if he would discover how the liquid and ointment were made, I would give him two guineas, and never discover it till after his death. He consented. The liquid is thus made:—HALF AN OUNCE OF QUICKSILVER IS PUT INTO A BOTTLE, WITH HALF AN OUNCE OF OIL OF TURPENTINE, FOR ABOUT EIGHT HOURS BEFORE USING IT: SHAKE THE BOTTLE FREQUENTLY, AND SHAKE IT ALWAYS WHEN YOU USE IT, for there will be a sediment at the bottom. The ointment is thus made:—TAKE HALF AN OUNCE OF QUICKSILVER; PUT IT INTO A BOTTLE, WITH HALF AN OUNCE OF OIL OF TURPENTINE; LET IT STAND FOR EIGHT HOURS, SHAKING THE BOTTLE FREQUENTLY; THEN TAKE FOUR OUNCES OF HOGS-LARD, AND BY DEGREES MIX BOTH TOGETHER, A LITTLE OF EACH AT A TIME, TILL THE WHOLE BE INCORPORATED.—He told me, that he always carried two pots of ointment with him, one stronger than the other, in case of a dog being very bad with the mange. The strongest ointment was made with *only three ounces of hog's-lard*, but with the same quantity of the quicksilver and turpentine.

(To be continued.)

COMMUNICATED FOR PUBLICATION IN THE AMERICAN FARMER.

To the Pennsylvania Agricultural Society.

As it is the implied duty of every member of this society, to contribute his mite to augment the great mass of agricultural information, which this association will doubtless collect, I cheerfully volunteer a short notice of the subject to which I have as a farmer, devoted more attention than to any other, namely, *the selection of the best breed of Cows for a butter dairy*. I have long been of the opinion that in England particularly, the great breeding country—from whence we derive our finest stock—too much attention was paid, and vast sums of money expended, in the vain endeavour to procure a race that shall excel in all the three great points of “the pail, the yoke, and the knife,” as they are technically termed; and whilst other gentlemen were selecting the finest forms to feast the eye, and a carcass which if well fed would grow to an enormous size, I wanted a small animal, whose carcass was too valuable for beef, that would subsist on a small quantity of food, bear the heat and drought of our summer and autumn, and produce the greatest quantity of rich and delicious butter, in proportion to the food consumed. In pursuance of this object, I procured a pair of the cattle of the island of Alderney, and, to compare with them, imported from Ireland the celebrated Kerry cow, and from France the beautiful little Brittany. I soon satisfied myself that neither these, nor any other breed in the country, would bear a comparison with the Alderneys. And an experience of now six years, has tended to confirm that conclusion. Still it was said the Alderney cattle were too delicate to bear our severe winters; and in compliance with the notion of the celebrated French naturalist, Buffon, that “man in America became a degenerate animal, and the stories related by those whose interests led them to end

our gigantic country, by stating that the valuable merino sheep introduced into our climate, would no longer produce fine wool. So it was asserted, that although the imported cattle might maintain their individual excellence, yet their descendants would only partake of their good qualities in an inferior degree. My experience has been sufficient to refute these unfounded allegations. I have now a little full bred Alderney cow, reared on my farm, that will be only four years old next harvest. She had her third calf on the first of last month; and on the 19th, we made rather more than ten pounds of delicious butter from twelve quarts of her cream, obtained from fourteen milkings, that is, in one week. Her only food through the winter has been good hay and brewer's grains; the latter article well known to be useful in promoting the secretion of milk, but not increasing the quantity, or improving the quality of butter. A sample of the butter obtained from this cow was sent to the exhibition held last year by the Philadelphia Society for the promotion of agriculture, and pronounced by the best judges to be far superior to the prize butter, though not offered for a premium. One remarkable property of the cream of the Alderney cow, is, the readiness with which it is converted into butter. The week in which we kept it separate, "it came" as the phrase is, in five minutes. And in churning it mixed with the cream of other cows, we usually have had the Alderney butter come first, be taken out of the churn, and the operation continued half an hour or more before a second gathering of butter has taken place.

As I have now an increasing stock of this valuable breed, I hope in future to give some further authentic details in relation to their superior qualities.

REUBEN HAINES.

Germantown, 4th mo. 12, 1823.

CATTLE SHOW AND FAIR—No. 4.

For the Exhibition and Sale of all kinds of Live Stock, Agricultural Implements and Household Manufactures—to be held at the Maryland Tavern, on the Frederick Turnpike Road, four miles from Baltimore, in the month of October next.

The Committee appointed on behalf of the Maryland Agricultural Society, to make arrangements for a Cattle Show and Fair, for the exhibition and sale of live-stock, agricultural implements, and household manufactures, have resolved that the said show and fair be held at the place and time above mentioned, and that the following premiums be offered and awarded, to the owners of the best—that is to say:

HORSES.

- For the best Stallion - - - - \$20
- the second best - - - - 10
- For the best brood Mare - - - - 15
- the second best - - - - 10

ASSES.

- For the best Jack - - - - \$10
- the best Jenny - - - - 5
- the best Mule - - - - 15
- the second best - - - - 10

CATTLE.

- For the best Bull over 2 years old - - \$15
- the best under 2 years - - - - 15
- the second best do. - - - - 10
- For the best Milch Cow - - - - 15
- the second best - - - - 10
- For the best Heifer - - - - 15
- the second best - - - - 10
- For the best yoke of Oxen - - - - 15
- the second best - - - - 10

SWINE.

- For the best Boar - - - - \$10
- the second best - - - - 5

- For the best Sow - - - - 10
- the second best - - - - 5

SHEEP.

- For the best Merino Ram - - - - \$10
- the best of any other do. - - - - 10
- For the best two Merino Ewes - - - - 10
- the best of any other breed - - - - 10
- For the five best fat Wethers - - - - 10

MACHINERY AND IMPLEMENTS.

- For the agricultural Machine or Implement that may be new, and be thought worthy of reward by the society - \$20
- And a second best - - - - 10

PLOUGHING MATCH.

- For the best Ploughing, by 3 horses - 10
- Ploughman - - - - 2
- For the best Ploughing, by 2 horses - 10
- Ploughman - - - - 2

HOUSEHOLD MANUFACTURES.

- For the best piece of Kersey, not less than 10 yards, - - - - \$5
- For the best piece of Flannel, not less than 10 yards, - - - - 5
- For the best piece of Cassinet, not less than 10 yards, - - - - 5
- For the best piece of Carpeting, not less than 20 yards, - - - - 5
- For the best Hearth Rug, - - - - 5
- For the best Counterpane, - - - - 5
- For the best piece of Sheeting, not less than 12 yards, - - - - 5
- For the best piece of Table Linen, not less than 10 yards, - - - - 5
- For the best piece of Towelling, not less than 10 yards, - - - - 3
- For the best pair of knit Woollen Stockings, - 1
- For the best pair of knit Cotton Stockings, - 1
- For the best pair of knit Thread Stockings, - 1
- Each of a size for men or women.
- For the best Grass or Straw Hat or Bonnet in imitation, - - - - 5

CROPS.

- For the best 1/4 acre of Carrots - - - - \$5
- acre of Mangel Wurtzel - - - - 10
- acre of Potatoes - - - - 5
- acre of Lucern - - - - 5
- acre of Ruta Baga - - - - 5
- acre of common Turnips - - - - 5
- ten acres of Indian Corn - - - - 10
- acre of Flax, (by John Travers, Esq., proprietor of a duck manufactory at Paterson, N. J.) a silver goblet, valued at twenty acres of Wheat, Rye and Oats—each - - - - 10
- ten acres of Barley - - - - 5

FERMENTED LIQUORS.

- For the barrel of best Cider - - - - \$5
- 5 gallons of best home-made Wine - - - - 5
- For the sample of the best Butter, not less than 5 pounds, a butter-knife with a silver blade, - - - - 5
- Second best, - - - - 3

A statement of the manner of managing the cream will be desirable.

The Show and Fair will be held between the middle and the last of October; notice will hereafter be given of the particular days; in designating them, particular regard will be had to the convenience of the Eastern-shore Society.

There will be reserved premiums, to consist of pieces of plate, making the whole sum offered, amount to 500 dollars.

The above premiums will be awarded only for animals bred within the State of Maryland, or within the District of Columbia. But male animals of the several kinds above specified may be entitled to premiums, though bred out of the State and District, provided the owner of such male animal shall secure his continuance in the

State of Maryland, to be bred from, for one year from the granting of the premium.

It is to be understood, that whenever a premium for any specimen of Agricultural Implement, piece of Machinery, or article of Manufacture, may be claimed merely from the want of competition, or where the thing presented for premium shall be considered as possessing no merit worthy of encouragement, the judges shall have a right at their discretion to withhold such premium.—But this regulation shall not extend to Live Stock, as the best offered will gain the premium without any exception.

In no case will a premium be given for Live Stock, unless the owner shall have notified Mr. J.S. Skinner, of his intention to offer for the same, and shall have entered the particular animal with him three days previous to the Exhibition.

Persons having fine animals, though not intended to be offered for premiums, will gratify the Society by exhibiting them in their field. And for the purpose of preparing proper arrangements, and stalls, for the accommodation of all stock offered for premiums or for show, it is requested that all persons intending to offer stock for show only, as well as those offering them for premium, should give notice to Mr. J.S. Skinner, of such intention at least ten days prior to the Exhibition.

All premiums awarded by the Committee, will be distributed in articles of Plate; and the Committee, to whom the charge of these regulations shall be entrusted, shall determine the nature and devices of the plate and medals so to be distributed.

C. RIDGELY, (of H.)
Chairman of the Committee of Arrangement.

JAMES HOWARD, Secretary.

Miscellaneous.

PERFUMES A PREVENTIVE AGAINST MOULDINESS.

Dr. M'Culloh, of Edinburgh, has published a paper in the Philosophical Transactions of the city, in which he points out that all essential oils possess the property of preventing the growth of mould. His observations are of such general utility, that we copy them into our more popularly circulated pages for the public benefit.

Ink, paste, leather and seeds, are among the common articles which suffer from this cause, and to which the remedy is usually applicable.—With respect to articles of food, such as bread, cold meats, or dried fish, it is less easy to apply a remedy, on account of the taste. Cloves, however, and other spices whose flavours are grateful, may sometimes be used for this end; and that they act in consequence of this principle, and not by any particular antiseptic virtue, seems plain, by their preventing equally the growth of those minute cryptogamous plants on ink, and other substances not of an animal nature.

"The effect of cloves in preventing the mouldiness in Ink, is indeed generally known; and it is obtained in the same way by oil of lavender, in a very minute quantity, or by any other of the perfumed oils.

"To preserve Leather in the same manner from this effect, is a matter of great importance, particularly in military store-houses, where the labour employed in cleaning harness and shoes is a cause of considerable expense, and where much injury is occasionally sustained from this cause. The same essential oils answer the purpose, as far as I have had an opportunity of trying effectually. The cheapest, of course, should be selected, and it would be necessary to try oil of turpentine, for this reason. The total interruption of all my pursuits has hitherto prevented me from carrying these trials as far as I intended

FROM THE CHARLESTON COURIER.

VALUABLE PRESENT.

We are informed, that John Humé, Jun. Esq. has presented to the Literary and Philosophical Society, for their Museum, a splendid collection of specimens of Ornithology.

The Santee and its neighbourhood, are abundantly fertile in the varieties of the feathered tribe. In the rivers, creeks and rice grounds, the various species of ducks are to be met with in every direction, as well as of other birds; a few months alone, would suffice to collect specimens sufficient to fill an elegant Museum.

The cedar swamp on Washa, the property of John Middleton, Esq. is well calculated to facilitate the study of the naturalist, and he who is an admirer of nature would there be gratified with a sight of her in one of her wildest moods. This swamp is upwards of 10 miles in extent; in most parts the water is deep. The cedar and other trees grow so closely together that the proprietor has been necessitated to cut a path for boats and canoes. At this season, the largest alligators may be seen on every dead log; and in the tops of the trees, the great American herons, white cranes, and fish hawks have built their nests. The Darter of Wilson, a bird so imperfectly known, may be seen in flocks in the air, or perched on trees looking for their food.

During the cold weather, nearly all the varieties of ducks that visit the United States, are to be found in this magnificent repository; and the naturalist who has obtained the proprietor's permission will then find ample field for his researches in this branch of science.

The fields and swamps of Carolina are important, not only for the staple commodities of life—but they yield to the student, faithful resources of information and of interest. The proverbial hospitality of our planters, affords the most ample access to the discovery of rare and valuable information; and the elegant leisure of the opulent cannot be more pleasingly employed, than by enriching the science of nature, and contributing to the treasures of art.

Hop Beer.—For a half barrel of beer take half a pound of hops and half a gallon of molasses; the latter must be poured by itself into the cask. Boil the hops, adding to them a teacupful of powdered ginger, in about a pailful and a half of water, that is, a quantity sufficient to extract the virtue of the hops. When sufficiently brewed, put it up warm into the cask, shaking it well in order to mix it with the molasses. Then fill it up with water quite to the bung, which must be left open to allow it to work. You must be careful to keep it constantly filled up with water whenever it works over. When sufficiently wrought to be bottled, put about a spoonful of molasses into each bottle.

Expeditions Travelling.—We are indebted, says the Albany Daily Advertiser, to a gentleman from Portland, lately on a visit to this city, for the following communication.

Distances from Albany to Portland, Maine, and time taken up in travelling, by steamboats and stages, via New-York, Providence and Boston.

	Miles.	Hours.
From Albany to New-York,	150	18
New-York to Providence,	200	20
Providence to Boston,	40	6
Boston to Portland,	110	12
	500	56

500 miles in 2 days and 8 hours, through the most interesting parts of the Northern and Eastern States, and the Capitals of four of them.

THE WET TAX.

A true statement of Mr. Ichabod Boozy's wet tax for the year 1822, viz.

One day spent each week at the store, equal to 52 days, which at 4s per day amounts to	\$34 67
Parts of other days spent at the stores every week, besides the above, say in all 20 days at 4s.	\$13 33
One gill new rum drank on each of those days, say 90 gills in all, at 4 cents is	3 60
The same quantity bought to treat his brother, Obadiah Boozy, and other good friends by way of reciprocal civility	3 60
Twenty-five glasses of brandy, bought occasionally to stimulate the system, give an appetite, and brighten the spirits, at 8 cents	2 00
Thirty glasses of gin and molasses, to counteract the evil effects of the brandy, at 6 cents	1 80
Losses sustained by reason of his being absent from home, viz:	
Damage to three tons of hay by rain, it not being got in season—good hay half spoiled, 3 tons, at 4 dollars	12 00
Damage to the corn by brother Obadiah's cattle, that broke in while the boys were gone a fishing—about 20 bushels lost	10 00
Loss on a yoke of steers which he was obliged to sacrifice to get money to pay his other taxes, worth \$40, sold for \$30,	10 00
Bill of cost paid on a suit by Capt. T. the trader, for his rum score for 1821	5 68

Total amount of Mr. B's wet tax, for 1822 \$96 68

Editorial Correspondence.

Cabin Point, Va. 14th May, 1823.

By an order of the Surry county Agricultural Society, I am directed to assure you of its gratitude, not only for your kindness in sending the seed, &c. but for your unremitting zeal in the promotion of agriculture and its rights. I am also, Sir, directed, through you, to present to General T. M. FOREMAN, of Maryland, the thanks of the society for the Bene Oil and Seeds, which, by the members of the society, is duly appreciated. I can assure you it affords me much pleasure in complying with this part of my duty as a member of the corresponding committee of the Surry Agricultural Society.

Waddington, (N.Y.) May 2, 1823.

"I am assured by a seedsman occasionally in my employ, who served his time with one of the first nursery-men and seedsmen in Ireland, that it is absolutely necessary in turnips, to transplant the young plants intended for seed, as soon as they are fit for the first year; so that before obtaining the seed, they will be twice transplanted."

Scotland Neck, May 8, 1823.

"SIR—I send you by mail, one half ounce of the Georgia Pea, and one half ounce of the Black Pea, which we have lately got in this neighbourhood. The Georgia Pea is prized for its being a good bearer, for its quantity of vine, and from their not rotting; they will lie in the field all the winter and come up in the spring, produce abundance of vines and some peas. From seeing this, I was first led to plant them, as I wrote you some weeks past. The black pea is said to be somewhat earlier, and if possible more hardy. Should you want any of them for another year, I can send you by the way of Plymouth a bushel two."

"It is a remarkable confirmation of this circumstance, that Russian leather, which is permeated with the tar of the birch tree, is not subject to mouldiness, as must be well known to all who possess books thus bound. They even prevent it from taking place in those books bound in calf near to which they happen to lie. The fact is particularly well known to Russia merchants, as they suffer bales of this article to lie in the London docks in the most careless manner, for a great length of time, knowing well that they can sustain no injury of this nature from dampness, whereas common curried leather requires to be opened, cleansed and ventilated. Collectors of books will not be sorry to learn, that a few drops of any perfumed oil will insure their libraries from this pest.

"Dr. M. began some experiments with the same agents on wood, to prevent the dry rot, but not having time to carry them on, he recommends the important investigation to others. With regard to paste, he prefers rosin to alum as a preservative; but lavender, or any other strong perfume, such as peppermint, anise, burgamot, are perfectly effectual for years, however the paste is composed." That which the Dr. himself employs in labelling, &c. is "made of flour in the usual way, but rather thick, with a proportion of brown sugar, and a small quantity of corrosive sublimate. The use of the sugar is to keep it flexible, so as to prevent its scaling off from smooth surfaces; and that of the corrosive sublimate, independently of preserving it from insects, as an effectual check against its fermentation. This salt, however, does not prevent the formation of mouldiness. But as a drop or two of the essential oils above mentioned is a complete security against this, all the causes of destruction are effectually guarded against. Paste made in this manner, and exposed to the air, dries without change to a state resembling horn; so that it may at any time be wetted again, and applied to use. When kept in a close covered pot, it may be preserved in a state for use at all times."

He proceeds—"This principle seems also applicable to the preservation of seeds, particularly in cases where they are sent from distant countries by sea, when it is well known that they often perish from this cause.—Dampness, of course, will perform its office at any rate, if moisture is not excluded; yet it is certain that the growth of the vegetables which constitute mould, accelerate the evil, whether by retaining moisture, or by what means, is not very apparent. This in fact, happens equally in the case of dry rot in wood, and indeed in all others where this cause operates. It is a curious illustration of the truth of this view of a remedy, that the aromatic seeds of all kinds are not subject to mould, and that their vicinity prevents it from others with which they are packed; they also produce the same effect daily, even in animal matters, without its being suspected. Not to remark any thing on the subject of cookery, I need only remark, that it is common to put pepper and collections of insects or birds, without its being remarked that it had the same power of keeping off mould, as of discouraging or destroying the *flinus omnivorous*, or other insects that commit ravages in these cases.

In concluding these hints, I might add, in illustration of them, that ginger-bread and bread, containing caraway seeds is far less liable to dampness, than plain bread. It will be a matter worthy of consideration how far flour might be preserved by some project of this kind.

[London Lit. Gaz.]

Albany, 13th May, 1823.

Mr. Clement Saidler, who has formerly been extensively engaged in the worsted manufactory in Ireland, has recently imported into this neighborhood a pair of English sheep (the name of the breed I do not know,) of very heavy carcase (the buck weighed 194 lbs.) and long fleece, suitable for worsted fabrics. He expects more of them this season. It is a fact worthy of remark, that perhaps a fourth or a third of the imported woollen goods are of worsted fabric; and yet no attempt has ever been made, to my knowledge, to establish a worsted manufactory among us, or to introduce the sheep whose fleece is peculiarly adapted for the manufacture of worsted goods. Mr. Saidler deserves lasting credit for his efforts to remedy the defect.

My indisposition prevented my calling up, at its proper time, the bill I reported relative to the agricultural school; for as it contemplated merely a plan of the organization of the studies and labours, and an estimate of the expense of the school, I had given it the latter form. I have very little doubt it would have passed; but as the subject was a novel one to many, I concluded to defer it for another year.

The season is remarkably backward with us. The apple is not in bloom, and probably will not be in less than ten days. Seeds put in the ground (corn, melons, &c.) two weeks ago, have not yet begun to vegetate. Winter grain, however, has a pretty good appearance: The winter was very favourable for those crops. Grass has, as yet, a promising aspect.

I am, dear sir, with sentiments of esteem,
Yours, &c. J. BUEL.
J. S. SKINNER, Esq.

Milford, Del. May 18th, 1823.

The wheat on the Eastern Shore and this part of Delaware is nearly destroyed by the fly. Farmers despair, in some places, of getting their seed. The best will not make more than half a crop.

HESSIAN FLY.

Centreville, Queen Ann's county, Md. }
May 15th, 1823. }

MR. SKINNER,

This is the second week of the session of the county court for this county, and we have, of course, the best information from every neighborhood in it respecting the growing crop of wheat; and most lamentable, indeed, it is. The prospect of an abundant crop, which existed three or four weeks ago, is now completely blasted. So great have been the ravages of the Hessian fly within that period, that many farmers now despair of making their seed, and the crops of almost every one has deteriorated from one half to a third. Our accounts from Kent and Talbot lead us to believe that our brother farmers in those counties will not fare better than ourselves.

A SUFFERING AGRICULTURIST.

Mr. Skinner,

SIR,—Observing in the American Farmer, vol. 5, No. 6, information wanting on the cultivation of Strawberries, I am induced to make known to you a conversation I had with an old and respectable lady, a few weeks since. I was making my complaints of a disappointment I had met with in raising hautboys; I had, after frequent trials, succeeded in raising a very handsome bed of vines—but they all proved to be male: she said she once met with a similar disappointment. Having a wish to plant out a new lot very early in the spring, she picked out all the biggest, best looking plants; the consequence was, that she never saw any strawberries from those vines. She was af-

terwards told that the male vines made their appearance first, and she had no doubt of that having been the way she lost her strawberries. Possibly that may have been the case with R. K. M. Should any of your correspondents cultivate hautboys, I wish they would be so obliging as to give all the information they can on the subject, and say where a few of the vines can be had. The writer of this assures them, that she would take the greatest delight in doing it for any subscriber to the American Farmer.

A LOVER OF FRUIT.

TO TAKE HONEY.

MR. SKINNER,

There is a gentleman in the lower part of your native county, who knows much better how to take honey from bees than the German mentioned in your paper, (No. 48, vol. 4,) and with less expense than Blake's patent hives. I was once an eye-witness of his taking it, and partook of the nice dainty. He has no need of cap, mask or gloves—so far from shielding himself, he rolls his sleeves up above his elbows, and goes at it when the sun is at its meridian, knowing that the bees are all at that time from home. The brighter the sun the better, and the month of August is his honey harvest. When he goes, as before mentioned, at mid-day, he takes off the top of the hive and takes out as much honey as he thinks proper; nails on the top and goes on to another, and another, until he is done. The honey is as nice and white as it can be—the bees will immediately fill up the vacant place, and the next year you have nice new honey again, as the gentleman informed me. A LOVER OF HONEY.

May 11th, 1823.

HOW TO RECLAIM FROZEN PICKLES.

Albermarle County, May 9, 1823.

DEAR SIR,

You have published very many valuable receipts in the American Farmer, please add this to the number, as one which has been frequently tested, and found always to answer. When vinegar in which pickles are preserved becomes frozen, it renders them soft, and unfit for use: in such cases, let the vinegar be drained from the same, put into a vessel and boiled, and again poured upon the pickles; they will then become firm and hard as before the frost. S.

IRON LANYARDS.

Mr. Rogers, a gentleman of Portsmouth, New-Hampshire, has invented and obtained a patent for a new method of setting up and securing Ships' Shrouds. Chains are used instead of Lanyards, and the Shrouds are tightened by a moveable Screw of such power, that one man can, with ease set up the rigging; securing at any time every half inch gained from the slack or stretch of the shrouds. For a ship of three hundred tons, each chain will weigh about thirty pounds; and considering their durability, are probably cheaper than rope Lanyards. The apparatus has been exhibited at Merchant's Hall, and approved by many competent judges.

THE FARMER.

BALTIMORE, FRIDAY, MAY 23, 1823.

INVASION OF SPAIN—COMMENCEMENT OF HOSTILITIES.

The regular packet ship Leeds, capt. Stoddart, which sailed from Liverpool on the 24th of April, arrived at New York on the 18th instant—she

brings news sixteen days later than that received by the Manhattan.

All doubt as to the intentions of the Bourbon Government respecting Spain, is now at an end. The troops of France crossed the Bidassoa, the frontier river, on the 7th of April, and by the latest accounts received at Paris, they appear to have occupied Vittoria, Bilbao, and the port and citadel of Guetaria [a small fishing town, containing about fifty houses] without meeting any serious opposition from the Constitutionalists.

In the British House of Lords, the Earl of Liverpool strongly deprecated the conduct of France towards Spain—and in the House of Commons, Mr. Canning said, "that to any menace or force against Spain, come from what quarter it might, the ministers of England would not be a party."

A letter from Liverpool dated the 24th of April says,—“Ere the receipt of this, you will have heard of hostilities having commenced between France and Spain. How the war will eventuate, time only will determine; but it is pretty apparent, the success of the French has not been equal to their expectation at the onset. Speculations in wheat, anticipating a continual demand, has been re-commenced, and prices here are about 3, and in London 4s. per qr. higher within the week. The business in cotton has been about an average extent, and without any alteration in prices. Nothing done in rice.

TOBACCO.—About 200 hhds. Kentucky Leaf have been sold at 2½ a 4d. per lb.—some small parcels of very fine Virginia for France, at 7 a 7½d.—and about 40 hhds. for Dublin, at 6½ a 9d. per lb.

BALTIMORE MARKET.

PRICES CURRENT.—CORRECTED WEEKLY.

Flour, best white wheat, \$8—Howard street Superfine, \$7 25—fine do. \$6 75—Wharf, do. \$7 25 sales—White wheat, \$1 60 to 1 64—Red do., \$1 57 to \$1 60—Rye, 85 cents—Corn, 56 to 58 cents—country Oats, 50 to 55 cents—Beef, 8 cts. per lb.—Live Cattle, \$6 to \$6 50 per cwt.—Bacon, round, 8 to 9 cents per lb.—Pork \$4 50 to 5 50 per c. lb.—6 to 8 cts. per pound—Mutton, 5 to 6 cts. per lb.—Beans, \$1 37½ to 1 50—Peas, black eyed, 55 to 60 cts.—Red Clover Seed, \$6—Orchard Grass do. \$3—Herds' Grass do. \$3—Timothy do. \$4 50—Millet, \$3—Flax Seed, 75 to 80 cts.—Whiskey, from the wagons, 32 to 35 cts. per gal.—Apple brandy, 30 to 32 cts.—Peach do., 65 to 70 cts.—Shad, none in market—Herrings, No. 1, \$2 50 per bbl.—No. 2, \$2 25—Fine salt 80 to 90 cts. per bush.—Coarse, do. 75—Butter, 20 to 25 cts per lb.—Eggs, 12½ cts. per doz.—Hay, \$18 per ton—Straw, \$11 to 12.

TOBACCO generally sells as per last accounts—we have received reports of the following particular sales:—James Mullikin, Montgomery county, Md. 2 hhds—1 sold at \$35 50, 1 at \$15 50—Thomas Davis, Frederick County, Md.—5 hhds. sold at \$20 round, in the County, before it was packed—W. C. Dorsey, Somerset, Pa 1 red hhd. sold at \$18—Richard Snowden, 2 hhds, sold at an average price of \$20—one of them was worth more than \$20.

The news of the actual commencement of hostilities between France and Spain does not appear to have had any effect on the prices of country produce.

Printed every Friday at \$4 per annum, for JOHN S. SKINNER Editor, by JOSEPH ROBINSON, on the North West corner of Market and Belvidere streets, Baltimore; where every description of Book and Job Printing is executed with neatness and dispatch—Orders from a distance for Printing or Binding, with proper directions promptly attended to, addressed to J. Robinson, Baltimore.

Internal Improvement.

First hear, or at least fully, and equally, understand both sides, and then Judge.—No. II.

9. The Baltimore American under date 2nd May, 1823, has announced that the whole of the stock required for the Chesapeake and Delaware canal is believed to be subscribed. Should this be the fact, it may be fairly presumed, that none of our money will be wanted upon that occasion, and in that event, also, our choice may, with great propriety, be reduced to a single alternative. The cross-cut and junction-canals, or such other substitute canal as may be adopted instead of the latter, in consequence of its being their avowed object to increase the benefits of the Potomac canal, to Maryland, may very correctly be considered as its appendages. Thus, it will only be necessary to collect the evidence in favour of the Susquehanna canal, and of the Potomac canal and its appendages, so as to become correctly acquainted with the merits of both, and then to decide accordingly between them.

10. I am aware that some members of the late Maryland Assembly advocated with zeal an appropriation of three hundred thousand, others of half a million of dollars, out of the state treasury for opening the Potomac canal, and that it also appears to be selected by some of our citizens as the object of our particular attention and munificence. But this, it is presumed, was nothing better than a very inconsiderate and over hasty conclusion; adopted without ever waiting to become acquainted with, and much less to investigate the clear and decided evidence that exists, in the greatest abundance, in favour of a new channel to the Susquehanna; and at the same time, without anything better in favour of the Potomac canal and its appendages, than mere assertion. This, I believe, has constituted the only evidence that has fallen under my notice, which the Potomac advocates have yet produced in its favour. From this circumstance it may, very rationally, be inferred that the subject admits of no other; for, as so judicious a mariner would ever substitute cobwebs instead of cordage for a cable, so neither can be it supposed, even for a moment, that anxious advocates, exerting themselves in support of a great public question, would commence with, and for months continue to deal out the cobweb evidence of assertion, but for the very substantial reason alone, of its being completely out of their power to avail themselves of any that was better.

11. Secretary Gallatin, in his celebrated report to Congress in 1808, on roads and canals, has observed that in order to be productive it is necessary that a canal should open a communication with a natural extensive navigation which will flow through that new channel. That a new channel to the Susquehanna, would in this respect, be greatly preferable to the Potomac canal, and its appendages must, at once, be conclusively evident to every person who is at all acquainted with the superior magnitude and extent of the former; and can only be necessary for those who are not, to see the different branches of the two rivers, upon a large and well executed map, to be perfectly assured of the fact.

12. The Philadelphians were some years past justly entreated by one of their authors, to bring to their city the trade of the Susquehanna, by whom they were also particularly congratulated upon this great geographical advantage, which he said, would give to their market the exclusive commerce of a numerous people inhabiting the upper branches of that river. The same author has so strongly urged the necessity of engrossing the commerce of the Susquehanna by completing what he said might, emphatically be called the main-link of the water-chain crossing from

Reading to Middletown, and in addition has observed that this last village is surrounded for 30 or 40 miles, in every direction, by a country the most fertile; the most fruitful, and the best cultivated in America; a country which may with great propriety be called the Belgium of the Union. By the same writer the vast country up the Susquehanna, is afterwards recognised as being excellent for wheat, or, in other words, an inexhaustible granary by which might be doubled the exports of Philadelphia.

13. What a vast acquisition then would this trade be, if it were added to the exports of Baltimore? Should the country prove very uneven indeed, so as to elongate our water route to Middletown to the length of 100 miles, (otherwise, it will, in all probability, be considerably less,) let it be remembered that the one which has been located from thence to Philadelphia is 140 miles. Thus, we have great cause for encouragement. Thus, there would be a difference of 40 miles, or perhaps more, in favour of Maryland; and it cannot be supposed, that boatmen, when at the point of separation, where they were either to take one route of 140 miles, or an equally advantageous one of only 100 or less, would ever be so regardless of their own interest as to prefer the more distant market, unless it should be understood that it would be so much better when there, as amply to reward them for the additional time, labour and expense that would be required.

14. In accordance with this evidence that of our Baltimore authors, who have written upon the subject is also highly favourable. By one of those it has been said, that, the Susquehanna alone is the natural outlet of a country, of itself sufficiently extensive to maintain a city of the first magnitude. By another, we are informed, that, the importance of the Susquehanna is but imperfectly understood; that it may be connected with the Allegany river, and with Lake Erie: that it taps every line of communication in Pennsylvania; that it reaches the Genesee country by the Seneca lake, in the richest part and in the centre of the state of New York; that its commerce is of vast importance, and that there can be no doubt of its immense utility to Baltimore; and consequently to the state of Maryland at large; for as it is natural for all fluids presently to find the true level, so also the benign influence of increasing intercourse, commerce and wealth, like that of the sun in the firmament, will speedily, and with infallible certainty expand and diffuse itself far and wide through the whole population.

15. But that portion of evidence to which, upon the present occasion, I desire most particularly and respectfully to invite the candid attention of every individual, and more especially of every advocate of the Potomac Canal and its appendages, remains yet to be noticed. The great preference justly due to the trade of the Susquehanna has been ably set forth, and with great force of reasoning confirmed by a Committee of the Senate of Maryland whose report is recognised under the article "Navigation Inland," pages 380 and 381, of the New Edinburgh Encyclopedia. In that report it is expressly stated that viewing the Navigation of the river Susquehanna as a subject of great and boundless importance, the Committee have given to it their fullest and most attentive consideration. Then, after advertising to the citizens of Maryland being convinced of its vast utility and benefit, and their anxious solicitude for legislative aid in its favour the next sentence of the report is in these words: Under these circumstances your Commit-

tee cannot but recommend it as a subject worthy of the deepest reflection, and fraught with considerations of vital importance to the State of Maryland.

16. In a subsequent part of the same Report, "That particular district of country to which the benefits of the turnpike roads in Maryland are most immediately extended, lying between the Susquehanna on the one side, and the Potomac on the other, and extending Northwestward from Baltimore to the North-mountain, comprehending the Conococheague valley, is said to have been, accurately measured on a map of the country, and found to contain 5000 square miles. Those portions of the country bordering upon the various tributary streams of the Potomac, westward of the South-mountain in Maryland, and the Blue Ridge in Virginia, have also been measured and found to contain 10,000 square miles." (Only ten thousand, let it be remembered.) "But when your Committee direct their attention to that portion of the country through which the Susquehanna flows, they embrace within their view a field of greater and more enlarged dimensions. By an accurate measurement of those expanded regions situated upon the Susquehanna and its numerous wide spreading branches they have been found to contain about 20,000 square miles, exclusive of 10,000 square miles more of adjacent country, lying upon other waters in the states of Pennsylvania and New York." (making together, thirty thousand square miles, let it be recollected, which is an extent of country equivalent to six times our wagon communication, and of three times the magnitude of but ten thousand square miles on the Potomac.) "for the produce of which country, should the navigation of the Susquehanna be improved to the extent contemplated, Baltimore must inevitably become the most convenient market.

17. "From these estimates it is abundantly evident that the trade of the Susquehanna, (flowing as it does through a country of vast extent and inferior in point of fertility, [let it be remembered,] to no portion of the United States,) is a trade involving in its nature, a very extensive, permanent and growing interest. Were the Potomac (continues the report,) improved to the utmost possible extent, its trade must be considered but of minor importance, (but of minor importance let it be recollected,) when compared with that of the Susquehanna; the Potomac, flowing as it does through a country of comparatively small extent, and by no means celebrated for its richness and fertility.

18. "In addition to this it may be remarked, that to however great an extent the productions of the soil may find their way into the Potomac, (and equally so of the Potomac Canal) however extensive the demand for foreign commodities at Georgetown and Washington, the state of Maryland can derive but little benefit from it. The advantages secured flow into a different channel: they go to fill other coffers—not those of the State of Maryland. (How very accurate is every syllable of this description!) "But improve the navigation of the Susquehanna, to the extent proposed, (say the Committee) and you bring to the city of Baltimore, a trade of incalculable extent and value," (let it be remembered,) the benefits of which must be imparted to every section of the state, and which cannot fail richly to remunerate us for whatever aid may be extended to it."

19. The foregoing evidence from its being partly geographical, and in other respects of an unequivocal and well attested character, I trust it will accordingly be appreciated by the public as being entirely divested of the cobweb texture,

* This report was also published in the Baltimore Morning Chronicle under date 18th February, 1822.

made up of the strongest materials, such as those of a three fold cord, which, it has been very justly observed, *is not easily broken.*

WILLIAM KENWORTHY.

AGRICULTURE.

JOHN S. SKINNER, ESQ.

DEAR SIR,

So much has been written and said, about "Improved Short Horns," that there is little to be given by me in their praise, but the results of my immediate observation. I had ample opportunities abroad, I have most sedulously availed myself of all the means within my reach at home, to obtain accurate information on the comparative merits, of the various breeds of neat cattle, of which we are possessed. I control more than a thousand acres of alluvious meadow, as well as many farms, and large bodies of wild lands, in Pennsylvania, New York, and Maine. I am thus led to mingle with farmers both in this and in other states, to examine their cattle, and ascertain their properties, as well as the products of the soil; whilst my own farm enables me to prosecute any system of experiments, which I may be led to attempt. I have had cattle bred in Kentucky, Maryland, Virginia, Maine, Massachusetts, Vermont, New York, and Pennsylvania. I have traced every importation, of which I had heard. I can distinguish Mr. O'Donnell's, Patterson's, Gough's, and Parkinson's importations for Maryland—the Holstein, *Alderny*, Irish, Dutch, Flanders, Brittany, Pole and Short Horn breeds brought into Pennsylvania by Mr. Sims, Cunningham, Ross, Waln, Hamilton, Kettland, Guest, and Haines: the families of various degrees of affinity, to the pure race of "Short Horns," carried to New York by Col. Deveaux, and Mr. Heaton—the Leicestershire, Lancashire, and Hereford cattle, taken to Connecticut, Massachusetts and Maine, by Mr. Wadsworth, Stewart and Vaughan. Of most of these importations I have had individuals, and of all, have carefully examined some of the progeny, either here, or at a distance.

I have possessed an hundred and fifty cows, calves, bullocks, and bulls within three years. I am a member of the society of learned farmers, I have attended cattle shows without number, I have read "Albion," "the Memoirs," and I reside near farms to "large dairies devoted;" thus without boasting of my brilliant accomplishments, or elaborate acquirements, in all that relates to the *tail of a sheep*, the buttock of a bull, or the bag of a cow, I may venture to state what I, and my cattle have done.

For some animals of the breeds, which I designate, I had given great prices; yet the best of them all, I sold for but sixty dollars a head, about the time, I gave nearly five hundred dollars for two imported "Improved Short Horn" cows—and from Mr. Williams of Massachusetts procured eighteen or twenty yearlings, and calves by his extraordinary Bull Denton. I have since obtained, three imported heifers; for one of them by North Star from a cow by Comet, I paid in England five hundred dollars. Among my stock a Chinese and Devon heifer, a yearling and cow from an imported Devon, by an English bull, all—also heifers, and cows bred upon our meadows and mountains have been placed, to decide the questions, which have caused among breeders so much dispute. All my experience has shown, that the extent of excellence in the animal, whether in *points, proportions, shape, disposition, early maturity, or tendency to secrete fat, or afford rich milk* is determined, by the degree of affinity to the pure race of Improved Short Horns. That by Durham cows are deep milkers, that they are *dy,** have elastic pliant hides with thick soft

that whilst yielding milk, they become thin, has been proved to my entire conviction. Might not "Albion" be asked whether he did not forget, that although it is difficult to "blow hot and cold at the same time," that it is possible to blow hot in June, and cold in January. The tendency towards fat, proceeds, I should presume, from the power of the animal's stomach, and intestines to separate the nutritious, from the excrementitious parts of its aliment. Nature wisely destines certain portions of nutritious matter at proper times, for the secretion of milk—that milk is an unctuous, and very nutritious fluid, cannot be questioned—much therefore of nutrition is withdrawn by the milk from the formation of fat—but does it follow, that such portions as have made butter, or produced *fat in the calf*, when no longer directed towards the secretion of milk, must necessarily lose all their properties, and pass off in urine or in dung? Do we not invariably find, that all cows when dry become more readily fat than when they give milk? Is it not to be inferred that the matter which would have passed off in milk, *may* be made to produce fat? Does not our experience show in all families of wild cattle, where the perverseness of nature, that when kept quiet, and well fed, they exhibit great tendency towards secretions of fat. In the cattle even of Asia and China, in the Kyoles of Scotland, in the wild breeds of Louisiana, and in the little mountain cows of America, such disposition is generally shown.

The mistaken ingenuity of the breeders of Holland, whence all the deepest milkers, whether Holderness, "Old Short Horns," Holstein, or whatever they may be termed in America, are in some measure derived, carried them into an absurd "cross," affording excessive secretions of bad milk; thus not only prematurely exhausting the animal by which they are given, but at all times requiring great quantities of food for her support. That disease, peculiar tendency towards *fatness, or leanness*, or copious supplies of thin, or lesser quantities of rich milk, or even the determination of a particular color, towards any definite part of the body, as white at the end of a Devon's tail, may be established by perseverance, and art, every man conversant with the subject, will readily believe. Because a Dutchman chooses to wear out his cow, or have a race of animals, which will not readily become fat, even when dry; and the cupidity of the venders of milk in the neighborhood of large towns in England, or America, has led them to propagate this unthrifty breed of cattle, is it to be inferred, that the efforts of Collings, and his coadjutors, could not obtain by crossing a family, which are fitted at *different times for the production of milk, and secretion of fat.*

Yours, &c.

CURWEN.

Philadelphia County, April 10th, 1823.

MURRAY'S System of Chemistry, says "the blood is a compound of this kind," &c. "and if we suppose a fluid thus passing through tubes of different diameters, and undergoing successive decompositions, we may easily conceive that very different products may be formed from the same original compound. This affords a simple view of the nature of secretion. No complicated apparatus is requisite for the performance of this change, all that is necessary being the propulsion of the blood through minute vessels, capable of contraction. It has accordingly frequently been observed, that new products are formed without the intervention of glands; such is the formation of the fat or of the muscular fibre. It is easy to conceive that the formation of these may take place in the extreme vessels, where these products are deposited; and in like manner, in the

mere course of the circulation, may be formed the gluten, albumen, and other principles of the blood itself. From secretion a variety of products are formed, as the bile, milk, fat, the bony matter, the matter of membranes, and a variety of others. These complete the formation of animal matter, and comprehend its several varieties. Such are the different steps of the process of animalization. The food is digested in the stomach, mixed with animal matter in the intestinal canal, and converted into chyle: this mingles with the blood, and loses a portion of carbon in the lungs: in the extreme vessels it is converted into the general principles of animal matter; and in the glands, is converted into various secreted products."

White, vol. 4, chapter 1. of the formation of the digestive organs of the cow, page 13. "The stomach then may be considered both as a muscular and as a vital organ. If we view it in another light we shall consider it as one continued bibulous surface, sucking up the chyle as it is formed, and conveying it by means of the milk-vessels to the four receptacles which are named the quarters of the udder. There is another order of absorbed vessels in the stomach, and in the small intestines also, especially in the upper part, named lacteals, which ramify through the mesentery, and terminate in the thoracic duct, having previously passed through what are named the mesenteric glands; that is for the most part, for some are seen going over their surface. These lacteals are subsidiary, and occasional in their office, serving to convey chyle when the mesenteric glands are inflamed and obstructed. Chyle, as we find it in the lacteals, is exactly like milk in every respect, and is, in fact, the same thing. The fluid of the thoracic duct is different; it is semitransparent, has always a little oil floating on it, and is now and then found mixed with a little blood, which probably falls into it after death, from the great vein in which it terminates. This depends on the value of that part giving way, in consequence of death. Chyle and milk are then precisely the same thing; and in the cow there are three thoracic ducts, two going to the udder and conveying milk, and one to a great vein near the heart, conveying that fluid from which the blood is formed. When the animal has young, the lactiferous vessels, for so the minute branches of the two former thoracic ducts should be named, have a predominant aptitude to absorb the chyle, and a sufficient quantity only is taken up by the chyloferous vessels going to the third thoracic duct to supply the heart."

* The hardness of this breed of cattle, was forcibly evinced, on the estate of a scientific and eloquent agriculturist, who in his contempt of the old fashioned mode of delving, and ploughing the earth, unluckily left his barns without fodder, and his fields bare of grass, to the great mortification of himself in the last spring, when he emerged from his closet, and discovered that his schemes had all failed, and his cattle had starved, except those of pure "Improved Short Horn" blood.

NOTE.—The Editor takes the liberty of adding the following extract from a letter from Col. Edward Lloyd, speaking of the Improved Short Horns, Champion, Shepherdess and White Rose—sent in by Mr. Charles Champion of Blythe, Nottinghamshire, England.—Col. Lloyd observes "I found Champion and the heifers in fine order on my return; they were, and still are too fat. I assure you that Shepherdess reduced *but slowly*, although I fed her alone on *corn tops*—and Champion is still too fat, although have reduced his feed to a half gallon of meal per day. Their *fattening qualities* far exceed my expectations, and are almost incredible."

From Phillips' History of Cultivated Vegetables.

FLAX, OR LINE.—LINUM.

Natural order, *Grecinales*. A genus of the *Pentandria Pentagynia* class.

The Greeks called this vegetable *Λίνον*, and the Latins had no other name for it than *Linum*, both in its growing state and when prepared for the spinner; hence the Italians and Spaniards have derived the word *Lino*; and the French, *Lin*. The ancient Britons called it *Lyne* from the same source. The word *Flax* is derived from the Saxon *Fleax*, or *Flex*; but we still term it *Linseed* and *Linum* cloth, although when speaking of the plant we call it *Flax*.

We know twenty-two species of *Linum*, four of which are said to be indigenous to our soil.

The flax is scarcely superior in appearance to the common grass; yet on no other vegetable has the ingenuity of man been so extensively employed, or exerted with such success.

Without the aid of flax, this island might have remained unknown and unpeopled. Its assistance enabled the European sailor to discover a new world, and people to whom we must have remained strangers but for the fibres of this herb, and from whose territories we have since enriched our isle with the most useful roots, the most luxurious fruits, and ornamental plants. It was with flax that we first made wings to our vessels, with which we travelled with the swiftness of the eagle, and extended our commerce to the most distant parts of the globe.

Dadalus is said to have been the inventor of sails for ships, by which he fled from *Crete*, to escape from the revenge of the incensed *Minos*, who had condemned him to be confined in the labyrinth which he had constructed. *Dadalus* arrived safe in *Sicily*, where he was hospitably received by *Cocalus*, king of that island. From this circumstance the ancient allegory states, that he made himself wings. This was at least 1350 years before Christ; and we find that sails were certainly used before *Homer's* time, who says

—“the winds aloud
Howl o'er the masts, and sing through every shroud.”

At that period the use of hemp was not discovered

Flax is a slender plant, that seldom exceeds two feet and a half in height. From its fibrous bark we procure the comfort of linen, and the beauty of lace; its very rags are manufactured into the most exquisite of all our luxuries, viz. the paper that enables distant friends to hold converse, and communicates the wisdom of the learned of every age and language.

How the fibrous qualities of this plant were first discovered, it is beyond the powers of research to ascertain; probably the earliest use of this pliable plant was to twist into bands for the purpose of attaching productive vines to unfruitful trees. Thus *Milton* describes the employment of our first parents:

—“or they led the vine
To wed her elm; she spoused, about him twines
Her marriageable arms, and with her brings
Her dower, adopted clusters, to adorn
His barren leaves.”

As man multiplied, the necessity of ensnaring wild animals and securing domestic ones, would naturally call his attention to the formation of a cord; and when once a band was formed of the whole plant, it would easily be discovered that the fibres were the part that afforded the strength. When *New Holland* was first discovered, it was observed that the natives, who subsisted principally on fish, had invented a kind of net made of the fibres of flax, by inserting the loops of each other without a knot; yet these people

had not the least idea of forming a covering, even to protect themselves from the inclemency of the weather, and were so barbarously ignorant as not to have the least knowledge of the art of cultivating plants or fruits of any description.

The making and use of linen cloth appears to have been invented previously to the *Deluge*, as we read that *Noah* slept in a tent.*

Egypt, which appears to be the country that *Ham*, the second son of *Noah*, resorted to, from its being called in Scripture, the Land of *Ham*, soon became the garden of the East, and the seat of arts.

“Israel also came into *Egypt*, and *Jacob* sojourned in the land of *Ham*.”†

Ham is supposed to have led a pastoral life, but his son *Mizraim*, who is mentioned in profane history by the appellation of *Menes*, assumed the style of king, and built the town of *Memphis*. His wife *Isis*, whom some suppose to be the same as *Io*, is said to have taught the art of agriculture, and employed herself diligently in cultivating the earth, for which she was deified, and the worship of *Isis* became universal in *Egypt*. The priests of this goddess were clothed in linen garments.

About 300 years after the flood, *Abram* and his family went into *Egypt* to avoid the famine; and on their return the following year, the book of *Genesis* notices, that *Lot*, the nephew of *Abram*, had flocks and herds, and tents.

Pharaoh arrayed *Joseph* in vestures of fine linen; and when *Moses* called down the plague of hail upon *Egypt*, it destroyed the flax.

“And the flax and the barley was smitten; for the barley was in the ear, and the flax was boiled.”‡

That the art of weaving had attained a wonderful perfection in *Egypt* in those days, we learn both from profane and sacred history.

The *Israelites* appear to have carried the art with them when they were delivered from bondage; for they were commanded in the wilderness to make offerings for the tabernacle, of “blue, and purple, and scarlet, and fine linen, and goats' hair.”

“Thou shalt make the tabernacle with ten curtains of fine twined linen, and blue, and purple, and scarlet: with cherubims of cunning work shalt thou make them.”§

In the 28th chapter of the same book, we have a description of the holy garments for *Aaron*, which were of fine linen. “And thou shalt embroider the coat of fine linen, and thou shalt make the mitre of fine linen, and thou shalt make the girdle of needle-work.”

“And all the women that were wise-hearted did spin with their hands, and brought that which they had spun, both of blue, and of purple, and of scarlet, and of fine linen. And all the women, whose heart stirred them up in wisdom, spun goats' hair.”¶

Egypt continued to be celebrated as the country of flax and linen in the days of *Solomon*, whose merchants traded thither nearly a thousand years after the time that *Abram* visited that land.

“And *Solomon* had horses brought out of *Egypt*, and linen yarn: the king's merchants received linen yarn at a price.”‡

“I have decked my bed with coverings of ta-

pestry, with carved works, with fine linen of *Egypt*.”*

The prophet *Isaiah* notices this manufacture of the *Egyptians*, about 250 years later than *Solomon*. This prophet menaces *Egypt* with a drought of so terrible a kind, that it should interrupt every kind of labour.

“Moreover, they that work in fine flax, they that weave net-works, shall be confounded.”†

Ezekiel the prophet, in his description of the riches and the merchandise of *Tyre*, speaks of the productions of *Egypt*, about 150 years after *Isaiah*.

“Fine linen with brodered work from *Egypt* was that which thou spreadest forth to be thy sail.”‡

From the *Egyptian* linen, the principal garments of the priests of the heathens, as well as those of the *Israeiites*, were formed. The Eastern kings and princes were also habited in linen, therefore flax formed a considerable branch of the trade of *Egypt*; and their method of making fine linen, was carried to such a wonderful perfection, that the threads which were drawn out of them were almost imperceptible to the keenest eye. *Pliny* states, that some of the thread made from flax was finer and more even, if possible, than the web of a spider, and yet so strong, that it would give a sound nearly as loud as a lute-string. This author states in the first chapter of his nineteenth book, that he had seen an *Egyptian* net made of so fine a thread, that, notwithstanding every cord in the mesh was made of 150 threads twisted, yet it could be drawn through the ring of a finger. “I have known,” says this writer, “one man who could carry about as many of these nets, as would encompass a whole forest.” He adds, that *Julius Lupus*, who was governor of *Egypt*, possessed one of these nets, but that the most extraordinary net-work was that which was shewn in the temple of *Minerva*, in the *Isle of Rhodes*; every thread of which was twisted 365 times double, agreeably to the number of days in the year. This singularly curious piece of workmanship had formerly belonged to *Amasis*, who from a common soldier became King of *Egypt*, about 526 years before the Christian era.

The author has now in his possession a piece of linen cloth, which was woven in *Egypt* as long back as the *Trojan* war. It will naturally be surmised, that it is a part of the envelope of a mummy. In comparing this cloth to that of our linen of the same fineness, and examining them through a microscope, it is observed, that the warp of the ancient linen is not so close as that of the present make, but that the woof is pressed much closer: it would consequently be more durable, wear softer, and be less susceptible of soil, than modern linen cloth.

The *Athenians*, who were an *Egyptian* colony from *Sais*, followed the custom of their ancestors, by applying themselves to raising flax for linen cloth: they therefore worshipped *Minerva*, who was also styled *Ergatis*, or the workwoman, for her excellence in spinning and weaving; and who is supposed to be no other than the *Egyptian* *Isis*; for the *Egyptians*, to remind the people of the importance of their linen manufactory, exposed in their festivals an image, bearing in its right hand the beam or instrument round which the weavers rolled the warp of their cloth. This image was called *Minerva*, from *Maneuva*, a weaver's loom. The name of *Athene*, that is also given to this goddess, is the very word denoting in *Egypt* the flaxen thread used in their

* *Proverbs, chap. vii. v. 16.*

‡ *Ezekiel, chap. xxvii. v. 7.*

looms. Near this figure, which was intended to warn the inhabitants of the approach of the weaving or winter season, they placed another of an insect, whose industry is supposed to have given rise to this art, and to which they gave the name of Arachne, (from *arach*, to make linen cloth) to denote its application. All these emblems, transplanted to Greece, were by the genius of a people fond of the marvellous, converted into real objects, and indeed afforded ample room for the imagination of their poets to invent the fable of the transformation of Arachne into a spider. Ovid, who has set this story in a beautiful light, says, Arachne was

"One at the loom so exquisitely skill'd,
That to the goddess she refused to yield.
Low was her birth, and small her native town,
She from her art alone obtained renown.

"Oft to admire the niceness of her skill,
The nymphs would quit their fountain, shade or hill."

After Minerva had accepted the challenge of Arachne, the poet thus elegantly describes their work:

"Straight to their posts appointed both repair,
And fix their threaded looms with equal care:
Around the solid beam the web is tied,
While hollow canes the parting warp divide;
Through which with nimble flight the shuttles play,
And for the woof prepare a ready way;
The woof and warp unite, press'd by the toothy slay.

Thus both, their mantles button'd to their breast,

Their skillful fingers ply with willing haste,
And work'd with pleasure: while they cheer the eye

With glowing purple of the Tyrian dye:
Or, justly intermixing shades with light,
Their colouring insensibly unite.

As when a shower transpierced with sunny rays
Its mighty arch along the heaven displays;
From whence a thousand different colours rise,
Whose fine transition cheats the clearest eyes:
So like the intermingled shading seems,
And only differs in the last extremes.

Then threads of gold both artfully dispose,
And, as each part in just proportion rose,
Some antique fable in their work disclose."

The Greeks made a linen of so fine a fabric, from the flax which they cultivated near Elis, (Now Belvedere,) that it sold by weight at the price of gold. This is the flax which Pliny calls *Byssus*, and from which a kind of lawn or tiffany was made. The same author says, a flax is now found out which will not consume in the fire; this he calls living flax, and says, he saw at a great feast, all the table-cloths, napkins, and towels, thrown into the fire, which received a cleanliness and lustre from the flames, which no water could have given it. This kind of cloth was used at the royal obsequies and funerals, to wrap round the corpse as a shroud or sheet, in order to preserve the ashes of the body, from mixing with those of the wood of the funeral pile. Pliny adds, that this flax grew in the deserts of India, where the country is parched and burnt with the sun; he says, it is difficult to be found, and as hard to be woven, being in short fibres. In its natural state, the colour was reddish, but by burning it became bright: it was esteemed as precious as oriental pearls. It does not appear by this account, that the Romans were acquainted with its being a mineral substance.

The art of making this fossil linen is nearly lost, although John Baptist Porta, the inventor of the camera-obscura, assures us, that in his time (from 1445 to 1515) the spinning of asbestos was

a thing known to every body at Venice; and it is said to be still in use by the Princes of Tartary, in burning their dead.

A handkerchief made of this substance, which Dr. Plot judges to be of a nature between stone and earth, was long since presented to the Royal Society of London. This has given several proofs of its resisting fire; and when taken out red hot, it did not burn a piece of white paper, on which it was laid.

The asbestos is found in the island of Anglesey in Wales, and in Aberdeenshire in Scotland, in some parts of France, in Tartary, Siberia, and several other places; and were there a demand for this incombustible cloth, or a price given equal to the trouble of manufacturing it, we soon should recover the art, and have it on sale in the shops of our metropolises.

But to return to flaxen linen: by looking back into history we shall find, that it was used for other purposes than garments at a very early period; for the stupendous temples of the heathens, and the courts of their palaces in ancient times, were open buildings surrounded with massy columns, and ornamented with gigantic statues of their gods, and colossal figures of their inferior deities. In these immense courts not only the inhabitants of a whole city, but often an entire kingdom assembled, to celebrate a festival, or to obey the mandate of their sovereign. As the art of weaving became more known, these gorgeous edifices were occasionally hung with rich curtains of linen cloth, to shade and protect the guest from the sun or weather. The first chapter of the book of Esther describes the feast which King Ahasuerus gave in the third year of his reign to all the princes and servants of the 127 provinces over which he reigned, from Ethiopia to India. This feast lasted 180 days, at the expiration of which he feasted all the people that were in Shusham, "both great and small," for seven days, "in the court of the garden of the king's palace," where were white, green, and blue hangings, fastened with cords of fine linen and purple, to silver rings and pillars of marble.

The Romans appear to have derived this idea from the Egyptians, as Lentulus Spinther was the first who caused the great amphitheatre at Rome to be covered with fine curtains. This was about the period when Antony was in Egypt; and Pliny observes, that the sails of the ship in which Antony and Cleopatra came to Actium, were dyed purple.

Julius Cæsar caused the Forum at Rome to be covered with fine curtains: as also the whole of the principal street called Sacra, from his own dwelling to the cliff of the Capitol. This sumptuous sight, says Pliny, was beheld with great wonder and admiration.

Marcellus, during his Ædileship, upon the calends (or first) of August, caused the roman Forum to be hung and canopied with curtains, that those who came to plead at the bar might stand under the shade. "What a change," says Pliny, "since the days of Cato the Censor, who advised that the said Forum should be paved over with *caltrope*, to keep away the lawyers and busy pleaders."

Nero caused the amphitheatre to be covered with curtains of a sky-blue, spangled with stars.

We now see the rustics of our own country enjoying their pipe and their ale beneath the linen canopy in a rural fair, as proud of their liberty as the Eastern monarchs were of their temples, or the Romans of their dictatorship.

"'Tis liberty that crowns Britannia's isle,
And makes her barren rocks and her bleak mountains smile."

ADDISON.

Spain was celebrated for her manufactory of

linen as early as the birth of Christ. The Spaniards were the inventors of fine Cyprus or clear lawn, which was made from the flax of Arragon and Catalonia. France then produced a flax from which sails were made: Holland and Flanders produced linen cloth at the same period. The Germans of those days carried on the spinning and weaving of linen in vaults and caves under ground, which was also the practice of the people of Lombardy in the time of Pliny.*

The fine muslins of the East Indies were also made by persons kept under ground, who were never allowed to see the light. Children were entombed from their infancy in these dark abodes, in order to gratify the vanity of the wealthy with a finer thread than could be drawn by the eye that was blessed with the sight of day. Our East India Company has suppressed this subterraneous weaving. The art is now happily lost, and no Christian can wish its revival.

Linen was not worn by the Hebrews, Greeks, or Romans, as any part of their ordinary dress: their under-tunics were made of fine wool or hair; and hence arose the occasion for frequent bathing. It has been observed that the introduction of linen shirts has been found to lessen the prevalence of leprosy.

The Emperor Alexander Severus, who was murdered in the year 235 A. D. was the first person who wore a linen shirt: but the general use of so necessary a garment did not become common till long after him.

The making of linen cloth in England was probably introduced by the Romans, who certainly cultivated flax in this country.

Before Britain had become so great a commercial nation, each town or village had its weaver, and every good housewife was expected to furnish her family with linen of her own spinning. The farmer's daughters were early instructed in this art, and their female domestics filled up all their vacant hours at the distaff or wheel. Tusser, in his advice to the farmer, for May, says, "Good flax and good hemp, for to have of hir owne,

In May a good huswife will see it be sown:

And afterward trim it, to serve at a need,

The fible to spin, and the carle for his seed."

In the same author's directions for July, he says, "Now pluck up thy flax, for thy maidens to spin, First see it dried, and timely got in."

Flax has for many ages employed and enriched the French nation. Their city of Cambrai first manufactured that beautiful linen called from thence Cambric, for the purchase of which, England for many years contributed not less than £200,000 per annum.

In the reign of George the Second, several salutary laws were enacted to prevent, this great loss of our wealth; and an Act passed in the 4th of George the Third, c. 26, to regulate the cambric manufactory, not long before introduced into Winchelsea in Sussex, but which soon failed, and was abolished. Laws have been made to prevent the selling and wearing of French cambrics and lawns in England, but which have only established their fame as being superior to our own.

The fine fibres of this plant have also afforded the French, as well as the Flemings, a valuable article for commerce in their lace of Brussels, Valenciennes, Lisle, Mechlin, Normandy, &c. Our legislators have laid heavy fines and duties to prevent the importation of this article of luxury, but with little success, for while it is admitted at court, it will naturally be seen in private society. Flax is not known in China.

From the seeds of this vegetable is drawn linseed oil, so useful to our house painters and other artists.

* Book xix. c. 1.

"Whether their hand strike out some free design,
Where life awakes, and dawns at every line,
Or blend in beautiful tints the colour'd mass,
And from the canvass call the mimic face."

POPE.

The seeds are esteemed an excellent emollient and anodyne: they are used externally in cataplasms, to assuage the pain of inflamed humours; internally, a slight infusion of linseed, by way of tea, is recommended in coughs as an excellent pectoral, and of great service in pleurisies, nephritic complaints, and suppressions of urine. Cold-drawn linseed oil is of great service in all diseases of the breast and lungs, as pleurisies, peripneumonies, coughs, asthmas, and consumptions. It likewise helps in the colic and stone.*

In pleuretic pains, says Raygerus†, I have often experienced linseed oil to be the most successfully facilitated respiration, and promoted spitting. In hæmoptoe, also, I exhibited the same oil with the desired success; for, by its balsamatic and emollient virtue, it consolidates the affected parts.

The oil, boiled with honey, clears the face and skin of spots, and all cutaneous blemishes.‡

Linseed oil consists of parts so subtle, that it cannot be kept in earthen vessels, without transmutation.

The lint made from linen rags has ever been in great use in surgical cases, from its softness, smoothness, and flexibility; whereas that made from cotton can never be used about wounds, on account of its denticulated parts, which dispose to inflammation.

Formerly the seed of the flax was occasionally used with corn to make bread, but it was considered hard of digestion, and hurtful to the stomach. In a scarcity of corn which happened in Zealand in the sixteenth century, the inhabitants of Middleburgh had recourse to linseed, which they made into cakes, and which caused the death of many of the citizens who ate it; causing dreadful swellings of the body and face. Pliny informs us, that the peasants in Lombardy and Piedmont had formerly used as food, a sweet kind of bread or cakes made from this seed, but which in his time was only used in their sacrifices to the gods.

The quantity of linseed annually imported into these kingdoms, was, in the year 1780, estimated to be not less than 240,000 bushels.

There is an act of parliament now in force, which forbids the steeping of flax in rivers or any waters where cattle are accustomed to drink, as it is found to communicate a poison destructive to the cattle which drink of it, and to the fish in such waters.

From the last Pamphlet published by the Essex Agricultural Society.

COLONEL PUTNAM'S FARM.

Col. Jesse Putnam's farm is situated in the North Parish in Danvers, about six miles from Salem. It contains about 114 acres; to wit—44 of tillage—40 of pasture—and 18 of wet or low-ground meadow. His wood land is not in Danvers.

Most of his tillage land is covered with orchards of apple trees; of which about 1200 are large enough to bear fruit; and 400 have been planted, or grafted, from two to six years. He raises his own trees in nurseries; which he renews from time to time, to supply his own wants. He considers the spring the best time for transplanting trees. In this operation he digs the holes four or five feet in diameter, and two feet deep: into which, in planting the tree, he introduces rich

soil, that the tree may sooner recover from the check it receives in the transplanting.* By giving such dimensions to the holes, the roots may be regularly spread out in every direction, without being crowded. He disapproves of making nurseries in very rich soils; because they will generally be transplanted to poorer soils, and so be sensibly and injuriously checked in their first growth. He thinks it better to transplant from a poor to a rich soil, than from a rich to a poor one. Most of his trees are grafted with winter fruit. In selecting his fruits, he is careful to choose the kinds that are good bearers, as well as of good qualities; grafting over again, with other fruits such trees as are not sufficiently productive. Col. Putnam has found it beneficial to young trees, to wash them in the spring with a composition of lime, clay, fresh cow dung and water; as it removes the moss, destroys the insects that find harbours in the rough bark, and gives a smooth, vigorous and lively appearance to the trees. He has found it serviceable to vary the manures applied to his trees, according to the nature of the soil. He has frequently sown barley, or other grain, around them, and when 18 or 20 inches high dug it in. This he has thought one of the best modes of manuring them; and (as well as every other way of manuring) should extend to three or four feet from the tree, all round; continuing this practice at least until the trees have attained a good size, and are in a good thriving and bearing state.

For several years past, he has annually broken up three or four acres of his pasture land where principally covered with small bushes and moss, and planted the same with potatoes or corn; and when laid down to grass found himself amply compensated.

It has been his practice to plough, in the warm weather in August, the land intended to be planted the ensuing spring; at which time it is cross-ploughed. By ploughing when the earth is warm, he says, the sod is better rotted, and more easily rendered fit for tillage crops. Ploughing late in autumn he thinks not advantageous. Thus cultivated one or two years, the land will be in a good condition for English grain and grass. The same land will need to be broken up again, as often as once in six or seven years.

"The raising and curing English hay (he remarks) occupies a large portion of our time; and rewards our labour as well as any thing that is done on the farm: and the object of cultivating other crops is, in a good degree, to prepare the land for this most important crop.

The produce of his farm, in 1821 and 1822, as near as he could estimate the same, he states as follows:

	1821.	1822.
English Hay	24 tons	30 tons
Oats for fodder	3 do.	4 do.
[Wet] Meadow Hay	8 do.	7 do.
Barley for fodder	0 do.	3 do.
Indian Corn	70 bush.	150 bush.
Potatoes	800 do.	300 do.
Barley	70 do.	cut for fodder.
Onions	0 do.	150 bushels.
Carrots	40 do.	90 do.
Turnips	20 do.	150 do.
Cabbages	10 doz.	30 doz.
White Beans	2 bush.	7 bush.
Green Peas for market	4 do.	50 bush.
Summer Apples	130 do.	150 do.
Winter Apples	600 do.	600 do.
Pork	2000 lbs.	2000 lbs.
Pumpkins	2 tons.	4 tons.

* In planting trees, the roots should be covered with earth at no greater depth than before their removal.

He kept no particular account of his dairy but his cows, six in number, had done well.

Col. Putnam's mode of making manure, he states as follows:

"In the autumn I clear the barn-yard, and carry the manure into large and compact heaps, in the fields where it is intended to be used. The yard is then covered with turf, loam, or pond mud, and such other materials as are found on the farm, suited to making manure. These, together with the droppings of the cattle in the winter and summer, and the relics of their fodder, are mixed together in the course of the summer, and made into fine manure. This I use principally on my grass land; spreading it from the cart, after the grass is grown several inches.

"I have a cellar under my barn, in which the winter dung and urine of the cattle are collected. By mixing with these, in the cellar, meadow turf (or sod) coarse hay and corn stalks, the quantity is much increased. I also carry large quantities of materials to my hog pen, which is so situated as to be kept moist; and from the industry of the swine in preparing this manure for the field, I find more benefit from them than in any other way."

His usual stock consists of six oxen, eight cows, one bull, two horses, and several extra cattle to be sold in the spring, and from six to twenty swine.

Col. Putnam closes his statement as follows:

"Some of my [wet] meadows have been converted into excellent English mowing grounds, by carrying about six inches of gravel on to them in the winter. In the first place I divide a meadow into lots about three rods wide, by ditches—turning the turf bottom upwards—and taking care to have the middle of the lots the highest, so that they may be a little sloping towards the ditches. Plough the turf and gravel together, in the spring, and plant it one season with potatoes: the crop will be as good as in common fields. Then carry on one or two inches of top soil, and a good coating of manure; and from land thus prepared, I have obtained my largest and best crops of English hay."

Were it even practicable to insert the proceedings of all the Agricultural Societies, there would be found in them so much sameness, as to render such a step uninteresting and inexpedient. Still it gives us pleasure, when we can, to record the incipient measures, relating to the formation of Societies, and the first proceedings which serve to shew that the zeal which created them is fairly in operation—producing beneficial effects to Society. In this light we view, and for this reason we now insert, the auspicious commencement of an association at Pittsburgh, under the Presidency of Judge WILKINS, an eminent civilian, deservedly amongst the most popular citizens in Western Pennsylvania.—*Edit. Am. Far.*

ALLEGHENY COUNTY AGRICULTURAL EXHIBITION AND FAIR.

In conformity with an Act of the Legislature of Pennsylvania, the first annual meeting of the "Society for the promotion of Agriculture and Domestic Manufactures, in and for the county of Allegheny," was held on Monday the 28th inst. at the town of Allegheny, opposite Pittsburgh.—The Society occupied the public grounds in the centre of the village, on one side of which enclosures were prepared for sheep and swine, and a temporary building erected for the exhibition of domestic manufactures.

At 12 o'clock, the business of the day being opened by the Rev. Mr. Stockton with an appropriate prayer, WILLIAM WILKINS, Esq. the president, delivered an interesting address, in

* James.
† Germ. An. 6 & 7.
‡ Hist. Plant. acrif. Boerhaave.

presence of a great concourse of citizens who attended from all parts of the county, notwithstanding the unfavourable weather.—After which the committees for the examination of the different subjects proceeded to discharge the duties assigned them.

The following list of Stock and Domestic Manufactures, were exhibited:

STALLIONS.

North Star, dark bay, by D. Phillips, St. Clair
Jolly Farmer, by Wm. Wilson, Elizabeth
Stallion by John Fife, St. Clair
Ditto from Westmoreland county, much admired, and pronounced to be the best.

BROOD MARES.

Dun, by Wm. Wilson, Elizabeth
Dark bay by Samuel Ewalt, Pitt
Messenger, by Ch. H. Israell, Mifflin
Grey, by — M'Fadden, Robinson

COLTS.

Dark Chesnut, 2 years old, H. Hultz, St. Clair
Sorrell, 18 mo's Jno. Morrow, do.
Bay do. George Wallace, Wilkins
Blooded Colt, Consul, (from Messenger and horse
Consul) 2 years old, Ch. H. Israell, Mifflin
Colt, 3 do S. Sinclair, Elizabeth
Filley Adam Coon, Versailles

NEAT CATTLE.

Bull by Chr. Cowan, Fayette
Ditto Geo. Wallace, Wilkins
Ditto James Gray, Ross
Bull Calf, under 2 years old, by do. do. do.

Cows.

Milk Cow Wm. B. Foster, Pitt.
Hieffer Wm. Robinson, Jr. Ross
Cow and Hieffer, James Gray, do.
These cattle of Mr. Gray, are of a very superior size and form, and exhibit strong marks of a stock of imported neat cattle.
A pair of Calves, yoked, well matched and tractable, were exhibited by Wm. Montgomery, of Ross.

Swine.

1 Sow R. Sylvester, St. Clair
1 do. Zenos Neal, Pittsburgh
1 do. with 4 pigs, James Miller, Ohio
1 Boar Robert Hays, St. Clair
1 Pig 16 mo's. old, wt. 218 lbs. A. Beelen, Pittsb.
Pigs Alexander Hill, Pitt

Sheep.

Merino Buck Jacob L. Glaser, Pitt
Ewes Ditto do

DOMESTIC MANUFACTURES.

1 piece Linen Shirting 30 yards, Mrs. Geo. Wallace, Braddock's Field
1 ditto 31 yards ditto do
3 ditto do. 73½ yards, J. Melvin, Ross
1 ditto do. Miss Snodgrass, St. Clair
1 ditto do. Mrs. M. Fleming, Wilkins
1 ditto Flannel 24 yards Miss A. M'Clure, Miff.
1 ditto do. Mrs. Chess, Ross
1 ditto do. 30 yards, Mrs. Bat. O'Hara, Ind.
1 ditto do. and 2 Coverlets, Mrs. Sample, Ross
3 ditto Woollen Cloth 3-4 wide, Wm. Arthurs, St. Clair
1 ditto Lindsey 31 yards, John Hodge, Pittsburg
1 ditto Birdseye, Miss Cowles, do
1 ditto Carpeting 40 yards, Mrs. Jno. Irwin, Ross
1 ditto do. Miss Chess, St. Clair
1 ditto do. A. Lee do
1 ditto do. Isaac Harris, Pittsburgh
1 ditto do. Mrs. Darlington, do.
2 ditto do. Mrs. Stockton, Ross
1 ditto do. John Hodge, Pittsburgh

The pieces of Carpeting exhibited, were all fine specimens, both as to color and texture, and much admired.

Blankets Mrs. O'Hara, Pittsburgh
Ditto Mrs. J. Irwin do
3 prs. Woollen Socks and Stockings, Mrs. M. M'Donnel, St. Clair
4 do. worsted Cotton ditto, Mrs. Habbet, Pittsb.
1 do. Stockings and 2 pr. Socks, of Thread, knit by Mrs. Jane Davis of Ross, aged 71.
1 do. Woollen Stockings, Miss Cowles, Pittsburgh
2 do. Socks and Stockings, Susanna Reese, Wilkins
2 Bonnets of split Straw by Mrs. Sheppard, Pittsburgh
1 do. do. Miss Petar, Ohio
1 do. do. and Hat Mrs. Miller, Indiana
1 do. imitation of Leghorn, Miss M'Clean, St. Clair

1 Hat Mrs. Mary J. Hays, Mifflin
Miss Weigly of Hempfield township, Westmoreland county, exhibited 2 elegant Bonnets of her own making, which rivalled in fineness and beauty, the best Leghorn.

Mrs. Mowry, of Pittsburgh, exhibited a very handsome piece of Table Linen.

Mr. Parsons, Razors and Pen-knives of his own manufacture.

Hugh M'Masters, several pieces of Cassinet and Cotton Cord.

Isaac Harris exhibited several pieces of Stuebenville Cloth, and also several pieces of Philadelphia manufactured Calicoes, which were superior in every respect to imported goods at the same price.

Miss Mary Ann Irwin of Franklin, Venango, exhibited a white Cape, made from Goose-down, which was much admired.

Mr. Matthews, a very handsome Saddle of peculiar workmanship, which sold for \$45.

George Evans had on the ground, an elegant Plough, of Woods' patent—also a Corn-sheller.

An Axe made by Wm. Montgomery, and a horse shoe, made of Union Rolling-mill Iron.

Nails, by Richard Bowen; weight 90 pounds, 600 nails in each pound, and made in 6 hours at his factory.

Locks and Latches, by Jas. Patterson, of Birmingham.

Handsome Japanese Waiters and Trays, made by John Whitaker, Grants Hill, Pittsburgh.

Water-proof Hats, by Edward Patchell.

U. S. 6 pounder, mounted; made in Pittsburgh, by M'Clurgs and M'Knight, (issued for the state of Kentucky, and on its way thither) sent by Lieut. Wells, through the direction of capt. Talcott, of the U. S. Arsenal.

Also, a very fine Musket, made at the Arsenal.

Fine specimens of Beets, Carrots, Celery and Ruta Baga, raised by John M'Garrowgill, and a very large Radish, by J. J. Neal, of Mifflin.

Crops.—Samuel Bell raised the average quantity of 32 bushels of wheat per acre, on 8 acres of ground.

PREMIUMS.

On Tuesday at 2 o'clock, the following premiums were awarded:

For the best Brood Mare, to Mr. M'Fadden, \$10 in silver plate.

Best Colt, C. H. Israell 5
Filly, Adam Coon 5
Bull, James Gray, silver cream jug 10
Bull Calf, James Gray, spoons 5
Milk Cow, Wm. B. Foster, ladle 10
Heifer, Wm. Robinson, jr. cup 6
Sow, Zenos Neal, spoons 5
Pigs, Alex. Hill do. 3
Merino Ewes, J. Glaser 5

Manufactured Articles.

Best Linen Shirting, Mrs. Geo. Wallace, silver cream jug \$10

2d best, James Melvin, spoons 5
3d do. Miss Snodgrass, do. 5
Best Flannel, Miss Ann M'Clure, ditto 5
Woollen Cloth, W. Arthurs, ditto 10
Lindsey, John Hodge, ditto 5
Carpeting, Mrs. Darlington, ladle 10

2d best, Mrs. J. Irwin, spoons 5
Best Bonnet, Mrs. Sheppard, ditto 5
2d do Miss Petar ditto 3
Hat, Mrs. Mary J. Hays, ditto 3
Linen Socks, Mrs. Jane Davis, ditto 5
Woollen Socks and Stockings, Mrs. Davis and Miss Cowles, spoons 5

Woollen Stockings, Miss Susan Rees, ditto 3
A piece of Thread Lace, Miss Haney, ditto 3
To Mrs. Flemming for her superior industry in manufacturing Coverlets, Shirting and Table Linen, spoons 5

To John Keen of Indiana township, for a sample of Castor Oil, from beans raised by him on his own farm. Mr. Keen has raised this year 15 acres of this plant—silver spoons \$5, and a Volume on Agriculture.

To Wm. Montgomery, for his yoke of young Oxen, spoons \$3.

To Anthony Beelen, for his Shelled Barley and 3 boxes of Cigars, spoons \$5.

Mr. Beelen raised the tobacco out of which these cigars were manufactured from seed procured from the Havana.

The Society had also before them a box of cigars presented by A. W. Foster, Esq. of Westmoreland county, as a specimen of tobacco cultivated by himself, near Greensburgh, from the Havana seed.

The cigars of both these gentlemen were well flavoured, and wanted only age to equal the imported; though mere luxuries it is well to have along with our luxuries the profits of their cultivation and manufacture.

This being the first exhibition of the kind in this county, many were not prepared to enter into competition in several subjects; the display of manufactured articles was therefore deficient in number and variety, though excellent and admirable in quality; Several specimens of live stock expected from a distance did not arrive, in consequence of the bad roads and disagreeable weather. Hereafter the society will fix an earlier time and more suitable day for the exhibition, provide larger accommodations for the show of domestic manufactures, and make such arrangements generally for the better as their experience has suggested and their means will permit.

In consequence of the number of gentlemen from different parts of the county who took this opportunity of joining this society, its funds have received a considerable accession, and will enable them on the next occasion to offer higher premiums and extend them to other objects. It is impossible here not to notice the liberality of our farmers and citizens generally in contributing to this institution; to feel gratified at the cordial support it has received from all quarters, the candour with which it is regarded, and the good sense and public spirit of the people at large.

HARMAR DENNY, Sec'y.

Wednesday, Oct. 30, 1822.

TO THE EDITOR OF THE AMERICAN FARMER.

FALLS OF THE GREAT WABASH,
Mount Carmel, Edward's county, Illinois,

DEAR SIR, March 20, 1822.

May success attend the labours of Mr. Ailes!

May Baltimore ever maintain a high rank for patriotism and individual enterprize! Being a "pioneer" as you have properly styled me, in these new regions of the earth, I feel disposed to

drop a line occasionally. On yesterday I received a letter from Boston, which has induced me just this minute to drop my "gun" (having been successful in procuring my wife a pair of fine ducks) and now, prompted by the impulse of the moment, to scribble a few lines, which if you can decipher you will do well.

You will recollect, that on the 16th of April last, I addressed you a letter containing a sample of cotton, the production of our soil, both of the timber and prairie lands. I marked the prairie cotton first rate, and the timbered lands (on the river) second rate; and at the same time enclosed like samples to the Postmasters at Philadelphia, New York and Boston, not having any knowledge of the manufacturers of those places; it was not till yesterday that I received the return from the latter place. I now, sir, lay before you the general opinion thus obtained of our cotton; the manufacturers having reversed my rates, and given the preference to the river-land production. Mr. Skinner in his answer (dated August 5th, 1822,) to my circular of April 16th, states "I have shewn the samples of your cotton to our chief manufacturers, who admire it on account of its beautiful whiteness, and the fineness of its fibre, but they find its staple somewhat shorter than desirable, still the best is very good, and would bring 16 cents per lb. here at present: the other would bring 14 cents."

Messrs. W. Young, Son, & Co. manufacturers, Rockland, on Brandywine, Delaware, under date of June 11th, 1822, in answer to my circular, states, that the Post Master of Philadelphia having put my circular into their hands, they found "the samples of cotton enclosed of a beautiful white, but in staple and strength resemble the Alabama and Tennessee (cotton); what staple they have is very weak, and that of the parcel marked first is worst. It is impossible to say at what rate they would pass in our market; there is but little demand for any thing that is not good staple, as there are few objects it could be applied unto at present. The samples would answer only for the coarser yarn, wadding, batt and candlewick. The colour is excellent, and perhaps the staple in general is better than that sent." (This was a fact, having only picked up the first locks that came to hand.) "All the manufacturers choose that cotton which is strong staple; it is that which brings their goods with reputation into use. Your cotton is also very clean. We have not yet spun any cotton. Our woollen factory produces every kind of cloths," &c. (prices stated.)

Peter H. Schenck, Esq. of New York, writes June 13th 1822, "The Post Master of this city Gen. T. Bailey handed me your letter of the 16th of April last, with two small samples of cotton. I own a cotton factory, and am manufacturing about 8000 yards of goods per week, and am using the first quality of Louisiana cotton, and no other (about 2000 lbs. per week.) The samples of cotton you sent are very handsome and clean. The latter quality is very important. The staple is not as long as the Louisiana. Such cotton would now bring 16 cents—any reasonable quantity, but it must be clean, and the staple not injured by the gin. You mention your wish to enter into a contract for a large supply, you will find no difficulty at any time to sell your cotton in this market, if it all turns out equal to the samples.—But I must have a much larger sample to judge of its real value."

As the cotton market is down, our country women are manufacturing our own cotton, and find it superior to any that has ever been brought from below. Indeed the Tennessee and Alabama cotton cannot come into competition with it.

William Hill, Esq. of Boston, under date 12th February, 1823, states "that your letter with samples of cotton was put into my hands several months since by the Post Master, &c. The cotton looks bright and clean, though the staple is rather short. Louisiana cotton is worth here 15 a 16 cents per lb. Georgia upland 10 a 13 cts.; cotton like your sample would bring 13 a 15 cts.; and I think an exchange might be made to advantage with the agents of some of the manufacturers for some domestics, &c. having been for several years past in this trade, have acquired considerable knowledge in the article of cotton, &c."

When the rage for settling new countries shall subside, I do not hesitate in stating that it will be found that the country situated between the Ohio and Mississippi, particularly that district embraced within the bounds of the state of Illinois, must become the garden of these western regions; and although the first settlement of this country has, and will be attended with serious difficulties on account of sickness, yet every impediment will be removed by that ardour and enterprize with which the climate and soil must unquestionably prompt its inhabitants to manifest. Such were the evils attending the settlement of Ohio, and much worse, but how speedily removed!

The soil is unquestionably the best in the world. It is superior to that of Ohio, Kentucky, Indiana, Tennessee, Alabama, or Missouri. The soil of Illinois is more uniform than that of any district of country of the same extent. It varies very little from Wabash to Mississippi, is high and breaking into waves in every direction, and presenting landscapes that I defy any artist to imitate. The prairies in spring, summer and autumn are beautiful beyond description: in winter they are gloomy—

"So fades the lovely blooming flow'r,
Frail smiling solace of an hour;
So soon our transient comforts fly,
And pleasure only blooms to die."

The highlands of the Missouri elevate the winds, and give stability to the climate, or rather more so than is enjoyed by the other western states; this is evident, as the grape, May duke, cherry, and Portugal peach will flourish here that will not grow elsewhere, this side the mountains. I will but add one more remark in relation to the soil, and that is from its appearance it will never wear out. The French have tried it for more than 100 years, and the land yields as kindly as ever, and as abundantly. From two to six feet (sometimes ten) we have the black mould, from ten to fifteen feet of yellow clay, and this generally founded on a strata of stone coal, or blue clay—and under this a slate or sand rock.

The following are the remarks of a medical gentleman on this subject. "I present you with some specimens of a substance found from the surface of the earth to the distance of fifteen or twenty feet, or more below it, in digging wells in this country; I suppose it to be sulphate of lime, gypsum, or in other words, plaster of paris. Be this as it may, it is worthy of remark, that on a bank of earth taken up in digging wells here, and where the substance abounds, grass, weeds, and I believe other vegetables grow as luxuriantly as in almost any other place. This substance exists in small bodies of from an inch to a quarter of an inch in diameter, very rough, sometimes branching, and of various lengths.

The conclusions I draw from these facts are, that the land here will be always highly productive, and that a thousand years from now, when the face of the land may be much worn, still vegeta-

tion will go on as kindly as at this time, the force of fertilization here being inexhaustible."

Respectfully yours, &c.

E. J.

December 13th, 1822.

All of which, I respectfully submit to your consideration, to do with as you see proper.

I am, dear sir,

Your obt. ser't.

THOS. S. HINDE.

P. S. The site we have selected, and now improving is a very beautiful one, at the junction of the White rivers and Wabash, and the Patoka river also—forming a junction with the Wabash, about an half, or three quarters of a mile below White river, and the falls are all above.

N. B. I find that Mr. Jefferson in his Notes on Virginia was correct in asserting that the Catawba (otherwise called Catalpa) tree was a native of the Wabash, I was at a loss at first to know what kind of tree it was, when I first saw it in its native state, growing like other trees very tall, being surrounded by the forests: trees as well as men will contend for the supremacy! but when unobstructed in an open space, they branched out as usual, and had the same appearance as those cultivated. The running rose, described by your correspondent of Carolina, is a native also of Ohio and Illinois; I ornamented a part of my house with them in Ohio, where they are abundant, and have planted them in my yard at this place; they are green in summer and winter; in the winter they are covered with leaves, and the stalks will run 15 or 20 feet or more.

Editorial Correspondence.

AGRICULTURAL PROSPECTS—REVERSED.

DEAR SIR, *Wheatland, May 19th, 1823.*

In No. 7, of the American Farmer, I observe an extract from my letter to you of the 23d ult. and a corresponding one from another correspondent, giving the most favorable representation of the state of our crops in this section of the country; as I conceive it to be of importance that the community should be kept correctly informed as to our "agricultural prospects," and as these prospects are most wofully and fatally changed since the date of the above communications, I deem it to be my duty to apprise you of the melancholy fact, to guard against the evils that might arise from erroneous impressions on this interesting subject. In consequence of the general failure of crops for the three preceding harvests, together with the reduced prices of the staples of the country; the body of our farmers had become awfully embarrassed in their pecuniary circumstances, and they laudably determined to make an extraordinary effort last fall to relieve themselves from their difficulties by putting in much larger crops of small grain than usual. The rye having been previously committed to the earth, the seeding of wheat commenced early in the month of September; and many of the largest crops were put in, and finished by the first of October. During the ploughing season not a drop of rain fell, and that operation was consequently performed in the best possible manner. At the latter end of September the rains set in—the wheat was brought up finely, and being liberally nourished by a continuation of the most genial seasons, vegetation advanced with a rapidity and vigor never before experienced, and our fields by the month of December were as verdant, and the growth as luxuriant as generally in the month of April. The winter was not considered to be unfavorable. Vegetation continued to advance with unprecedented rapidity during the early spring—and our

flattering prospects received no check, until a few days after the first of May, when the wheat was discovered to be at a stand; this was at first attributed to the May-weed which sprung up in our fields a thousand fold thicker than was ever known; but as this weed is very short-lived, and had heretofore been regarded as harmless, no apprehensions were entertained that as soon as its ephemeral growth was over, our crops would revive and flourish without farther interruption. Delusive hope! From that time the crops were perceived to decline daily and rapidly—and the farmer soon became assured that his hopes were blasted by the ravages of an enemy whose powers of desolation are unbounded, and against whose assault he possesses no means of resistance. The havock committed by the *Hessian Fly* is without example, and surpasses all description. Our fields are literally laid waste, and cattle are turned on many of them, which three or four weeks ago promised an ample remuneration to the industrious farmer for his anxious and toilsome care. His late hopes, so bright and so buoyant are converted suddenly into black despair. I have already said that our people are generally in debt. This misfortune exists to an alarming and awful extent. What they will now do under this new and severe calamity I cannot tell. It is only known to him who in his inscrutable wisdom dispenses it!—Our clover has wholly failed for the two last seasons, and its place occupied with innumerable weeds of the most pernicious kind.—The Rye crops are remarkably good.

I have given you, my dear sir, a gloomy, but a faithful picture—rest assured it is not exaggerated.

With sincere regard and esteem,

Yours truly,

H. S. TURNER.

N. B. Great complaints, as usual, of the grub or cut-worm, in the early planted corn. Even mine has been severely attacked under circumstances that have resisted its effect uniformly for many successive years.

TO THE EDITOR OF THE AMERICAN FARMER. DOMESTIC RESOURCES.

American genius is ever on the alert to supply the demands of science and the arts—as well to elevate national character abroad, as to promote its aggrandisement at home.

Whilst we proudly vaunt the discoveries of Perkins and others, who astonish the world with their philosophical speculations, and practical results, we should not be unmindful of more humble labours in the cause of *Internal Improvements*.

A late "National Intelligencer" announces an invention of no ordinary importance: "The Virginia Water-proof Cement"—If the article really merits the high character given to it, if like many visionary projects, and false conceptions, its obscure author would impose on public credulity, no doubt the *truth* of the case will be soon established under the *new order of things*, ordained by the legislative wisdom of Virginia.

The speedy consummation of (perhaps) the oldest enterprise of the kind, in the United States—the James' River canal, and up-country navigation, seems reduced to moral certainty. The renovated vigour and zeal with which the works are now said to be progressing, sensibly influences her southern sisters—Our contractors for aquatic masonry, may promise themselves great advantages by substituting native materials; as more economical than those imported from foreign countries.

Hence then, Mr. Skinner, may not the subject be worthy of your correspondents' attention, enquire into, and to investigate its merits? and

may we not, receive prompt and conclusive testimony of its usefulness, from the enlightened Virginians, and their lately appointed *engineers*?

The Virginians, ever conspicuous for their liberal patronage of patriotic pursuits, will not be wanting in justice to the individual citizen whom they have cherished, upon this occasion—nor will their regard for consistency of character, suffer imposture to escape their keenest sensibilities—if, indeed, there shall be any possible cause of suspicion, as to the *facts* upon which a general adoption of this Cement must mainly depend.

Since there appears to be no medium more apt, (or whose efforts will be more generally aided by public journalists) for free discussion and frank communications, than your widely extended paper, the public may be reasonably contented, under the hope and expectation, of soon seeing ample reports from the inquisitorial powers of the ancient dominion.

YADKIN.

15th April, 1823.

THE FARMER.

BALTIMORE, FRIDAY, MAY 30, 1823.

It has been already intimated that we were endeavoring to collect information in regard to *flax* and *hemp*—their natural history, culture, modes and means of preparation, &c. Our wishes have been accomplished to the extent anticipated. The Editor will be absent for a week or two on business of the General Post Office, and cannot hand to the printer the *practical* parts of this information, as they are chiefly in manuscript, and will require some attention to the *arrangement* of them. The particulars, obtained directly from and through the agency of S. Swartwort, Esq. of New York, are very interesting, more especially perhaps to our friends in the west, whose lands are so well adapted to the growth of hemp. They embrace an engraving of Goodsell's patent hemp and flax dresser, and will probably appear in number 12. In the mean time it is hoped that as a part of the natural history of vegetables, with which all farmers' sons and daughters ought to acquire some knowledge, we shall be justified in inserting these articles, long as they are.

A New York paper, speaking of the flax dresser and grain thresher, says, "one man can get about 150 pounds a day, or 100 lbs. flax ready for spinning; or 10 bushels clean clover seed; and two men will thrash and clean from 80 to 100 bushels of wheat with the same machine, with a very little variation. They are getting into general use in South Carolina, for cleaning rice, instead of the expensive mode of pounding, as heretofore."

BALTIMORE MARKET.

PRICES CURRENT.—CORRECTED WEEKLY.

Flour, best white wheat, \$8—Howard street Superfine, \$7 25—fine do. \$6 75—Wharf, do. \$7 25 sales—White wheat, \$1 60 to 1 64—Red do., \$1 57 to \$1 60—Rye, 85 cents—Corn, 56 to 58 cents—country Oats, 40 cents—Beef, 8 cts. per lb.—Live Cattle, \$6 to \$6 50 per cwt.—Bacon, round, 8 to 9 cents per lb.—Pork \$4 50 to 5 50 per c. lb.—6 to 8 cts. per pound—Mutton, 5 to 6 cts. per lb.—Beans, \$1 37½ to 1 50—Peas, black eyed, 55 to 60 cts.—Red Clover Seed, \$6—Orchard Grass do. \$3—Herds' Grass do. \$3—Timothy do. \$4 50—Millet, none—Flax Seed, 75 to 80 cts.—Whiskey, from the wagons, 32 to 35 cts. per gal.—Apple brandy, 30 to 32 cts.—Peach do., 65 to 70 cts.—Shad, \$6 50, scarce—Herrings, No. 1, \$3 per bbl.—No. 2, \$2 75—Fine salt,

60 to 65 cts. per bush.—Coarse, do. 70—Butter, 20 to 25 cts per lb.—Eggs, 12½ cts. per doz.—Hay, \$17 per ton—Straw, \$10.

Tobacco is selling nearly as per last report—Fine Red Patuxent Tobacco, part of the crop of R. W. Bowie, of Prince Georges, has been inspected and sold this week—8 hds. best, for \$15 50—two second, for \$8—five crop at \$11—two second at \$5—This crop came into the market in fine condition for exportation—Two hogsheads made in Calvert county by Mordcaai F. Smith, sold for \$18.

CIRCULAR.

Falls of the Great Wabash, Mount Carmel, Edwards county, Illinois, March 17th, 1823.

SIR,

The undersigned commission merchants of this place, have commenced the present season, the shipment of the produce of this country, and will keep a bacon establishment for curing and preparing it for foreign market, in the best manner: (the bacon and beef of this country, when well cured is of a superior quality.) They will also ship pork, beef, lard, tallow, beeswax, flour, kiln dried corn meal, venison hams, deer and bear skins, and poultry of all kinds; beans, peas, potatoes, &c. The want of a proper knowledge of the market and merchants of your place, has induced us to address our circular to you, sir, with a request that it be put into the hands of gentlemen who will feel an interest in participating in the trade of our infant country. We shall be happy to enter into a contract, or contracts almost to any amount on an advance of one third or one fourth of the amount required, and make the delivery here, at New Orleans, or at your port.

We are respectfully yours, &c.

THOS. S. HINDE, }
SCOBY STEWART. }

P. S. We will contract at a stipulated price for produce or purchase up, and ship on commission only.

N. B. Our cotton is gradually coming into market—a supply of this article may also be had The crops of wheat will be short, there will be all probability be a scarcity of pork.

FOR SALE

At a low price and on a long credit, the FARM on Elk Ridge, occupied by Mr. H. Scott, and formerly owned by Luther Martin, esq. containing about eleven hundred acres.

It is situated about eleven miles from this city, near the Washington road, and is considered remarkably healthy—The situation is handsome, and the land easily improved by plaster and clover. This property will be divided if required, and immediate possession given—For terms apply to

ROBERT & JOHN OLIVER.

Printed every Friday at \$4 per annum, for JOHN S. SKINNER, Editor, by JOSEPH ROBINSON, on the North West corner of Market and Belvidere streets, Baltimore: where every description of Book and Job Printing is executed with neatness and dispatch—Orders from a distance for Printing or Binding, with proper directions promptly attended to, addressed to J. Robinson, Baltimore.

Internal Improvement.

ON THE PARAMOUNT IMPORTANCE,
TO MARYLAND, OF A CANAL TO THE
SUSQUEHANNA.

No. III.

States and Communities, no less than Individuals, are hastening to the vortex of ruin, in proportion as they suffer their expenditures to exceed their income.

20. Under this proposition I propose to explain, the former prosperous situation of the principal emporium of Maryland, and the imminent danger which now appears to await it unless suitable, and effectual measures shall be adopted for its relief. By referring to the statistics of Baltimore, it appears, that in 1790 our population was only 13,503; that in 1800 it had increased to 26,514; in 1810 to 46,555; and in 1820, according to the last Census, to 62,627. Consequently, our number, during the three last intervals of ten years each, has been annually advancing at the rate of 1300, 2000, and 1600 respectively; and taking the whole average of the last 30 years, our yearly increase, during that period, has exceeded 1600. Were the same ratio of increase to continue for 30 years to come, our population in 1850 would be enlarged to 110,000; and if we might take the liberty of extending our views to the end of a second period of 30 years, our number in 1880, at the same rate of increase, would amount to 160,000.

21. But in the opinion of some this estimate is greatly below the number, that, with due encouragement, and a reasonable state of prosperity, that period may be expected to realize; and such an anticipation appears to be completely warranted by only giving our calculation a different form: It appears, that, within the last 30 years prior to 1820, an increase which then commenced at 13,503 had, in 1820, attained to 62,627. This, it may be recollected is more than four and a half to one; and by computing in that ratio, four and a half times our last innumeration will produce upwards of 280,000 for our number 30 years hence; and four and a half times that result amounts to 1,260,000 for our population in 1880.

22. I am aware that, to some, the latter estimate, may, at first sight, appear to be a visionary calculation; that by some it may even be denounced as a great and improbable result. But, before such a decision is formed, permit me to request that the subject may be fairly and deliberately examined. Upon examination it will be found that many instances have actually occurred in which none but large calculations are adequate to the purpose; in which none but very high numbers are even in the vicinity of the truth. The population of Jeddo, for example, is stated at one million; of London, at nearly eleven hundred thousand; of Canton, at one and a half to two; of Nankin at two; and of Pekin at three millions of inhabitants. Hence we have conclusive geographical evidence of cities, so great as to contain more than double the number anticipated in the estimate before us; so very great, as to exceed it nearly in the ratio of two and a half to one; of a population, so extremely numerous, as to have passed through the whole series of tens and hundreds of thousands, up, not only to a million, but to two and even to three millions. From what cause then, is it to be inferred, that the population, wealth and importance of Baltimore will never rise to an equal height with those cities in the scale of pre-eminence? Our local advantages for a very extensive prosecution of commerce, at home and abroad, are known to be numerous. They are

also appreciated as being of the first magnitude, and were their excellencies only judiciously developed and improved, capable of furnishing subsistence, habitation and clothing to a very extensive and crowded population.

23. But there can be no stronger earnest to Baltimore of a capacity for future greatness than our own rapid growth to an exalted rank among the most opulent and enterprising cities in the world. In less than a common life time we have risen from the rank of an obscure hamlet, to that of acknowledged importance. We are now the third in population and the fourth in commerce in the United States. To the great rapidity of our growth in size and in consequence it is believed that a parallel can no where be found in the annals of history. In the year 1752 the extent of our improvements consisted of 36 houses, and that of our population to 360 individuals, admitting that each house was occupied by a family of ten in number. Our present number in 1820 as has already been stated was 62,627. This amounts to an increase of 174 to 1; whereas were we to succeed in realising the anticipated population in 1880, of 1,260,000 the required ratio would very little exceed 20 to 1. Hence, then, if we may venture to judge of our future by our past increase of population the estimate in question instead of being denounced for extravagance, would appear to be entitled to confidence for its moderation. An increase of only 20 to 1 during a future period of 60 years, which has lately commenced, is very far short of 174 to 1 during a period of 67 years, only seven years longer, that has recently expired.

24. But whether Baltimore will continue to flourish, or not, essentially depends upon future events. It may most essentially depend upon our own attention or inattention to the improvement of those great local advantages peculiar to our situation. Had internal improvements been heretofore neglected, and had we continued destitute of the acknowledged advantages, to the community, of our numerous turnpike roads, there are many substantial reasons for believing we should not have risen to more than half our present wealth and importance, as an emporium of commerce; and it is presumed there are reasons equally numerous and substantial in favour of the conclusion, that it is impossible for us to experience half the advancement that otherwise awaits us, should we now relax in our efforts; should we now give up to content ourselves with what has already been done; and continue to neglect the far greater objects in point, utility and importance which still remain to be accomplished.

25. The time has now undoubtedly arrived when the great rapidity of our growth, has rendered it indispensible necessary, on our part, carefully to examine our present situation. To neglect this, will to a certainty, it is presumed, be neglecting the only possible means of our future prosperity. That abundant resources are required to supply our present population, even with subsistence, habitation and clothing, is too evident to be doubted. Every individual requires a daily supply of the necessaries and conveniences of life; the cost of which will be far greater in some instances than in others. Many who are wealthy "fare sumptuously every day," and spend an abundance. There are many, again, who have but little, and who of course can spend but little.

26. Under these circumstances, and including in the consideration, men, women and children of every description, I have procured a variety of estimates to be made, of the least sum that upon an average of the whole, might, most likely, be required for the support of each individual. These estimates made by different persons were very

different in amount, varying from two hundred dollars and higher, down to fifty the lowest of all. Hence one hundred dollars might be assumed as being under the medium; but upon the present occasion precision in the sum is by no means material. Every individual who pleases, is very respectfully, invited to make his own estimate according to his own mind. The general principles designed to be explained will be as certainly developed by a sum that is too high, or too low, as if it were correct. With this understanding let the most moderate sum of fifty dollars be selected, and at that rate the yearly expenditure of sixty thousand persons, (omitting the odd 2,627) will amount to three millions of dollars. Were the medium sum of one hundred dollars to be adopted, six millions would then be the result.

27. From the preceding calculations the evidence appears to be clear and conclusive, that there must be more than three millions of dollars annually expended by the citizens of Baltimore, for subsistence, habitation and clothing. This is certainly a very serious sum to be raised yearly; and it is equally certain, that the method and means by which it can best be accomplished, require to be very seriously considered. Nor is it by any means sufficient that they should be only considered, and for the business there to remain. It is in the next place, all-important, that the whole energies of Maryland should be consolidated and united together, as the strength of one man, to accomplish, whatever may, upon a candid and accurate investigation of this highly interesting subject, be certainly ascertained to be within the capacity of the state, and at the same time most extensively beneficial to the great bulk of its population.

28. This, it must be evident to every reflecting mind, is the only judicious and safe course for us to pursue; the only course, in fact, that can possibly secure to us a state of future prosperity. Should we on the contrary, unhappily for us, become divided in our opinions; should it, in consequence of any strange error of choice, be determined, at all hazards, to neglect the benefit of the many, for that of the few only; to reject an object of great and select one of little importance, in promoting the interests of the state at large; or should we injudiciously undertake more than we can accomplish, and by that means accomplish nothing; under these circumstances, what better can we, rationally, expect, than that our expenditures will presently exceed our income, than, that the vortex of ruin must of necessity open, all horrible before us; and that we, through the extravagance of our folly, cannot fail to be precipitated, headlong, into its most direful centre?

WILLIAM KENWORTHY.

TO THE EDITOR OF THE AMERICAN FARMER.

ROUTE RECOMMENDED FOR A CANAL
FROM THE POTOMAC.

Locust Level, Frederick County, }
May 18th, 1823. }

JOHN S. SKINNER, ESQ.

Sir—The contemplated Potomac canal begins to attract the attention of the citizens of Frederick and the county generally; and as the Potomac is the sole property of Maryland to low water mark, I deem it just, that the citizens of Maryland have the preference, if not the entire privilege, of using its waters for their own benefit, if they think proper; and a canal to the city of Washington, would be of no advantage to the citizens of Frederick county, (excepting a few individuals immediately on the banks of

river.) But a canal to pass through the Maryland tract, New-Town, (Trap) through Frederick, Newmarket, or to the Poplar springs, where it passes nearly through the centre of the richest land in the county, would be convenient for all; and from the wealth of the citizens of Frederick, and the county generally, I have no doubt but they would contribute largely either by taking stock, donatious, or suffer themselves to be heavily taxed, to aid in having the canal completed. I am well acquainted with every part of the route, which I presume would be most advantageous to conduct said canal through Frederick county. I would suggest commencing about two miles below Harper's Ferry, near the Stone mill, keeping nearly with the present road to Peynes' hill; where, by making a short curve, it would avoid the hill; then no material obstacle through the Maryland tract, crossing Catoctin creek, near Matthews' mill, or to New-Town, (Trap) to Catoctin mountain; and where the present road crosses is a chasm, and a small stream running down eastwardly, nearly from its summit, almost forming a natural canal; from thence, passing over two small branches of Ballengers' creek, which empties into Monocasy, about three miles S. E. of Frederick. No obstructions to Frederick, where it might unite with Carrol's creek, which runs through the town, and has been called a piece east of the town—from thence to Monocasy, nearly level—about half a mile below Monocasy turnpike bridge, is a chasm through the hill, (where a small rivulet runs, which empties into Monocasy,) almost forming a natural canal—from thence to New-Market, crossing the head of a branch of Bush creek, which runs S. W. into Monocasy; then keeping nearly with the present turnpike road to the Poplar springs, (crossing, probably, some of the head waters of Linganore.) At the Poplar springs, commences a branch, or small stream, which runs nearly direct to the Patapsco; from whence, I conceive, there would be but little difficulty of proceeding to Baltimore. From the knowledge I have of America, (and I have travelled through sixteen of the states, and principally with a view of exploring the country,) I candidly believe a canal can be conducted on, or near the route I have described, with as little (if not less) expense for the distance, than in any other part of America, (some parts of the southern states near tide water excepted;) and none could be constructed, which, in my opinion, would be more profitable. The advantages to Baltimore, Frederick, and the neighborhoods it would pass through, would be infinite.

I remain your friend,
And very ob't. serv't.
JOHN HUGHES.

AGRICULTURE.

FOR THE AMERICAN FARMER.

ON THE ORIGIN OF CHEAT.

SIR,

In looking over one of the numbers of your paper for the month of April, I observe an essay on cheat, signed S. V. S. This correspondent of your's, ridicules the notion, that cheat is produced from wheat—and styles those who believe it, the superstitious and the credulous. I have always believed that this metamorphosis did take place, and shall still run the risk of being classed among the credulous and superstitious, until I receive stronger proofs than any offered by S. V. S. that it does not. Passing over his pleasantry about the good old farmer and his book-learned son Tommy—let me enquire what has he brought forward to prove that wheat does not

produce cheat? Why, he asks, if we ever knew a dog to turn to a cat, or an ox to an ass; or orchis to a butterfly; or a polypos to become a sensitive plant, or a tubularia to a honey suckle? &c.—Now let me ask in my turn, if S. V. S. had lived before such discoveries were made, would he have known that a mule could be produced from the two distinct kinds of animal, the horse and the ass?—Or that good apples could be obtained by ingrafting on the stalk of a hawthorn? As he has introduced the names of Virgil and Ovid into his essay, let me ask, by the way, if those two great men might not have been acquainted with cheat, without ever ascertaining how it was produced? For how many ages do we find the world to have remained in the dark, on subjects of much greater magnitude, than the one under consideration?

The only attempt that S. V. S. makes to shew that cheat is not produced from wheat, is a bare assertion, and to me a very improbable one; that the seeds rise near the surface of the earth, and sprout, after lying in statu quo for a thousand years, at a considerable depth. Now, to take this essayist on his own ground of probabilities, I leave it to common sense to say which of these two theories is the most credible—that wheat turns to cheat, or that cheat seed remain one thousand years in the earth without rotting or sprouting? S. V. S. will never convince his readers of the truth of his theories by mere dogmatical assertions, unsupported by proof or argument.

I have, Mr. Editor, been for several years very much annoyed by cheat in my wheat crops—and have from every observation, been induced to believe, that this pest is the production of spurious wheat. Though I confess that, (like S. V. S.) I have considered it a strange production. The premises from which I draw this conclusion, are 1st—I never saw cheat grow in any land previous to a crop of wheat's being in it.—2dly. I have known the whole production of a yard where wheat, (and nothing but wheat,) had been trodden out, to be cheat. 3dly. If land is fallowed where wheat has been reaped, immediately after harvest, nearly half the produce will be cheat.—4thly. If you sow wheat, where an over quantity of ashes is deposited, a considerable portion of the produce will be cheat.—5thly. I never saw this result, under the abovementioned circumstances, after the seeding of any other grain but wheat. Why may not the grains of wheat be operated on by a combination of circumstances in climate and soil to change them to bromus canadensis, a plant varying very little from wheat in its growth and appearance, except in the head, which assimilates more to that of oats. We find that Indian corn will change its kind merely by moving it from a northern to a southern climate and soil. We also find that by a particular combination of circumstances in the climate and soil, this plant sometimes produces grains where nature intended the tassel to grow; and at others, that the place both of the ear and tassel is supplied by fungus. Is not this lusus naturæ as remarkable, as the change of wheat into a farinaceous production very similar to it?

I hope S. V. S. will not consider me as asserting positively that grains of wheat produce the bromus canadensis; nor as one unwilling to be convinced to the contrary, whenever he shall bring forward satisfactory proof. I should be glad to ascertain that it was not the production of wheat, and hear some plan devised for eradicating it from our wheat lands.

Respectfully your's,
PLAIN SENSE.

DESTRUCTION OF YOUNG FRUIT TREES.—I have in the last three or four years lost many

promising young apple trees, by a small brown worm, resembling in shape the common cut-worm, which gets into the body, and preys upon the soft wood, just under the bark. They attack the trees early in the summer. If the trees are not narrowly watched, the first intimation given of the presence of the worm, is a rapid decline of the tree; which, upon inspection, has the circulation of the sap completely cut off by the ravages of this worm, between the bark and hard wood of the tree.—A remedy for this evil, from some of your correspondents would be acceptable to—your's, &c.

P. S.

TO THE EDITOR OF THE AMERICAN FARMER.

HOW TO IMPROVE LAND BY GREEN FALLOW.

SIR,

On the 12th day of June, 1821, I broke up for the first time that year, a small lot of tolerably good ground, clean fallow; it was too dry, therefore turned up so much in lumps that the harrow could not reduce it to tolerable tilth; however, I sowed thereon, millet, and early in June, clover seed, and harrowed them in. Some of the millet on the most friable parts exceeded six feet in height—it was harvested when fully ripe. The clover seed took well, though the season was not favourable: stood the winter well, (though the ground was of that kind which throws up, or spues,) and produced a remarkably fine crop the ensuing spring.

This experiment, I may remark, was an accidental one, but the result excited attention. I have observed that of the clover seed sowed in February, on winter grain, much is washed off the general surface, (for it is to be kept in mind that most of my land is of the kind mentioned above, and two well known to need further description,) and deposited thickly in low places: many which germinate favourably, perish before harvest, and very many wither after that period under the scorching sun, not having acquired sufficient strength to stand the sudden and violent shock, the loss of so great a protector in time of utmost need; so that on the whole, the plants which are thriving in October, bear but a small proportion to the seed sown. Clover seed, I have found, stands a better chance when sown with oats; but the last difficulty stated above—the sudden exposure, takes place here; besides I must plough, and seed early, to ensure the crop. Now, supposing my ground to be previously set with clover, I must, in the first case, forego, in a great measure, the advantage which a growing crop will receive from the decomposition of vegetable matter; and in the second case, I shall have but little decomposition to profit by. May not these difficulties be greatly obviated by the use of millet, thus: From the first to the tenth of June, turn in the clover lay, and immediately sow clover and millet seed. The millet will give a crop of hay, excellent, I know it to be, when cut as it begins to ripen; and will protect the clover plants till after the dog days. They will be then uncovered in a thriving state, at a time when they can receive no considerable check from heat, and ready to profit by the autumnal dews. This process may be repeated the next year, and the next; thus annually giving and receiving. I believe, also, that we cannot find a better time than this to apply stable manure, either as it regards the fitness of the manure, the economy of using, or the immediate double benefit to result—I mean, to spread it moderately before the plough—its conjoint action, with the decomposing clover, will, I think, be peculiarly felicitous. Another advantage of considerable im-

portance, will result from this plan, viz: the destruction of noxious weeds, (*wild onion, or garlic* among the number,) which cultivation at this season tends to produce.

I intend to make a fair experiment this summer, and have made this communication, in hopes that some others may be induced to do likewise.

Respectfully yours,

W. B. R.

WAKE AGRICULTURAL SOCIETY.

At a meeting of farmers and other citizens of this county at the court-house, on Thursday last, a Society bearing this title, was constituted under the provisions of the late act of Assembly, for the encouragement of Agriculture. Moses Mordecai, Esq. was elected President; William Boylan, John Whitaker and Allen Rogers, Vice Presidents; Hartwell King, Treasurer; Joseph Galea, Secretary; and the following gentlemen were appointed Managers for the ensuing year, viz: William Polk, Charles L. Hinton, William Whitfield, William Hill, John W. Charles, Dempsey Powell and Wesley Jones.

The Society then adjourned to meet at Mrs. Jeter's long room, on Wednesday of May court, at 3 o'clock in the afternoon.

[N. C. paper.

From Phillips' History of Cultivated Vegetables.

HEMP.—CANNABIS.

Natural Order, Scabridæ. A genus of the Diactia Pentandria Class.

The Latin name of this plant is the same as the Greek *Kanabis*, from *Kanabos*, because it prospers best near watery places.

That this fibrous plant is indigenous to most of the European countries, as well as to Asia Minor, we have the authority of ancient authors, in opposition to the statements of some of our modern botanists, that it is a native plant of India only. Some of our Encyclopædias state, that the ancients used hemp only medicinally. Pliny is cited as their authority. In his 19th book, chapter 9, however, he informs us that hemp is equally good for making cordage; that the best for the purpose of making nets, and snares for wild beasts, was grown in Alabanda; and that the second in quality grew near Mylasium, both towns of Caria.

As a Phœnician colony settled there, it is probable that these people, so celebrated for their achievements in navigation, were the first who discovered the use of hemp in forming cables and tackle for their ships. They were in ancient times what the Britons are at present. Isaiah calls their country "the merchant city, the mart of nations, whose merchants are princes, whose traffickers are the honourables of the earth."

Pliny states, that the hemp which grew in some parts of Italy, and near Rosea in the Sabine's country, grew as high as shrubs; that it originally grew there in the very woods, without even sowing. It appears by the account of this author, that the Romans gathered the seed before the stalks, as he says the seed should be sown in February, and that the thicker it is sown, the finer the hemp grows. When the seed ripened in the autumn, it was rubbed out and dried in the sun, the wind, or in smoke, and the stalks were not plucked out of the earth, until after the vintage. "It is then," continues he, "the work of the husbandman to peel and cleanse it, which these people do in the evening by candle-light." It appears to have been diligently sorted; as this great observer of natural productions says, the worst part of hemp is next to the bark or rind; the principal part, and that of the best quality, was called *Messa*.

Although we do not produce lawn or lace from the fibres of hemp, yet it is a plant of great importance to Britons, as it forms the sails and tackle of our vessels, from the huge cable of a ship of war, to the more humble, but not less profitable net of the herring-boat.

The sails and cordage of a first-rate man-of-war, require 180,000 pounds of rough hemp for their construction; and it is said to average five acres of land to produce a ton of hemp: thus one of those monstrous towers of human ingenuity, that "Stems the vast main, and bears tremendous war, To distant nations, or with sovereign sway Awes the divided world to peace and love,"

consumes a year's produce of 424 acres of land to furnish its necessary tackle.

From this calculation it will be seen that Great Britain could not furnish itself with a sufficient quantity of hemp of her own growth to supply the immense demands of our shipping.

In the year 1763, we imported 11,000 tons from Russia; and Sir John Sinclair informs us, that in the year 1785, the quantity exported from St. Petersburg, in British ships, amounted to 17,695 tons, which would be the produce of 88,475 acres of land. In the year 1788, we imported from Russia 58,464 tons, the produce of nearly 300,000 acres, which at £20 per ton, would net the Russians £1,269,280. In the year 1783, France consumed 200,000 tons of hemp, of which more than one third was imported.

An act strongly demonstrating the folly of laying prohibitions on articles of commerce, (which often strengthens those whom it intends to disable,) was committed by the Russians in the year 1718, when they entered into a combination with the Swedes to deprive England of naval stores; and would suffer none to be exported out of their own dominions, but in their own ships, and at their own exorbitant prices; which instead of ruining our trade and navigation, turned our attention to our colonies, and induced us to procure from North America not only a sufficient supply for the use of Great Britain, but a large surplus for exportation.

Our government, fully aware of the important uses of hemp, has made several salutary laws, to render its culture an object of attention. In the year 1787, a bounty of three pence per stone, was allowed on all hemp raised in England, and duties have been laid on all that is imported.

China is celebrated for its abundance of hemp, particularly in the province of Kensi; but flax is not known to grow in that empire. The excellence of the Chinese hemp was noticed by Nievehoff, who attended the embassy which the Dutch East India Company sent to Peking in 1655 and 6. From this embassy more information is obtained on the policy and natural history of China, than from any accounts since published of our own embassies: whether this is owing to the limited observation of our naturalists, or to the jealous restrictions of the Chinese, we cannot decide.

The late Mr. Elliot sent some seeds of the Chinese hemp to Mr. Fitzgerald, vice-president of the Society for Encouragement of Arts: which being sown, produced plants fourteen feet high, and nearly seven inches in circumference. This induced Mr. Fitzgerald to apply to the Directors of the India Company, to obtain some of the seeds from China, which were procured in 1786; but few of the plants ripened their seed in this country. Dr. Hinton made a more successful trial of raising the Chinese hemp in 1787, which produced one-third more of marketable hemp than the best English hemp was ever known to yield on the same quantity of ground. Few of the hemp-seeds will vegetate if two years old; to this circumstance may be attributed the failure of many attempts to raise this new variety of hemp.

The English hemp is much superior in strength to that which grows in any other country. Suffolk is the principal county where hemp is grown and manufactured: this is seldom or ever used for cordage. The cloth made from this hemp is more durable than the flaxen linen, as well as warmer; and has the advantage of becoming whiter by age and use than that made from flax, which will not maintain its bleached whiteness.

We import a considerable quantity of sheeting from Russia, which has this great advantage over our own hempen cloth, that, being drawn from the distaff, the fibres are longer and less crossed than those in the thread made by machinery.

Tusser gave this valuable hint to the farmers in Queen Mary's time:

"Where plots full of nettels be noisom to eie,
sow there upon hemp-seed, and nettels wil die."

We cannot but observe, that with all the improvements in the cultivation of this country since the days of that author, there are still to be seen many wide hedgerows that are the nursery of thistles and other impoverishing weeds, which might turn to good account if sown with hemp; particularly if they were allowed to be planted by the poor cottagers, either with this valuable vegetable or the more necessary root of the potato. These poor parishioners would then have an interest in keeping off depredators, and in protecting the fences instead of destroying them; their leisure would be spent in their own little territory instead of the ale-house, and their children would acquire early habits of industry in tilling a plot for themselves.

It is observed by the Rev. Thomas Radcliff, in his Report on the Agriculture of Eastern and Western Flanders, "that each day-labourer has, in most cases, a small quantity of land, from a rood to half an acre, for his own cultivation." He adds, "Their comfortable supply of linen is remarkable; there are few of the labouring classes without many changes. In riding with a landed proprietor through a part of the country in which his property was situated, a neat cottage presented itself: the clipped hedge which surrounded the garden, covered with linen, very white, suggested an inquiry, 'whether it did not belong to a washerwoman?' The answer was, that it was occupied by a labourer and his family, and that the linen was all their own. In common times a beggar is scarcely to be seen, except in the towns, and but few there."

Every circumstance that is connected with the comforts of the lower classes, and every device that can be invented to keep them from receiving parochial relief, should be adopted; for when once they have become familiar to this aid, their natural pride forsakes them, and few are the instances of their ever endeavouring to become independent of the agriculturist, on whom they now weigh so heavily as to endanger the prosperity of their support.

Frugality disappears the moment the labourer cannot obtain a living on his own personal exertions; and to economise, when they once use the public purse, seems against the nature of their mortified spirit.

Hemp is said to possess a property which renders it almost invaluable to the farmer as well as the gardener: viz. that of driving away all insects that feed upon other vegetables. It is a common practice in many parts of the continent to sow a belt of hemp round their gardens, or any particular spot where they wish to preserve their crops from the mischievous attacks of flies or caterpillars. We would wish this experiment to be frequently made in turnip fields; for, should it succeed in protecting those crops from the ravages of flies, as well as the cabbages from the caterpillar, it would accomplish a most desirable end.

It is presumed that Tusser made his observation, that, where nettles will grow, hemp will thrive and destroy the nettle, from the opinion of the ancients as to assimilated juices, an opinion really not deserving the contempt it is generally treated with by planters. Plants requiring the same nourishment never thrive in neighbourhood, and the hemp is nearly allied to the nettle; from the latter plant a tolerably good linen may be made.

It will generally be observed that nettles occupy a good soil, which might be advantageously metamorphosed into plots and banks of hemp.

A Sussex manufacturer, who wrote on this article in the Annals of Agriculture, informs us, that hemp may be raised for many years successively on the same ground, provided it be well manured. The quantity of seed required to sow an acre of ground, varies from nine to twelve pecks, according to the nature of the soil; the quality of the hemp also differs from the soil. The common height of the plant is from five to six feet. Mr. Arthur Young informs us, that in his tour through Catalonia in Spain, he saw extraordinary crops of hemp, where the land was well watered, and that these plants were seven feet high. The hemp that is cultivated near Bischwiller, in Alsace, is often more than twelve feet high, and upwards of three inches in circumference.

From the class in which this plant is arranged in botany, it will be observed, that the same seeds produce both male and female plants promiscuously: this is one of the secrets, in the work of Nature, which cannot be accounted for. The Date has the same peculiar quality; for when we plant the kernel of this fruit, it is uncertain whether the offspring will be a male or female palm-tree.

The flowers of the fruitful hemp are hermaphroditical, and, like the lofty palm tree, or some of the lowly strawberry plants, produce abortive seed, without the aid of the farina of the barren plant. It is a curious misappellation of the cultivators of hemp, who call the fruitful plants male, and those that are barren female; we are more surprised that botanical writers should fall into the error; or, rather, copy this blunder from one work into another for so many ages, without correcting a mistake that inverts the order of Nature.

The unfruitful plants are forwarder than the fruitful ones by a month: this is ascertained by the fading of the blossoms, the falling of the farina fecundans, and the stalks becoming of a yellowish cast. These plants should be drawn out and worked, if possible, while green, the hemp being then finer than that which is previously dried. The Abbé Bralle, in a Treatise upon the culture and management of Hemp, directs, that little paths should be made lengthways through the fields, at about seven feet distance from each other, to allow a passage for the person who pulls up the unfruitful hemp from among the other, which requires to stand more than a month after the barren plants to ripen its seed. The fibres of the hemp are prepared for spinning, by a similar process to that of preparing flax. The beating of hemp, which was formerly performed by hand, is now done by a water-mill, which raises heavy beaters, and only requires the assistance of a boy to keep it turned. This laborious work was formerly imposed as a punishment for vice, in the houses of correction. Hogarth has noticed this circumstance in one of his celebrated pictures.

It is a duty incumbent on society, not to allow hempen rags, or even old ropes, to be destroyed. They are carefully sorted by the paper-maker, the finest being reserved for the purposes of literature and correspondence, while inferior sorts are selected for the various purposes of packages and paper-hangings.

The seed of hemp, being boiled in milk till it cracks, is accounted good for old coughs, and a specific for the jaundice.* Dodoens says, that, in his day, the hempseed, stamped and taken in white wine, was highly commended as a remedy for the jaundice and complaints of the liver.

The juice of the green plant, instilled into the ears, mitigates the pains therein.†

Coles, in his excellent History of Plants, notices the virtues of hemp thus laconically: "By this cordage ships are guided, bells are rung, beds are corded, and rogues are kept in awe."

FROM THE ALBANY ARGUS.

ON THE CULTURE OF PEAS.

The pea is a native of the southern parts of Europe, and is found growing spontaneously in the western parts of our own continent. The family is a large one, containing several species; but of these the *field pea* alone comes within the scope of our present purpose. Of this, there are two varieties, denominated from their colour, the grey and the green; both productive, and (when separated from the skin that surrounds them) a food of excellent quality for man; wholesome, nutritive, and pleasant; and for cattle, whether in a dry or green state, much to be recommended. Sheep, cows, and horses, are particularly fond of them; and hogs are more promptly and economically fattened on a mixture of pea and barley meal, in a state of acetous fermentation, than by any other food.

The structure of the roots would indicate, that peas are an exhausting crop: and it is on this evidence, that in Europe they are admitted only in long, or six years rotations; but if we examine the leaves, in regard to both number and form, we will probably find reason to modify this opinion, and allow that by stifling weeds, by checking evaporation, and eventually by their own fall, they meliorate the soil, and render it more favourable to subsequent crops.

Following turnips, the preparatory labour for a pea crop, is not great. One, or at most two ploughings, will be sufficient. Sowing, as a general rule, ought to follow ploughing, without loss of time; and care should be taken, that the seed be not laid too deeply. The two methods, row and broad cast sowing, may be indifferently pursued. By the former, the seed is economised, the product increased, and the soil better tilled; but not, as some have supposed, with such decided advantage as to outweigh the saving, in time and labour, of the latter.

The length and feebleness of the stems of peas, and the little tendrils they throw out for support, indicate the advantage of mixing with them, other plants of more erect growth, which may prevent the peas from falling and lodging. For this purpose rye, oats and beans have been selected, and with great advantage.

This crop is employed either in a dry or in a green state; between which every farmer will select, according to circumstances. If the market for peas be brisk and high, he will in harvest, thresh and sell the grain; if on the other hand, peas are low and pork high, the moment the pods fill, he will turn in his hogs upon them, and with the following advantages: 1st, the hogs feed and fatten themselves, without any additional interposition of his labour; 2d, no particle of their manure is lost; 3d, the debris of the crop, refused by the hogs, is given back to the soil; and 4th, the rooting of these animals, which in other cases is an injury, is in this a benefit.

* Miller's Bot. Off.

† Dioscorides, lib. iii. cap. 165,

AGRICULTURAL PREMIUMS.

Agreeably to the plan adopted by the Albany (N. Y.) county Agricultural society, of granting premiums for the best and cleanest wheat, barley timothy seed, clover seed and flax, without regard to the quantity raised on the acre; the executive committee, together with several of the chairmen of other standing committees, met at the capital on the 4th inst. and after a careful examination of the articles submitted to them, they awarded the premiums as follow, viz:—

To Stephen Haines, of Coeymans, for the best 10 bushels of wheat, having 50 bushels more of the same quality in his possession, all being of his own raising, weight 62 lb. per bushel. \$14

To Ebenezer Dennison, of Bethlehem, for the second best, under the same regulations, weight 60 lb. 11 oz.

To Aaron Fullner, of Bethlehem, for the third best, under like regulations, weight 61 lb. 8 oz. 8

To Aaron A. More, of Rensselaerville, for the best 10 bushels of barley, having 50 more of the same quality in his possession, all being of his own raising, weight 53 lb. 5 oz. 10

To Robert Bell, of Bern, for the second best under the same regulations, weight 52 lb. 10 ounces. 6

To Isaac Crary, of Bern, for the best bushel of timothy seed, having in his possession 5 bushels more of the same quality, all of his own raising. 8

To Gideon Dennison, of Bethlehem, for the best bushel of clover seed, having in his possession three bushels more of the same quality, all being of his own raising. 8

To Daniel Crary, of Bern, for 2d best do. 5

To Jonas Shear, of Coeymans, for the best 20 lb. of flax, having in his possession 100 lb. more of the same quality, all being of his own raising. 12

To Moses M. Stephens, of Coeymans, for the second best do. do. 8

To Ebenezer Dennison, of Bethlehem, for the third best do. do. 6

To Aaron A. More, of Rensselaerville, for the best acre of flat turnips, being 470 bu. 22 qts. to the acre. 10

The committee consider it to be due to those who did not receive premiums, to state the fact that between the articles offered by them and those which receive the premiums, there was scarcely a perceptible difference. This remark is particularly applicable to the articles of wheat and barley, both of which were of the very first quality. The grass seeds and flax were also excellent of their kind, and all taken together, evinced an attention to these branches of husbandry, very honorable to the farming interest of the county.

By order of the committee,
JOSEPH ALEXANDER, Sec'y.

FOR THE AMERICAN FARMER.

Scheme of Premiums to be awarded at the Annual Fair of the Agricultural Society of the Valley, to be held near the town of Winchester, (Va.) November 12th, 1823.

The committee appointed by the Agricultural Society of the Valley, to report a scheme of premiums, to be awarded by the society to the most successful in the pursuits of Agriculture, respectfully report:—

That it is estimated by the committee that the disposable funds of the society will amount, before any distribution of premiums, to the sum of \$300.

They therefore respectfully recommend that the following premiums be offered to candidates at the annual exhibition contemplated by the society:

I. CROPS.

1. To the owner or cultivator of the best organized and improved farm in the Valley, containing at least 100 acres under cultivation, considered in relation—1st, to yards and manures; 2d, fences and general division; 3d, rotation of crops; 4th, orchard; 5th, live stock; 6th, implements of husbandry, \$30 00
2. To the owner or cultivator of the next best, 20 00
3. For the best crop of wheat on at least ten acres, 10 00
4. For the next best on at least ten acres, 5 00
5. For the best crop of Indian corn on ten acres, 10 00
6. For the next best, 5 00
7. For the best crop of potatoes on one acre, 10 00
8. For the best crop of mangel wurtzel on half an acre, 10 00
9. For the best crop of wheat on not less than two acres, and the best crop of corn on two acres and upwards, premiums discretionary with the committee.
10. For the best crop of millet upon half an acre, 5 00
11. For the best crop of oats on five acres, 5 00

II. ANIMALS.

12. For the best bull over one and under four years old, 10 00
13. For the next best, 5 00
14. For the best bull calf under one year old, a silver medal valued at 2 50
15. For the two best milch cows, 15 00
16. For the best ram, in reference to carcass and fleece, 8 00
17. For the best boar, 8 00
18. For the best sow and pigs, 5 00
19. For the best yoke of oxen, 10 00
20. For the next best, 5 00
21. For the best stud horse kept in the Valley for six months previous to exhibition, 10 00
22. For the best raised by a member in the Valley, 15 00
23. For the best brood mare and colt, 10 00

III. MANUFACTURES.

24. For the best barrel of flour made of the smallest quantity of wheat, a medal valued at 2 50
 25. For the best 20 yds. of woollen cloth, at least $\frac{3}{4}$ of a yard wide, 6 00
 26. For the next best, same description, 4 00
 27. For the best 20 yds. of flannel, 7-8 wide, 5 00
 28. For the best carpeting, 20 yds. long, 6 00
 29. For the best 20 yds. of bleached linen, 5 00
 30. For the best 20 yds. of 6-4 diaper, 8 00
 31. For the greatest quantity and variety of domestic manufacture made in one family during twelve months preceding the award, 10 00
 32. For the best 50 lbs. of cheese made from one dairy, 5 00
 33. For the best 25 lbs. of butter, a medal valued at 5 00
 34. For the best bar share plough, a medal valued at 5 00
- Extra premiums, to be awarded at the discretion of the committee, not exceeding, in the whole, 27 50

Total amount of premiums, \$300 00

When there is only one candidate for a premium, a discretion will be retained in the committee to refuse it, if the article does not appear worthy of it.

Every candidate for a premium must at the time be a member of this society, or one of the

family of a member, and must make report under oath or affirmation.

Premiums will be awarded by the distributing committee for all kinds of domestic manufacture deserving them.

If any person shall make a false report or declaration on presenting an article for premium, he shall be expelled the society.

It is expressly understood that all premiums will be awarded in plate.

Those offering domestic manufactures, shall state the expense of making the article offered.

No crop shall be entitled to a premium, unless it shall amount to the quantity per acre following, that is to say: wheat 25 bushels; Indian corn 50 bushels; potatoes 250 bushels; mangel wurtzel, 500 bushels.

When a crop is offered for premium, the cultivator shall report to the society; 1st, The constituents of the soil, its situation, whether undulating or otherwise, and its preceding crop; 2d, The number of ploughings, harrowings, &c. &c.; 3d, The time of sowing, reaping, &c.; and lastly, The whole expense of tillage, including the value of manure applied. The whole of which shall be considered by the committee in awarding the premiums.

J. KEAN,
W. M. BARTON,
H. ST. G. TUCKER.

April 5th, 1823.

To the Corresponding Secretary of the Massachusetts Agricultural Society.

DESCRIPTION OF A BRUSH FOR DESTROYING CATERPILLAR'S NESTS.

DEAR SIR,
For the last three or four years, we have here had very few caterpillars. Last week I observed an increased number, though not many, on my young apple trees. How to destroy them *most easily*, was a question which occurred as often as I have seen orchards infested with them; while I always considered it disgraceful to a farmer to suffer his trees to be stripped of their leaves, and their fruit, for that season at least, to be destroyed; seeing it was very practicable to get rid of them, and without much trouble, by crushing them, when small, with the fingers. This was my father's mode, when I was a boy. The same long, light ladders, which served in autumn in gathering his winter fruit by hand, enabled one to come at most of the caterpillars' nests in the spring. On this effectual example, I have myself practised, since I became a farmer. Some over delicate persons might object to this mode; but it is really far less offensive than the bare sight of large and numerous nests with which apple trees are sometimes filled. And if the operation be performed early, when the caterpillars are only from a quarter to a half an inch long, the operator, (man or boy) will feel no repugnance to the process. But in full grown trees, some nests towards the extremities of their small limbs would escape, because not accessible by ladders. A narrow brush, formed with small bunches of bristles in a single row, I once thought might reach and destroy them; but it was not found effectual nor convenient. Last Saturday morning the idea of the proper kind of brush occurred to me, and in the forenoon I tried it with complete success.

I presume every farmer has observed, that the clusters of eggs producing caterpillars, are laid round the slender twigs of the apple tree and wild cherry, and effectually guarded by a gummy covering, until vegetation commences in the ensuing spring. When first hatched, the worms appear about the eighth of an inch long. The same warmth in the air which opens the buds, hatches the caterpillars to feed on the embryo

leaves. Their first object is to provide for themselves, a tent for shelter, in their new state, against the inclemencies of the weather. For this purpose, they crawl to a small fork of a limb, where the branches form a sharp angle; and there spin and weave a web with which they surround it, and where they are secure against undue cold and heat and rain. By this small white web they are discovered, and are then most easily destroyed. But the cluster of eggs are not all hatched at the same time. According to their situation for warmth or coolness, they are hatched some days earlier or later. At the distance, therefore, of a week or ten days after the first visit, an orchard should be again inspected, and all the latter broods destroyed. If neglected in this first state, they soon, by their growth, become straitened for room; and having also consumed the nearest forage, they march and take a new station, and there form a new and more ample tent. By such neglect the mischief of their ravages is increased, and they are with more difficulty destroyed.

The efficient and convenient instrument above mentioned, for this work, is nothing more than a common bottle brush fastened on the end of a pole. Having an old one in my house, I was enabled to make the experiment on the day when the idea of so applying it occurred to me. This brush is made of hogs' bristles, introduced between two stiff wires closely twisted; and being convenient in cleaning the insides of bottles, is probably familiarly known wherever liquors are bottled. For the information of others, I will mention, that a piece of wire full one tenth of an inch in diameter, about three feet long, doubled, and leaving a small loop in the middle, is closely twisted for the length of about eight or ten inches from the loop; and then the bristles, being introduced between the remainder of the branches of the wire, and these closely twisted upon them, the bristles are immovably fixed; and thus form (after being uniformly sheared) a cylindrical brush about six inches long and two and a half in diameter. To fasten this conveniently to a pole, with a small gouge, I made a groove about seven or eight inches long at the small end of the pole, in which nearly all the handle (the naked portion of the twisted wire) of the brush was laid, and bound on with three strings.

In using the brush, press it on the small nest, and turning the pole in the hand, the web is entangled with the bristles, and removed; otherwise, you rub the fork of the limb, inside and outside, with a brush, when nest and worms are surely killed or brought down. That the experimenter may see its mode of operation, he may apply the brush with his hand to a nest within his reach. Spruce poles are eligible, because that wood is light and stiff. For my small trees, I found a common bean pole (used for running beans to climb on) six or seven feet long, sufficient; and for them a longer pole would be inconvenient. For taller trees, poles proportionably long must be provided.

If you are satisfied by my account, of the utility of this simple instrument for destroying caterpillars, you may think it proper immediately to make it publicly known. Should the description be more minute than is requested for communicating a clear idea of it, and its application, you will abridge it.

With very great respect and esteem,
I am, dear Sir, truly your's,
TIMOTHY PICKERING.

From Willich's Domestic Encyclopedia.

Cisterns are vessels employed for the reception of rain, or other water, either under ground

as those of navigable canals, &c. or above ground, for domestic and other purposes. In this place we shall treat only of the latter. In London the cisterns are of lead.

As the water collected in leaden cisterns is apt to corrupt, either by stagnating for several days, when the pipes happen to be obstructed, or by the deposition of feculent matter, as well as the incrustation formed in such vessels, it follows that they ought to be frequently cleansed of the copious sediment they contain. This attention is the more necessary, as lead is a metal liable to be dissolved by acids; and, in that state, proves a slow, but fatal poison. Although the acidity contained in stagnant water, which has, in its course, been impregnated with animal and vegetable particles, cannot be very considerable, yet it will be more safe, and prudent, to prevent the formation of such acids, by an early attention to the purity of the water.

The deeper cisterns are, the better the water will be kept. Where the ground is not so bad as to require a round form, a cube is a good figure; a double cube must be better, as it gains depth and consequently coolness. A cistern of six cubic feet, holds 16 hogsheads of 100 gallons each, or 26 hogsheads. A double cube of five feet would hold above eighteen rum hogsheads of one hundred gallons. The pit should be dug exactly by square and plumb. On the face of the pit, lay potter's-clay, plasterwise, with a trowel, coat over coat (as it dries and cracks) two or three inches in all. Against this firm even face of plaster raise the brick or stone work. Bed the bottom, three or four inches thick with strong clay, beat to a smooth, even surface. Moisten the clay, and beat it with switches, or small hoop poles, but with nothing heavy. On this clay-floor, lay a double bed of brick: and, on the margin of this, carry up the side walls half brick thick, laying them in terras. Cover the cistern over, but leave room to fix a small pump, which must be two feet from the bottom: or a roller and bucket may be used to raise the water.

The above directions are taken from Mr. Bordley's Essays and will answer where lime cannot be had to make Mr. Hunn's cement, before noted. In many places of Europe, rain-water saved in cisterns is the only water drank. Stolberg says, he drank some in the vicinity of Naples, near three years old, and found it excellent. Mr. Bentham has lately taught us, that water may be kept during the above period perfectly sweet. On the flat coasts of the United States, these rain-water cisterns ought to be generally built: for the water from the ground is very bad, and occasions many of the disorders attributed to other causes.

[The mortar or plaister for cisterns, should be made of lime well and recently burnt, with the admixture of one fourth of terras, ochre, ground iron ore, or smithey slack, (the dust of a blacksmith's shop)—T. C.]

Anciently there were cisterns all over the country of Palestine. There were some likewise in cities and private houses. As the cities for the most part were built in mountains, and the rains fell regularly in Judea at two seasons of the year only, in spring and autumn, people were obliged to keep water in their cisterns in the country for the use of their cattle, and in cities for the convenience of the inhabitants. There are still cisterns of very large dimensions to be seen in Palestine, some whereof are 150 paces long and 54 wide. There is one to be seen at Ramah of 32 paces in length, and 28 in breadth. Wells and cisterns, springs and fountains, are generally confounded in Scripture language.

From Nicholson's Philos. Journal, vol. 22, p. 354.

Account of a well for preserving and filtering Rain-water for domestic purposes, where a supply of Spring-water was not easily to be obtained.

SIR,

TO MR. NICHOLSON,

You may perhaps deem the following account of a filtering rain-water well, which has been successfully tried here by the Earl of Caernarvon, not undeserving of notice in your valuable Journal. His lordship has lately erected upon a dry gravelly eminence in his park, an ornamental circular building, consisting of a room and open colonades above, and apartments for cottagers upon the basement floor. Considerable discussion arose upon the mode of supplying them with water, from the depth to which it was necessary to sink, in order to obtain an effective well. My friend, Mr. John Loat, builder, of Clapham, who had furnished the plan, for the construction of the dome roof, mentioned to me a contrivance of his father's to meet a similar difficulty, which had been attended with invariable success, and Lord Caernarvon immediately determined upon carrying it into execution.

Following Mr. Loat's instructions, we sunk two wells, 30 ft. deep by 4 ft. diameter each, which for greater perspicuity I shall call No. 1 and 2. They are a trifling distance asunder, and were carefully clayed, to prevent percolation into the surrounding soil, and lined with bricks in the usual manner. A well secured communication was made between the two wells, by a small leaden pipe inserted two feet from the bottom. All the pipes from the roof were directed into No. 1; and an oak floor, bored full of small holes, and supported upon posts, was laid in at No. 2, just above the pipe of communication. Upon this floor was first placed a stratum of well washed coarse gravel, then one of finer, next a stratum of coarse sand, and finally one of the finest sand we could procure, making altogether two feet in thickness of silicious substances. The water, which is received into No. 1, passes through the leaden pipe into No. 2. and filtrates by ascent through the strata of sand and gravel, the space below the level of the oak floor in both wells, acting as a cesspool, receives all sediment. The pump is of course affixed in the filtering well. Both wells are covered up, but plenty of air is admitted to them, through apertures made for this purpose.

You will immediately perceive, that the merit of this plan consists altogether in the filtration by ascent, with a competent space under the apparatus. The interstices of the sand are thus never clogged, and its power is preserved unimpaired for an indefinite period. The well fully answers its intended purpose, and the water is altogether excellent. I have been tempted to submit this statement to you from a persuasion that there are few houses, which may not be made in this manner to supply excellent water in sufficient quantity for domestic consumption; and that situations abound, where the filtrating well may be resorted to with equal comfort and advantage.

I am, Sir, your obedient humble servant,
J. R. GOWAN.

FROM THE NORTH AMERICAN REVIEW.

GEOGRAPHY OF PLANTS.

The geography of plants is one of the most curious instances of the connexion of the various arts and sciences with each other. Far from being a topic which ought to be assigned exclusively to the botanist, the subject of the locali-

ties, of the original country of plants, and the regions to which they have been transported, is one of the most precious documents for tracing the descent, the affinity, and the emigration of the ancient nations. Books, we have few, one might rather say none, which acquaint us with the primitive fortunes of our race.—Plain reading and writing, handy as we are at them now-a-days, are things of which the majority of men, taking the ages of the world together, have known nothing. We speak not now of the old and somewhat arbitrary division of the barbarous and civilized; but the people that built the pyramids and the temples of Thebes, knew nothing of what we call reading and writing. Their hieroglyphics were in the hands of the priests, and besides were about as much of a popular science as the integral and differential calculus at the present day; with the advantage in favour of the latter, that all who have the intellectual capacity to learn it, have the means, while the hieroglyphics, were its sacred mystery. The Assyrians, Chaldeans, and Persians, at the most flourishing periods of their politics, cannot have had any other kind of writing. There is no proof of any thing among them more commodious than the arrow headed character, of which the construction excludes every thing like a popular use. It may have served the purpose of religion and the state, and had been, perhaps associated with astronomical hieroglyphics, to record some observations of the heavenly bodies. No one who has ever looked at a Babylonian brick, or drawings of the Persepolitan ruins, can suppose, that it extended its use to the common purposes of life. But this is to speak of the most ancient days, and distant regions. The Trojan war has been fought, all the Grecian cities founded, and the laws of Lycurgus established, before the Greeks learned to read and write; and prose is so modern among them, that we can show the period of its origin. With the Romans, as with the Etruscans before them, writing was a mysterious art, in the hands of the priests, till the intercourse between Greece and Rome was established. Nor is it probable, that in common life, any extensive use was, at any time, made of the art. In the middle ages of Europe it was still less practised. Charlemagne himself was awkward at it, and set up schools, that his subjects might be better taught than their master. Even at the present day, if the human race were to pass in review before us, for one who could read a book, there would be about ten to whom it would be sad waste of fair rags. That almost idolatrous preference, therefore, which we give to written documents above all other means of information, has, as far as the oldest antiquity is concerned, little foundation in justice, and is much to be deplored, when it leads us to neglect more permanent documents of the history of our race. It is not in the form of books, that languages themselves are the best witnesses of the most remote antiquity.

The coincidence of the structure and vocabulary of languages carries us much farther back, than any record they contain, for the reasons, that the oldest records have perished, and still more, because men spoke long before they wrote, and ages on ages of speaking men, to whom writing in all its forms was unknown, transmitted their language to posterity. But language, in any application, is but one of the monuments, that survive the transitory generations of men. Their works and their institutions, their superstitions, and their ceremonies, in various forms, outlive them; and it is not without example, that the lineaments of the face descend, for thousands of years. Let men but make some progress in civilization, and they divide the starry heavens into arbitrary signs, of which the tradition tra-

vels down to the latest posterity, which establishes a connexion between the Hindoo, the Egyptian, and the Greek, anterior to any other record of it, and leave a memorial in their lunar houses and solar aspects, for ages after marble and paper are alike reduced to dust. This observation had not escaped philosophers. M. de Humboldt has called the attention of those who love to study the history of man, not in the genealogy of kings or the tale of battles, but in its grand features of humanity, to another most elevated and attractive speculation. Most of the vegetables, which serve for the nutriment of man, the grains, the roots, the berries, which make up his food, have undergone migrations with the human tribes, and in passing from region to region, and climate to climate, have gone through various stages of development and improvement. On an extensive collection of facts of this kind, notices of native places, the transportation, the improved form, and the use for food of the cereal vegetable, the potato, the palm, &c. M. de Humboldt has founded the most ingenious historical conclusions, and taught us, that if in one series of observations, the history of our race is written in the heavens above us, it may be traced in another on the surface beneath our feet. The essay on New Spain contains a number of speculations of this kind, of the most curious nature, that are more particularly pursued in the work before us; which is completed, and itself an independent and separate work.

The following letter has been handed to us for publication.

MIDDLEBURG, (Md.) 2nd May, 1823.

Dear Sir—In compliance with the desire that you have expressed in the last communication, that I have had the pleasure of receiving from you, relative to the fact of certain vegetables possessing the power of locomotion; I shall, in as succinct and comprehensive a way as the nature and elucidation of the subject will admit of, proceed with the following observations, which, I hope, will be considered sufficiently satisfactory upon the subject.

The power that animals are in possession of, by which they are enabled to move themselves from one place to another, is by very many supposed to constitute the difference between animals and plants; and it certainly, in the generality of instances, is the most correct criterion by which we distinguish the animal from the vegetable kingdom. But although every animal possesses, in a greater or less degree, the powers of locomotion, yet, nevertheless, the intelligent botanist is fully persuaded of the fact of certain plants having an inherent disposition in them to shift themselves from situation to situation, whenever they are placed in a position that is more or less unfavourable to the process and progress of vegetation. Plants, when forced from their natural situations are endowed with a spontaneous, and perhaps a voluntary power of recovering themselves. It is perfectly well ascertained, that they are endowed with life, and consequently subject to decay and death. They are doubtless sensible to the action of nutriment, air, light, and to every thing that excites an impression that is congenial to their rapid growth; or that may be calculated to produce destruction upon a part only, or upon their general organization. The unfolding and closing of many flowers at stated times, cannot but be considered as a proof sufficiently satisfactory of the truth of this sentiment. But to advance a little further. It is well known to the most superficial observer, that all the species of the sensitive plant, upon the slightest touch folds up its leaves similar to the snail, which, upon re-

ceiving the least impression, retires within its shell. There is one particular species of this interesting genus of plants, the *Dionæa*, the flower leaves of which, if a fly light upon them, closes instantaneously and crushes the insect in a moment to death. A hop-plant twisting around a stick, will, upon examination be invariably found to direct its course from south to west, as the sun does: turn it in the contrary direction and secure it in this position, and it dies. Leave it loose in the contrary direction and it will recover itself in the course of a single night. The root of a tree meeting with a ditch in its course, becomes exposed to the open air, the consequence of which is, it pursues a different direction like an intelligent being, plunges into the earth, surrounds the ditch, ascends upon the opposite side, and then proceeds on its former course. If a wet sponge be placed near a root that is exposed to the air, the root will alter its course, and direct itself to the sponge, shift the sponge to another situation, and it will alter its course again. If a pole be placed at a moderate distance from any chimney plant, it will direct its course to the pole, lay hold of it, and ascend to its usual height; and so of many others that I might at present mention. But I presume that the instances that I have already cited in support of the power of locomotion in vegetables, will be sufficient to satisfy your mind on this subject. I must now close with this communication by observing to you, that I shall always, with the greatest pleasure imaginable, give you any information connected with this department or branch of natural history. I have the honour to be, Dear Sir, your obedient servant,

W. ZOLLICKOFFER.

Miscellaneous.

FROM THE LONDON FARMERS' JOURNAL.
ON WHEELS.

Evesham, Sept. 14, 1822.

Sir,

In your Journal of the 9th instant, I perceive you have "selected an article" from the Geographical Essays, "to revive the subject of Cylindrical Wheels." As you have begun afresh this controversy, I trust you will not let the subject again subside until you shall have converted those who differ from you, or *vice versa*; and, whatever the result may ultimately be, let it be a *sine qua non* with the advocates for or against them, that all theory shall be brought to the test of experiment, with *carriages in common use, upon real roads*: and give me leave also to recommend all writers upon the subject, in your columns, to appear under real signatures.

In my letter published in your Journal of the 19th of June, 1820, I referred to the extensive, and I may say, exclusive use of cylindrical wheels by the Duke of Portland, at Welbeck, Notts. where they have answered perfectly, though of different dimensions, and from three to fifteen inches in breadth. Why the same success has not attended the North Britons, where you say they have failed, I cannot determine, but depend upon it, it will not be found to be owing to the principle, but somewhere in their mal-construction.

I have, since the date of my last letter, continued my researches, and made many experiments, which have invariably induced me to hold the cylindrical wheels in the highest estimation.

I have noticed several times in your Journal, a hint, which in the Number before me I find repeated, thus—"It is impossible" you say "for cylindrical wheels to run flat on the sole, and with equal pressure on roads which form (as all ours do) segments of circles." However mathematically correct as the solution of a problem, nothing of the kind will be perceptible with actual wheels

upon our roads, and which, if they are segments of circles, I hope ere long to see altered by a legislative enactment, into the segments of a flat ellipsis. I should still have remained silent upon this subject, if the Highway Committee had not abandoned in their last bill the plan of flat soles, as introduced in their former bills of 1820 and 1821. The moment I discovered the alteration in their bill, just now passed into an act, I hastened to offer my evidence, but found it too late, their report having been previously made. In the act in question, page 4, folio 9, 10, is an enactment to prevent wheels six inches in breadth, from deviating more than half an inch from a flat or level surface, or more than one quarter of an inch from a flat surface in wheels less than six inches in breadth; or in case the several nails of the tire of such wheels shall not be so countersunk as not to project above one quarter of an inch above the surface of such tire, which enactment is followed by a clause for the encouragement of cylindrical wheels with flat soles and countersunk nails. By still allowing barrelled soles and projecting nails, it appears as if the framers of the bill had an idea that *dished* wheels could not be made or used with flat soles, and the universality of this opinion has, I believe, been the chief obstacle to their general and immediate improvement: but the *fact is*, that notwithstanding the mathematical truth, that the lesser circumference of the conical wheel in a certain degree twists, or drags, when going in a straight line so as to keep pace with that part of the wheel rolling upon a greater circumference, yet such dragging or twisting, does not injure any road if the wheel is correctly flat upon the sole. In comparing the effects of the cylindrical and the conical wheel, when at work, little or no difference can be discovered; but between them and the barrelled soles with nails, deviating one quarter of an inch only, the superiority of both the former will be striking indeed. Cylindrical wheels could not be suddenly and exclusively brought into use without great injustice to individuals, but may be introduced gradually as new wheels are required, at an expense not exceeding any other sort, and in the mean time the common dished wheels may be so altered as very nearly to approach the perfection of the cylindrical wheel,* at the trifling expense of 27s. per pair. The alteration I have made upon many of the common wheels of the country, which are always more or less dished, and have barrelled soles, has been to remove the tire, cut down the sole to a flat and even surface, to rework the tire, and countersink the nails, at an expense 13s. 6d. each wheel, as above stated. All that the most enthusiastic improver of roads can wish the legislature to do with respect to wheels, is to encourage the least injurious wheel, viz. the broad cylindrical one, which is at the same time the strongest and the easiest of draught; to fix a minimum for the breadth of all wheels according to the number of horses drawing the same; and that every wheel, of whatever description, shall be flat on the sole, and that the nails of the tire shall be so countersunk as not to rise above the surface; or in other words, re-enact the 69th section of the 13th Geo. III. c. 84, which was unfortunately repealed by the 16th Geo. III. c. 39, before the time fixed by the framers of that excellent statute to take effect, under the mistaken apprehension that the provisions relating to flat soles and countersunk nails,

* Mr. S. here delivers the whole truth, and admits all that need be contended for; that is, if wheels be dished only as much as strength requires, they will run as well as cylindrical ones.

† The stronger it may be for perpendicular sure, but not in wear with time.

would be "attended with great inconvenience." My experiments have been made with cylindrical and conical wheels, flat and barrelled soles, countersunk and projecting nails, travelling with very heavy weights over almost every variety of road, from the native soil in deep ruts to the well consolidated and smooth modern road. The weight above alluded to was on six-inch carts weighing, when loaded, three tons four hundred weight each. These have not been experiments of an hour, or a day, but of continued labour for many months, not less than six thousand tons having been transported upon cylindrical and conical wheels alone, finding it requisite to discard the barrelled sole altogether, not only as destructive to the roads, but to the wheel itself; for it is the nature of the barrelled sole to be eternally upon the rock even upon the smoothest road, while the former consolidate and improve, and by their attrition bring a road into such a state of perfection as cannot be obtained without them, no more than the beautiful smoothness of a coach panel can be produced by the painter without the aid of his pumice stone.

I shall be most happy to give any explanation; or give me leave to say, I shall be glad to see you here, or any other gentleman interested in the general improvement of the roads throughout the kingdom, in which case I would exhibit the different wheels and their effects upon the roads, or make any experiments with them that might be suggested.

I beg to remain, Sir, your obedient servant,
JOHN ALLEN STOKES.

HEAD ACHEs AND APOPLEXY.

(From a Medical Work, entitled "Farmer on Head Aches," &c.)

"The alarming increase of apoplectic fits for several years past, has naturally given rise to the question—What do they proceed from? Various opinions have been given by writers on the subject, but none appear to be satisfactory.

"Now, from all the consideration I have given to the subject, and coupling it with many corroborative circumstances, I find no hesitation in coming to the conclusion, that the prevalence of apoplexy is owing, in a great measure, to the introduction of the custom of wearing cravats. This observation will appear less extraordinary, when we call to mind the fact that this addition to our dress was not adopted until the 16th century, previous to which period, the disorder in question was met with but as one to three compared to the present. In that day the neck was divested of every kind of covering, except a slight frill, which contained no warmth; and, instead of detracting from dignity, it added much to the majesty of the countenance. A mere shirt collar was worn on the neck by some people, but it did not operate in augmenting vascular action there.

"But I find another proof of the feasibility of my remarks, by the circumstances of females being less liable to apoplexy than the opposite sex, although the nature of their economy might be supposed to lead much oftener to the complaint. Now we find that their necks are not enveloped in padded ligatures, and consequently the proportion of sudden deaths amongst them is much less than in men.

‡ Not months, but years of labour must prove wheels. A good pair of dished wheels will last a farmer near twenty years with repair. Will cylindrical wheels work safely till they are as old?—Experience says, No.—Edit.

COMMUNICATION.

Mr. Editor,

I observe in your paper of the 21st inst. an extract from the "Harper's Ferry Free Press," stating that on the 28th of June, 1824, and 20th July, 1860, there will be "total" eclipses of the sun.—Now this is rather too wantonly sporting with the curiosity of those who are looking for wonders in the skies—for, there will be no eclipse at all on either of those days—June 26, 1824, there will be an eclipse of the sun, about sun set, but not visible here; also July 18, 1860, the sun will be about one half eclipsed.

The astronomer who furnished that article for the "press," had heard of the "Chaldean Period" of 18 years and some odd days and hours, when the same eclipse returns again, (and the two eclipses abovementioned are the first and third returns of the great eclipse of July 16th, 1806.) and he probably wisely concluded that the second return in 1842, would be invisible, because it would happen in the night. But he may yet learn, that eclipses of the sun appear very different, and are "total" or not even visible, depending entirely on the time of the day when they happen, and the situation of the observer—he may also learn to make proper calculations for Leap Years.

Were I to foretel the next "total" or central eclipse of the sun, I should say February 12th, 1831, about one o'clock, P. M. the sun will be centrally eclipsed, in the latitude of Boston, exhibiting a luminous ring.

Bethel, Vt. April 25, 1823.

FOR THE AMERICAN FARMER.

CURE FOR THE GRAVEL.

MR. SKINNER, SIR,

When we take a daily paper in hand, it is generally for the purpose of discussing the politics of the day, or noting the price of stocks: both pass away as the Ephemera. But when in company with the *American Farmer*, "we read, mark, learn, and inwardly digest" its valuable communications. I often copy receipts from it, and am inclined to measure "other people's corn by my own bushel;" and think the following receipt may be of as much service to suffering humanity, as one for making the Hamburg pickle. Should you be of the same way of thinking, it will find a place in your valuable paper.

Having been much troubled with the gravel, I was advised by a Mr. Zane, of this city, to try a decoction of wild carrot, *Daucus Carota*. I made a tea from the stalks and seed, with a few water melon seed, and drank about a quart a day; it is as palatable as China tea, when sweetened with sugar or honey. In less than a month from my first using it, I passed a stone 3-8ths of an inch long and 3-8ths circumference, of an egg-like form. I have ever since, when troubled with any pain in the region of the kidneys, taken a strong tea of it for my common drink, through the day, and always found relief. I take it with my children for breakfast, once a week—they make no objection to the taste.

This is a remedy that is to be found by every farmer on his own lands; and cannot well be mistaken, from its great resemblance to the culinary carrot seed and flower. Mr. Casey, Seedsman, Hanover-st. called to my recollection, a medicine used by my father, composed of beards of leeks, birch twigs, pennyroyal and wild carrot—ad libitum—but a compound is not so easily procured as a simple, which alone, often causes the receipt to be passed over.

Your's respectfully,
WASHINGTON SPENCER,
98, Granby-street.

May 18th, 1823.

HYSON TEA.

The fact has been demonstrated, that the genuine hyson tea may be successfully cultivated in this state. The experiment has been tried, and the result has been most satisfactory. A lady, the wife of Mr John Newland, of Chatham county, found a seed much resembling that of buck wheat, in the bottom of a box of tea which her husband had purchased in this town. She planted the seed in her garden and the produce was a splendid crop. She gave some of the seed to Mrs. Farrington, the lady of Mr. John Farrington, of Chatham county, who also planted the seed; and the writer of this article obtained his information from Mrs. Farrington, and also obtained from her some of the tea and seed.—He planted the seed in his garden, in this town, where it can be seen by those who are curious to witness the products of the East Indies transferred to this western hemisphere.

The writer of this article has distributed, of the small portion of the seed obtained by him, to many of his friends in this town and its vicinity.

A treatise on the mode of curing this valuable plant is quite desirable.

Fayetteville, (N. C.) May 20, 1823.

THE FARMER.

BALTIMORE, FRIDAY, JUNE 6, 1823.

BALTIMORE MARKET.

PRICES CURRENT.—CORRECTED WEEKLY.

Flour, best white wheat, \$8—Howard street Superfine, \$7 25—fine do. \$6 75—Wharf, do. \$7 25 sales—White wheat, \$1 52 to 155—Red, do. \$1 45 to \$1 50—Rye, 75 cents—Corn, 50 to 52 cents—country Oats, 40 cents—Beef, 8 cts. per lb.—Live Cattle, \$6 to \$6 50 per cwt.—Bacon, round, 8 to 9 cents per lb.—Pork \$4 50 to 5 50 per c. lb.—6 to 8 cts. per pound—Mutton, 5 to 6 cts. per lb.—Beans, \$1 37½ to 1 50—Peas, black eyed, 55 to 60 cts.—Red Clover Seed, \$6—Orchard Grass do. \$3—Herds' Grass do. \$3—Timothy do. \$4 50—Millet, none—Flax Seed, 75 to 80 cts.—Whiskey, from the wagons, 32 to 35 cts. per gal.—Apple brandy, 30 to 32 cts.—Peach do., 65 to 70 cts.—Shad, \$6 50, scarce—Herrings, No. 1, \$3 per bbl.—No. 2, \$2 75—Fine salt, 60 to 65 cts. per bush.—Coarse, do. 70—Butter, 20 to 25 cts per lb.—Eggs, 12½ cts. per doz.—Hay, \$17 per ton—Straw, \$10.

TOBACCO is selling nearly as per last report.

FOR SALE

At a low price and on a long credit, the FARM on Elk Ridge, occupied by Mr. H. Scott, and formerly owned by Luther Martin, Esq. containing about eleven hundred acres.

It is situated about eleven miles from this city, near the Washington road, and is considered remarkably healthy—The situation is handsome, and the land easily improved by plaster and clover. This property will be divided if required, and immediate possession given—For terms apply to

ROBERT & JOHN OLIVER.

Printed every Friday at \$4 per annum, for JOHN S. SKINNER, Editor, by JOSEPH ROBINSON, on the North West corner of Market and Belvidere streets, Baltimore; where every description of Book and Job Printing is executed with neatness and dispatch—Orders from a distance for Printing or Binding, with proper directions promptly attended to, addressed to J. Robinson, Baltimore.

Internal Improvement.

ON THE PARAMOUNT IMPORTANCE, TO MARYLAND, OF A CANAL TO THE SUSQUEHANNA.

No. IV.

The public would be great gainers, were they to lay out upon the making of every mile of Canal, twenty times as much as they expend upon a mile of Turnpike road; but a mile of Canal is often made at less expense than a mile of Turnpike.

29. In support of this very important proposition, it may be proper, in the first place, to state that it has in its favour the authority of Rees's celebrated Cyclopaedia, because it is an exact quotation from that elaborate work. But in a matter of the utmost importance, such as the present, to many, at least, it would be abundantly more satisfactory to enter into a minute investigation of the reality of the fact, rather than implicitly to depend upon any authority, however respectable. While we remain unacquainted with the truth of a proposition from our own knowledge of its certainty, the knowledge of others will never enable us clearly to comprehend it. Under these views, I have, with the most scrupulous attention to accuracy, collected, either from the writings or the personal information of men of the most extensive experience, the series of evidence which is the basis of the following calculations and conclusions.

30. From the evidence with which I have been thus furnished, two facts appear to be clearly developed: One, that a man, a boy and a horse, can, with facility, transport a 25 ton boat and its cargo 20 miles a day, upon a canal advantageously constructed with towing paths; the other, that first rate five horse teams do not usually travel more than 20 miles a day, nor carry more but less than two tons and a half upon a turnpike of the best description. Hence it follows that ten such teams would be required to convey 25 tons as far in a day as the same weight would be taken by the man, the boy and the horse. By a person of extensive experience I have been informed that the first cost of a new turnpike waggon and its appendages, admitting the tread to be four inches and a quarter, so as to pay but half toll, is frequently as high as \$200, and may be accounted low, when rated at \$190; that such a waggon, in constant use, if substantially made, will last about 18 months; that \$60 will then be required for new tire, which with about \$10 for incidental charges, may be expected to hold out a second 18 months; that in the next place, in addition to \$60 for new tire again, and \$10 for other charges, \$16 will be required for, new rimming the wheels; that at the end of the third term of 18 months a general repair may be anticipated amounting to \$60 for new tire, \$25 for new axle-trees, new bolsters, &c. with their respective irons, and about \$5 for incidental repairs during the fourth period of 18 months; that having now in the course of 6 years cost about \$436, the best plan would be to sell it, to be used on a farm, and for the value of the iron, for, perhaps, from 40 to \$50. Should the owner succeed in realising a sale at \$46, the remaining cost for six years, would be \$390, for one waggon, and for an outfit of ten waggons \$3900.

31. Waggon horses, for constant service upon a turnpike, would require to be well selected. For heavy draught they would require to be stout and strong, and in the prime of life, in order to be durable. Upon inquiry being made, respecting the price of such horses it appears, that, they usually cost from 120 to \$150, or higher; but I will adopt \$100 as a moderate estimate.

It is also stated that a set of new harness would cost about \$10, and its repairs in six years, including the new collars that would be necessary, as much more, at least. Thus each horse and his harness would cost \$120, and an outfit of 50 horses and harness, \$6,000, to which let \$3,900 be added for the before mentioned outfit of ten waggons, and the sum \$9,900 will be the required outfit for the turnpike.

32. Let inquiry be now made as to the durability of the horses. In McAdam on roads, printed by J. Robinson, Baltimore, 1821, page 86 to 92, it is stated on the authority of evidence that was given before a Committee of Parliament, that a stock of stage horses will fully wear out upon the roads near London in three years; but, that, at a distance from town where the work is lighter, and the roads as well as the food, stabling and lodging of the horses better, they are calculated to last six years. No mention is, however, made of any situation so favourable as to extend their duration beyond that period. Hence it may very rationally be inferred, that, waggon horses, constantly engaged in drawing heavy loads upon a turnpike, where the opportunity of their being supplied with good food, or a sufficiency of any kind, is often precarious, and where, instead of being in a comfortable stable during the night, (as is usual for stage horses,) they are exposed, destitute of any shelter, to all the injuries incident to the most inclement seasons, would not hold out longer than four years and a half, the average of three and six years, the two extremes above mentioned.

33. Again, according to the evidence of waggoners, and of persons of experience in the vicinity of Baltimore, turnpike teams of five horses, hauling two tons and a half, would not last longer than five years. It is understood that one horse, at least, upon an average, would be annually required to supply the places of those that should die, or otherwise become incapable of service. But in the foregoing instance from three to five years appeared to be the general estimate of the durability of a turnpike waggon. That the error, however, should there be any on either side, might be certain to be in favour of the turnpike, and not of the canal; I there made choice of six years in preference to five—for the same reason I have in this instance also concluded to adopt the term of six years; and having in conformity with this conclusion divided \$9,900 the aforesaid outfit by six instead of five, the yearly cost of outfit is \$1,650, instead of \$1,980; making an annual difference below what the general estimate would warrant of \$330 in favour of turnpike conveyance.

34. The waggoners would require to be trustworthy persons, and being understood to find themselves, their wages cannot reasonably be estimated at less than \$30 per month, that is \$360 each per year, or \$3,600 per annum for the ten. Upon turnpike roads where there is a great concourse of waggons, it is obvious that horse feed would, in all probability, be high. According to the evidence in this respect, the cost of each horse in 24 hours is usually from 62½ to 75 cents, and sometimes a dollar. But, for the reason before mentioned let 50 cents be taken as the average estimate, at which the yearly cost of each horse will be \$182 50, and of 50 horses \$9,125. By the evidence before me it further appears that each horse, upon an average, would require a new set of shoes every six weeks, or about 16 pair a year, which, at 50 cents a pair is \$8 per annum for one horse, and \$400 for 50 horses, with which, \$594, that is one year's interest on \$9,900 the turnpike outfit before mentioned (31) will require to be included.

35. The canal outfit would consist of a 25 ton boat, say 75 feet long and 9 feet beam, which at \$2 per foot would cost \$150. Owing to the comparatively light draught, that, for only twenty miles a day, would be presented by the boat, it may be fairly presumed that a horse equally competent to the performance, might, with greater facility, be purchased for \$80, than a waggon horse of the superior strength required for \$100. Owing again to the canal-horse having to travel on the smooth surface of a towing path instead of a turnpike, it may be further presumed, that his harness would cost much less, and his shoeing not more than half as much as the harness and shoeing of a waggon horse. But having before determined (33) that, should any thing, unintentionally, be either over or under-rated it should not operate in favour of the canal, but of the turnpike, I shall rate both these items at the same cost that has already been adopted for those of a waggon horse. Hence \$150 for the boat, 80 for the horse, and 20 for his harness, will together amount to \$250 for the cost of the canal outfit. Owing also to the turnpike wear and tear being abundantly more severe than that of the canal, the inference appears to be well founded, that this outfit would be quite as likely to last 8 or 10, as that of the turnpike 5 or 6 years. But for the reason before assigned I shall in this instance also adhere to the time of six-years; and hence one sixth of \$250, the sum above stated, will be \$42, nearly, the yearly cost of the canal outfit.

36. The boatman, it is true, ought to be equally as trust-worthy a person as a waggoner, but owing to the facility with which he may always take his needful accommodations in the boat, and by that means live nearly as cheap as at home, there is great reason to believe that \$25 per month, that is \$300 per annum, would be better for him than \$360 for a waggoner, under the disadvantages of being almost continually upon the turnpike. The boy's compensation, being usually estimated at half that of the boatman, will be \$150; and owing to the ease with which horse feed may be laid in, upon the best terms, and carried in the boat, \$100 per annum, (which is understood to be the cost of keeping waggon horses in the vicinity of Baltimore,) is believed to be an ample allowance for the cost of the canal horse, with which it will be necessary to include one year's interest, \$15, on \$250, the canal outfit before fore stated (35).

37. Having thus prepared the different items of charge on both sides, let them now be arranged together in one distinct view, to wit:

Charges on the Turnpike.

Annual cost for outfit	-	-	\$1650
Hire of ten waggons	-	-	3600
Keeping and shoeing of 50 horses	-	-	9525
One year's interest on 9,900	-	-	594
			<hr/>
			\$15,369

Charges on the Canal.

Annual cost for outfit	-	-	\$42
Boatman's wages	-	-	300
Boy's compensation	-	-	150
Keeping and shoeing one horse	-	-	108
One year's interest on \$250	-	-	15
			<hr/>
			\$615

38. In the next place let \$15,369 the sum of the turnpike charges, be divided by \$615 the amount of those of the canal, and the quotient being 25, it follows with all the certainty of correct calculation, founded upon clear and substantial evidence, that money appropriated and expended to the best advantage in the opening of

a canal, is expended in such a manner, as to be twenty-five as beneficial to the public as the same sum could be, had it been applied to the making of a turnpike road.—Q. E. D.

39. The last words of the proposition, stating, that, *a mile of canal is often made at less expense than a mile of turnpike*, is intended to be explained in my next number. But at present, it may be proper further to observe, that, as the toll usually estimated to be charged upon a canal is only *one cent per ton per mile*, or \$5 for 25 tons 20 miles, and that which is commonly collected upon a turnpike is twelve cents and a half for each horse the same distance, that is \$6 25 for 50 horses 20 miles, the turnpike toll exceeds that of the canal for equal weight and distance, 25 per cent. For further illustration, however, let it be admitted that this difference did not exist in favour of the canal; that on the contrary, the tolls in both cases were equal, and that the cost of the one was also equal to that of the other; then, by subtracting \$12,300, that is 20 times the canal charges, from \$15,369, the remainder, \$3,069, will be a clear surplus annual gain to the public, exclusive of the twenty-fold advantage that was proposed to be proved. The toll of 25 tons for passing 20 miles along the canal has already been stated to be \$5; or in other words, the toll per day is \$5, that is, \$1500 for 300 days, or a year, were the boat to be so many days upon the canal with a full cargo on board. To this yearly toll add \$615, the yearly charges, and the sum \$2,115 being taken from \$3,069, the surplus annual gain before mentioned, there is still a remainder of \$954, which proves not only the reality of the proposed twenty-fold benefit to the public, but also of the sum last mentioned remaining for incidental purposes, exclusive of an amount, equal to that of all the anticipated charges for freight and toll into the bargain.

WILLIAM KENWORTHY.

AGRICULTURE.

TO THE EDITOR OF THE AMERICAN FARMER.

ON THE CULTURE AND DRESSING OF HEMP AND FLAX.

New York, 24th April, 1823.

Dear Sir,

Agreeably to the promise which I made you some time since, I herewith send you a communication from a friend, upon the subject of preparing flax and hemp; and altho' my experience does not enable me to corroborate all of this gentleman's statement, yet, from his judgment and respectability, I have the fullest confidence in their correctness.—And if what he has so clearly and confidently stated, be correct, what is to prevent our country, within a very few years, from largely exporting what we are at present compelled to import from the interior of the frozen regions of Russia? It has been stated to me that the hemp which we import from Russia, is, in many instances, brought from one thousand miles in the interior. That it is two and three years getting from the spot where it is produced, to this country, and that it must consequently, in almost every instance, become more or less damaged. It is a fact perfectly well established, that every part of our extensive continent, and particularly the north and the west, are admirably adapted to the culture of both these articles. Our rich bottom lands, and even our hills are as well calculated for them, as any other part of the globe; and, the only difficulties hitherto felt upon the subject, have been the unpleasantness and difficulty of water rotting, and the almost insuperable one of dressing them afterwards. The latter, however, is universally admitted to be the

most appalling.—The machine which Mr. Goodsell has recently invented, has fully and completely removed this objection. The dressing, which comprehends the breaking and scutching of flax and hemp, is now performed with so much ease and expedition, that what was formerly considered a servile and excessively laborious occupation, and performed by slaves only, or the lowest class of labourers, is now considered as light, and not by any means unpleasant.—After having succeeded in contriving the only machine that I have ever seen or heard of, in this or any other country, that deserves the name of a flax and hemp dresser, Mr. G. was naturally led to the investigation of the important subject of preparing them for the machine, by the trials which he made, and the conclusions which he has drawn: I am induced to believe, with him, that in every instance where it can possibly be done, water rotting should be preferred. The bleaching process relates particularly to flax—for hemp, plain water, of which we all know there is enough in the country, without the aid of alkaline salts, to answer all the purposes of solvents, is quite sufficient.—Hemp that is immersed: 48 hours in warm weather, in common soft water, and the water changed and the plant suffered to remain forty-eight hours longer in it, and this too changed, will be found to be in a very trifling degree offensive, and entirely freed from the colouring matter, so apt in land rotting to become fixed in the fibre, and so exceedingly difficult afterwards to be removed by bleaching. It is the same with flax. But hemp, for ordinary purposes, wants no bleaching.

No subject, in the whole round of agricultural improvement, has excited more interest, for the last three years, than that of "preparing" and "dressing flax and hemp"—It has been vainly imagined that both might be done with machines without being compelled to resort to the tedious and disgusting process of previously rotting them. But this idea, hastily adopted, because greatly desired, has been timely abandoned by the most enthusiastic and confident.—It is found to be impracticable, and if it could be done, *even in quantity*, which is impossible, the expense and labour of extracting the gum and mucilaginous matter afterwards, would be found to quadruple that which is incurred while it remains in the plant. That project must, of consequence be abandoned. And it is known also that land or dew rotting, especially for hemp, is a waste of the article. The preparation of the land, the pulling or cutting of the crop, and the dressing of it, are all the same whether it is land or water rotted; all the expenses attending its culture are equally as great as is the labour, and yet the article when brought into market is, when water rotted, worth full forty dollars a ton more, than that which is land rotted—this is surely worth attending to.—Our Orange county land rotted hemp, although of as good a fibre as any in the world, seldom brings in market within forty dollars of the price of first rate Russia hemp, and it arises altogether from its being land rotted; and the cultivators know this fact.

We have the seed, soil and climate.—We have water to rot and a machine to dress them—and if our farmers do not cultivate flax, and hemp, and water rot and produce articles of as good, if not superior quality to the Irish and Russian, they ought not longer to complain of hard times and poor crops. We export flax seed to Ireland for them to sow at 5 and 10 guineas a cask, for the purpose of supplying us with flax and flaxen goods. I am credibly informed that the superior American canvass which is manufactured at Paterson, in New Jersey, is made of Irish flax, from American seed!—And that about \$60,000

is annually paid for this article alone, for this one factory—and this immense sum is gained by the Irish people, from their attention to the rotting alone, for we can certainly grow the plant as well—and I know that it can be better dressed here. But my dear sir, my subject has run away with me. In truth, I had forgotten myself, and must beg you to do with this letter what you think proper. Mr. Goodsell's, I think, may be of great service, and therefore desire to have it inserted at full length; but you may cut me up as you please. I send you a dozen engravings of my flax machine—pray distribute them amongst your friends. If you will publish the engraving, I will send the wood-cut on to you in a few days; but this I will not do until I hear from you, whether it will be convenient and agreeable, or not.

I remain, dear sir,

Your's most respectfully,

SAMUEL SWARTWOUT.

P. S. I have omitted, in the preceding part of my letter, to notice this machine as a most complete grain thrasher, as well as flax and hemp dresser. It is, in fact, a better thrasher than we have ever had here, for the reason that one horse and a man, if the grain should be reaped, can with ease thresh 100 bushels of wheat a day, for the sheaves need not pass away from your grasp, but are held to the beaters at K, (see engraving) and instantly thrashed. I have actually thrashed clean a sheaf in two seconds! When grain is cradled and uneven, containing scattering heads in the butts of the sheaves, the whole is suffered to pass under the beater, which will take up a little more time, and will require another hand to remove the straw. A fanning mill may be attached to it, and thus fan the grain as it is thrashed. But as this is not very important, the great labour being in separating the grain from the straw, it may, or may not be done by those who fix up one of the thrashers. You will also perceive that the very same machine answers the double purpose of grain thrasher and flax and hemp dresser—a trifling alteration, but no additional expense being necessary to produce the desired change.

Your's, &c.

S. S.

TO MR. SAMUEL SWARTWOUT.

Paris, Oneida County, April 1823.

DEAR SIR,

Having noticed in the American Farmer of the 27th of September last, a letter from his Excellency, Governor Wolcot of Connecticut, addressed to S. W. Pomroy, Esq. requesting "information upon the subject of preparing flax." I have thought that the following facts might throw some light upon the subject, and thereby induce, perhaps, some of our spirited agriculturists to aim at the production of an article of the first quality and value. And, although I am sensible that many serious objections will be made to the method which I have adopted, and which I would most strenuously recommend to others, from all apprehension of its being too troublesome, as well as offensive; yet if what I shall state, be thought worth publishing, you are at liberty to send it to Mr. Skinner.

I have made many experiments the year past, with flax and hemp. I do not allude to the cultivation of the land, but as to the best method of preparing the plant for a more expeditious way of dressing, whilst the article itself, should at the same time, be every way improved. Hitherto, dew or land rotting, for the reasons given in Gov. Wolcot's letter, has been generally practised; but, I am prepared to show, that *water rotting*, in all cases, where it can be done, is most un-

questionably to be preferred.—1st. It is more durable for all the purposes to which it is applied, a fact perfectly well known to those who manufacture sack and cordage. 2dly, It is more easily bleached—and 3rdly, It will yield a greater quantity of fibre from a given quantity of the plant. My own experiments with respect to the superior durability of water prepared flax were very satisfactory. I placed on the ground a quantity of flax that had been sufficiently water rotted for dressing, by the side of an equal quantity of *unrotted* flax, and turned them once in 3 days, until the new flax was sufficiently rotted for dressing also, and upon examination, I found that that which had been previously *water rotted*, had lost none of its strength, and that it had not altered in any respect, except in its colour, which was a little brighter than when laid out—both parcels were now suffered to remain upon the ground until the dew rotted became *worthless*, when the water rotted was found to be still strong and good—I repeated these experiments with dressed flax, and with the plant, and found the result the same.—This, in my mind, fully established the very important fact, that *water rotted flax or hemp* is infinitely superior to that which is dew rotted.

I made an attempt next, to ascertain the proportionate loss in weight, in each process of rotting, and found them both nearly equal, viz: about 25 per cent; but I found at the same time, that the produce of this equal quantity of plant, differed materially in weight. When it came to be dressed, the dew or land rotted averaged from 12 to 16 lbs. of fibre only, whilst the water prepared, gave from 16 to 25 per cent.—This difference in weight I consider to be quite sufficient to defray the extra expense of water rotting, whilst the value of the article would be enhanced one-third more.

My strong desire to investigate this subject fully, induced me to make other trials, by boiling and steaming, in order to avoid the rotting process altogether: but I did not succeed in any of them sufficiently, to warrant their recommendation to the public—on the contrary I became convinced that neither would answer.

My next investigation, was an attempt to ascertain the nature of the substance, in which the fibre lies embedded; and found it to consist of gum, mucilaginous matter, and a peculiar kind of vegetable extract, containing a small quantity of tan.—These substances were precipitated from their solutions, by means of re-agents; when, after drying, the gum bore a greater resemblance to gum lac, than to any other substance, and was perfectly soluble in solutions of pot-ash, whether caustic or carbonated—and also capable of being dissolved in alcohol.—The other parts, as mucilage and extractive matter, were soluble in water. Hence I conclude that pot-ash is the cheapest solvent for cleansing flax, and that this can be best applied when it has been cleansed from the woody part, and manufactured into cloth.

In the management of hemp and flax, I would recommend the following method, because it saves labour, and is more convenient to dress:—when the plants are pulled, care should be taken to sort them, by putting the longest lengths by themselves; and for the purpose of facilitating the handling of it at the machine, it is well to put about *one* pound of the plant into a bundle as soon as the seed is thrashed, which is done with exceeding expedition by the machine. Let it be put to rot in water. The surface, after the plant is immersed, to be covered with boards or straw, or any thing else to exclude the sun's rays, which will cause the whole to have the same colour.—If troughs or vats are made use of, I would certainly recommend them, where

the farmer can possibly procure them—after the plant has been forty-eight hours in water, it should be drawn off, when the water will be found to be exceedingly discoloured, and this should be repeated; after which let the plant remain immersed until it be sufficiently rotted, which must, of course, be determined by experience and judgment. The disagreeable smell, so much dreaded and deprecated, will by this pro-

cess, be greatly diminished.—When the weather and the water were both warm in summer, I have known them rot in seven days—in other instances, in cold weather, I have known them to lie buried for ninety days, without injury.

I am, Sir, with the greatest respect,
your ob'dt servant,
(Signed) NAMAN GOODSSELL.

GOODSELL'S PATENT HEMP AND FLAX DRESSER, AND GRAIN THRASHER.

REFERENCES.

A A A, the Frame—B, the Cylinder—C C C &c. 8 Beaters of wood, 2 inches by 1½, made of maple or other hard wood, and rounded on the inside. D D D D, &c. 8 Scutchers or Slats of wood, 2½ inches wide, and ¼ thick, 2 feet long, the outer points cut conically. E, the Hackle—F, Small Whirl, 8 inches diameter, fixed to the axis of the Cylinder—G, Vertical Drum, 6 feet diameter, on the axis of which is a Whirl, 18 inches diameter—H H, Leather Strap or Band 5 inches wide, which runs over the drum G and the small Whirl F—I, Horizontal Drum, 12 feet diameter, around which, and the large Whirl on the axis of G, passes a band or strap, which turns the Drum G, and puts the whole machine in motion. K, Husk or Rest, over which the Hemp, Flax or Grain, is held, when broken and beaten by the Cylinder. L, Scutching Board over which the Flax is held after being broken by the Cylinder, and when it is to be whipped out clean of the sheaves by the Scutchers D D D &c. *not used for Grain*.—M, Upright Plank, about three feet high, with a notch in the upper end, sufficiently large to allow the outer end of the Scutching Board L to play 3 inches.

The above proportions are calculated for a horse who walks 3 times round his path of 24 feet diameter in a minute. One horse is quite sufficient to drive it. When water power is made use of, the large wheel and its accompanying figures are dispensed with. The cylinder per-

forms best when driven at the rate of 200 revolutions in a minute.

The above described machine is cylindrical in its form, and made entirely of iron, excepting the beaters and scutchers. Weighs about 200 lbs.; is 5 feet long and 2½ feet diameter; may be made in 3 days, and is calculated alike to break and dress both hemp and flax, in a style superior to that dressed by hand, and at the same time to thrash from 60 to 80 bushels of any kind of grain a-day. It is not calculated, however, to dress either hemp or flax in an *unrotted state*. They are both to be well rotted, when 100 lbs. of flax and from 200 to 300 lbs. of hemp can be dressed by one man in a day.

For breaking flax, the frame or husk K, (which describes a segment of a circle under the cylinder) is placed within about ½ of an inch of the cylinder itself. Here the sheaves are forced endwise under the cylinder or breakers, the small end first, and when sufficiently broken, the other end is put under; and when the whole is broken, the operator turns to the scutchers, where the dirt and sheaves are entirely beaten out. For this operation, about one pound of the plant at a time, is found to be the most convenient and manageable quantity.

For thrashing grain, the frame or husk K, is to be moved back from the body of the cylinder, full 2 inches; a broad board to be fixed on the resting board, at an inclination of about 2°

greens, to prevent the grain from doubling and falling outside of the beaters. The sheaves (of about half the size of the common bundles) are then to be forced endwise under the breakers and turned, and if any heads of grain remain in the butts, they are to be suffered to pass under the cylinder.

This machine, for simplicity of construction, exceeding durability, ease and perfection of its performance, cannot be surpassed by any other

Fig. 2.

Brake, for Large Hemp, but not required for the small or ordinary sized Hemp, nor for flax.

REFERENCES.

A, the Frame—B, the Bed—C, Fluted Roller—D, Pendulum—E, Pitman, which is put in motion by means of crank F, attached to axis of the Drum G, at A, in fig. 1.

The Crank F, being attached to the axis of the drum G, sets it in motion. The small end of the hemp is first forced under the roller C and when broken the other end is in like manner broken. The slats in the bed B, are to be made from 2½ inches to three inches asunder, and the flutes of the roller C to correspond.

In reply to an enquiry of Mr. Swartwout at New York, about the price and demand for hemp, the editor is informed that "the price of dew or land rotted hemp, is from 100 to 120 dollars a ton. That of water rotted, is from 175 to 200—One of the most extensive as well as respectable dealers in the article, and a gentleman of as much judgment in it as any in our city, informed me to day, that although American dew or land rotted hemp was a very inferior article, and not worth within 70 dollars a ton as much as the Russia; yet, the American water rotted hemp, which is well dressed, is worth as much and will bring as great a price as the Russian. He is perfectly enthusiastic upon the subject; has seen our little Cylinder work, and has the promise of a ton at least, of my hemp the next fall; which I will rant shall be equal, if not superior to the ve-

work of art. In addition to the uses already enumerated, at a trifling expenditure for a covering of iron, perforated like a grater, it becomes a clover cleaner, that will clean 8 bushels per day; and by adding a set of steel plated knives, screwed to the beaters, it becomes at once a superior straw-cutter.

The price of a Machine, with the patent right, is 60 dollars.—Counties and Towns sold upon advantageous terms.

tended culture of flax and hemp, in a manner to become leading staples in the northern and western states. We do therefore recommend to all farmers to cultivate largely both flax and hemp the present year, in a full belief that they may safely repose confidence in the facilities they will derive by the introduction of said machine into general use.

Albany, April, 1823.

We the subscribers fully concur in the foregoing certificate, and beg leave to subjoin our testimony to its valuable properties as a *grain thrasher*, having seen it in operation at Mr. Samuel Swartwout's place, opposite the city of New York, May 3, 1823.

Signed,

Herman Le Roy, Jos. G. Swift, Thomas Morris, Thomas Freeborn, Franciscus C. Tucker, W. P. Van Ness.

S. Swartwout, Esq. Hoboken, near the city of New York, is the patentee of the machine.

TO THE EDITOR OF THE AMERICAN FARMER.

Poplar Grove, St. Paul's, S. Carolina, May, 20th, 1823.

SIR,

A correspondent in one of your late numbers, asks for information through the medium of your paper, relative to the reclamation of marsh land, which is covered with a heavy growth of trees—such as ash, maple and gum. He says, that an impression exists in his neighbourhood, where large bodies of that land are to be met with, that woodland marsh, when reclaimed, will sink more than that which is free from wood. If any conclusive experiment has been made of this kind of marsh, I should be pleased to know the result; when convenient, if you will make the necessary enquiries, to obtain information on the subject, I shall be obliged to you. As I have derived much instruction, and received a great deal of pleasure from the perusal of your interesting paper, I will lay before you the result of an experiment, which I think will be conclusive to the mind of your correspondent, that I have made upon two hundred acres of marsh land, which was once as heavily wooded with cypress trees, as perhaps any swamp in Carolina; and of which I gave you some little account in vol. 2, No. 44.

My plantation is so situated, that at the lower extremity, where I formerly embanked about two hundred acres, the tide water is generally brackish, and often times salt. It is so embodied with the old rice fields, that in order to supply it with the quantity of water necessary for the cultivation of rice, I dug a canal of twenty feet wide, and four miles long, entering the creek where the tide ceases to flow, and where from the drainings of a swamp many miles in extent, it is generally fresh; from whence at the flood tide my rice fields are supplied, and assisted in a drought by a long reservoir of water. The beautiful level appearance, all alluvial soils, exhibit to the eye, connected with its natural richness, induced me, about the years 1793 and 1794, to commence the undertaking, and which I have never had reason to repent. After many laborious and ineffectual attempts to get rid of the rushes, and turn up the land with ploughs and

...oes, I became almost disheartened, being at a loss in what manner to proceed to effect pulverization, without which, the scheme must prove abortive. It occurred to me, that notwithstanding my ditches were dug three feet deep, there yet remained too much sobbiness in the land, to allow the successful operation of the plough. Satisfied of that fact, I dug up my river trunks, and replaced them at six inches above low water mark, sunk the ditches to the depth of five feet, and struck quarter acre drains about three feet deep. The effect was visible in the course of a few months; the rushes being deprived of that nourishment, they had been accustomed to receive from the sobby state of the land, died away. A fire was then applied on a windy day, which consumed them. The plough and hoes were again resumed, and I had the satisfaction of seeing the work progress. The land having now assumed a light husky appearance, very much resembling the peat morasses in Scotland, was thrown into large potato, or corn beds. In a short time a fire was again applied, which burnt them smooth to the ground, leaving ashes of a red colour. It was repeated during the course of the winter, and in the spring, partial crops of corn, oats, barley and rye were planted upon a small scale—all of which failed. Perseverance, however, in tillage, and attention to the depth of my ditches, at length overcame all these discouraging results, the land, in due time, produced rice, cotton, corn, barley, rye and oats, all of which I have had since, growing as a part of my crop, particularly barley, which was harvested about the 15th May; and the land immediately planted in rice, making it produce two crops in one season.

The land, by constant cultivation, has sunk so much, that it is almost incredible to suppose the probability of a plough, drawn by oxen could have gone over many parts of it. Large cypress stumps and roots have since risen up, and now shew themselves 18 or 20 inches above the surface of the land, with the visible marks of the axe. The main bodies of the trees have been removed, many of them six feet in diameter; here and there a large limb is found, which has been squared by my carpenters, and carried home, for the purposes of building—and here, Mr. Editor, arises a question for those who are fond of diving into these matters, who were the persons that applied the axe, and to what market were the trees carried? From the above statement, I think your correspondent will view it in the light of a conclusive experiment, that heavy wooded marsh land sinks more than any other kind of land without wood.

Before I conclude, I will adduce one more instance, still more conclusive, of the excessive sinking of this kind of land. In digging the canal, above mentioned, a piece of the land in question, consisting of about 20 acres, was enclosed by the embankment, wooded with the identical kind mentioned by your correspondent—ash, maple, gum, besides a few very large lob-lolly pine trees, a quantity of palmetto and cedar bushes, and the greatest part covered with rushes. This land, through which a creek runs, was so completely raised, that nothing but a very high spring tide, aided by an easterly wind, could at all affect, (the tide with me rises six feet)—knowing it to be of the very first quality, I ordered it to be cleaned. Since which, it has produced abundantly of every kind of grain, planted on our low country. It now ranks among my first rate fields, and often produces fifty and sixty bushels of rough rice to the acre.

I remain,

Very respectfully,

CHA'S E. ROWAND.

ON THE MANAGEMENT OF HORSES AND DOGS—BY AN EXPERIENCED SPORTSMAN.

(Continued from page 69, vol. 5.)

Of the Queen's Dog Physician.

There was a fellow in this town (I forget his name) who was called the Queen's Dog Physician. From his attending her majesty's dogs, he went to all the women of fashion, to doctor their dogs also. He never would undertake them, unless he was permitted to take them home with him for ten days. There was seldom any thing more the matter with them than a gross habit of body; fat to a degree, from the scandalous method they are fed, giving them every day, more good meat than would supply two poor children. When he got Chloe home, he physicked her, and gave her nothing but dry bread for some time. She would not eat the first three or four days, of such insipid food, and, the first day, howled most bitterly; however he soon cured her of that, by giving her four or five sound floggings, to prevent her annoying his neighbours. I think it scandalous to give dogs what a human being would be grateful to receive: however this must be passed over in oblivion, provided a gentleman be making love to the lady, for then it is necessary to make a considerable deal of love to the lap-dog also. In about ten days the Queen's dog physician brings my lady her dog home, as fine as a star, sleek in his coat, and in tolerable good condition, for he has fed it tolerably well for the last four or five days. Her ladyship is charmed with the looks of her dog; he is as merry as a grig; jumps, frisks, and plays about; when, before, he could hardly walk down stairs to dinner. She says him very handsomely; he goes away contented, laughing in his sleeve at her ladyship.

Concerning Mad Dogs.

I have mentioned all the fatal and bad maladies to which a dog is subjected, excepting madness. Fortunately, no dog of mine ever went mad, or was bitten by a mad dog; therefore, on that subject, I can give no just opinion: but, provided I had a dog, ever so valuable, bitten very deep, particularly if near to the head, I would destroy him. If he were bitten but slightly, I would cut the bitten part out, and burn the wound well with a hot iron; then pour some *liquid caustic* on the wound, and rub in, two or three times every day, some very strong mercurial ointment; and, for certain I would give him *twelve grains of Turbith mineral*. Osmer asserts positively that he has given it to many dogs, badly bitten, and never knew it fail: and several others assert the same. I would rub strong mercurial ointment into the wound every day, for at least one month; and give him, every week, for a month, two doses of the Turbith mineral. Provided a dog went mad in my kennel, I would discharge the person who looks after them; for no dog goes mad without first rejecting his food. The moment a dog refuses his food, or feeds very sparingly, he should be taken from the others, and chained up in some safe place.*

Of Dog's Feet: how to treat them.

I shall now proceed, and speak concerning dogs' feet,—the most essential point about the animal; for, without a good, firm foot, he can never hunt long. I never look at a dog which has a thin, flat, wide, and spread foot; they are not worth two-pence.

It has been a constant custom with me to wash my pointer's feet with strong salt and water after the day's sport. I have found my error, and am convinced that it is a wrong practice. I never

* Any man who would keep a dog one day, after he was bitten by a dog known to be mad, ought himself, to be put in a strait jacket, and sent to the Lunatic's Hospital.—*Edit. Am. Far.*

altered my method until three years ago. A gamekeeper in Suffolk seeing that a boy was washing my dogs' feet with strong salt and water, (his name was Cooper,) said to me: "Sir, I think you do wrong to wash your dogs' feet in salt and water, at this early part of the shooting season, (it was the first week in September), at this time, sir, when the ground is uncommonly dry, and as hard as a rock. If you will feel their feet, you will find there is a considerable degree of feverish heat in the dogs' feet from having hunted all day on hard and dry ground. A dog, sir, in such weather, should have his feet suppled and comforted. As long as the ground is dry and hard, I always wash my dogs' feet with warm soap and water, and clean them well, particularly between the toes' and balls of the feet; this comforts his feet, allays the heat, and promotes the circulation in the feet. In the more advanced period of the season, when the ground is very wet, then salt and water may be proper." I approved much of the reasons he gave; it shewed the sense of his practice, and the folly of mine: since that period I have taken his advice.

Friar's Balsam for wounds in Dogs' Feet.

WHEN DOGS' FEET ARE CUT BY FLINT AND BY OTHER ACCIDENTS, FRIAR'S BALSAM I HAVE USED FOR YEARS, AND FIND EXCELLENT. You may generally hunt the dog the next day, with a piece of strong wash-leather, four double, tied round the foot; and when their feet are chafed or galled, or the skin is absolutely worn off, FRIAR'S BALSAM is the only thing I ever have used for many and many years.

Of the Canker in the inside of Dogs' Ears.

Dogs are sometimes afflicted with a disorder, called the canker, in the inside of the ear, and some distance in it also. In this disorder I have never had much practice, for I do not recollect that I ever had above four or five dogs so disordered. I have found the following method beneficial. Lay the dog down on his side, with that ear, in which the disorder lies, uppermost: put a lump of soft soap, as big as a walnut, into the ear; pour one table-spoonful of brandy on it; hold the ear close, and rub it well, until the soap comes to a lather; then pour another table-spoonful, and so continue to do, until you have used three or four table spoons-full, constantly rubbing the ear till the soap and brandy be well mixed. Use this method three or four days following. This disorder is known by the dog shaking his head perpetually, and by his smacking his ears against his head and neck; a nasty, stinking humour is also discharged from the ear.

The Canker on the outside of the Ear, with the Cure.

There is another sort of canker, which generally lies at the tip, or bottom side of the ear. This is very visible to the eye, and dogs are very subject to it. I will state to you a method of treating this disorder, invented and practised by that celebrated physician Doctor James, the inventor of the fever powders, who paid much attention to the disorders of dogs. I am certain I have used it to fifty dogs, and never knew it fail.

TAKE EQUAL PARTS OF RED PRECIPITATE AND HOG'S-LARD, WELL MIXED TOGETHER. Brush both sides of the dog's ear where the disorder lies, with a soft tooth-brush, having some of this ointment laid on it. Be sure never to brush against the hair, but always the way the hair lies. About four dressings, once every day, is generally sufficient.

Provided you do not choose to rub your dog in with the quick-silver ointment, and dab him with the quick-silver dissolved in oil of turpentine, when he has got the mange; (in the former pages of this book, I have told you how to make them;) the following is the best thing I know, after the mercurial ointment; and, before

I was acquainted with that, I always used it, and found it answer well; but then it must be used at least three times, which causes much trouble. It is made after the following method. Take HALF A PINT OF TRAIN-OIL, HALF A PINT OF OIL OF TURPENTINE, HALF A POUND OF SULPHUR VIVUM, (the black coloured sulphur, and not the flower of brimstone,) and ONE OUNCE OF ROACH ALUM, VERY FINELY POWDERED; MIX THEM ALL WELL TOGETHER. It certainly is not prudent to use a strong mercurial ointment and wash, in very cold weather, nor unless your dog lies warm and dry. I know not what might be the consequence of such imprudence; but surely with proper care, the dog can receive no injury.

The most cursed and tormenting malady a dog can have, is to be badly troubled with worms. Give him the best of food it does him but little good: he always looks unkindly in his coat, and will not carry flesh. I have generally been very successful in destroying the worms in dogs, BY THE USE OF CALOMEL; nor have I used any thing else for years: THE QUANTITY I GIVE IS TEN GRAINS; FOUR DOSES, STOPPING ONE DAY BETWEEN EACH DOSE. This year, 1813, I had a dog so troubled with them for about ten months, so very bad, that I could not destroy them. I tried many things: first, *four doses of calomel*, ten grains in each dose; then I gave him *savin*; then bear's-foot; after that, *powdered glass*, four doses, as much in each dose as would lie on a shilling, heaped up. Then a medical gentleman of my acquaintance told me that I did not give him enough calomel; but that first I should boil a pint of milk, cool it, and sweeten it well with brown sugar; give this first to the dog, that the worms might feed well on it, and in about twenty minutes afterwards, give him *twenty grains (one scruple)* of calomel. This I gave him three times; it brought a number of worms from him; but, in about 5 or 6 days, he had nearly as many as before; then I knew not what step to take with him. One day, by chance, I met with a very old acquaintance of mine, a tradesman, and happened to mention to him how terribly the dog was troubled with worms. He said: "It is very singular, sir, having known me for so many years, that you should not be aware that I have cured some hundreds of the human race, and my medicine is equally efficacious to the brute creation. This medicine is nothing but the LEAVES OF THE WALNUT TREE. In summer, when the leaves are green, they must be dried and baked in a plate before the fire, then rubbed to a fine powder with the hands. In winter, when dry, you must buy them at the medical herb-shop. I gave my dog TWO LARGISH TEA SPOONS-FUL, HEAPED UP; first boiling half a pint of milk, letting it cool, and putting the powdered leaves into it: the dog will take it well; but he will not take it in grease, for the leaves have a very strong taste and smell. By the by, I caution all sportsmen never to give dogs milk, which has not been boiled, for it will purge them as much as a dose of physic. I gave my dog, eight days following, one dose; after which, for *above two months*, he never voided one single worm.

There is a peculiar excellence in these leaves; they never, in the least, purged my dog: his body was in the same state, as if I never had given him any thing. This is a vast benefit; for, as it does not purge the dog, it may be given him even when he hunts. I am told by medical men, who have studied botany, that walnut leaves are a positive poison to worms, but by no means detrimental to man or beast.

You may observe, in the autumn, when the caterpillars and grubs eat the leaves of trees, and troy the garden-stuff, you will never see the leaves of walnut-trees eaten by them: no caterpillar or grub will approach a walnut-tree. Be-

sides, I give you another proof of their abhorrence of walnut leaves: in summer, when the ground is so dry that you cannot dig for worms to go fishing with, fill a pail, about one-third full, of walnut-tree leaves, and pour a large kettle of boiling water on them; cover the pail over with a thick cloth, and let them stand till cold; then go to a bowling-green, where you observe many worm-casts; spread the water over the grass, and the worms will immediately come up above the ground.—*This I have tried.*

Miscellaneous.

FROM THE ARCHIVES OF USEFUL KNOWLEDGE.

ON DISTILLING APPLE AND PEACH BRANDY.

Cooper's Point, 22d Oct. 1810.

The great plenty of fruit the present year, and the bad quality of the spirit distilled from it, in the common way, induce me to communicate some observations on that subject.

The first evil is, running it too long in the first stilling, which, beside injuring the spirit, will not pay for the time lost, and wood consumed thereby. The second, and most injurious is, in rectifying, or second 'stilling; the running it too long, or till the spirit has an ill or disagreeable flavour, which greatly injures the whole that it is mixed with. The third is, want of care to put the liquor into clean casks: the contents of one rusty or offensive one, will spoil the spirit of ten times its quantity, if mixed with it. From the experience of more than sixty years' practice in distillation, I find it best to shift the receiver as soon as the spirit runs as low as first proof, and to keep the remainder to 'still with the low wines, or till there is a sufficient quantity to fill the still, with the addition of about one-third water, which will imbibe much of the ill flavour, and leave the spirit more pure. But to make apple brandy to put into wine, or for other particular purposes, I would recommend filling the still half or two-thirds full of good spirit; then to fill it to a proper degree with water, run it so long as the flavour is good, and treat the remainder as before. This operation I call washing; and apple brandy, thus prepared, is preferable, for putting into wine or cider, to any other spirit whatever; and, for common use, I have been in the practice of reducing high proof spirit with the last running from a cheese of good cider or water cider, put in previously to the fermentation of the cider. That process will greatly improve the quality of the spirit, especially for mixing with water, and make it more mild to the taste in one week, than a year's age will when managed in the common way. A further improvement may be made in apple brandy, by putting in the still, when rectifying, two, three, or more pounds of sassafras root in what will make a barrel of proof spirit: a sufficient quantity of sassafras will give it the flavour of peach brandy, and in my opinion, if reduced as above, will make it full as good.

Although many persons are opposed to the distillation of cider, from religious principles, it appears to me that spirit is really necessary in many cases; and apple brandy, managed as above, and kept to a proper age, is as agreeable and more wholesome than what is generally procured, at great expense and risque, from other countries. Early-made cider, and that from rotten apples is unfit for other purposes.

JOSEPH COOPER.

MAJOR ADLUM'S WINE.

The editor of the National Intelligencer says: Having lately the pleasure of visiting his vine-

yard, we were agreeably surprised, as well at the extent and flourishing appearance of the vineyard, as at the goodness of his wines, especially considering their age. We have little doubt, that, with the advantages of a proper age to his wines before they are used, and the light of the experience which he has already had, Major A. will be able to furnish wines which will bear a fair comparison with some of the most delicate and approved wines of Europe. The successful introduction of this culture will be of great importance to this country, whether we regard the product as an article of merchandise or as a partial substitute for the corroding distilled liquors, now so generally used among us.

Old Wines.—The passion for old wine has been sometimes carried to a very ridiculous excess; for the "thick crust," the "bee's wing," and the several other criterions of the epicure, are but so many proofs of the decomposition and departure of some of the best qualities of the wine. Had the man that first filled the celebrated Heidelberg tun been placed as a centinel, to see that no other wine was put into it, he would have found it much better at 25 or 30 years old, than at 100 or 150, had he lived so long and been permitted now and then to taste it.

At Bremen there is a wine cellar, called the Store, where five hogsheads of Rhenish wine have been preserved since the year 1625. These five hogsheads cost 1200 francs. Had this sum been put out to compound interest, each hogshead would now be worth above a thousand millions of money; a bottle of this precious wine would cost 21,799,480 francs; and a single wine glass 2,723,808 francs.

THE REVENUE.

Abstract of the Net Produce of the Revenue of Great Britain in the Years and Quarters ended the 5th of April, 1822, and the 5th of April, 1823, shewing the increase or decrease on each head thereof.

	Years ended April 5.		Increase	Decr.
	1822.	1823.		
Customs	9,335,711	9,406,642	70,931	—
Excise	26,695,623	25,546,922	—	1,148,701
Stamps	6,227,318	6,200,060	—	27,258
Post Office	1,288,000	1,369,000	81,000	—
Taxes	7,518,708	6,874,855	—	643,853
Miscellan.	320,483	426,578	106,095	—
	51,385,843	49,824,057	258,026	1,819,812
	Deduct Increase			258,026
	Decrease on the year			1,561,786

	Qrs. ended April 5		Increase	Decr.
	1822.	1823.		
Customs	2,099,878	2,109,408	9,529	—
Excise	5,856,798	5,656,279	—	200,519
Stamps	1,582,346	1,573,854	—	8,492
Post Office	320,000	330,000	10,000	—
Taxes	980,916	861,764	—	119,152
Miscella.	63,621	76,799	13,178	—
	10,903,560	10,608,104	32,707	328,163
	Deduct Increase			32,707
	Decrease on the quarter			295,456

By the above abstract, there appears to be a decrease, in the year, of £1,561,786; and, in the quarter, of £295,456, as compared with the corresponding year and quarter. The decrease, however, has been produced by diminished taxation—namely, the reduction of the Excise Duties on malt, salt and leather, and the repeal of the Agricultural Horse Tax. There is a surplus over the charge on the Consolidated Fund of £2,133,769: in the corresponding quarter of last year it was only £1,545,047.

FROM NILES' WEEKLY REGISTER.

LONGEVITY.

According to the census of Great Britain, the population, in 1822, is as follows:

In England, Males	4,808,898	} 9,830,461
“ Females	5,021,563	
Wales, Males	342,154	} 880,210
“ Females	538,056	
Scotland, Males	923,546	} 1,956,706
“ Females	1,033,166	

Total, 12,667,377

In this population, there were 100 males and 191 females about the age of 100.

The population of Great Britain in the year 1720, according to Colquhoun, was 6,955,000—as there are now living therein 291 persons upwards of 100 years old, we then find it out, by the rule of three, that an original stock of twenty-four thousand individuals, is necessary in Great Britain to furnish one centenarian.

I do not know of any statement shewing the probable amount of the population of those then uninhabited regions, which now compose the United States, 100 years ago, more entitled to respect than that produced by my own calculations, and published in this work, vol. XIII. p. 179—on which occasion every thing like authority within my reach was resorted to. I supposed that the whole population, exclusive of Indians, may have amounted to 490,000, in the year 1725—if so, and in the year 1825, we shall have twenty individuals, only, of the age of 100 and upwards, it would appear that our climate and country are as favorable to long life as Great Britain. But some allowance must be made for the emigration of persons, of mature age or advanced in years, since 1725; and it is reasonable to believe that about thirty centenarians in all the United States in 1825, will fully establish the fact, that such aged persons are as common in our country as in the other. The allowance for emigration is regarded as liberal—for, according to the best estimate that I can make, (see volume and page referred to above,) the amount of all such, of all sorts and all ages, has not exceeded 327,000 persons from the year 1725 up to 1819—the addition, then, of a third as acting on the whole stock of 1725 for the production of centenarians, is large enough. But those who are curious in such things will estimate for themselves—and such estimates must considerably depend on opinion at last.

In vol. IX. page 97, there is a very valuable essay “on the probability of human life in the middle states, particularly at Wilmington, in the state of Delaware, and its vicinity.” This was furnished by one of the most acute and correct men of the age; a plain man that never knew his own worth, or put forth the strength of his own mind. I recommend it to the consideration of all who feel an interest in its subject. The following is the substance of a small part of that essay—in the year 1794, the borough of Wilmington, with about 3,000 inhabitants in all, contained 152 persons aged more than 60 years; some of these moved away, and it was uncertain

whether they were living or dead; but it was ascertained that 112 of the 152 had died previous to the year 1814, of whom 46 attained the 80th year, 26 the 85th, twelve the 90th, 2 the 92d, 1 the 94th, 1 the 95th, 2 the 96th, 1 the 102, 1 the 103. Now, though we cannot count the stock which gave these results, we see that a gross population, say of 4,000 souls, at or about the year 1814, furnished two centenarians—or one to two thousand living persons. At this rate, Great Britain ought now to have 6,338, of 1000 and upwards, instead of 291.

Again—The Rev. Dr. Perkins lately delivered his half-century sermon, at Hartford. Con. He was a minute observer and careful recorder of such things as are now before us—he stated that, “during the fifty years of his ministry, sixty persons had died in his parish who were over 70 years of age, thirty over 80 years, 8 over 90 years, and 2 over 100 years each. He had preached 3,550 sermons of his own writing.” We cannot tell the average number of persons in his “parish,” by which we understand those under his own pastoral charge: for a “parish,” in the United States, simply means a congregation of Christians, of any sort whatever, worshipping at one place—so any town, if it has five or ten ministers and as many places of worship, may have as many parishes. It would seem, then, a large allowance, to suppose that the congregation of the venerable doctor averaged 1500 persons for the 50 years, which would give one centenarian for, at the most 1500 existing persons.*

But Hartford, as well as Wilmington, are remarkably healthy places, and the people are of very temperate and sober habits—so that they cannot furnish us with general data; nor do the cities and large towns—for they are, in all countries, regarded as unfriendly to long life. The bills of mortality of these, however, shew a much larger proportion of centenarians than Great Britain exhibits—in which latter the amount of these is as one to about forty-two thousand five hundred of existing population.

In Baltimore, with 60,000 inhabitants, during the year 1821, five died over the age of 100—or, as 1 to 12,000. In Boston, in 1820, population 43,893, four died that were aged more than 100 years—or, as 1 to 11,000. In New York, the same year, population 124,000,† only 2 of 100 years and upwards—as 1 to 62,000; but there were 46 persons who died between the ages of 90 and 100. In Philadelphia, population 110,000, in the same year, there were 5 above 100 years old, or 1 to 22,000—and 18 between 90 and 100. The average of the four cities, of Boston, New York, Philadelphia, and Baltimore, together containing about 338,000, and having 16 centenarians, is as 1 to 21,000 inhabitants—twice the proportion that exists in Great Britain. We have no particular returns of the southern cities, but know that at Charleston, Savannah, &c. the decrease of persons of more than 100 years, is frequently noticed in the papers. My apprehension is, that they have a full proportion of such per-

* In 1810, there were three churches in Hartford: the city and township then contained, in all, 5,347 inhabitants. It has increased considerably since, and now has a population of nearly 7,000—so that the number suggested is rather large, as the average of Dr. Perkins' “parish” for fifty years.

† The whole island of New York is included in this number, as all the persons that die on it come within the range of the bills of mortality—in regard to Philadelphia, this is about the amount of persons of the city and county who are supposed to be within the range of such bills, and is pretty near the real number.

sons compared with their sister cities of the United States.

NATURAL WONDERS.

It is very surprising, that two of the greatest natural curiosities in the world are within the United States, and yet scarcely known to the best informed of our geographers and naturalists. The one is a beautiful fall in Franklin (Habersham) county, Georgia, the other a stupendous Precipice in Pendleton district, South Carolina; they are both faintly mentioned in the late edition of Morse's Geography, but not as they merit. The Tuccoa fall is much higher than the Falls of Niagara. The column of water is propelled beautifully over a perpendicular rock; and, when the stream is full, it passes down without being broken. All the prismatic effect, seen at Niagara, illustrates the spray of Tuccoa.

The Table mountain, in Pendleton district, South Carolina, is an awful precipice of 900 feet. Many persons reside within 5, 7, or 10 miles of this grand spectacle, who have never had the curiosity or taste enough to visit it. It is now, however, occasionally visited by curious travellers, and sometimes men of science. Very few persons who have once cast a glimpse into the almost boundless abyss, can again exercise sufficient fortitude to approach the margin of the chasm. Almost every one, in looking over, involuntarily falls to the ground senseless, and helpless, and would inevitably be precipitated and dashed to atoms, were it not for measures of caution and security that have always been deemed indispensable to a safe indulgence for the curiosity of the visitor or spectator. Every one, on proceeding to the spot whence it is usual to gaze over the wonderful deep, has, in his imagination, a limitation, graduated by a reference to distances with which his eye has been familiar. But, in a moment, eternity, as it were, is represented to his astonished senses, and he is instantly overwhelmed. His system is no longer subject to his volition or reason, and he falls like a mass of mere matter. He then revives, and in a wild delirium, surveys a scene, which, for a while, he is unable to define by description or imitation.

[Southern paper.]

TO THE EDITOR OF THE AMERICAN FARMER.

SIR,

Having observed in your very valuable paper, at different times, directions for the treatment of several diseases that the human family are subject to, and believing your willingness to contribute to the relief of your suffering fellow creatures—I have taken the liberty of requesting that you will enquire of some of your many able correspondents, and publish in the American Farmer, directions for the treatment and cure of dyspepsia, a most troublesome and dangerous disease that I have had for four or five years, without having obtained any relief from consulting the medical faculty, and taking much medicine. By giving this a little of your attention, I have no doubt, my dear friend, but that you will be extending relief to many of your afflicted fellow creatures besides myself. And may Heaven reward your exertions to relieve the distressed—and prosperity and happiness attend you through life.

I am your ob't serv't, and
CONSTANT READER.

From Hare's View of the Structure, Functions, and Disorders of the Stomach, &c. It was well observed by the late Dr. Saunders, that we are made gluttons from the cradle, by the officiousness of our nurses. A child's health

is disordered from being over fed. It cries and complains from the effects; and with a view to silence it more food is given; so that the evil is increased instead of remedied, and the capacity of the stomach gradually extended far beyond the bounds of nature. Both the quantity and quality of our food should be proportioned to our habits of bodily exercise.—When we have active exercise in the open air, we may with impunity eat a hearty dinner, taking care, even then, to leave off before the appetite is palled; but on days when persons of weak digestion do not go out of doors, and especially when the mind has not been energetically occupied, it would be well to abstain altogether from solid animal food, and satisfy themselves with simple farinaceous matters, in the composition of which care should be taken that eggs are as sparingly used as possible. Nothing is a grosser blunder than that eggs are eligible for weak digestion and for the diet of the sick. They never assimilate with the contents of a disordered stomach, but partly coagulate, and form various crudities; and partly generate a noxious vapour, which, under its real character of sulphuretted hydrogen, rises from the stomach into the mouth. The colouring material of the yolk of the egg is sulphur, which, combining with the watery contents of the stomach, forms the vapour alluded to. It is the sulphur naturally contained in an egg which tarnishes a silver spoon; it is the sulphuretted hydrogen of an impure atmosphere which tarnishes silver in general. Although anxious to impress the advantages of moderation in eating, and the evils which arise from undue indulgencies, I wish also to impress the disadvantages and imprudence to weak stomachs, of long fasting, conceiving that they should never be more than four hours without the accession of some easy kind of food; and that, even in good health, an interval of seven or eight hours is by far too long.

Editorial Correspondence.

ON THE CULTURE OF VINES, THE POPPY, &c.

Dear Sir,

My son has in a box, vine plants from the seeds of the grapes sent from Europe; and also from the seeds of the common shop raisins. These seeds produce fruit as soon as vine cuttings, put in the ground at the same time.—How easily and how cheaply we may have grapes throughout the United States, by this mode. Perhaps you may think it worth communicating by your useful American Farmer.—I wish you to come and see how I have improved my estate, by the ashes of burnt sod. My great want is poppy seed, for I am convinced that we might become exporters of opium, and of a better quality than that imported.—Opium and Laudanum are much used; and even in Asia, the opium is so much adulterated, that my physician always made his own opium. The doctors here, complain that laudanum is often so weak, that fifty or eighty drops from one apothecary, is not equal to twenty from another.—Every State government ought, I think, to establish a dispensary; that medical prescriptions may be certainly serviceable.—Surely the health of our fellow citizens merits attention—this is an important subject, and I hope you will obtain a good essay upon it. Druggists multiply, without controul, and there seems to me a strange blameable disregard of evils resulting from bad medicine.—Pardon this digression, produced by mentioning opium, the cultivation of which I strongly recommended in one of my addresses, from Prince Georges' county.—Many thanks for

the millet seed—when you have other seeds to dispose of, "Oh! then remember me."

Your's respectfully,

T. L.

THE FARMER.

BALTIMORE, FRIDAY, JUNE 13, 1823.

It does not require an editorial paragraph to attract attention to the communication, relating to the culture, preparation, and dressing of hemp and flax, given in this number. The subject is obviously important, and the information connected with it, derived from Messrs. Goodsell and Swartwout, is clear, explicit and valuable. It was, comparatively speaking, but yesterday, that partial attempts were made, first, we believe, in Calvert and Talbot counties, in Maryland, to cultivate cotton for family use. Who could then have anticipated, that it would soon constitute the great export staple of the southern states? Why may we not believe, that in a few years, if we do not export, at least, we shall not import hemp and flax, either in the raw, or the manufactured state? What the cotton gin has done in the former, Goodsell's flax breaker may accomplish in the latter case—but the consideration that renders this invention doubly important to the agriculturist, is the fact, well attested to the Editor, that the machine is admirably well adapted to the purpose of *thrashing grain*. A very distinguished agriculturist of Massachusetts, who has had great opportunities of observation, very recently saw this machine at work; and he says, it so far exceeds all other machines for this purpose, both European and our own, that he would not have any other. As to Mr. Dey's flax machine, which promised so fairly, we understand explicitly, that it has been finally abandoned, as being useless. We lament it, as we ought to do all abortive applications of zeal and ingenuity, and yet more, as we fear a considerable sum of money has been lost by misplaced confidence in the success of a principle, which has utterly failed.

TRIALS OF SPEED.

Upon the ground provided by the Society for the improvement of Horses, in the state of New York, several trials of speed have been made, which serve to show that we have now in the United States, some first rate horses; some, that for *continuance of swift running*, may be well compared with the best of which we have any record.—From these horses, great improvements may be made by the farmers of New York, and Virginia, who own suitable mares, and are willing to pay the requisite attention to rear valuable animals.

The great Match Race on Long Island, between Eclipse of New York, and Henry of Virginia, was run in the following time:

First heat, 7 minutes	37 seconds
Second do. 7 do.	49 do.
Third do. 8 do.	24 do.

In the first heat of four miles, Henry took the lead and beat Eclipse by about half a length.—In the second heat also, Henry took the lead for the first and second miles, when Eclipse passed him, and came out several lengths ahead.—In the third, and most decisive trial, Eclipse led between two and three lengths. In the third mile, Henry came up with his rival within about half a length—but in the fourth and last mile, Eclipse maintained his ascendancy and came out a length

and an half ahead, thus winning the sum of Forty Thousand Dollars.

The New York Society, we think, have judiciously directed their attention not only to *fleetness and continuance*, but to *power*, by requiring their horses to carry higher weights than usually borne on other courses.

On Monday last, commenced the races on the Fairview course, three miles from Baltimore. The first day's contest was between Col. Johnson's mare Betsey Richards, and Mr. Sleeper's mare Lady Lightfoot—the former easily won the first heat, not quite 4 miles, in 7 minutes and 31 seconds—after which, Lady Lightfoot was withdrawn.

On Tuesday the Virginia horse, Flying Childers, owned by Gen. Wynn, beat Gen. Ringgold's horse Partnership, and performed the heat, without whip or spur, in 5 minutes and 42 seconds—three mile heat.

On Wednesday the third and last day's race, (2 mile heats) was run between the Dutchess of Marlborough, Sir Harry, and Flaxen-Mane. The heats were handsomely contested and afforded great satisfaction to the numerous spectators who were assembled on this occasion. At the close of the first, the Dutchess of Marlborough came out about half a length ahead of Sir Harry, Flaxen-Mane some lengths behind. At the end of the second heat, the Dutchess was again ahead—Sir Harry two to three lengths behind, and Flaxen-Mane in the rear of all.

BALTIMORE MARKET.

PRICES CURRENT.—CORRECTED WEEKLY.

Flour, best white wheat, \$8—Howard street Superfine, \$7 25—fine do. \$6 75—Wharf, do. \$7 12 sales—White wheat, \$1 40 to 1 45—Red do. \$1 36 to \$1 40—Rye, 75 cents—Corn, 50 to 52 cents—country Oats, 40 cents—Beef, 8 cts. per lb.—Live Cattle, \$6 to \$6 50 per cwt.—Bacon, round, 8 to 9 cents per lb.—Pork \$4 50 to 5 50 per c. lb.—6 to 8 cts. per pound—Mutton, 5 to 6 cts. per lb.—Beans, \$1 37½ to 1 50—Peas, black eyed, 55 to 60 cts.—Red Clover Seed, \$6—Orchard Grass do. \$3—Herds' Grass do. \$3—Timothy do. \$4 50—Millet, none—Flax Seed, 75 to 80 cts.—Whiskey, from the wagons, 32 to 35 cts. per gal.—Apple brandy, 30 to 32 cts.—Peach do., 65 to 70 cts.—Shad, \$6 50, scarce—Herrings, No. 1, \$3 per bbl.—No. 2, \$2 75—Fine salt, 60 to 65 cts. per bush.—Coarse, do. 70—Butter, 20 to 25 cts per lb.—Eggs, 12½ cts. per doz.—Hay, \$17 per ton—Straw, \$10.

TOBACCO is selling nearly as per last report.

FOR SALE

At a low price and on a long credit, the FARM on Elk Ridge, occupied by Mr. H. Scott, and formerly owned by Luther Martin, Esq. containing about eleven hundred acres.

It is situated about eleven miles from this city, near the Washington road, and is considered remarkably healthy.—The situation is handsome, and the land easily improved by plaster and clover. This property will be divided if required, and immediate possession given.—For terms apply to

ROBERT & JOHN OLIVER.

Printed every Friday at \$4 per annum, for JOHN S. SKINNER, Editor, by JOSEPH ROBINSON, on the North West corner of Market and Belvidere streets, Baltimore; where every description of Book and Job Printing is executed with neatness and dispatch—Orders from a distance for Printing or Binding, with proper direction promptly attended to, addressed to J. Robinson, Baltimore.

AGRICULTURE.

AN ADDRESS

DELIVERED BEFORE THE MASSACHUSETTS AGRICULTURAL SOCIETY AT THE BRIGHTON CATTLE SHOW, OCT. 9, 1822. BY THE HON. TIMOTHY PICKERING.

Gentlemen of the Massachusetts Society for the promotion of Agriculture,

It appears to be expected, that at each of your anniversary meetings, a discourse on Agriculture should be delivered. The Trustees of the Society have requested me to address you at this time. But though willing to be laid under contribution to the great object of your institution, it has occasioned a degree of solicitude to present something meriting your attention. From the multitude of books written on the subject of Agriculture—embracing in that word whatever should employ the thoughts and labours of the skilful husbandman—the field would appear almost boundless: yet to select topics particularly interesting to the farmers of Massachusetts, and here to discuss them so as to communicate useful and acceptable information, was not unattended with difficulty. My address must necessarily be miscellaneous.

Philosophers and practical husbandmen have for ages employed their thoughts and their pens on the various operations in agriculture; yet diversities of opinion still exist; and the reasons of many of these operations have been little more than conjectural. What constitutes the food of plants, has long been a subject of diligent enquiry. It was natural to suppose that if this food could be discovered, it could be more easily provided, or at least be more efficaciously administered. The palpable differences which distinguish the immense variety of plants, in their forms, textures, colours, and tastes, naturally suggested the idea, that each variety required its specific nourishment. Yet it being a matter of common observation, that the same soil would nourish and bring to maturity multitudes of different plants, of very opposite qualities—some yielding wholesome food, and others a deadly poison—at the same time all growing together, and robbing one another: a nobler and more simple idea presented itself—that the food of all plants was the same; but that each species was endued with the power of converting that food to its own peculiar substance: as among animals, the same grain produced all the varieties of flesh which go to sustain the life of man. In the vegetable kingdom, this supposed power of conversion seemed strikingly apparent in the effects of grafting of fruits. The juice imbibed by the roots from the earth, and immediately changed to the proper sap of the native stock, ascend and spread through all the limbs; and if each of these be grafted with a different fruit, the varieties will be as numerous as the branches.

By the modern discoveries in chemistry, these mysterious effects seem to be accounted for. For it appears that all kinds of plants are composed of a small number of elements, whose different arrangements and combinations produce all the varieties in question. Seldom more than seven or eight of these elements belong to plants, and three constitute the greatest part of their organised matter. But each of these is a compound, consisting of the same materials, only in different proportions. The three principal ingredients in the food of plants, and which by them elaborated constitute the food of man and other animals, are named by chemists, carbon, oxygen, and hydrogen; in other words, are charcoal, vital air, and inflammable air; and these exist in the air we breathe, as well as in

manures consisting of vegetable and animal matters.

It may seem incredible that the thin air, an invisible matter, should be changed, in the process of vegetation, into solid substances, as wood and stone: but nothing has been more clearly ascertained, than that in 100 parts of pure limestone, 45 parts are fixed air, or carbonic acid; which it the act of burning the stone into lime, is expelled: for if at that time the stone be weighed, it will be found to have lost so much of its original weight. It is also well known that this same lime, which slaked with water, or exposed to the air, falls down into a powder, will immediately afterwards begin to imbibe fixed air from the atmosphere, and eventually, though slowly, recover its original weight. It is this same carbonic acid, or fixed air, which at the bottom of wells, every year proves fatal to a number of lives. For this air, when separate, being heavier than the air of the atmosphere, sinks and remains at the bottom of wells, and is a deadly poison. It is the oxygen in the atmosphere, called also vital air, because essential to animal life, which mingled with the fixed air, renders the latter harmless.

I have introduced these few remarks on the food of plants, to present an idea—a very faint one indeed—of that very interesting subject; which, as already observed, has so long employed the thoughts of philosophers and agricultural writers; but the satisfactory discovery of which seems to have been reserved for the present age. This view seems to account for the vast variety of plants which will grow on the same spot of earth; the ingredients of their food being substantially the same, but varied in the proportions peculiar to each; and which each has the faculty of appropriating to its own use; rejecting the rest, or casting it off as excrementitious.

But although the same articles of food will afford nourishment to a variety of plants, yet these are so formed as to require a variety of soils, adapted to their several constitutions; some preferring a stiff, others a loose or light soil—some a moist and others a dry one. Few, however, will refuse a well compounded loam. Soils (like plants) however diversified in appearance, consist of different proportions of the same elements. Four earths generally abound in soils; and these, by chemists, are called aluminous, silicious, calcareous, and magnesian; and of these, the three first are the principal; and, in familiar language, well known to every farmer, as clay, sand, and lime. Magnesia is often found in limestones; and the combination is said to give the strongest lime for the farmer's use; so as in smaller quantities to serve his purpose, as well as mild lime applied in much larger quantities.

The first object which claims the farmer's attention, is the nature or constitution of the soil. The next embraces the means of enriching it and preserving its fertility. That intimate mixture of clay and sand which is called loam, is the most desirable soil, as being already prepared for every operation in agriculture. A stiff clay demands opening by the addition of sand and other materials; and a sandy soil requires the addition of clay. But calcareous earth is considered as essential to give to soils the capacity of attaining the highest degree of fertility. Few soils, indeed, are wholly destitute of calcareous matter, though it may be invisible to the eye: but very few possess so large a portion of it as would be salutary. There can be little danger, therefore, of applying it to excess in Massachusetts, where so little in any form has been found. Limestone is the great source of calcareous matter. But this is of various qualities. Very little of it is purely calcareous. Some lime stones in

Great Britain have been found to contain eleven parts in twelve of sand. Of such lime, if sixty bushels were spread over an acre of ground, five bushels only of calcareous matter would be applied. To know then the constitution of the lime he uses, is important to the farmer; and not less so to the mason in preparing his mortar, which will require the addition of more or less sand, according to the composition of the lime. All marles contain calcareous matter, and are of greater or less value, according to the proportion which this bears to the clay, sand, or other substances mingled with it. All shell fish will supply this material. In some parts of the United States, remote from limestone, oyster shells are burnt to obtain lime for building; and in all seaport towns where many oysters are used for food their shells will be found in quantities deserving the neighbouring farmer's attention; and if raised in piles, mingled with wood, may be burnt to lime. Of the vast improvements of the lands in Scotland, within the last forty or fifty years, lime has been the basis: and the use of it the first step towards rendering the application of manures, strictly so called, highly productive. There they will lay from fifty to two hundred or more bushels on an acre. In Pennsylvania, where lime has been long and extensively used twenty to fifty bushels to the acre has been found sufficient, and safer than any larger quantity, at least in the first application. A remarkable instance of the beneficial use of lime, though only at the rate of about twenty bushels to the acre, well merits a recital. The experiment was made on a field of ten acres, for which the farmer had provided two hundred bushels; but it being his first essay in using lime, it so happened that the whole quantity was disposed of when he had gone over nine acres. Indian corn was planted; and the crop was very great. The next year, the field was fallowed, and at seed time sown, a part with wheat and a part with rye; and good crops were produced. "In the Spring (says the farmer) I sowed it with clover and timothy (Herdsgrass) and put two bushels of plaster on an acre; and had as great a crop of clover as could grow; it lay three weeks before the time of mowing." He adds—"The lime and plaster did all this; for no land could be poorer before. Where I laid no lime I got no clover, although I put on the plaster."* The kind of soil in which lime operated so powerfully, is not mentioned: but probably it was clayey; a very common soil in the country where this land lay. Another like instance occurred in the Delaware state, on a clay farm, on which plaster produced no effect until the land was limed.† While lime operates very beneficially on strong clays, it is said to be still more useful on lighter soils. To ascertain its effects on any lands, will require but little time and a small expense. A single cask of lime will be sufficient for a number of comparative experiments. If a few adjoining rods of land be set apart for the purpose, and the lime, by slacking, brought to a fine powder, it may be evenly spread on the several small strips, in different proportions, at the rate of twenty and any greater number of bushels to the acre. Then, by raking, or harrowing, mix the lime with the surface soil, and plant each strip equally and uniformly with Indian corn. One equal strip, tilled and planted exactly as the others, but left unlimed, will enable the experimenter to see what advantage may arise from liming. In the next year the effects of lime in its respective proportions may be further

* *Memoirs of the Philadelphia Society of Agriculture, Vol. 1, page 193.*

† *Ibid. Vol. II, page 187.*

tested, by sowing the same strips with equal quantities of one sort of grain and of grass seeds.

In like manner, small experiments may be made to try the effects of clay on light sandy or gravelly loams, and of sand on stiff clays. The clay should be carried on and spread, and lie on the surface during the winter, to break and moulder by the alternate frosts and thaws, that it may be more effectually mixed with the soil.

As to the manner of applying lime, I am satisfied the best is that recommended and practised where lime has been most extensively used; that is, to slake it with water, and as soon as it falls to a fine powder and is cool, to spread it evenly over the land, and with the harrow mix it with the soil: its greatest utility depending on its intimate incorporation. In liming extensively, the lime is often, perhaps most commonly, carried on and dropped in small heaps to be slaked by the moisture of the air: but it should be carefully attended to, that it may be spread as soon as it is slaked; or there will otherwise be danger of its settling in lumps, which may never again be duly pulverised.

If the application of lime be, as is represented, so important to the great and permanent fertility of the soil (and of this I entertain no doubt,) while the knowledge of the fact is all that is essential for the practical farmer to know; something more is desirable to satisfy inquisitive minds; and if the reason for using lime, or its mode of operating, could be shown, it would give confidence to the husbandman, while it gratified the philosophical enquirer.

A gentleman who is reputed to be one of the greatest chemists of the age (Sir Humphrey Davy) informs us that "when lime, whether freshly burnt or slacked, is mixed with any moist fibrous matter, there is a strong action between the lime and the vegetable matter, and they form a kind of compost together, of which, a part is soluble in water:"—"by this kind of operation, lime renders matter which was before comparatively inert, nutritive; and as charcoal and oxygene (vital air) abound in all vegetable matters, it (the quick lime) becomes at the same time converted into carbonate of lime, that is, it is restored, by again combining with carbonic acid or fixed air, to the state in which it existed before it was burnt, except its being reduced to powder. Again he says—"Mild lime, powdered limestone, marles or chalks (for chalk is a limestone) have no action of this kind upon vegetable matter; by their action they prevent the too rapid decomposition of substances already dissolved; but they have no tendency to form soluble matters." He then remarks, that "chalk, marle, or carbonate of lime, will only improve the texture of the soil; or its relation to absorption; acting merely as one of its earthy ingredients. Quick lime when it becomes mild, operates in the same manner as chalk; but in the act of becoming mild, it prepares soluble out of insoluble matter." Again he says—"All soils are improved by mild lime, and sands more than clays.

While quick lime, according to this celebrated chemist, is so usefully applied to land abounding in fibrous matter, to effect its speedy dissolution, he says its application should be avoided, where a soil contains much soluble vegetable manure; as it either tends to decompose the soluble matters by uniting to their carbon and oxygene, so as to become mild lime, or it combines with the soluble matters, and forms compounds having less attraction for water than the pure vegetable substance.

But an ingenious writer, under the signature of Agricola, in Nova-Scotia, says, that notwithstanding all these precautionary fears, the off-

spring of chemical creation, the British farmer is mostly in a habit of applying quick lime to all sorts of soils. And he assigns an adequate reason, that caustic lime cannot remain any length of time in the ground, without passing into a carbonate and becoming mild. This writer offers different reasons for the beneficial operation of lime; that it is capable of absorbing not only that quantity of carbonic acid which it possessed in its natural state (being 45 parts in 100) but an additional quantity; and can form what chemists call hypercarbonate. This, he says, is highly soluble in water: which accounts for the admission of lime into the structure of plants; and that this excess of carbonic acid adheres very loosely to its base (the mild lime) and is liberated without any extraordinary degree of heat. The carbonic acid, a most important article of vegetable food, is copiously evolved in the putrefactive process of manures; the calcareous earth fixes and prevents its escape—forms with it a hypercarbonate, and readily imparts it, in union with water, towards the nourishment of the crops. It is supposed to do more; it unites with the carbonic acid floating in the air; and when there is a scarcity of aliment in the soil, it seizes and secures this food in the atmosphere, and afterwards disperses it, according to the calls and necessities of vegetation. Hence the necessity of keeping lime on the surface. It is then ready to intercept, and combine, with the carbonic acid which is generated by the fermentation of the putrescent matter lying at lower depths, and to attract the same gas (the carbonic acid) from the surrounding air.

I confess myself much better satisfied with the observations of Agricola, in accounting for the operations of lime, than with the solution offered by Sir Humphrey Davy. If the statement of the former be correct, we can see a reason for the long continuance of the beneficial effects of lime on land; for although it is not itself food for plants, it is constantly employed in collecting and imparting to them that food, from the sources which have been mentioned. Does not the reasoning of Agricola also indicate the cause why lime benefits sands more than clays? The latter are opened and rendered lighter by its application: and to destroy their too great tenacity, seems to be a main advantage gained by liming clay soils; whereas sandy soils are already sufficiently porous.

An old English practice of burning clay for a manure, has lately been revived in England, and with some appearance of novelty. The facts stated in regard to its operation, preclude all doubt of its efficacy. On stiff clays, it has, in the practice of some farmers, superseded the use of lime: because, although much greater quantities of it are required, yet being on the spot, in the very field where it is wanted, it is much cheaper than lime, for which the farmers are often obliged to send upwards of twenty miles—it is said that clay thus burnt,—in which the process is so managed as to reduce the clay to the condition of ashes,—will not again, when wetted with rains, recover its original texture of a close compact substance too tenacious of water, and when dry, too hard for the roots of plants freely to penetrate. I have called the burning of clay for manure an old English practice: for I find an account of it in the second of Dr. Elliot's Essays on Field Husbandry, written and printed in Connecticut, upwards of seventy years ago. The Doctor gives a recipe, copied from an English book, for the process of burning it; which is with a *smothered fire*, a point of indispensable necessity, according to the present practice in England.

Many ways of improving lands, both in the manner of cultivating them, and in the kinds of useful plans to be introduced, have been often recommended; and certainly a spirit of improvement has been extensively excited; yet much remains to be done, to raise our crops to an equality to those in some European countries, whose lands and climates are no better than our own. But have we the means of accomplishing it? I answer, generally, that we have. Our animals for labor are equally efficient. Our instruments of husbandry are as good, or capable of being easily made so. Our husbandmen are as intelligent, and unquestionably less prejudiced, and less averse to adopt improved modes in farming. In England, a bigotted perseverance in ancient practices, however absurd, has in times past been astonishing. Her own writers inform us, for instance, that in one county all their common ploughing has long been performed with one pair of horses driven by the ploughman; while in an adjoining district four or five horses, in a single line have been put to the plough, with the addition of a driver, and yet ploughing no more land, nor with a deeper furrow, than was elsewhere effected with one pair of horses.

But although I suppose no prejudices equally strong exist among us, still we are, I think, too prone to adhere to old usages, where no good reasons can be given for them. New practices in husbandry are often—perhaps chiefly—attempted by persons not bred to that occupation, and these, for want of practical skill may often fail in the execution; and when successful, the success is ascribed to a liberal expenditure of money, beyond the ability of the mere farmer. But what risk will attend experiments made by farmers themselves, to test the value of these novelties? Each one for himself can try them on as small pieces of ground as shall suit his convenience, and at a very small expense of time and money. The introduction of improvements, would be facilitated, if the money expended, and especially the quantity of labor bestowed upon them, were always accurately stated, and their authenticity vouched by the names of the improvers. And if the experimenters, in these cases, who hire all the labor, and this often performed in their absence, are merely *not losers*,—practical farmers, always present, and working too with their own hands, would assuredly render such new practices *profitable*.

But I apprehend the knowledge of modern improvements in husbandry is far less extended than may commonly be supposed. That celebrated Travelling Agriculturist, the late Arthur Young, a man of science and literature as well as a practical farmer,—after visiting different districts in England, for the purpose of observing, and for the information of his countrymen describing their various modes of husbandry, commenced, about the close of the American War, his Annals of Agriculture. He afterwards travelled over France and parts of Spain and Italy with the same views. Thus fraught with agricultural knowledge, he continued his labors in that work; comprehending, in addition to his own observations, useful communications from practical farmers, bearing their signatures, for it was a general rule with him not to admit any unless thus vouched; yet, if my recollection be correct, that practical work was so little attended to by English farmers, that he once stated its sales as not exceeding 500 copies.—Since then, indeed, improvements have more readily been adopted, and agriculture has advanced with an accelerated pace, and in Scotland with great rapidity. *Reading*, to obtain agricultural information, has been extended, and

become fashionable; and book-farming knowledge is no longer despised. This knowledge is now of greatly increased value, because experiments, with a view to improvements, are not, as formerly, made at random, but on principles founded in the nature of things, and which rest on modern discoveries.

As we have no farmers who cannot read—in order to give to all opportunities of reading, I take leave to suggest for consideration, the expediency of forming, in each township in the State, a farming society, of which the members should meet monthly, to converse on farming affairs—to make mutual communications of their practices in husbandry—to commit to writing every practice not in common use, which may be beneficially extended—and to read and examine modern publications on their vocation; particularly those of the State Society, which the Trustees would gratuitously furnish. To these, such township-societies would find it agreeable and useful to add the best periodical publications which issue from the presses of our own country, either through the agency of Agricultural Societies, or of well informed individuals. With these and a few other books on the subject, each township-society would become possessed, at a very small expense, of a pleasing and instructive agricultural library.

After considering the constitution of the soil he has to cultivate, the next object of the farmer will embrace the means of enriching it, and of preserving its fertility. To enrich it, manure will present itself as of the first importance; and of manures, the dung of his live stock will obviously occur as the most essential ingredient. If the manure from the droppings of his stock could easily be doubled, how great would be the farmer's acquisition? That this is practicable I cannot permit myself to doubt. I am rather inclined to think it capable of a manifold increase. At another public meeting of farmers, I had occasion to suggest some means of preserving and greatly increasing this important article; particularly during that portion of the year when cattle are at pasture, but penned at night in the barn yard. Nothing is more common than to see these yards, after being cleared of manure for the spring crops, left naked until autumn, without litter or mud, or earth of any kind, to absorb the urine of the cattle and to mingle with their dung; but all is left open to our burning summer suns, by which the greater part, three fourths, perhaps seven eighths, of the essence of both are exhaled and given to the winds. To prevent this serious loss, I suggested the expediency of giving to the barn yard, as soon as it was cleared out, a covering of any kind of litter, and a coat of earth, mud from low grounds, loam where attainable, or any kind of earth to which a farmer can have easy access; and that as often as once in two weeks, a new coat of earth should be introduced. Weeds from road sides and waste places would make valuable additions to the summer manure. By such means manure may be increased in a four, perhaps an eight-fold degree.

But if in addition to this accumulated summer manure, the farmer, without any of the dung or litter of his cattle, could double the quantity usually made during the winter, would he not consider himself enriched? That this is practicable will appear from a statement I shall now recite; it being the result of careful experiments made in Scotland during a period of ten years. The fact is stated in one of a series of papers written with great ability by Mr. John Young, under the signature of Agricola, (already referred to) and published at Halifax. The urine of cattle produced this mighty effect. I cannot so

well occupy your time as by giving the statement in his own words, as abridged by him from the Farmer's Magazine, published in Scotland.

"I should be afraid (says Mr. Young) to hazard my character with the public, by stating in round and unqualified language, the value of this rich juice which is literally wasted and thrown away; and therefore I shall proceed with caution, and give a detail of facts, conclusive in their bearings, and substantiated by the best authority. They are contained in a letter* from Charles Alexander, near Peebles, in Scotland; and are addressed to Sir John Sinclair in 1812, for publication. This intelligent farmer had long been impressed with the great importance of the urine of cattle as a manure; and he sets about to discover, by a long and well conducted series of experiments, the best method of collecting and applying it. He began by digging a pit contiguous to the feeding stall, but distinct altogether from that which was appropriated for the reception of the dung. The dimensions of this pit, according to his own account, were 36 feet square, and four feet deep, surrounded on all sides by a wall; and the solid contents were 192 yards. Having selected the nearest spot where he could find loamy earth, and this he always took from the surface of some field under cultivation, he proceeded to fill it; and found that with three men and two horses, he could easily accomplish 28 cubic yards per day; and the whole expense of transporting the earth did not exceed £4 16. 0.† When the work was complete, he levelled the surface of the heap, in a line with the mouth of the sewer which conducted the urine from the interior of the building, on purpose that it might be distributed with regularity, and might saturate the whole from top to bottom. The quantity conveyed to it, he estimates at about 800 gallons; but as this calculation was founded partly on conjecture, for he measured not the liquor, it will be better and more instructive to furnish and proceed on data that are certain and incontrovertible. The urine was supplied by 14 cattle, weighing about 34 stone each,‡ and kept there for five months on fodder and turnips. The contents of the pit produced 288 loads, allowing two cubic yards to be taken out in three carts;§ and he spread 40 of these on each acre; so that this urine in five months, and from fourteen cattle, produced compost sufficient to fertilize seven acres of land.¶ He states further, that he tried this experiment for ten years, and had indiscriminately used, in the same field, either the rotted cow dung, or the saturated earth; and in all the stages of the crop he had never been able to discover any perceptible difference. But what is still more wonderful, he found that his compost lasted as many years as his best putrescent manure; and he therefore boldly avers, that a load of each is of equivalent value.—"The dung pit, which contained all the excrementitious matter of the 14 cattle, as well as the litter employed in bedding them, and which was kept separate for the purpose of the experiments, furnished, during the same period, only 240 loads; and these, at the same rate, could manure only six acres."

On this statement one remark forces itself into notice. That for the want of such a reser-

* "Farmer's Magazine, Vol. xiii, page 78."

† \$21 31. Seven days work for three men and two horses; each horse, I suppose, in a single cart, a common usage in Scotland.

‡ This would be the weight of a cow.

§ This gives 18 cubic feet to each load.

¶ Seven Scotch acres are nearly equal to nine English and American acres.

voir for saving the urine of our cattle, more than half of our winter made manure, and this is the farmer's chief dependence, is lost.

It is not stated whether the pit filled with loam was or was not covered: but unless covered, rains would saturate the earth, and thus in a manner exclude the urine conveyed to it from the cattle stall. It should also be noted, supposing the pit to have been covered, that the frosts in Scotland would seldom so freeze the earth in the pit as to prevent the absorption of the urine. The frosts in Massachusetts would doubtless require that the pit should be sunk to some depth, and certainly be under cover. In a word, a barn-cellar would seem to be the proper receptacle for this important manure. How it should be arranged, must depend on the situation of the barn. In Pennsylvania, barns, which are commonly of stone, are often erected by the side of a hill, by which means a story is gained for their cattle stalls. By digging where there is a gentle slope, a sufficient excavation for a barn-cellar would be easily made, to drive in a cart on a level, for carrying in the earth in autumn, and for removing the manure in the spring. With the increased fertility of his soil, the farmer will be able to increase his live stock; and the live stock, in return, will be constantly adding to the productions of the soil.

(To be continued.)

FROM THE BUFFALO PATRIOT.

The following article on the subject of *hemp*, has been digested, in part, from several approved essays, in the *Plough Boy*, *American Farmer*, and other agricultural works, and combined with the practical information of the subscriber.

H E M P.

Hemp is a very hardy plant, resists drought and severe frost—is easier cultivated, less exhausting, and more profitable than many other crops, with which this does not interfere in its cultivation (except the tobacco crop.) It is sown before and gathered after corn, and requires no attention when wheat is sown, harvested or threshed. It will grow year after year on the same ground, on which, if sufficiently rich, it is the surest crop. It is liable to no diseases, and injured by no insects.

The Soil.

The soil should be deep, clean, dry, rich and mellow. The plant has a tap root, which descends to a considerable depth, and therefore the soil should be deep, and be thoroughly mellowed by deep and frequent ploughings. Fall ploughing, and two or three ploughings in the spring, together with harrowing, so as to smooth the surface (and thereby enable the seed to be sown even, and the hemp to spring up equally, and be cut close to the roots,) are preparatory steps to the putting in of the seed.

The seed, and when sown.

The seed (to the amount of two bushels per acre on middling soil, and three on rich ground) should be sown as early as possible in the spring, after the ground becomes dry and well prepared. Early sowing renders the coat heavier and stronger, enables the hemp to cover the ground early, so as to smother weeds, and before the sun becomes powerful, to shade the soil and preserve its moisture. The seed, after being cast as even as possible, should be harrowed in to as equal a depth as may be, that it may all start together; and a heavy roller should then be passed over, or a bush drawn across to smooth the surface, in order that the hemp may be cut close to the roots.

Ripening and Harvesting.

When the hemp becomes fit to be cut, the stalks of the blossom or male hemp, turn yellow, become a good deal speckled, and drop most of their leaves, and if the air is still, a cloud of dust rises from the blossom stalks, and hangs over the field. When sown early, it will be fit to cut about the first of August. The above appearances will become indicative of the proper time; and then it should be cut without delay, for if suffered to stand longer (as about one half of the stalks blossom, and the other half bear seed) the stalks of the male will wither and blacken, and the coat be of but little value; and the female hemp, which has stood to ripen the seed, requires a longer time to rot than the male, and consequently both would be thereby injured. *The best way to get seed, would be to sow some thinly, in a separate patch.* The mode of cutting is preferable to that of pulling. A man will cut half an acre per day, and a quarter pulled is said to be a day's work. By the former practice the inconvenience of dust, and the dirt attached to the roots will be avoided. Cut hemp will be worth ten dollars a ton more than the pulled. Knives or hooks for that purpose, may be obtained for about \$1 25 cents each. When cut, spread the hemp a day or two to dry it; then bind it and put it up in shocks.

Wretting, (or Rotting.)

As soon as harvested, in order to prevent the rains from discolouring it, proceed as early as convenient to wret it, by placing it in *clean, pure water*, formed by a stream, spring or clear pond. If rotted shortly after cutting, about five days are generally required for the purpose. You will be able to judge by taking out a handful and drying it; and if the stalk of shieves will shake out and separate easily from the bark, leaving it clean and entire, the process of wretting is completed. The bark or lint of hemp is connected with the stalk by a substance which must be either wretted or dissolved before they will separate; produce the separation, and the work is accomplished. Experience will be the best criterion. The water in which it is rotted, should not run rapidly—as it would in that case wash away the coat. You may have three or four wagon loads of hemp to the depth of three or four feet, sunk at a time, but it should be completely submerged, though not suffered to touch the bottom. If separate quantities are put in on several successive days, the days and quantities should be noted, for the purpose of ascertaining which becomes first wretted, and which should, therefore, be first taken up—for if left in the water a day or two, too long, the hemp will be materially injured.

Dressing and Securing.

When rotted, open and spread it, that it may dry soon. The process for breaking and swinging is the same as that for flax. When it grows too long for dressing, (say from 6 to 10 feet) it may be cut into two equal parts without any injury. Be very particular in keeping the long and short hemp separate, and not have the seed and but ends put together. Be also careful to dress it clean. When dressing it, put twelve handfuls in one head, laying them straight the length of the hemp. The handfuls must not be tied, but bind the heads tight, with a small band, about one foot from the but end. It will then be ready to be put into such sized bales as may be suitable. Some bale it in to a box, across the bottom of which four ropes are laid to tie the hemp when pressed into it. When packed it should be perfectly dry, otherwise it will rot.

The following remarks from the Plough Boy, on the subject of water rotting in preference to w retting, coincide with the opinion of ex-

perienced cultivators. "If the crop is to be dew rotted and got out by hand, its profits must be comparatively small, because it cannot be thus prepared to command the highest price in market, compete in quality with the Russia hemp, much less drive it from our markets. But if the American hemp planter be prepared with proper conveniences to water rot, and with proper machinery to dress and prepare it, we ought not to doubt, much less to despair of his ultimately arriving at a perfection in the production and dress of the article to equal, if not excel the best samples of Russia hemp."

HENRY KIP.

Buffalo, Feb. 18th, 1822.

FROM THE SOUTHERN PATRIOT.

The following communication is well worthy the attention of Planters—it is from the pen of a gentleman who has acquired considerable experience on the subject. If a portion of our agricultural industry and capital could be diverted to the clearing and cultivating of our Inland Swamps, they must inevitably become at no distant day, a source of wealth to individuals and of strength to the State.

INLAND SWAMPS.

The recent as well as former accounts from Europe, respecting the market for cotton, do not authorise the hope of any considerable enhancement in the price of this article for several years to come, for although the demand may increase with the increased consumption; yet when we consider what immense tracts of our own country are admirably well adapted to this culture, in addition to other parts of the world, it is reasonable to suppose that there will be for a considerable length of time more than a sufficient supply; consequently the prices must continue low.—This circumstance would afford us but a melancholy prospect, were we not (particularly in this lower country,) cheered by the reflection, that we can direct our capital, and industry to what would be as profitable and likely to be a more permanently productive culture.—I mean the culture of rice. It is obvious to every man of the least observation, in glancing his eye over the map of this state, that the alluvial districts furnish the greatest facilities for the culture of that grain, which the Father of Political Economy has observed produces a much greater quantity of food than the most fertile corn field. In Carolina, (says he) where the planters are generally both farmers and landlords, the cultivation of rice is found to be more profitable than that of corn, though their rice fields produce only one crop in the year, and though from the prevalence of the customs of Europe, rice is not there the common vegetable food of the people.

If according to the principles laid down by politicians and economists, a numerous population is a great desideratum in the advancement of the wealth and happiness of a nation, it certainly must be a matter of serious concern, to every true friend to this country, to behold lands abounding in fertility, and well calculated under judicious drainage, and culture for the production of this valuable grain now lying waste, and sending forth nothing but the most pestilential miasma, thereby contaminating the otherwise wholesome atmosphere, and spreading disease and death through a whole region of a fine fertile country. Who could believe for a moment without assurances of the strongest nature, that those gloomy swamps and bogs, which now present nothing but desolation and ruin, were once considered as the choicest lands in the state; and what would our ancestors think, could they rise from the grave, and behold a once cultivated

country now returned to a wilderness; and hail which once resounded to the voice of festivity and mirth, now either buried under their own ruins, or remaining melancholy monuments of departed grandeur. The gloomy pictures of Ossian are here completely verified. "I have seen the walls of Balclutha, but they were desolate; the thistle shook there its lonely head, the moss whistled to the wind, the fox looked out of the window, the rank grass waved round his head—desolate is the dwelling of Moira—silence is in the house of her fathers."

Let us now enquire into the causes of this melancholy change; these are numerous. There are two, however, so obvious, that we need take no notice of the rest. These two are—1st. The peculiar aptitude of the tide lands which abound in the vicinity of our rivers, for the growth of this favourite staple; and 2dly. The introduction of that plant which has brought millions of wealth into the State, and produced a complete revolution in its agriculture. The introduction of cotton by offering to labour a more productive employment than any other in the agricultural line, at once diverted a vast portion of capital into this new direction, and so great for a length of time was the profit arising from its culture, that it justly became almost the sole object of attention to the agricultural community, and like the Turk, bore no rival near its throne. The consequence was, that no lands but such as were favourable to its growth, were for a moment thought of, except some few of the tide lands which were peculiarly adapted to the growth of rice. As this culture is now, if not overdone, at least brought to its natural limits, it may not be unreasonable to enquire whether the time is not propitious for the consideration of the propriety of restoring the inland swamps to that rank and estimation to which they are fairly entitled. As I am aware that there is considerable prejudice on this subject, and as I would not intentionally mislead any man on this or any other occasion, I must, nevertheless, with great deference to the opinion of those better qualified to judge than myself, beg leave to offer some observations in behalf of the inland swamps, which, when impartially considered, may shew that my views are not so extravagant as they may, at the first impression, appear.

The 1st consideration arises from their extraordinary and inexhaustible fertility, enabling them to produce the very best rice, equal, if not superior to the very best rice produced on tide land.

2dly. Their proximity in general, to towns, affording an opportunity of bringing their produce to market when prepared, at little cost, or to mill when in the rough.

3dly. Their great comparative security from gales, in as much as they are further removed from the coast, and more protected by woods and forests, than the tide lands in general, and are, when properly drained, less subject to freshets, having to contend only with the water that falls directly from Heaven, or from the immediate adjacent high lands; whereas the tide swamps have often to encounter the accumulated waters of a river of 150 or 200 miles in length, coming down sometimes in torrents and spreading in their course havoc and destruction. But I do not mean to be understood as disparaging the tide lands, or to institute an unfair comparison regarding them, for it must be allowed by all, that there are on each of our rivers tide plantations which are so fortunately situated as to render them the best property in the Southern country, as the wealth which their possessors display, most unequivocally demonstrate; but at the same time, I must remark, that the number is but small, and truth warrants the assertion, that

scarce a summer passes that we do not hear of some of the crops being destroyed by too much or too little water. But even admitting that there were no objections to these lands; it is well known that they are held at such high prices that they are above the means of ordinary purchasers, being frequently sold from 100 to 150 dollars per acre for cleared, and in the same proportion when uncleared. Now, I will appeal to every man at all conversant with the subject, whether the clearing, embanking and draining of a tide land plantation, is not a work of Herculean labour and expense, requiring constant and unremitting care to keep it in order. The same remark, it is true, applies with equal force to the inland swamps; but then it must be observed, that the most valuable of them, have been completely cleared, and many partly drained through the patience and perseverance of our forefathers, whose example, in this respect, cannot be too much applauded, and ought soon to be imitated.

The 4th consideration, is the superior health of the negroes. This is an important consideration; for although negro property may occasionally be depressed, as at present from circumstances of a temporary nature, it must, nevertheless, continue to be extremely valuable, so long as we have so many forests to clear, and so long as from the unhealthiness of our climate in the lower country, the most laborious agricultural employment must be carried on by black labourers. Although, therefore, I would not recommend altogether the example of that nation of antiquity, whose chief commerce was to supply the Roman market with slaves, still as they constitute the best part of our property, and are bought and sold frequently to great advantage; the clearing of them must be an object worthy of our attention, and forms an important item in the profit and loss account of the agriculturist.

5th. The better quality of the high lands for the culture of provisions, and may under proper management be frequently productive of good cotton, should that article ever again become an object of desirable culture.

6th. The abundance of the finest timber for building, either on the plantation or for market, if the proper and necessary means were taken to provide for its transportation.

7th. The superior health of the pine lands settlements in the neighbourhood, either for those who cannot afford to leave their plantations to the care of others, or for overseers, to such as are enabled to remove. These considerations, with others, which it would be tedious to enumerate, are, I trust, sufficient to induce those who may be at a loss to know how to appropriate their surplus capital, to reflect whether it would not be worthy of their attention to form companies to buy the present waste lands in the swamps, not far remote from the city, and by proper and systematic drainage, render them valuable, instead of going far from their native land and civilization, as has been too frequently the practice of late, to brave the dangers of the forest, in climes more unpropitious to health than our own. It would be unnecessary to furnish the many historical illustrations, where lands equally unpromising at first, have been made the best lands in the country after they have been properly cultivated. I would barely observe that this was the case with the Carse of Gowin, in Scotland, with the Pontine Marshes in Italy, which were formerly drained and made healthy, and most productive; and after being long left to go to ruin, were in a fair way of being restored to their former state, under the superintending intellect of the Engineer Prony, and assisted by the munificence of that master spirit

of all that was great and daring, the unhappy Exile to St. Helena. But when I reflect on the apathy that every where prevails in this lower country, I really confess that I indulge no hope of seeing any better state of things. I therefore must dismiss the subject, under the sincere impression that it is worthy of more consideration than it seems destined to receive.

RUSTICUS.

CURE FOR WEAK EYES, recommended from actual experience.—Take a small lump of white coppers—say about the size of a pea; put in a small phial, holding about two ounces of water; carry this in the pocket, and occasionally, taking out the cork, turn the phial upon the fingers end, and thus bathe the eyes. This will positively effect a real cure in a short time.

FOR THE AMERICAN FARMER.

Pittsfield 6th June, 1823.

Dear Sir,

I have noticed an article in your No. 5, of vol. 5, of "a New Jersey Subscriber," on the subject of *ruta бага*, in which he expresses his doubts, if it be a profitable crop, and gives his reasons.

Equally desirous with your correspondent of eliciting practical knowledge, I am induced to state, that five years experience, satisfies me that it may be raised to advantage, wherever the climate is adapted to its culture:—Because,

1st. To raise a good crop, it is necessary to put the land in a good state of tilth.

2d. The requisite care of the crop, while it extirpates weeds, prepares the soil in the best possible manner, for stocking to grass with the succeeding crop of grain.

3rd. All kinds of live stock are fond of it.

And 4th. It affords a most succulent food, at a time (the spring) when most wanted for every kind of stock.

Having remarked the advantages arising from the turnip culture in Europe, I was induced soon after entering on Agricultural pursuits, to give it a fair experiment; notwithstanding the general opinion in this section of the country, that turnips could not be raised, except on newly cleared, and burnt land; consequently, they were only cultivated in a partial manner, and merely for culinary purposes.

In 1817, I selected for the purpose an acre in a field, that might be termed *worn out land*; that is to say, it would produce a half ton of hay to the acre.—The soil, a dry gravelly loam—gave it three ploughings and two harrowings before drilling:—on the 24th June, manured with twenty-six loads of barn yard and hog's manure, and sowed the common English turnip—gave it a top dressing of about fifteen bushels slacked lime, and fifteen bushels leached ashes. It produced eight hundred and sixty-three bushels, and received the premium of the Massachusetts Agricultural Society—very many of the turnips weighed from ten to twelve pounds; generally from six to eight pounds.

Having raised at the same time a small quantity of RUTA BAGA, from seed procured direct from Russia, I was enabled to make a comparison of the relative value of the two kinds, and hence am satisfied, that with us at least (on account of our long winters and late springs) the RUTA BAGA, is preferable to the common turnip, because the latter, can only be used to advantage for fall feed, whereas the former will keep good through spring—and at this time I have them in perfection. It is true, an acre will not produce so

many bushels of the RUTA BAGA, as of the common kind of turnip, but that, I consider, as fully compensated, by the greater quantity of nutritive matter they contain.

Since 1818, I have raised the RUTA BAGA every year, and may safely state, that, in no year has the crop been less than five hundred bushels per acre, and entirely free from worms.

Notwithstanding this favourable result, it is with much regret, I am obliged to add, that I am, as yet, almost alone in this county, in the cultivation of turnips as food for live stock, although our soil and climate are peculiarly adapted to them.

AGRICOLA.

The climate of New England is so much moister than that of the southern states, that we apprehend both potatoes and turnips may well succeed there, in seasons, when they would fail even with us in Maryland. The suggestions above, are valuable and conclusive—however, as to New England, at least—and yet we see that even there, this great resource for winter feeding of stock is neglected. What immense advantages have resulted from the turnip culture to England. We regret that the communication from Agricola, was not sooner received—but any thing from his pen will be at all times highly acceptable.—*Edit. Am. Farm.*

GEOGRAPHY OF PLANTS.

EXTRACT TO THE EDITOR,
Duncansville, S. C. May, 21, 1823.

DEAR SIR,

I return you my thanks for the seeds you have so often sent me, all of which I divide among my neighbours, or plant myself. The cotton seed from the *Ile of France* failed—I have one stalk of the Ohio corn, (Mr. Rose) planted on the 8th ultimo, in good land, this day in tassell, and only 18 inches high. The golden Sioux, (the Missouri) is now in full silk, planted the 12th ultimo. The greatest objection to these early kinds of corn, is, that they mature too soon with us, and it appears to me from the experiments of this, and former years, we should not plant them till the last of this month or early in June. My first trial of the Connecticut yellow corn, planted in March, did not grow more than 4 and 5 feet high, yet when planted on the 13th of June, after oats, grew 10 and 12 feet high, and made over 50 bushels—the 'Ellicott' corn, and the Brazille, with the ('Pickering') millet, are promising; My acre of gourd seed corn, is fine, the first tassell came out this day, and the finest stalk from the top of the bed (a flat one) to the end of the longest blade, is eight feet ten inches high. This first crop or planting is so thick (more than 8000 stalks) I am not sure what may be the result, 4 or 5 weeks will determine it. About the 5th of June, I intend to plant the 2d crop in the alleys, this will consist of about 3000 stalks. If I had not the result of the last year's crop from this acre—I could not from the present appearance of the first crop, expect any thing from the 2d planting.

J. S. B.

FOR THE AMERICAN FARMER.

WOOL.

Fairfax county, Virginia, June 6th, 1823.

DEAR SIR,

In compliance with the request of one of your correspondents, I state, that I have just finished shearing a flock of 525 of mixed merino sheep, from which I have obtained, 2368½ lbs. of wool, free from tags, giving an average of a little more than 4½ pounds. My average is not as great as it has been in former years, in con

sequence, (I presume,) of my flock's containing at this time, a larger proportion of breeding ewes than usual. I have always been in the habit of preparing my wool for market, by laying each fleece, as it is taken from the sheep, on a table, taking off all around, about two or three inches of the coarsest wool, which is reserved for domestic purposes, and rolling the remainder up very nicely and firmly, with the inside of the fleece turned out. The whole is then packed away in coarse bags; and a wagon, will, at a single load, take a thousand dollars worth of it to market. My wool, thus prepared, has been readily sold, for the last four years, at 40 cents per pound, in Alexandria; and I am very much inclined to think would bring a great deal more, in the northern markets. But from some cause or other, we find it very difficult to ascertain the market price of wool in other places. I last year, made an enquiry through your paper, on this subject which was never answered. The growers of wool would certainly find it to their interest, to communicate freely with each other, on this subject. And wool is now becoming too important an article, not to be entitled to some little attention, in a paper, devoted, like yours, to the agricultural interests of the nation.

I have been told, that during the last summer, 70,000 lbs. of wool were imported from Europe into Boston alone, and sold, at public auction, at from 75 to 125 cts. per lb. Is this the fact? And if so, what was it's quality and condition? Will not some northern wool grower reply to these enquiries; and tell us also the usual price of American wool in the northern markets? In Ohio, I have been told, it readily commands from 50 to 100 cts.

I am no friend to any unnecessary commercial restrictions. But if congress have thought proper to give encouragement to our manufactures, is there any consideration either of justice or state policy, which should withhold a similar encouragement from the raw material, of which the manufacture is made?

F.

The Editor expects, with confidence, that the above article will attract the notice, and be favoured with an answer from several of his patrons in Connecticut and Massachusetts. How can gentlemen expect answers when they want information on some points, unless they communicate it when it is asked on other subjects, within their knowledge and experience?

FOR THE AMERICAN FARMER.

WOOL.

As some of the commission houses, for the purchase of wool, are circulating a report, that their eastern friends, write instructions for them not to bring good wool at more than twenty cents per lb. As this article must be reduced in price, in consequence of the war in Europe; and as this is undoubtedly a mere eastern trick, to obtain wool below its real value, I beg leave to call the attention of the wool growers to the same, and to suggest the propriety of forming themselves into a society, to obtain information on this, and also on all other matters relating to the growing and disposing of this indispensable article.

ALBION.

TO THE EDITOR OF THE AMERICAN FARMER.

HONEY.

Newbury Port, Massachusetts, May 28th, 1823
J. S. SKINNER, Eso.

"A lover of honey," in your paper, No. 9, vol. 5, says "there is a gentleman in the lower part

of your native county, who knows much better how to take honey from bees than the German, mentioned in your paper (No. 43, vol. 4.) and with less expense than Blake's patent hives; and goes on to state the process of taking off the top of the hive, &c. I confess I am not authorised to answer for your numerous patrons, but have the sanity to think a majority would prefer a hive like Mr. Blake's, that the top could be lifted like a chest cover, and the honey taken in a draw or box, that would be no disgrace to any table, if placed on it, to the method of knocking off the top of a hive, and breaking up a quantity of comb, as it must necessarily be broken; to say nothing of dropping the honey, and leaving the hive in a state of ruin, that would take the industrious little animals a long time to repair—even if the extra expense of the hive was 50 cents—as it cannot exceed that, unless you have a lock, (which is an improvement) and would probably add 25 cents more. If your correspondent has recommended a better way, of course it will be adopted, on the other hand, if Blake's hive is not considered too expensive, this notice may help him to sell a right.

B. P.

EXTRAORDINARY POWER OF LOCOMOTION, OR QUADRUPED TURNED BIPED.

Extract to the Editor, dated Allentown, N. J. June 10, 1823.

"A few days ago, in passing a flock of sheep, at some distance from me, I observed something of uncommon appearance moving about amongst them; it was owing, I found upon approaching nearer, to a lamb following its dam, walking upon its fore feet, with its body erect. Its hind feet, I was told upon inquiry, and legs as far as the gambrels, were frozen off, the night it was lambed, and very soon afterwards, it acquired this extraordinary kind of motion. It is three months old; quite fat, and of ordinary size for its age. It grazes and sucks, resting wholly upon its fore feet, with its body in the position just mentioned; and will walk, if not urged too fast, a quarter of a mile at once, without inconvenience.

The above fact may be familiar in the sheep districts of colder countries, but to me, and as far as I can learn, to the people of this neighbourhood, it is altogether novel, and exhibits the resources of the animal economy for the purposes of locomotion, to an extent, of which I have heretofore had no conception.

FROM THE NATIONAL INTELLIGENCER.

COMPOSITION TO PRESERVE WOOD.

Mr. Gales,

It becomes important to have a simple composition, in the application of which, the durability of bridges constructed of wood will be extended for a long period of time without a roof; whereas; if left exposed to the weather, ten years is their estimated limit of duration. It well deserves the attention of the directors of the city bridge company, for, as the timbers are new, well seasoned, and have suffered no apparent decay, the mixture being now put on will be in time to prevent the operation of the rot.

I send you two receipts, one for the preservation of wood or timbers liable to be injured by the weather; and one for the roof of a house, to defend it not only from the weather, but also from fire, and I doubt not, they will be both acceptable to many of your subscribers, among whom I am

City of Washington, 2
17th June, 1811. 5

Composition for preserving weather-boarding, and all other work liable to be injured by the weather.

Lime, it is well known, however well burnt, will soon become slacked by exposure in the open air, or even when confined in a situation, it is not remarkably dry, so as to crumble of itself into powder. This is what is called air-slacked lime, if contradistinction to that which is slacked in the usual way, by being mixed with water. For the purpose of making the present useful composition to preserve all sorts of wood works exposed to the vicissitudes of weather, take three parts of this air-slacked lime, two of wood ashes, and one of fine sand, pass them through a fine sieve, and add as much linseed oil to the composition as will bring it into a proper consistence of working with a painter's brush. As particular care must be taken to mix it carefully, it should be ground on a stone slab with a proper muller, in the same manner as painters grind their white lead, &c. But where these conveniences are not at hand, the ingredients may be mixed in a large pan and well beat up with a wooden spatula. Two coats of this composition being necessary, the first may be rather thin, but the second should be as thick as it can conveniently be worked.

This most excellent composition for preserving wood when exposed to the injuries of the weather, is highly preferable to the customary mode of laying on tar and ochre. It is indeed every way better calculated for the purpose; being totally impenetrable by water; and so far from being liable to injury by the action of the weather, or heat of the sun, that the latter, though such a powerful enemy to tarred and ochred sailings, &c. even hardens and consequently increases the durability of the present proposed composition.

Another receipt for the roof of a house, to defend it from the weather and from fire.

Take one measure of fine sand, two measures of wood ashes well sifted, three of slacked lime ground up with oil; laid on with a painter's brush; first coat thin, and second thick.

I painted on a board with this mixture, and it adheres so strongly to the board, that it resists an iron tool, and put thick on a shingle resists the operation of fire. I used only a part of the mixture; what remains, continues in an iron pot; water has lain on the mixture for some time without penetrating the substance, which is as hard as a stone.

FROM THE MORNING CHRONICLE.

TO THE PUBLIC.

As the season of the year is approaching, when persons owning horses become alarmed, in consequence of these animals passing off bots with their feces, I have thought proper to endeavour to remove such fears, by laying before the public some facts, which I have noticed, in the course of twenty-four years experience.

Bots, are generally found adhering to that portion of the horse's stomach, which is lined with a continuation of the Oesophagus membrane, to about one third or little more of its extent; sometimes they are found attached in great numbers to the pylorus, or the posterior opening of the stomach. The time that horses begin to pass them off, is generally in June; and so on through September to October. The bot remains in a Chrysalis state for an uncertain, but short time; and then assumes the same character, as the parent fly. To prove, without the possibility of doubt, that the bot is produced from the fly which deposits its ova, on the hair of the horse, I took twelve bots that came from twelve horses; these

put into separate vials, and with paper wrapped in a quill barrel, I made stoppers to give ventilation, and noted on each vial, the day that the bot came from the horse, this was convincing, as to the uncertainty of the Chrysalis; for some produced the fly in twenty one days, others forty-nine days, and others in the intermediate time. The flies thus produced, were the same as those that deposit their eggs so plentifully on different parts of the horse. What it may be, that causes this difference of time in the Chrysalis admits of speculation. It is proper to note, that a bot taken from the stomach of a dead horse, cannot produce the fly, as in this stage its progress through the canal, it is not sufficiently matured.

There is no worm that we know of, in the intestines of the human subject, which makes such an annual rotation; and in consequence of their continuance in the intestines, we find numbers of the human family destroyed by them. Whereas, it may be presumed there would be few or none killed by worms were their rotation annual. And as bots perform this annual course, it can be no cause of surprise that they are not destructive, as they are commonly supposed to be. Was it a fact that they were thus destructive, we should find very few colts raised to the age of four years, for colts generally run out unwell, they are considered ready for work, are fully exposed through the summer to the action of the fly. If a horse, by symptoms, expresses much pain, it is said to be the bots; and so much does this notion prevail, that people imagine, bots kill more horses than any other disease. If we reject this opinion, we shall perhaps come nearer the fact; for in all probability there is no disease that destroys so few.—When he is said to be sick with bots, it is generally *spasm* or *inflammation* of the intestines. That bots never kill I will not assert, though there are eminent veterinarians in England who say they never do. It is a common opinion, that a few bots are essential to the health of the horse. This erroneous idea arises from people opening but few for death, and those few being found to have got in them. But in the many hundreds that have opened, there have been some in which no bot was to be seen; and not one of these can be supposed to have died for the want of bots. The motive, I have in making this communication is to remove the fears that prevail with some persons, when they see bots coming from the horse, as if they were so numerous as to kill immediately. But for the information of such persons as would rather give something to alleviate their discharge, when they see a few coming away, I would advise one ounce of powdered savin, to be given in the horse's feed, once a day for three days. At the season above mentioned, I have recommended this medicine to such persons as I could not persuade, to be satisfied with the course of nature; and they were very much astonished at the quantity of bots, brought off by it.

JOHN HASLAM, Veterinary Surgeon.
Baltimore, April 13th, 1823.

FROM POULSON'S AMERICAN DAILY ADVERTISER.

UNION CANAL.

A traveller returned yesterday from the summit level of this highly important work, and after spending two days there, and inspecting every part of it, he can safely aver that the utmost diligence has been used in excavating the broad and deep channel which is to connect the rivers Delaware and Quittipahilla. Contracts are

now in hand for removing the residue of the limestone rock, and the feeders are nearly all in a state of forwardness, three of which flow at present into various parts of the Canal. One section of the summit Canal was full, and presented to the eye a most beautiful and satisfactory evidence of a sufficiency of water; there being only one feeder, out of seven, (which are the property of the Company,) employed to fill it, which was done in five days. There can be no doubt, indeed there never was any, of a supply of water, and, in less than three months, the whole length of the summit will be filled. Wherever sink holes have appeared in the limestone rock, they have been permanently stopped by puddling; in one instance, in a section of the Canal nearly a quarter of a mile long, in which the water has lain all winter and spring, without the smallest leak through stone.

All the excavation has been executed in a workmanlike manner, and five miles of the Canal to the east of the summit are under contract, and fast progressing. The Engineer, Mr. White, who is perfect master of his business, says, that the excavation this summer, will extend beyond Womelsdorf, and all the locks at the end of the summit be built. Materials for the gates, &c are on the spot, and stone is preparing, while a strong gang of men are digging out the lock pits.

In short, the prospect is entirely satisfactory, and the most sanguine hope is entertained of the whole Eastern section, down to the Schuylkill, consisting of 34 miles, being completed and fit for boating in 18 months. The Western Section, from the summit to the Susquehanna, is much the easiest, and will not take so long to finish; so that the public may expect, in three years, to see the commerce of the Susquehanna brought by the Schuylkill to our wharves on the Delaware.

CHESAPEAKE AND DELAWARE CANAL.

Mr. Wright, the engineer, has arrived from New York. He will proceed, after a thorough examination of all former surveys, levels, &c. to the Peninsula; and having made the necessary examinations of the ground, waters, &c. report what route, under all circumstances, ought to be preferred for the Chesapeake Canal. To the performance of a duty upon which materially depends the success of this great work, there is reason to believe that Mr. Wright brings an entire independence of mind, an unbiased judgment, scientific acquirement, and practical knowledge and experience. It is highly honourable to an individual to be selected for such a purpose. Public expectation is directed to Mr. Wright's decision, and will be followed by entire confidence. The managers of the company have done well in chusing an individual as umpire on this occasion, who adds to competency as engineer, in utter freedom from all prejudice; and if their final decision on the important question of the route be guided by his counsels, they will doubtless proceed with safety, and acquit themselves of the duty of their stations so as to satisfy the public and the stockholders.

Mr. Wright's report will be anxiously expected. A gentleman has been for some time engaged in sinking shafts, &c. preparatory to the commencement of his labours, in which he will be accompanied by Messrs. Strickland and Randal, and it is to be hoped by one or more of the most distinguished officers in the United States Engineer Department, for whose assistance, it is understood, application is made to the Secretary of war, and the President.

[Franklin Gaz.

Extract to the Editor of the Franklin Gazette, dated

PITTSBURGH, May 15.

"I have been delighted, since my residence here, to find the great revival and activity in business. Several manufactories have lately been established, and I understand are going on prosperously. Added to this, the course of the western trade has reverted to its old channel, and this city, which, if I may be allowed the expression, is the western capital of Pennsylvania, exhibits the most lively appearance. Already there have been 43 departures of steam boats, averaging sixty tons each, amounting to 2580 tons of goods, down the Ohio river, independently of the immense amount carried in arks and other boats.

I have just read a letter from the postmaster at Canonsburg, which narrates the circumstances of an attempt to set fire to the post office in that place. The effect proved abortive, and every exertion will be made to detect the incendiary. But slight injury was sustained."

Miscellaneous.

SPEED OF HORSES.

The following may be given as a just account of the most extraordinary English performances in speed upon the turf.

At New Market, there are two courses, the Beacon and the round; the first is exactly four miles, one furlong, and one hundred and thirty-eight yards, or 7398 yards, being three hundred and fifty-eight yards over four miles.—Childers run this course in seven minutes and thirty seconds, carrying nine stone, two lbs; and in doing this he must have done 4 miles in 7 minutes and 7 seconds. The Round Course is 3 miles, 6 furlongs, and 93 yards, or 6693 yards, being 347 yards less than 4 miles. Childers run this course in 6 minutes and 40 seconds, and if he could have continued *this*, would have done 4 miles in 7 minutes. It has never been questioned, that Childers was the swiftest horse ever known in England; and it is alleged, that no other horse has ever run the Beacon Course in less time than 7 minutes and 50 seconds, nor the Round Course in less than 7 minutes. He was foaled in 1715.

Bay Malton was bred by the then Marquis of Rockingham, and foaled in 1760. He was esteemed the first horse of his year in the kingdom, and won more prizes of consequence and value than any horse of his time. His most celebrated performance was 4 miles in 7 minutes, 43 seconds and a half, and done over York.

It is said that Col. O'Kelly's horse Eclipse, ran the same distance over York, in eight minutes, with *twelve stone*, though going only *at his rate*, without any inducement to speed. This horse stands second to Childers alone, and was foaled in 1764, during the eclipse of that year.

Merkin, a fox hound bitch, ran a trial of four miles, and crossed the ground in 7 minutes and half a second. This dog belonged to Col. Thornton, and is more distinguished in her family for speed, than Childers in his, and has certainly outdone every thing in actual performance. She once challenged any hound of her year for 10,000 guineas, to run five miles over New Market, giving 220 yards.

Can it be presumptuous in me then, to assert, that there is not on record any horse other than Childers, that has done the full fair four miles in less time than Sir Henry did his first four miles on Tuesday, and that there is no horse on record that has done the same distance in the same time with Eclipse at his age.

JOHNNY RAW.

The following interesting circumstance is communicated from the most respectable source, and there can be no doubt of the correctness of the statement.

Extract of a letter from London, Nov. 23.

"A great object of curiosity is now preparing on the Thames—a new Steam Vessel, intended for Calcutta. Her engine and boiler occupies only one-fifth part of the usual space—her furnace consumes its own smoke, will perform with one bushel what formerly took one chaldron of coals: her boiler is constructed to return its own steam, without one particle escaping, so that once filled it is enough for the voyage, which it is calculated she will perform in 36 or 40 days. The invention is American—PERKINS is the man, who does honour to his country. In two months time this vessel will sail (or go) for Calcutta."

George Clerk, the coachman of a Bristol and Bath coach, was tried under the new Act of Parliament, for Manslaughter, in having furiously driven a coach so that it was upset, and a person named James Hamilton killed. The case was clearly proved against the prisoner, and the Jury immediately found him *guilty*.

Mr. Justice Burrough, on addressing the prisoner, observed, that by a recent Act of Parliament he was empowered to sentence him to transportation for life; but as this was the first instance which his Lordship knew of, of a conviction for the offence of furiously driving, he did not think it necessary to visit him with the full measure of punishment which the law enabled him to inflict, and he should impose a more lenient punishment, in the hopes that that would operate as a first warning to those of his class. His Lordship, however, could not help observing, that a great portion of the evil was occasioned by the inattention of the proprietors themselves, who encouraged this system of driving furiously, for the purpose of out-stripping each other, and getting more money by performing journeys in a shorter time. Such a rate of travelling as twelve or fourteen miles an hour by a coach laden with passengers, was a rate which could not be sanctioned, for it was dangerous and illegal, and those who adopted it must beware, for they did it at their peril. He was afraid, however, they would go on driving faster and faster, until by repeated accidents it became necessary to put a stop to the system, by sentencing those who in the pursuit of it occasioned the death of any of his Majesty's subjects, to be transported for life. His Lordship sentenced the prisoner to be imprisoned for twelve months in the county gaol, and during that time to be kept to hard labour at the treadmill. There were many *Jehus* in Court, amongst whom the conviction and sentence appeared to excite a strong sensation.

At the Warwick Assizes, a plaintiff of the name of Heely, got a verdict of £100 damages against Waterhouse and others, for a broken leg, occasioned by the overturning of defendants' coach, the Balloon, on which Plaintiff was a passenger.

John Bolt, convicted at the late Exeter Assizes of having shot at Jane Jusland, was executed on Friday the 4th inst. He said, to the last, that his love for her was unabated, and that he was in a state of frenzy when he attempted her life.

In the case of Moses Long, convicted at the Suffolk Assizes of a burglary in the house of Mr. John Peck, Brockford, a curious confession was made by the prisoner, from which it ap-

peared that he entered by breaking a pane of glass, marched about the house, throwing open all the doors; lay down on the bed and slept, he supposed above an hour; came to another bedroom, and again lay down, but in a few minutes got up again, and "squatted down" upon the stairs; went into the kitchen, and ate a candle which he found there. He afterwards took up a parcel of bank-notes, and laid them down again, thinking them letters. Seeing something which looked like a desk, he opened it, and putting his hand upon some black and white stripes, to his great astonishment and terror a noise proceeded from them, and he ran away as fast as he could; this was a piano-forte! The Court was convulsed with laughter at this confession, from which, and other circumstances, it appeared that the prisoner, who was an inmate of the workhouse, was a man of very weak understanding, but capable of distinguishing right from wrong.

A man of the name of W. Harris, a convicted felon, now confined in the gaol of Portsmouth, has confessed that he was concerned with Hussey, and another man of the name of Lee, in the murder of Mr. Bird and his housekeeper, at Greenwich, about five years ago; and he has also confessed he was concerned in the murder of Lieut. Johnson, on the Deptford road, about 14 years ago.

An adjourned special meeting of the "Maryland Agricultural Society" will be held in the room over the Post Office, in the city of Baltimore, on the 23d inst. for the purpose of taking into consideration, the form of constitution, which shall then be submitted to their deliberation, by their committee appointed to propose the same.

By order, JAMES HOWARD, Sec'y.

THE FARMER.

BALTIMORE, FRIDAY, JUNE 20, 1823.

We placed on file for publication as soon as received, the valuable address from Col. Pickering, as one of those good things, which, being the fruit of sound judgment, and founded on great experience, would wear well, and be well received whenever we could find room to insert it. We regret that the arrangements of the paper did not conveniently admit its insertion entire, in one number—but it will be found that, as is usual with his communications, the address is so systematically framed, and the different subjects, so well defined and separated, that our division of it, will not break the continuity of his remarks on any particular topic.

A new use and application of sheep-power.—Gen. Ringgold, of Washington county, who sheared this year, upwards of one thousand sheep—and has marked 1600 for shearing the next—kept this flock *pasturing in his wheat* until near the middle of April. By this means the fly, then in the young shoots, was in a great measure extirpated. His system is to have them confined in their range, to a given space—and so pass them regularly over the whole field. This too, has the effect of distributing their manure equally.

BALTIMORE MARKET.

PRICES CURRENT.—CORRECTED WEEKLY.
Flour, best white wheat, \$8—Howard street Superfine, \$7 25—fine do. \$6 75—Wharf, do. \$7—

sales—White wheat, \$1 42 to 1 46—Red do. \$1 42 to \$1 43—Rye, 75 cents—Corn, 50 to 52 cents—country Oats, 40 cents—Beef, 8 cts. per lb.—Live Cattle, \$6 to \$6 50 per cwt.—Bacon, round, 8 to 9 cents per lb.—Pork \$4 50 to 5 50 per c. lb.—6 to 8 cts. per pound—Mutton, 5 to 6 cts. per lb.—Beans, \$1 37½ to 1 50—Peas, black eyed, 55 to 60 cts.—Red Clover Seed, \$5 50 a \$6—Orchard Grass do. \$3—Herds' Grass do. \$3—Timothy do. \$4 50—Millet, none—Buckwheat, \$1 50—Flax Seed, 75 to 80 cts.—Whiskey, from the wagons, 33 to 34 cts. per gal. including the barrel—Apple brandy, 30 to 32 cts.—Peach do., 65 to 70 cts.—Shad, \$6 50, scarce—Herrings, No. 1, \$2 75 per bbl.—No. 2, \$2 50—Fine salt, 60 to 65 cts. per bush.—Coarse, do. 70—Butter, (Firkin) 14 cts per lb.—Eggs, 12½ cts. per doz.—Hay, \$14 50 to \$15 per ton—Straw, \$9.

MARYLAND TOBACCO.—Fine Yellow, none—good do none—Fine Spangled, 15 to \$18—Fine Red, \$10 to 16—good do. 5 to \$8—Dark \$3 to \$4 50—Seconds, \$1 50 to \$8.

Sales.—1 hoghead \$24—3 do. \$12—3 do. \$11—1 Second, \$4—raised by Mr. John T. Wall, Truman's Point, Patuxent.

The following sales have been made within a few days, by a commission merchant here.—15 hds. Patuxent Fine Red, 10 first, \$13 to \$16—5 Seconds, at \$6—William D. Bowie's crop—28 do. do. do. 17 First, \$13 50—11 Seconds, \$6 50—William Bowie's do.—20 do. do. 16 First, and 4 Seconds, averaged over \$10—John B. Mullikin's crop—48 do. do. 35 First, \$10—13 Seconds, \$7—Benjamin Oden's crop—19 do. do. good Red, 17 at \$8, and 2 at \$5.

The above prices are fully maintained, and the good qualities are becoming scarce in the market—some further inquiry for the most inferior middle descriptions, same as last report.

Botetourt Springs.

We understand a watering place has lately been established in Virginia, called the Botetourt Springs, which is attracting a good deal of attention, and is likely to become a place of considerable public resort. There are two springs—one strongly impregnated with sulphur and magnesia—the other a tonic. The waters of which have been found very efficacious in a variety of diseases. There are hot, cold and shower baths. The buildings are of brick, and the accommodations throughout, are in a style of neatness and comfort, that few other watering places in the United States, it is said, can boast. It is situated in a most beautiful and healthy country on the main road, leading from Baltimore to Tennessee, (Alabama,) and the other South-Western states—and is about midway between Fincastle and Salem, Botetourt county.

FOR SALE

At a low price and on a long credit, the FARM on Elk Ridge, occupied by Mr. H. Scott, and formerly owned by Luther Martin, Esq. containing about eleven hundred acres.

It is situated about eleven miles from this city, near the Washington road, and is considered remarkably healthy—The situation is handsome, and the land easily improved by plaster and clover. This property will be divided if required, and immediate possession given—For terms apply to

ROBERT & JOHN OLIVER.

Printed every Friday at \$4 per annum, for JOHN S. SKINNER Editor, by JOSEPH ROBINSON, on the North West corner of Market and Biddle streets, Baltimore; where every description of Book and Job Printing is executed with neatness and dispatch. Orders from a distance for Printing or Binding, with proper directions promptly attended to, addressed to J. Robinson, Baltimore.

Internal Improvement.

ON THE PARAMOUNT IMPORTANCE, TO MARYLAND, OF A CANAL TO THE SUSQUEHANNA.

No. 5.

The great error of popular conjecture, in overrating, to an enormous extent, the difficulties and expense of opening a Canal.

40. Few occasions, I believe, have occurred, I know of none, upon which the public mind has strayed more widely from the truth than the present. In a pamphlet entitled "Considerations on the Great Western Canal," printed at Brooklyn in 1818, page 37, it is stated, that, when it was first seriously contemplated, to embark in that undertaking, it was objected, that, the making of three or four hundred miles of canal, would even baffle the whole collective energies of the Nation, at this early stage of our history, and that twenty millions of dollars was the round sum frequently set down as the probable cost; whereas it has been proved by subsequent experience that only one state, single handed, will be entirely adequate to accomplish the object, and for less than one fourth of the money. I might have said for about one fifth, as may be thus explained: the whole cost, as will hereafter be quoted, was estimated at \$4,571,813, and from its being since ascertained that the actual cost had generally fallen below the estimate, it has been understood that the sum total was in a fair way to be reduced half a million of dollars, which being taken from the sum above stated, the remainder will exceed four millions, that is the fifth part of twenty millions, by only a small amount, in proportion to the whole. Thus, it appears that, in this instance, public conjecture was nearly five to one above the reality.

41. Having for some years past been in the habit of devoting particular attention to the subject of canals, I have had many opportunities of hearing the inquiries, and becoming acquainted with the sentiments of others. Most of the estimates which have thus come to my knowledge, have been still more extravagant than the one above mentioned. Even the lowest, have been greatly above the probable cost, as it may, with rational certainty, be calculated from practical and other substantial data, both in America and Europe. Some have been ready to conclude, that to open one hundred miles of Canal from Baltimore to the Susquehanna, would be literally impossible; or, if possible at all, the city, should it be sold, would hardly produce an amount sufficient to defray the expense; others that the whole state of Maryland would be unable to furnish the money that such a prodigious undertaking would require. By an intelligent person, in other respects, but from want of opportunity, having little acquaintance with the business of cutting Canals, as is, in general, the case throughout the great mass of our population, I was lately asked whether in my opinion ten millions of dollars would be a sum sufficient; by another, whether eight millions, would in my estimation, answer; and again, whether six millions were likely to be adequate to the purpose. To these, and all similar inquiries, my reply has usually been, that I had no idea of any such amount being necessary; that on the contrary it was my firm persuasion that one million of dollars economically and judiciously expended, would be more than sufficient for meeting every expense. For the accuracy of this persuasion, I have frequently assigned my reasons to individuals, and as I believe them to be well founded, am now willing to submit them to the consideration of the public.

42. The late B. H. Latrobe, a professional engineer of extensive experience, and whose opinion is appreciated as being entitled to the greatest respect, in an essay published over the signature B, in the Baltimore Federal Gazette, under date 23d September, 1818, has estimated the cost of the Susquehanna Canal, now under discussion, supposing its length to be 100 miles at \$3,545 per mile, if cut through no worse ground than the Canal of New York; or, should the ground be more rocky and difficult, as he supposes would probably be the fact, he has on this account conceded that the cost per mile might amount to \$5,000, that is, half a million of dollars for the whole canal, should the distance be prolonged to one hundred miles.—Until lately, I was also inclined to believe that their route was likely to be much more advantageous for opening a Canal than any that could be selected between Baltimore and the Susquehanna; but from accounts, I have lately read, as well as verbal information that I recently met with, of their Herculean labours in opening the entire channel of their Canal through solid and slaty rock, very tedious to be excavated, and being likewise informed that the making of a Canal on sideling ground is attended with little, if any more difficulty, than if it were level, my prospect in relation to our route now is, provided we can bring a sufficiency of water to the summit level, that it will not be near as much worse than theirs, as I had formerly anticipated.

43. It is well known, that it is usual for houses to be built by contract, after the cost has been estimated by a competent architect. It is also common for Turnpike roads to be made, and Canals to be opened in like manner, and almost every kind of mechanical business is performed at a price previously ascertained. Hence it follows that the cost of opening a Canal is susceptible of being estimated as well as that of making a Turnpike road, or building a house. I am not about to imagine, however, that an estimate made in New York, in Philadelphia, in the District of Columbia, or at Richmond in Virginia, of the cost of building a house of a certain description, would be sufficiently accurate to be made the foundation of a contract for building a similar house in Baltimore. I am aware, that for this purpose, all the particular facilities and difficulties of the undertaking would require to be attentively considered. I am also aware that equal attention would be indispensable, were a contract proposed for the opening of a Canal in Maryland. But if it were known that the cost of a number of houses, similar to others that were wanted in Baltimore, had been particularly estimated in the places aforesaid, and that the accuracy of the estimates had been substantially verified by some being actually built, the citizens of Baltimore would, no doubt, consider the evidence conclusive, that if the amount of the estimates thus made, and confirmed by experiment, did not exceed six, seven, or eight thousand dollars, owing to the cost of labour and materials, being about the same, the cost would be about the same with us as with them. Thus, a conclusive criterion would be furnished for deciding to what extent it would, or would not be advisable to engage in the building of such houses in Baltimore. In like manner, were Canals of the size required, found to cost only from six to seven, or eight thousand dollars a mile, in other parts of the world, it might very rationally be concluded they would, in all probability, cost about the same, or at the very utmost, not more than ten thousand dollars a mile in Maryland, unless it were known that the route was particularly difficult. In other words, a well founded criterion may thus be afforded for deciding with

certainty to what extent it may, or may not, be advisable for the state, consistent with the extent of its resources, to embark in the opening of two or more Canals, or only of one.

44. But as no estimate could be made of the cost of a building, without knowing its size, and the style of its workmanship, so neither is it possible for that of a canal to be developed, without a previous knowledge of its dimensions. This being a question of superior importance, it appears to be the more indispensable that it should be minutely investigated. Such an examination may be the means of preventing many thousands of dollars being expended to very little purpose.—It will readily be admitted that the breadth and depth of any canal intended to be united with the Susquehanna or Potomac, ought to be adapted to the size of such boats as were best adapted to river navigation; so, as neither to occasion an unnecessary expenditure in opening the Canal, nor to counteract its utility afterwards, when in operation. In page VI, of the introduction to a collection of public documents relating to the New York Canals, published in 1821, it is stated that boats of 100 tons may be navigated on their waters; that their whole length will be 414, the Erie Canal 353, and the Northern Canal 61 miles; that the expenses of both are estimated at \$5,371,814, the sum of \$4,571,813 for the Western, and \$800,000 for the Northern Canal. The depth I find, page 104, to be 4 feet. Thus, the excavation required for every yard in length is 15 cubic yards and one ninth; and the average cost per mile, a small fraction under \$13,000. The aggregate rise and fall is elsewhere stated to be 661 feet 4 inches.

45. It is abundantly evident, that the less the cross-section of a boat can be, that is presented to the water, the less will be its resistance. By experiments also, which are recited in the New Edinburgh Encyclopedia, article Navigation Inland, page 411, it appears, that supposing one pound weight to be divided into 100 parts, the resistance against a square foot, as of a thin plate immersed in a stream, was found to be 181; against a square foot, as of the front of a box one foot long 142,—and against an equal front of a box 3 feet long 129 of those parts. Hence it follows, that the greater the length of a boat is, and the shorter its beam, that is, the less its width in proportion to its tonnage, the less will be its resistance. In conformity with this principle, it is understood, that the form of boat, most approved, both upon the Susquehanna and Potomac, is usually from 70 to 80 feet long, and between 7 and 8 feet wide, so as to carry about 15 tons, or 150 barrels of flour. Under these considerations, and from being informed by Joseph Ellicott, last summer, when in Baltimore, that wide Canals were, of late, very much exploded in England, the reasons appear to be strong, for believing, that a water-line of 24 feet, more than three times the width of the boat, would be sufficiently wide for the canal in question. With the usual slope of 18 inches base on both sides, to one foot rise, the bottom would then be 12 feet, and 8 cubic yards the excavation required for every yard in length.

46. In favour of the size thus adopted, it may be observed that it nearly corresponds with the size of the James River Canal which, agreeably to the information of Isaac Briggs, who assisted in its location, is to be 30 feet at the surface, 21 in the bottom and 3 deep, being an excavation of 8 cubic yards and a half in every yard of distance; and nearly agreeing also in size with 30 feet water line, 20 in the bottom, and 3 deep, as reported for the Potomac Canal, being an excavation, for every yard in length, of eight cubic yards and one third. I have been induced to

propose 4 feet for the depth, instead of 3, because the Canal would be less liable to be choaked by a collection of sediment, and would remain open for use a much greater length of time without being cleaned. Under these considerations, I have become entirely convinced that an abundance of useful economy may be applied to the opening of Canals, and having selected the size, that after the most mature reflection has appeared to me to be the most eligible for a boat navigation, the further calculations in relation to the required expenditure, will be made the subject of my next number.

WILLIAM KENWORTHY.

AGRICULTURE.

AN ADDRESS

DELIVERED BEFORE THE MASSACHUSETTS AGRICULTURAL SOCIETY AT THE BRIGHTON CATTLE SHOW, OCT. 9, 1822. BY THE HON. TIMOTHY PICKERING.

(Concluded from page 99.)

In respect to **LIVE STOCK**, it is gratifying to see the spirit excited within the last five or six years, to attend to their melioration, by preserving some of the most promising for breeders, instead of sending them to the shambles; and by introducing from other countries some individuals already highly improved. New England was originally granted to merchants of Plymouth, in the county of Devon, in England. It is natural to suppose that some of the early settlers sailed from Plymouth, and brought with them the Devon breed of cattle. The uniform red colour of various shades, some deep red, and approaching to brown, now so commonly seen among us, are probably descendants from the Devon race originally imported. Their uniform red colour corresponds with a distinguishing mark of the Devon breed, now so highly improved and celebrated in England. Among our own, individuals of this stock might be selected, admitting, with equal care, of equal improvements, on the principles now so well understood by the eminent English breeders, who, Mr. Arthur Young has said, are indebted for them to the celebrated Robert Bakewell. On the same principles all our other domestic animals may be improved. And this course appears to me indispensable for the speedy attainment of extensive improvements of our stock, of neat cattle especially. More than one generation must pass away before highly improved races, from the few imported animals, can be generally obtained. In this important work every substantial farmer in the country ought to engage; and by their rival efforts in every county, the great object might be accomplished. Beauty of form is desirable, and will merit attention: but strength for labour and ample supplies for the dairy are more important. A disposition to *fatten at an early age*—a point of excellence zealously sought for in England, where husbandry labors are chiefly performed by horses, is not of material consequence to New England farmers, where oxen for the draught and cows for the dairy constitute their most interesting stock. But what shall farmers, who live remote from a veal-market, do with their surplus calves, above the numbers of the best selected to keep up their stocks, and to supply those whose situation may induce them to purchase, and not breed for themselves?—I will mention what was some years since stated to me as the practice of a respectable farmer in Connecticut. He had cows for a large dairy, and cheese-making was his object. He allowed his supernumerary calves to suck their dam three days, (or until the milk was fit for the dairy) and then killed them; tak-

ing off their skins, and giving their flesh to his store-hogs. This was to me a singular instance of practice; but from the good sense of that farmer, I conclude he must have experienced it to be not merely a necessary but a saving practice. It may be in use among other great dairy farmers, although I do not know that it is.

The Trustees have already offered a premium to encourage the making of **FINE BUTTER**. But I am inclined to think it will be difficult, if not impracticable, to make any of the greatest excellence during summer, without the aid of ice-houses or spring-houses. The city of Philadelphia is admitted, I believe, to be supplied with *some* butter, during the warm months, superior to what is found in other cities of the United States. Yet their pastures are not better than those in the vicinity of some other cities and towns. I ascribe this superiority exclusively to the spring houses on many of the farms in the neighbourhood of Philadelphia. Pennsylvania is a well watered country. There it seems to have been an early practice, in taking up land for a farm, to search for a spring; and as near to it as the ground would permit, regardless of its situation in respect to the public road—to erect the dwelling house. Here the cattle, as well as the family, would at once find good water, without the labor of digging a well. Over these springs small houses are erected usually of stone. The room of the spring-house may be from ten to twenty feet square, according to the quantity of milk to be provided for. Trenches are made on the four sides of the floor, and bottomed and lined with flat stones. The residue of the floor is likewise paved with stones. The water from the spring enters at the side of one trench, runs all round, and at the opposite side passes away at a hole left in the wall. The under side of the hole is at such a height above the bottom of the trenches, as to raise the water just enough to keep the milk cool in the pans which are placed in it. This water runs perpetually from its source, and as constantly passes off at the outlet. In one of the trenches are also set the cream pots, and the pots with the butter the night before it is carried to market. Perhaps in the vicinity of Boston and other towns in the State, there may be some springs which may furnish the same accommodations.

Much has been said and written concerning an evil which pervades our whole country, from one extreme of the union to another—the general use of spirituous liquors—prevailing, in the opinion of wise and good men, to a mischievous excess. Sometimes it has been hoped that Agricultural Societies might find means to check the pernicious practice. But the class of farmers who abstain from it must be too numerous to become candidates for premiums on temperance. Besides, such prudent men need no remuneration for their abstinence. Here virtue is indeed its own reward.

It is said that in France and Spain the laborers in husbandry are remarkable for their temperance: but they drink small wines instead of ardent spirits. A French gentleman who for some years was endeavouring to establish vineyards in the Middle States, particularly in Pennsylvania, once mentioned to me how cheaply the French peasantry could be regaled with wine, purchasing a bottle for a few pence. At the same time, in answer to my question, he admitted that such wine was not equal to good American bottled cider. It has occurred to me that nothing might be so likely to check, and in a good degree to supersede the general and excessive use of ardent spirits, as the universal introduction of

Good Cider.

Were this beverage as well made, as easily it might be, it would be alike palatable and wholesome; and in the end might banish spirituous liquors from the houses of the great body of our citizens. Good cider might be furnished at half the expense of strong malt liquors; provided apple orchards were more extensively cultivated, and the fruits intended for cider, properly selected. We have a great deal of bad cider, because sound and unsound apples are ground together, and no regard is paid to fermentation, except to give it vent. No one can suppose the juice of rotten apples capable of becoming cider. But in whatever degree they are introduced, in the same degree the liquor must be debased. To make the finest cider, sound apples only should be used. But I must not enter into the minute particulars of the process of making and managing cider—it would not comport with the occasion, nor be practicable within the limits to which this discourse must be confined. I will barely suggest a few things which involve some principles.

In every orchard are found a great variety of apples generally used for cider. In New England I presume these are chiefly wild, that is, ungrafted fruit. And I have heard the opinion expressed, that such wild fruit would make the best cider. This surely is an error. For although in a large orchard some good natural fruits may be found, yet many of the trees produce apples so small as to cost too much labour to collect them, and others have juices so meagre as when collected to be of little worth. A few sorts which in England have been celebrated for yielding the finest ciders, were always grafted with as much attention as apples designed for the table are with us. But in England, the apples which a century ago furnished ciders of distinguished excellence,—to use the expressive words, in like case, of some of our own farmers *have run out*. They can no longer be continued by grafting. This well known fact in that country, has led an eminent naturalist there to advance the novel doctrine—doubtless as true as novel—that trees, like animals, have their infancy, youth, maturity and old age. Grafts from the last, though inserted in young stocks, soon perish. Hence the farmers there have been seeking for fine cider fruits from new trees growing from the seeds; and when any of these are found to possess the desired qualities, they are propagated and extended by grafting.

In some parts of New Jersey, in which ciders of superior excellence are made, the farmers produce them wholly by grafting: nor can we expect fully to rival them, until we adopt the same practice.

Perhaps there are few extensive natural orchards in Massachusetts in which valuable cider fruits may not be found, with rich yellow flesh, capable of yielding liquors strong and of excellent flavour. From such trees, if still young, or in vigorous life, whole orchards might soon be formed. And probably different kinds might be selected which ripen their fruits at the times most proper for making them into cider. Apples until mellow do not attain their highest flavor; and till then cannot give the highest flavor to cider. Many reach that mellow-ripe state in October and November, which may be called the cider-making months in Massachusetts. It would require but little attention to select and propagate the best apples thus ripening in succession. Such ciders, made of ripe and unmixed fruits, would be more easily managed in the most difficult and important part of the process of cider-making—its first fermentation: on the right or wrong conducting of which

the character of the cider depends. In one case it will be soft and pleasant—in the other hard and austere.

The Trustees of this Society have, I believe for several years, been offering a liberal premium to encourage the

Turning in of Green Crops, as a mode of manuring land; but I do not recollect that the premium has been claimed. It has been an ancient practice in other countries; and is not unknown in our own country. Dr. Eliot (whom I have already had occasion to mention) noticed it seventy years ago, in his *Essays on Field Husbandry*; and recommended millet as a plant well adapted to that purpose. The seed being but little bigger than cabbage seed, a small quantity will be sufficient for an acre. I have often heard of the turning in of green crops being occasionally practised in Pennsylvania. Many years since, an intelligent man of that state mentioned to me a farmer, who had purchased a farm in a township remarkable for the general poverty of the soil; and that he improved his own by ploughing in green crops—buckwheat, oats, rye;—turning them in repeatedly, until the land produced crops worth harvesting. Sir John Sinclair, in his *Code of Agriculture*, speaks of the practice of ploughing in buckwheat and other crops, when manure was deficient. But he says that in Lincolnshire, buckwheat had for several years been ploughed in as a manure, and ultimately given up as doing no good. He then adds—"Unless so far as nourished by the atmosphere, the vegetables thus treated are supposed merely to restore the nourishment obtained from the soil." And this is the very principle on which the ploughing in of green crops materially depends. The plants while growing derive a portion of their food from the air; and being turned in, so far at least add manure to the soil. But this is not all the benefit: weeds spring up with the sown green crops, and are sown in with them; thus increasing the manure, and at the same time cleaning the ground for a harvest crop. But besides the growing plants, the soil itself, under their shade, made light by the ploughing and harrowing, is also receiving a portion of the same fertilizing airs. Lord Kames, however, in his *Gentleman Farmer*, says—"I approve not of ploughing down buck-wheat, red clover, or any other crop, for manure. The best way of converting a crop into manure is, to pass it through the body of an animal. The dung and urine, not to mention the profit of feeding, will enrich the ground more than to plough down the crop." Notwithstanding these authorities—and the opinion of Lord Kames is entitled to very great respect.—I am inclined to think that the circumstances and condition of many farms may be such as to render the practice eligible; particularly when manure is deficient;—and where is it not deficient? Is it not a received fact, when lands have been impoverished by cropping without manuring, that by letting them lie a few years at rest, they acquire such a degree of fertility as to bear a crop of some sort that rewards the farmer's toil? Is this happen to unseeded land, thrown out as waste, how much sooner may it be recovered when sown with buck-wheat, oats, rye or millet, and the crops when in full blossom ploughed in? If this product be small, let the land be again sown, and a second crop be ploughed in. And if a third sowing and ploughing in were given, what would be the whole expense? A trifle compared with a dressing with stable or barn yard manure—if it could be procured. This is to be carted to the field and spread, in order to be ploughed in: but the green crop is on the ground, and evenly spread, ready for the operation of the plough. But leaving all theoretical

reasoning, I will recur to well authenticated facts.

The late distinguished agricultural writer, Arthur Young, Secretary to the English Board of Agriculture, so lately as the year 1811, delivered before that body an interesting lecture, to describe the husbandry and speak the praises of three celebrated British farmers. One of these was Mr. Ducket, who occupied in succession, two "sand farms;" that is, farms in whose soil sand was predominant. It was one of the practices of this very ingenious farmer, to plough in green crops to enrich his land. And to do it effectually, he contrived a plough with which, when drawn by four horses, he could open his furrows to the depth of eight or ten inches, and in them perfectly bury his green crops. The opening of so deep a furrow was called *trench ploughing*; and by the simple addition of an arm partly curved, and fixed on the right side of the coulter, at the desired height of eight or ten inches above the sole or bottom of the share, the growing crop was pressed to the ground; and the furrow-slice raised by the plough, following close behind and turned completely over, perfectly buried the crop and weeds. This coulter of Ducket's trench plough, with the curved arm attached to it, is called a *skim-coulter*. The arm must necessarily extend so far to the right as the breadth of the furrow; and just at that extreme, I conceive, the curve downward begins, so as, when the growing crop is pressed flat, the stems or straws may not spread out any further; and being thus confined, are completely overwhelmed. Hence there would be no vegetation in the seams of the furrows. "By means of this tool (says Mr. Young) I have repeatedly seen on his farm, stubbles completely turned down, and crops of turnips, tares and other plants instantly put in; which crops I have afterwards viewed with equal pleasure and surprise; the execution was as complete as the design was sagacious: but it went further—converting the nuisance of any weeds into manure. So effective was the work of the plough, that I once saw him turn down a crop of rye six feet high, and immediately roll in turnip seed. The effect did not depend so much on an extraordinary depth of ploughing, as on the subversion of the soil; for of the rye I have just alluded to, not an atom was left visible; and yet the depth did not exceed eight inches. But if there be Couch (twitch grass) in the soil, this ploughing is ten inches deep; and the succeeding crop in any case well hand-hoed. This trench-ploughing system is not practised above once in two or three years, and the successive tillage shallow, upon the surface. By such deep ploughing, seldom given, Mr. Ducket conceived that a due degree of moisture was preserved in his light land; by means of which his crops were flourishing in seasons of drought which destroyed those of his neighbours."

Here perhaps the question will occur—were Mr. Ducket's improvements adopted by other farmers? Mr. Young says they were, by some of his enlightened brethren. Why they were not generally imitated, Mr. Young ascribes (I repeat his words) to "the perversity which characterizes the ignorance of English farmers." Again he says, "If our farmers would have adopted the practices really excellent, as soon as they were known, British agriculture would forty years ago have arrived at its present state; and at this time the kingdom would have been a garden."

In connexion with this account of Mr. Ducket's practice, I take leave to suggest the necessity, or at least the great utility, of an occasional fallowing; primarily, in order to destroy the

weeds which infest so many fields, and essentially injure all crops of small grain, especially spring wheat, which ripening more slowly than rye and barley, is much more oppressed by the weeds. In effecting the object here suggested, and to enrich the soil while making a fallow, I would recommend the following mode of practice. As soon as it can be done in the spring, plough, sow and harrow in the seed of the crop intended to be turned in. Weeds will spring and grow with the crop.—When the latter is in full blossom, turn it in, immediately sow for a second crop. With this also will arise another crop of weeds; and both, as before, are to be turned in. Should the season permit, and the foulness of the ground require it, sow for a third crop, to be ploughed in, like the former, before winter. A field thus managed will be in good order for a crop of barley, summer wheat, rye or oats, in the ensuing spring; and of either a comparatively clean crop may be expected.

This dressing with green crops, valuable as I conceive it to be, need not be confined to sand farms; it will be not less beneficial in all light gravelly loams, which I suppose rather to abound in Massachusetts; certainly, stiff clayey loams are not common.

A few concise remarks on the general principle, and on some of the objects of these annual exhibitions, will conclude this address.

It is supposed, and justly, that these public shows, by exciting an emulation among farmers, will lead to important improvements in our husbandry. The general question which the case presents, is, what will be the easiest, cheapest, and most effectual means to accomplish this great object? A principal one has been to grant premiums for the greatest crops of specified plants on given quantities of land. One pleasing result has appeared—that by ample manuring and good culture, the usual crops of the same plants may be doubled and trebled. But is it necessary to continue premiums of this kind? May not now the management of farms rather claim attention? Instead of numerous small premiums dispersed on a variety of objects, might they not be advantageously concentrated for the purpose here intimated—the cleanest, most economical, the most productive management of farms? *For it must be such a general improvement of the entire farm that will constitute the farmer's permanent prosperity.* The decision of claims on this ground cannot be expected to be made by a committee of this Society to travel through the whole state: but will it not be practicable by county committees? Perhaps it may not be difficult for the Trustees of the State Society to prescribe some general principles and rules of proceeding, that may produce uniformity in the reports of county committees acting under their direction.

In ploughing, the just aim must be to make straight furrows, and of a uniform breadth and depth; and so turn over the furrow-slice as completely to cover whatever plants or manure are upon it. All this cannot be effected with a hurried step. And what benefit can possibly result from such a step? A farmer's oxen at the plough must labour a great part of the day properly to turn over an acre. To do this without a driver, will require a skilful ploughman and well trained oxen. To encourage the forming of such ploughmen and oxen, should, I conceive, be the sole object of ploughing matches. Working-oxen at the plough, may be considered as well trained when they obey the voice of the ploughman, keep the track in which they ought to move, and step as quick as will be compatible with the necessary continuance of their labour. And as the annual exhib

tions at this place have demonstrated the practicability of performing the *general* operations of the plough with one yoke of oxen, without a driver, it may merit consideration whether premiums should not be thus limited in all future trials with the plough. Under such limitations, every farmer who is ambitious to exhibit proofs of superiority in these points, would be sensible that his oxen must attain a certain size, and be, though not fat, yet well fleshed; which would give strength to their sinews and momentum to their exertions. With such oxen all our agricultural labours would be so well performed, that there would be no room to envy the condition of farmers in any of our sister states; in some of which, their horses consume perhaps as much grain as would furnish bread to all the inhabitants of New-England.

TO THE EDITOR OF THE AMERICAN FARMER.

OLD WHEAT RECOMMENDED FOR SEED.

Dear Sir,

In page 220 of your 4th volume, I find the use of old wheat for seed, recommended in preference to new seed, as a preventive against the smut and mildew. It would appear from the letter of Mr. Pitter, extracted from the London Farmer's Journal, that the use of old wheat for seed is very common in England; a practice, probably, introduced by the frequent failure of their crops. In this country, I believe, the use of new wheat is universal. Since the receipt of the information of the general destruction of our wheat crops, from every quarter of our country, I have searched many agricultural works of high authority, for information on this very interesting subject, without having met with a line throwing any light upon it. It is a consoling reflection, that there is in many parts of the United States, an abundant supply of wheat of the last year, of a good quality, to supply the deficiency of seed from the crop of the present season—and I have no doubt but a reference to the letter above alluded to, will satisfy any person as to the safety of depending on it, in preference to new wheat of an inferior quality. If doubts should exist in the minds of any of our practical farmers, I should like to see their reasons against the use of old wheat. It is now the proper time for inquiry into the merits of the question, previous to the seeding time of the approaching autumn.

Respectfully, your friend,

W. C.

June 6, 1823.

TO THE EDITOR OF THE AMERICAN FARMER.

LANDLORD AND TENANT.

“Ye landlords, then,
Be mindful of the rough laborious hands
That sinks you oft in elegance and ease;
Be mindful of those limbs in russet clad,
Whose toil to your's is warmth, and graceful
pride;
And oh! be mindful of that sparing board
Which covers your's with luxury profuse,
Makes your glass sparkle, and your sense rejoice!
Nor cruelly demand what the deep rains,
And all-involving winds have swept away.”

From every observation I have been able to make, during a period of several years, it appears to me that there is something wrong in the usual mode of letting lands, as we see that tenants are continually removing from one farm to another as a matter of course, and appear near-

ly as devoid of local attachment, as the wandering Arabs. I am aware there are some exceptions, but I think there are very few instances to be met with of a tenant who has lived for a number of years under the same landlord. It will, perhaps, be said, lands are so low priced that tenants soon acquire sufficient money to purchase a farm; but I by no means agree with this opinion, as I have seldom met with these fortunate tenants—indeed, on a careful examination, I think it will be found, that the language used by the House of Commons to Horne Tooke, is nearly applicable as respects tenants—namely—“Once Parson, always Parson.”

If on enquiry, it should be found, that there is not that cordiality between landlords and tenants, as there ought to be; and that this uneasiness of tenants arises principally from this cause, it would be well if the evil was enquired into, and if a remedy could be found for the same, it would be still better, as few people are aware of the vast loss that is sustained by the community, and how much the cause of agriculture is injured by this restlessness of tenants; indeed it may be safely affirmed, that no estate can improve under such circumstances; and we meet with but few estates that do not require improvement—but I fear landholders are in general more intent on present profit, than permanent improvement—and this kind of economy is the principal cause why so many estates appear so wretchedly managed in the southern states—indeed, so long as we hear men of influence undertaking to point out the advantages of doing without internal fences, and others preferring a poor dead one, to a living thorn fence, and some cultivating lands without comfortable buildings, and acting as though they were unnecessary, whilst almost every one has taken up the idea, that it is better to suffer vegetation of every description to be dried up by the atmosphere, and carry *pestilence in every direction*, rather than to consume it by stock; and some gravely asserting, that the grazing of sheep, has nearly ruined both England and Spain; and others letting out their estates in a manner that must entirely destroy them, and bring ruin on the tenants; and forgetting that the interest of both parties is in almost every instance the same—when we see this, Mr. Editor, we need not wonder at the wretched appearance of almost all large landed estates. It, perhaps, will be said that in a general way, tenants cannot be found who are worthy of generous and honourable indulgences; but the answer is obvious—let landlords set the example, and tenants will find it their *interest*, as well as their duty to follow it.

In order that the subject of landlords and tenants may be better understood, I beg leave to call the attention of some of your readers to it; and to suggest, that it would be well if all the various modes of letting lands, were more generally known, and with the view of obtaining this information, I should be glad if some of your readers, in different parts of the Union, would communicate to you, such information on this subject as they possess, and particularly the kind, and situation of the land they speak of, the rent; and whether in money or on shares, and if the latter, what proportion of the produce, and whether every production of the farm is included—whether the landlord finds any part of the labour or stock; or makes any part of the improvements, and whether leases are given for a number of years—or any other inducements held out to encourage tenants to improve their farms?

ALBION.

FROM THE SOUTHERN PATRIOT.

INLAND SWAMPS.

Mr. Editor—I am happy to find that a writer, under the signature of “Rusticus,” has called the attention of the public to the neglected and abandoned state of the Inland Swamps. I agree fully with that writer, that there are many advantages attending the culture of those lands, which make them extremely valuable, and I do not hesitate to express the belief, that were they put in any thing like the order, that is absolutely necessary to make the Tide Lands productive; they would be restored to their former rank in the agricultural community. For that they were once in high estimation, there is abundance of proof. As rice has risen, in consequence of the late advices from Europe, I think it fit time for the proprietors of those lands, to take suitable steps to restore them to their former culture, but before any thing effectual is done, prudence suggests the propriety as a preliminary step, that accurate surveys should be taken, that proper estimates of the probable costs should be made, and that the work should be conducted in such a manner, as that no irregularity nor distraction of councils should impede its progress.

The legal powers granted to the Commissioners on some of the Swamps, are fully sufficient for this purpose, and nothing but the most extraordinary apathy, can account for their reluctance, in coming forward to perform the duty, which they owe to themselves, to their posterity, and to their country. And here, Mr. Editor, let me deplore the careless and neglected condition of agriculture generally in these lower districts. At a time when every effort is making in our sister states, to advance the cause of enlightened agriculture, and to realize the expression of the Poet—“*O nimum fortunatos sua si bona norint, agricolas;*” it is our lot, with few exceptions, to witness its decline; and to find that instead of progressing from year to year, that we are gradually receding; for rural concerns, so far from being considered as of the highest importance and the most desirable employment, are in most cases looked upon as the surest road to ruin. “It is a lamentable fact,” observes that departed patriot, Gen. Davie, “that the generality of our citizens cultivate their lands as if they were but tenants at will; as if there was a general presentiment that we were all sooner or later destined to join in the current of Western emigration—and upon our present wretched system of agriculture, this presentiment is not ill founded. Apathy, or an ill directed avarice; looking only to the advantages of the present moment, may operate as decisively as the mandate of a despot to banish us from our country.” What is this system that is so emphatically pronounced *wretched*? Why, it is the constant succession of exhausting crops, such as cotton and corn, without any intervals of rest, or the use of any meliorating process, and is as applicable to one part of the country as to the other. If then we pursue the land killing system, as it has been justly called, until every principle of fertility is destroyed, and the country puts on an appearance most dreary and desolate, is our condition without hope? Who can we censure but ourselves?

But is there no remedy? and if there is, what is that remedy? Why, either to restore the exhausted lands, by judicious management, which must necessarily be the work of time, or introduce the culture of rice into those fields whose fertility is such that in spite of mismanagement they will remain permanently productive.—Can we look on with calmness, and behold our fellow citizens, year after year, quitting their native land? Can we contemplate, without emotions of sorrow the sad

reverses of fortune, which are hourly exhibiting themselves? That we may love our country (says Burke) it should be lovely, but how can we continue to love that country that fills us with so many bitter recollections of the past, sad contrasts of the present, and gloomy anticipations of the future. But are we to sink in despondency and despair? Certainly not: patriotism bids us make every generous effort to restore it to its loveliness; duty calls on us to shake off that fatal apathy which now enthral us, and which if it is longer indulged may banish us forever. If then by suitable efforts we can turn the tide of emigration from the Western country, and induce our fellow citizens, of the Upper Districts, who may be inclined to leave their homes, to bring their industry, skill and capital to be exerted in this favored portion of the State, we may hope to see a return of the former state of things; and after a long night of sorrow and suffering, joy may come at length in the morning.

Can any thing be more strange and inconsistent than that we should be lavishing treasures to facilitate our intercourse with districts beyond the mountains, whilst we are neglecting the mines of wealth which we have at home; not that I wish to be understood as disapproving the policy of facilitating commerce with the other States, by establishing good roads, canals, and so forth; but at the same time that we attend to the one, let us not neglect the other. I have now trespassed upon your patience long enough, I shall therefore conclude, by observing, that in a future number I will introduce the report of an able Engineer, after a survey made, at the request of the proprietors of one of those swamps.

PHILO-RUSTICUS.

Massachusetts Society for Promoting Agriculture.

At the annual meeting of this Society, the 11th inst. Aaron Dexter, Esq. the President, (and who has sustained various offices in the Society for thirty years) and Samuel W. Pomeroy, Esq. the 1st Vice President, declining a re-election, John Lowell, Esq. was elected *President*; Hon. Thomas L. Winthrop, *1st Vice President*; Hon. Israel Thorndike, *2d V. P.*; John Prince, Esq. *Treasurer*; Hon. Richard Sullivan, *Corresponding Secretary*; Gorham Parsons, Esq. *Recording Secretary*; Benj. Guild, Esq. *Ass. Rec. Sec.*; and Aaron Dexter, Esq. Hon. Peter C. Brooks, Hon. Josiah Quincy, Samuel Perkins, Esq. Hon. John Welles, and E. H. Derby, Esq. *Trustees*.

PRESERVATION OF GRAIN, &c. FROM MICE.

Mr. Macdonald, of Scalpa, in the Hebrides, having some years ago, suffered considerably by mice, put at the bottom, near the centre, and at the top of each stack, or mow, as it was raised, three or four stalks of wild mint, with the leaves on, gathered near a brook in a neighbouring field, and never after had any of his grain consumed. He then tried the same experiment with his cheese and other articles kept in store, and often injured by mice; and with equal effect, by laying a few leaves, green or dry, on the articles to be preserved.—[Philos. Magazine.

USURY LAWS.

No acts of legislation can have a more immediate and general bearing on the concerns and interests of civilized society, than those which are instituted to control and regulate the uses of money, by private individuals; and it is truly wonderful, that such remnants of barbarous and

less enlightened periods, should have been allowed to remain until this day, on the statute books of a country which has, in so many respects, risen above the prejudices engendered in darker times. The abolition of usury laws, one would suppose, would as naturally follow after the establishment of the great principles of free government, asserted in the declaration of independence, as has the abolition of church establishments, and other "odious monopolies." The prosecution of internal commerce, the pursuit of pleasure and of business of every kind, necessarily keeps half the community in a continual state of locomotion—vehicles of all kinds, from the majestic steam ship to the Jersey wagon, are indispensable as the means of intercourse between different parts of the community: Why then might we not limit the price of travelling *per mile*, with the same vexatious minuteness of regulation, as we undertake to prescribe the *terms* on which every individual shall loan his money? Why not say that a man shall charge but so much *per day* for the hire of his horse, as to prescribe the precise sum he should receive for the loan of the money for a given time, for which he bought the horse?—suppose I buy with one hundred dollars, one hundred barrels of flour—why should not the legislature, which in its officiousness, prohibits my lending the hundred dollars to my neighbour for a greater consideration than at the rate of six dollars per annum, also interpose and establish the exact advance at which I may let him have my flour? It may be said, that the one transaction is more specific in its nature and materials, more easily subjected to legal restraint, and less liable to evasion than the other: the fact is not so, and if so, the argument drawn from it is of no avail. The value of money is as liable to fluctuation, as that of other commodities—under certain circumstances, and such as often occur, it may promote my interest to lend it at five per cent—under others, it may be highly advantageous to me to borrow at ten—it may often afford the means not only of gain, to the lender and borrower, but of the salvation of the family of the latter. It is a matter which should be left like all other dealings, to regulate itself. Being so left, it will soon find its proper level—rising and falling according to the demand and the means of supply, and the securities offered—governed, in short, by numberless considerations and circumstances, which, as they cannot be foreseen or controlled, no legislature should make any specific regulation on the subject—neither should bodies of men be incorporated with exclusive privileges to lend. Such incorporations are contrary to the spirit of the age, and of the great improvements, in the science of government, which have been put in practice in this country.

It would not be saying too much, to aver, that Girard's bank in Philadelphia, is the only legitimate bank in America! why do the notes of his bank circulate at par?—because the publick have confidence in his prudence, and the solidity of his capital—Why does he not invoke the legislature to invest him with *chartered privileges*?—because he already enjoys all that should be granted, free access to judicial tribunals, and the impartial protection of the law in common with other citizens.

As we marvel at the continuation of absurd usury laws, and religious tests, so we know not in the country a statesman, on whom we should sooner have relied, to expose and denounce them, than Gov. Robertson; for we have always admired the originality and soundness of his publick views and character. In Congress, he was amongst the first to expunge error, and reform abuse—he was always ready to co-operate in whatever measures were calculated to purify and embellish our poli-

tical institutions, and to make them more conformable with the spirit of this enlightened age; we have been accustomed to regard him as an eminent and fearless statesman—inflexible in the cause of truth and free principles, and among the very last to become the slave of power or prejudice.

But why introduce the discussion of laws to regulate the interest of money, into the American Farmer?—Because, without any connexion with party politics, it is the concern of every day, and of every body—we could show, if we had room for further reflection, how properly it concerns the Farmers—how by the operation of usury laws and banks, the means of lending have been engrossed by a few—how the facilities of borrowing on landed security, have been destroyed—how the *few* have grown enormously wealthy, while the *many* have been ruined.

All that is necessary or proper is, that the Legislature should establish some rate of interest, whereby to adjust cases where no particular rate has been agreed upon by the parties.

Edit. Am. Far.

FROM NILES' WEEKLY REGISTER.

INTEREST ON MONEY—OR USURY.

It appears that the legislature of Louisiana, at the late session, passed a bill to prevent usury, or limit the amount of interest that might be legally recovered on money. The governor rejected the bill for the reasons stated below. In the senate, it was resolved to pass it, notwithstanding his objections, 14 to 2, but in the house of representatives, there were 25 for the bill and 11 against it. The whole number of members elected to this branch of the legislature is 48, and of these two-thirds must agree to set aside the governor's veto, and though more than two-thirds of those present were in favour of it, the veto had its designed effect.

Governor Robertson's objections to the Usury Bill.

TO THE SENATE

I have given to the act entitled "an act to prevent usury and for other purposes," all the consideration which the very short time it has been before me, would allow me to bestow on it; and for the purpose of enabling the legislature again to act on it, previous to their adjournment, return it with the following objections:

It belongs to a class of laws which I do not approve, to a kind of legislation, in the propriety of which I cannot concur.

Religion, the press, the price of labor, of articles of commerce, have all, from time to time, been subject to the regulations of government—one, by one, however, they have been reluctantly freed from restraint, and the great truth generally acknowledged, that mankind, when left to themselves, are better judges than their rulers, of what best promotes their happiness and interests.

Too much interference in the affairs of individuals has been attended with the worst effects. Despotism governments manage every thing: all wisdom, virtue, talent, is with those in power. The people, in their estimation, are ignorant, unworthy of confidence, unfit to be trusted even with their own concerns; others very kindly save them the trouble of acting or thinking for themselves, and make them pay usurious interest, indeed, for the care they take of their property, their body, and their souls. Free governments leave individuals, as much as possible, to themselves; indeed freedom of action and freedom of contract, abstaining always from injuring others by force or fraud, is the very definition of personal liberty—that liberty which it is the duty of governments to respect. The citizens of our Republic are not minors in a state

of pupillage; they have not constituted their public servants, their masters and guardians; they are not so modest as to deem themselves incompetent to attend to their own business, and they know very well that agents and managers do not take better views than their principals of transactions on which their property depends.

The act under consideration does not appear to me to have been demanded by the community—that part of our society in this city, whose interests are particularly concerned, and whose opinions deserve great weight, object to the measure as mischievous in its tendency. To the citizens of the country it is probably as unwelcome as unexpected. During the last summer and fall I travelled over the greater portion of the state; I heard complaints of the want of an organised militia—of the situation of the public lands—of the defenceless state of the marine frontier,—I heard nothing said of usury. If the evil exists, it is brought on individuals voluntarily, and mankind ordinarily are ashamed of denouncing their own follies, or whining over their own grievances.

That there is want of money, I am not disposed to deny; but that it can be made by legislation more abundant and cheap, I cannot admit. It is not wonderful that there should be a scarcity of specie, and, of course, any valuable representative of it, when we reflect on the falling off of the produce of the state, both as it respects quantity and price—on the need and occasion for funds always felt by an enterprising, flourishing and industrious people—on the exportation from the United States in the last eighteen months, of upwards of \$7,000,000. In Boston alone, in a few months, nearly \$2,000,000 were taken out of the accustomed range of its circulation—the pressure was great indeed, but that intelligent people resorted to no unusual expedients, neither to usury laws, nor stop laws, nor an increase of banks, and consequent inundation of paper—they knew very well that the movement of specie and its price were as independent of human ordinances as the currents of the ocean, which, ebbing and flowing, seek their level, regardless of the chains of a Xerxes, or the mandates of a Canute. No individual, no community, that has any thing of equal value to give for money, need be apprehensive of not obtaining it. It goes where it is wanted, and can be purchased with more certainty and more celerity than corn, cloth, or any article whatever—we as surely get money for produce, as produce for money—we as readily procure Spanish dollars for flour, cotton, &c. as in Spain they obtain these articles for their dollars: there is no danger of their being enabled to prevent their exportation—this experiment has been sufficiently tried in Spain, Portugal and other countries. Money escapes in spite of every effort to confine it—the attempt to do so is as futile as an effort to stop up the pores of the skin.

I am opposed for my part, to regulate the price of any thing—the bread of the baker, the meat of the butcher, the money of those who have it, is their own property, as much so as their house or goods—they have a perfect right to part with them or not on such terms, and on such alone, as they may chuse. Tolls at bridges, ferries, loans by chartered companies; these are privileges conferred by government, and of course subject to such conditions as government may impose; but the property of individuals, acquired by their skill and labor, stands on a widely different footing; its worth depends on the market price, a much better criterion of its value than any other by which it can be determined.

Such are the views of a general nature which have occurred to me, in the hasty examination of

the act now under consideration; but I object to it more particularly because it holds out inducements to individuals of full age, in the complete possession of their understanding, to violate contracts and promises which they have deliberately and voluntarily made; whereas the laws should never interfere but for the purpose of enforcing agreements fairly entered into.

The provision too may be considered nugatory; it exists already almost a dead letter in the codes of the several states in the union, and in that of our own—nothing can be more conclusive to prove how reprobated it is in its effects, than the fact of its being seldom or never resorted to. But as if it were not enough to enable the persons themselves, contracting with each other, to violate their pledged faith, strangers to the transaction are asked to intermeddle for the noble purpose of filling the coffers of colleges and schools, and their own pockets, with the money of others, although the party borrowing, and alone concerned, may have neither uttered a complaint, or have had reason to regret the loan he may have made—a business of bringing such suits would be among the most profitable and at the same time the most disreputable in which a man could engage.

The 3d section, from the oath which is required, takes for granted the probability of every creditor of an estate being an usurer—this is a suspicion which I would fain hope our constituents do not merit. It is the right at least of every man to be considered innocent until he is proved to be guilty.

At the commencement of the session I objected to the power now vested in the executive, of bestowing certain offices without the consent of the senate. I have seen no cause to change my opinion. The present act, in authorising the governor alone, to commission brokers, recognises that principle and adds to its evils. The same section punishes with imprisonment any person acting as a broker who shall not have been commissioned, or who shall have been deprived of his office.—Now, I agree with the author of a report on a plan of penal code for the state, “that no punishments greater than are necessary to effect the work of invention ought to be inflicted; that those which produce it, by uniting reformation with example, are best adapted to the end; that modes of punishment, inconsistent with the true maxims of penal law, have their advocates; that imprisonment, as a corrective, is nearly the worst that can be applied; that it is a school for vice and every species of corruption.”

The gentleman must have had the jail of New Orleans in his eye; and will you send a broker there for acting a single hour without a commission, for three or twelve months? No, surely not! Let us reserve that sink of horror and iniquity for those by whom it is now filled: murderers, thieves, and, shall I proceed? unfortunate debtors.

The section which authorises criminal prosecutions against those who shall receive more than legal interest, and directs that the sentence of conviction shall be published in the newspapers of the city at the expense too of the individual thus prosecuted, is a mockery of human feelings, as inexcusable as the disregard of the rights of liberty manifested in the provision just before alluded to—is usury, though called a misdemeanor, to be considered as worse than the blackest crime? the murderer is not required to be the herald of his having violated the law of God; shall we attempt to place lower in degradation one who disregards the arbitrary enactment of his fellow man?

The multiplication of oaths which the law produces, cannot but be regretted by its warmest advocates; and the litigation to which it will neces-

sarily give rise, will be felt as an evil greater and more certain than any it is intended to prevent.

The effects of the act on trade and commerce, and indeed on all the transactions of society, will be, I apprehend, in the highest degree unfavourable and ruinous. The 7th, 10th, 11th, and 12th sections are particularly objectionable; they have a tendency to embarrass all money and exchange negotiations, by creating doubts, suspicions and difficulties, the bane of all commerce, and as yet happily unknown to this community. The money of the country will vanish from circulation when banks and capitalists find themselves shackled with vexatious and inconvenient regulations, unusual punishment and destructive litigation. The course of borrowing and lending is just such as circumstances, and those whose interests are concerned, have made it.

It necessarily, in all intelligent and prudent societies, takes the best possible directions; if not, laws will but increase the evil. Men of principle will not borrow in a manner ruinous to their interests; men of honour will not lend as extortioners; these form the great body of the community; their rights ought not to be trampled upon under the vain expectation of reforming the prodigal, or of infusing charity into the bosom of those who are strangers to benevolence and liberal feelings.

Objecting then, on principle, to many of the provisions of the act; believing, as I conscientiously do, that its effects will be injurious, as well to the morals as to the pecuniary interests of society, I feel myself reluctantly compelled to withhold from it my approval.

THOS. B. ROBERTSON.

New Orleans, March 24, 1823.

Editorial Correspondence.

Pequea, Lancaster county, Penn. June 12, 1823.

A greater prospect of a more luxuriant crop of wheat than we had the beginning of the present spring, has not been observed in this county for some years. “Then the toil-worn farmer could pleasantly stroll round his fields, and in reviewing them, could justly anticipate a full and rich reward at harvest time, for all his toil and hard earned labour;” but lo, a sad reverse—now, instead of viewing his fields with that delight and pleasure before experienced in passing them, his eyes are rather inclined to the ground, at his feet, pondering upon what method the weaver, blacksmith, shoemaker, tailor and wheelwright should be paid—looking over his wheat field, he has no prospect of its coming out of it—for instead of wheat, there are cheat and numerous other weeds; the wheat standing fast, since about the first of May. That staple upon which

Duncansville, S. C. 24th May, 1823.

DEAR SIR,

Since sealing my letter this morning, I found from the enclosed from the National Intelligencer of the 10th inst. that I had forgot either to plant or send you some seed of the "Sword Bean," given me by Capt. Warley. I will plant in the morning—they require something to run on—will bear till frost—are said to be very productive; but I know not if any fair experiment has been made of their utility—the pods are often more than two feet long, and when young, are eaten by the negroes. But I never have heard of the trial as a vegetable for the table.

Your's, &c.

A bean pod from the south, (full of large beans,) which measured thirteen inches in length, and four in circumference, has been exhibited in Providence. It is in the shape of a Turkish sabre, of a yellowish hue, and beautifully seamed on both sides. This singular vegetable grew in Florida, and was sent to a gentleman in Providence, who will endeavour to propagate it. We presume this is the same kind of bean, upon the stalk of which the hero of the Nursery tale climbed to the moon.—*New York Com. Adver.*

Tuckersville, June 1, Wayne county, Georgia.

"As I believe it will please you, I will just add that I have one acre of guinea Grass, transplanted, and growing well. I have fed my horses with it since the 25th of May."

Ludlow Station, near Cincinnati, (Ohio,) May 23, 1823.

I send you the description of a mode of breaking refractory horses, which a friend of mine saw practised in Texas—it may be beneficial. I know the information to be correct, as it came from an honourable man.

A pen was made 18 feet square, and a refractory vicious Spanish horse confined in it. The gentleman who undertook the management of the horse, Mr. B. of Tennessee, went into the aforesaid pen with a bunch of switches, and exercised them on the animal. He was at first very violent; but at length, to save himself, kept as near his castigator as possible; then the man would mount the fence, and make the horse come to him. He would afterwards descend and whip the horse round again and again, and make him come up to the fence, and then mount him. In this manner the violence of the outrageous animal was subdued, and made tractable and gentle in less than two hours.

Fort Osage, (Missouri.) April 8, 1823.

"I am, at this moment, experimenting in my nursery.—I have grafted apples on sycamore and cotton tree stocks, close to the root. I am told that the most flourishing and surest orchards, of apples in the west, are growing on sycamore roots. I am trying peaches on the wild plum, and shall, by recommendation of one of my neighbours, graft some peaches on stocks of the common black walnut. This neighbour of mine assures me, that he has seen a very old and flourishing peach tree, growing on a walnut—it is easy to try it; and should it succeed, perhaps we may be able to obtain durable peach trees—at least, we shall escape the annoyance of the worm. I am determined to try all manner of ways to procure a good permanent peach orchard. The result of such of my experiments as prove successful, shall be made known to you in due time.

his hopes depended has vanished. Such has been the destruction of the Hessian Fly, that some seeds will not produce as much as the seed sown, which in April promised an abundant crop; though, properly, it is not so generally. Some fields will produce an abundant crop, while others adjoining, will not be worth cutting; upon the whole, we may anticipate a little better than half a crop of wheat. Rye is very good; cheat has not been sown in so great a quantity for a long time; as a short ride I made in this county a few days ago, I observed several fields, that, by enquiry, I understood were seeded with wheat last fall, and seemed to do very well until the shooting or coming; then, instead of wheat heads making their appearance, cheat sprang out; had it been wheat, it would have been a good crop; so uniform was the cheat, that by looking over the fields you would hardly believe there would be 100 bushels of wheat in a ten acre field.

In this, I am willing to take the side of our correspondent, "Plain Sense," in opposition to S. V. S., though I should run the risk of being classed among the superstitious and credulous. Every great failure of pasturage, and mowing, has been experienced here this season, more so than for a great length of time. In consequence of the dry seasons, and hard winter, clover will not remain more than one year in the ground; and it is more apt to draw out during the winter now, than formerly, is a question that I would wish to have solved. Some attribute it to plaster of paris, but I think wrongfully. In Chester county, to take it in general, the clover is good and abundant; while in Lancaster county, the very best land, there is none, comparatively speaking; if liming throws it in their favour, the farmers of this section of the country, are following their example; every farmer is anxious to get a lime-kiln built, and are in quite a spirit of liming; observing they have too long been neglecting their farms in their pockets.

In consequence of the failure of clover, there was a great quantity of millet sown by the farmers of the county, and much more would have been sown, could the seed have been obtained; but as yet but little known among us. Corn for the week past appears to be at a stand, having had no rain for two weeks. The cut-worm has made some depredations, but not generally; it is a white-worm, called by some here, the white-worm, and appears to vie with the Hessian Fly in its depredations. It travels about half an inch under the surface of the ground, and destroys every thing in its course—corn, oats, rye, barley, timothy, clover, &c. all suffer by its keen appetite.

Respectfully your's,
E—B—

Bladensburg, Md. 11th June, 1823.

"We are suffering thus early by a severe drought, accompanied by unusual cool weather, which gives the face of our country, the worst appearance I have ever witnessed, and renounces the prospects of the agriculturist truly gloomy. I thank you for the fine sample of tobacco you sent me; it is better than we can see on our highly manured lands; though the crop of the last year was much better than usual, more especially in the lower part of the county, where they never wanted rain to mature it fully."

Talbot county, (Md.) June 16, 1823.

"While in Philadelphia, in May last, I got for an hour to Col. Powell's—and was very much satisfied by a hasty walk with him over part of the beautiful grounds—his growing crop of man-c. wurtzel, was in the finest order and most fin-

ished style of cultivation; but I doubt whether 17 inches depth of ploughing will suit any one, who does not reside next door neighbour to the Augean stables of a great city.

"When I left home the middle of May, the Hessian Fly, the small white worm in the bud, and the chinch-bug had been for ten days committing the most terrible ravages on our wheat crops. It has pleased Heaven measurably to stay these plagues. On the light lands the crops are done—on our best wheat lands in a few instances the crops will be full; the average of these last, generally will be from a half to two-thirds of a crop—the heads are of very good size, and the quality promises to be good. It would now be improved by two or three good showers. We are excessively dry, and without them the ripening will be too rapid for the perfection of the grain."

Nottoway county, Va. June 3, 1823.

"As it may be a matter of curiosity to know the prospect of crops in this part of Virginia, I am sorry to say that our wheat will fall far short of the average quantity. The Hessian Fly has been unusually formidable, and the chinch-bug has done us great injury. The spring with us has been uncommonly dry, which from my observation, is favourable to the progress of the latter insect, as I always observe them more numerous on thirsty spots. Some of my old neighbours inform me that when they made their appearance some forty years since, they were entirely destroyed by a wet season."

Gloucester county, Va. May 24, 1823.

"The crops of wheat and barley, in these low grounds, exhibit a very flattering appearance; but the Hessian Fly, as I am informed, has done considerable injury to the wheat fields of those gentlemen, who reside in the high lands. In consequence of the unusually cool nights which we lately had, our corn, after being planted, stood badly; multitudes of corn grubs cutting it down, almost as soon as it made its appearance. We have, therefore encountered a good deal of trouble in replanting and setting our corn.

Next fall I hope to be able to set out cuttings of the CHEROKEE ROSE, sufficient to afford me a long and handsome hedge. The vegetation of the rose, so politely transmitted to me by Mr. Rowland of Charleston, has been very active upon these low grounds, and I have no doubt, but the rose will prove to us a most desirable acquisition.

It is really a beautiful prospect to contemplate a luxuriant bush of this rose, in all the glory of full bloom. It reminds me very much of the gay and gaudy drapery, which the Corns Florida displays in the vernal season of the year. Nor is the corolla of the rose wanting, in resemblance to that of the ornamental "pride of our forests." With joyful anticipation, therefore, do I look forward to the period, when a large portion of my farm will be embellished and adorned with a hedge so beautiful and so useful."

Richmond, 16th June, 1823.

"Crops of wheat in Virginia, notwithstanding the ravages of the Fly, will be much better than was expected some weeks ago."

Hertford, N. C. June 14, 1823.

"I regret to say that the crops of wheat are very much injured in this county, but in the adjoining county of Pasquotank, I am informed they are tolerably good. The fly, the bug and the cold weather have all been against wheat. We had some frost here on Thursday morning last."

TO THE EDITOR OF THE AMERICAN FARMER.

HOW TO PRESERVE PICKLES.

Dear Sir,

Observing in your paper of the 23d ult. an article on the subject of "reclaiming frozen pickles," reminds me of the manner my wife preserves them; by which means, let them be frozen ever so hard, they are not in the least injured, but are as hard, green, and bright at this moment as in the fall.

To twelve quarts of boiling water, put a pint of salt; as soon as it is dissolved, put in the cucumbers, peppers, or any other vegetable you wish to preserve, and set the vessel near the fire, so as to keep them blood warm. Change this brine every other day, during fourteen days, and keep it covered with fresh cabbage leaves. At the end of this time, take them from the brine, put them into the vessel in which you mean to preserve them, and pour on them boiling vinegar, to cure them. Be careful to stir them occasionally to prevent a scum rising on the top.

AGRICOLA.

Pittsfield, (Ms.) June, 1823.

On the 2d inst. Mr. Aaron Sherwood, of Bennington, Vt. sheared from one sheep eighteen pounds and fourteen ounces of washed wool, of a good quality, and about sixteen inches in length. The sheep was four years old this season, and weighed with the fleece on, one hundred and seventy-eight pounds. This is said to be the largest fleece ever sheared in Vermont, or perhaps in the United States.

Quere—was this the fleece of one year's growth?—*Edit. Am. Far.*

FROM THE FREDERICKTOWN HERALD.

Sir—As the hooping cough is at this time in Frederick-Town, and spreading through the county, you will render a service to the poor particularly, by publishing the following excellent remedy:

Dissolve 80 grains of salt of tartar in a pint of clear water, add to it 40 grains of cochineal, and sweeten it with loaf sugar. Give a child one year old, one tea spoonful four times a day, with a table spoonful of barley water immediately after. Boiled apples put into warm milk, may be the chief food, if they can be had. This will relieve the patient in two or three days, and cure in a week.

In the last stage of this complaint, take the tincture of bark one ounce and an half, paregoric half an ounce, tincture of cantharides one drachm, mix them, and give to a child of 12 months old 15 drops three times a day, and so on in proportion to the age of the patient.

Dinner Hour.—The modern hours of eating have reached an excess that is perfectly ridiculous. Now what do people get by this? If they make dinner their principal meal, and do not wish to pall their appetite by eating before it, they injure their health. Then in winter they have two or more hours of candlelight before dinner, and in summer they are all at table during the pleasantest part of the day, and in this to get a long morning—for idle people, to whom one would suppose the shortest morning would be too long! In the Northumberland household book for 1512, we are informed, "that the family rose at six in the morning. My Lord and my Lady had set on their table for breakfast at seven, a quart of beer, a quart of wine, two pieces of salt fish, half a dozen red herrings,

four white ones, and a dish of sprats. They dined at ten, and supped at four in the afternoon. The gates were shut at nine, and no farther ingress or egress permitted.

The famous Duke of Buckingham could afford to have his diamonds tacked so loosely on, that when he chose to shake a few off on the ground, he obtained all the fame he desired from the pickers-up, who were generally *les dames de la cour*; for our Duke never contended to accept what he himself had dropped. His cloaks were trimmed with great diamond buttons, and diamond hatbands, cockades, and ear-rings, yoked with great ropes and knots of pearls. This was, however, but for ordinary dances. "He had twenty-seven suits of clothes made, the richest that embroidery, lace, silk-velvet, silver, gold, and gems, could contribute; one of which was a white uncut velvet, set all over, both suit and cloak, with diamonds valued at fourscore thousand pounds, besides a great feather stuck all over with diamonds, as were also his sword-girdle, hat, and spurs." In the masques and banquets with which the Duke entertained the Court, he usually expended for the evening from one to five thousand pounds. To others, I leave to calculate the value of money; the sums of this gorgeous wastefulness, it must be recollected, occurred before this million age of ours.

Curiosities of Literature.

Holinshead says that the best wine was to be found in monasteries, for "that the merchant would have thought his soul would go straightway to the devil, if he should serve monks with other than the best."

Pulpit Candour.—A preacher in the west of England preached during the whole of Lent in a town where he was never invited to dine. He said in his farewell sermon, "I have preached against every vice except that of good living, which I believe is not to be found amongst you, and therefore needeth not my reproach."

Glue.—It has been erroneously stated in the public papers, that India rubber will make good glue; but it will never set or harden. For a strong, firm, cheap glue, nothing has yet been discovered superior to the best kind of that which is in general use; and for a fine, clear, and transparent kind, which will even unite glass so as to render the fracture almost imperceptible, nothing is equal to isinglass boiled in spirits of wine.

For the last two or three weeks, the town has been in a state of *anxious suspense*, respecting a Mademoiselle Mercandotti, a fascinating young lady, who had an engagement at the King's Theatre. The lady suddenly relinquished that connexion for another of a different nature, and quitted town. She is stated to be the natural daughter of the Earl of F. and was born in Spain but has been some time in this country under the care of her noble father. Her inclinations led her to the stage, where she was guarded with paternal solicitude; and where she became an object of general interest. A rich commoner, Mr. Ball, (called the *Golden Ball*) became attached to her, and the following appears to be the *denouement*.

Mr. Hughes Ball, and Mademoiselle Mercandotti.—By a letter we have received from Banff, N. B., this morning, it appears that the fair Lady was married there to Mr. H. Ball, on Sunday the 22nd ult. and immediately afterwards the happy pair set off for Dalgetty Castle, the seat of General Duff. The ceremony was performed at Duff-house, the seat of the Earl of Fife, which is in the immediate vicinity of Banff.

English paper.

THE FARMER.

BALTIMORE, FRIDAY, JUNE 27, 1823.

BALTIMORE MARKET.

PRICES CURRENT.—CORRECTED WEEKLY.

Flour, best white wheat, \$8—Howard street Superfine, \$7 25—fine do. \$6 75—Wharf, do. \$7—sales—White wheat, \$1 42 to 1 50—Red do. \$1 42 to \$1 43—Rye, 75 cents—Corn, 50 to 52 cents—country Oats, 40 cents—Beef, 8 cts. per lb.—Live Cattle, \$6 to \$6 50 per cwt.— Bacon, round, 8 to 9 cents per lb.—Pork \$4 50 to 5 50 per c. lb.—6 to 8 cts. per pound—Mutton, 5 to 6 cts. per lb.—Beans, \$1 37 1/2 to 1 50—Peas, black eyed, 55 to 60 cts.—Red Clover Seed, \$5 50 a \$6—Orchard Grass do. \$3—Herds' Grass do. \$2—Timothy do. \$4 50—Millet, none—Buckwheat, \$1 50—Flax Seed, 75 to 80 cts.—Whiskey, from the wagons, 30 to 31 cts. per gal. including the barrel—Apple brandy, 30 to 32 cts.—Peach do. 65 to 70 cts.—Shad, \$6 50, scarce—Herrings, No. 1, \$2 75 per bbl.—No. 2, \$2 50—Fine salt, 60 to 65 cts. per bush.—Coarse, do. 70—Butter (firkin) 12 cts per lb.—Eggs, 12 1/2 cts. per doz.—Hay, \$18 per ton—Straw, \$9.

MARYLAND TOBACCO, same as last report.

Seed Buckwheat.

Just received 100 bushels Buckwheat, particularly selected for seeding, for sale by

ROBERT SINCLAIR,

No. 1, Ellicott street, Pratt street wharf.

Also for sale as above,

White Norfolk } Turnip seeds of this year's
Yellow Bullock } growth,
and which can be warranted to vegetate.
Ruta Baga (Turnip) seed, imported from Sweden.

Sundry Implements of Husbandry as usual.
June 25, 1823.

A Gentleman and Lady

Who have for several years past, superintended a female seminary in Baltimore, are desirous of locating themselves somewhere in the country, where vicinage to a populous neighbourhood would justify the expectation of reasonable patronage.—The most respectable references can be given.—Information of such a situation, directed to A. B., will be thankfully received and promptly attended to.

FOR SALE

At a low price and on a long credit, the FARM on Elk Ridge, occupied by Mr. H. Scott, and formerly owned by Luther Martin, Esq. containing about eleven hundred acres.

It is situated about eleven miles from this city near the Washington road, and is considered remarkably healthy.—The situation is handsome, and the land easily improved by plaster and clover. This property will be divided if required, and immediate possession given.—For terms apply to

ROBERT & JOHN OLIVER.

Printed every Friday at \$4 per annum, for JOHN S. SKINNER, Editor, by JOSEPH ROBINSON, on the North West corner of Market and Belvidere streets, Baltimore; where every description of Book and Job Printing is executed with neatness and despatch.—Orders from a distance for PRINTING or BINDING, with proper recommendations promptly attended to, addressed to J. Robinson, Baltimore.

Internal Improvement.

ON THE PARAMOUNT IMPORTANCE, TO MARYLAND, OF A CANAL TO THE SUSQUEHANNA.

No. VI.

The evidence of experience, is decidedly in favour of ten thousand dollars a mile being amply sufficient, to open a Canal for boat-navigation, and to leave a handsome surplus remaining.

47. In ascertaining the most eligible route for the proposed Canal between Baltimore and the Susquehanna, it would certainly be desirable that it should be located as far to the westward as practicable, so as to come in contact with the waters of Great Pipe Creek. In this direction, I have believed it would be likely to be more easily made than further to the eastward. It is evident that it would embrace more advantages. Its facilities would be more immediately extended to a wider range of country, and an opportunity afforded of introducing into it, the Junction Canal, from that of the Potomac, to much greater advantage than in any other position. Under these views, it has appeared to me, that in exploring the route, it would be a very eligible plan to commence the surveying and levelling, *perhaps*, at Bower's mill, and from thence to proceed up the main branch of Great Pike Creek to its very source; carefully noting at the confluence of the several lateral streams, the number of square inches of running water, and the precise elevation at the junction of each. Let the same kind of examination be next applied to the principal head branches of the Patapsco, the Little Conewago, the Codorus, and the Great Falls of Gunpowder, as far downward as may appear to be necessary. Then by surveying and levelling so much of the summit of the dividing ridge, as shall be required for the purpose of determining all its lowest and narrowest situations, and by connecting, with this operation, the elevation of the different sources, whose levels were before taken, the data thus obtained, when duly compared and examined, will determine to a certainty, what quantity of water, *if any*, can be carried over any low or narrow place, *without cutting*, or otherwise, the real depth and extent of cutting that in any and every instance, will be required to admit a certain quantity of water to flow through from one side to the other; or, in other words, by these means, it may in a short time, be conclusively known whether the proposed Canal is in reality, easy or difficult, practicable, or impracticable in that direction.

48. Should the preceding operations result in the discovery of an advantageous position, where the required supply of water can be conducted over or through the summit of the dividing ridge, the primary desideratum will then be secured. It will then only remain to explore with attention the most eligible route from thence to the Susquehanna on the one side of the ridge, and to Baltimore on the other. But owing to no such route ever having been levelled or surveyed, the rise and fall, and the length, are, of course, both unknown. Robert Mills, page 93, in his Treatise on Inland Navigation, upon what authority he has not informed us, has stated the distance at 75 miles; but I am convinced it must certainly be more. My method of calculation is thus: The distance from Philadelphia to the mouth of Swatara, as measured on a map of the country, is 86 miles; from Baltimore to York-Haven, 58. Then, because a water route of 140 miles has been located and measured between the two former points, it follows by proportion, that 86 miles, in a direct line: are to 58: as 140

miles of water route: are to 94 miles and nearly a half, for the length of a new channel between Baltimore and York-Haven. This, I consider quite as likely to be *over* the true distance as *under* it; but to avoid with greater certainty the risk of its being *under-rated*, let its length be stated at the round number of 100 miles.—Agreeably to the most correct data, of which I have been able to avail myself, I should estimate the rise and fall of the whole route at about 360 feet; but for the same reason, as above, I will admit that it may amount to 400 feet; that is an average of 4 feet to every mile. Having thus estimated a Canal from Baltimore to the Susquehanna at 100 miles, which at ten thousand dollars per mile, would cost one million of dollars—I next propose to submit my reasons for believing that were this sum *judiciously and economically* applied, it would, in all probability, be sufficient, not only to meet every *necessary expense*, but also to leave a handsome surplus remaining.

49. Since my preceding number was put in type, I have had access to the Annual Report of the Canal Commissioners of the state of New York, dated 24th February, 1823. By this document, it appears to be announced, as a probable event, that the Erie and Champlain Canals, will cost \$7,603,386. But upon further glancing my eye over the document, I find that large disbursements are included in that sum which cannot, *with propriety*, be taken into the Canal estimates. It appears, for example, that in opening a connexion between the Salina side-cut, and Onandago lake, a work entirely new and distinct from the original 414 miles of canal; in improving the navigation of the Hudson; in the payment of interest and two other items; and for superintendance and the collection of tolls, upwards of \$764,000 have been expended out of the Canal fund. In addition to this, it appears by the Annual Report of 27th February, 1822, page 15, that contracts had then commenced to be *taken much lower than at any preceding period*. Again, it is understood that prior to the attainment of that *certainty and facility of operation*, which have been acquired by experience, the New-York movements were abundantly slower and more incident to error than at present. Great and numerous, no doubt, are the improvements, which in the course of a number of year's practice, have been developed in every department of the business, and *very great*, to a certainty, must now be the advantages of these improvements. Thus, I presume, it may rationally and safely be inferred, that had the citizens of New York been prepared, in the outset, to have brought into action all that skill and ability for which their engineers and their workmen have now become conspicuous, their canals might have been completed not only in much greater perfection, but at least twenty per cent. cheaper, (I am informed the estimates of many are much higher,) than under existing disadvantages was by any means possible.

50. But of all this superior skill and ability, we may now avail ourselves. The aid of their Engineers, their Canal-makers, and their implemets can be readily obtained for a moderate compensation. For these reasons, let 20 per cent. be deducted from the \$7,603,386 before mentioned, and the aforesaid \$764,000 from the remainder, there will then be left, for the cost of their Canals, *were they now to be made under all the advantages of the latest improvements, in the art of Canal-making*, \$5,318,709. But, by proportion 216, the cubic feet in a yard of Canal of 24 feet water-line: are to 408, the cubic feet for 40 feet water-line:: as 414 miles: are to 782 miles. Wherefore admitting the size before proposed, (45) to be sufficient, the New-York

414 miles of Canal are equivalent to 782 miles of that size. Consequently if \$5,318,709 be divided by 782 miles, the quotient \$6,800 is the average cost per mile, at the same rate, of a canal from Baltimore to the Susquehanna. Hence it conclusively follows, that taking for our data the actual experience of the state of New York, 100 miles of Canal ought *now* to be made by the state of Maryland for \$680,000; that is, out of an appropriation of one million of dollars, at ten thousand dollars per mile, a handsome surplus amounting to \$320,000, no less than 32 per cent. on the original appropriation, ought still to remain unexpended.

51. This appears, of itself, to be evidence sufficiently clear and conclusive to establish my proposition, but more remains to be offered, which will be made the subject of a subsequent number.

WILLIAM KENWORTHY.

AGRICULTURE.

TO THE EDITOR OF THE AMERICAN FARMER.

Cambridge, E. S. Md. June 14, 1823.

DEAR SIR,

Your favour some time past, enclosing some stalks of wheat, and a copy of a letter from Mr. Nelson of Virginia, containing his notice of a new enemy to that important staple of our country, I received, and thank you for the personal politeness, as well as for the zeal, which you discover, in the cause which you have undertaken, and by your devoted attentions have so highly promoted.

I am gratified to have the proof of Mr. Nelson's letter, that a gentleman of observation and talent is occasionally to be found, who discerns the important relation of entomology to agriculture, and fears not the imputation of "studying trifles," when the happiness, and the very existence of his fellow beings are involved in the study.

The insect, which I discovered in the stalks of wheat, forwarded by Mr. Nelson, I found also in my own wheat; and it has, the present year, done infinitely more injury to the crops of Dorchester, than the Hessian Fly, though the fact has not been generally noticed by the farmers, who are too apt in the vexatious mortification of disappointed hope, to adopt a sentiment of haughty indifference, "causa latet, vis est notissima."

This new insect and the Hessian Fly, very much resemble each other in the imago or parent state, when viewed with the naked eye: in that of the larva, or caterpillar, they are very dissimilar; the one incapable of locomotion, injures the plant, chiefly by mechanically interrupting the ascent of the sap; the other, by mastication, and actually feeding upon it.

In the imago, or fly state, viewed with a glass, it is plainly discoverable that this new insect belongs to the order "Hymenoptera" of Linneus, having four membranous wings, and a sting; and that it is of the genus "Tenthredo" or "Saw Fly," of which there are many species; most of which nidificate in the buds of flowers; and others, in the tender stalks of various plants, of southern growth; their sting, which is serrated, appears to be designed, rather for an oviduct, than a weapon; by means of this saw, and duct, they are enabled to deposit their ova, in the interior of the wheat stalk, where they are speedily metamorphosed into the larva or caterpillar, which feeds voraciously upon the stalk, until fitted for the chrysalis, from which it shortly evolves into the "parent fly;" and cuts its way out of the stalk, which, by this time, is necessarily weakened, or destroyed; and a few days only, will complete this whole routine of existence and destruction, both of which might

possibly be diminished, by the introduction of a solid-straw wheat, or, by the strong ligneous straw of the Egyptian wheat.

The Hessian Fly, when examined with a glass is found to belong to the order "Diptera" having two membranous wings; and to the genus "Tipula;" yet these two insects, so different in reality, have an appearance, to the naked eye, precisely similar, in the fly-state, the second pair of wings, of the Tenthredo, being generally concealed under the coarse upper wings, unless in the act of flying, or pierced with a sharp instrument.

It may appear to be a matter of idle curiosity to examine the minute differences of these animals; but, by accurate notice of their peculiar forms, habitudes, and modes of warfare upon the vegetable kingdom, their creation may be diminished, or their attacks considerably averted.

From causes accidental or unknown, insects may exist among us for ages, with unoffending characters, and suddenly, like swarms of infuriate Goths and Vandals, overrun and desolate the country; perhaps for a season alone; and, as unexpectedly, retire; others appear, which have never before been seen in our climate, commit ravages and disappear: such has been the fact, with the "Cassida," or "tortoise beetle," which appeared in immense swarms, and destroyed my crop of tobacco in 1819; of which I then gave you a description; they have not, since that period, been seen, except occasionally, in 1820, a few; and the oldest inhabitants, had never seen them before. The Tenthredo, I suspect, is no less a stranger to this climate; at least, it has never before rendered itself conspicuous, by the selection of so costly a diet, as that of wheat, and it is to be hoped, will shortly with the Cassida be satiated and retire. The origin of those incursive, ephemeral insects, is truly mysterious, and affords a wide field for philosophical enquiry.

Accept the best wishes of
Your obt'serv't,
JOSEPH E. MUSE.

TO THE EDITOR OF THE AMERICAN FARMER.

CHEAT.

SIR,
There is a manifest difference between the triticum and the plant called cheat—or rather the brumus, oat grass, or brome grass—an annual grass of this country. The circumstance of wheat changing into cheat, is a curious fact, if it was true. But I cannot believe it possesses such wonderful properties. It is very evident that the plants of the bromus are not issues from the roots of wheat stubble. On an examination of the two plants, wheat and oat grass, or cheat, if you please, (I enclose some plants of each for your inspection,) I am sure you will agree with your correspondent, "S. V. S." that wheat cannot change to another genera, and withhold your assent to the doctrine of "Plain Sense," that "wheat turns into cheat," which is completely void of foundation. It is true it is the general opinion of too many of our best informed farmers. I have heard many of them declare that should wheat be eaten down at a certain time of the moon, in the spring, by a horse, it would turn to cheat. That noble animal must alone perform the operation—any other beast will not answer. They maintain other opinions, equally erroneous, that the moon's influence on vegetables and pork, is very great; it is, if certain seeds are sown, at an improper time of the moon's age, the plants will not attain their proper perfection—and if you kill

your hogs in the wrong sign, your bacon in boiling, will shrink up to one half its size. I will add another opinion, very common and confidently maintained, by the wise ones, that there are, also, peculiar times in every month, *more safe than others*, for the castration of lambs, and the spaying of sows. That the greater part of your lambs and sows, will die, if the proper time is neglected in performing the operation. I consider the moon's influence, and all such notions, to be a *cheat*. The moon has, no doubt, some influence, in the maturing of plants; but it cannot possibly have any agency in the metamorphose of that inestimable plant, *wheat*, and the success or failure of altering your lambs and sows. The oat grass is to be found growing spontaneously every where in my neighbourhood, in places where wheat has never been cultivated—in woods, in meadows, and in damp situations, and even among bull rushes. The proof of the latter, accompanies this letter, *the rush and cheat growing together*. The probable failure of the crops of wheat with "Plain Sense," arises from the Hessian Fly, or other insects—the unfavourable winters, blue grass, and from sowing the same kind of grain, so repeatedly on the same ground, and not any aberration of nature, from her established course. The greater part of the plants growing in a stack yard, where wheat has been got out, or around a barn, to be cheat, is a very common occurrence. It is easily accounted for—the scattered grains of wheat, are soon culled by poultry, birds, &c. leaving the very small, or light seeds of the *cheat* to vegetate. This is no proof that wheat undergoes a change. It is true that wheat in some situations will degenerate; but it has not the faculty of transposing itself in the manner supposed by "Plain Sense," and neither is cheat, a mule plant, for it grows readily from seed, which is sufficient proof that it is not the production of spurious wheat. I now leave the matter to the advocates of the *doctrine of equivocal generation*, to prove that wheat turns to cheat.

Your humble serv't,

R.

June 13, 1823.

TO THE EDITOR OF THE AMERICAN FARMER.

WOOL.

Felicity Farm, June 23, 1823.

JOHN S. SKINNER, ESQ.

DEAR SIR,

The price of the different grades of wool, in the fleece, at Stubenville, Ohio, on the 10th of May, 1823, was as follows:

Prime full blooded Merino,	80 cents per lb.
Second rate,	65
7-8	55
3-4	40
1-2	30
Common,	25

The above prices are paid by Messrs. B. Wells, & Co. who carry on an extensive woollen manufactory. The cloths made at their valuable establishment, are reported to be of the very first reputation, as to fabric and durability of colour.

In the year 1822, the price of wool at the same factory, was for full blood, 80 cts.—7-8, 60 cts.— $\frac{1}{2}$ 50 cts.— $\frac{1}{2}$ blood, 40 cts. As the cost of transportation to Ohio, is small—it is to be hoped that our manufacturers will be able to give prices, for fine wool, sufficiently encouraging. We ought to pay particular attention to that inestimable animal, the sheep.

Your obedient servant,

R.

CULTURE OF THE HOP.

MY DEAR SIR, *Boston, June 3, 1823.*

I have to apologise to you, for my negligence, in delaying so long, to reply to your enquiries, respecting the culture of hops. The method which I have practised, has been to prepare the ground in the same manner as is common for raising Indian corn; after ploughing it well, to harrow it, and then furrow it cross ways, so as to leave the hills eight feet apart—then to manure in the hill with *quite* as much as you would do for corn. In the spring, cut your slips from the root of the hop-vine about nine inches long, and lay them upon the manure, three or four in a hill, and cover them with earth about as deep as is usual to cover corn—thus the planting, &c. is complete. You may for the *first* year, plant corn or potatoes between the hills, if you please; but I think it better economy, not to do it, because you may plough with oxen, between the rows, to lighten the ground preparatory for hoeing, which ought to be done three times during the summer. You get no produce the first year, and therefore it is unnecessary to pole them, unless perfectly convenient.

In the spring of the second year, you place, to each hill, two poles of about thirteen to fifteen feet above ground; and as the vine grows, you train it to the poles; it is best to hoe them three times in the season, and (unless your land is very rich) it will be well to add some manure at the first hoeing. In gathering in the produce, you cut the vine to the ground, and pull up the poles, lay them across large wooden bins or boxes, made of rough boards, about ten feet long and five or six feet wide, into which the hops may be stripped off. This work may be performed by women and children. You take them from these boxes in bags, and carry them to the drying kiln, which is generally placed at the side of a hill or rising ground, for the convenience of taking the hops in upon the cloth or netting, which is stretched upon the cills above the furnace, which is at the bottom, where the fire is made, which ought to be with charcoal, because it gives the hops a much better flavour than by curing them with a fire made of wood. It is necessary that some careful person should attend, constantly stirring the hops with a rake during the process of curing, so that they may be well dried, without discolouring them. After you take them from the kiln, they must be spread (under cover) in an airy room, and constantly moved with a rake, once or twice a day, for ten or twelve days, when you may bag them for market.

This hasty, imperfect sketch, is from my own experience only. I presume you may obtain better information from those who have been longer in the habit of cultivating this vine.

I am, with great respect,
Your friend, and obt'serv't,
ISRAEL THORNDIKE.

GORHAM PARSONS, ESQ.

The above information was obtained at the particular request of the Editor of this Journal, who is proud to shew amongst his patrons and correspondents, gentlemen so successful, and so much distinguished, in every walk of industry, to which they have turned their attention.

Edit. Am. Far.

"IMPROVED SHORT HORNS"—THEIR QUALITIES AS MILKERS.

We are happy to have it in our power to lay before our readers the following letters, which from various considerations should be read with

particular and respectful attention—Mr. Carpenter, it will be observed, speaks of the Short Horns by comparison with the cattle of Lancaster County; which, of themselves, we have always understood to be superior to the common cattle of our country, as, indeed might be expected, from the well known fertility of that county, and the proverbial care and attention bestowed upon their domestic animals, by the discreet, steady, and skilful farmers residing in it. To this, may be added the recollection that Mr. Carpenter is himself, a member of one of the oldest, most respectable, and wealthy families of that settlement; born on the land which he judiciously tills, and qualified by observation and experience, to form a correct estimate on any agricultural subject to which his attention may be directed.

Mr. Tomlinson is one of the most respectable, spirited, and successful practical farmers of Philadelphia County, well informed, in all that relates to his vocation, and particularly skilled in every thing connected with the properties of Farm Stock, and the production of butter.

The cream of which he speaks, was taken, we are assured, without preparation from the first drawn milk of a thorough bred, "two year old" Short Horn heifer, which had calved but five weeks before, and has been tied to a stake, on a field of artificial grass from which hay had been recently cut. The age of the animal, the period after calving, the want of nutrition, in the "after marth" of artificial grasses, and the absence of "Strippings" are well known to essentially affect the colour, richness, and flavour of cream.

Edit. Am. Far.

FOR THE AMERICAN FARMER.

Carpenter Hall, June 14, 1823.

DEAR SIR,

You desire to know the result of my experiments with the Short Horn stock, I purchased from you last year, and my opinion of the Neat Cattle of Lancaster county. Males of various breeds of Neat Cattle have been brought to this county some years back, but they have been so much crossed with the common stock, and so little attention has been paid to purity of blood, that at this time there are none that shew any marks of a distinct breed.

The two half blood heifers, by the Short Horn bull Denton, which you stated, had calved last July, produced through the course of last winter, butter of a better quality than any I ever saw made in the month of May—and it was always obtained in about ten minutes churning; one of these heifers produced a calf the beginning of June, the other (the three years old) has supplied nine labouring men all spring, with a sufficiency of milk, (and butter once a day;) which production exceeded that of a fresh milk cow of the common stock, which I had selected with great care, and that proved to be as good a milker, as the neighbourhood could produce. I am sorry that I cannot give you an account of the production of butter from the imported cow Moss Rose, in a given time, as her calf had got so old before the trial was made, that it would not take to other cows; but I do not hesitate to give it as my opinion, that twelve or fifteen pounds of butter, of the finest quality can be made from her in one week, as she possesses the power of secreting rich milk, in a greater degree than any animal I have ever seen. I expect that this is enough to satisfy you, that as milkers, the Durham Short Horns are not to be surpassed. The bulls are docile and good feeders.

These cattle are hardy; and their value can only be estimated by him, who considers the time it requires to alter the form and propensi-

ties of the animal, and the degree of perfection it may be brought to; I therefore think it a want of thorough knowledge of the animal, that makes any person object to the price of the Durham Short Horns.

All my neighbours express their astonishment, at viewing my cattle, and highly approve of the selection.

I am sir,
Your most ob't servt,
H. A. CARPENTER.

JOHN HARE POWEL, Esq. *Corres. Sec'y to the Penn. Ag. Society.*

Powelton, June 29, 1823.

Dear Sir,
Was the cream which I sent to you this afternoon very rich?

Was its colour deep?
Was it as good as any you recollect to have seen?

Had you not on a former occasion noticed the quality of cream from my cows, and did it not appear equal to that which you have seen to-day?

How many head of neat cattle do you keep?
How many have you of Mr. Joseph Sims' breed, so justly celebrated for the purposes of a dairy?

At what price did you sell your butter in the Philadelphia market in the last spring?

I am Your's, &c.

JOHN HARE POWEL.

Mr. JOHN TOMLINSON, }
Woodland Farm. }

Respected Friend,

The cream I tasted was very rich, its colour and quality were quite as good, as any I recollect to have seen. That which I had noticed at thy house, was I think as good. I have forty-five heifers and cows of various ages. I have twenty-nine head of Joseph Sims' breed. I sold my butter at thirty-seven and an half cents per pound, the price which I asked, when butter was selling at from twenty-five to thirty-nine cents in the same Market.

Respectfully,
JOHN TOMLINSON.

JOHN HARE POWEL,
Philad. County, 6th Mo. 30th, 1823.

FOR THE AMERICAN FARMER.

ALBION'S FIFTH LETTER TO HIS SON.

*"A various grouse the herds and flocks compose,
Rural confusion! on the grassy bank
Some ruminating lie; while others stand
Half in the flood, and, often bending, sip
The circling surface—in the middle droops
The strong laborious ox of honest front."*

In the summer season, a farmer and grazier who attends to his business, "till his feet throb, and his head thumps" can feel but little inclination to write, and this must be the apology for so long delaying the continuation of my letters to you.

I now propose saying a few words on the cattle of the Albion farm, but having given a description of them in a letter to the Hon. Henry Clay, which you may find in the "American Farmer," vol. 4, No. 33—it appears unnecessary to repeat here, what is already before the public.

In order that you may form a more correct opinion of cattle in general, I wish you to examine the proceedings of the Smithfield show in London, from its first establishment, as you will there find, that all the most celebrated breeds of cattle in the united kingdom, frequently came in contact for premiums at the christmas meeting;

and, that generally, the Herefordshire breed took the premium for the best oxen shown, until the Society passed a rule, that any person having a prize awarded him, should not receive a similar one the succeeding year; which shut out Mr. Westcar, and others, who were the zealous advocates of this breed; and then the short horned cattle came in.

As I have only a part of the Smithfield proceedings by me, I can give you only the following particulars, which may be found in the "Farmer's Journal" christmas show, 1810—class one, Mr. John Westcar a prize of twenty guineas for a Herefordshire ox, dead weight

4 quarters, skirts and kidneys	- - lbs.	1838
Loose fat,	- - - - -	190
Hide and horns,	- - - - -	119
Head, brains and tongue,	- - - - -	56
Feet,	- - - - -	33
Hart, lights, sweetbread and bladder,	- - - - -	56
Tripe, seck, reed, liver, gaul and melt	- - - - -	62

Dead weight, - - - - - 2,354
The particulars of the show in 1811 I cannot find.

In 1812, Mr. Westcar's Hereford ox, weighed as above, } Total lbs. 2266
and took the first premium. }

In 1813, do. do. - - - 2160
In 1814, do. do. - - - 2348

In 1815, Mr. Westcar's Hereford ox again took the first premium, but I cannot find his weight.

In January 1811, "a heifer, belonging to Mr. Vyse of Hockley House, near Birmingham," from my Herefordshire Bull, bred in and in and would not breed, "was killed, of the following weight: 4 quarters, 1376 lb.—fat 173 lb.—hide 99 lb., and cut seven inches of solid fat along the back"—at Christmas 1815, a similar heifer was shown at Smithfield, of exactly the same breed, which was so heavy that her owner was fearful she would die from fatigue during the show, and sold her in all haste, to Lord Somerville, who took her to his farm: this is the heifer I alluded to, in my letter to Mr. Clay, as being so fat on the back.

Many other particulars might be found of the great weight, and vast inclination to fatten, of the Herefordshire cattle; but enough has been said to satisfy you they are sufficiently large; and, that they are very beautiful, every person will admit, who has seen the best of them. I therefore some years since, after reviewing every kind of cattle in England, made up my mind that they were to be preferred to any other breed, and I still retain the same opinion; and the north Devonshire cattle stand next in my estimation; indeed, if you leave out these, and one or two other kind, England's cattle will be a "motely medley."

It would be difficult to trace the origin of the Hereford breed of cattle; it appears to me that they are a mixture of the north Devon and the best large long horned kind—but by a steady and uniform perseverance of the breeders in that country for a great length of time, their cattle are nearly uniform in colour and appearance, which will but be the case with the Durham or any other mixed breed for a number of years—and without uniformity in each kind of stock, ah, in each field too, on his farm, the owner never appears a man of a steady judgment; indeed, to excel as a farmer and grazier, a person must, early in life, possess fixed principles on every part of his business, and having once made up his mind what is best in every part of the same, he must persevere methodically, as one erroneous step may nearly ruin the beauty of the whole.

Animals from a mixed breed, are frequently as unlike each other, as can be well conceived—

the bull Patriot, sold by Mr. Coats to Connington & Loft for 500 guineas, and the bull Waddington, sold to Mr. Rodgers, were *full brothers*; yet as dissimilar both in colour and appearance, as two bulls could well be; the former being a fine animal of a dark colour, and the latter white, and just like the coarse, large boned, hard feeding Holstein cattle in Yorkshire. and on the Continent; yet the stock from Waddington was much better than that from Patriot, as I have often witnessed; but both were inferior in quantity and quality of flesh, to the Herefordshire cattle, which grazed in the adjoining pastures for years together.

That the Durham are a most valuable breed of cattle, there can be no doubt; but they require more support, than either the Herefords or Devons do, and I think, will not ultimately be so profitable to graze in the United States as either of these breeds, and without good management, the Durham will degenerate, as the Holstein blood in them is certainly but little inclined to fatten, and will require more judgment than is possessed by mankind in general, to keep it undermost; and if it once gets the ascendancy over the "*good Scotch blood*" in them, these cattle will be but little better than the common Yorkshire, which during the French war, were almost entirely sold to Mellish, the government contractor for the British navy, they being considered by Epicures "only sailor's meat."

I am inclined to think that about the same time the Holderness cattle were crossed with the Scotch breed, with the view to improve their flesh and frame, a similar attempt was made to improve them by a cross with the north Devon, as the first improved stock I saw of the former, were nearly all of a *red colour*, and it is to be lamented that a red or some dark colour, could not have been kept up amongst the improved breed, as it is well known, that all light coloured cattle are more tender, and far more liable to be filthy than those of a dark colour.

With respect to breeding cattle, nearly the same system may be observed with them, as in all other animals; that is, prefer those of best symmetry, that have descended through a long line of good ancestors, in preference to an upstart—and when these are of equal symmetry, prefer the largest—but never lose sight of symmetry; bearing in mind, that an imperfection in a *small* animal, may not be so glaring as in a larger one, and yet be in proportion with the size of it, and equally objectionable. Avoid, if you can, breeding in and in, and particularly if you want *female breeders*, as you will generally find their descendants have bad constitutions, and of course suckle and breed badly, and the young ones very difficult to keep alive, as you have often witnessed; you may occasionally, by this means, obtain an extraordinary animal, but they are to be considered rather as monsters, than as any proof of good management; and, ultimately, the system will disappoint those who try it—if you have some very choice stock that you must intermix too near, or lose the breed, try to keep the purity of the blood in the *male* line, for whenever both male and female are too nearly related, their descendants will ultimately degenerate, whatever may be said to the contrary respecting Mr. Bakewell's system; indeed, that sagacious breeder was too shrewd a man to tell the "busy bodies" his secrets; but as some "particular friends must know" he told them what he well knew would most certainly prevent their ever becoming his rivals, as some of his late neighbours know to their own cost.

In order to be a judge of the best symmetry of animals, you must be able to give a reason for your opinion, or you would be considered in your native country a mere-superficial novice—accus-

tom yourself therefore, without delay, to examine different kinds of animals with the greatest attention; beginning the examination at the nose, and going step by step to the tail, so that when you have finished, you can say where the animal is defective and where it excels—do this in a particular manner, with stock reputed first rate; and by practice, you may be able in a few minutes to form a pretty correct opinion.

It is pleasing to observe how readily some graziers in England, select in a market, a number of young animals from different droves, and how good they all prove as each kind arrives at maturity—and it is still more surprising to witness the London horse dealers, how readily they find out a first rate horse, from amongst hundreds and hundreds at a fair, and how uniform they can match them in pairs without bringing them together until they start for home, and how well their opinions agree respecting their value; this kind of information is principally obtained at the numerous markets and fairs in England, where farmers and others meet weekly to buy and sell their live stock and produce; an advantage much wanted in the United States.

ALBION.

ON THE USE OF FLAX SEED AS FOOD FOR STOCK.

Having the pleasure last summer, of a short visit from an English farmer of great experience and respectability, we requested him, at his leisure, on his return, to favour us with information as to the construction of perpetual lime kilns, the culture and cure of hops, the manner of using flax seed as feed for cattle, &c. and we publish now what we have received in relation to the last topic.—*Edit. Am. Far.*

Linseed is often used, boiled to a jelly and mixed with cut hay or straw for store cattle, and would be found very valuable if used in that way with you, until more ruta бага, (or what we commonly call Swedish turnips,) or other turnips, cabbages, or mangel wurtzel, are grown—but when linseed cakes are to be had from the oil mills at a reasonable rate, they feed cattle so much better, that the seed is not much used for that purpose. You generally cut the parts out of your newspapers which you think will be useful. I think it is probable you may not have the numbers of the Farmer's Journal of Feb. 1819; or others which contain letters on the subject; therefore I shall send you copies of several letters which were answers to the same question you have asked me about linseed.

To the Editor of the Farmer's Journal.

ON FEEDING OXEN WITH LINSEED.

Lincolnshire, Jan. 22, 1819.

SIR,

Being a constant reader, and well wisher of your valuable Journal, and knowing nothing will tend more to its wide circulation, than practical communications, on subjects in any way relating to agriculture, I feel myself (having used linseed largely) called upon to answer a letter, in your last Journal (signed *A Grazier*, on feeding oxen with linseed) and thus to endeavour to add to its usefulness, and at the same time to afford any information, which I may happen to possess, to those who have not had an opportunity of gaining it by experience or observation. I will now state my plan of giving linseed to oxen, and if your correspondent (*A Grazier*) derive the smallest benefit from it, the purport of this letter will be fully answered. Finding in the autumn, my Swedish turnips, on which I chiefly depended for stall feeding oxen, an indifferent crop, and oil-cakes excessively high in price,

I determined to try linseed boiled, knowing it to have been used with success in small quantities. I first erected my copper which holds 90 gallons, in a building just large enough to contain tubs to cool the liquors in when boiled: after a few trials, two pecks of linseed were found, when boiled, enough to produce a jelly of sufficient consistency to mix either with cut straw or wheat chaff, from the barn, being not too thin to drain from them, or too thick to unite properly. The seed is put into the copper with the water, and from the time it begins to boil, remains three hours; care is always taken to stir it continually for the first quarter of an hour after it is perceived to boil. The hot liquor is always put into a tub by itself, as when mixed with any boiled and cold, it causes fermentation, and an unpleasant smell to arise from it. At first in the morning, my oxen have about two pecks of cut Swedish turnips each, while the linseed feed is mixing. Hay, if more plentiful than turnips, would, perhaps, be equally as well. The linseed liquors, mixed with cut straw or chaff, is given to them as much as they will eat at once, at three separate times during the day; they also have one feed of turnips in the afternoon, the same as in the morning; they have neither hay nor water: water was given to them once, but they did not drink it. One man is kept constantly to boil; he boils sixteen coppers full in a week—six days—which at two pecks of linseed to each copper full, is just one quarter: two bushels of linseed per week—seven days—are allowed for nine oxen, which is when boiled, not quite six gallons of liquor per day for each ox; and which quantity of liquor will saturate as much chaff as a sixty stone ox, country weight, can consume, together with the turnips allowed. If the linseed were steeped, or gently crushed, it would be no worse. There is no doubt that an ox, with as many oil-cakes, and as much good hay as he could eat, would get fat sooner than with linseed, used so sparingly; but those who have no hay may use linseed with advantage, when they cannot use oil-cake. Yet I can assure those who may wish to try the quality of boiled linseed, my oxen rest well, and thrive quickly; and that I have succeeded so well this year, that if oil cake is £10 per ton, or turnips ever so good, I shall, (if health permits) pursue my plan another year with increased ardour. If you, sir, receive no letter which you deem likely to be of more service to (*A Grazier*), perhaps you will insert this, from your obedient servant,

R. S.

To the Editor of the Farmer's Journal.

ON THE USE OF LINSEED IN FATTENING OXEN.

SIR, *Sussex, Jan. 24, 1819.*

Observing in your paper of the 18th inst. a letter from Somersetshire, signed "*A Grazier*," requesting information on the method of using linseed for fattening oxen, I beg, in reply, to state, that the manner in which I have used linseed with good effect, is to grind one bushel of linseed with two bushels of bran. I began by giving it my oxen in small quantities, until they took to it kindly, gradually increasing, until each ox consumed about two gallons of linseed per day, with the proportionate quantity of bran, giving half in the morning and the remainder at night: their other food has been good meadow hay.

I consider linseed, according to the present price of corn, to be the cheapest food of this description that can be used. As I have before observed, it has answered my purpose extremely well.

I remain sir,
Your ob't serv't,
A SUSSEX GRAZIER.

To the Editor, &c. on the same subject.
Hollyport, January 24, 1819.

SIR,

The query of your correspondent, in your paper of Monday last, "on the manner of using linseed for fattening cattle," has induced me to offer to your notice the information I may be able to afford, from the instances which have fallen under my observation, of linseed being used instead of oil cake.

A friend of mine at Hare-Hall, in Essex, is now fattening eighty head of oxen, besides some calves, sheep, and pigs, from a mixture of bruised linseed, bruised barley, malt dust, and chaff of wheat straw; and the mode of preparation, is as follows:—

Three bushels of barley, well bruised in a mill for that purpose, two bushels of linseed bruised in like manner, and four bushels of malt dust, are put into a copper with 150 gallons of water, and boiled until the barley and linseed are reduced to half. The liquor being of the consistence of thick soup, is then poured upon 30 bushels of chaff of wheat straw, and well stirred—about a pail full of this mixture is given to each ox three times a day, warm. The calves at first, refused it, but the addition of a pail full of treacle to a copper full of the other ingredients, made them take to it with avidity: the sheep and pigs appear to relish this food as much as the oxen, and all thrive exceedingly.

I should have observed that the quantity of ingredients above mentioned, affords one meal to eighty oxen, forty calves, six sheep (Leicesters) besides some pigs.

The above observations are confined to one example, because it is conducted on a large scale. Some of your other correspondents may probably, favour us with some other communications on a subject, which appears to be of considerable importance to the agricultural interests, and to society at large.

H. WALTER.

From a Compendious Dictionary of the Veterinary Art.

ON THE DISEASES OF DOMESTIC ANIMALS, AND THEIR CURE.

DIURETICS. Medicines which increase the discharge by urine: diuretics may be given either in the form of balls or powder, receipts for which will be found in the *Veterinary Pharmacopœia*: but as some horses of delicate appetite refuse to eat the powder in their corn, the ball should, in such cases, be preferred. In dropsical swellings of the legs or other parts, diuretics are highly useful; they are also beneficial in chronic cough, and have in many instances proved the best palliative for broken wind. They are commonly given when a horse is observed to stale with difficulty, or when the urine is foul and of a whitish or whey colour, and often with good effect; it is necessary, however, to distinguish carefully between such cases, and inflammation of the kidneys or bladder. (See *Urine, Retention, and suppression of.*) Horses that are frequently rubbing themselves, or have pustules breaking out on different parts of the skin, or such as are disposed to those swellings commonly termed Humours, generally derive much benefit from the use of diuretics: they should not, however, be continued too long at any one time, as considerable weakness would probably be the consequence. The practice adopted by some grooms, of giving strong diuretics upon every trivial occasion, and often without any reason whatever, is highly injurious: the bladder and kidneys are often rendered so irritable by such indiscretion, that a horse will be obliged to stale several times during a short ride, and if urged to go on by an inconsiderate rider without being allowed to stale, some

serious disease of the bladder may ensue. I am inclined to believe, that the kidneys are sometimes considerably enlarged by the frequent use of strong diuretics, and that I have seen them incurably diseased from the same cause. A good diuretic ball may be made with

Soap, half an ounce.

Powdered yellow resin, half an ounce.

Common turpentine, two drachms.

Aniseed or caraway-seed powder, as much as will form a ball.

The diuretic powder may be made by mixing together

Nitre, half an ounce.

Yellow resin, half an ounce.

Tartarized antimony, one drachm.

See *Veterinary Pharmacopœia*, or vol. ii. of the *Veterinary Medicine*.

DOCKING. Cutting off part of the tail: the instrument used for this purpose is represented in plate 2, fig. 2, in the 4th vol. of the author's *Farrery*, where the operation also is described. I have only to observe here, that the earlier this operation is performed, the better will the horse carry his tail, as it is termed; it should never be delayed beyond the first year, and then very little if any searing will be required. It has been said, that by keeping up the tail in an almost perpendicular direction at the time of docking, and searing it in that position, nicking would be rendered unnecessary.

DRENCHES OR DRINKS. When it is necessary that any medicine should operate speedily, as in cases of colic or gripes, this is the best form in which it can be given. Cattle medicine is always given as a drench, though Mr. John Lawrence seems to think, that a ball would be often a more desirable form; those who have an opportunity of making the experiment on cattle might easily ascertain whether there be any well-founded objection to the exhibition of a ball. Drenches are usually given by means of a bullock's horn, the large end cut in the form of a spout; a bottle is sometimes substituted for it, but there is danger of its being broken in the horse's mouth. In giving a drench, the tongue is to be held down with the left hand, and the head being moderately elevated, it is to be poured gradually down the throat. The head is kept in this position until the drench is swallowed: but if the animal happen to cough while the drench is in his throat, the head should be immediately let down. In preparing drenches, farriers generally make use of ale, but this can only be proper for cordial drenches; on other occasions, water or gruel is the best vehicle. When the throat is inflamed and sore, no attempt should be made to give drenches.

DROPSY. This disease consists in a collection of serous or watery fluid, either in the circumscribed cavities of the body, as the abdomen or belly, the chest, and ventricles of the brain, or in the cellular membrane under the skin. (See *Cellular Membrane*.) The latter kind of dropsy is most common in animals, and often exists unaccompanied by the former; but whenever there is a collection of water in the cavities, there is generally at the same time dropsical swellings externally. External dropsy, or anasarca in medical language, is often named Water-farcy by farriers: and many of them have acquired considerable reputation for their success in curing the farcy; but there is not the least analogy or affinity between the two diseases; and their boasted specifics are generally strong diuretics, mixed with many useless ingredients. External dropsy sometimes affects particular parts, as the legs, belly, chest, or lips; at others, it is diffused over great part of the cellular membrane. A dropsical swelling may be distinguished by its

coldness, and by its retaining the impression of the finger for some time. Those swellings which sometimes affect the legs and other parts, in consequence of high feeding without sufficient exercise, arise from an inflammatory state of the system, and are soon removed by bleeding, exercise, and mild diuretics; but that kind of dropsy which arises from a weakened state of the system and particularly when attended with an accumulation of fluid, either in the chest or abdomen is not so easily got rid of, and sometimes terminates fatally. Colts are subject to a dangerous kind of dropsy, which is accompanied with quick pulse and loss of appetite, but without any remarkable appearance of inflammatory affection. The swelling generally begins about the sheath, extending to the belly and chest, and gradually increases until it becomes of an alarming size, particularly in the belly. When the disease terminates in death, a large quantity of fluid is found either in the chest or belly, often in both; the pericardium or heart-bag also partakes of the disease. On the commencement of this disorder, bleeding is generally proper, especially if the pulse is quick and the membrane under the eyelid unusually red; and in this case a large quantity of blood should be taken off. If, when the blood has coagulated, a coat of buff or size is found on the surface, it shows that the evacuation was necessary, and that it may be repeated with advantage if the symptoms do not abate. Mild diuretics should be given now and then, so as to keep up an increased discharge of urine: at the same time, the animal's strength should be supported by a moderate use of nourishing food. His drink should consist of oatmeal mixed with water, and he may be allowed to eat carrots, lucerne, vetches, or a small quantity of oats now and then. When there is considerable weakness, tonic medicines are proper, as Peruvian bark, cascarilla bark, with an aromatic, as cinnamon, caraway seeds, &c. Some practitioners give also the mineral tonics, such as salt of steel, white vitriol, &c. Diuretics, however, are the essential remedies, or sheet-anchor in all dropsical affections. When the swellings become so large as to be troublesome on account of their weight, it will be proper to scarify them, by which, in a short time, they will be considerably reduced. The best instrument for this purpose is the common horse lancet, which should be plunged, to the depth of nearly half an inch, into several places, choosing the most depending, or lowest parts of the swelling. Horses kept in low swampy land, or on moors, are also subject to a dangerous kind of dropsy, which in such districts is generally termed Moor-evil. I have been informed by an intelligent correspondent, a person of considerable experience in the complaint, that the following preparation has proved almost invariably an effectual remedy for this disorder, and that before this preparation was known, the disease very often ended fatally: he adds, "it comes the nearest to a specific of any medicine I ever knew; I never bleed, rowel, or scarify in dropsy." This receipt is an improvement on old Gervase Markham's for a "Dropisie or Evil Habit of the Body;" but this improvement, or rather addition, (from two to four ounces of soap,) is the most efficient ingredient, if not the only one in the formula. Take of strong ale, five quarts. (Markham directs a gallon,) set it on the fire, and skim off the white froth which rises; then put into it a handful of wormwood with the stalks, and let them boil together until reduced almost to a quart, then add three ounces of treacle, one ounce and an half of long pepper and grains of paradise in fine powder, and from two to four ounces of castile soap. The whole to be given at one dose, and the horse exercised immediately after till he sweats. I should have before observed, that

whenever costiveness occurs in dropsy, laxative medicines should be given.

DROPSY OF THE CHEST. This is a consequence of inflammation of the lungs; and when it happens, that important organ has generally been so far disorganised or injured, that there is not the least chance of the animal's recovery. In some instances it is less rapid in its progress than in others, and from an apparent abatement of the inflammatory symptoms and fever, the practitioner may be led to prognosticate a favourable termination of the disorder; but according to my experience, it almost always ends fatally. Diuretics and tonics, with a nourishing diet, are the remedies most likely to do good. Blistering the sides extensively may be worth a trial. Mr. Blaine recommends the operation of Tapping; that is, making an opening between two of the ribs, in such a situation as to allow the water to run off freely. I once tried this method, and drew off more than half a pail full of water; but it did no good, nor do I expect it ever will. The horse died in a short time after, and the lungs were found in a very diseased state, particularly on the surface or *pleura*, which was covered with flakes of coagulable lymph; the inner surface of the ribs and diaphragm, as well as the pericardium, were in the same state.

From a series of essays on agricultural and rural affairs. By "Agricola," a North-Carolina farmer.

PEACH TREES.

The Peach may be ranked with the most delicious fruit that can be produced in any country. It is generally raised from the stone, but the best kinds are those propagated by inoculation or grafting.

The peach tree is subject to many calamities, and is in general short lived; its preservation, to any considerable age, is only to be ensured by skill and attention—its precious fruit, is therefore forbidden to the slothful, the negligent and the ignorant.

The peach tree is liable to three misfortunes or calamities—first, the fly—second, the breaking of limbs, which brings on a decay—third, to wounds received on the body by bursting of the bark by severe frosts in winter, and the injuries done to it by birds, insects, &c.

But the most general decay of peach trees, is owing to a worm which originates from a large fly, that resembles a common wasp. This fly perforates the bark, and deposits an egg in the moist or sappy part of it. The most common place of perforation is at the surface of the earth, where the rougher and harder bark which is exposed to atmospherical influence begins to change to the softer character of that which covers the roots. In this particular part the fly is able to puncture the surface, and there introduce its eggs. This they perform in our climate from the middle of July through August and September. In August, for the most part, the worms assume the crysalis state, and in eight or ten days are transformed into flies. Then they immediately begin to deposit their eggs, which are soon hatched into worms, and thus the round of transformation common to the insect tribe is completed. The eggs deposited by the fly at the times and manner just stated, are changed into worms; and it is in the worm state they do the mischief, by preying upon the soft inner bark of the tree, which is the medium of circulation for the sap, thus interrupting the flow of the sap—the immediate consequence of which is, the destruction of the fruit, and finally the destruction of the tree. Gum issuing out of a peach tree at or near the surface of the ground, is a sure sign that there are worms under the bark.

Various means have been resorted to, and with various success, for the purpose of destroying those worms, or of preventing them from doing injury to the trees. These various methods shall now be given as practised by some of the most respectable and distinguished farmers of our country.

DR. TILTON OF THE STATE OF DELAWARE.

I shall say but little on the cultivation of this useful tree; but will barely remark, that it should always be planted shallow, with the soil raised about it in the form of a hill; that Forsythe's method of heading down the trees a year or two after planting, insures the most vigorous growth; and that tilling the ground, for some years, after setting them out in orchards, is essential to the rapid and successful growth of the trees. The diseases and early death of our peach trees, is a fertile source of observation, far from being exhausted. Among the insects which are great enemies to these trees is a little beetle, called *curculio*, about the size of a pea bug, which punctures the fruit and occasions it to fall off and rot before it comes to maturity. These insects may be exterminated by means of hogs. This voracious animal, if suffered to go at large in orchards, and among fruit trees, devours all the fruit that falls, and among others, the *curculions*, in the maggot state, which may be contained in them. Being thus generally destroyed in the embryo state, there will be few or no bugs to ascend from the earth in the spring to injure the fruit. Many experienced farmers have noted the advantage of hogs running in their orchards. The best method of destroying the wasp-like insect (which bores the bark of the tree, and delights in that region just below the surface of the earth) that I have ever employed, is to draw the dirt from the root of the tree, in the fall, and pour boiling water on the roots. In the spring, my practice is, to return the soil to the tree, in the form of a hill. By means of this sort, a tree may be preserved many years.

RICHARD PETERS, PENNSYLVANIA.

The worm or grub, produced by the wasp, depositing its progeny in the soft bark, near the surface of the ground, is the most common destroyer of the peach tree. I remove the earth a few inches round the tree in August or September. After July the wasp ceases to pierce the bark, and to make its deposits. I pour round the butt of the tree, beginning about one foot above the ground, a quart or more (not being nice about the quantity) of boiling hot soapsuds or water. This kills the eggs or worm lodged in the tender bark; and, of course, prevents its ravages the next season. I also have the trees bared at the roots and exposed to the winter. I have lost some in this way; but I still continue the practice. I have been in the habit of doing this for ten or twelve years, and prefer it to any other treatment. To supply deficiencies, I plant young trees every year. When trees become sickly, I grub them up; I find that sickly trees often infect those in vigor near them, by some morbid effluvia. The young trees supply their loss, and I have no trouble in nursing those in a state of decay; which is commonly a hopeless task.

WILLIAM COXE, BURLINGTON, NEW-JERSEY.

I always search the roots of my trees twice in the season, last of July and September. On the first of October, I open the ground around the roots so as to leave a basin of the size of a common wash basin—in this state they are left until the next spring—the ice and snow which fill the hole during winter, effectually kills the worm should it have eluded my search. I also endeavor to prevent the limbs from breaking and from excessive bearing, by close pruning, which I have long found more efficacious in peach than in any other fruit trees.

JOHN H. COCKE, VIRGINIA.

I think I have discovered a remedy for the worm which preys upon peach trees at or near their roots, and which is so destructive to their existence.—This remedy consists in tobacco. As much cured tobacco as is tied up in a bundle, viz: from four to six leaves, is sufficient for a tree. The tobacco in a moist state, so as to render it flexible, is bound around the body of the tree just at the surface of the earth, encircling the part where the fly deposits its eggs. This precaution is to be taken before the hatching of the flies—the first of July is early enough, but to make the experiment successful it should not be put off longer than this period. The tobacco, so generally deleterious to the insect tribe, is so also to this destructive fly, and thereby prevents its approach.

My first experiments with tobacco were confined to ten or twelve peach trees; the next spring I found that the trees still threw out gum near the surface, and I feared my experiment had failed; upon a close examination however, I perceived that the gum had issued out from the old wounds of the former year, which were not yet entirely healed. The last summer I again applied the tobacco, and this spring have assiduously examined the trees—upon the whole, I find that those trees which have enjoyed the benefits of the tobacco application for two years, have all their wounds entirely healed and thrown out no gum; and in no instance have I found the worm to have existed, when the tobacco was applied. From these facts, it is evident that tobacco stalks, when stripped of their leaves would be excellent to throw around the roots of fruit trees.

MECHANICKS.

FROM TILLOCH'S PHILOSOPHICAL MAGAZINE.

MR. PERKINS' STEAM ENGINE.

Mr. Perkins' invention is founded on a most valuable discovery—that water is capable of enduring an elevation of temperature even to a red heat, or perhaps an indefinite extent, by being subjected to a very high degree of pressure: which pressure, while it permits the expansion of the molecules of water as a *fluid*, prevents their further expansion, or the liquid assuming the *gaseous* form of steam.

Instead of the boiler of the ordinary engines, Mr. P. substitutes a cylinder, which he terms the *generator*. This cylinder is made of gun-metal, (the most tenacious and least liable to oxidation) of about three inches in thickness, closed at both ends, with a valve in the top, opening outwards; which valve is loaded with weights equal to the state of the pressure from the expansion of the heated water within. The cylinder is placed vertically in a cylindrical furnace; consequently it becomes surrounded on all sides with the fire, and soon acquires a temperature of 400° to 450° Fahrenheit. The production of steam is effected by an injecting pump, throwing in water at one part of the generator, which displaces through the valve an equal volume of hot water from the generator. This water, at 420°, passing into the induction or steam pipe, instantly expands into steam, communicates with the working cylinder, and gives motion to its piston, which is placed in a horizontal direction, for the more convenient application of its power to machinery. The reciprocal action of the piston opens and shuts the apertures of the *induction*, and *eduction* pipes, by means of rotary valves, as usual in some other engines. But the operation of generating and condensing the steam is effected so instantaneously by this engine, that the piston performs about two hundred strokes in a minute. when the

engine is at full work. Indeed, considering the small extent of surface, the power of this engine is almost incredible, the generator containing only about eight gallons of water, and the working cylinder not exceeding two inches diameter, with a stroke of the piston about twelve inches in length. The piston rod gives motion to a crank and fly-wheel similar to other engines.

A most decided improvement also made by Mr. Perkins in condensing the steam under a very great degree of pressure, and at a temperature of about 400° and in this state returning it into the reservoir for the successive supply of the generator. In consequence of this economical arrangement, the space occupied by the engine with all its appurtenances, does not exceed an area of six feet by eight. The present model is calculated equal to a ten horse power; and Mr. P. considers the whole of the apparatus of a sufficient size for a thirty horse engine; with the exception of the working cylinder and piston. The consumption of coal for this engine is within two bushels per day, when at full work.

All risk of accident is effectually provided against, by the following ingenious contrivance. It should be remembered, that owing to the small extent of surface exposed to the expansive force of the steam, and the latter being generated only in sufficient quantity for each succeeding stroke of the piston, there is much less liability of accident from this engine, than in most other high pressure engines. To prevent, however, the possibility of such an event, the induction pipe, in which the steam is produced, is calculated to withstand an internal force of 4000 pounds to the square inch, and it is also provided with a thin copper tube, which is calculated to burst at a pressure of 1000 pounds; while the pressure under which Mr. P. works the engine does not exceed 100 pounds on the square inch.

In order to demonstrate the perfect safety of the operation of this engine, notwithstanding this immense internal pressure, Mr. Perkins has on several occasions urged the power of the steam until it bursts open the sides of the copper tube, without occasioning the smallest risk, either to the spectator or to any other part of the apparatus. This mode of allowing the escape of the steam by rending open the sides of the ball, which is made of a determinate strength) is probably superior in the certainty of its operation to any modification of safety valves.

It is also a very remarkable fact, that the steam which escapes in this case is not by any means of that elevated temperature which might have been expected from its prodigious expansive force. This fact seems to involve some points connected with the doctrine of latent heat, or the conversion of fluid into gaseous matter and *de aëria*, with which we are at present but very imperfectly acquainted. We understand Mr. Perkins further engaged on some very important inquiries on this most intricate branch of natural philosophy.

We have not heard any comparative estimate of the price of Mr. P.'s engines, but we apprehend their original cost will be considerably lower than that of others; while they can be worked with one-tenth part of the fuel, and occupy but a fifth part of the space required for those of the low pressure construction. The latter point is one of the highest importance, in situations, where manufacturers are limited for room, in the metropolis and other great towns.

The very superior economy of these engines over all others, not only in the consumption of fuel and water, but in the weight of materials, must also render them peculiarly adapted for locomotive engines; and we entertain little doubt that steam carriages will, ere another twenty years have elapsed, become as generally adopted

among us as steam vessels are at the present. And when we take into consideration the immense saving in the consumption and tonnage of coals, we are of opinion that Mr. P.'s invention, will infinitely extend the use of the steam engine in navigation.

The following extract of a letter from a gentleman of this town, eminent for his scientific attainments and mechanical skill, now in England, to his friend in this town, gives a more clear and satisfactory account than we have yet seen published, of Mr. Perkins' important invention. The letter is dated April 26.—*Boston Daily Adv.*

As many enquiries were made concerning Mr. Perkins' new steam engine, before I left Boston, without any satisfactory information being had, I will attempt to give you some account of it. Before I begin, however, you must free your mind from all notions of a common engine, and call his, what you please afterwards. I do not mean that Mr. Perkins' machine is not a steam engine, but that its operation is so essentially different, in its principle, from all other machines under that name heretofore known, that you must prepare for a great novelty, such an one as must, in a short period, throw out of use all the steam engines, on whatever principles hitherto made. I saw it on Monday last, the day after my arrival, being the first time he publicly exhibited it.

In the common machines, a great mass of water is made to boil violently in a strong iron or copper vessel, called a boiler, upon the surface of which water, thus boiling, is raised the steam, heated to a degree, and conveyed by pipes to the working cylinder, and thrown by opening and closing cocks, alternately upon the upper and lower side of the piston. In Mr. Perkins', nothing of this kind takes place, nor does the water even boil, nor is any steam produced except the engine is worked. He confines in a very strong vessel, a small quantity of water, keeping the vessel constantly full, which is heated to a very considerable degree. This vessel, corresponding to the old fashioned boiler, he calls the generator, and holds about seven gallons in the machine I saw working. It is of cast iron, or rather bell metal, about three inches thick, and is placed in another sheet iron vessel or case, which encloses it, leaving a space all round of eight inches. Within this case the generator stands on a grating, so as to admit of coal being placed under it and round the sides, perhaps two or three inches high. To work his engine all day, about a bushel of coal is necessary, and on removing the iron cover from a hole in the top of the enclosing vessel, I perceived no more fire than is often seen in a common parlour grate. The power of this engine is ten horses.

The cylinder in which the piston works, is horizontal; the piston is two inches diameter, having a stroke of twelve inches only. Near this cylinder stands the generator, which communicate with each other by means of a short strong pipe, so that the operating valve alternately closing and shutting, this communication is brought as near as possible to the cylinder. When this valve is opened in common engines the steam passes from the boiler to the piston; but in Mr. Perkins', nothing but water, immediately compressed by heat, is passed—and at the moment of passing, the small quantity which issues, bursts into steam with great power. This explosion of water (and I see no reason why it may not be so termed) immediately fills the space between the piston and one end of the cylinder, and drives the piston the whole length of the stroke. On alternating, this steam is condensed, and the same operation then takes place from the opposite end. A small pump is moved, to throw the exceedingly small quantity of water, resulting from the con-

densation of the steam, into the condenser; a strong iron vessel standing near the generator, from which it is forced by the same pump into the generator again. Such is the general description of Mr. Perkins' new engine. It has the power of ten horses, and Mr. Perkins offered to bet that he would make it do the work of a fifteen horse power. The whole machinery weighs probably, less than a ton, and he says his machines and whole apparatus for any power, say fifty horses, will weigh only about as much as the water alone in common engines of the same power. He is now building a steam-boat of three hundred tons, to have two engines of sixty horse power each, the cylinders of which will be only seven inches diameter, with a five foot stroke, and the whole work will be below deck, at the bow of the boat. It is strictly true, in principle, that when the engine is once filled, no additional water is required. But owing to some small quantity inevitably escaping through the joints of the tubes, &c. a small loss is sustained, which must be supplied by the pump: for this purpose he has a bucket of water ready. From the compact form, simplicity, lightness, and power of his machines, I see no reason why steam carriages should not, especially on good roads, in a very few years, supersede all other kinds of land carriage, and a mail coach soon be running between this place and Liverpool, at the rate of twenty or twenty-five miles an hour.

Another letter from London, dated April 24, and published in the Boston Daily Advertiser, communicates the following additional information respecting Perkins' Improved Steam Engine.

"You have probably heard of Mr. Perkins' new and important improvement of the Steam Engine—but as I have seen it in operation and have conversed with Mr. Perkins on the subject, I will merely mention the principle on which the improvement is founded. He was never able to account for the fact that the bottom of a copper vessel is burnt through even when kept full of water. It occurred to him at length, that whenever great heat is applied, there is always a large space, between the bottom and the water, occupied by steam, which acts as a non-conductor.—His object then was to place the water under such pressure that it should be kept in contact with the bottom of the vessel; and that no room should be left for the admission of steam, and then, of course, all the calorific would be transmitted into the water. This he has effected, and a saving is made of nine-tenths of the fuel usually consumed. The water is raised to the temperature of 400 or more degrees of Fahrenheit, and on its escape from the boiler is converted into steam.—This system unites the two objects which were wanting to render the steam engine useful on long voyages. It is worked with so little fuel that it will be no inconvenience to carry enough for the longest voyages—and the machine occupies but one tenth part of the space of the old ones. Indeed one vessel is now preparing to sail for India with an engine of this construction of sixty horse power.

"It is said that Mr. P. has had great offers made him for rights to use his invention. He offers to make engines at half the price of Watt and Bolton, and demands only one third of the value of the savings in fuel. One singular fact is observed, viz. that the higher the temperature of the water is, the lower is that of the steam—That of boiling water, at a certain distance, scalds—that of water at a temperature of 400 degrees at the same distance is merely tepid. It is explained on the principle of its extreme expansion. Perkins thinks he could raise the water to so high a temperature, that the steam would b

converted into snow. He is certainly playing strange tricks with his mechanics. A great number of lords and ladies have been to see his workshop—and the savans, among others Mr. Wollaston and Sir Humphrey Davy, though at first incredulous, are now satisfied of the truth of his pretensions. The Marquis of — told him he would engage to go to America with him, if he would carry him in 15 days—Perkins told him he thought he could do it in something less. People amuse themselves in speculations of what changes are to be produced by this invention—sails and rigging of course will be laid aside, and people expect soon to see a steam engine traveling along the roads instead of horses—and as the explosive power of steam can be made greater than that of gunpowder, the same power which moves the cannon, may discharge the balls, and all the batteries may be converted into flying artillery. Mons. Gautler (a nephew of the balloon man) carries his views still higher and suggests that a small engine might be found very useful in giving direction to balloons, by operating on something in the shape of wings!"

FOR THE AMERICAN FARMER.
METEOROLOGY.

MR. SRINNER,

As in our very dry seasons, the most of your readers are watching the winds and the signs, as they are termed, for rain. I have thought the following translation from a French work, called "Erreurs et Préjugés," might be acceptable to them.

"The Abbé Toaldo has demonstrated that in 1106 new moons, 950 have been followed by remarkable changes of weather. There are then 950 chances to 156, or what is the same thing, six to one that a new moon will produce a change of weather. The other phases have less influence. The full moon gives but five chances to one. The first and last quarters give but two and a half to one."

MARYLAND AGRICULTURAL SOCIETY.
Baltimore, June 23, 1823.

At an adjourned special meeting, in pursuance of notice given, of the members of the Maryland Agricultural Society, R. Smith, Esq. in the chair, and James Howard, Esq. Secretary, held in the city of Baltimore, on the 23d June, 1823, the following proceedings were approved and adopted:

Resolved, that the Articles of Association of "The Maryland Agricultural Society," be amended according to the following form, and that the same so amended, be and hereby are adopted as the constitution of the said society.

ARTICLES OF ASSOCIATION OF THE MARYLAND AGRICULTURAL SOCIETY.

We the subscribers do hereby agree to associate ourselves under the style and title of

"The Maryland Agricultural Society."

Art. I. The object of this association is the promotion of Agriculture, and Rural Economy.

Art. II. The officers of this society, shall be a President, a Vice President, a Recording Secretary, a Corresponding Secretary, an Assistant Recording Secretary, a Professor of Agricultural Chymistry, a Treasurer, an Assistant Treasurer, and two Collectors—one for each Shore, twenty-four Trustees, and such other officers as the by-laws of the Society shall from time to time direct. All officers, where not otherwise directed, shall be chosen by ballot, to serve until the close of the next exhibition, and then and thereafter be annually elected at the meeting held on the Western Shore, in the month of November.

Art. III. The duty of the President shall be

to preside at all meetings, to direct such correspondence as may be necessary, to superintend the affairs of the Society, and to make such communications as from time to time may be deemed useful.

Art. IV. The Vice President in case of the absence of the President shall fulfil his duties; and in case of the absence, death, or resignation of any officer, the Society shall have power to appoint in his place a member to act until the appearance of such absent officer, or in case of death or resignation, until another officer shall be duly elected.

Art. V. Twenty-four trustees shall be elected, of whom twelve shall be from the Western Shore, and twelve shall be from the Eastern Shore. They shall meet as often as their respective chairmen, or any two members may deem it necessary, and any three members shall constitute a quorum. The trustees shall from time to time examine in person the management and condition of such farms as they may consider objects worthy of their attention; and they shall make report to the society of such as may merit their approbation. They shall severally take charge of all the property and articles of the Society, on their respective Shores; the books and papers of the other departments excepted. It shall be their duty to take the most efficient measures for collecting and distributing the best samples of all the useful grains, roots, and seeds; for collecting all native fossils, marls, earth or substances, proper for manures; for causing the same to be analysed, and report the results to the society; for procuring experiments, to be made by careful agriculturists, of all such fossils, marls, earth or substances; for collecting models of the best agricultural implements, and to report their properties and usefulness; to designate from time to time all subjects and objects for which premiums should be offered, and to fix and declare the several premiums for the same; to appoint committees to examine into the merits of, and report on all claims for premiums; to designate the time, and make the requisite preparatory arrangements every year for the meeting of the Society, and to keep regular minutes of all their proceedings.

Art. VI. The Assistant Secretary, the Assistant Treasurer, and the twelve Trustees for the Eastern Shore of Maryland, shall be chosen at a meeting to be called on that shore, by the Vice President, and, when so chosen, shall serve until the close of the next exhibition on the Eastern Shore; and the Trustees for said shore, shall then and thereafter be chosen annually.

Art. VII. The first Exhibition of the Society shall be on the Western Shore, on the first Wednesday in November next. The next Exhibition of the Society shall be on the Eastern Shore on such day thereafter as may be designated by the Trustees hereafter to be chosen on that shore.

Art. VIII. The Society shall have power to make such bye-laws and regulations, as they shall from time to time deem necessary for carrying into effect the objects of the institution.

Art. IX. Every member on joining this association, shall pay to the treasurer, or to the assistant treasurer, a sum not less than two dollars, and shall annually thereafter in the month of November, pay a sum not less than two dollars, so long as he may continue to be a member of said Society.

Art. X. All expenses incurred in the procuring of premiums to be distributed by the Society, at their meeting on the Western Shore, and all expenses incurred by the trustees in the preparatory arrangements for such meeting or otherwise, shall be paid by the treasurer, under an or-

der signed by the President, and countersigned by the Corresponding Secretary; and all expenses incurred on the Eastern Shore for premiums or otherwise as aforesaid, shall be paid by the Assistant Treasurer, under an order signed by the Vice President, and countersigned by the Assistant Recording Secretary.

Art. XI. At every meeting of the Society, the President or the Vice President, if attending, shall with the members present form a Quorum.

Art. XII. The Society shall consist of inhabitants of the State of Maryland, and of the District of Columbia, friendly to agriculture; and provision shall be made for the election and admission of honorary members.

The foregoing amended Constitution having been unanimously approved and adopted, it was ordered to be published in the American Farmer; and the meeting then agreed to adjourn to Friday, the 18th day of July, when they would meet again at Baltimore, to choose the general officers of the Society, the Trustees, &c. for the Western Shore.

R. SMITH, President.

JAMES HOWARD, Secretary.

THE FARMER.

BALTIMORE, FRIDAY, JULY 4, 1823.

Is it not wonderful, that to this hour, intelligent farmers should be obstinately divided in opinion about the *origin of cheat*? One would suppose that a question so susceptible of demonstration, and so immediately and much connected with their interests would have been fully settled. For the next paper, we have sent to the Printer a letter, wherein the writer states that he has "*twenty acres turned to cheat this ear*." Is there in all the circle of arts, in all the variety of men's business, an instance of such indolence in not clearing off all doubt in regard to an evil of such extent? Will not agricultural schools and professorships, connected with pattern farms, diffuse skill and science amongst agriculturists, as our admirable military academy preserves and distributes the *art of war*? But man in the boasted superiority and perfection of his nature, has ever been most ingenious in the arts of destruction!

The Editor was absent when the last number of the Farmer was published, until nearly the whole impression was stricken off—the Editorial observations on Usury laws, abound in errors of the press, "too tedious to enumerate."

BALTIMORE MARKET.

PRICES CURRENT.—CORRECTED WEEKLY.
Flour, best white wheat, \$8—Howard street Superfine, \$7 25—fine do. \$6 75—Wharf, do. \$7 sales—White wheat, \$1 42 to 1 50—Red do. \$1 42 to \$1 43—Rye, 75 cents—Corn, 50 to 52 cents—country Oats, 40 cents—Beef, 8 cts. per lb.—Live Cattle, \$6 to \$6 50 per cwt.—Bacon, round, 8 to 9 cents per lb.—Pork \$4 50 to 5 50 per c. lb.—6 to 8 cts. per pound—Mutton, 5 to 6 cts. per lb.—Beans, \$1 37½ to 1 50—Peas, black eyed, 55 to 60 cts.—Red Clover Seed, \$5 50 a \$6—Orchard Grass do. \$3—Herds' Grass do. \$3—Timothy do. \$4 50—Millet, none—Buckwheat, \$1 50—Flax Seed, 75 to 80 cts.—Whiskey, from the wagons, 34 cts. per gal. including the barrel—Apple brandy, 30 to 32 cts.—Peach do. 65 to 70 cts.—Shad, \$5 50, scarce—Herrings, No. 1, \$2 75 per bbl.—No. 2, \$2 50—Fine salt, 60 to 65 cts. per bush.—Coarse, do. 70—Butter, (firkin) 12 cts per lb.—Eggs, 12½ cts. per doz.—Hay, \$18 per ton—Straw, \$9.

MARYLAND TOBACCO, Red, has improved from \$1 to \$2 per hundred.

Internal Improvement.

ON THE PARAMOUNT IMPORTANCE, TO MARYLAND, OF A CANAL TO THE SUSQUEHANNA.

No. VII.

Further substantial evidence of the ample sufficiency, in general, of ten thousand dollars a mile to open a Canal competent for Boat navigation.

52. By the "Fourth Annual Report of the Board of Public Works of Virginia;" page 84 of the principal Engineer's Report, it appears that in estimating the cost of the James' River Canal, it was divided into four sections, the distance of each in miles; the average cost per mile; the surplus, that would be remaining, at the same rate, out of an appropriation of one million of dollars, for 100 miles of Canal; and the rate per cent, at which that surplus would accrue in proportion to the estimated cost, as they have been carefully collected, and calculated, from the Report above mentioned, may be clearly exhibited in one distinct view, as follows:

No of sect'n	Miles of distance	Aver. cost per mile	\$ saved in 100 miles	Rate per cent sav'd
1	24½	\$ 6560	\$344,000	34
2	120½	5730	427,000	43
3	85	8100	190,000	19
4	19	12659		
Total	249	7154	284,600	28

53. The lockage reported in this instance is 152 feet and a half, at \$625 per foot except 47 feet and a half in the first section at \$1000. The estimated cost of the whole 249 miles of Canal is \$1,781,419 that is at the rate of \$7164 per mile, and a saving of 28 per cent, as above stated. The cost of the Potomac Canal, was estimated in five sections, as appears by the Commissioner's official Report, transmitted by the governor, to the Assembly of Maryland, January 1, 1823, pages 77 to 84; a similar view of which is presented as follows:

No of sect'n	Miles of distance	Aver. cost per mile	\$ saved in 100 miles	Rate per cent sav'd
1	54½	\$7,711	\$228,900	23
2	33½	8,055	194,500	19
3	38½	8,483	151,700	15
4	46½	7,499	250,100	25
5	9	23,702		
Total	182	8,676	132,400	13

54. Upon this occasion 487 feet of Lockage are estimated at \$650, except 62 feet in the last section, at \$750. The whole cost is estimated at \$1,578,954 for 182 miles. The greater cost, and saving, upon this route than upon that of the James' River, appear to be owing to the great difficulties that must, of course, be encountered in opening a Canal along the narrow, rocky range of the Potomac, through the South mountain, and also around the Great and Little Falls, to tide water, where, in a distance of only 9 miles, it is stated, that the Lockage required, is less than 102 feet, that is no less than one fourth part of the whole estimated Lockage, in a distance of 100 miles, between Baltimore and the Susquehanna. And as it may fairly and rationally be presumed, that no such difficult situations

exist upon this last route, so the presumption is equally fair and rational, that in this direction, the cost will be less, and the saving greater, than upon the Potomac route, provided it shall be found practicable to bring the required supply of water over or through the summit level in an eligible situation, which is an important desideratum, to be determined by the survey and leveling, now about to be commenced.

55. Again, agreeably to Niles' Weekly Register, Vol. No. 22, page 275, the Housatonic Canal, in New England, will be 66 miles long; the ascent 604 feet, and the supply of water abundant, the whole cost of which, is estimated at \$699,400. This, I perceive, exceeds ten thousand dollars a mile—and I also very plainly perceive the reason of it. The ascent is 604 feet; whereas, at 4 feet in the mile, the estimated rise and fall in the proposed route to the Susquehanna, the Lockage would be only 264 feet in 66 miles. Consequently, if 264 feet be taken from 604 feet, the excess is 340 feet, which at \$625, the lowest estimated cost per foot, the amount is \$212,500. This sum being deducted from \$699,400 the estimated cost, and the remainder divided by 66 miles, the distance, the quotient is \$7377 per mile, were it not on account of the excessive Lockage. At this rate, the saving, out of a million of dollars, for 100 miles, would be \$262,300, that is upwards of 26 per cent. upon the required proportion of the original estimate.

56. The foregoing estimate has reminded me of a small omission in my last number. In the calculation of the amount of saving (50) agreeably to the test of experience, upon the Canals of New York, no notice was taken of the Lockage there, that is 661 feet in the Erie Canal of 353 miles, being less in proportion, than the estimated rise and fall of 400 feet in 100 miles. Instead of 400, there should be only 187 feet at the rate of 661 feet in 353 miles. Hence the excess is 213 feet, the amount of which, at \$625 per foot is \$133,125 for extra Lockage. But according to information that I have since received from one of our Susquehanna Canal Commissioners, for only 20 per cent. to be saved, in consequence of the incalculable advantages derived from experience, is too low. I am told that these advantages were estimated by a superintendent, in the business, who was very capable of forming a very correct opinion, at thirty three and a third per cent. That I may be certain, however, not to exceed the reality, let 25 per cent. be adopted, which rate being deducted from \$7,603,386, and \$764,000 from the remainder, then by adding the above \$133,125 for extra Lockage we obtain \$5,071,665 for the cost of 782 miles, as before (50) of Canal, competent for Boat navigation, that is \$6473 per mile, equal to a saving of \$352,700, or 35 per cent. out of an appropriation of a million of dollars for 100 miles. The difference between 4 feet, and nearly 3 feet Lockage, on the Potomac route, and upwards of 4 and a half on the James' River, are both deemed too small to be made particular subjects of calculation.

57. The Canal of Languedoc, in France, called, also, the Canal of the two seas, is stated in the French Encyclopedia, to be 64 leagues, 192 miles in length, and to have cost 25 millions of livres, valued according to the period when work was prepared for publication. Computing 16 livres, as being equal to \$3 the cost of 192 miles, was \$4,687,500, that is, \$24,414 per mile. From other authorities, it appears that the summit level of this stupendous Canal, is about 600 feet above the two waters, between which, it forms a communication; that under the patronage of Louis XIV. who furnished more than half the money expended upon it—it was begun, and finished in 16 years; that it is 6 feet deep,

and 144 wide, including the towing paths, and a water line of 60 feet. Hence, its width in the bottom, allowing 18 inches base on each side, to one foot rise, would be 42 feet, and the excavation in every yard of distance, 34 cubic yards; so that by proportion, 34 cubic yards: are to 8:: as \$24,414: are to \$5745, including every expense at that rate, for a Canal of 24 feet water line, and 4 deep, as before mentioned.

58. Again, the Holstein Canal, begun in 1777, and finished in 1785, is stated in the New Edinburgh Encyclopedia, Article Navigation Inland, page 360, to extend about 50 miles. Its water line is said to be 100 feet, bottom 54, and depth not less than 10 in any part. The whole expense of this ship navigation, where vessels drawing 9 feet 4 inches water, pass through between the Baltic and the German Ocean; and from two to three thousand ships have passed in one year, was a little more than a million and a half of dollars, that is \$30,000 per mile. According to the above dimensions, each yard in length would contain 85 cubic yards of excavation, which: are to 8 cubic yards:: as \$30,000 per mile: are to \$2824. I consider it probable that this low amount may be owing to there being but little, if any Lockage in this instance, and if so, \$3000 being added for 4 feet Lockage, at \$750 per foot, will produce, for the cost of a Canal, competent for Boat navigation, \$5284 per mile, at that rate, a sum nearly agreeing with several of the foregoing calculations.

59. Evidence of a similar nature, might be added to a much greater extent; but more appears to be unnecessary. From that which has already been offered, it is evident 1153 miles of Canal have been located, and about one half of it has also been made, as follows: the cost of the large Canals being reduced to the proposed size of 24 feet surface and 4 feet deep:

Paragraph	Miles of distance	Aver. cost per mile	\$ saved in 100 miles	Rate per cent sav'd
52	249	\$7,154	284,600	28
53	182	8,676	132,400	13
55	66	7,377	262,300	26
56	414	6,473	352,700	35
57	192	5,745	425,500	42
58	50	5,284	471,600	47
Total	1153	6,760	324,000	32

60. Thus it is evident that out of sixteen items of calculation there are only two, and out of 1153 only 28 miles in which the cost has been recognized to exceed \$10,000 per mile. Owing to 221 feet of lockage being required in the last 19 miles of the James' River route, that is nearly 12 feet in the mile instead of 4, the excess is 8 feet, the cost of which at \$625 per foot, is \$5,000, and this being taken from \$12,659 leaves \$7,659 for the cost per mile, exclusive of the extra lockage—which is equivalent to a saving of 234,100, or nearly 23 and a half per cent, out of a million of dollars for 100 miles. Thus, there are now only nine miles out of 1153, which constitute any exception to the entire sufficiency of \$10,000 a mile; and in consequence of these 9 miles including 102 feet of lockage, (54) and otherwise presenting difficulties that are believed to be of a more formidable character than any that will probably be presented upon the other contemplated routes in Maryland, this last exception, also, completely vanishes from before us.

61. Thus it is evident that the popular conjecture of twenty millions of dollars being required to open the Erie canal of New-York, was the

mere whim of uninformed minds. Thus, also, the wild ideas of 100 miles of canal between Baltimore and the Susquehanna, costing six, eight, or ten millions; of its being an enormous undertaking, beyond the reach of Maryland to accomplish; that if possible, at all, it would require the sale of our city to carry it into effect, are whims still more idle and extravagant—whims, by which those who imbibe and indulge them, swell into mountains, expenditures and difficulties, that, when correctly understood, are but as mole-hills, in comparison.

62. It is now nearly 40 years since I knew an instance of a young man, who had then lately completed his education at school; or, as the common expression is, *who had gone through the assistant*, being closely questioned by an old man, in relation to his learning, and in particular whether he was well acquainted with vulgar fractions. These inquiries were so managed as to apprise the youth that a question was about to be proposed to him, and to make him believe it would be extremely difficult. It was briefly this: *How much is the third and half-third of three pence?* Supposing that it must at least require an operation, such as was usual in the addition of fractions, the student, without making the least effort to discover the answer, modestly answered, *if he had a slate and pencil he thought he could work it*. But, how extremely was he afterwards mortified, when he came to reflect, that neither slate nor pencil was at all necessary; that the third of three pence being a penny, and the half of a penny a half-penny, the answer was a penny-half-penny.

63. Thus, this young man, though very capable of having answered the old man's question with the greatest facility, was completely deterred from making the least effort, merely by imagining a great difficulty, where, in fact, there was none. May then the citizens of Maryland no longer hesitate to prosecute with energy a canal to the Susquehanna. May they remember that the third and half-third of three pence is easily told; and also that the evidence in favour of the ample sufficiency of one million of dollars to accomplish the object, has been shown to be abundant, *without a single instance of exception remaining; all the mistaken and extravagant conjectures of inexperience to the contrary in any wise notwithstanding.* WM. KENWORTHY.

FOR THE AMERICAN FARMER.

TO THE CITIZENS OF THE STATE OF MARYLAND,
My Fellow Citizens,

The subject of Internal Improvements—of improvements in Agriculture and in the arts auxiliary to its prosperity, especially in making canals, railroads, and other roads for diminishing the expense of conveying its productions to market and bringing back its returns, so as to leave to the farmer a profit on his labour larger than that which he now enjoys, has, for a few years past, been pressed upon our attention; and it is a subject worthy of our most serious consideration.

When my letter to Clement Dorsey, on this interesting subject was published in the American Farmer, (vol. 4, pages 19, 20,) I intended to present to your view some further reflections—but my engagements in executing a part of the new canal near Richmond, in Virginia, and some other imperative duties, have so fully occupied my time, as not to leave it in my power, until now, to pursue the theme.

The gigantic strides, the rapid march of the state of New York toward wealth, power and happiness; the efforts of Virginia on one side of us, and of Pennsylvania on the other, to appropriate,

each to herself, the trade of a large portion of the Western country, speak a language which we cannot misunderstand, and which we ought not to disregard. Were we to blame them, we should be wanting in magnanimity—yet, while we admire and applaud their enterprising spirit, let us avail ourselves of *our own* advantages, and not, by neglecting the auspicious moment, suffer them to pass from us, or be greatly diminished in value. Nature offers to our acceptance, the *cheapest* and *most easy* communication with the Western Country, by means of the Potomac and Youghiogany rivers and their tributary streams. We have the advantage of our immediate neighbours, in our location and the facilities for a cheap and profitable intercourse. Nature and the enterprising spirit of her own citizens, have given to New York, beyond competition, in addition to her own internal trade, which is very rich, the trade of St. Lawrence river, that of an immense extent of Lake-shores, and of the northern part of the states of Ohio, Indiana, and Illinois, as far as the ridge separating the waters which flow into the Lakes from those which flow into the Ohio and Mississippi rivers, but this ridge should be her *southern limit*. If we be not wanting to ourselves, we can meet her *here*, and say to her “Hitherto shalt thou come but no further”—south of this boundary is ours. New York has indeed taken the lead in this glorious race of Internal Improvement, but let us not suffer ourselves to be so far eclipsed by her as to be discouraged and lose our energies, let us rather emulate her and profit by her example. Respecting the Potomac, as a channel of commercial intercourse and as a powerful bond of union between the Eastern and Western countries, the pen has been several times dexterously wielded by various hands, yet so important is the subject, and so fruitful in highly interesting considerations, that it is by no means exhausted.

Since the commencement of operations, in the year 1817, in making the great Erie canal, my continual employment, as civil engineer, on objects of improvement in inland navigation, in the states of New York and Virginia, has afforded me abundant opportunities of becoming acquainted as far as my capacity would admit, with this great subject, in its various important bearings—in theory and practice: And it has been my favourite study. I may therefore be permitted to add my mite.

Look at the map of the middle states—see the noble Susquehanna, with her widely spreading arms—See the Potomac pointing to the West. Both discharge their waters through *our* state, and their wealth will naturally flow through the same channels, if the proper improvements be made. The former river drains the southern border of New York and the middle parts of Pennsylvania, and Maryland has exclusive jurisdiction over a few miles at or near its mouth—the latter may be easily connected, in *continual navigation*, with rivers which drain the south-western parts of New York, the western parts of Pennsylvania, the northern parts of Virginia, most of the states of Ohio, Kentucky, Indiana, Illinois, &c., and Maryland has, with Virginia, concurrent jurisdiction over its whole extent from its source to its mouth, except about ten miles, over which the United States have exclu-

* On this point, the comparative advantages of the Potomac route, see an excellent Essay, in two numbers, with the signature “*Lookers-on*,” from the pen of our late lamented friend THOMAS MOORE, published in the National Intelligencer and in the American Farmer—see particularly, page 412 of the American Farmer, Vol. 3.

sive jurisdiction. The improvements which may be made, and which ought to be made on both these rivers are, therefore, highly interesting to us—but those on the Potomac are, in my estimation, vastly the most so, as I hope will plainly appear from the considerations I shall be able to present.

We may realize, from these improvements, benefits beyond the expectations of even the most sanguine—they will be not only possible, but easily practicable, if we be united—if we are in unison; but if we be so unwise as to suffer sectional jealousies to predominate, one section of part to be set in array against another, as if the interests were hostile, all our plans may fail. Many a noble scheme has been ruined in this way; and, as it respects public improvement, no principle can be more fallacious. Each proposed improvement will afford *positive benefit* to every part or section, although some one part may be benefited *more* than the others—the truth of this is proved by the history of every commercial town and city, and of every adjacent country. Let us, for the sake of illustration, suppose a state to consist of three parts or sections, which we will designate by A, B, and C—and that three different plans of improvement are proposed, all good plans, and fraught with important benefits to the whole state, and each yielding advantages, in a greater or less degree, to every one of the parts A, B and C—but, as it almost always happens in practice, the first plan is calculated to benefit A in a much greater degree than it will B or C—in the spirit of jealousy, they consider it and treat it as an injury, oppose it, and, being the majority, defeat it; the second plan is calculated to benefit B much more than it will A or C—they in like manner, treat it as an injury to them, combine against it, and defeat it; and the third plan, being calculated to benefit C most, is defeated by A and B, in the same way, and by the same process of feeling rather than of reasoning. Neither will accept of even positive wealth, by any plan which he fears will give to his neighbor still greater wealth. Such is the spirit of jealousy, and where it reigns paramount, it never fails to keep a state weak and poor. How much more noble and magnanimous it is, to cast from our view exclusive advantages to particular parts and, with a steady aim, to pursue only the general good; and such, I trust, will be our course.

Agriculture is, beyond all question, our primary interest. Three-fourths, at least, of the population of Maryland are cultivators of the soil—the remaining fourth pursue Commerce and the Mechanic Arts. These are indeed auxiliary to agriculture, and necessary to its prosperity, and ought to have their just share of legislative patronage; but agriculture is paramount—the first and noblest of arts, and the parent and nurse of all others. It ought not to be under the control of minor interests. I therefore address myself principally to farmers and planters,—you, who cultivate the soil—you are the strength and sinews of the state,—you ought to be, according to your importance, independent, to give tone to secondary interests, instead of being governed by them. Exercise your right of suffrage, at the ensuing election, judiciously and independently; and then you will infuse your spirit into the next legislature.

Take into your serious consideration, the subject of the contemplated connexion, for commercial intercourse, between the Eastern and Western country, by a navigable canal along the valley of the Potomac river. In consequence of the long and narrow form of Maryland, this proposed improvement will bring almost to our very doors the cheapest, safest, and most perfect of all possible modes of conveying our produce to market and of bringing home its returns. It will present to our choice more than one market—it will pre-

sent a number of markets in active competition with each other, which, while it will be a positive benefit to each commercial city and town, will, by making each a better market, yield incalculable advantage to, and establish the predominance of the agricultural interest. The western parts of Pennsylvania, the northern parts of Virginia, the rich state of Ohio, &c. &c. by making this their channel of commerce, will pour countless treasures into the lap of Maryland, and, at the same time, enrich themselves; for the benefits of commerce must be *reciprocal*, otherwise it cannot flourish, and will soon cease to exist. It is just so with agriculture, commerce and manufactures; unless they cherish and support each other, in honest and harmonious *reciprocity*, instead of each endeavouring to overreach and take advantage of the others, neither can long prosper. Let us do our part toward making the proposed improvement. It requires from us nothing beyond what a willing and industrious people can do without difficulty, and nothing but what a wise people will see it their best interest to do. From Pittsburg to Washington-City and Baltimore, the whole line of canal will be a chain of beautiful and flourishing villages. We have not yet fully considered these things, but enquiry is awakened; before the next election we will understand the subject, and when we do, if we do not act rightly the fault will be our own.

Permit me to say a few words more on the advantages of several markets in competition with each other. Where the cultivators of the soil have but one great commercial market, the mercantile interest acquires too much influence over the agricultural—the less over the greater. This injurious influence tends to paralyse and chill the spirit and energies of agriculture, and to destroy that fair reciprocity which is essential to the prosperity of both interests. Among farmers, individual competition operates in its fullest extent; among merchants of the same city or town, individual competition is easily controlled and regulated by combinations; this circumstance gives to the latter a great advantage over the former. Let the farmer have a choice of markets so nearly equal in magnitude as to be rivals for his custom, his condition is thereby vastly meliorated; both markets are rendered better for him, and he stands on ground comparatively independent. Even those, who, from their proximity to one market, never contemplate using any other, will find that one which they do use a better market in consequence of the competition.

The proposed improvement, it is true, would place one market, and probably a considerable one, in the District of Columbia, and, technically speaking, this is not in the state of Maryland—but it is *technically only* that the District is foreign. Its inhabitants have *Maryland-feelings*—separated from us only in name, they have, with us, identity of interests, and are our brethren still. But admitting this to be a foreign market, which essentially it is not, how would that circumstance affect our interests? If we can sell our produce there for a better price than we can obtain elsewhere (otherwise we will not go there) and bring thence a greater value home, is not the advantage ours? This is precisely the argument we use to prove that foreign trade is profitable, our receiving a greater value in exchange for a less. Let us not be deceived—fine-spun logic may puzzle and betray us into obscurity and error—but plain common sense will not mislead us. It is our true interest to encourage, in connexion with the main canal, every lateral one, on which nature has not placed insurmountable difficulties. No one place should be a *favorite*, but all should have equal privileges, and in every measure the leading object should be the *general good*.

I have heard it alleged, by some of my neighbors, as, on their part, an objection to the proposed canal, that, if the friends of that project be correct in their estimates of the cheapness of conveyance, it will place those who come 100 miles by the canal on a par with those who have only 5 miles of land carriage; and those (say they) who have to encounter the expense of a greater distance than five miles of land carriage will be undersold, and, by the reduction of prices generally, be placed in a condition much worse than their present one. This apprehension is altogether chimerical.—Its assumptions are contradicted by the history of the rise and progress of every commercial city; for instance, New York, Philadelphia, Baltimore, &c. &c. Prices are regulated universally by *demand and supply*, and they advance or recede, *with equal step*, or with very moderate vibrations.

By the operation of the contemplated canal, a vast amount of capital in wagons and horses will be set free for a more profitable investment—to promote and extend agriculture—to increase its products—and to enable the country to maintain in comfort, a greater population than is possible under the present state of things, by appropriating to the support of *man* what is now necessary for the sustenance of *horses*, which would be rendered supernumerary.

If I shall have time and opportunity, it is my intention to pursue this very interesting subject, and to submit for your consideration some of my views and reflections on the following topics:

1. The probable cost of a canal from Cumberland to the line of the District of Columbia—making the most liberal allowances in every doubtful case.

2. The probable amount of tonnage that would pass—and the profit it would yield on the stock—the benefits to agriculture, arising from the saving in the expense of transportation, and from the many new productions becoming profitable, which the farmer cannot now cultivate without loss, on account of the heavy cost of conveyance to market.

3. An enquiry, whether in her present circumstances, it would be *wise and prudent* for the state of Maryland to take stock—and to what amount—or *simply* to grant a charter.

4. The probable amount of capital in wagons and horses, set free.

5. Objections answered more extensively and particularly than the present number would permit: and if any have objections not yet stated, I invite them to come forward and propose them. Where candour regulates the debate, truth is always promoted and knowledge extended by discussion.

I shall be glad if the hints I have given, put in motion other pens. The field is large, and much, very much of it remains unoccupied.

ISAAC BRIGGS.

AGRICULTURE.

TO THE EDITOR OF THE AMERICAN FARMER.

HESSIAN FLY, CLOVER, CHEAT, &c.
Fairfax County, 28th June, 1823.

SIR,

I am just closing a wretched harvest, which, until the last week in April, gave me the hope of a very abundant one. This as far as report may be credited, is the case through a great part of Virginia—believing, sir, that much good may result from a free communication, through your useful paper, touching any matter directly or remotely relating to this destructive and ruinous insect, I

shall proceed to give you an account of my preparation for a crop, and its results—150 acres of land was cultivated in corn, which produced a good crop of that grain; about the 12th of September, I commenced seeding wheat among the corn, and continued until the 26th, when believing that the corn was dry enough to cut and stack, I proceeded to do so, and then had more command of the surface of the earth—my wheat was all seeded by the 8th of October, and came up well and grew with great vigour; the winter made little or no injurious impression upon it, and until the last week in April it promised well; it then became very pale, and began to disappear, upon the thinnest spots particularly, where those places were dry and elevated. Upon the last of May I did not think the crop worth any thing, and verily believe I should have pastured it, but for some good Rye which was within the same enclosure, and the hope I had of the young clover—March and April were very wet; the weather then became dry, and we had but two very light rains from that till harvest; these rains brought up a surprising quantity of small wheat upon manure land. The first thirty acres of this field which was seeded has produced very little more than the seed—that which was seeded after cutting the corn and stacking it, recovered from the attack of the fly, better than any other part of the field.—Since the year 1815 I had failed entirely in my clover, without one exception, though I seeded one hundred and fifty to two hundred acres every year, and gave it a dressing of plaster—I this year seeded my clover upon fresh ploughed land, as fast as it was laid down in wheat, and gave it a dressing of plaster in the Spring; it now looks well, and I have no doubt of its success, and believe that Autumn is the best and only proper time for seeding it. An opinion has become very prevalent that land would *tire* of clover—and plaster was worse than nothing as a dressing; from 1800 to 1815, I had sowed clover and plaster with great liberality without a single failure; since that I have entirely failed, having used as much as eight hundred and one thousand bushels of plaster a year, and upon a part of my farm, ploughed in the clover produced; the abrupt and sudden failure afterwards gave occasion to nice discriminators and philosophers to conclude *positively* that the land had *tired*.—In England, it is said, that land has tired of the production of clover, and it may be so; but is clover the natural grass of that land? Let me ask in the name of our injured and impoverished land, that gentlemen would re-consider this opinion, and commence by seeding their clover in the fall, and with it as many Timothy or Orchard grass seeds as they can obtain—grass roots, like animals, will be regulated by the food within their reach. The cost is nothing—the succeeding crop will pay one hundred per cent. upon money thus expended.

I had also a fallow field of sixty acres, all of which was well broken up with a good three horse plough, twenty of which, because of a grass called Couch or Twitch, was crossed with the plough, and well harrowed, and then seeded with Freeborn's one horse plough. Forty acres were well harrowed two or three times and then seeded—the whole came up well and looked very fine until the last of April; the 20 acre lot is cut and may produce eight or ten bushels to the acre—the forty acres all *degenerated* or *changed* into *cheat*, and I have cut it for rack food for my horses—the whole sixty acres is good land, the best produced most cheat—I should not fear making three hundred or three hundred and fifty bushels of corn upon it.

Your's,
A VIRGINIAN of F. County.

TO THE EDITOR OF THE AMERICAN FARMER.

VINES.

Oakley Farm, June 18, 1823.

JOHN S. SKINNER, ESQ.

Dear Sir,

I have just been in my little vineyard, witnessing a repetition of the disappointment which has constantly attended my culture of the vine—my grapes are rotting by hundreds of bunches. I know the same fate has followed, even in more favourable soils than mine, the like attempts with us here, and as it is a disease not noticed by any of your correspondents on the "culture of the vine," I should be obliged to Mr. Adlum or some of your successful vigneron, could they point out the probable cause and best remedy.

It is about ten years since I began to attend to the vine, and have persevered with diligence and patience, but with little success. I have three fourths of an acre in vine, and yet do not get grapes enough for my table. My soil is, I believe, not very favourable, being thin, and bot-tomed on stiff clay; this it has been endeavoured to remedy with manure, deep ploughing, and digging round the vines with a three pronged hoe. I have tried raising vines from cuttings, with one, two, three and four eyes, and have taken the pains of pursuing the Madeira practice, of digging a trench five feet wide and two deep, and covering in it cuttings four and five feet long—in all which ways, except the last, they have grown well, borne in due time abundantly; but rotted equally. I have grafted on our native grapes without benefit; my vines have been pruned according to rule, and not permitted to bear until the fourth year. They have been pruned close, and the heads kept near the ground. They have been trained on espaliers six feet from the ground—they have rotted alike, and out of twelve different kinds of grapes, I have only two, (the white Malaga and Muscat-rouge) that I ever get any from.

The disease which destroys my grapes is certainly not an insect. Many of my grapes are injured by a curculio that attacks the berry, and a caterpillar that feeds on the leaf, but they are nothing in comparison to the rot, which may well be termed a blast from its sudden extensive destruction; for I am sure there has been upwards of two thousand bunches blasted in one night. Its first appearance on the grape is like a blister arising from a scald, and is only skin deep; the berries then gradually turn brown and rot, sometimes a few at a time, sometimes entire clusters rot at once.

The white Malaga and Muscat-rouge rot a little, but triflingly in comparison with the rest—they fail sometimes by not ripening in autumn, but shrivel up green and insipid: they are, however, my most certain grape, and I am extending their stock. They are not shewing at present any rot—but the black Hamburgh, Meunier, Sauvignon (a delightful grape brought by the late Gen. Davie, from France) white and black Sweetwater, Madeira grape, &c. are all rotting as usual.

I have one fine black Hamburgh vine, extending thirty or forty feet along the eaves of my piazza, about fifteen feet from the ground, and although the grapes on it do rot in some degree, it ripens much more than fifty vines of the same kind do in my vineyard, believing it probably owing to the height at which they hang, and knowing that in parts of Italy they train their vines to trees. I cut down some small trees last autumn, lopped off the limbs two feet from the stems, fixed them up near to some black Hamburghs, and trained the vine up about fifteen feet high; as yet, although many of the lower

bunches are rotting, the higher ones are still sound.

The interest you are taking in this subject, as well as our other agricultural concerns, for it ought to become an agricultural one, has induced me to trouble you with the foregoing sketch, in hopes you may be able to obtain me some information in point.

One of your correspondents complains that his strawberry plants grow well, but give him no fruit. Many years ago some fine Chili plants were given me, and were cultivated a foot a part with the utmost care; they grew most luxuriantly, blossomed abundantly, but did not give me a single berry. After three years of disappointment, the bed was neglected, from believing it was filled with male plants, and became over run with grass. The next year, to my surprise, it was loaded with fine large strawberries, and in that state continued in full bearing many years. The same thing nearly has occurred to me here. I have been in the habit of making new beds every two years—and a few years ago ordered the old bed to be broken up; my gardener fortunately neglected to do so; for the new plants flourished famously—they gave little or no fruit; whilst the old ones intermingled with grass bore an abundance of fine fruit; and this year, though six years old, gave more than my family could consume of fruit nearly equal in size, and quite so in flavour to the very best of their kind—growing on tall stems, and having the advantage of being free from sand and dirt. This may be considered a slovenly mode of culture; be that as it may—I merely state the facts, how I have obtained fine fruit, when the secundum artem system gave me none. We derive most of our agricultural and Horticultural information from Great Britain, and are, perhaps, too apt implicitly to apply to our dry climate, rules drawn from a cool and moist one.

With my best wishes, believe me,

Respectfully your obt^d serv^t;
W. S. GIBBES.

FOR THE AMERICAN FARMER.

May 23, 1823.

SIR,

Of the various seeds which you kindly sent to me, none have as yet vegetated, but the purple or blue corn, the eight grains of which have been planted in a field of rich clover, upon the patent plan of the late Mr. Hall. Not one of the seventeen seed of ice rind melon has vegetated; they were planted so carefully distinct, that you might have relied upon the purity of the produce—but as I cultivate ten varieties of my own, in 286 hills, it is, to me, more a fancied than a real loss.

The tobacco which grew upon Sideling Hill is beautiful, and will be fairly exhibited, and it gives me an opportunity to repeat, my so often repeated advice to agriculturists, to emulate the enterprize of our manufacturers, and endeavour to increase the value of their labours by improving the quality of the article raised—I also made an attempt to cultivate tobacco, and sold at \$2. Your friend's hogshead was equal to seventeen and a half of mine, to say nothing of the cost and charges upon the sixteen and a half. It is essential to increase the profit of industry, that the article should be the best of its kind; and taken to market in the best and neatest condition.

The flour barrel of Philadelphia, is in every respect neater than the barrel of Baltimore; and may it not be owing to this circumstance that the flour of the former, commands a higher price in Europe, than that of the latter?

It is but justice to assure you, that the farmer is supported with a spirit and in a manner, much beyond my expectation, and much to the satisfaction of your subscribers. But I think you might enlarge your plan, and include within its scope, rural sports, domestic improvements for profit, comfort, or ornament; nor need you be ashamed to select from books, and domestic and foreign journals: for instance, I now enclose to you a piece upon Hydraulics, taken from a newspaper. This is a subject all important, not only as it regards our rural comforts, but may it not have great influence over the health and comfort of our cities. Who will say that the hills of Baltimore may not (if this narrative is true) produce fountains of living water, more delicious, and at less expense, than what you now receive from your excellent water works?

With this you will receive some cymblin seed, but the season is too far advanced to expect a full crop from them. This variety is much earlier than the long kind, and to make a full crop, should be planted as soon as the frost is out of the ground; they will not vegetate one day before their appointed time. I recommend to your friend to plant in drills at eight feet apart, and a single plant two feet apart in the drill. The bunch cymblin, of which I have lost the seed, is, I think, the most productive, upon a given space. Rich land is necessary for success—and as the season is so far advanced, it should be land disposed to produce moisture.

Your obedient servant,

F.

J. S. SKINNER, ESQ.

N. B. Gourds should be planted in February.

From a Compendious Dictionary of the Veterinary Art.

ON THE DISEASES OF DOMESTIC ANIMALS, AND THEIR CURE.

DYSENTERY. I have never seen a disease which exactly corresponds with the dysentery of the human body: it is said, however, to be "not uncommon in the horse, and more frequent in cattle and sheep. It very commonly begins with some degree of fever, as a trembling, dryness of the mouth, loss of appetite, a great degree of weakness, drooping of the head and ears, sometimes a copious sweating, but more commonly a dryness and heat of the skin; there is usually a heaving of the flanks, and the animal turns his head towards them as if griped: there are frequent stools, but these seldom consist of the natural excrement, but of a mucous slimy discharge, accompanied with a peculiar fatty substance like soft suet; there is evidently much distress during these evacuations, and sometimes the fundament appears excoriated: it is not uncommon to see blood pass with the stools, generally in streaks, but sometimes in such quantity as to tinge the whole discharge of a red colour; and in the latter stage of the disease there generally appear membranous filmy substances, which have been compared to soaked leather. The pulse towards the beginning of the disease is hard and full; but as the disease goes on, it becomes quick, small, and sometimes irregular. The animal is very stiff and averse to motion; and, if the disease continues long, there usually comes on a swelling of the legs. This disease does not appear so dangerous among the inferior animals of this climate as in warmer countries: but it sometimes proves fatal, or terminates in a weakness of the bowels and scouring that are not easily removed. It is necessary to distinguish this complaint from the common purging or scouring, with which it is very generally confounded. It must therefore be observed, that in scouring there is no fever, whereas this is common in dysentery; that the

discharge in scouring, though thin, has almost always the appearance of excrement, is not bloody, and is scarcely ever mixed with fatty matter. Dysentery is more common in hot weather and in hot seasons than at other times; but is very commonly produced by the sudden application of cold, especially to the legs and belly, when the body is over-heated and fatigued by exercise; hence swimming in autumn, drinking largely of cold water when in a profuse sweat, or other sudden changes from heat to cold, have commonly produced it. It is said to be brought on by riding a horse very hard in hot weather. As it seems certain that dysentery is of an inflammatory nature, it is proper to begin the cure by bleeding." If the pulse is quick, and the blood when coagulated has much buff, or size upon it, it may be proper to repeat the operation after a few hours. Some laxative medicine should then be given, and an opening clyster thrown up. The following laxative will be found to answer the purpose:

Powdered aloes from two to three drachms.

Carbonate of potash, two drachms.

Warm water, eight ounces.—Mix, and add of castor oil, twelve ounces, for one dose.

When purging has taken place, the horse should be well supplied with gruel made of wheat-flour, and if he refuse to drink it, he should be drenched. The body should be kept warm and well rubbed, and the legs bandaged. When the disease has been subdued, the horse's strength is to be recruited by tonic medicines and a nourishing diet. When the disease continues after the bowels have been emptied, a ball composed of

Opium, a drachm,
Ipecacuanha, half an ounce,

has been recommended; but this, I believe, will rarely be found necessary. It is said that cattle are subject to a similar disease, only that in them there is not perhaps so much mucus or slime discharged with the dung; and that it is not uncommon in sheep; in the latter animal it is commonly named Brackshaw or Breakshaw, and in cattle Fardle-bound. In these animals a laxative of Epsom salts, gruel, and castor oil, should be first given, particularly to cattle; but in sheep, a practical farmer, Mr. Lock, has usually given warm milk: he proposes, however, to try, in addition to this, nitre, in half drachm doses, with chalk, or some other absorbent powder, and twenty or thirty drops of laudanum, twice or thrice a day, with frequent clysters of warm milk and water. We may infer, I presume, from his adopting this new plan, that the old one did not prove successful. According to Mr. Gillespie (quoted by Mr. Findlater,) the disorder is often produced by over-heating, when the sheep are hunted by dogs in folding them, &c. He thinks the disease infectious, and recommends tarring as the best preventive. Mr. Blaine, as well as the author from whom great part of this article has been taken, considers dysentery and Moltengrease to be the same disorder; but according to my experience, Moltengrease is very unlike the Dysentery of the human body, nor does it altogether resemble the disease above described. See *Moltengrease and Costiveness*.

EPILEPSY. Falling sickness or fits.—*Symptoms.* The horse reels about and falls down; sometimes he rears up and suddenly falls. The muscles of the eye act irregularly or are affected with spasm, so that the eye is shockingly distorted and fixed during the fit. Sometimes he lies in a state of insensibility for several hours; the pulse continues to beat, and there is often a disturbed kind of breathing. Sometimes there is also a violent motion of the legs. The duration of the fit varies; sometimes the horse gets up again in a short time, at another it continues several hours.

—*Treatment.* Bleed plentifully, and if the fit continues, give the following drench:

Take of Fetid spirit of ammonia, one ounce.

Compound spirit of lavender, half an ounce.

Water, about twelve ounces.—Mix, for one dose. ♀

To prevent a return of the fit, give a mild purgative. I examined the brain of a horse that had several attacks of this disease; they came on indeed whenever he was put into brisk motion, but lasted only a few minutes. There were about six ounces of water in its ventricles or cavities.

EXERCISE. It has been asserted by Mr. Clark, an author of some eminence, that "a much greater number of horses that are high fed, and stand much at rest in close warm stables, die of diseases which are brought on them from the want of regular exercise, especially in great towns, than from any other class of diseases to which they are liable." I perfectly agree with Mr. Clark in this opinion; and feel no hesitation in adding, that almost all the diseases of horses may be justly attributed to improper treatment or management; either in regard to feeding, exercise, state of the stable, or shoeing and general treatment of the feet. Though regular exercise is so salutary and even necessary in preserving the health of horses, they should not be suddenly put to such active exertions as they have not been accustomed to; for all sudden changes, whether from idleness to active exercises, or from these exercises to idleness, produce considerable changes in the system, and render both the solids and the fluids liable to disease. When a horse is gradually brought to that degree of exertion or labour in which he is to be employed, it becomes easy to him, and does not produce fatigue or difficulty of breathing; and when he has arrived at this state or habit of body, he is said to be in good wind and condition. But one great source of disease in horses is the improper treatment of them after they have been heated by exercise or hard labour. For though they come in covered with sweat, they are often exposed to the cold air uncovered, while their legs and thighs are washed with cold water; and not unfrequently they are allowed to drink freely of cold water while in this heated state. Hence arise inflammation of the lungs, bowels, or other internal parts; colds, chills, and a long catalogue of disorders, which it is needless to enumerate.

The time and manner of regulating a horse's exercise deserve attention. Thus it would be imprudent to make a horse exert himself too suddenly immediately after he is fed and watered. It is likewise improper to exercise horses in the rain, or when they are unable to bear it, either from former fatigue, sickness, or lameness. The greatest caution is necessary in exercising horses that are very fat and unaccustomed to labour. If ridden hard in this state, internal inflammation, fever, chill, or molten grease is likely to be the consequence. Horses in this state should have only walking exercise for a week or two, they should always take some mild purgatives or diuretics, and be fed rather sparingly. After this their exercise should be gradually increased until the wind and condition are adequate to the work for which they are wanted. This subject has been more fully discussed in the 1st vol. of *Veterinary Medicine*, in the chapter on Feeding, Exercise, and Grooming, and in the preceding chapters on the Ventilation of stables, and Condition.

From a series of essays on agricultural and rural affairs. By "Agricola," a North-Carolina farmer.

CIDER.

As this is a general fruit year, and much cider is intended to be made, it will no doubt be accept-

able to farmers, to state the best modes of cider making. It is much to be lamented that so little good cider is made in this state, which must arise from inattention to the subject, or from a want of knowledge of the best modes of making it; owing to one or other of these circumstances, many permit their apples to rot on the ground, or to be given to their hogs, whereas were they converted into cider, properly made, it would keep good the year round, affording for the table a wholesome and agreeable beverage little inferior to wine, and by many preferred to it.

In the northern states, the art of making good cider is so well understood, that almost every farmer has it by him the year round, and to their general use of cider, instead of ardent spirits, we may, in a measure, ascribe that temperance, health, and morality, for which they are remarkable. To encourage the manufacture of good cider, and to prevent its conversion into ardent spirits, by distillation, as much as possible, the latter of which is proving a curse to our country in the most lamentable manner, I will proceed to detail the best modes of making cider, as practised by the best cider makers in the northern states.

One of the first errors with respect to cider is, gathering apples when wet; the second is, throwing them together exposed to sun and rain, until a sourness prevades the whole mass; thirdly, making so large a cheese, that fermentation will come on before the juice can all be pressed out; for certain it is, that a small quantity of the juice pressed out after fermentation comes on, will spoil the product of a whole cheese; and fourthly, permitting cider, after it has undergone fermentation or working, to remain, on the lees, instead of racking it off. If, then, either of the above circumstances will spoil the cider; which I know to be the case, what must be the effect of a combination of the whole which frequently happens.

Having pointed out the errors to be avoided, I now proceed to state the methods to be observed, in the making of good cider.

Gather the apples that are intended for cider, when they are perfectly dry, and lay them down in layers, in the cider house, and other outhouses on floors, not exceeding two feet thick; where there is space sufficient, thinner will be preferable, for the object is to promote the ripening of the fruit, and the evaporation of the watery particles. In this situation they are left about two weeks, secured from rain and wet, but exposed to the air as much as possible, when they are again to be sorted, the rotten ones to be thrown out, and the sound ground in the mill or beat.—Here it will be proper to observe that the mill, the press, and all the materials used, be sweet and clean, and the straw clear from must. The pumice is then laid in troughs for 12 or 24 hours—this tends to sweeten the juice, enrich the cider, and give it a fine amber color. But the time in which the pumice remains in this state, must be regulated by the state of the weather, without measuring the length of time by hours; for it is evident that at one season the same length of time will produce no sensible effect, which at a much warmer season would induce the commencement of an acid fermentation. As soon as the juice is pressed out, the great art in making cider commences, as nature begins to work a wonderful change in it. The juice of fruit, if left to itself, will undergo three distinct fermentations, all of which change the quality of this fluid. The 1st is, the vinous; the 2nd, the acetous; and the 3d, the putrid. The first fermentation is the only one which the juice of apples should undergo to make good cider.—It is this operation which separates the filth from the juice, and leaves it a clear, sweet, vinous liquor. To preserve it in this state, is the great secret; this is done by racking it off from the lees or dre-

fumigating it with sulphur, which checks any further fermentation, and lastly, by fining it.

The juice, as it comes from the press, should be placed in open headed casks, or in the largest vessels that can be procured, in which it should remain until the fermentation ceases. The person attending may, with great correctness, ascertain when this first fermentation ceases—this is of great importance, and must be particularly attended to.

The fermentation is attended with a hissing noise, which is heard by putting the ear to the bung-hole, or in open headed casks by observing the bubbles rising to the surface, and there forming a soft spongy crust over the liquor; when the hissing noise ceases or the crust begins to crack, and a white froth appears in the cracks level with the surface of the head, the fermentation is about stopping. When the fermentation has entirely subsided, the liquor is fine and clear, and is then in a proper state to be drawn off—and if then neglected, the particles of pumice that had settled down to the bottom of the cask, will, during a warm or damp state of the weather, rise up again, mix with the juice, and thus produce a second fermentation, which is always acctous and injurious to the cider.

The cider should, therefore, immediately after the first fermentation ceases, be drawn off into sweet clean casks or hogsheads that have been well scalded and rinsed. To preserve the cider in its fine vinous state, and to check any further fermentation, it must be fumigated with sulphur. To do this, take a strip of canvas, or rag about two inches broad and twelve inches long; dip this into melted sulphur, (brimstone,) and when a few pails of worked cider are put into the cask, set this match on fire, and hold it in the cask until it is consumed, then bung the cask and shake it, that the liquor may incorporate with and retain the fumes; after this fill the cask, and bung it perfectly close by running pitch over the bung, so as entirely to exclude the air. Cider thus prepared will keep good and sweet until late in the spring, and if not consumed by that time, and intended for sale or further keeping, it must undergo the following more particular process:

At the time of fining cider there should not be the least degree of fermentation; and perhaps the best time for fining is, in winter, in steady cool weather. Draw off some gallons of cider, proportioned to the quantity of cider to be fined, into a vessel, to this add of isinglass pounded and unravelled into shreds, about two ounces to the hogshead, containing 112 or 116 gallons, or an ounce to a barrel. The liquor with the isinglass is frequently stirred up for three or four days, so that it is completely diluted into a thin jelly, and is then strained through a flannel or hair sieve. The fining may now be added to the cider without drawing it off, but the best general practice is, to pour your fining into the empty cask, and then draw off your cider and pour it on the fining. This leaves behind a great part of the sediment, checks insensible fermentation, and mixes intimately the cider with the fining. The cider thus fined, will generally become fine and bright in eight or ten days, and should then be drawn off from the lees of the fining, and bunged close or bottled. If drawn into casks, they should be bunged close and pitched over the bung to keep the air entirely out.

To do this effectually, after the bung is carefully driven in, bore a gimblet hole near the bung-hole, and leave it open until you have covered the bung with the cement, to admit the air below, increased by the warmth of the cement, to pass off; when the cement is cooled and hardened, the gimblet hole is completely closed by driving a white oak square plug into it. When

bottled, by cutting off the corks even with the bottles, and dipping its mouth into boiling pitch, it is as completely closed, as the best bottled claret or burgundy.

It will also be proper, previous to closing up the cider, to put one large and not more than two raisins to each bottle, and a proportionate quantity to each barrel.

Cider thus made, will keep good for years, and will exhibit that sparkling or bounding up, when poured into a glass, so pleasing in the finest champagne wine.

FOR THE AMERICAN FARMER.

ON THE DISEASE COMMONLY CALLED THE HOLLOW HORN.

MR. SKINNER,

There is, perhaps, no disease in this climate from which our neat cattle have suffered so much, as that commonly called the Hollow Horn; and unfortunately, few persons have thought it necessary to give any attention to it, or its cure, for we find but little said in any agricultural work relative to its treatment.

The name appears to me, to be badly applied, as the horn alone is not the seat of the disease; it pervades the whole system—and cattle without horns are quite as subject to it, as those with them—having often seen those without horns have it.

The hollowness of the horn, proceeds from the violence of the fever throughout the system. I have known cattle feeding in the stall to be attacked with it, as well as those in poor condition, and no doubt those in bad plight are more liable to its attack, their system not being in a state to resist any disease; it occurs too at all seasons of the year, but more particularly in the spring.

The animal attacked with it looks rough; stares much in its coat, and falls off very fast in flesh, its food having but little effect in nourishing it. The eyes look very hollow and dead, and run with a yellow matter which collects in the corners, and around them. Many persons rely upon the feel of the horn, as the best indicative of the disease, but this, I think very uncertain: in some cases it is at the root, cold to the feel, while in others very hot. A very small gimblet will, however, remove all doubts, and the mark on the horn not visible after a few days. If the disease does exist, the horn will be found without pith, and little or no blood will follow the boring; whereas if the disease does not exist, you will find blood immediately upon entering the horn. The gimblet used for boring, should be well washed and greased after using; for if it is not, and should be used to try the horn of an animal not actually affected with the disease, it will most generally give it to them. It is a disease that is highly inflammatory and infectious; and the animal having it, ought to be removed from the herd until well. The following mode of treatment, I have found very successful, and the beast soon restored to a thriving state. As soon as I discover an animal affected with the hollow horn, I bleed it from the neck (in the same vein in which a horse is bled) from two to six or seven quarts, according to its age, size and condition, and give from three quarters to one pound and a half glauber salts; with a middle sized gimblet open the horns through and through, making the holes, so that they be perpendicular in the usual position the animal carries its head, so that the pus formed may have a free discharge as soon as the horns are opened; put through the hole into each about a table spoonful of strong vinegar, in which some salt and black pepper ground, has been put. The day

following, the horns must be again opened and cleaned from the pus, which generally is now formed, and about a half a teaspoonfull of spirits turpentine, put into each horn, and a little on the poll of the animal daily, during the continuance of the disease. One bleeding is generally sufficient; but I have known cases in which it was necessary to repeat it three times, as also the salts.

The food during the continuance of the disease is important—corn in every shape is bad—potatoes are of great use, (with a small quantity of Brewer's grains, if to be had,) and the animal ought to have from one to one and a half pecks daily, with hay in the winter, and grass if in summer.

Potatoes have a wonderful effect on the animal as soon as the bowels are well cleansed, the importance of which, any person will be convinced of, who observes the discharge from the animal. In some obstinate cases I have given daily, from a half to one ounce of nitre, sprinkled on the potatoes. It is important the first bleeding to take as much blood as the animal will bear, as the fever is more easily checked by one large bleeding, than two small ones, and the animal better able to bear it. In many cases the bleeding and salts have been sufficient, without opening the horns; and when taken in the early stage will generally be found to answer, but the boring certainly assists in forming anew the internal part of the horn, and which, as soon as it commences forming, the holes in the horn should be allowed to close.

An animal having the hollow horn, should be sheltered from the inclemency of the weather, during its continuance. No age appears exempt from its attack, having seen it in a yearling as well as at all subsequent ages. I am induced to offer this mode of treatment to your subscribers, having never in any instance failed of restoring the animal, whereas before this mode of treatment was adopted I annually lost several. The fleam for bleeding cattle should be rather deeper than that used for a horse, the vein in the neck, not laying so near the surface, the orifice is closed with a pin, in the same way as in bleeding a horse.

AN AGRICULTURIST OF DELAWARE.
June 30, 1823.

FROM POULSON'S AMERICAN DAILY ADVERTISER.

GOODSELL'S FLAX DRESSER.

Powellton, June 26, 1823.

DEAR SIR,

I have the honour to communicate the result of a trial of Goodsell's Flax Dresser, before a committee of the Directors of our Society. The total failure of the various Machines which had been brought into view, to effect the important objects which Mr. Goodsell's ingenious and simple contrivance has completely accomplished, produced evident doubt in most of us, as to its successful operation. Yet, after the experiment, we are all convinced, that the liberality, and well directed zeal of Mr. Swartwout, has placed within our reach, the valuable Implement, for which premiums had been offered, and applications made in vain to European ingenuity.

I am very respectfully,
Your obdt^s Servt.

JOHN HARE POWELL,
Corresponding Secretary.

JONATHAN ROBERTS, Esq.
President of the Pennsylvania
Agricultural Society.

Fifteen pounds of Flax plants, were, in our presence subjected to the operation of Goodsell's

Machine, by which they were perfectly broken in four and an half minutes—were scutched in seven minutes, and left entirely free from shives. Two pounds two ounces of *very fine* Flax, were thus obtained, at the rate of more than ten pounds per hour, although the plants had not been well watered.

Philadelphia County, June 20th.

YEAST FOR BREAD.

The following methods of making yeast for bread are both easy and expeditious: Boil one pound of good flour, a quarter of a pound of brown sugar and a little salt, in two gallons of water for one hour; when milk warm, bottle it and cork it close; it will be fit for use in twenty-four hours. One pint of this will make 18 lbs. of bread. To a pound of mashed potatoes (mealy ones are best) add two ounces of brown sugar, and two spoonfuls of common yeast; the potatoes first to be pulled through a cullender, and mixed with warm water to a proper consistence. Thus a pound of potatoes will make a pound of good yeast. Keep it moderately warm while fermenting. This recipe is in substance from Dr. Hunter, who observes, that yeast so made will keep well. No sugar is used by bakers, when adding the pulp of potatoes to their rising.

[We are informed by a most respectable friend a miller of great experience, that a small quantity of *sprouted* wheat, say a teacupfull in a bushel, will prevent the flour from *rising* when made into bread, let yeast be never so good. This is often the cause of bread not rising, when housewives cannot account for it.]—*Ed. Am. Far.*

FROM THE NEW YORK AMERICAN.

There is a disposition with some of our countrymen to make invidious comparisons of whatever is both English and American. We have conceded to this love of every thing on the other side of the water, that our sky is too high; our moon considerably too small; our lightning less vivid; and our thunder barely audible, in comparison with the British; and since the war, in the same conciliatory spirit, we have yielded the superiority they maintained over us, in ships, and men, and artillery, and riflemen, and the bayonet. Z., in the Post last evening, would prove, from the Sporting Magazine, that many horses in England have greatly exceeded the performance of Henry and Eclipse on Tuesday last; and this, too, might have been conceded, had he not undertaken seriously to prove the fact, and then to assert more than he had proved, that there are many instances of recent date, &c.—Flying Childers is the admitted *nonpareil* of the turf, and his alleged performances are so great, that many impartial, but judicious men, suspect them to be erroneously reported. Taplin, however, asserts, without reserve, that Childers ran the distance of four miles in six minutes and forty-eight seconds, carrying nine stone and two lbs. It is alleged in Rees' Cyclopaedia, that he ran the Beacon Course in seven minutes and a half, and the round course in six minutes forty seconds; this is certainly prodigious, but not to be denied. Z. has introduced us to two horses, not of sufficient celebrity to have been ever named in the Sporting Dictionary, both of whom, by his account, ran the Beacon Course in ten seconds less time than Childers; and these are Chatham and Trajan; and Hambletonian and Diamond, by his account, ran the same course in fifteen seconds less time than Childers.—This is surely proving,

too much. If Z. will look into his Sporting Magazine for the two long and precise accounts of the famous race last mentioned, written at the time it took place, he will find one, stating the time of performance to have been *about* eight minutes; and the other more positively "eight minutes and a half," both horses having been merely galloped the first three miles.

Under the article *speed* in the Sporting Dictionary, written and published in 1803, Mr. Taplin has mentioned but two horses, Childers and Bay Malton. The last was great grandson of Childers—his dam from the Godolphin Arabian; he was bred by the Marquis of Rockingham, and "was esteemed the first horse of his years in the kingdom, and won more prizes of value and consequence than any horse of his time."

Bay Malton's most distinguished performance was *four miles at York, in seven minutes, forty-three seconds and a half*, carrying eight stone seven pounds. The celebrated Eclipse was "*a horse of his time*," and O'Kelly, his owner, is jeered at in the Sporting Magazine, for not having matched him with Bay Malton; and Eclipse's reputed speed is denied for that reason.

We are sure that Henry and Eclipse run four full-measured miles in seven minutes thirty-seven seconds, and can prove it, beyond all manner of doubt. There is no evidence like this, and we say, none has come to our knowledge, after an elaborate investigation too, on which we can place any reliance, that this distance has been done in England, in the same time, by any other horse than Childers. Running and fighting are two very distinct performances; but their Chronicles in England have a remarkable similitude, in their most important feature.

And per-se-and.

P. S. Will these chronicles even furnish their evidence, that three four-mile heats have ever been done in England, by any horse, in less than 24 minutes; for that, after all, is our boast.

From the New York Evening Post, June 2.

TO THE EDITORS.

In order to enable the public to form a correct opinion of "Southern pluck and Northern bottom," and whether it is really believed that Eclipse is "the best courser of his day"—"Too fast for the speedy, and too strong for the stout," will you be so good as to publish the inclosed correspondence. It is to be observed that the race proposed was to be run in the same year and within a few months of the one just decided, and surely the lapse of a few months could make no difference to Eclipse, a horse in his prime: but there would have been a difference between the races—Henry, in the last race carried, by the rules of the turf, the weight of a four years old, although he was not a four years old, but only three, and in the proposed race he would have carried only his proper weight, and have had to run on a different course, where he would have had, in the language of ancient chivalry, "a clear field and an equal sun."

Long Island, May 28, 1823.

TO JOHN C. STEVENS, ESQ.

Sir—I will run the horse Henry against the horse Eclipse, at Washington City, next fall, the day before the Jockey Club purse is run for, for any sum from twenty to fifty thousand dollars, or forfeit 10,000 dollars. The forfeit and stake to be deposited in the Branch Bank of the United States, at Washington, at any nameable time to be appointed by you.

Although this is addressed to you individually, it is intended for all the betters on Eclipse; and, if agreeable to you and them, you may have the

liberty of substituting, at the starting post, in place of Eclipse, any horse, mare or gelding foaled and owned on the northern and eastern side of the North River, provided I have the liberty of substituting in the place of Henry, at the starting post, any horse, mare or gelding, foaled and owned on the south side of the Potomac.

As we propose running at Washington City, the rules of that Jockey club must govern of course.

I am respectfully yours,
W. R. JOHNSON.

ANSWER.

DEAR SIR,

The bet just decided, was made under circumstances of excitement, which might, in some measure, apologise for its rashness, but would scarcely justify it as an example: and I trust the part I took will not be considered as a proof of my intention to become a professional patron of sporting on so extensive a scale—for myself, then, I must decline your offer. For the gentlemen, who with me, backed Eclipse, their confidence in his superiority, I may safely say, is not in the least impaired; but even they do not hesitate to believe that old age and hard service may one day accomplish, what strength and fleetness, directed by consummate skill, has hitherto failed to accomplish. For Mr. Van Ranst, I answer, that he owes it to the association, who have so confidently supported him, to the state at large, who have felt and expressed so much interest in his success, and to himself as a man, not totally divested of feeling, never, on any consideration, to risque the life or reputation of the noble animal, whose generous and almost incredible exertion, have gained for the North so signal a victory, and for himself, such well earned and never fading renown.

I remain, sir,

Your most ob't serv't,

JOHN C. STEVENS.

The race was run, and the toasts drank on the 27th inst. The challenge for another race given on the 28th, and Mr. Stevens' answer (without date) for himself, Mr. Van Ranst, and the gentlemen who with him backed Eclipse, declining the offer, delivered on the 30th. The public will remark the difference between the cool, prudent resolve, and the rash, boastful toasts, even if none more offensive and boastful had been drunk than those which have been published.

A SOUTHERN SPORTSMAN.

ANOTHER CHALLENGE!

TO THE NEW YORK UNION ASSOCIATION.

Gentlemen—I have been, and still am of opinion, that your Northern bred race-horses of the first class are not superior to ours of the second and third order; and I am willing to venture a small sum upon this opinion, on the following terms:—I will run a horse for each day's race over the Union Course next fall, against any Northern bred horse, for one, two, or three thousand dollars each day, horses to be entered, and in every respect to be governed by your rules. That Henry, Betsey Richards John Richards, Childers, Sumpter, and Washington—as also Eclipse on your side, shall be excepted; the selection shall be made from horses that General Johnson never thought of when engaged in the great Match Race, and it is rational to suppose that the sum betted would induce him to recollect every trump in his hand. I propose this method, as I have seen your indisposition to match for a large sum by your non-acceptance of the late challenge. As I first commenced the rivalry, I am willing to keep it up, believing it

to be the best plan (and I might add the only method) to improve and keep alive our stock of race horses; and too, from my acquaintance with the Sportsmen of the Union Course, I can meet them, beat them, or be beaten, and still be friends. If the proposition meet your approbation, please to answer me—or change it in any way you think proper, that shall be equitable, liberal, and convenient. Be good enough to name the sum, and in what manner the forfeit shall be secured. I will also run a three years old (untried) colt, against any Northern bred three years old, two mile heats, for 1500, 2000, or \$2500, half forfeit, to be named at the starting post. I wish to meet the Northern Sportsmen again, and it cannot be expected that I, or any other sportsman can travel horses 500 miles for small purses, not winning enough to defray expenses, if successful—for that reason I offer the additional sum to be raised by betting. So that should you at any time feel disposed to meet me on the Virginia courses, I pledge myself that you shall be accommodated with bets to that amount, as I know you can afford to travel the distance for our purses only, notwithstanding they are nearly as large as yours, and ten different Courses to run over. A pledge in any newspaper on your part to comply with the proposition here made, will be satisfactory to me—you can name in what way you wish me bound.

I am, very respectfully,

JAMES J. HARRISON.

Petersburg, Va. June 27.

GARLIC.

Some time since, when the Fall Fever raged violently in the neighbourhood of a canal, then in a state of progress, numbers of the workmen engaged on it eat plentifully of garlic, and wholly escaped, while those who abstained from the use of this article, were severely afflicted by the disorder.

That this may have been accidental I freely admit: but garlic may, nevertheless, be a specific against Autumnal Fevers. If so, it is an invaluable article in the *Materia Medica*. Persons in the neighbourhood of canals and stagnant waters generally, are advised to make trial in the course of the ensuing fall, and communicate the result.—*Poulston's Daily Advertiser*.

Silk Worm.—In a communication to the Society for Arts and Manufactures, (vol iv. p. 163,) it is stated by Miss Henrietta Rhodes, that one line of the silk worm, when unwound, measured 404 yards, and, when dry, weighed 3 grains. Hence it follows, that one pound Avoirdupois of the thread, as spun by the worm, may be extended into a line 535 miles long, and that a thread which would encompass the earth would weigh no more than 47 pounds.

THE FARMER.

BALTIMORE, FRIDAY, JULY 11, 1823.

INTERNAL IMPROVEMENT.—The space appropriated in this Journal to the consideration of the means and the advantages of improved roads and canals, has, we are glad to find, been promptly claimed, and well filled by writers qualified to develope and explain them; and we presume they have chosen this medium, to promulgate the result of their patriotic and valuable researches, under the consideration that the prosecution of great publick works of this nature, will promote, in an especial degree, the welfare of the *landed* interest—which interest is best addressed and enlightened through the medium of a journal exclusively devoted to it; and, patronised in fact, by many of the most intelligent farmers in all the States of the Union—our vanity at least, leads us to lay this “flattering unction” to our bosom—and whether the conjecture be vain or valid, we are assuredly well pleased with being made the channel, through which the publick may be awakened to the sources from, and the means by which, under a free government, our country may be pushed to a yet higher degree of wealth, prosperity and power, than she or any other has ever yet attained.

We have, however, been apprehensive that some would be dissatisfied with seeing in a single paper, *so much* on one topick—but again, we have anticipated, that in relation for instance, to the Potowmac and the Susquehanna Canals, they would reflect that there is no time to be lost. The legislature, in a spirit which augurs well, has moved in these cases—Commissioners have been appointed—the time is at hand for them to act—the subject is comparatively new—the work is extensive, and calls for much personal investigation and labour, and their report is to be prepared and made to the *next* legislature. Hence it is that we are bound to present, and our subscribers to accept, more as relates to these objects, than otherwise might comport with our desire to give variety to our pages.

These explanations will account too, for our departure from the course we had marked out, as it was our intention to have *first* published *general* views of the great outlines, courses and advantages of improved national roads and canals—and to have given the most condensed and well arranged expositions of the *constitutional* questions, *pro* and *con*, as to the *power* of the *general* government over such subjects.

In pursuance of the first object, we had put on file the luminous report of Mr. Calhoun, the secretary at war, whose views of National policy are always magnificent, and exhibited in colours as resplendent and captivating as his own genius; and in regard to the *constitutionality* of this exercise of national sovereignty, on turning to our files, we find that for that purpose, the able speech of Judge Hemphill in favour of the power, and one from Gen. Smyth against it; the latter delivered on the occasion of the appropriation for the Cumberland road—are all the papers we have; but we have been compelled to postpone these for the sake of letting in the practical remarks of our friends, Kenworthy and Briggs, as being applicable to two important projects, now *actually* under way.

These writers are to be judged by their works—of Mr Briggs, whose first essay appears in this number, it may be observed that he is, already, extensively known to the community. It would appear that mathematics, and the application of mathematical, mechanical, and physi-

cal principles to the useful arts, have been his favourite study. And it has been his lot to be employed, during the years 1817 and 1818, in the state of New York, as civil engineer, on some difficult parts of her Great Western, or Erie Canal; during the years 1819 and 1820, in the state of Virginia, on the James and Kanawha rivers, and in locating and designing a *new* canal near Richmond; and during the years 1821 and 1822, in finishing the survey, and making all the calculations and estimates for the proposed Potomac Canal. These things are mentioned, in order to show that he ought to be admitted to have some *practical* acquaintance with the subject on which he now addresses the publick. We do not permit ourselves to take any sectional view of these branches of publick improvements, which might incline us to the right or left, and much regret the *singular temper* of some who claim all the merit and money for one scheme, and would grant nothing to the other. They remind us of naughty boys who won't relish their own stick of sugar candy, because their brother's portion is a morsel larger.

It will be remembered that the Editor received for distribution from Com. Porter, some seed of cotton, of singular growth, from *Manilla*. A much valued correspondent is preparing for the Farmer, some remarks on that important plant, but wishes, before he concludes them, to have a view of the Manilla cotton and seed. Will any one of the gentlemen to whom the seed was sent, have the goodness to supply the Editor with a small portion of them immediately?

BALTIMORE MARKET.

PRICES CURRENT.—CORRECTED WEEKLY.

Flour, best white wheat, \$8—Howard street Superfine, \$7 25—fine do. \$6 75—Wharf, do. \$7—sales—White wheat, \$1 42 to 1 50—Red do. \$1 42 to \$1 43—Rye, 75 cents—Corn, 50 to 52 cents—country Oats, 40 cents—Beef, 8 cts. per lb.—Live Cattle, \$5 to \$6 50 per cwt.—Bacon, round, 8 to 9 cents per lb.—Pork \$4 50 to 5 50 per c. lb.—6 to 8 cts. per pound—Mutton, 5 to 6 cts. per lb.—Beans, \$1 37 1/2 to 1 50—Peas, black eyed, 55 to 60 cts.—Red Clover Seed, \$5 50 a \$6—Orchard Grass do. \$3—Herds' Grass do. \$3—Timothy do. \$4 50—Millet, none—Buckwheat, none—Flax Seed, 75 to 80 cts.—Whiskey, from the wagons, 34 cts. per gal. including the barrel—Apple brandy, 30 to 32 cts.—Peach do., 65 to 70 cts.—Shad, \$6 50, scarce—Herrings, No. 1, \$2 75 per bbl.—No. 2, \$2 50—Fine salt, 60 to 65 cts. per bush.—Coarse, do. 70—Butter, (firkin) 12 cts per lb.—Eggs, 12 1/2 cts. per doz.—Hay, \$18 per ton—Straw, \$9.

MARYLAND TOBACCO.—The following sales made this week of Prince George's County Tobacco—26 hhds. being the entire crop of B. H. Mullikin, say 19 First and 7 Seconds assorted from common dark to fine Reds at \$9 round—30 hhds. crop tobacco, raised by Benjamin Oden, at \$10—1 hhd. raised by John Duvall near Nottingham, at \$20.

Prices of all descriptions are fully maintained, and the good qualities improving.

SKINNER, Editor, by JOSEPH ROBINSON, on the North West corner of Market and Belvidere streets, Baltimore; where every description of Book and Job Printing is executed with neatness and despatch—Orders from a distance for PRINTING or BINDING, with proper directions promptly attended to, addressed to J. Robinson, Baltimore.

Internal Improvement.

ON THE PARAMOUNT IMPORTANCE, TO MARYLAND, OF A CANAL TO THE SUSQUEHANNA.

No. VIII.

Good evidence, is a certain indication, and the invincible support of a good cause.

64. The trade of the Susquehanna stands characterised, by the most ample testimony in its favour, (12 to 18) as being a trade of a *very superior extent and importance, at present*; and from the plain nature of the case, it cannot fail to be a *greatly increasing trade for ages to come*. Being derived from a country (16) containing 30,000 square miles; equal in extent (16) to six times our Turnpike conveyance, which is but 5,000 square miles; from a country (14) sufficient, *of itself*, to maintain a city of the first magnitude; including (12) the Belgium of the Union; inferior, in richness and fertility (17) to no portion of the United States; an inexhaustible granary for wheat, (12) competent to double the exports of Philadelphia; a country, in short, whose extent and importance (14) are but imperfectly understood; it must be evident, *at first sight*, that the trade of the Susquehanna, will be certain to amount to a most *astonishing magnitude*; to more than six times the trade from the country, upon our turnpikes.

65. I have said *more than six times*; because with the advantages of improvement, which in a few years may be effected upon the Susquehanna, *were there only a good water communication provided*, by which the immense productions of the soil, could, *with facility, be diametred in Baltimore*, it would be entirely a rational event, for six times the extent of country, such as is above described, to be the means of *more than six times the amount of trade*, and consequently of *more than six times the clear profit*, that can reasonably be expected from our turnpike conveyance; more especially as it is well known to be the fact, that within these limits there are, in the barrens of Baltimore county, and elsewhere, large portions of country so very unproductive that *very little, if any thing*, is ever to be seen from them, in any of our markets.

66. From this view of the subject it cannot reasonably be doubted, but money appropriated to the opening of a Canal between Baltimore and the Susquehanna, would be excellent stock; abundantly better than bank-stock, or any other stock in which capital can, at present, be vested. In illustration of the certainty of this fact, permit me to offer, a few observations: Being some time past, in Philadelphia, I was present in a company where the great advantages appreciated in favour of that city, by means of their improved water communications, became the topic of conversation; among other benefits, it was stated that when the improvements, then in progress, should be completed, the best Lehigh coal, *exactly similar to that of the Susquehanna*, could be delivered as low as 20 cents per bushel, throughout the city. Ten bushels of this coal, that would thus cost only \$2, it was added, were equal to a cord of wood, that at a moderate calculation would cost \$5. Hence, it was observed, that if coal were substituted instead of wood, \$3 might be saved upon every cord, and that, in consequence of 300,000 cords, being required for the yearly supply of the city, it was entirely practicable to save \$900,000 per annum in the article of fuel alone.

67. Were Baltimore disposed, by a similar course of economy, to realize a saving of \$3 per cord on 120,000 cords of wood, by substituting in lieu of it, 1,200,000 bushels of Susquehanna

coal, this single item would amount to an income of 36 per cent. per annum, attainable with the utmost facility, could our *citizens only be persuaded*, to put forth their energies, and adopt the noble resolution of making the whole Canal themselves; which, it is believed, might readily be done, provided *they were but as certainly and entirely willing, as they are certainly and entirely able*, to accomplish the object without a single auxiliary. But by the citizens of Maryland, it can doubtless be effected with too much ease, even to deserve the name of an enterprise; and in the capacity of stockholders, this calculation leads to a very important item, as follows:

68. Computing 28 bushels to the ton, which is understood to be about the usual weight of the anthracite coal, the above quantity amounts to nearly 43,000 tons for family use, and including the additional supply for iron works, blacksmiths, and other purposes, it may fairly be presumed that 60,000 tons would not exceed the demand. In other words should the Canal be 100 miles, the amount of toll, at \$1 per ton, will be \$60,000, that is *six per cent. per annum*, upon one million of dollars, were the *whole to be expended*, or, *eight per cent. per annum*, in the event of 25 per cent. of the appropriation being saved. Both the foregoing proceeds, being added together, are equivalent to *42 per cent. per annum*, in the former case, and to *56 per cent. per annum*, in the latter case, which is certainly far preferable to the best stock of which we have any knowledge, Canal stock only excepted.

69. But if one solitary article of transport, be capable of furnishing such an *animating prospect* in favour of the Canal, how much more *animating must that prospect be*, could all the countless articles be included in the estimate, to which it will certainly afford the most advantageous conveyance possible. By stone cutters in this city, for example, it has been estimated that the yearly demand for marble, from up the Susquehanna, and for free stone, from quarries, of an excellent quality, in the vicinity of Harrisburg and Middle-town, would with Canal conveyance, exceed 25,000 tons. From the numerous furnaces and forges up the Susquehanna, the quantity of bar iron and castings that would yearly be sent to market, would, in all probability, amount to 20,000 tons. I have seen the iron estimated at more than double the weight that is here adopted. Again, from 8 to 10 millions of feet of lumber, together with shingles, staves and heading, to a vast amount, even supposing a part of it, *at times*, to brave the *terrific dangers of descending the river*, would, no doubt, constitute another very extensive item; but as some difference of opinion might occur in this respect, I shall decline an estimate of particulars, and pursue it, *only*, upon general principles. Enough has been said, I presume, to prove, to a certainty, that the transport upon the Canal would be very abundant; and that a large portion of that abundance, would consist of articles, that, without its facilities, would naturally be excluded from market, for want of conveyance.

70. It is evident, that, were the anticipated Canal opened, between Baltimore and the Susquehanna, and were boats of from 10 to 15 tons, also employed in the transport up it, that their medium cargo, that is 12 tons and a half, would be more than equal to the loads of six waggons carrying two tons each. Again, owing to the country up the Susquehanna, being more productive (65) than that upon our turnpikes, and of six times the extent (16) it follows, with certainty, that boats of the size above proposed, would require to be *more numerous*, and *more constantly* passing along the Canal, to and from market, than the waggons now are, upon all our turn-

pikes, supposing them to be reduced into one. Again, were the toll, that was to be collected, one cent per ton per mile, (which is the usual estimate) the toll of one of these boats and its cargo, supposing the distance to be 100 miles, (48) would be from 10 to \$15, the average of which sums is \$12 and 50 cents.

71. From the keeper at the first gate, upon the Frederick turnpike, it has been ascertained, that agreeably to the accounts which have been kept by himself, and certain facts, which are within his own knowledge, upwards of 23,000 waggons come into Baltimore in a year, loaded with flour; but to avoid too high a calculation let the round number 20,000 be adopted. Exclusive of flour waggons it has been estimated, again, that an equal number of other waggons annually arrive loaded with all other articles. Hence, the number of waggons coming to our city, in the course of a year, must be upwards of 40,000. Hence too, according to the premises already stated, the number of boats required to traverse the Canal, must exceed 40,000. But the toll of 40,000 boats, at \$12 and a half each (70) coming to market, and of the same number, on their return, supposing them to be half loaded, at \$6 and a quarter each, would amount to \$750,000 for the yearly collection of tolls; being at the rate of 75 per cent. per annum, on the contemplated appropriation of one million of dollars, were it so to happen, that *the whole should be expended*; or, in the event that *25 per cent. were to remain unexpended*, *cent per cent. per annum*, would then be the amount produced by the Canal to the stockholders.

72. Can it be possible? Did I dare to say, *cent per cent. per annum*? The incredulity of popular opinion, will I fear, be ready to discredit the truth of my essay. Perhaps be almost tempted to cast it down in disgust, and resolve never to look at another. But let me entreat all such, should there be any, not to be over-hasty in coming to a judgment. Permit me, to remind them, that, it is equally as necessary to have a *certain and correct reason for disbelieving, as for believing*. What then, in this case, may I take the liberty to inquire, is the reason for with holding belief? The answer perhaps, in every instance, would be equal to this. I cannot exactly tell; but I am very certain it must be impossible. In the very same manner any man unacquainted with the *polarity of the magnetic needle*, or, the *power of steam*, might contend against their *known reality*. But, notwithstanding his disbelief, the facts could easily be made to *stare him in the face*, and be proof positive against him. So in the instance before us, *cent per cent. per annum*, has been proved by one calculation, and others may be adduced to confirm it.

73. By referring, for example, to the Records of the Register, in the Mayor's Office, it will be found, that, to take a round number, the quantity of flour annually brought to the Baltimore market, is nearly half a million of barrels. Of this number it is understood that from 40 to 50,000 barrels, rush yearly down the Susquehanna, and that other small quantities come from Virginia, and the Western country, by waggons. To make a very liberal allowance, let the whole, thus required, be estimated at 80,000 barrels. There will then remain 420,000 barrels for the quantity received from our 5000 square miles of turnpike conveyance, which at 10 barrels to the ton, are equivalent to 42,000 tons. Adding to this an equal tonnage to include all other articles, coming to our market, and the same quantity for half cargoes returning, the sum will be 126,000 tons, at \$1 per ton, is equal to \$126,000 toll, on the ton-

nage from 5000 square miles, or \$756,000, from a more productive country, of six times the extent.

74. Thus, the former calculation appears to be substantially confirmed, with the addition of \$600 in favour of the Canal. Thus, it appears that the evidence, at home, is highly favourable for men of capital to embark their funds, in opening the proposed new channel to the Susquehanna, with the most ample assurance of an abundant emolument in return; far exceeding any other stock, except canal stock, and far beyond all competition, from any business, even the best, in which money can possibly be vested. Merchants have many serious risks to encounter. Adventurers abroad, and bad debts at home, are often the means of their ruin. The farmer, owing to an unfavourable season, or the depredations of some destroying insect, frequently enjoys but a very reduced part of a crop. The collections of mechanics and labourers are in general very precarious. But, in the case of the Canal, the risk is almost too small to admit of an actual discovery. Let the banks be well secured in the commencement, and as long as water shall continue to flow; while men shall remain to inhabit the earth, and to have occasion for intercourse one with another, the canal will be, certain to continue in use, and to be a productive source of revenue to the stockholding parties.

75. Having thus, as I hope, explained in a manner too certain to be doubted, the vast emoluments secured to the stockholders, I come now to investigate a portion of those super-abundant advantages that are to accrue to the public. That the annual expenditure of our Baltimore population, for subsistence, habitation and clothing, cannot be less than three millions of dollars; that at a medium calculation, it must, in fact, amount to six millions (26) has already been explained. From the nature of the case, however, it is evident that the three millions, to wit, only \$50 for each individual, would require a very economical mode of living. But, as has before been observed, (25) many there are, who fare sumptuously every day, and spend an abundance. Hence, it may rationally be inferred, that a large excess is created over and above the economical sum of three millions. Admit the bay-trade that is found in the Baltimore market, and that portion of our waggon trade coming from beyond our turnpike conveyance, to be competent to meet that excess, whatever it may be, and it will then follow that the profits on the trade of 5000 square miles, must amount to three millions of dollars. If not, it is evident, our capital must be in a wasting condition.

76. In the event of there being any deficiency, our expenditures must of necessity exceed our income, and be the means of hastening us, (28) with a rapidity, in proportion, to the vortex of ruin. But with the trade of 5000 square miles, we have enjoyed a state of prosperity; consequently the profits of its trade must be equal to three millions, at least; and at the same rate the profits on the trade of six times the extent of a more productive country up the Susquehanna, may safely be estimated at 18 millions, at least. This would certainly be a very handsome amount for the citizens of Maryland, to put into their pockets yearly; and it is, with equal certainty, a very handsome inducement for them to embark in the business with energy, and to make the Canal. Every dollar of this money, as it was received, would be so much added to the wealth of the state of Maryland. It would first go into the coffers of our own merchants; and others immediately concerned in the trade, and from thence it would naturally flow into the coffers of other, and other individuals, and those of the state, until by a wider, and wider extension of inter-

course, all classes of the community would liberally partake of the general benefit; the common prosperity would be greatly promoted, and all would have cause to rejoice.

77. But as we proceed, let us be careful not to extend our views beyond the bounds of reasonable realities. Let us remember that the exertions of Philadelphia will certainly be very great, to draw from us a part of these profits. It is presumed, however, that there will be an abundance for both. In point of competition, a serious disadvantage is decidedly against our rival. Being 40 miles more remote from the place of separation, between the two routes, the consideration of interest will naturally award to ours the preference. But should they, by the mere dint of buying higher, and selling lower, than either party can reasonably afford, to compensate their customers for the difference in the time and expense required, so as to succeed in turning out of the shortest, as well as the most direct and natural route, one third, or at most one half of the trade, in question, an annual advantage of from 9 to 12 millions of dollars, would still be remaining for our encouragement. Again, let it be further observed, that it is by no means my prospect, that the whole energies of the country up the Susquehanna, either could, or would be put forth at the very commencement. Neither can it be desirable they should. We, ourselves, would most undoubtedly, require time to grow with the growth, and strengthen with the strength, of a trade so unwieldy, and super-abundant.

78. I have already recognised the Potomac Canal as an object (2) of great importance. I am not only entirely willing, but sincerely desirous, that all its facilities, all its advantages, should be duly appreciated and improved. But though I am thus fully disposed to admit all that is right in its favour, it will by no means follow, that I am equally bound to admit, all that is wrong. Its patrons appear to step forward, and to arrogate, as exclusively belonging to the object of their choice, the possibility of forming a Canal navigation between the Eastern and the Western waters. But in this respect the correctness of their pretensions may, with great reason, be doubted. It is at least, very possible, and from information now before me, very probable, that the required facilities for extending a water communication across the Allegany, may, upon examination, be found in greater perfection, and in a form vastly more susceptible of improvement, in a different part of the mountain.

79. According to the report of the Potomac Commissioners, page 23, it appears that a tunnel of two miles in length, will be required to pass through the dividing ridge, at a depth of 200 feet below its summit, to connect the waters of Deep creek, a branch of the Yahogany, on the west side of the mountain, with those of Crab tree run, on the east side, a branch of Savage river, which empties into the Potomac. Such an extensive tunnel, it would certainly be desirable to avoid, should an opportunity, more favourable, be discovered in another situation. The information to which I have alluded, is to the following effect: that a branch of Bob's creek, whose direction is towards the Susquehanna, heads far west, in the Allegany mountain, and runs to the eastward; also that a branch of the Little Conemaugh, whose course is towards the Ohio, heads far east in the mountain, and runs to the westward; that these two branches, pass each other in a situation not more than 200 or 300 yards apart, where either of them is of a size sufficient to turn a mill, and where in the estimation of my informant, the elevation of the ground between them, does not exceed 30 or 40

feet. This account I received from a person who stated to me that he had been on the ground; and that in his opinion there would be no obstacle to prevent a Canal being opened from that part of the mountain, to the Frank's Town branch of the Junita, with convenience; as the descent in that direction, as far as he could recollect, was a general descent, without being interrupted by any high hills, or deep hollows.

80. In a communication by letter, which is now before me, I am also informed, that, by an old hunter, well acquainted with that part of the Allegany mountain, between the head waters of Bob's creek, and those of the Conemaugh, it has been stated, that a large never failing spring, breaks out within a stone's cast of the top of the mountain, on the west side, and another on the east side, not far distant, which empties into Bob's creek. These, are undoubtedly circumstances, which, if correctly stated, it is highly important the facts should be minutely investigated, and certainly known. The Herculean task of forcing, through the base of an elevated mountain, a tunnel of two tedious miles in length, at all times as dark as a dungeon, and far more dismal and uncomfortable than midnight, to be navigated, ought not, in my humble opinion, to be attempted but in consequence of the real and unavoidable dint of necessity. This dint of necessity, however, cannot even be supposed to exist, in our case, unless the persons from whom the foregoing representations have been received, were more widely mistaken, than would appear to be possible, for men of common intelligence. Under these considerations permit me to suggest, whether it would not be entirely proper, at an early period, for the situations in question to be correctly investigated, that if the superior advantages, which have been adverted to, shall be found to exist, it may be so understood and explained, before the public mind shall be further deceived and led astray upon the subject.

81. Should this route across the Allegany be found, upon examination, to claim a decided preference, the proposed Canal from Baltimore to the Susquehanna will from that moment become doubly, and trebly pre-eminent. That event, it is presumed, would place it completely beyond the reach of all reasonable competition. The Ohio Valley is estimated to contain 200,000 square miles. Could we only extend our facilities to that prolific region, through the Susquehanna Canal, it would hardly be able to sustain the transport that would presently be required upon it. I will not suppose that another Canal would be necessary, but it is altogether likely, that a double set of locks would be indispensable. Were the trade of the Ohio to be collected into the same channel with that of the Susquehanna, the sum of the whole would become almost immense. In this case, it might, with justice, be inferred that the mind would need "new powers of comprehension" to form an adequate idea of its great and wonderful dimensions.

WILLIAM KENWORTHY.

AGRICULTURE.

The Pennsylvania Agricultural Society will hold their First Exhibition and Cattle Show on Wednesday, Thursday, and Friday, the 22^d, 23^d, and 24th of October next, near the PAOLI, in Chester County, eighteen miles from Philadelphia, (on the Lancaster turnpike road) when, in conformity with the Act of Incorporation, the following Premiums will be awarded.

NEAT CATTLE.

For the best bull, not more than 6 nor less than 2 years old, \$50—next best, 20—next best 10.—

for the best bull, not more than two years old \$30—next best, 15—next best, 10—for the best Cow, not more than 7 nor less than 3 years old \$20—next best, 25—next best 10—for the best Heifer, not more than 3 nor less than 1 year old \$20—next best, 10—next best, 5—for the best Bull of Durham blood, \$20—for the best Bull of Devon blood, not more than three years old \$20—for the best Heifer, of Durham blood, not more than 3 years old, \$15—for the best Heifer, of Devon blood, not more than three years old \$15.

SHEEP.

For the best Ram, not more than 2 years old, \$10—next best, 5—next best, 5—for the best Ewe, not more than 2 years old, \$10—next best, 5—for the best Ram not less than 2 years old, \$10—next best, 5—for the best Ewe, not less than 2 years old, \$10—next best, 5—for the best Ram, of Dishley blood, not more than 2 years old, \$10—for the best Ewe, do. do. do. \$10—for the best Ram, do. do. not less than do. \$10—for the best Ewe, do. do. not less than do. \$10—for the best Ram, of Southdown blood, not more than 2 years old, \$20—for the best Ewe, do. do. do. 20—for the best Ram, do. do. not less than 2 years old, \$20—for the best Ewe, do. do. do. \$20—for the best Merino Ram, not more than 2 years old, \$10—for the best do Ewe, do. do. do. \$10—for the best Merino Ram, not less than 2 years old, \$10—for do. do. Ewe, do. do. do. \$10—for the best Broad-tail Ram, of Tunisian blood, not more than 2 years old, \$10—for the best do. Ewe, do. do. do. \$10—for the best do. Ram, do. not less than 2 years old, \$10—for the best do. Ewe, do. do. do. \$10.

HORSES.

For the best thorough-bred Stallion, not less than 3 years old, \$50—for the best do. fit for draught, not less than 3 years old, \$50—for the best thorough-bred brood Mare, not less than 3 years old, \$30—for the best Mare, fit for draught, not less than 3 years old, \$30—for the best pair of Draught horses (reference being had to their performance in the plough,) \$25.

OXEN.

For the best yoke of Working Oxen not more than 9 nor less than 3 years old (reference being had to their performance in the plough) \$25—for the best Ox, not more than 9 nor less than 3 years old, \$15—for the best Steer, not more than 3 nor less than 1 year old (reference being had to the mode of feeding,) \$10.

SWINE.

For the best Boar, not more than 4 nor less than 1 year old, \$10—next best, \$5—for the best Sow not more than 4 nor less than 1 year old, \$10—next best, \$5—for the best Pigs, not less than 5 in number, not more than 9 nor less than 3 months old, \$10.

All persons to whom premiums shall have been awarded for Breeding Animals at the Exhibition, will be required to give such assurance, for their continuance in Pennsylvania, one year thereafter, as shall be demanded by the Directors.

CROPS.

For the largest quantity of Flax, produced on one acre, \$20; for the best crop of Wheat, on not less than 10 acres, \$25; for the best crop of Indian Corn, on not less than 10 acres, \$25; for the best crop of Barley, on not less than 10 acres, \$25—for the best crop of Potatoes, on one acre, \$10—for the best crop of Mangel Wurtzel on one acre, \$20—for the best crop of Pumpkins or Squashes on one acre, fitted to withstand the winter (reference being had in all cases to the mode of cultivation,) \$20.

No person shall be entitled to the Premium offered for Flax, Barley, or Wheat, unless he shall have declared in writing, before the 1st day of July next, his intention to contend for the prize

—nor for Indian Corn, Mangel Wurtzel, Pumpkins or Potatoes, unless he shall have declared in like manner his intention, on or before the 1st day of August next.

BUTTER AND CHEESE.

For the best Cheese, not less than 100 pounds, made in Pennsylvania, \$20—for the best preserved Butter, not less than 50 pounds, made in Pennsylvania, which shall have been kept at least 3 months, \$20.

SUGAR.

For the best Sugar made in Pennsylvania, not less than 100 pounds, \$10.

POT OR PEARL ASH.

For the best Pot or Pearl Ash, not less than 200 pounds, \$10.

CIDER.

For the best Cider not less than 30 gallons, \$10. IMPLEMENTS OF HUSBANDRY AND USEFUL INVENTIONS.

For the best Plough \$10—for the best Harrow, \$5—for the best Winnowing Mill or Fan, \$10.

Premiums will be awarded for such Inventions and Discoveries, as shall tend to facilitate the operations of Husbandry or advance the cultivation of the soil.

HOUSEHOLD MANUFACTURES.

For the best Linen Cloth, (for shirting or sheeting) 1 yard wide, and not less than 25 yards long, \$15—for the best Linen Diaper, 5-8 wide, and not less than 30 yards long, \$15—for the best Flannel, 7-8 wide, and not less than 25 yards long, \$10—second best, 5—for the best Carpeting, 1 yard wide, and not less than 30 yards long, \$20—second best, 10—for the best Hearth Rug, \$5—for the best Woolen Cloth, 3-4 wide, not less than 20 yards long, \$10—second best, 5—for the best pair of Blankets, not less than 2 yards wide, nor 2½ long, \$10—second best 5—for the best Woolen Knit Hose, not less than 2 pair, \$3—for the best Cloth made of Hemp, 1 yard wide, not less than 25 yards long, \$10—for the best Man's Hat, made of grass, straw, chip, or other vegetable material, \$5—for the best Woman's Hat, \$10—second best, 5—for the best specimen of Raw Silk, not less than 100 pounds, \$40.

All household manufactures and implements of husbandry, offered for premiums, must be deposited at the place of exhibition, on Tuesday, the 21st of October, before 6 o'clock, P. M.

It is explicitly declared, that in every case, where the Board of Directors shall consider the object presented unworthy of distinction, they reserve to themselves the right of rejecting it, although by literal construction it should be entitled to reward—and that in all instances, where premiums shall be demanded, they will require such evidence from the claimants, as shall be satisfactory to the Directors.

The trial of oxen, the examination of Farming implements, the distribution of prizes, and the sale of animals, will take place on the last day of the exhibition.

It will be at the option of the successful competitors for the highest premiums which shall have been awarded for neat Cattle, Horses and Sheep, to receive gold medals in lieu of money; and it will be at the option of those to whom premiums of the second class shall have been awarded for animals of the same kind, to receive silver medals in lieu of money.

No person will be entitled to a premium for any animal, of which he is not the owner at the time of exhibition, nor for any article of household manufacture, any implement of husbandry, useful invention, or product of the soil, whereof he or she shall not have contributed to the production or formation.

No person can become a competitor for prizes offered for animals or manufactured articles, who

shall not have given notice of such intention, to one of the Committee of Arrangement, before 12 o'clock on Tuesday, the 21st of October; nor shall he be entitled to any prize, unless he shall have put the animal or article offered in the place assigned by the Committee for its exhibition.

No animal will be received after 10 o'clock on Wednesday the 22d of October.

At a meeting of the Directors held on Saturday the 12th of April, the following Committees were appointed.

For Stock—Manuel Eyre, Thomas Smith, George Sheaff, William Evans, George Blight.

For Products of the Soil—Job Roberts, George Holstein, Joshua Hunt, Samuel West, Aaron Clement.

For Manufactures—Stephen Duncan, John G. Watmough, John Elliott.

For Implements of Husbandry—Joseph Kersey, Moses Pennock, Reuben Haines.

And it was also Resolved, That a Committee of three Directors be appointed, to be styled the Committee of Arrangement, who shall have full power to publish in such manner, and form, as they shall deem fit, the objects for which the Society have offered premiums—to establish and declare the conditions upon which they are to be given—to make all contracts and arrangements necessary for the First Annual Exhibition—to direct and control upon the ground, all matters necessary to carry into effect the intentions of the Association. Whereupon,

John Hare Powel, John G. Watmough, and William Harris were appointed.

JOHN HARE POWEL,
JOHN G. WATMOUGH,
WILLIAM HARRIS.

Committee.

Extract from the Act of Incorporation.

SECTION 10. *And be it further enacted, &c.* That from and after the passing of this Act, if any person or persons shall bring ANY KIND OF SPIRITUOUS LIQUORS, CIDER, OR MALT LIQUORS, for the purpose of retailing, giving away, or vending the same, within the distance of two miles of the place where the Agricultural Meetings, or Exhibitions shall be held, except in stores or licensed taverns, he, she, or they shall forfeit the liquors so brought, or offered for sale, and on conviction before any justice of the peace of the proper county, shall pay a fine not exceeding ten dollars for the use of the Company incorporated by this Act.

CHEAT—CONTINUED.

Elmwood, July 8, 1823.

MR. SKINNER,

An essay in your No. 11, Vol. 5, signed "Plain Sense," with the avowed intention of combating mine on the subject of cheat, (published last April) serves, in my opinion, no other purpose than to prove more fully how deeply this error is rooted in the minds of some sensible men. I am therefore led, contrary to my intention, into the field of dispute, and I hope, at least, to push down some of the weak pillars with which he has supported this modern temple to equivocal generation. My arguments which he passes over, almost without notice, though not positive proof, were such as should have shaken the faith of an attentive observer of nature; and as some of your readers may not have the paper at hand, I will repeat them. 1. That a parallel case of the true production of cheat was to be found in the production of white clover, in almost any field dressed with wood ashes; and no person ever asserted that wood ashes was seminal, or ever pointed out the grass metamorphosed into clover by this alkaline dressing. 2. That

in all the animal and vegetable kingdoms, there was no parallel to be found to this supposed change of wheat seed into bromus grass, merely by barometer and thermometer variations. 3. That two countries, unluckily for their superstition, had fixed on two distinct articles for their cheat,* thus multiplying each other's testimony, and subverting their theory. 4th. That the keen-eyed ancients, in the time of their glory—when this article was a great pest to them—when equivocal generation was in force, and when the prince of metamorphosis (Ovid) had touched the article in his immortal lines, never suspected any unnatural production. I will now add to these arguments a fact known to every settler in a new country, viz: that after clearing off a forest, a new and dissimilar set of trees are apt to make their appearance, whilst the most illiterate of these foresters, would blush to propose that the acorns of the oak and the nuts of the hickory had changed to the burs of the pines that succeeded; or that a generic alteration had ensued after they were sprung up. I must insist upon it, that an egg (and a seed is the egg of a vegetable) be it pure or hybridous, bears a strict relation to its sires, and therefore if a cheat seed, or a cheat plant, had any tritricene matter in its composition, it would be as readily discovered as the jack's ears on a mule; wheat is a spike on a rachis, and if cheat was a hybrid, (the only rational supposition) we might expect a pretty close head, instead of a loose pannicle, and we should surely see in the seed an alteration from the true wheat. But I am straying into philosophy, and leaving superstition. I must, therefore, return to the charge.

If an egg does not contain the complete embryo of its future offspring, it is then a mere molecule, and may by heat, moisture, &c. capriciously be changed into a bird, a beast, or a fish. This absurdity would just lead us back to the chaos from whence the present glorious traits of philosophic truth have emerged. But the sound doctrine of every thing living from the egg, and every thing producing after its own kind, stands faster than the pillars of Hercules. These may sink and disappear in the sea, whilst those must survive the wreck of time. I perceive, that Plain Sense, has an advocate in E. B. a gentleman of Pennsylvania. He asserts that his seed wheat came up wheat, and then threw out a cheat head—was this a whim of the wheat, or of E. B.? I wish he would next year tie a few of these plants to splinters, having first delineated them well. I will engage that he will, before harvest, have to abandon his camp, and entrench himself under ground, where the operations of heat and moisture are not so tangible. E. B. by subdividing the sect, has done as much for S. V. S. as for P. S.—we may, therefore both dismiss him. My opponent thinks my only argument to be contained in the improbable assertion, that cheat seed may remain under ground a thousand years, and then vegetate.

It is worthy of remark, that seed may be revived by oxygenated muriatic acid, when thirty years old. It is too true that I cannot positively

* How much more difficult it would be to swallow this doctrine, were it transferred to the animal race, and why not? My neighbour A. says his hens eggs in very wet weather hatch young crows—B. says that his, in like case hatch hawks. C. that after the head comes out chicken, the bill bends, the eyes enlarge, and it turns to an owl. Would not even Plain Sense, (were he judge) tell these men—you are deceived—these are the genuine offspring of the voracious birds who have eaten your hen eggs, and deposited their own.

prove this. I am no Methusala to make such patient experiments, and even if an hundred years would be sufficient to convince him, I am still unable. Nevertheless, I know there are solid facts of greater difficulty that fully embrace this. It is well known that frogs have been exploded with rocks thirty feet beneath the surface, and that they have been inclosed in these rocks, rather longer than they naturally hold their breath. You will object to the rarity of these cases, but numbers could not add to the proof, even if they were raised up as thick as they once covered the land of Egypt, and I must confess, as few as they may be, I should be very unwilling to see all the frogs, and all the locusts, and other insects that may be now alive, and coeval with future crops of cheat, raised upon my land. I am so far, I think, at liberty, in this dispute, as to enlarge my boundaries, and take in every mode of propagation of the vegetable, whether seed, bud, slip, gland or root. Various roots have enlarged joints on them, and it has been supposed that a subterraneous life and growth may take place in these depositories, so as to throw out new shoots, and form new ganglions without a top; we see something of this in the lombardy poplar after severing the roots from the trunk, they live till getting air between the bricks in our pavements, they shoot up. The reigning crop must ever keep many articles beneath the sod; but when a free sun operates, and they absorb oxygene, they foliate. Dr. Darwin, on this account, probably adopted the idea that every joint in a stalk of wheat was an additional offspring, and a real distinct plant—and as of the plume so no doubt of the root.

Permit me now to examine those parallel metamorphose which you bring forward as grand pillars to support this modern temple, to equivocal generation.—First, the varieties of corn—are they greater than of our hogs?—Colour—shape—size—precocity. Surely there is no metamorphosis in this; nor can we well say which is the most natural variety. The genera is untouched, and they will still be hogs, so long as we love bacon. When that taste fails they will no doubt die, but never become another beast.

The fungus; excrescence that appears in corn, to the destruction of the part, is another of your metamorphosis.—Well, sir, I leave you to judge whether you think an animal has undergone any radical change, because he has an ulcer filled with proud flesh, and that substance alive with insects—and yet this is a perfectly parallel case—instead of insects, those in corn are young fungi.

I come now to your great pillar, by far, the most specious—the ear of corn on the tassel. However formidable to a superficial observer, I assure you that it will not bear the axe—it is but corn-stalk in all its constitution, and will soon yield to close investigation. To explain this phenomena, I must refer to a little botany.—Corn has two distinct generative issues—the cobs, the receptacle of the female; and the tassel, of the male: in these extra cases, there has been a transposition, and not a metamorphosis—the real cause of which I do not exactly know—whether a surplus of female juices, or a mere act of arrogance in her ladyship, who ought in modesty to have occupied the lower parts of the stalk, I do not pretend to say; but as in domestics, it sometimes so happens that the female assumes the upper hand, and in this place she always makes an odd figure, as in the corn—and moreover, is always in a peck of trouble when it is a little squally. Plain Sense may reject this explanation as too figurative—I am pretty sure the ladies will—but if so, I will give you another:—In these extra cases the corn has merely become a hermaphrodite in the tassel; a thing so far from being strange, that nine plants

in ten are naturally so; and even the converse of this case takes place, viz: plants naturally hermaphrodite will have some species in distinct flowers, (diclines.)

And now that this great pillar has given way, methinks I hear the cumbrous superstructure rushing to the earth with its own weight, leaving nothing but a solitary grafted tree near it, that shaded its Portico. A few antiquarians and alchemists appear busy in picking up the rubbish; from one of the former I have the following story of the tree: “One of the ancients having a favourite young tree broken off by the wind, he was about replanting it, when it occurred to him that cuttings grew very freely in the ground; he therefore rationally concluded, that if he could stick one in a living stump it would be as ready to concoct the juices of the broken tree as the cruder juices of the earth—all his difficulty was in uniting them—and as he had seen fretted boughs adhere, he took the hint and cemented them easily, not doubting but the cutting would produce its own kind as much so as if stuck in the earth. But the curiosity so drew the attention of the old philosophers, who believed that all things were from the slime of mud and shells, that they purchased the curiosity, and there built the old temple of which this new one is a model.”

S. V. S.

FOR THE AMERICAN FARMER.

ON REARING CALVES.

Mr. SKINNER,

The attention of many of your subscribers being now turned towards the raising and improving of stock, I offer a few remarks upon the management of that part of a stock farm, which I think highly important: namely, the rearing of calves.

The rage appears now to be for large and fat calves; many persons allowing the milk of two cows to a calf, while others feed it largely with indian meal in addition to the milk of the mother.—This, no doubt, makes the calf larger than it otherwise would be, but what is the effect on the animal when it arrives at maturity?—What is its condition should it during the time it is growing, change owners and be put upon the ordinary fare of a farm: I do not mean a neglected farm, but one in good cultivation? It is utterly impossible for a farmer (who derives his support from his farm) to allow two cows to rear a calf, or give it large quantities of meal; and I contend, that it is not to the advantage of the animal that it should be so. A calf should be allowed a sufficiency of new milk to keep it in a healthy growing state, and when four and a half or five months old, should be entirely weaned. Indeed, it is preferable to take it from the cow at a week old (if the state of her bag will permit it) and let it be fed afterwards with new milk from a bucket. This makes it much more gentle than when allowed to suck so long, and prevents what we not unfrequently see, cows that suck each other, or a bull that sucks the cows.

In this I differ from most of those who direct the premiums for cattle shows. As there is generally a premium for the finest calf, without reference to what has been consumed in rearing it; perhaps, and most probably, it would not sell for what would cover the cost of its raising. The various premiums of an agricultural show, should be exclusively directed to that part, which is within the reach of every attentive farmer, and not allow premiums for unnaturally forced stock.

Premiums are also given for cattle having the earliest calves, and you may see calves with calves at their side. Why should a premium be given

for this? It is the nature of the animal to take the bull at a year old, and nine out of ten will do it, if permitted. Why then should this be held out as any recommendation? By this system of forcing, no doubt, the calves are better grown, and better able to rear their young at two years old, but are the farmers better able to feed and force them, in the mode now used by some, or would they not make more profit, by feeding with moderate food, and wait until three years old for a calf, and would not the progeny of the animal be better? I contend that it would.—There is a great deal of fashion in most things, and this may do well for gentlemen with large fortunes, but it is entirely out of the reach of practical men, and will after a few years, be found so unprofitable and expensive, as to be laid aside by its most strenuous supporters. No man I think, deserves the character of a good farmer, who does not, at the end of the year, receive from his farm, more than his expenses.—How is he to live, possessing nothing more? Do not think by this, that I look with indifference upon those gentlemen of fortune, who annually expend large sums on their lands. Many of them deserve much credit, and do much good, in bringing into the country different breeds of animals, and which, without them, would probably never be introduced. My object, is to call the attention of farmers generally, to a mode of rearing stock, that while it gives every reasonable stimulus to the young animal, is at the same time, one within the reach of every practical man, and one from which he will be enabled at the same time to reap a profit.

I think it would be well in all premiums bestowed by agricultural societies, for young stock, to look particularly and attentively, to the mode of rearing.—No matter how large or how handsome an animal is, if to make it so, costs more than its carcase will bring in the market.

Calves, the first winter in particular, should be well sheltered, and have good hay. The usual mode of letting them run at large, is certainly bad. They are driven off by the older stock, get but a scanty supply of food, and in the ensuing spring, make a wretched appearance.

I have been accustomed to tying them in stalls the first winter. They take up less room, become more gentle, each gets his allowance without contention, and is more convenient to the feeder, bringing the stock into a small compass. My object is to feed well, and keep the young animals in a growing thriving state, without unnaturally forcing it; by which means I contend, it will make a more healthy and useful animal, and its progeny not subjected to the necessary ill health, that this unnatural forcing must in time, engender.

I believe animals are like man in this respect, and we have proof sufficient of the bad effects of too high living upon the human system.

An Agriculturist of Delaware.

From the Massachusetts Agricultural Journal.

ON THE CULTURE OF SEAKALE (CRAMBE MARITIMA.) AND OF THE SALSIFY, OR OYSTER PLANT, (TRAGGOPOON,) FOR THE MARKET, AND FOR PRIVATE USE. BY J. LOWELL.

We have introduced these plants some years since to the notice of our cultivators, but there has been but small progress yet made in their use, and of course in their cultivation. This cannot have arisen from any dislike to them, because when introduced to the table, they are universally approved, and used. They are both favourites at European tables, and are accounted

luxuries. The first is an earlier product than asparagus, and much preferred by those who relish the Cauliflower, which it resembles in its flavour. They have been sent to our market, but do not meet a ready sale, and of course, those who supply the market are not encouraged to raise them. It cannot be supposed that the taste of the people in this country is essentially different from that of the inhabitants of Europe.—The truth is, that we are contented with a much narrower list of articles of luxury than the taste of Europeans demand. They are not contented with potatoes only in the species, a new plant, even with them, unknown before the reign of Elizabeth. They require a new vegetable every month, and we are fast advancing to a state of luxury, which will require and demand variety. Even in England, two hundred years since, they could furnish no salad, but water cresses, and in our own country, thirty years ago, we were strangers to the Rhubarb, (Rheum Rhaponticum) which has now become an article of extensive culture, far preferable in many respects to the unripe goosberry, for tarts, puddings and preserves. It comes into use some weeks earlier—is raised with unfailing certainty and with trifling care—is perennial and abundant—is supposed to be more wholesome than the goosberry. It is now in general use, and constantly at market. We are indebted for its introduction to an amateur in Horticulture in the state of Maine. This example shows, that we may introduce something new, and that our horticulture was not at its highest point before.

The Sea Kale is a plant of recent introduction in Europe. Perhaps its culture cannot be traced back beyond forty years. It is a native of the sea coast of the southern parts of England, where it is found growing in sea sand.

It is very hardy—grows in any tolerable soil—is perennial, and costs not half the labour bestowed on asparagus. It may be raised from the seed or from the root, and fifty plants, occupying a very small space, will supply a single family. In its taste it resembles the Cauliflower. The only labour it requires is to cover it with sand, or earth, or with pots, or boxes in March, so as to exclude the light, and to blanch it, or make it white. If not blanched it is neither so beautiful to the eye, or so tender, or so delicate to the taste as if blanched. It should be thoroughly boiled and is better if boiled in milk and water. It should be served up like Cauliflowers, with melted butter. It comes in at a season in which our vegetables in this country are very deficient.

If in England and France where it has to compare at the same table with green pease, and spinach, it is admired as a luxury, can it be possible that it will not eventually succeed with us?

We shall be happy to furnish seeds of it to any persons who may be disposed to introduce it. I am not discouraged by the tardiness of its progress in coming into use; I have seen such changes in our horticulture, that I feel convinced, that we shall eventually have a vegetable market nearly equal to that of Covent Garden, though at present we are to be sure at a mortifying distance from it. One remark must impress itself, I am sure, deeply, on every man who is interested in such subjects, small to be sure in some views, but important in others—and that is, that if in older countries with milder and shorter winters, in which they give you green vegetables nine months in the year, they value such a plant as the Sea Kale, it must be of greater value to us, whose soil is bound in frost from the 16th of November to the first of April, and sterile till the first of May.

There is another reflection of some moment. Every new plant introduced for the table increas-

es the comforts and diminishes the expenses of the middling classes of citizens. A vegetable market fully supplied, extends very materially the means of subsistence. Competition will produce abundance, and of course cheapness. The Sea Kale is easily raised, and endures forever. It requires no manure as the Asparagus does. It is indeed injured by it, and if our farmers in the interior had a patch of it in their gardens, they would have an earlier succulent vegetable to eat with their salted provisions, than any other they could raise.

The Salsify, or Oyster plant, is another vegetable of easy production, and universally eaten, when introduced to the table. I know no one vegetable which is more esteemed.

Yet though it has been in our gardens for ten years, it has never been extensively cultivated for the market, and I think it is owing to its not being generally known. It resembles a small parsnip in its appearance. It is raised annually from seeds, and as easily, requiring no more care than the carrot. It bears a tolerable crop. In Europe it is eaten both boiled and fried. In this country it is parboiled, and then fried either in butter, or without. It forms an admirable garnish for boiled fowls or turkies. In its taste, it so strongly resembles the oyster, than when sliced and fried in butter, it can scarcely be distinguished from it. If our gardeners would introduce it into the market, and our citizens once try it, there would be no danger of its ever failing hereafter to be raised. It is in eating from November to May, precisely the period in which our vegetable market is most deficient in variety.

It is not possible for any one to believe without experience, how much we are below every part of Europe in vegetables. The great difficulty in introducing a new plant for the table, is, the want of attention on the part of the consumers. The raisers of vegetables are prompt, and attentive. We shall state one instance in proof of it.—A few sweet potatoes, raised here, (inferior to be sure to those of Carolina) were sold in our market at the price of two dollars per bushel. A great many applications were made for slips, but no one succeeded in keeping them over the winter. This spring, we found several of our cultivators for the market, had on their own account, and risk, imported them from the south, and are raising them with spirit. We have no doubt of their success. We are confident they will be regularly for sale in Boston market, from this time forward. We have had experience this spring of their hardihood. They encountered a severe frost on the sixth of May, after having been transplanted from a hot bed, where they were made paternally tender. They were cut down by the frost, but have started again more freely than the common potato. They are now one month earlier, than any we ever raised, and we feel no doubt that they will produce an abundant crop, and those which will not sell, will furnish the best possible food, for pigs, cows, and poultry. This is no speculative theory, but the result of four years constant observation and experiment. We have no idea of its being an object of general culture, but it will, and must form a part of the cultivation for the market, and of gentlemen, who feel a taste for horticulture.

From the Massachusetts Agricultural Journal.
ON GRASSES.

[To the Recording Secretary.]

DEAR SIR,

At your suggestion, that there might be some utility in publishing the result of some experiments made the past season upon the evaporation of certain Grasses, &c. in the process of drying or making, for safe and useful preservation

herein inclose the same to you for such disposition as you may think proper.

The great object of research seems to be, what is that admirable process of nature, (as yet too little understood,) by which vegetable life is sustained and promoted? And how can this be traced or pursued so as to allow to human skill and ingenuity the nearest approach to the wonderful perfection of the great design? That this may be usefully done—that it is indeed partly accomplished, and that we are in full progression to this effect, cannot be doubted. The discoveries and improvements in those sciences, particularly in Europe, which have a reference to the theory of agriculture, have of late shed such a light upon the subject, and these have been so followed up by practice and confirmed by experience, that the result is indeed most auspicious, and marks the present age, as an era of improvement.

But the process of nature is indeed subtle and mysterious, and can only be unfolded to the most earnest and diligent inquirer.

An accurate knowledge of the elements which compose vegetable life, and the different degrees in which they prevail in its formation, cannot be useless, in looking back for its origin and first principles. The tendency of most modern discoveries in relation to vegetation has been to shew the great prevalence of water in its composition. This has not only been made to appear by the analysis of plants, but it has to the astonishment of those who prosecuted those researches, appeared, that an acre of ground gave, according to its humidity, from 2 to 4000 gallons of water to the atmosphere in a day by evaporation only. The operation of this element has appeared so extensive, that it has led to the most delicate experiments, and induced some even to suppose it the sole source of vegetation.

A curious instance has been frequently published, of a willow inserted in a leaden vessel with a given quantity of earth, and supplied constantly with water; the willow thrived and acquired great growth and weight in a few years;—whilst on a subsequent examination of the soil, it appeared no sensible diminution had taken place.

It is observed by an ingenious writer,* to whom agricultural science is much indebted, "That although the mode in which manures operate on soil is not so obvious to the senses as to be fully understood, there are three ways in which water promotes their improvement. It preserves a favourable degree of temperature; feeds by conveying nourishing substances; and so as a pure element it is beneficial." To prove that water enters largely into the composition of vegetables, and is thus advantageous, the same writer observes: "That plants cut green, and afterwards dried, lose by exsiccation 66 to 70 parts out of 100."

The loss of weight by drying will be found in this country to vary very essentially from what takes place in Scotland, especially as it respects different plants. But our hay is of necessity made lighter by the heat of our summer, as well as for the purpose of its being stowed in large bodies and tight barns.

It should be premised, that the time of cutting the several grasses, &c. in the following statement was the same as is usually practised by husbandmen in our State.

Of 100 lbs. of vegetables cured in 1822, the product was as follows, viz:	
100 lbs. of Green white clover, gave of hay	17½ lbs.
100 „ of Red do. gave	27½ „
100 „ of Herds' Grass, gave	40 „
100 „ of Fresh Meadow, gave	38 „
100 „ of Salt Grass, gave	39 „

* Sir John Sinclair.

100 lbs. of Mixed 2d crop on English Rowan, gave 18½ lbs.
100 „ of Corn Stalks, gave 25 „
100 „ of do. cut in milk with the ear, 25

It is to be observed, that the weight will vary from ripeness, and many other causes, such as wetness of season, shade, thickness of growth, &c.

I am, Sir, with much respect, your's,
JOHN WELLES.

Dorchester, October, 1822.

FROM THE NATIONAL INTELLIGENCER.

AMERICAN WINES, &c.

Messrs. Gales and Seaton.—In my letter printed in your paper of the 26th ult. (taken from the American Farmer, which I did not intend should be published, but for Mr. Skinner to make an editorial article of, and the letters enclosed to him,*) I have asserted that, before the end of the present century, the Vineyards of the United States will add one hundred of millions of dollars annually to the agricultural products, which renders it necessary to give an explanation of my ideas on the subject; as I suppose there is not one person in five thousand that has ever reflected seriously on this business, or has any idea of the advantage it will be eventually of to this country.

We have it from the best authority, that the Vineyards in France produce, annually, on an average of years, more than *one hundred millions of dollars*. The extent of the Vineyards in France are about two millions of Arpents, which is about equal to one million and six hundred and ninety thousand of our acres. France, according to A. Young, and others, contains one hundred and thirty one millions of acres; consequently, there is about one acre in seventy-seven in vines, in the whole extent of that kingdom. The average produce is about five hogsheads, of sixty-three gallons each, on an arpent, or three hundred and fifteen gallons. A Vineyard, to produce, in the same proportion, on one of our acres, would be upwards of three hundred and seventy gallons.

For the sake of comparison, I will select the state of Virginia, which, according to Morse's Geography, contains seventy thousand square miles, which at 640 acres to the square mile, will make 44,800,000 acres in that state, and which is a little more than one-third of the extent of France; and, instead of having one acre in seventy-seven in vines, the proportion in France, I will say Virginia will have *one in four hundred in vines*, which is less than one-fifth of the proportion in France, and will make one hundred and twelve thousand acres: and, at 370 gallons of wine to the acre, will produce 41,441,000 gallons.

Upon inquiry, I have it from the best authority, that there are wines in France which sell for six hundred crowns the ton of 250 gallons, which

* Note by the Editor of the American Farmer, to whom this seems to be a good opportunity to explain.—Major Adlum left the whole matter to him, to make of it if he chose, an editorial article.—The Editor was very busy at the moment when it was necessary to send his letters to the printer, and he gave directions to have it all put in type that he might afterwards make, in the proof sheet, the little alterations that might be necessary, to give them an editorial form—unfortunately before the paper came out, he was called from home; so that the letter appeared in its original shape, including a paragraph expressly forbidding his publishing it in that way—when he returned, a good part of the impression was already off—but this ludicrous error was rectified as far as practicable, as soon as discovered.

is equal to \$2 64 per gallon, and other good wines sell in proportion, and greater quantities are not sold at higher prices than our cider. And, for the sake of brevity, I will state an account, which every one who chooses may vary according to his own ideas, as to price, &c.

1,000,000 of gallons of Wine at \$2 00	\$2,000,000
2,000,000 do. do. 1 50	3,000,000
3,000,000 do. do. 1 00	3,000,000
5,000,000 do. do. 0 75	3,750,000
7,000,000 do. do. 0 50	3,500,000
23,440,000 do. do. 0 25	5,860,000

Total prod. at the prices above stated, \$21,110,000 and a greater portion of it valued at a price (25 cents) which would generally be cheap as vinegar, or it may where it is not a pleasant beverage, be turned into brandy; and at an average of fifty cents the gallon, it will amount to the sum of \$20,720,000; or even at twenty-five cents, will add \$10,360,000 to the agricultural produce if the cultivation of the vine is pursued, and most of it may be got from lands that are now lying idle and useless. It will be a pleasant amusement for gentlemen to have from one to five acres, with the assistance of their house servants, without interfering with the labourers of their farms.

I have here stated facts from which gentlemen may make their own calculations, and draw their own conclusions; any one who will take the trouble of looking at a map south of the 50th degree of latitude, and east of the Mississippi, will see that there is more than sufficient extent of country in the United States to produce more wine and money at the lowest rate above stated, and to amount to a much greater sum than one hundred millions of dollars, even if there was but one acre in five hundred cultivated in vines.

JOHN ADLUM.

THE HESSIAN FLY.

This destructive insect is propagated from the eggs of the fly deposited on the grains of wheat when ripening: the truth of which I learned from actual observations. The fly may be seen by the middle of June, and from that time till wheat is cut, flying about and lighting upon ears of wheat. It deposits its eggs upon the outer ends of the grain, where they may be seen with a good microscope or optic glass; sometimes to the number of 6 or 7 on one grain.

They remain there till the grain is sown. The warmth necessary to produce vegetation is sufficient to animate the insect. It bursts its shell and enters the shoot, where it lies in a torpid state till the next spring, except in some instances when wheat is sown early, the fly commences its ravages in the fall: when this is discovered, the best method is to turn sheep upon it and pasture it short either in the fall or in the winter.

The most effectual way to check the propagation, is in preparing the seed before sown, which should be in the following manner;—Put your seed into a hoghead, tub or vat, and cover it with water; let it stand 10 or 12 hours; then put off the water, put the wheat upon a barn floor and sprinkle lime over and with a shovel mix it till it is well covered with lime. Let it remain in that state about 24 hours, and the eggs will be destroyed without any injury to the seed.

The following brief sketch of the observations which led to the discovery abovementioned, is given, that all who wish to be satisfied of the truth of it, may have ocular demonstration of the fact, if they will take the trouble. On viewing several grains of wheat in a microscope, something resembling the eggs of insects was observed upon them: 20 grains were selected with those appearances; they were put upon some raw cot-

ton and a little earth in a tumbler of water, and observed every day; and on the day the grain opened and put forth its tender fibre, the insect burst from its shell and was not to be seen.

Ten days after, five of the grains with their roots and blades were taken from the glass and carefully examined. In three of them the insects were found. The other 15 remained, and overspread the top of the glass. They were preserved till spring, when, on examining, every stalk had an insect in it, some two and one four.

Twenty other grains were selected, and the lime applied for 12 hours. It was then washed, and the color of the eggs was changed, and being put into a glass, in like manner as the other, the wheat grew, but the eggs did not produce.—The roots were transplanted and grew well, and ten bushels of wheat limed as above, produced a good crop, while the neighbouring fields suffered materially, and some were almost wholly destroyed by the fly.

A Farmer of Bucks County.

Among the many advantages to be derived from the *Tread Mill* it is stated that its salutary discipline completely cures the rheumatism.

To preserve Fruits and Flowers the whole year without spoiling.—Mix 1 lb. of nitre with 2 lbs. of bole ammoniac and 3 lbs. of clean common sand; then, in dry weather, take fruit of any sort, which is not fully ripe, allowing the stalks to remain, and put them one by one into an empty glass till it is quite full: cover the glass with oiled cloth closely tied down. Put the glass three or four inches down in the earth in a dry cellar, and surround it on all sides to the depth of three or four inches with the above mixture. The fruit will thus be preserved quite fresh all the year round.

Two ancient shields, which no doubt were worn in the celebrated battle of Shrewsbury, and which were ploughed up at Battlefield, are now in the possession of Sir Andrew Corbet, Bart. of Acton Reynard Hall. The one is a specimen of those worn by the horse soldier, and the other, of those worn by the foot soldier.

Shrewsbury Chronicle.

Editorial Correspondence.

Extract—Talbot County, July 8, 1823.

The wheat crop being now secured, we are enabled to judge accurately of its product.—It is certainly much better than was generally anticipated six months ago, and may be called a fair average crop of very good quality, but little having been injured by the uncommon rainy spell during harvest.

There are a few farms in this county which have made full and fair crops—many more that will not yield three for one; a few that will scarcely return the seed, and the great majority will average about a half crop—that finely cultivated and rich district of wheat land lying on Wye River, will scarcely average more than half a crop, and all the light soils have universally failed. This statement is said to be justly descriptive of the crop in Queen Ann's county.

The corn crop, although it has often been more forward at this season, never promised better until within a few days past; it has been almost universally assailed by the chinch bug, in greater quantities than was ever remembered. The wheat fields during harvest were every where remarked to be covered with this noxious and nauseous insect; and as soon as the wheat was

reaped, they went over to the corn fields, and the stalks of corn are literally black with them. I consider the corn crop was never in more extreme danger of great, if not total loss; for there is no calculating the probable damage that may be occasioned by so extraordinary a quantity of this destructive insect.

Charleston, July 2, 1823.

DEAR SIR,

I received your letter of the 23d ult. enclosing a note from Dr. Mease, wishing an explanation of a paragraph at the conclusion of my communication which appeared in the American Farmer, No. 12, vol. 5, in these words: "That the land" was so completely raised, that nothing but a "very high spring tide could at all affect"—My meaning of the word "raised" was, that the land in its native state was so high as to be out of the reach of common tides, but by the removal of the original growth of trees, &c. and the immediate and constant cultivation of oats, barley, rye and corn, it had sunk so much as to admit freely the tide from the river; thereby putting it upon the same level with the rest of my tide swamp. I give the explanation with pleasure—it may, perhaps, prevent others from being at the trouble of making the same enquiry.

Permit me to request your attention also to two typographical errors—"Probability" of a plough drawn by oxen, &c.—It ought to be as it was in the manuscript, "possibility," altering the sense materially—also, near the conclusion, instead of, I ordered it to be "cleaned," it ought to be "cleared;" that is, the woods cut down and then cleaned.

CHARLES E. ROWAND,

PUBLISHED IN THE AMERICAN FARMER, BY ORDER OF THE STATE.

THE FARMER.

BALTIMORE, FRIDAY, JULY 18, 1823.

The Editor will be thankful for a few Sea Kale seed—sound, and of recent growth.—They should be put up and sent in small parcels not exceeding half an ounce. They are for persons who have asked them of the Editor, and who wish to make trial of that vegetable.—Also, a small quantity of Guinea Grass Seed.

NEW YORK BOARD OF AGRICULTURE.

This institution was organized in the year 1820, under the patronage of the state of New York. By an Act of their Legislature, farmers within her borders, who form themselves into county Agricultural Societies, and raise a premium fund, are authorized to claim and receive a like amount from the State Treasury, provided that it does not exceed what was allotted to the county. The whole sum appropriated by the state to this object, is 10,000 dollars per annum.

The Board of Agriculture is composed of the Presidents or delegates of the county societies. It holds an annual meeting for general purposes at Albany, during the session of the Legislature, and transacts its ordinary business, at other times, by a permanent committee, aided by its officers.

The state requires that each society, that claims its patronage, shall obtain from persons who gain their joint rewards, an accurate description of the process used in cultivating the soil, and in raising the crop, or of feeding the animal, as may be, before such persons receive their premiums: and further, it requires that reports thereof shall be forwarded to the Secretary of State, for the use of the Board of Agriculture, who are authorized by law, to select, publish, and circulate valuable essays and reports, at the public expense, and also to purchase and distribute useful seeds or plants.

A liberal and wise government, has thus conspicuously placed before the Agriculturists of that great state, the most animating inducements to organize themselves into societies, which will become a powerful and active means to convey the best information, and most approved plants or seeds, even to the most retired farmers—to encourage all of them, to improve the breeds of their domestic animals, whilst they augment the fertility of their soil; and to induce very many, to engage in household manufactures.

The tendency of such inducements has been already, and most satisfactorily seen wherever they have been employed—the New York board has abundant reason to be encouraged, and we hope and believe, that they will continue to enjoy the support of their state, and the gratitude of their fellow citizens. They have imported the latest, interesting publications of Europe, to commence an Agricultural Library; they have procured from other countries, and distributed through their state, many useful seeds, and they have published two volumes of memoirs, for a copy of which we are indebted to the kindness of their President and Secretary, to whom, and with peculiar pleasure, we shall send in return, for the acceptance of their board, a complete set of our Journal.

We feel that the Agriculturists of our country, are greatly indebted to those zealous and enlightened officers of that board. To the distinguished and munificent liberality of their President, Stephen Van Ransselaer, boundless praise is justly due—he has bestowed ample premium funds for several years, upon as many agricultural societies—he has caused geological surveys of counties to be executed and published, and

now pushing these valuable researches along the precincts of their grand canal, and he has offered a pattern-farm, to the free acceptance of the state—but above all, are the agriculturists of this nation indebted to him for the pure and bright example, of unostentatious usefulness, which the liberality and exertions of this interesting citizen, place so broadly, yet so modestly before his countrymen; for who among us, can perceive his merits, and comprehend the scope of his designs, without wishing to co-operate with a leader at once, so munificent, yet so unassuming—so active, and inquisitive, yet so retiring? The services of such men may be made extremely beneficial to society, and it behoves the rulers of these states, to patronize agricultural associations, which are, in their nature so well adapted to call such talents, feelings and means, into congenial and profitable operation.

To the secretary of the board, Mr. George W. Featherstonhaugh, a learned, enterprising, and practical farmer, the people of New York, and of this union, are under heavy but grateful obligations for his persevering and successful efforts, to unfold the principles, and correct the precepts of our Rural Economy—for we owe to his labors the opportunity of benefiting, by the perusal of a well digested, and very instructive essay, written upon these important subjects, at the desire of the board of Agriculture, who approved and published it, in their first volume of the memoirs, of which it makes the chief part.—That the board could have obtained numerous communications from actual, and active farmers with which, to form their first annual volume, was not to have been expected—they, therefore, very judiciously sought at the hands of their intelligent and worthy secretary, an original essay that should furnish correct information, and useful advice, upon the various subjects of a farmer's hopes and cares. This they freely obtained, and promptly published, and it has undoubtedly been received by every body as a most acceptable substitute for a score of addresses that had been received by the board for publication; as these no doubt, were conformably to usage, mere fervid exhortations, to efforts and changes of declared importance, without a sufficient designation of the means of their accomplishment, or the evidence of their utility—errors which cannot too soon be corrected by our Agricultural orators.

But from the mass of addresses in the possession of the board, they wisely selected, that which Mr. Madison delivered before the Agricultural Society of Albemarle, Virginia, to complete their first volume; for as they have very justly remarked, "this address confirms his reputation as one of the most enlightened men of the age."

Their second volume of memoirs gives us the most welcome evidence of a growing zeal, for the advancement of Agriculture, throughout their state; and we believe that it may be very correctly ascribed to that spirit of emulation which the Legislative bounty, and judicious measures of the board of agriculture, have called into generous activity. Their second volume contains many interesting communications, from practical farmers, which abundantly prove the willingness of this great body of our population, to impart knowledge, whenever they can be persuaded to lay aside their characteristic diffidence, which alone prevents those who excel from publicly giving their advice to others—but this feeling invariably yields, when we persuade them of the useful tendency of such communications, and bring the obligation of each member of society to the test, under their consideration—of this fact we have had abundant proofs, in the

progress of our Editorial labors, and we think that the New York board of agriculture, has also received sufficient encouragement, to induce them to call upon their fellow citizens, specifically, for any information that may be peculiarly within the power of certain persons, to procure or give—and if they will continue to employ their influence, in this way, we are satisfied that the farmers of this country, would have great cause to be grateful, for the many benefits which they would derive from the authentic answers that could thus be obtained, from men of experience, in every department of agriculture. Already much useful knowledge has been unfolded by their efforts, and we hope that they will persevere as they have begun. That the rulers of their state, will continue to patronize such efforts, there is every reason to believe, when we advert to the objects of their solicitude, and the boundless advantages that must flow from the prosecution of their labors.

The enlightened policy of their state, guarantees perpetual and ample patronage, to the board of agriculture, from whose future services, judging from the past, we anticipate great benefit to our countrymen.

The policy of that state, is worthy of general imitation; she fosters education, the sciences, agriculture, and internal improvements, with a munificent and enterprising spirit, that will extend the knowledge, and augment the resources of her citizens, to a degree, that cannot now, be even faintly sketched, by the most sanguine mind.

How long will the people of her sister states suffer this example to remain, as if lost to them? Upon some, it imperiously calls, in modes that cannot be neglected with impunity—and we rejoice at it—we are glad that self-protection urges us and our neighbours to imitate her bold and wise policy. The work of improvement will thus necessarily proceed, and the enjoyments of society be augmented; universities, and primary schools; turnpike roads, and canals; agricultural societies, and pattern farms, are thus elsewhere assured of state support, by the noble example of New York.

In Pennsylvania and Virginia, the people are alive to the necessity of immediate and co-extensive efforts, and even in Maryland, we have felt the impulse of their movements—we have been driven to contemplations, from which much good may arise—a Canal from the Susquehanna linked with the lakes, and another from the Potomac stretched to the western waters, are necessary to the future prosperity of Baltimore—these would preserve it a great market, and their revenue would more than defray the whole expenses of the State Government. Shall not this common good be secured by a general effort? Will not the whole state embrace and execute the design?

But to return to the memoirs—we long since determined to make copious extracts from the first volume, and we shall still do it; nor will we make less free with many parts of the second volume; indeed, we would copy the greater part of each, if we did not feel obliged to consult the interests of many of our patrons who already possess these memoirs in their original form.

We will, in our next, lay before our readers the introductory letter to Mr. Featherstonhaugh's Essay, as a suitable prelude to other extracts, and an appropriate explanation of its origin; and, because it gives some account of the difficulties which the Board had to encounter, together with a fair view of the tendency of their labors.

To CORRESPONDENTS.—"S." is informed that his remarks on the Fly, have been read with much satisfaction, and shall be inserted as soon as

possible—The delay will not diminish the effect of his observations, and will, we hope, not prevent him from repeating his acceptable favours.

SEED, GRAIN, &c. RECEIVED FOR DISTRIBUTION SINCE LAST NOTICE.

From Commodore Chauncey, a small box of wheat, with the following note:

MY DEAR SIR,
I leave with you a sample of Chili wheat, which I have lately received, and I pray you to make such disposition of it as you may think best for the farmer's interest.

Your's truly,
I. CHAUNCEY.
LIMA BEANS, direct from Lima, sent to the Editor by Mr. Didier.

BALTIMORE MARKET.
PRICES CURRENT.—CORRECTED WEEKLY.
Flour, best white wheat, \$8—Howard street Superfine, \$7 25—fine do. \$6 75—Wharf, do. \$6 75—sales—New wheat, \$1 25 to 1 27—Red do. \$1 42 to \$1 43—Rye, 75 cents—Corn, 50 to 52 cents—country Oats, 40 cents—Beef, 8 cts. per lb.—Live Cattle, \$6 to \$6 50 per cwt.—Bacon, round, 8 to 9 cents per lb.—Pork \$4 50 to 5 50 per c. lb.—6 to 8 cts. per pound—Mutton, 5 to 6 cts. per lb.—Beans, \$1 37½ to 1 50—Peas, black eyed, 55 to 60 cts.—Red Clover Seed, \$5 50 a \$6—Orchard Grass do. \$3—Herds' Grass do. \$3—Timothy do. \$4 50—Millet, none—Buckwheat, none—Flax Seed, 75 to 80 cts.—Whiskey, from the wagons 35 cts. per gal. including the barrel—Apple brandy, 30 to 32 cts.—Peach do., 65 to 70 cts.—Shad, \$6 50, scarce—Herrings, No. 1, \$2 75 per bbl.—No. 2, \$2 50—Fine salt, 60 to 65 cts. per bush.—Coarse, do. 70—Butter, (firkin) 14 cts per lb.—Eggs, 16 cts. per doz.—Hay, \$16 per ton—Straw, \$10.

MARYLAND TOBACCO.—Same as last report.—Sales, 8 hds. spangled and red, Mr. Nottley Young, Prince George's \$15—21 hds. good red, Mr. Charles Hill, Prince George's \$10—1 hhd. fine yellow, Mr. George Cook, Elk Ridge \$49.—Highest price ever obtained in the state—this hogshead weighed but 276 pounds, each leaf had been carefully picked and ironed out, and the sample left at the office of the American Farmer, is of clear yellow, resembling gold leaf.

PATENT Cylinder Straw Cutters.

The subscriber would respectfully inform the publick, that he continues to manufacture his patent CYLINDER STRAW CUTTERS at the usual place, 6 doors above Eutaw, in Market-street, and at his usual prices—(see American Farmer, vol. 4, No. 18, p. 144) which he warrants to cut hay and straw of every description, straight or tangled, and to feed themselves without difficulty; and also corn tops, stocks and husks, and likewise cane tops. He makes a large sized machine to be worked with two cranks, or by a horse, capable of cutting from 4 to 5 tons per day, with extra knives, price 100 dolls. Gentlemen intending to get either size of the above described Machines would oblige the subscriber by sending in their orders as soon as may be convenient.

JONATHAN S. EASTMAN,
Baltimore.

Printed every Friday at \$4 per annum, for JOHN S. SKINNER, Editor, by JOSEPH ROBINSON, on the North West corner of Market and Belvidere streets, Baltimore; where every description of Book and Job Printing is executed with neatness and despatch—Order, from a distance for PRINTING or BINDING, with proper directions promptly attended to, addressed to J. Robinson, Baltimore.

AGRICULTURE.

AN ESSAY ON THE PRINCIPLES AND PRACTICE OF RURAL ECONOMY, WITH AN INTRODUCTORY LETTER TO THE HON. STEPHEN VAN RENSSELAER, PRESIDENT OF THE BOARD OF AGRICULTURE OF THE STATE OF NEW-YORK—BY G. W. FEATHERSTONHAUGH, ESQ.

[Referred to, and promised in our last number.]

INTRODUCTORY LETTER.

To the Hon. Stephen Van Rensselaer, President of the Board of Agriculture.

SIR,

I partook with yourself and the members of the General Committee of the Board of Agriculture, the regret which was felt on learning that the communications received from the county agricultural societies, at the close of the year 1819, were altogether insufficient for the purpose contemplated by the legislature, of forming an annual volume out of such communications, and of essays on agriculture. Yet when we reflect, that the establishment of a board of agriculture was an entirely new feature in the economical institutions of this country, and that many of the county societies might be fairly supposed unacquainted with the value of what they might deem a doubtful experiment, it may have been, and was probably anticipated, that few communications of interest could be expected during the first season subsequent to the enactment of the law. There was therefore a manifest propriety on the part of the general committee, when, in their first annual address to the county societies, they so strongly urged the necessity of an active correspondence with the board, and furnished them at the same time with the proper forms of schedules, with a view to have the annual returns made in a useful, constant and systematic manner. The ground work could only then be considered as properly laid upon which the superstructure was to be raised, and if the officers of those societies are careful to make their returns after the method suggested to them by the board, in a very few years the agricultural interest will possess in the annual volumes to be published by authority of the state, a faithful picture of the nature and progress of agricultural improvements, and of the resources of the state at large. We have cause to believe that the interest excited by this important subject is becoming general, and that great advantages have been gained upon the state of apathy in which we were a few years ago, which point to profitable and enduring consequences, springing from the munificent law, hitherto, I believe, peculiar to this state.

It was at a period subsequent to the introduction of Fairs in this state, but previous I believe to the enactment of the law, that I had considered with myself what would be the most effectual way of giving the spur to the agricultural interest, which was at that time beginning to draw a large share of public attention; and being passionately fond of the vocation of a farmer, to which I am indebted for more health and satisfaction than I have possessed at any other period of my life, I committed occasionally my ideas to paper, and even entertained the thought of enlarging them into a form proper for public inspection at a favourable moment. When the subject of the publication of an annual volume was under discussion by the general committee, and various methods were suggested of filling the volume, in consequence of the insufficiency of the communications from the county societies, I took occasion to observe to some of the gentlemen of the committee, that since we were obliged by

circumstances to eke out our first annual volume with detached essays from such sources as might be accessible to us, it would probably be more useful to present the agricultural public at once with a treatise on agriculture and rural economy: wherein the principles upon which a successful husbandry must always depend, should be familiarly explained, and the application of their necessary results be applied to the present condition of agriculture in the state of New-York. I thought that in a work of this kind, the nature of the connexion betwixt chemistry and agriculture could be unfolded to that class of plain men, who think much, although they say little, perhaps from being conscious of a defective education. Many individuals of the laborious classes of the yeomanry are unable to penetrate beyond the first intellectual difficulty, for want of slight assistance in the elementary parts of knowledge; and I have often witnessed the extraordinary elasticity of minds from which the pressure has been judiciously removed. This suggestion of mine led to many conversations, which terminated in my consenting to furnish for the first annual volume of the board of agriculture an essay after the plan alluded to, upon agriculture and rural economy. I shall here say nothing of my incompetency to do justice to the subject; but an imperfect attempt of this kind by an unpractised hand, cannot bring discredit on any man. It is my intention to throw into a familiar form the amount of the knowledge I have acquired on the subject, from books and from a somewhat extensive practice; not conducted, however, I confess, under the most auspicious circumstances; for with little previous knowledge that way, I commenced my operations in what was scarce better than a wilderness, and without an intelligent neighbour of any description to correct my errors by his advice or example. I would here content myself with remarking, that those persons who contemplate embracing a rural life, and I believe them to be very numerous, considering the condition of human business as it now stands, cannot be indifferent to what is here stated, that it is possible to acquire a great deal of health, of happiness, and some knowledge withal, by attending to rural affairs: and I feel that it would have been incalculably advantageous to myself, if proper views on this important subject had been thrown in my way when I first settled in the country, somewhat in the form in which I now contemplate to offer my own to the public.

To say that we are entirely ignorant of true agriculture, would be asserting too much; but it is true, that there are very few persons in the state, who have ventured beyond the humble operations in use amongst our least instructed farmers; and those few, I have the strongest reasons for believing, have not escaped the charge of being visionary and improvident. My first attempt to raise a field of turnips, ten years ago, under the drill system, was considered ridiculous. I was repeatedly assured they would not grow, and then if they did grow, what could I do with ten acres of turnips? But as to draining, and liming, and erecting threshing mills, all that was absolute ruin.—These opinions, no doubt, grew out of the neglected condition of the landed interest. Commerce was the reigning occupation. Our merchants were the princes of the country; and farmers were considered but as their purveyors. Many of that small class of proprietors, who had retired into the country with slender means, had apparently not succeeded, for their necessary improvements had in most instances, absorbed their resources, and their occasional visits to the cities, were generally induced by the necessity of raising money; and thus they acquired the character of needy men, who were sure to

be ruined in the end.—These opinions have gradually given way. Adverse circumstances have arisen in their turn, and convinced the reluctant merchant, that the true resources of the country are to be looked for in the land, and in the skill and industry of the farmer. This is a happy revolution in public opinion; and promises that notwithstanding the partial derangement of general affairs, the country will soon become prosperous and contented. It is true, we are but in the infancy of agriculture, as an art, and although many intelligent agriculturists are spread through the state, yet they are not numerous enough at present, to visit each other conveniently, or to extend sufficiently the knowledge of many improvements in husbandry, which are intrinsically valuable; these inconveniences will be gradually corrected. It is probable, that henceforward, every year will add to the number of successful and intelligent farmers; and the moment it is perceived that any one man, or any particular set of men, succeed uniformly better than their neighbours, it follows of course, they will be imitated; and when that is done, the great point is gained, and the state will feel the benefit of it. To accelerate so desired a moment, it is just that we all contribute as we conveniently can to the general stock of information. The judicious enactments of the legislature, have made the efforts of the friends of the farming interest, comparatively easy. Never was munificent encouragement better timed, and I may add confidently, it has not been extended in vain. It is evident that the agricultural societies of most of the counties in this state, are rapidly gaining hold of the confidence of the people: it is universally conceded, that they have been productive of very beneficial effects; and those which have held their annual fairs for this year, have been attended and supported with greater spirit than the preceding year; and this unquestionably could not be, if the people had not had just reasons to perceive the utility of these institutions. All the accounts concur in stating that there has been an obvious improvement in the condition of farms, and a manifest anxiety on the important subject of improved breeds of cattle, sheep and horses. The institution, therefore, of county agricultural societies, and of annual fairs, is no longer to be considered a doubtful experiment, but is now entitled to be fairly pronounced a great salutary undertaking on the part of the community, which has produced unexpected advantages in a very brief space of time; and which only requires to be persevered in, with prudence and energy, to ensure benefits of the most lasting kind.

Example amongst farmers, is unquestionably a better teacher than precept; and I apprehend that it is principally by example, that a more perfect kind of husbandry is eventually to be established amongst us; yet a necessary consequence of the accumulation of examples or facts, is the disclosure of the principles out of which they grow, and to which they owe their constancy. A successful fact shows us, indeed, the possibility of the thing, and that we may hope to be equally fortunate, by imitating carefully the process which was observed to produce it at first; but the advantage is limited here, whilst a perfect knowledge of the principles upon which the fact depended, would, perhaps, teach that we might have been still more successful under the same circumstances, or have made a better use of the same means. An ordinary farmer observes his neighbour raising fine crops of turnips with fresh spring dung, which hitherto he himself has only used when it was a year or two old, and perfectly black and short. He therefore spreads his own spring dung on his wheat, which notwithstanding its luxuriant growth, is struck

with the rust, whilst his neighbour's wheat raised upon a turnip lay, is sound. A moderate knowledge of the theory of this art, would have prevented his making this mistake. It would have taught him that the diseases of wheat are chiefly owing to insects; that insects deposit their eggs in innumerable quantities in rank animal dung, whose fermentation quickly hatches them; that the plants, too rapidly forced by the fermentation, become the easy prey of their enemies, who penetrate the soft straw at pleasure, and interrupt the determination of the juices to the head: It would have taught him also, what perhaps his more wary neighbour knew, that there is a certain order after which all things are to be used, or confusion ensues; that the best way to keep spring dung out of the reach of flies, is to bury it in the earth in rows, where the fermentation and the evanescent particles, which under any other plan would be lost, would greatly tend to ensure a crop of turnips: and that the rank animal parts being thus expended, wheat might be safely and advantageously sown as the second crop. In short, a little book knowledge would tend to keep him within the rules of his art, and prevent him from making continual mistakes; whilst it would place within his reach numerous resources, of the existence of which he perhaps never dreamt. I think that no good argument can be maintained against some study of theory, as well as practice; that is, a theory sustained by facts universally conceded. Every farmer who is ignorant of the true theory of his art, is, at the best, a farmer very imperfectly informed, and will always be considered so. To argue, therefore, altogether against theory, is to argue against knowledge. But it will probably be objected, that there are already treatises on husbandry, and that if they have not produced good effects, it is in vain to write any more. Why good treatises have not produced corresponding effects it is not easy to say. Perhaps they have, in a partial degree; and what I dare say is perfectly true, is, that they have not been extensively read. The great body of farmers, for whose benefit they may be supposed to have been written, have hitherto not been in the habit of looking to books for agricultural knowledge; and I apprehend before that habit can be induced upon them, books of that description must be made more attractive. Few of the best English works have been re-published in this country, nor do any of them appear to me to be elementary enough. A treatise on agriculture, evidently the production of a man of great talents for the purpose, was published last winter, but it appears to have been very little read, and this does not afford much encouragement to one engaged in the same object. One circumstance, however, which has not been mentioned, has probably had its share in limiting the circulation of useful works upon agriculture. Ordinary farmers, particularly in these times, have not sufficient confidence in books to lay out their money upon them; and men of more intelligence, have been generally disappointed in agricultural works which have hitherto been published. They have too often found them immethodical, and have risen from their perusal conscious of that confusion of ideas, which invariably is occasioned by flinging even the most valuable materials injudiciously together. In some instances they are too scientific. The ancient history of agriculture, the profuseness of the technical terms of art, and the elaborate accounts of operations not fitted for their own affairs, forbid the hope that such books could ever become popular. It is probably owing to considerations of this nature, that many of the European works have not been re-published; and that intelligent men here, have not felt more

interest in recommending the books to which they have had access.

The real capital of this state, is its land, which is to be made productive by the skill and industry of its inhabitants, who for all the purposes of a general statement, may be considered as farmers; and as must always be the case, in a country which is still in a state of progressive occupation, these farmers may be described as men with strong prejudices in favour of the simple agricultural operations practised by their fathers; the chopping and burning; the sowing and reaping, as long as the soil would make any returns. Men, too, with such limited acquirements from education, as belong to their stage of society. A very large portion, however, of the state has gone through the severe process of clearing and cropping, and has reached the first step, where agriculture, as an art, commences; which is, when the stumps are sufficiently decayed to admit of the plough passing freely through their roots. In this situation, there would be little encouragement for untaught and prejudiced men to pursue their vocation, if they were obliged to toil almost fruitlessly upon their exhausted lands, with the sole assistance of the scanty manure, furnished by a very limited and ill-provided stock. It is here, therefore, the absolute necessity of knowledge is apparent. A people fertile in resources, ingenious in discerning their interests, and constant in pursuing them, are capable of carrying rural economy to perfection in a very few years, if only their prejudices could be easily overcome. The liberality of our state government, has, I apprehend, obviated a very serious part of the difficulty, by providing that the annual volume to be published by the board of agriculture, is to be distributed to the county societies, at the expense of the state.* It is therefore probable that such a volume would be read, if put into proper channels for circulation, and that it would be of essential service to the country, if the contents were suited to the character of the people, and to the importance of the subject. On this head, there will undoubtedly be a difference of opinion; and from the moment I was obliged to deliberate upon the method which promised most utility, I have continually felt all the difficulties belonging to the subject.

I have before observed, that we are not entirely ignorant of true agriculture, although there are very few persons in the state who have ventured beyond the humble operations in use amongst our least instructed farmers, and I believe this to be strictly true. A great majority of the better order of farmers, as far as I am acquainted with the state, pursue habitually an agriculture at random: they pay it is true, more or less attention to manuring and perhaps generally get better crops than their less careful neighbours. But they do not even seem to suspect, that whilst they are carrying on their business so much better than others, they are really but pursuing a single branch of their art, and that only in an imperfect manner. They are yet to be taught that agriculture, or ploughing and sowing, is but a part of the true business which rural economy comprehends; and that this can never be made to flourish as it ought to do, without keeping a steady eye upon the natural order of the various branches which compose the whole system. There are,

** I hope the board of agriculture will deem it worth recommending to the county societies, that these volumes be judiciously distributed; perhaps it would be well, as the number of volumes for each county society will not equal the number of members, to add a volume to some particular premium, with injunctions to lend it to their neighbours who are members.*

no doubt, thousands of resolute, industrious men, who notwithstanding the occasional success which attends their operations, feel that they are in the dark, and that they do not entirely understand their own business; they hear of novelties being introduced which promise great advantages, and dare not venture to imitate them, because being ignorant of the principles of their art, they are unable to form a judgment whether any experiment has even chance of succeeding; and therefore they remain contented with the sort of practical knowledge which a defective education and a very limited experience have furnished them with. There is a more vulgar prejudice which governs many men; a sort of conceit that they understand a thing perfectly well, and are not in want of advice: but I believe the advancement of knowledge has been more retarded by the absence of fair opportunities to acquire it, and that this circumstance has principally affected the most numerous and most valuable part of the community. If this be true, the remedy is at once apparent: it is to enable them to judge for themselves of the probable value of any novelty, by unfolding to them in a sound and intelligible manner the true connexion of all the principles which govern their humblest operations; by enlarging not their knowledge of facts, but of the remote causes of these facts; by giving them a general view of the economy of creation, and teaching them to think for themselves. If habits of reasoning upon such matters could be established, then indeed the experiments and facts which may be put into their possession in future publications may be eminently valuable; but I apprehend if the labors of the board of agriculture should be limited to publishing from time to time, detached essays and experiments in the various branches of husbandry, that the general condition of knowledge on such subjects would not be much changed. The people will read them with as much distrust as they have previously listened to other matters to which they have paid little attention. On this point, however, I have had it objected to me, that the people for whose benefit this volume is to be published, are not in a situation to receive knowledge of this kind; that it is impossible to explain the relation of principles to each other, as they affect agriculture, without entering somewhat into the domains of the kindred sciences of chemistry and geology, which men without education do not understand, nor can be made to comprehend in a brief treatise. To this objection as it concerns the people, I do not attach much importance: the difficulty must be to the writer of such a treatise, and not to the people. A long residence in the interior amongst plain farmers, with whom I have had constant intercourse, has convinced me that there is nothing lacking to them on the score of intelligence; and they can understand any thing perfectly well, and put it to the best use, if it is imparted to them in a plain and regular way, consistent with their own habits of thinking and acting. The many conversations I have held with men of this description, have long ago convinced me, that there is but one way of instructing farmers with a view of promoting the general prosperity: indeed it is impossible to hold any conversation with an intelligent man, anxious for information of a more enlarged kind than what he possesses, without coming at once to the difficulty which is here objected. An ingenious, yet unlettered farmer who lives in the neighbourhood of lime, yet has never dared to use it, hears of the extraordinary success attending its operation on land, and comes to witness it. After enquiring how and in what quantities it was used, he expresses his astonishment; he listens with anxiety to an account of the varieties of lime,

and marl, and gravel, and sand; of the extraordinary fertility which is induced by mixing them in proper proportions with each other, or with other soils; he exclaims, "I see it is all true, but I cannot for the world imagine how it works." The condition of such a man is somewhat affecting. He stands upon the threshold of knowledge, and yet it is to him perfect darkness and confusion. It would shew little humanity to leave so ingenious a man in that situation, when, if we remove with a judicious hand the film before his eyes, he can fearlessly enter, and partake all the glories and blessings of the sanctuary of nature; there is no difficulty in this; a clear headed practical farmer, may be made sufficiently to comprehend enough of chemistry to convince him of the unerring truth of the principles which must always govern his vocation. In acquiring knowledge too of this kind, he will be enabled more distinctly to perceive that order which is established naturally in all the branches of his pursuit, and which he must observe if he follows it in the best manner. With his capacities thus enlarged, he will gradually come to consider the natural order of the economy of creation; the unvarying benevolence of design to man apparent in that order: his condition will be elevated, and he will feel in a more deep and constant manner, his great responsibility to the divine author of all things. Whatever may be said to ridicule the idea of imbuing the thoughts of plain farmers with a philosophical turn, yet if it is to be done, it would unquestionably lead to very beneficial results, and the sum of human happiness be thereby greatly increased. To such men, knowledge would be as wealth; and a just estimate of the real value of all the objects of human life, would tend to reconcile them to the humbleness of their lot; and teach them, perhaps, the most important of all lessons, contentment. With this explanation of the views which have governed me in forming the plan of this essay, I shall now proceed to give a general view of the true relations of the branches of rural economy, necessary to precede the three divisions into which the essay naturally resolves itself.

— 20 —

FOR THE AMERICAN FARMER.
HESSIAN FLY.

The great complaints of the Fly in the present crops of wheat, induced me to look through the volumes of the American Farmer, and in other places to which I had access at the moment, to see what I could learn on the subject. And I must acknowledge myself unable to draw any rules for practice from all that I find.

There appears great variety of opinion on every point, excepting one; *i. e.* the place of deposit of the egg. Excepting two, all agree that the eggs are placed on the blade or leaf; these two assert, "from their actual observation," that the eggs are deposited in the grain while ripening.

Mr. J. H. Cocke, (American Farmer, Vol. I. page 295) says, the Hessian Fly deposits its eggs on the blades of the wheat indifferently, at from half an inch to three inches from the main stalk or central shoot, in the furrows which run longitudinally. He suggests grazing as a remedy.

"A Farmer," in a Baltimore paper of May 1817, asserts, that "from actual observation," the Fly deposits its eggs on the grain of wheat while ripening. It would perhaps be well for us that this should be the case; as it is probable, that steeping in brine and liming the seed, would eradicate the Fly.

"A Baltimore Farmer," in the same paper, says he sowed his wheat late in October, and at the time he wrote (May following) it was very much infested with the fly. He recommends sowing in rich land.

"A Lancaster County Farmer," (American Farmer, Vol. I. p. 382) says, he found the eggs of the insect in the root (plant) of the wheat, in the month of March, before vegetation had commenced; and in June they had again deposited their eggs in the wheat plant near the root, which was then beginning to shoot out the head. He approves the first week in October for seeding.

"A King William Farmer," (American Farmer, Vol. II. p. 127) is of opinion, that the fly deposits its eggs in the central blade in a few days or hours after the wheat comes up; and has no doubt that they continue to deposit as long as they live. He recommends early sowing, and covering at least three inches deep.

"William Merriweather," (American Farmer, Vol. I. p. 125) says, he has often seen deep covering of wheat totally destructive of the crop; and that deep seeding is not a preventive against the fly.

"James M. Garnet (American Farmer, Vol. II. p. 173) coincides with the King William Farmer. "A Frederick County, Md. Farmer," (American Farmer, Vol. II. p. 135) says, it is a fact well known, that late sown wheat has frequently produced tolerably good crops, where more early sown has been much injured.

"Jeremiah Simple," (American Farmer, Vol. II. p. 159) says the Hessian Fly is born with the grain. When the grains are about half ripe, a small maggot may be discovered in every one of them. When the grain is fully ripe, the fly leaves it; and by the time early wheat is up, they are ready to deposit their eggs on the young stalk.—His rule is to sow after the fly has been killed by the frost, and covers at the usual depth.

"A Correspondent," (American Farmer, Vol. II. p. 200) says, very intense frosts do not kill the fly. And that in many instances of late years, the wheat last sowed, *i. e.* after hard frosts, has been more injured by the fly than that which was first put into the ground. He dissents from Jeremiah Simple's opinion, that the fly deposits its egg in the grain.

"Hezekiah McClelland (American Farmer, Vol. II. p. 234) says, the fly with its weapon, similar to the locust, opens or makes an incision in the tender wheat, blade, stalk, or grain, and there deposits its egg. And that early sown wheat always suffers most. That the fly is very hardy; he having seen them very active when the ground was hard frozen, and a large white frost—even the house-fly in his chamber quite torpid and helpless. And he concludes that they deposit their eggs at any time by incision.

In the American Farmer, Vol. II. p. 235, is stated "proof positive that early sowing will not answer. We had a frost last night; a fortnight since I observed the flies thick in the fields; this morning I could not find one."

Edward Tilghman 3d (American Farmer, Vol. II. p. 235) commenced seeding *Lawler* wheat the 18th September. The 5th of October, the first seeding being up, and having generally put forth the second blade from two to three inches, observed the eggs on the blades, and also the flies in numerous instances in the very act of making their deposits. As far as his observation had extended, they uniformly make their deposit from one to two or three inches indiscriminately, above the fork formed by the second blade with the first shoot, on the inner or ridged surface of the second blade, and in the cavity between the ridges thereof.

"Clodpole," (American Farmer, Vol. IV. p. 269) explodes the ridiculous idea of the egg of the fly being deposited in the grain. Opinion that early sowing is always best.

Dr. Isaac Chapman in 1797 said (American Farmer, Vol. III. p. 166,) the fly deposits its egg on the leaf or blade of the wheat, the latter end of April and the beginning of May, and the latter end of August to the 20th of September, when they may be seen laying their eggs on the leaves that have grown that season. They deposit them in the small creases that are longitudinal in the leaf. Upwards of twenty years' experience (American Farmer, Vol. III. p. 176) has convinced him, that the last three or four days in September, and the first week in October, is the best time for sowing wheat.

James Worth (American Farmer, Vol. II. p. 180,) says the fly had completed the work of depositing its eggs on the 11th of October, 1819. He thinks it probable, that another deposit of eggs will take place early in the spring, and perhaps another between that and fall. (American Farmer, Vol. III. pages 187, 188, 189 and 213.) He recommends a change of course of crops; and to begin sowing wheat the last week in September, and finish the first week in October.

In 1822, September 2, I commenced turning in clover for wheat, and began to sow on the 17th of September, and finished this field the 1st of October. On an adjoining field I sowed wheat after corn, and began to flush it the 21st of October. The 24th began to sow, and finished seeding the 31st of October. The first field has some little fly in it, but not to hurt it. The other, the fly has destroyed perhaps a fourth. Both put in very handsomely, and both rich land. I sowed what is called the blue stem. In this one instance at least, the early sowing has succeeded best.

It is said that *fish pickle* put on the ground intended for wheat, appears to prevent the attack of the fly. I have heard of a field of wheat, part of which was dressed with pickle, and part not: the part not dressed has a great deal of fly, the other none at all.

The knowledge of the effect of the pickle cannot perhaps benefit any, but such farmers as live in the neighbourhood of fisheries; yet to inquiring minds, it may afford a hint that shall be of general utility. S.

June 30th, 1823.

THE HESSIAN FLY.

May 1817.

This destructive insect is propagated from the eggs of the fly deposited on the grains of wheat when ripening, the truth of which I learned from actual observation. The fly may be seen by the middle of June, and from that time till wheat is cut, flying about and lighting on the ears of wheat. It deposits its eggs upon the outer end of the grain, where they may be seen with a good microscope or optic glass, sometimes to the number of six or seven on one grain. They remain there till the grain is sown, the warmth necessary to produce vegetation, is sufficient to animate the insect; it bursts its shell and enters the shoot, where it lies in a torpid state till the next spring, except in some instances, when wheat is sown early, the fly commences its ravages in the fall; when this is discovered, the best method is to turn sheep upon it, and pasture it short in the fall and winter. The most effectual way to check their propagation, is in preparing the seed before sown, which should be in the following manner: Put your seed into a hogs-head, tub or vat, and cover it with water; let it stand about ten or twelve hours, then pour off the water, put the wheat upon a barn floor, and sprinkle lime over it, and with a shovel mix it all it is well covered with lime; let it remain in that state twenty-four hours, and the eggs will be destroyed without any injury to the seed. The following brief sketch of the obser-

which led to the discovery above-mentioned is given, that all who wish to be satisfied of the truth of it, may have ocular demonstration of the fact, if they will take the trouble. On viewing several grains of wheat in a microscope, something resembling the eggs of insects was observed upon them: twenty grains were selected with those appearances; they were put upon some raw cotton and a little earth, in a tumbler of water, and observed every day, and on the day the grain opened and put forth its tender fibre, the insect burst from its shell and was not to be seen. Ten days after, five of the grains, with their roots and blades, were taken from the glass and carefully examined; in three of them the insects were found; the other fifteen remained, and overspread the top of the glass—they were preserved till spring, when on examining them, every stalk had an insect in it, some had two, and one four. Twenty other grains were selected, and the lime applied for twelve hours; it was then washed, and the colour of the eggs was changed; and being put into a glass in like manner as the other, the wheat grew, but the eggs did not produce—the roots were transplanted and grew well. And ten bushels of wheat limed as above, produced a good crop, while the neighbouring fields suffered materially, and some were almost wholly destroyed by the fly.

A FARMER.

From the Federal Republican.

A writer in your paper of the 23d, asserts that late sowing, say "after the first frost," is a certain security for wheat against the Hessian Fly. He is unhappily deceived; and, that his unqualified assertion may not mislead others, I communicate, for public use, this fact—that I sowed my wheat (not five miles from Baltimore) late in October last year; it is now very much infested by the fly, and has a sickly appearance. Contrary, perhaps, to good farming, I sowed on a clover and blue grass sod. The field was also plastered early this spring, about a bushel to the acre.

The writer of this is of opinion, that the best security, under Providence, for a full crop, is to sow in rich land. Five acres well manured, are worth more than twenty of "pretty good land."

A BALTIMORE FARMER.

FROM THE NATIONAL INTELLIGENCER.

Buckland, Va. May 10, 1817.

Messrs. Gales and Seaton,

The ravages of the Hessian Fly, of which we have so general accounts this season, are certainly a subject of melancholy concern. As far as I have been able to learn, in all the counties of Virginia where the growth of wheat is sufficiently advanced to produce the discovery of the visitation of this insect, it has invariably appeared. And I now very much lament that some of my neighbours, or myself, did not, last year, give publicity to the facts on the subject, which for several years have been known to us, and of which the present year affords additional evidence.

About five years ago, a kind of wheat was introduced into this neighborhood, which has been found, by invariable experience, to resist the fly. It was brought here by James Lawler, in a small quantity in his saddle-bags, from Chester county, Pennsylvania, where he had been on a visit to his friends. He stated, that it was there called Jones's White Wheat, and had never been infected with the fly. From this circumstance considerable attention was paid to the propagation of it. The second year after it had been cultivated in this neighborhood, I was so fortunate as to get five bushels of it; I sowed it on

one side of the field of about 120 acres, the balance of the field in the golden beard; there was no difference in the soil, and the Lawler wheat produced eleven for one, while the other did not exceed three for one. The fly that year was very fatal, and the golden beard, which was sowed much more thick than the other, became, after the commencement of spring, thin and scattering, and continued to decline in prospect; much of that which had survived falling till it was harvested, while the Lawler wheat grew to a fine height, and was without any fly in it.

I sowed the succeeding year my product of fifty-five bushels, and twenty more, which I obtained by giving four bushels for one. I sowed that year 270 bushels of different kinds, and made as much from the seventy-five of Lawler wheat as from all the rest, for that was also a fatal year to the general crops, from the ravages of the fly. I afterwards sowed my whole crop of the Lawler wheat; but the last fall, being lulled into a false security, from the circumstance of the fly not having made its appearance the preceding season, I sowed a portion again of the bearded wheat, in order to divide, for convenience, the time of the harvest coming in, as the Lawler wheat comes later than any, except the old yellow bearded wheat generally in use some years ago, and is about as late as that. But this year has again more fatally testified to the value of the Lawler wheat. I have almost wholly lost my seeding of the golden beard, while the other has continued to grow in proportion to the benignity of the season, and has a perfectly healthful appearance, without the trace of any fly; while in that adjoining it, of a different kind, you may immediately see deposited in the stalk, six, eight, or ten of the embryo. Among my neighbours, as far as I have learned of the state of their crops, the same result has occurred. The Lawler wheat is invariably exempt from fly, and every other kind is invariably destroyed.

Experiments were, in the first three or four successive years after its introduction, made of its efficacy, with the most satisfactory success. I will only mention one:—Mr. John Brown, in the fall of 1814, sowed equal quantities of the purple straw and Lawler mixed; the fly commenced its depredations as usual in the spring, and by harvest scarcely a straw of the purple wheat was left, while the Lawler remained alone, and apparently uninjured.

Of this valuable wheat much was this year ground, the anxiety to get of the seed having subsided, from the favourableness of the last season. At some other time it may be proper to assign the reason of this extraordinary exemption, if indeed they can be satisfactorily traced, (of which there is much doubt,) if not, we must content ourselves with the utility of knowing the fact.

To those who cultivate it, my experience would lead to the recommendation of sowing it thicker than usual, although it branches more than is common, and of plastering it in broad cast early in the spring, in preference to any other mode, both as means of sustaining its maturity, and enhancing its increase, it being a late wheat and of tall growth.

A SUBSCRIBER.

From the Federal Gazette.

SIR,—I have promised more than once, to send you an account of the mode which is successfully practised in England by all good farmers, of preparing seed wheat, with the view of preventing the disease called smut. I now beg leave to trouble you with the fulfilment of that promise.

I call upon all farmers, by every motive of

public and private interest, to attend to it, and put it into practice. It may not be improper if I make a few preliminary observations. The nature of smut is well enough known to practical men, but to others it may not; the ear, instead of being filled with sound grains of wheat, is filled with little black balls, which being broken betwixt the finger and thumb, yield a most disagreeable smell, unlike any thing that I know of in nature. The powder of these balls, which get broken in the operation of threshing out the wheat, is supposed, and I believe truly supposed, to impregnate or inoculate the sound grains, and thus the evil is propagated and extended. The preparation of the seed is intended to destroy the inoculating power of the infectious black powder of the smut balls. A number of expedients have been tried with this view, and none, I believe, has been found so effectual as that which I will presently describe. What the true history of this remedy is I cannot answer for, but have often heard the following anecdote:

That a ship laden with wheat happened to be sunk in the channel; that some of the cargo was got up, and though damaged so as to be unfit for the mill, some one thought it might possibly do for seed if sown immediately, and accordingly some of it was sown. It was remarked the following year with surprise, that the crop from this wheat was free from smut, in a neighbourhood where smut abounded all around, and it was obvious to conclude, that it was owing to the seed having been steeped in sea water. Whether this was the origin of steeping in brine, I cannot tell, nor is it material now; it has become the almost universal and invariable practice with good farmers in England, to steep their seed-wheat in brine. The following decisive experiment was also made to ascertain the efficacy or non-efficacy of brining:—Some clean wheat was sown dry, (not brined) and some of the produce of this the following year, also dry, and so continued for five years, the smut gained ground every year, and the fifth year it was nearly one third smut; this smutty produce was then brined and sown, and the brining applied every year for five years in succession, and the disorder was completely cured by it, so that the sample was as clean and good the tenth year, as it was the first. This experiment seems to be complete and decisive, and corresponds entirely with my own experience.

I come now to describe the manner of proceeding in making the brine, and also of using it, and of preparing the seed for the field.

1st. As much salt is to be put to water as will make it strong enough to swim a new laid egg, bold and well up. [I did not attend to this, but put as much salt as the water would dissolve.]

2d. The wheat must be steeped in this brine at least twelve hours.

3. It is then to be put on a clean floor, and hot slacked lime sifted over it, sufficient to separate the grains of wheat; and candy, as it were, every grain with a coat of lime: to do this, it must be well turned, and stirred with an iron shovel; in this state it is to be taken immediately to the field, sown, and harrowed in; or if early in the season it is sometimes ploughed in.

OBSERVATIONS

The most convenient practical manner of performing the operation of brining is as follows:—Procure a tub of any sort that will hold as much wheat as is likely to be wanted for any one day's sowing, as 4, 6, 8, or 10 bushels; mount this tub upon a stand, so that the brine may be drawn off by a spigot and faucet into another tub below; then put your wheat into the upper tub at six or seven o'clock on the morning of the day before you intend to sow it; the brine having been pre-

ously prepared in the lower tub, is to be ladled up into the upper tub upon the wheat, till it is quite covered an inch or two; let it stand in this state all day, and at night, the last thing before going to bed, take out the spigot and let the brine draw off all night into the lower tub, (by this means the brine will not be unnecessarily wasted;) the next morning the wheat must be taken out, and limed with the hot slaked lime as before described. Flour barrels with one end up, are very convenient to carry the seed to the field.

Before putting the wheat into the upper tub, collect to place a wisp of straw on the mouth of the faucet to keep back the wheat when the brine is let off.

Observe, the *time* is every thing in this operation. I have heard many assert, that brining was of no avail; that they had tried it, and found it fail. But I always found, upon strict inquiry, in every instance of this sort, that the operation was imperfectly done, and chiefly with regard to time. Farmers will do well to see to this operation themselves.

As this is the season for sowing turnips, I will here give a method of preventing (at least in a small degree), the ravages of a fly called the turnip fly. Wet the turnip-seed with *linseed oil*, stirring it till all is wet, then add as much flour of brimstone as will completely separate the seed, and coat it over. As the first leaves of the plant are formed by the opening of the seed itself, and as the injury is chiefly done by the fly on the seminal leaves, the brimstone and oil will defend them from attack till the rough leaves are thrown out, and the plant escapes.

I am sir, &c.

S. B.

Light-street.

FOR THE AMERICAN FARMER.

PLANTATION OF TIMBER.

MR. SKINNER,

Having lost my mother at an early age, I was left to her parents, to receive that care which a beloved father could not bestow on my infancy; and being in the vicinity of the Valley Forge, in Chester county, I witnessed the destruction of the timber of that estate, and of several adjoining ones, by the continental army huddled there in the winter of 1777. Every tree was cut down, and all the fence rails taken, to shelter and warm those heroes, who, though unable to prevent Sir William Howe from entering Philadelphia, were willing to brave the inclemency of a winter season, badly clad and badly fed, to keep him prisoner there; so that the proprietors, unable to enclose their grounds immediately afterwards, and scarcely able to purchase fuel, considered themselves utterly ruined. The effect of their complaints remained impressed on my mind, until I went to Europe in 1791, and induced me, while there, to make particular enquiries how these old countries obtained continual supplies of an article so indispensable for domestic and manufacturing purposes.

I learned with astonishment, that there was not probably one single tree in England or France, that had grown from the stump of another tree, which had been planted by the hand of man; or was itself one of those identical monuments of human industry, patience and foresight, in planting.

The planting of chesnuts, and most other tree trees, was as familiar to many, as the planting of corn with us; and except the aquatics, which are grown from cuttings mostly, and the evergreens, whose little seed are put in beds of sand, and replanted, is preserved very much in the same way, both objects requiring a preparation

and protection well known to farmers. Of these, however, I have given some details to the Agricultural Society of this State, from a translation of a French treatise, and which they may one day give to the public. The want of timber will not be so much felt in the United States, whilst the increased population is spreading over the immense forests of the west, as to require a knowledge of the science; except as concerns those who are proprietors of grounds on the borders of fresh water streams, which render the clearing unhealthy; or others, who have cleared, hilly, broken or stony grounds, fit for timber, and fit for nothing else. But the science of cutting to grow again, if it may be called a *science*, should be known to every farmer, planter or proprietor, because the weight and value of the article will not allow of much transportation; and the advantage of a second growth *on the spot* is superior to trees already grown at a distance, if all had means to spare to procure them. There is nothing mysterious, or difficult, or costly, in procuring the second growth of trees of the common kind, and in greater quantities than the first growth, as the experience of every iron-master in the country has shown; and indeed, those very farmers about the Valley Forge, who had witnessed the cutting of the timber by the owner of that estate for years, and who were so much alarmed at their situation and prospects in 1778, were, on my return in 1799, abundantly supplied by wood of second growth, and as rich and contented as ever. Patience they found of necessity; observation of what had passed so completely under their eyes, was all that was wanted.

What is most essential here now, perhaps, is a disposition to look to futurity—to PROVIDE IN TIME; but, I will add, from what I learned and saw abroad,

1. That the felling of trees is confined to the winter season; or rather, to that time in which the sap is under ground.
2. That every tree, young and old, on a certain space, is cut in the same season, for old dead stumps do not re-produce.
3. That they are cut as smooth and level with the ground as possible; and
4. That, while young, they are kept from the browsing of cattle.

Your very obedient servant,

THOMAS W. GRIFFITH.

Baltimore, July 11, 1823.

From the Massachusetts Agricultural Journal.
ON RAISING THE OAK FROM THE ACORN, AND THE BEST MODE OF DOING IT.

[By the Editors.]

It is very extraordinary, that, notwithstanding the Massachusetts Agricultural Society has for thirty years offered great premiums for the culture of the oak in plantations, and especially since the legislature enjoined it upon the several agricultural societies throughout the state, to offer premiums for the raising of forest trees, but two claims should have been made. We can only account for it on one of the following grounds; either that the premium has not attracted the attention of our farmers, or that they have not sufficient spirit and enterprise, or that they are averse from any new culture, however important and reasonable. We shall take the article of White Oaks, which were selected by our society, as being the most valuable timber of the Northern States.

The premium offered in 1822, for one acre planted with white oaks, and found to be in the best state in September 1823, (that is, at eighteen months old,) was 100 dollars per acre. The average price of good land throughout the state

does not exceed twenty dollars per acre. The expense of raising seedlings of eighteen months old would not exceed twenty dollars more, if the following account be correct; indeed, we believe it would not exceed ten dollars, as we can see no reason why the expense of planting an acre of acorns should exceed the expense of planting an acre of corn. There would be left then, of clear profit to the raiser of an acre of oaks a profit of sixty dollars at least for two years culture, and as is remarked in the following article, a crop of grain may be raised at the same time sufficient to pay the whole expense. Have we no man in the state who is spirited enough to set the example, and carry away the honour and profit? The acre of oaks will *afterwards be his*, and there is no mode in which he could employ his land to so great advantage. It will not surely be said, that our farmers *cannot spare any of their land*, when our great error consists in holding more than we can, or do cultivate well.

On the mode of raising the Oak, "from Hunter's Notes on Evelyn's Sylva."

"Having the ground properly prepared, by breaking it up and reducing it to a fine tilth, either by potatoes or repeated ploughings, and having a sufficient quantity of acorns, all gathered from the most vigorous, healthy, and thriving trees, proceed to the setting them in the following manner. In the month of February or March [but in this country we say *from experience*, the months of November or December, if the latter month be open.] let lines be drawn across the ground for the rows, at the distance of four feet from each other; but if this be thought too great an interval, the rows may be made three feet, in which case the acorns must be put down at a greater distance from each other. Then having sticks properly rounded to make the holes, [a common dibble] plant the acorns in rows at ten inches asunder. Let them be put down about two inches below the surface, and see that the earth be properly closed upon them to prevent mice or crows from injuring the seed. In some places it is customary to sow the acorns after the plough in furrows; but where the ground happens to be stiff, great care should be taken not to cover the seed with too thick a furrow.

"The first year after planting the acorns, the weeds must be kept down by hoeing and hand-weeding; and this must be done early in the spring, before the weeds get so strong as to hide the tender plants, which would occasion many of them to be destroyed in cleaning. It is also the cheapest, as well as neatest husbandry, to take weeds down, before they grow too large; for though the ground may require an additional hoeing in spring, yet the weeds being hoed down when young, a man may hoe over a great quantity of ground in a day. Weeds cut in their tender state immediately die; whereas, when they are old and strong, they frequently grow again, especially if rain falls soon after, they perfect their seeds in a short time, and thereby injure the whole plantation.

"The second year of their growth, the common plough may be made use of, to cultivate and keep the ground clean. [Or potatoes might be raised between the rows, if proper care be taken not to trample on the plants.—Editors.]

As these acorns sometimes fail, the author proposes a nursery in the same field, to supply the deficiencies.

"Having then given directions for the raising of wood, I proceed," says the author, "to their future management. And first, the rows being four feet asunder, and the plants two feet apart in the rows, they may stand in this manner for

twelve or fourteen years, when every second plant may be taken out, and sold for hoops or poles. After every second plant is taken away, let the roots of those taken away be grubbed up, to give the remaining plants more room freely to extend their roots. The plants being now four feet apart each way, they will require no more thinning for seven or eight years, that is, till they are twenty years old, when the healthiest and most thriving trees must be marked to stand for timber, and the others cut down for poles, and their roots left to produce future underwood.

"The oak will grow and thrive in almost any soil, if properly planted, though it cannot be supposed that their success will be equal in all places. A rich, deep, loamy soil, is what oaks most delight in, though they will grow exceedingly well in clays of all kinds; and in sandy soils, in which last, the finest grained timber is produced."

The author then proceeds to inquire, which of the different modes of raising oaks produces the best timber, from the acorn, the seed-bed, or the nursery. Mr. Evelyn decides in favour of *planting the acorn*, and Mr. Hunter adds, that whoever will look at the woods which were *sown*, and compare them with those which were *planted from nurseries*, will not hesitate a moment to declare in favour of Evelyn's opinion.

What are the obstacles to our following this excellent example of the great farmers of England, in the age in which our ancestors emigrated? Is it because we are too impatient, and unwilling to await so tardy a return? Yet there are constant pleasures in the annual growth of our forests; they seem to be the work of our own hands, at least of our own providence and care. They are subject to fewer hazards, and their profit is certainly greater than that of any other employment of capital on land. Or is this aversion to planting the effect of an hereditary prejudice against trees? Our ancestors found their *extirpation* their greatest labour; and do we continue to feel their prejudice, when woodland is far the most valuable, and most constantly increase in its comparative value?

WATER PONDS FOR THE USE OF CATTLE AND FOR OTHER PURPOSES.

Our attention has been invited by several judicious correspondents, to the consideration of the means of accumulating, and of economically using and applying WATER—for all the various purposes for which it can be wanting on a farm.—The necessity of the case is, in fact, forced upon public attention, by the great change which has of late years taken place in our seasons—to such a degree is this change felt—perhaps more especially in limestone districts of country, that it has really become an object of pressing importance to husband *rain water* for the sustenance of live stock, if not for common culinary purposes.

In contemplating this item of rural economy, a wide field is spread before us, requiring no less than a knowledge of the laws of Hydrostatics to an extent beyond our limited acquirements.—In the feebleness of our own lights, we must then borrow from the labors of others—we do not know to what extent we may be led, but we shall endeavour to select for our readers, such views and facts, as appear to be of *practical utility*, beginning as we now do, with remarks on the construction of DRINKING PONDS for cattle.

Edit. Am. Far.

The management of the water of ponds is often very troublesome and inconvenient in the time of heavy rains or floods, from the want of proper means of contrivance for letting it off. The following is the sketch of a very easy, convenient, and effectual method of discharging the over abun-

dant water from all sorts of ponds, basins, and reservoirs, without the necessity of attending to them at such seasons. It is the invention of Mr. Ley, a very ingenious clergyman in the county of Devon, in the agricultural report of which it is described. The plan of it is represented at *fig. 6*, Rees' Encyclopedia, article *Ponds*; in which A is the head of the pond; B, a beam of wood, suspended by an iron pin on the block W, so as to form a sort of lever, or balance, having attached to one end of it the box C, which is made so as to be rather leaky, and to the other the plug D, which when the water of the feeding stream, or from rains, rises to the level of the surface of the pond F, is conveyed through the trunk or gutter, X Z, into the box C, by the weight of which the plug is drawn out, and the water carried off by the trunk E, at the bottom of the pond, as seen by the letter G. On account of the box, C, being so constructed as to let out the water very slowly, by the time the whole of the water has been discharged from the pond, basin, or reservoir, it will likewise have escaped from it, when, by the weight of the beam and plug, the empty box is raised, and the plug again placed in the trunk in its former situation.

It is evident that, from this ready method of getting quit of the water, no mischief can ever be sustained by its sudden rising and overflowing the banks of the ponds or other excavations; accidents which, under other circumstances, not unfrequently happens, to the great inconvenience and injury of those to whom they belong.

The importance and necessity of water, in all pastures, is self-evident; as cattle cannot live without it, and the driving of them far for it, is known to be prejudicial to their health, in hot weather, besides being attended with great trouble and a considerable loss of time. This is so sensibly felt in many parts that people are obliged to dig wells, even to such a depth as frequently to require the assistance of a horse to draw up the water. The means of rendering it easily come at, must therefore enhance the value of the land where it can be procured, and are of very essential consequence to the husbandman.

Where the surface of the ground is sand or gravel, there seldom is occasion to dig deep for water; because such soils generally lie upon marle or some other rich earth through which the water cannot descend. Beds of clay are most commonly thicker than those of sand or gravel; and chalk is, often, the thickest of all. But wherever water is wanting the farmer should bore through the incumbent earth, if he intends to fit his land for pasture; and if he finds the expense of obtaining it too great, his best way will be to convert the ground so circumstanced into arable, or to plant it with timber trees suited to the nature of the soil.

Various indications of the presence of water below the surface of lands have been suggested by the ancient writers on husbandry; such as the

spontaneous growth of different aquatic plants vapours near the surface, &c. but the best mode of ascertaining it is by boring: and about the latter end of August, when the ground begins to be a little moist, is probably the most proper season for the purpose.

But in whatever method water is found, the means of coming easily at it are the next consideration. If it be on a plain, there is no other way than digging a well. In doing this, the substance under the sand or light soil must be dug into, to form a reservoir of water for occasional wants; and this reservoir should be made deep and large in proportion to the quantity wanted. If there were no such reservoir, the water, after having risen a little above the impervious body underneath, would glide along its surface, as usual, and very little of it then could be obtained, either by pumps, buckets or any other way employed to raise it. If the well is made in a sloping ground, and the declivity is sufficient to give it an horizontal vent, it will be worth the husbandman's while to dig such a passage, and by means of pipes, or any other conveyance, to carry the water across the light soil, through which it would otherwise sink: the greatest quantity of water will be obtained in this manner, because there will then be a continual stream.

If the soil is very deep, and its surface has inequalities into which rain water runs in any quantity; this may be collected in ponds made in the lowest parts of such ground.

If a body of clay is found near the surface, it is worth the farmer's while to bore, that he may know at what depth a bed of sand or gravel may be met with; for he will be sure to find plenty of water in this last. If this be in a declivity, he need only cut an horizontal passage, and the water will flow so freely, as even to double the value of his land.

Here again the farmer needs not ever to be at a loss, because it cannot be very difficult to make a pond in a clayey soil, which is, of itself, retentive of water. But it may perhaps be advisable, even in this, to cover the bottom of the pond with a coat of gravel, in order to prevent its being poached by cattle, whose feet would otherwise be apt to sink deep into the clay. Some farmers judiciously pave the declivity by which the cattle enter into the pond, and this renders it much more lasting than it would otherwise be, and preserves the water clean.

When ponds are made in a loose soil, much more care is necessary. The bottom and sides must be covered with a thick coat of the toughest clay, from a foot to two feet thick, well rammed down. Some have added hair and loam to the outer part of this covering, with a view of rendering it less liable to chap: but a thick coat of gravel is more necessary here, that the feet of the cattle may not pierce through the clay. Perhaps the expense of paving the whole inside of a pond might, in the end, be money well laid out.

The greatest difficulty in finding water is in chalky soils, because they are not, in themselves very retentive of it, and generally lie in such thick beds, that it is expensive to dig through them. However, it should be tried; and if sand or gravel be found underneath, water may be depended upon. Even here, ponds are easily made by digging into the chalk, and lining them with a coat of clay, as before directed. If there is a supply of proper manure, such as clay, or marle, the situation is well adapted to grain, which loves to stand dry; and as this kind of ground produces more forward crops than clayey or strong soil, it may be sowed early with corn, which will not in that case, be so apt to be parched up as grain is, by the summer's drought. If a good soil can be made here a foot deep, it will yield plenty of

various sorts of pasture, either roots or grasses, as the farmer shall judge most proper; or it may be planted with different kinds of timber-trees.

The following method of constructing ponds has been proposed in the sixth volume of the Annals of Agriculture for the Yorkshire wold land, which is a dry tract of country, in order at all times, and in all situations, to supply water sufficient for the numerous flocks of sheep, and other cattle, kept upon it, and sufficiently good in quality for domestic purposes.

It is observed that, about twelve or fifteen years ago, a man by profession a well-sinker, first discovered the method of making these ponds; within this period the number of them has been so increased, that scarce a sheep-walk, or even field, is now without one; and the use of them is creeping into the neighbouring country. In situations where water could not be otherwise had: so general and sudden an adoption is suffi-

CONSTRUCTION OF PONDS.

Fig. 1.

The plan "is shewn at fig. 1, in plate XLX, in The Complete Farmer's Dictionary of Agriculture and Husbandry, in which the line A marks a circular hole dug in the ground of the size required, which upon a layer of clay B, sufficiently moistened, is to be carefully beaten and trod down into a compact and solid body of about the thickness of a foot.

Upon this C is a layer of quick lime finely and uniformly spread over the whole, of one inch or upwards in thickness.

D is another layer of clay of about one foot in thickness, which is to be trodden and ramm'd down as the former; upon this are spread stones or coarse gravel E of such thickness as may prevent the pond receiving any injury from the treading of cattle, who would otherwise break through the body of the clay and lime, and by so doing let out the water; after this, according to the section, the pond will remain five feet deep and forty five feet diameter; the size they are usually made, F being the line of the water and of the ground.

Brick-clay is by no means required for the ponds; any earth sufficiently tenacious to bear being into a solid compact body, though not approaching to a pure clay, will answer the purpose very well.

It is usual, where there is an opportunity, to make the pond in a little valley, or at the bottom of a declivity, or near a high road, in which situation a stream of water may be brought into it after sudden showers or thaws, the object being to get it filled as soon as possible after it is made, but the sun and winds may not crack the clay; it is not likely to be filled soon, some straw or other must be spread over it; but in general, after it is once filled, the rains that fall in the course of the year will keep it full, no water being lost otherwise than by evaporation and the consumption of cattle.

A pond of this size is usually made for from £4 to £6, exclusive of the time, and expense of the carriage of the clay, when that is necessary; the first varies in price in different counties, the second will depend upon the distance.

It is to be remembered that the whole excellence of the pond depends upon the lime; care must be taken to spread it regularly and uniformly over the surface of the lower bed of the clay;

cient proof of their utility; before this period many sheep-walks were entirely destitute of water; it is, however, worthy of remark, that most of those sheep which have now a constant supply of water, are by many intelligent persons, thought, from that circumstance only, to be considerably improved; whether, however, this opinion is well founded, he cannot, from his own experience assert, not having had the opportunity to make the necessary observations; but it does not admit of a doubt, that in very dry weather, much fewer sheep die than formerly; this, in several instances, was fully proved during the uncommon drought of a late summer, where the loss among sheep which had not this resource, was very great, while that among others of the same kind, and in similar situations, which did not labour under that want was very trifling; perhaps not greater than would have taken place in any other space of time."

It is well known that ponds made with clay alone, however good its quality, and whatever care may be exerted in the execution, will frequently not hold water; these with the above precautions rarely fail. Never having seen a pond dug up after it had been made some time, he cannot say by what means the lime prevents the loss of water; one of these two is probably the cause; either the lime sets like terrace into a body impervious to water; or what he should rather think, the causticity of the lime prevents the worms in dry weather from penetrating through the clay in search of the water; certain, however, it is, that with lime, thus applied, ponds may be made in sand, however porous, or on rocks however open, in neither of which situations are they to be depended upon when made with clay alone."

(To be continued.)

FROM THE BERKSHIRE STAR.

July, 1821.

There is obviously no means by which the interests of Berkshire, can be so essentially advanced, as the promotion of measures tending to increase, diversify, and improve the productive powers of human industry. It is, therefore, with a view to draw the public attention to this subject, and to lead to an investigation of it, combined with the hope of enlisting the abilities and talents this county possesses in developing a system that shall give energy and action to our resources, that the writer of these articles is induced from time to time to contribute his feeble efforts, towards the advancement of this interesting subject.

Influenced by these motives, a few remarks will now be offered on the following subjects, namely:

1st. Ploughing.
2d. Collecting and diffusing agricultural information.

3d. Education, (as requisite for farmers, as for professional men.)

And 4thly. The necessity of union and concert of the agricultural interest.

The various benefits arising from good tillage, cannot be too strongly inculcated; when it is imperfect, there can be no good or complete husbandry, and it cannot be perfect, but by the union of good ploughs, and skill in the art of using them.

Since the establishment of agricultural societies, this important branch of rural economy has become a subject of considerable investigation.

In respect to the plough, very interesting improvements have been made in various parts of our country; much, however, remains to be done: and as it too frequently happens that obstacles are thrown in the way of ingenious men, by local prejudices and habits, we would suggest it as a remark, applicable in a special manner to the plough, that success and present benefit may be obtained by adopting the general construction of the ploughs in common use; altering the proportions, and giving the operative parts, the requisite cast. Those, also, who project improvements, whether it be in ploughs or any other implement of husbandry, will do well to bear in mind the importance, 1st, of simplicity and strength of construction, so as not to be liable to get out of order, and that when repairs are necessary, they may be done by any common workman. And 2dly, of reasonable prices; that every one can afford to purchase them.

In respect to ploughing, every effort should be made to extend a practical knowledge of the art; no plan, perhaps, can be found more effectual for that purpose, than that of establishing a competition by ploughing matches, with rewards to those who excel in good workmanship. The utility of their meetings begins to be generally admitted, in those places where they have been introduced. It is desirable they were more general, and that annual ploughing matches were established in every county town. They would not only tend to afford and to disseminate instruction, to remove prejudice, and ameliorate our breed of working cattle, but they would offer rural and rational amusement worthy of the American farmer.

Agricultural societies, although of recent date, have produced the happiest effects by the spirit of enquiry and emulation they have excited, and the knowledge they have been the means of circulating. But their efforts to be extensively useful, and fully successful, must be seconded by the zeal, liberality and good sense of the public; combined with a willingness on the part of practical agriculturists, to contribute to the general fund of useful knowledge, from the stores of their individual experience, and observation. Extensive good can only be achieved by united efforts.

With a view to attain this great desideratum it is proposed to institute FARMER'S CLUBS, to consist of practical farmers only, in each town in the county.

These associations would, in my opinion, combine the means, and energy necessary, to give complete success to the zealous and laudable efforts of the agricultural societies; by the facilities they would afford for inquiring into, and comparing the different practices at home, and abroad; for practical investigation of the merits of systems and inventions; and for an effectual circulation of useful information. In the course of friendly and familiar conversation, useful observations are made, new facts are stated, errors discovered, and practical knowledge derived from experience is elicited, which otherwise might have lain dormant, or remained confined for years to an individual, or small district.

Such institutions could not only cherish and keep alive a laudable zeal for the improvement of the great and fundamental source of national prosperity, but would in their operation have a tendency to illustrate the important truth that "there is no science in which so great a variety of knowledge is necessary, as in that of agriculture."

This truth once admitted, it would become fashionable for parents to educate some of their sons for, and bring them up to the profession of farmers. The existing propensity to inundate our country with lawyers, doctors, and shop keepers, would sensibly decrease; thus increasing the productive classes, the produce of our soil and our industry would augment, as pettifoggery, quackery, and the means of vending foreign manufactures would diminish.

Another, and very important effect of these institutions would be, to cause farmers to think more of themselves individually, and collectively, as well as of the importance of their profession, than they now do.

The commercial, manufacturing, and professional classes, have each their associations, and organized systems, for the collection and diffusion of useful knowledge in their several callings, as well as for the maintenance of their respective interests and rights. While the farmers, (the most valuable body in society, and in point of numbers and productiveness, greatly superior to all the other classes in the community,) are insulated from each other; and being without union or concert, they voluntarily deprive themselves of that collective influence which of right belongs to them.

Merchants have their chambers of commerce, manufacturers their committees, professional men their societies and bar meetings;—it is very desirable that farmers should, at length, "look to their interests," and institute clubs.

SINCLAIR.

AGRICULTURAL PRODUCTS AND PROSPECTS.

EXTRACT TO THE EDITOR.

Dear Sir, Wheatland, July 13, 1823.

I had the pleasure to receive your favor of the 9th current, yesterday; and thank you for this renewed instance of friendly attention to my requests.

Our Grain Harvest is now nearly completed, and we are enabled to form a more accurate estimate of the results than heretofore; and it gives me great pleasure to inform you that the general crop very far exceeds the expectations of the most sanguine calculation.—In some instances, the crop is as heavy as I have ever seen—in most I think it may be estimated at nearly an average—while in others, the yield has been only meagre, and some fields have wholly failed.—These results are pretty much produced by the standard of fertility and cultivation; but the fluctuation of our prospects during the progression of the season, was truly remarkable, and without example—at first the promise was extremely flattering; during May and the early part of June, it became very alarming, and almost hopeless—after which period resuscitation was miraculous, which is ascribable, I think, to the original strength and vigour of the root, and the occurrences of the most propitious seasons. Our fields of young clover exhibit the most splendid appearance, and the growth of volunteer clover is superior to that which we have been able to produce for some years past, by the most skilful and careful cultivation. Our corn, millet, &c. present the most satisfactory promise. and, in fine, there is a probability of the present year being far more prolific in the aggregate of agricultural products, than any which has been experienced for a long time. Having given you this general account of our crops, since you have been so kind, my dear sir, as to express a solicitude about mine in particular, I have the satisfaction to say that it is very good, indeed nearly double what I at one time expected. My wheat and

eye will be between five and six thousand bushels, and the various other products of the farm promise extremely well.

Your's, my dear sir,
With sincere regard and esteem,
H. S. TURNER.

FROM THE GENIUS OF LIBERTY.

Mr. Patton—Please give the following a place in your next paper, as it is now time to use it.—I have for more than twenty years past, kept meat hanging up in my smokehouse, through the summer season and no fly, worm or bug has injured it.

To prevent such injury, about this time of year, I take clear strong ley made of wood ashes. I commonly boil it to make it stronger than it generally runs off, then I take my bacon and smoked beef, having two or three gallons of the ley in a large iron kettle, I take each piece of meat and dip it into the ley, so that it is completely wetted with it, then I let it dry—then I hang the meat in its former place. By this process I have invariably found that it kept the meat free from bugs and worms, and no taste of ley is ever perceived, not even on the outside. Yours, &c.

JOHN POTTER.

To prevent Moulding in Books, Ink, Paste and Leather.—Collectors of Books will not be sorry to learn that a few drops of Oil of Lavender will insure their libraries from this pest. A single drop of the same oil, will prevent a pint of ink from mouldiness for any length of time. Paste may be kept from mould entirely by the same addition; and leather is also effectually secured from injury by the same agency.

GRAPES—ANSWER TO MR. GIBBS.

SIR, July 18th, 1823.

If your correspondent, Mr. Gibbs, will procure some coarse brown wrapping paper, and have bags made so as to admit of the growth of the bunch to its full size, and put them on when the grape is about the size of a pea, I think he will find it to answer the purpose desired.

The cause, as far as my experience goes, proceeds from dampness, either from heavy dews, or showers of rain, and the sun shining out with great heat before the moisture has had time to evaporate, the grape is scalded, which causes it to rot, and afterwards dry up. It is also necessary to keep the ground perfectly free from weeds or any vegetable production, to promote a free circulation of air, which is of great advantage. There is, also, another advantage attending the bags, they are generally taken possession of by one or more spiders, which effectually prevents the entrance of every other insect, which, without that protection, frequently destroy the finest bunches. When the fruit is gathered, the bags may be kept, as they will answer very well for another season. If Mr. G. is successful on making the above experiment, (of which I make no doubt he will) it would give great satisfaction if the result was communicated through the medium of your very useful paper, as I have always taken a great interest in the cultivation of the grape. A Cultivator of the Vine.

THE FARMER.

BALTIMORE, FRIDAY, JULY 25, 1823.

BALTIMORE MARKET.

PRICES CURRENT.—CORRECTED WEEKLY.

Flour, best white wheat, \$8—Howard street Superfine, \$7 25—fine do. \$6 75—Wharf, do. \$6 75—New wheat, \$1 25 to 1 27—Red do. \$1 42 to \$1 43—Rye, 75 cents—Corn, 50 to 52 cents—country Oats, 40 cents—Beef, 8 cts. per lb.—Live Cattle, \$6 to \$6 50 per cwt.—Bacon, round, 8 to 9 cents per lb.—Pork, \$4 50 to \$5 50 per c. lb.—5 to 8 cts. per pound—Mutton, 6 to 6 cts. per lb.—Beans, \$1 37 1/2 to 1 50—Peas, black eyed, 55 to 60 cts.—Red Clover Seed, \$5 50 a \$6—Orchard Grass do. \$3—Herds' Grass do. \$2—Timothy do. \$4 50—Millet, none—Buckwheat, none—Flax Seed, 75 to 80 cts.—Whiskey, from the wagons 36 cts. per gal. including the barrel—Apple brandy, 30 to 32 cts.—Peach do. 65 to 70 cts.—Shad, \$6 50, scarce—Herrings No. 1, \$2 75 per bbl.—No. 2, \$2 50—Fine do. 60 to 65 cts. per bush.—Coarse, do. 70—Butter (firkin) 14 cts. per lb.—Eggs, 16 cts. per doz.—New Hay, \$14 per ton—Straw, \$8.

MARYLAND TOBACCO.—One hhd. made by Elkannah Waters, sold for 14 50—no material change in prices since last notice.

Internal Improvement.

ON THE PARAMOUNT IMPORTANCE,
TO MARYLAND, OF A CANAL TO THE
SUSQUEHANNA.

No. IX.

To whatever extent the agency of an intriguing, or log-rolling policy is required in the support of an object, we may rest assured, that, all is not right, that the object itself must be destitute of real merit, in an equal proportion.

82. The country up the Potomac has already been stated (16) to contain 10,000 square miles. It has also been characterised (17) by the high authority of a Committee of the Senate of Maryland, as being a country by no means celebrated for its richness and fertility. By the same authority it is also stated (17) that *were the Potomac improved to the utmost possible extent, its trade must be considered but of minor importance, when compared with that of the Susquehanna.* But it is by no means my intention to avail myself of this evidence for the purpose of undervaluing the Potomac or any one of its appendages. On the contrary, I have stated (78) that I was, *not only entirely willing but sincerely desirous for all the facilities, all the capacities of the Potomac to be duly appreciated and improved.* And such I still maintain to be the fact. But at the same time, let it be recollected, that *no facilities, no cities, however great they may be, can, with propriety, be said to be duly appreciated, if rated above their merit, and that the performance of every enterprise most naturally and correctly belongs to those portions of the community who are most deeply interested in its benefits.*

83. Owing to the double advantage of 30,000 square miles being accommodated with the facilities of a water conveyance, to and from market, by means of 100 miles of Canal, instead of 182 miles, nearly double the distance, being required for only 10,000 square miles, that is, for only one third of the extent of country, the trade of the Susquehanna, at once assumes an attitude of importance to Maryland, surpassing that of the Potomac, in the proportion of between 5 and 6 to one. The annual amount of profits to be divided to the stockholders, from 30,000 square miles of country, such as is described up the Susquehanna, have already been estimated at \$750,000; beside an annual gratuity of 18 millions to the public. At the same rate the annual amount from a country of only 10,000 square miles, such as is described upon the Potomac, ought to be less than \$250,000. Accordingly, it appears that the Potomac Commissioners, pages 38, 39, 40 of their report, have given an estimate in detail, founded on data entirely different from mine, amounting to \$240,000. Hence it is presumed, no patron of the Potomac can, with propriety, object to my estimate, for two reasons: in the first place, it coincides so very nearly with the official amount as to differ from it only one twenty fourth part of the whole, and again, that difference, instead of being opposed to his side of the question, is directly in its favour.

84. The Commissioners' estimate of profit upon \$1,578,954 their estimate of expenditure, is equivalent to 15 per cent. per annum, with an excess of \$3157 yearly, to meet incidental expenses. Agreeably to my general estimate of \$10,000 a mile, \$250,000 on the cost of 182 miles, is nearly 13½ per cent; but admitting the Commissioners' 15 per cent. to be the correct sum to be derived from 10,000 square miles, 45 per cent. must be a sum equally correct to be derived from 30,000, supposing contrary to the evidence, (82) that both countries were equally rich and fertile. But admitting the average cost per mile

of both Canals to be equal, it is evident, that this per cent. to be in proportion to the expenditure, must yet be enlarged in the same proportion that the Susquehanna route is shorter than that of the Potomac; that is, divide the product of the 45 per cent. and the 182 miles, by the 100 miles, and the quotient which is nearly 82, is the per cent. for the Susquehanna trade, that is equivalent to 15 on that of the Potomac. This may justly be considered as proof positive that if the Commissioners' 15 per cent. in favour of the Potomac, is not too high, neither is my 75 per cent. in favour of the Susquehanna too high; but on the contrary, too low, by almost 7 per cent. per annum.

85. It has already been adverted to as a possible event for the Philadelphians by dint of exertion to draw off to their city, perhaps, one third, or at most one half of the Susquehanna trade. But were one third to be thus drawn off, the residue would amount to 50 per cent. per annum to the stockholders, and a gratuity of 12 millions annually to the community; or should it so happen that one half were to be taken, the remaining half would be equal to 37½ per cent. per annum on the stock, and a gratuity of 9 millions to the public; either of which fractions of the Susquehanna trade, even the least, would greatly transcend in importance to Maryland, the whole of the Potomac trade, were it offered, subject to no division whatever. Owing, however, to the proposed Potomac appropriation of \$500,000, being somewhat less than the whole estimated expense, (84) and considering that there are in the District three markets to be supplied, it may, rationally be inferred that it would be deemed *very unreasonable indeed*, for Maryland to expect more than one third of the Potomac trade in return.

86. Thus, then, supposing the situation of Maryland to be equally as advantageous as that of the District, for participating in the benefits of the Potomac, the utmost expectation that could be indulged, even in that case, would be 15 per cent. annually on \$500,000, that is \$75,000, together with a gratuity of two millions annually to the public. The sum of these benefits, that is \$2,075,000, it is true, would appear to be large, were there no opportunity for Maryland to do better with the treasures of the state; but certainly, the amount is but small when compared with a moderate expectation from the Susquehanna, to wit: \$500,000 per annum, that is 50 per cent. upon one million, in addition to a gratuity of 12 millions to the public, being together equivalent to \$12,500,000, that is more than six times the amount presented from the Potomac.

87. But the difference above stated, though very great, does not include the whole difference in favour of the Susquehanna. The Potomac Canal, without its proposed appendages; without a substitute Canal between Baltimore and the mouth of Monocacy, or Harper's Ferry; and the cross cut Canal between Baltimore and Bladensburg, would be directly calculated to operate as a very great injury to Maryland, instead of a benefit. From its local situation, it would naturally intercept and turn to the District a great mass of Western trade, that by means of our turnpikes, would otherwise find its way to the Baltimore market. Without its appendages the Potomac Canal would sweep from Maryland and transfer to the District every dollar of mercantile profit upon all the trade that by means of its facilities, should be drawn into it from off our turnpikes.

88. Neither would it be possible for the advantages of the Potomac Canal, alone, to be very extensive to the farmers of Maryland; and from the little interest generally that the state

can have in it, I am inclined to believe it cannot be very important for the state to aid in the enterprise. I have said (82) *it was not my intention to undervalue the Potomac, nor any one of its appendages.* Neither is it. I am aware that *South of the river*, upon the Shenandoah, the Opucon, the South Branch, and other tributary streams, there are excellent lands; but these are all known to be the property of Virginia. *North of the river* too, upon the Antictam, the Conococheague, and Conoloway waters, the soil is very productive; but Pennsylvania, is presently its owner. Hence, it is evident, that were the trade of ten times the value that the best lands could make it, the interest of Maryland would constitute but a very small item in the business; because, from the very nature of the case, the profits of the farmer would, principally, go directly into Pennsylvania and Virginia, while those of the merchant would centre in the District of Columbia. From geographical and other authentic information, I have no doubt but there are many luxuriant districts of country in Egypt and the Land of Promise. I am not, however, prepared to believe that if the Egyptians, or the Turks, were in want of a canal, that it would be incumbent on Maryland to aid in the work.

89. In countries so foreign, those who were to receive the benefits, ought to encounter the labour. And by parity of reason, the same rule may very well apply to our situation at home. West of the South Mountain, there are only two counties in Maryland. For the benefit of these, and as an *object of public good*, let the state authorise the opening of the Canal by a chartered company, taking care to reserve such privileges as may be necessary; after which our own citizens, and all others, will be at liberty to subscribe as much as they please; and to accomplish the work as soon as they please. But for my part, I would suppose that as the state has already been very liberal towards the Potomac, without the least return, *worthy of notice*, it would be advisable not to be *doubly liberal* there, at a time when any aid that can be afforded, would be of the utmost importance in promoting the proposed Canal to the Susquehanna; an undertaking that if any dependance can be placed in careful and accurate calculation, appears, from the same data, to possess more than six times the promise of its importunate rival.

90. In 1820 the population of Maryland was 407,300. The subsistence, habitation and clothing of this number, at the very low rate of \$50 each, amounts to upwards of twenty millions of dollars annually. This, no doubt, is a very serious sum to be raised yearly, and there are thousands amongst us, who are under very great difficulty to accomplish their part of it. It would, at least, be worthy of strict examination, whether only \$2,075,000, per annum, the utmost expectation (86) from the Potomac, would be competent to afford the required relief. Lest it should prove to be incompetent, let us turn our attention to the more ample sum of \$12,500,000, annually from the Susquehanna. It is one of the doctrines of the eminent Apostle Paul, 1st Tim. 5th chap. 8th verse. *But if any provide not for his own, especially those of his own house, he hath denied the faith, and is worse than an infidel.* What more conclusive evidence then, permit me to ask, would it be possible to urge against those, to whom the choice, upon the present occasion, may be confided, of their having denied the faith, and being worse than infidels, should they, regardless of every principle of common sense, and common prudence, reject the large sum above mentioned, and give the preference to the small one? Were any candidate for office

known to be capable of such an error, it would certainly be a crime to put it in his power to be the disgraceful agent of his own folly.

(To be Continued.)

AGRICULTURE.

WATER PONDS FOR THE USE OF CATTLE AND FOR OTHER PURPOSES.

(Continued from page 143.)

On this mode of making ponds for the use of live stock, (described in the last number of the Farmer) there are several circumstances of the process more fully detailed in the Rural Economy of Yorkshire, under the heads of, 1. the run, or collecting surface; 2. the reservoir; 3. the liming; 4. the claying; 5. the covering; 6. the time of making; and 7. the cost.

In regard to the 1, or the run, the author remarks that "a bare firm surface, as a road, collects the greatest quantity of water." But that "a grassy surface retains the rain water which falls upon it, and which, in level situations, is conducted into the soil, by worm-holes and other inlets, with which grass land generally abound; especially in summer, when a collection is of the greatest value. However, if the subsoil be retentive, ditches, especially of arable inclosures, will frequently afford a supply, even in summer; but in an upland situation, where the subsoil is generally absorbent, a road, or an artificial run, becomes necessary. But that in upland districts, as the wolds of Yorkshire, and the downs of Surrey and Kent, the surface is generally broken into hill and dale, and diversified by smaller vallies and inequalities. In situations of this kind, he says, artificial runs are most wanted, and may be most easily made. He has seen some faint attempts at making them on the wolds of this district by cutting a few grips, with a spade, above the reservoir; but they were too few, too short, and too seldom scoured, to answer, in any considerable degree, the intended purpose. They nevertheless, he observes, shewed plainly enough, the utility of channels for catching hasty showers, falling on grassy slopes, off which a considerable quantity of water will escape, provided there be channels at proper distances, to receive it." But in order to reap the greatest benefit from an artificial run, and to make it with the greatest ease,—he advises to "form the basin at some considerable distance from the head of a valley; from which, down to the reservoir, to open a main channel by two furrows of a plough turned outward. From this main stem to plough lateral branches, with an easy descent toward's it, along the sides of the slopes, by single furrows, turned down hill; by which means the ploughing will be rendered easy, the channels made free on the upper sides for the admission of water, and high on the lower sides for retaining it." And he thinks "the plough would not be less expeditious in scouring than in making the channels: or perhaps a more sledge-like implement would be still more effectual than the plough, in closing the fissures and worm-holes, which presently are formed in watercourses laid dry; and which, if left open, absorb an inconceivable quantity of water before they be saturated; especially if the current of water be retarded, by grass or other obstructions that may be formed in them."

In respect to the 2d, or the reservoir, he says, "the situation in them should depend principally on the run. Near the side of a road is, in general, he supposes the most desirable situation, provided a sufficient descent can be had from the road to the reservoir. Roads leading along the sides of slopes can only afford a supply to the grounds on their lower sides. But in this country

when a road leads down the descent, it is generally, he says, furnished on both sides with ponds, some of them, perhaps, not having more than an hundred yards of run, off a narrow roadway; yet, from that small quantity of surface, are sufficiently supplied with water." He adds, that, "in the situation of a pond, there is one thing requisite, which does not seem to be attended to, even by the most skilful in the art. The requisite he speaks of is that of admitting a waste water place, on the upper side of the reservoir, to prevent the water, when the pond is full, from running through it, by which means it becomes filled up unnecessarily. For the nature of foul water is such, that whenever it changes from a current to a stagnant state, it deposits a considerable part of its foulness; so that the water which leaves a full reservoir, is finer than that which enters it, the sediment, of course, being left behind in the reservoir. Whereas, if the current into the pond were to cease when the pond is sufficiently filled, the sediment of the overplus water would, he imagines, be got rid of. The pond would receive, in this case, no other foulness than that which was given by the quantity of water requisite to fill it. He thinks that a small catch pool, between the run and the reservoir, would arrest much of the foulness of water collected from a road: and, in a situation which could admit of it, would be worth the trouble of forming. In many situations, the mud it might collect, would, he supposes, amply repay the expense of forming it."

He states that "the form of the reservoir is, universally, that of a shallow bason, or more strictly speaking, that of a flat cone inverted; the sides shelving straight from the brim to an angle or point in the centre. If the excavation be made sixty feet diameter, its greatest depth is about seven feet: if forty feet diameter, the depth is about five,—before the coats of clay, &c. be laid on." And that, "a reservoir set out twenty-two yards diameter, by seven feet deep, will, when finished, measure about sixty feet by six, and will hold about two hundred and ten cubical yards, or near seven hundred hogheads of water. Forty feet diameter by four feet deep, when finished, contains sixty-two cubical yards, or two hundred hogheads (of sixty-three gallons, wine measure)."

In undertaking the work, "the first business in setting out a reservoir, is to take the level of the site, and drive piles, as a guide in forming the banks, and in making the conducting channel and waste water place. If the situation be on a slope, the excavated mould is, he says, used in forming the bank on the lower side: if nearly level, the mould requires to be removed, or, (if laid round the edge) the conducting channel to be raised. But if the clay or stone be excavated, it is laid separately aside to save carriage. And, if the lower side be raised with the excavated materials, they ought to be firmly worked together, or should lie a sufficient time to settle; otherwise, he says, the side thus formed, is liable to settle after the reservoir is finished; by which means cracks are formed and a miscarriage ensues. When the excavation has received the intended form, its sides are made firm and smooth, for the reception of the lime, or first coat."

With regard to the 3d, or liming, its use is, he says, "merely that of preventing earth-worms from perforating the coat of clay; the proper quantity depends, in some measure, on the nature of the soil. A fat rich earth, among which worms always abound, requires more, he says, than a dead hungry mould, or a dry stony bottom; on which retentive pools are said to have been made, without lime. However, as no soil, perhaps, is entirely free from those enemies to ponds, it would be folly to risk a miscarriage in any situation; as the expense of liming makes but a small

portion of the whole expense; and the only preparation of the lime is that of slaking it and picking out the cores; no sifting or skreening being, in general used; though obviously useful where it is usually laid on with a spade or shovel; but a sieve would, perhaps, be found by the inexperienced, a better tool; and the extra labor no object." And, "the thickness of the coat laid on is, he adds, about half an inch. Half a chaldron of lime is sufficient to complete a pond of forty feet diameter. The principal part of it is laid on beneath the clay; a few bushels only being reserved for scattering round the edges, to prevent the worms from getting into the clay." He here states that, "a still more secure, and on the whole, a more eligible method of liming has lately been thought of, and is now [June 1787] in practice, at Lockton, (in that neighbourhood) by the commissioners of inclosure, in making public drinking pools, for the use of the township. Instead of scattering the lime in powder, it is formed with sand, into mortar; a regular coat of which is spread about an inch thick, not only beneath, and at the edges of the clay, but over the entire surface. This is, he thinks, an obvious improvement, which appears, to human foresight, to bring this method of forming pools near to perfection. The clay becomes cased on either side, with a regular coat of cement, and is thereby secured, in perhaps the completest manner possible, from the attack of worms. The labor and expense, however, is by this method increased. A pond, nineteen feet diameter, he says, took two chaldrons and a half of lime, and five small cart loads of sand. Both the materials were sifted, and worked up in the usual way, into mortar. Great caution is necessary in laying on the clay, in this case. And, he adds that, "if the mortar does not lie some time to stiffen, the clay displaces it; if it get too dry before it be covered, it is liable to crack."

In respect to the 4th, or claying, it is, he says, in this operation, the manual art, and the labour, principally centre. And that, upon the wolds, clay is sometimes fetched six or seven miles; and is seldom found at hand, in situations where artificial pools are most wanted: the carriage of the clay, therefore, generally becomes a heavy article of expense. But, "the choice of clay, he observes, thought to be less essential, than the working of it. Good ponds are said, he adds, to have been made with common loamy mould; but it is wrong, he thinks, to depend on any thing, but a strong ductile clay, if it can be had within a moderate distance. And, "the thickness of the coat, now pretty generally laid on is, he says, about five or six inches, in the rough; beating it down to about three inches. In the infancy of the art, two coats of clay, of about that thickness, were laid on; but one coat has been found effectual, and much less expensive. However, it is probable, it will not prove so durable." But, "the method of beating will, he says, be difficult to describe; yet it most especially requires description." And, "the drier the clay is worked, the less liable it will be to crack with drought, when finished. In a dry season, however, it is necessary to moisten it: for which purpose the centre of the pit is sometimes finished first, to collect the water of showers; the carriage of water being, in some cases expensive." In executing the work of laying on the clay, "the workmen, he says, begin at the bottom of the pit, and work upward; laying patch after patch, or circle after circle, until the brim be reached: taking great care not to carry on sticks, straws, dirt, or any kind of foulness, among the clay or with their feet; and being careful not to displace the lime, in throwing it on; to prevent which, the lime is not spread over the whole at once; but is scattered on, as it is wanted to be

covered with clay." And as soon as "a plot of clay is laid on, and adjusted, it is beaten flat, with a wooden 'mell,' or beetle, made, at present, of these dimensions, the head fourteen inches long, and three inches diameter; the handle four feet long, and suited in thickness, to the hand of the workman. Beetles of different sizes have been in use, in different stages of the art; but none of them have been found to be so well adapted to the operation, as that in use at present. The first operation is performed with the side of the beetle, to level the protuberances, and smooth the roughnesses, so as to make the whole into a regular sheet of an even thickness." And when "this is effected, it is struck forcibly, with the end of the beetle, which is driven down nearly, but not quite to the lime; leaving the surface full of some what honey-comb-like cells or dints. If the beetle be struck unguardedly, quite through to the lime, a piece of clay, and a little lime, if required, is carefully placed in the breach, to prevent a defect in the part thus injured." And, "the whole being gone over in this manner, with the end, the surface is again levelled down with the side of the tool; the workman passing backward," as the business proceeds.

In regard to "the next beating, it is with the end, but not quite so deep as before; and the roughnesses being again levelled with the side, it is again worked over with the end; but still shallower than in the middle beating." He observes that, "the first strokes with the end of the beetle ought to close the bottom of the clay firmly, with the lime and the bed on which it is spread;—the second ought to unite the middle of the clay with the bottom;—and the last to close, without a pore, the upper part with the middle;—and the last strokes, with the side of the beetle, ought to be sufficiently forcible to close, entirely, the dimples formed by the last given strokes with the end." When "these several operations are thought insufficient, it is continued to be worked with the end and side of the beetle, alternately, until not a flaw can be found; the entire coat of clay being manufactured into a lead-like sheet, firm enough to bear a man without an impression, and a horse without injury; and, when two coats of clay were in use, the upper one was, he says, laid upon the rough surface of the last end-beating; by which means, the two coats became, by the subsequent beatings, incorporated in one thick sheet. A substantial method, this, of which, he says, the present appears to be rather a refinement, than an improvement" of the practice.

In the 5th operation, or covering, he remarks that "the first coat is of common earth, to assist in keeping out the drought, and to make a bed for the stones; to prevent their asperities from piercing, and thereby injuring the sheet of clay. This coat may be three or four inches thick, according to the nature of the stones with which it is to be covered. If these be large and irregular, more earth is requisite, than when the stones are small, smooth, or flat. The leanest, most infertile soil is fittest for this purpose. Worms and weeds are equally to be feared; and a rich soil is genial to both. In this point of view, two coats of clay are, in his opinion, much preferable to a coat of clay and a coat of rich mould." He thinks that the persons employed in this sort of business, are not "sufficiently aware of the mischievousness of weeds: indeed, some ponds will remain, for several years, in a manner free from them. But he has seen others, in which weeds, even docks (near the edge) have grown luxuriantly. It is probable that the tap-rooted weeds strike through the several coats; and, whenever the roots decay, a perforation must be left." And he supposes that "mould taken from a dry

sound highland situation is, in all human probability, less liable to propagate aquatic weeds, than the earth of a low situation or a bog." He thinks the following an ingenious and simple method of keeping the weeds under; especially at the edges, where they are generally most abundant. Though all the sides of a drinking pool be open, cattle will go to particular places to drink; and in these places, the weeds are trampled upon and killed. Therefore, to check the rankest, the parts which are most free are covered with thorns, while those which are weedy are left open for the cattle to drink at."

He adds that "the mould being rendered level and smooth, the stones are laid on; first covering the mould with the largest, laid with a flat side downward, to prevent their sinking down to the clay; and upon these laying smaller, until the coat be made five or six inches thick." He also states that "straw has been used between the clay and the stones; and, that in the instance in which an improved method of liming was practised, a layer of thick sods was laid, grass-side downward, upon the lime; and, upon the sods about six inches thick of loose stones," so as to form a secure coat.

(To be continued.)

FROM THE SOUTHERN PATRIOT.

INLAND SWAMPS.

Mr. Editor—Agreeably to the intimation given in my last number,* I now beg leave to introduce a part of the report, of the engineer who examined the swamp that leads into the southwest branch of Stono River, or Wallace's creek: Report—"According to my instructions, I have examined the situation of the Swamp from the high bridge on the Stono new road to the mouth of the public drain near Rutledge's landing. The present drain, by following the natural course of the water, has in my opinion, been judiciously laid out, and ought not to be altered except so far as to cut off a few sharp angles that the water may pass off more freely—from the New Road to Laurel Hill, the swamp rises gradually as you approach the creek in consequence of the alluvial deposits, which have been formed there for centuries. The only outlet to this extensive swamp, including its different branches, is ten feet wide and two feet deep. How is it possible that such an immense body of water should find a passage through so small an outlet." The report then goes on to make such remarks as are not necessary to be repeated here, as they are merely local. I shall make no comment on the report, but will repeat the observations of the Engineer; how is it possible that such a body of water can be carried off by so small an outlet? Permit me now, to introduce the remarks of the Editor of the American Farmer, "when the swamps of this county (Prince George, Virginia,) are said to be scarcely worth bringing into cultivation, the assertion is intended to apply to the only course, which can now be adopted for draining them; that is, by the unconnected efforts of different individuals, who are compelled always to begin at the wrong end; on the outskirts and head branches instead of at the outlet, and through the middle of the swamp. Therefore all attempts have been attended with great labor and expense, and have never had more than partial success. But draining on a rational plan, the improvement would be one of the most valuable, and decidedly the cheapest that could take place in lower Virginia." The very error of which this writer complains, is the fatal error, that has been committed on all the swamps that I am acquaint-

ed with; and has been the cause of immense capitals being sunk and destroyed. If this would be so important an improvement to Virginia, how much more so to South Carolina, where we have a grain so well adapted to low lands. The resources of the state would be materially increased, and so fully were our ancestors convinced of this truth, that ample powers were vested in the Commissioners—all the powers of Commissioners of Roads. In introducing these remarks before the public, some apology may be deemed necessary, and if the subject were altogether of a private nature, I should most willingly do so; but as I consider the state as being intimately concerned in the prosperity of all its citizens, any improvement which may take place in a part is interesting to the whole. Candor bids me state, that my chief object is to call the attention of those who have capital at their disposal, and to ask whether it is not an object worthy of attention, as a speculation, to purchase up these neglected lands, or assist the present proprietors who are too poor to commence the undertaking; and by a rational plan of improvement not only increase their own fortunes, but deserve the thanks of their country. The citizens of Charleston are interested in these improvements, for they will not only swell the amount of exports, but furnish at a cheaper rate than at present, those articles in the farming line, which contribute so much to our comfort, and which are at present so extravagant, as to force those who have small incomes to leave the city. When I look through the vista of time, and contemplate the rising glory and happiness of my country, my imagination swells with the brightest visions, but *medio de fonte leporum surgit amari aliquid quod in iphis floribus angat*; I no sooner turn and behold the monuments of decay which surround me, than my heart almost sinks in despondency and despair.—Should I, however, by calling the attention of the public to this subject, become the humble instrument of producing a better state of things; happy, aye thrice happy shall I be. Be the result as it may, I shall have the consolation to think, that I have made an effort. I now, Mr. Editor, take my leave, and thank you for your kindness in giving publicity to these crude but well intended remarks.

PHILO RUSTICUS.

FLAX AND HEMP.

We have in this number commenced the publication of a pamphlet published in Ireland, by the Dublin Linen Board, the last fall, and which we believe to contain very valuable information upon the subjects of flax and hemp. The important facts stated therein, with respect to the mode of managing flax in Holland, are, we think, calculated to benefit Ireland to the manifest loss of the United States. For, if the fibre is better when made from the matured plant, and they should adopt the principle, what is to prevent the Irish from growing their own seed? We cannot but consider it as very strange indeed, that the Linen Board should have remained so long ignorant of the important fact, that the flax is better from the seeded plant, than it is when pulled green. It will be perceived that Mr. Bernard attaches the utmost importance to the rotting of the plant, and therein we are inclined to think he is right. We believe it to be all essential. The importance of the subject, and the new light which is here thrown upon it by a person specially selected by the Board of Linen Trade in Ireland—and who may, therefore, be presumed to be peculiarly qualified to make the investigations—will be a sufficient apology for giving to this little pamphlet so large a portion of the Farmer. We are not well informed as to the

* See Am. Far. No 14, vol 5.

extent of the culture of flax and hemp in this country, but our impression is, that in Ohio, Kentucky, and other western states, they are objects of increasing importance, and that they must grow in consequence, as with the augmentation of capital, factories shall be multiplied in the West. Indeed, when we reflect on the eminent advantages enjoyed in the Western country, we are surprised that the raw material which is produced there, is not to a greater extent manufactured on the spot. Water power, fuel, the raw material, &c. &c. &c. being there eminently proximated.—*Edit. Am. Far.*

Report of an inquiry into the mode of cultivating and treating Flax, in the Netherlands, &c. by Peter Besnard, Esq. Inspector-General for Leinster, Munster, and Connaught.

INSTRUCTIONS TO INSPECTOR-GENERAL.

No. I.

Letter of the Trustees of the Linen Board, to James Corry, Esq.

"LONDON, June 21st, 1822.

"SIR,

"Aware that the law will not justify a regular meeting of the Linen Board of Ireland, but in Dublin, we, the undersigned members of that Board, viewing the great and growing importance of the culture and proper management of flax and hemp within Ireland, and conscious of the superiority of that which is sent to these countries from Holland and the Netherlands, request that you will immediately direct the Inspector-General of Leinster, Munster and Connaught, Mr. Besnard, to proceed thither, as soon as dismissed from his attendance on the Committee of the House of Commons now sitting on the Linen Laws. You will hand to him such letters as shall be furnished to you by the House of Mr. Maberly, and in your instructions will direct him carefully and diligently to examine into, and report, his observations upon the mode of treatment both of flax and hemp, as well in the tillage and preparation of the soil, as in the after-management and regulations of the market, until bought for exportation. We consider all these objects attainable in a tour not to exceed three weeks in duration, and that it should be performed at an expense not exceeding one hundred pounds to the Board.

"Confident that this act will be hereafter sanctioned by the Board, and feeling that the season of the year will not admit one week's delay, we affix our signatures as your authority for so acting.

Secretary to the Linen Board. (*Copy.*)

No. II.

Letter of James Corry, Esq. to Peter Besnard, Esq.

"LONDON, Blake's-Hotel, Jermyn-st.
June 24th, 1822.

"SIR,

"In obedience to the commands of several members of the Linen Board of Ireland, communicated to me by their letter of the 21st inst.

a copy of which I inclose you, I have to desire, in their name, that you do forthwith proceed to Holland and the Netherlands, for the purpose therein stated.

"You will be able to collect, from a perusal of this document, that the Linen Board is anxious to ascertain, through your inquiries, the probable reasons why those countries are able to produce a flax of a softer and more silky quality, applicable therefore to finer fabrics than the flax of Ireland is usually adapted to, and what the regulations are in those countries for dividing their flax into different sorts, or numbers, according to its fineness or coarseness, whereby it comes to the British market in a condition suited to every description of buyer.

"To attain these objects, you will commence your duty by inquiring into the nature of the soils which are considered in those countries to be best suited to the growth of flax, their manner of preparing the ground, and their time of sowing; whether the seed they use be the growth of their own, or any other country, and their time of pulling; with a full detail of all the after-management of steeping, drying, breaking, beetling, scutching, and hackling; a detail also of the mode observed in sorting and dividing it for market, with respect to quality, as well as the quantity contained in each parcel or bundle, with the market prices of each, and the fabrics to which they are suited. It would also be very desirable to ascertain whether the regulations observed in bringing it to market are directed and enforced by any legislative or municipal authority, or from whence they may otherwise derive their force; and obtain, if it be practicable, a copy of any such regulations. You will of course make the same inquiries in respect to hemp. Mr. Maberly, a member of the Linen Trade Committee, to whose useful suggestions much is due on this subject, has kindly offered me to give you letters to agents of his own in Holland, who will be able to assist you in effecting the wishes of the Board. I have written to Edward Stewart, Esq. the British Agent of the Board in London, requesting him to render you every assistance in his power; and Viscount Forbes, a member of the Board, and of the Committee, has kindly written a letter of introduction, to be presented by you to Sir James Gambier, His Majesty's Consul at the Hague, which I inclose. You must obviously see, however, the necessity of avoiding every appearance of being sent to that country in a public capacity, or of exciting, by too much anxiety in your research, any suspicions that might be likely to frustrate the objects of your mission.

"As your Report will be, of course, required for public purposes, you will please to bestow every necessary care in preparing it.

I have the honour to be, sir,

Your most humble servant,

JAMES CORRY."

To PETER BESNARD, Esq. (*Copy.*)

REPORT.

My Lords, and Gentlemen,

In compliance with your commands, conveyed to me in London on the 24th June last, by Mr. Corry, I proceeded on the 5th of July following, being the day after I was dismissed from my attendance on the committee of the Honorable House of Commons, for Holland, and arrived at Helvoetsluys on Tuesday, the 9th, and have now the honour to present to you the result of my inquiries on the several subjects contained in my Letter of Instructions from your honorable board. Having been informed, previous to my departure from London, that it would be impossible to acquire in detail from

the flax growers in Holland and Flanders, the necessary information required, without the presence of some person well versed in the Dutch and Flemish Language, none of those people (as I experienced,) being able to speak either French or English, I felt it my duty to engage in London, a respectable person to accompany me, Mr. James Quantrille, whom I found not only conversant with both Languages, but well acquainted with the manners and customs of the people, and whose services I found particularly useful in this respect, as likewise as a companion in my visits to remote places, often amongst persons of various classes in society, with whom it was actually necessary to hold frequent communication. I further beg leave to observe, that however anxious I felt to execute the trust reposed in me by your honorable board, within the time (three weeks) in which you were pleased to express your expectation that I could perform my mission, I found it quite impossible within that period to obtain the information set forth in my instructions; first, because on my arrival in Holland the general flax crops of that country had not been pulled; secondly, because the distance I had to travel to obtain information, could not be accomplished in a less time than was appropriated for that purpose; and lastly, because the great flax crops of Zealand and Holland were not prepared for the process of rippling and steeping until after my return from my tour in Flanders, France, &c.; considering those operations of the first moment, I conceived I should badly have executed my duty, had I not remained to examine in detail, at my full leisure, every matter relative to the after-treatment of flax, which I had an opportunity of doing during the last week of my stay in the Netherlands, from the rippling of the seed, until the article was fully prepared for market. I therefore hope that your honorable board will feel satisfied, that my stay was only occasioned by an anxious desire to procure the most perfect information in my power, relative to my mission.

Being desirous, on my arrival at Helvoetsluys on the 9th of July, to proceed, I set out forthwith for Rotterdam by land, and, on the journey, observed in various places flax cultivated to the amount of several hundred acres, the entire of which was standing, except one field, which was pulled, and the flax placed up to dry. On my arrival in Rotterdam I sent a message to the gentleman for whom I had letters, who instantly attended me, having been previously informed of my proposed visit. On the 10th, this gentleman introduced me to some extensive and respectable merchants and dealers in flax and seed, in whose stores I examined large quantities of flax, the growth of Holland and Zealand, all of which was made up in so regular a form, according to the various qualities, that a buyer might make a selection of any kind without fear of disappointment; this is a most important and necessary arrangement, and greatly facilitates the sale of flax in Holland. Same day I proceeded to Schiedam, about five miles from Rotterdam, and inspected two large fields of flax which had been some days pulled and set up to dry; on examination of this flax I found that the seed had been fully formed before it was pulled, and I understood that it was to remain to dry until the bole or shell would part freely from the plant in process of rippling.

Thursday 11th, proceeded to the Hague, and presented my letter of introduction from Lord Forbes to Sir James Gambier, His Majesty's Consul General in the Netherlands. Sir James Gambier offered me every service in his power, but finding that his connexions were unacquainted with the objects I had in view, and being anx-

ious to proceed on my mission with the least possible delay, I left the Hague the same evening for Leyden, where there is a linen thread manufacture, as also a manufacture of shawls from fine wool. In Leyden I particularly examined the flax used for thread, and the wheel on which it was spun, which, having found to differ in the spindle, and other parts of what is called the tackling, I considered it my duty to purchase one set of tackling, which can be attached with ease to a common wheel, and will sufficiently illustrate, whether it be an improvement or not. On the wheels which I examined, combed wool for the shawl manufacture is spun to a great extent, and it appears to me, that wool for the finest tabinets, manufactured in Ireland, might be advantageously spun on wheels of this description.

From Leyden, proceeded on Saturday to Amsterdam; on this line very little flax is cultivated, but in the immediate neighbourhood of Amsterdam the oil business is carried on to a very great extent, upwards of two hundred mills being constantly employed chiefly in Zaandam, a very large village on the opposite side of the river, and it is the Amsterdam merchants that regulate the prices of the several kinds of this valuable article, throughout the entire of Holland.

From Amsterdam, proceeded in the Night boat to Rotterdam, and attended the flax market of that city on Monday morning, the 15th, accompanied by some friends, by whose means I obtained a copy of the original regulations of the flax market of Rotterdam, which I have the honor to annex to this report. The vlas market, or flax market, is situated on a small square, to which it gives name; two buildings, covered over, and supported by pillars, stand parallel to each other, under which the vlas boeren, or flax farmers, stand with their samples before them, placed on the ground in clean linen bags; each sample contains one stone of 6½ lbs. and has affixed to it a ticket descriptive of the number of stones of that quality the boer has ready for sale; when the purchase is made, the buyer writes the terms in his memorandum book, and the sample is conveyed to his office, where it remains until the parcel is delivered; should any difference occur as to quality, reference is made to the market master, who, with two dealers in flax, decides between the parties. The master of the market is always in attendance during the time of sale, and sees the regulations enforced, and the greatest order prevails during the market hours. The same regularity which exists in the flax market also takes place in the sale of seed, which is likewise sold by sample, and is brought in bags containing about a quart each.

Tuesday 16th, proceeded from Rotterdam on a tour through Holland, Brabant, Flanders, &c. accompanied by Mr. — and Mr. Quantrille, my interpreter. On my route this day to Dordrecht, passed through the village of Ryssoort and Swyndrecht, in the immediate neighbourhood of which, large quantities of flax are grown, and many flax boers reside, who cultivate it in very considerable quantities in Zealand, whence they bring it in vessels, after it is pulled and sufficiently dry to ripple the seed. Those persons having large barns, and every accommodation for cleaning and storing flax in every stage of preparation, carry on a very considerable trade in this article. On my arrival in Dordrecht, viewed the flax-seed market, which is conducted with great order and regularity, and all sold by sample. In this town there are two sworn brokers, who examine every description of seed and corn, and when any dispute arises between buyer and seller, as to quality, it is usually settled by those persons; but should the seller appeal to the

tribunal of the town, the brokers are then publicly examined as to their opinion; such an occurrence, as this, however, seldom takes place in any part of Holland, the farmers knowing the value of bringing their articles to market honestly, seldom vary from the quality of the sample.

Wednesday 17th, proceeded from Dordrecht, through Breda and Antwerp, to St. Nicolas, in Flanders. On this line flax is also cultivated in large quantities; that nearest to Holland I found the shortest and worst in quality, in consequence of the great and continued drought; but as I entered further into Flanders the crops greatly improved, and in many parts of that country, and Brabant, I found it growing in great abundance, and of excellent quality.

Thursday, inspected the flax market of St. Nicolas, which is held on that day of the week throughout the year, commencing at eight o'clock in the morning. In this market, flax is not sold by sample, because it is grown in small portions, and the quantity offered for sale by different individuals, is what they grow in the season, which varies from four to twenty stone, of 6½ lbs. to the stone, and seldom exceeds the latter quantity. The flax in this market is thought to be better cleaned than the Dutch, and is said to yield ten per cent. more; the aggregate amount sold is considerable, and may be computed at about two thousand tons annually. Some of this flax is purchased for English and Scotch mill-spinners, and shipped at Antwerp, and some is sent to the South of France. The seed of this district is mostly sold for crushing, as the growers are poor compared with those in Holland, and obliged to sell it as early as possible.

From St. Nicolas, proceeded to Lokeran, where a seed, flax, and linen market is held every Friday throughout the year; in this market flax is also bought for Scotch and English houses, and the South of France; it is considered of a better quality, and commands a higher price than the Dutch flax; it is also purchased by different dealers residing in the town, the principal one of whom, *Mr. —, I was introduced to, and from whom I received all the information I could wish. Mr. — has dressed at his establishment about 200 tons of flax annually, the fine of which is made up in pounds, and packed in small boxes, and sent to Italy and Switzerland, in which countries it is spun for the finest lace manufacture, and sent, when in yarn, to France and Flanders, to be bleached and manufactured. Mr. — gets all his flax dressed by women, who take it to their own houses, and usually receive twenty-four pounds at a time, which they return made up in pounds, each pound subdivided into small parts, each sufficient to be placed on the Rockstaff at a time. The process of flax-dressing is performed here, and in France, on a hackle, somewhat different from ours; it is nearly square, and the teeth not more than two inches and a half long, and, although the work is well performed on it, it is not considered by some English flax-dressers, as equal to an English hackle. Of Mr. — I particularly inquired, if all the flax purchased by him gave seed, which he informed me it did even if intended for the finest purposes. Anxious that the honorable board should have an opportunity of seeing flax that had given seed, and which was prepared for the finest works, I purchased from Mr. — a sufficient quantity of the article for their inspection. The market of Lokeran is on the same plan as that of St. Nicolas, as to the usual quantity offered for sale; but the article is

* This person received a silver medal from the Agricultural Society of Ghent for producing the cleanest and best flax in Flanders.

considered to be rather of a better quality. In the vicinity of this town there are seventy small bleach greens, and fifteen linseed oil-mills; the small farmers have, therefore, at all times, an opportunity of disposing of their seed, which they are in the habit of doing, as soon as it is ready for market. With respect to the bleaching establishments in this neighbourhood, they are on the old plan, without machinery, every article being washed by the hands and feet, and every description of linen bucked, and not boiled; they are watered twice a day on the grass, and, towards the finish, are rubbed over while on the grass, with a solution of a soft soap and ley, which is applied with mops, made of hair, such as is used in painter's brushes, but, in point of size, are similar to carpet brushes. This operation is performed by two men, who walk one on each side of the piece, gently rubbing in the solution. The last preparation, previous to the finish, is a steep in sour milk.

Proceeded from Lokeran to Ghent, where one of the largest linen markets in Flanders is held every Friday; but not being able to reach it in time for the market, I was obliged to defer my inspection of it until my return through that city. In Ghent, considerable quantities of yarn is spun (for the lace manufacture,) and bleached near Antwerp.

Proceeded from Ghent to Aalst; on the road, saw extensive crops of flax, and stopped at a flax farmers, who has a small hand machine for scutching, made by himself, and which he lets out to different persons in the country. This machine is similar to the Irish vertical mill, but on a small scale, and performs its work exceedingly well. Two women, one to turn and the other to scutch, attended by a girl, clean perfectly 56 lbs. of flax per day, if previously broken. In this neighbourhood there is a set of bruising machines, attached to a wind-mill, where the largest farmers bruise their flax, but the small ones break it by hand-blocks, &c.—In every case, however, the breaking of the flax in Flanders is easily performed, it is so well prepared in steeping.

Same day arrived at Aalst, a seed, flax, and linen market, and waited on Mr. —, a flax dealer, to whom I had an introduction, and from whom I received the most useful information. At present he buys flax for English merchants, and other persons, and attends the several markets in his neighbourhood. While in Aalst, viewed a bleach-green, which is conducted on the same plan as those at Lokeran.

From Aalst proceeded to Brussels, where a small flax and linen market is held; in this town I examined several pieces of linen, bleached and unbleached; the former are very rudely made up, and great quantities of the latter are very coarse, and are dyed blue, for the use of the peasants of that country and Flanders, who uniformly wear blue frocks, or jackets and trousers: those for working days are a deep blue, of coarse linen, but those for Sundays and holy-days are of finer linen, and a brighter, or sky blue, and make a very neat, pretty, and desirable dress; the latter are often used by many of the better classes in the country, when travelling or attending country business.

Proceeded from Brussels to Tournay, by Halle Enghien, Ath, and Leuse, in all of which towns the linen manufacture is carried on. On the whole line from Brussels to Tournay excellent flax is grown in considerable quantities; the greatest part of it was pulled, and set up to dry, in a manner differing from the practice in Holland. In this country, and in France, flax, when put to dry, is not tied in bundles, but is placed loose, in a sloping direction, in long rows,

or ridges, the heads or boles to meet, and the root ends spread out so as to form a V reversed. At each end of the double rows of flax, and at certain intervals, stakes are driven into the ground to support them. This mode is decidedly preferable to bundles, because every part of the plant is equally presented to the influence of the air; but it should be observed, that it is suitable to a country where mild, calm weather prevails in the flax season. In the immediate vicinity of Tournay, extensive crops of flax are grown, and many persons are engaged in spinning coarse linen yarns for the celebrated carpet manufactory of Messrs. Lefevre, the whole of which establishment they were so kind as to conduct me through, and where I saw large quantities of *linen yarn* dyed as perfectly as worsted. In this manufactory 4,000 persons are at present engaged, 1,400 within the buildings, which I went through, and the remainder at their own houses. All the carpets sold in Brussels, and bearing the name of that city, are here made; there being no manufacture of them in that place. Considerable quantities of linen are also made in this district, but chiefly for home consumption.

From Tournay proceeded to Valenciennes, through the village of St. Amand, in which the spinning of linen yarn and manufacture of cordage, from native hemp, is extensively carried on, and great quantities of hemp and seed are sent by water to Antwerp for shipment. In this village I saw some remarkably fine flax, of this year's growth, that had given seed; and on the road from there to Valenciennes, very fine crops of hemp were to be seen in every direction. On this line, for the first time, I met with the *Œillet* plant, which all the way to Cambay I saw very generally cultivated, and which, as I understood, forms a considerable branch of trade.—The *Œillet* is a species of the poppy, is sown in April, and pulled in July and August, and appeared to me to be a plant that could be advantageously cultivated in the South of Ireland. The seed is shaken from it in the field, in large baskets, with sheets under them, and thence conveyed to the stores. From this seed is obtained a very superior description of oil, the first run of which is sent to Marseilles, and there mixed with olive oil, for sallads, &c. and sent to Paris and other markets. The next run is used by painters, having the qualities of very quickly drying, and not discolouring the finest shades of paint, which linseed oil often does, by drying with a yellow tint: the second is also used in making a very particular kind of soft soap for bleachers, and is found to clear and give a softness to linen, not to be obtained from common soap; it is in general use amongst all the bleachers of Cambay, for bleaching cambrics, linens, muslins, and every other description of fine goods, and produces a lather, or froth, as white as snow; without this soap or composition, a bleacher in Cambay told me he could not give his goods the softness and mellowness which they possess. The oil cake from the seed of this plant is also given to the cattle.—In Cambay I made inquiries relative to the article of cambric peculiar to that town, or, as it is there called, *Batistè*, from the name of the man who first introduced it, which it is said he was induced to do, in consequence of the extreme softness of the water in the neighbourhood. Here I was so fortunate as to see every process of this manufacture, from the preparation of the flax at the hackle, to its finish for the consumer; and I was assured by many persons conversant with the business, that except for some very superior kinds of cambric, on a very limited and inconsiderable scale, all flax used in that manufacture

gives seed, for it is in the after management of the flax-plant, the people of Cambay say, that every thing depends to render it fit for fine works. So tenacious is the government of France of this seed, as well as of flax, that the export of both is prohibited. The process of steeping and cleaning flax in this part of France, and in Flanders, from whence they get some supplies, differs little from the plan followed in Holland, every thing being done by hand; but the greatest care is observed in every stage of preparation for the hackle. The process of hackling in Cambay is performed, as in Flanders, by women, and with utensils of a similar description; and from every inquiry I was enabled to make, I could not find any inferiority in the quality of the flax thus prepared for the foot-wheel, or what is of equal importance, in the *produce* from any given quantity of material, to what is produced by our experienced flax dressers with the most costly utensils. In every stage of hackling in France and Flanders a brush is used, but of a very different description to any I have ever seen in Ireland, and, in my humble judgment, is well calculated to open the minute fibres of the plant, without injury to its substance or strength. One of those brushes I have purchased, for the inspection of the honorable board; and I doubt not, but its adoption by flax-dressers and spinners of fine yarn, will be found advantageous. In the construction of the tackling of the wheel for spinning cambric and lace, there is a material difference in the weight of the spindle, flyer, and bobbins, to those used in Ireland, the French being considerably lighter than ours, and the mode of applying motion to the bobbin is different, as it can be regulated with much more care and certainty than in the Irish wheel; the mode of placing the flax on the distaff also differs *materially* from the general practice. That an opportunity may be afforded to the *Irish spinners of fine yarn* of making trial of the plan followed in Cambay, without incurring any expense to themselves or the honorable board, I have procured a spindle, flyer, &c. for the finest yarn, which can be attached to one of the wheels in the Board's model room, and thus afford an opportunity for a fair trial of the French mode of spinning. It is here necessary to observe, that the yarn spun for cambric in France is *never reeled*; it is sold by the spinner on the bobbins, from which she winds it from the spinning spool, and which she receives back when it is wound off by the purchaser; the general custom in Cambay is, for those who spin on *their own account*, to sell the yarn to manufacturers, or dealers in that description of yarn, who are generally respectable, wealthy people, that keep establishments for warping, which they do from bobbins that the spinner winds on, and thus prepare the warps according to the several sets the yarn is suited for; those persons also prepare the yarn for the weft, and a weaver can be at once supplied with a warp and weft suitable to his business. Into one of those warping concerns I was introduced, and purchased a warp ready for the loom, and I there saw several hundred warps, of different sets, ticketed and prepared for the weaver. The loom for weaving cambric which I examined, differed little from a *good Irish loom*, except its being what the weavers call very short in the reach, but it was in every respect *well put together*, and made of *sound and stout materials*. The dressing used in weaving cambrics I particularly examined, and found it made of the *finest flour* that could be procured, which the weaver told me was always the case.

Having made every inquiry that to me seemed necessary to ascertain the *fact* of the general fa-

bricks in Cambay being made from flax that had given seed, I next visited the proprietor of the most extensive bleach-green near Cambay; having communicated to that gentleman my desire to view his establishment, he with great politeness took me through every part of it, and explained every process; in this concern, two millions of French ells, each of which contains 1½ English yard, were bleached, *last season* without the aid of any kind of machinery, every process being performed by men and women; on going through the various departments I reckoned 60 men and 50 women employed, the latter are generally engaged in the *finishing process*, that is, as the goods approach to their final colour, they are washed in soap and water in *large tubs*, and, if occasion require, brushed with a soft brush in those places where any *spot of ley* may remain. It is here unnecessary for me to enter into a detail of the process of bleaching, which is so well understood in the North of Ireland; but it may not be unimportant to observe, that the greatest pains are taken between every boil and buck, not to let the linen be exposed to the air, until every particle of ley be completely discharged from it. From every information I received throughout my tour, I could not learn that linen is ever injured in the bleaching process, either in France or Flanders.

From Cambay proceeded to Mons, in the vicinity of which large quantities of hemp are grown. On Monday met Mr. _____, at Brussels, who procured me considerable information relative to the several linen markets in Flanders.

From Brussels went to Aalst, and from Aalst to Ghent, and inspected the linen market of that city. At this market there were eight hundred weavers, and three thousand pieces of linen exposed for sale, from 5*d.* to 2*s.* 4*d.* per ell Flemish, which is ¾ yard English; gross value in market from seven to eight thousand pounds; this market is held in a large square, in which are placed a number of standards, marked with the breadths or the different kinds of linen sold in the market; the standards are placed at one end of the square, at sufficient distances to let the buyers pass between the weavers, who stand in parallel lines, in conformity with the respective breadths of their pieces as marked on the standards; those of the same quality likewise stand together, and all lodge their pieces on boards, raised a few inches from the ground. Every description of linens in Flanders being made up the full breadth, are placed on one end on the planks, and are in this state examined by the purchasers; previous to exposure for sale, every piece is inspected and breadthed by a public Sealmaster, appointed by the magistrates of the town, to whom he gives security, and engages to procure a sufficient number of deputies; after sale, the pieces are taken to a large measuring room where they are measured, not by a machine or a stick like the Irish yard* measure; they are drawn over a long table, on which is fixed, at the distance of five ells, a brass plate with a rise in the centre of it about four inches long, two inches wide, and an inch and an half high; of these tables there were six; two men attended each table, when the end of the first fold of the piece is drawn over the table to the opposite end of it, from where the piece lies on the ground, the man at the brass plate makes a stripe with red chalk on the piece where it rests upon the brass, calling aloud the mark,

* This mode of measuring seems to me to be peculiarly applicable to the Drogheda linens, of the short measure of which constant complaints are made in London, Dublin, &c. &c. and I should most respectfully suggest a grant of one measuring-table for the service of that market.

and so goes on marking, every time the piece is drawn over, until the end, when the number of times it passed are chalked on the end of the piece, with the odd ells less than five, which are ascertained by narrow brass plates let into the table, close to the side on which the ells, with their subdivisions, are marked; under the measurement-mark is stamped, the arms of the town, and the initials of the Sealmaster's name; this mode of measuring seems to give general satisfaction to the weavers, who have an opportunity of keeping an account of every time their pieces are passed over the table; in this manner above 20,000 ells of linen were measured the day I visited Ghent, and the entire business was done by one o'clock. The sum paid by the weaver for measuring is nearly the same as paid by our weavers, but the buyers make a deduction of fivepence per piece for the pay table, &c. and some other charges are made for town dues.

After having inspected the market of Ghent, returned to Aalst, and next day (Saturday) visited the linen market of that town, in which the same regularity in breaching, sealing and measuring is observed, as in Ghent; there were about 1000 pieces of Linen in this market, value upwards of £3000; many of them were of a better description than the Ghent linens, and were from 6d. to 2s. 4d. the Flemish ell, the general breadths from one yard and half-quarter to one yard and quarter.

From Aalst proceeded on Saturday to Antwerp, where I remained Sunday, and on Monday visited La Blancherie Royale near that city, which was erected by Philip, king of Spain, when in possession of Antwerp; at this concern I was shown by the proprietor every process of bleaching the finest yarn used in the making of thread lace in France and Flanders, as at the bleach-ground in Cambay; every operation is performed without the aid of machinery, and the yarn washed by women, who sit in small boxes by the side of the river, and, while washing, are perfectly secure from wet. All yarn bleached for lace is previously twisted from the spools on which it is spun, and made into very short skeins, carefully lay and water-banded. In every operation of whitening this yarn the greatest care is taken, and the bleach ground, which is laid down in planets, is kept close cut at all times, and the yarn watered morning and evening with scoops. The boilers in this establishment are all small, and not capable of holding more than one cwt. of yarn each, yet the proprietor told me, he has had in one of them, 10,000 florins value of yarn at a time. The boilers are of hammered brass kept perfectly clean, with close covers that have vent holes to let off the steam, and in the process of boiling, the yarn is placed in a thin sheet; exclusive of boiling, this yarn receives the buck and gentle steeping in weak warm ley; it is in all cases finished by a steep in new milk, which is here considered actually necessary to give it the clear white, for which all yarn for lace made in France and Flanders is distinguished. The extreme delicacy of this yarn rendering it impossible to wring it in the usual way of other yarn, it is placed in a coarse cloth, resembling a sailor's hammock, both ends of which are fastened to two very large irons fixed in pots, one of them standing, and the other moveable, like a common ring; at the moveable end is a kind of fly-wheel attached to the moveable hook, from which wheel there are projecting pins or sticks, like cogs of a wheel: when the yarn is carefully placed in rows in the bag or cloth, the fly-wheel is turned, and as the pressure becomes greater at every turn, two men tread, one on each side of the wheel, on the projecting pins or cogs, and so give their whole weight to the fly, until by degrees

they squeeze the yarn perfectly dry, and likewise give it a degree of softness, without in the least injuring it. The potashes used in boiling and bucking this yarn is at all times best sweet Alicant barilla, which is pounded and sifted through a copper seive. The proprietor having told me that he only bleached the yarn, and that it was finished and made up for sale by a person in the city of Antwerp, I called at the manufactory and purchased a small quantity of the yarn for the inspection of the honorable board, and which is sold at the rate of £47,786 13s. 4d. per ton. The yarn which I purchased is not of the finest kind, but I have every reason to suppose, from the enquiries I made, that it was spun from flax that had given seed, a strong proof that allowing flax to seed is no injury to its quality, if all the after-operations be duly attended to.

From Antwerp proceeded to Dordrecht, where I inspected several oil mills, on which large quantities of the linseed saved in that neighbourhood is consumed.

From Dordrecht visited the villages of Swyndrecht and S'Gravendaal, and examined several cargoes of flax, of this year's growth, from Zealand, particularly some grown in the vicinity of Zirczee and Targoos; this flax was of an excellent quality, was brought in large sailing vessels direct from the field, and had on it the seed, which is never rippled until it reaches the boer's barn; in transporting this article from Zealand, the greatest care is taken by every person employed, and every sheaf is counted into the boer's wagon; numerous crafts are employed in this business, which is considered one of great importance to the country, and *fast extending*, and it is to be presumed must be a profitable one, as a great number of wealthy boers who reside between Dordrecht and Rotterdam are at present extensively engaged in that branch of cultivation, many of them having *this season* grown in Zealand from 30 to 40 markens of flax, which measure is nearly equal to an acre and a half English, and for which they pay at the rate of £10 English per marken. For one season, one of the most intelligent of the flax boer's informed me that, *without rent*, the charges for sowing, weeding, pulling, drying, freight, rippling, and cleaning, on an average, were about 16d. per stone of 6½ lbs. the entire of which goes amongst the peasantry, embracing every age of both sexes, and is in the flax district their principal dependence.

On Thursday, the 8th of August, proceeded to the village of Rysort, situated between Dordrecht and Rotterdam, and which may be justly styled the centre of the flax country of Holland, not only from the quantities of that article grown in its immediate neighbourhood, but because three-fourths of the flax grown in Zealand is conveyed there from the field, when sufficiently dry, to undergo the various processes of rippling, steeping, &c. Having remained in this part of the country for four days, the *entire of which time* I devoted to visits amongst the flax boers and peasantry, who were engaged in every process of flax preparation, (from rippling to bringing it to the break and swingle.) I had ample leisure to obtain a perfect knowledge of the *detail* of every process, which I humbly hope I shall be able to communicate in such a manner as may be satisfactory to your honorable board. The *time* chosen for staying, amongst the flax-farmers in and about Rysort was the most *favourable* that could possibly be selected, for all were performing every different process; and having in Flanders and France (where the crops are from ten to twelve days earlier) seen similar operations, I had an opportunity of judging of the merits of the different systems. Here I feel it my duty to state, that for *regularity and method*, in every operation, the plan pur-

sued by the Dutch boers is to be preferred to any other. In all cases their mode of saving seed has decidedly the preference, in my estimation; and it may be necessary to add, and to impress on the minds of the flax cultivators in Ireland, who sow that plant as an *article of general commerce*, that, without the seed, the Dutch boers would consider their business a very unprofitable one. It is generally computed, that after all expenses of rippling, &c. the seed leaves at least from £8 to £9 the English acre; and one of the most convincing proofs that can be adduced in favour of the Dutch mode of flax cultivation is, that all the growers are independent, and many of them have, within a few years, risen from very humble beginnings to considerable wealth. In the progress of my several tours through the countries which I have visited, I made it a particular point to examine, with care and attention, the soil in which flax is grown, and to ascertain, if possible, whether these places possessed any local advantages for the cultivation of that plant, which were not also possessed by the growers in Ireland: as far as my humble judgment serves, I could not observe on this mission, nor call to mind from the experience of many years, that the South of Ireland does not possess every requisite to admit of her growing flax of the same quality, and to the same profit, as is experienced in Holland, which however cannot be done without obtaining the seed, and presenting the article to market in that merchantable shape, which must always insure a demand, and a remunerating price.

Why so general an opinion, as has prevailed in Ireland for a series of years, that flax which gives seed is not adapted for her fine linens, should have taken place, I cannot conjecture, nor is it here necessary for me to dwell on; but I can undertake to assert, without fear of contradiction, that I have seen on this tour, flax, the growth of Holland, Zealand, Brabant, Flanders, and France, which has given seed, fully equal in quality to what is grown in other countries, and applied to the manufacture of articles of as fine a texture as any made in Ireland. In a word, the growers of flax, in any of the countries I have named, would be considered as persons void of common understanding, did they not partake of every advantage and benefit which nature gives to the flax crop, or, in other terms, if they did not save the seed with the same care, as is usually bestowed on every description of grain.

In thus submitting my opinions, which I feel myself called on to do in obedience to the instructions of your honorable board, I wish to be *understood* as by no means recommending, that the cultivators of flax *generally, particularly* those in the *North of Ireland*, where the *linen trade* is of vital importance, should vary from the plan they have hitherto pursued, until they have had *full and ample proofs* by practical *experience*, that flax may be rendered suitable for the finest linens, and at the same time yield seed. To accomplish this object I would again respectfully suggest, that some arrangement be made by your honorable board to introduce in different districts the plan of cultivating flax, as practised universally throughout the Netherlands—a system that affords the industrious farmer a full remuneration for his labour and capital, and gives employment to thousands of the labouring poor, which, if attainable, in the present state of the peasantry in the West and South of Ireland, would be of the greatest moment. Annexed to the report which I have now the honor to present to your honorable board, I have given, under the head of *Observations*, a detail of the mode practised throughout the entire of Holland, &c. in every process of cultivation, and treatment of the flax plant, from

the sowing of the seed until it was prepared for market. In thus following the instructions of your honorable board, I learned that permitting the flax plant to seed is not only found to be of the highest importance by the cultivators, as a matter of profit in that respect, but is likewise considered as adding much to its tension and produce of material, if properly steeped and treated in the after process; under this impression, whilst on my tour, I took the liberty of addressing your honorable board, and of suggesting to you such matters as then seemed to me likely to further the objects your honorable board has always had in view, that of promoting the general interest of the linen trade of Ireland, by improving the cultivation of flax; and I have now only to hope, that my humble efforts in your service in the Netherlands, may meet your approbation.

I have the honor to be,
My Lords and Gentlemen,
Your most ob't humble serv't,
PETER BESNARD.

To the Right Hon. the Trustees of the }
Linen and Hempen manufactures. }
(To be continued.)

ALBION'S SIXTH LETTER TO HIS SON.

"And thou that stalk'st

In pondrous boots beside thy reeking team,
Thy day rolls on, exempt from household care,
Thy wagon is thy mate, and the poor beasts
That drag thy dull companion to and fro,
Thine helpless charge, dependent on thy care—
Ah! treat them kindly! rude as thou appear'st,
Yet show that thou hast mercy."

I now intend giving you a few observations on the horses of the Albion farm—these horses were the large Flanders' dray, and the hackney kinds; the former, a bright black color, about sixteen and an half hands high, ears short, nostrils wide, under the jaws wide, eyes prominent—neck, short, arched, deep and thick, requiring a very large collar—withers, thick, and inclining towards the back—shoulders very deep, and projecting at the collar bone—chest, remarkably wide and low—ribs, very round and long—back, short and broad—loin, broad—rump, clefted, and joining well to the loin—tail, thick and nearly in a line with the back—fundament, small—sheath, large—and the whole body deep, short and well rounded—thighs, full, particularly on the outside nearly down to the hock, and also on the inside, where they unite—knees and hocks, large—legs, short, flat at the sides, and surprisingly strong made—feet, large and round—hoof, of a dark color and wrinkley; and the whole animal put together in the most complete manner—these horses formerly had manes nearly down to their knees, and legs covered with curled hair, with tails of an immense size, but of late, these peculiarities have got out of vogue; nor is the black color so much preferred as formerly; which is to be lamented, as it has induced people to cross them, with the view of getting stock of different colours, and of course a great many inferior horses will be produced.

These kind of horses, excited in a particular manner, the admiration of the Emperor of Russia, when in London, in the year 1814, where he viewed at several of the Porter breweries, from sixty to an hundred of them in teams, at each establishment, in harness of the best kind, with polished brass hames and mountings, engraved with the owner's names, and equipped in the best manner for carrying porter to the various sale-houses in that city.—These horses frequently sold during the French war, at from \$500 to \$1000 each, they being almost invaluable in the narrow and crowded streets of London, as it is said they

often draw in a drag cart, full three tons each; and they rarely refuse to draw their very best, even if harnessed to a post, being cool in temper, and very good natured.

"Affection to thy memory ever true,
Shall boast of mighty loads that Dobbin drew,
And back to childhood shall the mind with pride
Recount thy gentleness in many a ride
To pond, or field, or village fair, when thou
Held'st high thy braided mane and comely brow,
Or freely bore thy burden to the mill,
Obey'd but one short law, thy driver's will,
And oft the tale shall rise to homely fame
Upon thy gen'rous spirit and thy name."

As I have nearly got to the end of my paper, and having no more by me just now, I must defer what I have to say on the hackney horses, until another opportunity.

ALBION.
P. S.—Albion writes with a pen made from a "Dutch quill"—of course, it is slow and periodical in its movements, and it would be as easy to drive a "restive Donkey," as to force his little Dutch friend into action, when the moon, or some other ruling planet is unpropitious; however, in all probability, it will keep going on at its own jog trot, which is about the speed of a snail's gallop.

USE OF THE SWEET SPRINGS.

Directions for travelling to and using the waters of the Sweet Springs—given by the late deservedly lamented and celebrated Doctor Brown, to a much respected patient, who was far advanced in a pulmonary disorder, and on the eve of setting out for the Sweet Springs, in the hope of relief.—*Edit. Am. Far.*

DEAR SIR,

Agreeably to my promise, I set down to prepare you a few directions relative to the best manner of using the Sweet Spring waters. In pectoral disorders, to which class your's belong, these waters are only used as drink. The patients never use a cold bath.

Experience has uniformly shown these springs to be very purgative on first using them. Hence it has been found expedient to commence with very sparing portions. I generally have directed a gill three or four times daily for the first three days, increasing them gradually till they can be drank without regard to quantity. These waters are highly efficacious over almost every secretion of the body. They promote urine and perspiration freely, and give great perfection to the digestive organs, as will be proved by the keen appetite for food soon acquired there.

On these pervading powers, which they so eminently possess, are reasonably conceived to depend their distinguished use in disorders of the breast, obstructions of which organ they seem so well fitted to overcome. While using this medicinal spring, patients generally find it best to discontinue any courses of medicines which they may have found proper to have before employed. It being only necessary to have occasional resort to medicine, to operate any accidental symptom which may occur—for instance, should a lax come on, either from a too hasty use of the water, or from catching cold, it is necessary to check it by occasional doses of either laudanum or paregoric. On the contrary, should the habit become costive by journeying, or any other cause, it will be proper to use on such occasions, one or two of the laxative pills which you shall be furnished with. It will also not be amiss to have a sufficient stock of those pectoral medicines which have been in use this spring, as you may find them serviceable on the road, or at some other particular times, even at

the springs, should the weather be damp and rainy. Let your diet be such as you have been directed to use, as nearly as you can procure it. As a general rule, let it be light, and easy of digestion.

As the fogs are great and frequent in those elevated mountainous regions, it is not right to go out of your hut in the morning, till those vapours are gone. I have heard of much mischief from neglecting such precautions. In journeying from here you must be careful not to fatigue yourself by too long stages. Recollect that by travelling slowly at first, the great journey is performed, in event, with more despatch, safety and usefulness.

On the subject of bed and body clothes, let me remind you of the necessity of being well provided with flannel. That country is very cold through the morning and evenings. Before you get far from here, it is likely you, in your route, may pass over limestone countries, where the water is all of that kind. On such occasions, it is not uncommon for the travellers to feel the purgative effects of these waters to an inconvenient degree. On such incidents, have recourse to occasional doses of iaudanum or paregoric, as discharges from the bowels in your weakened situation would be very undesirable. I do not recollect, at present, any other circumstance worth communicating to you.

I have only to add my sincere wishes for the success of your expedition, and my earnest prayer that the kind preserver of mankind may guide you to streams of health, which in due time, will remove all your infirmities.

GEORGE BROWN.

Friday Evening, June 8th, 1798.

THE FARMER.

BALTIMORE MARKET.

PRICES CURRENT.—CORRECTED WEEKLY.
Flour, best white wheat, \$8—Howard street Superfine, \$7 25—fine do. \$6 75—Wharf, do. \$6 50—New wheat, \$1 25 to 1 27—Red do. \$1 10 to \$1 18—Rye, 50 cents—Corn, 50 to 57 cents—country Oats, 31½ cents—Beef, 8 cts. per lb.—Live Cattle, \$6 to \$6 50 per cwt.—Bacon, hog round, \$10—Pork, \$4 50 to 5 50 per c. lb.—6 to 8 cts. per pound—Mutton, 5 to 6 cts. per lb.—Beans, \$1 37½ to 1 50—Peas, black eyed, 55 to 60 cts.—Red Clover Seed, \$5 50 a \$6—Orchard Grass do. \$3—Herds' Grass do. \$3—Timothy do. \$4 50—Millet, none—Buckwheat, none—Flax Seed, 75 to 80 cts.—Whiskey, from the wagons 36 cts. per gal. including the barrel—Apple brandy, 30 to 32 cts.—Peach do., 65 to 70 cts.—Shad, \$6 50, scarce—Herrings, No. 1, \$2 75 per bbl.—No. 2, \$2 50—Fine salt, 60 to 65 cts. per bush.—Coarse, do. 70—Butter, (firkin) 14 cts. per lb.—Eggs, 16 cts. per doz.—New Hay, \$14 per ton—Straw, \$8.

MARYLAND TOBACCO.—Extra Fine Yellow, \$35 to \$45—Fine do., \$18 to \$30—Fine Spangled and Red, \$12 to \$18—good Red, \$6 to \$10—common crop, \$3 to \$5.

Sales.—1 hhd. extra Fine Yellow, raised by Major John Graham of Frederick county, sold at \$45 per hundred; a sample of which is left at this office, for the inspection of planters.—95 hhd. raised by Thomas B. Crawford of Prince George's County, say 28 Seconds averaged \$6 50—67 First at \$18 3-8—30 hhd. very fine Patuxent \$10 to \$25, by different planters.

Printed every Friday at \$4 per annum, for JOHN S. SKINNER, Editor, by JOSEPH ROBINSON, on the North West corner of Market and Bravard streets, Baltimore; where every description of Book and Job Printing is executed with neatness and dispatch—Orders from a distance for PRINTING or BINDING, with proper directions promptly attended to, addressed to J. Robinson, Baltimore.

direction the extra lockage would be still greater than upon the Potomac route, owing to the mountain being higher. To make a liberal allowance let it be estimated at 2,400 feet, which at \$625 per foot, as before, would cost \$1,500,000 and produce for the aggregate estimate of the Susquehanna connexion two millions of dollars. Thus the difference between the two estimated expenditures is half a million of dollars in favour of making *not the Potomac*, but the *Susquehanna* the medium of connexion.

100. My object in submitting the foregoing estimates for consideration has not been with any prospect of exhibiting to view the precise number of dollars and cents of expenditure that would be required; but to endeavour to explain *with certainty*, in what direction dollars and cents may be expended to the greatest advantage. In this, I trust, I have succeeded beyond contradiction. Under existing circumstances, it would appear to be impossible, for a single doubt to obtrude itself into any candid and intelligent mind upon the subject. Even in the economy of \$360,000 on the article of fuel, were the coal to be equally well supplied from the Potomac, the benefit would be reduced in the same proportion that \$1,850,000 the estimated cost of the Potomac Canal and its appendages, exceeds that of one million for a Canal to the Susquehanna; that is, it would be reduced in the ratio of 37 to 20, and instead of being \$360,000, it would be only \$194,600. Upon the same principle \$83,333 to the stockholders, would be reduced to \$45,045; and two millions towards supplying the population with subsistence, habitation and clothing, to \$1,081,081. The sum of these advantages in favour of the Susquehanna may be thus represented:

	From the Potomac.	From the Susque'na
Economy in fuel	194,600	360,000
Am't to the stockhold's	45,045	500,000
Benefit to the population	1,081,081	12,000,000
	1,320,726	12,860,000
		1,320,726

Difference in favour of the Susque'na 11,539,274

101. Or, the aggregate advantage in favour of the Susquehanna may be more distinctly comprehended in the following form: By 1,121,121 the sum of the two lower amounts in the above table in favour of the Potomac, divide \$12,500,000 the sum of the two opposite amounts in favour of the Susquehanna, and the quotient, which is eleven and one tenth, is proof positive from actual calculation, that leaving out of the question both the economy on fuel, and the advantage of half a million (99) in the cost of extending a Canal navigation over the Allegany, to unite with the waters of the West, the importance to Maryland, of a Canal to the Susquehanna is more than eleven times greater, in proportion to the required expenditure, than that of the Potomac Canal and its appendages.

102. This is evidence, in my estimation, at least, of a character too incontrovertible to be disputed. It appears to be sufficiently conclusive to carry complete conviction to every candid and intelligent mind, of the great and decided preference that is certainly and justly due to the Susquehanna Canal as the first and pre-eminent object of attention. Were even the most determined Potomac advocate to have a trial depending in court, of the utmost importance, and to possess equally invincible evidence in favour of his pretensions, he would, no doubt, feel himself entirely confident of success,

unless he had reason to believe he was to be opposed by *bribery and corruption*, or the tantamount operations of an *intriguing and log-rolling policy*. Bribery and corruption are terms too familiar not to be well understood; but for the information of any who may be unacquainted with the origin of a *log-rolling policy*, the following short explanation may be useful: Among a neighbourhood of farmers in the interior of our country, should they happen to have parcels of their land greatly incumbered with heavy timber, it is a very common practice to make *log-rollings*, at which a number of them *help each other for help again*, in rolling and collecting the logs into large heaps, that are afterwards set on fire and consumed out of the way. Hence the very significant epithet of *log-rolling politicians* has been conferred upon that unprincipled class of law makers, who, descending from their incumbent duty, and the high responsibility and dignity of their station, debase themselves into creatures of mere barter and compromise for party purposes: *Come vote for our Bill, and we, in return will vote for yours.*

103. In the American Farmer under date 11th July, 1823, page 123 column 3, a Potomac advocate has preferred his address, *principally to farmers and planters,—you who cultivate the soil,—you are the strength and sinews of the state,—you ought to be, according to your importance, independent, to give tone to secondary interests, instead of being governed by them. Exercise your right of suffrage at the ensuing election, judiciously and independently; and then you will infuse your spirit into the next Legislature.* But I trust that the farmers and planters, the strength and sinews of the state, who are thus addressed and called upon to exert their energies, will be more guarded in what they do than to suffer the fire of party to consume their intelligence. It must be conclusively evident to you, that it would be an extremely injudicious *exercise of your right of suffrage*, should you infuse into the next legislature a spirit sufficiently obstinate and perverted to give any interests either *primary or secondary*, the very irrational and discordant tone of selecting one enterprise to the exclusion of another of more than eleven times its promise of real utility and importance to the community. Does that wrong-headed candidate for office really exist, who could avow himself ready and willing to make such a most unwarrantable choice? Does he unworthily breathe the air of Maryland? Permit me, if such be the fact, to appeal, most strenuously, not only to the farmers and planters, but to the whole body of the population *en masse*, to all who have any due regard to the future prosperity of the state, their own interest, or the benefit of posterity, whether it is not high time that an alarm were proclaimed aloud from Dan to Beer-Sheba, that a watch word were impressively given to every individual, to all classes of society: *Be on your guard. Beware of that log-rolling politician.* Put it not in his power to do you an injury. Withhold from him your votes, *to a man*, and reserve them for another who is better than he.

WILLIAM KENWORTHY.

AGRICULTURE.

WATER PONDS FOR THE USE OF CATTLE AND FOR OTHER PURPOSES.

(Concluded from page 146.)

Mr. Marshall suggests that "a pavement would be a more regular covering; and, if the stones were set in lime and sand, would not only prevent worms from getting into the mould, and

upper side of the clay, when the pond happened to be dry; but would, in all probability, prevent weeds; and, when the pond required to be cleaned from mud, would be a regular floor to work upon." And the "only objection he has heard made to paving the bottoms of ponds, is, that it would be a temptation to cattle to go into the water, in hot weather; and, by standing there, would not only foul the water, but in time tread up the pavement, and injure the clay; whereas sharp loose stones prevent their going farther than the edge. If the stones made use of in a pavement were sufficiently large, the latter part of the objection would fall; and whether cattle standing in a pool, in summer, be detrimental or beneficial may, he thinks, be a disputable point." But that "whether or not the inside of the bason ought to be paved, the rim should certainly be a broad smooth causeway, with a gentle grassy slope from it; especially on the lower side; that the cattle may approach the water, without wading in dirt, to the injury of the bank; and without having sharp loose stones to walk and stand on, while drinking." He thinks that "a drinking pool, formed by a skilful artist, full to the brim free from weeds, and smooth round the edge, is, in a green pasture ground, as agreeable an object, as the eye can be entertained with," in such situations.

With respect to the "6, or the season of making them, the autumn is esteemed the best time, as has been seen above. Drought and frost are both enemies to new made ponds. In autumn, drought has generally abated, and a sufficiency of rain water may be expected in this season, to fill them before frost sets in. A covering of straw over the stones is the usual guard against the extremities of seasons." And where "a reservoir is formed in a slope, where the lower side requires to be raised with loose earth, it ought to remain a considerable time to settle, before the coatings be put on, otherwise, it is liable to settle afterwards, and crack the clay. He has seen an instance of miscarriage through this neglect. If there be much made earth requisite to be raised, the excavation ought to be formed twelve months before the claying be done," and if longer it is the better.

In speaking of the 7, or expense, Mr. Marshall remarks that though "it is not now twenty years since the discovery was made, the art is still partially hid under the veil of mystery; and is not yet become familiar to common farm laborers. In this neighbourhood, ponds still continue to be made, by men from the wolds; all of them, in reality or pretence, pupils of the first inventors." And "these men generally work by the gross; the price being in proportion to the diameter; but they seem, he says, to have no regular method of calculation" on the subject.

It is added that "ten pounds were formerly given, and may now be considered as a medium price, for twenty yards diameter; forming, claying, covering, and, generally, digging the clay, included; all carriage and extra labor being done by the employer. But in the early days of the art, and when two coats of clay were used, twenty pounds were, he says, given for ponds of this dimension." He states that "a circle twenty yards in diameter contains in its area 314 square yards. Therefore, each square yard of surface costs, at this price, seven pence-halfpenny." And that the solid contents of a cone, whose base is 60 feet diameter, and whose height is six feet is 269.4 cubical yards; each of which costs, in the above instance, eleven-pence-half penny." It is further stated that "five pounds have been given for a pond, twelve yards in diameter: which is ten-pence-half penny, each square yard of surface; and supposing it four feet deep, two shilling

each cubical yard of water." And three guineas were given for forty feet diameter, and four feet deep, the excavation having been previously formed. This may be called four pounds for the gross; which is about sevenpence a square yard of surface: or fifteen-pence-halfpenny, each cubical yard of water." He adds that "the men, in the last case, earned about three shillings and sixpence a day, without extraordinary exertion. In the first-mentioned instance, the same workmen did (according to their own assertion) make more than two shillings and sixpence a day. But a large pond gives longer employment; and the business of pond-making being uncertain and inconsistent, travelling workmen can, he says, afford to make a large pond at a cheaper rate, than a small one." And "the curve superficies, or superficial contents of the sides, of a cone twenty yards in diameter at the base, and two yards high, is, he observes, about 320 square yards. This in making a pond of those dimensions, is the quantity of coating: for each yard of which near 7d. was given in the first instance, and less than 7d. in the last. Sixpence each square yard of surface to be coated, may perhaps be taken as a fair medium price." At present, however, work of this sort is performed at a much higher price, as from ten pence to a shilling or more.

In order "to ascertain the quantity of coating to be done, he advises to measure the exact circumference or rim of the pit, when finally formed and adjusted for claying; this dimension multiplied by half the length (or depth) of the side (measuring from the brink, down the slope, to the centre) is the quantity of surface to be clayed and coated. The digging would (under this mode of calculation) fall proportionably heavier, on a large pond than on a small one; but this would be counterbalanced by the advantage above mentioned."

It is added that "the quantity of clay used, in the first instance, was about forty cart loads, fetched about three miles: in the last, about fifteen loads fetched one mile. The quantity of lime, in the former case, one chaldron; in the latter, half a chaldron."

On these grounds, he says, "it is plain that the larger the pond, the less in proportion is the expense. A reservoir, to contain two hundred cubical yards of water, requires little more than three hundred square yards of coating; whereas one to contain only fifty yards of water, would require one hundred and twenty yards of coating; consequently, a cubical yard of the former, would only cost (at nine pence a yard for manual labor, materials and carriage) eighteen pence; while the same quantity of the latter, would cost near two shillings and sixpence. This is therefore a point that should be attended to in this sort of work.

In speaking of the benefits of these ponds, it is remarked that, "the superiority of those made in the manner above described, to those which have formerly been made, by some other art, or which have been formed by nature or accident, may be mentioned. During the dry seasons which have prevailed of late years, it has been observed, he says, that newly made ponds retain a supply of water, when the waters of other stagnant drinking places are dried up. This can only be accounted for, he thinks, perhaps, by their perfect retentiveness, and by their being free from weeds, which convert to their own nourishment, and throw off daily by perspiration, a great quantity of water. Upon the wolds their excellence was, he says, most conspicuous:—while one man was driving his stock, three or four miles to water, his neighbours, "who had made ponds" upon their farms, were free from

this serious inconveniency. In many situations, artificial ponds may, he thinks, repay the expense of making, the first dry season. Driving stock to distant water, in hot weather, and in a busy season, is an expense, and detriment to the stock so driven, which it would be difficult to estimate in many instances."

This important subject is concluded by remarking that on "examining the ponds in this neighbourhood, which have been made some years, the evil effect of covering with loose stones is evident. As for one, two, three, or more yards round the edges, according to the time they have been made, the use they have been liable to, and to the steepness of their sides,—the stones are entirely displaced, or trodden into the clay; which is, by this means, exposed to the feet of cattle, and to the open attack of drought and worms. For a while, he says, the clay even thus exposed, preserves its retentiveness; but in time it is destroyed, and the most valuable part of the pond entirely lost." He adds that "this effect is so probable, so evident to be foreseen, that, on the first reflection, it seems astonishing so unsuitable a covering should be universally adopted. A beast when it goes into a drinking pit, necessarily throws the chief part of its weight upon its fore-feet; which, in the act of drinking, most especially are placed, as for the intention of forcing, whatever they stand on, down the slope, toward the bottom of the pit. Upon loose stones, laid on a steep surface, cattle cannot make a step, or move a foot without producing this effect in a greater or less degree, and, by repetition and length of time, the entire coat (except some few stones which happen to be trodden into the clay) must, in the nature of things, be forced into the centre." But this absurd practice "was first established upon the wolds, whose stone is of a perishable nature; a species of chalk; which on being exposed to air and water, and to the treading of cattle, unites into a cement, which, forming a regular casing, preserves the clay from injury, for a considerable length of time. Loose chalk, as a covering was, therefore, a good thought of the first inventors; (indeed upon the wolds there was no alternative); and it is not to be wondered at, that their pupils, mostly day laborers, should imitate the practice in this country, by making use of loose stones for the purpose." But "perishable or soft stones of any species, a strong rough gravel, or even sand, would, he believes, be better than loose, hard, unperishable stones." Though "in this neighbourhood, where stones of various kinds abound, or, in any country, where stones of a proper size can be procured, at a moderate expense, there appears to him to be no choice, with respect to covering. A regular firm pavement, strong enough to bear stock without an impression, would last through ages; and although the expense, in the first instance, would be something more than that of loose stones, its durability would, in the end, doubly repay it. Even the wold ponds, which have been made fifteen or twenty years, are many of them beginning to fail, and will, in a few years more, require to be fresh coated: whereas, a pond properly paved would, in all human probability, remain perfect, for at least a century. Where rough stones are used they should be placed with the smooth side downwards, upon the clay." And besides this the pavement of stones has, he thinks much less tendency to be disturbed by the pressure of the feet of the animals, from its being a sort of an inverted dome which acts as an arch against the materials underneath it. See *Rills and Drinking ponds*.

The following hints have been suggested by Dr. Anderson in his *Recreations in Agriculture*, &c. for collecting water in different cases for

farm uses, in situations where it is not easily procured.

For this purpose he would "beg leave to direct the attention to one never-failing source of water in this island, which if duly husbanded, will certainly, he says, preclude the danger of want at any season for almost any purpose, either for man or beast that can ever occur. He here refers to the rain that falls upon the roofs of houses, which amounts to a much greater quantity than most persons are aware of. It has been ascertained by repeated experiments that in scarcely any part of this island does there fall less than 28 inches deep in a year. At this rate there will fall upon every square foot of roof of any house above seventeen gallons and a half of water; or upwards of two hogsheads and a half on every square yard. At that rate, a house of thirty feet in length and twenty in width (which is not larger than an ordinary cottage), would collect one hundred and seventy-five hogsheads in a year, which would afford the expenditure of half a hogshead per day. There are few farms with their offices that have not roofs to ten times the extent of the above; so that were this water all preserved they could expend at the rate of five hogsheads a day throughout the whole year, which would be sufficient for a very extensive stock of cattle. But when we consider that in almost every situation cattle can be easily supplied with water from other sources for the greatest part of the year, it will appear very plain, that if all this water were carefully preserved, no farm could ever be in want of water for cattle or other purposes. All that is wanted then is, to discover an easy manner of collecting and preserving that water till it shall be wanted;" which he proceeds to show is not a difficult matter. "Few houses are now built, he says, without having spouts placed along the eaves to collect the rain-water and convey it into a reservoir, usually a wooden cask, for the purpose of washing. But this reservoir is usually so small as soon to be filled, when the surplus runs over and is lost. Instead of that let the whole of the water thus collected, be led by pipes to one place, where it may be let into a well, dug in the ground to a proper depth for that purpose, and covered at top. It will there be screened from the sun, and prevented from evaporation, so as to be kept sweet and cool as long as is necessary; and it is well known that no water is so pure and wholesome as rain water. But to those who are peculiarly delicate it may occur, that some impurities may be washed off by the rain from the roof, which they would wish to get rid of. This may be easily and effectually done. By sinking another well at a moderate distance from the first, making a passage between the two near the bottom, to be filled up with small clean sand and gravel, through which the water must percolate before it reach the last well; in consequence of which it will be perfectly purified. The pump for supplying the family should be fixed in this last well, where it will of course find nothing but pure water."

But "for the sake of cattle, if it be necessary, he advises that another reservoir be formed, also under ground near to the pump well, with which it may communicate by means of an opening at one side near the top of the well through which the superfluous water will run off when it raises above that level. This may be made in the form of a trough, covered as far as may be found convenient, and open towards one end for the cattle to drink, without allowing them to set their feet in it."

In cases "where the house is upon an eminence, it will be very easy to convey the water from this last reservoir, by means of a pipe

under ground, to any convenient part of the fields, or the garden, where it may terminate in a box, to communicate with a trough for the cattle by means of a ball-cock, which always allows water to flow into the trough as it is drawn off, and closes of itself when it is full, so as to keep it always full without ever running over. In this way abundance may at all times be had without any waste; and the pure element procured for the cattle, without any extravagance of expenditure. If pools are made in the lower places of the fields, the cattle may in these occasionally cool themselves: but if they have ready access to the troughs, they never will drink there. But for fields which are at a distance from the house, where the surface of the ground is not a dead level, wells of this sort may be formed by collecting the water that flows over the surface of the ground, during rainy weather, and leading it into these wells. But these reservoirs should be always covered, and only have an open trough at one place to allow cattle to drink. He supposes that by these very simple contrivances, many parts of the country that are now much distressed at times for want of water, may be effectually relieved, so as never to suffer any future inconvenience; and much expense in carting water to many villages might be entirely saved."

Report of an inquiry into the mode of cultivating and treating Flax, in the Netherlands, &c. by Peter Besnard, Esq. Inspector-General for Leinster, Munster, and Connaught.

(Continued from our last.)

OBSERVATIONS ON THE MANNER OF TREATING FLAX IN IRELAND.

SOIL.—In selecting soil for the cultivation of flax in Ireland, the best and richest that can be procured is always preferred, but from the number of persons engaged in that branch of agriculture, such is not always to be had. The country likewise presents so great a variety of soils, and the article being grown in small quantities, by poor persons, who are of necessity governed by local circumstances, that no rule can be named for the exact quality of ground under flax tillage, and it may be found growing in wheat, barley, and oat stubble, and sometimes in lea-ground, but more frequently after a potato crop, which is generally preferred to any other.

PREPARATION OF THE SOIL.—It does not appear that there is any given rule followed in Ireland, for the preparation of the soil for flax cultivation, every person pursuing his own plan, some ploughing deep, others lightly, some sow under the harrow in potato ground, without ploughing, whilst others plough two or three times, and more prepare with the spade.

SOWING.—The seed sown in Ireland is of various kinds, Riga, Dutch, English, Home-saved and American;* in the South-West provinces, the latter mostly prevails, and is decidedly the worst of any named, as it is subject to fall at every blast of wind, or heavy shower, and often brings with it a long twining weed, highly injurious to the plant; it is also subject to mildew, or, as it is termed, to fire. As to the quantity sown to the acre, it varies in every district, according to the quality of the soil, and description of seed; no given rule can therefore be named, but on the data, of all ground being

equally suitable; four bushels to the plantation acre is calculated on as the quantity necessary. The time of sowing varies greatly, often from the end of March, to the first and sometimes second week in June.

PULLING.—In Ireland it is generally believed that flax should not be allowed to arrive at maturity, in order to render it fine and soft for the manufacture of linen; under this impression the cultivators pull it green, and in nine cases out of ten, take it at once with the capsule or seed* on it to the steeping pool.

That the seed of the flax grown in Ireland, for a series of years past, would, if properly attended to, have added considerably to the profits of the cultivator, may be estimated on a view of the following extracts from the returns made to the Linen Board, and from which it appears that a sum scarcely credible has been lost to the country.

RIPPLING.—In taking the capsule from the flax plant in Ireland, where it is but partially done, the process is performed with machines, somewhat similar to those used in Holland, but

* If, instead of suffering the seed capsules to go to waste, by throwing them prematurely into the steeping-pool, they were allowed to ripen, it occurred to me, that they might turn to account in a way that would have many advantages; for the seeds being known to contain a large quantity of oil, and as the expressed oil is used for the purpose of making an inflammable gas, now coming into extensive use for affording light, we might render unnecessary the previous process of pressing out the oil, and prepare the gas directly from the capsules. Impressed with this idea, I requested of my friend, Mr. Donovan, Professor of chemistry to the Apothecaries' Hall in Dublin, to make the experiment; which he most obligingly performed and found that the capsules, when exposed to destructive distillation, afforded the usual products of vegetables similarly treated. Pyroligneous acid, tar, and carburetted hydrogen, were produced, as in other cases, but with this difference, that the gas, which, under ordinary circumstances, burns blue, was so far changed with the vapour of volatilised oil held in chemical solution, that it burned white, and possessed a tolerable degree of illuminating power. There was also a faint blue light surrounding the white: but there can be, in my opinion, but little doubt, that had the capsules been sufficiently ripe, and the oil fully developed in the seeds, the light would have been perfectly white.

† Return of flaxseed sown in Ireland for the last ten years:

* In Pennsylvania the previous crop for flax culture is Indian corn, after which the ground is lightly ploughed, once only, in the month of March following; the seed is sown early in April, and the crop pulled in the middle of July. The twining weed that grows with flax in America is there called wild buck wheat.

This flax, if treated according to the practice in the Netherlands, would have produced, at the most moderate rate of calculation in that country, of 20 bushels to the English acre, 15,272,820 bushels of seed, and which valued at the low rate of 10s. per bushel, or £3 10s. per hogshead, would amount to £7,636,410.

not made on so regular a plan as they are in that country, where those implements are as carefully laid by, after the flax season, as any other farming utensil.

STEEPING.—For this very necessary process there is no settled rule: the growers of flax, as in the case of preparing the soil, following each his own plan; whilst in the Netherlands, where flax is the best prepared, generally speaking, of any in Europe, one settled rule is adopted, and uniformly practised.

In Ireland, flax is steeped in every description of water that may be met with, without regard to the situation or dimensions of the pools, and it may be seen, in many instances, several feet under water, in bog-holes, whilst in other cases it is laid in running streams, near the surface, subject to floods and partial dryness; and it rarely happens, that two flax-growers follow one method of steeping in every particular; generally speaking, in placing the sheaves in the steeping-pool, no order is observed, but they are all promiscuously thrown in, often in large bundles of various sizes, and thus it lies, heads and points together, crowded and pressed down with stones, sticks, or sods, &c. by which means the discharge from the upper bundles frequently lodges on those below, and stains them in that irregular manner so much complained of. Again, the quantity of resin contained in the bole, so unnecessarily left on the plant, not only adds considerably to the general discharge of coloring matter, but also retards the fermentive process; to these injurious practices may be added, the bad effects arising from the partial exposure of the plant in the steeping-pool to the influence of the air, those parts on which the stones, &c. rest, to keep it down, being covered, whilst all the rest is exposed.

In taking flax from the steep, in many cases, great neglect occurs, the sheaves not being washed before grassing, and it often happens, that the middle ones, on which the mucilage from the upper sheaves had rested, are exposed to the air in that state, and thus become incrustated with the drops of the coloring matter discharged: of the ill effects arising from the improper treatment of flax in this process, in many parts of Ireland, but particularly in the West and South, we have innumerable instances, and daily complaints are made by the Northern bleachers of the difficulty they find in bringing to an even color, linen manufactured in the provinces of Munster and Connaught. This fact has been stated to me by many of the most respectable merchants in the trade since my return from the Netherlands, and I am satisfied, that unless the process of steeping flax, as practised in that country, be generally introduced into the South and West of Ireland, the cultivation of flax cannot be advantageously carried on, or extended, so as to become an article of commerce, nor can the linens made from flax, prepared as it is at present in those provinces, be as well finished for any purpose as if they were manufactured from flax properly steeped.

DRYING.—The fuel used to dry flax in many parts of the South and West of Ireland is turf, which, like almost every other vegetable, gives out, on combustion, pyroligneous acid and empyreumatic oil, both of which are highly colored; and in cases where flax is badly steeped, and the mucilage not discharged, or strained by impregnated water, the acid and oil from the turf may be found to act as mordants, and so fix the colours, that the most experienced bleacher cannot completely eradicate them from linen made of flax so treated.—The difficulty of discharging stains in linen, the manufacture of the South and West, is well known to many of the factors in the Linen Hall of Dublin.

BREAKING AND SCUTCHING.—In Ireland those processes are performed in various ways, sometimes by mill machinery, with breakers and scutchers, and in other cases with every variety of hand implement that can be procured, often of the most simple and imperfect kind, and such as contribute much to the labor of the worker, and proves ineffectual in execution. In Munster and Connaught, those imperfect implements are most in use, and, until within the last few years, scutching machinery by power was unknown in those places. In Ulster, scutch mills are in very general use; that which moves vertically is most approved of in that quarter, because it is said to take less power, and is less expensive than that with the horizontal motion; the latter, however, are in general use in Scotland; but it seems as yet a matter of doubt in both countries which of the plans is the best, so much depends on the skill of the workmen, the state of the flax, and its quality.—It is, however, necessary to remark that no description of machine, whether worked by hand or by moving power, can be operatively useful, if the flax be not well prepared in every previous process.

An Essay on the principles and practice of Rural Economy, by G. W. Featherstonhaugh, Esq. published by the New York Board of Agriculture.

SECTION I.

This earth, as we all know, is a round and firm globe, carrying upon its surface men and beasts. These, however, would soon perish and the earth become void of inhabitants, if the means of preservation were not abundantly and conveniently provided for them. By a beautiful providential arrangement of our Creator, the earth is endowed with a capacity to produce vegetable matter, fitted to sustain and preserve the beings which inhabit it; and this vegetable matter, in obedience to the law which governs it, remains permanently where it first grew; whilst to men and animals, the power of sight and motion is given, to enable them to change their places in search of new food, and to perceive it when it is found.—This capacity, which is in the earth, of producing vegetable matter, is not, strictly speaking, contained solely within itself; because the action of the sun and of the air we breathe, is necessary to unfold it. A globe of solid iron would not, probably, acquire the property of producing abundance of vegetable matter by exposure to the sun and air; nor would a globe of rich vegetable mould, probably possess that property without their influence. All the parts of creation depend harmoniously upon each other. The fertility of our earth depends upon the great luminary of our system; and the power of the sun, itself, may be derived from bodies extraneous to it, the chain of a dependence extending through the universe, and ending only with Omnipotence. This property of producing vegetable matter, arises from the loose and friable materials upon the surface of the earth, being acted upon by the combined influence of the sun and air. It is a further providential arrangement, that all this vegetable and animal matter which is found upon the surface of the earth, when it comes to maturity, gradually decays and dies; and the remains, if collected and returned into the bosom of the earth, are there, by the agency of heat and moisture, converted again into such elementary substances as are the proper food and sustenance of new organized plants; but this admirable providence does not end here: The elements of which all matter is formed, are in this last stage, of a very light and evanescent

nature, and consequently a very large portion, perhaps nearly the whole of dead organized bodies, from its levity, the exhalations of the sun, and the action of the wind, is carried far away from the surface of the earth, and apparently lost for the purpose of re-production; if this were true, the earth would be constantly diminishing in size, and its duration be limited; but Omniscience has guarded the whole. The atmosphere which surrounds the earth, is not only the salutary fountain of the air necessary to our existence and to the existence of all organized forms, but it is a convenient receptacle for the light bodies which escape from the earth. The heavier particles which float in the atmosphere are brought down by fertilizing rains, and the more evanescent ones, which are exhaled by the hot beams of the sun, are, upon the setting of that planet, condensed, and fall again by their own weight, with the kindly dews. Whatever falls upon the ocean, is converted to the sustenance of its innumerable inhabitants; and whatever is lodged on the highest mountains, is, by the agency of rain, washed into the vallies. The vegetation which covers the face of the earth, supports the herbivorous beasts and insects, and they, in turn, support the carnivorous class of animals. The varieties are innumerable yet no one kind is permitted to increase beyond its bounds. A check is found in the propensities of the varieties themselves; each in its turn, lives its appointed time, then decays and dies, and by its death, furnishes materials for new forms of bodies. Thus the whole of this wonderful economical system, is perpetual in its nature, as long as the Almighty hand that formed the universe, is pleased to continue it in its present relations. God, however, in this, as in all his works, has abundantly provided his creatures with the means of carrying on his fair scheme of creation, in a prosperous way; he has set good and evil, abundance and want, before us, and has left us free agents to choose betwixt them. We may, if we please, assist in the accomplishment of his intentions, by securing our comforts, and advancing the general interests of mankind; and we may, if we please, run counter to his benevolence; yet the power we possess of distinguishing betwixt good and evil, infers that we are responsible to God for the existence of that power.

The business of a farmer is clearly, then, to extract from the earth as much produce as it is capable of yielding to him; and when it has yielded to him as it can, and will do abundantly, he must return to that earth, a sufficient quantity of manure, to enable it to yield a new supply to him; for manure is the food and sustenance of plants, as they are of animals. Mankind flourishes by providing abundantly for its nourishment, and negligence of that great duty, produces famine and misery. He who cultivates an exhausted soil, without enriching it with manure, is acting in opposition to his general duty to God and to his neighbour. In a country like this we inhabit, clothed with thick woods, the first operation in farming is easy, and does not demand much skill. The cutting down of timber is achieved by strength. The decayed leaves and limbs of the forest, which fall upon the surface of the earth, furnish a convenient and valuable nourishment to the plants destined to grow there. This natural manure would probably endure for a very long time, but the almost necessary practice of burning those fallows, contributes to hasten its consumption, and dissipates a very large portion of its essential parts. It would be better for farmers to content themselves with one or two crops at most, from land in that situation; because some strength should be left for the future crop of grass. Grass must have something to nourish it,

or it will die, and weeds grow in the place of it, and these new fallows, if not seeded down with grass seeds, will eventually produce weeds. There are few weeds that domestic animals will eat; the weeds, therefore, will go to seed, the seed will be deposited on the earth, and be scattered on the surrounding fields; and when the roots of these fallows are sufficiently decayed to yield to the plough, many of those pernicious seeds, which last for years, will be turned in, and the ground kept continually foul; whilst if the fallow is immediately laid down to grass, before it is exhausted, a rich and clean bite will be furnished, and the dung of the animals, particularly sheep, will strengthen the soil, and nourish and preserve the grass in a pure and clean state, until the ground is fit for the plough. The difference betwixt these two modes is, that in the one, an acre of weeds will maintain two or three sheep scantily, and when it is ploughed, a foul and indifferent crop; in the other, an acre of rich grass will maintain from six to ten sheep well, and when ploughed, will give a plentiful and clean crop. It is at this point, when the roots of the forest-trees are sufficiently decayed to admit the plough freely, that agriculture properly begins.—The roots are to be removed, and the stones are to be gathered, and built into substantial and convenient fences, with as much expedition as general circumstances will admit. By attending to this important point without loss of time, the farmer is in fact, enjoying the utmost extent of his means; for an acre of ground, incumbered with heavy roots, and numerous stones, is to all practical and useful purposes, scarcely half an acre; the tillage of which is attended with much trouble, and wear and tear of teams, ploughs and gear; besides it is impossible to cultivate the ground properly and profitably, whilst it is thus encumbered. A well cultivated piece of ground, is in a condition the very reverse of this; it is without incumbrances of any kind; it is as clean as a garden ought to be, and every inch of it is producing some profit to the cultivator. It would be a fruitless effort to advert to any particular method of ploughing amongst stumps and stones, or to endeavour to patch up by expedients, a bad course of husbandry. It is sufficiently obvious, that the true business of a farmer is to draw from the earth as much as it can yield; and this he cannot do without first clearing the surface of his fields from every obstruction.

But the natural impediments to a successful agriculture, do not consist entirely of those obstructions which are found upon the surface. Some of the richest soils, and which are to be found on almost every farm, even when the stumps and stones are removed, are incapable of sustaining a profitable vegetation, on account of the excess of moisture with which they are charged, either from their sunken situation, or the spongy nature of their component parts, and this excess is only to be diminished by the agricultural operation called draining. Delicate plants, proper for the food of domestic animals, do not flourish in swampy soils; their tender fibres must have a lighter bed to extend themselves in, and which should be sufficiently dry to admit the genial rays of the sun. This remark is particularly appropriate to clovers, which are tap-rooted. The Linotny or Herd's grass, however, which has a bulbous root, flourishes best in a moist rich soil; but in soils however rich which are continually saturated with water, the most valuable grasses will not thrive, and if they are not drained, coarse sedges, and tufts of bog grass will continually cover a portion of the farm which ought to bring in the greatest profit to the farmer. Draining, therefore, is an operation as necessary as ploughing, and ought always to precede it. In ordinary sit-

tuations, where there are no obstructions above, and the declivity easy, the task is not so great, nor very expensive: a cut two feet wide made in the right situation, three feet deep, and narrowed to a foot at the bottom, is sufficient to lay the land dry for a great distance, if it is carefully cleaned out every fall; for the distant water will in twelve months make itself small channels beneath the surface to the cut, which will be kept open by continual percolation: by this simple operation, lands which never produced any thing, are made to produce heavy crops of turnips, or grain, and become productive hereafter: the expense even when the labour is to be paid for, is nothing compared to the benefit. A laborer may easily make three rods a day, which at fifteen dollars per month, for board and wages, is about eighteen cents a rod. A cut of this description, with smaller ones leading to it if necessary, is amply sufficient, and will stand to all effective purposes in the place of those expensive methods practised in Europe. If it be an extensive bottom, and proper for a permanent meadow the cut may be enlarged to any width at the same expense, by varying the method. The plough and the scraper should be used instead of the spade, taking care to finish the banks with a neat slope to the bottom, by the spade and rake, and sowing a few grass seeds upon it at a proper season to take root before the freshets come on. If this be done in a proper manner, the grass will grow as well on the slopes and the bottom as on the surface of the meadow, and be cut with as much ease and advantage. Wide drains of this description seldom want cleaning out: The sod prevents the soil washing in. A cut of this description, which I made eight years ago in a piece of interval of 200 acres, has not wanted cleaning out till this moment.

Let us suppose all this done. Let us imagine a prudent man anxious to do well, and prepared to adopt a permanent system for the management of his farm. His well arranged dwelling and its out-houses, are conveniently situated on that part of his farm from whence he can survey the greatest portion of it; this is a point of the first importance. If they are not protected from the inclement violence of the north-west winds of our climate by natural woods, he has provided against that defect by transplanting trees into proper situations; he will feel the benefit of them more and more every year. If water can be led into his barn-yard from an adjacent spring, it is done; and if there is no such thing, a well or a cistern must supply the place of it: His comfortable cow stable is divided into convenient stalls, where his milch and working kine are secured in the night time against the severity of the season, and are only turned out into the barn-yard from ten to four during the day: His yearlings, of every description, are to have the best food, and the warmest births; for he knows they must be kept growing the whole winter, or they can never be expected to become perfect of their kind: His necessary pair of horses are well provided; for they are to take his family to church, and his produce to market: His ploughing, he thinks, upon the whole, can be more advantageously done with smart oxen, though the horses are to assist a great portion of the season: He prefers mares too to horses; for if an accident should disable one of them from working, it is not a dead loss, as he could sell her or keep her as a breeder: His fields are laid out into convenient divisions, and substantially fenced with stone wall, if stone is found on his estate; for he reasons thus: "It costs as much to go into the woods to cut down trees, split them into rails, draw them to the field, and set them up, stake and rider them, as it does to lay a good wall. The rail fence must be

righted a little every spring, and every four or five years must be completely re-set; the storms too, often blow great portions of it down to the ground; it never turns stock in a perfect manner, and in eight or ten years from the time the rails were split, they are all rotten, I shall therefore have to go into the woods and cut more timber: whilst the timber is thus wasting, the stones are occupying the ground instead of grass; they are stopping the plough and harrow, increasing the blacksmith's bill, and for all the real purposes of farming, a field of four acres is really only a field of three acres of land, and one acre of stones; whilst the same field enclosed with a wall, would contain four acres of land in a proper state for tillage; would save a great deal of money in my tools, give me a permanent fence, and leave my timber standing in the woods." If there is not a run of living water in each of his pastures, he knows too well the importance of animals having access to water at their own pleasure, and particularly in times of drought, not to excavate a pond in some low situation, where the ground inclines most naturally for that purpose, and this is most conveniently done at the junction of four fields, where the occupants of each field can have recourse to the same pond. On clayey bottoms this is not an expensive operation: a pond of sixty feet in diameter, sloping from the edge to about seven feet deep in the centre, can be worked out with the plough and scraper, and will contain water enough in the driest season for four tolerably large fields. The size, however, can be accommodated to the field or fields, and the quantity of stock intended to be served. It is a most bitter piece of cruelty to leave animals sometimes a whole week without water, in the hottest part of the season, when any rough excavation, made in a day, would have sufficed to relieve them. On sandy and porous bottoms the operation is a very nice one, and more expensive. When the excavation is made, the sides raked smooth, and beaten down to a uniform surface, fine slacked lime to the depth of three inches, must be carefully spread over every part of it. The lime is then watered to make it more compact. Clay of a proper quality being already provided, and moistened enough to render it manageable, it is laid on the lime in small portions, and well beat down with solid beetles. A little water is occasionally sprinkled over to facilitate this work; the clay is thus gradually laid on, till it is six inches thick, has acquired a proper temper, and an uniform consistency. No crack of any kind must be there, as it would carry off the water. Upon the clay, when thus prepared, coarse gravel or any hard materials of small size are evenly laid on to the thickness of a foot. The sooner the pond is filled the better, after it is finished; and it is better if it is placed in a situation sufficiently high to prevent dirt from washing in and choking it. The water lime so recently discovered in this state, and of which so beneficial a use is reported to have been made in the great canal, would be an admirable substitute for common lime. The object of the lime is principally to prevent worms boring in the pond, but the water lime, if used in sufficiently quantities, and in a proper manner, might possibly serve the purpose of the clay also. A pond of sixty feet diameter will contain upwards of seven hundred hogsheads of water, and may be completely finished, as I have been informed by an intelligent Yorkshire man, who has followed the occupation of constructing ponds in his own country, where they were first introduced, for about fifty dollars. A farmer thus prepared, deliberates upon the system he ought to follow in order to derive the greatest advantage from his land. Must he persevere in the

common course of husbandry prevailing around him, or shall he abandon it in favour of another? In order satisfactorily to answer this question, we must first consider what is the nature of the soil and region we occupy. There are two systems into which husbandry divides itself: one, the raising of grain, the other, the raising of domestic animals; and the soil and the region are the guides that point out to the farmer which of these two systems he ought to follow and adhere to; for the laws of nature will prevail, and the utmost we can do is to assist her in her operations. Under the grain system, it is understood that a farmer depends upon that for all his resources; and under the stock system, it is understood that he depends upon that for all his resources. A farmer who exclusively follows the grain system, is obviously acting in opposition to the laws of nature, and to his own interest: for when he has exhausted his lands, which he soon will do, he will have no vegetable and animal manures in sufficient quantities to restore them. The greatest error, therefore, may be committed on this side; for if we reverse the matter, and suppose a farmer to follow exclusively the stock system, on a soil well calculated for grain; the great quantity of manure that he would produce, would certainly ensure him a succession of excellent crops, whenever he might choose to change his system. There are countries, however, which have been so rich and fertile, such as Sicily, which is a volcanic country, and abundantly charged with fossil manures, that the ground has yielded continually the most abundant crops without any manure; and there, undoubtedly, the grain system is the true one to follow. And there are countries where the soil is so poor, and the winter is so extremely rigorous, that grain can rarely be raised of any kind; and it is in such countries that the stock system is the true one, because the dependence of the inhabitants must be altogether upon animal food. The rein-deer supplies to the Laplander all his wants. It furnishes him with meat, milk and cheese; he uses curds in the place of bread; his raiment is made altogether from its skin, and from that and its intestines, and its bones, he derives all the artificial subsistence which we get from flax, hemp, wool and wood. Betwixt these extreme points, there is a medium where they mutually support each other; there the live stock keeps the ground in heart, and the ground keeps the cattle and the owner of them. The state of New-York is situated in that happy medium: in many parts, however, of the state, there are entire districts of country where, under this union of circumstances, one of the systematic characters predominates over the other; and indeed frequently upon the same farm, soils so totally different in nature are found, as to indicate at once the particular uses to which they ought to be referred. In tenacious soils the loam, or lighter part of the ground, generally rests upon a bed of clay at no very great distance from the surface: the clay retains the moisture and keeps it sufficiently near the top to be within reach of the roots of the plants, which is the cause of the perpetual verdure that is exhibited in some districts: and as it is often found combined with an inexhaustible strength of soil, and a great elevation of country, over which continued currents of salubrious air are passing, as necessary to health in animals, as in man: such lands may be considered as the natural grazing districts of the state. In these situations, and under a proper system of cultivation, as fine crops of grain may be raised as in the most favoured grain districts; but the system which is there imposed by situation, is that of raising live stock; for there it is that the greatest quantity of vegetable matter can be

comparatively produced in the course of the year. It is a happy reflection to those who inhabit such regions, that possessing a soil eminently calculated to furnish them with the means of taking the seed in the various breeds of fine animals, they at the same time enjoy the additional resource of raising abundance of every kind of grain. Yet it is susceptible of demonstration that the raising of grain in such situations, more than is necessary to our families, and the support of our animals should not be a main object; but ought to come incidentally into the course of husbandry we are bound to follow.

It is not here the place to enter upon the many details belonging to the successful management of live stock, or to attempt to describe the various qualities by which one breed of animals of the same family is distinguished in excellence from another. Little attention has been hitherto paid to this important subject: Farmers have been hitherto in the habit of judging of the value of the breed from the bulk of the animal, which is totally wrong; but the country is rapidly advancing in improvements of this nature, and the finer breeds of animals will soon be sufficiently increased to afford every farmer convenient opportunities of acquiring an exact judgment in these matters. Every man should use diligence in doing this, and when he hears of a more valuable breed of any kind of stock, than that which he possesses, he should go without loss of time and acquire it, if it is convenient to him.

Editorial Correspondence.

MISCELLANEOUS ITEMS—*Extracted from Editorial Correspondence since our last, and touching, amongst other topics, the prospects of agriculture in Pennsylvania, New Jersey, Virginia, North Carolina, and Maryland.*

CHEAT—NAKED BARLEY—FIELD PEA—GRAPE, AND OTHER VINES

Washington, (Penn.) July 19, 1823.

In this part of Pennsylvania, our crops, considered collectively, are unusually fine. Although many fields of wheat were destroyed by the fly, such as escaped turn out well. It may be set down at about *one fourth under an average crop*. The rye may be set down at about as much above. We have not had so fine a prospect of corn for many years. Oats remarkably heavy. Grass nearly double last year's crop. The season has been uncommonly wet. More rain has fallen during the last four weeks than fell the whole of the last two summers. This has produced a plentiful crop of *cheat*; if your friend "Plain Sense" were here, I could shew him plenty in my *timothy meadows*, where wheat never grew. This upsets his "first premises." One of my clover fields, where there has been neither wheat nor cheat for several years, is now one third cheat. A large portion of another of my clover fields is thickly set with a very troublesome article, commonly known here by the name of rag-weed. Now if "Plain Sense" will explain to me how this rag-weed got into my field, I will explain to him how the cheat got into his, without being obliged to resort to transmutation. I am clearly of the opinion that the cheat and the rag-weed are both produced precisely in the same way. I believe the seed was in the ground, and the open and the changeable winter froze out my clover roots, and the Hessian fly, or some other enemy, destroyed "Plain Sense's" wheat; and this furnished an opportunity to these pests to spring up. Let me here remark

that nature will not be idle; and it becomes our place to keep her usefully employed, by furnishing the earth such seeds and plants as will produce the greatest quantity of wholesome and nutritious food for man and beast. I would ask the advocates for transmutation if any of them ever saw a stalk of cheat and a stalk of wheat grow from the same root? I have frequently examined and never found this the case. I have enquired of many others and have uniformly been answered in the negative. It is somewhat singular, that the change should be always so complete, as to leave no traces or appearance of the wheat, in any of the numerous stalks that frequently grow from the same grain. I would further inform "Plain Sense" that I have frequently seen rye put in on wheat stubble, and no cheat made its appearance. I am led to believe that the mistaken opinion that wheat will actually change to cheat, arises from the circumstance of wheat being a crop more liable to failure than any other we cultivate, and thus more frequently leaves room for the cheat to take its place.

The naked barley and field pea you were so good as to send me, both turn out finely. The pea, I think, will be as suitable for the garden as the field. The Egyptian millet does not promise well. It is not now more than half the size of the common kind, and no appearance of its going to seed. I am led to think it requires a warmer climate than ours.

I am pleased to inform you that the method recommended in the Farmer of planting the grape cutting, entirely under ground, has succeeded with me extremely well. A greater number than usual grew, and the shoots came up unusually strong. I also adopted the plan of protecting my cucumber and melon vines by boxes covered with millinet. I think it will answer an excellent purpose. We did not lose a single vine, whilst those of most of our neighbours were entirely destroyed by the striped bug.

I am very sincerely your's, &c.

Allentown, New Jersey, 15th July, 1823.

Our harvest is secured, and is abundant. Your agricultural eye, would be delighted with looking over, at this moment, the fine Indian corn counties of Monmouth and Burlington; which are covered with the most luxuriant crops I have ever seen. Oats and potatoes look well; and the average of fodder will be exceeded. We begin to grow millet extensively. An excellent resource, whenever the early grasses fail.

Upon the whole, regarding the aggregate of crops, our agricultural report promises to be more gratifying than it has been for many years.

The biped-lamb of which I informed you, continues to live. It can walk for miles without inconvenience, and even with rapidity.

STRAWBERRIES.

MR. SKINNER,

Notwithstanding the information very obligingly given by some of your subscribers on the subject of strawberries, there appears to me so many doubts and difficulties in the way, as to make some further enquiries necessary: be so good as to make them, although they are of less importance than many others. Can it be possible that after the cultivation of this berry for centuries, that there is no individual who can give us a systematic way of raising them with success? if not, is it not full time for us to devote a part of our researches that way? Can it be in general right, to permit them to be intermingled with grass and weeds? It is insinuated by one of your correspondents, that as our climate is a dry one, it may be beneficial; but on examination, the ground will

be always found to be most wet or moist, around those plants which have been kept free from weeds, &c. I planted out last fall, several hundred sets, in drills three feet apart; one foot the near way, in very fertile ground—they have been hand wed four times in the course of the spring and summer, and looked very well, (bearing a few berries) until the last weeding, when I had the runners taken from them, shortly after which a few of the vines died, and the patch generally ceased to have its fine appearance and vigorous growth. Is it improper to have the runners taken off the first year, or at any particular time of the year?—I should be much pleased to obtain some light on the subject, as I cannot but suppose the great Creator has intended they should add to our health and happiness in their season.

I am, very respectfully,

Your's,

R. K. M.

The Editor unites with "R. K. M." in requesting information on this subject.

SALIVATION OF HORSES.

Moorfield, (Va.) July 1, 1823.

MR. SKINNER,

Some of your correspondents have expressed their opinions of the cause of the salivation of stock during the summer; as it affects horses in particular. As it seems to be a question of some considerable difficulty, and as there are a variety of conflicting sentiments upon the subject, I will submit to you my opinion also; having repeatedly observed its effects, and as often endeavoured to ascertain the cause.

The supposition that appears to me most probable, is, that it is produced by the mould on the grass, to which it is extremely subject. An attentive observer may, about sunrise, frequently perceive streaks of blue mould on the grass, and by reviewing it more closely with a magnifying glass, he can distinguish two complete rows of mushrooms, or fungi, one on each edge of the spear grass.—As the sun rises over the horizon, he discovers these to ripen, open at the extremity, and expose a small cluster of four or five seed, after which they soon disappear. About this period the blade is destroyed, and it becomes visible by the grass becoming dry—the mould is not so easily discovered in clover as in spear grass; the former resembling it in color more than the latter. I have for some time been impressed with the belief, that the salivation of stock is caused by their feeding upon this mould, or rather the grass, after the fungus had matured; and I have been almost confirmed in my opinion by the result of a practice we have pursued of confining our labouring horses on newly mowed meadows, from which the old grass is entirely removed. By adopting the above course, the salivation is effectually prevented, or at least considerably abated. In addition to the above practical proof, I have observed that our brood mares and younger horses, which are generally pastured upon our most barren lands, where the grass is not so luxuriant in its growth as to produce the mould, are scarcely ever affected with the above mentioned malady.

Respectfully your's,

ABEL SEYMOUR.

This subject really demands the fullest investigation: Is it not an evil of comparatively *modern date*? Is it not aggravated by wet weather, when vegetation is more luxuriant? Why is it produced by second crop clover hay, and not by first? Do not neat cattle and other ruminating animals suffer with it, although the effect is not exhibited by salivation, as in the case of horses?

We ask this question because the editor is now in his native Calvert County, where he has been struck with the extraordinary low condition of neat cattle, both cows and oxen.—He never saw weather more seasonable, or grass more abundant in the pastures, and yet the cattle as well as horses, are extremely reduced in flesh, while the latter only are slabbering at a degree, that one would suppose would exhaust them unto death.

The aggregate of wood has visibly increased throughout this county, within the last fifteen years—the springs and streams of water have permanently diminished, and many of them are totally exhausted, while the land has improved in quality and product, beyond any improvement in the systems of cultivation and management—though in this respect, there is undoubtedly a change for the better. Asking some old people how it has happened that certain fields, to which not an ounce of manure has been applied since the memory of man, now display better crops than fifteen years since, they attribute it to the absence for many years past, of the heavy dashing thunder gust rains, which were formerly so common, and by which the fields were so often, and so *severely washed*. This may have its effect, but we rather ascribe the increase in the crops, especially of corn, where it is most visible, to a general improvement in the *structure and use of the plough*. Ploughing is generally better performed than it was before the publication of the late venerable Thomas Moore's treatise on deep ploughing.—*Edit. Am. Far.*

DYSPEPSIA.

MR. SKINNER,

I observe in number 12, of your 5th vol. "A Constant Reader" "requests that, you will enquire of some of your many correspondents, and publish in the American Farmer, directions for the treatment and cure of Dyspepsia." Having seen no reply to the request, I am induced to offer the result of my own experience; without entering into any investigation of the causes of this fashionable disease either remote or proximate. A rigid attention to diet, both as to quantity and quality is indispensable; I do not mean that sort of abstinence where the patient eats small quantities at a time, but by eating frequently, consumes more than people usually do who only eat at the ordinary and regular meals: beef, mutton or chicken, roasted or broiled, will be found as innocent, perhaps, as any other food. High seasoned dishes should be particularly avoided, as being not only pernicious in themselves, but by provoking the appetite to take more than sufficient; and for this last reason, spirits, wine, or strong beer should not be indulged in until after eating, and then sparingly. Coffee was found to disagree with my stomach, being generally thrown up by eructation soon after drinking it in a morning, if exercise was used immediately after. Tea and milk produced nearly the same result; which lead me to seek for a succedaneum; some warm beverage having become by habit, not only comfortable, but almost a necessary. Accident led me several years past, when riding, to chew the leaves, and sometimes the buds of the sassafras to allay the intolerable heat and pain produced by the highly concentrated acid on the stomach; the effect of which caused me to think of sassafras tea, which, in a few weeks, produced the most happy effect; the symptoms having been entirely removed, and no return having been as yet experienced, although five months have passed over. There are two species of sassafras, the one having a red, the other a white root—the red is much the most pleasant, and should not

be made very strong. Sugar and cream may be used as with other tea. A little experience will teach the most agreeable method of preparing it. Candour induces me to mention a fact in my own case, which possibly, may cause medical gentlemen to doubt the efficacy of my nostrum. About six or eight weeks after commencing the use of the sassafras tea, the first joint of the great toe on my right foot was for the first time inflamed, and very painful for three or four days; and in a day or two after that, the outside of my left foot was so tender as to prevent me from bearing my weight on it. I should, myself, have believed that those attacks in the feet had produced the relief to the stomach, if that viscus had not been relieved, two weeks previously. More might be added, but you will, no doubt, think that I have already trespassed sufficiently.

If you think these observations worthy of a place in your paper, you are at liberty to publish them—without, however, giving my name, unless you may think proper to give it to a "Constant Reader."

Our corn crops are promising here—cotton only tolerable.

West River, A. A. county, Md. July 20, 1823.

I was much gratified by my visit to Mr. S. whom I found to be as you had represented, a most intelligent and interesting, as well as enterprising man; and I beg you to accept my thanks for an introduction, which has given me so much pleasure.

His flax breaker is decidedly the most efficacious implement for cleaning flax, I have ever seen. The saving it makes in the labour of preparing this valuable product for market, will, no doubt, speedily increase the cultivation of it, and give a staple article almost as important to the middle and Eastern states, as the cotton is to the South. The same machine is used for threshing grain, which it gets out very clear from the straw, and although not so powerful as the threshing machine in use amongst us, yet its cheapness and the small power required to work it, (one horse only being necessary) must ultimately recommend it to very general use on farms of moderate size.

I examined his reclaimed marshes with much interest. They must become, when put in perfect order, an immensely valuable estate. The tide ebbs and flows about six feet. There is great doubt in my mind, whether there is sufficient fall of water below the surface of the marshes on the Chesapeake, to admit of their reclamation, without the aid of windmills, or other expensive machinery, to lift the water over the embankment.

PREVENTION BETTER THAN CURE.

July 9, 1823.

MR. SKINNER,

That it is a much more desirable object to prevent disease by removing the cause, than to be able to effect a cure, I think, will be admitted by every one. Those who are of opinion that Epidemics in our cities, particularly Yellow Fever, are of domestic origin, attribute them, in a great measure to the effects of foul air secreted in drains, cellars, wells and vaults. This noxious vapour escaping gradually, from the places in which it is generated or collected, is taken up with the atmospheric air, and I have no doubt, at particular seasons, becomes a preponderating component part of the atmosphere. Under these impressions it has occurred to me, that some plan might be devised, to get rid of this vapour as fast as it is formed. I would propose, in any situation where it is known that this vapour collects, to erect a column containing two funnels

—it should be so high that the top would be constantly acted upon by a current of fresh air—over one of the funnels I would erect, (if I may use the term) a sheet iron wind sail, so constructed, as always to face the wind—this funnel should extend nearly to the bottom of the drain or cellar. The other funnel should be furnished with a similar apparatus, but arranged directly the reverse—it should extend barely into the drain or cellar—a strong current of fresh air would be thrown down through the first funnel, which would mingle with and take up the foul air through the second funnel, as fast as it could collect. It would be raised, by these means, so high in the air, that it would be effectually carried off before it could possibly have a chance of contaminating the immediate atmosphere in which we live.—This plan, when used for wells, may also have the effect of making the water much cooler, by increasing the evaporation. With a sincere wish that what I have now suggested, may lead to something useful,

I am Sir

Respectfully your's,

CAROLINIUS.

ELECTRICITY OF A CAT.

The Electricity excited upon rubbing the back of a Cat is well known, and that it is rendered evident by snapping noise and sparks of light. Mr. Glover in a letter to the Editor of the Philosophical Magazine, describes so intense an action of this kind, as to enable the animal to give a very sensible electrical shock. This effect was obtained at pleasure by Mr. Glover, and also by some friends. When the Cat was sitting on the lap of the person, if the left hand, were placed under the throat with the middle finger and the thumb gently pressing the bones of the animal's shoulder, and the right hand were passed along her back, shocks were felt in the left hand; and then the right hand was placed under the throat, whilst the left hand rubbed the back, the shocks were felt in the right hand. When the atmosphere had been favourable, and the Cat had lain some time before the fire, the experiment always succeeded.

Phil. M. lx. 467.

THE FARMER.

BALTIMORE, FRIDAY, AUGUST 8, 1823.

BALTIMORE MARKET.

PRICES CURRENT.—CORRECTED WEEKLY.

Flour, best white wheat, \$7—Howard street Superfine, \$7 25—fine do. \$6 75—Wharf, do. \$6 00—White wheat, \$1 22 to 1 30—Red do. \$1 18 to \$1 21—Rye, 50 cents—Corn, 45 to 50 cents—country Oats, 35 cents—Beef, 8 cents per lb.—Live Cattle, \$6 to \$6 50 per cwt.—Bacon, hog round, \$10—Pork, \$4 50 to 5 50 per c. lb.—5 to 8 cts. 10 pound—Mutton, 5 to 6 cts. per lb.—Beans, \$1 37½ to 1 50—Peas, black eyed, 55 to 60 cts.—Red Clover Seed, \$3 50 a \$6—Orchard Grass do. \$3—Herds' Grass do. \$3—Timothy do. \$4 50—Millet, none—Buckwheat, none—Flax Seed, 75 to 80 cts.—Whiskey, none in the wagons 36 cts. per gal. including the barrel—Apple brandy, 30 to 32 cts.—Peach do. 65 to 70 cts.—Shad, \$6 50, scarce—Herring, No. 1, \$2 75 per bbl.—No. 2, \$2 50—Fine salt, 60 to 65 cts. per bush.—Coarse, do. 70—Butter, (firkin) 14 cts. per lb.—Eggs, 16 cts. per doz.—New Hay, \$14 per ton—Straw, \$8.

MARYLAND TOBACCO.—Sales corrected from last report.—95 hhds. raised by Thomas B. Crawford of Prince George's County, say 28 seconds averaged \$6 50—67 First at \$10 3-8.

Internal Improvement.

ON THE PARAMOUNT IMPORTANCE, TO MARYLAND, OF A CANAL TO THE SUSQUEHANNA.

No. XI.

Independent of any advantage on fuel, (67) or in extending a Canal navigation over the Allegany, (99) for every dollar of profit to Maryland from the Potomac Canal and its appendages, an eagle, in proportion to the cost, may be adopted as a moderate estimate (101) from the Susquehanna; with this important difference, that it is understood the enterprise for securing the eagles may be put into advantageous operation with an expenditure of only one million, whereas, nearly two millions will be required to commence receiving the dollars.

104. The certainty of every conclusion depends upon the certainty of its premises. From uncertain premises, it is abundantly evident, that no certain conclusion can possibly be drawn. Under these views permit me to propose as premises *too certain to be doubted*, that according to strict justice and established usage, the profits of all partnerships are required to be divided in proportion to the inputs of the parties. Hence it follows, that were Maryland to appropriate towards opening the Potomac Canal \$500,000, somewhat less than one third of the estimated expenditure, one third part of the trade of 10,000 square miles, that is the trade of 3,333 square miles of country (17) *by no means celebrated for its richness and fertility*, is somewhat more than would be compatible with *strict justice, and established usage*, to be received in return. But in relation to the proposed new channel to the Susquehanna, the case is entirely different. Were this Canal to be opened by the state of Maryland, Maryland would then be fairly entitled to the benefit of all the trade that should float upon its surface.

105. Considering, *also*, that the Baltimore market which is already excellent, may, in the course of a few years, by a due improvement of the great local advantages of its situation, be rendered *nearly*, or, perhaps, *equally* as desirable as that of Philadelphia, and more especially when we appreciate the *importance of 80 miles being saved in the length of every trip* in coming to and returning from Baltimore, it appears to be a moderate estimate to account the Susquehanna Canal capable of securing to Maryland, the benefit of the trade of two thirds, at least, of 30,000 square miles; that is, of 20,000 square miles of country (17) *inferior in point of fertility to no part of the United States*. But independent of all the advantages of *superior fertility*, 20,000 square miles are equally as capable of producing a profit of six dollars, as 3,333 can be to produce a profit of one dollar. Owing, again, to the estimated expenditure for the Potomac income of dollars being greater (100) in the ratio of 20 to 37, than that for the Susquehanna income of six dollars, for one; it conclusively follows that, to be in proportion to the cost, these six dollars must be increased in the same ratio, thus: 20: is to 37:: as \$6: are to \$11, and 10 cents from the Susquehanna, for every dollar from the Potomac; consequently, *an eagle for every dollar* cannot be otherwise than a moderate estimate. Q. E. D.

106. I am well aware that the foregoing demonstration, as well as the general term of my calculations, which correspond with it, are completely at variance with certain resolutions that have been formed, it is presumed, without the authority of correct information upon the subject, and also widely different from numerous confident

assertions, which from anonymous individuals, and other incorrect sources have from time to time found their way into some of our public papers. As far, however, as has yet come under my notice, no better evidence than *mere assertion* has been produced in support of these opposite pretensions. But *mere assertion*, it is well known, is *no evidence*. It is so understood in all judicial proceedings, and would *there* be totally unavailing towards establishing any controverted claim whatever, were it only for a single cent in amount. It must, in fact, be conclusively evident from the very nature of the case, that *mere assertions* are too liable to be founded in error of opinion; too frequently detected in being destitute of truth; too completely susceptible of being moulded into any form, or coined in any manner, agreeably to the pleasure or the motives of their authors, to be suffered to have the least influence in the decision of a great public question, of the utmost importance to millions of the great family of mankind.

107. When the attempt has been made, and often repeated to obtrude *mere assertion* as evidence upon any occasion, and more especially in a case of superior importance, the inference becomes *irresistible*, that it is the only alternative of the parties; that it is, in fact, the only evidence of which they have it in their power to avail themselves. But it must be obvious to every intelligent mind that *mere assertion*, independent of all other evidence to give it credit, is of a character entirely too doubtful for any person to be under the least obligation to believe it. Were I, for example, to meet with a cart load of resolutions, and anonymous newspaper assertions, all declaring in the most positive terms that a snow-white swan was certainly *black*; or a coal-black crow, *white*, would it, *permit me to ask*, be incumbent on me, contrary to my own certain knowledge, to admit that such was the fact? Most certainly not. I should be perfectly at liberty never to believe that any *white swan*, was *black*; or any *black crow*, *white*, until good and substantial evidence were produced to establish the fact. In like manner every individual in the community is equally at liberty to disbelieve whatever *incredible advantages* have been, or may be asserted in favour of the Potomac Canal, until *conclusive evidence* shall be adduced to prove, *beyond doubt*, the reality of the facts asserted; or the certainty, at least, of its being capable of producing more than a dollar profit, *in proportion to the cost*, for an eagle from the Susquehanna.

(To be continued.)

TO THE EDITOR OF THE AMERICAN FARMER.

No. I.

THE JUNCTION CANALS OF POTOMAC AND SUSQUEHANNAH.

DEAR SIR,

I am pleased to find the subject of Internal Improvement occupying the attention of the people of Maryland, and that its citizens of capital and intelligence, are turning their thoughts to the consideration of those plans, which will tend to advance the improvement of their internal navigation.—Sectional feeling appears to be absorbed now in the great question,—*what measures ought to be pursued, which will best promote the interests of the state?* We live at present in too enlightened an age, to be jealous of *local* advantages, morally speaking, purely accidental, the effect of certain favourable positions of country.—Our citizens have too much wisdom and liberality, to deny their support or good wishes to any scheme, which has for its object, the advancement of the public good; because its tendency is to benefit one particular section of

country more than another. Our legislators will not regard *place*, but the degree of public good resulting from the location, and execution of any public work.—If there is one spot in a state which merits more privileges, and to which more legislative patronage should be shewn than to another, that spot is its *commercial emporium*.—In proportion as this rises in respectability and wealth, in the same ratio, is the political importance of the commonwealth increased. We form our opinion generally, of the power of a state, or kingdom, by the *commercial standing of its Capital*. Under this view of the subject, the best policy for a state to pursue, is, to contribute by every means in its power, to advance the interests of its chief place of business; allowing it every privilege consistent with the rights of the people. The welfare of Baltimore, then, should be highly cherished by Maryland. No city is better located than this, to rise in commercial importance, provided its citizens do their duty; the state will find that its best interests are concerned in granting its patronage.—I find by the perusal of your valuable paper, that an effort is now making to place Maryland upon the high ground which its geographical position so fully entitles it to—may this effort be crowned with success. I have read with considerable interest, the various papers relating to the formation of a navigable canal between Baltimore and Susquehanna, and between Washington and the Potomac above the Ridge. The association of these two works you will recollect, was what I advocated in my treatise on the Inland Navigation of Maryland, published 1820.

The public are much indebted to your correspondent, Mr. Kenworthy, for entering into the detail he has, on this subject—his positions are very satisfactory, and I should judge his fellow citizens will rightly appreciate his valuable services.

In No. 6 of his papers, (section 43) speaking of the distance to canal, between Baltimore and the Susquehanna, he observes, I have stated this at 75 miles; but that he is convinced it must be more.—This I have *admitted* under the *same circumstances* of locality of canal, that he lays down; for instance, in page 96 of my treatise, you will find this position noted "If our views at present should be confined to the Canal of Susquehanna," (for the Potomac canal was also taken into view in stating the first distance,) then the estimates will stand as follows: "From Susquehanna above the falls of Conewago, (allowing for the sinuosities of the canal to accommodate the hilly character of the country, supposing we should have to depend upon the head waters of Monocacy and Conewago to feed the locks) 85 miles—at, &c.

My former distance of 75 miles is predicated upon the capacity which the Potomac canal would furnish, to choose our ground, in the elevated regions between Baltimore and the Susquehanna river, thus avoiding many a circuitous turn, which a more depressed head of water would subject us to.—Mr. K. and myself therefore, may be both right in own calculations of distance.—But I think, the *rule of proportion* which he has assumed, to determine this distance, by taking the relative difference in extent, between the land and water route from Philadelphia to Susquehanna, and drawing correspondent results from the distance by land being given from Baltimore to York-Haven, is not correct in the case of our canal; for the local circumstances of the water route from Philadelphia to that river, widely differ from that of our canal, the former being confined to the circuitous beds of the Schuylkill, Tulpihoken and Swatara rivers—whereas our canal, owing to the superior elevation of its summit

waters, can be made to sweep along the most favorable grounds.

After clearing up this difference, permit me to take a brief view of this interesting subject.

It is with regret I have learnt, that an idea still exists, in the minds of some of your citizens, that it would be the most expedient plan, in opening a navigation between the Susquehannah and Baltimore, to keep to the bed of the river.—In so important an undertaking, as the one before us, I trust that we will allow our past experience to guide us to a right decision—we know how insufficient this system of improvement has been to our navigation—all attempts to render efficient the natural beds of our rivers above tide waters for navigation, where obstructions occur, have proved abortive, that is, they have not answered the ends contemplated; and the reason is very obvious:—every obstruction that is removed, increases the velocity of the water above and below, and frequently injures, if not destroys the navigation above—nothing is more difficult than to effect a safe and easy passage through the rapids of a river; because, often, when you have accomplished the removal of one impediment, you create another; thus, in nine cases out of ten, a greater evil is produced than is removed—neither science nor art can effectually aid us, whilst we contend with the torrents of a river, such as occur in the Susquehannah below York Haven.—If we succeed in overcoming the violence of these, and make a safe navigation, we must quit the natural bed of the river, and creep along its banks with a small portion of its waters, artfully using them to subserve the purposes we have in view. Independent of what our experience has taught us on the subject, the practice of all those nations that have had works of this nature executed, is opposed to keeping the beds of the rivers, when contemplating a great improvement in the navigation, whether on the ground of economy or propriety.—Since the introduction of canals, they are satisfied, that to attempt to remove the natural obstructions in the river, is like throwing so much labor and money away: they rather strove to push the navigation by canals far from them. I trust, therefore, we shall have too much prudence and foresight, to subject our hopes to disappointment, and our works to ruin or inutility, by attempting to remove the obstructions in the bed of our river.—Whatever work we do accomplish, let us make it answer the end for which it was intended, and permanent in its character. Rivers are the natural drains of a country, and are perpetually subject to interruption and change in their navigable capacities, from the torrents of rain which frequently deluge them. Where obstructions often occur, from rapids, and it is expedient to perfect a navigation through the section of country which a river waters, experience has shewn it to be the best policy to abandon its bed altogether, and substitute an artificial navigation; this practice most generally shortens the route, and reduces the expenses incident to the removal of the original difficulties in the river:—for a navigation that lies between a grand inland depot and a sea port, this rule applies more particularly.—That a navigation may truly benefit a country, it is necessary that the passage be performed with equal ease, each way,—that the nearest course should be taken to the principal points of the country; and for both these reasons the beds of rivers beyond tide water, must most generally be forsaken; because torrents in time of rain, which are extremely injurious to works of art, with the shoals in dry seasons; together with the current ever setting one way, will very frequently interrupt the intercourse, and render fresh water river navigation precarious.—True, there are some of our

rivers to which these remarks will not apply in the general—for instance, in the case of the Susquehannah, whose navigable capacities are so extensive above tide water; but it forcibly applies in one point of this river, where the navigation ceases; the difficulties which occur here, seem to render all the benefits of the upper navigation comparatively nugatory.—Under such circumstances, it is doubly binding on us to adhere strictly to the rule laid down, to leave the natural bed. Nature has done much for the Susquehannah river, and the citizens of Baltimore would be wanting in attention to the interests of their city and state, to neglect perfecting its navigation; this, as has been shewn, can only be done by leaving its bed at York Haven, and constructing an artificial way.

The only question then ought to be, whether this artificial channel should course the banks of the river to tide water, or strike across the country in the nearest practicable route to Baltimore: the latter unquestionably, should be preferred, for its advantages over the other are so manifest—this will appear from the following premises:

1st. The great difference there is in the distance of the two routes to Baltimore.—2d. The difference in point of safety, in transporting articles of produce, &c. to market, as well as the security given the works against freshets.—3d. The fine country which the direct route would pass through, and the value the canal would give to the lands through which it would flow—from the health enjoyed in this country, settlements and villages would be located on its banks, which we know would not probably be the case were the canal carried along the banks of the river.—These, among other reasons might be adduced, to prove the propriety of adopting the inland route in preference to that of the river—satisfied on this head, we will review briefly the plan by which I propose to effect this important object.

With sentiments of respect,

Dear Sir,

I salute you,

ROBERT MILLS.

Columbia, (S. C.) July 27, 1823.

The following papers were forwarded by a friend, in whose taste and judgment as to the designation of suitable subjects for our Journal, we have great confidence. That a plentiful supply of pure water at all seasons, and at the least expense, is a concern of the very first consequence to all farmers, nobody will deny; but as to the practicability of procuring it "in all situations," it would be one of those discoveries which we are wont to consider "too good to be true".—Ingenuity, it is true, may work wonders, but it must work by the aid, and not in violation of the laws of nature, and the rules of philosophy.—The age of miracles has passed with the age of ignorance. In reference to the subject of finding water, and the point to which it may be elevated, to prevent the entertainment of any false hopes we thought it best to submit the extracts which have been published in so many papers without comment, to the consideration of one of the first teachers of mathematics and natural philosophy in America—and by him they were returned with the plain and satisfactory philosophical observations which follow the extracts in this paper.—*Edit. Am. Far.*

FROM THE UNITED STATES GAZETTE.

Messrs. EDITORS,—The two pieces under the head of "Hydraulicks," and "Directions for Boring for Water," &c. have been selected from a late European publication, and are furnished you for insertion, accompanied by a request that

some of your ingenious correspondents would furnish such observations as to the comparative expense of boring and well digging, &c. &c. in our country as may occur, a circumstance that will prove particularly acceptable to

MANY.

HYDRAULICKS.

"The facility by which a constant supply of spring water may be obtained at comparatively little expense, by boring, may, through the medium of your miscellany, be made public. It is desirable to be known, that in almost all situations water may be obtained by this method at the expense of a few pounds; whereas the expense of sinking a well to the main spring, too often deters the party from attempting it. Should you consider this communication sufficiently interesting, I hope you will give it publicity, that persons in all situations of life may have the opportunity of procuring one of the greatest luxuries in nature—good, pure and wholesome water, in a short space of time, with little trouble, and at a trifling expense. Although some of the inhabitants of Tottenham have obtained a good supply of excellent water from deep sunk wells to the main spring, there are a great proportion who are obliged to buy water of the carriers, who procure it from the well on Tottenham green which was dug, and a pump erected at the expense of the late Thomas Smith, Esq. &c. in 1791. Mr. Mathew in the summer of last year, adopted the method of boring through the earth to the main spring, at his farm in Broad lane, Page green, Tottenham, when he obtained a constant and copious supply of water from a depth of 120 feet, which rises eight feet above the surface, and flowing over, forms an elegant little cascade. It has neither increased nor diminished since the spring was tapped. Having succeeded on his own premises, he thought a similar experiment might be tried with equal success on the waste ground on the west side of the high road, opposite the gateway leading to the work house, and which would be of most essential benefit, not only to the inhabitants residing in that part of the parish, but to the public at large. This suggestion being made to the vestry, it was acceded to on the part of the Parish, and the work commenced. The ground was bored to the depth of 105 feet, when a fine spring of water issued forth, which rises 6 feet above the surface of the ground, through a tube within a cast iron pedestal, and flowing over the lip or edge of a vase, forms a bell-shaped continual sheet of water, inclosing the vase, as in a glass case: it is collected, and again conducted downward through the pedestal to the place of its discharge, out of the mouth of a dolphin, about eighteen inches from the ground for the convenience of placing a pitcher under. The quantity of water thrown up and discharged, is at the rate of fourteen gallons a minute. The peculiar advantages of boring the ground for water instead of digging, particularly at great depths, renders the former method of great importance to the public, since water is obtained by boring at a small expense, as is exemplified by the following table. This table shows the price of boring and well sinking respectively, at every ten feet of depth, from ten feet to two hundred feet, viz: Boring at four pence per foot for the first ten feet, eight pence per foot for the second ten feet, and four pence per foot additional and progressive for each following ten feet; and of well sinking at two shillings and six pence per foot for the first ten feet, three shillings and six pence per foot for the second ten feet, and one shilling per foot additional and progressive for each succeeding ten feet.

0 0 4	0 7		

Since the introduction of this cheap and simple method of obtaining a constant supply of water, many of the inhabitants of the parish have adopted it, whose example is followed by many in the adjoining parishes, and also in the county of Essex, with universal success. The ornamental purposes also to which it may be applied are innumerable, and present themselves to the men of taste in endless varieties of forms, such as fountains, waterfalls, or basins for dressed grounds; for baths, or for ornament, as well as the uses of the garden and the conservatory; but the man of science will hereafter employ it as a principle of motion, and direct it to various mechanical operations.

Description of the tools used in boring for water, &c. &c.

"The first tool used is an auger: the shell part, which forms the hole or bore in the earth or strata through which it passes, is mostly from two and a half to three inches in diameter; the hollow part of it being about one foot four inches in length, and constructed nearly in the form of the carpenter's common auger. The rod parts are formed in separate pieces, of four feet long each, which screw into one another by means of what is usually termed a male and female screw, to any suitable length, one after another as the depth of the hole or bore may require. The size of the stem above the auger part is about an inch square, except at the joints, where, for the sake of strength, they are a quarter of an inch more. There are also a chisel and punch for screwing on, in going through hard gravel or metallic substances, in order to expedite the passage of the auger, which could not otherwise perforate such hard bodies. The punch is often used when the auger is not applied, to pierce or open the land or gravel, and give a more easy issue or discharge to the water. The chisel is an inch and a half or two inches broad at the point, and made very sharp for cutting stone, and the punch an inch square like the other part of the rods, with a sharp point also. There is a shifting handle of wood which is fastened with two iron wedges affixed to it, for the purpose of turning round the rods in boring, and also two iron keys for screwing and unscrewing the rods, and for assisting the handle when the soil is very stiff, more than two men being required to turn the tool; sometimes a windlass is used. The manner of using the auger in working of it is simply thus: two or three men

are necessary. Two stand on a stage, erected about twelve or fourteen feet above the ground, who turn it round by means of the wooden handle, and when the auger part is full, they draw it up out of the hole, and the man below clears out the earth with an instrument for the purpose, and assists in pulling the auger up out of the hole or bore, and in directing it into it again, and can also assist in turning with the iron handle or key, when the depth and length of the rods require additional force to perform the operation. The workmen should be careful in boring, not to go deeper at one time, without drawing an exact length of the shell of the auger, otherwise the earth, clay or sand, through which it is boring after the shell is full, may make it difficult to pull out. A cylindrical pipe being placed in the hole, and driven downward with a mallet, and the boring continued, the pipe may be forced down to a greater depth, so as to reach the water or spring. Wells made in this manner are superior to those constructed in the common method, not only in point of cheapness, but also by affording a more certain and constant supply of water. In case the water near the surface should not be of a good quality, the perforation may be continued to a greater depth, till a pure fluid can be procured.

The pipes should be either of cast iron, or other metallic substance, and made to fit, with great exactness, the aperture made by the boring auger, or they would not be durable, but speedily become leaky and out of order. The best mode would, therefore, probably be that of having metallic pipes cast for the purpose, and formed so as to fit exactly upon each other, to any depth that might be necessary in boring for water. When old wells have become injured or tainted from any circumstance or accident, being previously emptied, the bottom may be perforated in a similar manner, so as to reach the lower sheet of water or main spring. The water will then rise in the cylindrical tube in a pure state, and flow into the body of the well or pump fixed for the purpose of bringing it up."

SIR,

Tottenham, from such imperfect accounts as I have seen of it, appears to be a valley, five or six miles North-easterly from London, skirted on one side by the river Lea, navigable to its junction with the Thames; about eight miles below. The place is principally composed of rich meadow ground, and so flat as to be flooded during a great part of the winter. It is, therefore, easy to conceive, that some of the surrounding hills, one of which, is said to be 400 feet high, may contain caverns, suitable for reservoirs of water, from which veins will flow in various directions, among the strata of rocks which form the common base that supports both the valley and surrounding hills. If then an orifice be opened down to any such vein, the water according to the general laws of Hydrostatics, will rise to the level of the reservoir, or fountain head: and it will be quite immaterial, whether the orifice be three inches, or three times three feet, in diameter; the height, to which the water will ascend, being in both cases, the same. The introduction of an air-tight tube, however, may be necessary, as otherwise, the porosity of the surrounding mass, might absorb the water.

But surely no person in the least acquainted with hydrostatic principles, could for a moment suppose, that, by boring in the manner described, water could be had in any situation. The thing is absolutely impossible, in any other case than where a reservoir exists in a higher

position than the surface where the water is to be raised: and even there, the vein penetrated must have an air-tight communication with the reservoir. No doubt, there are many situations, adjacent to, and in the vales between our mountains, and even hills of moderate height, where water might be procured in the manner described; but unfortunately, these are not the situations where it is most wanted; and to search for it where there is no commanding eminence of rock formation, capable of containing reservoirs, will be found to terminate in lost labour.

Your's respectfully,
JOHN D. CRAIG.

JOHN S. SKINNER, Esq.

A prospectus has been circulated in Paris, of a new machine, which, if we may believe its inventors, will entirely overturn the present system of hydraulics. They engage to supply a small steam engine, which will raise water to the height of sixty feet, at the rate of fifteen quarts per minute. The machine will, it is said, consume but a pennyworth of coals in an hour, in which time it will raise nine hundred quarts to the specified height. It is to cost six hundred francs, and to last more than a hundred years. No payment is required until the engine has been tried and given satisfaction; until it is fixed, and raises the water from the well to the roof of the house, which will thus be secured against the destructive ravages of fire. The proprietors likewise offer, at a progressive advance, machines which will raise double, triple and decuple quantities of water, to double, triple and decuple heights, (that is to one hundred and twenty, one hundred and eighty, or six hundred feet,) and thus in infinite progression. They at first concealed their names, and this mysterious conduct excited suspicion; they have since, however, made themselves known, and prove to be Messrs. Crosson, brothers, both of them pupils in the Polytechnic school, and one of them a commandant of artillery, whose talents are said, in the Parisian circles, to inspire the greatest confidence. They keep their discovery a secret, and will not divulge it till they have raised subscriptions for twenty thousand inches of water according to their mode of calculating.—*U. S. Gaz.*

AGRICULTURE.

Report of an inquiry into the mode of cultivating and treating Flax, in the Netherlands, &c. by Peter Besnard, Esq. Inspector-General for Leinster, Munster, and Connaught.

(Continued from our last.)

OBSERVATIONS ON THE TREATMENT OF FLAX IN THE NETHERLANDS.

SOIL.—The soil preferred by the cultivators of flax in the Netherlands, is a deep loamy clay, or what they term (fat land) free from weeds, and capable of giving wheat, which is in almost every case the previous crop; except when land after producing madder is to be had, which is esteemed the best of all; but the cultivation of that plant, being rather limited, it is rarely to be met in quantity, compared with wheat-stubble; it is, however, a general practice in that country, never to sow flax but in rich, good ground.

PREPARATION OF THE SOIL.—The mode usually followed in the Netherlands of preparing ground for flax, if from wheat-stubble, (the general previous crop) is, after reaping, to have it immediately lightly ploughed, and let to lie in fallow until the ensuing spring, when it is again lightly ploughed, preparatively to the sowing of the seed; but if grown after a mad-

der crop, the custom is to give a light ploughing in spring, a little before sowing.

SOWING.—With respect to the seed sown in Holland and Zealand, it is invariably either Riga, or home-saved, none other being used; the latter is sown for two, sometimes three seasons, in succession, never longer, and, at the end of that time, Riga seed is again sown: but some of the rich and judicious flax boers, every year, sow a small parcel of Riga seed, so as to keep up a constant succession of fresh. When selecting seed for sowing, either of Riga, or home-saved, the most scrupulous attention is paid to procure it of the best and cleanest kind. As to the quantity sown in any given portion of ground, much depends on the quality of the soil, and the age of the seed, which *experience alone* can determine; but as well as I could collect information from the boers on this subject, comparing their measurement with the English and Irish acre, the quantity sown bears a due proportion to that of Riga seed usually sown in England and Ireland. The time of sowing is generally between the end of March and middle of April.

PULLING.—In the Netherlands, and in France, flax is always allowed to arrive at maturity, and is *never pulled, particularly in Holland and Zealand, until the seed is perfectly formed, and the capsule brown and hard, so as to be easily disengaged from the stalk; when in that state it is pulled, and at once made into small sheaves, which are placed in stocks of eight to the stock; the root ends on the ground, projecting, and the heads meeting at the top in such a manner as to present the entire of them to the influence of the air; in this way it remains eight, ten, and sometimes fourteen days, according to the state of the weather; should occasional rain fall during this time, it is considered of great service to wash off the impurities and withered leaves that attach to the plant when ripening.*

RIPLING.—When the flax is sufficiently dried, it is carried to the barn, and the process of taking off the seed immediately commences; this operation in the Netherlands is chiefly done by ripples or iron pins, about sixteen inches long, and one inch square at the bottom, gradually narrowing to the top, and formed into squares: the pins are fastened in a block of timber, above four inches thick, eighteen inches wide, and made in the form of an octagon, the upper part sloped off, so as to let the boles run down to the floor; those pins are set at about a quarter of an inch asunder, thirty of them in each block, which is fastened by means of two staples and wedges, to a two-inch plank, that rests on trestles of a sufficient height for grown persons to sit on whilst rippling; two usually work at the same ripple, sitting opposite each other, and drawing the flax alternately through the teeth. During this process, great care is taken not to let it slip through the hands, so as to entangle the root ends, which in every process are kept as even as possible. When the seed is discharged the flax is again made into small sheaves, and, in every instance, bound together by platted cords three and a half feet long, made of strong rushes, that usually last for years, and are carefully put up from one season to another; when the entire quantity of flax prepared for rippling has undergone that operation, the boles are immediately run through a very coarse screen, sufficiently open to admit every particle of waste or dirt to pass through, so that they remain free of all impurities. The waste discharged in this manner is used by bakers in heating ovens, and the bole, by being thus cleaned, remains safe, and the seed can be kept for any time required. The mode most approved of for

taking the seed from the bole, is to thrash it, which is done by a flail, the handle of which is similar to a common one, but the *working part* is not more than half the usual length, about four inches diameter; the *hulls*, after the seed is discharged, are sold at the rate of twopence the *sack*, for feeding *cattle* in the winter; they are chiefly bought by Brabant farmers, who mix them with various other vegetables and *carrots*, which they grow with their flax, in ground suitable; and I have seen, in Brabant particularly, numerous fields, with flax standing to dry, and the peasantry weeding carrots that had grown with it, and which appeared in a prosperous state.

STEEPING.—This process, being the most important one which flax undergoes, and on which its value in a great measure depends, claimed my most serious attention, and occupied me for a considerable time, in observing it in detail, as performed by various steepers, and with flax the growth of different places. In general the steeping pools in Holland are similar to what are known in Ireland as *trenches* of water to drain and divide low grounds, such as abound in various parts of the South and West provinces, particularly where the soil is best suited for the growth of flax, and most like that of Holland and Zealand. Those trenches, in the summer months, are grown over with light grass and weeds, which are cut a little before steeping time, from the *edges* of the bank *only*, leaving the middle of the trench undisturbed. Previous to steeping, a sod or mud bank is thrown across each end of that *portion* of the trench required, which is seldom more than sixty to eighty yards. In making those banks the mud for a distance of eleven to twelve feet from each, is drawn with iron scrapers from the bottom and middle of the trench, and sloped against each of them, leaving a space of water free from weeds and mud, sufficient to put in a set of sheaves, and admit of a pool eight to ten feet between the cross-bank and last layer of flax. The steeping pool being thus prepared, a bundle of sheaves is opened, and eight of them laid in with small light forks, with which they are as *regularly* placed, as if laid with a line, each sheaf being put down with the root end towards the cross bank, and the top end towards the bottom of the pool; when the first layer is down, a second and third set of eight sheaves is put in, the root end of every layer meeting the *hands* of the former one, and all placed in an oblique direction. When *three layers*, or twenty-four sheaves, (which is *always* the number put in at a time,) are laid, the steepers, who are provided with scrapers and forks, draw from the bottom of the trench, *mud, slime, weeds, &c. &c.* just as it comes to hand, and which they place, to the thickness of six to eight inches, on the flax, leaving *only* as much of the last layer uncovered, as may be sufficient to receive the first layer of the next, and for which room is made by the removal of the mud, slime, &c. used as a covering for the former layer. In laying on the mud, great care is taken to plaster it together, and so combine it as to exclude the air and light completely from the flax.* The entire quantity being thus placed in the pool, nothing appears but a surface of mud. The next operation is to throw from that part of the trench not wanted, a sufficient quantity of water

to cover the entire mass to the depth of six to eight inches: although the mode of throwing the water into the steeping pool is done by a simple contrivance, it is nevertheless worthy of observation, as it abridges labour, and saves time, points duly appreciated by the working classes in Holland. This business is performed by means of a triangle made of slight poles, placed across the trench near one of the banks; from the centre of the triangle is suspended, by a slight cord, a shute or oblong box capable of containing about five to six gallons, and which lies a small depth in the water; to the shute is attached a long handle, with which the steeper works it, and so throws the water into a cut made in one corner of the cross bank, by which it is conveyed over the mud; when this is done, the flax remains from six to thirteen days, according to its quality, the temperature of the weather, and in some cases the properties of the water and mud; and I witnessed myself the taking out of flax grown in Holland and Zealand, some of which had been steeped in seven days, whilst others required fourteen to prepare it. It is here necessary to observe, that the flax growers in the Netherlands carefully watch the flax during the steeping process, particularly after the fifth day, when they once in every twenty-four hours take out a sheaf with a fork, and examine it; if not sufficiently steeped, it is carefully replaced and covered. When the flax is found sufficiently steeped, it is drawn out with great care by forks, beginning with the sheafs *laid in*, one sheaf only being taken out at a time, which is turned over into the water to disengage the mud from it, when it is gently washed in the pool, and left at the end of the cross bank for that purpose; after washing, it is laid in rows by the side of the pool to drain, from which it is spread on the grass, where it remains until the cultivator finds it ready for breaking; for this process, there is no defined time, every farmer judging for himself when his flax should be raised; but it is the uniform practice in those parts of the Netherlands and France where I have been, *to grass* all flax after steeping; no regard whatever is paid to the situation of the steeping pools as to aspect; those which I saw in various places lay in every direction; nor did it appear to me to be of any moment, in consequence of the total exclusion of the *light and air* by the covering of mud, &c. When removing the flax from the field to the barn, or store, it is again made into *small sheaves* nearly of an equal size, *twelve* of which are bound together similarly to what they were when going to be steeped.

DRYING.—Should the flax which has been raised from the grass be found partially damp, which often happens in Holland, it is dried, or rather *aired*, on what is called a kiln, but which is merely a brick building in an open space, about twelve feet long, with a slight brick wall in the centre, and projecting walls at each end, about three and a half feet deep. The fire pit which runs the length of the entire building, is from two to three feet under the surface of the ground; the fuel used is always the shoves and other waste that drop in scutching, which is kept continually stirring, so as to throw a regular and gentle heat to every part of the plant, which lies across strong rods that rests on each end of the projecting walls; when the flax can be cleaned without this process, it is so done; but, when necessary, it is performed with the greatest care; immediately after the flax is sufficiently aired, it is put in a small building air-tight, where it remains until it cools; putting flax in this building after airing, is, I believe, what gave rise to the idea of its being stoved in Holland previous to cleaning, as I could not learn

* Only one set of layers of sheaves in depth is put in each steeping pool at a time, it being found injurious to the flax to let the discharge of mucilage from one parcel blend with another. About one foot of water is in the pool when the flax is laid in.

in the course of my enquiries on that subject, that such a practice had ever existed.

BREAKING AND SCUTCHING.—In the Netherlands, flax is always broken and scutched by hand machines, for the most part with breakers and scutchers, similar to those known in many parts of England, where flax is much grown, and known also in some parts of Ireland. In one part of Flanders, a hand machine, similar to that described in p. 6, is used, and it appears to be very applicable to those districts where flax is grown in small quantities, and does not arrive to that length and strength of staple, produced in the rich grounds of many parts of Munster. In no instance, however, could I discover that any kind of machinery worked by moving power was ever used in Holland; but it is worthy of remark, that throughout the Netherlands, the flax plant is so carefully attended to, in every operation, that it breaks and dresses with great facility, and comparative ease, and presents a more finished and better article, than is to be found in most other countries.

(To be continued.)

FROM THE SOUTHERN PATRIOT.
INLAND SWAMPS.

Mr. Editor—I embrace the first moment of leisure, since my arrival in town, which was but a few days ago, to offer some remarks, in answer to the observations of a writer, under the signature of "Old School."—The picture which this writer presents of the present situation of the inland swamps; although it partakes somewhat of the caricature, is in the main correct, and I fully agree with him, that to cultivate those lands, as they are now cultivated, is a species of gambling of the worst sort, in as much as it is sure to be attended with loss; but at the same time, I say that a lucrative culture is impracticable, provided the only proper and feasible plan is adopted; which is by a regular and joint effort, to give them proper and systematic drainage; without this, it would be the height of folly to attempt their cultivation; and with it I am still persuaded that thousands of acres, which now lie waste and desolate, would then be made not only profitable to their owners, but highly advantageous to the citizens of Charleston.

This persuasion is not a little strengthened by the observations of "Old School" himself, who states, (and I presume he is accurate,) that from the year 1812, to the present time, there were only three years of drought, viz: 1814, 1816, 1818; every other year to use his own expression, was remarkable for excessive rain; if then in a period of eleven years, there have been only three years of drought, it unquestionably shews that the inland swamps, have to contend chiefly with but one enemy, which is a superabundance of water. Conquer this enemy, and you put them upon a footing with the best rice lands in the state; in as much as their fertility is undoubted, and there are few, if any situations, where with the proper care, sufficient reservoirs may not be established. Should, however, the pointers of the *Old School*, still persist in keeping shallow reservoirs, and these extended over a great surface, instead of narrow and deep backwaters, where the evaporation cannot be great; they will look up and suffer them, day by day, to diminish, until they become a mere puddle for snakes, and cranes to dive in; then they deserve like the frogs and fish, to be swallowed up alive.

Old School is certainly under a great mistake when he observes that the levels of the swamps, are every where lower than the levels of the rivers, into which they empty themselves; it is true, that some of the swamps are subject to inundation, from the overflowing of the rivers,

but this is not applicable to such as run into tide waters, and it is to these that my remarks are chiefly to be applied. Our forefathers, says Old School, "were not wanting in industry, the whole country abounds with evidences of their perseverance," yes, truly, and these evidences are the accusing witnesses, that testify to our neglect; and methinks, I hear from the tombs where repose their ashes, the voice of censure and of sorrow. In vain have they laboured, if we are to abandon all their labours; in vain have they planted the monarch of the wood, if we refuse to take shelter under its shade. I disagree with Old School in the remark, that the cases of the cause of Gourie and the Pontine marshes do not apply; they were quoted by Rusticus to shew what had been done in other countries on lands similarly situated to ours, and in addition to these, I would add the example of the salt marsh company of New-Jersey, where the efforts of a few enterprising individuals, have been seconded by a company, for the laudable purpose of reclaiming marsh lands, in the vicinity of New-York.

Before I take my leave of this subject, I must be permitted again to call the attention of the citizens of Charleston to its importance. If this city is destined, as I trust it is, to be the grand emporium of Southern trade, we should embrace every opportunity of calling into action, all the resources of the neighbouring country, we should arouse the torpid energies of its inhabitants, we should encourage that enterprise which properly applied, would not only increase the supply of the chief staple of the country, but multiply in a tenfold ratio, those little articles of domestic comfort, with which we are now so miserably furnished; if our rice lands were successfully cultivated, we should soon abound in the best beef, pork, poultry, &c. Our live stock partaking in the abundance of offal which is afforded them during the winter, would be kept in good condition; whereas they are left at present to gather the coarse and scanty herbage which they can find in the woods, where they either die by hundreds, or are left in such a state of debility, as requires the whole summer to restore them to their strength.

Is it not extraordinary that a country possessing such capabilities as this for the rearing of live stock, should (instead of exporting the above-named articles) be indebted to the North not only for them, but for the very butter we consume at our tables? Does not policy require, that by making every effort to multiply and cheapen the necessaries of life, we may offer strong inducements to strangers to come among us, who are now deterred by the almost proverbial extravagance of living in Charleston, and at the same time by multiplying the temptations arising from the health of the city, which is now pretty well established, the cheapness of living, &c. direct our fellow citizens from the ruinous practice of spending their time and money in the Northern states; a practice which not only deprives their country of their services in time of danger, but drains the state and city of a considerable portion of their resources.

But it may be asked where are the laborers to carry these plans into effect? In reply I would observe, that in addition to those now in the country that would soon be employed, there are idlers enough in the city itself, such as supernumerary servants, vagrant tradesmen and others, who might then be profitably and usefully occupied, instead of being nuisances and pests, intent only in plotting mischief. I thank Old School for the polite manner in which he speaks of my motives, and I trust that this subject will be fully investigated, as I wish to advocate no doctrines but such as are founded on the basis of truth;

nor to recommend any scheme which cannot bear the test of reason; but I can confidently assert, that although I were not personally interested, as I candidly confess I am, still it would give me great pleasure to contribute in the smallest manner to the prosperity of my native land, whose interests wherever he may be placed, or whatever may be his fortune, will ever be dear to the heart of

RUSTICUS.

HESSIAN FLY.

We insert the following communication, with many thanks to the writer. He has certainly furnished some useful hints to farmers, which, if improved, may lead the curious enquirer, into a knowledge of facts relating to that destructive insect, the Hessian Fly, and a method of extirpating it, which may be of great importance to the farming interest generally.

Cape May, June 27, 1823.

Mr. Clarke,

I saw published in your paper of June 14th, an account of the Hessian fly, which says the fly deposits its eggs on the grains of wheat. I think the person who made that statement, has not examined the progress of what is called the Hessian fly, closely, or has he taken the fly we see before harvest to be the Hessian fly. The fly we see before harvest on the heads of grain, is a long black fly that is propagated from a worm, and this worm becomes a fly. It eats into the straw about the second or third joint; they are not numerous, and do but little injury to the grain, but the Hessian fly is innumerable, it is shaped like a locust, some are green and some brown, and are not larger than the fly that deposits the skipper in the cheese. There appears to be male and female, as some have eggs in them and others have not. The eggs may be squeezed out of them, and any person with good eyesight may perceive them without glasses. They deposit their eggs or skippers in the fall. As soon as the grain, (wheat or rye,) gets through the ground so as to have two blades, they deposit the eggs in the fork between the blades, and the nit creeps down below the surface of the ground, and in three or four weeks they change to the chrysalis or flax-seed state. They hatch out in the spring at different times and become a locust or fly, and begin depositing their eggs or nits again. You will find them from below the ground, to at or about the third joint of the straw. The spring crop does not hatch out till after harvest. I have more than once taken the stubble and put it into a glass jar, covered it with perforated paper, and very few have come out before the month of August. This fly deposits its eggs in grass or in oats. They do but little injury to any thing that grows fast, for in that case, the straw gets hard before the chrysalis; they do not indent it much. But poor land and an unfavourable season, in consequence of its being dry so long, like as the present has been, the chrysalis gets hard before the straw, and the straw perishes. For the information of those that may not know how to find the fly in the fall, they will look for the spears that are the darkest green, and stand the most upright.

I think that fall pasturing with sheep is an advantage to early sowed grain, as the spears that have the fly stand more upright, the sheep are apt to take them first, as the sap has ceased flowing up the main stalk, a number of young shoots start from the root, and they are clear of the fly at least till spring; and where the grain is bit off close it lets in the water and the fly perishes, which will lessen the quantity of the fly, that hatches out in the spring to deposit a new crop of nits. I think those deposited in the spring do more injury than those in the fall,

My object and wish in making this communication, is, that farmers may examine for themselves; and perhaps the result may be, that we shall be able to make some discovery that may be beneficial to farmers in general.

Sir, if you think the above worthy a place in your paper, you are at liberty to insert it.

Respectfully your's,

THOMAS BEESLEY.

TEA PLANT.

An interesting and encouraging account has lately been given in the National Intelligencer, of a considerable experiment made in North Carolina, in the cultivation of the tea plant—we shall copy that account before long—in the mean time, for the information of those who may have the good disposition and enterprise to extend the experiments, already made, and which have been attended with flattering results; we give the following, as a more rational method of curing the leaves, than any that has yet appeared in the Farmer.—*Edit. Am. Far.*

From the Monthly Magazine.

ACCOUNT OF THE INTRODUCTION OF THE TEA PLANT INTO CAYENNE, WITH OBSERVATIONS ON ITS CULTURE.

The recent importation of some young plants of the tea tree into Cayenne, has induced the *Society for Instruction*, in Guiana, to circulate the following information respecting this valuable plant.

The tea tree does not grow naturally any where but in China, but it is cultivated in many gardens of Europe and America. It rises to the height of five or six feet; its leaves are oval or elliptical, from one to two inches in length, and of a deep and glossy green. Its flowers (which are always numerous, rather large, and of a very pleasing appearance) are white, and are each composed of a calix of five or six divisions, five or six petals, and a great number of stamina.

China and Japan are the only countries at present, in which the plant is cultivated in large quantities, and where the leaves are prepared in the manner in which we see them.

According to Kemfer, it will grow in any soil and climate; others say it prefers a pliable soil, and an aspect partly shaded.

At the age of three years it begins to be fit for use: and every six or eight years, the ground is replanted with new trees.

We shall now give all that we have been able to learn respecting the gathering and the preparation of the leaves, which is the only part of the tree of which any use is made.

In February and March, the cultivator gathers the young and tender leaves when they are only of a few days growth; and in consequence of their comparative scarcity, and their high price, these are generally consumed only by the rich. This is called the *imperial tea*.

The second gathering is made in May, when some of the leaves have attained their usual growth, but others are not so far advanced. Both of these are plucked indiscriminately, as they occur, and this mixture of the young and mature leaf is the *Bohea*.

The third and last gathering is made about the middle of summer, when all the leaves are at their full growth. This kind of tea is the coarsest, and is usually consumed by the poor.

Although each leaf is carefully plucked one by one, not to injure the plant, a labourer will gather from six to twelve pounds per day. The leaves are dried upon heated iron plates. They

are continually turned with great quickness till they are so hot that they can scarcely be any longer touched with the hand. They are then thrown upon mats, from which the workmen afterwards takes them, one by one, and rolls them in his hands, while others fan them continually, to cool them rapidly, in order that they may preserve their rolled-up form.

This process is repeated several times, until all the humidity of the leaves is extracted: but the iron plates are heated less and less, and the rolling is made more slowly and with greater care.

When the leaves are thus made perfectly dry, they are packed in boxes, that they may preserve their perfume until they go into the market.

The use of tea in China, is of the highest antiquity. We are unacquainted with the motives which led the Chinese to drink this infusion, and are ignorant of the time when this custom commenced. It is conjectured that their first design, in using it, was to correct the water, which is said to be of a brackish taste in many parts of that vast empire.

It was about the commencement of the seventeenth century, that the Dutch East India Company introduced tea into Europe, and that the use of it first began. Its cultivation in the gardens of the curious, in this quarter of the globe, has been known for a century past.

We do not enter into the discussion respecting the properties or virtues of tea. We merely recollect to the public mind, that it is an important object of commerce; and we believe that it will familiarize itself with great ease to the climate of this colony; and, unquestionably, its culture is highly worthy of the attention of the colonists.

The six plants which were brought to Cayenne, by the French ship of war *l'Ariège*, from San Salvador (Brazil,) have taken extremely well, up to this time. Three of them, according to the *Annales Maritimes*, are in the Royal Botanic Garden at Cayenne; and the other three are in the plantations of M. de Kerchove.

May we not hope that the Americans, who like the French, are independent of those intrigues which have deprived the British colonies of the cultivation of this plant, will be induced to attempt its culture in Louisiana and the Floridas.

TO THE EDITOR OF THE AMERICAN FARMER.

TO CURE BEEF AND KEEP IT SWEET.

Bowling Green, Va. July 20, 1823.

SIR,

We have for the last two years preserved our beef in so easy and simple a manner, and with so much certainty that it may deserve to be publicly known. In the year 1821, after hanging up our bacon to smoke, we put into the bacon brine, two or three pieces of beef that we could not well cover in the beef brine, they were permitted to remain there unattended to until late in summer, when our stock was pretty well exhausted—they were then used and found to be perfectly sound, and we thought possessed a peculiarly fine flavor. This circumstance determined us last year to try our whole year's stock in that way, for the purpose of avoiding the very great trouble of renewing and boiling brine as heretofore, and also of avoiding the partial loss every year sustained. We did so, and found it to keep sound and very sweet. We have made the same experiment this year, and the result is the same thus far, and feel confident we shall not lose a single piece. Our bacon is salted in large gum-troughs placed round the meat house; and when the bacon is taken out, the brine is collected and placed all in one trough, in which the beef then salted is put. Any beef that we

kill after that period we salt in the usual way, and after a week or fortnight put in the brine with the other.

If you think the above worthy a place in your useful paper, you are at liberty to insert it—omitting the name of your well wisher.

FROM THE AMERICAN ECONOMIST.

The following communication on the subject of botts in horses, is from the pen of one of our most intelligent farmers, and may be relied on in every particular. I was exceedingly surprised to see the botts which had been cut out as mentioned towards the close of the article, alive, when the part of the stomach to which they were attached was dry and hard. This is indeed an extremely interesting subject, and it is to be hoped that the experiments made by my friend may lead to the discovery of a plan to dislodge those voracious worms from the stomach of the horse, ere they prove fatal to him.

Edit. Economist.

THE BOTTS.

MR. LUNDY.—In your paper of the 24th inst. I observed an extract from a Lexington paper, purporting to be an effectual remedy for the botts; and in which the author states, he has not known, an instance of its failure;—I have been so unfortunate as to lose this summer, two valuable horses, with the first of which I followed very minutely the directions of that writer;—but on the morning of the third day he died; and, upon examination, it was found the botts had killed him. There is no disease to which the horse is subject, more alarming in its attack, or difficult to cure, than when sickened by the botts. An attack of the botts is generally thought to be incurable; but I am led to believe the lives of many valuable horses might be saved in such cases by forcing down the throat some small pieces of fresh meat, followed by a brisk purge. I dropped into the stomach of a horse, filled with botts, a piece of fresh meat, and they seized upon it with avidity.—There is seldom any thing done for a horse, when afflicted in this way, until he commences rolling and tumbling about in great agony and distress; and it is not until the botts have fastened upon the sensible coat of the stomach, that he shows such symptoms of violent suffering, at which time nothing short of killing them will ever compel them to let go their hold. I sprinkled a quantity of pulverised salt petre and alum upon some botts, fastened upon the stomach of a horse; I also poured upon them sugar and milk, spirits of turpentine, and of laudanum, hot water* and whiskey; none of which would induce them to let go their hold. I then made a strong decoction of salt petre, of alum, of spirits of turpentine, and of laudanum, and dropped a living bott into a spoonful of each. The laudanum in two hours killed one. Those dropped in the other liquids I am satisfied would have lived forty-eight hours in them; and I believe the bott dropped in the laudanum, was injured in separating from the stomach. From the second horse that died I cut a piece of his stomach, containing on it about fifty botts, and hung it in

* Some writer on the subject of botts, in the *American Farmer*, denies there being botts in the stomach of a horse, while living, and says they could not exist in so much heat. I did not try them in boiling water, but in water warmer, I apprehend, than the fermentation in a horse's stomach to be, I believe they would live comfortably.

the open air until it dried as hard as a board. At the end of three weeks I showed them to you, and you recollect they were still alive. In two weeks after that, many of them had formed wings, and were putting on all the appearance of a perfect bott-fly, at which time I killed them.

Editorial Correspondence.

*The Pines, near Greenville, Miss. }
July 2, 1823. }*

DEAR SIR,

The lupins which you favoured me with, were distributed among my friends—those I planted were attended to by myself, but all rotted in the ground before the process of vegetation commenced—all attentions from you in that way, will be most gratefully received.

I have made a full and fair experiment of some of your Northern or Eastern grasses, viz. the Timothy, Red Clover, and Orchard grass—they all do well on proper soils, when kept clean of our indigenous weeds and grasses; but as soon as they are left to their own exertions, they are smothered and gradually decline.—The best grass for a Southern summer grass, is the old Crab grass, it grows with very little attention, is abundant in product, and rich and fattening as food—when well cured, no Northern grass is preferred to it by Northern horses or oxen.

Your most obedient servant,

COWLES MEAD.

J. S. SKINNER, Esq.

P. S.—The cotton crops on the Mississippi river, estimated to be between 70 and 100,000 bales, are lost by inundation.

EXTRACT TO THE EDITOR.

MR. SKINNER,

I would recommend to your correspondent, who questions whether wheat will turn to cheat, to make the following experiments.

1st. Take one pint of Lawler wheat (that being most subject to the metamorphosis) two pints of ground Plaster of Paris, and with water make the mass into a paste; roll it into balls, about the size of an English walnut, and at the usual time of sowing wheat, plant the balls two inches deep, and twelve inches apart, in a rich soil.

2d. Take of the same kind of wheat, and sow immediately on a rich land, at the rate of five bushels to the acre.

3d. Sow the same kind on a rich Timothy meadow, not very wet, about the 25th of September, at the rate of two bushels to the acre; I mean, sow it on the grass, and sow no more.

4th. Sow another parcel on good land at the usual time, and of the usual thickness, and suffer it to be grazed from the 12th to the 15th of May.

S

SEED—Received for distribution since last notice.

SEA KALE SEED—From President MADISON he says, "and with my thanks return a few seeds of the Sea Kale, saved from the small rock in my garden. My limited experience recommends it as well deserving a place in our culinary list of vegetables."

Ditto—of imported, and of domestic growth, from Doctor Samuel M'ulloh.

SEEDS OF TOBACCO—of a peculiar kind—From the Hon. Secretary at War—with the following note, which is given, that reference to it may be made, as historical of its introduction, should it prove to be a valuable variety of that plant.

War Department, August 5, 1823.

DEAR SIR,

I have just received a letter from Doctor James of the Army, from St. Louis, in which are enclosed some tobacco seeds of a peculiar kind, as you will perceive by the letter which I have the pleasure of sending you, and the seeds, requesting that you will be pleased to present them to the President of the Agricultural Society of Maryland, as the most certain way of securing the proper culture of them.

Doctor James, who was attached to the Topographical Department, and accompanied Major Long to the Rocky Mountains, was prevented from going on the present expedition by ill health, and other circumstances. He is at present stationed at St. Louis, and from his devotedness to botanical, and other pursuits of that nature, I hope his researches may be useful; and you shall be informed of any such that may be communicated to me.

I am very respectfully,

Dear sir,

Your obt' serv't,

J. C. CALHOUN.

JOHN S. SKINNER, Esq. }
Editor Am. Farmer. }

Saint Louis, July 11, 1823.

SIR,

Enclosed, are a few seeds of a species of tobacco, indigenous to the Rocky mountains, about Santa Fe, and to the hilly parts of North California, whence I received them by a gentleman recently from that quarter. Some plants have been reared from seeds of the same parcel, and are now growing in the garden of Gen. William Rector of this place. This species is abundantly distinguished from the common tobacco, also from that cultivated by the Aborigines of the Missouri, by the long and conspicuous foot stalks of the leaves; it is also, as I think, (judging from recollection,) distinct from the *rustico*, the only remaining species heretofore noticed in North America, and which has been met with, principally, if not entirely, in the vicinity of old French or Indian stations in the interior of New York. The leaves of this plant possess, as I am informed, in a great degree of concentration, the peculiar properties of the common tobacco, and it is probably much better adapted than that species, to the climate of the more cool and temperate parts of the United States.

I have taken the liberty to transmit the seeds to you, as I am persuaded you will attach so much importance to any attempt to spread the knowledge of our indigenous productions, as to cause them to be planted in the ensuing spring, and in the following summer it is probable a quantity of seed will be produced, sufficient to be distributed to every part of the Union.

I have the honour to be,

With great respect,

Your obt' serv't,

EDWIN JAMES.

Hon. J. C. CALHOUN, }
Sec'y of War, &c. &c. }

Gleanings from Foreign Journals.

RUM JELLY.—Among the novelties of the Parisian circles, rum jelly has become an universal favourite. It is made in the following manner. To a quart bottle of common white wine take a pound of sugar, which is to be reduced to a syrup, and clarified. Then take an ounce of isinglass, which put on the fire till it is thoroughly melted, pass it through a cloth, and mix it with the syrup half

warm. When this mixture is nearly cold, pour it into the white wine, and stir it well so as to mix it completely. Then add a spoonful or a spoonful and a half (according to the strength which you desire to give to the jelly) of old Jamaica rum. Stir again this mixture, and pour it into the mould that it may take the shape in cooling, which you design to give it, if intended as a *plat* for the table, or into glasses, if designed to be handed round at an evening party.

CURIOSITIES.—A well of extraordinary depth is now sunk at his Majesty's cottage in Windsor Great Park. During the progress of the work, many curious minerals have been discovered: at the depth of 360 feet, several fossil remains, among which is a very perfect specimen of an oyster-shell, have been dug out. At this immense distance below the surface, a very large tooth has also been found, which is in beautiful preservation. It is of double fangs, which are at present about two inches long, but have been evidently broken off. The face of the tooth, which is of the sort denominated a grinder, is about one inch and a half long by one inch wide. It is of a dark brown color, and bears a fine polish.

ON THE CASTRATION OF ANIMALS.

April 27, 1822.

SIR,

Some of my neighbours differ with me in opinion respecting the age at which calves and lambs should be castrated, and some of us keep our young stock twelve or eighteen months, and our lambs four or five months before castrating them, that they look more like bulls and tups than bullocks and wethers; thinking that, by keeping them thus long, they will grow larger and fat better. I am of opinion that these animals should be castrated when very young, before they are taken off the dam; there is not then so much risk; they suffer less by the operation, and that any loss in size is amply made up by the superior quality of the meat.

We shall be obliged if some of your correspondents will inform us, through the medium of your useful Journal, of the most approved practice among experienced breeders, as to the age when this operation should be performed, and the best mode of performing it, together, with any other information upon the subject they may be pleased to favour us with.

I am sir,

Your obt' serv't,

A SUBSCRIBER.

The Editor agrees with the writer, the younger the better, provided that lambs be not less than six or seven days old, and calves not under a fortnight. The mode of operation is the simpler and safer, when the animals are quite young, but the description can hardly be made fit for a newspaper.—*Edit. Farm's Journal.*

ON ABORTION IN COWS.

Norfolk, September 1, 1821.

SIR,

In answer to the Queries on Abortion in Cows, in your Journal, No. 727, the most common cause perhaps is relaxation, from want of air and exercise. In most instances that I have known of cows slipping their calves, they have either been tied up in houses or kept in yards: the same cows, when ranging at will in a pasture of a sufficient size, have done well. Cases of this kind are by no means confined to cows. All breeding animals suffer from want of a good range, and cows may gain in flesh, but they will always lose in milk, when kept in a yard, besides the risk of abortion. In Arthur Young's *Suffolk*, which

better than any of his Reports, he blames the farmers of that county for throwing cabbages and turnips about their fields in winter for their cows instead of giving them in bins in a yard. The farmers were quite right; they did not want any calves split, and they wanted their cows to milk; and again no animal ever suffers from cold, which has shelter to retire to at will. In speaking of Suffolk, it may not be amiss to mention the excellence of its small polled cattle. Without any reflection on other breeds, they may be truly said to be inferior in real use to no breed of cattle on the island. They are excellent milkers, and fatten easily and early. There are no better cutters in Smithfield, where a good Norfolk or Suffolk home-bred is worth as much per stone as a Scot, which is the most that can be wished for.* Our larger breeds at per stone fail greatly. I never saw a Suffolk cow, such as is spoken of by Young, which would give eight gallons of milk a day, but I have had one which gave six gallons a day for more than five months, and milked well till within six or eight weeks of calving, when I chose to dry her up. This cow, eight weeks after calving, gave 11 lbs. 10 oz. of butter.

B. HARWOOD, Tr. W. S. Md.

* We conceive that the important difference between the Suffolks and the best improved breeds, is, that there are more inferior animals among them. In all our observations in Smithfield market although we see some good Norfolk and Suffolk home-breeds, we notice more of these sorts, that are not well shaped, and not early feeders. Our correspondent's assertion is nevertheless true, that a good one makes as good a price as any other d one.—EDIT. FAR. JOUR.

THE FARMER.

BALTIMORE, FRIDAY, AUGUST 15, 1823.

The Editor has received intimations from distant subscribers, who are friends of exceedingly good judgment, that the Patrons of this Journal are not well satisfied with having so much of it taken up with discussions respecting the Potomac and Susquehanna canal.—It is our inclination, as well as obvious, duty to consult the wishes and interests of our subscribers generally, and we must accordingly suspend for a time, further notice of these subjects.—The letter from Mr. Robert Mills, will be finished in the next Farmer, and then we shall reserve the pages which have been lately filled with these topics, for matters more various, and more generally acceptable.

We embrace this opportunity to not only disclaim any unwillingness to be advised, as to the manner and the matter of our Journal, but to solicit hints from any quarter; being well assured that such hints will oftentimes prove useful and valuable, and that they will always flow from friendly motives.

BALTIMORE MARKET.

PRICES CURRENT.—CORRECTED WEEKLY.

Flour; best white wheat, \$7—Howard street Superfine, \$6 75—fine do. \$6 25—Wharf, do. \$6 25—White wheat, \$1 22 to 1 26—Red do. \$1 18 to \$1 21—Rye, 45 cents—Corn, 45 cents—country Oats, 25 cents—Beef, 8 cents per lb.—Live Cattle, \$6 to \$6 50 per cwt.—Bacon, hog round, \$10—Pork, \$4 50 to 5 50 per c. lb.—6 to 8 cts. per pound—Mutton, 5 to 6 cts. per lb.—Beans, \$1 37½ to 1 50—Peas, black eyed, 55 to 60 cts.—Red Clover Seed, \$5 50 a \$6—Orchard Grass do. \$3—Herds' Grass do. \$3—Timothy do. \$4 50—Millet, \$1 50—Buckwheat, \$1 50—Flax Seed, 75 to 80 cts.—Whiskey, from the wagons 35 to 36 cts. per gal. including the barrel—Apple brandy, 30 to 32 cts.—Peach do. 65 to 70 cts.—Shad, \$6 00.—Herrings, No. 1, \$2 70 per bbl.—No. 2, \$2 37½—Fine salt, 60 to 65 cts. per bush.—Coarse, do. 70—Butter, (firkin) 14 cts. per lb.—Eggs, 10 cts. per doz.—New Hay, \$14 to \$15 per ton—Old do. \$18—Straw, do. none.

MARYLAND TOBACCO.—Fine Tobacco, as last report, scarce—inferior qualities, plenty—no demand.

Valuable Lands For Sale.

The subscriber, agent for William D. Mercer, Esq. will offer at public vendue, on Thursday the 28th of August, inst. that well known, valuable property, called WORSELL MANOR, situate and lying in Sassafras Neck, Cecil county, Maryland, containing 550 acres (more or less,) about 40 whereof is first quality Bottom Meadow, which may be put in good mowing order, at very little expense. This property is now in a high state of cultivation, and no land in the United States has exhibited stronger proofs of the efficacy of plaster and clover. There is a large proportion of Wood-land on the farm.

The improvements are, a large two-story Brick House, with a good Kitchen attached thereto; a large and excellent Barn, good Stabling, &c.

This farm is surrounded by agreeable and intelligent neighbors—it is only eight miles from the mouth of Apoquinimink creek, where Philadelphia prices are given for produce—it is also, but two miles from Bohemia river.

To suit purchasers, this property can be handsomely divided into two farms—three hundred acres sold with the improvements—each farm will retain a sufficient quantity of arable and woodland.

This property affords a fine prospect for the man of enterprise, and will be sold on accommodating terms.

Persons wishing to view the premises, previous to the day of sale, can, (in the absence of Mr. Mercer) apply to the subscriber.

Sale to commence at ten o'clock, in the forenoon of said day, when the terms will be made known, by

GEORGE FORD.
of Cecilton.

Superior Cabbage Seed.

The Subscriber hath received by the Fabius from Liverpool, a supply of very fine Early York Cabbage Seed, which he will sell at the low price of Four Dollars per pound. He has also lately received a fresh supply of that very excellent seed, called Early George Cabbage, the production of William Waitland, Esq. who has discovered the method of raising the seed, so as to prevent any of the plants from running to seed in the Spring.—This seed produces very genuine plants, which are very hardy in standing the winter; and they make hard White Heads from two to three weeks sooner than the Early Yorks.

In confirmation of the above, I here subjoin the testimony of some of the most respectable Gardeners of Baltimore market, who have made use of this seed four or five years.

Baltimore, July 14th, 1821.

We the undersigned, do certify, that the cabbage seed called Early George, which is imported and sold by Samuel Ault, is of the very best quality, being very early and genuine; likewise very hard in standing the winter.

John Mycroft, Peter Hatman,
Thomas Lewis, Samuel Register.
Edmund Evans, Valentine Lutz.

The prices of the above seed is 37½ cents per oz. or \$5 per pound—the ounce will yield upwards of 2000 fine cabbages.—The time to sow this seed, is from the 8th to the 15th of September. Printed directions respecting the proper soil, treatment and cultivation of these cabbages, will accompany each parcel of the seed—orders, with remittances, from all parts of the Union, will be promptly attended to, if directed to "Samuel Ault, No. 78 Bridge-street, Baltimore"—and to prevent mistakes, impositions, &c., upon each parcel of seed will be pasted a printed label, in words as follows:—"Early George Cabbage Seed, imported and warranted by Samuel Ault."

N. B.—Any seed that may be offered to the public as Early George Cabbage, unaccompanied by the label as above, is spurious, as I am at present the proprietor's only agent in this country.

SAMUEL AULT.

Timothy, Orchard Grass, and Millet Seeds.

The subscriber has just received a quantity of each kind of the above described SEEDS, and now offers them for sale,

ROBERT SINCLAIR.

No. 1, Ellicott-st. Pratt-st. wharf.

On hand and for sale as above,

A general assortment of

Agricultural Implements.

ALSO,

GARDEN SEEDS,
CLOVER SEED,
And HERDS GRASS SEED.

Printed every Friday at \$4 per annum, for JOHN B. SKINNER, Editor, by JOSEPH ROBINSON, on the North West corner of Market and Belvidere streets, Baltimore; where every description of Book and Job Printing is executed with neatness and despatch—Orders from a distance for PRINTING or BINDING, with proper directions promptly attended to, addressed to J. Robinson, Baltimore.

Internal Improvement.

TO THE EDITOR OF THE AMERICAN FARMER.

THE JUNCTION CANALS OF POTOMAC AND SUSQUEHANNAH.

No. II.—AND LAST.

From the great elevation of country, intervening between Baltimore and the Susquehanna river, it was requisite that some efficient means should be found to surmount the difficulty, which here presented itself—namely, the want of a sufficient head of water, to feed the locks, which would be required.

The waters of Potomac, fortunately, offered such means. From actual levels taken, this river at Harper's ferry, was found to be upwards of 300 feet above the tide, and nearly twice as high as the waters of Susquehanna at Yorkhaven.—This fact was of immense importance, to effect our object, and it was embraced—I proposed therefore to bring in the *aid* of the Potomac, to furnish the necessary supply of waters, to the summit canal, and to the locks descending to Baltimore and Susquehanna.

In taking this river into view, I had a higher design to accomplish, than merely to make it subservient to the canal of Susquehanna, for I considered a canal from Potomac of equal importance; as affording to the seat of the general government, as well as to Baltimore, the means of communicating by the shortest route with the western waters, and also with the lakes, through the medium of the Susquehanna; an object of vast consequence to the operations of government, in time of war especially. The proposition therefore, to bring in the aid of the Potomac, to enable us to communicate by a canal from Baltimore to the Susquehanna at Yorkhaven, ceases to appear extravagant, and thus are we furnished with the most ample means, to surmount the chief and only difficulty in the way to forming such navigation. That the dividing ridge, between the waters falling into the Potomac and Susquehanna, is not higher than the waters at or near Harper's ferry, I infer from the characters of the streams rising on each side of this ridge, particularly the Conewago creek, which empties into the Susquehanna at Yorkhaven. This stream is known to be *not rapid*, nor interrupted with many falls. It rises near the top of the ridge, and meanders about 35 miles, before it discharges its waters. Now, if its head were 150 feet above its mouth, (and this is the supposed elevation of the ridge above the Susquehanna at Yorkhaven,) then would it have an average fall of 4 feet in the mile, which is sufficient to create a continuous rapid in its whole length, (for the velocity acquired by a stream, having this fall, is enough to move stones of some magnitude;) but this is not the character of the Conewago creek, consequently its head cannot be as elevated as we have supposed.*

It is of the utmost importance, wherever we do form a canal communication, between the Susquehanna and Baltimore, to take into serious consideration, the canal to Potomac, at the same time, because it is very questionable whether any waters can be found elevated enough, or in sufficient quantities near the summit level, to feed the locks—and without a full supply of water can be secured at all times for this purpose, our canal would be of little comparative utility

* We may form a tolerably correct opinion of the elevation of a country, by noticing the velocity of its streams, with the distance they run; this velocity being always (nearly) in proportion to this slope.

—The reasonable prospects we have, that a great trade will pass through this channel, makes it imperative on us to attend to this particular. From the character of the country in the vicinity of the summit canal, where these streams rise, (a limestone region,) I should doubt their capacity to effect a constant and full supply of water, for such a trade: I may be mistaken, but I should think it indispensably necessary, that we should resort to a source which would not disappoint our hopes in this momentous business. The worth of the Potomac canal on this ground simply, is immense, and would probably justify the expense of cutting it, merely for a supply canal, to the locks—but its value is beyond calculation, when viewed as a part of that great channel of communication, which some day, not far distant, will be opened with the western waters: until this is completed, it will form the medium of intercourse with the rich and populous country, lying between the Blue ridge and the Alleghany mountains, on each side of the Potomac. I perceive by a late number of the Farmer, (just received,) that the importance of a canal from the Potomac above Harper's ferry, to Washington, is to be made a subject of discussion by Mr. Briggs; I shall anticipate very interesting matter from the pen of this gentleman, who possesses much valuable information on this head. As the canal of Potomac properly excites equal interest at Washington, with the canal of Susquehanna at Baltimore; and it is to be presumed, the execution of both will be simultaneous, I would take the liberty, through your valuable paper, to call the attention of the citizens of Washington and Baltimore, to the importance of forming a *union canal*, as the interests of both cities would be thereby consulted, and the expenses of the work considerably reduced.

The great advantages which would result to each of these places, by adopting this plan, can be easily pointed out; if they have not been already made manifest, a further proof of them will appear as we proceed. The route which I located for the Potomac canal, (in my Treatise, page 83,) would range through a populous, fertile and interesting section of country. The great elevation of its waters, would enable branch canals to be taken to every town and village in its vicinity, thus diffusing its benefits to a wide extent. It would run through, we might almost say, the heart of the state, and admit, were it required, to lead a branch down to the extreme end of Point Look Out; (this however is merely stated to prove its capacity, to promote the general interests of the state.) From the knowledge I have of the Potomac river, it appears to me, there are strong objections to the location of a canal on or near its margin, arising out of the precipitous and rocky nature of its banks, and from the depth of the ravines that intersect them, which would require a very circuitous canal. But admitting that every obstacle of this kind can be overcome, there are *greater objections* on political grounds, namely, the *partial character* of this canal, to subserve the *general interests of the state*, (for we must bear in mind, that the Potomac constitutes the southern boundary of Maryland.) Located along the banks of this river, a rich and populous section of this state and Pennsylvania, would derive no benefit from the work—only a small portion of either Maryland or Virginia would be advantaged, and the chief commercial city of the state, *not at all*. Whereas, by the route proposed, not only would the interests of Washington and Baltimore be equally benefitted, but those of a *fine region of country*. With such a prospect of general advantage to the state before us, we should not

hesitate to adopt the plan which would make the canal of Potomac form a *junction* with that leading to Baltimore, from the Susquehanna. Let us examine this part of the subject more closely, and draw a comparison between the two routes; one pursuing the sinuosities of the river banks, subject to perpetual difficulties, and the other ranging along the side of the rich vallies of Catoctin and Monocacy, through Frederick, down to Washington and Baltimore.

Estimate of the canal to Washington, by the lower or river route.

By the official report transmitted by the Governor, to the Assembly of Maryland, January 1, 1823, the total length of the canal of Potomac to Washington, is stated at 182 miles, which at the estimate made per mile \$8676, is

\$1,579,032

Upper route of Canal to Washington, from Potomac above Harper's Ferry, viz. Williamsport, through Frederick and Montgomery counties to Washington, say 130 miles at \$7000 per mile.

910,000

Probable diff. in favor of upper route \$669,032

(I have taken the average cost of canals, such as ours would be, both in size and location, from the data furnished us of the cost of executing various canals in this country, and presume that this is at least as high in comparison, as that affixed to the canal of the river.)

These calculations, (if I have been correct in fixing the point of starting from Potomac, which is not stated in Mr. Kenworthy's abstract, to which I have referred) will tend to prove to the citizens of Washington, how much it would be to their interest, to adopt the upper route; even should the distance be greater, than by the river, which there is no likelihood would be the case; besides the expenses of the work would be less, and the benefits vastly superior, because of the difference in the character (for fertility) of the country it would pass through, and because an intercourse would be thereby opened with the Susquehanna by which a double interest would be gained from the work.

Expenses of the canal to Susquehanna from Baltimore, with the continuation and cost of that from Potomac to intersect it. From the diverging point of the Potomac, canal to Washington, (somewhere near Emmetsburg,) to Baltimore, say 55 miles at \$7000 per mile	\$385,000
From the great basin or feeder (from which branch off the several canals) to the Susquehanna at Yorkhaven, say 50 miles at \$7000 per mile	350,000
Cost of canals from Potomac and Susquehanna to Baltimore	735,000
Cost of Potomac canal to Washington	910,000
Total cost of both canals	\$1,645,000

Thus we see, that by making choice of the upper route for our canal from Potomac, the expenses of the work will be considerably reduced, to what amount we cannot with certainty determine, until a correct survey be made of the routes; if our data above is correct, this difference of expense will be very great, but as was before observed, we might have erred in the point of beginning for the canal of the lower route. Yet in any case I am under the impression the result would be in favor of the upper route.

I have thus endeavoured to point out the superior claims which the plan proposed has to our attention, whether on the ground of economy or utility. Its practicability is inferred not only from the known geological character of the country, where it is proposed to locate this canal, but from personal examination—true—not with an instrument, but with an eye, having a reference to the original object. I will not pretend to point out the *direct line*, which our canal would take, but I am led to think it would, in the general, be not very wide apart of that located in the large map, which I deposited in the Exchange at Baltimore. If then the route under consideration, is of the value represented, should not early measures be taken to explore the country where it is located, and ascertain the practicability of cutting a canal there, together with the expenses of the work, so that we may be able to present a proper and correct view of the subject to the next Legislature, when they shall have different plans of Internal Improvement laid before them, so that they may be able to form a correct judgment which canal they should patronise, as tending most effectually to advance the general interests of the state. I hope these remarks will throw some light on this momentous business, and induce the citizens of Maryland to take an enlarged view of the subject. Should you have a spare column in your useful journal, I will thank you to lay this paper before them.

With sentiments of respect,

Dear Sir, I salute you,

ROBERT MILLS.

Columbia, S. C. July 22, 1823.

AGRICULTURE.

Report of an inquiry into the mode of cultivating and treating Flax, in the Netherlands, &c. by Peter Besnard, Esq. Inspector-General for Leinater, Munster, and Connaught.
(Concluded from our last.)

GENERAL OBSERVATIONS.

Whilst viewing the treatment of Flax in the Netherlands, I was not a little surprised at seeing cattle of every kind grazing in the field where it was steeping, and with free access to the steeping pools, the water of which is considered in Ireland to be highly injurious to every animal; having questioned a Boer on this matter, he told me he never knew an instance of cattle being injured by flax-water, nor is any precaution whatever used to keep them from it; on examining the water in which the flax is steeped, I found the color of it to differ much from that of the flax-pools in Ireland: and I am led to think, on further consideration of the subject, that the vegetable matters which are blended with the mud, when spread over the flax, being decomposed into the fermentive process that takes place, mingle with the mucilage of the plant, and act as agents to neutralize its injurious qualities; how far this may be the case, or whether the plant, being ripe before watering, and totally excluded from light and air in this process, may produce effects different from those in Ireland, I shall not pretend to say; but the fact is as I have described it.

That the mode practised in Holland, Zealand, Flanders and France, of excluding light and air in the steeping of flax, has a powerful effect on the color of the plant, cannot be doubted; and that the properties of the water and mud employed have considerable influence in that point, as well as on the texture of it, is equally certain, and is fully exemplified in each of those countries, as will be seen by the following statement:

In that part of Holland where flax, the growth of that country and of Zealand, is steeped, and where the soil is dark and of a slimy nature, the

water soft and clear, and perfectly suited for culinary and other domestic uses, it is found that it comes from the steeping pool of a dark blay colour, varying only in shades, according to the quality of the soil or mud with which it is covered: but every parcel is uniformly of one color from each pool; it is likewise of a soft and silky nature.

In Zealand, when flax is steeped as in Holland, with respect to the exclusion of the air and light, it is always of an uniform color, but from the quality of the water and soil, comes from the pool of a light straw color, and is harder in its nature than that steeped in Holland; this is attributed to the brackishness of the water and soil, which purges the plant in the steeping pools, and deprives it of its extractive matter, so much so, that it is calculated to lose in steeping in Zealand, from twenty to twenty-five per cent more than when steeped in Holland; for this reason the Dutch flax Boers bring the flax that they grow in Zealand from the field, dried with the boles on it, to be steeped, &c. at home, often fifty and sixty miles distant. When flax in Zealand is not steeped with the same care as in Holland, by excluding it from the air and light with mud and slime, it comes from the pool precisely as it does in many parts of the South and West of Ireland, of various colors and qualities, even in one strick or bunch, in consequence of which it sells at all times in the Rotterdam market at an under price, for inferior work. This is a strong proof of the effects produced by the exclusion of light and air in the steeping process.

In Flanders, where the soil is lighter in quality and color, and the water clearer and fresher than in Holland, the flax is some shades brighter than that steeped in Holland, but not of the straw color, or harsh description of that steeped in Zealand; it is, however, uniformly of one shade from every steeping pool, doubtless in consequence of the exclusion of light and air.

In France, where the soil is still lighter than in Flanders, the flax is of a lighter color than in that country or Holland, and is between a straw and blay color, neither so hard as the Zealand flax, nor so soft as that steeped in Holland; it is, however, like all the others, when excluded from the light and air, of one color from every pool; nor did I see in the course of my examination of flax in the several countries* I visited, any of that article striped in color, or of different qualities in one head or strick, but that grown in a part of Zealand, where the cultivation may be said to be in its infancy, as compared to other places.

On the whole, it appears to me, from every information I have received, and from the best consideration I have given the subject, according to my humble judgment, that the exclusion of light and air from the flax in the steeping process, as practised in the Netherlands and France, forms the most important points in the treatment of that plant: and I am of opinion, that a due attention to the mode practised in these countries, would eventually lead to the cultivation of flax in Ireland, on a scale that would be of the greatest importance to the landlords, tenantry, and peasantry of the country.

With respect to the regulations in those countries for dividing the flax into different sorts or numbers, according to its fineness or coarseness, there is no law or public examination, as in Petersburg and Riga, nor does there seem to be the smallest necessity for such a measure: the flax growers themselves, being sensible of the advantages derived from a regular system, carefully as

* In speaking of the qualities of the soil in Holland, Flanders, and France, I allude to those places only, where I have seen flax cultivated.

sort each quality before they offer it for sale, and set a price on it accordingly: on this point the merchants are equally particular, as they separate with great care every quality they purchase. In making up for a foreign market, there is no rule as to the size of the bundle or pack; the merchant being governed by the orders of his correspondents, who, for the most part differ in respect to the size of them; some directing them to be made up in bales of one cwt. while others order them in bales of four and six cwt.

Average quantity of Flax and Linseed sold in Holland, from the best information I could obtain, may be about 12,000 tons annually, and 10 000 hogsheads of seed.

HEMP.—The time for pulling this plant not having commenced during my stay in the Netherlands, it was impossible for me to obtain by personal inspection, any knowledge of their mode of treating it in the steeping process, &c. I therefore could only examine it in its growing state, and make inquiry as to the general practice of treating it, which I found to be similar to that followed in most other places; as to quality, it was excellent in its green state, and promised to be a most productive crop. From the inquiries I made, I learned, that the greatest part of the Hemp grown in the Netherlands is consumed at home; but that large quantities of the seed are shipped for various places, from Antwerp.

The following discovery made by Mr. Bander, of Kew, was communicated to me by a gentleman of the first respectability and professional skill in Manchester, who was so kind as to show me specimens of linen taken from the Egyptian Mummies:

"On a recent examination by Mr. Bander, of Kew, of the material which covers the Egyptian Mummies, it was found to be made from flax, some of it plain linen, and some from twisted yarn, similar to sewing thread, varying in the quality of the texture, according (as it is supposed) to the rank of the deceased. In making this discovery, Mr. Bander ascertained that the fibres of the flax plant are cylindrical tubes, the surface preventing a spiral appearance."

The fact of the fibre of flax being a tube, appears to me to elucidate most clearly the cause of the slowness in the fermentive process of the finer plants compared with the coarser,* because an equal portion in circumference of the fine, contains a greater number of fibres, or cylinders, of more minute dimensions, than the coarse, and do not, therefore, discharge the air and mucilage† so rapidly as the latter, which is composed of considerable quantities of wood, and less fibre than the fine; it likewise demonstrates the necessity for depriving the plant before steeping of the bole or capsule, which may be said to act as a stopper to the fibres or cylinders, and actually seals them at their tops, thereby preventing the necessary discharge until the bole separates from the plant, which it always does with great uncertainty: thus occasioning portions of it to be over-steeped, and other parts not sufficiently done, which causes the variety of colors, and inequality of texture so often found in Irish flax.

* It is well known to those conversant with the treatment of flax in Ireland, that the fine plant requires more time to steep than the coarse; it is also known that the top ends are not so well steeped as the other parts. Allowing the capsule to remain on the plant in the steeping process, seems to account for the latter defect.

† The mucilage, or, more properly speaking, the resin of flax, is a permanent dye, from which a variety of shades of color has been obtained

In Russia, and in every part of the Continent, flax is deprived of the bole before steeping, and it is a fact well known, that flax grown in Ireland, generally speaking, is the most irregularly prepared for market of any in Europe, though the soil of the country, is at least equally fertile, and the climate as congenial, as that of Holland, or the provinces on the shores of the Baltic.

The mellowness and evenness of every description of Continental linen, so well known and admired by those acquainted with that manufacture, is considered to arise from the superior quality of the flax of which it is composed, in the preparation of which the greatest pains are taken. Viewing, therefore, the treatment of this valuable plant in the Netherlands, in all its bearings, it seems to me, that the great art (if such it may be called) of producing it of a better quality, and in a more merchantable form, than it is done in Ireland, rests solely on a well regulated system, from which no person deviates, from the sower of the seed to the Export merchant;—a practice worthy the imitation of every person concerned in the cultivation of flax in this country.

REMARKS TAKEN FROM DIFFERENT SOURCES, SHOWING THE ADVANTAGES TO BE DERIVED FROM THE CULTIVATION OF FLAX.—In a Treatise, published by the *Dublin Society*, in 1735, it is stated, that an acre of ground in Leinster yielded six stone of flax, which, in that day, produced £22 10s. Sir William Petty, in his *Political Arithmetic*, p. 203, speaking of Ireland, says, that forty feet square, or the fifteenth part of an acre, will produce 10s. worth of flax, making the produce of the acre £25. And it appears in a treatise, entitled "*The Interest of Scotland considered*," written by a gentleman of very great knowledge and worth, p. 159, that the lint that was produced from one acre of ground, belonging to a *Flanders Flax Dresser*, in the year 1732, was estimated at £40 value; allowing him £20 for his labor in it, there is a great profit left. The same author says, p. 153, that the produce of an acre about *Cambray*, was frequently about 1000 lbs. weight, which, in the year 1732, (a scarce one) sold for 3s. the pound, making the acre worth £150; and he further says, I have known numbers in *Holland*, who, after having paid £16 or more per acre for the flax, have owned that they made £300, £700, and even £1000 per annum, although few contracted for more than 50 acres.—If the *Dutch*, who so well understand trade, follow this practice, we may safely conclude, that they find it most beneficial, and that we should do so, too, if we pursued it with equal assiduity.

Amongst the numerous advantages which the extension of flax cultivation in Ireland presents, that of the manufacture of oil, is one of the greatest importance, not only as adding to our general trade an article of great consumption in the country, but as introducing a species of food for cattle, in certain districts where the want of green food, and of almost every kind of fodder, has often been severely felt, and has in many cases been attended with very ruinous consequences. In the counties of Kerry, Clare and Galway, and the mountainous parts of Cork, Tipperary, &c. the loss of cattle, in severe winters and in spring, has frequently been experienced from want of fodder; whilst in *Holland*, where the winters are more severe, the cattle are fully supplied with that excellent article, Oil-cake. The establishment therefore, of small Oil-mills in the vicinity of Scotch mills, and districts where flax is extensively grown, would afford to the mountain proprietors of cattle a cheap and nourishing food, in the worst of seasons, and give to the growers of flax a certain home market for all the seed they could spare from their own consumption.

Extract of a letter from Mr. ———, of France, to PETER BERNARD, Esq. dated London, August 23d, 1822.

"DEAR SIR,

"In answer to your question respecting the causes of the different appearances of Irish and Dutch flax, I have endeavoured to give you, as follows, the best solution in my power.

"The Irish mode of steeping flax, compared with that used in *Holland*, is defective in principle, and injurious in the result, to those qualities essential to constitute a good article.

"When flax is steeped in a green state, whilst the plant has not yet attained maturity, it is plain, that all the fibre of which it was susceptible, is not formed, and its constituent principles, being but imperfectly combined are the easier separated; this occasions substantial loss; the carbon, which should go to form the fibre, is, by the process of fermentation, sent off in the shape of Carbonic Acid Gas, which rising to the surface of the water, escapes, and forms that deleterious atmosphere, so fatal to animal existence; again, the flax being partially exposed to the influence of the light becomes variegated, and the decomposition is so rapid and tumultuous, that not only much of the tender plant is destroyed, but the volatile products fly off, and meeting no resistance mix with the air forming a mixture of Sulphurated and Ammoniated Hydrogen, which is but too evident to the olfactory senses of those who come within the sphere of the nauseous and noxious effluvia. The defence set up in favor of this mode, namely, that the younger the plant the finer the tissue, even if true, I doubt would compensate for the actual waste occasioned.

"In *Holland*, the flax is not put to steep until at perfect maturity, and even then it is covered over in the steep with a thick layer of earth or mud, which, while it defends the flax from the action of the light, furnishes certain affinities, which do not fail to take up, and form with the substance thrown off by the fermentation, insoluble compounds, such as earthy Carbonates, Sulphates, &c. and thus it is, that the tissue suffers less, and maintains its uniform quality and color."

FOR THE AMERICAN FARMER.

REMARKS ON HEDGING,

And the interest of land holders, as it regards various kinds of fencing.

I have several times read in the *American Farmer*, exhortations to plant timber of the forest kind, to supply the waste that is daily going on in that necessary article, which deserve consideration.

I shall first note a practice which some have adopted, to cut where they have occasion, and clear all off the ground, large and small; it seems at the time of doing it like waste to cut the young and thriving kind, but a few years demonstrates the propriety of the measure, when the second growth begins to progress, as there is then no obstruction, to prevent an equal start of sprouts from the stumps. The various nuts and seeds, too, are encouraged by being open to sun and air. The ground ought to be fenced from cattle and hogs, and the rapidity of the growth is in many instances really astonishing in a few years.

I have timber land that had been taken clean off, say thirty, and from that to forty years back, (before I owned it,) for the sake of timber alone, and grew up even without being enclosed, until as much as the ground could support, was left standing. (the under wood naturally declined) and now there is a crop of three or four fold the quantity that there is growing on the adjoining

land, that was never cleared. This demonstrates the benefit of wholly clearing the land, if left for timber again, in preference to partially cutting the old, and leaving the young to grow on to keep up the supply.

As saving timber is an object in all the old settled districts of the country, the most effectual way of doing so, is the next enquiry. Dr. Franklin published an almanack, when I was quite young, called "*Poor Richard's Almanack*," amongst other wise sayings, interspersed through it was, "*a penny saved, is a penny earned*," this saying no doubt helped to make many a wealthy man—it made some misers out of contracted minds; but, nevertheless, the saying was good advice, and the maxim ought never to be forgotten—and as it will apply to the case of timber, it should always be kept in view by the land owner. That being the case, I shall call the attention to the destructive waste, made by such a large portion of it, being every year consumed in fencing—a circumstance, that because it is customary, is not regarded—nay, is even considered necessary, when the following will shew the contrary, as matter of fact—(no visionary scheme.)

In the first place, I feel it an incumbent duty, to answer the fallacy of arguments that have been admitted into the *Farmer*, and coming from an *Agricultural Society*. An address or essay on fences was written by James Worth, and read before the *Agricultural Society of Buck's County*, November 1820, and ordered to be published in the *National Recorder*, from whence it got into the *Farmer*, August 10th, 1821, at which time I remarked it, as I had previously wrote some sketches of my experiments and observations on hedging and hedges, and that experience has increased the stock of knowledge on that head sufficiently for the disclosure of further useful information, as hedging is rapidly progressing in my neighborhood, and with the desired success.

J. W. in his essay, speaking of trees, instead of posts for wire fence, exhausting the soil, says.—"Thus it is with hedges, they seem to be cheap in the first instance, but the exhausting the soil alone would in my opinion render them a dear gift, nor do I believe they will be so durable as has been imagined, for I am told a grub has attacked one species of the thorn, and I have often seen sassafras, cherry, and other trees, with abundance of grass, growing along hedge rows, which will assuredly bring on a decline, in the course of a few years; besides I have never seen a hedge, that was proof against hogs; I admit they might be kept in better order, but it will be expensive, and will require more attention than our farmers are willing to bestow; upon the whole, I am surprised that this species of fencing should have been produced amongst us in the present state of our country, and can attribute it to the prejudice of foreigners who have been accustomed to it from necessity."

I shall take the objections as given, and give matters of fact in reply to them.

- Objection 1—Exhaustion of soil.
- do. 2—Want of durability.
- do. 3—Not hog tight.
- do. 4—Expensive.

Answer 1st. As the objection appears to more particularly belong to a "*hedge row*," as by the description it was truly named a hedge row, this is a point that ought to be better understood, than it generally is, see Vol. 3, page 117 of the *American Farmer*, a definition of a *hedge row*, and a *hedge proper*. There can be no doubt of the former, composed of an assemblage of forest trees combined with a variety of other products, of spontaneous growth, having the same ef-

fect, that the borders of a forest would have on the soil adjoining. But I presume the essayist nor the Society either, had ever seen a *hedge proper*; my presumption is founded on the ground that they are not common, nor are they in any way mentioned by them—further, many experienced farmers have, on viewing a hedge in its proper trim, declared the want of a *conception of the thing in reality*, before ocular demonstration furnished the idea.

Therefore I draw the inference, that to condemn thus publicly, so important an improvement in husbandry, was premature in either an individual or society, before they were acquainted with the subject matter.—2d, as to their durability see Vol. 3d, page 118, (my own knowledge of their duration, without any marks of decay, has extended to half a century.)

3d. The objection to their not stopping of hogs, is in part removed, by admitting the want of being "kept in better order," yet this only as it concerns a hedge row, not a plashed hedge; my plashed hedge the first year 1812, caused the rabbits to cut holes through the bank under the hedge to get a ready passage to their pasture ground.

4th. The expense alluded to, as a frightful thing, is all visionary—I made no calculation when I began the experiment, because I was determined to have a trial at any cost, and was really astonished, when I made the calculation, for the publication, which see in Vol. 1st, pages 350, 403, where the expense will be found to be two-thirds less than a post and rail fence. It will be seen in divers places in those sketches, that a hedge will make a sufficient fence, when plashed, at seven years old, that ought never to be forgotten; if taken proper care of, agreeably to the sketches already published in the American Farmer.

One part of the Buck's County publication, recommends planting chestnut and locust timber for fencing, and after *twenty years*, to begin to cut; when it may be observed that three thorn hedges may be raised and matured in succession, while the timber is *growing* to make a *perishable* fence.

The latter project is all founded on theory—the former,—living fences, are founded on fact, and since they have been brought into notice, are becoming almost daily visited, and of course more extensively known. J. W. expresses a surprise, that hedging should have been introduced in the present state of the country, and attributes it to the prejudice of foreigners, and they being accustomed to it from necessity—does he not admit necessity to reign here, as a spur to doing of something, or why recommend planting chestnut and locust timber for fencing?—timber we know to be diminishing in many of the most populous parts of the country, and called into aid in every building that is raised either in town or country—why then continue in the practice of dooming so large a portion, to certain destruction in fencing? Neither can a vessel of any kind be put under sail, for our needful commerce, nor a hearth warmed, or a meal of victuals cooked, without the aid of timber, (except in our coal districts,) and after all those considerations, how should it remain a doubt about the adoption of living and durable, I might say everlasting fences!! As to the material, it has been shewn that the thorn, so unfit for any other of those purposes, is so well adapted to *fencing*, that I have been struck with awful astonishment, when I have discovered its propensities to serve our purpose; for when we have mismanaged it in training, we may cut it away and destroy what is above ground, and the great author of nature has placed that property in it, to subserve our purposes, that it will put forth another top to the same root, to

exercise our skill again, and so on, ad infinitum. It is a shrub, and never soars out of our reach: it is armed with defensive armour, as must strike every beholder, *this is for some useful purpose*. and although that is the case, it may be mathematically ornamental to a farm, and in fact has become so, to the honor and credit of some of our small farms, which though deficient in other respects, lessen not the value of this improvement.

Let them who may not be fully satisfied with my statements, view for themselves.

CALEB KIRK.

Brandywine, 4th of 8 month, 1823.
(To be continued.)

TO THE EDITOR OF THE AMERICAN FARMER.

ON THE MANAGEMENT OF CALVES.

Mr. Skinnr,

I was much gratified by perusing in your seventeenth number, (Vol. 5.) an article on the subject of rearing calves, by "an Agriculturist of Delaware," for in my opinion there are in general, few objects on a farm more neglected, and none that deserve or require more attention; and having had some experience, and taken much pleasure in attending to them, I am induced to offer a few remarks, and hope they may prove acceptable to your readers.

It is a practice with too many, to turn calves, when only a few days old, into what is called the "calf lot," and suffered only to approach the mother twice a day for a few weeks, and even then, after half her milk has been taken from her—others permit the calves to run with their mothers for several weeks, and sometimes months, before they attempt to wean them, the consequence of such treatment is, they are never effectually weaned, but continue to suck the mother whenever they can approach her, and if in separate, although adjoining pastures, will put their heads through a fence, and the mother afford every facility to gratify her offspring; both these customs are bad, and ought to be discontinued upon all occasions.

The most proper way of rearing calves is, to wean them at about eight days old, to keep them constantly in the stable, and teach them to drink out of a bucket, which is easily accomplished, by putting new milk into a basin, and letting them suck your fingers with the hand immersed into the milk, and in a few days, withdrawing the fingers gradually from the mouth, afterwards giving as much new milk as they can drink, for five or six weeks, when they will begin to eat a little grass or clover, which can be pulled and given in small quantities twice a day, and when they eat freely, you may mix a little water with the milk; or at eight or ten weeks old, give sweet skimmed milk, slightly warmed, which soon after dilute with water and add a little meal; should milk be wanted for other purposes, give flax seed tea, which commence by mixing with milk slightly warmed; indeed by keeping calves constantly in the house, you may induce them to eat almost any kind of nutritious food; they also become perfectly docile, have fine round bodies, with clean smooth hair, and a sprightly look, but if turned out into a field, they are tormented by flies and heat, never in good condition the first year, but remarkable for pot bellies, rough hair, heavy look, and ugly flat sides; indeed the contrast in appearance is so great, that I think laziness alone would induce any one to turn their calves into a field the first summer. If change of food produces either costiveness or looseness, give about half a pint of Spermaceti oil, to be repeated if found necessary; it will prove a cur-

and can easily be given out of a black bottle; it is also good for cows, that are drooping or unwell, adding of course to the above quantity.

Calves intended for the butcher, ought always to be tied up in a stable, and if kept in darkness so much better, as they will be less disturbed by flies, and will sleep more than if constantly in the light; the mother ought to be turned in twice or thrice a day, and the calf permitted to suck as much as it wants, never taking any milk from the mother until it is satisfied; if every farmer would thus manage, we should see less poor veal than is now exhibited in our market.

On the subject of cows having calves too early, no excuse can be offered and none ought to be admitted; yet how frequently are we told, that by accident or the negligence of an overseer, a young cow had a calf at 15 or 16 months old, whereas in my opinion, the blame ought to rest on the indolence or carelessness of the master, who should himself see that his fences are good, and the young heifers well secured by themselves, and the male and female calves separated at four months old, but in order to guard effectually against such accidents, the bull should never be suffered to go at large with other cattle, but be kept in a small lot, having a shed in it, and well secured with a strong post and rail fence, with a gate to be kept locked; here you may feed him, when and how you please, and turn in as occasion requires such cows only as you desire; this method would also make him less vicious than if going at large, and effectually prevent his becoming mischievous.

Although I recommend the keeping of calves housed the first summer, it is not the less necessary to be observed during winter; and I will here ask those of a contrary opinion, what benefit is derived from any description of cattle going at large in winter? do they obtain any food by rambling about in the wet and cold? no, on the contrary, any thing which they do pick up is dead, and more or less indigestible, whereas, in the house they would at least be kept dry and warm, and unless owned by an idle and niggardly farmer, would have something in the racks to nourish them; by keeping them housed you also preserve all their dung, which ought of itself, (if none more important was the result,) to be a sufficient inducement; indeed whenever I see cattle roaming at large in winter, "thinks I to myself," there lives a lazy, and consequently, a bad farmer.

NORTH DEVON.

Baltimore county, Aug. 1, 1823.

(From Memoirs of the Board of Agriculture of the state of New York.)

ON THE MANAGEMENT OF SHEEP.

By the President of the Agricultural Society of Steuben County, to the New York Board of Agriculture.

I am very much pleased with the prospect of another agricultural volume, and wish to contribute to it whatever lies in my power. Having turned my attention for a few years past, to the raising of sheep, I think my experience has enabled me to make some observations, which may be of service to my brother farmers.

There are two subjects, connected with the raising of sheep, to which I beg leave to direct your attention. The one is, the most proper time of the year to turn the bucks into the flock—the other is, the shearing of lambs. On the former subject my practice differs from most farmers. I am an advocate for raising early lambs. The practice of keeping the bucks away till the fore part of November, I believe pernicious, and one cause why so many flocks degenerate. It is unnatural. Providence has pointed out the best season for animals to breed; at that time the

females are in season, and I do not believe we shall gain any thing by altering the course of nature. We suffer every other animal to take its own course. My arguments in favor of the practice of suffering the bucks to lie with the flock during the whole season, are the following:—When the bucks are turned into a flock late in the season, so many of the ewes are in season at the same time, that the offspring are feeble. The cold winds and frequent storms of the spring, together with the difficulty of keeping sheep confined at that time of the year, I have found more destructive to lambs than the cold nights of winter. It is also more difficult to keep late lambs over the next winter. Early lambs are also more apt to have lambs the first year. My practice is to keep my sheep sheltered from rain by open sheds, and shut up the sheep and lambs about one week in a warm stable; and when they are a month old they will cat hay with the flock. But the sheep must be continually kept up with corn and succulent vegetables, or they will neither give milk for their lambs or bear fine wool.

There is one more benefit which arises from the practice of raising early lambs, which is, the opportunity it gives for shearing them in the summer.

I have had two year's experience in that practice, and am much pleased with it. My wool averaged, when washed perfectly clean, twenty ounces to the lamb, and sold for fifty cents a pound. The fleeces of the yearlings, having been well washed on the sheep's back, averaged about two pounds and a half. The wool was the best I ever sheared. It was of short staple, but even, and exceedingly fine and soft. It is well known to the growers of fine wool, that the fleeces of yearling sheep are not good, because the outer ends of the wool are coarse and dead. Hence it is necessary to clip such fleeces, before they can be manufactured into fine cloth. This evil is wholly remedied by shearing the lambs.

The time for shearing is generally supposed to be about the first of August; but if lambs are allowed to fall in the winter, I think that almost a month too late. They ought to be sheared as early as possible, that the succeeding fleece may have more time to grow, and that the lamb may be eased of his "cumbrous load," before the hot weather is in a measure past.

I submit these remarks with diffidence, as I am not much accustomed to writing; and especially as my ideas, in one particular, differ from those of most of my brethren in the profession.

From page 165, vol. 2.

HOPS.

Further information on the curing of Hops—procured at the request of the Editor of the American Farmer.

BEVERLY, 4th July, 1823.

GORHAM PARSONS, Esq.

Dear Sir—I did not keep a copy of the letter I wrote you respecting the culture and curing of hops, and I do not recollect particularly the further information you requested of me, but I believe it was principally respecting the kiln.

A kiln for the purpose of drying hops should be at the side of a hill or rising ground, so that the top should be about nine feet from the bottom, twelve feet square at the top, tapering on all sides to about three and a half feet at the bottom in the clear, built up tapering, with stone laid in lime mortar, and plastered with clay from top to bottom with an aperture at the bottom, about the size of the mouth of a common oven, for the convenience of putting in the coal, firing it, and regulating it afterwards.

Upon the stones at the top, is placed a cill of

four pieces of timber of about eight inches square, and of course about twelve feet long, that being the size of the kiln at the top, upon which you place strips of boards, half inch thick and two inches wide, and within three and a half to four inches of each other, over which you stretch tow or coarse linen cloth, for a bed to place the hops upon, for the purpose of drying, and under which, at the bottom of the kiln, is made a charcoal fire, regulated at the discretion of the man who attends the drying. It will of course be necessary to have a board round the kiln at the top, of about one foot high, to confine the hops on the bed. I think it would be a further improvement to have a covered roof, and open at the sides, to protect the hops in case of rain, while they are drying.

It will be necessary to stir them constantly with a rake, while they are drying, and you may with convenience dry about fifty pound each time. I believe you may calculate about one pound to a hill, or 800 lbs. to the acre, for the second and third year, after planting, if the land is in good order. It will be well to renew your fields once in three or four years, because the vine degenerates.

I am, Dear Sir, with great respect,
Your friend and obedient servant,
ISRAEL THORNDIKE.

TO THE EDITOR OF THE AMERICAN FARMER.

THE PEACH TREE;

How can we prolong its life, and promote the soundness of the fruit?

SIR,

I wish information through the medium of your paper, of the best method of raising that most valuable fruit, the peach, with a view to the greater, than usual, durability of the tree. I have tried nearly all the common methods in use, for preserving peach trees, and have always failed of success. The trunk is so universally liable to the attacks of the worm, that it seems necessary we should resort to some other stocks on which to engraft or inoculate the peach. I have tried the plum, but have never yet had any fruit, not having tried it long enough; but have my doubts whether I shall succeed, as the trees look very sickly.

An idea has struck me as being likely to answer, but never having heard of its being tried, and the budding season near at hand, I concluded to make the inquiry, that if any of your readers have tried it, they may make the result known, so that if favorable, others may have the benefit; if otherwise, we may all be saved the trouble of trying it.

It is well known that the peach flourishes as well upon the apricot as upon stocks of its own kind; but the apricot is liable to the same attacks by the worm, and therefore not durable.—But as the apricot flourishes remarkably well upon the plum, and the peach upon the apricot, could they not be so engrafted or inoculated upon one another as to answer our purpose?—First, graft or inoculate the apricot upon the plum, and a year or two after, graft or inoculate the peach upon that apricot; we should then have a plum stock for our apricot, and an apricot stock for the peach.

FOR THE AMERICAN FARMER.

WATERING HIGH LANDS,

Especially with muddy Salt Water—easily done, and very useful.

Charleston, S. C. July 9, 1823.

DEAR SIR,

I inclose you a draft of a machine for watering high-lands with salt water. It was handed to me a few days ago, and I intend presenting it to our

Agricultural Society, which meets on Tuesday next. In my conversations with gentlemen living near the salt water, I have always recommended the use of watering carts, and it is well established that marsh mud as manure, has answered equal to expectation, and is now in general use among the cotton and corn planters. The present machine is certainly more simple and less expensive than a watering cart, and will answer the same purpose. I have copied it as well as I could, to represent the intention, and beg you will make what use you please of it.

Before I conclude, permit me merely to mention, that I have a small quantity of the 1st of France cotton, growing very luxuriantly—it is yet in blossom. I remain respectfully,

CHARLES E. ROWAND.

THE IRRIGATOR.

This machine is calculated to water meadows, cotton and provision land, and with a boy and horse, ought to water one or two acres per day, according to the distance of the river from the field. The cask should contain 120 gallons. 1800 gallons of salt water are equal to eight bushels of salt; salt is one of the best manures; eight bushels of salt would cost \$5 60 cents, and eight bushels is said to be sufficient for an acre, at one time. The expense of putting 1800 gallons of salt water on one acre of land with this machine would not exceed 75 cents. A cheaper manure or a better, cannot be had. The fellos ought to be eight or ten inches wide and have 4 inches tread. The axle should be square, until it passes through the heads of the cask, afterwards round, to receive the shafts. Traces may be used to go on the axles for the convenience of turning out of one alley into another, to prevent injury to the cotton or corn bed. Four of these machines would in five days water twenty acres of land, which in dry seasons might be thus prepared for potatoes or slips, without being obliged to wait for rain, besides the advantage of the salt and muddy manure. The cost of the whole machine would be a mere trifle. The planters on the salts need not cultivate poor or exhausted lands, for salt water made very muddy is a most excellent manure. Plug holes must be made at each head, that the water may be always running as the cask revolves.

Were this hogshead suspended and moved on a pair of low wheels, the draft would undoubtedly be much easier—and were the contents to pass in the first instance, into a box perforated in the bottom with small augur holes, the

distribution over the land would be more regular. At Orange Farm, where there are kept more than 100 cows, the liquid portion of the manure is collected by drains into a cistern, in the centre of the barn yard. It is there pumped up, taken out and distributed in the manner here described.

Edit. Am. Far.

FROM THE NEW-HAMPSHIRE STATESMAN.
CIDER.

Our farmers are beginning to feel an interest in the manufacture of cider, since they have ascertained that its value in the market can be increased tenfold by increased attention; and that the flavour of it can be made to rival many imported wines.

We have obtained permission to publish, for the information of all who duly appreciate the importance of the healthy liquor, the following remarks concerning it, communicated to Governor Woodbury, by the society of Friends at Canterbury.

CANTERBURY, June 9th, 1823.

To His Excellency Levi Woodbury.

“Justly esteemed and much respected friend—The process of making and refining cider, in order to have it good, is so simple, (though important,) that many people entirely overlook it, supposing the mystery so deep as to be entirely out of their reach; and others, tenacious of the customs of their forefathers, shut their eyes and ears to any improvement, however propitious to their interest and comfort. Such will probably be contented with their ill-flavored and unwholesome beverage during life. Should we exhibit what we know with regard to the management of cider, some people would laugh and say, we do all that and a great deal more—and probably they do, and add many more ingredients, such as water, pomace and rotted fruit; and perhaps something more from fowls, beasts, and vermin; none of which make the cider any better. However, we shall not hesitate to give it as our decided opinion, that Northern or cool climates are much more favorable to cider than those which are more southern or warm; though what greatly contributes to the goodness and delicacy of cider is the cleanliness of the casks which contain it. In fine, all the utensils employed in making cider should be kept clean, and not suffered to get sour through the whole process: even the press should be frequently rinsed down during the time of making cider in order to prevent sourness or a change in the cider.

To clean casks which have been used for cider, we take them from the cellar as soon as convenient after the cider is out, (reserving the lees for stilling) and rinse each clean, first with a pailful of scalding water, then with cold, leaving the casks with the bungs down till dry; then we bung them tight and return them to the cellar; or some other convenient place (not too dry) for their reception. Previous to filling these casks with cider the ensuing season, we scald and rinse them again as above.

Apples that drop early, we make into cider for stilling, it being unfit for table use; the spirit of which, together with that of the lees, we return back to our store cider at the time of racking, which is generally about the 1st of January.

Cider made of apples before they are fully ripe, we deem unfit for drinking; and even when ripe, if they are made into cider during warm weather, so as to produce a sudden and rapid fermentation, it will unavoidably be hard and unpleasant.

The fact is, the slower cider is in fermenting, the better it will be at any age; consequently the later in the season it is made, and the cooler the weather, (if the business can be conveniently

performed) the better, especially for long keeping.

About the 1st of November, we think a suitable season, if the weather be dry, to gather, and put under cover, apples for store cider. After lying in this situation till mellow, (not rotten) we commence grinding. The cider trough should be large enough to contain a whole cheese, in order to admit the pomace (if the weather be cool) to lie over one night before pressing. This method contributes much to the color and goodness of the cider. In the morning, press it out gradually and put it up into the casks through straw or rather a sieve fitted and placed within the tunnel to stop the pomace; after which we convey it immediately to a cool cellar, leaving out the bungs till the fermentation chiefly subsides, which may be ascertained by the froth settling back at the bung-hole. We then drive in the bungs tight, leaving a small spigot vent a while longer, if need require to check the pressure; but which must finally be made air tight.

About the first of January we rack it off free from the lees into clean casks; those that have been used for spirit are to be preferred: Otherwise, having drawn off one cask, we turn out the lees, scald and rinse as before mentioned, put in three or four pailfuls of cider; then burn in the cask a match of brimstone attached to a hooked wire fixed in the end of a long tapering bung, fitting any bung-hole. When the match is burnt out, take off the remnant, apply the bung again and shake the cask in order to impregnate the cider with the fume. Put in more cider and then another match, add from one to three gallons of spirit (obtain from the lees and windfalls as above) to one hogshead; fill up the cask with cider, and bung it down air-tight and let it remain till it becomes of mature age, which will require at least two years. Cider managed in this way, we presume, will keep pleasant for ten years, and perhaps for twenty, though we have never kept it over six, being necessitated to make a premature use of it in scarce seasons.

We would not be understood by any means to suggest a notion that good cider, cannot be obtained without the addition of spirit, but the contrary, especially that which is intended for use within one or two years; yet spirit gives it a permanent body and will insure its preservation if the above directions are strictly attended to.”

Editorial Correspondence.

PROLIFICK MELONS.

DEAR SIR,

I send you below a piece of information, just as I received it, after having observed the fact of the difference in form, at the blossom end of different melons, as stated. There are many of these notions that are developments of the real secrets of nature.

T. T.

The best seed is of the greatest importance in raising every thing. It is not generally known, but it is said to be perfectly understood in Jersey, where they raise most uncommonly abundant crops, that there is a male and female water melon. And that seed ought to be saved, not only from the female melon, but from the half that grows uppermost, or next the sun. The male melon is said to be formed full out—the female to have a small indenture, or depression at the blossom end, in which you may lay the ball of your finger.

A. B.

Extract from Pennsylvania.

“You have given a long account of the mode of making ponds. We generally find it cheaper to sink a pump in the field, and fill a trough once

in 24 hours, than in any other way to obtain water. A well with a simple wind-mill has in this state, perfectly effected the object.”

Gleanings from Foreign Journals.

FAT SHEEP.

On the 13th of May last was killed at Stow fair, Gloucestershire, by Mr. Marshall, a wether sheep, bred and fed by Mr. Large, of Broadwell, in the county of Oxford, which weighed 66½ lbs. per quarter; and on the morrow, the 14th of May, was exhibited alive at Stratford on Avon fair, Warwickshire, before many hundreds of the first breeders of sheep, and afterwards killed and shewn dead by Mr. Tasker—another fat sheep, which was also bred and fed by Mr. Large, which weighed 68½ lbs. per quarter, and was allowed by all who saw him to surpass any sheep ever before seen for symmetry and size. Mr. Large begs to inform his friends that his RAMS will be open for inspection and letting, any time after the 30th instant.

ON PRESERVING POTATOES.

Lee Hall, Worcestershire, March 29, 1823.

SIR,

It is not at all surprising, from the present low price of farming produce, that inquiry should be made respecting the best mode of employing it at home, instead of taking it to market; and amongst your numerous correspondents is “W. G.,” who, in a letter dated from Bromyard (which is situated in the midst of the cider and hop plantations,) is making inquiry after the best construction of a kiln for baking potatoes. It is not in my power to give him any information upon that subject; but I beg leave to recommend to him the following process for the management of the potato, which I have no doubt will preserve all the nutritious parts of this valuable root for years, and if now put in practice, may be the means of preserving much food for man and beast. The process is as follows: Let the potatoes be particularly well washed, then put into the cider mill, and ground to a perfect pulp; put this pulp under a powerful press (in hair cloths, as in cider making), and press it as dry as possible; then take it from the press, and put it upon the hop kiln, and carefully and well dry it; and then let it be packed in casks, or kept in any other manner, so that it be always preserved in a completely dry state. If this simple process is carefully conducted, I have no doubt the potatoes may be preserved for years.

“W. G.” may try the experiment with the greatest facility, as cider mills and hop-kilns (if he has none of his own) are upon every farm in his neighbourhood, and at this season of the year not in use. Should he be induced to try the experiment, I hope he will have the goodness to give the result to the public by means of your journal.

I am, Sir,

Your's, &c.

JOHN BLOUNT.

ON FEEDING EWES WITH MANGEL WURZEL.

Herefordshire, Dec. 12, 1821.

SIR,

As I consider it to be the duty of every individual connected with the agricultural interest, to communicate to the public the result of satisfactory and beneficial experiments, I will briefly answer the several queries of “M. W.” in your Journal of this week.

From the principal part of my turnip crop failing in the year 1820, I was compelled to feed my stock on my crop of mangel wurzel; the ewes,

before lambing, were taken off the few turnips I had, and put into the fold, where they were fed with mangel wurzel, and a very small quantity of hay, and without water. After lambing, they were given the same food, and from the great flow of milk produced, the lambs were in very high condition. The whole of my flock were kept entirely on this food, from the beginning of January 1821, to the end of March; during which period I weighed eight wether sheep, and put them into a barn, when they were given twenty-five pounds of mangel wurzel, and about five pounds of good hay for each sheep every twenty-four hours, for five successive weeks; some of them gained more than others: but on weighing them out, at the expiration of that time, they had increased, upon an average, eight pounds per quarter. I can also state that, having killed several of the sheep, the mutton was particularly mild and sweet. I am fully persuaded that there never was better food for sheep, or food that will create so great a flow of milk from the ewes. If you consider this a sufficiently minute reply to the queries of your correspondent, I think the sooner it is made known, through the medium of your valuable journal, the more satisfactory it will be to "M. W."

I remain your well-wisher,

P.

P. S.—It is necessary to observe, that the mangel wurzel must be carefully cleaned, without washing, and given whole.

ETYMOLOGY OF RYEGRASS.

Mr. Whitworth having offered some remarks on this subject, we beg to subjoin a few general observations. The word *Lolium*, is used by the ancients for *cockle* or *tares*, two plants, though very unlike, yet both reckoned equally injurious to corn in those times. So Dr. Thornton derives the word *Lolium* from two Gr words, signifying *corn* and *injury*. Modern writers have applied the term *darnel* to the genus *Lolium*, contemplating the species *temulentum*, as before mentioned, because it was an injury to the bread in which it might be mixed, and consequently to the growing crop, or rather to the sale of the corn in which it appeared. All this appears very satisfactory, although it is unfortunate that *darnel* should be applied as above, it being with us a different plant; but these particulars, together with the French word, and the rest mentioned by Mr. W. have nothing to do with the origin of the name *Ryegrass*.

It appears that the term *Ryegrass*, was originally applied to the *hordeum murinum*, or *wall barley grass* mentioned before; and that something of a dispute or misunderstanding had taken place about the plant at first designated by this term, even at the very outset of its cultivation. Thus Mr. Mills, at p. 353 of the 3d volume of his *Complete System*:—"The *wall barley* or *way bloom*, as some people improperly term it, is evidently, from the shape of its ear, and from every other characteristic circumstance, a *ryegrass* or *wild rye*, as Mr. Ray observes, [Hist. Plant. p. 1258, and Synops. p. 391.]" Here is Mr. Ray himself introduced, talking of *Ryegrass*, which word it now appears, arose from the resemblance of certain spikes to *rye*; and however much the plant was mistaken, and the term transferred to a grass whose spike does not resemble *rye* at all, yet the etymology will by no means allow us to substitute *ray*. It is quite another thing as far as custom may hereafter sanction the introduction of *Kuwell-grass*, as applied to an improved sort; because every one is at liberty to give a new name to the thing which he originates; and it is in some measure his duty to distinguish it from other particulars of like kind. This does not suppose that *Kuwell-grass* will be received in

Botany as the common name of *Lolium* (although it is improper that *Darnel* should be used there,) neither is *ryegrass* the common botanical name of the genus, but only applied to a certain sort in agriculture, by mistake, by custom, and by imitation, and the neglect or ignorance of the early writers on this subject. Finally, it is desirable that as far as we can get rid of the old sort of this grass, we should get rid also of a name so misapplied and improper as *ryegrass*: whether these desirable particulars will hereafter proceed together remains to be proved by time, and will be decided without any reference either to Mr. Whitworth's opinion or ours.

QUERIES ON THE PRINCIPLES OF FERTILITY.

Eastwood, Nov. 30, 1821.

SIR—As this is a time of general distress amongst farmers, having much to contend with, and many enemies, they ought to be as closely united, and feel as great a sympathy for each other, as the members of their own bodies; and if one knows any thing which would benefit the rest, and neglects to communicate it, I conceive he is criminal.

Farmers are very much divided in opinion on essential points of managing land of the same quality. For instance, some think manure made from vegetables ought to be well covered, and that it has a tendency to *rise*: others prefer it on the surface, and suppose it will sink into the soil. Some think exposing the land to the sun exhausts its fertility; others say, the oftener land is turned over by the plough, and *exposed to the sun*, the better. Some contend land is benefitted by deep ploughing from Michaelmas to Lady-day; others, for shallow ploughing at all times,—and some for working with scarifiers, and never ploughing. Now, as light and darkness scarcely differ more than these opinions, surely something may be done by you, or some of your correspondents, to point out the errors, and if only one be benefitted, it will be worth the attempt.

If you have no objection, I shall be glad to ask the following questions:—

Ought manure (intended to be useful to more than one crop) to be well covered, or left on or so near the surface, that a considerable quantity may be brought up, when harrowing in corn or turnips?

Does exposure to the sun, by frequent ploughing in summer, benefit, or injure, the land?

What are the benefits land derives from summer fallow? What quantity of land is supposed to be summer fallowed in England annually, and the expense of rent, rates, taxes, and labour per acre?

Can any crop be grown, and the land be equally benefitted, and as fit for the same course of crops afterwards, as if summer fallowed?

I am, Sir, your obedient servant,

THOS. WRIGHT.

We shall take an early opportunity of replying to these queries generally; in the mean time any hints from our correspondents will be thankfully received.—*Edit. Far. Jour.*

Answer to our Correspondent on the cost of the Preparation for dressing Harness.—We have made due enquiries as to the cost of the mixture recommended in our Journal, No. 727, and find it to be nearly as follows:—Neatsfoot oil, 1s. per pint; spirit of tar, 3d. per ounce; bees wax, 2d. per ounce; naphtha, 1s. per ounce; (this ingre-

redient not necessary for common purposes). Then dissolve two ounces of wax (with gentle heat,) in four ounces of spirits of tar, and add this quantity to two quarts of oil, and the price is about 2s. 3d. per quart. The whole should be incorporated with gentle heat, leaving out the naphtha.

The Duke d'Angouleme's character is become a subject of humour in the Saloons of Paris. The following is ingeniously imagined, and neatly expressed:—

Intrepid a l'Eglise, et pieux au combat,
D'Angouleme se fait paraitre;
"C'est un saist," dit le soldat;
"C'est un heros," dit le pretre.

IMITATION.

So brave in prayer—devout in fight,
See Angouleme appear, O;
The soldier cries—"Behold a Saint! !"
The priest exclaims—"a Hero! !"

CONVERSATION.

[The following lively description, although from the pen of an author so well known as Cooper, presents such a faithful picture that we do not hesitate to extract it, in hopes of its attracting the attention of all such convalescents and invalids as are justly complained of.]

Some men employ their health, an ugly trick,
In making known how oft they have been sick,
And gives us in recital of disease,
A doctor's trouble, but without the fees;
Relate how many weeks they kept their bed,
How an emetic or cathartic sped;
Nothing is slightly touched, much less forgot,
Nose, ears, and eyes seem present on the spot,
Now the distemper, spite of draught or pill,
Victorious seemed, and now the doctor's skill;
And now—alas for unforeseen mishaps!
They put on a damp nightcap and relapse;
They thought they must have died, they were
so bad;
Their peevish hearers almost wish they had.

ESTIMATE OF MORTALITY.—According to a statistical chart published in a Neapolitan Journal, the population of the globe is 632 millions. It estimates by approximation that there occur,

Yearly.	Daily.	Hourly.	Minute.	Second.
Births, 23,407,407	64,130	2,672	148	8
Deaths 18,588,235	50,927	2,122	135	7

The following is given in the *Asiatic Journal*: Lieut. Collet, of the Bombay army, having heard that a very large tiger had destroyed seven inhabitants of an adjacent village, resolved, with another officer, to attempt the destruction of the monster. Having ordered seven elephants, they went in quest of the animal, which they found sleeping beneath a bush. Roused by the noise of the elephants, he made a furious charge on them, and Lieut. C.'s elephant received him on her shoulder, the other six having turned about and run off, notwithstanding the exertions of the riders. The elephant shook off the tiger, and Lieut. Collet having fired two balls at him he fell, but again recovering himself, he made a spring at Lieut. Collet. Having missed his object, he seized the elephant by her hind leg, and having received a kick from her, and another ball, he let go his hold, and fell a second time. Supposing that he was now disabled, Lieut. C. very rashly dismounted, with the resolution of killing him with his pistols; but the tiger, who had only been crouching to take another spring, flew on Lieut. C., and caught him in his mouth. The strength and intrepidity of the Lieut. (and, however, and not for a moment) he immediately fired his pistol into the

* See *American Farmer*, No. 22, vol. 4, p. 167.

tiger's body, and finding that this had no effect, he disengaged his arm with all his force, and directing the other pistol to his heart, he at last destroyed him, after receiving twenty-five severe wounds.

THE FARMER.

BALTIMORE, FRIDAY, AUGUST 22, 1823.

VERY BEAUTIFUL SEED WHEAT.

Within the last week, some hundred bushels of white wheat, sent to this market by Tench Tilghman, Esq. of Talbot county, have been sold for seed wheat to southern farmers, at \$1 65 per bushel; being about forty-five cents over the price of common white wheat—but twenty-five cents only above what the same wheat would have brought from the millers, one of whom offered \$1 40 for one thousand bushels.—This extra price is certainly nothing beyond a fair remuneration for the extraordinary pains which has been taken by Mr. Tilghman for a series of years, to give to his wheat a pure and uniform character, in which he has eminently succeeded—for assuredly, judging from the sample left with us, we have never seen any so remarkable for its thorough cleanness and total freedom not only from all filth and ofal, but from wheat of any other species. Those who have curiosity to see the justly celebrated white wheat of the Eastern Shore of Maryland, in its perfection, may be gratified by calling at the office of the American Farmer.—Such specimens and such success, ought to gratify the eye and stimulate the pride of all good farmers—young and old.

More of this wheat may be had on application to William Cook, Esq., Light-street wharf.

A NEW WHEAT.—In the Editor's absence, a bunch of very fine looking wheat, in the straw, was left by Mr. W. D. Mercer of Sassafras neck, Cæcil County. It is remarkable for the stoutness of the straw, and the broadness of the blade, and is said to be much less liable than other wheat to lodge—the head is uncommonly large, but the stalks left being pulled when green, to prevent shattering, the grain is not a fair sample—we understand it to have been originally brought from Pennsylvania to Cæcil County, where it has acquired a very high character, for its beautiful appearance in the field, and great yield to the acre—some hundred bushels will be deposited about the middle of September, for sale with Messrs. Wilmer & Palmer of this city, to whom application may be made by those wishing to engage some of it for seed.

PRICES CURRENT.—CORRECTED WEEKLY.

Flour, best white wheat, \$7—Howard street, from wagons, \$6 50—Superfine, \$6 50—fine do. \$6 25—Wharf, do. \$6 25—White wheat, \$1 22 to 1 26—Red do. \$1 18 to \$1 20—Rye, 45 cents—Corn, 40 cents—country Oats, 25 cents—Beef, 8 cents per lb.—Live Cattle, \$6 to \$6 50 per cwt.—Bacon, hog round, \$10—Pork, \$4 50 to 5 50 per c. lb.—6 to 8 cts. per pound—Mutton, 5 to 6 cts. per lb.—Beans, \$1 37½ to 1 50—Peas, black eyed, 55 to 60 cts.—Red Clover Seed, \$5 50 a \$6—Orchard Grass do. \$3—Herds' Grass do. \$3—Timothy do. \$4 50—Millet, \$1 50—Flax Seed, 75 to 80 cts.—Whiskey, from the wagons 35 to 36 cts. per gal. including the barrel—Apple brandy, 30 to 32 cts.—Peach do., 65 to 70 cts.—Shad, \$6 00.—Herrings, No. 1, \$2 70 per bbl.—No. 2, \$2 37½—Fine salt, 60 to 65 cts. per bush.—Coarse, do. 70—Butter, (firkin) 14 cts. per lb.—Eggs, 10 cts. per doz.

RYLAND TOBACCO.—same as last report.

University of Maryland.

The MEDICAL LECTURES will commence, as usual, on the last Monday of October next.—Surgery, John B. Davidge, M. D.—Chemistry, Elisha De Butts, M. D.—Practice of Physick, Nathaniel Potter, M. D.—Anatomy, Granville Sharp Pattison, M. D.—Materia Medica, Samuel Baker, M. D.—Institutes of Physick, Maxwell McDowell, M. D.—Midwifery, Richard W. Hall, M. D.

By order,
ELISHA DE BUTTS, M. D.
Dean of the Medical Faculty.

BALTIMORE, AUG. 1, 1823.

BALTIMORE INFIRMARY.

A CLINICAL INFIRMARY having, since last session, been united to the MEDICAL DEPARTMENT of the UNIVERSITY of MARYLAND, the FACULTY of PHYSICK consider it their duty, in making the annual annunciation of the MEDICAL LECTURES, to offer to the public a statement of the plan on which the INSTITUTION is to be conducted, and the advantages which its connexion with the University will give to the MEDICAL STUDENTS.

The Infirmary having been built with the view of securing to the Students of the University the benefits of CLINICAL INSTRUCTION, patients with incurable diseases will not be considered fit subjects for admission. The progress of chronic complaints is so gradual, that the features of disease are not in them marked by those striking characters, nor attended with those remarkable phenomena which belong to acute affections.—As the object of the Institution is to unite practical with theoretical instruction, and to enforce and support the doctrines taught in the University, not by idle hypothesis but by demonstration, the latter class of patients, being the one best suited for illustrating the principles of pathology, will be the one selected for occupying the wards of the Infirmary.

The patients will be divided into two classes, MEDICAL and SURGICAL. With the view of instructing the students in the principles and practice of OPHTHALMIC SURGERY, one ward will be appropriated for the reception of patients afflicted with diseases of the Eye.

The Infirmary will be visited daily by the attending physician and surgeon, at twelve o'clock noon, and, at these visitations, they will be accompanied by the students. The case of every patient will on his admission, be written out by one of the house-pupils, and, having been examined by the physician or surgeon, it will be entered in the journal, and read, at the following visit, to the students at the bed-side of the patient. It will then become the duty of the Medical attendant to call, generally, the attention of the pupils to the facts of the case—the Diagnosis and Prognosis, and the views which have influenced him in the prescription of particular remedies. It will further be his duty to enter at the bed-sides of the patients, daily reports on the progress of the different cases, and to comment on the nature of the symptoms which manifest themselves.

When the visiting Surgeon is of opinion that an operation is required for the relief of any of the patients under his care, it will be necessary for him, before proceeding to its performance, to summon a consultation of the visiting and consulting physicians and surgeons of the Infirmary. It will likewise be the duty of the visiting physician to summon a consultation on every case, when he may be in doubt as to its true nature.—This regulation secures to the poor the advantages of the opinion and advice of a large and respectable body of the Faculty on the subject of

their particular cases, and is a sufficient guard against any surgical operation being performed where its necessity is not fully indicated.

Four Clinical lectures will be delivered in the Infirmary every week. Two medical, and two surgical. The journals, containing the cases and daily reports, will form the subject of these lectures; and the visiting physician and surgeon, will, in them have an opportunity of entering more minutely and critically into an investigation of the nature of the cases under treatment, and an explanation of the views and intentions which have guided their practice, than they could possibly do at the bed-sides of the patients.

In every case, where the consent of the friends of the patients can be obtained, an examination of the bodies of those who die will be made, in the presence of the students. This practice will have the effect of conveying to their minds a knowledge of that most important branch of anatomy—the anatomy of morbid structures, and likewise of testing the justness of the opinions delivered by the medical attendants.

The patients of the institution will be principally selected from the citizens of Baltimore, but as the managers are aware that numerous cases of a surgical nature occur in distant parts of the country, where, from the situation and circumstances of the individuals, professional aid cannot be obtained, they take this opportunity of informing the public, that they will receive such patients on board, at three dollars per week, no extra charge being made for professional attendance, &c. &c. They would also state, that gentlemen's servants requiring operations will be received on the same moderate terms.

The Medical Faculty conceive, that the best and strongest pledge which they have to offer to the public for the patients being attended with care, and treated with tenderness and humanity, is the character and high respectability of the gentlemen who form the board of managers.

The Infirmary will be completely finished and ready for the reception of patients, by the 20th of October next, and the Clinical Lectures will commence during the first week of the session.

The election of House Pupils will take place on the first Monday of October. Those gentlemen who may feel disposed to become candidates for the situation, are requested to apply, by letter, to Dr De Butts, Dean of the Medical Faculty. The board, including washing, firewood, &c. &c. is fixed at \$300 per annum, payable in advance.

President.—His Excellency SAMUEL STEVENS, Governor of the state of Maryland.

Vice-President.—EDWARD JOHNSON, Esq. Mayor of the city of Baltimore.

Managers.—Charles Carroll, Esq. of Carrollton—Robert Smith, Esq.—Bishop Kemp—Isaac McKim, Esq.—George Hoffman, Esq.—Luke Tierman, Esq.—William H. Winder, Esq.—Philip Moore, Esq.—David Hoffman, Esq.—Benjamin C. Howard, Esq.—Jonathan Meredith, Esq.—Robert Gilmor, Esq.—Archbishop Marechal—Richard Caton Esq.—Philip E. Thomas, Esq.—Alexander Fridge, Esq.—George Warner, Esq.—Reverdy Johnson, Esq.

Attending Physicians.—Nathaniel Potter, M. D.—Elisha De Butts, M. D.—Samuel Baker, M. D.—Maxwell McDowell, M. D.—Richard W. Hall, M. D.

Attending Surgeons.—John B. Davidge, M. D.—Granville Sharp Pattison, M. D.—The attending physicians and surgeons of the Infirmary are *ex officio* managers.

The Boards of Examiners of the Medico-Chirurgical Faculty of Maryland, for the Eastern and Western Shores, are *ex officio* consulting physicians and surgeons to the Infirmary.

AGRICULTURE.

From *Memoirs of the Board of Agriculture of the State of New York.*

LETTER

TO THE HONOURABLE STEPHEN VAN RENSEL LAER, PRESIDENT OF THE BOARD OF AGRICULTURE, UPON SHEEP HUSBANDRY, AND THE CULTIVATION AND USE OF TURNIPS.

SIR,

I have been solicited by letter from numerous quarters to furnish to the Board of Agriculture a detailed account of the cultivation of turnips, and of the uses to which large quantities may be put.

The method which I have followed ten years, and which has been uniformly successful, particularly this year, is the row system, sown with the drill, as it has been long practised in the best farming districts in England and Scotland. It is described in most of the published agricultural works of Europe, and at page 127, 1st. vol. of *Memoirs of the Board of Agriculture.* To this description nothing can be added: the process is very simple, and if faithfully executed under favorable circumstances as to soil and season, is sure to succeed. I repeat that I have tried it in various parts of an extensive farm for ten years past, and have never been disappointed. I am confident that upon proper soils, it would succeed with any other person, as I know it has already done, especially with yourself.

It would therefore be superfluous to recapitulate the description of so simple a process; but being a branch of farming as connected with sheep husbandry, susceptible of being placed in a very interesting point of view, I have thought that I should do a useful and acceptable thing to the public in submitting to it some opinions upon sheep husbandry, which would give me a full opportunity of incidentally speaking of the cultivation of turnips, and of the invaluable uses to which they may be put.

Before the introduction of Merino sheep into this state by that worthy and spirited friend to this country, the late Chancellor Livingston, very little attention had been paid to sheep. Every farmer had a certain number of what are usually called *common sheep*, sufficient to furnish him with wool for domestic uses. It was not his interest to have more, for as manufactories had not arisen, and it would not bear exportation, wool was an article scarcely marketable in large quantities. The drovers also, to make up a lot of fat wethers, had to travel from farm to farm, picking up a few here and a few there. I have never heard of a single instance where the common sheep were kept under a regular system of improvement, by which is meant the necessary precautions of selecting those ewes which unite the qualities essential to good breeders; observing the same with the males; weaning the lambs at a proper season; keeping the males and females separate until the tupping season, and finally taking the best care that they were kept in good condition the whole winter. On the contrary, those sheep which have fallen under my observation, bore evident marks of having none of these attentions paid to them, and were in fact such bad sheep as promiscuous intercourse and careless management is sure to make, and averaging perhaps two pounds of wool a head.

But the introduction of Merinos was the point upon which the revolution has turned which has taken place in sheep husbandry. The very high prices of these sheep and their wool fastened strongly upon the imagination of many farmers, and the numerous importations in 1811 and 1812, which brought their prices down from one thou-

sand dollars to ten dollars, enabled many practical farmers to get hold of them: large flocks too were sent into the interior, on speculation, by the importers, and they got generally diffused in the country. At length the prices of these sheep fell so low, notwithstanding that fine wool has always maintained its value better than any other agricultural production, that the speculating holders of the Merinos, gradually ceased to take an interest in them, and many large flocks in consequence were broken up and destroyed. Such has been the history of the race of Merinos in this state, which in 1809, were valued at one thousand dollars each, and which I have seen sold for a dollar a head in 1815. Their introduction was nevertheless one of the most substantial benefits this state ever received from the hands of an individual; for independent of their intrinsic value at this moment, which in certain situations is great, (in distant counties,) and will probably always remain so, the attention of the farming interest has been strongly drawn to sheep husbandry, which undoubtedly is the bottom of all good farming; nor in Great Britain, where the just economy of farming is properly understood and practised, is there a doubt on this subject: and if in that country they have arrived at this conclusion, it is only because they have a denser population and greater experience, both circumstances which lay before, and must necessarily occur to us, and to meet which it is well to prepare ourselves.

Amongst the persons who at an early moment entered into the breeding of Merinos with great earnestness, I was one, and I persevered with zeal in that pursuit until a few years ago, when after duly taking into consideration every thing connected with their present profits, and those which they might yield ten years hence, I came to a conclusion which I had been anticipating for some time, and parted with every Merino ram that I was possessed of, and have never owned one since. The reasons however, which caused this determination, are principally applicable to those, who being favorably situated as to the best markets in the state, look to carcass as a great source of the profit to be derived from sheep husbandry, and these reasons I shall proceed to give.

The Merino sheep then having fallen in price to a level with the common sheep of the country, there was an end of every expectation of that branch of profit, which had induced most purchasers to go into this breed, viz: the disposing of superfluous stock at from ten to twenty dollars a head. And if that expectation had not been entertained at first, I apprehend these sheep would have made very little progress in this country. The only advantage then which Merinos were found to possess above the common sheep of the country, was the higher price of the wool which its superior fineness always insured it.

Upon reviewing the facts which had transpired connected with my Merino flocks, up to 1818, and which had been carefully observed, I became satisfied, that after washing the wool well on their backs, removing every thing like dirt from the fleeces, and sending it perfectly dry to market, all of which precautions I found necessary to secure respectable purchasers, the average weight of the fleeces did not exceed two and a half pounds of wool, which sold at seventy cents per pound, (a high average price) would make the wool of each sheep amount to \$1 75 a head per annum. A well regulated flock of sheep increases so fast, that it evidently must be kept down, by thinning off annually to that number which the farm has the steady ability to keep in good order; and this is usually done by selling

on foot in the fall, or by butchering and sending the carcasses to market. This last resource is a very indifferent one for a large farmer. The Merino is a small animal not exceeding 8 lbs. a quarter when grass fed in November, and does not look well alongside of other mutton; besides there is a great prejudice existing against it, and nothing can be more troublesome than disposing of a large quantity of these sheep in this mode, at a time of the year when days are short, and bad weather common. The other method is the most prompt, and least disadvantageous. It being the interest of every farmer to keep young stock on hand, that which has come to maturity will of course be parted with. A sheep which has given six fleeces, is a proper subject to turn off, and I consider a flock of store Merino sheep at that age well sold at 12s. a head. Be that as it may, they are frequently to be bought for less money. Beyond that age, the productiveness of these sheep when kept in quantities, may be said to be past; for they fail very fast, and fleeces diminish rapidly in value. It may be assumed then that the productive part of the life of a Merino, is comprehended within the first six years and six months, and if then sold, according to the foregoing statement—six fleeces at \$14s. each, and the sale of the animal at 12s. will give 96s. for the intrinsic value during its whole life. From this sum is to be deducted the charge of maintaining it during that period. The winters here average about 135 days of feeding, and I know by actual experiment, that 7 healthy sheep during that period will eat a ton of hay, which valued at 7 dollars; leaves each sheep charged with a dollar a head for wintering, independent of all the incidental expenses of attendance, fencing, expense of seeding down the land, &c. which will always bring an additional charge of 4s. a head per annum against them. Deduct then these two charges of 12s. annually for six years, and 24s. are left as the neat profit upon each sheep for a period of six years, or the sum of 4 shillings a year neat profit. I am persuaded that every practical sheep farmer, who has had much to do with Merino sheep of late years, and who will have the candour to review these observations, and compare them with his own experience, will admit that the details are reasonable and the deductions fairly drawn. It would appear then that a flock of 1000 Merino sheep only gives a return of \$500 per annum neat profit to the owner: which it must be admitted is a very inconsiderable sum, when the circumstances of rent, and an anxious personal attention, are taken into consideration. These conclusions were familiar to me, long before I had the courage to determine upon encountering the forbidding task of remoulding a large flock of sheep, and of changing a breed to which I was partial from the fineness of its wool, and from the remembrance of the great value it bore, when I first engaged in it. No one but an extensive practical farmer can form an adequate idea of the toil attending such an operation, particularly where the new breed itself was yet to be created. It was obvious then that the great defect in Merino sheep, as it concerned my situation, (having several considerable market towns to resort to, and being only 20 miles distant from a navigable communication with New York, which the great canal when in operation would reduce to five,) was in the want of carcass. My object then clearly was to raise a breed of sheep with a sufficient weight of carcass, to ensure the best prices in the large markets, and to have the wool of a sufficient degree of fineness to ensure a prompt sale. My attention therefore was turned to the new Leicester sheep, a breed established by the care of the celebrated Mr. Bakewell,

and remarkable for its weight of carcass and fleece, and to the South Downs, a breed celebrated for a fine carcass, with a moderate fleece of fine wool. But all my attempts to procure them from England failed, from the rigour of the laws which prevent their exportation from that country.

I had then recourse to another breed which by a happy accident had been introduced into the state of New-York. They were of the mixed *Bakewell* and *Teeswater* sheep, were only three in number on their arrival, but they fell into the hands of persons who knew their value, and had been judiciously and successfully increased in number. These sheep at a ripe age, (rising three years) weigh from 25 to 30 lbs. the quarter. The mutton is extremely fat, and by high feeding can be carried to 40 and 50 lbs. the quarter. The fleece is rather coarse, but gives a clip of from 7 to 12 lbs. when in condition, and is sometimes carried so high, that entire flocks in Great Britain, are reported to have averaged 12 lbs. of wool a head. When breeders turn their attention to increasing the weight of the fleece, it is almost incredible the quantity of wool which these animals may be made to carry on their backs. On this subject I have thought it would be interesting to copy the following paragraph from Evans and Ruffin's Agricultural Newspaper, dated "London, September 16, 1822. The large quantity of 74 lbs. of wool was clipped this year from three sheep, (two rams and one wether) belonging to J. Chatterton, Esq. of South Somerset, near Louth. The sheep were descended from his Lincolnshire ewes, by a *Teeswater* ram." Here is an average of almost 25 lbs. a head, from a *Teeswater* ram, being the identical blood we possess, mixed with the *Bakewell* or *New Leicester*.

If a very heavy carcass then was the only circumstance wanting to make my sheep stock profitable, the blood was at hand. I had frequently seen quarters from 25 to 30 lbs and knew that wethers of this breed had been sold at three years at 15 dollars a head. This was very encouraging, but as the changing my breed was a matter of serious concern to me, my object being to settle down upon a stock that would be permanent, profitable, and not subject to vicissitudes as the Merinos had been, I was very careful to give the subject proper consideration before I acted upon it. In the end I did not adopt this mixed *Bakewell* and *Teeswater* stock, as a breed by itself, for the following reasons.

They were so few in number in the state, and held so high, that it would have been an endless business to have waited a period sufficiently long to form a large flock.

The wool was very coarse, and not fitted for any sort of manufactures then prevailing.

And the most experienced butchers informed me that the high prices they had given for some of these sheep, was principally on account of the novelty of the breed, and to encourage the holders; but that mutton of 25 lbs. a quarter was not likely to prevail here; being too gross for genteel tables, and would probably never become a staple commodity amongst the labouring classes, who are accustomed to pork: whilst in Great Britain, those classes feed entirely upon fat mutton. They almost all agreed that mutton of from 15 to 20 lbs. a quarter would be more profitable to the grower as well as the retailer.

I was satisfied with this reasoning, and determined at once to procure some of the finest rams of the mixed *Bakewell* and *Teeswater*, and couple them with my Merino ewes. In this manner I hoped to raise the carcass of my flock from 8 lbs to 18 lbs. a quarter, and still have a quality of wool on hand sufficiently fine to command a ready sale—a sort of half *Bakewell* half

Merino. Accordingly, in the fall of 1819, I selected 200 very fine Merino ewes, and had them tupped by some heavy English rams, with moderate even fleeces, and thighs less coarse than they usually have. The ewes lambed in March, and from the first the lambs very much resembled their sires. The lambs continued the next summer to increase in size, far beyond the Merino lambs which had been dropped at the same time. In October most of them were heavier than their mothers, having carcasses from thirty to forty pounds. The next shearing time they averaged four pounds a head of wool, and many of the best, five pounds, clean washed on the back. Their wool is equal to what is called average half blooded Merino, some much finer—it was all sold immediately for fifty cents a pound. I was so pleased with the success of this experiment, that I put away the whole of my Merino rams, and have continued every year to breed from the best English rams I could meet with. The ewe lambs which dropped from this cross in spring, 1820, had attained a fine growth in fall 1821, and in spring 1822 produced me a crop of lambs three quarters blood, which at this moment (November) are equally admirable for their size, and the even fineness of their fleece. I am now satisfied that perseverance will enable me to establish a breed of sheep that will be invaluable to this state. Sheep which at three years will give from 16 to 20 lbs. the quarter, and 6 or 7 lbs. of wool, of a long staple and equal fineness to the ordinary half blooded Merino. I have at present about 600 of this mixed breed on my farm, besides 300 ewes that have been tupped this fall. By attention and judicious selections, I hope by and by to produce rams equal in every point of form to the best English rams that have ever been in this country, and with fleeces fine enough to perpetuate a breed, that will unite the rare value of the Dishley carcass to the Merino wool.

I have before stated that the fleece being the most valuable part of the Merino sheep, it is of course the interest of holders of Merinos to keep them as long as the fleece is productive, and I have assumed six years therefore as the productive part of the life of a Merino. It is difficult to form a very accurate estimate of the comparative advantages of the different systems after which sheep husbandry may be pursued. These are various. Such as maintaining a stated number of ewes, keeping the most thriving wether lambs, and selling them grass fed, or stall fed, when at a mature age: or keeping nothing but ewes, selling all their male lambs when fat, and keeping the ewe lambs, with a view to have greater number of ewe lambs to select from as breeders, and thereby being able to turn off as many inferior ewes to make room for them. This would seem to be the true way to build up a race of superior sheep in the shortest period of time. Calculations in which the returns and charges are fairly stated of these different systems are rather intricate, as all practical men know; because ewes and their female progeny breed fast, and yet their productiveness varies with the uncertainty of the weather during the lambing time. The worst of all systems unfortunately is the one generally followed, that of selling the finest lambs, whether ewes or males, to the butcher, and keeping the worst as store stock. Nevertheless although such estimates are not frequently very accurate, yet where there exists a real difference in the advantages betwixt two systems or two breeds, an approximation to truth may always be shown in a sufficiently striking manner, and I shall endeavour to give a comparative statement of the Merino sheep and the mixed Dishley and Merino, in a very simple

form, discarding every circumstance that could make it intricate or very uncertain, and adhering to facts known to me by experience.

I shall suppose a grazier entering into the sheep business who keeps no ewes, and who forms his stock by the annual purchase of wether lambs, which he maintains until they are of a mature age.

He begins with the Merino stock, and gives \$2 50 for a wether lamb, in the year 1822. In the year 1828 he will have wintered and summered it six years, at a charge of \$1 50 per annum, and will have taken six fleeces from it of 4 lbs. of wool, sold at 70 cents a lb. In the fall of this last year he sells it at 12s. All of which may be thus stated.

Six fleeces of 4 lbs. each, or 24 lbs. at 70 cents,	-	-	-	\$16 80
Sale of the sheep,	-	-	-	1 50
				<hr/> \$18 30
			<i>Charges.</i>	
Cost,	-	-	-	\$2 50
6 years maintenance at 12s.	-	-	-	9 00
				<hr/> \$11 50
				<hr/> \$11 50

This divided by six gives him \$1 13, as the neat profit per annum on this sheep. Twenty-four pounds of wool for the first six years of the life of a Merino wether, I consider a good return, if it is clean and fine enough to fetch 70 cents a pound. He then tries the mixed Dishley and Merino. He gives \$2 50 for a wether lamb; but as this sheep when it has attained its third year, is at its maturity, and has a fat carcass that will dress down to 20 lbs. a quarter; he sells it at that period as first rate mutton, and purchases another wether lamb, which when it has attained its third year, he sells as he did the first. Having wintered and summered each of them three years, and taken three fleeces from each, the statement may be thus made.

Six fleeces of *7 lbs. each, or 42 lbs. at 50 cents,	-	-	-	\$21 00
Sale of two heavy wethers,	-	-	-	10 00
				<hr/> \$31 00
			<i>Charges.</i>	
Cost of two wether lambs,	\$5 00			
6 years mixed maintenance at 12s.	9 00			
				<hr/> \$14 00
				<hr/> \$14 00

This divided by six, gives him \$2 83 as the neat profit per annum on these two sheep. According to these two statements, a flock of 500 Merino wethers, would make a return of \$565, neat profit per annum, whilst a flock of 500 Dishley and Merino wethers would, under the same circumstances, make a return of \$1,415, a difference of \$350 per annum, in favour of these last.

I consider this the fairest way of stating the subject for an examination of the comparative

* I subjoin one of many communications to me: it is from a respectable farmer in Washington county.

DEAR SIR,

I have the pleasure to inform you, that the ram lamb I had from your flock of the Dishley and Merino breed, in the year 1820, has continued to thrive and is become a remarkable sheep. At shearing time, 1821, he gave me 7 lb. 5 oz. of fine washed wool, and this year betwixt 8 and 9 lbs. as clean as it could be washed on his back.

I remain, Sir, Your's,

I. EMUEL SIMMONS.

Easton, August 10, 1822.

advantages of these different breeds made after the common practice of keeping some ewes, some wethers and some lambs, would be intricate, and certainly not so susceptible of a clear statement. Besides the practice of buying young stock, and grazing it to a proper age, is deemed by some experienced men, as less troublesome and more profitable than breeding their own stock. Some persons wishing to look more critically into this matter, will perhaps enquire if it is not more expensive to maintain these heavy sheep than the light bodied Merinos, or in other words, if they do not consume more grass and fodder, enough to balance the stated difference in their productive value. To this I would answer, that it is reasonable to believe that a large animal usually requires more food to sustain it than a small one, but that I believe there are considerations which again compensate for this apparent objection. Mr. Bakewell, to whom the world is indebted for the invaluable breed of sheep usually called Dishley, spent a long life devoted in the most unremitting manner to carrying the breed of various animals to a perfection unknown up to his time. He met with great opposition, but his success at length was complete. It is stated that the first ram he ever let out was for twenty shillings. In the end however, so much was public opinion changed, that he has received the sum of one thousand guineas for the hire of a single favorite ram in the course of the season. Mr. Bakewell has been accused of sedulously throwing a mystery over his proceedings, with a view to embarrass those who were anxious to imitate his peculiar plan of improving animals, and to rival him. This may very well be believed, and hence perhaps he has not left behind him a very accurate account of all the details of his system. Enough however has transpired to show that he was a very close observer of nature, and that he owed his success more to natural sagacity, than to any accidental discovery.

It was a favorite thought with him, to consider the best animal to be, one which brought most money to the farmer in the shortest period of time. Hence the faculty of being ready for market at an early age, was one he anxiously sought to impart to his sheep.

With this object in view, he looked rather to the constitutional habit of sheep, than to their external points. Lambs that would feed quick, get fat soon, loll and sleep a great deal, were sure to attract his attention. He perhaps thought as many others do, that a propensity to fatness, is constitutional with animals, as well as with our own species, and that fat sheep, as well as fat people, do not require so much more nutriment than lean ones, but that the same quantity of food keeps up their condition, because they sleep a great deal, and do not ramble about as thinner animals do. Following this thought up, he would necessarily see the importance of encouraging further this natural propensity, by providing them with the best pastures, where they could satiate themselves at the least expense of motion. This natural reasoning shews the inseparable alliance between good husbandry and good agriculture.

The principles which regulated Mr. Bakewell's practice were so just, and led him to such unrivalled success, that at this moment there is not a good flock of sheep in Great Britain (pure Merinos and South Downs excepted) which is not bottomed upon the Dishley blood. A fact which I am intimately convinced will be common to this country in a very few years.

I trust this digression on the merits of Mr. Bakewell's system, will not be thought impertinent to the subject, but will rather suggest a satis-

factory answer to the question, whether "it is not more expensive to maintain these heavy sheep than the light bodied Merinos?" That a large lean animal will always eat a great deal more than a small lean one, I readily concede; but giving due consideration to the theory of the foregoing observations, sustained as it unquestionably has been by my own experience, I declare it to be my belief that fat animals thrive more upon the same quantity of food than lean ones, and that an acre of produce consumed by fat sheep, will produce more money in the end to the farmer, than a like acre consumed by lean sheep, and this is saying every thing in favour of the former.

But there are many considerations to be urged in favor of these sheep, which were I to enter largely into them, would extend this letter too much. The first in importance however is, that whoever goes into this breed, and does it justice, in despite of every circumstance, must get his farm into a profitable condition. These sheep must always be kept in a thriving state, and never suffered to fall off. Hence in times of drought, when grass is low, fields of rape or turnips, or some succulent vegetable, should be at hand to turn into, and rape and turnips, requiring manure and careful cultivation, leave the ground in the best possible state for a succeeding crop of grain; to the crops of grain, succeed clean grass seeds, and as every year new fields of rape and turnips are required, so every year a fresh part of the farm, is put into the best condition, and by steadily following this train, at length the whole farm is brought into the most productive state it is capable of being placed in. It is universally considered in Great Britain, that a well selected stock of sheep is the essential item of the prosperity of the farmer. The turnips, the rape, the tares, he sows are all for his sheep, it is to their wool and his fat wethers that he trusts for the payment of a rent perhaps from four to ten thousand dollars, rather than to precarious crops of grain; which, if they were his only resource, and were to fail him, would bring down ruin at once. Sheep are then truly the foundation upon which all his operations are raised. Without them he could not manure his fields, nor could he, without manuring, raise grain to pay any rent whatever, or perhaps even to pay the unavoidable expenses of his farm.

A regular system of husbandry resembling this must soon prevail here, and there is nothing to prevent it but a supineness with some, and an obstinacy with others, of which perhaps farmers have as full a share, as any class of men. The circumstance, I apprehend, which most tends to protract the universal introduction of an improved husbandry, is the easy condition of the occupiers of land; happily ignorant of the burdens of the excessive rent, tithes, and poor rates, which have in a great measure by compulsion produced the improvements in husbandry of the English Farmer. There is certainly nothing in the difference of soil and climate which stands in the way of their being introduced here, for all the green crops and roots upon which so great a dependence is placed in European husbandry, grow quite as well in this country. Nor have they one single apparent advantage over us, save the mildness of their winters, which admits of turnips being fed on the ground where they grew; and which, when every disadvantage is considered of the diseases which are introduced upon their sheep by the moisture of the climate, and the consequent necessity of feeding them continually on low wet ground, give us absolutely a better prospect of establishing a successful husbandry than the British farmers.

(To be continued.)

FOR THE AMERICAN FARMER.

REMARKS ON HEDGING,

And the interest of land holders, as it regards various kinds of fencing.

(Concluded from our last.)

The inclosing our land, whether arable or wood, has become in many parts of the country, a serious expense, and such an one as cannot be well avoided. To adopt that which is least expensive, and at the same time most durable, is certainly most desirable. There are two kinds to be recommended for their duration, *stone* and *thorn*. The former must be limited to districts where the means are present, as it is composed of too heavy a material for distant transportation, (yet an excellent fence when well built,) of which I shall say something in future. The thorn may be cultivated in any part of the United States, as there is a variety of kinds suited to all parts of the country, as is indicated by their spontaneous production.

The cockspur and Virginia kinds have been mostly brought into use for fencing; the former a native in my state, (Delaware.) The Virginia introduced about the year 1808, has been used with success, being found congenial to our climate. The rivet and English thorn was brought and used by some of the early settlers from Europe, but finding a better substitute in the country, they naturally were neglected.

The mode practised by those that continued hedging, was by planting and throwing up a ditch bank; and when the thorn grew to their full height, or so as to become cambrous they were cut near the root, but not wholly off, and bent down on the defensive side, (or into the roads when they happened in those situations.) Thus they lay, encouraging a growth of rubbish, while a new hedge rose by sprouts from the stumps, the fallen part yet living also; thus it remained until it proved truly a *hedge row* of various productions, even the forest trees partook of the shelter, for the nut or seed grew amongst the general assemblage. Other farmers, who paid a little more attention, when the young growth was advanced, would cut away the fallen part, to prevent rubbish, and burn it, letting the second growth advance, until it became large enough to undergo the same operation of the former. This was the kind of living fence, that has been in use many years in some of our native thorn districts, all tending to the same thing a *hedge row*, as they were all more or less combined with various natural products of some kind, therefore not a distinct thorn hedge. Neither were they clipped or trimmed, because they became too forbidding for that operation; after passing the proper size, and before they attained the sufficiency to make a fence, they were considered not to require it. Thus the business went on, presenting an unpleasant appearance; for when at their height, the traveller, on passing the road, could have no view of the farm he was passing, more than if he were in the midst of a forest.

These are the appearances that have given a paralytic stroke to hedging, but they are *hedge rows*, not hedges, and it is the confounding the idea of the two that brings the hedges into disrepute. I had for several years thought much of live fence, but discouraged by those that I saw, until a friend sent me some quicks as a present, raised from the seed of the Newcastle thorn, which I planted, being in the spring of 1800—the Virginia kind was not then known with us.

I then began the work unexpectedly, but formed a determination to make a *hedge*, a thing I had never seen, though I had formed an idea in

my mind as a pattern for the purpose, and kept that idea in prospect, which has long since been fully verified and produced ocular demonstration. The Virginia kind had the effect to perfect the thing in a more delicate feature, the former makes a good hedge, the latter generally is propagated now.

Soon after this, the first number of the American Farmer was very politely sent me by its Editor, requesting any useful matter for that paper—I had nothing better, as I conceived, than a few remarks on my progress in hedging, pointing out my misfortunes as well as success, and as leisure offered, communicated my experiments, from time to time, which were published in the first volume, and one in the third volume, page 116, on trimming.

I expected some able hand to have taken up the subject, on seeing some attempt made, and from whom I should have gained the knowledge requisite to go through with perfecting my object—but nothing appeared as it regards the encouragement of thorn; some other substitutes have been proposed; I have therefore advocated the thorn, until I have had the gratification of seeing it succeed with unrivalled excellence, and approbated by all that have seen *our best hedges*, theorists as well as practical farmers.

I am able now to say with clearness, what a hedge will cost, made of the Virginia kind; there are men who have undertaken to raise them from the seed plant, prune and trim at stated prices, until matured; this led me to calculate from our progressive knowledge, and I find *forty cents* a rod will complete the raising to mature age, and one cent a rod will fully maintain them for ever after, if duly attended to, and applied with judgment. No failure has ever appeared, except some local cause is present, therefore durability is now well established.

This is the best time to give the last trimming for the season, at least we think so, (August.)

We must be allowed to adhere to our practice, while it shews good effects, and none other to contradict it.

Stone is a very good article for fencing, where they abound and need clearing off the land for cultivation. The mode I have adopted is never to reduce them by breaking less than convenient to draw, and that may be easily done, if under a ton weight. I place the large ones in the bottom, laying cross ways in the foundation of the wall, if stony land on the surface, no digging is necessary for foundation. If clear of stone, excavate from eight inches to a foot for foundation; by laying the large stone cross the wall, it projects on each side, as you build on them, a wall in width according to the size of the stone battering on each side, consequently thin at the top.

My stone being of a quality to build on those foundations, two feet, falling off to eighteen inches on the top, then capped with the round or roughest ones, such as will not so readily build in the wall, they are rolled up a plank, and laid across the top. This forms a forbidding cap or top to the fence, and is the readiest built foot in the wall. The foundation stone generally raises from one to two feet high in the first place, so that no line is wanting, other than to stake out with, then line on the top of them, and not more than three feet is wanted built to line, before the rough capping comes on, no matter how much they project over, they are the more defensive, and keep all safe from being shoved off, as light stones are more liable to be.

Now to transport those heavy stones, say from ten to twenty hundred weight, a pair of cart or wagon wheels may be used for that purpose,

with simply an axle and tongue, or shafts, as the case may be, for oxen or horses—a roller is fixed across on the top immediately before the axle, with holes through it, for crow bars, to put in as levers to raise by a chain, which is put round the stone, and a link slipt on a strong iron pin that is drove into the roller by the strength of two men. A stone of a ton weight is hoisted in half a minute, and a pair of oxen travels with it to the place wanted, and may be dropped on the spot with ease; this mode lays the foundation of the wall, and at the same time raises the heaviest part of it, according to the size, the larger the better.

If wheels be made purposely, we have them higher than those of a wagon, and the axle longer, they will carry larger stone, and if you have blown rocks to move, they are better adapted to the purpose; if you can pass a chain under them, they may be raised out of the pit or bed where they lay, and by this means you clear land and fence at the same time; this will apply to land that is stony and yet worth clearing.

But if the stone is very distant from the place that the fence is required—thorn is to be preferred.

It should not be forgotten in calculations of this kind, how much land is gained by the removal, and how much is saved in ploughs, harrows and implements of husbandry in farming. Such land some may deem it impracticable to clear, but a little resolution and good management soon overcomes all those difficulties.

CALEB KIRK.

Brandywine, 8mo. 1823.

FOR THE AMERICAN FARMER.

ALBION'S 7th LETTER TO HIS SON.

*"Distressing hour! 'tis very late!
O mercy, mercy, guide him home!
Hark! then I heard the distant gate,
Repeat it, Echo! quickly come!
O blest assurance—trusty steed,
To thee the hurried road is known;
Home all the spur thy footsteps need,
When loose the frozen rein is thrown—
Where have you stray'd? put down your load,
How have you borne the storm,—the cold?
What horrors did I not forebode,
That Horse is worth his weight in gold!
Thus spake the joyful wife."*

The hackney horses on the Albion farm, were descended from Regulus, Atlas and Fireaway, three famed horses, the two former for blood, and the latter for fast trotting—he having trotted about the year 1790, from Newmarket to Cambridge, a distance of sixteen miles, within the hour, for two hundred guineas, against a horse descended from Atlas—the Albion horses had also a small admixture of Wildmore blood in them, a breed now nearly lost, in consequence of the drainage and enclosure of the Wildmore and adjoining fens, since the year 1800, containing about fifty thousand acres of land, reclaimed from the ocean, and washes on the eastern coast of the kingdom, and formerly, almost entirely stocked with wild horses and geese, although now it is nearly the garden of England; as perhaps it and the adjoining lands, surpass any other tract of land in the world in productiveness, particularly fat cattle, horses, sheep, long wool, wheat, oats, thorn fences and good farm buildings.

In describing these horses, much must be repeated, that has been said of the dray kind, but

perhaps it is as well to do so, as to omit any observation that may chance tend to give you more just ideas of a good horse, which of all animals is the most difficult to select, nice *action* being required also with a nice frame; what however is here said, as indeed in my other letters, is not theory, but the result of my own observations, and therefore I would have you take them for just what they may appear to be worth, after being tried by your own mature judgment.

In examining an animal, begin at the head and go step by step, to its other extremity, so that when you have finished, you can give a *good reason*, for your opinion of it, and never consider yourself as having acquired even the first rudiments of your business, until you can do this; for although you may tell me, you "possess lands from Pennsylvania to Maine, and own flocks and herds more numerous than Jacob, or have the honor of being a member of the society of *learned farmers!*" Yet these advantages are all within the reach of a man of wealth, and do not necessarily constitute him a man of judgment; just as well might you say, as the wit did to Dr. Johnson, "he who drives fat oxen, must himself be fat."

The best of the Albion hackneys were from 14 to 16 hands high, and had wide nostrils, which enabled them to breathe freely—lips thin and mouths small, when young—ears long, bespeaking blood, and also enabled them to hear well—eye sockets wide apart, and eyes bold, enabling them to see various ways at once—the ridge of the nose rather hollow, bespeaking barb blood—head small, and hanging nearly perpendicular from the ears, free from flesh, and wide between the lower part of the jaws, which occasioned them to rein up handsomely, without pressing on the windpipe, and is of vast importance in a hackney, as a horse seldom rides light and pliable on the rein, if he be contracted under the jaws, and of course sets out his nose like a goose, (the American horses are frequently defective in this respect, which occasions them to require those formidable bridle bits, reins, martingals and the like, we so often meet with, and after all, their riders have but little command over them)—neck rather short and inclining upwards from the withers to the ears, giving a ready passage from the lungs to the nostrils, and the rider a good command of the head—withers high, thin, and inclining backwards, by which means the saddle is kept from the shoulders, and the rider far more comfortably seated—shoulder blades fitted neatly to the withers, long, inclining backwards, and nearly together at the top, and wide apart, and forward at the lower extremity—arms rather long, strong, and full of muscle, so that a great proportion of his height was between the knee and the withers, as in action, the shoulders and arms act like levers, and of course should be long—kneejoints, thick and wide apart—legs from the knee to the fetlock, short, strong, black, free from rough hair, and full of hard strong sinews at the back part of them, occasioning them to look flat at the sides, (here the American horses are also frequently deficient; their legs mostly being too round)—fetlock joints short, feet round, that being their natural shape—hoof of a dark color, and in horizontal wrinkles, frog large and free from moisture, or the hoof will soon contract, and the horse have tender feet—chest broad and forward—back short—loin broad, and joining neatly to the back—ribs long, broad and well rounded—rumps long, neatly turned, not clifted, not wide at the top, nearly in a line from the setting on of the tail to the back—tail strong—fundiment small, bespeaking all right within—hips fitting snug to the

join and ribs,—sheath large—this form of body bespeaking a strong hackney of good constitution—thighs long, full of muscles and flesh, nearly down to the hock—hocks rather large, flat at the sides, very firm and boney—in colour, prefer a horse of a blood bay, or brown, with black man, tail, and legs—without any white.

In forming an opinion of the action of a hackney, let the groom put on a snaffle bridle, and without a saddle, ride him from you at an easy natural walk, and place yourself directly behind the horse—he should now go off freely, carrying his head rather upwards, and his nose projecting a little from the perpendicular with his ears, his eyes being about level with his withers, his knees rather wide apart, inclining outwards, and carried high, and forward, with a considerable deal of action—fetlock joints carried in a similar manner, so that the whole shoe may be very visible to you—his toes going straight forward, or by no means turning out, or he will cut, and of course tumble—his hind legs and feet going about square with, or rather nearer together than the fore feet, and as forward and under him as possible, but by no means even reaching or striking against the fore shoes, unless he be only a colt, and then perhaps he may mend of it—when he returns, and when he passes you, see that he sets the heels of his feet on the ground first, for if the toes strike first, he will stumble, and next tumble—his knees cannot be too forward, nor his weight too much on his hind legs—then put him into any easy trot, and place yourself as before—the peculiarities of the above action should now be more perceptible, and as the groom keeps increasing his speed, and passing you, observe that the horse stops and turns freely, without thrusting out his nose—and on starting, that he first raises his forehead, by drawing his hind legs forward, and goes off freely, bearing light on the rein, and carrying himself airy, and his principal weight on his hind legs—the forelegs being intended principally to balance the body, should nearly do all their work from the elbow downward, and play very freely—then desire the groom to canter; this being a ladies mode of quick riding, should be done with great ease, the horse should now, from the walk, raise himself on his hind legs, and throwing forward the off fore foot, go at once into a canter, feeling to the rider to incline his forehead a little to the near side, his forehead high, and nearly all his weight on his hind legs, treading on the ground very light, and his whole action airy—from this pace you may, if you choose, have his action increased to his full speed, but if he does the first two or three paces well, never mind his galloping, as farmers have no business with race horses, leave these to men of fortune; indeed you must not expect to meet with a fast galloper, and a good hackney united, the former going near to the ground, and the latter high from it—but bear in mind, that no horse ought to be considered a good hackney, that cannot readily and freely walk five miles, and trot, with perfect ease to himself and rider, from eight to twelve miles within the hour. When you have thus far examined the action of a horse, let the groom alight, and walk and trot him in hand, this he should do with perfect freedom, carrying himself as before, then let him be saddled, and all the same scene repeated, then, and not before, mount him yourself; you must now principally judge of him by feeling, you should feel to have nearly the whole horse before you, perfectly light and tractable in hand, with his hind legs very much under him, and nearly all his weight on them, his forehead rising high, and going light over the ground, his knees being very perceptible to you, high, much bended, and for-

ward; these peculiarities should be very perceptible in all his paces—and when he canters, his off knee far advanced before the other, or he will never carry a lady with comfort to herself; but walking and trotting, in a superior manner, are the peculiarities of a good hackney, and if he can also canter well, so much the better, but never suffer a horse to rack or pace—the walk, trot and gallop are the only natural paces of the horse, and no others are becoming, or of any use to a gentleman to practice in riding.

Hackney horses ought to be well trained when young at the leaping pole, as they are good soldier's horses, and frequently make good hunters—indeed the late king George generally preferred fast trotting horses, when hunting the stag, or on the road, and he mostly left all his courtiers and attendants behind him, when he was on horse back, and tried to do so.

ALBION.

FROM THE DARTMOUTH (N. H.) HERALD.

KEEPING HORSES.

Every gentleman, who is obliged by his health or his business to keep a horse, complains of the enormous expense incurred by it. If allowed to eat and waste as much as he chooses, a horse will consume from four to five tons of hay in a year, besides the necessary grain. But it is asserted, from actual experiment, that ten pounds of good hay, with two quarts of corn a day, are enough to keep a common horse in fine order.—Ten pounds of hay a day are 3650 pounds, little more than a ton and a half, a year—and two quarts of corn per day, are about twenty-three bushels a year. Call hay seven dollars a ton, and corn four shillings a bushel, and you make the annual expense of feeding a horse twenty-six or seven dollars, about half as much as it commonly costs.

To keep a horse in the cheapest manner, let him stand on green turf, dug up pretty thick, and placed on the floor of his stable—let him be carefully and faithfully curried every day. This is of more importance than is sometimes imagined. It opens the pores, and preserves a healthful state of the skin, on which, in horses, as in men, depends, as much as on almost any thing else, the proper and healthy operation of the various animal functions.

Although the inferior animals are not, like men, subject to unnatural appetites, on account of unnatural stimulants received into the stomach, they unquestionably often consume more food than is necessary to maintain their vigour and spirit. This surplus it is economy to ascertain and retrench.

Corn is cheaper than oats for horses, because there is more heart in a quantity of the same price. It is better to be given two or three times a day in small messes—and to be given dry, that the mastication of it may keep the mouth in a healthy state.

To measure hay, the tare of a basket may be taken, and the hay given from it in small quantities through the day, but chiefly at night.

A horse that is not used, should be fed with corn but sparingly. It should be occasionally salted.

It is not perhaps generally considered, that horses are subject to colds and fevers, as really as men. They should therefore be used with great tenderness and delicacy, and often washed in cold water. The pulse generally indicates the health of a horse. It may be felt about an inch back of the eye, and in health beats about 35 strokes a minute.

The great secret in making horses look well and do well, is attention to them. Men who are above looking to their horses, will seldom ride good ones.

In using horses, it is better to drive briskly and stop often, than to drive even slowly by long stages.

FROM THE GLASGOW JOURNAL, (SCOTLAND).•

MANGEL WURZEL.

Mr. John Hall, of Little Marshall, Ide, near Exeter, recommends the cultivation of Mangel Wurzel. The land is dressed, drilled, and manured in the same way as turnips are cultivated in Scotland. The seed is covered not more than an inch deep; when up, and having six leaves, let the plants be hoed out to one foot distance in the rows, which, (the rows,) if two feet apart, will give upwards of 20,000 plants an acre; and should these average 10 lbs. each, (I had many last season upwards of 18 lbs. although an unfavorable time prevailed,) the produce would be between 80 and 100 tons of food.

Keep the intervals horse-hoed as often as convenient, and as long as the luxuriant growth of the leaves will permit. The seed-time for this plant is best between the 20th of April, and the 1st of May, by which last named period those who are desirous of a superior crop will do well to have their sowing finished.

The same care that is bestowed on potatoes for their goodly preservation is requisite for well keeping mangel wurzel; and it is of particular consequence that the roots be housed in dry weather, and before frost sets in, as, if housed wet, they are apt to get woolly and bad tasted, (not, therefore, so suitable for milch kine, for whom they are, when good, peculiarly desirable;) and, if frosted, they become slimy and rotten, or what is provincially termed here, "they slope away." When taken care of, by caving or housing in a dry situation, they will remain good till May or June. If these roots are given carelessly to cattle when first taken up, or, to speak generally, any time before Christmas, they, containing as they then do so much moisture, are apt to blast and scour them; and I have seen intoxication produced by them, given fresh-gathered, and in too great quantity; and had not bleeding been had recourse to, death would have ensued. All that is necessary to be observed in the early season, is, that the supply of roots be moderate at a time, and hay, straw, or chaff, given between the servings with mangel wurzel; as the season advances, the quantity of roots may be increased, and the dry food diminished. Milk and butter from mangel wurzel are peculiarly sweet and fine; and beef, produced from feeding with this root, is excessively juicy and rich flavored.

The root will not require such excessive deep land as many have imagined, its chief growth being out of the ground; and though much benefited by frequent hoeing, it is by no means right to earth it up, as by that plan the growth is retarded till fresh fibrous roots are thrown out in search of nourishment near the new made surface of the surrounding earth.

Nor let the grower of mangel wurzel shrink from giving his field an ample supply of good rich manure, as his well fattened land will return him five fold profit if he gives it with an unsparing hand.

And now, though last, not least, for the cultivator's consideration, mangel wurzel is not subject to the depredations of the turnip beetle.—Neither will that farmer be troubled with smut in his corn who steeps his seed wheat in a solution of sulphate of copper.

FOR THE AMERICAN FARMER.

In answer to Thos. Wright, of Eastwood—*American Farmer*, Vol. 5, p. 175.

FERTILITY.—This expression embraces a subject of vast importance to all who wish to profit by Agriculture. To assist nature is the art of husbandry. And they, who wish to profit by farming, should be careful not to apply their labour in an improper manner, or at an improper time; in answer the present enquiry is a subject of much interest.

MANURE.—As we can only assist nature, we should be careful, and not operate against her long established laws, lest we should be the losers by so doing. Nature places the manure, (or vegetable matter,) on the top of the ground, but under the shade of timber in the forest, and grass on the plain, which protect it sufficiently from the rays of the sun to prevent evaporation; but there the atmosphere has the greatest influence on it, of course there it will decompose fastest; therefore the most proper situation to place it, because the quicker it decomposes, the more benefit will be derived from it, as it can be of no use to vegetation, until it is not only decomposed but in solution. But in applying manure in the field, where there is shade of neither timber nor grass to protect it from the rays of the sun, which would cause too great an evaporation; there can be no doubt but it would be best to cover it with earth, but the shallower the better, say from one to two, or at most three inches.—I have seen clover (and other vegetable substances) which had been turned in seven or eight inches deep, and laid there 12 months, and then turned up again, without any apparant alteration, except the colour, whilst that which had been turned in only two, three or four inches, was entirely rotten, (or decomposed.) Those circumstances have confirmed my opinion, that it is best to cover manure entirely, but the shallower the better.

PLOUGHING.—Deep ploughing is much the best on many accounts. 1st, on inclined situations, it qualifies the ground to receive and retain more moisture, which produces two good effects, one is that it prevents the land from washing, because so long as the ground will absorb the water it cannot wash; the other is, that the crop suffers less with drought. 2dly, on very flat (or level situations) it affords an opportunity for the water to settle down a little from the surface, and prevents vegetation from scalding (or drowning) out in the summer, and also prevents the frost from injuring vegetation so much in the winter. Husbandmen who have not been in the habit of ploughing deep, cannot well conceive how valuable deep ploughing is in tillage as to the washing of land, moisture retained, and the effects of sun and frost. But in the common process of deep ploughing at one operation; there is very strong objections; that is turning the soil down too deep, or mixing too much of the clay or under strata with it; to remedy this unpleasant effect, the ground should be ploughed at two operations, first shallow with the barshare (or fallow) plough, and fallowed, or the ground cross ploughed with a substratum plough.

The substratum plough works on the principle of the scarifier, to any depth, without turning the soil down, or mixing the under strata with it. For the husbandman to see his land in a perfect state of tillage, from 10 to 15, and even 18 inches deep, and that without turning the soil down too deep, or mixing any of the under strata with it, but having all the manure and soil, or vegetable matter at or as near the top of the ground as he may find it best, is a subject which must be well pleasing to every interesting hus-

bandman, that wishes to fertilize his land in the most perfect manner.

SUMMER FALLOWS, must be the best preparation for a crop of wheat, except in very rich land, because a preceding crop will certainly exhaust the land, and render it less productive.

With a desire for the improvement of Agriculture, and the benefit of the patrons of the *American Farmer*, and its Editor, this is forwarded with great respect.

GIDEON DAVIS.

George Town, D. C. *Smo.* 23, 1823.

N. B. I think it right just to say, that I am much pleased with Charles E. Rowand's mode of Irrigation, and would take the liberty of differing with the Editor of the *American Farmer*, as to the draft being made easier by placing the hogshead on a pair of low wheels. If he will look at this subject again, he will soon see, that as this hogshead is to move over uneven and soft ground, that the higher the diameter of the circle on (or within) which it is drawn, the easier it will surmount the obstacles which impede its progress. I suppose that instead of rendering the draft easier, that addition would add 100 per cent. to it—and lest some might try the experiment, and be discouraged with it, on account of the draft, I have taken this liberty. I suppose that to roll the hogshead is the easiest manner in which that much weight could possibly be moved along.

G. D.

TO THE EDITOR OF THE AMERICAN FARMER.

Sir—The facility with which a wheel carriage is moved, all other circumstances being supposed to remain the same, is *directly* proportionable to the diameter of the wheels, and *inversely* as the depth to which they sink in the earth; but the depth to which they sink, is *inversely* as their breadth, or "tread," therefore, the facility of moving them will be as the diameter and breadth, conjointly.

In the machine for irrigating with salt water, the "felloes" supply the place of wheels, and therefore, to place the barrel on a carriage, with wheels, would only add to the weight and expense, unless the wheels were made larger and broader, than the "felloes" on the barrel; but these may be increased at pleasure: consequently, wheels are useless.

In soft ground, where the felloes would sink considerably, perhaps the best plan would be to connect them by strong staves, so as to form a complete cylinder round the barrel, at the distance of 3 or 4 inches from its surface. By this means, the machine instead of injuring the ground, might be highly beneficial, by supplying the place of a roller.

Respectfully your's,
JOHN D. CRAIG.

HORTICULTURAL.

PECULIAR CHINESE PEACHES.

The London Society for the encouragement of Gardening, (called the London *Horticultural Society*) has lately given an account of the flat peach of the Chinese, with a finely coloured engraving of the fruit; which has an open top like the English fruit called the medlar. It was imported into England in 1820. It appears, according to later accounts, to possess an excitability exceeding any that is to be found in peaches of other kinds; that is, its sap is put in motion by a much smaller increase of warmth. In 1821, its blossoms unfolded in January in a peach house, the glass lights (or windows) of which were all off; and the fruit set freely with the protection

only of a mat. In 1822, it blossomed in November, before the lights of the house was put on, and on January 3d, when the account of this was written, the peaches were as large as peas, with no more artificial heat than would just exclude the frost. It is also remarkable in this peach tree from China, that it retains its old leaves in full vigor, until after the new ones are put forth.

PERENNIAL CABBAGE—WINTER BEAN.

In the Duke of Bedford's garden, at Woburn, in Bedfordshire, they have a variety of cabbage, which yields cabbage yearly from the same root; and is thence called *perennial*. If the sort be good it might be advantageous perhaps to cultivate it here, on account of the frequent destruction of young cabbage plants from insects. Perhaps too this cabbage may be produced earlier; or may bear to have cuttings taken from it for early greens.

A Winter Bean, which is of the string kind, has lately been cultivated under this name in the north of Italy, and round Geneva in Switzerland. It is sown in the fall, and when cut off by the frost in the Spring, pushes out fresh shoots, and comes earlier into bearing, and is freer from accidents, than our common string beans.

Latterly the English have endeavoured, by peculiar management, to make the English Cranberry grow in dry beds; and probably they will succeed in their attempts. Should this happen, without much trouble, it will be easy to copy their practice in our gardens in the United States.

The industrious Mr. Osgood, of South Salem, is gathering in his currant vintage. He will make about 1000 gallons of wine this season.—His wine has sometimes sold, at the south, for three dollars a gallon.—*Salem Gazette.*

Norridgewock, (Maine,) August 4.

COFFEE.—There are now growing, in full bloom, in gardens in this town, a number of Coffee plants. The seeds from which these plants sprang, were raised in this place, the last season, from a seed which was accidentally found among some raisins. Seventy kernels were produced from one seed, last year, perfectly ripe; and we should judge that on a plant in the garden of Mr. Manly, there will be considerably over a hundred. The coffee ripens and comes to maturity in about the same time that Indian corn does. If one plant will come to maturity and yield in this manner, why will not any quantity?

OPIUM.

This is an article of general use and of great value, and every effort has been made to encourage its manufacture in England. The London Society of Arts has awarded a premium of thirty guineas to two persons, for preparing 143 lbs. of opium, from English poppies; and the success of the experiment warrants the conclusion, that if the article can be manufactured in a climate so moist and cool, we certainly have degrees of latitude in this country promising greater success. The article of opium, which is prepared in vast quantities in India, forms a profitable item in the commercial exports of that country. The *papaver album*, or white poppy, is cultivated in great abundance over the east, and grows in every section and variety of climate, excepting on the ridges and summit of mountains. A rich strong soil is required, and the plants should be well attended, and watered daily. The process of making the opium is simple:—After the flowering is finished, and the capsules have attained full size, an incision is made in them at sunset, for three or four evenings; the

milky juice, when suffered to run into vessels, soon concretes, and forms into cakes of a tough brown substance. This is opium. Chemists inform us, that it is a very compound substance, containing sulphat of lime, sulphat of potash, an oil, a resinous body, an extractive matter, gluten, mucilage, &c.

There are many plants in this country possessing narcotic qualities, but we doubt whether there are any from which the opium can be extracted of a quality equal to that from the poppy. The *sativa* or garden lettuce, yields a milky juice, from which a substance like opium can be made. The *atropa belladonna*, or deadly nightshade, is a remarkably narcotic plant; the *degitatio purpurea*, or fox glove; henbane, hemlock, stramonium, &c. &c. are equally narcotic; but the medicinal value of the opium may be safely calculated upon from the poppy only.

Good Turkey opium is \$8 per pound; and when we take into consideration the vast sums of money expended for that article, and for laudanum, it would justify an attempt to manufacture opium, by endeavoring to raise the poppy in several states in the union.

The dry heat of India, and the strong soil necessary for the poppy, may be found in Alabama, and some other states to the south and west.—We think the plant would thrive in Maryland and Virginia; at all events, we suggest the propriety of making the experiment in gardens and hot houses, and if the plant can be cultivated to any extent, it will be a great source of profit.

N. Y. Nat. Adv.

HYDROSTATIC PRESS.

A Hydrostatic press has recently been erected in Gardiner, (Maine) for the purpose of pressing hay for market. It was constructed by Mr. Kendall; and the forcing pump, which is of bell metal, was cast by Mr. Wing, both of Gardiner.—Mr. K. had no other information respecting the proper construction, but what was obtained from Kees' Encyclopedia. But his ingenuity has enabled him not only to construct so nice a machine, but to improve and greatly to simplify it. The operation and advantages of the press are thus described in the *Hallowell Gazette*.

The size of the press when the hay is first put into it is twenty-seven inches wide, by forty-two inches, and fourteen feet high. In this, the hay is first trodden down by foot, as close as possible; the follower is then forced down three feet three inches by a powerful lever, moved by a double pulley, and is firmly secured; the piston is then raised by the forcing pump eight feet two inches, which reduces the capacity of the box containing the hay to about twenty cubic feet. The hay is then bound with iron bands, made of nailrods; and is driven out of the press by a perpetual lever, working with a cogge joint, and moved by the water wheel. Wooden hoops of the best quality were tried at first for binding the hay, instead of nailrods; but they instantly broke. Only a few bundles have yet been pressed. They have weighed from six hundred and thirteen to eight hundred and fifty-four pounds according to the kind of hay that was used. An attempt was made to re-press one bundle in order to get it more compact, but as soon as the piston was lowered, it burst the iron bands, and proved that it was pressed sufficiently for practical purposes. If pressed more it would require much stronger hands; the expense of which would more than counterbalance the advantage gained by the greater compactness of the hay. When the bundles are taken out of the press, they gradually expand and stretch the bands, so that the next day, they will measure from twenty-three to twenty-

six cubic feet, according to the dryness and elasticity of the hay. From several experiment it is found, that the white pine timber of this country, partly seasoned, weighs about twenty-eight and an half pounds to the cubic foot. The heaviest bundle of hay when in the press weighed forty-two and a half pounds to the cubic foot, or fifty per cent heavier than pine timber, and when expanded, thirty-four pounds to the cubic foot, or twenty-five per cent heavier than pine timber. The safety valve has yet been loaded, so as only to give a purchase of two hundred and twenty-five tons, which is not two-thirds of the power of the press. It is therefore apparent how much closer hay might be pressed, if it would pay the additional expense.

The expense of the press, including the barn in which it is placed has exceeded three thousand dollars. The iron, of which great quantities were necessary to enable the press to resist the enormous pressure, forms the principal item in the expense.

In a country so peculiarly favorable to the raising of grass, hay must become a great article of export, when it can be compressed, so as completely to load a vessel without the necessity of using ballast; and when it is not liable to injury from exposure to the weather. Some persons have supposed, that the exportation of hay would injure the country, by depriving it of the manure, which would have been made, had the hay been consumed at home; but the farmer is as likely to injure his farm by raising and selling grain as hay; and when he finds a good and certain market for an article, so easily raised as hay, he will be induced to use plaster and other artificial manures, by which he may certainly double his crop; and while therefore he sells a portion of his crop, he will still retain more to be consumed on his farm, than he would have had but for the stimulus given to his exertion by the foreign demand.

E. RUCK'S Meadow Grass, or perpetual Ryegrass.

Any one desirous of laying down land for permanent grass, or for one, two, or more years, will find this grass answer the greatest expectation: it has been tried for many years, and in all parts of the kingdom, and has given great satisfaction. The price this year is 5s. per bushel, and 4s. per ten bushel bag. Will not sell less than twenty bushels: will not give more than two months credit. Any orders directed to E. Ruck, Down Ampney, near Cricklade, Wilts, will be immediately attended to.

N. B. Had orders last year for many hundred bushels that he could not supply, therefore begs those who intend having some, to apply immediately, and it might then be sent by water carriage, which is much the cheapest.

Will some one of our patriotic merchants impart some of the above seed?—*Edit. Am. Far.*

The following circumstances are stated in the *Discourse* recently delivered at Schenectady, by the Hon. De Witt Clinton:

"At this moment, a respectable mechanic of the city of London is collecting materials for writing our history. He is favorably noticed by distinguished members of Parliament; and although his mind has not been disciplined by regular education, yet its productions display vigour and cultivated powers."

Lord Kennedy has gained his bet, (we believe of 1,500 guineas,) that he would ride 150 miles, walk ten miles, shoot forty brace of grouse, and

walk ten miles back, all in twenty-four hours; which he performed in twenty-one hours; and shot forty-nine brace, being nine brace more than his number, and in three hours less time.

Monday afternoon, in the vicinity of Melkham, Spa, Mr. Charles Newcomb, of Bath, undertook, for a considerable wager, to run nine miles and a half within the hour, which, notwithstanding the dust and extreme heat, he accomplished in a masterly style 1½ minute within the time.

THE FARMER.

BALTIMORE, FRIDAY, AUGUST 29, 1823.

There are on our files, a dozen or more of "ADDRESSES," to Agricultural Societies—to the kindness of the friends who have forwarded them, the Editor is much indebted, and he takes this occasion to solicit from his subscribers generally, the favour of being furnished with such of these productions, as may be offered or published in various parts of the United States—at the same time it is proper to explain, that in few cases can they be published *in extenso*, for reasons which, if not hitherto stated, must be obvious to all. But we shall take much pleasure, as we can get time, in overlooking and extracting for the *Farmer*, such parts, of which there are many in all of these addresses, as contain suggestions of a novel and generally interesting character.

ICE AND ICE HOUSES.

The editor of the American Farmer has been requested by several correspondents, to collect and communicate through his Journal, information as to the construction of Ice Houses.—The following is a copy of his letter to one of these friends, and as the subject is one of general interest, it is here inserted for the perusal of his subscribers:

On this subject there can be no doubt that the *cheapest and simplest* construction is the best.—In the philosophical transactions it is stated, that in Italy, great use is made of chaff to preserve ice—that the ice house for this purpose need only be a *deep hole*, dug in the ground on the side of a hill, from the bottom of which they can easily carry out a drain to let out the water which is separated at any time from the ice, that it may not melt and spoil the rest. If the ground is tolerably dry, they do not line the sides with any thing, but leave them naked, and only make a thatch roof over the top of the whole; this pit they fill either with pure snow or ice from the purest water, because in Italy they do not use ice, as we do, to set the bottles in, but really mix it with their wine. They first cover the bottom of the whole with chaff or straw, and then lay in the ice, not letting it any where touch the sides, but ramming in a large bed of chaff all the way up between the ice and the earth.—They thus carry on the filling to the top, and then cover the whole surface with chaff; and in this manner it will keep as long as is desired.—There is no doubt that even this simple plan would answer in many situations, especially where the soil is firm and dry and the situation elevated—but, on the score of simplicity and cheapness, there can be no reasonable difficulty with any farmer, who is not restrained by slyard indolence, from enjoying, through the whole summer, one of the greatest luxuries, or rather, one of the most indispensable comforts, that can be imagined.—For it is well ascertained, that nothing more is necessary to the preservation of abundant ice, for all the uses of a large family, than to sink in the ground a *common log house*—such for example, as is generally built for negroes.—A simple pen of unhewed logs, ten or twelve feet square, sunk about eight or ten feet below the surface, with a taunt roof, covered with dirt, or with a *thick straw* thatching, is all sufficient. The chief object is to keep the ice *dry*, and to *exclude the sun and rain*—for this purpose, make a small pit in the centre of the bottom of the ice house, to receive the drippings from the ice, and cover it with logs and straw—or rather, the whole bottom of the house must be covered with logs and straw, before the ice is thrown in. Stuff in straw between the ice and the sides of the house as it is filled, and then a thick covering of straw over the whole—whenever ice is taken out, the straw is thrown aside, to come at it, and then thrown back again when the quantity of ice required has been obtained. This we believe, from all our enquiries and personal observation, and from all we have seen in print on the subject, is the whole secret of keeping ice—and we have been truly astonished, that so few farmers will take the trouble to procure for themselves and their families, a convenience so indispensable to comfortable living, during five months of the year—seeing that the house may be provided at little more expense than is incurred in sinking a pair of gate posts, and with no more skill than is exercised in the building of a good poultry house.—Some excuse themselves for their indolence, by saying that there is little occasion for ice, and even that the use of it is unhealthy—and yet put the pleasure of ice in their way in the month of August, and these

very gentlemen will be the first to have recourse to it.—Is it no pleasure to have your milk—butter—melons—your cider—your liquors—your drinking water—all kept cool by ice?—Is it no advantage to have an ice house, where lamb or veal, or other fresh meats may be kept, and improved by keeping, for a week—or more?

Let the gentleman of the house take his people, and in less than one week complete his ice house, and fill it with ice, and we will stipulate to pay all the expense, if the Lady of the house does not find abundant occasion for, and infinite pleasure and comfort in using the contents; and we will warrant that he will not forego the many nice things prepared by means of the ice—for fear of injuring his health—where an ice house is provided, instead of sending, as is the custom in many parts of the country, a little negro with a wooden pail a thousand times a day to the spring, and after all having your water warm and impure, let a barrel be put under the spout the night before, and placed in the ice house in the morning, and when water is wanting, a large *STONE JUG* or *PITCHER* may be filled and set in a tub of ice, in one corner of the room, and then there will be some satisfaction in drinking *pure cool water*; and less excuse or occasion to correct any ill taste, by the addition of *ardent spirits*.

To procure the ice, nothing more is necessary than a stream of water, as thick as one's wrist; select some spot, where by means of a small dam, the water may be made to overflow a large space, and if the pond be not more than six inches deep, you will soon have an abundant supply, according to the extent of ground covered by the water—when the ice is thrown into the house, have it, with rammers, broken tolerably fine, and finally well covered with straw—it may be well for sake of ventilation, to let the roof overjet the leaves, which may then be left open all round—suppose the pit to be dug eight or ten feet deep, the dirt thrown out will raise the body of the house two or three feet above the ground.

We have thus hastily sketched, what we know to be the simple principles for constructing ice houses, but in some early number, we may publish from some of our books, what Boardley and others have said from experience. It will be found to agree essentially with what we have stated. In the mean time, let the farmer, who would avoid the reputation of a sluggard, who deserves and likes to enjoy the cheap and essential comforts of gentlemanly living; send Ned or Dick to cut and cart in the logs; for all the materials should be on the spot before the pit is dug, and by that time, if any further information is requisite, we engage to place it in his hands.—He shall have no excuse on that head.*

† Please sir hand this to the lady of the house, that she may know at how little expense and trouble, she might treat her friends to iced-cream, and give them their strawberries and cream, as cold as ice.

* In our ideas of knowledge, we profess to resemble rich men in their notions of competency, that is, that enough always means a little more—so we shall thank any of our readers for an essay on ICE HOUSES, and there are many who can speak experimentally.

† You see I take it for granted, that you keep up in your garden a succession of beds of fine strawberries—as I know it may be done with labour, not exceeding that of one man for two or three days in a whole year.

‡ We are frequently asked to give our private impressions about live stock, implements, machinery, &c.—It will therefore save trouble to

all parties, and *time*, which to us is very precious, to state once for all, that all the information we get, which is worthy of being made known, we make publick through the Farmer; to that we must refer those interested, and from what is there found, every one can make up his own opinion.—It is our province to communicate *impartially*, the *pro* and the *con*; in reference to Short Horns, Herefords, Long Horns, Devons, Merinos, Dishleys, Broad Tails, Straw Cutters and Ploughs of every body's importation, make and invention, leaving others to decide on their relative merits.

BALTIMORE MARKET.

PRICES CURRENT—CORRECTED WEEKLY.
Flour, best white wheat, \$7—Howard street, from wagons, \$6 37½—Superfine, \$6 50—fine do, \$6 25—Wharf, do, \$6 12½—White wheat, \$1 17 to 1 20—Red do, \$1 10 to \$1 15—Rye, 45 cents—Corn, 41 cents—country Oats, 28 cents—Beef, 8 cents per lb.—Live Cattle, \$6 to \$6 50 per cwt.—Bacon, hog round, \$10—Pork, \$4 50 to 5 50 per c. lb.—6 to 8 cts. per pound—Mutton, 5 to 6 cts. per lb.—Beans, \$1 37½ to 1 50—Peas, black eyed, 55 to 60 cts.—Red Clover Seed, \$6—Orchard Grass do, \$3—Herds' Grass do, \$3—Timothy do, \$4 50—Millet, \$1 50—Flax Seed, 75 to 80 cts.—Whiskey, from the wagons, 35 to 36 cts. per gal. including the barrel—Apple brandy, 30 to 32 cts.—Peach do, 65 to 70 cts.—Shad, \$6 00.—Herrings, No. 1, \$2 70 per bbl.—No. 2, \$2 37½—Fine salt, 60 to 65 cts. per bush.—Coarse, do, 70—Butter, (firkin) 14 cts. per lb.—Eggs, 10 cts. per doz.—New Hay, \$14 to \$15 per ton—Old do, \$18—Straw, do, none.

MARYLAND TOBACCO.—Extra Fine Yellow, 28 to \$35, scarce, wanted—Fine, do, 18 to \$25, do. do.—Fine Spangled, 12 to \$20, do. do.—Fine Red, 6 to \$10—good do, 4 to 6, plenty, no demand—common, 2 to 4, do. do.—Seconds, 1½ to 2.

Sales.—6 hogsheads—5 First, and 1 Second, Extra Fine Yellow, raised by Thomas Davis, Esq., of Montgomery county, sold by the single hogshead—1 at \$30½—1 at \$31½—1 at \$32—1 at \$32½—1 at \$24—1 at 12, Second.

Seed Wheat.

The Subscriber has just received upwards of 100 bushels of WHITE WHEAT, (blue stemmed,) free from garlic, &c. Having sowed some of this kind of Seed this summer, I think I can now offer the above mentioned parcel, for sale, as a very superior quality.

ALSO,

100 bushels of good clean Seed Rye.
100 bushels of Timothy Seed, of this year's production.
100 bushels of Orchard Grass and Garden Seeds.

On hand as usual.—A general assortment of Agricultural Implements; consisting of all kinds and sizes of Ploughs; self-feeding Straw Cutters, Superior Wheat Fans, such as were so highly recommended at the last Cattle Show in this state; Corn Shellers, and many other articles of husbandry, too numerous to mention.

Also, WOVEN WIRE.
All the above described seeds and implements, &c. will be sold on very reasonable terms, for cash.

ROBERT SINCLAIR.

No. 1, Ellicott-street, Pratt-street wharf.

Printed every Friday at \$4 per annum, for JOHN S. SKINNER, Editor, and JOSEPH ROBINSON, on the North West corner of Market and Belvidere streets, Baltimore; where every description of Book and Job Printing is executed with neatness and dispatch—Orders from a distance for PRINTING or BINDING, with proper directions promptly attended to, addressed to J. Robinson, Baltimore.

AGRICULTURE.

From Memoirs of the Board of Agriculture of the State of New York.

LETTER

TO THE HONOURABLE STEPHEN VAN RENSELLAER, PRESIDENT OF THE BOARD OF AGRICULTURE, UPON SHEEP HUSBANDRY, AND THE CULTIVATION AND USE OF TURNIPS.
(Concluded from our last.)

These preceding observations upon sheep husbandry, will appropriately introduce some account of the cultivation of turnips, and the uses to which they ought to be put, including the method of preserving them during winter from the frost, the winters being altogether too rigorous to admit of their being left in the open ground in this part of the state. And as many persons who have received rape with other seeds from the Board of Agriculture have informed me that they succeeded perfectly in raising fine plants, yet from being unaccustomed to it, were apprehensive they had not put it to the most profitable uses, I shall, in the hope it may gratify some of the numerous persons who have applied to me, give a brief sketch of what I consider a profitable course for sheep husbandry, of which rape and turnips will form the principal articles of cultivation.

The important business of lambing being well got through with, and the grass nicely up, the sheep are taken to their summer pastures. It being supposed that these are sufficiently extensive, I shall only consider the agricultural part necessary for rape and turnips.

Fifteen acres of land will be a sufficient appropriation for a flock of five hundred sheep, and less in proportion.

Of these we will suppose five acres for rape, and ten acres for turnips, all brought into a good mellow state the preceding fall. Rape being of the cabbage kind, will do to sow very early. The ground being manured with from ten to twenty loads to the acre, well ploughed in, the rape may be sown either broadcast or in rows with a drill, or the plants may be first raised as cabbage plants are, and transplanted. A quart will sow an acre broadcast. If sown in rows, less will do, and I prefer and practice the row culture both in rape and turnips, as the land is more easily brought into a clean state. The rows eighteen inches apart will do, and the plants a foot apart. It will be found most convenient to get it in by degrees, one acre about the end of April, or as soon as the ground is dry and warm. Another in the middle of May, another at the end, and the rest in the early part of June; the latest sown of these may be fed off in time to sow winter wheat on the ground.

Rape is a remarkable oily plant, and sheep, which are sometimes rather shy of it at first, soon become voraciously fond of it, and fatten quicker than upon any other vegetable. Where the winters are sufficiently temperate, it is common to feed down the plant with sheep, and let it produce seed the next year, which is subsequently converted into rape oil.

As soon as the rape has become a stately plant, with abundance of large broad green leaves, it may be turned in upon; the first crops may be fed down with store sheep, such as aged ewes, or wethers intended to fatten and dispose of before winter; and it is considered more economical to set off a small part of the crop at a time, with huroles or nets, and turn the sheep in, rather than to let them ramble through the whole.

But as profitable a way as now, in which rape can be used, is, I think, that of turning the ewe

lambs in, intended to keep as future breeders, as soon as ever they are weaned, and on my farm the weaning invariably takes place, early in August. This gives them that seasonable start which ensures their continual growth, and that early maturity so important in sheep husbandry. When the weaning takes place, the aged ewes which have bred that year, may be profitably turned upon rape, where they will be sure to get fat. In short, where there is plenty of rape, sheep are sure to go into the winter in excellent condition; which condition, if it is subsequently kept up with turnips, the flock is sure to pay the owner well the succeeding year. Upon ground so well manured, there need be no apprehension of the future crop if the season is favorable. If the rape is all fed off in season for sowing winter wheat, the most sanguine expectations may be entertained of a great crop; and if a spring crop is more convenient, barley may be advantageously substituted; and both with a very shallow ploughing, to keep the manure within reach of the roots of the future plants. This is merely taking a lesson from nature, whereas in the case of new land, we see heavy crops produced by the vegetable mould on the surface.

I shall close this account of rape, with observing, that plants fed down seldom survive the next winter with us, and go to seed; and as it is important always to have successive supplies of seed, I have been obliged, to ensure them, to sow a small quantity in a warm place, and not feed them at all, but let them go to seed the next year in the situation where they grew.

The remaining ten acres appropriated for turnips, may be cultivated in the following mode, which I have adhered to for many years, with uniform success. I should propose seven acres to be sown with white Norfolk turnips, of the Globe and Tankard kind, and three acres with Swedish turnips, or Ruta Baga. The white turnips begin to vegetate rapidly on the approach of spring, and are consequently pithy in the inside; they should therefore be fed off first. The Swedes keep sound into the summer months, and are in season to be profitably fed out when the whites are finished.

The ground being placed in a mellow state, should be well manured with twenty to twenty-five loads of manure, spread very evenly on the surface, covering every part of it, and ploughed in about the 12th of June. After this it is to be harrowed well down, and then ploughed into small ridges about thirty inches apart, and certainly not wider than three feet. Some persons plough the ground in this manner before manuring, and then when the manure is evenly spread on the surface, rake it into the furrows, and then convert them into ridges covering the manure. Swedish turnips exhaust a great deal of manure, and by this method it will expend further, which is an object where manure is scarce; but as I have never been pinched in that valuable article, and have looked to an evenness in the succeeding crops, I have always preferred to spread the manure before making the ridges, and to cover every part of the land to a palm of the hand with it. On the 15th of June my seeds were sown this year after these previous steps, with a drill barrow, moderately thick. As soon as the turnips were in the rough leaf, I had them separated by expert hands with hoes to about the distance of eight inches apart, killing at the same time all the weeds on the tops of the ridges. When the turnips have become well fixed again, for many must be loosened in this operation, and the sides of these ridges are covered with weeds, we introduce a small plough, and take a slice from both sides of every ridge, close to the turnips: these slices of course fall into the

furrow, carrying the weeds which grew on their sides. A day or two after, in dry weather, another plough with a double mould board is introduced into the furrow, and sweeps back the mould to its place. This operation may be repeated as often as weeds appear; but if it is effectually done once, it will not be wanted again; though a repetition will do the crop no harm: the more the soil is pulverised, the more easily the fibres of the roots can multiply and extend themselves in search of food, and eventually carry more nourishment to the bulb.

About the 15th of July the white turnips may be sown, and treated in every circumstance from the beginning to the end as I have directed for the Swedes. Nothing can look more beautiful and fresh in the months of October and November, when grass is upon the decline, than fields of turnips with their ample, green and flourishing tops. Nor can any crop be more valuable than the turnips themselves. It is almost incredible the quantity which, in a favorable season, may be grown on an acre. I have within the last ten years had some crops so very productive, that I have found it difficult to persuade some of my farming friends that so many turnips could grow on an acre. Being determined upon some favorable occasion to put this to a rigorous test, I judged at the commencement of the autumn that the present season would afford me a proper opportunity. We had taken great pains with our turnip crops. Two fields of nine acres, half Swedes, half whites, had been in a most flourishing state, and would have surpassed every expectation, but for a pinching drought of four weeks, which kept them stationary. Towards autumn they revived under the rains, and accordingly I requested two gentlemen from the city of Schenectady, entirely disinterested in the matter, to do me the favor to call and make an estimate of the quantity on an acre of the respective kinds. This they were obliging enough to do, but as it was not convenient to draw them all in one day, and they had (it being the 7th of October) a month or six weeks of the best of their time to grow, they took the trouble to ascertain by themselves, in the only then practicable manner, the quantity. The certificate which they gave me, and which was read at the proceedings of our annual fair, I subjoin, as it will explain the result.

I certify, that this 7th day of October, 1822, I surveyed upon the farm of G. W. Featherstonhaugh, in Duaneburgh, two separate acres of turnips, each out of a distinct field of four and a half acres of turnips.

Signed,
JAMES FROST, Surveyor.

We the subscribers did upon this 7th day of October 1822, inspect upon the farm of G. W. Featherstonhaugh, one acre of Swedish turnips, and one acre of White Globe turnips, which had been this day surveyed by Mr. Frost, out of two separate turnip fields of four and a half acres each. The turnips being at the height of vegetation, and having perhaps four or six weeks to grow, the following method of computation was adopted. The number of turnips in each acre was ascertained, and turnips of various sizes drawn, weighed and averaged.

The acre of Swedish turnips had 15,925 turnips, and amounted to one thousand and ninety-six bushels.

The acre of White Globe turnips, had 16,000 turnips, and amounted to eleven hundred and forty-three bushels.

We further certify, that both the fields were a very even crop, and had withstood a severe drought.

Signed,
THOMAS POWELL,
JOEL B. NOTT.

Many of the turnips weighed ten and twelve pounds, nor is this crop very extraordinary, when we remember that there are authenticated accounts of upwards of two thousand bushels being raised to the acre in Great Britain.

As it may be interesting to many to know the method adopted to secure so great a quantity of turnips, I shall relate it.

We began on the 8th of November to draw them from the ground, but as this was an operation which would have occupied all the hands on the farm, a month of fine weather, which we had no right to expect; I sent round to my neighbours who had not raised any turnips, with proposals to give them entertainment for the day, and two bushels to each man for their labour; directing them on what particular days to come. Some days we had twenty people, and some less. In one week we had them all secured in the following manner: Six men were directed to take each a row, draw the turnips, strike off the long thin tap-root and the soil with it, with a knife made out of old scythes, and throw them into one row, with their bottoms to the ground, and keeping their tops as free from dirt as possible. When a sufficient quantity was drawn for the day, the parties of six men went back to their drawn rows, took up the turnips, and struck off the leafy tops into small convenient heaps, dropping the bulbs on the ground, which were taken up and carried in carts and sleds to cellars near the sheep-folds, containing about five hundred bushels each. When these were full, long square pits were prepared on dry knolls in the fields, about a foot deep, and the turnips piled up in each to the number perhaps of three hundred bushels. Straw was put over them, and subsequently a foot deep of earth, making this covering somewhat thicker to the northwest. This by experience I know to be a sufficient covering, having taken them out perfectly sound in the month of May. The tops were fed out constantly to the horned cattle as long as they lasted. The handsomest turnips with the smallest necks and tops were selected for seed without cutting the roots, and only a part of the tops, and then secured by themselves. These are planted out in dry, mellow and rich ground, on the first opening of the spring, a foot apart, and hoed and kept perfectly clean. The seed when ripe is gathered early in the morning, whilst the dew is on the pods, and before they split open. I have preferred to give this detailed account of the cultivation and preservation of this valuable root, that persons who choose to follow my method, may not, in the event of failure, lay the blame upon the description's being too general, as is frequently done. To ensure perfect success, one part of the process is as essential as the other; and negligence in any stage of it is almost fatal: if at the beginning, they won't grow: if at the end, they will all be lost. We begin to use them immediately, feeding them amply to fatten cattle, and to the calves raised the same season. Cattle fatten rapidly upon them, and make better beef than upon oil cake, it being usually rather rancid when made upon this last article. And calves which are easily taught to eat them, by tempting them with small pieces at first, soon become very fond of them; and if fed abundantly with them, will hold their condition, and continue to grow the whole winter, which ensures the desirable point of early maturity. Turnips also are a very convenient food to give to animals during the winter months in another point of view, as they scarce ever wish to drink, if they have plenty of turnips. Cows, if kept indoors the whole winter on turnips, will never want water. The Swedish turnips are so sweet and nourishing, that horses will live upon them, and store hogs will want nothing else.

But the especial use for which such large quantities are destined, is the sheep yards during the winter months. This feeding time will average, where I reside, 135 days.

These yards being all comfortably arranged, and protected sufficiently from storms, with ample sheds for the sheep to sleep under, and the hay-stacks and the turnip-cellars conveniently at hand, the breeding ewes and ewe lambs are divided into companies of not exceeding 150, and reduced in number when the former begin to grow heavy. Turnips are fed abundantly out to them in the yards every day, whole, which is no inconvenience to strong young sheep that have got all their teeth. In consequence of the sheep being kept in this fine condition, I am enabled to commence my lambing towards the end of February, which continues perhaps for a month. The ewes have abundance of milk, and raise their lambs as well as if they were dropped in May. The start which the lambs thus get is an advantage to them for life. When common lambs dropped in May, are saleable to the butcher, weighing perhaps 6 lbs. the quarter, the others will weigh from 10 to 15 lbs. and are become heavy sheep, whilst the others are getting a protracted growth. The consequence is particularly obvious with the ewe lambs, which, when 18 months forward, are stately animals, in the best condition for breeding. A general opinion prevails that it is very hazardous to have great numbers of lambs dropped so very early. We do not consider it so. Ewes kept so comfortable, and in such high condition, have plenty of milk and bring strong lambs. It is true, an essential part of the system is, to have a shepherd with an assistant during the lambing time, alternately up every night to assist those which are in any difficulty, particularly ewes with their first lamb. When the nose of the lamb is well out with the fore feet, they frequently struggle in this situation until exhausted, and the lamb is lost. On this account 25 per cent. loss is usually allowed with young sheep in estimates, about lambing: but a well brought up shepherd does his duty cheerfully, by night as well as by day; and when he perceives a ewe in that critical situation, lays her with care on her back, extricates gently one leg to the full extent, then the other; and taking both in one hand, draws the lamb steadily out, and lays it before its dam. By pursuing precisely every circumstance as I have here stated it, connected with the sheep, from the setting in of the winter through the lambing time, I was so fortunate as only to lose six lambs out of 236 young ewes of my Dishley and Merino breed this last lambing time.

The same attention in regard to feeding is paid to the ewe lambs, from the setting in of the winter. They have the finest young clover hay, cut when in blossom, given to them, and as many turnips as they will eat. The other yards containing the rams, the fattening wethers, and wether lambs, are all served with abundance of food. The most essential part of the whole of this system is to give them as much as they will eat.

How great the difference to individuals as well as to the country, betwixt a careful husbandry of this sort, and the usual practice prevailing all over the state with the common sheep of the country, facts speak loudly enough. On the one hand a flock of 100 sheep will bring at shearing time, 700 lbs. of wool to market, and the sheep in such condition, that if fodder is scarce, or the owner wishes to part with them, they are all good mutton, and promptly saleable at the highest prices.

On the other hand, a flock of 100 common sheep will perhaps bring 250 lbs. of wool to market; and if fodder is scarce, and conse-

quently dear, the owner must either expend more money to keep them during the winter, than they will be worth in the spring, or sell them in the fall for what they will fetch, at perhaps a dollar a head.

Besides all the other great considerations, connected with the substantial improvement in husbandry, and every other branch of a farmer's care, which belongs to a good system. The consequent prosperity of individuals—the increased wealth and power of the country, and the inestimable satisfaction of having things done as they ought to be done.

In offering these imperfect observations to the public, it has been by no means my intention to discourage the breeding of pure Merino sheep. I am satisfied they do not degenerate here. The main difference which I have endeavoured to shew betwixt them and the mixed Dishley and Merino is, that to farmers who reside within the reach of the great markets of the state, they are not the sheep "that will raise the most money in the shortest time;" and this ought to be number one of every farmer's considerations. But if I resided in a very remote part of the state, where there was no market for carcass, I would confine my cares to Merinos, and would bend all my attention to improving their fleeces, both as to weight and fineness. For the Merino sheep have a great intrinsic value in such a situation, and will, I think, be more profitable than any other branch of husbandry.

The time appears to be approaching, when this frugal and wise government may be induced somewhat to change its policy. A constant surplus of revenue will open a safe road to the gradual encouragement of manufactures in wool, and which the increasing wealth and skill of the country seems to call for. A moderate aid to manufactures would probably produce great effects. A prompt home market for wool would be created: a great impulse would be given to sheep husbandry, and to the inseparable improvements in agriculture. There would be a steady demand for the finest as well as the coarsest wools, and the agriculturist would soon become independent and contented in every part of the state, wherein is comprehended every blessing that wise men desire.

At the conclusion of this letter, permit me to say, that if in thus freely imparting the result of my experience, I should be so unfortunate as to draw forth unfriendly observations, that I have been governed by considerations of self-interest, in speaking so highly of a breed of sheep brought forwards by myself; I must rest my justification with liberal minds, who have fairly examined the whole scope of the subject. If I have rendered it sufficiently plausible to attract public attention still more to the breed, at least I have enabled others to enter into competition with me, and have only thus reserved to myself that share of prosperity which is to arise from my own exertions. I desire nothing more; convinced that individual as well as public interest is best promoted by a spirited competition for excellence in every thing. I am assured however that you will give a proper interpretation to my motives, and have a true satisfaction in subscribing myself,

Sir,

Your faithful ob't servant,

G. W. FEATHERSTONHAUGH.

Duanesburg, State of New-York, Nov. 1822.

* The state of New-York does not clip perhaps more than three million pounds of wool. Some of the counties in England clip 20 millions of pounds. An encouragement to manufactures would, I think, in ten years enable this state annually to clip 50 million of pounds.

COMMUNICATED FOR INSERTION IN THE AMERICAN FARMER.

Report of the Committee, appointed by the South Carolina Agricultural Society, to consider what beneficial effects would result to the Agricultural interests of the State, by importing Foreign Seeds, Plants and Implements of Husbandry.

The Committee, appointed to consider what beneficial effects would result to the Agricultural interests of the State, by importing FOREIGN SEEDS, PLANTS AND IMPLEMENTS OF HUSBANDRY:—

REPORT, that, in their opinion, the situation and circumstances of the Agricultural concerns of the State, render it very probable, that the introduction of foreign seeds and plants, judiciously selected, may prove highly advantageous: for, when we reflect, that the sources of our Agricultural prosperity, as it relates to our exports, are the result of the importation of foreign seeds, an inference may be fairly drawn, that a continuance of the practice will prove beneficial.—When our fore-fathers emigrated to this country, they found it inhabited by nations of hunters, who, subsisting by the chase, paid little attention to Agriculture: and, it is believed, that Maize is the only vegetable production of great value which they found established here. They had emigrated from a country, whose climate, unfortunately, differed so materially from that of their new abode, that the seeds and culture adapted to the former, could not succeed in the latter; and it is probable, that had it not been for the invaluable article of Maize, they could not have subsisted. The efforts of infant colonies, must, necessarily, at first, be confined, merely to subsistence; but this toilsome condition may fairly be presumed to have been prolonged in this country, by the want of an early supply of seeds adapted to the climate: for it was nearly thirty years from the first settlement of Charleston, before we find any considerable exportation of the produce of the fields. Fortunately, about the close of the seventeenth century, a small quantity of Seed Rice, (said to have been intended as food for the sea stock of a vessel from Africa,) was landed in Charleston; this was successfully cultivated, and within a few years, the export of Rice had reached to an important amount. It is also worthy of remark that we owe, not only the original acquisition of this valuable staple to the importation of the seed, but the improved variety of it, now generally cultivated, is derived from the same source; it being understood that the late Col. HENRY LAURENS imported a small quantity of what is called the Gold-seed Rice, soon after the revolutionary war, which was found to be so far superior to the white-hulled Rice before cultivated, that the latter is now scarcely to be met with. The culture of the Indigo plant, which for many years proved a fund of great riches to the State, was introduced by similar means: A lady, who was a native of the West Indies, married in this State, having observed the advantages derived from this plant in her native country, imported thence a small quantity of the seed, and distributed it by the thimble full to persons willing to attempt its establishment here. In a few years a great proportion of the fields in the middle and lower sections of our country were covered with Indigo.

The still more valuable staple of Cotton, is also of foreign origin; some of it was introduced and used for domestic purposes, anterior to our Revolution; but the improved varieties, such as the Sea-Island, the Mexican, &c. are derived from the intelligent enterprise of individuals,

who imported their seed: but, to whom we are thus indebted, your Committee are not certainly informed. Considering, then, how considerable a portion of mankind is clothed and nourished by our two great staple commodities, it can scarcely be doubted that they may be improved by well directed efforts to obtain the best seed from congenial climates. For, though it may be admitted, that our Cotton is already superior to most of what is carried to the European market, still, it is probable, that in the widely extended regions which furnish their principle clothing to such an immense population, some species of the plant may exist, which would prove a valuable addition to our present stock, but which is now prevented from entering into competition with ours, by the dearth of Agricultural skill, the want of proper machines for preparing it for market; the absence of commercial enterprise to find a vent for it; or impolitic regulations of government, discouraging its culture or its export.

The same may be observed with respect to Rice. It is upon the Journals of this Society, that some years ago, seventy different sorts of rice, cultivated in the Ladrone Islands, were brought from Manilla, by an English vessel, and presented to the Society by Mr. H. M. BIRD, of London: the parcel was but small, and a few grains only of each sort could be distributed to the members, unfortunately none of them germinated, probably occasioned by its being too old: for, it is a remarkable property in Rice, that, although, almost imperishable as food, and though growing freely after being deeply buried many years in the ground, yet, when exposed to the influence of the atmosphere, its germinating quality can scarcely be preserved beyond the year. A list of the different sorts of Rice from Manilla, describing the qualities of each, accompanied the above mentioned parcel; but though only about seventy sorts reached the Society, the list gave an account of no less than one hundred and ten. It can, therefore, be scarcely doubted that of so great a number, some of them may possess qualities which would make them valuable additions to this branch of our culture.

If then, sufficient reasons have been adduced, founded principally on the experience of this country, to prove that the introduction of foreign seeds may occasion some improvement in our present staple commodities, a similar course of reasoning will show that the introduction of new objects of culture may likewise much benefit our rural concerns: for, it is certain that the change from wheat and the other grains of the North of Europe, which our ancestors brought with them, to the culture of Rice, first made us an Agricultural exporting country; and the adoption of Cotton instead of Indigo, no longer profitable, saved a numerous and respectable class of our citizens from ruin, and diffused riches into every section of the State. And do not the late low prices for the products of our land; the disease to which the most valuable of them has lately been subject; and the danger of its production greatly exceeding the demand, point to the propriety of endeavouring in time, to provide, a *succedaneum* should it unfortunately fail.

It is also fairly to be presumed, that by this measure, valuable additions may be made of roots and grain, to our present stock of articles, cultivated as provisions and merely for domestic consumption.

Your Committee, therefore, having investigated the situation of the funds of the society, recommend the following RESOLUTIONS:

1. That the sum of two hundred dollars be an-

nually appropriated to the purchase and importation of foreign seeds and plants.

2. That a Committee to consist of three members, be appointed; to be denominated the *Importing Committee*; whose business it shall be to import such seeds and plants as may be designated by the Society, or, for want of such direction, as they may deem calculated to improve the Agricultural interests of the State: and that, for this purpose, they shall correspond with the Consuls of the United States, and such other persons as they may think proper, in countries not differing in a considerable degree in climate and situation from our own, where valuable articles are the product of the soil. And, as your Committee have observed, with pleasure and with pride, that the officers of our Navy, not confining their patriotic exertions, to elevating the glory of our country and protecting its commerce and its coasts, have, with intelligent zeal added to its Agricultural prosperity, by the introduction of various valuable animals and plants; it is recommended, that the Importing Committee should, through the proper channel, communicate to the Naval Department, the views of the Society; respectfully soliciting their aid in carrying them into effect. It is likewise recommended that the Committee shall select from the publications containing them, or obtain elsewhere, the best mode of *packing and preserving the Seed*, a copy whereof shall accompany the orders for their importation; directing, in general, that they shall be forwarded so as to arrive in this country, and be sown, within a twelvemonth from the time, when they were gathered; but where this cannot be effected, advising the most efficient mode to be adopted for their preservation, particularly in guarding them against the influence of the atmosphere.

It is also important, that, with the Seeds or Plants which they may obtain, the Committee should endeavour to procure accounts of the mode of culture and soil best adapted to them, and information of the time they occupy in coming to maturity. And, as we cannot rely on an exemption of more than eight months from frost, it is deemed advisable that no annuals liable to be injured thereby, should be imported, provided it requires more than that period to arrive at maturity.

3. That the Seed, when imported, shall be distributed *gratis* to the members of the Society, and portions of it presented to our sister Societies in the State, and to any other individual to whose skill and intelligence the Society may wish to intrust them; requesting, in all cases, that the result of their trial shall be communicated to the Society.

Your Committee, being informed of the approaching departure from the State, of a fellow-citizen, distinguished by his patriotic exertions to improve our internal resources; so extensive a traveller, and endowed with such useful acquisitions, that, to liberate his countrymen, captured among the inhabitants of Chili, he availed himself of the military science, which he had studied in a campaign against their antipodes, the Persians; and, believing that it would accord with the views of the Society to obtain such information, as he could impart, application was made to him for this purpose; the result of his enlightened observations was cheerfully communicated, and is herewith presented to the Society.

Your Committee have also deliberated on the propriety of importing *Instruments of Agriculture*; but they are of opinion that it would be far beyond the resources of the Society to import them for distribution, even among the mem-

bers of the Society, and that it is not important to introduce them as models, because various recent and accessible publications, and particularly that valuable work the *American Farmer*, contains drawings and descriptions of all modern improvements which deserve notice.

They, therefore, recommend that this subject be referred to the *Committee on Premiums*, to consider of the propriety of encouraging, thereby, the introduction and use of the best *Implements of Husbandry*.

Charleston, July 15th, 1823.

LETTER.
CHARLESTON, 1st July, 1823.

DEAR SIR,

I have this instant received your letter of the 30th ult. informing me of the Resolutions, adopted by the *Agricultural Society*, at their last meeting.

My attention has not been very much turned to the subject of Agriculture, but it will afford me great satisfaction to promote the views of the Society, by imparting to you the limited information I possess, on the subject of the Plants, which might be introduced into this state. Many useful plants have been introduced into Europe from New-Zealand, among them is the *Phormium Tenax*, which has been successfully cultivated in the South of France; a few of the plants were sent to me, and I believe Noisette has succeeded in rearing them. The fibre is nearly as fine as the ordinary flax, and nearly as long as that of hemp. An attempt is now making by the Commissioners of our Navy, to substitute the use of flax for that of hemp for the sails of our ships of war, as being more durable and much lighter than Russia sail cloth; for this purpose, the manufacture of New-Zealand Flax would answer admirably; it succeeds in low, rich grounds, and might be cultivated in rice swamps.

When last in France, in 1821, I saw all the oleaginous grains cultivated very extensively, and was informed that it was the most profitable branch of Agriculture. The seeds there used, are the *pophy* and *colzat*. The oil of these seeds when perfectly fresh, is used as a mean substitute for olive oil; and the *colzat* and *pophy* oil, are preferred for burning in house lamps, as being more pure and inodorous than fish oil. These oils are sold at the low price of five francs a gallon. It has appeared to me, that the Planters, who have attempted to make oils from the *Sesame* and *Palma Christi*, have failed, because they did not cultivate it in such quantities, as to be able to sell the oils wholesale, at a cheap rate, for burning. That the *Olive* will thrive here is very generally known: This tree will succeed best on our own Sea-Islands: If any member of the Society wishes to try the experiment on a large scale, he may import shoots from France at an expense of about \$10, a thousand. The *Agave Americana*, or the *American Aloe* would thrive in South-Carolina. They are long in coming to maturity, but in Mexico, a plantation of these plants, when in maturity, yield \$150 the acre per annum. Our people would not drink the pulque, but the juice of the *Agave* yields a great deal of spirit, much more than any other plant: an acre of the *Agave* will give more ardent spirits than an acre of Corn.

About four years ago I received a root of *Scotch grass* from Jamaica, which, although not quite so valuable a grass, within the tropics, as

the *Guinea grass*, is much better adapted to the climate of South-Carolina. Every one who has tried the experiment, must be aware of the great difficulty of propagating the *Guinea grass*. Our summers are not long enough to allow the plant to attain maturity and to seed, and our winters are so severe as to kill the roots of this delicate grass. The *Scotch grass* does not seed in this climate, but the roots resist our frosts, and it puts out in the Spring very vigorously. It attains the height of five feet, and is very succulent; cattle and horses are very fond of it. It will flourish in lands a little salt, and the late high spring tides, have been over some of the plants, in my garden without injuring them in the least. The Committee are welcome to roots and cuttings of this useful grass.

The number of trees, which would thrive in our mild climate is very great. Those which occur to me, are, 1st, The *Cork Tree*: *Acorns* may be brought from Portugal: The best method to preserve them, is to envelope them in green moss, shaven from the earth, and put up moist.

2d. The *Quercus Bellota*, from Portugal: The acorn is four times the size of that of an ordinary oak, and is eaten by the Portuguese: the taste somewhat like that of the chesnut.

3d. The *Pinus Pinca*; the nuts are very large and sweet, and the tree ornamental.

4th. The *Pistachio*; a delicious nut.

5th. The *Jujuba*; a beautiful tree of Syria, bearing a pleasant fruit.

6th. The *Rhammus Lotus*, of Barbary; another kind of *Jujuba*.

7th. *Cratægus Azarolus*, two varieties; with white and red fruit; it is one of the most delicious fruits, when perfectly ripe of the size of a pigeon's egg.

8th. *Cerantonia Siliqua*; a large and beautiful tree of the South of Europe, which grows well in a sandy soil; its fruit always abundant, is good aliment for cattle and cows. This plant is cultivated extensively in Spain and Portugal.—Being polygamous, a male branch is engrafted on a female tree, and the male ones are extirpated when numerous. The timber is excellent. This tree may be raised for seed, and would be a real acquisition to South-Carolina.

9th. The *Chinese Persimmon*; a very good fruit.

10th. The *Euphoria Litchi*; the favorite fruit of the Chinese. The seed may be had from Canton.

11th. The *Euphoria Longan*; another species of the same genus; both are large trees, and in China are called *Litchi* and *Longan*.

12th. The *Arbutus Unedo*, from the South of Europe.

13. The *Arbutus Andrachne*, is a native of Greece: both very beautiful evergreen trees, very showy in blossom and in fruit.

14th. *Agalophythem Ravensaca*; one of the most aromatic and beautiful trees of East Africa, now become common in the Isle of France.

15th. The *Schinus*, a beautiful evergreen; the leaves and berries are highly aromatic, and are used by the Mexicans as a condiment with their food. The seed of this tree has been brought from the Table land of Mexico.

16th. The *Fraxinus Ornus*, of Italy; a tall tree bearing the blossom of the *Chionanthus*; the *Manna*, used in medicine, is furnished by making incisions in the bark of this tree. It thrives in Paris, and would flourish very well here; it may be procured from France, where it is called *Frere a fleurs*.

17th. You could procure from England, the *Arundo Arinaria*, to cover and keep together the loose sands on the sea coast.

18th. The *Tropa Natans*, a beautiful plant of the fresh water swamps; the fruit is not bad, and is sold in the markets in France, where it is called the *Chataigne d'eau*. The plant is there called *Mauve*.

19th. We could procure from Naples a very great variety of *Figs*, superior to ours.

20th. The *Sweet Lime* and *Sweet Lemon* of Portugal, are pleasant and wholesome fruits, and would probably thrive here.

21st. *Machrophylla Japonica*, an excellent fruit; thrives in France.

I am indebted to Mr. Correa de Serra, former Minister for Portugal to the United States, for the knowledge of some of these plants.

I send herewith some *Cotton seed* from the Isle of France, which I lately received from the Secretary of War. As the season is so far advanced, permit me to suggest the propriety of raising some plants, in a hot house, in order to preserve the seed, Noisette would undertake to do it. You are aware, I presume, that all the Chinese and Japan plants thrive perfectly well in this climate. The tea plants might all be cultivated here, but the labour of harvesting and of preparing the leaves is very great.

It will afford me great pleasure to give you any further information you may require, in relation to the manner of procuring these plants and seed.

I am, very respectfully,

Dear sir,

Your obedient servant,
J. R. POINSETT.

At a meeting of the Society, July 15th, 1823, the foregoing Report was agreed to, and the following Resolutions passed:

Resolved, That the thanks of the Society be presented to the Hon. J. R. POINSETT, for the information politely communicated by him.

Resolved, That a Committee of three members be appointed, to be denominated the Importing Committee; and that it consist of ELIAS HORRY, THOMAS H. DEAS, and FRANCIS D. QUASH.

Extract from the Minutes,

CHARLES E. ROWAND,
Secretary to the South-Carolina
Agricultural Society.

From *Bordley's Husbandry and Rural Affairs*.

ICE HOUSES.

Ice is applicable to economical purposes in hot weather, especially in country families.*

* "I never was in better spirits than here in this hot country (Sicily.) I believe the quantities of ice we eat, in ices, contribute to it; for I find, in a very violent heat there is no such cordial to the spirits as ice, or a draught of iced water. Its cold braces the stomach, and gives a new tone to the fibres. I knew an English lady, at Nice, soon cured of a threatening consumption, by a free indulgence in the use of ices"—Probably attended with internal bleeding; which it is said cucumbers, cold in their nature, have cured. "It is the common practice here, Sicily, to give quantities of ice waters to drink in inflammatory fevers." BRIDGEMAN.—But great caution is to be observed that it be not drunk when you are warmed at all by any kind of motion: much less when you are in a heat from exercise.

"The custom in Sicily and Italy of taking ice, is considered as a powerful remedy in many diseases. The physicians of these countries do not give many medicines; but frequently prescribe

In 1771. I built an ice-house in the peninsula of Chesapeake, where the ground is flat and the surface only seventeen feet above the high water mark of a salt water river, and 80 yards from it. It was constructed with great care to prevent entrance of air, according to the then universal practice; and it was filled with 1700 solid feet of ice, the pit being 12 feet square and 12 feet deep; but it failed of keeping the ice till summer, because of its moisture and closeness. When the pit was dug it shewed some appearance of moisture near the bottom: the least moisture is too much for an ice-house. Moisture at the sides or bottom of an ice-pit, is raised to the inside surface of the dome by a heat which, in the deepest pits that can be dug, is much above the freezing degree, and if the pit be close it recoils in the ice for want of a vent. If the close pit is not frequently opened it becomes very warm, and the ice is soft and pappy at the top. The deepest and coolest pits are about twenty degrees warmer than the freezing point: so that the depth of a pit can preserve ice from melting, it is from a greediness for depth that we too often meet with damp earth.

Some years afterwards, I made another ice-house, 150 yards from the above mentioned, on the principles and in the manner following: vent was an essential object; and dryness with coolness led me to the design of insulating the mass with a bed of straw surrounding a pen of logs which was to contain the ice. The pit was dug on a spot open to wind and sun, for the sake of dryness. It was 9 feet deep. Within it was the pen of logs, of that depth, and 9 feet square in the clear. It contained but a little more than 700 solid feet—only half the quantity stored in common ice-pits. A house was over the whole; rather for excluding rain than air. The sides of the house were 5 or 6 feet high. The eaves were boarded up, but not close, and the principal vent was at the top of a pavilion roof.

Straw is a considerable resister or non-conductor of heat. Let it be clean, sound and dry; and lay it close between the logs and bank, with an abundance of it upon the ice. The small mass of ice stored in the above insulated pen, 700 feet, was daily used of very freely, and lasted near as long as double the quantity stored in a close ice-pit as commonly constructed, and which is on the hill in Union street, Philadelphia; the earth whereof is dry and gravelly, from near the surface down to the bottom.

In plate V. is a section of this insulated ice-pit. The pen or cell inside of the logs, is 11 feet square, 11 feet deep, whereof 5½ are under ground and 5½ above ground, and it contains 1330 solid feet. The space between the logs and the bank, at bottom is near one foot; the same at top is about 2 or 2½ feet. The sink for receiving water from the melting ice need be only 5 or 6 inches deep if it be good ground, and 8 or 9 feet square. Logs are laid across it. An ice-pit of 1000 solid feet, if insulated as above, I believe would keep more ice than any private family could want; supposing the pit is not deep, and the ground is dry. If 1500 feet of ice should not be sufficient, in another year heap upon it a foot more in thickness; and so foot upon foot, as may be requisite. These additions are above ground. Ice, in ice-houses, melts more at the bottom and sides than on the top; unless it may be otherwise in very close pits seldom opened. A pen of

eleven feet cube, requires a house over it of only eleven or twelve feet square.

The winds most injurious to ice are from the south to the east. The door being on the north side, needs no passage. Rats are to be guarded against. The eaves are to be closed against them: but openings may be left on the north side, at the eaves, for admitting the steam to pass out, there as well as at the common vent on the top of the roof. These openings may be from lattice work in wood or wire: or a plank may be projected below the opening, and beyond the reach of rats.

All the building materials are to be on the spot, ready to be put up as soon as the pit is dug, lest rain damage the pit before the house can be covered.

Pound the ice small, and prefer to store it in keen weather. In such weather a neighbour dashed water on his pounded ice, a painful or two to each cart load, as soon as it was stored and pounded, load by load: and he informed me it answered well, in closing and cementing the mass.

Ice-houses are to be left open some time, till dry, before filling them with ice. When the house is to be charged with ice, first lay small faggots on the grate; and on these reeds, rather than straw, as is common. Corn or maize stalks are very spongy, and holding water seem improper. The thinner the ice, the easier it is broken to powder; and the smaller it is broke, the better it will unite into a close mass.—Run the ice close as possible in its place. Count Stolberg, says, in Sicily they prefer snow, as it is more easily preserved than ice. The snow is closely packed together, and covered with straw.*

FOR THE AMERICAN FARMER.

CHEAT,

Or as it is called in the Eastern States, CHESS. MR. SKINNER,

Sir—I have been much puzzled by reading several publications in the American Farmer, on the subject of the production of cheat; and as to its origin, whether it was produced from seed of its own species, or a metamorphose of wheat into a weed called cheat, owing to some unknown cause, either from unfavourable seasons for the cultivation of wheat, or from a bad location, as to soil, &c. Now Sir, what puzzled me was my total ignorance as to what is called cheat in Maryland, having never heard of such a weed amongst the wheat, or other crops of grain, in New England, or in the state of New York or New Jersey, in all of which States and country I have been long acquainted. But from the last American Farmer, a plan is proposed for ascertaining the origin of this same cheat, from which I am led

* January 1797. Viewed the ice house at the tavern, on Gloster point near Philadelphia.—It is built within a few steps on the north side of the tavern, and near the margin of a drained low meadow of some miles extent, and of the river Delaware; but a few feet higher than the meadow and river. It was dug 5 feet deep (seemingly 3 feet too deep.) Then filled up 2 feet with logs, and straw upon them; leaving 3 feet of ice under ground; and about 6 feet above ground, the ice inclosed in straw; which also is a lining to the house of slabs, covered with a slight roof of slabs. It was then full of ice, in pieces the size of small apples. Sixty-one loads of a one horse cart filled it. In the year preceding 27 such loads supplied the tavern with ice till some time of August.

to suppose it is the same troublesome weed, that in the parts of the country above alluded to, is known as chess, often growing amongst wheat, and in fact, other winter crops—now sir, I claim to know something of this troublesome weed, so frequently seen growing amongst our wheat. I also know, that the generally received opinion, respecting its origin is, that where clean seed wheat is sown on land liable to be winter killed, as it is termed by farmers, from hard frosts in February and March, when there is not snow to cover the ground and protect the wheat plants, that an abundance of chess is found growing with the wheat. This also takes place, where water is suffered to pond and remain on low parts of a wheat field, for want of regular drains to carry off the water, and the wheat is thus injured and many of the plants killed; yet in such unfavourable spots chess is seen to grow and flourish. Besides this supposed origin of chess, from unfavourable seasons, &c. I have observed it growing on newly drained land, where no crop of any kind was ever before put into the ground; and that in such quantities, as could not be supposed to arise from foul seed wheat, but from some other cause, such as a too wet or cold season, that destroyed the wheat plants. How these should turn wheat into chess, I have no pretensions of deciding. As to chess when produced, I am confident, that it will from its seeds reproduce chess, the same as any other weed—chess grows up with a slender hard stalk, and with a bushy head, not unlike orchard grass, and about as tall, the seed is long and slender, more like oats than wheat; from this imperfect description, your farmers will easily know whether your cheat and our chess is the same weed. A farmer who does not sow more than 20 or 30 acres of wheat, may easily clean his field of this pernicious weed, by passing through the field, and pulling up all the chess or cheat, before the seed is sufficiently ripe to vegetate; but those who sow fields too large for that experiment, may always clean their seed wheat by washing it in clean water—the chess will swim on the surface, with any light grains of wheat, and are easily separated from the heavy grains of wheat—by this means all light grains as well as smutty wheat is got rid of.

If you deem this of any information or use to your farmers, you are at liberty to publish it in whole, or such part, as you deem worthy of being communicated.

Your friend, B. C.

Essex County, N. J.

TO THE EDITOR OF THE AMERICAN FARMER,

MEADOW GRASS,

OR PERPETUAL RYE-GRASS—LOLLIUM PERENNIS—PERENNIAL RAY-GRASS.

Mr. J. S. Skinner,

Sir—In reply to your question in the American Farmer of yesterday.

“Will some of our patriotic merchants, impart some of the above seed?”

I beg leave to inform you that I have transmitted an order to Great Britain, for a small parcel of it for my own use, and should be very happy to procure any quantity for your friends, the price of which I find from the cost of some I imported last spring, would be about \$3 per bushel, all charges at Baltimore. On the score of quality, I can speak confidently—I sowed down a grass plat with ray-grass, and Dutch white clover, in preference to sodding it, and in less than a week, it was up and covered the ground—in June it was apparently quite burnt out, being as brown as a

“a severe regimen; and prevent the baneful effects of various diseases, by suffering the sick, for several days, to take nothing but water cooled by ice, sweet oranges, and iced fruit.”

STOLBERG.

Gravel walk, but the first rain revived it, and it now most luxuriant.

I had been told that it would not do well in the United States, but am very agreeably disappointed. In England it is esteemed as a highly valuable grass, and is a very favorite sheep pasture.—The hay is selected in preference for hunters and race horses, for which purpose it is sown without the admixture of other seeds; but usually it is sown down with clover or trefoil, under a spring grain crop, and it has the good quality of being ready to cut as early as red clover, and requires only, that diligence should be used in getting it together when mown for hay. It exceeds cocksfoot in many of its qualities, and is exceeded by it only, in the latter preserving a strong growth during even severe droughts. But let the ray-grass be ever so much burnt, the first rain revives its luxuriance and beauty.

I imported also the last spring, for myself and a few friends, a selection of turnip seeds, of which the following sorts are, I believe, not much known here. They were procured for me from some of the celebrated agriculturists in the neighbourhood of Aberdeen, in Scotland, viz:—Golden yellow, an excellent table sort—green top yellow, most highly spoken of—red top Swedes, an improvement on the ruta бага. I have sown of each, the latter about the middle of July, and they now show great promise indeed. Of these sorts I shall be able to spare a small supply, as I have sent also for an additional quantity.

In regard to hedging, I think the Virginia thorn will have no comparison with the English, in point of toughness and durability—I have them both, raised by myself from seed. Of the English I imported the haws. I also raised crabs from the pumice of the cyder press, and from the present appearances I think that the crabs will be superior to any thorn, both in ease of raising, and thickness, strength, and durability of the fence. It is in the power of any man, who has a cyder press, to raise in a very few years, live fencing enough for his farm; and all that is required, when the hedge is planted out, is to be careful to keep it clean and very free from weeds, or the labor is lost. But what can we raise well without labor and attention? and what more desirable, or more ornamental to a farm, than good live fences, in preference to dead rail, requiring eternal expense and labor?

I remain sir,

Your very obedient servant,
ROBERT BARNARD.

STRAWBERRIES.

Sharon, Bucks County, Pa. }
August 28, 1823. }

DEAR SIR,
