In your valuable paper, twentieth number of the volume now publishing, some inquiries are made as to the best mode of cultivating the Strawberry plant; and I have thought, that the most direct or effectual way of getting at the subject, is, for each individual concerned to give in his stock of information—and therefore it is that I tender you mine, however little it may add to the general capital.

I have succeeded pretty well in raising several species of the strawberry, and have tried different modes of cultivation—those planted in rows eighteen inches apart, and twelve inches in the rows, did very well; but from my experience,

(which I confess is limited to a few years,) I conclude, that the proper management is, to plant in a very rich soil, in rows two and a half to three feet asunder, and from three to six inches apart in the rows according to the quantity of plants at hand—suffer the plants to close in the rows, and to increase in width about one foot; or the ground may be laid out in beds twelve inches wide and two feet asunder—and where there is a sufficient supply of plants, the whole ground allotted for the vines, may at once be occupied, by setting three rows in each bed, six inches apart, and the same distance in the rows; but I prefer the former plan, because the vines can be more easily kept clean during the first season, so as to leave nothing to interrupt their future growth. After the first year, the spaces left between the beds should be kept covered with straw, in order to preserve the fruit perfectly clean, and cause a more abundant yield; and it will ensure a moisture far beyond what grass or weeds can do. When the beds become properly filled, the plants will be too close set to admit of straw being intermixed among them with convenience, except in a short or cut state—but those who will take the trouble will be amply rewarded, and if well done, it will answer the purpose of manure which is annually required to produce a good crop of fine fruit. The ground should be kept clear of all trash, but the plants ought not to be disturbed during their bloom or fruiting. I suffer the runners to continue until the next spring, but give a good dressing as early in the season as practicable; (perhaps late in Autumn would do equally well, or better) trimming to the width above mentioned; and if the plants should appear too thick, I take out such as are old, or in a weak and declining state. Some persons plant in borders, keeping them a foot or less wide, and I think it a good plan. Where the winters are severe, the plants ought to be covered lightly with straw, corstalks, or other litter. In some species, particularly the Hautboys, the barren and fruitful plants are separate, and therefore when in bloom, the superfluous quantity of males should be carefully taken out, as then they can be readily distinguished, and it would also be a good turn to set out a new bed, as the two kinds could be rightly apportioned, and they will succeed very well by taking up some earth with them. I have not satisfactorily ascertained what is the best apportionment, but it is stated by your "New Jersey Subscriber," in No. 8, to be one male plant to ten females, which I should suppose a good arrangement if planted as I have suggested; but if in hills, I would advise about one male to eight females—in both cases however, much will depend on placing the males at equal and proper distances. If in narrow beds, the males should be confined to the centre: if in hills, they should be planted in the following order—first row, all females—second row, first hill females, second male, two next females, then one male and two females throughout the row—third and fourth rows, females—fifth, a mixt row (as before), then two rows of females, and so on until the whole ground is planted; finishing however, with a single row of females as in the beginning; and so should each row be ended. The male flowers are known by their stamens; or those who are not acquainted with the sexual organs, can make a choice after the decline of the flower, taking such as do not yield fruit, for males. Last year my plants were attacked by the White Grub, and I believe that it frequently happens, that old beds are infested by a species of aphid or louse; when this is the case, it is best to prepare a new bed. I am of opinion that it is with this, as with most of our other crops; that the principal failure is owing to the depredation of insects; and this may account for the success which attended the case men-

tioned by Mr. W. S. Gibbs, in No. 16, where grass was intermingled with the strawberries—but instead of following a practice so slovenly, and which, (I think) must eventually prove ruinous, I would urge the necessity of investigating the particular species and habits of the depredating insect; and having ascertained these, we should not be long without a remedy.

I heartily join with your other correspondents in requesting further information; as a fruit so delicious and wholesome, ought to be especially attended to—and I am persuaded, that our bountiful Creator has given us a capacity rightly to manage all things which he has been pleased to place under our direction, and that whereinsoever we fail, it is because we do not properly exercise our faculties.

Your's, very respectfully,

JAMES WORTH.

The London Horticultural Society have lately sent out to this country Mr. David Douglas, an eminent botanist, for the purpose of collecting specimens of rare plants, vegetables, and fruits in the United States and Canada. In his instructions; Mr. Douglas is directed, immediately after his arrival at New-York, to call on Dr. Hosack, of this city, and subsequently on Mr. Clinton, at Albany, for the purpose of receiving their advice and aid in furthering the objects of the agency. Both of these gentlemen are honorary members of the Horticultural Society of London, and have already contributed largely to enrich the spacious grounds belonging to that institution, with the indigenous plants of this country. Among other contributions, Dr. Hosack has sent to the society all the varieties of maize, which are found in the United States. In acknowledgment of this liberal and very acceptable addition to the collections of the society, an elegant medal has recently been presented to Dr. Hosack, having on one side the head of Sir Joseph Banks, which is said to be a striking likeness; and on the reverse, the name of the person to whom it was presented, as a special honor. The same gentleman has also forwarded to the society a new species of plum, which he discovered in a garden in this city, additional specimens of which went to London by a vessel that sailed yesterday.

Mr. Douglas has now gone to Philadelphia. After visiting that city and its environs, together with the state of New-Jersey, which is rich in fruits, he will return to New-York. As soon as he has completed his examinations and collections in the vicinity of this city, including the extensive gardens of the Messrs. Princes, at Flushing, he will visit Albany, to confer with Mr. Clinton, and take his advice with respect to his route to Niagara, through the western counties of this state. He is authorised to deviate as much from a direct route to Niagara, as may be deemed advisable, and he will probably visit most parts of the state. We doubt not our citizens will afford him every facility in making a collection of such rare varieties of vegetables and fruits as our extensive and diversified territory produces.

At Amherstburgh, in Upper Canada, Mr. Douglas is instructed to call on Mr. Briscoe, who we believe is a member of the society, and confer with him, as to his route and collections in the British Provinces. He will visit the banks of the Thames, and some of the plants now growing on the margin of that remote and solitary river, which is near the borders of Lake Huron, are destined to drink the waters of the Thames in England and to bloom in the gardens of the metropolis.

The whole of this survey is to be completed

before the setting in of winter, when Mr. Douglas will re-embark, for his native country, taking with him the result of his botanical researches. The instructions of Mr. Sabine, the secretary of the London Society, who is understood to be a gentleman eminent for his scientific attainments, breathe a spirit of liberality and good feeling towards this country, and some of its distinguished citizens, which have not on all occasions characterised the intercourse of foreigners. We are gratified to learn, that measures have been taken, for opening a correspondence between the Horticultural Societies of London and of New York. The institution in this city is yet in its infancy; while that in London has been long established, and has become one of the most respectable and valuable associations in England. Its transactions, the last two numbers of which have just been received by Dr. Hosack, are published in a very superior style with plates, and contain a great variety of interesting matter. It is believed there is but one copy of the work in this city.

Little attention has hitherto been paid in any part of the United States, to the science of horticulture, which like a regular system of gardening has our knowledge been introduced. Few, if any books on the subject are consulted; and the first principles of one of the fine and useful arts, (for horticulture unites both of these characteristics) are but little understood in a country which opens a wider field than any other on the globe for such improvements. If the horticultural society of this city were somewhat extended, and the efforts of its members stimulated by the stated publication of its transactions, it might perhaps form a rallying point, and lead to the institution of similar societies in other parts of the country. But these are suggestions which belong more properly to the members of the society than to the editors of newspapers; and we conclude with expressing a hope, that the measures about to be taken will be prosecuted with vigor and crowned with success.—*N. Y. Statesman.*

TO THE EDITOR OF THE AMERICAN FARMER.

Baltimore, August 15th, 1823.

SIR,

I beg leave to call your attention to a weed or insect, that bids fair to be a pest to this country, not noticed in time—it may be found ten miles from this city, though only four years since, it was first brought to this country and emptied on a vacant lot S. E. corner of Wolf and Fleet streets, (F. P.) where it is now to be seen so thick and briery, as scarcely to admit a rat to run in it; also in great abundance on all vacant lots on the Point.

As no one appears to have noticed this important pest, I have thought proper, hoping some ways and means may be taken to arrest its progress, which may be done if taken in time, otherwise from its rapid progress, may spread so as to become a curse to our agricultural country.

J. WRIGHT.

Editorial Correspondence.

CROPS IN GEORGIA.

Extract of a letter to the Editor, dated Eatonton, Geo. 15th August, 1823.

"Crops of wheat the present year in this section of the state have been very good: wheat is worth from 75 to \$1 25 per bushel. The prospect for a crop of corn is unusually good.—The very low price of cotton the last winter, induced a number of our farmers to plant much less than heretofore, and much more corn. It is now

the general opinion, that corn will not sell the next winter, in this section of the state, for more than 25 or 30 cents per bushel, and it is calculated that about the time crops of corn are gathered, that it may be had for 20 cents per bushel.

"The quantity of land cultivated in cotton, is less this year by a fourth or fifth, than has been for the last several years. The crops of cotton are now very promising, but the rot has made its appearance, and we can make no calculation as to its ravages; if, however, it should not be more fatal than it was last year, we may calculate on more cotton from each acre in cultivation than the last year."

A late number of the National Intelligencer contained a Thermometrical Table of the state of the weather at Thompson's Island, during the month of July. This table was furnished for publication by Commodore Porter, and has called forth the following communication from Mr. Robert Little, of Washington, which gives quite an interesting fact relative to the difference of temperature between that city and Thompson's Island:

Gentlemen—Your communication this morning of the Thermometrical Register, received from our gallant and scientific friend Commodore Porter, at Key West, is a valuable document. It is an addition to our knowledge of the relative temperature of our immense country, and is another gratifying indication of what kind of men our leading naval officers are.—While natural and moral courage are thus found connected with love of

science and patient observation, America has every thing to hope for from her sons.

In comparing the register kept at Thompson's Island for July 1823, with that kept in Washington City, during the same month, I notice the following results. We have here a much wider range; our mornings and evenings are cooler, but at the hottest period of the day, the difference is inconsiderable, not averaging more than two degrees in the whole month. There was only one day in the whole month in which the thermometer was one degree higher than at Washington. But on the other hand, owing to the little variation of that instrument in the Gulf of Mexico, the temperature at 8 o'clock A. M. was seven degrees higher than at Washington on the average.

AMERICAN DUCK.

An article has appeared in the "Nantucket Enquirer," calculated to injure the deserved reputation of American canvass, other than that manufactured by George Johnston, of Salem, by stating that government has contracted for the exclusive use of the Salem Duck in the Navy.—Now this is not the fact, the Commissioners of the Navy having subsequently to their orders to Mr. Johnston, renewed their contracts, with at least one of the Patterson manufacturers, for a considerable quantity. Government has been supplied for several years with canvass from Patterson, and its superiority in every respect over imported canvass has been actually and fully tested both in the U.S. navy, and in the Merchant's service, and it needs no disparaging assertions to bolster it into notice. Exclusive claims to superiority in sciences and the arts, too, cannot be granted by
NEW JERSEY.

Perfection of the Arts with a Witness.—A man in London has brought to light the wonderful property of steam in Incubation. The papers give quite a laughable account of his examination before the Lord Mayor, during which, he said that in the incipency of the business, he had to sit up thirty days and nights and turn the eggs lest the birds should be deformed; but now he could produce a thousand chickens in one night, and of much more unexceptionable character than if brought up under the immediate care of their mothers—and that chickens produced in this way, laid eggs at all seasons while those that came in the natural way, only exercised their faculties at stated seasons.

EXTRACTS FROM THE

London Farmer's Journal.

RYE GRASS.

Mr. Mills (Editor of Duhamel's Husbandry,) published in 1763, in three volumes, "New and Complete System of Practical Husbandry," which is a curious compilation of sense and nonsense. In his chapter on natural grasses, he particularly recommends to cultivation, the common couch; the wall barley grass or way bennet; the annual poa, or Suffolk-grass, and the floba fescue. All these are very strongly described in his treatise, although they are sufficiently identified; and he laments very earnestly, the great ignorance of practical farmers, and their inattention to these important improvements! Of rye-grass he says, "Duhamel rightly observes, the

ground that has been under this crop, is not so able to bear *wheat the next year*, as if it had been cropped with lucerne, sainfoin, or clover." This proves to be an ancient remark as to the deteriorating quality of the old rye-grass; and the reason he says probably is, that "*The multitude of matty roots of the rye-grass, which run on the surface of the ground, hold the earth so strongly together, that they cannot easily be disentangled from it by ploughing.*"

"We distinguish, (says he,) two considerably different species of the rye-grass, viz:—the *Lolium rubrum*, and the *Lolium album*," which latter he makes to be the *Yuraie* of the French, and adds, that it is the sort chiefly cultivated in England; but it is very coarse, and unless it be not quite early for hay, it becomes so hard and wery that few cattle care to eat it: for this sort of grass has but few leaves, and runs all to stalks." Afterwards he adds, "the red darnel is a considerably inferior species of rye-grass; for it has yet narrower leaves, and its stalks grow hard much sooner. It is very common in most pasture grounds, because it flowers early, and its seeds ripen and sow themselves before the hay is cut." In this description (excepting the narrow leaves,) he evidently means the *bromus arvensis*; and in this manner have grown the notions of *red and white darnel*, recognised by botanists as belonging to the genus *Lolium*, and supposed to be known in agriculture. The *white darnel* here called *Lolium Album* (although the writer evidently speaks of the common perennial rye-grass) is the *temlutumc*, an annual species, and supposed to be the *darnel* of the south of Europe, (the term *Yuraie* or *intoxicating*, applied by the French, is no more than a translation of the Latin name of the species,) but the only *darnel* of British agriculture is the *bromus secalinus*. Further on the author adds, "Mr. Lisle agrees with all other experienced husbandmen, that though rye-grass will maintain as many cattle on an acre, as hop clover will do, yet it does not, like it, improve the land for a subsequent crop of corn." This just and useful impression was soon made among attentive and discriminating cultivators, where rye-grass first spread; but the seeds continued to spread, and left the impression behind, so that in all parts of the kingdom the like consequences were to be experienced. The public is very much indebted to Mr. Coke, of Holkham, for bringing this subject forward at his meetings, where he has frequently declared that he could not get wheat after one year's lay of rye-grass; and we quite believe that *sowing the old rye-grass generally to turn convertible lands to grass*, (in ten countries and elsewhere,) has been the cause of much injury to the soil. We gladly take every opportunity in our power to give currency to this important conclusion, and to enforce the cultivation of the improved sorts, which are very greatly superior in every respect. No local patron, or friend to agricultural improvement, can do a more useful thing in his district, than to procure a few bushels of the improved sorts, and shew them in pasturage, and raise seeds, and distribute them at a convenient price; for the progress of individual observation needs to be accelerated by the aid of more active intel-

USEFUL RECEIPTS.

Celery Sauce for Roasted or Boiled Fowls.—Take a large bunch of celery, wash it very clean, cut it in little thin bits, and boil it softly in a little water till it is tender, then add a little beaten mace, some nutmegs, pepper and salt, thickened with a good piece of butter rolled in flour, then boil it up and pour it in your dish; you may

add a half pint of cream, a glass of white wine, and a spoonful of catsup.

Brown Celery Sauce.—Stew the celery in a little water, then add mace, nutmeg, pepper, salt, a piece of butter rolled in flour, with a glass of red wine, a spoonful of catsup and half a pint of good gravy, boil all those together and pour them into the dish.

To dress Calf's Head Soup.—Take a calf's head, (with the skin on if you can get it) part of the liver and lights, boil it in six quarts of water, until you can take the bones out, put it on a dish, season it with pepper, salt, and sweet margarum, thyme and sage, mace and cloves, skim the water if there be any fat on it, then put it all back in the same water that you boiled it in, and let it boil till done; just before you take it up, put one glass of wine and brown it with a little burnt sugar, thicken it with a little butter and flour. If you want to make a great deal of soup, you must add a knuckle of veal, as the head only, will not make it rich enough, fry some forcemeat balls and put in it. If you wish to make the dish without soup, boil the head in the same way, and season it in the same manner, in the dish, with a little of the water it was boiled in, thicken it a little with butter and flour, put it in the oven till you think it is done.

Pea Soup.—To two quarts of peas put two gallons of water, three large onions, a handful of parsley, a little thyme, pepper, and salt.

Mrs. G's Famous Bunns.—One pound and a half of flour, (a quarter pound left to sift in last) and a half a pound of butter cut up fine together; then add four eggs beat to a high froth, four teacups of milk, half a wine glass of brandy, wine, and rose water each, and one wine glass of yeast; stir it all together with a knife, and add half a pound of sugar, then sift in the quarter of a pound of flour, and when the lumps are all beaten fine, set them to rise in the pans they are to be baked in. This quantity will make four square pans full.

Black Cake, much esteemed.—Three pounds of butter and three pounds of sugar beat to a cream, three glasses of brandy and two of rose water, twenty-eight eggs, and three pounds of flour added by degrees together, six pounds of currants, six pounds of seeded raisins, one ounce of cinnamon, one ounce of nutmeg, three quarters of an ounce of cloves, half an ounce of mace, one pound of citron. (Two large loaves baked five hours.)

THE FARMER.

BALTIMORE, FRIDAY, SEPTEMBER 5, 1823.

Every housewife ought to be informed, that a very useful and economical utensil has been lately introduced here from Philadelphia, which may be called a *conserving furnace*, by means of which great saving is attained in the cost of fuel, and the person using it, instead of stooping frequently before a large wooden fire, places it on a table in her kitchen or breakfast room, and with a cent's worth of charcoal prepares a large dish of fruit. These furnaces are of different sizes and of the shape of the common copper skillet. To have an idea of its construction, the fair reader may imagine a stone milk pan, wherewith we suppose them to be familiar—with sides nearly straight, and with two

bottoms, so to say, with an hollow space between them, of about two inches—the upper bottom on which the charcoal is placed, is perforated with several holes, the size of a pistareen; or rather the holes are left in the clay, when the furnace is baked to the consistence of rough stone.—There is then a little aperture, or door, left through the outside of the furnace, to admit the air between the two bottoms, by means of which the charcoal is made to burn; should the fire become too brisk, and the stewing of the fruit proceed too rapidly, this aperture below is closed, which immediately checks it. We are told by ladies who have used them, that the idea of this furnace must have been conceived, like the Frenchman's new fashioned shoe, in "a moment of enthusiasm," and that it is in short regarded, in their department, as one of the grandest inventions of modern days. It is easy to see that it saves the person from distressing exposure to heat, and is far more cleanly and economical, than the old way of conserving fruits. We believe they are sold by the Messrs. Grundy's, in Charles street.

It will be seen in another part of this paper, that the London Horticultural Society have sent out an eminent botanist, Mr. David Douglass, to make a botanical tour through New-York and Canada; and has been instructed, very properly, to call on Dr. Hosack and Governor Clinton, in his way—from these gentlemen he will doubtless derive essential aids; and we trust, that in the spirit of kindly feeling, which is generated by the cultivation of the sciences, Mr. Douglass will everywhere experience attention and assistance. It may be in the power of the correspondents of the editor of this paper, to make some acceptable offers through Mr. Douglas, to the horticultural Society of London—and any thing in the way of indigenous plants, grass, grain, &c. or native and natural curiosities, which any of our friends may have the kindness to send for that purpose, will be forwarded to Mr. D. with great pleasure. Let nations and politicians differ as they may, kindred spirits of all sects and countries, in the pursuit of knowledge, will cheerfully co-operate, to explore new fields, and to embellish those already in cultivation.

BALTIMORE MARKET.

PRICES CURRENT—CORRECTED WEEKLY.

Flour, best white wheat, \$7—Howard street, from wagons, \$6 3/4—Superfine, \$6 50—fine do. \$6 25—Wharf, do. \$6 12 1/2—White wheat, \$14 to 1 25—Red do. \$1 05 to \$1 10—Rye, 45 cents—Corn, 36 a 37 cts.—country Oats, 28 cts.—Beef, 8 cents per lb.—Live Cattle, \$6 to \$6 50 per cwt.—Bacon, hog round, \$10—Pork, \$4 50 to 5 50 per c. lb.—5 to 8 cts. per pound—Mutton, 5 to 6 cts. per lb.—Beans, \$1 37, to 1 50—Peas, black eyed, 55 to 60 cts.—Red Clover Seed, \$6—Orchard Grass do. \$3—Herds' Grass do. \$3—Timothy do. \$4—Flax Seed, 75 to 80 cents—Whiskey, from the wagons, 35 to 36 cts. per gal. including the barrel—Apple brandy, 30 to 32 cts.—Peach do, 65 to 70 cts.—Shad, \$6 00,—Herrings, No. 1, \$2 70 per bbl.—No. 2, \$2 37 1/2—Fine salt, 60 to 65 cts. per bush.—Coarse, do. 70—Butter, (Irish) 14 cts. per lb.—Eggs, 10 cts. per doz.—New Hay, \$15 per ton—Old do. \$18—Straw, \$10.

MARYLAND TOBACCO.—No sales.

Printed every Friday at \$4 per annum, for JOHN S. SKIDMORE, by JOSEPH ROBINSON, on the North West corner of M. and Belvidere streets, Baltimore; where every day, from 10 o'clock to 12 o'clock, and Job Printing is executed with neatness. All communications from a distance for PRINTING or BINDING, with particular directions promptly attended to, addressed to J. Robinson, Baltimore.

AGRICULTURE.

INTERESTING EXTRACTS—*from Agricultural and other addresses and memoirs, on the files of the Editor of the American Farmer.*

FROM AN ADDRESS DELIVERED BEFORE THE ROCKINGHAM, (N. H.) AGRICULTURAL SOCIETY—BY THE HON. WILLIAM PLUMER, JR.

The institution of agricultural societies, and the public meetings and exhibitions to which they lead, are of essential service to agriculture, as they tend to raise the character and improve the condition of the farmer; and by securing to us pursuit its just rank and influence in society, to much towards preserving him from the ignorance, the poverty, and consequent servitude, in which, in other countries, the cultivators of the soil have too often fallen.

Particular circumstances render these public meetings more necessary to farmers than to any other class of men. Merchants and manufacturers are collected in towns and cities, where great numbers come daily together; and activity and emulation are easily excited and preserved. With them, therefore, the sense of a common interest is constant and intense. Improvements made by one are immediately known and adopted by all the rest; in every new undertaking, the best models are followed; and the progress of society is seldom retarded by an obstinate attachment to old methods, after new and more convenient ones have been invented. This readiness to improve—this ambition of excellence, and quick instinct of interest—is always produced by the presence of multitudes in the same place; and is the natural result of the alternate union and opposition of many kindred minds, of numbers warmed by collision, roused by difficulties, bent upon the same object, and eager in the pursuit of one common good. Agriculture, on the contrary, seems almost deprived of this maintaining of action. Farmers live necessarily at a distance from each other, and pursue their humble, but useful labor in the solitude of forests, and amidst the silence of nature; with few friends to applaud their success, or rivals to call forth, by competition, new efforts of skill or fresh exertions of industry. It is to supply this want of emulation, to rouse this sluggish indifference of spirit, and present more powerful motives to rural activity and enterprise, that agricultural societies have been recently formed in different parts of our country, and premiums offered, in proofs of uncommon success, in the various branches of practical husbandry.

The more any pursuit is made the subject of general enquiry and scientific arrangement, the higher it rises in the scale of improvement, and the greater dignity and importance it acquires. Fortunately for agriculture, it has, from the earliest ages, been more practised as an *art* than as a *science*. It seems indeed to have been taken for granted, that this most extensive and fruitful of all the arts, could be brought to perfection, without those aids of science, to which we owe their chief success. The greatest improvements in many, if not all, the arts of life, are acknowledged to have been made, not by persons engaged immediately, and exclusively, in the practice of those arts; but by men of extensive information and general science, whose minds were enlarged by study, and trained to a general survey and intimate acquaintance with the various objects of human knowledge. Proofs of this position might easily be adduced. The farmer traverses the ocean, by the aid of instruments, which he did not invent, and of tables,

whose principles he does not understand; but which were discovered, and adapted to his use, by men who never set foot on board of a ship, and who knew nothing of navigation beyond its theory. The same dependence of art on science might, if necessary, be instanced in many agricultural processes. It ought, therefore, gentlemen, to be our study, as it is the object of our society, to encourage agriculture, by a judicious combination of science and practice; to excite enquiry, and impart information; to suggest new experiments, and communicate the result of those already tried; to rouse by premiums and honorary rewards, a spirit of honest pride and generous emulation; to cherish in the farmer, an ambition—the wisest he can indulge—to excel his neighbors, in the amount and goodness of his crops, in the breed and fatness of his cattle, in his mode of doing business, and in the general appearance, order and neatness of his farm; in a word, it should be our endeavour to render agriculture more regular and systematic in its arrangements, more certain and profitable in its returns, and consequently an object of more general attention and greater regard.

The leading principles of agriculture are the same in all countries. The object every where pursued should be, with a given amount of labor and expense, to obtain from the earth the greatest possible amount of produce which, without impoverishment, it can be made to yield. The means employed for this purpose must indeed vary with the soil and climate, and the kind of crops intended to be raised; but these are principally matters of detail, and do not materially affect the great outlines of a good system of husbandry, which being derived from nature, are uniform and invariable. To drain the earth of its superfluous moisture; to keep it loose and clean, by frequent ploughing and careful cultivation; to enrich it by suitable manures; to select the crops best adapted to the different kinds of soil; and to vary and assist them, by a judicious rotation;—these few operations, plain and obvious as they appear, form, of themselves, a system of husbandry, which is at once simple, comprehensive, and distinct. A few remarks under each of these heads, will enable us, at the same time, to bring into view some of the most important principles of agriculture, and to notice briefly some of the leading defects of our own practice.

1st. DRAINING.—To drain the earth of its superfluous moisture, though an obvious dictate of reason, has been, in general, so little practised in this state, that draining is hardly considered, among us, as a regular agricultural operation. And yet in countries, where the earth has been cultivated with the most success, this branch of improvement has always been considered, as of the first importance. "Lay your land dry?" says a celebrated English Farmer, "before you attempt any thing else." A due proportion of moisture is indeed necessary to the growth of plants; and there are some soils, composed principally of sand and gravel, in which draining is not only useless, but might be injurious. But on most farms there is much land, which is, every fall and spring, filled with water; and thus rendered cold, sour, and unproductive, for want of drains and ditches to convey off the stagnant mass. Our low lands are thus converted into swamps and morasses, of little or no value to the owner, though in themselves capable of being made the richest parts of the farm. The waters collected in these bogs and pools, serve in wet seasons, to drown the land, and in dry, to infect the air. Both health and profit equally require their speedy removal.

Wherever the soil rests on a bottom of clay, or compact sand, as is the case with much of our

low land, the water which falls upon it, or runs in from the surrounding hills, being unable to enter this impervious substratum, must remain upon the surface, till evaporated by the sun. But this evaporation does not take place, till long after the proper season for sowing and planting has passed. These operations are, therefore, usually performed, on such lands, while the earth is still wet and cold; and the seed, thus sown or planted, either rots in the ground, or comes up so late and imperfect, as hardly to repay the cost of cultivation. In such cases, a little time judiciously employed in constructing drains, and opening ditches, would add more value to the land, than twice the amount of labor spent upon any other part of the farm. Nor is it to be apprehended that on higher lands, the earth will be deprived, by draining, of any moisture which is either necessary or useful to the soil. It is to the copious dews, and gentle rains that fall from May to October, that the farmer is indebted for his crops, so far as water is concerned in their production; and these he is in no danger of losing by the course here recommended. But the floods of spring, and the long drenching rains of autumn, which inundate his low lands, and render his fields cold and unproductive, should never be suffered to stagnate within his bounds; but should be provided with an easy and ample outlet, wherever the situation of the land admits (as it generally does) of being drained.

2d. TILLAGE.—Having thus provided against the excesses of the watery element, the farmer's next object should be to keep his lands loose and clean, by frequent ploughing, and careful cultivation. The earth, in its natural state yields a supply, worthless and scanty compared with that, which the skill and labour of man enable him to draw from its bosom. This increase of produce rises principally from the manner in which the soil is prepared for the reception of seed and the growth of the intended crop. For this purpose, it is a settled maxim of agriculture, that the *finer, and deeper the till, the better and more productive the husbandry*. The finer the particles of matter are divided, the more readily will they assume the forms of vegetable life, and the more copious is the supply which they furnished as food to plants. To loosen, divide, and pulverise the soil, in every possible form, and to the utmost practical extent, is therefore, the first great step towards rendering it fertile and productive. This can be effected only by a constant and liberal use of the plough,—that most important of all agricultural implements, which never runs without enriching its owner.

But the quality of the soil should not only be improved, but its depth increased; and this must be done by deep, as the former, by frequent ploughing. The sun and air exert a steady and powerful influence upon whatever substances fall under their action; and it is to this influence that the earth is indebted for much of its fertility. The deeper, therefore, land is ploughed, provided it be done gradually from year to year, so as not to bring up too much dead earth at once, the more its value is increased, and the greater will be its returns to the diligent cultivator. The object of ploughing being to obtain a fine mould, it ought to be done, principally, in the fall, that our severe and frequent frosts, which are, in other respects, so injurious to the farmer, may here come in aid of human industry; and the great process of deepening and pulverizing the soil, be carried on by the elements, almost without the labour of man. If the land be low and wet, it should be thrown into ridges, as well as ploughed, in the fall, that it may not suffer from the water.

Nor are these the only good effects of deep and frequent ploughing. The careful husbandman suffers nothing to encumber his ground, which does not add to its value. To prevent the growth of weeds is therefore, with him, an object scarcely less important, than to promote the growth of corn or grain. The necessity of destroying them, when they appear, is admitted by all; but this after-prudence, by which evils are attacked only when they have reached their maturity, is surely much inferior to that preventive wisdom, which foresees the evil, and prevents its existence. By shallow ploughing, the seeds of grass and weeds, with which the earth is always full, and deposited near the surface, ready to spring up with the intended crop, and requiring much time and labour to keep them down. By deep ploughing, on the contrary, they are buried so low in the earth, that few of them ever quicken into life; and those few pierce the surface, so late in the season, as to do little injury to the harvest. A constant, liberal, and judicious use of the plough may, therefore, be recommended as the best means of promoting the growth of plants, while it prevents the growth of weeds; of deepening the soil, by exposing all its parts to the sun and air; and thus of rendering it loose and friable, pervious to the roots of plants, and ready to give forth all its strength in the production of useful crops.

3d. MANURES.—But however well the earth may be prepared, by these means, for the purpose of agriculture, it must in time be exhausted, by a continued course of cropping, if its fertility be not preserved and sustained, by the application of suitable manures.—The food of plants is derived either from the earth, air, or water; and the proportion drawn from each depends upon the nature of the plant. Some plants derive their chief support from the atmosphere, and will grow and flourish, at least for a time, without even touching the ground; others live only in water or on its surface; but the greater part require the combined aid of all three to sustain and perfect their growth. The favourable effects of water upon plants are well known and obvious. A heavy dew, or slight fall of rain, revives vegetation, and gives a refreshing glow and animation to the face of nature. These agents are, however, very little subject to the power of man. In our rough and uneven country, and in the present state of our agriculture, irrigation could not generally be attempted with any prospect of success. We may indeed guard against the bad effects of too much water, by draining; but cannot expect to collect it in tanks, as in India; or to lead it, as in Lombardy and other parts of Europe, in ducts and canals, to irrigate and refresh our thirsty soils.

With respect to the fertilizing influence of the air, or rather of the putrescent matter floating in the atmosphere, the only method by which we can avail ourselves of it, in greater abundance than is spontaneously furnished by nature, is to cultivate such plants as have a peculiar attraction for this floating manure, and absorb it, from the air, more copiously than others. This is the case generally with broad-leaved and wide-spreading plants, which, drawing their nutriment principally from air and water, are, on that account, less exhausting to the soil. It is to its peculiar power of enabling plants to extract, and transfer to the earth, this inexhaustible wealth of the atmosphere, that *Gypsum*, or plaster of paris, seems to owe its principal value as an agricultural agent. It accordingly produces the greatest effects on dry or calcareous soils, where a deficiency of moisture is usually felt; and succeeds best when applied to

clover, corn, and other large plants. Ashes is another manure which seems to act, something in the same way, by its power to attract moisture from the atmosphere; and therefore does best, where this moisture is most wanted, on light lands with a loose or gravelly soil.

But it is principally on the nutriment drawn from the earth, that the husbandman must rely, for the goodness of his crops. His great object here, is to extract much produce, with little impoverishment to the soil. For if he loses, in the value of his lands, what he gains in the amount of his crops, his industry is worse than useless; and he is becoming daily poorer by his labour. Much good land has been in this way destroyed, for want of considering that the earth requires food as well as man; and that a field may be starved, if not as quickly, yet as certainly, as an ox or a horse. Any course of husbandry which leaves the land, year after year, worse than it was before, must be pronounced decidedly bad; to keep it where it was, is barely tolerable; and it cannot be called good, if every year does not render it richer and more productive than the last. By returning the whole crop to the ground on which it grew, the strength of the soil would not only be preserved, but its fertility increased. It is in this way, that lands in a state of nature are enriched, by the mere progress of vegetation, and are always found eminently productive by the first cultivators. But to raise crops, with no other view than merely to enrich his lands, would be of no service to the farmer. He ought, however, always to recollect, that if, for any length of time, he would preserve his lands in good heart, under constant cultivation, he must bestow upon them, in the form of manure, animal and vegetable matter, equal to that taken from them in the form of crops.

Nor is this so difficult to be effected as might at first be supposed. Beside the ordinary supplies of the barn-yard, upon which I need not here enlarge, the refuse of his crops, which though useless to him, is invaluable to his lands, and the aid which may be derived from lime, gypsum, salt, marl, and other extrinsic sources—our swamps, and meadows, and low lands, are every where filled with a rich mass of vegetable mould, which may be truly pronounced inestimable in value, as it is inexhaustible in amount. It has been here accumulating, for ages, from the decay of vegetables, the fall of leaves and trees, and the wash of the surrounding lands. Into these neglected nooks, and dark recesses of his farm, the industrious husbandman ought to dig as for mines of gold. If rightly improved, they will furnish him with the means of restoring vigour to his exhausted lands, of preserving those that are still unimpaired, and enable him, by the aid of drains, to convert his useless wastes into fertile fields. I need hardly remark how few among us have availed themselves, in its full extent, of this great source of agricultural improvement.

* * * * *

In the early settlement of the country, there was no want of land, but a very great want of men. The object with the first settlers, was, therefore, to spread their labour over as large a surface as possible. The permanent improvement of the soil was, with them, an object of no importance. When one spot was stripped and plundered of its wealth,—the wealth of ages, accumulated on its surface,—another was at hand, as cheap as the former, and of unexhausted fertility. While engaged in clearing up new lands, and strug-

gling with the difficulties of a new country, much system or regularity was hardly to be expected. But this excuse for bad husbandry, once so valid, can be no longer justly urged, at least, in the lower parts of the state. A new era has accordingly arisen in our agriculture, produced by the increase of our population, the diminution of foreign commerce, and the sudden growth of manufactures amongst us.

With this change of circumstances, a spirit of activity and improvement has displayed itself, which, if properly directed, will produce the most happy results for the whole community. If any inducement, to assist in giving it this direction could be wanted, beyond that found in the pleasure and profit of the pursuit, it would be perceived, by every generous mind, in the peculiar value which even small improvements in agriculture possess, on account of the immense number to whom the benefit of such improvements accrues. Great favors conferred on a few, contribute less to human happiness, than small advantages which reach to many. The erection of a palace, though at the expense of millions, is an achievement of less importance to mankind, than an improvement, however small, in the form or structure of the plough, by means of which four oxen should perform the labor now required of six. In the former case the pride of one man only would be gratified; in the latter a whole nation is enriched.—That such improvements may be made, cannot be doubted by those who know what has been already done. We read in scripture, that when Elijah went to meet Elisha, he found the prophet in a field "ploughing with twelve yoke of oxen." We are not told how many men it took to drive, nor how many more to hold this unwieldy plough; but we may judge something of its rudeness of construction, by the team which it required. The Indians, when this country was first discovered, broke up their land with a stake, and had no better hoe than a clamshell.

When we compare these rude inventions with our present agricultural implements, (imperfect as these latter still are,) we can be at no loss to decide who were the greatest benefactors of mankind—those ingenious mechanics, who first turned the stake of the savage into a plough, and by subsequent improvements reduced the team from twelve to two yoke of oxen,—or those sanguinary warriors, who, to enslave nations, converted ploughshares into swords, and, to feed their rapacious armies, robbed the husbandman of his harvest. Yet the former are forgotten or despised, while the latter are remembered and admired. The same misapplication of applause, on the one hand, and exertion on the other, may be traced in every walk of life. Half the ingenuity expended, in vain, upon the *perpetual motion*, would have supplied us with innumerable implements of husbandry, more perfect than any we now possess; and a tenth part of the time and talent devoted to astrology, to the transmutation of metals, or the *elixir vitae*, would have discovered the various properties of soils, and made us familiar with the best modes of farming. The art of making cider,—the best and healthiest of our liquors,—is still in its infancy; while that of making rum, whose deadly poison sends thousands yearly to the grave, has been for centuries perfectly understood!

* * * * *

The connexion of virtue with regular industry, and of happiness with the gradual acquisition of property, is among the kindest and most benevolent of the dispensations of Providence to man. He who from want of system and economy in his pursuits, adds nothing to his fortune

but is every day becoming poorer and more dependent, will be rarely found to be either a very happy man, or a very useful member of society. Acquiring nothing permanent by his industry, he takes little satisfaction in his business or profession, whatever it may be; and can never experience those pleasures of gain—of constant, regular, though moderate gain—which every thrifty farmer feels; and which,—however nobler minds may be swayed by higher motives—contributes, more than honor, wealth, or power, to make the mass of men cheerful, happy, and contented, industrious in their own pursuits, friendly in their intercourse with others, and useful, virtuous, and upright, in the various relations of social life.

For such men, vice and folly, extravagance and dissipation, the waste of luxury, and the idleness which bringeth want, possess but few attractions. Occupied incessantly with some useful labor, or some innocent enjoyment, they have no need of scandal to amuse their vacant hours; envy comes not to corrode their tempers, nor disappointed ambition to corrupt their hearts. The idler finds them too busy for vice, and the demagogue too happy for factious discontent. Exempt from the noise and tumult of the bustling crowd, they enjoy, in calm contemplation, the beauties and the bounties of nature, before which the works of art, and the schemes of ambition, vanish and are forgotten. In the quiet dignity of rural retirement, they are wise, without the parade of learning; powerful, without a wish to injure, and happy without the pomp of office, or the ensigns of power. It might be thought too much to say, that he who conducts, with perfect skill and judgment, all the complicated concerns of an extensive farm, might as well direct an army or govern a state. And yet the one talent is, perhaps, as rare as the other, and the perfect farmer as seldom found as the able general, or accomplished statesman. His value is at least equal to theirs; and if rank depended upon utility, the place assigned him, in public estimation, would not be less distinguished.

FROM THE PITTSFIELD SUN.

ON GRAFTING APPLE TREES.

To the Editor of the New England Farmer.

SIR—Having seen in your papers some observations on the grafting and raising of apple trees, in which I have had much experience, am free to communicate the result of my observations.

I differ in opinion from such European authors as recommend the ground for nurseries to be made extraordinarily rich, as I observed that young trees, transplanted from a richer to a poorer soil, do not flourish or become so productive as such are transplanted from a poorer to a richer soil.

The seeds of apple will not produce the same kind of fruit; that I have fully proved, by one experiment. I raised in my garden, from the seeds of one favorite apple, ten trees, that after being planted in my orchard, grew to bear fruit, and one of them resembled their mother apple, and two were like each other. Seven others produced very small sour apples, some white, some tipped, some yellow, some early, others late. Of the other five trees I marked for grafting, one tree produced the largest and most thrifty apple, of good quality, pleasant, long, striped autumn, neither very mellow and juicy largest tree produced nor sour.—The next tree produced the flat piped, sweet apple, about the size of the flat piped, and will keep in the winter bear as well. The other, the smallest

tree of the ten, which grew the longest time before it produced, bore large, yellow, flat, sweet apples, that weigh about one pound, and fall off in due time for drying or making cider.

I have estimated such parts of my orchard as have been planted with trees, without grafting, to average about three good and valuable kinds of apples, from every ten trees. I disapprove of grafting the trees, when small in the nursery, as we may cut off better fruit than we insert, and destroy some better and larger kinds than are yet known.

I believe in Darwin's ideas, that the different kinds of apples have their certain age, after which they depreciate and expire, and that grafting is but an elongation of the same declining kind of tree; especially as the Vandaveer that used to be so large and fine since my remembrance is now extinct in the place of my nativity with a bitter rot, and the flat pippins, Rhode-Island greenings and blue pearmain, are very much depreciated in size and flavour.

At an early period of life, I was instructed in the practice of grafting, and thought I understood it perfectly, but a circumstance took place to convince me to the contrary, by some important facts in that art, which should be generally known.

Thirty-five years ago, last winter, I was travelling in the upper part of Maryland, near the banks of the Potomac river, and was informed that they had a curious old German doctor, a man of great science, that had paid much attention to arboriculture; that he had made between 200 and 300 acres of grafted orchard, and made vast quantities of cider all winter to supply the cities of Baltimore and Alexandria, besides feeding and fattening a large stock of creatures. I turned out of the road and went to see him, and was surprised, as I rode to the door, to hear him tell his negro, in German, to give my horse half a bushel of sweet apples. His situation was on a lime stone land, of a S. W. descent; some very rough; but his trees appeared to grow well amongst the rocks. In places where the ground suited it with lime stone springs, for mowing land. His orchards were too extensive for my view. He had a number of large framed buildings, in which he had large quantities of apples gathered to freeze, and said that apples after being frozen made the most and best cider. It was a mild thawing time, and he had abundance of people making cider. They ground their soft apples under large wooden wheels, turning in circular troughs. On the beds of the presses they had frames of slats in which they put straw to retain the soft pomace. Their presses were long beams, say 60 feet, raised and drawn down with levers. As the establishment stood on descending ground the cider ran from the presses, in troughs, and passed through several strainers before it entered the casks.

He informed me that he had been bred to orcharding in Germany, that he had raised and planted all his trees, and grafted the greater part of them, after they began to bear, if he disliked the fruit.

I observed that I thought the season would be too short for grafting so many trees. He told me that it might be performed at any time in the fore part of summer, if a wet growing time, and I would observe the following directions:

1st. Be careful not to loosen the bark of the stock in splitting it; and the safest way to guard against that is to split the bark with a sharp pointed knife, before the splitting of the stock.

2d. As after the leaves are grown it is not expected to use scions from a distance, but to cut them out of the orchard as wanted, be sure in selecting the grafts to cut them in such manner

as to always take the bulge, between the year's growth, to shave and set in the stock, as in that joint or bulge, between the year's growth, the wood is curled open, and porous, to receive the sap readily from the stock, and such scions will grow and flourish—when if taken from any other part of the twig they would not grow.

3d. The clay should be very fine and tough, and pressed and bound water tight round the stock below the split to retain all the sap that oozes out to support the graft.

By strictly adhering to this German science, I have grafted several apple trees as late in the season as the latter part of June, that flourished and grew well, and are the best of bearing trees.

From all the experiments that I have tried in raising orchards, I would advise setting out of the trees, and seeing a sample of their fruit before grafting, as all the best kinds of apples were at first natural, and perhaps by such a general trial some better kinds may appear than are yet known.

I would also advise in grafting such bearing trees, to only take off half the top in one season. I have often taken off the whole, and if the season is wet they have done well, but if the season proves hot and dry, the trees generally die, or the sun kills the bark on the south sides of them, and then they are ever defective; a rot takes place, and such trees generally blow down.

I have also observed that apple trees grow and bear the best when planted beside a stone wall, more especially these late seasons of great drought, that in parts of the country where the fences are generally of stone, abundance of apples might be raised without the trees incommencing the plough, and where there is only one row of trees across a field they may be planted within 15 or 20 feet of each other. In planting trees by a wall I would recommend as much as may be, to plant them on the north sides to keep the blossoms back and secure from the late frosts.

SAMUEL PRESTON.

Stockport, Penn. Oct. 10, 1822.

FROM THE NEW ENGLAND FARMER.

Admiral Sir ISAAC COFFIN, member of the British Parliament, having from a regard to his native State, and with a wish to promote its agriculture, purchased at great expense, a bull of the first breed in Great Britain, and sent him as a present to the trustees of the Massachusetts Society for promoting agriculture—

At a meeting of the Trustees held this 21st day of August, 1823:

VOTED, That the thanks of this Board be presented by the Corresponding Secretary to Admiral COFFIN, for his very valuable present, and that he express to him their sense of his patriotism, and attachment to his native soil, which neither time nor distance had been competent to weaken.

That the animal presented by him, is a noble one, and affords in his own person, proof of his descent from the most approved stocks, independent of the historical pedigree which accompanies him.

That for the present season, he be placed at the farm of John Prince, Esq. of Roxbury, and that he will be permitted to be used by any farmers at the moderate price of five dollars for each cow. In future years he shall be removed from time to time, to various parts of the Commonwealth, at the discretion of the trustees, and in no case shall an higher premium be required than is above stated, it being the wish of this Board to improve the stock of the country as rapidly as possible; and as the trustees receive no

emolument from him, should there be any, it will go to support the great interest of agriculture. If a lower sum should be demanded, farmers might be careless of his progeny; if an higher, they might not choose to incur so great an expense, at so much risk; his cost in England was \$581 64; the expenses of his transportation, &c. \$113 26 cents; whole amount \$694 90. His pedigree, as follows:—got by Mr. Wetherell's North Star; dam by Comet; grandam by Wellington; great grandam by Granby.

North Star was by Comet; dam by Baronet; grandam by Cripple; great grandam by Irish man; great great grandam by Hubback.

Notice will be given seasonably, every spring, in what county and town this bull will be placed, to the intent of affording to all parts of the state the advantages which may be derived from a stock, which the first agriculturists of Europe have deemed the most perfect, in regard to disposition for fattening, and aptitude for the dairy. This improved breed is not the result of accident, but of great care and attention, to make such crosses of the breed of horned cattle, as should combine the most valuable qualities. The trustees have every reason to believe, that the bull presented by Admiral COFFIN, (which arrived in fine order) combines all these qualities, judging from his pedigree and appearance.

When the trustees speak of the price of five dollars for each cow, being moderate, they have no reference to ordinary prices, but to the value affixed to bulls of this approved race, in England and America. Bull calves, of six months old, have been sold as high as 50 guineas, or \$233, in England, and in this country, at \$50. If the price were diminished, the best cows would not be sent to the animal; and it is the desire of the trustees that only the best cows should be sent. Breeds of cattle can never be improved, until there be sufficient encouragement offered for their production, and high prices alone can effect this desirable end.

Admiral Coffin was elected an honorary member of the Society, and a vote passed to present him the Society's Gold Medal, and the numbers of their Journal.

A copy from the record,
BENJ. GUILD, *Asst. Rec. Sec.*

The Trustees of the *Massachusetts Agricultural Society* cannot omit the opportunity of tendering, publicly, their thanks to Captain JACKSON, of the ship *Herald*, for the great care and attention bestowed by him on their fine imported bull, Admiral, presented to the Society by Sir Isaac Coffin, without which care he must probably have perished during his long and boisterous passage. This example is worthy of imitation, as upon the patriotic assiduity of ship-masters often depends the acquisition of plants and animals, which may prove of importance to their country.

In behalf of the Trustees,
JOHN LOWELL, *President.*

Roxbury, August 28, 1823.

Remarkable Occurrence.—In the year 1664, on the 5th of December, a boat on the Menai (North Wales,) crossing that strait, with 81 passengers, was upset, and only one passenger, named Hugh Williams, was saved. On the same day, in the year 1785, was upset another boat, containing about 60 persons, and every soul perished, with the exception of one, whose name also was Hugh Williams; and on the 5th August, 1820, a third boat met the same disaster, but the passengers of this were no more than 25, and, singular to relate, the whole perished,

with the exception of one, whose name was Hugh Williams!—*Bristol Mercury.*

Several interesting and very useful publications, connected with the every day's operations of house wifery, and domestic economy generally, have been published in England by Frederick Accum—of these we have received his "TREATISE ON ADULTERATIONS OF FOOD AND CULINARY POISONS," his "CULINARY CHEMISTRY, EXHIBITING THE SCIENTIFIC PRINCIPLES OF COOKERY," and his "ART OF MAKING WINE FROM NATIVE FRUITS." To give the reader an idea of the scope of the first above mentioned, we have taken a notice of it from Blackwood's Edinburgh Magazine, and as the time is at hand, and the fruit ready for the ladies to make their preserves, we have also given some recipes on that subject from his culinary chemistry; we shall continue to make these extracts, with reference to the season, rather than to the order in which they are presented in the work, and though we have the vanity to hope that the Farmer is generally read by the *mistress*, as well as the master of the families in which it is taken; to be useful to the *former* is our particular expectation and wish, in making these extracts; we desire therefore that the numbers containing them may be placed in their hands. Of their correctness and utility, they are more competent judges than we, the husbands—*Edit. Am. Farmer.*

A TREATISE ON ADULTERATED PROVISIONS.—BY FREDRICK ACCUM.

"THERE IS DEATH IN THE POT."

II. Kings—Chap. vi. Verse xi.

Mr. Accum, it appears, is one of those very good natured friends, who is quite resolved not to allow us to be cheated and poisoned as our fathers were before us, and our children will be after us, without cackling to us of our danger, and opening our eyes to abysses of fraud and imposition, of the very existence of which we had until now the good fortune to be entirely ignorant. His book is a perfect death's head, a memento mori, the perusal of any single chapter of which is enough to throw any man into the blue devils for a fortnight. Mr. Accum puts us something in mind of an officious blockhead, who, instead of comforting his dying friend, is continually jogging him on the elbow with such cheering assurances as the following. "I am sorry there is no hope; my dear fellow, you must kick the bucket soon. Your liver is diseased, your lungs gone, your bowels as impenetrable as marble, your legs swelled like door-posts, your face as yellow as a guinea, and the doctor just now assured me you could not live a week."

Mr. Accum's work is evidently written in the same spirit of dark and melancholy anticipation, which pervades Dr. Robinson's celebrated "Proofs of a Conspiracy, &c. against all the crowned heads of Europe." The conspiracy disclosed by Mr. Accum is certainly of a still more dreadful nature, and is even more widely ramified than that which excited so much horror in the worthy professor. It is a conspiracy of brewers, bakers, grocers, wine merchants, confectioners, apothecaries, and cooks, against the lives of all and every one of his majesty's liege subjects. It is easy to see that Mr. Accum's nerves are considerably agitated, that—

"Sad forebodings shake him as he writes."

Not only at the festive board is he haunted by

chimeras dire of danger—not only does he tremble over the tureen—and faint over the flesh-pot: but even in his chintz night gown, and red morocco slippers, he is not secure. An imaginary sexton is continually jogging his elbow as he writes; a death's head and cross bones rise on his library table: and at the visionary tombstone of the best end of his sofa he beholds a granite—

ON WHICH ARE INSCRIBED THE DREADFUL WORDS—

Hic Jacet,
FREDRICK ACCUM,
Operative Chemist,
OLD COMPTON STREET,
SOHO.

Since we read his book, our appetite has visibly decreased. At the Celtic club, yesterday, we dined almost entirely on roast beef; Mr. Oman's London-particular Madeira lost all its relish, and we turned pale in the act of eating a custard, when we recollected the dreadful punishment inflicted on custard eaters, in page 336 of the present work. We beg to assure our friends, therefore, that at the present moment they may invite us to dinner with the greatest impunity. Our diet is at present quite similar to that of Parnel's hermit,

"Our food the fruits, our drink the crystal well;"

though we trust a few days will recover us from our panic, and enable us to resume our former habits of life. Those of our friends, therefore, who have any intention of pasturing us, had better not lose the present opportunity of doing so. So favourable a combination of circumstances must have been quite unthought of on their part, and most probably will never occur again. V. S.

Since by the publication of Mr. Accum's book, an end has been for ever put to our former blessed state of ignorance, let us arm ourselves with philosophy, and boldly venture to look our danger in the face; or, as the poet beautifully expresses it, in language singularly applicable,

"Come, Christopher, and leave all meaner things,

To low ambition and the pride of kings;
Let us, since life can little else supply;
Than just to swallow poison and to die;
Expatiate free o'er all this dreadful field,
Try what the brewer, what the baker yield;
Explore the druggist's shop, the butchers' stall
Expose their roguery, and—damn them all!"

Por

Melancholy as the details are, there is something almost ludicrous, we think, in the very extent to which the deceptions are carried. So intricably are we all immersed in this mighty labyrinth of fraud, that even the victims of retribution themselves are forced, by a turn.—Thus tive justice, to swallow it in the honous ingredients to the brewer, chuckle at his daily copious and swallows his own drugs.

* To save some trouble, we may announce that we are already engaged, and to evening parties, on the 22d, 23d, 24th, 25th, 26th, 27th, and 28th of this month, on the 29th, and 30th of March.

exhibitions of brown stout. The brewer in his turn, is poisoned by the baker, the wine-merchant, and the grocer. And, whenever the baker's stomach fails him, he meets his *coup de grace* in the adulterated drugs of his friend the apothecary, whose health he has been gradually contributing to undermine, by feeding him every morning on chalk and alum, in the shape of hot rolls.

Our readers will now, we think, be able to form a general idea of the perils to which they are exposed by every meal.

Mr. Accum's details on the adulteration of wine are extremely ample; and so interesting, that we regret our limits prevent our making more copious extracts, and oblige us to refer our readers for further information to the work itself.

Having thus laid open to our view the arcana of the cellar, Mr. Accum next treats us with an exposé of the secrets of the brew-house. Verily, the wine-merchant and brewer are *par nobile futurum*; and after the following disclosures, it will henceforth be a matter of the greatest indifference to us, whether we drink Perry or Champagne, Hermitage or Brown stout. *Latet anguis in poculo*, there is a disease and death in them all, and one is only preferable to the other, because it will poison us at about one-tenth of the expense.

"Malt liquors, and particularly porter, the favourite beverage of the inhabitants of London and of other large towns, is amongst those articles, in the manufacture of which the greatest frauds are frequently committed.

"The practice of adulterating beer appears to be of early date. To shew that they have augmented in our own days, we shall exhibit an abstract from documents laid lately before Parliament."

Mr. Accum not only amply proves, that unwholesome ingredients are used by fraudulent brewers, and that very deleterious substances are also vended both to brewers and publicans for adulterating beer, but that the ingredients mixed up in the brewer's enchanting cauldron are placed above all competition, even with the potent charms of Macbeth's witches:

'Root of hemlock, digg'd i' the dark,

* * * * *

For a charm of pow'ful trouble,
Like a hell-broth boil and bubble;
Double, double, toil and trouble,
Fire burn and cauldron bubble.'

Mr. Accum very properly gives us a list of those miscreants who have been convicted of adulterating their porter with poisonous ingredients, and want of room alone prevents us from damning them to everlasting fame, by inserting their names along with that of the Rev. Sennacherib Terrot, in the imperishable pages of this miscellany.

Mr. Accum gives us a long dissertation on counterfeit tea, and another on spurious coffee; but as these are impositions by which we are little affected, we shall not allow them to detain us. The leaves of the sloe-thorn are substituted for the former, and roasted horse beans for the latter. These frauds, it appears, are carried to a very great extent.

We must now draw our extracts to a close; but we can assure our readers, that we have not yet introduced them to one tythe of the poisonous articles in common use, detected by Mr. Accum. We shall give the titles of a few to satisfy the curious:—Poisonous confectionary, poisonous pickles, poisonous Cayenne pepper, poisonous custards, poisonous anchovy sauce, poi-

sonous lozenges, poisonous lemon acid, poisonous mushrooms, poisonous catsup, and poisonous soda water! Read this and wonder how you live!

While we thus suffer under accumulated miseries brought upon us by the unprincipled avarice and cupidity of others, it is surely incumbent on us not wantonly to increase the catalogue by any negligence or follies of our own. Will it be believed, that in the cookery book, which forms the prevailing oracle of the kitchens in this part of the island, there is an express injunction to "boil greens with halfpence in order to improve their colour?" That our puddings are frequently seasoned with laurel leaves, and our sweet-meats almost uniformly prepared in copper vessels? Why are we thus compelled to swallow a supererogatory quantity of poison which may so easily be avoided? And why are we constantly made to run the risk of our lives by participating in custards, trifles, and blanc-manges, seasoned by a most deadly poison extracted from the *prunus lauro-cerasus*? Verily, while our present detestable system of cookery remains, we may exclaim with the sacred historian, that there is indeed "Death in the Pot."

CONSERVED FRUITS.

The preserving of the pulpy fruits employed in housekeeping for making fruit pies, tarts and puddings, so as to render them fit for that purpose, when they cannot be procured in their recent state, is an object of considerable importance in every well regulated family.

The expense of sugar is frequently urged as a reason for not conserving fruits in housekeeping, and to this may be added the uncertainty of success from the strong fermentable quality of many fruits, if the sugar has not been very liberally added. They may indeed be conserved for a length of time without sugar, by baking them in an oven and then closely stopping them up; but if the cork becomes dry, the atmospheric air exchanges place with what is impregnated by the fruit, which then soon becomes mouldy; some pulpy fruits may be conserved in good condition by the following method, for years, or even it is probable for a longer period, in hot climates.

CONSERVATION OF RECENT FRUITS WITHOUT SUGAR.

The following fruits may be conserved without sugar. The more juicy fruits of the berry kind, such as currants, mulberries, strawberries, raspberries, are not well calculated for this process.

METHOD OF CONSERVING GOOSEBERRIES,

Orlean Plums	Peaches
Green Gages	Nectarines
Damsons	Ballaces.

Let the fruit be clean picked, and not too ripe, put it into wide-mouthed, or what are called gooseberry bottles, let the bottles be filled as full as they can be packed, and stick the corks lightly into them; then place them upright in a saucepan of water, heated gradually to about 100 or 170° F. that is, until the water feels very hot to the finger, but does not scald. Let this degree of heat be kept up for half an hour, then remove the bottles one by one, and fill them up to within half an inch of the cork with boiling water; when cold let the cork be fitted very close, and lay the bottles on their sides, that the cork may be kept moist by the water. To prevent fermentation and mould, the bottles must be turned once or twice a week for the first month or two, and once or twice a month after-

wards. When applied to use, some of the liquor first poured off may serve to be put into the pie, or pudding, instead of water, and the remainder being boiled up with a little sugar, makes a rich and agreeable syrup.

The fruit ought not to be cracked by the heat; some trials were made by keeping the bottles in a heat of 190° for three quarters of an hour, but the fruit was reduced nearly to a pulp. It is also advisable that the fruit be not quite ripe, nor should it be bruised.

Some fruits may be preserved in a succulent state by being kept in water, without boiling—This is practised in regard to the cranberry: it also succeeds with the smaller kinds of apples.—All pulpy fruits, such as damsons, plums, &c., if gathered when not quite ripe, and not wounded, may likewise be preserved, by putting them into dry bottles, so as to exclude the air, by sealing over the cork, and then burying them in a trench, with the cork downwards.

CONSERVATION OF RECENT FRUITS, BY MEANS OF SUGAR, IN A LIQUID STATE.

A great number of fruits in their natural state may be conserved in a fluid, transparent syrup, of such a consistence as will prevent them from spoiling. This method of conserving fruits requires some care; for if they are too little impregnated with sugar, they do not keep, and if the syrup is too concentrated, the sugar crystallizes, and thus spoils the conserved fruit.

METHOD OF CONSERVING APRICOTS BY MEANS OF SUGAR.

Plums	Peaches
Damsons	Nectarines.
Green Gages	

Take apricots, not too ripe, cut a small slit near the stem end of the fruit, and push out the stone; simmer them in water till nearly half done, then peel them, and simmer them again for about twenty minutes in a syrup, made of two parts by measure of water, and one part by weight of loaf sugar. When this has been done, put them aside for about twelve hours; strain off the syrup, and to one pint of it add four ounces of lump sugar, simmer the fruit again for about ten minutes in this concentrated syrup; skim off the impurities that rise to the surface, and repeat the simmering of the fruit in the syrup three or four times; and, lastly, put the apricots into pots, and cover them with a syrup made of seven ounces, by measure, of water, and one pound of loaf sugar. Tie over or cork the jar to exclude the air.

CONSERVED PINE APPLES.

Break off the top and stalk of the pine apple, cut the fruit into slices, about one fifth of an inch in thickness; put the slices into an earthenware jar, at the bottom of which has been previously put a layer of powdered lump sugar, about one-eighth of an inch in thickness. Place on this stratum of sugar, a layer of the slices of the fruit, then put another layer of sugar, and so on; lastly, put the jar up to the neck into a saucepan of boiling water, and keep the water boiling for about half an hour, or till the sugar is completely dissolved, taking care to remove the scum that rises on the surface. Tie over the mouth of the jar with a wet bladder, or keep it well corked.

CONSERVED PEARS.

Put peeled pears in a stone pan with water, let them simmer till they are soft, skim them, and when cold simmer them for about ten minutes in a syrup made of three parts by measure

of water, and one by weight of loaf sugar, let them remain in the syrup till the next day; then pour off the syrup from the pears, simmer them again for about ten minutes, and repeat the simmering in the syrup three or four times successively. They are usually coloured red by powdered cochineal, a small portion of which is added during the boiling process. Some persons add cinnamon, and other spices, and a portion of port wine. If the pears be not intended to keep, they may be simmered till done in a syrup, composed of one pound of sugar and three pints and a half of water.

CONSERVATION OF RECENT FRUITS, BY MEANS OF SUGAR, IN A SOLID FORM.

The name of *candied fruits*, or *confits*, is given to such substances as are preserved by means of sugar in a solid state, so that the whole substance is impregnated and covered with sugar, in a crystalline, or solid state.

CANDIED ORANGE, OR LEMON PEEL.

Soak Seville orange peel, well cleaned from the pulp in several waters, till it loses its bitterness; cut it into thin slips, simmer them in a syrup composed of two parts, by weight, of lump sugar, and one of water, and continue the simmering till they are become tender, and nearly transparent. Then take them out, put them aside for about twenty-four hours; and simmer them again in a sufficient quantity of a syrup composed of six ounces, by measure, of water, and one pound of loaf sugar, and continue the simmering till the sugar candies about the pan and peel. Now lay them separately on a wire sieve to drain; sift finely powdered sugar over them, whilst still hot, and put them to dry in a warm stove.

Candied lemon peel may be prepared in the same manner.

Natural History.

FROM THE N. Y. MEDICAL AND PHYSICAL JOURNAL.

Remarks on the Columba Migratoria, or Passenger Pigeon. In a letter to Dr. J. W. Francis, from De Witt Clinton, Esq. L. L. D.

ALBANY, April 24, 1823.

Dear Sir—The Columba Migratoria, or Passenger Pigeon, is a bird peculiar to North America. It extends its migrations from Hudson's Bay to the Gulf of Mexico, and it occupies occasionally that vast region which reaches from the Gulf of St. Lawrence to the Rocky Mountains. Its change of residence is not owing to the influence of heat or cold, of rain or drought, but is made with a view to the acquisition of food. The vast flocks in which this bird congregates, are unequalled as to extent. La Hontan says, that the Bishop of Canada has been forced to exorcise them oftener than once, on account of the damage they do to the products of the earth. Weld, an English traveller, speaks of a flock eighty miles long flying over Lake Ontario; and Wilson, the great ornithologist, estimates one seen in Kentucky, two hundred and forty miles long, a mile broad, and containing two thousand two hundred and thirty millions and two hundred and seventy two thousand pigeons, which would consume on a moderate allowance, seventeen millions four hundred and twenty-four thousand bushels of mast a day.

The gregarious habits and vast flocks of this bird will of course occasion a correspondent consumption of food; and it is therefore compelled to be constantly erratic, and to be among the feathered race what the nomades are among

mankind. The rapidity of its flight is superior to that of the carrier pigeon which has been known to pass from St. Edmundsbury to London in two hours and a half. At this rate, the Passenger Pigeon can travel seven hundred miles in twenty-four hours; and at the rate of a mile a minute, the same distance in less than twelve hours: and this velocity may account for undigested rice being found in its craw six hundred miles from the rice fields; but as this has been observed in the spring of the year, it must have been derived in that case from the gleanings of a former season, or procured at a greater distance, or confounded with the zizania aquatica of the western waters. The favourite food of this bird is the beech nut, and it prefers to establish its roosting quarters and its breeding place within the reach of this aliment. It also subsists on the acorn, chesnut, wild cherry, seeds of the red maple, and of some weeds, poke, and other kinds of berry, buckwheat and the principal cerealia. It resorts to the sea shore and the salines of the west for salt, and it is frequently seen at the mineral springs of Saratoga enjoying the luxury of the waters.

This bird is in much request as an article of food; and in the spring it arrives at an opportune period for our markets, during a scarcity of domestic poultry, and in the interval after the consumption of most of the old stock, and before the maturity of the new brood. In the hard winter, as it is commonly called of 1741, the weather was intensely cold from the middle of November to the latter end of March. The snow was six feet deep. The Hudson River was passed on ice at the city of New York. The cattle perished; and the deer were starved for want of food. The prices of food and fuel were exorbitant, and the sufferings of the poor were severe. In this crisis, and five or six weeks earlier than the time of their usual appearance, flights of wild pigeons appeared in greater numbers than were ever before known, and which, by the abundance of the food thus afforded, greatly relieved the prevalent distress. This at the time was attributed to a special interposition of Providence, under a supposition that this bird is incapable of resisting severe cold; and this is now the general impression, which shows that its nature is not well understood. It has been seen at Hudson's Bay in the month of December, and large flocks were observed in Albany and the north western parts of this state in January and February, 1819.

There are other errors with respect to this bird. It is generally believed, that it will not breed in captivity, and that it is incapable of domestication. And our distinguished ornithologist, Wilson, has unhesitatingly asserted, that it only has one squab or young at a time.

If this latter position were true, it would furnish an anomaly in ornithology. All birds of the Columba genus, have heretofore been supposed to produce by pairing, and to have two young at a time, generally a male and female. The male pigeon participates in the labours of nidification and incubation, supplies the female with food when on the nest, and assists in feeding the young. But where polygamy prevails among birds, the whole labour devolves on the mother. The domestic or exotic pigeon lays two eggs at a time; and our only indigenous birds of the Columba genus, (besides the Passenger Pigeon,) the turtle dove and the ground dove, do the same. Why then should the Passenger Pigeon be an exception? The male assists in building the nest, and occasionally relieves the female in incubation; and it is remarked, that in the breeding season, the two sexes are never seen together. This is owing to their divided labours: for the male makes up for the greater devotedness of the fe-

male to incubation, by occasionally supplying her and the young with food. We then can see no reason for so strange a departure from the general rule, attributed by Wilson to the Passenger Pigeon in the extent of its production: and when we further consider the prodigious flocks of this bird, transcending all other collections of birds, we cannot easily acquiesce in his opinion, especially as he admits that it only produces three or four times in a year. But there is no reasoning down facts, and this is a question of fact. On diligent inquiry, I am satisfied that Wilson has been misled by inaccurate information. Benjamin Wright, Esq. one of the principal engineers on the Erie canal, says in a letter dated the 14th of August, 1822, "Wilson is under a great mistake when he asserts that the wild pigeon has but one young. I am confident of seeing, when a boy, two eggs in the same nest. In order to be certain that my memory was not treacherous, I have consulted Mr. Green, a man of observation, and famous for taking pigeons. He is also positive that two eggs and two young are often found in one nest. He says, that the nest is built with little twigs loosely put together, and that the eggs frequently fall through, but that he is confident of observing, when only one egg could be found in the nest, that the other could be discovered to have fallen out of it." Mr. Wright, some months after this communication, informed me that subsequent inquiry had confirmed, in this respect, the accuracy of his impressions.

David Thomas, Esq. another principal engineer and a distinguished naturalist, in a letter dated 22d August last, says,

"I have not ascertained any particular fact relative to the young of the wild pigeon, though the common opinion is that it has two at one time."

But to remove all doubts on this question, I shall now mention an experiment successfully tried by Mr. Paul Clark, a respectable citizen of Albany.

This gentleman informs me that he has frequently seen in the woods, two eggs and two young in the nest of the wild pigeon. He has tried, for many years, to breed pigeons from those caught in the net, and has never succeeded. At last it occurred to him to vary the experiment. He took a female squab from a nest in the woods and brought it up in a cage. He put with her a male which had been taken in a net, but having been caged for three years, it was quite tame. They were placed in a wide and high coop, about which they could fly, and a small pine tree was planted in it, upon which they built a nest and bred, and their offspring kept in a similar way, have also produced. Last year two pair began to breed in May, and continued until September. One pair produced seven and the other eight times. Thirteen of the young survived. They laid sometimes one, but oftener two eggs for the same sitting. The confinement prevented in Mr. Clark's opinion, a greater increase. In twenty-three days from the laying of the eggs the young ones could fly; and in eight days from their being hatched, they are completely feathered, and fly from the nest; whereas the tame pigeon is hardly feathered in eight days, and according to a memoir of M. Tessier, to the Royal Academy of Sciences, of Paris, its period of incubation is from seventeen to twenty days. Latham, in his general Synopsis of Birds, says that the domestic pigeon, Columba domestica, or Columba Oenas of Linnaeus, has, in its wild state, not more than two broods in a year, but after being domesticated, ten or twelve. Other writers say but eight or nine.

The difference between our wild pigeon, and the tame pigeon in its wild state, is, as to pro-

ductiveness, greatly in favor of the former. It breeds, it is believed, twice as often; its period of incubation is shorter; its produce the same as to number, and its young arrive sooner to maturity, and, in an unreclaimed state, it vastly transcends the pigeon of the old world in number. If Mr. Clark's experiment shall be more extensively realized, so as to secure the residence of the American pigeon in an open pigeon house, then it will be an important addition to our domestic poultry. This is its appropriate climate, and domestication will enlarge its size, and augment its productiveness. The parent stock of the tame pigeon, and all its twenty beautiful varieties of carriers, pouts, nuns, owls, fan-tails, tumblers, &c. is the stock dove, or *Columba Oenas*; and this bird, in its wild state, does not exceed thirteen and a half inches in length, and twenty-two in breadth; whereas, our wild pigeon is sixteen inches in length, and twenty-four in extent.* Domestication will have the same effect on the character and beauty, plumage and variety, fertility and usefulness, of our wild pi-

* *Vide Montagu's Ornithological Dictionary, and Wilson's Ornithology.*

geon, as it has had on that of the old continent. According to Pliny, if you suppose two pigeons to hatch but nine times a year, they may produce, in four years, fourteen thousand six hundred and seventy young. Our pigeon, if Mr. Clark's experiment fully succeeds, will be more productive.

The tame pigeon is whimsical and fluctuating in its attachments to home. It prefers according to Buffon, elevated buildings, and habitations on elevated ground. Trifling circumstances will sometimes induce it to abandon its home, and it has even been known to change its partner in the most capricious manner. A person in Albany had two tame pigeons in a coop; the female was on the nest. A strange female visited the inside of the coop, and a courtship took place with the male, which was resented by the wife, who came out from her nest and made a great noise.— Finding her efforts unavailing, she left her house in the course of a week, and the stranger occupied her place. What is called a *salt eat*, which is composed of loam, old rubbish, and salt, will entice pigeons to remain where they are and allure them from other places. *Assafœtida*, common salt, and a looking glass, are said to

have a similar effect, and plenty of food deposited in their houses, will check their truant propensities.

Although some birds are peculiarly wild, and have never yet been domesticated, yet it may be observed, generally, that they are more tameable than quadrupeds. The latter flee from man, while the former gather round cultivation. The attainment of food is the efficient cause of this approach to the habitations of men; and if Mr. Clark shall, by proper treatment, and a judicious application of appropriate allurements, carry his experiment to completion, as it respects permanence of residence, as well as breeding he will be entitled to the credit of having tamed for the benefit of man, an animal more useful and productive, than its congener, the tame pigeon, which has been prized as an important acquisition since its first domestication. *Columella* says, that in ancient Rome, four thousand *nummi*, (which is upwards of one hundred and forty-three dollars,) have been given for a pair; and *Pococke* observes, that a pigeon house is considered a great part of the estate of the husbandman in Egypt.

D. W. C.

FROM THE PHILADELPHIA AGRICULTURAL ALMANACK OF 1823.

THE MOWING MACHINE.

THE MOWING MACHINE,

Of which the annexed cut is a representation, was invented by Jeremiah Bailey, of Chester county, who has obtained a patent for the same.

It has been extensively used and approved of during the last season, in the neighbourhood of the patentee, and promises to be of great public utility. It is understood that it will mow ten acres per day. The following description will explain its operation and shew the skill and ingenuity of the inventor.

This machine is supported by two wheels on different axles. The left wheel is fixed to its axle so that they revolve together. The right revolves on its axle like a common cart wheel, and is placed about a foot further back than the other. The left works within the frame and has a circle of cogs screwed on the outside of the fellows, but of a less diameter, to keep them from the ground. These cogs work into a vertical cog wheel in front, that turns an iron shaft extending

horizontally towards the centre of the machine: upon the inner end of this shaft is fixed a vertical fuce wheel, whose cogs turn a trundle head or a vertical shaft. To the bottom of this shaft, near the ground, is fixed a circular horizontal frame work, on the circumference of which is screwed the scythes in six parts, laid horizontally, with the edges turned outward, so as to form a complete circle. To keep the scythes at a proper distance from the ground, the bottom of the shaft is supported on a piece of wood of the machine, secured by a tye from the tail, somewhat resembling a sled runner in which it works in the manner of a *gudgeon*—with the inequalities of the ground, the scythe frame, shaft and trundle head rise and fall.

The edge of the scythe in its revolution passes under a whetstone fixed on an axis and revolving with the scythe. To create friction, this axis is more or less inclined to the line of direction of

the revolution according to the friction required. This stone, by means of a sliding roll, by which it is attached to the machine, rises and falls with the scythes.

To prevent too great a pressure of the trundle shaft and scythe frames on the ground, a lever like a steel-yard is fixed to the top of the shaft, extending to the tail of the machine where it is weighed according to the nature of the ground and grass.

The horse is put into shafts and *walks* in front of the left side of the machine, and always on the mowed ground after the first swarth is cut.

By the increase of velocity, the scythes revolve with great swiftness. The grass as it is cut is first thrown by the progressive motion against a rise in the sythe-frame toward the centre, and by the same motion, is afterwards thrown off in a regular row, following the centre of the machine.

EXTRACTS FROM LATE NUMBERS OF THE
London Farmer's Journal.

ON MANURE.

Hunton, Dec. 14, 1821.

Induced by Mr. Wright's questions, and your own note thereon, I presume to send you a few observations in reply. To the first question, as to the proper depth of covering manure, I conceive the shallower the manure, be it of whatsoever kind, is buried in the soil, the better; but, at the same time, it is necessary that it should all be covered with the natural soil, if possible. In answer to the second question whether exposure to the sun by frequent ploughing in summer, benefits or injures, the land; I have no hesitation in saying, that it is decidedly beneficial to all soils, but by far most so to those of a heavy and tenacious kind. As to what are the benefits land derives from summer fallow, I have to reply, that they are various in nature and degrees. The benefits I have witnessed are these;—to expose the insects, which prey on vegetation, to devouring birds to give greater effect to that primary source of warmth and life, and fertility, the sun; to destroy noxious weeds, and to bring the earth to a pulverised state, on which the genial rains can act with greater effect. These advantages follow on light soils, and on heavy tenacious lands, they are experienced in a much greater degree; indeed, the heaviest soils become barren without summer fallowing. As to the next question, which embraces so wide an inquiry, I must leave it to better-informed persons than myself. The last question I will presume to answer, by assuring the enquirer, that no crop of any kind can ever render the soil so fit for the same course of crops again, as if summer fallowed; for there is no growing crop whatever, but must deprive the land of some portion of its fertility, unless accompanied or immediately followed by manure.

ON FEEDING WITH MANGEL WURZEL.

Kilton, Dec. 28, 1821.

SIR—I perfectly agree with your correspondent P.* in his answer to M. W. in your last Journal, as to the value of Mangel Wurzel as food, not only for sheep, but also for bullocks, pigs, &c; but experience has taught me that it should be used with caution at the commencement of feeding, that is, a small quantity only should be given: I therefore offer M. W. the result of my experience in the use of it.—The frost and snow of the winter 1820, depriving me of my other succulent food for my breeding ewes, I was obliged to make use of the store of Mangel Wurzel, which was placed in troughs; hay was also allowed. Not having given any to ewes before, I was induced (in consequence of the Holkham cows being palsied a few years since, and having witnessed similar effects in my own) to notice particularly the effect: some of them fed voraciously; these, in a short time, sickened, and in a few days began to lose their wool, and a part became quite naked; those were also the first that weaned their lambs in the spring. I would therefore recommend to M. W. to give his ewes near the time of lambing, and those recently lambed, but a small quantity, increasing it as the lambs increase in size, as experience has convinced me, that to create, by any succulent food, the greatest possible flow of milk in the ewe, when the lamb is young and not able to draw the whole quantity from the udder is a bad practice of shepherding.

As Mangel Wurzel stands, in my opinion, pre-eminence of all cattle crops, and having been a cultivator of it several years, and having tried

several modes of cultivation, I intend the first opportunity, to detail for your service, the mode I found most successful. I am, Sir, Your's truly,
C. ADDAMS.

P. S. As a specimen of the ability of farmers being enabled to drink their "pint of wine," or their "noxious dram," as your Hampshire correspondent describes in your last Journal;—at a sale of farming stock, a few days since in this county, (Somerset), distrained for rent (now a very common practice), a pig which was stated to be near or quite three months old, was knocked down at only one sixpence! and another at 1s.; the other stock was sold at or less than one third of the price it would have made seven or eight years since.

CHALLENGE FROM THE HEREFORDS.

Lynch Court, June 25, 1823.

Several challenges having been offered at different times to show Short Horns against Herefords, I am induced to make an offer, which if accepted, I am inclined to think, would go farther to throw some light upon this interesting question, than could be obtained by the bringing of single animals of a particular description into opposition. A man may by accident, or by superior keeping, possess a very excellent animal, whose general stock may be nothing extraordinary; but if the whole or the greater part of his breeding stock is found to excel, he is fairly entitled to pre-eminence. I wish to bring such a portion of my breeding stock into competition with any other breed, as shall afford a fair specimen of the whole, without being so numerous as to render their exhibition seriously inconvenient. I therefore hereby offer to shew two bulls, two cows, two three-years-old heifers, two two-years-old ditto, two yearling ditto, two heifer calves, and a bull calf. I would have made it two bull calves, but I have only two, and one of them has met with an accident, and will probably be too lame to travel. In order to take in all persons who may wish to accept this challenge, I profess myself willing to shew my stock for any sum not exceeding one hundred guineas, or merely *four l' honneur*, or, as we say in English, *for love*. The stock to be shewn at Sir Charles Morgan's next show: none of the cattle to have had any milk except what was afforded them by their own dams, and none to have had cake or corn in any way, since they were four months old (except the bulls) and to be the property of the person accepting the challenge at the date of this letter. As my object in making this offer is avowedly to establish the excellence of the Hereford breed of cattle, my challenge only extends to those of other breeds.

I remain, Sir, your obedient servant,
J. R. SMYTHIES.

Editorial Correspondence.

Extract to the Editor, dated

LANCASTER C. H. (Virg.) 27th May, 1823.

"I have recently passed through several of the upper counties of this State, and never in my life saw such promising corn crops. From a field of about fifteen acres, Major Peter, the proprietor, expects to make twenty-five barrels to the acre. The corn was planted in double rows about eighteen inches apart and eighteen inches in the drill, two stalks in a place; a space of five feet then intervened, the double rows as before, and so on through the field."

Charleston, September 1, 1823.

DEAR SIR,
Permit me to request you will correct a typographical omission, at the conclusion of my let-

ter of the 9th July, inserted in your paper of the 22d August, No 22; upon the subject of the Isle of France Cotton.—"It is yet in blossom,"—it ought to be as in the manuscript—"It is *not* yet in blossom." At this advanced period, cotton of every description is in bloom—our Island Planters are at present picking 40 and 50 pounds to each negro per day.

I visited my plantation a few days ago.—The Isle of France cotton, of which I have about twenty or thirty stalks, had grown to the height of five feet, and had branched out very much—it was *not even yet* in blossom—I do not think it will answer in our climate.

I remain, very respectfully,
CHARLES E. ROWAND.

J. S. SKINNER, Esq.

THE FARMER.

BALTIMORE, FRIDAY, SEPTEMBER 12, 1823.

✓ HEDGES.—We have been informed that the modern practice in England, is to trim hedges to the shape of the wedge,—point upwards.—The object is to ensure to the whole surface an equal action of sun and air, and by that means an uniform verdure and thickness. In the usual square form, the sides and bottom part are shaded, while the sun shines full upon the top—hence so much irregularity in the verdure and growth, spoiling the appearance and destroying the strength of the hedge.

LATE FROM FRANCE.—The ship Paris, Captain Robinson, has just arrived from Havre, from which port she sailed the 1st of August.—We have received Paris dates of the 29th, and London of the 27th.

A battle had been fought at Corunna, in which the French were defeated with the loss of 700 men. Sir Robert Wilson had been wounded in this engagement. Things did not look as well in France as formerly—the people having expressed complaints of the tardy operations of the armies in Spain.

Cotton has risen in Havre, in consequence of the rise in England—New-Orleans 27 to 33 sous, Upland 25 to 28.

BALTIMORE MARKET.

PRICES CURRENT—CORRECTED WEEKLY.
Flour, best white wheat, \$7—Howard street, from wagons, \$6 3/4—Superfine, \$6 50—fine do. \$6 25—Wharf, do. \$6 00—White wheat, \$1 14 to 1 25—Red do. \$1 05 to \$1 12—Rye. 45 cts.—Corn, 36 a 39 cts.—wharf Oats, 25 a 26 cts.—wagon Oats, 28 cents—Beef, 8 cents per lb.—Live Cattle, 26 to \$6 50, per cwt.—Bacon, hog round, \$10—Pork, \$4 50 to 5 50 per c. lb., 6 to 8 cts. per pound—Mutton, 5 to 6 cts. per lb.—Beans, retail, \$1 50, cargo price, 1 12—Peas, retail, 75 a 80 cts., cargo price 58 a 60 cts.—Red Clover Seed, \$6—Orchard Grass do. \$3—Herds' Grass do. \$3—Timothy do. \$4—Flax Seed, 75 to 80 cents—Whiskey, from the wagons, 35 to 36 cts. per gal. including the barrel—Apple brandy, 30 to 32 cts.—Peach do. 65 to 70 cts.—Shad, \$6 00,—Herrings, No. 1, \$2 70 per bbl., No. 2, \$2 3/4—Fine Salt, 60 to 65 cts. per bush., coarse, do. 70—Butter, (firkin) 14 cts. per lb.—Eggs, 10 cts. per doz.—New Hay, \$15 per ton, old do. \$18—Straw, \$10.

MARYLAND TOBACCO.—No sales.

Prices of fresh seeds at Philadelphia.
Clover \$7—Timothy, \$3 to \$4—Orchard, \$2—Herd, 75 to 100 cents—Millet 50 cents.

AGRICULTURE.

INTERESTING EXTRACTS—*from Agricultural and other addresses, memoirs, &c. on the files in the office of the American Farmer.*

FROM AN ADDRESS DELIVERED BEFORE THE AGRICULTURAL SOCIETY OF NORTH CAROLINA, DECEMBER, 1822, BY DR. R. H. HELME, OF JOHNSTON COUNTY.

The low estimation in which agriculture has heretofore been held in this country, has militated much against its encouragement and improvement; it has been confined to those chiefly who were ignorant of its first principles, although some individuals of scientific acquirements are engaged in what they call farming, yet in nine cases in ten it is with them a secondary object; their attention is taken up with some more lucrative and fascinating pursuit than the dull and monotonous labor of tillage. Every parent who can give to his son an education above that of mediocrity, sees with eyes of parental partiality in this son, the germ of a great man, and he would think it a culpable neglect of his duty, a derogation of his fatherly discernment, and a blighting frost to the budding genius of his son, were he to make any thing less of him than a lawyer or a doctor; *but of the many lawyers and doctors that are called, how few are chosen*; little does the blind and fond parent think that in placing his son in a sphere nature never intended him to occupy, he is entailing upon him misery and disgrace; how many are there this day of thirty, forty, and fifty years of age, who repent in bitter agony this misapplication of talents; as farmers, as mechanics, they might have been respected and honored in their stations, but having spent their youths in the pursuit of an object beyond their capacity to reach, they are at this day unfitted for the one or the other, displeased with themselves and envying those who outstrip them in their professions, they will go down to the grave "unwept, unhonored and unsung." The minds of men are not all cast in the same mould, nor fitted to follow in life's devious path the same pursuit,

"For not alike to every mortal eye

Is this great scene unveil'd. For since the claims

Of social life, to different labors urge

The active powers of man; with wise intent

The hand of nature on peculiar minds

Imprints a different bias, and to each

Decrees its province in the common toil.

To some she taught the fabric of the sphere

The changeful moon; the circuit of the stars

The golden zones of heaven; to some she gave

To weigh the moment of eternal things.

Of time, of space, and fate's unbroken chain,

And will's quick impulse. Others by the hand

She led o'er vales and mountains, to explore

What healing virtue swells the tender veins

Of herbs and flowers, or what the beams of

morn

Draw forth."

To place agriculture upon that high and honorable ground, which it ought to sustain, and to make the knowledge of it worthy the ambition and the pride of the youths of our state, there ought to be established a Professorship of Agriculture in our university. If I am not misinformed, the pecuniary situation of that institution is amply sufficient for the purpose, and if it is not, I certainly believe that the present legislature emphatically styled the collected wisdom of the state, representing with others, the agricultural interest of the community, would give their undivided support to a measure, as I humbly conceive, wise in its project, and beneficial in its

ends. The Agricultural Society of Albemarle, in Virginia, have proposed such a measure to the citizens of that state, and Mr. Madison has undertaken to see it carried into effect. With such a noble example before us, we ought not to hesitate.

Were the funds of this society sufficient, I would recommend the appointment of a skilful and scientific agriculturist, assisted by Professor Olmstead, of our university, as a geologist, to make an agricultural and geological tour of the state; it would tend much to the promotion of our art, and have a happy influence in harmonising the jarring interests which now divide its western and eastern sections. As connected with the advancement of agriculture, good roads and navigable streams, are of primary importance; but to carry this object into effect depends upon those who hold the purse strings of the state. Upon the internal improvement of the state much money has been expended, and little benefit derived; public excitement is aroused, and I am fearful public opinion is against it. In my humble opinion, if those who have had the superintendence of the improvement of our rivers had begun at their mouths and worked against the stream, they would have brought with them the good wishes and the purses of the people. Instead of seeing the members of the legislature, for fear of losing their seats, voting against a measure of such vital importance to all classes of the community, you would see them vying with each other who should be most zealous in its promotion. I am sorry to say that we are deficient in state pride, and have borne the scourge of ridicule from our sisters of the union, until we have become insensible to the smart. Look at New York, she has brought the lakes to the ocean, and the mountains to the sea board; she has opened her treasury for the encouragement of agriculture, and by the sound policy and political wisdom of her rulers, she is destined to become the greatest agricultural and commercial state in the union.

It becomes necessary for farmers in their endeavours to improve the husbandry of the state, to relinquish the old method of shallow ploughing up and down hills, and taking from the land for a succession of years, a crop of the same kind: to this injudicious method is it owing, that so many barren "old fields" lay waste. Few farms in the hilly part of our state are intrinsically worth, by fifty per cent. as much as they were twenty years ago. By shallow ploughing, the soil of hills has floated down our rivers, fertilizing their banks, choking their channels, and stopping their mouths: deep and horizontal ploughing, a judicious rotation of crops, and a liberal application of manure, will yet restore them to their former fertility. Our farming utensils are, in the general, illy calculated to answer the purposes for which they are intended; like the mechanic, the farmer cannot do good work without good tools.

There is no better evidence in any country of the state of its agriculture than the appearance of domestic animals. To judge of North-Carolina husbandry by this criterion, the result would not be much in its favor. Maryland is retrieving fast her former supineness, by her Agricultural Societies, her Fairs and cattle shows, and the great attention she is now paying to the improvement of neat cattle, horses and mules. These societies are creating a new era in the agricultural history of this country.—Ours is the only one whose beneficial influence has not extended beyond the walls of the room in which we meet. Why so much apathy in a cause so important to ourselves and our country? We may meet here once a year, salute, shake hands, and depart;

but unless we do something more efficient than we have done, little good will agriculture derive from our labours. Why cannot we have a Fair and Cattle Show in the city of Raleigh? (I name this place as being near the centre of the state.) Once commenced it will grow of itself; and the advantages to be derived from it to agriculture will be incalculable.—If our funds are not sufficient to meet the premiums we may wish to award, petition the legislature now in session for assistance, and I have no doubt that a body so wise and patriotic will not hesitate to grant it. Let us, however, recollect the fable of Hercules and the wagoner.

The geological knowledge that I possess of this state is confined to a small portion. This city is the western boundary of my travels. I should feel great satisfaction in being able to communicate to you the different soils that variegates its surface.

From this to the Atlantic the predominant constituent of the soil is silicia, or sand. The margins of our rivers, which is the most productive lands I have seen in the state, afford, upon analysing, sand, lime, clay, and that dark powder which is the effect of decomposition of dead vegetable and animal matter, called by Davy an extractive matter, and by the French chemists, Terreau.

Probably there is no State in the Union which would afford a greater diversity of soil than ours, or which is better adapted to the purposes of agriculture. Almost every plant necessary to our immediate want or comfort, that will grow this side of the tropics, will flourish here. It was thought for a long time that the cotton plant required a warmer climate, and more congenial soil; experience, however, has proven the fallacy of this opinion. The cotton of North Carolina sustains as fair a character in the European markets as any upland cotton in the union.

This plant known in Botany by the name of *Gossypium Herbaceum*, is a native of the East Indies, and by that great naturalist, Linnæus, is arranged in the sixteenth class of his sexual system, Monodelphia, (or one brotherhood) which not only embraces vegetables of the smallest but of the most stupendous size. The dimensions of the *Bombax Petandrum*, a tree of Africa, is incredible to those who have not made natural history their study. According to the account of William Bosman, who saw it in its native soil, it would afford shelter to an army of twenty thousand men, without incommoding each other under its branches.

"Nature! great parent! whose unceasing hand
Rolls round the seasons of the changeful year,
How mighty, how majestic are thy works!"

I have little doubt but that the sugar cane might be brought to assimilate to the climate of this state. It is a wise provision of Providence, and calculated to draw from us the warmest feelings of gratitude to the great Giver of all Gifts, that vegetables necessary for our subsistence are made subservient to our industry and perseverance. Wheat, which has been aptly styled the king of grain, and which constitutes such a large proportion of the bread-stuffs of the civilized world, flourishes beneath the soft and vivifying beams of an Italian sun, and lives in the icy fetters of a Canada winter.—It has followed civilized man, in his migrations from the fertile banks of Euphrates.

"To where dread winter spreads its latest glooms
And reigns tremendous o'er the conquer'd year."

Naturalists inform us, that so influential is the power of climate and cultivation over the habi-

of vegetables, "that when transplanted into cold climates, many of the perennial plants become annular, and the species are perpetuated by seed. Thus in its native warm climate, the Ricinus Communis, or Castor Oil plant, has a shrubby stem, and is a perennial, but in cold climates both the root and the stem perish, and the vegetable is continued by its seed." Evergreens, when carried from a cold to a warm climate, become peridifols, and vice versa. The Quince tree is a peridifol in cold climates, but becomes an evergreen when transplanted to Italy and the south of France; and professor Barton has informed us, that "that truly beautiful vegetable, the Franklina Altamahaw, since its first introduction into Pennsylvania, has changed its time of flowering nearly two months." The oaks and the poplars of Europe, when carried to the Cape of Good Hope, put forth their leaves on one side of the equator, while they are shedding them on the other. If vegetables are thus made to bend to the force of climate, is it an idle conjecture to suppose that the cane or the olive might be made to mature here? The cultivation of the vine would be both a pleasing and profitable business. I know nothing of its culture from experience, but am warranted in saying that both soil and climate are suitable to its growth. Our forests teem with indigenous vines, and I have no doubt, were they properly tamed and controlled by cultivation, their produce would equal the wines of Europe in flavor and quality. "The vinous latitude extends from 25° to 51° north." The cultivation of the vine is of high antiquity: "Noah planted vineyards and made wine." The heathens deified Bacchus for having learnt them the uses of wine. The Grecians and the Romans paid great assiduity to its culture. Plato says that wine is the most invaluable gift of God to man. Portugal, France, Switzerland, Germany, Spain and Hungary cultivate the vine with great success. The island of Madeira exports annually about 35,000 pipes of wine, which costs in this country from three to six dollars per gallon. The cultivation of the vine commenced in that island about four hundred years ago, when the first cuttings were carried there from Cyprus. France at present excels the rest of Europe in this branch of Agriculture, and it is supposed the brandies made from the grape in that country produces annually from eight to ten millions of dollars.

Agriculture in its slow and sober movements, teaches us economy, temperance and frugality. The prudent farmer looks unmoved upon the fickle goddess of fortune, as she sports with the feelings of those who flock to her temple, but pities the subjects of her waywardness. *Few indeed are the instances in this country of a farmer's becoming insolvent, who has devoted his whole time and attention to the pursuits of his vocation, and been contented with its slow but sure gains.*

The riches of a moment's growth, in a moment takes wings and fly away; but that competency which is the reward of honest industry travels with us to the grave, and certainly if there ever was a country which held out inducements to the husbandman to exert his industry and enterprise, it is this—the land of liberty and the abode of freemen—our civil, political and religious rights secured to us by a government whose foundation rests upon the will of the people, and so long as that adamant chain of unanimity which binds together the north and the south, the east and the west, shall remain unbroken, it will continue to be

"The land of the brave, and the home of the free."

December 16, 1822.

FOR THE AMERICAN FARMER.

ON THE CULTURE OF SEA KALE.

This is a deep rooting plant, and therefore requires a good depth of soil, either of a sandy or light loose loamy nature: if it be not naturally this, it should be made so by trenching it two and a half feet deep, and then it may be made after the manner of an asparagus bed, but it will not, like asparagus, require a repetition of manure afterwards, except for forcing.

SOWING.

The bed may be four and a half feet wide, and when ready for sowing, stretch a line lengthways the bed, and one foot on from each side, and along these two lines at the distance of every two feet, mark a circle of five inches diameter, in which plant five seeds thus,

two inches deep; if two beds are wanted, a second may be made and planted in like manner, alongside of the former, with an alley between them of eighteen inches wide. This should be done in the fall.

First year's management.

In the spring the seeds will vegetate, and as they appear, protection should be given them against the turnip fly, which otherwise will soon destroy them. In about a month or six weeks the plants will become sufficiently strong to withstand the ravages of the fly, and then three only of the strongest plants, should be suffered to remain in each circle, and the rest removed and planted out with their tap roots perfect, either to supply vacancies or form another bed if required.

The plants should be plentifully watered in June and July, and kept free from weeds through the summer, and in the fall as soon as their leaves are decayed, clear them away, and cover the beds over evenly, two or three inches thick, with sand or light loose earth, which finishes every thing for the first year.

Second and subsequent years.

None of the plants should be cut this year, but as some of them will rise strong, and throw up flower stems, these should be nipped off as long as they appear, unless seeds are wanted. The beds are to be kept clean from weeds through the summer, and all decayed leaves removed and cleared away in the fall, and this practice should be followed in all succeeding years. As the plants will henceforward allow of being cut every year, the autumnal covering to the beds, now and hereafter, must be adapted to the mode in which it is intended, the plants are to be blanched. If according to the two first methods after mentioned, then the fall covering may be the same as in the first year, and sticks should be fixed in the centres of the circles to mark the places of the plants, that the blanching pots after described, may be placed exactly over them; but if they are to be blanched according to the third method, then the fall covering should not be less than eight inches thick.

The following are the three modes of blanching.

First method.—About the middle of March, place blanching pots over the circles marked by the sticks; remove the sticks, and press down the pots firmly and close on the ground—then cover the whole bed, pots and all, with fresh stable dung three feet thick, extending it outwards from the sides and ends of the bed two feet, and pressing it down close in all places, par-

ticularly between the pots, and fix heat sticks at proper intervals, to ascertain the heat of the bed. Examine the progress of the plants from time to time, which may be done by carefully uncovering the dung from over the top of any one pot, and taking off the lid, and immediately replacing the same, and the removed dung upon it. The middle of a mild day will be the best time to do this. When any of the plants have filled the pots, which they will do in the space of a month or five weeks, according to the heat of the bed and state of the weather, they may then be cut, and in doing this care should be taken not to injure the hearts of the plants. The pots should be replaced over the crowns of the plants as they are cut, but they need not be again covered with the dung; nor should the lids remain on the pots but for two or three days afterwards, according to the weather, that the plants may be inured to the open air as soon as may be, and when all the plants have been cut, and become gradually exposed to the air, the dung and pots should be wholly cleared away, and the plants suffered to take their free growth, through the summer, and the following spring it will be advisable to blanch them according to the second or third method.

Second method.—Put on the pots at the same time, and in the same manner as before-mentioned, and cut and treat the plants in all respects the same, except that no dung is here to be used for forcing, and therefore the plants will be much slower in blanching; but this will be an advantage, as by treating one bed thus, and another according to the first method, a successional and long supply of this delicious vegetable will be obtained.

Third method.—Here neither blanching pots nor dung are used, but the plants are suffered to come up through the autumnal covering, and as they appear above the surface, they should be immediately and carefully cut; but the plants thus blanched will not be so pure and delicate as those raised by the two first methods.

BLANCHING POTS.

These are earthen pots of the following shape and size, viz.: eighteen inches inside diameter at the bottom, nine inches inside diameter at the top, and fifteen inches high, with a lid to take on and off. These pots, when not wanted for blanching, will answer for protecting melon plants from late frosts, and for forcing and screening newly transplanted flower and other plants from the sun, and other purposes.

C. S.

August 30, 1823.

TO THE EDITOR OF THE AMERICAN FARMER.

FENCES—COMPARISON OF DIFFERENT KINDS.
Sharon, 8th September, 1823.

In the 22d number of your work, vol. 5, there are some strictures from the pen of Mr. Caleb Kirk, of Brandywine, on a paper which I read before the Agricultural Society of Buck's county, upon fences. Whatever censure is due to that paper, is applicable to myself alone; it bears my signature, and, therefore, neither the society in giving it up, nor you in publishing it, are in any way responsible for its contents—and as no argu-

ment has been adduced to convince me of error, I shall now offer some additional remarks.

Mr. Kirk arranges my objections to hedges, in the following order—1st, exhaustion of soil—2d, want of durability—3d, not hog-tight—4th, expensive.

His answer to the first objection certainly does not meet the case; he makes a distinction between a hedge-row, and a hedge-proper, and admits that the former has an effect on the adjoining soil, but he fails to prove that the latter has not; and is it possible that a hedge, such as he describes, of three feet in width and five or six feet high, so close as not to suffer a rabbit to pass, can grow without affecting the soil? to what extent is, perhaps, not clearly ascertained, but I presume that Mr. Kirk himself will acknowledge, that it amounts to the space actually occupied by the hedge. My meaning of a hedge-row, was simply a hedge planted in a row, but I hope I may now be permitted to speak a little of a hedge proper, although I have never seen one. I apprehend Mr. K. was incorrect in his inference that I publicly condemned hedges; I only took the liberty of expressing my opinion.

His second answer, as to durability, refers to the 3d volume of the Farmer page 118, where he says, "I have been able to trace them back half a century, under my own observation, without decay, and from other sources of information from Europe, three hundred years, and one case six hundred years." I would ask how long have they been growing in a "hedge-proper," for that is the test to determine their durability, as to a fence; their continuance in Europe is no proof of their durability in this country, where the climate is essentially different, and where the insect tribe are making a most alarming inroad upon almost every part of the vegetable kingdom; nor is it now here, as it was half a century ago; for is it not a lamentable fact, that many of our valuable trees, which formerly flourished, are at this time in a state of decay. I make the inquiry as to the "hedge proper," supposing that Mr. K.'s knowledge for half a century, must have been in some other form, as he mentions that his first plashing was done in 1812.

To his third answer, I will only say, that I have no doubt but that the hedge he speaks of, would be hog-tight; nevertheless I have fears, that the great majority would be of a different description, say "hedge-rows," that could never be depended on as a protection from all kinds of stock.

His fourth answer, that "the expense alluded to, as a frightful thing, is all visionary," deserves particular consideration. I confess that he makes the cost of a hedge much less than I had supposed, but I think he omits a charge of some consequence, that is, the protecting fence; taking, however, his own calculation, I must still contend, that it is expensive, or not so cheap as the kind of dead fence, which I prefer. Now let us proceed to make the comparison. In volume 1, page 413, Mr. K. supposes that a farm of one hundred acres, will require 2500 pannels of post and rail fence—then a hedge three feet wide, of the same length, would actually occupy more than one and a half acres of ground, say nothing about exhaustion of soil, which I should suppose might reasonably be rated at half a perch wide, amounting in the whole to about four and a half acres; nor shall I notice the soil, that by "repeated dressing," is drawn from the adjacent ground to form the bank from twelve to eighteen inches high, as spoken of by Mr. K. in volume 1, page 118—then 2500 pannels of ten feet each, will be equal to

1515 perches of hedge at 40 cents \$606
1½ acres of land, say at \$50 per acre 75

Exhaustion of soil, and protecting fence not taken into account. \$681

I prefer the post and rail fence, that is, locust posts with five chesnut rails; and I propose to plant the trees where they are not already growing, and I say that six hundred will grow on an acre of land, (see my calculations in vol. 3, page 160,) which will require one and a quarter acres to produce the 2500 pannels, then

1½ acres of land at \$50 per acre \$62 50
Making and putting up 2500 pannels, at 20 cents per pannel, 500 00

\$562 50
the price for making, is what persons who follow the business in this neighbourhood charge, but the work can be done by most of the farm hands, and the materials prepared in the winter season, and thereby the expense would be materially lessened.

Now the difference between Mr. Kirk's hedge, and my post and rail fence is \$118 50, and I have stated the amount as much in his favour as I possibly can do. It is true that a hedge can be brought to perfection, sooner than chesnut and locust trees will mature; but let us take into consideration another matter, which, in my opinion, will very far outweigh that item. I suppose that a fence, with locust posts and chesnut rails, will last at least sixty years, (only requiring every third cutting of the timber,) which will allow the sale of two cuttings, and each yielding 15,000 posts and rails, or 30,000 together, estimated at five dollars per hundred, amounts to fifteen hundred dollars; and I apprehend, that there will be no difficulty of selling the surplus at that price, even if not wanted for fencing, and the locust can be disposed of at a much higher rate; then if an acre and a quarter of land will so produce, it is equivalent to twenty dollars per acre per annum, over and above fencing the farm; besides it is not at all likely, that the farm will be so destitute of fences, as to require more than half the first cutting, so that I think we may safely calculate upon a handsome profit from the commencement.

But it is said that my "project is all founded on theory;" now is it not as much a matter of fact, that locust and chesnut trees will grow from the seed or nut, as that a thorn bush can be raised from the berry? and it is equally clear that the former are very durable; they bear no more likeness to timber frequently used for fences, than a hedge-proper, is like a hedge-row.—An old farmer of this neighbourhood, of strict veracity, tells me, that he knows of chesnut rails, which are sound, at eighty years old. "A Subscriber," in volume 1, page 413, says "chesnuts will grow ten feet apart, and locusts six feet apart, and the latter may be cut every tenth year. Mr. Garnett in his address, as published in the Farmer, volume 4, page 49, says, "I also know, from my own experience, that either cedar, chesnut or locust, (the last of which is still more durable than either) will, in 14 years, grow sufficiently large, to make the fence anew," and there are other remarks upon fences in Mr. Garnett's address worthy of attention; and I am happy to find in him, an individual, who has dared, publicly and pointedly, to disapprove of hedges; another serious, and as Mr. G. says, "insurmountable" objection to live fences is, the frequent changes of farms in size and shape, so as to render a new arrangement of the fence proper; in every such case, the hedge must

either be grubbed up, at great labour and expense, or the owner suffer much inconvenience and be perpetually exclaiming, Oh that my hedge was in the right place! Further, it appears to me, that the annual expense of keeping up such a fence, as I have described, is a mere nothing, in comparison of trimming and dressing a hedge.

I was aware when I wrote my former essay, that I should subject myself to censure; as it seemed to me that a kind of mania with respect to hedges had commenced, which, if suffered to go on, might prove highly injurious to our country. I therefore felt it my duty then, as I do now, to bear my humble testimony against that species of fencing for general purposes; and although I may conceive that my essay has been treated with some degree of severity, yet, I am well pleased that Mr. Kirk has noticed it, because I hope it will be instrumental in inducing others to express their ideas upon that important subject; and whether he is, or I am, in error, I trust the public will decide correctly. I however beg to be understood, that I do not disapprove of hedges as ornamental; I have no doubt but that Mr. Kirk's hedge is a very beautiful thing; I only differ in taste from him as to the material; I prefer the juniper to the thorn, or indeed to any other live fence that I have ever seen, the former being a lively evergreen, easily and soon raised, grows very close and has prickly leaves.

I also highly approve of Mr. K.'s manner of felling timber, that is, to cut all down without respect to size or age; for I have seen several instances of the great superiority of that mode—and I unite with him in opinion, that where stone is near at hand, that kind of fencing is preferable to all others, except in the case of sheep. Last year I put up about half a mile of stone fence, along the Nishamanly Creek—where my fences had before been carried off by the freshets. I placed it below the bank, in order to have it supported against the pressure of the water, and the creek, in time of floods, rises high enough, for timber and ice floating down, to pass above the top of the wall, without doing any damage—besides, the additional ground thus inclosed, about pays me for the fence. I think it is not necessary to make a stone fence higher than 3½ feet, and along the water edge 3 feet will be sufficient.

Your's very respectfully,

JAMES WORTH.

THE FOUR HUNDRED MILES' MATCH.

Powell's match to York and back, 394 miles in five days and thirteen hours, has been outtrivalled by Mark Hawkins, the Lancashire man, who completed his task of 400 miles in five days and twelve hours, at half past eleven o'clock on Thursday morning. His progress up to Sunday night, the second day, has been stated at 152 miles. He went thirteen miles to breakfast on Monday morning, and at two o'clock he reached the two hundred mile-stone in sixty-two hours, in good health, and returned back to Chirk to refresh, and arrived 165 miles from London to sleep. On the fourth day he felt much inconvenience from blisters on the feet, which were relieved by introducing worsted through the blisters. He did 65 miles only this day, leaving himself the remaining distance at tolerable easy work. On the fifth day he arrived three miles from Oxford, at nine o'clock in the evening. He had 54 miles to perform, and appeared somewhat distressed. His stoppages were short, and he travelled but four miles and less each hour. He passed Gerrard's Cross at six o'clock, and did the match in half an hour within the time. It is the greatest pedestrian match on record.

DESCRIPTION OF MR. PERKINS' NEW STEAM ENGINE.

From the *Edinburgh Philosophical Journal*, for July 1823.

The generator, which supplies the place of the boiler in ordinary steam engines, is a cylinder A B C D, made of gun metal, which is more tenacious, and less liable to oxidation than any other. The metal is about 3 inches thick; and the vessel, containing 8 gallons of water, is closed at both ends, with the exception of the five openings for tubes, shown in the figure. The generator is placed vertically in a cylindrical furnace E F, whose chimney is G, the heat being sustained by a pair of bellows H, wrought by the engine, and conveying its blast in the direction I K to F. A heat from 400 to 450 degrees of Fahrenheit is thus applied to the generator, which is entirely filled with water. The valves in the tubes *m n*, which are steel cylinders working in hollow steel pipes, are loaded, the one with 37, and the other with 35 atmospheres; so that none of them can rise till the heat creates a force greater than the least of these weights.

Let us now suppose, that by means of the compressing pump L, whose handle M is wrought by the engine, water is forced into the generator; this opens the valve above *n*, loaded with 35 atmospheres; and instantly a portion of the heated and compressed water *flashes* out in the form of steam of high elasticity, and of a temperature of 420 deg.; and communicating by the steam pipe 2, 2, 2 with the valve box V, it enters the cylinder P P, lying horizontally, and gives motion to its piston P Q, which performs 200 strokes in a minute, and drives a crank R,

which gives a rotatory motion to a fly wheel as seen in the figure.* When the eduction valve is opened, the steam, after having produced its stroke, is carried by the eduction pipe 3, 3, 3, into the condenser S T X U, where it is condensed into water at a temperature of about 320 degrees, and under a pressure of five atmospheres; from thence, by the pipe 6, 6, 6, it is drawn into the pump L, whence it is forced along the pipe 4, 4, 4, to the generator, thus performing a complete circuit.

The forcing pump acts with a pressure exceeding 35 atmospheres; consequently, when the water received in it from the condenser is urged into the generator, it must expel a portion equal to itself in volume—this portion, as above described, flashes instantly into highly elastic steam. The forcing pump, too, is so contrived as to act with a steady force, and consequently the expelled water must be driven from the generator in a steady current, and thus steam of a constant elasticity is supplied to produce the power.

Some philosophers are of opinion, that the heat of the portion of water which escapes is of itself sufficient to maintain the steam at that high degree of heat and elasticity with which it reaches the piston—and consequently that this

* The parallel motion represented at P Q, is not the correct one used by Mr. Perkins. The piston rod is connected by a flexible joint, with a sort of carriage with four wheels at each end, and working in a strong horizontal box of steel.

engine is nothing more than a High Pressure Engine. Other persons, however, have supposed, and we confess we are among that number, that the portion of water which escapes must necessarily carry off a quantity of heat from the adjoining stratum (the temperature of which *may be* thus reduced below the freezing point.) But it is more likely, that in virtue of some new law of the transmission of heat under the combined conditions of elevated temperature and high pressure, while the water, also, is forced to remain in contact with the red hot generator; the whole water in the boiler may be laid under requisition to furnish the discharged fluid with its necessary supply of caloric [heat.]

It is almost unnecessary to state, that the motion of the engine is produced by the difference in elasticity between the steam pressing on one side of the piston and that pressing on the other. In the first case, the steam recently produced acts with a force, say of 500 pounds on the square inch, while that on the weak side, or that communicating with the condenser, acts with only 70; the difference 430 lbs. being the true power gained.

When there is a surplus of water in the generator, occasioned either by working the forcing pump too violently, or by too vehement a heat, the water will escape by the tube *m* with a valve above, loaded with 37 atmospheres, and will pass by the pipe 5, 5, 5, into the condenser S T X U.

In order to explain the ingenious manner in which the pipe 4, 4, 4, supplies the generator with water, we must observe that this pipe com

municates with the pump L, which is wrought by the engine.

This pump draws the water by the pipe 6, 6, 6, from the condenser S T X U, and returns it by the pipe 4, 4, 4; that is to say, when the handle M is drawn up, the water rushes into the cylinder of the forcing pump, through a valve in the pipe 6, 6, 6, opening into that cylinder. This valve, of course, instantly closes when the downward stroke of the pump is made; and the water now escapes through a valve opening outwards, along 4, 4, 4, thus effectually cutting off all direct or uninterrupted communication between the generator and condenser. In order to keep the water in the condenser at a pressure of five atmospheres, the blast of the bellows H goes round the condenser S T X U; but, when it is not sufficient for this purpose, cold water is introduced from the reservoir L, by means of the pipe 7, 7, 7, loaded with five atmospheres.

From the high elasticity of the steam employed in this engine, it has been supposed to be very liable to explosion. This, however, is a vulgar error. Since there is no reservoir of steam exposing a large surface to its expansive force, as in the common high pressure engines, the steam being generated only in sufficient quantity to produce each succeeding stroke of the piston, the ordinary source of danger is entirely removed. But in order to take away all apprehensions on that subject, the induction pipe 2, 2, 2, in which the steam is actually generated, is made so strong as to sustain an internal force of 4000 pounds on the square inch, which is eight times more powerful than the actual pressure, viz. 500 pounds on the square inch, with which the engine works.

This enormous superabundance of strength is still further secured by means of the safety pipe, 8, 8, 8, provided with a thin copper "safety bulb," a b, which is made so as to burst at a pressure of 1000 pounds on the square inch. In order to satisfy his friends on this very important point, Mr. Perkins has repeatedly urged the power of the steam to such a degree as to burst the copper bulb in their presence. This tube merely rends or is torn asunder like a piece of paper, and occasions no injury either to the spectator, or to the apparatus; so that we have no hesitation in considering this engine, notwithstanding its tremendous energies, as much more safe in its operations than even the common low pressure engines.

The safety tube 8, 8, 8, communicates also with the indication c d, having a dial plate c c, and an index e f, which, by means of a suitable contrivance at v v, indicates the pressure or number of atmospheres with which the engine is working.

The cylinder and piston P P Q, have been separated from the rest of the engine, for the sake of distinctness. Their proper position, however, will be understood by supposing, the two lines 99; 99 to coincide as well as tubes 2 3; 2 3.

This engine which we have now described, is at present performing actual work in Mr. Perkins' manufactory. It is calculated as equal to a ten horse power, though the cylinder is no more than 2 inches in diameter, and 18 inches long, with a stroke of only 12 inches. Although the space occupied by the engine is not more than 6 feet by 8, yet Mr. Perkins considers that the apparatus, (with the exception of working cylinder, P P, and piston P Q,) is perfectly sufficient for a thirty horse engine. When the engine performs full work, it consumes only two bushels of coal a one day.

FROM ACCUM'S CULINARY CHEMISTRY.

COOKERY IS A BRANCH OF CHEMICAL SCIENCE.

Cookery, or the art of preparing good and wholesome food, and of preserving all sorts of alimentary substances in a state fit for human sustenance, of rendering that agreeable to the taste which is essential to the support of life, and of pleasing the palate without injury to the system, is, strictly speaking, a branch of chemistry; but, important as it is both to our enjoyments and our health, it is also one of the least cultivated branches of that science. The culinary processes of roasting, boiling, baking, stewing, frying, broiling, the art of preserving meats, bacon, and hams; the preparations of sauces, pickles, and other condiments; the conserving of fruits; the care and keeping of vegetables; the making of jellies, jams, and marmalades, are all founded upon the principles of this science, and much waste of the material, as well as labour to the parties might often be spared, were those to whom the performance of such tasks is committed, made acquainted with simple chemical truths which would invariably lead to certain results. And, besides, the same knowledge would enable them to attain a much greater degree of perfection in curing and preserving all kinds of animal and vegetable aliments, and in combining the three grand requisites of taste, nutriment, and salubrity, in whatever manner they may be prepared. And, though this art is at present in rude hands, as all branches of chemistry were originally, there is no reason that it should remain so. A kitchen is, in fact, a chemical laboratory; the boilers, stew-pans, and cradle spit of the cook, correspond to the digestors, the evaporating basins, and the crucibles of the chemist. And numerous as the receipts of cookery are, the general operations (like the general process of chemistry) are but few. In some the object aimed at, is, to extract the constituent parts of the food, so as to exhibit them in a separate state, or to combine them with other substances, to produce new compounds which differ widely from those from which they originated. In others, the qualities of the substances are simply altered by the action of fire, to render them more palatable and nutritious.

From the multiplicity of circumstances to be attended to in this art, the whole of which is founded upon the principles of chemistry, we may easily see that it must be a very precarious one; and, there is reason to believe, that among the variety of circumstances which produce diseases, the improper modes of cooking food, are often the primary cause. Will it be believed, that in the cookery books which form the prevailing oracles of the kitchens in this part of the island, there are express injunctions to "boil greens with halfpence, or verdigrise, in order to improve their colour!"* That our puddings are frequently seasoned with laurel leaves, and our sweatmeats almost uniformly prepared in copper vessels?† Why are we thus compelled to swallow a supererogatory quantity of poison which may so easily be avoided? And why are we constantly made to run the risk of our lives by participating in custards, trifles, and blancmanges, seasoned by a most deadly poison extracted from the *prunus lourocerasus*?‡ Verily, where such detestable systems of cookery are

* *The Ladies Library*, vol. ii. p. 203; and also *Modern Cookery*, 2d edition, p. 94.

† *Literary Chronicle*, No. xxiii. p. 348, 1819.

‡ *Philosophical Magazine*, No. cclviii. vol. 54, p. 317.

practised, we may exclaim with the sacred historian, that there is "Death in the Pot."

Food badly cooked is wasted to no purpose. It seems to have been a complaint familiar in the mouth of our ancestors, and which we may have too often seen reason to re-echo in the present day—"That God sends good meat, but the devil sends cooks."

Observations on the Food of Man.

No animal eats such variety of food as man; he claims, more justly than any other creature, the title of *omnivorous*! for since he is distinguished beyond all animals, by the capability of living in the most distant parts of the globe, under every variety of climate which the earth affords, his food could not be confined exclusively to either the vegetable or animal kingdom, because he inhabits regions that afford aliments widely different from each other. Cattle content themselves with green vegetables; rapacious animals live on flesh of the other creatures.

Those of the Linnæan order, *gliræ*,* live on grain and fruits; each order of birds, keeps, in the same manner, to one sort of food, animal or vegetable. Fishes, reptiles, and insects, also have each their peculiar and exclusive bill of fare, beyond which even hunger will scarcely force them to wander. But however various each class, and order, and species of animated nature may be in the choice of food, man—all devouring man, will embrace the whole range of the creation, "scarce a berry or a mushroom can escape him."

With the lion and the wolf he will eat of fresh slain animals; with the dogs and the vulture he will feed on putrid flesh; † with the ox and the guinea-pig he will devour raw vegetables, under the name of salads; with the squirrel and the mouse he will feast on nuts and grain; with birds of prey he feeds on fowl of almost every species; with fishes he feeds on fish; and with insects and reptiles he sometimes lives on insects and reptiles. Nor is he satisfied even with this abundant variety, but must go to the mineral kingdom for salt, as a condiment before he can furnish out his meal.

Nations living wholly upon vegetable food.

The variety of alimentary substances used not only by individuals, but among whole nations, are prodigiously diversified, and climate seems to have some effect in producing the diversity of taste, though it must in a great measure depend upon the natural productions of particular countries, their religion, and their commercial intercourse.

A vegetable diet seems suitable to the hot countries under the Equator, and we accordingly find nations there, who have completely adopted it, and who abstain so much the more from all animal food, in as much as it is an article of their religious faith.

Potatoes, chesnuts, and the leguminous and cereal seeds, satisfy the want of the Alpine peasant, and numerous tribes solely feed on vegetables and water. In the most remote antiquity, we read of whole nations in Africa, and of the Indian priests, who lived entirely on vegetable substances. Some wandering Moors subsist almost entirely on gum senegal.

Nations living wholly on animal food.

The nations which live on animal food are very numerous.

* *The hare, rabbit, guinea pig, &c.*

† *Every person knows in what a putrid state game is often eaten.*

The Ethiopians, Scythians, and Arabians, eat nothing but flesh.

The miserable inhabitants of New Holland lived wholly on fish when that country was first discovered, and other tribes on the Arabian and Persian gulph.

In the Faro islands, in Iceland and Greenland, the food arises from the same source.

The shepherds in the province of Caracas, or the Oronoko, live wholly on flesh. The Tartars in Asia, and some savage nations in North America, live on raw and half putrid flesh, and some barbarous tribes eat their meat raw.

It appears to be the effect of climate and religion that makes the Hindoo adopt vegetable rather than animal food; it is the effect of natural production that makes the Greenlander relish whale-blubber and train-oil. It is to one or other of these causes that we must refer all such diversity of national tastes, though it would be difficult in many cases to separate the influence of each. We see the Englishman enjoying his under-done roast beef and his plum-pudding; the Scotsman his hodge-podge and his haggis; the Frenchman his ragouts, omelets, and fricandeaus; the German his sour-cROUT, sausages, and smoked hams; the Italian his maccheroni; and the Tartar his horse-flesh.* "*De gustibus non est disputandum.*" There is no disputing about tastes. They are too many, and too various, to be objects of rational discussion.

Singular kind of Aliments of various Nations

Besides the before-mentioned diversities of national and individual taste for different kinds of substances, used as aliments, there are other kinds of food which we at least think more singular. Some of the tribes of Arabs, Moors, the Californians, and Ethiopians, eat tad-poles, locusts, and spiders.

In some places the flesh of serpents, that of the *coluber natrix* for example, is eaten; and the viper is made into broth. Several other reptiles are used as food by the European settlers in America, such as the *rana bombina* and *rana taurina*, two species of toads.

In the East, the *lacerta cinctus* is considered a great luxury, and also an appropisiac. Even the rattle-snake has been eaten, and the head boiled along with the rest of the body of the animal.

The horse, ass, and camel, are eaten in several regions of the earth, and the seal, walrus, and Arctic bear, have often yielded a supply to sailors.

On the singular taste of epicures it is not necessary to speak. Mæcenas, the prime minister of Augustus, and refined patron of Horace, had young asses served upon his table when he treated his friends; and according to Pliny,* the Romans delighted in the flavour of young and well fattened puppies. This strange practice subsists still in China, and among the Esquimaux. Plump, and well roasted bats, laid upon a bed of olives, are eaten in the Levant as a dainty.

The Roman luxury, *garum*, which bore so high a price, consisted of the putrid entrails of fishes, (first of the *garum*,) stewed in wine, and a similar dish is still considered as a great luxury, in some parts of the East. Some modern epicures delight in the trail of the woodcock, and even collect with care the contents of the intestines which distill from it in the process of roasting.

* An article of food which has lately been seriously recommended by Mr. Grey to Europeans as a most advantageous measure of political economy.

* 2 Book 29, c. 4.

"The Irishman loves usquebah,
The Scot loves ale called blue cap,
The Welchman, he loves toasted cheese,
And makes his mouth like a mouse trap."

APICIUS,* among other whimsical personages of ancient Rome, presented to his guests ragouts, exclusively composed of tongues of peacocks and nightingales. This celebrated epicure, who instituted a gormandizing academy at Rome, having heard that shrimps and prawns of a superior flavour were to be met with on the coasts of Africa than on the Italian shore, freighted a ship, and sailed in search of these far famed marine insects. This person spent more than £60,000 merely to vary the taste of culinary sauces.

Vitellus was treated by his brother with a dinner, consisting of 2,000 dishes of fish, and 7,000 of poultry—surely this is not doing things by halves.

A Mr. Verditch de Bourbonne† is said to have bought 3,000 carps for the mere sake of their tongues, which were brought, well seasoned and learnedly dressed, to his table, in one dish.

Difference between an Epicure and a Glutton.

However extravagant and whimsical the rational pleasures of the table may appear to a sober and sensible mind, we must, in justice to epicures, cursorily observe, that there exists a material difference between a *gormand*, or epicure, and a *glutton*‡. The first seeks for peculiar delicacy and distinct flavour in the various dishes presented to the judgment and enjoyment of his discerning palate; while the other lays aside nearly all that relates to the rational pleasures of creating or stimulating an appetite of the cates, and looks merely to a quantity; this, has his stomach in view, and tries how heavy it may be laden, without endangering his health.

"The *gormand* never loses sight of the exquisite organs of taste, so admirably disposed by Providence in the crimson chamber, where sits the discriminating judge, the human tongue.

"The *glutton* is anathematised in the Scripture with those brutes *quorum deus venter est*. The other appears guilty of no other sin than of too great, and too minute, an attention to refinement in commercial sensuality."

Our neighbours on the other side of the channel, so famous for indulging in the worship of Comus, consider the epicure again under two distinct views, namely: as a *gormand*, or a *gourmet*. The epicure or *gormand* is defined—a man having accidentally been able to study the different tastes of eatables, does accordingly select the best food and the most pleasing to his palate. His character is that of a *practitioner*. The *gourmet* speculates more than he practises, and eminently prides himself in discerning the nicest degrees, and most evanescent shades of goodness and perfection in the different subjects proposed to him. He may be designated a man, who, by shipping a few drops out of the silver cup of the vintner, can instantly tell from what country the wine comes, and its age.

The *glutton* practices without any regard to theory.

The *gormand*, or epicure, unites theory with practice.

The *gourmet* is merely theoretical.

(To be continued.)

* Three brothers of that name were celebrated at Rome, on account of their unparalleled love of good eating.

From Memoirs of the Board of Agriculture of the State of New York.

ON THE MANAGEMENT OF BEES, &c.

[By SETH COUCH, of Ulaters.]

Mr. Jesse Buel,

DEAR SIR,—Having observed, some time last summer, an advertisement or request from you, or some other member of the Albany County Agricultural Society, for agricultural information, I have thought proper to give you my views and experience, on a subject which, however, may be considered by some as not belonging to agriculture, yet if you think proper, you can give it a place in your next annual agricultural report.

It is on the manner and mode of raising bees, and getting the honey without destroying them, which is as follows:

I make my hives of inch boards, nearly of one size, say 12 to 14 inches square, and 15 inches high, and put four sticks crosswise through each hive, to prevent the comb from falling; in these I put my swarms, and when they have nearly filled that hive, I raise it up, and place another of the same size under it, without any lid, so that the bees may continue the comb through both hives, which an early swarm will often do the first season. These I let stand, until they have done swarming the next year, say about the 20th of July, when the young ones will be principally hatched. I then prepare another hive of the same size, without any lid, which I place on a cloth, spread on two small sticks, laid on the ground near the hive, so that it will be a little bagging below to hold the bees; this I tie tight round the hive with a string. I then take the two hives together, which contain the bees, and set them gently over the empty hive, so that the bees may go down in the lower hive, at the same time tying a cloth round where the hives meet, to prevent the bees from coming out, (if any place should be left large enough.) I then bore two or three large gimblet holes in the lid of the top hive, and blow in a little tobacco smoke, say two or three pipes full, which drives the bees down in the lower hive in fifteen or twenty minutes. I then take a long knife, and run it in between the first and second hives, and cut the comb all off as square as I can between them. I then loosen the top hive, and set it in a tub, and spread a cloth over it, to prevent the bees from coming out, and carry it in the cellar. At the same time I put a new lid on the other hive, and either nail it gently on, or put some weight on to steady it; the cloth may then be loosened, when the bees will return into the hive. I then set the two hives in the old place, or set them there before I loose the cloths, as may be most convenient. All this should be done in the evening, as soon as the bees have done coming in. The next morning, I leave my outside cellar door open, when the bees which remain in the hive which I carry in the cellar gradually leave it, and go to the old place. If they do not leave it soon, if they come out of the hive, I brush them off with a quill; if they do not come out, I blow tobacco smoke in as before, and continue blowing in smoke and brushing at intervals, until they do leave it. I generally hang the hive up by the lid, so as to get them out the better; by these means I always get the best of the honey, as the tops of the hives are filled in the early part of the season, and are the best. I also preserve all my bees by leaving them a sufficient quantity of honey to winter on. Most persons, unacquainted with this mode, would suppose it dangerous, on account of getting stung, but this is seldom the case with me; after I get them in the cellar, they appear to be inoffensive; if I get stung, I apply a little laudanum or cam-

phor, to prevent it from swelling. If my swarms are late, I wait until the next year, after they have done swarming, before I double them, and always have them double one year before I take them off. I have kept bees a number of years, and have always got my honey in this way, and have never killed a swarm yet. I last year took about five hundred pounds of honey in this way, and the present year have taken about eight hundred pounds. I think they swarm nearly as much in this way as in the ordinary way, and make nearly double the quantity of honey, as the swarms are larger out of large hives than out of small ones. I wintered over seventeen hives last winter, and got eighteen swarms from them, most of which I have set other hives under, which are nearly full, and all of them have more honey than they will want to winter on. I had two large hives, which were very full of bees that did not swarm; them I took in the evening, towards the last of June, and turned them bottom up, and set a new hive over, and gently knocked on the under hive, when the bees separated, and part went in the new hive and part staid in the old one, and after about five minutes I took the new hive and sat it in the place of the old one, and put the old one a little distance off, and in this way they both did well, and the bees in the new hives, have both filled them, thus making me twenty swarms, which are all likely to winter well. I think I have now rising two thousand pounds of honey in my hives on the benches, and if nothing extraordinary happens, I think I may safely calculate on getting twelve or fourteen hundred pounds from them next season, and leave them enough to winter on the next winter.

The above method is from self-taught experience, as I have never seen it practised, except where I have given the information.

Kingston, October 25, 1822.

EXTRACTS FROM LATE NUMBERS OF THE London Farmer's Journal.

IN ANSWER TO MR. SMYTHIES.

Acton, Beauchamp, July 1, 1823.

SIR,

The same person who conveyed my letter of this day's date, addressed to you, to the post-office, brought me your Journal containing Mr. Smythies' challenge.* I am not enabled at the present moment to state positively that it will be accepted, but believing Mr. Smythies to be serious in his proposal, I am desirous to point out to him where it ought to be amended.

In the first place, your correspondent has made his own peculiar selection, no doubt well considered, for his own particular avowed purpose, viz. "to establish the superiority of the Hereford breed of cattle." Now, it is more than probable that at this season no Short-horned breeder can come forward to accede to his proposal, because the well bred Short-horned bulls, such as he would wish to encounter, drive a thrifty and not idle trade, whilst his two Herefords may probably have been pampered at home. On this circumstance I ground one objection to Mr. Smythies' proposal. But I have yet others to state. The animals are to be confined (I wish them no worse) to the mother's milk. But Mr. Smythies, I dare say, is ignorant that generally it would be dangerous to give a Short-horned calf the whole of its mother's milk, although the plan may be very safely pursued with Herefords. I say generally, because there are exceptions in all breeds. But a Short-horned cow generally giving much more milk than her calf can take, and her owner having every purpose of utility in view, a different system is adopted

with them to that which Hereford breeders use: Short-horned calves are chiefly brought up by hand, or by a cow which, having calved long, gives little milk. How then can calves so reared be rendered fit by subsequent management to be accounted qualified for competition, according to the tenor of Mr. Smythies' proposals?

Other objections present themselves, but I shall mention only one, which is very material to the success of the negotiation—namely, that not Tredegar (which is far out of the way,) but a convenient central situation be chosen, at which, if possible, by a drift of fifty or sixty miles, both parties may be equally accommodated. Indeed I consider this to be essential to the character of a serious proposal.

What has been above advanced will, I am convinced, be deemed sufficient to call on Mr. Smythies for amended proposals. I will venture to assure him the breeders of Short-horns desire nothing so much as a meeting on fair terms, and will beg leave to suggest, that as he proposes in the proposed meeting to establish the superiority of Herefords, a similar advantage ought to be assured the Short-horns in case they prove fortunate; and that the Hereford breeders be called on to declare that in the fate of Mr. Smythies' stock, they are willing to involve that of their own. This seems only reasonable, as the trial must be attended with considerable expense and risk, and ought to be productive of gratification to the fortunate party.

I am, sir,

your ob't serv't,

HENRY BERRY.

DEAD MARKETS.

We have noticed some of the prize carcasses, and others of extra quality, in Leadenhall and elsewhere, during the last week. The heaviest sheep we have heard of are Mr. Turner's, of Exmouth, (not in the Smithfield shew,) one of which weighed twenty-eight stone two pounds,* and the others twenty-five stone each; besides their weight, they were of very excellent frame, and very fat within. One of Mr. Rowland's sheep we saw, which weighed twenty-two and a half stone. Mr. Eillman's prize Southdowns weighed fourteen stones together, they were good sheep dead. An exceedingly fat Scot, of Lord Harborough's; hung up in Leadenhall-market—it was small in size and great in value, weighing thirty stone per quarter.—one of the sheep shewed by Mr. Guerrier, in Sadler's Yard, weighing eighteen stone had the extraordinary proof of five stone one pound, namely, the caul thirty-two pounds, and loose fat nine pounds, thirty two months old, never had corn or pulse; bred by Mr. Wm. Haver, of Northleach. We saw also the prize sheep of Mr. Plaskett, but did not learn the weight.—To add to our Christmas bill of fare, the house-lamb was, as usual, excellent; but the price, for the best, is down £2 a piece since last year; the largest weigh seventeen pounds a quarter, and are now sold for £4 a piece.—A prize turkey weighed twenty-five and a half pounds; and Mrs. Wood's fat rabbits (dressed by John Smith, house-lamb butcher, of Leadenhall,) weighed eleven pounds each.

Dr. Wolcot, better known by the name of Peter Pindar, from the prodigious sale of his early pieces, became a desirable object of book-selling speculation; and about the year 1795, Robi-son, Golding, and Walker, entered into a treaty to grant him an annuity for his published works, and on certain conditions for his unpublished ones. While this was pending, Peter had

an attack of asthma, which he did not conceal of palliate, but at meetings of the parties his asthma always interrupted the business. A fatal result was of course anticipated, and, instead of a sum of money, an annuity of £250 per annum was preferred. Soon after the bond was signed, Peter called on Walker, the manager for the parties, who, surveying him with a scrutinizing eye, asked him how he did? "Much better, thank you," said Peter: "I have taken measure of my asthma; the fellow is troublesome, but I know his strength, and am his master." "Oh!" said Mr. Walker, gravely, and turned into an adjoining room, where Mrs. Walker, a prudent woman, had been listening to the conversation. Peter, aware of the feeling, paid a keen attention to the husband and wife, and heard the latter exclaim, "There now, didn't I tell you he wou'n't die? fool that you've been; I knew he wou'n't die." Peter enjoyed the joke, and outlived all the parties, receiving the annuity for twenty-four years, during which various efforts were improperly used to frustrate his claims.

THE DEAD.—David Morrison has been sentenced to seven years' banishment by the Scotch High Court of Justiciary, for violating the sepulchres of the dead. On his trial, Dr. Barclay, a teacher of anatomy, deposed, that some bodies became decomposed in a few days, others lasted much longer; in some the features could not be known in forty-eight hours, while in others they might be recognised for a week; but much depended on the previous illness: the longest he ever knew was the features of a Lascar, which remained recognizable for a fortnight. In three weeks a subject would be unfit for the purposes of dissection. In two weeks the outer skin comes off, with it the nails, and the hair would be loose, but marks on the body might be identified. He had known frequent cases where relatives were mistaken in the bodies they claimed, and instanced one where a body made of leather was insisted on as being the one they were in search of. Dissectors are obliged, in order to distinguish one subject from another, to affix marks.

Fonthill Abbey was again opened for view on Monday. So powerful are the impressions of last year, that visitors presented themselves at the gate before the regular time of admission, and during the day a greater number entered than during the first month of the last view. The variety and splendour of the additional rooms now thrown open is astonishing. The whole gallery of pictures is arranged and displayed in the most judicious manner, and every volume of the extraordinary library may be examined. The American garden is in flower. All description must fail to give an accurate idea of this Transatlantic scene, where rhododendrons, magnolias, and other exotics, cover a surface of several acres.

Latterly the English have endeavoured, by peculiar management, to make the English Cranberry grow in dry beds; and probably they will succeed in their attempts. Should this happen, without much trouble, it will be easy to copy their practice in our gardens in the United States.

Rice Sponge Cake.—Nine eggs, the weight of them in sugar, the weight of six in rice flour, have the sugar finely sifted, mix the sugar and rice together, have the whites and yolks beat separately, pour the eggs all at the same time into the rice and sugar, beat them together for a quarter of an hour, add of the essence of lemon twenty drops, or rose water.

* As published in our last.

* 226 pounds.

Editorial Correspondence.

Springdale, August 28th, 1823.

DEAR SIR,

Within the last few weeks much has been said on the subject of wheat degenerating into cheat, and many doubts expressed whether cheat would re-produce its kind, and, indeed, whether it possessed at all, vegetative powers. The degeneracy of wheat is involved in so much mystery that it would be imprudent in a young farmer to suffer himself to form, without satisfactory experiment, an opinion on the subject. After a few months, I hope I shall, without diffidence, be willing to express an opinion, whether opposed to the most learned philosophers, or the best practical farmer. As to the fact of cheat producing cheat, I have never entertained a doubt. To convince others, however, I, a few weeks since, obtained some clean seed, and put it in a drinking glass filled with cotton, kept moist by daily adding water to it; in about ten days it sprouted, and I now have it growing six inches high on my mantlepiece.

Your's respectfully,

WILLIAM M. BARTON.

Extract from Columbia, S. C. August 22, 1823.

"I have nothing particular to mention. My Egyptian millet grows very handsomely, and I have lately, for the first time, made some wine from the vines I cultivate in our sand hills. I made about sixty gallons of it; but it appears to me that it will prove a very weak wine. The causes of this, however, are evident. The vines are very young, and the season has been very rainy."

J. S. SKINNER, ESQ.

Extract of a letter from a correspondent, dated MILLEDGVILLE, (Geo.) 14th July.

"I have prevailed on a number of merchants to make enquiries of the farmers, and take memorandums of the quantity of ground planted in cotton the present and last year, and so far as our enquiries have gone, the present crop is one fourth less than the last was, and the last was a favourable season:—It is believed there will be at least that difference, (if no more) in the crop."

Kingston, Tennessee, 28th August, 1823.

MR. J. S. SKINNER,

Sir—In your paper of the 15th, I notice some remarks on the subject of the botts in the stomach of horses: my means of cure, when I have a horse attacked with botts, is to kill a chicken immediately, pull out its entrails as quick as possible, and put them down the throat of the horse—this done in a short time after attacked, I never knew to fail. I find my oxen, when well fed, will travel with a loaded wagon from fifteen to eighteen miles per day, in the hottest days of summer.

SAMUEL MARTIN.

Hillsborough, N. Carolina.

JOHN S. SKINNER, ESQ.

Dear Sir—Accept my thanks for the 175 grains of wheat received by the last mail. They shall be soon carefully and well attended to. The icc-rind melon seed was planted and produced well: the melon is delicious, though not a rarity among us; there being many this season for sale in our market.

The Senna was also planted, and grew well for a short time, but was accidentally destroyed. The Egyptian millet received by you from Columbia, South Carolina, grows luxuriantly, looks well.

The small green pea did not vegetate.

I have raised two excellent musk-melons from a seed of the quantity you received from Charleston. The flavour is exquisite.

I remain, dear sir,

Your's respectfully,

JOHN SCOTT.

EXPERIMENTS IN CHEMISTRY.

Preservation of Eggs from putrefaction.

To transport eggs in a fresh state from one country to another, varnish, by dipping them in a solution of Gum Arabic in water; and then imbed them in powdered charcoal. The Gum Arabic answers the purpose of a varnish for eggs much better than any resinous gum, as it can be easily removed by washing in either warm or cold water; besides, it is much cheaper. Eggs preserved in this manner, will keep for many years, as the bed of Charcoal, from its porous nature, is a non-conductor of heat, and consequently maintains around the eggs an uniform temperature; preventing them from suffering by alternations of heat and cold, when they are removed from one climate to another.

Observation. This method is infinitely preferable to that of greasing them, for when the grease becomes rancid, it hastens or promotes putrefaction of the animal matter in the egg.

Preservation of Grapes.

In a cask or barrel, having its crevices well closed to prevent access of the external air, place a layer of bran, which has been well dried in an oven; upon this place a layer of bunches of Grapes, well cleaned, and gathered in the afternoon of a dry day, before they are perfectly ripe; proceed then with alternate layers of bran and Grapes till the barrel is full, taking care that the Grapes do not touch each other, and to let the last layer be of bran; then close the barrel so that the air may not be able to penetrate. Grapes thus packed will keep for a twelvemonth. To restore their freshness, cut the end of each bunch and put that of white Grapes into white wine, and that of black Grapes into red wine, as flowers are put into water to keep them fresh.

Observations. It is customary in France to pack grapes for the London markets in saw-dust. If the precaution of drying the saw-dust by a gentle heat, before use, be had recourse to, this expedient may answer very well; but if this is not done, and if the wood has been cut fresh, the turpentine, and other odours of the wood cannot fail to injure the fruit. Oak saw dust will answer best.

Varnish for boots and shoes, by which they are rendered impervious to water.

The following method of effecting this useful purpose is related in Sir John Hawkins's edition of Isaac Walton's complete Angler:—Take a pint of Linseed Oil, with half a pound of Mutton Suet, six or eight ounces of Bees' Wax, and a small piece of Rosin. Boil all this in a pipkin together; and let it cool till it be milk-warm.—Then with a hair brush; lay it on new boots or shoes; but it is best that this Varnish be laid on the Leather, before the boots are made. The boots should also be brushed over with it, after they come from the maker. If old boots or shoes are to be varnished, the mixture is to be laid on, when the Leather is perfectly dry.

Method of Cleaning Silks, Woollens, and Cottons, without Damage to their Texture and Colour.

Grate raw Potatoes to a fine pulp in clean water, and pass the liquid matter, through a coarse sieve, into another vessel of Water; let the mixture stand still till the fine white particles of

the Potatoes are precipitated; then pour the mucilaginous liquor from the fecula, and preserve the liquor for use. The article to be cleaned should then be laid upon a linen cloth on a table, and having provided a clean sponge, dip it into the Potato liquor and apply it to the article to be cleaned, till the dirt is perfectly separated; then wash it in clean Water several times. Two middle sized Potatoes will be sufficient for a pint of Water.

Observations. The coarse pulp, which does not pass through the sieve, is of great use in cleaning worsted curtains, tapestry, carpets, and other coarse goods. The mucilaginous liquor will clean all sorts of silk, cotton, or woollen goods, without hurting or spoiling the colour; it may be also used in cleaning oil paintings, or furniture that is soiled. Dirtied painted wainscots may be cleaned by wetting a sponge in the liquor; then dipping it in a little fine clean sand, and afterwards rubbing the wainscot with it.

THE FARMER.

BALTIMORE, FRIDAY, SEPTEMBER 19, 1823.

BALTIMORE MARKET.

PRICES CURRENT—CORRECTED WEEKLY.

Flour, best white wheat, \$7—Howard street, from wagons, \$6 75—Superfine, \$6 50—fine do. \$6 25—Wharf, do. \$6 00—White wheat, \$1 20 to 1 30—Red do. \$1 15 to \$1 20—Rye, 40 to 45 cts—Corn, 38 a 40 cts.—wharf Oats, 26 a 30 cts.—wagon Oats, 31 cents—Beef, 8 cents per lb.—Live Cattle, \$6 to \$6 50, per cwt.—Bacon, hog round, \$10—Pork, \$4 50 to 5 50 per c. lb., 6 to 8 cts. per pound—Mutton, 5 to 6 cts. per lb.—Beans, retail, \$1 50, cargo price, 1 12½—Peas, retail, 75 a 80 cts., cargo price 58 a 60 cts.—Red Clover Seed, \$6—Orchard Grass do. \$3—Herds' Grass do. \$3—Timothy do. \$4—Flax Seed, 75 to 80 cents—Whiskey, from the wagons, 30 cts. per gallon including the barrel—Apple brandy, 30 to 32 cts.—Peach do. 65 to 70 cts.—Shad, \$6 00.—Herrings, No. 1, \$2 70 per bbl., No. 2, \$2 37½—Fine Salt, 60 to 65 cts. per bush., coarse, do. 70—Butter, (firkin) 14 cts. per lb.—Eggs, 12½ cts. per doz.—New Hay, \$15 per ton, old do. \$18—Straw, \$9. MARYLAND TOBACCO.—No sales.

A NEW ARTICLE FOR HOUSEKEEPERS.

The subscribers have just received from the manufactory, an additional supply of the much approved portable cooking and preserving FURNACES.—Price \$1 to \$2.

These furnaces, to those unacquainted with the use of them, are best suited for charcoal or other light condensed fuel, and afford a great heat, at a small expense; besides saving the body from unnecessary exposure to heat.

Their uses are various—preserving, baking cakes, stewing oysters, &c. Broiling steaks, (for which they are peculiarly well adapted) boiling and culinary purposes generally, for heating smoothing irons, &c.

We have also received CHYMICAL FURNACES.

GEORGE GRUNDY & SONS,

No. 3, N. Charles street,

Who are duly authorised by the manufactory, as their agents to sell the same.

Printed every Friday at \$4 per annum, for JOHN S. SKINNER, Editor, by JOSEPH ROBINSON, on the North West corner of Market and Belvidere streets, Baltimore: where every description of Book and Job Printing is executed with neatness and dispatch—Orders from a distance for PRINTING or FINDING, with proper directions promptly attended to, addressed to J. Robinson, Baltimore.

HORTICULTURAL.

BRIEF NOTICE OF THE HORTICULTURAL SOCIETY OF LONDON—AND ITS PRESIDENT, T. A. KNIGHT, ESQ.

In number 24, page 192 of this volume, we adverted to the arrival of Mr. Douglas in New York, as a botanical missionary from the horticultural society of London—we are gratified to learn that he was kindly received and entertained by Doctor Hosack and other members of the horticultural society of New York, and that after an interview with Governor Clinton, to whom he was especially instructed to address himself,—he has proceeded through the western parts of New York, to Amherstbury in Canada, intending to return by the same route to re-embark sometime in Autumn for England.

We take this occasion to repeat that we shall esteem it a favour to be made the medium of adding to Mr. Douglas' collection of native American plants, grasses, vines, flowers, &c.

The following sketch of the distinguished institution of which we are speaking, is from a New York paper, and presumed to be from the pen of a scholar whose various useful and elegant acquisitions have made him known to all countries, and an ornament to his own.

Editor American Farmer.

Horticultural Society of London.—Among the many laudable and magnificent institutions in Great Britain, the Horticultural Society of London is entitled to distinguished rank. It is countenanced by the first men in the kingdom, and is a noble confederacy of science and practice, to elevate horticulture above the state of an empirical art. This institution is principally under the direction of Thomas Andrew Knight, and Joseph Sabine, Esquires. The former is its President, and is particularly distinguished as a writer on vegetable physiology; the latter is its Secretary, and is celebrated for his scientific acquisitions.

The horticultural society was instituted in 1804 and incorporated in 1808. In 1822 a subscription of £5000 sterling was raised for the formation of a garden on an extensive scale, and thirty-three acres were procured on a lease for that purpose, at Chiswick, five miles from Hyde Park Corner, London. The lease is for sixty years, renewable every thirty years, forever, upon a fine certain, and at a rental of £300 per annum, with power to the society of relinquishing its obligations at any time on giving twelve months notice. These grounds are very judiciously laid out into an orchard; a kitchen garden with thirty six compartments; stock ground for a succession of fruit trees; places for stoves, green-houses and forcing-houses; a flower garden; an arboretum for ornamental trees and shrubs, and hardy perennial plants; a fruit and kitchen garden for experimental purposes; and also an ornamental garden for the like purposes.

The orchard contains already 3000 standard trees of the best fruit. The flower garden has 1200 varieties of roses; the most splendid assemblage of the kind in Europe.

Fruit and esculent vegetables are principally cultivated. Vegetables of a different description are not attended to, unless of an ornamental or useful character. In one year, 435 samples of lettuces, 261 of peas, and 240 of potatoes were produced and examined.

The society is indefatigable in its exertions and munificent in its expenditures, in order to augment its collections and to extend the benefits of horticulture. An agent has been sent to China and Hindostan for that purpose: Another has been employed on the west coast of Africa, in South America, and the West Indies, and a

third has explored the eastern coast of Africa, Lisbon, Madeira, Brazil, and the Cape of Good Hope. The vegetable treasures of the United States have been put in requisition, and besides resident agents, Mr. David Douglas is specially employed to collect plants, seeds, and specimens for the society. He has recently arrived in New York, and will proceed on his mission through this state to Upper Canada. He is intelligent and well informed, and it is hoped that every liberal and enlightened man will promote a mission so important to the best interests of mankind.

The institution is composed of Fellows, Practical Gardeners admitted to the privilege of Fellows, Honorary members, Foreign members, Corresponding members at home, and Corresponding members abroad. There are three foreign members in the United States and several corresponding members. Each Fellow pays an initiation fee of six guineas, and an annual contribution of four guineas. One guinea of the admission fee and one of the annual fee are appropriated to the ordinary support of the garden.—The residue is applied to the increase of its collections and to its other expenses. The number of Fellows is about 1500, and as all spare productions are sold, the income of the institution is adequate to the most munificent exertions.

The superintendence of the establishment is conducted by the President and Secretary, under the direction of a committee of four, composed of those officers, the Treasurer and Vice-Secretary. The Society have an anniversary dinner and general meeting, where there is a splendid exhibition of choice and curious fruits, flowers, and esculent vegetables.

In this establishment, experiments of every nature are instituted with a view to verify former results, or to try new practices, and it forms an excellent school for gardeners. The under gardeners and laborers become in time perfectly well acquainted with Horticulture and qualified as principals in the care of other establishments.

The Society published in 1805, a quarto volume of its transactions; since which four additional volumes have appeared, replete with the most useful information and adorned with the most elegant and beautiful delineation of fruits and flowers that have ever appeared.

As a further inducement if any be wanting to aid Mr. Douglas in his laudable enterprise, we would refer the reader to the last volume of the memoirs of the Agricultural Society of Massachusetts, page 331, for "SOME NOTICE OF THOMAS ANDREW KNIGHT, ESQ. PRESIDENT OF THE HORTICULTURAL SOCIETY OF LONDON, HIS EXPERIMENTS AND PRESENT TO THIS SOCIETY," written by the Hon. John Lowell, then corresponding secretary, and now President of that most respectable and efficient association.—We would gladly copy all that Mr. Lowell has so well and so justly said of the useful and scientific labours of Mr. Knight, if we had room for the whole article; but we are forced to confine ourselves at present to so much of it, as more particularly evinces his kindness to our country and the obligation that exists on the ground of sheer gratitude to reciprocate his attentions, by sending to that society, the seeds of such indigenous plants, vegetables, vines, flowers &c. as it may be imagined, would be new to them, and useful either for culinary purposes, for dyeing, for ornament, for medicine, &c.—*Edit. Am. Far.*

But these are but a part of Mr. Knight's labors and services. Following up the Linnæan theory of the sexual system of plants, (or to speak in language better adapted to all classes of

readers,) proceeding upon the well established fact, that certain parts of the flower, called Anthers, produce a dust called Pollen, which is indispensable to the fertilization of the germ or fruit, a fact known to be true, before Linnaeus existed, but which never received perfect confidence, till he demonstrated it. Mr. Knight has devoted thirty-five years of his life to the practical application of his theory, which he has not only demonstrated by hundreds of experiments, but he may be said to have created many new and valuable varieties of fruits hitherto unknown. He has obtained new varieties of the pear, the apple, the grape, the plum, and the strawberry. He has demonstrated that we can correct the defects of one variety of fruit by another, by introducing the farina of a pear for example, which has too much austerity or acidity into the flower of another pear, which has too much sweetness, too insipid a sweet, you may give to the new product a taste and flavour, which may be perfectly agreeable. So it has been ascertained by Mr. Knight, that by the same process, a fruit which is defective in vigour, which bears with great reluctance a cold climate, may, by intermixing it, or coupling it with another tree of the same species of a hardy character, acquire the vigorous constitution of one of its parents, and still retain the excellent qualities of the other parent. There is, indeed, no end to the changes which have been produced by Mr. Knight and others, not in fruits, but in flowers, by this process. We are aware that this statement, to those who are ignorant of his exertions and success, may seem to be extravagant; but we can affirm, that he has done more to improve horticulture than any person of whom we, in this western world, have any knowledge.

These remarks were intended as an introduction to a notice of the efforts which Mr. Knight has generously made to communicate to America some of his improved fruits. In 1822, I had occasion to write to Mr. Knight to procure the last numbers of the Horticultural Transactions, for the college; he replied to my letter in the most friendly manner, appeared to be highly gratified with opening an intercourse with our country, expressed his strong attachment to it, his disgust at the libels on our country in some of the presses of Great Britain, and his intention to send to us the best new fruits which the late improvements had introduced; declaring at the same time, that though he should confide them to my care, it was under the full belief and expectation that I should disseminate them as extensively as possible. I need not say, that he could not have given me a charge more agreeable; and that without the smallest regard to personal interest, I shall circulate as largely as possible, by buds and scions, every variety of fruit he may send. I shall consider myself steward for the public—but I ought to remark, that as he sends but one individual specimen, the progress must be slow, and that I must exercise a discretion in giving scions and buds to such persons as will be most like to take good care of them; but I shall do it in all cases on the express condition, that the same freedom of circulation shall be practised by all.

I shall close this article by inserting Mr. Knight's last letter to me, accompanying certain fruit trees sent this spring.

"Downton Castle, Feb. 15th 1823.

"JOHN LOWELL, ESQ.

"Dear Sir,—I have this day sent to Messrs. Thornely, of Liverpool, to be forwarded to you, a box containing trees and grafts of ten new varieties of pears, which here ripen in succession from October to May, and which I conclude in your warmer summer climate will ripen in succession.

—I could have sent a larger number of varieties, but those sent are the best and the most productive, and inferior varieties that would ripen at the same seasons, I did not think worth sending. Each tree has a label and is also numbered besides, and I will now give you a *concise description* of each variety. I have also sent grafts of each variety from bearing trees, that you may certainly have each variety.

No. 1. Cassiomont—a large pear, yellow upon one side and red upon the other, ripens in October.

No. 2. Tillington—This is described in the Horticultural Transactions. It is perfectly melting or rather perfectly beurree, and very rich, sprang from a seed of the autumn bergamot,—and the pollen of the Jargonelle, and its form is precisely such as you would expect from such a mixture. It is ripe in November.*

[N. B. by the Corresponding Secretary.]—This example will shew our cultivators the process of Mr. Knight and the great changes produced by it. He removed from the flowers of the autumn Bergamot all the anthers. He impregnated the germ with the pollen of the Jargonelle. He took the seeds of the fruit, thus obtained, sowed them, and produced a *new pear*, having a mixed form, between that of the Jargonelle, which is long and eminently pear shaped—and that of the autumn Bergamot, which is flattened and rather apple shaped—and it ripens nearly two months *later* than either of its parents. Being a new seedling, it will have strength and vigour and endure many years. Mr. Knight computes the longevity of a new variety of pear at more than 150 years. We may then form some judgment of the value of such an acquisition, when we know and have perceived for many years the gradual deterioration of the St. Germain, St. Michaels, Chamontelle, &c.

No. 3. Urbaniste—A large and nearly globular pear—color yellowish green—the flavor of rose water. Season, November.

No. 4. Beurree Knox—Large, pear shaped, yellow. Season, November and December, an excellent pear.

No. 5. Marie Louise—Middle sized—colour, pale yellow. Season, November and December, a most excellent variety.

No. 6. Napoleon—Somewhat smaller than the Marie Louise, exceedingly melting and juicy. Season, November and December.

No. 7. Florelle—Middle size and pear shaped, colour bright red, nearly scarlet, with minute dark points, a most beautiful and excellent variety. Season November.

No. 8. Colmar d'Hyver—shape varying from nearly globular to pear shaped, colour yellowish green. Season, January—a melting pear of first rate excellence and very productive.

No. 9. Passe Colmar—Large and pear shaped, but very broad towards the eye. An exceedingly fine melting pear, which by being kept in different temperatures, may *here* be brought to table in perfection from the beginning of January to the middle or end of April. This variety is productive to a fault. I am generally obliged to take off 9-10ths of the fruit.

No. 10. Hardenpont de Printemps*—a large pale green pear with rather a rough skin. It ripens *here* (in England) in the end of April or beginning of May—and its flesh at that period nearly resembles that of the Brown Beurree in Autumn. It is a very productive variety, and in

* So named I have observed from Monsr. Hardenpont of Mons. in Brabant, who raised it as a seedling. It is christened by the French Gardeners Beurree Rance, but the English cultivators give credit to its creator, or raiser.—Cor. Sec.

your climate will, I believe, prove the most valuable variety of all.

No. 11. Gilliflower apple—*Grafts only sent*—Form angular flesh perfumed and remarkably yellow. It is in perfection in *winter and spring*. It would afford in a warmer climate a most excellent cider.

No. 12. Sweetney Nonpareil Apple—A very large variety of the Nonpareil, very excellent ripened on a south wall, or in a very warm season, and good situation, but too late for our climate. I believe it would suit yours. It is entirely new.

No. 13. Black Eagle Cherry.

No. 14. Elton Cherry.

No. 15. Waterloo Cherry.

All these cherries are new varieties produced by Mr. Knight—they have been described in the horticultural transactions and colored plates of them given—they have all of them valuable properties.

It should be recollected, that Mr. Knight often fails in his numerous experiments, and it is only the excellent new varieties which he presents to the public.

No. 16. Downton Cherry—It is a white or pale red cherry with white flesh, and it is believed will prove an excellent variety.

No. 17. Cooes Golden drop plum—A fine variety from the original stock.

No. 18. A very large new plum of a green color, which promises well.

Mr. Knight added also two hundred Downton Strawberry plants; a new variety, but they perished in the passage.

The trees were admirably packed, and although they started more than could have been desired on the passage, yet there is no doubt we shall save every variety except perhaps one or two of the cherries—but had they all perished, our feelings towards Mr. Knight would not have been affected. His good intentions—his kindness towards our country, his philanthropy, would not have been the less. Unsolicited, he has bestowed upon us, what is of no small value, independent of the excellent intention. One new, and excellent variety of fruit is a great gain. How much have the St. Germain and St. Michaels Pear contributed to the pleasures of our tables?

Who would not be pleased to have *ten new and excellent varieties* of pears, in the prime of youth, to supply the place of these, which we must soon lose? We trust we shall find some apologists for the zeal with which this article is written. There is something so kind, in this intercommunication between cultivators of different countries; it seems to be such a forgetting of the old circumstances of separation, that one cannot but be pleased with it.

HOPS.

Our readers have observed our anxiety to procure for them, the most authentic and particular information respecting the cultivation and curing of hops in New England, where that subject is best understood. If there be any thing material omitted in the accounts hitherto published, that omission will be supplied in the following treatise, which we find in the last number of that excellent Journal, the *New England Farmer*, communicated for that paper by W. Blanchard Jr. Esq. of Wilmington, Massachusetts:—that, we understand to be the town where hops were first cultivated to any considerable extent in that part of our country—as late as the year 92, there were probably more hops grown in that town, than in all the others in New England.

Edit. Am. Far.

FROM THE NEW ENGLAND FARMER.

Thomas G. Fessenden, Esq.

SIR—The cultivation of hops is becoming an

important branch of agriculture with our farmers, both as an article for exportation and domestic consumption. The quantity now raised in this country, annually, does not vary much from a million of pounds. Great improvements have been made, within a few years, in the cultivation and management of this article; and with such success, that we have had several lots which would compare (without prejudice to their reputation) with the best English hops. In consequence of which, our hops are gaining a fair reputation abroad; and our home consumption is rapidly increasing:—a prospect highly gratifying to every friend to society, to see the wholesome liquor made from this article introduced, and supplying the place of ardent spirits.

If, Sir, you deem the following observations on the culture and management of hops, worthy a place in your paper, you are at liberty to publish them.

Your's respectfully, &c.

WILLIAM BLANCHARD, JR.

Wilmington, August 26, 1823.

The hop is a native plant. It is found growing spontaneously on the banks and intervals of many of our large rivers. There are several distinct species, all bearing a near affinity to each other; (I have noticed five.) At present they are cultivated together, promiscuously; no preference having been given to any particular one of them by the brewer. But I am of the opinion that there is an essential difference in their qualities—that one may be the best for pale ale; another for strong beer; and a third for porter; and I presume, ere long, particular attention will be paid to ascertain their different qualities.

The soil best calculated for the production of hops, I consider to be a sandy loam, rather low and moist. I am led to this conclusion, partly from my own observation, and further (considering Nature an infallible instructor,) from finding the lands which produce them naturally (intervals and the banks of large rivers) to be of this kind. Yet, I must observe, I have seen very fine crops raised on different soils.*

I should recommend the following mode of preparing the land and manuring the crop. In the fall (October) plough the land deep—nine or ten inches. In the spring following pass a heavy sharp iron toothed harrow over the land in the same direction it was ploughed; after which, spread your manure evenly over the same, sixteen chords per acre, and more if the land be much reduced; then cross-plough the land nearly the same depth, and furrow it as for planting corn—the furrows to be at least four feet apart.

It is customary to plant corn or potatoes with the hops, (I should prefer potatoes.) Plant every other hill in every other row with hops, thus placing the hop hills at least eight feet apart. Put four cuttings, from the running roots, about eight inches in length, into each hill, and cover them the common depth of potatoes.

Many yards have been much injured by being planted too closely. It is of great importance to have the hills so far distant from each other as to

* In passing from one to another of the numerous sulphur springs in Virginia, one is there struck with the exceedingly luxuriant growth of the hop vine, in the *narrow vallies* which separate the mountains—and comes at once to the conclusion, that there must be something particularly congenial to their nature in the soil and climate—the former of which is a rich black and rather a sandy or slate loam, and the latter moistened to an extreme degree, by almost perpetual fogs.—*Edit. Am. Far.*

to a free current of air to pass through the
ard.
And the attention requisite the first season, af-
ter the hops are planted, is to keep them clean
from weeds, which is easily done when hoeing
a crop planted amongst them. In the fall (Oc-
tober) to prevent their being injured by the hard
frosts of winter, carry on, and lay out of your cart,
a shovel full of compost manure on the top of
each hill;—manure from the hog-stye I should
prefer.

In each following spring, before the hops are
planted, as it is termed, spread evenly over the
land about eight cords of manure per acre,—
course, straw manure, I should prefer, as it
will have a tendency to keep the land loose;) and
rough the field both ways at the first hoeing.
They require but three hoeings in a season, un-
less necessary to subdue the weeds; the last of
which should be performed when the hops are in
full blossom, (about the beginning of August.)

After the first crop, it is necessary to open the
rows, every spring, by the middle of May; which
is performed by making four furrows between the
rows, turning the furrows from the hills, and run-
ning the plough as near to the same as possible
without injuring the main roots. Then the earth
is removed from the roots with a hoe—all the
siding roots cut in, with a sharp knife, within
two inches of the main roots—the tops of the
main roots must also be cut in—and then the
rows covered with earth about two inches deep.

The next thing necessary to be done, is to set
up the poles. This should be done as soon as the
hops begin to make their appearance. By
doing, much time and labour will be saved in
tying up the vines to the poles, as many of the
vines will naturally take to the poles.—There
should not be to exceed two vines to one pole, nor
to exceed two poles to one hill, nor any pole to
exceed sixteen feet in height. Many yards have
been very much injured by letting a greater num-
ber of vines grow on one pole; and almost de-
stroyed by over polling.

Very much depends on paying due attention in
the spring, to select the most thrifty vines, and
tying them to the poles, which is done by fas-
sening them to the poles with a piece of yarn,
loosely twisted together with the thumb and finger.
It will be necessary to inspect your hop-yard
frequently, until the hops begin to blossom, and
"tie up the vines," as it is termed, as they are
subject to be blown off the poles by every high
wind.

As soon as the hops are ripe, which is about
the beginning of September, they must be imme-
diately gathered, or the crop is lost. The quali-
ty of the hops depends considerably on their be-
ing picked clean from leaves and stems. The la-
bour of picking or gathering the hops, may be
well performed by women and children, having
the man to a bin to handle the poles, and to in-
spect the pickers. The bin is a wooden box,
about nine feet long, three feet wide, and two and
a half feet high, made of thin pine boards, that
it may be easily moved over the yard, across
which the poles are laid, and into which the hops
are picked by hand. Care should be taken, when
gathering the hops, to put the vines two feet from
the ground, that the roots may not be injured by
freezing.

The most important part in the management
of hops, is the curing or drying of them. Here
I would note, that hops always grow first sort;
and that all second sort and refuse hops, are
made so by unfortunate or unskilful management.
Much depends on having a well constructed
bin. For the convenience of putting the hops
in the kiln, the side of an hill is generally chosen
for its situation. Care should be taken that it

be a dry situation. The kiln should be dug out
to the same bigness at the bottom as at the top; the
side walls laid up perpendicularly, and filled in so-
lid with stone to give it a tunnel form. Twelve
feet square at the top, two feet square at the bot-
tom, and at least eight feet deep, is deemed a
convenient size. On the top of the wall sills are
laid, having joists let into them in like manner as
for laying a floor—on which laths, about 1½ in-
ches wide, are nailed, leaving open spaces between
them ½ of an inch, over which a thin linen cloth is
spread, and nailed at the edges to the sills. A
board about 12 inches wide is set up on each side
of the kiln, on the inner edge of the sill, to form
a bin to receive the hops. The larger the stones
made use of in the construction of the kiln, the
better; as it will give a more steady and dense
heat. The inside of the kiln, should be well
plastered with mortar to make it completely air-
tight. Charcoal (that made from yellow birch
or maple I should prefer,) is the only fuel proper
to be used in drying hops. The kiln should be
well heated before any hops are put on, and care-
fully attended to keep a steady and regular heat.

Fifty pounds of hops, when dried, is the larg-
est quantity that should be dried, at one time, on
a kiln of this size; and unless absolutely necessa-
ry to put on that quantity, a less would dry bet-
ter. The green hops should be spread as even-
ly and as light as possible over the kiln. The
fire at first should be moderate, but it may be in-
creased as the hops dry and the steam is evapo-
rated.

Hops should not remain long in the bin or bag
after they are picked, as they will very soon
heat and become insipid. The hops should not
be stirred on the kiln until they are completely
and fully dried. Then they should be removed
from the kiln into a dry room and laid in a heap,
and there remain unmoved and unstirred, until
bagged, which is done with a screw, having a box
made of plank the size the bag is wished, into
which the cloth is laid, and the hops screwed in-
to the box, which is so constructed that the sides
may be removed, and the bag sewed together
while in the press.

The hops, after laying a few days, will gather
a partial moisture, called a sweat. The sweat
will probably begin to subside in about eight
days, at which time, and before the sweat is off,
they ought to be bagged in clear dry weather.
As the exact time when the hops will begin to
sweat, and when the sweat will begin to subside
or dry off, (the proper time to bag them) will
vary with the state of the atmosphere, it will
be necessary to examine the hops from day to day,
which is easily done by taking some of them from
the centre of the heap with your hand. If on
examination you find the hops to be very damp,
and their color altering,—which will be the case
if they were not completely dried on the kiln,
and not otherwise—you must overhale them and
dry them in the air.

The most convenient size for a bag of hops to
handle and transport, is about five feet in length,
and to contain about 250 pounds. The best bag-
ging is coarse strong tow cloth of our domestic
manufacturing; next to that, Russia hemp bag-
ging. The East India sugar, and gurney bags, so
called ought never to be used. The sugar bags
are of an unreasonable weight, and both they and
the gurney bags are of no value to the brewer;
whereas the other bags are worth prime cost.

It is now common for those who have entered
considerably into the cultivation of hops, to build
houses over their kilns, which, in wet weather,
are very convenient; otherwise, a kiln in the
open air, would, in my opinion, be preferable. It
is necessary to have these buildings well venti-
lated with doors and windows: and to have them

kept open night and day, except in wet weather,
and then shut those only which are necessary to
keep out the rain. If a ventilator was put in the
roof of the building, directly over the centre of
the kiln, about six feet square, built like those in
breweries and distilleries, I am of the opinion
they would be found very advantageous. I have
seen many lots of hops much injured, both in col-
or and flavor, by being dried in close buildings.

Where the houses over the kilns are built
large, for the purpose of storing the hops as
they are dried,—which is a great saving of la-
bor,—a close partition should be made between
the kilns and the room in which the hops are
stored, to prevent the damp steam from the
kilns coming to them, as it will color them and
injure their flavour and quality very much.

I expect that many of our farmers will object
to the mode of manuring hops which I have re-
commended, their common practice being to put
the manure in the hills when they plant the hops,
and afterwards to apply the manure on the hills
at the first and second hoeings. I find the hop-
roots are very liable to be injured by worms,
and to decay. My opinion is, that the manure
in the hill has a tendency to produce the worms,
and its fermentation at their roots to cause their
decay; and that the crop is not more, if as abun-
dant, as when manured in the manner I have re-
commended. And further, that a hop yard ma-
nured in this manner, will continue in a healthy
state for many years.

I also expect the quantity of manure I have re-
commended, will be objected to by many, it being
the common received opinion that hops should
have little or no manure. I find it a general com-
plaint amongst the farmers where hops have
been cultivated many years, that the quantity
raised per acre does not exceed the one half raised
by their ancestors, on the same land; infer-
ring that the "hops are running out," as it is
termed, and cannot now be cultivated to advan-
tage. Hops, I believe, in common with all sorts
of grain and vegetables, flourish best and produce
the finest crops, when cultivated on new lands
which require little or no manure—and such
were the lands which their ancestors cultivated.
The same complaint I presume would be made
against all sorts of grain and vegetables, if raised
with little or no manure, on lands that have
long been cultivated.

From my own observations I am confident that
no crop can be more improved and increased by
high cultivation than hops.

AGRICULTURE.

TO THE EDITOR OF THE AMERICAN FARMER.

DUB GRASS.

Darien, August 12th, 1823.

DEAR SIR,

Inclosed you will receive a drawing, taken
from the 5th volume (octavo edition) of Sir Wil-
liam Jones's work, and in the same paper a spe-
cimen of grass, which I conceive, or rather am
satisfied is the same. Two or three years ago,
Mr. Crawford, among other things, forwarded to
Georgia, a small quantity of the *dub grass*,
which had been brought from India for him, as a
grass of great value. From the dry specimen, I
then considered it as our Bermuda grass, but it
was only the other day, from accidentally turn-
ing over Sir William Jones's work, I was satisfied
of the fact. I am fearful that the fructification
being so tender and minute, will be destroyed be-
fore you receive it. This grass is not only the
best feed for cattle, but is capable of feeding
more stock than any grass we are acquainted
with. Every where in the southern states, you

find small parcels of it about the house, but justice has never been done it, from an apprehension of its getting into the fields, where certainly it is much to be dreaded, as it is not again to be eradicated, for it would place the plough and the harrow at defiance; or rather they would increase its luxuriance. This grass is very sensible here, as in India, of drought above ground, but a single shower renews its vegetation. It should be grown in meadows, apart from other fields, where, too, it does best.—Fifteen acres of it opposite Savannah, which was land embanked from the river, fed, as I am informed, twenty head of horses, forty head of cattle, and one hundred sheep, under a former proprietor. Anxiety to keep it out of the rice fields, has been the cause why it has not been cultivated in such situations.

In your 3d vol. I see a letter from a gentleman in Bengal, to Dr. Mease of Philadelphia, giving directions about making indigo. This sounds a little curious to those who know that it was a Mr. Gray, who went from Georgia, at the commencement of the revolutionary war, and who carried the American mode of manufacturing indigo to Bengal. Before that the Hindoos made indigo for their own use, but not for export; and in a manner that would never have been injurious to us. They employed two or three earthen vessels, into which they put small bundles of indigo, and then poured warm water upon it; and after steeping a little while, they took out the indigo weed, added a small quantity of lime water, and, with ladles, stirred the fluid, until the fecula separated. All this is to be seen in the Asiatic researches and Asiatic registers, and probably may be remembered by the venerable Mr. Law. Mr. Gray was a young man of cleverness, in the employment of a Mr. Bowman of Charleston, making indigo on some plantations of his below Savannah. But differing in politics from his employer, he probably obtained letters to England, and patronage which carried him from there to India, where he introduced large steepers which would contain an acre of indigo weed at a time, and large beaters which would hold the contents of the steeper. The description of each is tolerably correct in the letter alluded to. Mr. Gray returned to England some years back a man of fortune and consideration. I have myself believed, that the indifferent quality of our indigo was attributable to the badness of water on the Sea Islands, where it was principally cultivated; for how could it be expected that a delicate dye could be extracted where the menstruum that was employed was a turbid water, surcharged with salt and other extraneous substances: and what has confirmed me in this opinion is to have seen through our pine country, in our domestic manufactories, some of the most beautiful, the most intense, and the most permanent blues, formed from indigo grown and manufactured in that quarter. And this pine region is not more distinguished for its health, than for the excellence of its water, found in pure white sand at the bottom of deep wells, sunk through hard and ponderous clay. If ever, therefore, indigo is again a staple in this country, it should be cultivated in that region. The quantity grown to the laborer, used to be four acres, producing from 20 to 25 lbs. per acre. At the present price of indigo, this would very well remunerate, but was nothing at 50 cents per lb. It is a crop, however, like flax and hemp, unpleasant, and even offensive in its preparation.

One of your correspondents makes some enquiries as to the mode of planting the palmetto royal, or Spanish bayonet, as a hedge. There is nothing so easily raised. If a trench is made, and the stocks cut, and laid down horizontally,

two or three inches under the ground in the fall or winter, it will sprout along the stem every few inches, and in 12 months will make a fence of fair appearance. It is so easily done that an old man of mine went round 27 acres in a month or two. But it is only a fence against strangers. As soon as cattle and hogs are acquainted with it, they take to eating it as freely as so much clover. My fence has been completely destroyed by them, although it was beautiful for a season and was protected by a deep ditch.

I am fearful that the high expectations formed of the *guinea grass* will fail. My neighbors and myself have tried it repeatedly, and although at each time, flattered for a while, with finding some means of perpetuating it, have in the end failed: and this is the difficulty, for the seed vegetates irregularly and reluctantly, and the roots are, nine times out of ten, destroyed by the winter frosts.

I have seen some remarks from a Pensacola correspondent respecting the *kermes oak*. We have plenty of it growing about Darien, and if you desire it, can send you some branches with the balls upon it.

Very respectfully, dear sir,
Your obedient servant,
T. SPALDING.

The grass enclosed, together with the drawing, has been sent to an eminent Botanist, for his observation and remarks.—*Edit. Am. Far.*

TO THE EDITOR OF THE AMERICAN FARMER.

GUINEA GRASS.

Oaken Grove, Jefferson County, (Geo.) }
26th August, 1823. }

Sir,

The guinea grass has exceeded my most sanguine expectation; on the 25th April 1822, I sowed the small parcel of seeds (that you were polite enough to send me,) in my garden, in drills five feet apart; in the month of August following, the grass was 12 and 14 feet high; in the month of September, when it shot out, it was 15 and 16 feet high—a rich luxuriant crop, which shaded the ground completely from the rays of the sun; from the above portion of seeds I got better than half a bushel—after distributing many portions in my vicinity, I planted a large lot, on the 21st of April last, in drills six feet wide, on dry upland, rather sandy, what we call good bottom land in this section of the state—the original growth was oak and hickory, on this soil it grows without difficulty; on this day, the 26th August, it is on an average 10 feet high, and completely overshadows the ground, notwithstanding the wideness of the drills. I think it would easily bear three cuttings during our summer, though as yet I have cut the part, that I do not wish to stand for seed, but once, and this again is five feet high and upwards—I think four or five feet is the best height for cutting; when it stands longer, the stems become too thick, and it is hard to cure it yields an immense fodder from the quantity of ground planted, and the cultivation of the crop is very trifling.

An estimate of what it would yield per acre, would indeed appear to be wonderful, until our citizens become a little better acquainted with its cultivation—however, I have little doubt but that it will become very desirable in some parts of our southern states.—Last year the seeds came to complete perfection, and are much more hardy than I could conceive, as those seeds that fell from the grass, before I gathered the remainder in the month of October, remained on the ground all winter, came up in vast abundance on the

first days of May following—from which, I would infer that a short time before this period, would be a good time for sowing the seeds, and if we suffer the grass to come to perfection, we will be in no danger of losing the seed.

As all our trials to form meadows, in the end, prove abortive with us, I have hoped that in the guinea grass we have found a good substitute, as it appears perfectly adapted to the warmth of our soil, the moisture of our atmosphere, and the intense heat of our sun.

Respectfully your's, &c.
ROBERT LOWRY.

J. S. SKINNER, Esq.

HARDY RICE SEED—FROM GOVERNOR CLINTON.

TO THE EDITOR OF THE AMERICAN FARMER.

Aibany, 25th August, 1823.

SIR—I have lately received from Joseph Sabine, Esq. Secretary of the Horticultural Society of London, a small package containing hardy rice seed from Ivomlah, a district in Nepal, situated north-west from the great valley adjoining to Ilimimaleh, and about six weeks journey from Kalmandu. It was procured from Me.ice by the intercession of the British agent through the Court of Kalmandu; and it was accompanied by the following memorandum

“Mode of sowing and cultivating the rice commonly called Ivomlah Dhan. Take the quantity of grain you intend to sow, and having collected it into a heap in any cool place, cover the heap entirely with layers of moistened earth and rich manure mixed together. In the course of ten or twelve days, the grains of rice that have been thus covered up, will sprout and send forth green shoots. Whenever this operation takes place they are ready for sowing. The ground on which you intend to sow must be prepared as follows. It is to be plentifully covered with water, and ploughed until the water becomes well mixed with the earth. The grain is to be strewed upon the ground whilst in this saturated state, and it will assuredly thrive. Should it appear to require water afterwards, as the crop advances, water must be given.”

From the position of the country of Nepal, which, I believe, forms one of the ridges of the Ilimimaleh mountains, I take it for granted that the Ivomlah Dhan is a hardy grain, calculated for a climate considerably cold. It may probably suit Maryland—and with a view that the experiment may be made, I have sent a small parcel of the seed, under a persuasion that you will dispose of it in a way best calculated to promote the interests of agriculture.

I avail myself of this opportunity to forward a discourse, which I hope may amuse a vacant hour, if any such occur in your well employed life.

I am,
With great consideration,
Your most o.b.t servant,
DEWITT CLINTON.

J. S. SKINNER, Esq.

The following extracts are made from the Editor's reply to Governor Clinton, that it may be known hereafter what disposition has been made of his offering; and that the result may be more certainly ascertained, we have requested a friend to furnish us with an account of the trial making to cultivate rice on the Eastern Shore of Maryland.

Editor American Farmer.

Baltimore Post Office,
30th August 1823.

DEAR SIR,

This day brought me your favor of the 25th of August, and along with it a small parcel of rice seed, which is the more acceptable, as a considerably extensive experiment is now making in the reclamation of the marsh lands, near Vienna, on the Eastern Shore of this State, by some gentlemen of South Carolina, with a view to the culture of rice:—To this enterprise they have probably been tempted by the very low price of such lands in this state:—To ensure to it the most favourable result it will be of importance to have obtained this small supply of "hardy grain calculated for a climate considerably cold."

The apprehension to be entertained is, that its terminating quality may have been destroyed by exposure to atmospheric influence, as I see it has been recently stated, by a committee of the South Carolina Agricultural Society, as one of the remarkable properties of this grain, that though almost imperishable as food, and though growing freely after being deeply buried many years in the ground, yet when exposed to the influence of the atmosphere, its vegetating power can scarcely be preserved beyond the year.

You may rely on my making such disposition of your offering of this precious grain, as will afford the best chance of a successful result, happy in the opportunity of serving the most numerous class of my patrons.

The first leisure hour which may present itself in the course of toilsome duties, shall be appropriated to the perusal of your discourse, from which I anticipate both pleasure and profit. Your essay on the habits of the Columbia Pigeon has been given to the Printer of the Farmer, as an interesting contribution to our stock of natural history—and here permit me to use this occasion to mention a curious fact which I have often observed in regard to the common grey squirrel of our country—the castration of a large portion of the males—any one in the habit of shooting them, will recollect that many of the males are found to have been emasculated at an early age. For this extraordinary and cruel mutilation, some reason must exist in the economy of that animal; we might suppose it to be the desperate but necessary device of a policy, teaching them to keep the increase of the species within the diminishing means of subsistence in old settlements; but that end would be better attained by extinguishing the power of generation in the female. Can it be to prevent by anticipation, the fierce contention and exterminating battles, that would ensue from a too great proportion of males to females, as in the case of some other animals? But I forbear to trouble you with conjectures as to the cause or the object of a fact, about the existence of which, only, do I feel assured; and would not have mentioned the fact itself, but that I do not recollect to have observed any such measure in the police of any other family of the animal kingdom—nor have I seen this one alluded to by any naturalist.

With great respect sir,

I remain your obedient servant,

J. S. SKINNER.

To Gov. CLINTON.

Extract from Gov. Clinton's answer.

"The fact which you mention respecting the castration of a large portion of the males of squirrels is an anomaly in natural history. By whom is the mutilation inflicted? The old males, the mothers or young rivals? Does it

extend to all the species, or is it confined to the common grey or black squirrel?"

WOOL.

A Mammoth Fleece.—On the 2d June, Aaron Sherwood, of Bennington, Vt. sheared from one sheep eighteen pounds and fourteen ounces washed wool; which is of a good quality, and about sixteen inches in length. The sheep is four years old this season, and weighed, with the fleece on, one hundred and seventy eight pounds. This we believe to be the largest fleece ever sheared in Vermont, or perhaps in the United States.—*Bennington Gazette.*

On seeing the above in a Vermont paper, we wrote to Mr. Sherwood to ascertain the truth of the statement, and to ask,—the breed of the sheep—whether the fleece was not of more than one year's growth—if not, the weight of previous fleeces, and for a sample of the wool—to these enquiries we received the following prompt, polite and satisfactory answer. The fibre of the sample received is as stated—about 16 inches long.—*Edif. Am. Far.*

Bennington, September 8th, 1823.

Mr. Sherwood received your letter of the 3d August, and wished me to answer it.

The statement as to the amount of wool, is correct. He further says, that when the fleece was taken off it weighed 24 lbs. 6 ounces, owing perhaps to the dampness of the wool. The sheep having been washed three days previous to the shearing; he then dried it thoroughly in the sun, and it weighed as stated.

The buck was said to be a full blooded merino, of the Livingston breed, the ewe perhaps half merino, and of the common sheep of this country.

The sheep was never before sheared—these facts may be relied on.

He sends you a sample agreeably to your request.

The sheep was remarkably covered on his head and legs, so that he looked more like a bundle of wool, than a living animal.

For AARON SHERWOOD,
DAVID ROBINSON, Jr.

I rather expect, myself, that the buck was not quite what was represented to Mr. Sherwood, though nearly so.

TO THE EDITOR OF THE AMERICAN FARMER.

RACE HORSES.

SIR,

In a Petersburg newspaper of the 11th of July, I have read a piece extracted from the "Farmer," under the head of "THE HORSE," which seems to have for its object the repressing of a spirit that has slept too long, and has but very lately begun to revive: I mean the breeding and training of THE GENUINE BLOOD HORSE. In opposition to the experience of "one of your constant readers," &c. &c. I will not oppose my own, but confidently rely upon that of every distinguished writer on the subject, among whom I would refer more particularly to John Lawrence—meanwhile I shall endeavour as concisely as possible to note some of the more glaring errors of your "constant reader."

1. "The race horse is long backed," and "flat-sided." This is not generally true: neither is it necessary for him to be "not less than sixteen hands high;" nineteen out of twenty not reaching that height.

2. "The race horse is a stumbler." When this is the case, it proceeds from his being train-

ed very young to throw his whole weight on his shoulders. Put him in the riding house, and teach him to carry his chief weight on his haunches, and you will not find him to be a stumbler. His "thin deep shoulders," "narrow breast," and "clean legs," are the best securities against stumbling. The difference between him and the cold blooded horse, is as a carriage on springs to a cart. It is notorious that the best saddle horses ever bred in Virginia were of "the good old stocks," enumerated by your correspondent, which were the highest bred horses and best racers of their day. To this blood the cavalry of Washington and Lee were indebted for their superiority over any other on the continent; "unfit," as your "constant reader," pronounces it to be, "for the purpose of war," and the true cause of "the superiority of the saddle horses thirty years ago" is to be found in the superior pedigrees and performance of their sires and dams, when racing flourished all over the state.

So far from being "unmanageable," "vicious," or "timid," they have been reproached with sluggishness. I never saw a thorough bred horse that, on the first trial flinched from the firing of a gun off his back: I never saw a cold blooded horse that would stand fire. They are dangerously subject to take fright.

The blood horse is originally from a hot climate and arid soil; and where the base born suffocates with heat, and faints with fatigue, his wind and strength are untouched. Our sun burnt fields are green pastures to the deserts of Arabia, but we require the blood which is patient of hunger, thirst, heat, and labour, and that is the genuine Arabian. It will not bear exposure to wet and cold, so well as the other, neither does it produce the fastest trotters: in every other respect it has the decided advantage. "The long slouching walk" tells on the road and in the plough, especially on a hot sultry summer's day.

4. I knew the late Col. John Hoomes, of the Bowling Green, well, and a most valuable man he was. He imported some very bad stallions that have much injured our breed of horses; but we are indebted to him for the sire of Sir Archey, whose dam also was imported. Peace and honour to his hospitable memory!

5. The English have injured their breed of horses by training two year olds, and even yearlings, and running short races with light weights. Newmarket, and Epsom, and Doncaster, have doubtless melted princely fortunes, but where one has perished on the turf, a hundred have been ingulphed in the "Hell's," and subscription houses of St. James's street and its neighbourhood. We have put down billiard tables effectually, nearly abolished cards and dice, and racing has been unknown, except in some three or four counties. Meanwhile the gambling spirit, inherent in man, has taken the direction of *bank stock, town property and wild lands*. What has been lost at these games? It were curious, but I fear, impossible to tell, although we see the losers every where; the winners no where.

A traveller, not "sixty years since," gives the following picture of our horses.

"There are races at Williamsburg twice a year. Their purses are gained by the horse that wins two four mile heats out of three. They amount to £100 each, for the first day, and £50 each every day after; the races commonly continuing for a week. There are also matches and sweepstakes very often for considerable sums.— Besides these at Williamsburg, there are races established almost at every town and considerable place in Virginia; and frequent matches, on which large sums of money depend; the inhabitants, almost to a man, being quite devoted to the diversion of horse racing.

"Very capital horses are started here, such as would make no despicable figure at Newmarket; nor is their speed, bottom, or blood inferior to their appearance; the gentlemen of Virginia sparing no pains, trouble, or expense, in importing the best stock and improving the breed by judicious crossing.

"Indeed nothing can be more elegant and beautiful than the horses bred here, whether for the turf, field, road or coach; and they have always fine, long, full flowing tails. Their stock is from old Cade, old Crab, old Partner, Regulus, Babraham, Bosphorus, Devonshire Childers, the Cullen Arabian, Cumberland Arabian, &c. in England, and a horse from Arabia, named the Bellsizé, which was imported into America, and is now in existence.

"The Virginians of all rank and denominations, are excessively fond of horses, and especially those of the race breed. The gentlemen of fortune expend great sums on their studs, generally keeping handsome carriages, and several elegant sets of horses, as well as others for the race and road; even the most indigent person has his saddle horse, which he rides to every place, and on every occasion; for in this country nobody walks on foot. In short their horses are their pleasure and their pride."

The best horses are now found, where the racing spirit has not been suffered entirely to die; in a few contiguous counties of North Carolina and Virginia. I cheerfully concur with your "constant reader," in devotion to "the good old stocks of Janus, Fearnought, Jolly Roger, and Mark Anthony," &c. and where such blood, (and I may add that of Morton's Traveller, Kitty Fisher, Baylor's Shakespeare mare, Selima, and though last not least, Medley,) has been preserved undefiled, we need not look abroad for better. But I fear, where not extinct, it is greatly contaminated by unskilful and inconsiderate crosses. I am acquainted with but one breeder, who possesses it in purity.

PHILIP.

FOR THE AMERICAN FARMER.

SALIVATION OF HORSES.

MR. SKINNER,

Having seen in your paper of the 8th instant, some remarks on the salivation of horses, it put me in mind of a remark of a young Irishman who resides in this neighbourhood, "that if parsley seeds were sown with the clover seeds, horses would not be liable to salivation." The experiment is worth the trial, as no expense will be incurred thereby. I also recollect that several years ago, I saw a publication recommending the sowing parsley as a pasture for sheep, the writer having cured his flock of the rot by its use.

Your's &c.

A friend to Agricultural Improvement.
Raleigh 15th August, 1823.

STRAWBERRIES.—If the opinion of Arator is correct that plants receive more nutriment from the air than from the earth, may not the runners of strawberries be necessary for the collection of that food.

TO THE EDITOR OF THE AMERICAN FARMER.

BOTTS IN HORSES.

Fountain-Rock, August 25, 1823.

DEAR SIR,

I have read in the American Farmer, of the 15th instant, a communication on the subject of botts in the stomach of horses, addressed "to

Mr. Lundy," referring to an extract from a Lexington paper, purporting to be an effectual remedy for the botts, (that prescription I have not seen, having mislaid that number,) signed "A Subscriber"—I have made similar attempts to destroy them, after dissecting the maw or stomach of horses which have been killed by botts, but have discovered nothing would kill the botts (which I tried) that would not kill the horse, if given to destroy the botts while in the horse. I have concluded the only way to save or cure horses, when attacked by botts, is to extract or make the horse discharge them—I have found them troublesome to horses before they had eaten into, or fastened on the maw or stomach; indeed I have seen the botts collected in the throat of the horse, in such lumps or quantities, as to choke and kill the horse instantly; which will always be the case if relief is not given, by inserting into the throat a mop, or the hand of the groom to dislodge them, returning them into the stomach, when they so collect in the throat. The best and most effectual cure I have yet discovered, is to dislodge and bring away the botts, which I have done, by drenching the horse affected, with warm blood, say one or two quarts, or more if it can be conveniently obtained, as there is no danger in giving any quantity injuring the horse. As soon as the dose thus given, reaches the botts in the stomach, they will let go the maw or stomach to feast on the blood thus given.—which gives the horse instant relief, but of short continuance if they are not speedily removed, which must be done by cathartics.—Say Linseed Oil, 1 quart, or such quantity judiciously given as will purge freely; keeping food, (except drinks, or bran tea warm) from the horse until the operation is over, during which gentle exercise is advisable, when it will be found the botts will be freely discharged in so healthy a state, that aquafortis will be found scarcely sufficient to kill them—I have during the month when soft corn (roasting ears) were to be had, given the horse of them to eat plentifully in preference to oil—they purge freely, and the slime brings the worm away forcibly. I have often tried this remedy after all efforts were suspended, and have rarely known it fail, and never when first used, or before the bott had eaten thro' the stomach. I was led to the experiment of giving blood, from the reflection that it was the food of the bott, which they were in pursuit of—to obtain it I always have recourse to one or more of my healthy strong horses, as the quantity desired maybe. Though I have bled in the neck, and used the blood of the horse affected, (when no other horse was convenient) without any hesitation, and I believe it will not be found injurious to bleed horses occasionally when in health, but rather beneficial to most horses.

I have known horses relieved when attacked by botts in some instances, by killing the dung-hill fowl and taking the entrails while warm and cramming them into the stomach of the horse, though I have not myself confidence in its curing or relieving, where the botts have taken fast hold—to prevent botts, burn hickory wood into ashes and keep on hand for use, giving once a week about one pint to each horse in his food; if oats, wet and sprinkle the oats; the horse will eat them without objection, and I think it, perhaps, the means of keeping horses in health, where they would, without the ashes fed, have been diseased from other causes, which your own investigation will, no doubt, inform you they are subject to.

I give you the trouble of reading this reluctantly, leaving it for gentlemen of more leisure and experience to attempt instruction or edification.

NIMROD OWINGS.

Our distant readers are warned that they may have confidence in what they see from the pen of our correspondent above, in relation to that noble animal, the horse.—Mr. O. is known to possess a stock of very superior horses, and to be one of the best judges and masters of that animal in this country.—Edit. Am. Far.

From the New-Brunswick Times.

It may materially promote the interests of agriculture, to offer, through the medium of your paper, a few remarks on the culture of Lucerne. This article (frequently denominated French clover,) I have found by experience to be not only one of the most convenient, but also the most profitable of any grass which can be cultivated. It vegetates quicker in the spring than any other grass, it resists the effects of droughts—it may be cut four or five times in the course of the season, and it will endure for at least twelve years without being renewed—of all other grass, it is the most profitable for soiling—I am fully of opinion, that one acre properly got in would be sufficient to maintain six head of cattle, from the first of May until November, for before it can be cut down in this way, the first part of it will be ready for the scythe. English writers have recommended the drill system for this article, but in this climate I have found this to be entirely fallacious. The proper mode to be adopted is, to have your land in good order, to sow it broad cast, and to get the seed in during the month of April or May. The plan I would recommend, would have to sow at the rate of 15 to 20 pounds to the acre to be sowed with it. The effect of this is, that the rye vegetates quickly, and serves as a nurse to the young grass, against the heat of the scorching sun, and by the time the grass attains sufficient strength to protect itself, say in four or five weeks, the rye withers and apparently dies. In the spring, however the rye will again come forth mixed with the Lucerne, will add much to the quantity on the ground, and prove a most excellent feed for cattle. The rye cut green in this way, and before getting into seed will admit of being cut two or three times in the course of the season, with the lucern, before it decays.

The kind of soil most suitable for this culture, is a dry mellow loam—but a sandy or clay loam will also answer, provided it is not wet. In a favorable season, the Lucerne may be cut the next fall after sowing. After the first season, you may generally begin to cut green for cattle, by the first of May, which saves your young pasture and is, in every respect, a very great convenience, as hogs and every description of animals devour it with equal avidity. Backward as this season has been, I have been furnishing a copious supply every day to seven cattle, since 5th May, inst. The seed can be procured at Thornburn's or other seed stores in New-York, at 40 to 50 cents per pound.

A NEW-JERSEY FARMER.

Perth-Amboy, May 15, 1823.

EXTRACTS FROM LATE NUMBERS OF THE London Farmer's Journal.

An extraordinary Yearling Ram has been bred by Mr. Howgate, of Hay Park, near Knaresborough. He was yearned in 1822; has had no other extra food than a few oats and beans; he was shorn on the 21st April, 1823, which produced 17½ lb. of good without salve: live weight, without wool, 17 st. 4 lb. (14 lb. to the stone*) he stripped kind and handsome. Mr. Howgate also

* 242 pounds.

bred his sire, dam, dam's sire, and grand sire; all which are pure Leicester: this account is correct, though stated rather different in some other papers.

Trotting Match for Two Hundred Sovereigns.

The sporting match between Capt. Millard's bay horse, Godolphin, and Mr. Harrington's brown mare, took place on Monday, over two miles of turf at Wroxham, Essex. The match was to trot 18 miles against each other, and to carry nine stone. The horses started at opposite ends, and the race was won by the mare easy in the last two miles. She performed the task in 68 min. 57 sec., the horse in 69 min. 25 sec. The horse was backed at 5 to 4 after the first two miles.

Mahratta Justice.—The Prime Minister himself perambulates the bazaars, or market-places; and if he should happen to detect a tradesman, selling goods by false weight or measure, this great officer breaks the culprit's head with a large wooden mallet kept especially for that purpose.

Magnetism.—It is recorded and generally believed by Mahomedans, that the tomb of their Prophet is supported in the air, at Mecca, by the action of equal and potent load-stones. The possibility of such an occurrence has been justly ridiculed as false and fabulous. Notwithstanding, it appears from the *Leeds Independent*, that it is practicable to suspend a person by these means. Mr. Abraham, lecturer on this subject, by way of illustration, suspended by means of an artificial magnet, a young gentleman, who, with the apparatus, weighed upwards of seven stone.

Died a few days since, at Preston, in a fit of apoplexy, the Rev. John Harrison, Incumbent Curate of Grimsburgh, near Preston, and late one of the Masters of the Free Grammar-school at the latter place. This gentleman was preparing for publication an *Etymological Enchiridion*, great part of which is printed; and what renders it more remarkable is, that at the time of his death, he was transcribing part of the copy, and that moment finished writing the line "subpoena, a summons," the ink of which was wet on the paper when he was found a lifeless corpse on the floor, his spirit having been summoned to the bar of the Almighty.

Died on the 8th inst. at Oatley, suddenly, Miss M. Ward, of that place. She had been so excessively terrified by the thunder-storm of that day, as to be thrown into strong convulsion fits, which defied all medical and surgical aid, and terminated in her death the same evening.

A woman residing in Duke-street dreamt one night last week, that her house was on fire, and actually got up in her sleep, and made her way out of the house, then suddenly returned, ascended the stairs, and was upon the point of getting into bed, when she awoke; being terrified by the remembrance of her terrific dream, she shrieked, and the fright had the effect of turning the whole mass of her blood. The pressure seems to have centred in her hand, which is frightfully swelled—we are grieved to add, that her medical attendant fears mortification will ensue.—*Brighton Herald*.

A man and his wife, living in Sandgate, Newcastle, having quarrelled on Tuesday last, the wife, in a fit of passion, threw one of the children behind the fire, and before it could be rescued, it was most dreadfully burnt and scorched

in various parts of the body. The poor child was conveyed as soon as possible to the infirmary.

By a comparison of expenses attending parish work-houses throughout Devonshire, up to Midsummer, it appears that, on an average, they amount 27d pence per week for each person therein; the greater at 30d. and the lesser at 22d.

The French are at an enormous expense in Spain—not less, it is calculated than two millions of francs per day! The country is so exhausted, that the Regency of Madrid have called on the French Government to pay its numerous Secretaries, the Ministers, and the Public Functionaries of Madrid. The conduct of the Regency does not please the French Cabinet.

The King of Sweden's son, the Crown Prince Oscar, married at Stockholm, on the 19th June, the Princess Leuchtenberg, who is daughter of Prince Eugene Beauharnois of Josephine, late Empress of France.

Madame de Reboul, who was instrumental in converting Loveday's daughters to Catholicism, in Paris, for her talent in the art, and as a compensation for the persecutions she then underwent, is thought by King Louis worthy of being canonised and is now therefore Saint Reboul!

The Sir William Curtis, which sailed on Friday for the river, has on board £100,000 in specie for the Russian Government; also two bulls and two cows, of the best English breed, purchased by Count Lieven for the Emperor of Russia.

An arrangement has taken place between the Directors of the Bank and the East India Company, by which the former agree to lend the latter £2,000,000 sterling, for two years, at the rate of 3½ per cent. interest, on the security of stock.

A Frenchman being afflicted with the gout, was asked, what difference there was between that and the rheumatism. "One very great difference!" replied Monsieur—"Suppose you take one vice, you put your finger in, you turn the screw, till you bear him no longer—dat is de Rheumatis—den, sponse you give him one turn more, dat is de Gout."

USEFUL RECEIPTS.

Flannel Cakes.—Two pounds of flour, six eggs well beaten, one wine glass of yeast, a little salt, wet it with milk into a thick batter, and set it to rise, bake them on a griddle.

Cocoa-Nut Pudding.—Half a pound of butter and half a pound of sugar beat to a cream, the whites of eight eggs well beaten, half a glass of brandy, wine, and rose water; and half a pound of cocoa-nut grated fine, and mixed in together by degrees. This quantity will make three puddings. One cocoa-nut is half a pound generally.

Lemon Pudding.—Half a pound of butter and half a pound of sugar beat to a cream, five eggs beat to a high froth, grate in the rind of one large lemon, and squeeze in the juice, then add half a glass of brandy, wine, and rose water, (the three together to make the half glass.)—Two puddings.

Pumpkin Pudding.—Half a pound of butter, half a pound of sugar, beat to a cream, one pound of pumpkin, stewed and passed through the cul-

lender, four eggs, one wine glass of brandy, wine, and rose water, one tea-spoonful of spice.

Potato Pudding.—One pound of butter, one pound of sugar, beat to a cream, one pound of potatoes boiled and passed through the cullender, eight eggs, one glass of brandy, one of wine, half a glass of rose water, one tea-spoonful of spice.

Orange Pudding.—One pound of butter, one pound of sugar, beat to a cream, one glass of brandy, wine, and rose water, ten eggs beat to a high froth, pare two oranges and boil the rind till it is tender, (change the water twice or three times) then beat it in a mortar, and squeeze in the juice together with the rind of one lemon grated, and the juice of the same. For apple pudding, add four large spoonfuls of strained apples to each pudding.

Almond Pudding.—Half a pound of butter, half a pound of sugar, beat to a cream, half a pound of almonds blanched, and beaten very fine; beat them well together and add five eggs, one wine glass of brandy, wine, and rose water. Two puddings.

Tomata Cataup.—Wipe the tomatas clean, and slice them in a deep pan, to every layer sprinkle a handful of salt, let them lie twelve hours, put them in a skillet and let them boil four or five minutes, then strain them through a coarse cloth, to get all the juice, pour it in the skillet again, and boil it briskly thirty minutes; to one quart of liquor add a quarter of an ounce of mace, ginger, and half a quarter of an ounce of white pepper, strain it through a thin cloth, and when cold, bottle it, and cork it tight; put four or five blades of mace, and six cloves in each bottle, and some nutmeg. Shake the bottle when used.

TO PREVENT WOOD BLOCKS FROM WARPING.

When the blocks are not in actual use, and especially after being wet, let them be taken out of the form, or exposed to the air so as to dry equally on both sides. If taken out of the form when wet, let them be set up on end or edge to dry, but not in the sunshine or near a fire.

Expensive blocks intended to furnish a great quantity of impressions, ought to be washed with spirits of turpentine, and not wet with any thing else.

When blocks have already warped or sprung, place them on a damp cloth or paper for a few hours, with the rounding side up.

When straight set them up on end to dry.

Unexperienced and careless workmen are too apt to leave them on the stone or elsewhere, with the bottoms very wet, and sometimes at least one fourth immersed. This causes the bottoms of the blocks to expand, while the face remains of the original size; of course it warps, and the ends become too high, and the first impression from it in this situation generally splits it, which the above suggestions if attended to, will prevent.

The Tomb of Napoleon Bonaparte.—Several officers of a British vessel visited the tomb of Bonaparte in May last. The place where this great chief lies, is called Rupert's Valley, and is said to have been a very beautiful spot. It excites much interest, and all visitors to the Island repair to the tomb. Twelve hundred persons visited the spot last year. One of the officers above mentioned says—"We sat down, John Bull like, about twenty of us, and very unceremoniously emptied our basket and drank 'Peace to his shade.'" Being anxious to have something to shew that we brought from the tomb and his house, we cut slips of geraniums and weeping

wallows, and part of the branch of one of the trees large enough to make a snuff box."

It is estimated that the extent of the water and gas pipes under the pavements of London, is between one thousand and one thousand two hundred miles! The roads of England only are above fifty-six thousand leagues—more than one hundred and twenty thousand miles—five times the circumference of the globe!

Prize Ox.—The Ox which obtained the first premium at Brighton, has been purchased and slaughtered by Mr. Walter Welsh, of this town, and will be for sale this day at his stall No. 4, Fanueil-Hall. He was fatted by Mr. Josiah Morton, of Hatfield; and weighed as follows:

	lbs.		lbs.
Fore Quarter,	443	Tallow,	169
Do.	442	Hide,	155
Hind Quarter,	336		
Do.	353	Total,	1898

Boston paper.

Editorial Correspondence.

Extract from Nelson County, Sept. 3d, 1823.
"The crop of wheat generally very fine with us, better than they have been since 1820. The rye is better than I ever saw it. The oat crop, not so good—the crop of corn, which is now made, is a very abundant one:—I think there was much more than an average crop planted, owing to the great scarcity, and very high price of that article for the last two years. The corn crop being larger, the tobacco crop is consequently smaller than usual, but what is in cultivation promises to turn out well. The clover sown last spring has taken, with me, better than it ever did."

INFORMATION REQUESTED.

You will greatly oblige me, and probably a great number of your subscribers, by giving any information you may possess, or be able to procure, as to the erection of grist or saw mills, upon brick instead of stone foundations. Has the experiment ever been made, and has it been found to answer well, and be impervious to water? If it has, then how thick were the walls at the foundation, and at top, and will they answer where the head of water is from 10 to 15 feet high? What is the best and cheapest cement for such walls? and will not the brick moulder away when they come in contact with the water? Information upon these points, as well as any other, which may be deemed important for a man desirous of making the experiment, will be thankfully received by your friend.

Edisto Island, S. C. September 14, 1823.

SIR—It affords me great pleasure to state that an association has recently been organised on this Island, under the style and title of "the Agricultural Society of St. John's, Colleton, S. C." The Constitution of this society would have been transmitted for publication, but as its provisions differ in no essential points, from the fundamental articles of any similar institution, it was deemed unnecessary.

The following are the officers elected for the ensuing year, to wit:

Joseph Jenkins, Sen'r. President,
William Seabrook, Sen'r. Vice-President,
Whitemarsh B. Seabrook, Cor. Sec.
Col. Joseph E. Jenkins, Rec. Sec.
Edward Whaley, Treasurer.

I have the honor to be,

Very respectfully,

Your obdt' servant,

W. B. SEABROOK, Cor. Sec.

THE FARMER.

BALTIMORE, FRIDAY, SEPTEMBER 26, 1823.

In compliance with an invitation from the President of the board, the TRUSTEES OF THE MARYLAND AGRICULTURAL SOCIETY, had their first meeting on Wednesday last, at Hampton.—It was gratifying to see the punctuality with which they attended at an early hour, and the cheerfulness and zeal with which they proceeded to make the necessary arrangements for the next Agricultural Fair and Exhibition, by the appointment of committees to award premiums—the designation of marshals, &c. After dinner the trustees, with other invited guests, were very agreeably entertained with a view of General Ridgely's fine stock of horses, cattle, sheep, and hogs, and at the close of the afternoon separated, with the understanding, that the next meeting will be held on Wednesday the 15th day of October at 10 o'clock, A. M., at Col. Nicholas M. Bosley's residence on the York turnpike. The proceedings of the day will be published in detail.

LATEST FROM EUROPE.—The old line ship AMITY, Capt. Maxwell, arrived yesterday morning from Liverpool, whence she sailed early on the morning of the 18th of August.—It would appear from the remarks of the *Traveller* that the object of the Duke d'Angouleme in leaving Madrid, was to put a speedy termination to the present war, for which purpose he had actually opened a correspondence with a few members of the Cortes. His views were, however, defeated in consequence of the refusal of the Cortes to enter into any negotiation unless through the mediation of England, which of course the Duke could not accede to. What will be the result of this state of affairs it is impossible for us to form any opinion.

[*New York paper.*]

LIVERPOOL, Au u t 16.

COTTONS at the beginning of the week were excessively dull, the sales for the first three days amounting only to 1200 bags; on Thursday, however there was a revival of demand, which continued during yesterday, and a slight improvement in price took place in bowed. We still, however, have to quote an average depression of about 4d per lb. from the quotations of Saturday last. Bowed have been chiefly sought after, and about 1500 bags principally of this description have been taken by speculators, scarcely any one of the trade having visited us this week. Brazils have been neglected, and scarcely any thing has been done in Orleans. The total sales amount to 4800 bags, viz. 2770 Bowed, 8 3-8 to 10d; 80 Orleans, 9 1/2d. to 10 1/2d; 240 do. 11 1/2d. to 12d; 240 Tennessee and Mobile, 8 1/2d. to 9 7-8d; 145 Sea Islands, 15d. to 18d; 10 Stained do. 10d.

The transactions in Tobacco have been very limited, and prices are without alteration.

The arrivals of Stockholm Tar have become rather numerous, and prices have consequently receded a little; 1400 barrels have been sold at 16s. 6d.; some of the largest holders, however, still require 17s.

Montreal Pot Ashes have improved in demand, and 280 barrels have found buyers at 42s. to 42s. 6d.; Pearl Ashes also have advanced, 200 barrels having been sold at 39s. 6d. to 40s.; both descriptions are very firm at the advanced prices, and holders are very reluctant to proceed in their sales, even at the highest currency of this day. States' Ashes also are in demand and have found buyers at 43s. 6d. to 45s. for Pots; about 150 barrels have been sold.

The inquiries for Carolina rice, have been frequent, but not so frequent as might have been expected from the very unfavorable weather during the present week; 130 tierces have been sold at 17s. 6d. to 18s. 6d. for good old, and at 20s. for pretty good new, which is an advance of 1s. per cwt. Larger sales might have been effected, but the holders were unwilling to sell at the present currency.

The weather during the week having continued wet and unsettled, we have experienced rather an extensive demand for grain, and wheat has advanced 4d. to 6c. and Oats 1d. to 2d. per bushel, since Saturday last.

The Turkish fleet, consisting of 120 sail, among which are several frigates of the largest size, and 15,000 troops, sailed on the 4th June from Andre Capo d'Oro towards the Peloponnesus. The Greeks are preparing for the struggle, which it is anticipated will be an arduous one. Recent accounts from Tripoliza give a very favorable view of the affairs of the Greeks.

Private letters from Smyrna, dated June 2, state that it was the general opinion there, that a war would ensue between Russia and the Porte.

BALTIMORE MARKET.

PRICES CURRENT—CORRECTED WEEKLY.
Flour, best white wheat, \$7—Howard street, from wagons, \$6 87 1/2 a 7—Superfine, \$6 50—fine do. \$6 25—Wheat, do. \$6 25, cash—White wheat, \$1 25 to 1 35—Red do. \$1 18 to \$1 23, a few sales at \$1 25—Rye, 40 to 45 cts.—Corn, 38 a 40 cts.—wheat Oats, 26 a 30 cts.—wagon Oats, 31 cents—Beef, 8 cts. per lb.—Live Cattle, \$6 to \$6 50, per cwt.—Bacon, hog round, \$10—Pork, \$7 50 per c. lb., 6 to 8 cts. per pound—Mutton, 5 to 6 cts. per lb.—Beans, retail, \$1 50, cargo price, 1 1/2—Peas, retail, 75 a 80 cts., cargo price 58 a 60 cts.—Red Clover Seed, \$6—Orchard Grass do. \$3—Herds' Grass do. \$3—Timothy do. \$4—Flax Seed, 75 to 80 cents—Whiskey, from the wagons, 28 to 30 cts. per gallon including the barrel—Apple brandy, 30 to 32 cts.—Peach do. 65 to 70 cts.—Shad, \$6 00.—Herrings, No. 1, \$2 70 per bbl., No. 2, \$2 37 1/2—Fine Salt, 60 to 65 cts. per bush., coarse, do. 70—Butter, (firkin) 14 cts. per lb.—Eggs, 12 1/2 cts. per doz.—New Hay, \$15 per ton, old do. \$18—Straw, \$8.
MARYLAND TOBACCO.—No sales.

To Farmers and others.

EASTMAN'S PATENT CYLINDRICK STRAW CUTTER.

The proprietor continues to manufacture the above machines, six doors above Eutaw, in Market-street, where he has a considerable number on hand for sale, and where gentlemen are respectfully invited to call and examine their workmanship, and witness their operations.—They are warranted to feed and cut with ease and facility every kind of long forage, straight or tangled, even corn stalks and cane tops. His smallest sized machines are capable of cutting from 60 to 70 bushels per hour, price \$45 to 50.—His next size, price \$60, from 80 to 100 bushels per hour. The simplicity and durability of these machines must render them an object to every farmer, particularly as they can be worked by the most awkward hands and by boys.—All orders, money enclosed, will be punctually attended to.

JONATHAN S. EASTMAN.

N. B. He will dispose of the patent right for any state in the Union on reasonable terms.

Printed every Friday at \$4 per annum, for JOHN S. SKINNER Editor, by JOSEPH ROBINSON, on the North West corner of Market and Belvidere streets, Baltimore; where every description of Book and Job Printing is executed with neatness and dispatch—and is from a distance for PRINTING or BINDING, with proper directions promptly attended to, addressed to J. Robinson, Baltimore.

AGRICULTURE.

INTERESTING EXTRACTS.—From *Agricultural and other Addresses and Memoirs, on file in the office of the American Farmer.*

AN ADDRESS TO THE PUBLIC FROM THE TRUSTEES OF THE GARDINER LYCEUM.

It will doubtless be remembered by the citizens of this state, that at the last session of the Legislature, an institution was incorporated by the name of the *Gardiner Lyceum*, the object of which was stated to be, "to give to mechanics and farmers such a scientific education, as would enable them to become skillful in their professions." The trustees, having began an edifice of stone for the use of the Lyceum, and having made arrangements for the commencement of instruction the ensuing winter: think proper to give to the public, a more detailed account of the origin of the institution, and of the plan, upon which they mean to proceed.

The small number of mechanics acquainted with those principles of natural philosophy, upon which the successful operation of their arts depend, has been long a subject of regret. Artists, it is true, are found in various departments, who by means of uncommon natural talents are able to acquire the knowledge of those scientific principles which are most needful to them; but those to whom nature has been less liberal, can only execute in the way in which they have been taught; and while they adopt the rules and recipes of their predecessors, are obliged to perform much unnecessary labor, because they are unable to distinguish the essential from the accidental parts of their processes. And even those of superior endowments are obliged to spend much labor in acquiring principles, which are among the first rudiments of a regular education. Nor have our farmers hitherto had that knowledge, which would enable them to improve the powers of their soil, or the machines necessary for cultivating it, and preparing their produce for market. The knowledge necessary for these descriptions of persons is confined to colleges; but science is there taught, not to persons, who are to make a practical use of it in after life, but as a part of a course of general education to those, who are destined for the liberal professions. The details of the practical application of science to the particular arts would be altogether inconsistent with the objects of these institutions. Neither could those, who are to support themselves by manual labor, spare the time, or meet the expense of a collegiate course, with its long train of preparatory studies, particularly when a large part of that course would not only be useless, but would serve to give them a distaste for their future pursuits in life.

To supply this deficiency was the object of the projectors of the Lyceum; and although there was no existing institution to which they could refer as a prototype; yet they felt a confidence, that their views were so practical, and so obviously useful, and so easily carried into effect, that they must meet with the approbation of the public. Nor have they hitherto been disappointed. Having obtained what aid they could from the neighborhood, where the institution was to be located; they stated their views to the legislature, and the great benefits which they expected to be derived from the establishment of the Lyceum; but at the same time the inadequacy of their own means to carry it into effect, without pecuniary aid from the State. An act of incorporation was readily granted; and the trustees after mature deliberation determined to do every thing upon their part to carry the institution into effect, with

confidence, that the legislature having approved their object and encouraged them to proceed, would not suffer their exertions to be lost, or the public to be deprived of the benefits of so important an institution for want of its fostering aid. Their plan has likewise received the approbation of many gentlemen of intelligence, some of whom have been engaged in the higher departments of instruction themselves, and others of whom have visited the most celebrated places for education in different parts of Europe. They have all thought the institution much wanted, and that if properly conducted, it could not fail of being highly useful, and of being the means of similar institutions arising in other parts of the country.

The practical utility of science cannot be doubted, in an age where its investigations have produced such astonishing improvements as in the present. There is scarcely an art, which has not directly or indirectly received from it important services, for science must necessarily be the foundation of every art. Not that the arts originate in the speculations of the philosopher, or cannot be practised without an acquaintance with science. On the contrary they frequently owe their beginnings to accident; and the knowledge of the art is but the knowledge of a few insulated facts. These facts, observed by the man of science, lead him to an investigation of their nature, and the laws according to which they are produced. He discovers what is necessary and what is accidental in the process, and thus infers an easier and cheaper mode of arriving at the same result. Chemistry, as a science, has scarcely existed half a century, and yet no science can so proudly boast its contributions to the arts. To many trades it is absolutely necessary; and to almost all, highly beneficial. The tanner, the bleacher, the dyer, the druggist, the manufacturer of pot and pearl ashes, of soap, of coppers, and all the salts of commerce, of spirituous and fermented liquors; all these and very many more find their arts dependant upon chemical processes. The mason needs chemistry to mix properly the ingredients of his mortar, the blacksmith to temper his edged tools, and even the baker to ferment his bread. It is true, these arts may be, and are successfully practised by attentive and intelligent persons, ignorant of science; but a knowledge of chemistry would enable men of an inferior class of mind to become skillful, would make the success of all more certain, enable them to investigate the causes of occasional failures, and to guard against their recurrence.

Agriculture, too, depends much upon chemistry. It is the business of this science to investigate the nature of soils, the causes of their fertility or barrenness, to ascertain the composition of manure, and the kind best suited to give fruitfulness to each kind of soil. The experience of Lavoisier, who in a few years, doubled his crops, is sufficient to prove the utility of chemistry, when applied to the cultivation of the earth.

But chemistry is not alone in its practical utility. All the sciences which come under the name of natural philosophy are useful. A knowledge of mechanics, which teaches the laws of motion, the general principles, upon which all machinery is constructed and operates, and the nature and laws of the various moving forces, is almost indispensably necessary to the practical mechanic, who is charged with the care of the construction of machinery. In the construction it will enable him to accomplish his business with more ease and certainty. The formation of the teeth of wheels and pinions, e. g. so that machines shall neither be retarded by unnecessary friction, nor rendered irregular in their motions, which is

difficult to an uneducated mechanic, is made perfectly simple and easy by science. The value of science is particularly felt by the mechanic, when any thing is to be accomplished out of the common course of his business. Instead of wasting his labors in guessing and trying ill-conceived experiments, the scientific mechanic knows at once, where to direct his efforts; and can predict with some degree of certainty, the result, before the experiment is made.

All machines are capable of modification and improvement; and it is not so much by the invention of new machines as by the modification of old ones, that ingenious mechanics have rendered so much service to the public. This is particularly the case in a new country. The expensive machinery of Europe, however useful among a dense population, could not be rendered profitable in a country with so thin and scattered a population and so little capital as our own; and where therefore machinery must be cheap, and easy in its construction before it can be of general utility. But a mechanic must be extensively acquainted with machinery, and the principles upon which it is constructed, before he is able by slight alterations to apply machines to new purposes; or so to simplify their construction as to bring into general use those, that were otherwise too expensive.

With a view to furnish to farmers and mechanics the education here represented as so useful, the Gardiner Lyceum has been established; and the course of study will be arranged with a particular reference to the wants of those classes, for whose particular benefit it is designed. As soon as a suitable apparatus can be procured, lectures will be given upon the sciences there taught; and the application of those sciences to the arts will be illustrated as fully, as the nature of lectures will admit. As fast as the funds of the institution will allow, models will be procured of the best machines employed in the useful arts. Specimens will likewise be collected of the natural productions of the country, as opportunity offers; and they will be deposited in a cabinet in the Lyceum.

Candidates for admission to the Lyceum will be required to produce certificates of good moral character, and will be examined in the four fundamental operations of Arithmetic; Addition, Subtraction, Multiplication, and Division, both upon simple and compound numbers, and in Reduction. It is also very desirable, that English Grammar should be understood by those entering the Lyceum; and although the trustees do not at present consider it as an indispensable requisite, yet they hope it will have been studied by persons, applying for admission. The studies at the Lyceum will be—

For the first year. Arithmetic, Algebra Geometry, the Trigonometry, Mensuration of Surfaces and Solids, and Book Keeping.

In the second year. Surveying, Navigation, Mechanics, Hydrostatics, Pneumatics and Chemistry.

No student will be required to attend to all the branches of instruction for the second year; but only those, which are best adapted to his future wants. He will likewise be instructed in the practical application of the knowledge thus acquired to the particular art, which he is to practice.

Two years will complete what is deemed an essential course; but instruction will be afforded to those who wish to continue their studies another year.

The studies for the third year will be—Other branches of Natural Philosophy, the higher branches of Mathematics, Natural History, and the first volume of Stewart's Philosophy of the Mind.

There will be regular exercises in English composition; and each Monday morning all the classes will be instructed in the principles of natural and revealed religion. There will be three terms, and three vacations in each year. One vacation will be of five weeks from the first Wednesday in July, one of two weeks from the third Wednesday in December, and one of the two weeks from the first Wednesday in April. The price of tuition will be eight dollars a term. Four students of good talents, but needy, will be admitted without charge. Boarding and lodging can be obtained near the Lyceum at one dollar and a half per week.

The trustees consider the location of the Lyceum in the town of Gardiner as peculiarly fortunate, from its central position, on a navigable river, in a populous neighbourhood and fertile country, where commerce is continually extending; and in a town possessing uncommonly fine mill privileges, and which already offers to the student in mechanics the exhibition of a greater variety of machinery moved by water, than can be found in any other town in the State. In the first organization of an institution, so novel in its nature, it seemed necessary, that the trustees should be selected from its immediate neighborhood, for the convenience of frequent meetings; but this necessity will no longer exist when the institution is fairly in operation; and for the purpose of obtaining the views of different classes of citizens, respecting the management of an institution of such general utility, the trustees have determined to petition the legislature at their next session, to enlarge the board of trustees, and to form a board of visitors, composed of gentlemen of respectability, but residing principally at a distance; before whom the proceedings of the trustees may be brought at stated periods, and confirmed, modified or annulled as they may deem proper.

The trustees inform the public that the institution will go into operation early in January, under the auspices of the Rev. Benjamin Hale, recently a tutor in Bowdoin College, whom they have chosen Principal of the Lyceum, and Lecturer in Natural Philosophy; and that from his zeal, capacity and acquirements they feel assured, that the experiment (for such it must be yet considered) will be fairly tried.

The trustees conclude their address with expressing their confidence, that as they are engaged in an object calculated to meet the wants of a state, which possesses all the requisites for becoming great, and distinguished in agriculture, manufactures and commerce, that they shall not want the support and encouragement of the public. They are engaged in no private enterprise. They expect to profit no particular class of men; but to aid those, who form the bone and sinew, and muscle of the body politic. They aim at the public good, and they hope for the public patronage.

R. H. GARDINER, PER ORDER.

From the Memoirs of the Board of Agriculture of the State of New York.

OBSERVATIONS ON FATTENING CATTLE.

[By a Gentleman of Columbia.]

This subject offers to our consideration these points:—Can it be made a distinct branch of agriculture, with advantage to the farmer?—And what is the best and most profitable mode of attaining this object?

It is every where observed, that this business, on a small scale or the feeding of a few cattle,

is more for convenience than gain. Every farmer wants, and, it is presumed, provides his family with a sufficiency of this necessary article, the cost or trouble of which he seldom or never counts; and most farmers have some cattle to dispose of in the course of the year—young stock that are supernumerary, some cows to turn off, and a yoke or two of old oxen. These must be disposed of at any rate.

Now we all know, that selling lean cattle, either in spring or fall, is a poor business at best, even when they can be sold at all; and the only way to obtain any thing like a fair price, is to get them ready for the butcher as early as possible. If they are in good pasture from the middle of May to the middle of August, they will sell, as there is generally a demand by those who retail them in the country villages and towns; poor enough to be sure is the meat, but it goes by the name of beef. To keep on hand this kind of stock for three months longer, that is, to the middle of November, when the markets are so fully supplied, they will seldom pay for their keeping. As an article of agricultural profit, it will never do; as a matter of convenience and necessity, we must make use of it. If then, in a domestic way, this turns to so little profit, let us next examine whether, on a large scale, it can be made better. In the spring, lean cattle, as steers and oxen, may generally be purchased low, and in six months, being kept in good pasture all that time, they will be fat, or at least in good order. Now what have they cost? An ox, on the 15th of May, of moderate size, will cost, on an average, \$25; keeping till the 15th of November, will not be less than \$1 per month, that is, \$6; expense of sending to market, 100 miles distant, \$2 50; interest on the purchase money, including risk, at 10 per cent, is \$2 50—then your ox has cost \$36. He will not sell at that season for more than \$40—a poor profit indeed of \$4. This article will then seldom answer, unless where land is at a low price, and very distant from market. I have known several trials made, and by attentive experienced farmers, who have, after a year or two, given it up.

Let us next examine whether winter stall feeding will do better. If cattle are in very good order, or half fat, the 1st of December, they may be made fit for market in three months, and feeding for that time will cost \$25. If they are in ordinary store order, it will require six months feeding, which will cost at least \$30. Now it is easy to calculate whether the price you will then obtain for them will pay the first cost, risk, interest, and expenses; if so, stall feeding will do, otherwise not. My own experience has taught me that it will not do—others will judge for themselves.

These observations apply particularly to farmers at a distance from the city markets; those who are near have the advantage of waiting, and watching the rise and fall; not so with those at a distance. The inference from the observations made, lead to the conclusion, that stall feeding is not so profitable as is generally thought; yet some able and intelligent farmers pursue the practice. How they manage, it would be very desirable to know. We, who have been unsuccessful, would be enabled to correct our errors, and others would obtain information which they may otherwise search for in vain. When the farmer or grazier undertakes to make the fattening of cattle his business, the first prerequisite is, that he be a judge, and a good one too, of the worth of cattle in all their different stages, of which he judges by the eye and hand; next he must have at command a capital in cash, to enable him to buy with most advantage; and then he must have provid-

ed feed in sufficient quantity for whatever mode of feeding he undertakes. Fattening on grass, or in the stall, are the two modes of managing this business: on grass, the best way is to buy young cattle, particularly three or four year old steers, in the month of November; to keep them in the yard all winter, fed partly with straw and partly with hay, but so as to have them in good order in the spring; and these cattle should not be of the largest sizes, rather middling, such as will come to about six hundred weight the four quarters, when fattened. Such may generally be bought for \$20 or \$25. They must have good pasture for four months, for if that fails, the profit is gone. But as we cannot controul the seasons, in case a severe drought takes place, the only remedy is a little grain, or rather meal, given daily. Provided they are thus fed, they will be ready for sale by the middle of September, and generally at this time, cattle of the above size are in good demand; if kept later, the markets are glutted, and the price always lower.

The middle of September, such cattle, weighing 600 pounds the quarters, will not sell for more than \$36, or \$6 per hundred. They have cost, first \$20, next winter keeping, hay \$2 50, straw, \$2 50, four and a half months grass, \$4 50, interest for ten months on \$20, at 7 per cent, \$1 16,—then the profit is about \$5,—besides the risk. This is no great encouragement, yet I can make no more of it, and have often made less.

In pursuing this subject, we now enquire, what is the most economical and profitable way of winter feeding? We must first know what an ox requires to fatten him, suppose he will give 800 pounds of beef. It has been already said that he may be made fat in three months, or one hundred days, if in good store order when put up. Let this time be allowed. He will eat, every twenty-four hours, 14 pounds of hay, cost 6 cents; half a bushel of potatoes, 12½ cents, and 8 quarts Indian meal, 12½ cent; being 31 cents a day, or \$31 for the hundred days. This I have verified by many trials; and the interest \$1 75, together making \$32 75, which, added to the first cost, \$25, then the ox has cost \$57 75. If the beef is sold at \$8 per cwt. in March, it leaves only \$5 25, profit. There are several other articles of food on which cattle may be fatted; but the above is the most economical that I know. Oil cake is the quickest to fatten with, and where it can be had, it is advisable to use it instead of Indian meal; the price is about 56 cents per bushel, ground, and the quantity from 4 to 8 quarts per day.

To fatten an ox on turnips will require two bushels a day, with 10 lbs. of hay. Carrots answer well, but are more expensive still—cabbage the same. From all these we exempt premium cattle, and those made up for shew. Sure I am that the fee never gets paid, unless he is gratified with seeing his oxen dressed up with ribbons, and his name in the papers. It was told me as a fact, that one gentleman from Orange county, who had just sold in New York ten very fine cattle, being asked how much profit he had made by these as they had been fed eighteen months, answered he had just made a loss of \$30 a head, although they were sold at a high price. Where then go all the profits, for beef is still at a good price when cut up? The answer is, to the butcher, who realizes from 25 to 30 per cent. on good cattle. No wonder then that they make such ample fortunes, and that they wallow in wealth, while the poor industrious farmer plods along with very small gains indeed. I have only to add, that these observations are the result of experience, and not of idle speculation.

ON THE APPLICATION OF STABLE MANURES.

[By J. BURT, of Albany.]

The experiments of Arthur Young, and of other practical and scientific farmers, have demonstrated, that animal and vegetable manures, which undergo a complete process of fermentation in the cattle yard, or upon the surface of the ground, lose from 30 to 60 per cent. of their fertilizing properties; and if properly spread, and buried under the soil, that this loss is prevented—and that a decomposition does immediately take place, even of dry straw, sufficient to answer valuable purposes to the first crop. Mr. Young, whose correctness and practical knowledge will not be questioned by any one who knows his biography or his usefulness, measured five equal pieces of ground: upon the first piece he put nothing; on the second he buried dry straw, chopped fine; on the third, straw steeped three hours in fresh urine; on the fourth, straw steeped fifteen hours; and on the fifth, straw steeped three days in like manner. The whole was sowed with barley. The produce of each piece, in grain, and in weight of grain and straw, was as follows:—

No.	Grain	Wt. of grain and straw
1,	9	48
2,	39	100
3,	50	120
4,	63	130
5,	126	300

This experiment demonstrates two important facts. 1st. that even dry straw, buried under the soil, decomposes, and greatly improves the first crop. 2d. that the urine of animals, which is ordinarily lost to our farmers, is the most fertilizing product of the stable and yard. We have a strong corroboration of the latter, in the history of Flemish husbandry. Radcliff, in his report of the agriculture of Flanders, speaks of urine as constituting the most valuable part of the manure used in those highly cultivated provinces. He cites an instance, where the urine of 44 cattle, by the adventitious aid of rape-cake, and the *vidanges* from the privies, manured in the best manner 21 English acres per annum. The urine is collected in large cisterns under ground, into which drains lead from the stables, where the cattle are kept winter and summer. Although I do not expect to see this practice of the Flemings imitated by our farmers, yet I hope the narrative of the preceding fact will not be lost upon them. It shows the importance of constructing concave yards for our cattle, which will retain the urine and moisture, until it is absorbed by the straw, husks, stalks, and other vegetable litter of the yard.

It has become a pretty well settled principle among good farmers, that we should never delay applying manures, because it is unfermented or unrotted; but, on the contrary, that they are the most profitably applied before fermentation commences, or while it is an incipient state. The main object of this essay remains to be considered. To what crops shall we apply them?

The experience of almost every farmer will testify, that, except on very poor soils, they ought not to be applied, in any considerable quantity, to wheat, rye, barley, or any of the small grains. They often cause, in these, a too luxuriant growth, and a greater product of straw than of grain. The straw is tender, subject to the rust and the mildew, and the grain is liable to blast—besides, the crop is apt to lodge and spoil, in consequence. Another serious injury is the propagation of weeds and grasses, the seeds of which are carried out in the manure, and which cannot be extirpated in the growing crop. To apply manures upon the surface of grass lands, unless of a mineral kind, or in the form of

a liquid, or impalpable powder, is throwing away one half of their value. And peas and flax do not do well under their first operation. Arthur Young's rule, and it is a good one, is, always to apply your manure to hoeing crops.

These are Indian corn, potatoes, beans, and the whole family of vegetables. These can bear, and they want, all the gasses which are evolved in the first process of fermentation. The gasses open the texture of the soil, and render it pervious to heat, air, and light, and impart food to the young plants; and the hoeing process exterminates all useless plants and renders the ground clean and loose. When applied to the maize crop, the manure should be spread before the last ploughing. The roots of this grain are numerous, extend to a great length, and elongate most where there is nutriment and tilth to invite. Placed in the hill, the manure gives a temporary impulse to the growth of the plant, and fails in its benefits when most wanted to the maturing seed. It answers also best, when spread, for the succeeding crop, which is always some small grain. These reasons all hold good in regard to spreading manure for the bean crop, whether that is cultivated in hills, drills, or the broadcast method. For potatoes, whose roots do not extend far, the manure is most serviceable, when applied to the hills, or drills. For ruta бага, mangel wurtzel, cabbage or turnips, its benefits are multiplied when it is placed under the ridges upon which these crops are planted. It renders the recumbent soil light and friable, attracts moisture, and yields an abundance of food where it is alone wanted for the growing crop.

Either of these crops, if manured, leave the ground in good tilth, and free from weeds, and may be followed with advantage by wheat, rye, barley or oats, according to the quality of the soil. The manure, applied in the spring, gives most of the benefits to the small grain crop which it would have done, had it been left to ferment in the yard; and then applied to that in the first instance.

ON THE PRESERVATION OF CABBAGE.

[By BELA FOSGATE, of Cayuga.]

If the raising of vegetables is an object to the farmer, their preservation will be found no less so. I am convinced, from a partial experiment, that the following mode of keeping cabbage will be found useful. After they are gathered, and freed from their loose leaves and stalks, that nothing remains but the sound part of the head, head them up in a tight cask. By thus excluding them from the air, they may be kept for a long time. Those intended for the longest keeping should be put into small casks, as they will soon spoil when exposed to the air.

MAN-TRAINING—DESCRIBED.

As most of our readers have seen accounts of the extraordinary performances of Pugilists and Pedestrians in England, they may be entertained with a description of the previous *training*, which is practised, to qualify a man to fight for an hour with unabating courage, and exertion, or to walk one hundred miles in twenty-four hours—we have therefore extracted from "SPORTING ANECDOTES," an account of the process recommended and pursued by the famous CAPT. BARCLAY, one of the most extraordinary of modern actors in this line of performance. One would suppose that whatever mode of living would augment the elasticity and power of the mind and body, would, of course, ensure to both, the soundest state of health—we accordingly recommend the trial of the training process to all our gouty, rheumatic, bilious, dyspeptic and hypo-

condraic friends. It must be acknowledged that the sweating part of the business is rather severe. To run four miles, at the top of one's speed, take the hot drink, put on flannels, and then lie down in the month of August under eight blankets and a feather bed!! one might as well be doomed to walk on un-boiled peas—yet it seems this is done to diminish the volume and increase the activity of the human frame.

Edit. Am. Farmer.

The most effectual process for training, is that practised by Captain Barclay; and the particular mode which he has adopted has not only been sanctioned by professional men, but has met with the unqualified approbation of amateurs. The following statement, therefore, contains the most approved rules; and it is presented to the reader, as the result of much experience, founded on the theoretic principles of the art.

The pedestrian, who may be supposed in tolerable condition, enters upon his training with a regular course of physic, which consists of three doses. Glauber's salts are generally preferred; and from one ounce and a half to two ounces are taken each time, with an interval of four days between each dose.* After having gone through the course of physic, he commences regular exercise, which is gradually increased as he proceeds in the training. When the object in view is the accomplishment of a pedestrian match, his regular exercise may be from 24 miles a day.—He must rise at five in the morning, run half a mile at the top of his speed up hill, and then walk six miles at a moderate pace, coming in about seven to breakfast, which should consist of beef-stakes or mutton-chops under-done, with stale bread and old beer. After breakfast, he must again walk six miles at a moderate pace; and at twelve lie down in bed without his clothes for half an hour. On getting up, he must walk four miles, and return by four to dinner, which should also be beef-stakes or mutton-chops, with bread and beer as at breakfast. Immediately after dinner, he must resume his exercise by running half a mile at the top of his speed, and walking six miles at a moderate pace. He takes no more exercise for that day, but retires to bed about eight, and next morning proceeds in the same manner. After having gone on in this regular course for three or four weeks, the pedestrian must take a four mile sweat, which is produced by running four miles in flannel, at the top of his speed. Immediately on returning, a hot liquor is prescribed, in order to promote the perspiration, of which he must drink one English pint.—It is termed sweating liquor, an is composed of the following ingredients: viz. one ounce of caraway seed, half an ounce of coriander seed, one ounce of root liquorice, and half an ounce of sugar candy, mixed with two bottles of cyder, and boiled down to one half. He is then put to bed in his flannels, and being covered with six or eight pair of blankets, and a feather bed, must remain in this state from twenty five to thirty minutes; when he is to be taken out and rubbed perfectly dry. Being then well wrapped up in a great coat he walks out gently for two miles to breakfast, which on such occasions, should con-

* It is not so generally known as it ought to be, that a salt, introduced into medical practice by Dr. George Pearson, of London, is an excellent a purge as Glauber's salt, and has none of the nauseous taste which renders that purge so disagreeable to many persons. The phosphate of soda, is very similar to common salt in taste, and may be given in a basin of gruel or broth, in which it will be scarcely perceptible to the palate, and will also agree with the most delicate stomach.

sist of a roasted fowl. He afterwards proceeds with his usual exercise. These sweats are continued weekly, till within a few days of the performance of the match, or, in other words he must undergo three or four of these operations. If the stomach of the pedestrian be foul, an emetic or two must be given, about a week before the conclusion of the training, and he is now supposed to be in the highest condition. Besides his usual or regular exercise, a person under training ought to employ himself in the intervals in every kind of exertion which tends to activity, such as cricket, bowls, throwing quits, &c. that during the whole day, both body and mind may be constantly occupied.

The diet or regimen is the next point of consideration, and it is very simple. As the intention of the trainer is to preserve the strength of the pedestrian, he must take care to keep him in good condition by nourishing food. Animal diet is alone prescribed, and beef, and mutton are preferred. The lean of fat beef, cooked in stakes, with very little salt is the best, and it should be rather under-done than otherwise.—Mutton being reckoned easy of digestion, may be occasionally given, to vary the diet and gratify the taste. The legs of fowls are highly esteemed. It is preferable to have the meat broiled, as much of its nutritive quality is lost by roasting or boiling.* Biscuit and stale bread are the only preparation of vegetable matter which are permitted to be given; and every thing inducing flatulency must be carefully avoided. Veal and lamb are never allowed, nor pork, which operates as a laxative on some people; and all fat or greasy substances are prohibited, as they induce bile, and consequently injure the stomach. But it has been proved by experience that the lean meat contains more nourishment than the fat, and in every case the most substantial food is preferable to any other kind.

Vegetables, such as turnips, carrots, or potatoes, are never given, as they are watery and of difficult digestion. On the same principle fish must be avoided, and, besides, they are not sufficiently nutritious. Neither butter nor cheese is allowed; the one being very indigestible, and the other apt to turn rancid on the stomach.—Eggs are also forbidden, excepting the yolk, taken raw in the morning. And it must be remarked, that salt, spices, and all kinds of seasonings, with the exception of vinegar, are prohibited.

With respect to liquors, they must always be taken cold; and home brewed beer, old, but not bottled, is the best. A little red wine, however, may be given to those who are fond of malt liquor, but never more than half a pint after dinner. Too much liquor swells the abdomen, and of course injures the breath. The quantity of beer, therefore, should not exceed three pints during the whole day, and it must be taken with breakfast and dinner, no supper being allowed. Water is never given alone, and ardent spirits are strictly prohibited, however diluted. It is an established rule to avoid liquids as much as possible, and no more liquor of any kind is allowed to be taken than what is merely requisite to quench the thirst. Milk is never allowed, as it curdles on the stomach. Soups are not used; nor is any thing liquid taken warm

* "It may serve as a preliminary rule, that fresh meat is the most wholesome and nourishing. To preserve these qualities, however, it ought to be dressed so as to remain tender and juicy; for it is by this means it will be easily digested, and afford most nourishment."—Willich on Diet and Regimen, p. 313.

* "Broths and soups require little digestion,

but gruel or broth, to promote the operation of the physic; and the sweating liquor mentioned above. The broth must be cooled, in order to take off the fat, when it may be again warmed; or beef-tea may be used in the same manner, with little or no salt. In the days between the purges, the pedestrian must be fed as usual, strictly adhering to the nourishing diet, by which he is invigorated.

Profuse sweating is resorted to as an expedient for removing the superfluities of flesh and fat.—Three or four sweats are generally requisite, and they may be considered the severest part of the process.

Emetics are only prescribed if the stomach be disordered, which may sometimes happen, when due care is not taken to proportion the quantity of food to the digestive powers; but, in general, the quantity of aliment is not limited by the trainer, but left entirely to the discretion of the pedestrian, whose appetite would regulate him in this respect. Although the chief parts of the training system depend upon sweating, exercise and feeding, yet the object to be obtained by the pedestrian would be defeated, if they were not adjusted each to the other, and to his constitution. The skilful trainer will, therefore, constantly study the progress of his art, by observing the effects of the process separately, and in combination.

If a man retain his health and spirits during the process, improve in wind, and increase in strength, it is certain that the object intended will be obtained. But, if otherwise, it is to be apprehended that some defect exists, through the unskilfulness or mismanagement of the trainer, which ought instantly to be remedied by such alterations as the circumstances of the case may demand. It is evident, therefore, that, in many instances, the trainer must be guided by his judgment, and that no fixed rules of management can, with absolute certainty, be depended upon for producing an invariable and determinate result.

It is farther necessary to remark, that the trainer, before he proceeds to apply his theory, should make himself acquainted with the constitution and habits of his patient, that he may be able to judge how far he can, with safety, carry the different parts of the process. The nature of his disposition should also be known, that every cause of irritation may be avoided; for, as it requires great patience and perseverance to undergo training, every expedient to soothe and encourage the mind should be adopted.

It is impossible to fix a precise period for the completion of the training process, as it depends upon the condition of the pedestrian; but from two to three months, in most cases, will be sufficient, especially if he be in tolerable condition at the commencement, and possessed of sufficient perseverance and courage to submit cheerfully to the privations and hardships to which he must unavoidably be subjected.

Training is indispensably necessary to those who are to engage in corporeal exertions beyond their ordinary powers. Pedestrians, therefore who are matched either against others or against time, and pugilists who engage to fight, must undergo the training process before they contend, as the issue of the contest, if their powers be nearly equal, will, in a great measure, depend upon their relative condition. But the advantages of the training system are not confined to pedestrians and pugilists alone, they extend to eve-

weaken the stomach, and are attended by all the pernicious effects of other warm and relaxing drink.—Willich on Diet, &c. p. 304.

ry man; and were training generally introduced, instead of medicines, as an expedient for the prevention and cure of diseases, its beneficial consequences would promote his happiness and prolong his life.

It is well known to physiologists, that both the solids and fluids which compose the human frame are successively absorbed and deposited; hence, a perpetual renovation of the part ensues, regulated, as they are, by the nature of our food and general habits.* It, therefore, follows, that our health, vigour, and activity must depend upon regimen and exercise; or, in other words, upon the observance of those rules which constitute the theory of the training process. The effect has accordingly corresponded with the cause in all instances where training has been adopted; and although not commonly resorted to as the means of restoring invalids to health, yet there is every reason to believe that it would prove effectual in curing many obstinate diseases, such as the gout, rheumatism, bilious complaints, &c.

"Training (says Mr. Jackson) always appears to improve the state of the lungs; one of the most striking effects is to improve the wind, that is, it enables a man to draw a larger inspiration, and to hold his breath longer." He farther observes, "By training, the mental faculties are also improved." The attention is more ready, and the perception more acute, probably owing to the clearness of the stomach and better digestion.†

It has been made a question whether training produces a lasting or only temporary effect on the constitution. It is undeniable, that if a man be brought to a better condition, if corpulency and the impurities of his body disappear, and if his wind and strength be improved by any process whatever, his good state of health will continue, until some derangement of his frame shall take place from accidental or natural causes.—If he shall relapse into intemperance, or neglect the means of preserving his health, either by omitting to take the necessary exercise, or by indulging in debilitating propensities, he must expect such encroachments to be made on his constitution as must soon unhinge his system.—But if he shall observe a different plan, the beneficial effects of the training process will remain until the gradual decay of his natural functions shall, in mature old age, intimate the approach of his dissolution.

TO THE EDITOR OF THE AMERICAN FARMER.

THE CULTIVATION OF RICE AND THE RECLAMATION OF MARSH LANDS IN MARYLAND.

Cambridge, (Md.) September 23, 1823.

DEAR SIR,

I received your favor, enclosing some rice from Gov. Clinton, and have committed it to the care and culture of the gentlemen from the Carolinas, who have been reclaiming marshes on the Nanticoke, chiefly, though not wholly, with a view to the culture of that article; and in return I send you a specimen of the kind which they have grown, and are now growing, on those reclaimed grounds, though yet on a very small scale, and designed for experiment alone: this seed they brought from South Carolina; it is, in appearance, far superior to Gov. Clinton's, and twice the size, but may not be as well adapted to the climate of Maryland, as that which may have been acclimated, by its Northern

grown; of which, from the strong evidence, exhibited by those gentlemen of intelligence and enterprise, we shall be faithfully informed, in the course of another season.

You desire to know the particulars of this undertaking, to reclaim marsh, and grow rice in Dorchester, and the probability of success:—On this subject I have often conversed with the gentlemen, and have recently received a communication from one of them; they are quite sanguine in the success of their undertaking; but having made but little progress, their impressions are derived, chiefly from a comparison of the grounds, they are attempting, with those on which similar attempts have been, under their own management, crowned with success: this remark, necessarily, has only a geological reference; in this respect, they inform me, they have a decided advantage over the Carolinas; their Dorchester soil is a black rich loam several feet in depth; in fact, it is a congeries of the carbonaceous remains of animal and vegetable decomposition, mixed with the products of the more recent stages of the process, and a good proportion of sand and clay, to place it in the first order of soils, when dried.

As to the drying and draining of this soil, no doubt can remain; the tides ebb and flow from three and a half to four feet, (ordinary tides), and as they can drain to low water mark, they can, necessarily, keep the lands dry, at least two and a half feet deep; and, consequently, can grow any article which the climate will admit of: indeed they say, "they are most advantageously situated, as to water, and all other requisites to make them safe and sure, and not as liable to the influence of equinoctial gales, and sudden inundations from the overflowing of the tides, as those of the Carolinas."

In regard to the only remaining question of climate in the state of Maryland, to grow rice; very little, if any, doubt can remain; both reason and facts concur to settle the point; we have more than five months of a fine vegetative season, and a majority of the time warm; and to grow rice, requires only five months, "fully to mature the grain." Moreover, we have instances of successful experiment; I am informed by Robert Dennis, Esq. of Vienna, a gentleman of the most unquestionable veracity, that his father owned an African, who used to raise as much rice, annually, as served the family, in Worcester county; an old negro in my family who formerly belonged to John Leeds, Esq. a most respectable and intelligent farmer of Talbot, says that her master frequently raised rice: the Domestic Encyclopedia records "that Mr. Bordley raised rice, many years since, near Annapolis; and also in Talbot county." Finally, the gentlemen from Carolina, have, though on a small scale, tested the fact, "perfectly to their satisfaction," and express themselves as "certain of success."

But even admitting the failure of rice, to grow with sufficient certainty and abundance, to authorize its culture; what an infinite boon of providence have we, for ag. s spurned and neglected, in those rich fountains of wealth; the whole range of vegetable nature, for luxury and profit, which our climate will afford, may be most brilliantly substituted on these marshes, for worthless reeds and bushes; so fully convinced have I been of this, that I have reclaimed sixty acres of a deep morass on the Transquakin, which has now become sufficiently dry and firm to be ploughed, and will yield me, no doubt, in corn, wheat and grass, a handsome return for the trouble and expense incurred, to reclaim it.

In addition to the small quantity of rice, which the gentlemen from Carolina are growing, for

further experiment, and which they inform me is very flourishing, they have raised on their reclaimed grounds, the present year, a small crop of oats, which yielded largely; and they have "a small crop of cotton growing prettily, and bearing well," also "some corn which looks well," and "pumpkins which are fine."

In respect to the price of those lands, and cost of reclaiming, the gentlemen cannot, yet, render an accurate account; the maximum price paid by the acre, was fifty cents; some were bought in large unknown quantities, for much less; and the State granted them permission to take up, free of composition money, three thousand acres, which cost them, only the expenses of location.

The cost of reclaiming, may be estimated (they say) by the following data: sct. six hundred cubic feet of earth can be thrown out, by one laborer, with ease, in one day; and if the margin of the bank be no more than ten feet from the ditch, he will at once, make the bank; out, if the bank be made further from the ditch, the laborer is under the necessity of removing the mud, which will consume as much more time, as the first operation, and consequently cost double the price: their ditches on the river side of the marsh are fifteen feet from the river; and their banks ten feet from the ditch: these river-banks are eight feet base, and six feet high: those on the high-land side of the marsh and the interior banks, which subdivide their grounds into twenty acre lots, are smaller.

With a confidence that you will excuse a hasty and imperfect compliance with your request,

I am,

Your's respectfully,
JOSEPH E. MUSE.

EXTRACTS FROM LATE NUMBERS OF THE London Farmer's Journal.

HEREFORDS AND SHORT-HORNS.

Park Farm, Woburn, June 11, 1823.

SIR,

Although not in the practice of writing for public inspection, perhaps you will give the following a place in your Journal.

I have for some time past seen in your paper much said respecting the superior qualities of both the Short Horn or Durham, and Hereford breeds of cattle, without any thing conclusive to prove the great advantages arising from the one, more than the other, either to the breeder or grazier; and it does not appear that any fair comparative trial has been made, although several challenges have been given by individuals who happened to have something at the time out of the common way: so much, however, depends upon the treatment each animal has had previously, the state of flesh when put to feed, the difference of quality of grazing land, and likewise the food given when stall fed, that unless the animals are put together at an early age, and kept together under proper restrictions, as was done by his Grace the Duke of Bedford and Lord Althorp, it will be impossible to gain any real information upon the subject by challenging one another about producing the fattest cow, &c.

His Grace the Duke of Bedford and Lord Althorp entered into an agreement, and put together on the first day of November 1820, the former a Hereford, the latter a Short horn of the Durham breed, both steers, calved in the month of January 1820, and fed together until the great market at Smithfield, 1822, where they were shown alive, and afterwards slaughtered; when the judges, after taking all the merits, &c. of each into consideration, with the quantity of food

consumed, gave it as their opinion, that it was an undecided bet. While the above two steers were upon trial, his Grace the Duke of Bedford, and the Right Hon. Charles Arbuthnot, were of opinion that one animal of each breed could not be a satisfactory trial, and being anxious to prove the advantage the one breed has over the other, if any, they entered into an agreement of the same kind upon a larger scale, which is now going on; a copy of it I have, by permission of the parties, given you annexed, to lay before the public, and I hope it may prove an inducement to some of our most meritorious breeders to follow the example of such characters as the above, whose principal object in making the experiment is to obtain such information as will in all probability be of great service both to the breeders and graziers in general, and may eventually be the means of doing away with the prejudice that seems at present to exist on both sides.

I am, Sir,

Your obdt servant,
THOMAS TODD.

COPY.

Terms of agreement for a trial between his Grace the Duke of Bedford, and the Right Hon. Charles Arbuthnot.

The Duke of Bedford on one part to produce four ox-calves of the Hereford breed on the 1st of November, 1822, all of which shall have been calved subsequently to the 15th November, 1821.*

Mr. Arbuthnot on his part, to produce four of the Short-horned or Durham breed, with the like restrictions.

Two of each breed to be kept upon the Duke of Bedford's farm, and two of each ditto upon Mr. Arbuthnot's farm.

All the calves to be from bulls which have been used by the parties, and from cows which, on the 15th Nov., 1821, were in their possession.—None of the calves to have milk after five months old. The parties, until the period of sending their respective steers to be put together, to be allowed to give them hay, or chaff, and roots, and green food of all descriptions; but to be restricted from giving them any sort of corn or flour, or artificial food under any denomination.

The steers of the two parties to be kept at the respective places upon food of similar quality, with the addition of cake, or meal, during the last year of feeding, if required by the parties, until the Christmas market day of December, 1824, and then to be shown together at Smithfield, in order to have it ascertained which of the breeds is the most profitable to the breeder and grazier.

Each of the parties to name a judge, and the third judge to be chosen by casting of lots between the parties, in order to guard as much as possible against partiality or favour; the drawing of lots for the choice of the third judge to take place for each of the four lots of steers.

Upon the requisition of any one of the judges, one or more of the beasts to be slaughtered, in order that the real value may be accurately ascertained; but this to take place only in the event of there being a difference of opinion as to the value among the judges.

A regular and detailed account to be kept of the quantity and quality of food consumed by each of the eight animals, during the time that they are stall-fed.

* Some variation as to the first period of calving took place subsequently to this agreement being drawn up.

The accounts thus kept to be delivered to the judges previously to their giving their decisions, and the judges to be directed to take into their consideration the extra quantity of grass which may be supposed to have been consumed during the months of pasture, by such of the animals as may have required more food than the others while they were stall-fed.

The day when each of the eight animals was ealed to be written on a label, and to be fixed to their horns respectively at the time that they shall be shown to the judges for their decision.

A copy of the terms of agreement to be given to the judges.

From Griscom's "Year in Europe."

BARCLAY'S BREWERY.

The director of this establishment, to whom I was introduced by a letter from one of the Barclays, put me in the way of seeing its various parts, and communicated such information as I wished respecting its extent and operations. If any private concern in England, or in the world, is entitled to the epithet of *vastness*, this is one. It covers about eight acres of ground, and manufactured last year 340,000 barrels of 36 gallons each. The building which contains the vats, and the vats themselves, are enormous. The largest of the latter contain each 4000 barrels. The average number of vats is nearly one hundred. A steam engine of twenty-two horse power is employed in driving the machinery, and about two hundred men are engaged in the various works of the establishment: while it is supposed that the number of persons, dependent upon it without, in the sale and transportation of the beer, is three or four thousand. The three coppers in which the beer is boiled, hold each 150 barrels.

Twenty-five gentlemen once dined in one of them, after which fifty of the workmen got in and regaled themselves. One hundred and ninety pounds of beef steaks, were thus consumed in one day, in this novel kind of dining room. The tuns in which the beer ferments, hold 1400 barrels each. The carbonic acid in one of them stood about three and a half feet above the liquor, and poured over the side in a continued stream. A candle is instantly extinguished on being placed near the outer edge of this receptacle, and on holding one's face near it, a sharp pungent sensation is felt in the mouth and fauces, not unlike that produced by ardent spirits. An immersion of a few moments would be sufficient to occasion a suspension of voluntary motion.

One hundred and sixty horses are kept on the premises, for the purpose chiefly of transporting the materials to and from different parts of the city. A finer collection of animals employed in one concern, I imagine, is no where to be seen.

This is, upon the whole, I believe, the largest brewery in London. It formerly belonged to Thrale, the friend of Dr. Johnson, who, as executor to the estate, sold the establishment to its present owners. One of the latter informed a friend of mine, that the Doctor, in treating with them for the purchase, remarked in his characteristic manner: "Gentlemen, it is not merely these boilers and these vats that I am selling you, but the potentiality of acquiring wealth, beyond the dreams of avarice."

TO THE EDITOR OF THE AMERICAN FARMER.

ON SHEEP.

Washington, (Pa.) Sept. 20, 1823.

SIR,

The pages of your valuable paper, are seldom more usefully occupied, than with the production

of the pen of Mr. Featherstonhaugh—they are well calculated both to entertain and instruct. Few gentlemen in our country, possess the practical and scientific agricultural knowledge that he does. And although I subscribe most heartily to most of his opinions, I cannot believe that his plan of raising a stock of sheep, is equal to the one generally practised in this part of Pennsylvania. We have now very numerous flocks of good sized, well formed sheep, by serving the large common ewes of our country, with full blooded Merino rams. It is somewhat singular, but it is a fact, that half or three quarter blooded Merinos yield heavier fleeces than either the pure Merinos, or the common coarse kind. I am certain that I am under the mark, when I state that my two-year old wethers at this moment, would average from eighteen to twenty pounds per quarter—their fleeces run from five to eight pounds.—I consider them a hardier sheep than the unmixed of either side—they certainly combine the two great objects which every sheep raiser ought to keep steadily in view; I mean heavy carcase and valuable fleece—I must here remark, that in this section of country, we have had weight and fineness of fleece solely in view. Had we attended to size, we might have attained that object in a much greater degree.

Mr. Featherstonhaugh's plan of large males and small females, is in direct opposition to the principle laid down by Cline, for breeding perfect formed animals—these principles, I believe incontrovertible. I have no doubt that Mr. F. has raised a very fine stock of sheep, as perseverance will accomplish almost any thing. I still am satisfied that had he commenced with a selected flock of healthy, good sized common ewes, and first rate Merino bucks—with his great skill and care, he would now have owned a very superior flock. I will just add that I have lost all my ambition for raising great overgrown stock of any kind—experience has convinced me, that moderate sized, compactly built, suitably proportioned animals are the most profitable for the farmer.

I am, very sincerely,
Yours, &c.

A. R.

FALL RACES.

IN VIRGINIA—at *Belfield*—8th day of October—1st day for 3 year olds; a sweepstake, 2 mile heats for \$200.

2d. day—Jockey Club, 3 mile heats, for from 3 to \$400.

3d day—Proprietor's purse for \$200—2 mile heats, free for any horse except the winner of jockey club.

At *NEW MARKET*, 13th of October.

1st day—Sweepstakes for three year olds, 2 mile heats, entrance \$500, half forfeit, 3 subscribers and closed.

2d day—Proprietor's purse \$300, 3 mile heats.

3d day—Jockey Club, \$600, four mile heats.

4th day—Handy Cap, \$100, 2 mile heats.

WARRENTON, 28th October.

1st day—Sweepstakes one mile heats for for 3 year olds, \$100 entrance—3 or more make a race.

2d day—Jockey Club purse \$300, 3 mile heats.

3d day—Proprietor's purse 2 mile heats, \$200.

4th day—Handy Cap.

LAWRENCEVILLE RACES, Wednesday, the 1st of October.

1st day—Sweepstakes 2 mile heats, for \$200.

2d day—Jockey Club purse worth about \$500, four mile heats.

3d day—Proprietor's purse \$200, 2 mile heats, same evening a *mule race*.

BOYD TOWN RACES, 5th November.

1st day—Sweepstakes for 3 year old colts and

fillies—entrance \$200, 2 mile heats; subscription to close the evening preceding the race.

2d day—Proprietor's purse, \$200.

3d day—Jockey Club purse, \$500, 4 mile heats.

4th day—A Handy Cap purse, — mile heats.

MARYLAND ASSOCIATION FOR THE IMPROVEMENT OF THE BREED OF HORSES.

At a meeting of this Association, held agreeably to notice, at Barnum's hotel, on Friday the 22d August, 1823,

GEN. WM. H. WINDER, *Chairman*.

E. L. FINLEY, *Secretary*.

The Association was organised for five years, to commence from the 7th of August, 1823, and rules and regulations were adopted for the government of the association. The following gentlemen were then unanimously elected officers of the association.

President, Thomas Tenant.

Vice-Presidents, Edward Lloyd, Samuel Sprigg, Frisby Tilghman, Joseph Gales, William H. Winder.

Treasurer, B. I. Cohen.

Secretary, E. L. Finley.

Managers, John S. Skinner, James L. Hawkins, W. G. D. Worthington, John Thomas, James Howard, Jacob G. Davies, Thomas Kell, William Frick, James Clark, John McPherson of Frederick, B. D. Mullikin, Charles Worthington, of William.

Committee of Elections, U. S. Heath, John Merryman, John Glenn, Charles Tiernan, S. C. Leakin.

It was resolved that the first Annual Races of the Association, should take place at the Canton course near Baltimore, on the 22d of October, 1823, for the following purses,—free for any Horse, Mare, or Gelding, to carry weight, &c. agreeably to the rules of this Association.

1st Day. Two mile Heats for a purse of \$250

2d Day. Three mile Heats for a purse of \$500

3d Day. Four mile Heats for a purse of \$1000

The winning horse of each day to be excluded from running for any of the other purses during that meeting.

WM. H. WINDER, *Chairman*.

E. L. FINLEY, *Secretary*.

FOR THE AMERICAN FARMER.

MARYLAND CATTLE SHOW AND FAIR, No. 4.

The Board of Trustees elected under the new organization of the Maryland Agricultural Society, held their first meeting at Hampton, on Wednesday the 24th September, in pursuance of an invitation from General Ridgely, the President of the Board: and then and there proceeded to make arrangements for the next Cattle Show and Fair, to be held at the Maryland tavern, on Wednesday the 5th of November next.

Extract from the Minutes.

COMMITTEES APPOINTED TO AWARD THE PREMIUMS OFFERED BY THE SOCIETY.

ON HORSES.

Henry Thompson,
Christopher Carnan,
Nich. Goldsborough,

Frisby Tilghman,
William Riggia.

ON MULES AND ASSES.

Col. Thomas Emory,

CROPS.

Nicholas Hammond, Robert Sinclair,
B. W. Hall, Daniel Martin,
Joseph Blake, Samuel Hardin.

FERMENTED LIQUORS.

John McLean, Joseph Kent,
Stevenson Archer, Ely Balderston,
William Gibson, Daniel Murray.

COMMITTEE OF ADMISSION.

James Cox, John Wm. Thompson,
W. F. Redding, James Piper,
Philip Tyson, W. E. Cole,
Elisha Tyson, Jr., John Schwartz,
Evan Poultney, John Hewes.

MARSHALLS.

Dr. A. Thomas, W. F. Johnson,
George Howard, Theodore Anderson,
Doyd N. Rogers, Benjamin I. Cohen,
S. Smith, Jr., John Beckett,
K. Kiddell, D. R. Guest,
A. Sterling, Henry Carroll,

James Carroll, Jr. J. W. McCulloh, and J. S. Skinner, were appointed a committee to prepare and publish rules and regulations for the government of the exhibition, and R. Gilmor, James Cox and H. V. Somerville Esqrs. were appointed a committee to prepare and cause to be engraved the design and form of a certificate, to be issued with each premium, under the seal of the Society, and the signature of the President.

The Secretary was instructed in behalf of the Trustees, to request Gen R. G. Harper, to deliver an address on the affairs of the Society, and the subject of Agriculture, [to which Gen. H. has politely assented.]

The Trustees then adjourned to hold their next meeting, at the residence of Col. Nicholas M. Bosley, on the York Turnpike road, on Wednesday the 15th of October.

JAMES HOWARD,

Secretary.

It will be recollected that in June last, the constitution of the Society was remodelled, and in

lieu of a committee of Arrangement, a PERMANENT BOARD OF TWELVE TRUSTEES, was provided for each Shore. This was done in imitation of a similar feature in the constitution of that eminent and excellent institution, the Agricultural Society of Massachusetts.

These twelve trustees have been duly elected for the Western Shore, with the understanding that, as in Massachusetts, they are to meet at each others houses, in rotation, at an early hour, on a given day in each month. When convened, the affairs of the Society are to be in the first instance, the exclusive subject of attention and business. That being finished, the conversation naturally turns on the prospects and interests, the practice and the science of Agriculture generally. It is understood that the entertainment on these occasions is to be plain and substantial, without ostentation or extravagance; and that every one is at liberty and expected to bring with him for exhibition, specimens of any thing very remarkable, such as beautiful samples of any kind of grain, or grass, tobacco, or extraordinary productions, fruits, &c. &c.

Before rising from the table, the host is expected to designate the gentleman at whose house the trustees will dine, on that day four weeks.

It will be readily seen how well this system of monthly meetings in the country, is calculated to keep alive the zeal for agricultural improvement. The intervals are so short that it has not time to languish, and we venture to say that were the same system adopted wherever agricultural societies are established, we should see them go on as that in Massachusetts has done; increasing from year to year, in publick spirit and usefulness—constantly augmenting its resources, multiplying the objects of its patronage, and extending the sphere of its influence.

We regret exceedingly to hear that no steps have been taken by our friends on the Eastern Shore of Maryland, towards another exhibition at Easton. How different this result, from what was indicated by their first attempt last fall! We venture to assert that no association to promote improvements in husbandry, ever commenced more happily than they did.—For the first essay, it was whether in the animals and household manufactures exhibited, in the solid character and gentlemanly deportment of the farmers attending, or in the whole style and conduct of the exhibition, to say the least, certainly not inferior to any ever held in the United States. We cannot, we will not believe, that where means are so abundant, intelligence so ample, and advantages so obvious, they will allow an association to be dissolved, whose services are so well calculated to ensure to a profession, by which their sons are destined to live, that degree of pleasure and respectability, which it has not always enjoyed, but to which it is so justly entitled.—*Edit. Am. Far.*

The Editors of all the papers in the State of Maryland and District of Columbia, are respectfully requested to copy the foregoing proceedings and remarks.

FOR THE AMERICAN FARMER.

PERFORMANCE OF POSTBOY.

Postboy was foaled in 1800, sire, the imported Gabriel; Dam, by Hyder Ally.

On the 12th of October 1803, for the Baltimore Jockey Club's colt's purse of \$150, Postboy carrying a feather, beat Rosebud, by Grev Medley, 97 lb; Vulcan, by Paul Jones; and Cleonor by Gabriel, each a feather, two mile heats.

In October 1804 he won the Baltimore Jockey Club's colt's purse for \$200, beating Mr. Lloyd's Goldfinder, two mile heats.

The same fall he won the colt's purse at Annapolis, of \$200 beating Oscar by Gabriel, and a grey colt, two mile heats.

The same fall he beat Col. Selden's Sting, at Washington, a match race for \$1000 a side, two mile heats.

The next day, at the same place, he won a silver cup, value 50 guineas, beating Col. Tayloe's Hambletonian; Mr. Lloyd's Rapid; Col. Selden's grey horse, and Mr. Duckett's Republican President, distancing the field, except Rapid, who barely saved his distance; a single four mile heat.

In the spring of 1805, he won \$200 at Canton, beating Mr. Duckett's Financier, three mile heats.

In October 1805, he won the silver cup, value 50 guineas, at Washington, beating Col. Tayloe's Hambletonian and Mr. Lloyd's Mount Vernon, a single four mile heat.

In the spring of 1806, he walked over for \$300 at Canton.

On the 29th of October 1806, for the Washington Jockey Club's second day's purse of \$500, carrying 120 lb., he beat Miller's Damsel, by Messenger, 97 lb; Sally Nailor, by Spread Eagle 117 lb; Cut-and-come-again, by Cormorant, 123 lb; and Paragon, by Spread Eagle, 112 lbs. three mile heats.

The following week he won \$250 at Lancaster, beating Mr. Bond's famous First Consul, and Mr. Lloyd's Lavinia, three mile heats.

In October 1807, for the Washington Jockey Club's first day's purse of \$600, he beat Major Bean's Maria by Punch, four mile heats.

The next week he walked over for the Alexandria Jockey Club's first day's purse of \$500.

On the 10th of May, 1808, for a subscription purse of \$1000 at Hunting Park, near Philadelphia, he beat Mr. Badger's famous Hicory, by whip, 4 years old, and distanced Mr. Bond's Bright Phœbus, by Messenger, same age, four mile heats.

Editorial Correspondence.

AMERICAN OLIVES.

Extract to the Editor—Darieu Georgia, September 14th, 1823.

SIR—The enclosed is a branch of olive and its fruit, from a plant sent to Mr. Thomas Spaulding of Sapelo Island, by the Hon. W. H. Crawford, four years ago, and is now bearing fruit.—This experiment shows that the olive can be reared sooner, and much more to the advantage of the cultivator, than has heretofore been supposed.

Your's respectfully,

H.

Can the writer conveniently send another specimen?—*Edit. Am. Far.*

FROM "EXPERIMENTS IN CHEMISTRY."
Lithography; or Printing from Stone.

A very ingenious process has of late year been employed to answer, at the same time, both the purposes of designing and engraving; or, in other words, to produce an engraving by the art of designing. This art is called *Lithography* or *Stone Engraving*; and among the German artists, *chemische druckery*, or *chemical printing*. It consists in being provided with a few slabs of marble, about the size of Dutch tiles, or larger, according to the intended dimensions of the print; the thickness should be about two inches.

The Landscape, or other subject, is then to be traced over with a pencil; and the pencilled lines are to be afterwards at leisure retraced with a particular ink which was at first a great secret. It is now, however, known to consist of a solution of Shell-lac, in Potass, colored black by soot from burning wax. When the design has been gone over with this ink, it is left to dry, which commonly takes about two hours, though this will depend upon the temperature and dryness of the atmosphere. The face of the marble being, after this process, washed with Nitric Acid, more or less diluted, according to the degree of relief desired, the whole surface will be corroded, *except where defended by the resinous ink*. The operation is now completed; and to obtain printed copies, nothing more is necessary than to wash the marble clean; to distribute over it, by means of printer's balls, an ink similar to that commonly used by printers; and to press down upon the design, by a roller, or copper-plate press, a sheet of paper properly disposed in a frame.

Blackening-Balls for Shoes.

Take mutton suet, 4 ounces; bees-wax, one ounce; sweet oil, one ounce; sugar-candy and gum-arabic, one dram each, in fine powder: melt these well together over a gentle fire, and add thereto about a spoonful of turpentine, and lamp black sufficient to give it a good black color. While hot enough to run, make it into a ball, by pouring the liquor into a tin mould; or let it stand till almost cold: or it may be moulded by the hand.

Liquid Japan Blacking.

Take three ounces of Ivory-black, 2 ounces of coarse sugar, one ounce of Sulphuric Acid, one ounce of Muriatic Acid, one lemon, one table-spoonful of sweet oil, and one pint of vinegar.—First mix the ivory-black and sweet oil together, then the lemon and sugar, with a little vinegar to qualify the blacking; then add the Sulphuric and Muriatic Acids, and mix them all well together.

Observation. The sugar, oil, and vinegar, prevent the acids from injuring the leather, and add to the lustre of the blacking.

Another Method.

A quarter of a pound of Ivory black, a quarter of a pound of moist sugar, a table spoonful of flour, a piece of tallow about the size of a walnut, and a small piece of gum arabic.—Make a paste of the flour, and whilst hot put in the tallow, then the sugar, and afterwards mix the whole well together in a quart of water.

French Varnish, for Cabinets, &c.

Take Shell-Lac, three parts; Gum Mastich, one part; Gum Sandarach, one part; Alcohol, forty parts. The Mastich and Sandarach must first be dissolved in the Alcohol, and then the Shell-Lac: this may be done either by putting them into a bottle loosely corked, and placing it in a vessel of water, heated below the boiling point of Alcohol, until the solution is effected; or

by putting the ingredients into a clean Florence oil-flask, (the neck of which is partially closed by a cork, having a narrow slit along it,) it is to be heated over a spirit-lamp. The Alcohol which escapes during the process must be replaced by an equal weight of it, after the operation is over; as it is desirable that the Varnish should consist of the proportions given, in order to be good. The solution may be poured off for use, from the impurities which remain, but it must not be filtered, as that operation would deprive the Lac of some of its qualities.

Observation. In cases where a greater degree of hardness in the varnish is desirable, and its color is but a secondary consideration, one part of shell-lac with eight parts of alcohol, is to be preferred,

Varnish for Oil Paintings.

Mix six ounces of pure Mastich Gum with the same quantity of pounded glass, and introduce the compound into a bottle containing a pint of Oil of Turpentine; (treated with Alkali as above,) now add half an ounce of Camphor bruised in a mortar. When the Mastich is dissolved, put in an ounce of Venice Turpentine, and agitate the whole till the Turpentine be perfectly dissolved.

Observations. When to be used, this varnish must be gently poured off the glass sediment at the bottom of the bottle; or it may be filtered through muslin. The intention of using ground glass, is to present a greater surface of mastich, to the solvent, by throwing the particles as much apart as possible.

The following lines were addressed to THOMAS MOORE, ESQ. on the birth of his third daughter. They are by the Eaton Stannard Barret, of this city, the author of the *Heroine*.

I'm sorry, dear Moore, there's a damp to your joy,
Nor think my old strain of mythology stupid,
When I say that your wife had a right to a boy,
For Venus is nothing without a young Cupid.

But since fate the boon that you wished for refuses,
By granting three girls to your happy embrace—
He meant when you wandered abroad with the muses,

That your wife should be circled at home with the Graces.

A fashionable Doctor lately informed his friends in a large company, that he had been passing eight days in the country. "Yes," (said one of the party) it has been announced in one of the Journals." "Ah! (said the Doctor, stretching his neck very importantly) pray in what terms?" "In what terms? Why, as well as I can remember, in the following: 'There were last week seventy-seven interments less than the week before.'" The Doctor's neck was seen suddenly to shrink down, till his head nearly touched his shoulders; and shortly after he was missed from the saloon, to the no small diversion of the company.

Learning for Ladies.—"I should be glad to know (said a learned lady to a gentleman) how knowledge is incompatible with a woman's situation in life. I should like to be told why chemistry, geography, algebra, languages, and the whole circle of arts and sciences, are not as becoming in her as a man?" "I cannot say (replied the gentleman) that they are entirely unbecoming; but I think a very little will answer the purpose. In my opinion, a woman's knowledge of chemistry should extend no farther than to the melting of butter; her geography should extend no farther than to a thorough acquaintance with every hole and corner of her house; her

algebra to keeping an exact account of the expenses of the family; and as for *conques*, heaven knows that *one* is enough in all conscience, and the less use she makes of it the better."

THE FARMER.

BALTIMORE, FRIDAY, OCTOBER 3, 1823.

The Editor feels persuaded that such an establishment as the "Gardiner Lyceum," if not altogether new in practice in this country, is at least so little known, and yet so highly useful in its tendency, that his readers will be pleased to be made acquainted with its existence and its objects. It may lead to the establishment of similar institutions in other parts of our country with great advantage.—We have therefore given in this number, the Address to the public from the Trustees of the Gardiner Lyceum, at Gardiner, Maine; and in the next number, we shall copy parts of the address delivered at the opening of the institution by the Rev. BENJAMIN HALL, Principal of the Lyceum, and Lecturer on Natural Philosophy.

Very remarkable mammoth rye was raised the last season by WILLIAM KRESS, Esq. of Baltimore county—and a beautiful specimen has been left with the Editor for distribution.

Applications have recently been made to the Editor for Guinea Grass Seed—a small quantity from any of his subscribers would be very acceptable.

BALTIMORE MARKET.

PRICES CURRENT—CORRECTED WEEKLY.

Flour, best white wheat, \$7 25—Howard street, from wagons, \$7—Superfine, \$6 50—fine do. \$6 25—Wharf, do. \$6 25, cash—White wheat, \$1 25 to 1 35—Red do. \$1 15 to \$1 16, a few sales at \$1 25—Rye, 40 to 45 cts.—Corn, 38 cts.—wharf Oats, 26 a 30 cts.—wagon Oats, 31 cts.—Beef, 8 cts. per lb.—Live Cattle, \$6 to \$6 50, per cwt.—Bacon, hog round, \$10—Pork, \$7 50 per c. lb., 5 to 8 cts. per pound—Mutton, 5 to 6 cts. per lb.—Beans, retail, \$1 50, cargo price, 1 12½—Peas, retail, 75 a 80 cts., cargo price 58 a 60 cts.—Red Clover Seed, \$6—Orchard Grass do. \$5—Herds' Grass do. \$3—Timothy do. \$4—Flax Seed, 75 to 80 cents—Whiskey, from the wagons, 28 to 30 cts. per gallon including the barrel—Apple brandy, 30 to 32 cts.—Peach do. 65 to 70 cts.—Shad, \$6 00.—Herrings, No. 1, \$2 70 per bbl., No. 2, \$2 37½—Fine Salt, 60 to 65 cts. per bush., coarse, do. 70—Butter, (firkin) 14 cts. per lb.—Eggs, 12½ cts. per doz.—New Hay, \$15 per ton, old do. \$18—Straw, \$8.

MARYLAND TOBACCO.—Fine Yellow, none—good do do.—Fine Spangled, \$18 to \$25—Fine Red, \$10 to \$16—good do. \$6 to \$8—common do. \$4 to \$6—Dark Brown, \$2½ to \$3½.

Sales.—A crop of Fine Red and Spangled, 7 hhds. raised by Mr. Noah Worthington of Baltimore county, \$20—Fine Upper Patuxent, \$12 to \$16—inferior qualities, large sales, from \$2½ to \$6.

Cow and Calf For Sale.

A very fine cow with her second calf; she was got by an imported bull of the Herefordshire breed, and her present calf by a full bred Devon Bull—she is remarkably gentle, and easy to keep in fine order.—Enquire of the Editor.

Printed every Friday at \$4 per annum, for JOHN S. SKINNER, Editor, by JOSEPH ROBINSON, on the North West corner of Market and Belvidere streets, Baltimore; where every description of Book and Job Printing is executed with neatness and dispatch.—O. C. from a distance for PRINTING or BINDING, with proper sections promptly attended to, addressed to J. Robinson, Baltimore.

AGRICULTURE.

INTERESTING EXTRACTS.—From *Agricultural and other Addresses and Memoirs, on file in the office of the American Farmer.*

FROM THE INAUGURAL ADDRESS, DELIVERED AT GARDINER, ME. JANUARY 1, 1823, BY BENJAMIN HALE, PRINCIPAL OF THE GARDINER LYCEUM AND LECTURER ON NATURAL PHILOSOPHY.

The discoveries of modern science have opened to us more just views, and led to a more rational mode of investigation. The operations of nature are no longer regarded with a mysterious dread, or as the capricious movements of a doubtful agent, or under the control of stellar influence;—but as subject to fixed and unvaried laws, established by a benevolent Deity, and accommodated to the wants and the highest happiness of his sentient creation.

Philosophers too have thrown aside their veil of mystery, and have become the public teachers of mankind. They disclose the secrets of nature, and the manner in which they may be made subservient to the uses of life. They have interpreted the written scroll, which shines in golden characters above our heads, not as a book of fate, which like the hand writing upon the wall, is full of terrible but unintelligible import, but as a chart, which kindly serves to guide the wanderer upon the trackless ocean, or over the unknown desert, to his desired home.

In consequence of this change in the character of science, in the dispositions of its votaries and the benefits it has laid at the door of every man, prejudice against it has nearly ceased. We would say quite. But there are still many who receive its benefits, without confessing their obligations,—who yet look upon it as something of a useless nature. And perhaps most men regard it as belonging to the closet, the laboratory or the lecture room, rather than the work-shop, the manufactory, or the field.

But though philosophers have hitherto been for the most part, secluded from the common pursuits of life, and have made their attainments from the study of books, or from private experiments, they are not the only men of science.—There are thousands, who call themselves practical men in distinction from men of science, who in truth derive all their merit from the science, which they have unknowingly united with their practical skill. It is forgotten, that every operation in the arts is really an experiment in philosophy, and as truly illustrative of some law of nature, as any performed in the laboratory or the lecture room; and that every artist, who understands the reason of the operation is so far a man of science.

The connexion between science and the arts will be still more manifest, if we observe its nature. From what cause is it, that the mechanic is able to carry on the process of his art; or why do these processes produce the result, that is desired and obtained by them? Why is it, e. g. that the tanner is able, by immersing his hides in an infusion of bark, to give them the closeness and firmness and insolubility of leather? We learn from chemistry, that it is in consequence of a union between an ingredient in the skin and a principle of the bark. The whole operation then is founded upon the law of nature, which establishes the affinity between these two substances, and which it is the province of science to investigate. In the same manner, it is science which discovers the nature of all the operations in the arts. It is science therefore, which must explain these operations, and though a man of ingenuity will sometimes un instructed attain a ge-

neral understanding of his processes, yet with out it he can never fully comprehend them.

Such then being the connexion between science and the arts, it is manifest, that the artist might expect many advantages from uniting scientific views with practical skill. Among others,

He would be able to go through his processes with greater certainty of success. We will illustrate our idea by reference to the art of dyeing. How many circumstances are there which may concur to prevent success in giving the colours or shades, which are desired! The materials used in making a dye may vary in their quality, may contain more or less than usual of the colouring matter, may contain it mixed with foreign ingredients, and thus by destroying the proportions or otherwise changing the nature of the compound, may fail to produce the colour desired.—Against such an accident, the unlearned artist is not provided. He has but one rule for mixing his ingredients, and this always supposes them to be of an invariable quality. But science by giving him the means of ascertaining their quality, enables him to vary his proportions according to their strength, or to remove any causes of failure, which may exist. The art of dyeing, in all its branches, depends upon chemical principles, and every one who attempts to practice it without a knowledge of this science, must always proceed in the dark, and be always doubtful of his success.

The same benefit of science is illustrated in a case, with which the public prints have lately furnished us. A Scottish gentleman, acquainted with Chemistry, went a few years ago to India, in the service of the East India Company. His knowledge of Chemistry recommended him to the Governor, and he was employed in the manufactory of Gunpowder. He applied his knowledge to correcting the operations of the ignorant manufacturers whom he found there, and with such success, that he was soon placed at the head of the establishment, and has since returned to his native island with the wealth of an eastern prince.

Another advantage, which the arts might expect from a connexion with science, is the discovery of new and improved processes. On this point too, recent improvements furnish us with a striking instance, by which it can be at once illustrated and confirmed.—The process of bleaching, which formerly consumed many weeks is now the work almost of fewer hours, and the texture of the cloth is preserved from the injury, which it sustained from the long exposure of the ancient method. This great saving of time, and improvement in the fabric has been effected by the introduction of what is called the *chemical method*.—It was discovered by Scheele, that chlorine would discharge the colour from animal and vegetable substances. A few years after this, Berthollet applied the discovery to bleaching. The application was made about the same time in England, and the first considerable experiment, which was made to establish the utility of the discovery, was upon a piece of calico, the whole of which, “taken in the state, in which it left the loom was bleached, printed in permanent colours, and produced in the Manchester market for sale, having undergone the whole of these operations in 48 hours.” This was in the spring of 1788. The experiment was immediately followed by a large bleaching establishment. The origin of this valuable improvement was in the discovery of a chemist; the first applications of it to bleaching were made by chemists, and the art, from its early stages to its present improved state, is to be regarded as a monument of the practical utility of science.

We may name, as another of the benefits, which science has conferred, and may still be expected to confer upon the arts, the immense saving of labour and expense. In the process of bleaching, to which we have just referred, many thousands are annually saved to single bleaching greens, by one discovery. How much expense as well as danger, is avoided in the large manufacturing establishments of Great Britain, by the use of gas lights!—Of what incalculable benefit have Watt's improvements in the Steam Engine, been to his native country, and to our own by its application to the Steam Boat:—and with what extreme cheapness are your cotton, and other fabrics furnished in comparison with their former expensiveness!

We may be told, that improvements in manufactures and the arts have been made by men unskilled in science. This is true: indeed to some extent, but by no means so far as is supposed by those who assert it. Sometimes discoveries are made by ignorant men, but they are then the result of accident, and such instances would hardly be urged, if it were known how many fortunate accidents are daily lost to the world, through want of that knowledge, which would enable an artist to turn them to advantage. Most of the inventions and improvements, which have been made by men, who have not been favoured with early education, have not been made in ignorance of science. These men, by superior capacity and superior industry, united to a strong native propensity to such studies, have been able notwithstanding the disadvantage of their situation, to make those attainments in the elements of science, which we recommend, though their science is often overlooked, because they are not familiar with its phraseology, and are not able to state the results, at which they have arrived.

It is easy to see that we cannot calculate upon great improvements or discoveries from men of no education. Compare the ability of such men with the improvements, made by Watt, [and Perkins] in the steam engine: How many are the impassable barriers, which meet them in the very outset! What do they know of the subject of latent heat?—of the elasticity of steam?—of the quantity of latent heat, existing in steam?—of the ratio between the elasticity of steam and the degree of heat? and what do they know of, or how shall they investigate, a thousand other things, upon which the scientific, as well as ingenious Watt, founded his improvements?—The truth is, such men do not know even the very existence of the agents, which are necessary, in a great variety of cases, to be employed, and what then can be more unreasonable than to expect them to make discoveries, or to suggest improvements!

The value of science in facilitating useful discoveries may be well illustrated by the history of Sir H. Davy's beautiful invention of the safety Lamp, not only because this invention is one of the noblest triumphs of science, but because we can retrace the steps by which it was attained.—In the coal mines of England there is often found a mixture of gases, called by the miners *fire lamp*, because it immediately extinguishes the lamp which lights their labor. But this is not its worst effect. The fire damp explodes, and few of the miners escape instantaneous destruction. The danger arising from this source, had caused several valuable mines to be abandoned, and in those, which were still worked, there were yearly more or less of these fatal accidents. Several attempts to light the mines without danger, had been made before the invention of Davy, and with tolerable success. But his, uniting simplicity with safety, has taken the place of every other, and has left scarcely any thing fur-

th to be devised.—Davy had discovered that explosions could not be propagated through a long tube of small diameter, and upon this hint he proceeded. He diminished the strength of his tube, and found it to have the same property, till in a very small tube the length was reduced to an equality with the diameter. He then had a lamp covered with a fine wire gauze, having the diameter of the interstices equal to that of the wire, and these acting like tubes, prevented explosion, although the lamp was immersed in an explosive mixture: and a lamp thus covered, and furnished with little other apparatus, is the lamp, with which mines the most dangerous, can now be traversed in safety.

Though we have thus far illustrated our remarks upon the benefits to be expected from a union of science and the arts, principally by examples drawn from those, which are dependent upon chemical principles and which are not the most common, especially in our country; yet it must not therefore be inferred, either that chemistry is the only science which is of practical importance, or that the more common arts have not equally with others, their foundation in scientific principles. The remarks which have been made are general, and the illustrations we have given, were selected for their aptness, and not for their singularity.

The truth is, there is no art which is not so connected with science, that it may expect important improvements from scientific investigations, and there is perhaps no science, which has not almost innumerable practical relations. What knowledge, for example, can be more useful to a certain class of men, than *mechanics*.—that science, which treats of the laws of moving bodies; their velocities, their momenta, and their direction;—of the nature of the various moving forces; the laws of their operation; the manner in which they are applied, and of the composition and direction of forces. Without an acquaintance with this science, how shall the mechanic accommodate the power of his machine to the quantity of effect to be produced? How shall he adapt its parts so as to give it a free and easy motion, and to obtain with a given velocity in the power, a required velocity in the weight? How important to him also are the investigations of the philosophers concerning friction; of the laws by which it varies with the weights, or surfaces, or velocities of moving bodies; and the means of overcoming it. But valuable as is a knowledge of this science in all cases, to those who have the direction of machinery, its value is doubled, or rather it becomes absolutely indispensable, when any new machine is to be constructed, or an old one is to be adapted to some new purpose. It is then the only guide. It makes the mechanic understand the means by which his end is to be attained; and after his ingenuity has suggested a plan upon which his machine shall be constructed, it enables him to calculate its power, and to ascertain to a considerable degree of certainty, its value, without the loss of time and labor and expense in experiment. How many times would this science, in this way, prevent the failures of ingenious men;—how often would it prevent ingenuity being wasted to no purpose, in attempting to construct impossible machines, or in proceeding upon false principles. How often would it prevent the abandonment of a valuable design, by assisting the inventor to discover the impediments which hinder his success, or to make a more judicious application of his principle! How often would it enable the mechanic to make new applications of principles, which are developed in machines of attested excellence; and how many times would it suggest such simplifications of valuable but ex-

pensive machinery, as to facilitate its introduction into countries, and its use by corporations of limited capital!

The mathematical sciences too, are capable of applications to useful purposes, to an extent almost as unlimited as the infinity of their own numbers, or as quantity itself. They embrace every thing capable of being measured, and they are the foundation of all calculations. They aid the astronomer in investigating the laws, which govern the revolutions of the heavenly orbs; and to deduce from them all those principles, and to construct those tables which enable the mariner to ascertain his situation, when he can see nothing around him but the monotony of the dashing waves, and to direct his bark to his distant and invisible home.

But the path, in which we are leading you, is without an end, and we will require you to follow us but little farther. Agriculture is in itself, too important, and it will be an object of too much attention in the Lyceum, not to be noticed on this occasion. The intimate connexion of this art with chemistry, is now well understood and generally acknowledged. The superior success, with which the earth has recently been cultivated by men who have brought to this employment, minds expanded by science and stored with its principles, is enough to adduce in reply to all the objections of ignorance, and of the most bigoted prejudice in favor of the modes, which age and the practice of ancestors have sanctioned. Though agriculture is the most ancient of the arts, it was not so the gift of Heaven to man, that it is not like other arts capable of his improvement; and its progress from its primitive rudeness to its present state, is sufficient to induce the hope, that it may still advance, and that future generations may carry it to a degree of perfection, beyond what even the most sanguine have ever conceived. But our expectations of great improvements are founded in the rapid advances of science, and of that just philosophy, which makes science the handmaid of the arts. The illustrious Davy and many others have directed their attention to the different subjects of inquiry in agriculture, and they have raised Agricultural Chemistry almost to the rank of a distinct science. If its claims to this rank were to rest upon the extent of the field, which it opens for investigation, they must certainly be admitted. To quote the words of the distinguished chemist, whom we have just named, "Agricultural Chemistry has for its objects all those changes in the arrangements of matter, connected with the growth and nourishment of plants; the comparative values of their produce as food; the constitution of soils; and the manner in which lands are enriched by manure, or rendered fertile by the different processes of cultivation. Enquiries of such a nature cannot but be interesting and important both to the theoretical agriculturist, and to the practical farmer. To the first they are necessary in supplying most of the fundamental principles, upon which the theory of the art depends: to the second they are useful in directing his labors, and for enabling him to pursue a certain and systematic plan of improvement."

"It is scarcely possible," as the same writer remarks, "to enter upon any investigation in agriculture without finding it connected, more or less, with doctrines or elucidations derived from Chemistry."

In exhibiting, as we have endeavoured briefly to do, the connexion of science with the useful arts, and shewing the importance of the former as the foundation of the latter, we have given you

in part the views, which led to the establishment of the Gardiner Lyceum.—It is the object of this institution to give instruction in those branches, which are most intimately connected with the arts, and to teach them as the foundation of the arts. In this respect we believe its design to be original. There are many institutions in our country, where these sciences are taught, and we are proud to boast of one in our own state, where they are taught with singular success. But the education at College is designed only as a general introduction to the liberal sciences; it furnishes a mental discipline and is intended to enlarge the views of those, who are afterwards to pursue the study of some particular profession. It embraces too wide an extent—it consumes too much time, and is attended with too great expence, to be attained by the greater part of the community, and especially by those, who are to pursue Agriculture, or some mechanical profession for their support.—But were it otherwise; were it in the power of these classes to obtain an education at College, it is not an education suited to their wants. They do not merely require to be instructed in the sciences, but to be taught these sciences in a practical manner. It is not sufficient for them, as for the general scholar, to be taught the common laws of chemistry;—they must be instructed particularly in the chemistry of Agriculture and the Arts. It is not sufficient for them, to be able to repeat and to demonstrate a few of the general laws of mechanics;—they must be taught the application of the laws; they must be made acquainted with machines; and they must understand the sources of error in applying theory to practice. These things are not done at our Colleges—not from any defect in their systems, but because it would be aside from their design. One class of students could with no more propriety expect that the physical sciences should be taught with minute and constant reference to the wants of the mechanic and farmer; than another, that all instruction in the learned languages should be directed to making proficient in biblical criticism; or a third, that Ethics and Political Law should be so taught, as to prepare them for the litigations of the bar, or the deliberations of the Senate chamber. But it is plain that to practical men, science must be taught in a practical manner. We are taught this by the frequent failures of men who are not deficient in the general principles of science, but who are unacquainted with the particular science of the arts. It will not be said then that the founders of this institution have assisted in unnecessarily multiplying seminaries of education, for it is new in character, and it is designed to supply the wants of a large portion of the community, for which no provision had hitherto been made. Nor will it be said, that these wants are not real. The education of the advocate or divine is scarcely more necessary to his success, than that of the mechanic or the farmer. If the professions of the former are themselves branches of science, those of the latter are founded in science. And as we expect empiricism from those, who enter the learned professions without a suitable preparatory education, so we can expect nothing but deficiency of skill in mechanics, who have been taught only the manual exercise of their arts. There surely can be no reason, why mechanics and agriculturists should not be instructed in that science, which will enable them to follow their pursuits not blindly, but from rational views. Those who have not this education, may indeed copy faithfully the practices of their fathers, but we cannot expect from them improvements which shall enrich their country and benefit the world. Is it extravagant to suppose that there may be many Watts and Wedgewoods scattered through our country; their

ments buried in obscurity, and not known even to themselves from the want of opportunity for their development? And would it be presumptuous to hope, that at this institution, some of these intellects may receive their first impulse, and be first directed into that path which will lead them to honour and extensive usefulness.

APPENDIX.

Instruction at the Lyceum will be given at recitations, of which there will be three each day. According to the plan in our Colleges, there will be but one class admitted each year. The year will commence in August at the close of the Summer vacation, and those who offer themselves for admission at any other time, will be examined not only in the preparatory studies, but in those which the class into which they enter have passed, previously to their admission. For admission to the Lyceum, a knowledge of the four fundamental operations of arithmetic, both upon simple and compound numbers, and of reduction is required. After July next will be added the rudiments of English Grammar.

The whole course of instruction will occupy three years. The studies of the first year will be Arithmetic, Algebra, Geometry, the Measurements of Surfaces and Solids, Trigonometry, with its application to Heights and Distances, Book-keeping and Rhetoric. Those of the second year, Surveying, Navigation, Mechanics, theoretical and practical; Hydrostatics and Hydraulics; Pneumatics and Chemistry, with its application to Agriculture and the Arts. Those of the third year, Magnetism, Electricity, Optics, Astronomy, Fluxions, Natural History, and the Philosophy of the Mind.

The studies are so arranged that those of the two first years will make a course of themselves, and students who may be unable to remain longer than two years, can leave at the end of the second. To the second and third classes, lectures, accompanied with suitable experiments, will be given upon Natural Philosophy and Chemistry.

—O—

TO THE EDITOR OF THE AMERICAN FARMER.

Charleston, September 25, 1823.

DEAR SIR,

As I am sure you will feel gratified to suppose our Agricultural Society are attempting to be useful in promoting the cause of agriculture, I send you a list of Premiums for the year 1825, which were proposed and adopted at our last meeting on the 16th inst.—Whenever you can find room to insert them in your paper, you will oblige not only the members, but also

Your faithful friend,

and obd't servant,

CHARLES E. ROWAND.

As soon as my Harvest is over, I shall plant the Woad in a paddock where there shall also be planted oats—in the course of the winter, I shall be able to judge of the practicability of its being used as a winter pasture; and also which of the two, the cow or horse will prefer.

The South-Carolina Agricultural Society, at their last meeting, held on the 10th inst. received from their Committee of Arrangements the annual list of premiums intended to be awarded by them in the year 1825. Although it has been customary to announce the premiums of a subsequent year after those of a former year have been disposed of, it is now nevertheless thought proper to publish their list at this early period, with a view to give sufficient time to competitors, to bestow that labor upon the land intended for the cultivation of flax that is absolutely requisite,

preparatory to the time of planting, which is in November. The society actuated by the prosperous state of the funds, and the great accession of members, have increased the number of their premiums, in the hope that it may operate as a stimulus to induce planters to come forward with the result of their attempts, and thereby forward the views of the society, by promoting the good cause of Agriculture. As a further incentive to exertion, they have extended their design to imported animals, provided they have been kept for service the preceding twelve months.

Report of the Committee on Premiums to be awarded by the South-Carolina Agricultural Society in the year 1825.

The improvement of the agriculture of our country being the object of our institution, the society has judiciously resorted to the exhibition of premiums, as one of the means of promoting it; but much of the success to be hence derived, must depend on the proper management of this auxiliary.

Premiums may be considered as useful in three points of view—First, as an encouragement to industry; secondly, as an incitement to intelligent enterprise; and thirdly, as the instrument of communicating the results of the two first points, and thereby diffusing the knowledge acquired by the experience of individuals throughout our country. It may perhaps be thought, that with respect to the encouragement of industry, the prevailing principle of self-interest is a sufficient inducement to impel the agriculturist to make exertions to procure the best crops. Yet when we consider how powerful a motive is the love of distinction—how much may be effected by the stimulus of emulation—and that to the pecuniary circumstance of some, our premiums, however small, may occasionally be convenient, it may be hoped that it will prove useful to offer this additional encouragement to industry. But while we hold out this inducement, it is important that premiums be so calculated as to draw the attention of our brother farmers only to useful pursuits.

In promoting the second point of bringing into operation the intelligence and inventive faculties of our agricultural friends, by proposing to them the application of new modes of culture to our present crops, and the introduction of new articles as substitutes or auxiliaries to what we now possess, our premiums may be expected to have a more powerful effect; hence the caution recommended in the former point is more necessary here, when we abandon the useful guide of former experience, and venture on untried ground. For unless our premiums shall be dictated by sound, enlightened judgment, they will have the effect of the ignis fatuus, while it is our ambition to become the polar star of our country's agriculture. In order to render more certainly beneficial the diffusion of agricultural information, which is the object of the third point, it will be necessary that it be made a condition for the attainment of every premium, that a detailed account be rendered in writing by the candidates, not only of the product, but by the mode of culture, and cost in money, and labor expended on it, together with the situation and quality of the land, and its value at the present prices; and in order to avoid being misled by the results, if favorable or adverse seasons, or by the extraordinary natural quality of the land, it is proper that each experiment should be so far comparative, that an account be given of the product of an adjoining or neighbouring piece of land of equal size; bearing the same article, in the same season and cultivated in the usual manner. So the breed of all animals exhibited for premiums, the food on which they have been raised, and their general treatment while young, together with

cost of raising them, and an estimate of their present value should be required. The reasons for these conditions are obvious, because it would be of little advantage to those whom we desire to benefit to know that large crops have been made, and fine animals raised, unless they are informed of the means whereby they have been obtained, and are shown that they have remunerated the labor and expense of procuring them.

While considering what objects it would be proper to recommend to the Society for premiums the ensuing year, the committee have reviewed those of the present year, and as they in general accord with the views of the subject above stated, they have inserted them in the list now presented, because they are fully of opinion that no practical inference can safely be made from the result of a single experiment, but a concurrence of several, and those made in different seasons, should take place, before extensive practice should be founded on them. To these the society have added, for which they believe our funds will be adequate. The first is for the encouragement of a class of our agricultural fellow citizens, whose agency is of the utmost importance in our rural concerns. The Gold medal offered to the most meritorious manager of two or more plantations, it is hoped will be an additional stimulus to the gentlemen of intelligence, education and good conduct, who have of late years dedicated themselves to this profession, and whose management has already improved our planting system, and may at the same time induce others of good education and respectable connexions to adopt the same pursuit. The encouragement offered by the second to overseers, may excite their exertions to good conduct, and when obtained, will be the best recommendation they can produce on change of situation. The premium for the experiment on the culture of flax, is suggested with the view that this article, which is considered of such high importance in the agricultural districts of Flanders, Holland, Germany, Ireland, and other regions where the profits of husbandry are accurately understood, may be introduced as a substitute, if necessary, to the articles which at present occupy our fields.

Flax in this climate derives an additional value from the circumstance that it may be cultivated here in the winter, and although this occasionally takes place in the colder countries above referred to, yet the severity of their winters materially injures the quality of the flax, while the mildness of our season seems only to retard its growth a sufficient time to enable the staple to acquire the length and firmness requisite for its perfection. In proof of this assertion, your committee present for the inspection of the society, a sample of flax raised by one of their members, which was sown in the middle of November and pulled on the 18th April last. If no regard was paid to the production of the seed, it might have been gathered on the first of April, when it was in full bloom, and it is probable that if sown here in the end of October, it would be fit for the fabric of fine linen early in March, and for seed by the first of April, leaving the field free for any other purpose during the whole summer and autumn. It is unnecessary to use arguments to prove the immense importance of a product, said to be equal in value to a crop of cotton, which may be obtained in addition to the crops usually cultivated on the same land.

The subject of encouraging by premiums the introduction of improved instruments of husbandry, has also occupied the attention of your committee, and they have found that the plough, which is the most important of these, and indeed forms the basis of husbandry, has been of late so highly improved in its construction, and so extensively diffused through the state that it requires

no further encouragement.—The most important desiderata appear to be a good threshing machine applicable to rice, and a moating machine for cotton, which they have added to their list of premiums. The committee therefore present for the consideration of the society the succeeding resolutions.

Resolved, That the following premiums be awarded by the society at their stated meeting in February, one thousand eight hundred and twenty-five, to consist of the Gold Medal, value twenty dollars, or the Silver Medal, value ten dollars, or pieces of plate of equal value, at the option of the fortunate competitor, with appropriate inscriptions:—

For the best conducted experiment to be made in the year one thousand eight hundred and twenty-four, on not less than one acre of land, not more than 210 feet square, wherein, by any mode of culture not heretofore generally used in the state, or by the application of any manure, in quantities not generally practised, the production of black seed cotton shall be materially improved—the Gold Medal.

For a similar experiment on green seed cotton—the Gold Medal.

For ditto on Rice—the Gold Medal.

For ditto on Flint Corn—the Gold Medal.

For ditto on Gourd Seed Corn—the Gold Medal.

For ditto on Sweet Potatoes—the Gold Medal.

But the committee will not consider either of the above experiments entitled to the premium, unless the product of black seed cotton shall amount to 100 pounds per acre, that of green seed 400 lbs.—of rice to 80 bushels, of Flint Corn to 40 bushels, of Gourd Seed Corn to 70 bushels, and of Sweet Potatoes to 450 heaped bushels.

For the best Stallion—the Gold Medal.

For the best full blooded Mare—the Gold Medal.

For the best Mare for improving the breed of farm horses—the Gold Medal.

For the best Bull for raising working Oxen—the Gold Medal.

For the best Bull for raising milch cattle—the Gold Medal.

For the best Cow for each of the above purposes—the Gold Medal.

For the best Ass—the Gold Medal.

For the best Boar—the Silver Medal.

For the best Sow—the Silver Medal.

For the best Ram—the Silver Medal.

For the best Ewe—the Silver Medal.

For the best conducted experiment of the cultivation of winter Flax on swamp or marsh land—the Gold Medal.

For the same on high land—the Gold Medal.

In order to obtain either of the above prizes, the candidate must forward to the Secretary of the Society a particular detail of the quality of soil, the preparatory culture, the quantity and preparation, if any of the seed, the kind and quantity of manure, and time of its application, the culture while the crop is growing, the mode of collecting in harvest, and the produce; stating also the produce of the same quantity of land, of similar natural quality, cultivated in the usual manner in the same season. The facts and circumstances to be attested by one or more respectable witnesses. In order to facilitate the compliance with this condition, printed returns with the heads of such information as the society requires, compendiously arranged, will be furnished to those who may require them, by the Secretary of the Society, on application at his house, No. 35 Meeting street, Charleston.

For the best constructed machine for threshing Rice, which has been in actual operation for one season, adapted to general use, by the small power necessary to give it effect—the Gold Medal.

For the best machine whereby the moating of cotton, usually executed by hand, may be completely performed—the Gold Medal.

To the Manager of two or more plantations, who shall produce the most satisfactory testimonials from those by whom he has been employed, of his diligence, skill, good management and humanity, for three preceding years—the Gold Medal.

To the Overseer of one plantation, who shall produce similar testimonials—the Silver Medal.

The animals to be produced before the Society at the house of their meeting, at the old Race Course, on the Monday and Tuesday previous to the Charleston Races; when convenient, a specimen of the progeny of each to be produced, as the best evidence of the value of the animal; without it, a certificate of their ability will be required; and, in all cases, certificates of their having been bred within the state, or having been imported, and kept for service the preceding twelve months.

JOHN HUME, President.

CHARLES E. ROWAND, Secretary.
Charleston, Sept. 23, 1823.

FROM THE NORTH AMERICAN REVIEW.

ARTICLE—ENCOURAGEMENT OF MANUFACTURES.

When we witness the zeal, with which the cause of manufactures is pleaded, and duties on foreign importation are demanded, we cannot but ask, with what justice so large a portion of the agricultural, the commercial, nay the manufacturing capital and industry of the country is to be forced out of the channels, in which it has flowed so long and so profitably, for the sake of providing a bounty for those branches of industry, which, were they profitable, would need no bounty! To destroy the importation of foreign manufactures would, as its first effect, be to reduce very low, if not to annihilate the market for our great southern staples. It would be to force the South Americans and the Hindoos to supply the British market with cotton, which they soon would be able to do, if the British manufacturer were unable to pay for our cotton with his fabrics. Let it not be said we should at home consume all the cotton which we now export. On the contrary, if it be correctly maintained that in general raw materials increase seven fold in value by manufacture, we should consume only one seventh of what is sold in England. We should be committing therefore on a large scale, the same error which England has committed on a small one, in forbidding the importation of timber from the north of Europe. She has injured her manufactures by taking away a market from them, and she provides timber for her navy at a greater expense. But this is not the worst, that would happen to us, by building up manufactures at the expense of our commerce; we should destroy the most flourishing manufacture now existing in America. After the little domestic manufactures, by which single families supply themselves with the necessaries of life, and small mechanics and artisans provide the most essential commodities for their villages (which, though insignificant in any one instance, probably amount, in the aggregate to one hundred millions of annual value, throughout the United States) next to these and far before any of the great manufacturing establishments of cotton, of wool, of iron, or of glass, we place the manufacture of ships. The tonnage of America in 1810, was estimated at seventy one millions of dollars in value; two thirds of which were employed in the foreign trade. With the exception of a con-

siderable part of the sailcloth, and an inconsiderable sum for hunting for colors*, this vast amount of value is produced out of the growth of our own soil, and of our own forests. On an average of all the years from 1803 to 1816, Dr. Seybert found,† that the annual amount of new tonnage in America, was 102,811 tons exceeding that of the British Empire. This gives an annual manufacture of tonnage of five millions of dollars. This orchard of manufacturing industry therefore must be two-thirds of it, sacrificed, and to promote other manufactures. And yet this vast amount of manufacturing industry is employed and paid by commerce, only in the very first step of her operations. This annual bounty of five millions of dollars paid to the forester and woodman, to the iron founder and smith, to the carpenter and shipwright, does but bring the vessel to the quay. Seventy thousand seamen, with their wives and children are next to be clothed and fed, or, in other words, more than nine millions of dollars are paid annually by commerce, in the single article of wages to seamen, at the rate of eleven dollars per month. As no account is here made of the superior wages of captains and officers, this estimate is quite within bounds. The subsistence of the crews, at the rate of twenty cents the man per day, amounts to over five millions of dollars per annum. And thus, in the pay and sustenance of seamen alone, fourteen millions of dollars are annually expended by the commerce of this country, in the wages and subsistence of the laborers it employs. Combining this with the five millions annually required to keep the American tonnage in repair, we have nineteen millions annually disbursed by the ship manufactory, to the laboring classes of the community. Here we stop, though it is as we have said, the first stage of commercial operations. We say not a word of the industry required to prepare the outward cargo, or vend the return cargo, each of which is put in motion by commerce, the former to the enriching of the great agricultural states, and the latter resulting in the growth of the great commercial cities. We say nothing of the service rendered to every individual, however remote or distant he may be, who is enabled by commerce to take advantage of the crowded population, the accumulated capital, and the intense competition which prevail in foreign countries; and thus purchase the most useful and necessary articles at the cheapest rate. We say nothing of all these, but we rest on the simple preliminary fact, that the commerce of this country, in the outset of its operations, without reckoning profit on an ounce of produce shipped for exportation, pays to the hard working industry of the country, nineteen millions of dollars annually. When it shall be proved that any or all of the manufacturing establishments of the United States do this, it may be argued with some plausibility, that they deserve to be built up at the cost of our commerce. Meantime a moment's reflection on this vast amount, which is paid by commerce in annual wages to those whom it employs, abundantly shews, that in commercial enterprises, comparatively speaking there is a vast consumption of labor and a small one of capital. To erect any manufacturing establishment, with tolerable prospects of success, a hundred or two hundred thousand dollars are wanted in the outset. There is not probably an American merchant ship that floats, worth forty thousand dollars, and the great mass of our navigation consists of vessels which are built and fitted

* Trench Coxe's Statement of the Arts and Manufactures of the United States of America, p. xix.

† Seybert, p. 310, 311.

for sea, at a cost of from four to twenty thousand dollars. With this small outfit, the globe is circumnavigated, and the fertility, the cheapness of labor, the peculiar staples, the accumulated capital and improved arts of every country, are laid under contribution to enrich ours. Certainly this is the circumstance which has caused our commerce to flourish so much beyond our manufactures. Not a want of capital, as some writers allege, but a want of capital in those great masses, which are required to set up manufacturing establishments. Capital, instead of being scarce, is abundant in this country, if by capital we mean such an amount of value as enables a man to undertake and prosecute an independent business. But it is in small amounts—Without reflecting that the existence of capital in small and widely diffused portions is, like the statute of distributions which is one great cause of it, not a disadvantage, but the happiest feature of our political condition; without reflecting that our progress is so rapid, that notwithstanding its perpetual division and distribution, capital is already gathering itself into masses, competent to the most expensive undertakings; our manufacturing writers have hit upon the notable device of raising a capital to carry on this business; and the burden of all their writings and addresses is 'we wish to raise a capital large enough to carry on a woollen factory, and we call upon every consumer in the country to pay us twenty cents on every dollar he consumes, toward raising this capital, of which we stand in need.' Such claims need but be plainly stated.

ON MILDEWED WHEAT.

Remarks by the Editor of the London Farmer's Journal, dated, August 11, 1823.

Our very respectable correspondent (Mr. Hilliard) has, in this day's Journal, revived the discussion of the mildew subject; having, it appears, adopted the opinion that excess of nutriment causes the disease, under certain circumstances, by exuding through the straw. It is certain that when the mildew takes place, the ascent of the sap is in proportion arrested and the perfect filling of the grain is prevented, or stayed, in proportion as the disease takes place, early or late, as to the progress of ripening. If the grain be filled, and a little approaching to hardness, the disease only takes off somewhat of the brightness of the quality, by shrivelling the later grains; but if the grains be milky, and the disease bad, the produce may be shrivelled up, and the ears ripened perpendicularly with nothing in them that can be threshed out.

But if the nutriment, by excess, burst through the straw, why or how should it take the form of a fungus? for this fact is not to be doubted. Neither if accidental frosts arrested the sap, and caused it to come through, would this consequence follow. The sap might form a gummy, or, at last, a powdery matter: but clearly it must be a semi-liquid substance at first. It is not, therefore, the exuding of the sap. There have been facts observed, and stated in this Journal, which sufficiently refute the above notions; and, unfortunately, there have not been any theories of the mildew but what are rendered nugatory by the contradictory circumstances under which the disease takes place. The Editor once observed in a field near Lynn, a crop of wheat, growing part on a rising hill, which was short and standing, and part in a hollow down towards the fence, which was long and laid flat. The first part was nearly destroyed with mildew, but the latter was bright and good. The hilly part of this field was rather a poor sandy loam, but, deepening to

the hollow, the soil was approaching to clay. This latter had by far the most nutriment, but it did not burst through. On a farm at Ketton, near Stamford, some years ago, they were reaping early wheats about the middle of August, very much mildewed, though light and middling crops. Some crops on the same farm were then green and much heavier, and would not be reaped in less than a fortnight: these proved bright and good. Upon due examination, the soil where the first grew was shallow and full of small loose stones, but the other part of the land was clay, though not good, yet well worked. These and all other facts which we have observed, go to prove that good clay soils seldom mildew their wheats; if there be an over proportion of vegetable mould, or of raw dung, or if the bottom be impenetrable to the fibres, or ill-drained where it is impervious to water, the mildew may take place. It appears, therefore, to be not the quantity, but the kind of nutriment, which may cause or prevent the disease; or rather, it is owing to the atmospheric changes to which light and pulverulent soils are liable: frequent rains after a series of warm weather (and contrariwise) may affect the fibres having but loose hold of the earth, in a very different manner from those which, on the approach of harvest, are impacted in a self-moist clay soil. The effect seems to be that the health of the plants is interrupted, they fall into a state of premature decay, and, like all decaying vegetables, throw out fungi.

Excepting what is indicated by this general mode of expression, our agricultural readers may rest assured that the cause of the mildew will never be discovered. Sir Joseph Banks having ascertained that in every speck, or blotch, in the straw, there was a crop of fungi, and that the heads of these ripened and discharged a black powder, directly inferred that this powder would spread on other straws and propagate the disease. In the same manner those persons must have argued who have ascribed the disease to neighboring barberry-bushes. But the truth is, that the mildew cannot be propagated by any outward application of diseased plants to healthy ones; nor by any mode of contact however varied, as to heat or moisture, and progress of ripening. It is also quite certain that the disease, in making its appearance, breaks through the cuticle, or outward skin of the plant, indicating the fact that the seed which, by vegetating, produces the visible effect, is enclosed in the parenchymous substance of the culm. It seems, therefore, that we are under the necessity of believing that these seeds (inconceivably minute) are absorbed from the soil with the food of the plant; and if so, there is no difficulty in supposing that soils most liable to mildew, are most charged with these seeds—and that the crops growing thereon are more filled with them than such as grow on good clays, where the straw is reedy and hard. If this reasoning be not satisfactory, we have nothing else to say, but that it is the nature of certain soils to mildew their wheats in certain seasons. The disease being a parasitic plant, we must say that nature has endowed the straw with a formative niais, or power of producing the plant under certain effects of the atmosphere. But really there are innumerable other facts in nature which are equally inexplicable, and which give us no disturbance at all. It is, however, very creditable to the ingenuity and research of those who have done all in their power to open this source of knowledge, so as to render benefit to agriculture; though unfortunately it amounts to no more than a steady conviction, now taking place, that the disease is by no means to be prevented.

MEMOIRS OF MR. ROTHSCHILD.

Mr. N. M. Rothschild is descended from a German lineage. Mr. R. sought to establish his fortune in England. Various were his vicissitudes in early life; by his industry and prudent conduct, he acquired considerable property in the linen trade at Manchester, vast quantities of which article, were exported during the last war to the Continent, where Mr. Rothschild availed himself of the peculiar advantage of his brother's agency in that quarter of Europe. Previously to the close of the late war, Mr. Rothschild transferred the scene of commercial operations from Manchester to London. He then became a considerable speculator in the Foreign and British Securities on the Stock Exchange; and after the melancholy death of Mr. Goldsmid, assumed a very prominent station in the money market. But the principal accident which contributed to the rapid elevation of our Modern Cræsus, was the escape of Buonaparte from Elba, in 1814.—In consequence of Mr. R.'s superior means of information on the Continent, this important occurrence was known to him nearly forty-eight hours before it was in the possession of any other person in this country. He did not fail to avail himself of every advantage which this priority of intelligence presented. His agents went into the market and sold prodigious quantities of stock. The consternation was dreadful! Every one suspected danger, none knew where to look for it. The panic was epidemic! On the disclosure of the fact, the general cry was *sauve qui peut*; and the object of our present article bore off the immense sum, gained by his success on this great and extraordinary occasion.

Mr. Rothschild, thus fortified in wealth, and enjoying at this time the almost exclusive means of acquiring the first intelligence from the Continent, soon established for himself a reputation and importance, the maturity of which can scarcely be said to have been accomplished at the present moment. He availed himself of a conjunction with his brothers, (who are also great capitalists on the Continent,) of the opportunity of administering to the wants of the King of Prussia, the Emperor of Russia, the Kings of Naples and Spain; the Republic of Columbia and other States, who negotiated loans on terms highly profitable to him; and which have, with the advantages of the courses of exchange, and other incidental benefits, realized immense sums in addition to his fortunate speculations in British Stock. But the great *coup de main* of Mr. R. consisted in his out-generalling the Gallic Financiers in the recent French Loan. In that transaction he is supposed to have cleared upwards of £100,000, by the commission alone, independent of the advantages of the courses of Exchange!

By the fortuitous occurrence of favourable circumstances, Mr. R. has been enabled to amass greater wealth, than any man that ever existed in England. It would be impossible for others to estimate his property, when Mr. R. has declared that he could not do it himself. It has been asserted, however, that he can command upwards of Fifteen Millions sterling at any time, if required! When it is considered that "money, the sinew of war," is in its amount illimitable, and in its control so much at the mere volition of Mr. R. it ceases to surprise the reader, that such a man should be necessary to the Potentates of Europe, and that his friendship and assistance should be no less anxiously sought, than promptly and powerfully afforded.

Mr. Rothschild is a Baron of the German empire, to the Emperor of which, he has rendered some essential services. He is about 43 years of age, and possesses a family of nine children. His

mode of life is remarkable for its retired description. Unlike his great predecessor, (Goldsmidt,) he does not boast of his choice and exquisite wines, or herald his hospitality towards the Princes of the blood. His appearance is unostentatious; his deportment familiar; and his manners unaffected and affable. His conversational style on 'Change is rapid, acute, and discriminating. He carries about him no aristocratical feeling; neither does he affect a singularity, the common concomitant of extraordinary genius, and the impotence of mental pecuniary plenitude. His face is distinguished by a lack of that piercing intelligence, which lights up and animates the expressions of those proverbial for their acuteness; but there is a quickness in the eye, which denotes a lively and unremitting watchfulness of the mind, on every subject of general interest.

When engaged in conversation, Mr. R. usually dangles a bunch of keys in his right hand, and indulges a habit of abruptly turning from the object to whom he is speaking, and suddenly renewing the colloquy. He possesses a memory so remarkably retentive, and the powers of mental addition so copiously strong, that he effects all his immense calculations without the agency of pen or paper: and often at those times, when the din of business "gives note of preparation" for a "rise or fall." His genius is of that order, which often enables him to perceive the benefit or disadvantage of a proposition, before the parties have fully viewed the surface. His movements are characterised by profound judgment: his attack is no less able, than his retreat judicious.

Mr. Rothschild's private character is, we believe, as amiable as his public life is important. He diffuses his benevolence with judgment and liberality. When solicited to countenance an Institution with his name, he answers, "You know I never take a public part; if you want (as I suppose you do,) money; name the sum, and you shall have it; but don't make me look ostentatious or mean, by naming too large or too small a sum." His eleemosynary contributions are chiefly distributed amongst objects of the Jewish persuasion; who have in many instances arrived at a state of opulence through his instrumentality. Such a liberality of disposition, and philanthropy of character, has divested envy of her deadly influence; and created for Mr. Rothschild, an imperishable reputation, which will descend with advantage to his family in after ages.

FOR THE AMERICAN FARMER.

FOUNDATION WALLS FOR MILLS.

In reply to some enquiries made in the American Farmer No. 27, on the subject of securing the foundation of brick walls for mills. The writer has not actually built any of that kind of material, but has often seen defects in the bad management of foundations of brick and stone both, by not laying them deep enough, more especially when the water wheel was placed close on the our side. It ought to be an universal rule to avoid placing the water wheel near to the main house walls; it should be distant enough to admit a safeguard wall between the water wheel and house, which will of course require a longer shaft.

Now, if the situation of ground will admit, I should prefer the placing the water wheel in the centre of the building; then you avoid any bad effect of water undermining any but the pit walls which are easily repaired, if any failure happened, they not being higher than the ground floor. I have built two stone mill houses with heavy walls, and one was 85 feet long, 35 wide, which gave ample room for the water passing

through the centre and water pit, that received a 6½ feet water wheel having both ends of the shaft at liberty to receive cogwheels to communicate motion to any part of three stories, and the house is now fully occupied with machinery; my foundations being 4 feet base, heavy stone laid across the wall. I built another since, and had no reason to alter the plan of the former, but pursued it—the house was 55 feet long, and 45 wide; my walls 2 feet 6 inches, the first story, 2 feet the next, and 20 inches to the third, leaving an offset of 6 inches at each floor, to rest the ends of the main girders on, and to prevent any break in the walls: both of these mills are sound walls without a crack; the first has been built thirty years, the other twenty years, the former was burnt and rebuilt on the same walls.

Respecting brick walls, I have not had experience further than observation has given, except their duration in water—I once had a full experiment; the brick was hard and well burnt; as any one of the slightest observation must know, that slack burnt ones will absorb water, and burst to pieces the first of their freezing and thawing afterwards. Those were hard, well burnt to top the chimney of a sawmill; a great freshet about 4 years after moved my saw mill, so far as to cause it to be taken to pieces; we collected most of the brick, but some was buried under the gravel, so as not to be found until ten years after; they were hooked out, a lump of half a dozen sticking together, being a corner locked so together, as not to be readily broken, by lifting them up and dashing them on the ground, until some of the brick, to my astonishment broke, rather than leave the mortar, that had lain under water ten years—this proved that water had no effect on the mortar cement, after being first fairly dry.

I do not know of a better cement, than a due proportion of good sand and good lime well burnt, and well worked, and not to put in a very large portion of lime, leaving it to mellow in mass covered up with sand; if it should be a week or even a month all the better, then work it all over well.

Now as to the thickness, it ought to be governed by the size and dimension of the building; the base secured by heavy plank laid in the bottom two abreast, or flatted logs equally good, to give the wall an equal bearing; this will do for any common soil; if very soft, piling is the only remedy. It is the well securing the foundation that is of the first importance, no good is to be had from the extra thickness—I have seen a 3 feet wall of brick built to a large and powerful mill, becoming thinner, as it advanced up; I do not know the proportion.

I should think 24 inches up to the ground floor, then 20 inches the first story, and eighteen above, amply strong, and grout the walls at every layer, by pouring in mortar in a liquid state, this fills it solid, and it becomes as one solid mass—and I think less than that would do, except the house is designed for a great and uncommon burthen.—But seasoned timber is important; if green, they shrink and leave vacancies, and the walls depending on the wood, leaves a vacancy to settle one side of the wall more than the other.

C. K.

TO THE EDITOR OF THE AMERICAN FARMER.

MAKING WINE—PRACTICAL AND USEFUL FACTS.

Vineyard, near George-Town, }
D. C. Sept. 30th, 1823. }

DEAR SIR,

I have this day put the last barrel of wine of this vintage in my cellar—I have twenty-five bar-

rels of the different kinds (the produce of about two acres,) viz:

9 barrels of Constantia, containing	301 galls.
6 do. Tokay, do.	202 do.
3 do. Bland Madeira, do.	102 do.
5 do. of the above grapes mix'd do.	158 do.
2 do. Worthington grape, do.	64 do.
1 keg made of the Fox Grape, cultivated,	10 do.

Total 837 galls.

of which about one seventh will be lees, &c.

The grapes did not ripen so well nor so equally this, as they did last year, and were upwards of two weeks later in ripening; and a great many more mildewed and rotted than usual, owing to the wet weather in August.

To answer a number of enquiries, of how much wine will a bushel of grapes produce? I had twenty-two bushels of the Constantia grapes picked, and in the bunches they weighed 45 lbs. the bushel, and when picked off the bunches, they measured 12½ bushels, and weighed sixty-six pounds the bushel.—They were then bruised and put into a vat, and after the pulp and coloring matter was dissolved, (which took three days) the juice was drawn off from the bottom of the vat, and produced fifty four gallons of pure juice.—Then the skins and seeds were put to the press, and produced ten and a half gallons more; making on the whole sixty four and a half gallons of juice from twenty-two bushels of bunches of grapes—I then had twenty bushels of the Tokay grapes gathered, and in the bunches they weighed forty-four and a half pounds.—They were bruised and fermented one night, when there was forty three gallons of pure juice drawn from them, and when they were submitted to the press, they produced sixteen gallons more; making in all fifty-nine gallons.—If the season had been drier, I suppose there would not have been so much juice in the grapes but it would have been richer—but I have no doubt on an average of years, the above-mentioned grapes will produce more than two and a half gallons to the bushel of bunches.

About one third of all my Bland Madeira grapes became mildewed or otherwise perished—and it has been the worst year that I ever knew of for ripening grapes.

About eleven bushels of grapes in the bunches, on an average, made a barrel of wine—and an acre will on an average, make upwards of four hundred gallons.

I am, Dear Sir,
Very respectfully,
Your's &c.

JOHN ADLUM.

P. S.—As there were considerable quantities of grapes sold in the market, and otherwise disposed of and given away, I think I must have had near 300 bushels.

The Egyptian millet you sent me, grew upwards of 10 feet high, and has heads of more than 20 inches long, only one of which blossomed, and was destroyed last night by the frost.—The Sena grew very luxuriantly, being now more than seven feet high—the frost has not yet injured it—it is full of blossoms, and has some seed pods which I fear will not ripen, and as it appears to be an annual plant, will of course be lost.

J. A.

Cheap Method of making Blacking for Shoes.

Ivory-black, two ounces; brown sugar, one ounce and a half; and sweet oil, half a tablespoonful—Mix them well, and then gradually add half a pint of small beer.

From Memoirs of the Board of Agriculture of the State of New York.

ON THE NECESSITY OF CHANGING SEED.

[From the Farmer's Magazine.]

*Have you found it of service to change the seed of plants, from one soil or climate to another, and why?—From the almost universal adoption of the practice, it seems that experience has fully justified it. In the case of exotics, that do not arrive at perfection in an alien climate, it does not seem wonderful; but in the case of naturalized vegetables, I cannot explain it.—*Bath Society Papers*

Sir—Not having access to a complete set of your useful work, I am not aware of what discussions it has furnished on the subject of the necessity of a change of seed in the cultivation of corn; but, as an endeavour, however humble, to fix the principles of that necessity, may at the approaching season not be uninteresting to farmers, I have taken the liberty of submitting what has occurred to me from an imperfect consideration of it.

I understand a belief in an abstract necessity for an occasional change of seed to be very generally entertained, and to be founded on a supposed repugnance between the soil of a farm and a succession of plants descended from a particular stock of seed. This antipathy is said to be a secret principle in the economy of plants; and those with whom I have conversed, unable to account for it, consider it sufficient to say, the soil tires of the plants, or the plants of the soil. In this, it appears to me, there is much delusion; for I hold that, abstractedly, there is no efficacy in, and therefore no necessity for a change of seed. The grounds of this opinion I shall endeavour to explain.

Without going into the never-to-be-determined question, What is the food of plants? I take it for granted that each species of vegetable has its peculiar pabulum; and that this peculiar matter must exist in the soil in which the seed of that plant is sown, otherwise it will not be produced in a perfect state. If any particular species of vegetable be repeatedly cultivated in the same field, it may so exhaust its food in that soil, that the latter will become unfit to produce the plant in perfection; and other circumstances, such as the application of certain manures, may incapacitate a piece of land from carrying a particular species of plant to maturity. But, in this case, a mere change of seed will not prove a remedy. Something must be done to restore to the land the pabulum of the plant sought to be cultivated in it, otherwise a change of seed will prove of no avail. Again, I conceive that a plant, after being deteriorated, by unfitness of soil, inadequacy of climate, or faulty cultivation, may be restored, by being transferred to better soil, or a more genial climate, or by being more carefully cultivated. But this is no proof of an abstract efficacy in a change of seed. Here there is a concomitant change of circumstances, which plausibly accounts for the improvement: for we are entitled to hold, that corn, once degenerated, cannot be reproduced in a more vigorous state, unless it be transferred to land different in the circumstances either of climate, soil, or mode of cultivation. Still further, corn crops may degenerate by the gradual operation of an unfavourable climate, or by the natural barrenness of the soil in which they are raised. In such a case, the farmer finds an advantage in having recourse to fresh seed the produce of a more genial climate or better land, or

even of a neighbouring farm under the same circumstances of soil and climate as his own, if the corn produced on that farm, from being more nearly related to a good stock of seed, happens to be less degenerated. This, however, does not furnish evidence of an abstract efficacy in a change of seed; for it is clear, that the farmer would not have bettered his circumstances had he not obtained seed of a quality superior to what was produced on his own farm. Again, we know that crops may become deteriorated, by the adoption of the too general practice of sowing corn nearly as it grows, using little pains to separate the good seeds from weak and imperfect ones; or by a faulty rotation, or by many other circumstances of mismanagement. In such a case, it may be a temporary improvement to obtain a fresh supply of seed. But this does not establish the abstract efficacy of a change; for still the improvement depends solely on the farmer having selected seed of a quality better than his own, otherwise it would be absurd to suppose that his crops could have been meliorated by a change. In short, in every supposable case of change of seed, any improvement that takes place must be the effect of some concomitant change of obvious circumstances; and the necessity of the change seems to have no relation to the *je ne sais quoi*, that mysterious antipathy between the soil and a particular race of plants, which is said to be excited by their long familiarity. This is the abstract necessity of which I presume to dispute the existence; maintaining, that there is no necessity for "changing the seed of plants from one soil or climate to another," unless in the case of a degeneracy of crops, from some of the obvious causes I have alluded to; and in such a case, an improvement can be effected only by obtaining a supply of better seed. This, too, is the only case in which there can be any efficacy in a change, except the object be to obtain a better variety of a particular plant than what is already possessed. With this view, it may be justifiable to sow seed, though even inferior, as a sample, to what is already produced on the farm, if superiority of soil, climate, or cultivation, afford a reasonable prospect of improving the quality of the new variety.

I am quite aware of the nicety of this question, and sensible of my own incompetency in the discussion of it; but I shall think I have done enough, if some of your enlightened correspondents should be induced, from what I have said, to edify us with their sentiments. XN.

Stonehaven, 3d January, 1820

Editorial Correspondence.

TO KILL INSECTS WHICH ATTACK FRUIT TREES.

Springfield, 4th October, 1823.

So many complaints prevail about the insects that injure fruit trees, and particularly the peach, that I take the liberty to ask an idle corner for the following application, which is believed to be very efficacious. Let one drachm of corrosive sublimate be dissolved in a gill of gin, and diluted with four quarts of soft water, then apply the mixture with a paint brush, it does no injury to the trees, but effectually destroys all the vermin.

J. S. SKINNER, Esq.

PYROLIGNEOUS ACID.

Extract of a letter from a correspondent dated MORGANTON, 12th September, 1823.

"Will some of your correspondents have the goodness to give us the method of preparing the Pyroligneous acid, whether by saturation, by distillation, or in what way,—the kind of wood that yields it in the greatest quantity?"

FROM "EXPERIMENTS IN CHEMISTRY."

To prevent Beer from growing flat.

Put into a cask, containing eighteen gallons, a pint of ground malt, suspended in a bag, and close the bung perfectly; the beer will be improved during the whole time of drawing it for use.

To recover Beer when sour.

When beer is become sour, add some oyster shells, calcined to whiteness, or a little powdered chalk. Either of these will correct the acidity, and will make it brisk and sparkling. It should be drank almost immediately afterwards. Some use salt of tartar.

To bottle Porter.

It has been supposed by many persons, that in bottling porter there is some preparation made use of not generally understood: readers may rest assured, that nothing more is necessary to produce good bottled porter, than attention to the following rules:

Let the bottles be clean washed and drained dry—the corks sound and good, for this is essential. Fill the bottles on one day, and let them stand open till the next: this will bring the beer to a proper flatness, and prevent the corks from flying, or the bottles from bursting. Let the bottles be corked as close as possible.

These rules will apply equally well to the bottling of ales.

Cheap and wholesome Table Beer.

To four pounds of coarse brown sugar, add ten gallons of water, then put in three ounces of hops, and let the whole boil for three-quarters of an hour, and work it as usual. It should be kept a week or ten days before it is tapped, when it will improve daily afterwards, within a moderate time of consumption.

Another method, and for a smaller quantity, is, to put a pound of treacle to eight quarts of boiling water; add two bay-leaves, and a quarter of an ounce of Ginger in powder. Boil the whole for fifteen minutes, then let it become cool and work it with yeast.

Ginger Beer.

To every gallon of spring water add one ounce of sliced white ginger, one pound of common loaf sugar, and two ounces of lemon juice; boil the mixture nearly an hour, and take off the scum; then run it through a hair sieve into a tub, and when cool (viz. at 70°) add yeast in the proportion of half a pint to nine gallons; keep it in a temperate situation two days, during which it may be stirred six or eight times; then put it into a cask, which must be kept full, and the yeast taken off at the bung-hole with a spoon.—In a fortnight, add half a pint of fining (isinglass picked and steeped in beer) to nine gallons, which will, if it has been properly fermented, clear it by ascent. The cask must be kept full, and the rising particles taken off at the bung-hole.—When fine (which may be expected in twenty-four hours) bottle it, cork it well, and in summer it will be ripe and fit to drink in a fortnight.

Preparation of Yeast.

It has been mentioned before, that yeast is the barm or froth which rises in Beer, and other Malt-liquors luring a state of fermentation. When thrown up by one quantity of Malt or Vinous liquid, it may be preserved to be put into another, at a future period; on which it will exert a similar fermentative action. Yeast is likewise used in the making of bread, which without

such an addition would be heavy and unwholesome.

It has a vinous, sour odour; a bitter taste, arising from the hops in the malt liquor; and it reddens the vegetable blues. When it is filtered, a matter remains which possesses properties similar to vegetable gluten; by this separation the Yeast loses the property of exciting fermentation, but recovers it again when the gluten is added. The addition of Yeast to any vegetable substance, containing saccharine matter, excites fermentation by generating a quantity of Carbonic Acid-Gas. This very useful substance cannot be always procured conveniently from malt-liquor for baking and brewing; the following methods will be found useful for its extemporaneous preparation.

Mix two quarts of soft water with wheat flour, to the consistence of thick gruel, boil it gently for half an hour, and when almost cold, stir into it half a pound of sugar and four spoonfuls of good yeast. Put the whole into a large jug, or earthen vessel, with a narrow top, and place it before the fire, so that it may, by a moderate heat, ferment. The fermentation will throw up a thin liquor, which pour off and throw away; keep the remainder for use (in a cool place) in a bottle, or jug tied over. The same quantity of this, as of common yeast, will suffice to bake or brew with. Four spoonfuls of this yeast will make a fresh quantity as before, and the stock may be always kept up, by fermenting the new with the remainder of the former quantity.

Permanent Ink for Marking Linen.

This useful Ink is composed of Nitrate of Silver (Lunar Caustic;) and Tincture, or Infusion of Galls; in the proportions of one dram of the former in a dry state, to two drams of the latter. The Linen, Cotton, or other fabric, must be first wetted with the following liquid, viz. Salt of Tartar, one ounce, dissolved in one ounce and a half of Water; and must be perfectly dry before any attempt is made to write upon it.

THE FARMER.

BALTIMORE, FRIDAY, OCTOBER 10, 1823.

The Editor of the American Farmer, well aware of the taste and patriotism of the ladies of the Eastern Shore of Maryland, and how materially and honorably they contribute, by their notable housewifery and good management, to the comfort and independence of their families, begs leave respectfully, to present to them his respects, and to offer his services, to show for them such articles of household manufacture, as they may wish to send for premium, to the next Maryland Agricultural exhibition, to be held near Baltimore, on the 5th of November—to explain what he wishes to be understood by this tender of his services.—It may happen that ladies may have prepared or manufactured, certain commodities, and have difficulty in sending them for want of some one, to take charge of and attend to them—what we mean then, is, that if in all such cases they will have them carefully put up and labelled, and sent by Capt. Vickers, of the steam boat, addressed to the Editor of this paper, he will cause them to be taken out and fairly exhibited, and either sold, if the owner so wish, or safely returned by the same conveyance. Premiums awarded for any such articles, will be received and carefully deposited with Capt. Vickers.

SUPERIOR WHITE WHEAT AND OATS.

Messrs. Haven & Smith of Philadelphia, have rendered a very acceptable service to the Agricultural community by the importation of white wheat and oats, both of very superior quality, from Rotterdam. Farmers and millers, are invited to call at the office of the American Farmer, where samples of each may be seen, and will be much admired.—Messrs. Hammond & Newman, of this city, will have a few bushels of the wheat for sale, and farmers in the white wheat district, on the Eastern Shore of Maryland, ought to secure some of it for seed, by way of experiment. In Philadelphia, the wheat is held at \$2, and the oats at 75 cents per bushel.

VERY FINE RACING EXPECTED.

The association formed in this city for the improvement of the breed of that noble animal, the horse, have proceeded with great spirit and directness to their object. Subscriptions already made, have warranted the Club, in offering very liberal purses for three days racing, to commence on Tuesday the 22d of this month. The sum to be run for on Thursday, is ONE THOUSAND DOLLARS, and will doubtless bring upon the turf, the swiftest coursers of Virginia and other States.

Some good citizens object to racing altogether, while others deprecate with too much reason, the manner in which they are often conducted, as being promotive of gaming and other species of dissipation. Those therefore who take pleasure in the sports of the turf, as a source of manly and rational amusement, and as the only effective means of preserving the blood horse in his purity, have long desired to see these sports revived, with such precautionary arrangements and guarantees, as will replace them on the most respectable footing, and preclude from the course, every thing offensive to the eye or ear of the most scrupulous. This we trust in regard to the Baltimore races, has been fully accomplished; such at least is the hope and the intention of the gentlemen now associated, who will use every possible effort to justify the expectation, which their names have excited, and they ask and expect the co-operation of all those of their fellow citizens, who take an interest in the character of the city, and in the particular objects of the society.

DESTRUCTION OF THE TOBACCO CROP BY FROST.

Extract of a letter from one of the most opulent and judicious Planters in Prince George's County, to the Editor of the American Farmer, dated 30th September, 1823.

Last night we had, quite unexpectedly, a severe frost. I think I speak within bounds, when I say it has destroyed at least one half of the present crop of tobacco in Prince George's—which you know to be a large proportion of the tobacco made in the State of Maryland. If we have suffered so considerably here, in the upper counties they must have suffered still more severely. I have before seen considerable loss by frost, but nothing like the present—yesterday the forepart of the day was quite mild, and about 12 o'clock, in the field, the shade was quite agreeable; nor did it turn cool till towards night, when the wind was from the North-West; and after night it blew a gale, and continued so for some hours. The frost this morning astonished me, and I have no doubt did others; indeed, it stole on us as a thief in the night.—Mr. Hogoverth and Mr. John H. Hodges, of your city, were with me yesterday, would lodge somewhere in the neighborhood

of Upper Marlborough, and I have no doubt have seen enough this morning, and on their return to-day to Baltimore, will confirm what I have said. You may rely on the devastation being greater than you can have any idea of, remaining, as you do, in a city so closely built, you would not feel it.

All the accounts, of which we have many from different quarters, go to shew the loss of one half the crop. The peculiarities of the season had kept the tobacco in a growing state, and prevented it from ripening, to a later period than usual,—and the frost being earlier, and for a few hours very severe, the calamity has been heavy and extensive. It is a fact too, that a much greater number of houses filled with tobacco, have been burned, than ever were in one season before, and this is ascribed to the great desire to give their tobacco the highest possible color, to which the planters have been prompted by the great difference now made between dull and bright, and the very high prices at which the latter has been sold.—Firing, to be effectual, is at all times a dangerous process, and in pushing it too far, there has been a great number of houses burned.

Edit. Am. Farmer.

BALTIMORE MARKET.

PRICES CURRENT—CORRECTED WEEKLY.
Flour, best white wheat, \$7 25—Howard street, from wagons, \$7—fine do. \$6 50—Wharf, do. \$6 to \$6 25, do. do. \$6 cash—White wheat, \$1 20 to 1 30—Red do. \$1 10 to \$1 15, for Maryland, and \$1 to \$1 09 for Virginia—Rye, 44 to 45 cents—Corn, 36 to 38 cents—wharf Oats, 27 to 30 cts.—wagon Oats, 31 cents—Beef, 8 cts. per lb.—Live Cattle, \$6 to \$6 50, per cwt.—Bacon, hog round, \$10—Pork, \$7 50 per c. lb., 6 to 8 cts. per pound—Mutton, 5 to 6 cts. per lb.—Beans, retail, \$1 50, cargo price, 1 12½—Peas, retail, 75 a 80 cts., cargo price 58 a 60 cts.—Red Clover Seed, \$6—Orchard Grass do. \$3—Herds' Grass do. \$3—Timothy do. \$4—Flax Seed, 75 to 80 cents—Whiskey, from the wagons, 30 cents per gallon including the barrel—Apple brandy, 30 to 32 cts.—Peach do. 65 to 70 cts.—Shad, \$6 00.—Herrings, No. 1, \$2 70 per bbl., No. 2, \$2 37½—Fine Salt, 75 cents per bush., coarse, do. 70—Butter, (firkin) 14 cts. per lb.—Eggs, 12½ cts. per doz.—New Hay, \$15 per ton, old do. \$16—Straw, \$9.

MARYLAND TOBACCO.—As last report, except the inferior qualities, which may be quoted from 50 cents to \$1, higher in demand.

University of Maryland.

THE MEDICAL LECTURES will commence as usual, on the last MONDAY of October next.

Surgery,	<i>John B. Davidge, M. D.</i>
Chemistry,	<i>Elisha De Butts, M. D.</i>
Practice of Physic,	<i>Nathaniel Potter, M. D.</i>
Anatomy,	<i>Granville Sharp Pattison, M. D.</i>
Materia Medica,	<i>Samuel Baker, M. D.</i>
Institutes of Physic,	<i>Maxwell McDowell, M. D.</i>
Midwifery,	<i>Richard W. Hall, M. D.</i>

As the Infirmary attached to the University will be finished before the last week of October, the Clinical Lectures on Medicine and Surgery, will commence the first week of the session.

ELISHA DE BUTTS,
Dean of the Medical Faculty.

Printed every Friday at \$4 per annum, for JOHN S. SKINNER, Editor, by JOSEPH ROBINSON, on the North West corner of Market and Belvidere streets, Baltimore; where every description of Book and Job Printing is executed with neatness and despatch—Orders from a distance for PRINTING or BINDING, with proper directions promptly attended to, addressed to J. Robinson, Baltimore.

AGRICULTURE.

From Memoirs of the Board of Agriculture of the State of New York.

ON PRUNING OF ORCHARDS.

[From COXE on Fruit Trees.]

There is no branch of the management of orchards less understood, or more unskillfully performed, than the operation of pruning; a belief of its necessity is so general, that even the most careless will seldom omit it—such however, is the want of skill in many of the operators, that total neglect would be less prejudicial, than their performance of it. If judiciously done, pruning promotes health and early fruitfulness; and will continue a tree in vigor, long after the common period of its duration. Nothing has contributed more to the imperfect knowledge of this operation, than the wordy and unintelligible systems which have been published respecting it; in a mere practical system, it is unnecessary to lay much stress on *wood branches* and *fruit branches*; which, however well understood by an observing intelligent gardener, can scarcely be comprehended by the labourer, employed in the business of pruning an orchard—from the rapidity of vegetation, which is generally ascribed to the nature of our climate, excessive pruning is very apt to generate an infinite number of suckers from the limbs of apple trees; which, if suffered to grow are more injurious to the production of fruit, than the woody branches which are removed; our great heat, and dry atmosphere, render close pruning less necessary here than in England, whence we derive most of our instruction on this point. A good general rule is, never to shorten the branches, unless to improve the figure of the tree; and then to take them off at the separation, very close, so that the wound may heal well and soon: the branches should shoot as much as possible in increasing distances, as they proceed from the common centre, inclining a little upwards, by which means the sap will be more evenly impelled, and better distributed; the ranges should not approach too near to each other; for the admission of the rays of the sun is necessary to the production and perfect maturity of fine flavoured fruit—in cutting off a branch, it should be done as close as possible, never leaving a stump, for the bark cannot grow over it, and disease in the wood will inevitably follow. If the wound produced by the separation be very large, cover it with tar, or thick paint; if small, fresh cow dung will be the best plaster: I have healed very large wounds from the gnawing of calves, horses, and sheep, by a liberal application of this plaster, secured by a bandage of paper or linen.

When trees are much pruned they are apt to throw out numerous suckers from the boughs in the following summer; these should be rubbed off when they first appear, or they may be easily broken off while young and brittle—cutting is apt to increase their number. Trees differ much in their form, and require very different treatment in pruning; it may not be necessary in our warm climate to trim quite so close as in England, but great care should be observed to take off every limb which crosses another, or is likely so to do at a future time; those who can conveniently do it, will find a benefit from forming the heads of their trees in the nursery, the year before they remove them—when transplanted, they will thrive more rapidly from not having been pruned, at the time of removal, which in some measure exhausts and weakens the tree; I have been latterly in the habit of giving the principal pruning to my orchards, after they have been planted out about five or six years; their growth, with proper cultivation is then so vigorous, as to permit any natu-

ral defects in their forms to be corrected with safety, by free pruning, and forming their branches; the peculiarity of growth which characterizes each kind, is then visible, and uniformity of shape may be more easily attained.

Apple trees should be so formed, as to allow a man and horse to pass under them in ploughing; this elevation of the branches, while it protects them from cattle, opens the ground to the salutary influence of the sun, on the crops of grain and grass.

No error is more universal, than an anxiety for early productiveness in an orchard; it is generally obtained at the expense of much eventual profit, and by a great diminution of the size and vigor of the trees; believing early fecundity to be injurious to the vigor and perfection of plants, I am always attentive to pluck from the trees these evidences of early maturity, in the first stages of their existence.

It was a common practice, some years since, to apply Mr. Forsyth's celebrated composition to large wounds produced by pruning; that novelty like many others, had its day among us; and has finally lost its popularity, from a general belief of its inefficacy—Mr. Forsyth, at a later period, announced as a new discovery, what had been long known in this part of our country; that an application of cow dung and urine, was more efficacious in healing the wounds of trees than his plaster, even in the moist climate of England: In America our winter frosts decompose it, and our summer heats dry it up so completely, as to render it useless for the purposes intended.

FROM THE SAME.

ON THE MANAGEMENT OF COWS.

By RUSSELL WOODWARD, of Suffolk.

Having formerly kept a large number of cows, I observed many amongst them that dried up their milk so early in the fall, that they were not profitable, while others, with the same keeping, gave milk in plenty until late in the season. I likewise have often heard my neighbors observe, that some of their cows, though very good in the fore part of the season, dried up of their milk so early, that they were unprofitable, and they should have to put them off; I accordingly found it expedient to find out the cause, if possible: and when I brought to mind the ways that some of my young cows had been kept and milked, I attributed the cause to the milking of them the first season they gave milk; and by many experiments since, I have found that young cows, the first year they give milk, may be made, with careful milking and good keeping, to give milk almost any length of time required, say from the first of May to the first of February following, and will give milk late always after, with careful milking. But if they are let to dry up of their milk early in the fall, they will be sure to dry up their milk each proceeding year, if they have a calf near the same season of the year; and nothing but extraordinary keeping will prevent it, and that but for a short time. I have had them dried up of their milk in August, and could not by any means make them give milk much past that time in any proceeding year. In 1820, I had two heifers, which had calves in April, and after getting them gentle, I set a boy to milk them for the season, (which is often done the first season, on account of their having small teats:) he was careless, and dried them both off in August. Although I felt satisfied I should lose the greater part of the profit of them afterwards yet I took it upon me the following year to milk them myself, and give them good feed, but to no purpose. I could not make them give milk much past the same time they

dried the year before. I have two cows now that were milked the first year they had calves, until near the time of their calving again, and I have continued to give milk as late ever since, if we will milk them.

FOR THE AMERICAN FARMER.

THE IRRIGATOR.

Charleston September 10, 1823.

DEAR SIR,

The notice that has been taken of the irrigator, by the Editor of that valuable repository of agricultural information, the American Farmer, in consequence of your communication to him—calls for an acknowledgment on my part, of his liberality and friendly disposition towards individual research and industry—and of your flattering attentions on the occasion, which I must be allowed to impute, more to the public spirit, which animates your exertions in the cause of agricultural improvements, than to any claim that I would otherwise have on them. It is with reluctance that I trouble you again on the same subject; but as the irrigator has attracted the notice of several gentlemen, pro and con, and as the faults and deficiencies of the machine, ought not to be laid at your door, it seems but just and proper, that I should give the reasons, which led to the construction of it. Believing that salt-water, particularly if made very muddy, would be a valuable acquisition to planters and farmers on the sea board, if it could be got on the land, in such quantity, and at such an expense, as to gain time, save labour, and not to interfere with the general modes, or rules of planting—I began to turn the thing in my mind. Several plans presented themselves, and among others, a carriage with wheels and a box or cask; but as our farms and plantations are generally cultivated, to wit—on beds or ridges, from four to eight feet apart, and the great desideratum, was to get a machine that would run through the alleys, without injury to the growth on the beds or ridges, and which would be used at all times of the year—I soon found that no box or cask, could be used on wheels, without being reduced to so small a size, as to defeat the original design; inasmuch as the multiplicity of turns which so small a machine would have to make, to carry out the requisite quantity of water for an acre of ground, would take up so much time, and would require so much additional labor, as to render it unwise and imprudent, to resort to this mode in preference, to the ways and means hitherto resorted to, to manure land. It was evident also, that if even it was constructed upon a scale of seven feet wide—(the only dimensions that I conceive, could really render it beneficial,) and supposing the alleys to be eight feet wide, there would be great danger of the wheels destroying the plants on the beds, or of their so compressing or binding the earth around them, that it would be better to dispense with the watering, than to risk the destruction of the previous labour. Hence, I concluded to try the cask in the manner in which it was represented to you, in the draft; and finally adopted it, as the most eligible mode, of realizing the principle of economy, which ought never to be lost sight of in matters of experiment, and of gaining the end proposed by the labour. I beg leave to notice the following, as some of the advantages of the cask on felloes, over a cask on wheels. If the alleys are no more than five feet wide, a hogshead four feet long, can discharge its contents from both heads as it revolves. (which was the original intention,) without injuring any thing on the beds, or the beds themselves, while they would be watered, or manured if you

please, on each side, leaving the alleys, where the fellos run, to absorb the surplus water, keeping the earth mellow, and in a state to be profitable when hauled up to the plants—a cask on fellos, can be, at very little expense, and with very little trouble, brought immediately into use, can be employed in any stage of the crop, provided the beds are five feet apart, saves time, and considerable labour, both to man and beast—the economy of the thing alone, is obvious, in regard to the difference between the cost of a pair of wheels and a hog-head. Another reason in favour of the fellos, is that at every revolution of the cask, the water itself, taking the direction of the moving power becomes a considerable *impellent*, from its motion and weight against the cask, as long as there is any water in it. I presume it will not be denied, that a weight raised, though no more than four feet from the earth, is more likely in consequence of that very elevation on *wheels*, to make a greater resistance, and to have a more direct tendency to sink them deeper in soft ground, than if the same weight was running on the ground on its own axis, or so near the ground as to be influenced by *every jostle*, which it is liable to experience, from uneven ground. It is an acknowledged principle, that the farther any body is removed from the point to which it is attracted by the force of gravity, the greater will be its progressive velocity in its descent, according to its space, through which it has to pass; of course, the greater will be its pressure, wherever it falls or rests—this ought to give the fellos a preference over wheels—as well, because they have *no friction*—“as because there are no bodies sliding one over another, which, is proportionate to the weight laid upon them; and as friction not only depends upon the moving bodies, but on the irregularities on the surfaces, upon which they move.” but it is not necessary to my purpose, that I should enter into a discussion of this kind. I am satisfied with the few hints, that have been given, by Mr. Gideon Davis and Mr. John D. Craig, who I am pleased to find, are favourably impressed with the practicable operations of the machine. It is clear to my mind, that fellos cannot be subject to as many difficulties and inconveniences as wheels; for if owing to the softness of the ground, the fellos should sink to their whole depth, (an extreme case,) still the cask, bearing then its own weight, would ease the draft, by running on its own surface, and would relieve the fellos, without having the constant effect, (now not wanted) of the roller.

The idea suggested by Mr. John D. Craig, respecting *small staves*, agrees with my own view of the case, when the machine is intended to be used as a roller, as well as for watering; but in that case a cask without fellos had better be resorted to, and to avoid any difficulty with regard to the bung, a tapering plug could be used; since however hard it might be forced in, it could easily be started, when wanted to be drawn to fill the cask: this kind of stopper for the bung hole, I would recommend at all times. I cannot conceive, nevertheless, that those staves, could be often wanted, for although the ground might be soft, there can be no reason to apprehend, that the fellos, with a face or tread of six or nine inches, would ever sink to any thing like the depth, to which a wheel would go. In addition to the weight of the wheels themselves, and the carriage, the very elevation of the cask, would, at every surge or jostle, and by its weight, force the wheels deeper into the earth, than the same weight, running on its own axis, and liable to no such effects, could possibly sink a pair of fellos, standing not more than two feet apart.

Upon the whole I think, that whether on the score of economy, practicability, or usefulness—the cask on fellos, is the least complex, the least subject to be put out of order, and the most at the command of every planter or farmer. I could have made additions to it—but whether they would have been improvements, is questionable; they certainly would have increased the expense, and it was an object to avoid that—for instance, I might have recommended that a spout, such as is attached to a watering pot of the largest size, should be fixed in each head of the cask, and of such length and diameter as to allow full play to the shafts on the axle. This would have answered the purpose of the *box with holes*, but this would have been expensive, liable to repairs, not easily made, without any real solid advantage; because the main object, is to get the water on the land at the least expense, the most expedition, and the least trouble: and if this can be effected by a spigot and faucet, a plug, or otherwise, it was immaterial, the mode least liable to casualties was the best; I therefore adopted the plug, (which if lost could be easily replaced on the spot,) as being less objectionable, than a box with holes, or the spout of a watering pot: besides, it did not strike me, that any injury would arise from the water being discharged through a plug hole; nor that any special benefit would arise from its being scattered like rain. Such however, as the irrigator is, such it must remain for the present. If it turns out to be of any public utility, I shall be gratified. 'Tis certain that no one inclined to give it a fair trial, can ever have cause to regret his having made the experiment on the score of costs.—Excuse my trespassing so long on your time and patience. I thought it due to your politeness, to furnish you with my view, in originating the draft of the machine in question, and at the same time, to make you my acknowledgments for the trouble you have taken on the occasion. Should you deem any thing that I have said, worthy of being adverted to, I will thank you to do so under any name but my own, as it still is my wish not to appear “*in print*.”

Very respectfully,

Your's obedient,

C. R. C.

CHARLES E. ROWAND, ESQ.

FROM THE NATIONAL GAZETTE.

Mr. Editor,

A paragraph upon the subject of Silk Worms in your paper of the 7th inst. taken from the New York Merchantile Advertiser, appears to be going the rounds in all our city papers. What I allude to is this—

“The beautiful piece of silk, wrought by Silk worms in the factory of Mr. Bottom, at Lisbon, Connecticut, recently described in the papers, has been brought to this city, and was purchased by Mr. Scudder, to be placed in his Museum. The gentleman who exhibited it to us, states, that it was worked on a rough piece of board about three and a half feet long and varying in width from five to six inches, the piece being shaped precisely to the surface of the board, and having a border or selvage which resembles gold embroidery. The board was accidentally lying on a shelf where the worms, twenty-five in number, were placed, and upon which in three days time, they unwound themselves so as to form this elegant fabric, surpassing in texture any thing ever produced from the loom. Immediately after completing this work, the worms all died.

N. Y. Mer. Adv.

Last summer I reared some silk worms from the eggs, of the finest kind, which I brought from

the South of Europe, and after they had completed their spinning, and I succeeded with a little management in winding off *entire* many of the best I could select for the purpose, and found that, upon an average, each produced about 300 yards, finer than any human hair. But Miss Rhodes, in her communication to the Society for Arts and Manufactures, states, that she had taken from a single worm 404 yards. Now supposing that lady's number to be correct, and that the *twenty five* worms that wrought the silk in the factory of Mr. B. produced each four hundred and four yards, which would be ten thousand one hundred yards; is it possible, Mr. Editor, that that number of yards would cover a surface of three and a half feet long, and five to six inches wide? I cannot believe it! That a number of worms, but a greater number than *twenty-five*, put on a “rough board” of the above dimensions, to spin, will cover the surface, I can readily believe. The most costly fans in China, are made by silk worms in somewhat a similar manner. The wonder therefore manifested in the New York Merchantile Advertiser, that silk worms should produce their silk on a “rough board” when not better provided, is I conceive no wonder at all.—“The worms” say the Editors, “*unwound themselves so as to form this elegant fabric*.” What is meant by this, I know not. And who ever before heard of silk worms unwinding the silk which is spun from their mouth. If there had been obstructions at the edges of the “rough board,” the worms would have enveloped themselves in their silk and formed what is termed a cocoon, in which a transformation takes place, and the worm becomes an aurelia or chrysalis; nor is it at all surprising, on the contrary, extremely natural, that the worms immediately after completing their work, should all have died, when destitute of their silk or cocoon. I would send the Editors of the New York Merchantile Advertiser, a few cocoons, and some silk worms' eggs, for their curiosity:—At the same time supply them or their friends, with any quantity of Murdoch, Yuille, Wardrop & Co's. fine Madeira Wine.

SAMUEL ALEXANDER.

Philadelphia. }

FROM THE BOSTON RECORDER.

LIGHTNING RODS.

MR. WILLIS—I see in the Recorder frequent accounts of damage done to buildings, and lives lost, by lightning; and also frequent recommendations to the people to secure their buildings by proper conductors. All this is very well; but people will never be persuaded to erect Lightning Rods, till they are in some measure convinced of their utility. The popular opinion is, that a conductor for lightning, instead of security against, only serves to invite the bolt; and that there are more buildings injured by lightning that have conductors, than there are that have not, in proportion to the whole; and this opinion is probably not altogether ill founded.

I have for several years been in the habit of examining all the conductors I conveniently could, and I find the greater part of them very deficient in one way or another.

The greatest deficiency I have noticed is in the want of a free communication with moist earth. When a rod is in all other respects perfect, and deficient in this, so far from being a safeguard, it only increases the danger it was intended to avert.

I have known, and by good authority have heard of several buildings, having conductors, but which did hardly touch the earth, being

damaged by lightning. Among the many is the meeting house in Reading, Massachusetts. In the course of the present summer the lightning came down the rod, and went off near the bottom, into and damaged the house. This was undoubtedly because, by reason of the rod not going more than two inches into the ground, the electrical fluid could not pass off as fast as it was received, and the rod became overcharged.

Lightning rods are generally made and put up by persons wholly unacquainted with the principles of electricity, and what is necessary to constitute a safe conductor.

I shall, therefore, endeavor to give some directions for the information of those who are unacquainted with the subject, and who have not the means of information.

The rod should be made of round, smooth iron, at least three quarters of an inch in diameter, and when it can conveniently be done, instead of linking, should be smoothly welded together; but when by reason of its length or otherwise it is inconvenient to weld the whole rod, let it be smoothly connected, by screwing the end of one part into the end of another.—There should be five or more points, one in the centre, perpendicular, and the other oblique.—They should be filed to a sharp, slender point, and tipped with silver. The points should be elevated at least five or six feet above the highest part of the building. The bottom of the rod should go into the earth six or seven feet, and terminate in a bed of two or three bushels of wet charcoal. The wet coal covered with earth will probably retain dampness longer than any other substance.

A conductor constructed and put up agreeably to the above directions, will perfectly secure a building for twenty feet on every side. When a building is more than forty feet long, for perfect security, there should be two or more rods, calculating one rod for every forty feet.

The whole expense of one rod for a two story building, including the silvering the points will not exceed \$50.

We do not recollect, says the editor of the National Gazette, to have read of any *Water Spout*, so destructive as the one described in the following article, which we have translated from the Paris Journal des Debats, of the 30th of August.

To the Editor of the Journal des Debats.

Sir—A meteor extraordinary for its violence, rapid movement, and injurious effect, has just spread alarm and desolation in several parts of the district *Dieux et Mantes*. On the 26th August, about 3 o'clock, P. M. the great heat of the atmosphere produced a storm which took the direction, from the south west, towards the village of Boncourt; not far from this place, there appeared, suddenly, a water spout of extraordinary dimensions, whose broad base rested upon the ground, while its top was lost in the clouds: it appeared to consist of a thick and black vapour, in the centre of which flames were frequently perceived in several directions. Moving impetuously with the storm, through the upper valleys and over the mountains, it uprooted or dashed down, in the compass of a league. seven or eight hundred trees of different sizes; and, in reaching the village of Marchefray, demolished in an instant one half of its houses. The walls shaken to their foundations, fell in on every side, and the ruins were scattered to the distance of half a league, before the aerial torrent. Some of the inhabitants who remained in the villages were crushed or wounded by the fall of the houses: those who were working in the

fields (luckily the greater number) were thrown down or borne along by the whirlpool, that destroyed at the same time the harvest and the cattle. It discharged hail as large as the fist, stones, and other foreign bodies, which struck some persons and caused severe contusions. Wagons heavily laden were dashed in pieces; wheels of the largest size, torn off, were found at the distance of three or four hundred feet from the places in which they were struck. One heavy vehicle was carried upon a tile kiln, which was razed. A stepple, several hamlets, a number of detached houses, some new walls, were tumbled down and other villages than those mentioned, suffered considerably. To judge from the devastation which it spread, this waterspout must have been about six hundred feet diameter at the base. It has deprived a multitude of individuals of their means of subsistence.

“FOURSALT.”

Selections.

THE USEFUL ARTS.—BLEACHING.

The art of bleaching is of great antiquity.—The ancients were acquainted with the detersive quality of some kinds of clay, and the effects produced by the action of the atmosphere, moisture, and light, on the stuffs exposed to them. Health and cleanliness rendered it necessary to devise quicker methods than these; and the properties of soaps, and leys of wood-ashes were therefore soon discovered.

In the present age, the arts have taken advantage of processes and detersive menstrua, the existence of which, was before unknown; these discoveries have succeeded each other with such rapidity, that the last twenty years have effected a complete revolution in the art of bleaching.

This art is naturally divided into two distinct branches; the bleaching of vegetable and of animal substances. These being of very different natures, require different processes for whitening them. Vegetables consist of Oxygen, Hydrogen, and Carbon, of which the latter is in the greatest proportion; while animal substances, besides these, contain also a large quantity of Azote, and also Phosphorous and Sulphur.

Bleaching of Flax and Hemp.

If ripe flax is examined, it will be found to be composed of fibres or filaments united together by the sap, enveloping a semi-ligneous substance, and covered by a thin bark. It is the fibrous part only that is used for making cloth, and it must therefore be previously separated from the other matters.

The sap, or succulent part, is composed of extractive principle and water, and the first process is to separate this substance, which holds the filaments together. As soon as the flax is pulled, it is steeped in soft water until the putrefactive fermentation takes place. This degree of fermentation begins with the succulent part, as being more susceptible of decomposition than the rest. Was the flax to be continued long in this state the whole substance of it would be decomposed or destroyed: upon the same principle that malt is injured by too long steeping, or that wort loses its substance by too long a fermentation. It must therefore be taken out of the water while yet green, and before the whole of its sap is separated. Well water, and brackish water, must be carefully avoided, as well as that which flows over a gypseous soil. Such waters accelerate putrefaction, and hurt the quality of the hemp and flax.

The flax when taken from the water, is spread out upon the grass to dry. During the fermenta-

tion and decomposition which thence result, there is a speedy combination of oxygen and carbon. Exposure on the grass facilitates the escape of the carbonic acid into the atmosphere, and the plants become of a whitish grey color.

It is known that a ley, very slightly alkaline, may be substituted with advantage, for this long and noxious operation: it is therefore certain, that a chamber from twenty to thirty feet in length, into which the steam of alkaline caustic water, (of the strength of one-fourth of a degree only,) is introduced, will be sufficient to produce the same effect as watering on an immense quantity of hemp and flax, suspended on basket-work; and that, too, in less time, and with less expense, than are required from the different manipulations of watering. The losses occasioned by the negligence of workmen, who by suffering the hemp and flax to macerate too long, give time to the decomposition to reach the filaments, which renders them brittle, and occasions a considerable waste, will also be avoided. In this process, the artist can follow every moment the progress of his operation, and stop it at the favorable period.

Nothing now remains but the wood, and the flax or fibrous part. The wood is a hollow tube covered over very compactly with the flax.

To separate the wood, it must be kiln-dried, in order to render it frangible or brittle; but care must be taken not to apply too much heat, for fear of injuring the flax.

It is next to be beaten or broken, by which means the flax is not only divided into small fibres, but most of the wood is separated, and the part which adheres is reduced to small fragments. To separate these again, the flax is to be threshed, in small parcels at a time, either by manual labor, or mills contrived for the purpose. Hackling is the last process; which is drawing or combing the flax in small parcels at a time, through a pile or group of polished and sharp iron spikes, placed firmly in wood through an iron-plate.

The linen, as it comes from the loom, is charged with what is called the *weaver's dressing*, which is a paste of flour boiled in water; and as this is brushed into the yarn of the warp before it is woven, it is somewhat difficult to separate it when dry. To discharge this paste, the linen must be steeped in water for about forty-eight hours, when this extraneous substance undergoes a kind of fermentation; this does not extend to the substance of the linen itself, upon the same principle that the green sap is disengaged from the flax without injury to its texture.

When the linen is well washed after this last process, it contains nothing that water can separate; it is of a greyish-white color, although the fibres of which it is composed, when divested of every adventitious substance, are naturally very white.

The matter which thus colors the linen, is of a resinous nature, insoluble in water, and from its intimate union or dissemination through the very fibres of the flax, is difficult of separation, even by those substances which have a solvent power over it.

To disengage it, however, in as cheap and expeditious a manner as possible, without injuring the texture of the fabric, is the sole object of the process of bleaching.

Bleaching.

In a paper lately published by Mr. Gavin Inglis, it appears, that if flax be pulled before it is too ripe, it parts with its coloring matter much more readily than it does when left till the usual time; and it is also found that this great advantage might again be lost by improper watering.

It has been uniformly found, that flax the greenest pulled is most proper for the finest purposes, and that the whitest flax after drying must be watered in a stream so small, as to require a dam being necessary to receive the water into a temporary pond to cover the flax. The succession of clean water, Mr. Inglis conceives, prevents the deposition of coloring matter, by washing or carrying it away, after being extracted from the flax; while the same flax, from several stagnant ponds, dug in the same ground, and filled with water from the same spring, was very dark in color. The color of the flax, after watering very much, depends upon the following causes;—the ripeness of the flax before pulling; the state of putridity of the stagnant water; the minerals which the water may contain; whether it is steeped in a pond dug, or one formed by damming a small stream; or, if a succession of parcels of flax (which is sometimes the case,) be watered in the same pond, where every succeeding parcel must partake of the contaminating dye produced by the fermentation of the former.—In the course of Mr. I.'s observations, he found the quantity and solubility of the coloring matter in proportion to the degree of ripeness; and in the ripest on a principle which he never till then knew to have an existence in flax, viz. iron,—which may be said to abound in ripe flax. In unripe flax the coloring matter is soluble in water; but, if the flax be allowed so stand on the ground till it has attained a rust-brown color, and the seed be fully ripened, the juices of the plant are then changed from mucilage to resinous matter, and certainly no longer soluble in water, so far as the resin is concerned,—unless assisted by solvents. Alkalies are the common solvents used by bleachers, but Mr. I. did not conceive them altogether adapted to his purpose; he took alcohol, and succeeded in bleaching, to a very beautiful whiteness, flax in its unripe state and its early stages; but as the flax ripened, its power lessened. He exposed full ripe flax to the action of alcohol, both in a liquid state and in a state of vapor, till all the resinous matter was extracted; still a color remained. He subjected it to the action of an oxymuriate, and was astonished to see the presence of iron so strongly indicated.

Test for Alum in Bread.

On macerating a small piece of the crumb of new-baked bread in cold water, sufficient to dissolve it, the taste of the latter, if alum has been used by the baker, will acquire a sweet astringency; or a heated knife may be thrust into the loaf before it has grown cold, and if it be free from that ingredient, scarcely any alteration will be visible on the blade; but, in the contrary case, its surface, after being allowed to cool, will appear slightly covered with an aluminous incrustation.

Prevention of Rust.

The prevention of Rust, on such articles of furniture as are made of polished steel, is an object of great importance in domestic economy. The cutlers in Sheffield, when they have given knife or razor blade the requisite degree of polish, rub them with powdered quicklime, in order to prevent them from tarnishing; and we have been informed, that articles made of polished steel, are dipt in lime water by the manufacturer, before they are sent into the retail market.

Preservation of Wood by Charcoal.

The following mode of preventing rotteness in Pales, Water-shoots, &c. is recommended by Dr.

Parry, who paid much attention to this important subject. He says:

"More than thirty years ago this subject presented itself to my mind, on seeing some Water-shoots which had been pitched and painted in the common way, taken down in a state of complete rottenness. I had read that charcoal buried in the moist earth, had come down to us perfectly sound from the times of the Romans: and that posts long withstood the same moisture, if the part intended to be put into the ground was charred all round to a certain depth. Impressed with these facts, I determined to try an artificial coat of Charcoal, and when new Water-shoots were constructed, I strongly and carefully rubbed them with a coat of drying oil, which I immediately dredged all over with a thick layer of Charcoal finely powdered, and contained in a muslin bag. After two or three days, when the oil was thoroughly dried, and firmly retained the greatest part of the charcoal, I brushed off what was loose, and over that which adhered, I applied a coat of common lead-colored paint, and a few days after, a second. The whole became a firm and solid crust; after which the shoots were put in their places, and being examined many years afterwards, appeared perfectly sound."

Observations. Any other color would probably have succeeded equally well with that which I employed. I do not think that lampblack, which is a pure species of charcoal, would have answered the purpose of forming a thick defensive covering so well as the grosser charcoal which I used. But whatever sort of charcoal is employed, it ought either to be *fresh made, or heated again in close vessels, so as to expel the water* which it greedily attracts from the air.

It is to be observed here, that the practice of pitching pales, &c. is both incommodious, and inefficacious, as pitch is so liable to be melted by the heat of the sun.

Mode of painting Sail-Cloth, &c. so as to be pliable, durable, and impervious to water.

This process which is extracted from the *Transactions of the Society of Arts*, is now universally practised in the public Dock-yards.

The paint usually laid upon canvass, hardens to such a degree as to crack, and eventually to break the canvass, which renders it unserviceable in a short time; but the canvass painted in the new manner, is so superior, that all canvass used in the navy is thus prepared; and a saving of a guinea is made in every hundred square yards of canvass so painted.

The old mode of painting canvass was to wet the canvass, and prime it with Spanish brown; then to give it a second coat of a Chocolate color, made by mixing Spanish brown and black paint; and lastly to finish it with black.

The new method is to grind ninety-six pounds of English Ochre with boiled oil, and to add sixteen pounds of black paint, which mixture forms an indifferent black. A pound of *yellow soap* dissolved in six pints of water over the fire, is mixed, while hot, with the paint. This composition is then laid upon the canvass (without being wetted, as in the usual way,) as stiff as can conveniently be done with the brush, so as to form a smooth surface; the next day, or still better, on the second day, a second coat of ochre and black (without any, or but a very small portion of soap) is laid on, and allowing this coat an intermediate day for drying, the canvass is then finished with black paint as usual. Three days being then allowed for it to dry and harden, it does not stick together when taken down, and folded in cloths containing sixty or seventy yards each; and canvass finished entirely with the composition, leav-

ing it to dry one day between each coat, will not stick together, if laid in quantities.

Observations. It has been ascertained from actual trials, that the solution of yellow soap is a preservative to red, yellow and black paints, when ground in oil and put into casks, as they acquire no improper hardness, and dry in a remarkable manner when laid on with the brush, without the use of the usual drying articles.

It is surprising that the adoption of soap, which is so well known to be miscible with oily substances, or at least the alkali of which it is composed, has not already been brought into use in the composition of oil colors.

Preparation of Saur-Kraut.

Every Russian family, from that of the boor to the nobleman, lays in its stock of cabbage to make Saur-Kraut, about the month of October, before the setting in of the winter frost. It is prepared in the following manner;—They take a large strong wooden vessel, or cask, with which every family is furnished, resembling the salt beef cask of the Scotch farmers, and capable of containing as much as is sufficient for the winter's consumption of the family. They then gradually break down or chop the cabbage, (deprived entirely of the loose outside green leaves,) into very small pieces, beginning with one or two cabbages at the bottom of the cask, and adding others at intervals, pressing and rubbing them by means of a wooden spade, against the sides of the cask, until the vessel is nearly full. They then place a heavy weight upon the top of it, and allow it to stand near to the peach stove, or any other warm place, for four or five days. By this time it will have undergone fermentation, and be ready for use. Whilst the cabbage is passing through the process of fermentation, a very disagreeably fetid, acid smell is exhaled from it; and this is strongly perceptible to the olfactory nerves of a person passing near the house, in which the preparation of the Saur-Kraut is going on. They now remove the cask to a cool situation, and keep it always covered up. Aniseeds which are strewed amongst the layers of the cabbage during its preparation, communicate a peculiar flavor to the Saur-Kraut at an after period.

In the boiling of the Saur-Kraut, and preparation of it for the table, two hours are the least period which they allow it to be on the fire. It forms an excellent, nutritious, and antiscorbutic food for winter use. For the greater part of the year, this article, in one form or another, supplies a daily dish to the table of the Russian peasant. It may be made use of as a separate dish by itself, made into soup, or it may be eaten with-boiled animal food.

An Estimation of the Loss of WEIGHT which takes place in Cooking Animal Food. From Mr. TILLOCH'S Philosophical Magazine.

It is well known that, in whatever way the flesh of animals is prepared for food, a considerable diminution takes place in its weight. We do not recollect, however, to have seen any where a statement of the loss which meat sustains in the various culinary processes, although it is pretty obvious that a series of experiments on this subject would not be without their use in domestic economy.

"We shall here give the result of a series of experiments which were actually made on this subject in a public establishment; premising that, as they were not undertaken from mere curiosity, but, on the contrary, to serve a purpose of practical utility, absolute accuracy was not attended to. Considering, however, the large quantities

of provisions which were actually examined, it is presumed that the results may be safely depended upon for any practical purpose. It would no doubt have been desirable to have known not only the whole diminution of weight, but also the parts which were separated from the meat in the form of aqueous vapour, jelly, fat, &c. but the determination of these did not fall within the scope of the enquiry.

28 pieces of beef weighing
Lost in boiling
Hence the weight lost by beef in boiling was in this case about 26½ lbs. in 100 lbs.

lbs. ozs.
280 0
73 14

19 pieces of beef weighing
Lost in roasting
The weight lost by beef in roasting appears to be 32 per cent.

10 necks of mutton weighing
Lost in roasting
The loss of necks of mutton, by roasting, is about 32½ per cent.

lbs. ozs.
100 0
32 6

We shall only draw two practical inferences from the foregoing statement. 1st. In respect of economy, it is more profitable to boil meat than to roast it. 2d. Whether we roast or boil meat, it loses by being cooked, from one-fifth to one-third of its whole weight."

The loss in ROASTING arises from the melting out of the Fat, and evaporating the water; but the nutritious matters remain condensed in the cooked solid.

In BOILING, the loss arises partly from the fat melted out, but chiefly from Gelatine and Gumazone being extracted and dissolved by the water in which the meat is boiled; there is, therefore, a real loss of nourishment unless the Broth be used;—when this mode of cooking becomes the most economical.

FROM NILES' REGISTER.

GOOD INK.

The following notice, copied from the Richmond "Enquirer," and addressed to the "clerks of courts of justice" in Virginia, involves a matter of great importance to the public; and that every one may possess himself of ink that is durable, I republish, from the 17th Vol of the "Register" the following receipt, which was furnished to me by the late Joseph James, Esq. who was remarkable for his attention to matters of this nature, and withal a good chemist, and

exceedingly fond of useful experiments. The character of the ink, made according to his directions, is this—it is very strong and durable, yet flows freely from the pen; it is uncommonly black, but dries very quickly.

I repeat, once more, it to be important, in the highest degree, that records, (which are to endure for ages), be written with strong durable ink; and it is much to be regretted that my former mild and friendly admonitions to clerks, on this subject, have had little, or no effect; the evil seems, indeed, to be progressive and gaining ground, as there has been lately brought to me several records from different sections of the state, so obscure as scarcely to be legible, even to those whose eyesight remains unimpaired! If clerks, who make use of pale ink, for records, were impeached and deprived of their clerkships, for misbehaviour in office, a few examples might have a salutary effect, and be beneficial to the community at large.

WILLIAM FLEMING,

President of the Court of Appeals.
Somerville, Sept. 1, 1823.

FROM THE REGISTER, VOL. 17, PAGE 64.

Improved Composition of Black Writing Ink.

Take a gallon of soft water, and boil in one pound of chips of logwood, for about half an hour, then take the decoction from the fire, and pour it from off the chips, while boiling hot, on a pound of the best Aleppo galls, reduced to a fine powder, and two ounces of pomegranate peels, put into a proper vessel. After having stirred them well together, with a wooden spatula, for some time, place them in the sunshine, in summer, or within the warmth of the fire, if in winter, for three or four days, stirring the mixture as often as may be convenient. At the end of that time, add a half pound of green vitriol, powdered, and let the mixture remain four or five days more, stirring it frequently, and then add further four ounces gum Arabic, dissolved in a quart of boiling water, and after giving the ink some time to settle, strain it off from the dregs, and keep it well stopped for use.

If the ink be desired to shine more, the proportion of the pomegranate peel must be increased; and, in the country where the logwood cannot be so easily obtained, a pound of ripe privet-berries may be substituted for it.

In order to secure this ink from growing mouldy, a quarter of a pint or more, of spirits of wine may be added; but to prevent its containing any acid, which may injure the ink, a little salt of tartar, or pearl ashes, should be added previously, and the spirit poured off from it, which will render it innocent with regard to the color of the ink.

THE HORSE.

Every young gentleman, brought up in the country and destined to be a farmer, ought to become familiar with the good and bad points of the horse; that being the animal which will be most associated with him, in his rural labours, and in many of his pleasures. In truth there are very few, be their avocations what they may, that will not be benefitted by a knowledge of the figure and qualities best calculated to impart power, activity and durability to that useful animal, and it is presumed that we cannot more usefully appropriate a portion of this paper, than in using it for the illustration of this subject.—The following extract from LAWRENCE'S PHILOSOPHICAL AND PRACTICAL TREATISE ON HORSES, contains a good general description of the external figure, grounded, as he observes, on the just principles of theory, and confirmed by experience. This general description applies equally to the cart horse and the racer. There are

however other particulars in which horses designed for these two purposes differ, which will be adverted to hereafter.—*Edit. Am. Far.*

THE HEAD OF A HORSE should be void of flesh, and for length and size appear to hold fair proportion with the size of his body; his eye full, and somewhat prominent; eye-lids thin and dry; ears thin, narrow, erect, of middling length, and not distant from each other; forehead flat, not too large or square, and running nearly in a straight line to the muzzle, which should be small and fine; nostrils capacious; lips thin; mouth of sufficient depth, and the tongue not too large; the jaw-bones wide at top, where they join the neck; the head not abruptly affixed to the extremity of the neck, but with a moderate curve and tapering of the latter.

The NECK must be of moderate, not too great length, nor too thick and gross on the upper part, nor too large and deep, but rising from the withers or forehead, and afterwards declining and tapering at the extremity, it will form somewhat of an arch; underneath, the neck should be straight from the chest, and by no means convex or bellying out.

The SHOULDERS capacious, and of large extent, so as to appear the most conspicuous part of the body, but without being loaded with flesh; they should reach fairly to the top of the withers, which must be well raised; the chest should be sufficiently full, not narrow or pinched.

The BODY deep and substantial; back, a plane of good width, but handsomely rounded; backbone straight, or with a trifling inclination, and not too short; loins wide, and the muscles of the reins, or fillets, full, and swelling on each side the back-bone; the space sufficient between the ribs and hipbones, the bones themselves round, and the buttocks deep and oval; the rump level with, or not too much elevated above, the height of the withers; the croup must have reasonable space, and not sink too suddenly, in which case, the tail would be set on too low, which ought to be nearly on a level with the back.

The HINDER QUARTERS should spread to a wider extent than the fore-parts, and the hind-feet stand farther asunder than those before; the thighs should be straight, large, muscular, and of considerable length; the hock wide and clean; the shank not too long, but flat, and of sufficient substance, its sinew large and distinct, the fetlocks long; the hocks should form an angle of such extent as to place the feet immediately under the flanks. The fore-arms, like the thighs, should be large, muscular, and of good length, the elbows not turning outwards; the knees large and lean; the shank or cannon-bone, flat, strong, and not too long; the tendon large; the fore-arm and shank must form nearly a straight line; fetlock-joints large and clean; pasterns inclining to a certain degree, not too long, but large in proportion to their length; the coronary rings not thick or swelled, but clean, dry, and hairy; the feet neither too high nor too flat, and of size apparently a sufficient base for the weight they have to sustain; hoofs, of colour dark and shining, without seams or wrinkles, tough and strong, not hard like oak; foot internally concave, soal hard, but not shrunken, heels wide, and of middling height; frog not too large or fleshy, but tough and sound; the feet of equal size, should stand exactly parallel, so that the front or toe incline neither inward nor outward; the fore-feet should stand perpendicular to the chest, not too much under it, and they should be less wide apart than the fore-arms; the legs should not be loaded with hair.

ECLIPSE AND HENRY.

A writer in the last Number of the London Sporting Magazine, received at this office, makes the following remarks on the great New York Race.

When on the subject of jockeyship, and racing, I was very much amused with the account of the grand match that has been lately run at New York, between the American Eclipse, and Henry, who, it seems, was brought thither from a distant part of the country for the purpose; by which it appears, that unless a transatlantic mile is shorter than an English one, they have got some good horses in that country, as, in one heat, the four miles were run in seven minutes and thirty-nine seconds, being almost equal to any thing upon record*—particularly as the heat before it, had been run within a second of the same time—but, unfortunately, they have not given us the weights.—The horses starting by the "tap of the drum," is quite a novel idea, and, perhaps, might not exactly suit some of our young ones, who are rather queer at getting off; but the ebullition of feeling exhibited by the people at New-York, shews that under all climates, the sports of the field are congenial to human nature. To be sure, it is diverting, to picture to oneself Sam Chiffney, on the shoulders of a Yankee, borne off in triumph after having won his race, to the tune of "See the conquering hero comes!" and, it appears, Mr. Purdy felt more at home on the back of his favorite Eclipse. I wish the Editor of the New York paper had gone a little more into detail, and given us the reasons why Taylor did not ride Henry the two first heats, and why Purdy was not put on Eclipse at first, as we are led to believe they are the Buckle and Chiffney of that country. Perhaps, had Taylor ridden Henry the two first heats, and not made all the running as he did, it might have altered matters considerably, for it will be observed that he waited on Eclipse the last heat, and was only beat by a head. On the other hand, had Purdy been on Eclipse the first heat, he might have saved him running the last at all. They wanted your Newmarket correspondent, OBSERVATOR, Mr. Editor, to have given us the age, "names, weights, and colors of the riders," in technical lingo; and how amusing would it be, if some good artist were to go around the world, and give us sketches of the different costumes of the riders, and the forms of their horses, in all different countries; as well as some account of their method of training, trials, &c.! I have often thought how it must have surprised my Lord Charles Somerset, when he landed at the Cape of Good Hope, during the races, to see the black jockies riding without shoes or stockings, a ludicrous account of which I saw in a letter from the late Lady Charles, to one of her sisters. What a contrast to Tom Goodison upon Sunbeam!

Indeed, we have only to cross the water to Ireland, to see a little difference in these things. Some years since I had a horse in training at the Currah of Kildare, and making a match with the celebrated Colonel Wardle over the bottle, to be run the next day. I went off in the night seventeen Irish miles, to have my horse set for the race. When I arrived at the stables, about one o'clock in the morning, I saw by the light of the moon, that the key was in the door. Accompanied by a friend, I entered. There were seven horses in the stable, and one of them the best of his year! And after walking two or three times up and down it, a young voice exclaimed—"Ah!

* We should like to know when, and by what horses, three successive heats were run in England in as short time as those by Eclipse and Henry?—Edit. Am. Far.

what are you after here?" "What am I after!" said I—"what is your master after, that he leaves his horses in this way?" "Sure, didn't master lock me in here to take care of them," said a ragged urchin in a hay bin. However, it is an old story, and I will not tell the sequel. I set my horse myself, and lost the race.

To return to New York. I can easily conceive this to have been a most interesting race, not only as relates to the stakes—20,000 dollars—but as being made by one party of sportsmen against another (as if York and Doncaster were to coalesce against Newmarket), that interest must have been increased an hundred fold. We cannot wonder at the backers of Eclipse being proud of their horse; neither can we wonder, in the moment of triumph, that "Long Island Eclipse" was to beat all the world; but the world is a wide place, and no doubt Mr. Fan Rast, his owner, is aware of this. I always take a leaf out of another man's book, when I think it will suit my own; and I like Yankee's idea much, that "size and bone, are essential to strength, and ought to be taken into calculation; and supposing blood and bottom to be equal, must always win." To encourage horses of this description, they have Welter weights in the United States.

FOR THE AMERICAN FARMER.

RULES AND REGULATIONS OF THE "MARYLAND ASSOCIATION."

- 1. This association shall be called the "Maryland association for the improvement of the breed of horses."
2. The president or one of the vice-presidents, together with eight members shall be necessary to form a quorum to transact the business of the association.
3. There shall be annually appointed, on the first Monday of June in each and every year, during the continuance of this association, twelve managers; and a committee of elections for the admission of new members, to consist of five members, who shall decide upon all applications for membership by ballot. Two black balls to exclude.
4. The subscription of every member shall be twenty dollars annually, to be paid to the Treasurer on or before the 15th day of September in each and every year.
5. The officers and managers of the association in regular meeting convened, may by a vote of two thirds of the members present, expel any member for improper conduct.
6. The association shall be free for any horse, mare, or gelding, to be subject to the rules and regulations of the association, and to carry the following weight, viz:
Aged horses, 126 lbs.
Six years old, 120
Five years old, 112
Four years old, 100
Three years old, 86
An allowance of three pounds will be made to all mares, fillies and geldings: No horse, mare, or gelding, which shall not be entered with the Secretary on the day previous to the day on which they run, between the hours of eight in the morning and five in the evening, shall be permitted to run, unless the owner of such horse, mare or gelding pay double entrance.
7. Every rider at starting shall be dressed neatly, in a silk or satin jacket, jockey cap, and boots or half boots.
8. The heats to be run for during the existence of this association shall be two, three and four mile heats: to rub thirty minutes between the heats of two miles; and thirty minutes be-

tween the heats of three miles; and thirty minutes between the heats of four miles; the time of rubbing to commence from the weighing of the last rider; and the following shall be the distances, viz:

Table with 2 columns: Distance/Heat description and Time. For two mile heats, 120 yds. For three mile heats, 180. For four mile heats, 240.

And all horses, mares, or geldings not coming within the said distances, before the first horse, mare, or gelding pass the starting pole, shall be deemed distanced, and not allowed to run on that day for the same purse.

9. No combination or partnership shall be permitted. If therefore any horse shall win a purse and it shall appear to the satisfaction of the Judges, before the purse is paid, that such horse did run in partnership, with any other horse the purse shall go to the fair winner and the combined horses shall be deemed distanced, and never be allowed to start again for any of the purses.

10. The horse, mare, or gelding winning two clear heats and bringing in the proper weight shall be entitled to the purse, unless he distance all the others in one heat, in which case the winner shall not be obliged to start again: but if three several horses win each a heat, then those three and they only, are to run for a fourth heat, and such horses as are excluded by this rule from running for a fourth heat, shall be deemed only drawn, and not distanced.

11. In sweepstakes, &c. of one heat, when two horses come in so near each other, that it cannot be decided which is first, they two only must start again to determine which shall be the winner.

12. When running heats, if it cannot be decided which is first, they may all start again, except the dead heat be between two horses, that if either had been winner the race would have been over;—in which case they two only shall start again to decide which shall be entitled to the purse. Such horses as are prevented by this rule from starting again, shall be deemed only drawn and not distanced; and all bets made on such horses being distanced, shall be pronounced as drawn bets; and a dead heat is to operate as no heat.

13. If but one horse is entered for any purse, such one by galloping over the course, two, three, or four times according to the distance to be run, shall be entitled to the purse.

14. The hour of starting each day shall be twelve o'clock, and in case of bad weather, a majority of those who start horses may postpone the race to the next day, provided they agree to do so before nine o'clock, in the association rooms, in which case the other races are to be postponed a day longer.

15. No testimony shall be received respecting foul riding, &c. except that of the judges and managers, and all disputes shall be decided by the three judges in the starting stand: but should it so happen that one or two of the said judges, shall be to give testimony, then all the other judges shall be called in: but where foul riding &c. is discovered by all the judges in the starting stand, then they, and they alone shall decide; but it is to be understood that the testimony of judges and managers is to be only on honor.

16. There shall be three judges in the starting stand, one in the distance stand, and one in each of the other two stands; and they shall not admit any person or persons, except the officers of the association, to enter the stands with them.

17. On weighing after each heat, one pound shall be allowed each rider in lieu of the bridle; and in case any rider be deficient in weight, the horse, mare, or gelding rode by such rider, shall

deemed distanced, and the heat be given to the best horse that shall bring in the proper weight.

18. After each heat the riders are to come up to the pole and not dismount until so ordered by the judges; and any rider or riders disobeying this rule, shall be precluded on weighing, from the benefit of his saddle, whip, and two pounds allowance in lieu thereof; and if his bodily weight does not make his exact weight, the horse weighed by such rider is to be deemed distanced.

19. When any horse shall be entered with the secretary, the person so entering him, must at the same time enter his age and name, and deposit with the secretary such documents as he may think necessary in support of the truth of the entries so entered—the sufficiency of such documents to be decided on by the judges: such documents to be regularly endorsed and filed by the Secretary.

20. The winning horse of each day shall be excluded from running for any of the other purses during that meeting.

21. All races shall be run with the left hand to the poles.

22. If a rider accidentally falling from his horse and the horse is rode in by any person of sufficient weight, he shall take place the same as if the accident had not happened, provided he goes back to the place where the rider fell.

23. All bets are understood to relate to the horse, if nothing is said to the contrary.

24. When two horses are bet against each other for the purse, if each win a heat, and neither are distanced, they are equal; if neither win a heat, and neither are distanced, they are equal; but if one win a heat and the other do not, the winner of the heat is best, unless he shall be distanced; in such case, the other, if he save his distance, shall be considered best; and when both are distanced, they shall in all cases be deemed equal.

25. When a bet is made upon a heat, the horse that comes first to the starting (or ending) post is best, provided no circumstance shall cause him to be deemed drawn or distanced.

26. A bet made upon a purse or heat is void, if the horse betted on does not start.

27. The meetings of this association shall be held twice in each year, viz. at Barnum's Hotel in the city of Baltimore, on the first Monday in July, and at the association rooms on the race course, on the first day of the October races: but should circumstances render more meetings necessary, five days notice thereof, shall be given in some one of the newspapers of the city of Baltimore.

28. On the death or resignation of any of the officers of the association, the vacancy or vacancies shall be filled by ballot, at the next meeting of the association thereafter.

29. The members of the association will dine together on the day of the third day's race: and early in the morning of that day, the members shall give in their names to the secretary, who shall provide a dinner accordingly, to be on the table at three o'clock, P. M.

30. The secretary shall provide a good set of scales, together with good weights, for the use of the association.

31. E. L. Finley Esq. having contracted with the association to furnish them with a race course on his farm, (Canton) near Baltimore, in full charge, during the continuance of this association, he shall enter into an obligation to the president, to have the said course properly prepared and kept in good order.

32. The officers of the association and members of the committee of elections shall be elected by ballot.

33. The judges of the races shall be appointed by the managers on the day of each race.

34. The secretary shall keep a book in which he shall enter the proceedings of the association, an account of each day's race, and the names of the members of the association; and the treasurer shall keep a book in which he shall enter an account against each member, and a general one against the association.

35. No horse shall be permitted to start for any of the purses, unless entered by a member of the association.

36. The president, vice-presidents and managers, or any five of them, shall make, and cause to be enforced all rules and regulations for the good order and decorum of the course, and decide on all matters not otherwise provided for by these regulations.

37. *Gambling of every description shall be prohibited, and the president, vice-presidents and other officers of the association, shall cause this regulation to be respected.*

38. No rider who has been or may hereafter be expelled from any established course, shall be permitted to ride for any of the purses of this association; and in the event of any rider being dismissed from this course, it shall be the duty of the secretary to notify other racing institutions thereof.

B. HARWOOD, Tr. W. S. Md.

TO THE EDITOR OF THE AMERICAN FARMER.

DEAR SIR,
In a late paper of your's, I find some gentlemen from the South, are about reclaiming a part of the extensive wet lands, on the Eastern Shore of this State, for the purpose of raising rice—a

doubt seems to be entertained of its being raised in our climate. In my youthful days, which is many years past, there were many African negroes in Prince George's, most of them would have small patches of rice on low grounds on the edges of a spring branch; it was drilled and grew well, being hoed and kept quite clean of weeds and grass, and produced good rice, which was cleaned by them of the husk, by beating lightly in mortars prepared for beating corn for homony.

An old and intelligent family servant, now 78 years of age, says that before the war, (the Revolutionary,) much of it was raised by the African negroes, and sold by them to the whites.

A PLANTER.

TO THE EDITOR OF THE AMERICAN FARMER.
SIR,

You gave a satisfactory proof of the interest you take in the plantation of Forest Trees, by adding to my communication on that subject, some directions for raising the oak; but Chesnut is scarcely less valuable, and I apprehend, we have in this part of the country, at least, more lands laying waste, suitable for this last kind of timber, than for oaks.

Permit me therefore, to call the attention of gentlemen possessing old and worn out tobacco lands, or hilly, washed and barren old fields; unfit for any other culture, to the chesnut, which may now be gathered in abundance in almost every neighborhood. These may be planted at any time between this and March or April, either in the burr or without; and any quantity, no matter if but a hundred, to some advantage, even without great preparation. Let those who can do no more, take a strong hoe and loosen the earth five or six inches deep and ten or twelve wide, in different parts of such old fields, scattered promiscuously and not in rows; cover the nut about four inches, with the best mould at hand, and then a few small branches of furze or briars. It is supposed that if one out of the hundred should succeed, the planter will be amply rewarded for his trouble, whilst this kind of timber is so valuable in making fences. If such experiments should succeed in a few instances only, there will be encouragement to repeat and extend the planting annually, so that by degrees, many farmers short of timber for rails now, may be abundantly provided in the course of a few years.

Your's respectfully,
THOMAS W. GRIFFITH.

Oct. 14, 1823.

TO THE EDITOR OF THE AMERICAN FARMER.

TO PREVENT THE FEMALE BREAST FROM GATHERING.

[Communicated by a Mother.]

SIR—You are a husband and a father, and I greatly mistake your character, if it would not give you particular satisfaction, to communicate in the Farmer, any means of mitigating the sufferings which MOTHERS experience, in endeavouring to give to their infants from their own breasts, their most congenial and healthful sustenance. There is perhaps in the catalogue of human pains, none more acute than those which are experienced from the gathering of the female breast, in time of giving suck—pains which too often drive the devoted mother, with heartfelt reluctance, to consign to a strange bosom, the beloved offspring of her dearest affections, therein relinquishing the most interesting of all her maternal cares and duties, and losing

the effect of the most endearing associations, provided by nature, between mother and child. But the faithful wife and the tender mother, only can understand, for she alone can feel the nameless pleasure of imparting to her child in helpless infancy, its chief pleasure, its only nourishment.

None else therefore can estimate the privation. It is for them and their benefit I send you a remedy which I know by experience to be effectual.

To prevent the female breast from gathering, or to cure them after they have gathered.

To the yellow of one egg, add one table spoonful of brown sugar, one of honey, and one of rum, a small tea spoonful of powdered alum, and as much of rosin, this mixture should be put in a pewter vessel, and mixed well together, then put over a slow fire, and stirred all the time with the finger*, until it comes to a consistence that will spread easily.†

A plaster of this spread over the breast before the child is put to them, will prevent their gathering, or should a fever at any time fall in them, a plaster of this salve should immediately be applied, and it will certainly prevent gathering—should matter be formed before the application of the salve, the breast should be kept covered with a thick brown paper made wet with rum, and the salve over the diseased part only; when it breaks, there should be a tent kept in it, and the salve spread on *lint*, the salve side next the ulcer—the child should be taken from the breast as soon as matter is discovered, which may be done without the least danger of losing the use of the breast, (which is too often the case by the skin cleaving to the bones,)—after the cure is made the child may be allowed to suck, the milk will soon return.

* It must never be made too hot to bear your finger in.

† On *lint* in order to keep the salve alive.

EXTRACTS FROM LATE NUMBERS OF THE

London Farmer's Journal.

VICE CHANCELLOR'S COURT.—Lord Byron having a short time since, obtained an injunction to restrain a Mr. Dugdale from publishing several of the Cantos of *Don Juan*, the latter attended on Friday in person, to shew cause why the injunction should be dissolved. The defendant exhibited considerable talent in the course of his argument, and read various passages to shew, that the work, from its disloyal and immoral tendency, was not entitled to the protection of the Court. The following were among the stanzas quoted:—

"But still there is unto a patriot nation
Which loves so well its country and its King,
A subject of sublimest exultation,
How'er the mighty locust, desolation,
Strip your green fields, and to your harvest
cling:

Gaunt famine never shall approach the throne,
Though Ireland starve, great George weighs
twenty stone."

"But never mind:—God save the King! and
kings!

For if he don't, I doubt if men will longer—
I think I hear a little bird who sings,
The people by and by will be the stronger.

The veriest jade will wince whose harness
wings

So much into the raw as quite to wrong her
Beyond the rules of posting,—and the Mob
At last fall sick of imitating Job."

The Vice Chancellor dissolved the injunction, thinking the question ought to be determined by a Court of law, where, if plaintiff obtained a verdict, he might come with more propriety in this Court.

Too much of a good thing.—A certain country squire had a *warren*, and the village curate was Sunday after Sunday, regaled with the delicacy of rabbits, till he became as sick of them, that he took the liberty of *hinting* his dislike of the standing dish to the host, in the following grace, on rising from the table:

"Of rabbits *hot*, of rabbits *cold*,

"Of rabbits *tender*, rabbits *tough*;

"Of rabbits *young*, of rabbits *old*,

"I thank thee L—d, we've had enough!

Wine.—A Danish chemist has demonstrated that apple juice mixed with a great quantity of sugar produces a drink which more nearly resembles wine than any other substitute. Cherries and currants, he says, are not so proper for wine as the apple.

THE FARMER.

BALTIMORE, FRIDAY, OCTOBER 17, 1823.

The communication signed Hamilton, sent for insertion in the Farmer, as a reply to an article in the last number from the North American Review, was received too late for insertion in this paper—the Editor is required to furnish copy for the Printer, one week before hand, except the prices and editorial scraps, and has little control over the mechanical part of the business. The paper though dated on Friday, is issued in fact on Thursday evening.

Several other communications are on hand, to the writers whereof the Editor is much indebted.

THE NEXT CATTLE SHOW.

Those who propose to put in claims for the premiums offered for crops, have only to exhibit to the judges, the certificates of their neighbors, or some other satisfactory proof on which the judges can safely rest their decision.

In regard to fermented liquors, it is understood that it will not be necessary to produce, on the ground, the five gallons of home made wine—it will only be necessary to exhibit a sample and to show that it is a fair sample of a quantity not less than five gallons.

An impression seems to exist that to obtain the premiums offered for Live stock, it will be necessary to have animals of very superior qualities. This impression is certainly erroneous, and, if not removed, will be the cause of many premiums remaining on hand, which might be carried off by almost any farmer in the state. It requires many years influence of an association, like ours, before its effect becomes visible in a general improvement of domestic animals. Such improvement is not the work of a day or a year, and therefore, a cow, a sheep, or a hog, which would now be richly entitled to a premium, would not be worthy of exhibition some years hence, when the effects of our annual exhibitions shall have been now fully developed.

It does then, evidently behove every well-wisher of our institution—every farmer who has any thing good, by comparison with that of his neighbors, to send it to the show.—In the commencement of peaceful emulations, such as are the objects of our society, before there has been time for the exercise of perseverance and the display of skill, the farmer who shews the best, though he takes

the plate, is entitled to no more credit than he who shews the best he can—and, those who refuse to bring any thing for fear it may be excelled, remind us of the young ladies we often meet in society, who, though they can sing very well, refuse to entertain the company because they cannot sing better than any one else. But what is excusable pride in a Miss in her teens, may be nonsense in a plain farmer. Let us make the exhibition as large and as respectable as we can, and if deficiencies appear, time and attention will remove them.

BALTIMORE MARKET.

PRICES CURRENT—CORRECTED WEEKLY.
Flour, best white wheat, \$7 25—Howard street, from wagons, \$7—fine do. \$6 50—Wharf, do. \$6 to \$6 25, do. do. \$6 cash—White wheat, \$1 20 to 1 30—Red do. \$1 10 to \$1 18, for Maryland, and \$1 to \$1 09 for Virginia—Rye, 44 to 45 cents—Corn, 36 to 38 cents—wheat Oats, 33 cts.—wagon Oats, 37½ cents—Beef, 8 cts. per lb.—Live Cattle, \$6 to \$6 50, per cwt.—Bacon, hog round, \$10—Pork, \$7 50 per c. lb., 6 to 8 cts. per pound—Mutton, 5 to 6 cts. per lb.—Beans, retail, \$1 50, cargo price, 1 12½—Peas, retail, 75 a 80 cts., cargo price 58 a 60 cts.—Red Clover Seed, \$6—Orchard Grass do. \$3—Herds' Grass do. \$3—Timothy do. \$4—Flax Seed, 75 to 80 cents—Whiskey, from the wagons, 33 cents per gallon including the barrel—Apple brandy, 30 to 32 cts.—Peach do. 65 to 70 cts.—Shad, \$6 00,—Herrings, No. 1, \$2 70 per bbl., No. 2, \$2 37½—Fine Salt, 75 cents per bush., coarse, do. 70—Butter, (firkin) 14 cts. per lb.—Eggs, 12½ cts. per doz.—New Hay, \$15 per ton, old do. \$16—Straw, \$9.

MARYLAND TOBACCO.—Five hogsheads Ohio tobacco sold from \$7 to \$13.

WASHINGTON JOCKEY CLUB RACES.

The races will be run over the Washington Course, commencing on Tuesday, the 28th of October, viz:

1st day 4 mile heats—purse \$500, free for any horse, mare or gelding:

2d day 2 mile heats—purse \$200, free for 3 and 4 years old only; and the

3d day 3 mile heats—purse \$300, free for any horse, mare, or gelding, the winning horse of the first day only excepted.

The purse of each day will be delivered, in due form, by the Treasurer, at the starting pole, to the successful rider.

A copy of the rules and regulations of the Club will be forwarded by the secretary to any one making application, who contemplates entering for the purses.

THE STEWARDS.

The following, forms one of the standing regulations of the Club, and at a full meeting on the 27th inst. it was specially determined to enforce it rigorously, viz:

"Resolved, That Gambling of every description be prohibited, and that the President, Vice-President, and other officers of the Club, cause this rule to be respected."

The officers hope for the countenance of the public in their determination to enforce this regulation with the utmost rigor and energy.

Printed every Friday at \$4 per annum, for JOHN S. SKINNER, Editor, by JOSEPH ROBINSON, on the North West corner of Market and B-widewere streets, Baltimore; where every description of Book and Job Printing is executed with neatness and dispatch—Orders from a distance for PRINTING or BINDING, with proper directions promptly attended to, addressed to J. Robinson, Baltimore.

AGRICULTURE.

TO THE EDITOR OF THE AMERICAN FARMER.

FISH AS MANURE—STATEMENT FOUNDED ON EXPERIMENT.

SIR,

I promised you when I had the pleasure of seeing you here last year, that I would give you the result of an experiment made by using herrings as a manure; and since I have fully tested the experiment, I now give you the result, with all its minutiae. In May 1822, I purchased 32,000 herrings, and placed them in drills 4 feet apart, on 4023 square yards of ground which is 817 yards less than an acre—they were placed quite thick in the drills—and then covered with a plough, by throwing two furrows together.—On the 24th May, I finished planting the ground in corn, by dropping the same on each side of the drill at about three feet apart; but found when the corn grew about three feet high it was much too thick, and was compelled to plough out every other row.—The corn was once ploughed with a small Corn plough, and twice with the Cultivator, which was all the cultivation I gave it—the corn yielded, when gathered, a fraction more than thirty bushels; and although last year the corn in this neighborhood, suffered much from the long drought, it had upon this corn no apparent injurious effect. While the leaves of other corn in its immediate neighborhood were dead and dried up above the ear, this was perfectly fresh; and the dry weather appeared not at all to affect its verdure.

On the 10th of October I again ploughed the ground, and on the same day sowed the same with two bushels of wheat—in the spring, the wheat grew so luxuriantly, I found it necessary to cut an acre with a scythe. It again very soon covered the ground.—The weather preceding harvest was very favorable to this wheat, being uncommonly dry—had it been wet, I believe not one bushel would have been gathered.—Dry as the weather was, it was cut with much difficulty, it had fallen to the ground so much.—It yielded, when carefully taken from the straw, twenty nine bushels—you saw the ground yourself, and know how very poor it was; and I am persuaded, had the fish been placed with some regularity on the surface of the ground, in the place of drills at so great a distance apart, by which the ground would have been regularly manured, it would have produced several more bushels of wheat than it did.—As it is, it yielded at the rate of 34½ bushels to the acre—I now give you the cost and profit:—

32,000 herrings, at 31 cts.	\$9 22
Hauling 5 loads of herrings } at \$1 25,	6 25
Ploughing in do.	1 00
Expense of planting and cultivating corn,	3 00
	<hr/>
	\$20 17
Cr.	
By 30 bushels corn at 75 cts. which was } the price last fall	22 50
Clear profit on the first crop.	2 33
I say nothing of the fodder, leaving that to pay the expense of getting in corn.	
39 bushels of wheat at \$1 25, - -	36 25
	<hr/>
	38 58
EXPENSES.	
2 bushels of wheat at 1 25,	\$2 50
Cultivation, - - - -	2 50
	<hr/>
	5 00
Clear profit, leaving the land rich,	\$33 58

I would here remark, that although I used 32,000 herrings, 20,000 to the acre is quite sufficient, and will make a more certain crop than a greater quantity. I have used this spring, Catfish and Perch for my potatoes, and find them as good again as the best stable manure; and you will find at Messrs. Bradford & Cooch's in a few days, a barrel of potatoes made from the fish—also a few at the top of the barrel in paper, the seed of which you gave me last fall—they were, I think, sent you from the North—they grew well with me, and are the finest potatoes for the table I ever saw.

Your respectfully,
BENJAMIN F. MACKALL.
Wilna Mills, Cecil County,
October 12, 1823.

FOR THE AMERICAN FARMER.

OBSERVATIONS ON THE VINE, AT SUNSWICK, N. Y. FOR 1823.

The season has been more unfavorable than I have known for years, but it has given us a favorable opportunity of judging of the effects of one of our worst seasons upon the various species of the grape, and of course, has added much to our experience in determining what kinds are most to be relied on in our climate. The wet and cold spring, injured very much the blossoms of the vine, and the same weather at times through the summer, caused a variety of vines, chiefly purple and black; such as the Black Hamburgh, and others of a delicate kind from France, to mildew. All my white grapes succeeded without any precaution, and the Chasselas of Fontainebleau was the most vigorous and prolific. All the grapes abovementioned were procured the last autumn, and remained entirely exposed to the winter's frost, except that a small heap of earth was drawn up over the roots six or eight inches on the stem. This was a precaution to preserve the root of the plant, if the experiment on the bearing wood should fail. American grapes, as the Dorchester from South Carolina, and Skuppernong from North Carolina, have done well. The Orwicksburg from the Schuylkill, appears also very thriving. I had a small bunch of grapes from a cutting put in the ground last March. This species, as well as the preceding, deserve particular notice.—I have now fifteen species of American grape, but only the three have produced fruit.

The Hungarian and German vines which I received the last year from Vienna, have done remarkably well, considering the long voyage. The Blue Cartager, which produces the Bunda or Osen wine, and by a particular process the Munster Tokay, is as vigorous as any of our American vines, and is also an excellent table grape. Some of the cuttings put down in 1822, have borne three or four large bunches, and produced shoots 20 feet long. This vine will probably become the favorite in this country.

The White Tokay has also produced fruit from cuttings of 1822.

The Queen Grape produced bunches 15 inches long.

The Rough Black and the Red Sheerkats produced large delicious grapes.

The White Muscat and White Chasselas, from the same place has also succeeded well.

The following is the order of their ripening this year.

- Chasselas and White Muscat, 5th September.
- Queen Grape, 12th September.
- Tokay, Cartager, Sheerkats, Rough Black, 20th to 25th September.
- Dorchester, or Isabella, 25th of September.
- Skuppernong, 1st of October.

It is probable that these grapes would ripen, in ordinary seasons, ten days earlier. The early frosts of this year, did not seem to affect any of the fruit. It is proper to mention here, that my vines suffered this year very much from bleeding profusely at the ends and eyes, in the spring, in consequence of having used a large quantity of stimulating manure the last year—(horn shavings.) Insects have not been troublesome this year, to the vine.

Your's, &c.

GEORGE GIBBS.

Sunswick, Oct. 10, 1823.

JOHN S. SKINNER, ESQ.

P. S.—The Watermelons from the seed you sent me, have ripened this year, but they are much inferior to the Chauncey melon, which I got from the Commodore, on his return from the Mediterranean. If you will accept a few seed I will send them on.

TO THE EDITOR OF THE AMERICAN FARMER.

HESSIAN FLY.

Bremo, October 11, 1823.

DEAR SIR,

I send you herein some blades of wheat, with the eggs of the Hessian Fly upon them. They are too minute to be examined satisfactorily without the aid of a magnifying glass, though they are discoverable by a good naked eye.

After keeping some blades of wheat three days, wrapt in paper in my pocket, and finding the eggs were still discernible, although the blades are much withered, and some of the eggs missing,—I hope the fresh ones, inclosed this morning, may reach you in such preservation, as to enable you in future to recognise the eggs in your own fields.

I have observed for seven years past, about the 10th of October, in this part of Virginia, the eggs are every where to be found upon the volunteer and early sown wheat—they remain in this state from six to ten days, when they hatch into very minute worms, and immediately descend to the tender parts of the plant, enveloped by the blade near the root, where, for a few days, at this season, they may be seen in this minute magot form, which they soon change into the chrysalis—at first, of a clear transparent white, which as it enlarges shows a split in the middle, and finally assumes the flax seed color and size.

I have been thus particular, although I published this account of the Hessian Fly several years ago, as subsequent observations more particularly excited by Dr. Say's account of this insect, in his communication to the Philadelphia Society for the promotion of the Natural Sciences, have fully satisfied me, that that learned and distinguished naturalist, has fallen into an error in relation to the propagation of this destructive insect.

It may be said that these eggs may be the deposit of some other fly—but I have uniformly found them when the well known hessian flies are seen to make their first appearance in the fall, and immediately preceding the fatal influence of this enemy to our wheat crops. I have seen the worms descending from the deserted shell of the egg towards the stalk of the plant, and upon stripping down the blade, I have discovered a worm of the same appearance attached to the tender stalk of the wheat near the root—and finally, in the course of successive examinations, I found these worms, after a few days, disappearing, and in their place the white transparent chrysalis.

By giving the foregoing a place in your valuable paper, it may possibly lead to some further

discoveries of greater value to the community than the mere *modus propagandi*, of this hitherto unassailable enemy to the most valuable of our agricultural products.

Your's, &c.

JOHN H. COCKE.

TO THE EDITOR OF THE AMERICAN FARMER.

ON BUILDING & FILLING ICE HOUSES.

Latitude 39° }
October 15, 1823. }

SIR,

I would not give one solid ounce of experience for a whole ton of theory.—I have an ice house, the pit of which is 6½ feet, the earth thrown out raised a good mound 2½ feet more, making nine feet to the bottom, which is a tolerably dry sand. It was for many years a pit with a pen inside, made of flat pieces of mauled oak—the earth came to the back of the logs.—In the centre of the bottom there was what was called a dry well,—that is, a round hole a foot deep, of which I have never perceived the advantage.—The same kind of mauled pieces laid on the bottom, formed the floor—the pen was about 11 feet square in the clear, with a capacity of about one thousand cubic feet. A thatch of corn tops on poles, formed the roof and cover, with a door of entrance into the north end. This house used to hold about from 30 to 35 common sized ox cart loads; the ice pounded from the size of a walnut to a brick.—It generally kept ice till the middle of August, and then left us more disagreeably off, than if we had not enjoyed it at all. It was near the poultry yard, and the blame was laid on the poor hens, who, fond of a cool place to nest in midsummer, used to scratch holes in the bottom of the thatch, and let in the rain water.—This was often one cause of the loss of the ice, but not the only one. The fact was too well established, the ice seldom reached September—and I became fully convinced that the principal reason of the early loss was, that the mass of ice was too small. The rats also plagued us very much in the chief use of a country ice house, the preservation of fresh provisions.

I determined to endeavour to remedy all the faults. With this view, the old work, now much out of repair, was broken up—the pit enlarged to 16 feet by 24, in which a 9 inch brick wall was run up to 6 inches above the ground, and the floor was paved two bricks thick—the pit was then 14½ feet by 22½ feet in the clear; and 8½ feet deep to the surface of the earth. On the pavement I laid four sills, on which I raised a frame, 11 feet by 19 feet in the clear, with sleepers 6 inches deep, resting on the pavement. The top of the frame even with the brick work.—A tight floor of good plank was laid, and the frame planked up tight on the inside.

This plank pen, or pit, is 11 feet by 19 in the clear. There is of course, a space of about 20 inches all round, between the plank and the brick work.

The design in making the pit oblong, was to take off 7 feet of one end, and appropriate it to milk in the summer season—but having a cool dairy which keeps milk pretty well, this was never done; and the whole pit, containing upwards of 1500 cubic feet, has been used for ice.

Above ground, upon the brick work, there is a framed house 24 feet by 16 feet; and 5 or 6 feet pitch. This house is but half boxed, and the air is freely admitted between the main and false plates. There is an upper floor laid on the joists, except a space about 2 feet by 6 in the centre.—

Directly over this space there is an aperture 6 feet by 6 or 8 inches, in the ridge of the roof, over which aperture there is a bonnet to keep the rain out. The sides and ends from the aperture in the floor, to that in the roof, are planked, so as to prevent any opening between the loft and this centre ventilator. By these contrivances, the loft is kept stowed full of straw to produce more than the coolness of a thatched roof, and yet the air has an uninterrupted passage in at the eaves, and out at the ridge. There are a few narrow strips of plank nailed a foot apart on the innersides of the studs—and the space between the weatherboarding and the strips is also filled with straw.

On the south side of this house there are trees, which break the rays of the mid-day sun from the roof.—The body of the house is kept white, and sometimes the roof.

When first used, the space between the bricks and planks was kept clear; with the idea that the air would prevent the damp from the earth and bricks going to the planks—but experience has fully proved in this latitude, that from the last of February the air should be kept as far from your mass of ice as possible.—For several years this space has been kept well filled with dry straw. We have ice in this house, at this time, and since it has been packed in the manner now pursued, it has not been unusual to have ice, till ice has again returned.

The mode of putting the ice up, is considered very material, and is as follows.—The space between the bricks and planks is examined, and seen to be well packed with dry straw—the plank pit is made perfectly clean. The ice is brought in as large cakes as can be conveniently handled, and in as regular squares or oblongs, as they can be conveniently cut and broken by the eye and axe.—These cakes are laid upon the naked plank floor of the pit, leaving as small joints and crevices between as possible. A trough or old canoe is placed near the door of the house—into this the small pieces and broken bits are put and pulverised quite fine, and the crevices between the layer of cakes is well filled with it; the surface of the cakes being kept clean.—A second layer of cakes is then laid down, and the crevices filled as before—and this simple method is continued till the pit is full. A very little care will keep the surface of each layer level, and the whole will go in as solid as a piece of stone mason's work.

No straw is put on the floor under the ice; because experience has proved, it is not necessary, and because if it should become wet and need to be removed ever so much, it cannot be got at.—Nor is there any put between the side planks of the pit and the ice at the time of packing, because it is not then necessary, nor can it be well done at that time.—With all possible care the straw will mix with the ice and be put in irregularly.—Whereas if the pit be filled solidly and entirely with ice, as soon as the ice begins to shrink from and leave the sides of the pit, this regular vacancy can be well crammed with dry straw, and if this straw get damp, it can be easily taken out and changed. But if the straw had been put in the ice, it would take up more space, and from its irregular stuffing, would be found much more difficult to remove, should it become damp or mouldy.

About the last of February, the mass of ice is covered over with dry straw, not less than three feet thick, and if straw is plenty, the house from the ice to the joists, is filled with it. It is considered very necessary to keep it wrapped under a thick coat of straw, sedge, or dry leaves. Should the straw next the ice become damp, be careful not to expose the ice to the air, but begin at one

end, and let the damp straw be pulled out—and the next straw above, which is not only dry, but cool, be suffered to settle down on the ice. If you have more dry straw, let as much as was taken out wet, be brought and put on the top of the straw in the house—or let the damp straw be dried and sunned and then returned on top of the straw in the house. Never think of changing the whole mass of straw on the ice at one time, by bringing fresh straw from the barn yard—for this dry straw from the barnyard will always be of a much warmer temperature, than your ice, and will be sure to melt it very much.

The advantages of packing ice in the above mode, over the common method of pounding into small lumps, are many, and striking.—In the first place, if the ice be three inches thick, or more, it can be stowed quicker with the same hands.—Again, you can pack much more ice in the same space—my house that used to be filled with forty-eight ox cart loads of ice when pounded, has often taken in seventy of the same sized loads, when packed in the whole cake—and this will not appear at all surprising upon a moment's reflection. By *pounding*, you do not pack it; but infinitely multiply the pores and crevices—any miller knows, that a bushel of corn when pulverised, or ground into fine meal, will measure out not far short of a bushel and a half. Any wood-cutter knows, that a cord of round logs, say a foot diameter, with the interstices filled with small round wood, if the logs be split or mauled into marketable wood, will measure near a cord and a half fair measure. But Sir, I will give you an example exactly in point, and which, at least, any countryman can try.—Recollect, *pounding* ice is very far from *packing* it. It is not compressible like flour in a barrel under the action of the packer. Take an ear of corn, roll it in half a sheet of paper—let the paper come just even with the but, or large end of the year, and an inch or two beyond the small end—twist the paper at the small end, and tie it with a string all round, so that when the ear is drawn out, the paper will form the exact case of it. Draw the ear, shell it, and return the grains into the paper case. If the ear is of the the gourd seed, or of a kind having long grains and a small cob, the grains which will lay packed exactly like the slippery hard pounded ice, will be found nearly to fill the paper case, notwithstanding the whole cob has been withdrawn.

If, sir, you are not now convinced that seventy loads of ice can be packed where forty-eight only will stow, when pounded—nothing need be said to attempt to convince you, that a mass containing the greater number of loads, will keep longer than one containing only the less number. But this is not all—when the ice comes into use, that which was packed is easily raised in large, native, solid, brilliant lumps, which will last more than twice as long, after being brought to the cooler, &c. as that which has been pounded.

I thought I would have given you the size and plan of a good cheap ice house, but I have already trespassed too far with the long story of my experience.

Your obedient servant,

CRÆSINUS.

THE CELEBRATED RACE HORSE ECLIPSE.

To those of our readers who are fond of fine horses, and of the sports of the turf as promotive of their improvement—it may be gratifying to know something of the pedigree and performances of the celebrated ECLIPSE. We understand that an English nobleman, distinguished in the annals of the turf, has been prompted by the

great achievements of this wonderful horse, to write to Mr. Van Ranst for the particulars of his family and his deeds. In the absence of more particular information, we here place on record some items gathered from an advertisement.

ECLIPSE

Will be six years old this spring, a beautiful sorrel, one white foot and star, fifteen hands three inches high, and exhibits more bone and muscle, and elegant symmetry of form, than any horse ever bred in the United States.

PEDIGREE.—Eclipse was bred by General Coles, from one of the first blood mares in this country, and sired by Duroc; his dam, Miller's Damsel, by Old Messenger; her dam, the imported English Mare Pot 8 o's, bred by Lord Grosvenor, sired by Pot 8 o's and Pot 8 o's by the celebrated horse Eclipse; her grand dam by Gimcrack; her great grand dam by Cripple, and Cripple by the Arabian of Lord Godolphin.

ECLIPSE, in May, 1818, when four years old, ran over the New Market Course the three mile heats, beating with ease, Mr. Van Mater's horse Sea Gull, and Mr. Correll's mare Black Ey'd Susan.—In June 1819, he ran the four mile heats over the New Course at Bath, beating Mr. Bond's horse Eclipse, Mr. Purdy's horse Little John, and Mr. Petter's horse Fitz-James.—In October 1819, he again ran the four mile heats at Bath, beating Mr. Purdy's horse Little John and distancing Mr. Schenck's horse Fear-Not, and Mr. Bond's colt, running the first heat in 8m. 13s. and the second heat in 8m. 8s. In all his running he never lost a heat, and when it is considered that the Bath Course instead of falling short, measures 15 links over a mile, the last running was truly great, and yet it was done with great ease.

THE TERMS.—Five Pounds the Season, to be paid, with the expense of keeping, when the mares are sent for and, in the character of Mr. Thorn and Mr. Snedeker, the public have an assurance that the best attention will be paid to the mares, but accidents and escapes at the risk of the owner. Insurance to be made by agreement.

C. W. VAN RANST.

New York, May 16, 1820.

Thus it appears that he can trace his pedigree through a line of "noble ancestry," up to the celebrated English Racer ECLIPSE—his great great grandsire—of that horse we have a portrait, and the following history, by LAWRENCE in his splendid work, entitled "THE HISTORY AND DELINEATION OF THE HORSE IN ALL HIS VARIETIES," which may be seen at the office of the American Farmer.

Eclipse, a chesnut Horse, foaled during the great Eclipse in 1764, whence his name, given by the Duke of Cumberland. Got by Marske,*

* I will, in this place, speak a few words on the pedigree of the renowned Eclipse. It has always been taken for granted, that he was a son of Marske, a fact, beyond the power of man to ascertain. Eclipse's dam was covered both by Shakespeare and Marske, and she came to Marske's time, so the honour was awarded to him. If I recollect aright, she had missed by him the previous year. But the circumstance of a mare coming regularly to her time, determines nothing, since they are so uncertain in that respect, in which I have repeatedly known variations from a week or ten days, to two or three weeks. Great stress was laid upon the supposed likeness of Basilus, one of the earliest sons of Eclipse, to old Marske, and indeed the resem-

blance appeared to me strong; but I could discover no common family-resemblance between Eclipse and his presumed full-brother Garrick. On the other hand, I think Eclipse strongly resembled the family of Shakespeare, in colour, in certain particulars of form, and in temper. Nothing can be more unimportant than these speculations, and Eclipse's pedigree would suffer no loss of honour or credit, should Shakespeare be placed at the head of it; which horse had more of the Darley Arabian in him, than Marske, and in all respects, was equally well-bred, and full as good a runner. Shakespeare, like Marske, was a great-grandson of the Darley Arabian, through Hobgoblin and Aleppo, and his dam the little Harteley mare; the dam also of Blank, was a grand-daughter of the same Arabian, and out of the famous Flying Whig. One or two of the sons of Eclipse, yet alive, appear to me strongly to resemble the Shakespeare.

It is necessary, however, to subjoin the late intelligence on this subject, with which I have been favoured by Mr. Sandiver, of Newmarket, which goes to assert, on the authority of the stud-groom, that Eclipse's dam really never was covered by Shakespeare. On this I can only observe, that in the year 1778, I was frequently in the habit of visiting Old Eclipse, then at Epsom, on which occasions I often discoursed the subject of the disputed pedigree, with Colonel O'Kelly's then groom, who assured me that the mare was covered by Shakespeare, which account I also had from various other persons, as a well-known fact. And to conceal nothing, it had been reported, that a groom had been bribed to ascribe the get of Eclipse to Marske, there being a strong interest in the reputation of that stallion. I have no doubt, but Mr. Vauxhall Clarke will recollect this report. The reader will observe in the annexed plate, the two horses together, and will judge for himself, as far as resemblance may be supposed to determine. Both horses are shewn in a racing condition, but Shakespeare, why, I know not, appears full of flesh, and in such state, was much resembled by Eclipse, whilst that Horse was in his loose stable as a stallion.

Why Eclipse was withheld from the course, until five years old, I have never heard, but he was privately tried at Epsom, about that time; and indeed, it is impossible his proprietor could have remained so long unconscious of his vast powers. When I first saw him, he appeared in high health, of a robust constitution, and to promise a long life. I paid particular attention to his shoulder, which according to the common notion, was in truth very thick, but very extensive and well placed; his hinder quarters, or croup, appeared higher than his forehead, and in his gallop it was said, no horse ever threw in his haunches with greater effect, his agility and his stride being upon a par, from his fortunate conformation in every part, and his uncommon strength. He had considerable length of waist, and stood over a great deal of ground, in which particular he was of the opposite form to Flying Childers, a short-backed compact Horse, whose reach laid in his lower limbs; and if there be any common sense in forming such a comparative judgment, I should suppose Eclipse calculated to excel over the course, Childers, for a mile. Eclipse was an excellent, but thick-winded Horse, and breathed hard and loud in his exercise. When viewed in his flesh, as a stallion, there was a certain coarseness about him, but a critical eye could discover the high bred Racer in every part.

Eclipse won eleven King's Plates, the weight for ten of which was twelve stone, the remainder ten. He was never beaten, never had a whip flourish over him, or felt the tickling of a spur, or was ever, for a moment, distressed by the speed, or rate of a competitor; out-footing, out-striding, and out-lasting, every Horse which started against him. His proprietor acknowledged that he gained twenty-five thousand pounds by Eclipse. In twenty-three years, three hundred and forty-four winners, the progeny of this transcendent courser, produced to their owners, the sum of £158,047 12s. various prizes not included. The general character of the descendants of Eclipse is speed, although some, both immediate and remote, have been remarkable for their stoutness or game; for example, Lord Surrey's Whizgig, and the present celebrated stallion Gohanna, by Mercury, the best four-mile horse of his day. Many of the Eclipses, I remember, bent their knees, and were remarkable high-goers.

A vineyard of Mr. Eichelberger, in York, Pennsylvania, contains ten acres, covered with vines of Lisbon, white and other grapes. He will make 40 barrels of wine this season, and he intends to extend his vineyard to 20 acres next year.

FOR THE AMERICAN FARMER.

DEAD FENCES—VERSUS LIVE ONES.

Your friends, Messrs. Kirk and North, having engaged in this controversy, it may possibly be deemed an invidious task for a third person to take a hand; and the man who dares thus to volunteer, will probably fare no better than the unlucky wight who intermeddles in a dispute between husband and wife. Be this as it may, the subject being of general interest, and the business of live hedging in many parts of our country, threatening to become a hobbyhorse affair, I will, at all hazards, contribute my mite towards preventing the expenditure of too much time, labour, and money in the attempt to render this mode of inclosure, general. The account between the two systems, I think may be fairly stated thus:

Live fences take from cultivation, all the land upon which they grow; say, a space at maturity, (even from what Mr. Kirk calls a hedge-proper,) of not less than 5 or 6 feet. And they impoverish the earth on each side, to a distance, at least 5 or 6 feet more.

Live fences are an annual expense forever; great or small according to the part of the country in which they are made, but considerable every where.—It consists of the following items; a *dead fence* and generally a *ditch* to guard the live one, for at least 4 or 5 years, and often 7 or 8; manuring, unless in very good land, planting, cultivating for 2 or 4 years, and pruning every year after it rises a few feet in height, as long as it lives.

Live fences (unless made of holly, which requires 15 or 20 years to gain sufficient size,) are subject to various diseases, that often kill considerable portions of them; and the breaches must be repaired either by a *dead fence*, or by setting other plants which are many years in acquiring the requisite size and strength to stand alone without their *dead protector*. Add to this the well known fact, that young plants never thrive well between old ones.

Live fences under the best possible management—in the best land, are never above an adequate protection in less than 7 or 8 years; and in general, are 12 or 14 years in acquiring sufficient strength.

Lastly, and irremediably; live fences are *immoveable*, which in the continually fluctuating state of our farms, as respects size and form, necessarily produced by our law of descents in conjunction with public sentiment, constitutes a permanent and insuperable objection to them as a general system of inclosure in most, if not all of the United States.

Dead fences impoverish not a particle of soil, and cover at most, not more than 9 or 10 inches in breadth.

Dead fences cost nothing, (there being no market for timber in most parts of our country,) but the preparation of the posts and rails, and putting them up, which can be done by almost any common labourer. And, if made of locust and red cedar, either singly or mixed, they will last from 15 to 25, or 30 years, without one cent's worth either of labour or money being expended on them. A common worm fence is still cheaper in regard to labour, and when made of chesnut or white oak will last 10 or 15 years.

Dead fences are liable to no disease whatever, but a natural decay, very long delayed; and a few days work repairs all the damage.

Dead fences can be made in a few weeks, and are as effectual the moment they are planted, as they ever are afterwards; requiring no guardian to protect them during a helpless minority.

Dead fences need only a few days transportation to be changed from place to place, as often as interest, convenience, or fancy may dictate.

These remarks, Mr. Editor, are not the conjectural estimates of a mere theorist, but of one who, although no cultivator of live hedges, (except on a small scale and in a single case,) has seen many of them in different parts of our country, and taken considerable pains to inform himself in regard to the advantages and disadvantages of all the different modes of inclosure practised in the United States. The result of my enquiries and reflections is, that live hedges are nowhere to be preferred, unless perhaps in the most thickly populated parts of our country, where timber is both very scarce, and very dear. As ornaments and protections from theft for fruit gardens, I should also admit that where full grown, they are better than dead fences.

In making a comparison between the two, the only fair way is, to determine—not what *might*, but what *would* be the state of live hedges, were they to become general. It is therefore *unfair* to conclude, that because Mr. Kirk, an excellent manager of hedges, an industrious, careful, persevering man; one too, who appears to take a very natural and laudable pride in the business, has succeeded, consequently every body would succeed. We know the contrary to be the fact; and I would go no farther than his own State, (the hedges of which I have several times seen,) to prove it, then for our "hedges proper," as Mr. Kirk very properly calls it, you will see 20 "hedge rows," as he very *improperly* terms them, for there is no row at all on considerable portions of space designed to be occupied by the hedges.—Even in England, I am well informed that this is frequently the case; and that the proportion of "hedges proper," to "hedge rows," is very small indeed, compared to what we should expect, if we consulted only the panagers of English hedges. I take this fact from Marshall and other English writers on husbandry; as well as from several observing friends who have travelled over England. Let it not be said that this arguing against the use of a thing from its abuse; for it is not only a sound, but unanswerable argument, where the abuse is continually much more frequent, than the good use.

The last objection stated in my contrast, is peculiar perhaps to our country, but never likely to be removed. The law of entails which had a powerful tendency to keep landed estates together, has been abolished with us not quite 50 years I believe; yet in co-operation with the public sentiment which produced it, so effectual has been the operations of the *repealing* law, that in Virginia at least, there is scarceley a single fence, unless along a public road, which remains where it did, when I was a boy. The same proprietor rarely ever retains the same farm in the same shape, long enough to raise live hedges exactly where he wants them, for he either augments it by purchase, or diminishes it by sales, which is more commonly the case, in such a way as to render a frequent change of inclosure absolutely necessary. But should the size and form continue the same during the father's life, which they very seldom do, both are immediately changed, when the farm comes to be divided among the children, who always have to *undo* and alter the greater part of what the father has done in the way of fencing.

A word or two on Mr. Kirk's comparative estimate of costs: however accurate they are for his own neighbourhood, I know them to be incorrect in regard to many parts of our country.—But the question is, not what hedging costs *him* and *his neighbours*, but what would it cost the people of the United States generally, if every proprietor of land should choose to make living, instead of dead fences. I know also that locust, red cedar, chesnut and white oak grow well in a

great majority of the States: and I have experimental knowledge that the two first, if planted along a post and rail fence, in tolerably good land, one at each pannel, will attain full size for posts and rails long before the first fence requires to be renewed. The locust will live upon transplanting as readily as a cabbage plant, and needs only one or two slight prunings. It grows also, rapidly from the seed, and is the most durable wood known in our country, 30 and 40 years being a common period for posts to continue sound, if well selected. Red cedar is also very durable, and may easily be raised either by transplanting with a sod about the roots, or from seed having their resinous skin either broken, or partially rubbed off.

To conclude, whatever may be thought of the foregoing remarks I claim for them, at least the merit of impartiality: for I have no personal knowledge either of Mr. Kirk or Mr. North; and have neither pride of opinion, hobbyhorse predilection, nor pecuniary interest to serve by any thing that I have written.

As my name can be of no importance to any body, I subscribe myself, your constant reader and friend.

CUI BONO.

PETERSBURG, Va. Oct. 15.—Our races commenced yesterday with the \$1500 sweepstake for three years old only, and was won by General Winn's Elizabeth, full sister of Rattler and Childers—beating Mr. Johnson's Defiance, and Mr. Harrison's Arab.—Defiance took the first heat. Time 3.53—3.57 and 4.

Second day's purse of \$300—3 mile heats, was won by Mr. Johnston's Washington, beating Mr. Harrison's Tyro. Time 5.48—5.53½.

To-morrow, John Richards and Betsey Richards, are to run—a great race is expected—betting even.

General Winn has arrived at Baltimore with Childers, Sumpter, and Vanity: afterwards will attend the races at Washington.

Mammoth Beets.—Were raised this season, in the garden of Daniel Schnebly, Esq. in Hagerstown, Maryland, twenty beets, which averaged upwards of ten pounds each; the heaviest weighed fourteen pounds, and measured thirty-two inches in circumference.

Good News for Cotton Dealers.—We learn that letters were received in this city by the John Wells, dated Liverpool, September 8th, which inform, that on that day there was a brisk demand for cotton by the manufacturers, and that holders demanded an advance of a farthing per pound upon the prices of the 6th.

PATERSON, N. J. Oct. 8.—*Extraordinary product*.—Mr. Jacob Berry, of Pompton Plains, authorizes us to give the following statement of an extraordinary product from one grain of Corn. It came up in the month of May last, but being nipped by the frost, was cut off level with the ground with a knife. It sprouted again soon, and produced five stalks, besides the main one—four of which had two ears of Corn a piece, and the main stalk had four; one stalk nothing. The whole twelve ears yielded one quart and one pint of shelled Corn, heaped measure, making 1½ all three thousand seven hundred and ten grains from the one grain.

RICHMOND, VA. Oct. 14.—It rarely occurs in our climate, that the same fruit tree bears two crops in one year. On the 12th inst. however,

we met with an instance of this description. A soil-peach tree has ripened its fruit twice this year in a garden near this city. The last peaches were, of course, very small; but they were very sweet. The stones were of the Lilliputian order, without kernels. In the same garden, there are a number of blossoms on the pear trees; but it is remarkable, they are all upon those branches of the trees which are technically said to be ravished; that is, the bark of which has been cut around to force the ripening of the fruit in the Spring. This process, however, has shewn its effects this fall in the way we have mentioned. Blossoms have put out, and some young pears formed; but the early frost will most probably nip all the fruit.—*Enquirer.*

COFFEE POT.

The following description of a newly invented coffee pot is from the *New Monthly Magazine*.

Ingenious and useful Invention—Among the new inventions for which Paris is famous, is a coffee pot constructed of three pieces; the first is a plain boiler—over that is a double filterer—and at the top is an inverted coffee pot, which fits on exactly. Cold water is placed in the first vessel, and the coffee in the filtering box. Under the whole is a spirit lamp, which in the course of five or six minutes causes the water to boil, the vapour arising from which completely saturates the coffee. When the water boils, which is ascertained by the discharge of the vapour from the spout of the inverted coffee pot, the whole machine is lifted from the lamp, and completely inverted—so that the pot, which was uppermost, is at the bottom, and the boiling water, which had saturated the coffee, flows through the filterer, clear, into what was before the inverted coffee pot, which in the space of two minutes it is ready for use. This mode of preparing coffee is a saving of at least 25 per cent. and it secures the fine flavour of the berry. In another part of the service is a coffee roaster, of glass, over another lamp of a long wide flame. The process of roasting requires about three minutes, and even so small a quantity as an ounce may be thus prepared.

Progress of Printing, &c.—In the English Parliament, the annual motion for reform in the representation had been made by Lord John Russell, and negatived by a vote of 269 to 164. The result was received with loud cheering by the opposition, as showing an accession of strength to their cause. In the course of his speech, Lord Russell, stated several facts to show the improved state of all classes from the increased means of instruction, and the propriety and justice of giving to the mass of population a representation proportioned to its increased relative weight and improvement. He stated, as among the results of his inquiries into the extension of the means of instruction, that the sales by one bookseller's house in London, amounts to £5,000,000 sterling, (upwards of \$22,000,000,) worth of books; that they employed sixty clerks, paid £5,500, for advertisements, and gave constant employment to no fewer than 250 bookbinders. The increase of circulating libraries had also been very great, there being about 1000 of those establishments in the kingdom, and from 1500 to 2000 marts for the sale of books distributed throughout the country; in addition to all which was the quantity of newspapers annually distributed, the number of which, for the year 1821, he estimated at 25,000,000, and of those 11,000,000 were London daily papers; country papers, 7,000,000. The increase of presses in 40 years had been from 79,

the whole number in 1781, to 284, in 1822; yet with a population of 18,000,000 so provided with the means of knowledge, a majority of the representation in the Parliament was returned by less than 8,000 electors.

Children's Food.—A lady of Yorkshire observes, in a letter dated May 2, that, in consequence of her losing her first three children, one during teething, and two of inflammation in the bowels, she gave her fourth child a little lime water in every article of food, adding a dessert, and sometimes only a teaspoonful of lime water to every article, whether liquid or thick. It succeeded in keeping up healthy digestion, and a regular state of the bowels: the child, instead of being feverish, flatulent, and fretful, as all her preceding children have been, continued cool and cheerful, free from any system of indigestion, and cut its teeth without any constitutional disturbance. She has continued this practice with two or more children with the same good effects. We have known this simple addition to the food of children, prove very efficacious in incipient cases of rickets and of irritable bowels, attended with looseness, &c.: but if the child be disposed to costiveness on account of its astringent quality, a little magnesia should be occasionally added to it.—*Gazette of Health.*

A very healthy old gentleman was once asked, in a mixed company, what physician and apothecary he employed, in reference to the unusual vigor and healthiness of his appearance; he answered, "I have in my earlier days, expended a considerable fortune in the purchase of health, and in the continual search after professional skill and integrity. I have found it in combination as various as its professors are numerous; but I have in no case found myself so honestly served, or so completely satisfied, as with those I have employed the last twenty years; for, during that time, a horse has been my physician; an ass my apothecary."

Cramp.—Extract of a letter to the Editor of the Gentleman's Magazine for May, 1762, containing an easy remedy for the cramp:—"Near five years ago, being from home, and obliged to lie upon a very hard bed for two nights, though I could not sleep the first night through the uneasiness of my lodging, yet I had no cramp. The second night I slept well, but no cramp. The loss of my old tormenting companion for two nights together, a circumstance I had not experienced for years before, set me on thinking what could be the cause. I could not recollect any other alteration in my manner of living than passing from a soft bed to a hard one, I therefore imagined that that might be the cause; and likewise reflecting that this disorder almost always makes its attack in the night, I guessed it must, in a great measure, proceed from the unnatural position of the body in a soft bed, where the body sinks down and the feet rise up. I immediately set my joiner to work, and made my bedstead regularly sloping, so that there was about a foot difference in height between the head and the feet. I likewise put a hard mattress upon the bed; my project succeeded, and (I thank God) I immediately got rid of my grievous pain, which I have not felt since, near five years, unless a few times, when, through mistake of servants, the feathers of the bed were left too full at bottom, and, by that means, the feet raised higher than they should be. If this should be looked upon by the learned as trifling, yet 'facts are stubborn things,' and will not bow down to the most learn-

ed and ingenious hypothesis. It may be necessary to add, that as the bed slopes so much, something ought to be fixed at the bottom, for the feet to rest against."

New Process in Tanning.—We have heard Tanners, of intelligence as well as experience, speak highly of the mode of tanning leather, advertised by Mr. Charles Monroe, of Northborough. It is said that leather may be tanned by his process, in ten or twelve days, as well as it is in the more tedious method now practised. We understand some specimens of leather, tanned in this way, will be exhibited next Wednesday.

Hops.—The growth of Hops in England is said to have nearly wholly failed this season. We understand, that the growth in this State has been heavy, and turns out well. The reputation of Massachusetts hops stands high in Europe—thanks to the fidelity with which our Inspection Laws are executed. We learn, that more than a million pounds weight are annually raised in this State, and principally in the county of Middlesex.

NETTLES.

Every body knows that the leaves of stinging nettles are thick set with sharp prickles that penetrate the skin when touched, and occasion pain, heat and swelling, which symptoms were imagined formerly to ensue from the prickles being left in the wounds they made. But the microscope discovers something much more wonderful in this common vegetable, and shows that its prickles are formed and act in the same manner as the stings of living animals. Every one of them is found to be a rigid hollow body, terminating in the most acute point possible, with an opening near its end. At the bottom of this cavity lies a minute vessel or bag, containing a limpid liquor, which upon the least touching of the prickle, is squirted through the little outlet and if it enters the skin, produces the mischief before mentioned, by the pungency of its salts. Hence it comes to pass that when the leaves of nettles are considerably dried; by the heat of the sun, they sting but very little: whereas such as are green and juicy produce violent pain and inflammation.—*N. Y. Minerva.*

Editorial Correspondence.

Extract to the Editor, dated Charleston, September 22, 1823.

"I paid a visit to my plantation the day before yesterday, and found the Isle of France cotton beginning to throw out forms, from whence come the blossoms, which makes it too late to bring any thing of consequence. We are now harvesting our rice and cotton crops—a more plentiful one I never saw."

To the Editor of the American Farmer, or to any person who has any information on the subject.

A dreadful malady has appeared among the cattle in Talbot on two different farms. The animals are seized with a muscular or nervous catching, that resembles hiccoughs, when the complaint seizes them in the head, which it chiefly does; but some have been affected behind, some in one leg, some in the chest, and some across the loins—the catching increases—the part affected is hot and appears to itch so violently, that they soon rub all the hair off, and lacerate the flesh—they appear to have high fever; take to the water; and can be with

difficulty kept out of the creeks. They appear costive, and die in 24 or 36 hours—bleeding, purging, medicine and Antispasmodic balls have been tried without any success.—*Easton Gazette.*

The Editor solicits the immediate attention of his correspondents to the above, and will himself investigate the subject, by all the means in his power. In the mean time he sends to the gentleman, whose losses dictated the paragraph, the latest treatise on the disorders of cattle, which he begs him to accept.

The symptoms, as here described, seem to indicate a disease arising from some incidental, or local, rather than general or epidemic influence. It is probable, in other words, that some poisonous seeds, or other vegetation are developed at this season, in particular places, or by the peculiar weather, to cause such effects; which are, in this instance, more conformable to the symptoms of poisonous diet, than those of infected atmosphere. This view is taken from a comparison of the general aspect of symptoms, as described by authors, in those two conditions of disease, arising from the one or the other of those sources. The remedy in the present case would be, to shut up the cattle, and to treat those affected, by evacuating the stomach and bowels, as quickly as possible, and drenching copiously with mild diluents, as flax seed and melon seed tea—horse radish added, would probably counteract the effects of poisons, in producing cramps, as they usually do, in the stomach and limbs. Any one attentive to these subjects, could readily perceive why a poison taken into the stomach should act differently on the system, from one taken by breathing or infection:—the former disturbing the digestive organs first, and causing some other local affections, by their peculiar influence on particular organs—the latter, more general, causing coldness and fever, debility, thirst, costiveness, &c. before the stomach and brain are much disturbed, such being the difference between atmospheric exhalations and poisonous food. If they proceed, even in the present instance, from the former cause, the shutting them up would exclude them from the more direct influence of the cause, morbid exhalation, and besides, would tend to obviate its influence by a more tonic or bracing diet. In either case, the itching and heat of the skin, would indicate a want of transpiration at the surface—or morbid humour thrown there, which the free internal use of sulphur, say one ounce, three or four times a day, would counteract in a warm place, with the flax seed, &c. as stated above, especially after the passages were evacuated. The malady is indeed a serious one, as will appear by the following extract to the Editor:—"Since Thursday week, I have lost eight of my grown, and most valuable cattle—my pet cow Europa—5 working oxen and another one of the finest spirited animals that ever bowed his neck to the yoke, is now sick!"—*Edit. Am. Far.*

FOR THE AMERICAN FARMER.

OIL FROM COTTON SEED.

I find among my memorandums that in the year 1806, I imported from Charleston nine bushels of cotton seed, weighing forty pounds per bushel, on which I caused an experiment to be made to ascertain the quantity of oil it would yield by the process usually practised in extracting oil from flax seed. The result was that the nine bushels produced six and a quarter gallons of clear oil of a quality quite equal, if not superior, to flaxseed oil for painting—the seed was not of the best quality, nor was the experiment very perfectly made. T. E.

ENCOURAGEMENT OF MANUFACTURES.

It is a wise policy in a government to furnish employment for all its subjects. Yet no advantage is gained by crowding persons into trades, occupations or professions which are already sufficiently full. But, when a new field for industry and enterprise is opened, this redundancy of the body politick is removed; the supernumeraries are drawn off from the various occupations; each individual finds full employment at reasonable

wages; all the various classes of society increase at the same time, preserving their proportion to each other; and the country makes a regular and uninterrupted advance in wealth, population, refinement and happiness.

These considerations, if founded on truth, afford a plain direction in relation to the measures which a government ought to adopt, with regard to the admission of foreign manufactures. If the country is capable of producing the raw material in the greatest abundance, and, besides, furnishes every natural facility for manufacturing; if there are thousands of people sitting still for want of employment; if there are thousands of others, who merely overstock agriculture, and the other various occupations of society, keeping down the prices of every thing, from a vain attempt to sell what there is no demand for, and ruining each other by clogging and embarrassing business; then, notwithstanding the low price at which the surplus produce of a foreign market may be afforded, it is the dictate of sound policy to lay such a duty on it, that the people may be encouraged to engage in manufactures.

This is apparent from two considerations: 1. Because such a policy would relieve the other occupations, of their supernumeraries. 2. Because, in this, all the various classes of society would be able to make a living with the profits which they would derive from supplying each other, with the respective products of their industry.

It is very disheartening to be obliged to bestow labour in producing or manufacturing when there is little or no demand for the product; or when it becomes necessary to make great sacrifices in the price of a commodity to secure the sale of it, or anticipate competitors in the market. And lowering the price will not relieve the dealers as a body—for though those individuals who sell cheapest will sell first, those who ask a high price will not sell at all; and if all set a low price on their goods, yet they will not all be sold, unless absolutely sacrificed. For the extent of the demand for consumption will remain the same, whether the price is cheap or dear. For instance, if the regular demand of the market, is for 1,000 of a particular article, and the supply regularly consists of 1,100, the consumers will buy 1,000 cheaper or dearer, and will buy no more, cheap or dear. If those 1,000 are worth \$100,000, when the supply and demand are equal, then when the demand is for 1,000, and the supply is 1,100, the 1,000 will bring less than \$100,000, the 100 will not be sold at all in the home market for consumption. Thus every kind of business, will be found to be like a boat, which will carry a certain number with safety, but if more will embark, it is not merely the supernumeraries who will sink, but if they rashly stick to it, and hold out against each other, they must all drown together.

From such a state of embarrassment it would be very difficult to free the country in any other way than by encouraging home manufactures.

Selections.

Conversion of Animal-Hides or Skins into Leather.

This process is what is generally termed *Tanning*. It is founded on the affinity which is known to exist between the gelatinous part of the Hide, and the *Tan* or astringent principle of Oak bark, and other vegetable substances.

It is well known that unless Hides are speedily dried, they become putrid, and consequently unfit for use. But even although they be successfully dried, they are still unfit for the manufacture of shoes or other necessary articles; being permeable to moisture, and liable to be soon destroyed by friction. Consequently in almost every

ry country where animal hides are used for purposes of convenience, they are made to undergo certain modes of treatment, which render them not only impermeable to water, but also tougher, and more pliable, so as to be easily and advantageously worked.

The combination of the Vegetable Astringent principle, or Tannin, with the gelatine (which forms almost the whole of the hide,) changes it into leather, which is a substance totally different in its properties to the hide in the raw state. To tan a hide then is to saturate it with Tannin.

Previous to the operation of tanning, the raw or green hides must undergo the process of washing and scouring, to free them from foreign matter, and to remove the hair. Hides are first put to steep in water, either pure or acidulated, to clear them of the blood and filth they may have collected in the slaughter-house. They are left to soak in the water for some time; and then handled, or trod upon by the feet, the better to cleanse them of all impurities. If the hides are dry they are steeped a longer time, sometimes for four days or longer, according to the season of the year, and care is taken to draw them out once a day, in order to stretch them on a wooden horse or beam. These two operations are repeated till the skin becomes raised or well softened. A running stream is necessary in these operations, else the hides cannot fail of being ill prepared.

When the hides have been well raised, and softened, they are next freed from the hair, by the application of lime. In all tanneries, pits are formed having their sides lined with stone or brick, in which limestone is slacked, so as to form milk of lime. Of these there are three kinds, according to the strength of the lime. The hides intended to be scoured are first put into the weakest of these pits, wherein they are allowed to remain, until the hair readily yields to the touch.

If this liquor be not sufficiently active, the hides are removed to the next in gradation, and the time they have for soaking, is longer or shorter, in proportion to the strength of the lime, the temperature of the air, and the nature of the hides. Those of sheep require to remain in the pits only a few days. It has been proposed to substitute lime water in place of the milk of lime. But though the lime water acts at first with sufficient strength, its action is not sufficiently permanent, and in order to succeed in clearing the hides, it is necessary to renew it occasionally. In some tanneries, after the hides have been kept in the pits for a short time, they are piled up in a heap on the ground; in which state they are suffered to remain for eight days, after which they are returned into the same pits from whence they were taken, and this process is repeated till the hair can be easily scraped off.

Hides may also be cleansed, by subjecting them to an incipient fermentation, produced by scouring a mixture of barley-flour in warm water, and soaking the hides in it, till they are sufficiently swelled and softened to admit of being cleared from the hair. In each tan house are placed several tubs full of this acid liquor, which is of different strengths in proportion as it is soured. In those containing the weakest liquor, the hides are first soaked, handled, and washed; and after two, or at most, three of these operations, they are sufficiently prepared to admit of being freed from the hair. If more easily procured, rye flour may be substituted for barley.

The Calmuck Tartars employ sour milk with the same view, and Pfeiffer proposes the use of the Acid water obtained from the distillation of Coal and Turf. It indeed appears sufficiently ascertained, that all the vegetable acids, and even

diluted Sulphuric Acid, answer equally well for this purpose.

In some tanneries, they cleanse the hides by throwing salt over one-half of the skin, and doubling the other half over it; in proportion as each hide is salted, they are laid one above another, and the whole are covered with straw or flax; fermentation soon begins, after which they are turned once or twice daily, until they are found to be in a proper state for removing the hair. They may be cleansed, however, much in the same manner, without the employment of salt, by piling them up on a bed of litter, and covering them with the same material for twenty-four hours. At the end of this period they are turned over, and afterwards examined twice a day, in order to ascertain when the hair may be readily removed.

In some tanneries the hides are buried in dung, while in others, they are simply exposed in a close apartment, termed a *smoke house*, heated by means of a tan fire, which gives out smoke without flame. The hides are suspended on long poles placed across these apartments, which are heated very considerably.

All the methods in which fermentation is employed, are termed *heating processes*. In whatever manner this operation has been conducted, as soon as the hair is in a fit state to be removed, it is scraped off, on the wooden horse, by means of a blunt knife, or by a whet-stone. This operation is not only intended to remove the hair, but likewise the Scarf-skin or Epidermis, which is of a very different nature from that of the true skin. It is insoluble in Water, and Alcohol; is soluble in Acids, but not susceptible of combination with Tan, so that when left on the hide the Tan can only penetrate through the under side, by which means the process of Tanning is rendered extremely tedious.

There are many vegetable substances which possess the tanning principle, or Tannin; but those which possess most, are the oak, alder, willow, and Peruvian bark, also the gall nut.—The Peruvian bark from its scarcity and high price, is only used in Medicine. As oak bark possesses more tan than any other vegetable substance, it is generally used for Tanning.—This bark, being stripped from those trees which are cut down in the Spring of the year, is dried in covered heaps, in the open air. It is then ground to a coarse powder in a mill, and mixed with water in the Tan-pits. The infusion, or liquor, which is of a brownish Amber colour, is called *ooze*; but is, properly speaking, a solution of Tannin and other vegetable matters.

The Hides, being scoured, raised, and softened, are first subjected to the action of weak *ooze* in one of these pits: here they remain for several weeks, and in the interim, are frequently agitated, or handled. From thence, it is removed to a pit containing a stronger infusion, where it remains for a considerable time; that is, until it has absorbed all the Tan. It is now immersed in a still stronger infusion, and so on. When the Hide has attained the colour of Cinnamon bark on its outside, and when its internal parts are equally brown when cut through with a knife; it has received its full dose of Tan, and is converted into Leather. But if a white or greyish streak appear in the centre of the Hide or Skin, it is to be again immersed in the Tan-pit. Calf-skins require only about two or three months before the process of tanning is finished, whereas Ox-hides are not perfectly converted into Leather, for 6, 8 or even 15 months.

When perfectly tanned, the hides are taken out, drained, passed between two Iron cylinders, that they may become pliant, and are then hung up in a drying house, until they become perfectly dry

by exposure to the air. The smaller hides now undergo the operation of *currying*, which renders them pliant, and reduces them to an uniform thickness. This consists in cutting, soaking, paring, scouring, stretching and oiling. The Leather is then blackened by a composition of lamp-black, oil, and tallow, which is rubbed hard into the fleshy side. It is now fit for sale.

Observations. It is to be observed, that leather would be tanned much sooner, and equally well, if the tan-pits were made *within* a building so as to be secured from rain; and if the building were furnished with flues or steam pipes, so as to keep the temperature of the vats constantly at a full summer heat. Another important improvement might be made in tanning, if the skins were hung vertically in the pits, so that the tanning liquor might, from the first part of the process, touch every part of the skin equally.

German mode of curing Hams.

In Westphalia, Hams are cured between November and March. The Germans pile them up in deep tubs covering them with layers of salt, saltpetre, and a small quantity of Bay-leaves. In this situation they let them remain about four or five days, when they make a strong pickle of salt and water, with which they cover them completely; and at the expiration of three weeks they take them out of pickle, soak them twelve hours in clean water*, and hang them up for three weeks longer in a smoke made from the *juniper bushes*, which in that country are met with in great quantities.

* This accounts for the freshness always observable in Westphalia Hams.—*Edit. Am. Fur.*

Successful Method of curing Butter, as practised in Scotland.

It is well known, that butter as it is generally cured does not keep for any length of time, without spoiling or becoming rancid. The butter with which the metropolis is supplied, may be seen at every cheesemonger's, in the greatest variety of quality and color; and it is too often the case, that even the worst butter, is compounded with better sorts in order to procure a sale. These practices are detestable, and should be discontinued by the legislature. Indeed no butter should be permitted to be sold, but such as is of the best quality when fresh, and well cured when salted; as there is hardly any article more capable of exciting disgust than bad butter.

But to obtain a reform in this matter, it is necessary to commence with the practices of the dairy; and the following process is recommended as the best at present known: Reduce separately to fine powder in a dry mortar, 2 pounds of the best, or whitest common salt; 1 pound of Saltpetre; and 1 pound of Lump Sugar. Sift these ingredients, one above another on two sheets of paper joined together; and then mix them well with the hands, or with a spatula. Now preserve the whole in a covered jar placed in a dry situation. When required to be used, one ounce of this composition is to be proportioned to every pound of butter, and the whole is to be well worked into the mass. The butter is to be packed in casks, &c. in the usual way.

Observations. The above method is practised in many parts of Scotland; and is found to preserve the butter much better, than by using common salt alone. If butter made at one time be divided into two parts, and one be salted in the common way, while the mixture abovementioned is worked into the other, the difference in the quality of the two, will be found to be beyond all conception.

The butter cured with this mixture appears of a rich marrowy consistence and fine color, and never acquires a brittle hardness, nor tastes salt; the other will be comparatively hard and brittle, approaching more nearly to the appearance of tallow, and is much saltier to the taste. Butter cured by the above composition has been kept three years, and was as sweet as at first; but it must be noted, that butter thus cured requires to stand at least three weeks or a month before it is used. If it be sooner opened, the salts are not sufficiently blended with it, and sometimes the coolness of the nitre will then be perceived, which totally disappears afterwards.

One more observation on the preservation of butter is necessary. It is universally allowed that cleanliness is indispensable, but it is not generally suspected, that butter from being made in vessels or troughs lined with lead, or in glazed earthen ware pans (which glaze is principally composed of lead) is too apt to be contaminated by particles of that deleterious metal. If the butter is in the least degree rancid, this can hardly fail to take place, and it cannot be doubted, that during the decomposition of the salts, the glazing is acted on. It is better therefore, to use tinned vessels for mixing the preservative with the butter, and to pack it either in wooden vessels, or in jars of the Vauxhall ware, which, being vitrified throughout, do not require an inside glazing.

SURNAMES.

Men once were surnamed from their shape or estate,

(You all may from history worm it,)

There was Louis the Bulky, and Henry the Great,
John Lackland and Peter the Hermit.

But now when the door plates of Mist'ers and Dames

Are read, each so constantly varies

From the owner's trade, figure and calling, Surnames

Seem given by the rule of contraries.

Mr. *Box*, though provoked, never doubles his fist,

Mr. *Burns* in his grate has no fuel,
Mr. *Playfair* won't catch me at hazard or whist,
Mr. *Coward* was wing'd in a duel.

Mr. *Wise* is a dunce, Mr. *King* is a whig,
Mr. *Coffin's* uncommonly sprightly,
And huge Mr. *Little* broke down in a gig
While driving fat Mrs. *Golightly*.

Mrs. *Drinkwater's* apt to indulge in a dram,
Mrs. *Angel's* an absolute fury,

And meek Mr. *Lyon* let fierce Mr. *Lamb*
Tweak his nose in the lobby of Drury.
At Bath, where the feeble go more than the stout,
(A conduct well worthy of Nero)

Over poor Mr. *Lightfoot* confin'd with the gout
Mr. *Heavyside* danced a Bulero.

Miss *Joy*, wretched maid, when she chose Mr.
Love,

Found nothing but sorrow await her:
She now holds in wedlock, as true as a dove,
That fondest of mates, Mr. *Hayter*.

Mr. *Oldcastle* dwells in a modern built hut;
Miss *Sage* is of madcaps the archest;
Of all the queer bachelors Cupid e'er cut,
Old Mr. *Younghusband's* the starchest.

Mr. *Child* in a passion knocked down Mr. *Rock*
Mr. *Stone* like an aspen-leaf shivers;
Miss *Poole* used to dance, but she stands like a stock

Ever since she became Mrs. *Rivers*.
Mr. *Swift* hobbles onward no mortal knows how,
He moves as though cords had entwined him;
Mr. *Metcalf* ran off upon meeting a cow
With pale Mr. *Turnbull* behind him.

Mr. *Barker's* as mute as a fish in the sea,
Mr. *Miles* never moves on a journey,
Mr. *Gotobed* sits up till half after three,
Mr. *Makepeace* was bred an attorney.
Mr. *Gardener* can't tell a flow'r from a root,
Mr. *Wild* with timidity draws back,
Mr. *Ryder* performs all his journeys on foot,
Mr. *Footo* all his journey's on horseback.

Mr. *Penny*, whose father was rolling in wealth
Kicked down all the fortune his dad won;
Large Mr. *Le Fever's* the picture of health,
Mr. *Goodenough* is but a bad one.
Mr. *Crookshank* stepped into three thousand a year,

By showing his leg to an heiress.
Now I hope you'll acknowledge I've made it quite clear

Surnames ever go by contraries.

Monthly Magazine.

THE FARMER.

BALTIMORE, FRIDAY, OCTOBER 24, 1823.

MARYLAND AGRICULTURAL SOCIETY, Last Monthly Session of the Trustees.

The trustees of this institution assembled on Wednesday the 15th inst. at HAYFIELDS, the residence of Col. N. M. Bosley. The weather was very fine and after talking over the affairs of the Society, they rambled over the farm, which is divided into fields of Indian corn, small grain, just seeded on summer fallow, artificial meadows, and pasture.

One of the trustees has been good enough to hand us the following rough sketch of their observations—made, we have no doubt impartially, and somewhat after the manner of the examining committees appointed by the agricultural societies in the Eastern States, to make excursions of review over the farms of their members.

"THE INDIAN CORN, promises a fine crop for the appearance of the land which, notwithstanding the indefatigable pains of the owner, is still very stony—we were sorry to see that Col. B. had sustained a heavy loss by the entire destruction of his corn fodder—both tops and blades by frost.—This is a blow which that enemy occasionally inflicts by *stolen marches*, on the most wary commander. In this case fine weather like a flag of truce, seemed the harbinger of peace, but General Frost stole on Col. Bosley as a thief, in the night, and scathed every thing in his route like a desolating fire.—There is no provender for any stock superior to the tops and blades of Indian corn when well cured—an old Farmer present, whose word is authority, observed that for *milch cows*, nothing is preferable to *corn tops*.

"GRAIN ON FALLOW—This consists of Rye, which Col. B. prefers to Wheat for a general crop, and as a protector of young grass—against Oats he sets his face, as the greatest of exhausters, drawing the land like blister plasters, except that they draw out the good humours of the soil and leave the bad behind.—We were gratified and instructed by the complete farmer-like manner in which this important operation had been performed.—The land had been well broken at a proper season, and put in the best condition to receive the grain and grass seeds. The owner had well done his part—may a beneficent Providence consummate his labors with a plentiful harvest.

"GRASSES, CLOVER and TIMOTHY.—These valuable grasses, especially the latter, are obviously the great staples of Hayfields.—To this, he has for some years given his chief attention, and the result is a gratifying evidence of what may be done in a few years, with the roughest land, by

the energies of an individual, under the guidance of good judgment. Hills high and steep, declivities the most precipitous, and ravines the most forbidding, have been subjected and overrun by his dread-nought ploughs, until, on spots which lately presented the aspect of poverty and barrenness, heavy swarms of timothy now fall before every sweep of the scythe—as a *grass farm*, for its size and original condition, perhaps none in Maryland equals Col. Bosley's, and to his credit be it said, it is the work of his own hands, or rather of his own head—we saw on his books accounts of sales of timothy in one year, amounting to upwards of \$6,500, but that article then sold as high as \$30 per ton—LIMESTONE, quarried and burned on the land, appears to have been the magic wand by which this enterprising cultivator has changed the face of his estate, and caused the roughest hills to rival the smoothest vallies in verdure. The course of his culture is generally Indian corn, with lime, at the rate of 100 bushels to the acre to be fallowed the next fall for rye and timothy, which are sowed about the 10th of September, to be finished before the equinox. The effect of the lime is prodigious as is obvious from the aftermath of clover and timothy at this time.

"DOMESTIC ANIMALS—Totally neglected, except for his own table, the best eaten, and the worst left for breeders. The tail ends of all breeds without the good points of any—the Colonel seems to have been laying the foundation of all good farming, clearing off stone, and putting the land in good heart, with the maxim in his mind's eye, "one thing at a time." He intends now to turn his attention to his stables, his cow yard, his sheep fold and his piggery, and experience will soon teach him that it costs less to keep good animals beautiful in all their points and profitable in all their qualities, than to keep bad ones, unseemly to the eye, and unthrifty in constitution—in short, any thing but what they should be.—He means to commence the improvement of his stock, by some purchases from General Ridgely, of one or two beautiful Bergami heifers, &c. Choice cattle and hogs, would appear to be the spontaneous growth of a fine grass farm, and an overflowing dairy, its most interesting appendage, especially where watered by lime stone springs cool and copious—when the Colonel has provided a better race of milkers, he will, we predict, no longer monopolize the honors of Hayfields. The dairy will yield its trophies to other and fairer hands, judging from the bounteous repast which awaited us on returning from our excursion; but which, on account of its great variety and exceeding elegance, we resolved it would not be good policy to praise in public while each gave the best practical "proof" of his admiration."

Such is the report we received; of its impartiality there can be no question. The trustees adjourned in the evening to hold their next monthly session at Bloomsbury, the residence of H. V. Somerville, Esq.

CANTON RACES—FIRST DAY.

The first purse of \$250 was taken yesterday by Gen. Winn's mare *Vanity*—she ran against Mr. Howard's filly, *Miranda*. *Vanity* took the lead and kept it throughout the heat. This was the first trial of *Miranda*, and when called for the second heat she was withdrawn.

SECOND DAY.—Col. Johnson's horse Washington, and Gen. Winn's horse Childers, contended for the purse of \$500—both heats were won with great ease by Washington.

Baltimore Prices same as last week.

PUBLISHED BY J. S. SKINNER.

AGRICULTURE.

EXTRACTS

FROM MORE MODERN WRITERS ON THE USE OF SALT IN AGRICULTURE.—No. I.

"I am well assured from a Scotch gentleman, that they have long used salt in that part of Great Britain, always sowing ten or twelve bushels by hand of their coarse salt on an acre of young green wheat, some time in November, December, January, or February, it being, from the several accounts which I have had of it, very effectual in the killing of tender weeds amongst corn, yet at the same time cherishing the corn; and though it does not add altogether to the bulk or height of the straw, yet it does much to the goodness and plumpness of the grain. And whoever has been curious in their remarks abroad, will find that it is the usual practice of the Milanese to sow salt on their pastures, as I have been informed by one who has sold great quantities for that purpose; as also by a merchant of Liverpool, who is well acquainted with that trade, who affirms that the finest crops they have of hemp and flax amongst the Dantzickers and others, who raise those commodities in those countries, are from lands on which salt is strewed."—*The Practical Husbandman*, page 48, vol. i. London, 1733.

"Salt certainly sweetens the grass much; and it may on all such occasions be mixed with a proper quantity of dung, which is more sulphureous than salt, and will make grass shoot away much faster than any other manure. Lime in its own nature makes grass sour, but when mixed with salt, that acidity will be taken away."—*Practical Husbandman*, vol. i. page 57.

"As to the proportion of salt to be used on land, it ought to be according to the nature of it; cold, wet, clayey land requiring more, and loose soft land, though it be poor, requiring less. Again, the proportion of salt ought to be either more or less, according to the crops of grass or grain you would improve. For cold, wet, and spewy land, ten loads of dung, six of earth, and eight bushels of salt, per acre.

"For lean, hungry, sandy land, fourteen loads of pond-earth, six loads of dung, and six bushels of salt per acre, when employed for corn and grazing.

For meadow land, fourteen or fifteen loads of dung, five bushels of salt, and four of pond-earth, the quantity of each to be altered according to the quality of the ground."—*Practical Husbandman*, London, 1738, page 59.

"Thus have I made out what I proposed, viz: that every acre of land in England which wants to be improved, may be done ten or twelve shillings an acre cheaper by salt than any other way.

Suppose then, that out of the forty millions of acres of land which are calculated to be in England and Wales, there is but one-eighth part, which is five millions, to be improved every year: and that one-half of those five millions may be manured by some other manure, there yet remains two millions and a half to be done by salt still; which, reckoning the savings at ten shillings per acre only, (the expenses being about the same) comes to one million two hundred and fifty thousand pounds; which, if the old proverb be true, that so much saved is so much earned, then that sum is a real addition to the landed interest of Britain; and this calculation is not at all disserviceable to what is affirmed by some Cornish and Devonshire men, when they say that the money laid out in salt sea-sand, for the improvement of lands in those two counties, comes to thirty-two thousand pounds per annum."—*Practical Husbandman*, vol. i. page 63.

"On watering meadows with solution of salt, we are directed to make a large pit about twenty or thirty feet square, and five or six feet deep, more or less, as there will be occasion, in the method tan or salt pits are made, and put therein ten or twelve bushels of salt, and as much of lime, soot, or any other ingredient of that kind, and, having a pump near at hand, or some conduit or spring of water, fill the pit up by degrees, at first to three or four feet high, letting the ingredients dissolve in the water, by being there twenty-four hours at least, stirring them sometimes about, and after that, by dipping in of the finger it will be found whether the water is salt enough (as near as you can to the strength of sea-water); if it is not sufficient, then may be added a reasonable quantity more of the above mentioned materials; but if it be too salt, then more water may be poured in till it is just right and fit for use; and being possessed of a moving pump or a skip, pump the water into a hoghead, with a leather pipe, and a watering rose at the end of it, just as is practised in watering the streets in London, and so (having the hoghead placed on a roil) may both meadows and corn land be watered to a good advantage."—*Practical Husbandman*, vol. i. page 74.

"Salt provokes the appetite, strengthens the stomach, promotes the digestion and concoction of the aliments, resists putrefaction, prevents unnatural concretions of the humours, and is most friendly and agreeable to the human body, entering its composition as a necessary ingredient. No wonder, therefore, that the Laplanders, amongst whom the use of salt is unknown seem to discover the want of it by the exility of their bodies, and the weakness of their constitutions; being much less robust and strong than other northern nations who enjoy this excellent gift of God. Moreover, its uses extend to many other animals besides the human race: black cattle and sheep take a pleasure in licking it, and by it are preserved from many diseases; they also thrive to admiration, and quickly grow fat in marshy grounds that are frequently overflowed by the sea. And if we descend to the vegetable tribe, we shall find that salt contributes greatly to fructify the earth; and when properly used as a manure, affords ample nourishment to corn and other vegetables; and renders kingdoms rich and fertile where it happens to abound in the soil."—*Dr. Brownrigg's Art of Salt*, 8vo. London, 1748 page 157.

"To shew an acquaintance of mine the effects and advantages of salt properly applied to vegetables, I made the following experiment, in an extreme dry summer, upon a bare piece of pasture land, out of which the cattle were all taken for want of grass; I marked four places with stakes, each of which I watered nine nights successively, in the following manner:—the first with spring water alone, to the quantity of a gallon; the second with the same quantity of water, adding an ounce of common salt; the third and fourth with the same quantity, mixing the water in the third place with two ounces of salt; and that in the fourth with three ounces, which produced the following different effects.

"The grass in the second place grew more and of a darker green than that in the first; in the third it only grew by spets, for part of it was killed where the greatest quantity of water fell, and the fourth was quite brown for a greater compass than the third; by which it appeared that an ounce of salt in a gallon of water had a better effect than the water had alone; and that three ounces of salt, mixed with a gallon of water, was more than the grass could immediately receive; but the fourth place in the ensuing spring was the most fertile of them all."—*Trea-*

tre of Fruit Trees, by Thos. Hitt, 8vo. Third edition, London, 1768, page 17.

"Soils which are subject to the grub, and must be fertilized by common dung, which is a proper nest for the mother beetle to deposit its eggs, must be well impregnated with the brine of dissolved salt, after the dung is first cut up: two large hogheads of salt will make brine enough for a dung pan of fifty feet square. This cure for the grub is a late discovery, for which I am obliged to a judicious planter, and which I have tried with success so far as the experiment is made. But though it proves effectual to destroy that pernicious insect in plantations, I much doubt and believe it will not be sufficient to save rattoons without a new application of salt pounded to a powder; because the first brine must be washed away by the time when rattoons spring up. I therefore advise the planter who would save his rattoons from grub, to cut off the heads of the stools by sharp hoes, three inches below the surface of the soil, and then strew a handful of salt round each stool, and cover it up to a level with fine mould taken from the edges."—*From an Essay on Plantership by Samuel Martin, Esq. of Antigua*.

"Having tried salt upon a small scale on a sandy soil, I can assert sixteen bushels to be a proper quantity for one acre. It gradually advanced in its effects to sixteen, and as gradually diminished to forty bushels when vegetation was destroyed. Twice only have I had an opportunity of buying a few tons of foul salt, and used it both times on a barley tilth, sowing the salt immediately after the barley. The event was perfectly satisfactory. The verdure of the spring exceeded any thing of the kind I ever saw; and the ripened appearance was whiter by many shades than I ever beheld. N. B. Salt is noxious both to weeds and vermin."—*R. Legrand, Esq. on Manures, in the Annals of Agriculture*, vol. v. page 149.

"Mr. Legrand's Observations on Manure are so truly valuable, that I wish anxiously for their continuance."—*Arthur Young*.

(To be continued.)

NATURAL HISTORY, No. 2.

[Continued from page 61.]

In Number 8 of this volume, we commenced laying before our readers, some extracts under the above heading—taken from a new and able work, entitled "THE PHILOSOPHY OF ZOOLOGY" by John Fleming, D. D: Minister of Flisk, Fifeshire, Scotland. It was our intention to continue them from time to time, as we might find room—being persuaded that while they would serve the purpose of entertaining variety to all our patrons, they might open to the view of our young readers, especially farmers' sons and daughters, some of the beauties, which abound in the study of Natural History.

Some long articles with which the paper was filled at that time, compelled us to break off—and the subject has been overlooked until now—it would be better if we could take it up anew. There is, however, no alternative, but to refer the reader back to pages 60 and 61, where the author treats of THE DURATION OF ANIMAL LIFE—the DISTRIBUTION OF ANIMALS, and the influence of TEMPERATURE.—But perhaps the connexion between what has already been, and that which will now be extracted, will be sufficiently perceived by the repetition of the last paragraph, viz:

The variations of the seasons, which bring along with them corresponding changes of heat and cold, exercise a powerful influence on the distribution of animals in reference to temperature. Some

species appear to possess a considerable range of temperature, within which life can be easily preserved and all its functions regularly performed. We do not mean to intimate, that there is any animal which can live in our climate, for example, and remain uninfluenced by a difference of temperature of upwards of twenty degrees between summer and winter. The constitutional arrangement suited to the one season, would be prejudicial during the continuance of the other. But there are many animals which live in the same districts both in summer and winter, and even in districts differing considerably in their mean annual temperature. What, then, are the means employed by these species to preserve life in the midst of such vicissitudes? The power of producing heat or cold, is a property obviously possessed by the warm blooded animals, and probably in an inferior degree by those which are termed cold-blooded. But in all the efforts made by the system to secrete extraordinary degrees of either heat or cold, there is so great a portion of vital energy expended, that exhaustion and death follow its long continuance. In all cases where the influence of the seasons are to be resisted by efforts of this kind, it would be requisite to continue them uninterrupted for many months. These efforts, however, are diminished in extent and duration by a variety of the most wonderful arrangements, exhibiting the infinite resources of that Wisdom which planned the constitution and continuance of the animal kingdom. To the chief of these compensating or counteracting circumstances we shall now briefly advert.

1. *Changes take place in the quantity of Clothing.*—The same circumstances which enable the negro to go about in a state approaching to nakedness, and impel the inhabitants of the arctic regions to cover themselves with woollen cloth or skins, operate in regulating the clothing of quadrupeds and birds. In the warmer regions, it is requisite to suffer the temperature of the body to be diminished, while, in the colder regions, the very opposite object is aimed at. In the former case, the hair or feathers are thinly spread over the body, while, in the latter, they form a close and continuous covering. In the dogs of Guinea, and in the African and Indian sheep, the fur is so very thin that they may almost be denominated naked. In the Siberian dog and Iceland sheep, on the other hand, the body is protected by a thicker and longer covering.

The clothing of animals, living in cold countries, is not only different from that of the animals of warm regions in its quantity, but in its arrangement. If we examine the covering of swine of warm countries, we find it consisting of bristles or hair of the same form and texture; while the same animals which live in colder districts, possess not only common bristles or strong hair, but a fine frizzled wool next the skin, over which the long hairs project. Between the swine of the south of England, and the Scottish Highlands, such differences may be observed. Similar appearances present themselves among the sheep of warm and cold countries. The fleece of those of England consists entirely of wool; while the sheep of Zetland and Iceland possess a fleece, containing, besides the wool, a number of long hairs, which give to it, when on the back of the animal, the appearance of being very coarse. The living races of Rhinoceros and Elephant, inhabitants of the warm regions, have scarcely any hair upon their bodies; while those which formerly lived in the northern plains of Europe, the entire carcasses of which have been preserved in the ice in Siberia, were covered with fur similar to the Icelandic Sheep, consisting of a thick covering of short frizzled wool, protected by long coarse hairs. These species, now extinct, pos-

sessed clothing suiting them for the climate where they lived, and where they became at last enveloped in ice. Had they been transported by any accident from a warmer region, they would have exhibited in the thinness of their covering, unequivocal marks of the climate in which they were reared.

By means of this arrangement, in reference to the quantity of clothing, individuals of the same species can maintain life, comfortably, in climates which differ considerably in their average annual temperature. By the same arrangements, the individuals residing in a particular district, are able to provide against the varying temperature of the seasons. The covering is diminished during summer and increased in winter, as may be witnessed in many of our domestic quadrupeds.

Previous to winter, the hair is increased in quantity and length. This increase bears a constant ratio to the temperature; so that when the temperature decreases with the elevation, we find the cattle and horses, living on farms near the level of the sea, covered with a shorter and thinner fur than those which inhabit districts of a higher level. Cattle and horses, housed during the winter, have shorter and thinner hair than those which live constantly in the open air. The hair is likewise shorter and thinner in a mild, than during a severe winter.

This winter covering, if continued during the summer, would prove inconveniently warm. It is, therefore, thrown off by degrees as the summer advances; so that the animals which were shaggy during the cold months become sleek in the hot season.

This process of *casting the hair* takes place at different seasons, according to the constitution of the animal with respect to heat. The mole has in general, finished this operation before the end of May. The fleece of the sheep, when suffered to fall, is seldom cast before the end of June. In the northern islands of Scotland, where the shears are never used, the inhabitants watch the time when the fleece is ready to fall, and pull it off with their fingers. The long hairs, which likewise form a part of the covering, remain for several weeks, as they are not ripe for casting at the same time with the fine wool. This operation of pulling off the wool, provincially called *rooing*, is represented by some writers, more humane than well-informed, as a painful process to the animal. That it is not even disagreeable, is evident from the quiet manner in which the sheep lie during the pulling, and from the ease with which the fleece separates from the skin.

We are in general inattentive with respect to the annual changes in the clothing of our domestic animals; but when in search of those beasts which yield us our most valuable furs, we are compelled to watch these operations of the seasons. During the summer months the fur is thin and short, and is scarcely ever an object of pursuit; while during the winter, it possesses in perfection all its valuable qualities. When the beginning of winter is remarkable for its mildness, the fur is longer in *ripening*, as the animal stands in no need of the additional quantity for a covering; but as soon as the rigors of the season commence, the fleece speedily increases in the quantity and length of hair. This increase is sometimes very rapid in the hare and the rabbit, the skins of which are seldom ripe in the fur until there is a fall of snow, or a few days of frosty weather; the growth of hair in such instances being dependent on the temperature of the atmosphere.

The *moult*ing of birds is another preparation for winter, which is analogous to the casting of the hair in quadrupeds. During summer, the feathers of birds are exposed to many accidents.

Not a few spontaneously fall; some of them are torn off during their amorous quarrels; others are broken or damaged; while in many species they are pulled from their bodies to line their nests. Hence their summer dress become thin and suitable. Previous to winter, however, and immediately after the process of incubation and rearing of the young is finished, the old feathers are pushed off in succession by the new ones, and in this manner the greater part of the plumage of the bird is renewed. During this process of moulting, the bird seems much enfeebled, and, if previously in a weak state, is in danger of dying during the process. In consequence of this renewal of the feathers, the winter covering is rendered perfect, and the birds prepared for withstanding all the rigors of the season. In those birds whose plumage changes color with the seasons, the moulting takes place in subserviency to the purposes of these variations, as we shall shortly have occasion to notice.

By this addition to the non-conducting appendices of the skin, quadrupeds and birds are enabled to preserve the heat generated in their bodies, from being readily transmitted to the surrounding air, and carried off by its motions and diminished temperature. But along with a change of quantity, there is frequently also a change of color.

(To be contin. ed.)

ADVICE TO YOUNG FARMERS.

The Horse—how to know his age.

The Editor believes, from much observation, that the following directions are the plainest and best he has ever met with on this subject.

The AGE OF A HORSE, it is sufficiently well known, is only determinable with precision by his teeth; and that rule fails after a certain period, and is sometimes equivocal and uncertain, even within that period. A horse has forty teeth; namely, twenty-four double teeth or grinders, four tushes, or single teeth, and twelve front teeth, or gatherers. Mares have no tushes in general. The mark, which discovers the age, is to be found in the front teeth, next the tushes. In a few weeks, with some, the foal's twelve fore teeth begin to shoot; these are short, round, white, and easily distinguishable from the adult or horse's teeth, with which they come afterwards to be mixed. At some period, between two and three years old, the colt changes his teeth; that is to say, he sheds the four middle fore teeth, two above and two below, which are sometime after replaced with horse's teeth. After three years old, two others are changed, one on each side the former; he has then eight colt's and four horse's teeth. After four years old, he cuts four new teeth, one on each side those last replaced, and has at that age, eight horse's and four foal's teeth. These last new teeth are slow growers, compared with the preceding; they are the corner teeth, next the tushes, are called pincers, and are those which bear the mark: this mark consists in the tooth being hollow, and in the cavity bearing a black spot, resembling the eye of a bean. The tushes may then be felt. At four years and a half old, these mark teeth are just visible above the gum, and the cavity is very conspicuous. At five years old, the horse has shed his remaining four colt's teeth, and his tushes appear. At six, his tushes are up, and appear white, small, and sharp, near about which is observable a small circle of young growing flesh; the horse's mouth is now complete, and the black mark has arrived at, or very near the upper extremity of the corner teeth. At seven, the two middle teeth fill up. Between the seventh and eighth year, all the teeth

are filled up, the black mark hath vanished, and the horse is then said to be aged, and his mouth full.

From that time forward, the age of the horse can only be guessed at from certain indications; but these guesses are usually made with considerable accuracy by experienced people. If his teeth shut close, and meet even, are tolerably white, not over long, and his gums appear plump, you may conclude he is not yet nine years old. At that age, and as he advances, his teeth become yellow and foul, and appear to lengthen, from the shrinking and receding of the gums. The tushes are blunt at nine; but at ten years old, the cavity or channel, on the inside in the upper tushes, until that period to be felt by the finger, are entirely filled up. At eleven, the teeth will be very long, black, and foul, but will generally meet even; at twelve, his upper-jaw teeth will overhang the nether; at thirteen and upwards, his tushes will be either worn to the stumps, or long, black, and foul, like those of an old boar. Beside those exhibited by the mouth, nature ever furnishes variety of signals, denoting the approach of old age and decay, throughout the bodies of all animals. After a horse has past his prime, a hollowness of his temples will be perceived; his muscles will be continually losing something of their plumpness; and his hair, that gloss and burnish, which is the characteristic of youth and prime, will look dead, faded, or entirely lose its colour in various parts. In proportion to the excess of these appearances, will be the horse's age.

The following are among the devices practised by a set of unfeeling rascals, who have no other rule of conduct than their supposed interest, to counterfeit the marks of age in horses. At four years old they will frequently knock out the remaining colt's teeth, in order to make the horse appear five; but you will be convinced of the fraud, by the non-appearance of the tushes; and if it be a mare, by the shortness and smallness of the corner teeth and indeed of the teeth in general. To give an old horse the mark, is termed, to bishop him; of the derivation of this term I have no knowledge. They burn a hole in each of the corner teeth, and make the shell fine and thin, with some iron instrument, scraping all the teeth to make them white; sometimes they even file them all down short and even. To this they add another operation; they pierce the skin over the hollows of the eye, and blow it up with a quill: but such manœuvres can deceive only the inexperienced, and in case of dispute would be detected in an instant.

Of the colours of horses, nothing, in my opinion, can be said more to the purpose than to repeat an adage of old Bracken,—"A good horse is never of a bad colour." Modern light and experience have been happily employed in detecting and exploding the theoretic whimseys of antiquity upon almost all subjects; among the rest, upon that of attributing this or that, good or evil quality, or temperament, to the colour of a horse. All that I am warranted in saying, from my own observation, is, that I have seen more bad horses of all kinds, among the light bays, with light coloured legs and muzzle, than amongst any other colours; and the most good saddle and coach-horses, among the common bays, with black legs and manes, and the chocolate browns. This, in all probability, has been accidental.

CULTURE OF THE VINE.

York, (Penn.) October 24.

This has become an object of great promise in York county. Experiments have already shown

that the vine will not only flourish in the poorer soils of this county, but that excellent wine can be made, and that raising vine yards will become as profitable as any other agricultural pursuit.

A portion of the land in York county is thin and poor, commonly called barren; it has been proved that the vine succeeds well on this land; and 20 acres of it which can now be bought for from 6 to 10 dollars per acre, when planted with vines, and those at maturity, will be more productive to the owner than 200 acres of the best land in the county. No capital is required in rearing a vineyard; the proceeding requires only attention and perseverance.

Mr. Thomas Eichelberger, an enterprising citizen of this place, was the first who seriously commenced the cultivation of the vine with a view to profit. Having a ridge of slate land which runs through his farm—he conceived the idea of turning it into a vine yard; and he engaged a German emigrant, who had been a vine dresser, and wine maker, in his native country. To this man he gave a permanent interest in 4 acres of land, and its produce, which was set apart for planting with vines; a small house was also put up for the working partner, near the premises. Mr. E. advanced the means of procuring the cuttings for planting, and other expenses, and also for the subsistence of the laboring partner, till the vine yard should become productive, when he was to be repaid.

Under this arrangement, in 1813, the 4 acres were planted in rows, with wide intervals, and those intervals were filled up in the following years, with the suckers, or sprouts, which grew from the original plants; these therefore are 1 or 2 years later than the first plantings. It required one hand to manage all this and keep the grass down during the summer; in the winter, the vine dresser was at liberty to work days' work where he could get employment. It will be observed that although the whole 4 acres were planted over in the beginning, yet only one-third of the vines were set. These had the start of the others, and began to bear in the 3d. year. In the vintage of 1821, Mr. Eichelberger made two or three barrels of wine, which was of a good quality.

In the vintage of 1822, he made eleven barrels of wine, and sold a considerable quantity of grapes. The oldest vines having now acquired strength, and the second plantings also beginning to bear, though yet in small quantities, he was able to make thirty-one barrels in 1823, besides selling grapes for perhaps \$200. During the time that the grapes were ripening, the vine yard was crowded with visitors, all of whom bought more or less. This considerably diminished the grapes which were designed for the press. After 3 years Mr. E. had no more advances to make, as the vine yard produced enough to support itself. The profits arose from the sale of grapes; of the wine made the preceding year, and from the sale of cuttings at \$30 per 1000.

The wine of 1822 was sold in 1823, to visitors, at the rate of \$3 per gallon. It is difficult to compute what the profits may amount to, in seven years hence; as the vines become more robust, they will produce more fruit, and this increase will probably continue for ten or twenty years. The oldest of the vines are yet in their infancy; and the vine dressers from France and Germany, who have seen Mr. Eichelberger's vine yard, say, that it is more flourishing and further advanced for its age, than any thing of the kind that they have seen in Europe.

It is no extravagant conjecture, that Mr. Eichelberger's four acres will, at the end of two years from this time, produce grapes to make

100 barrels of wine. This is what the vine dressers confidently assert. Mr. E. has, since the commencement of his first vine yard, planted two other portions of ground, of three acres each, contiguous to the other. For each of these he has a German vine dresser, to whom he has given an interest, as in the first case, but pays nothing else.

He proposes to extend this vine yard to 20 acres, though under different tenant;—four acres being as much as one man can well attend to.

Mr. E. has also made two plantations of vines on a farm about ten miles from York, in the very heart of the poorest land in the barren;—These flourish and promise as well as his first vine yard, though they are but two and three years old. The oldest bore grapes this season.

Judge Barnitz, and Mr. Nes, have each planted vine yards in the vicinity of York. They are but three years old. They made about two barrels of wine each. Last year they made each a small quantity, which, after fermentation, became very fine, and of an excellent taste and flavour. Competent judges are satisfied that these wines will be equal to the wines of France and Germany. Mr. Eichelberger has the Madeira, Lisbon and Burgundy grape.

A German emigrant, fifteen miles from York, has made a vine yard on lands of his own. He has two acres, and it is four years since he planted it. This year he made ten barrels of wine.

Mr. Crull has made a vine yard on the side of a steep river hill, 12 miles north of York. The hill has been cut into steps, and planted in the Alpine style. His also flourishes, and bore grapes this season.

Besides these, there are several more in the neighborhood; and preparations are making to plant at least 15 or 20 more in the ensuing year.

It is a matter of encouragement, that there does not appear to be much danger of a failure of crops, as Mr. Eichelberger has not perceived that the cold spring weather has injured his vines. Last spring was unfavourable for fruit, so much so, that the peach trees, apple trees, and other fruit, were much injured; yet his vines did not suffer, except a particular kind of white grape appeared to be a little injured.

The wine which has been made, appears to contain sufficient alcohol to preserve it from acetous fermentation. Mr. E. has some two years old, which has been racked several times, and is perfectly sound, although it has had nothing added to it, but has been allowed to depend altogether upon its own intrinsic strength. Mr. Nes, and Judge Barnitz, also have preserved their wine without any additional aid.

It should not be understood that the spirit which has got up among us, about raising vine yards, is of a speculating character, and therefore in danger of blowing out in a few years. It is bottomed on something solid and permanent, as much so as any other branch of tillage or agriculture. For those who make experiments, put no capital to hazard; they feel their way as they go; and enough is already proved to convince every one that the pursuit will be profitable.—There is land of a suitable soil enough in York county to raise wine for the consumption of all the United States; and twenty years from this day, more wine will be made in Pennsylvania than is now imported into it. When once a vine yard has come to maturity, the owner will be able to sell his wine at 50 cents per gallon, and have abundance of profit.

Most of the sites where vines have been planted, are on the sides of hills, with a gradual slope, and southern aspect; though practical men say that they succeed equally well on the north side.

Observation and experience will teach in due time what kind of grapes will suit best to the soil and climate, and also how to manage the grapes, and the juice, to obtain the best wine.—Mr. Eichelberger has sufficiently proved that both the white and red wine will succeed.

Many interesting considerations are suggested by the successful cultivation of the vine in this country. In a moral, statistical, and national view it is important, and will be hailed as one of the greatest acquisitions that has been made to our domestic economy.

NOTE.—Since writing the above, I have been informed, that Mr. Overdoff, who has a very flourishing vine yard, raised his plants from the seed, which were sown in a bed in the garden, and after one year, were transplanted. Having roots, they are not so liable to fail, as the cuttings, which are joints of a vine, one end of which is stuck in the ground.—Recorder.

TO THE EDITOR OF THE AMERICAN FARMER.

ICE HOUSES—WITH ICE CLOSETS ATTACHED.
Highlands, 2d October, 1820.

DEAR SIR,

I herewith hand you a sketch of my ice closet attached to my ice house, which I recently described to you cursorily, and of which you requested a more minute description. Having tested its value, I can with truth declare it to be a most valuable appendage. The citizen and farmer may both enjoy its comforts—the latter more particularly, will soon know its value, where he is deprived of the benefits of a good spring. The greatest importance, however, attached to its use, I conceive to be the preservation of fresh meats, which I have kept for three weeks, as sound and wholesome, as the day it was placed in the closet, being entirely free from the musty and clammy flavour which it is apt to partake of, when confined in the customary way on the top of the ice. The only danger I apprehended, was the fear of losing my ice sooner in the season, from the closet drawing its quantum of cold atmosphere from the ice; I am happy to find, however, that my house still contains a body of ice, although it was little more than half filled, and (from my absence,) very imperfectly rammed.—The size of my house is twelve feet square, and in depth to the floor, there being a space of one foot underneath, sloped to the centre where there is a well of two feet, to receive any water which may pass from the ice. The closet is four feet in width, which affords sufficient room for a private family—to enlarge it, would be drawing too largely from the ice, which might occasion it to melt more rapidly. If it should be required of larger dimensions, (particularly for butchers to whom it will be invaluable,) I would advise that the house be enlarged in proportion. The pit is dug about three feet wider at top than bottom, the house being built perpendicular, (of logs or plank, mine is of the former,) will leave a cavity eighteen inches wide at top, round the house, in which straw is to be closely crammed; this, with a layer of straw at bottom and straw mats laid over the top of the ice, will be quite sufficient for its preservation. The partition is made of the same materials the house is built of, observing not to join it too close, leaving the slightest opening, so as to admit the escape of cold atmosphere into the closet, the top of which to be tightly closed up. The communication to the closet must be by a descent from one end of it to a door, to be cut immediately under the plate of the house and from thence by a small flight of steps to the bottom of the closet, which is to be a line with the bottom of the ice room, the

top of the steps on the side to be secured by a sloping door; the lower door of the closet to be made only large enough to admit one person at a time, both tight, and to be opened as seldom as possible. The roof ought to project wide enough over the pit to secure it from the weather; where the ground is tenacious, I conceive it unnecessary to wall up the pit, but when this is not the case it will be most prudent to do so—I have been I think, unnecessarily particular in the description, and if you agree with me, you can make use of only such parts of it as may be thought requisite.

I have added also a ground and elevated view, of the interior of the house, as it may serve to elucidate some parts of this hasty sketch.

I am your's

Very respectfully,
J. S. WILLIAMS.

Ground View.

Elevated View.

TO THE EDITOR OF THE AMERICAN FARMER.

WATER CART.

DEAR SIR,

Not only the book authority, but the experience of hundreds of our own agriculturists, have established the fact, that salt, common sea salt, is an excellent manure. The chief virtue in the sea ooze, or sea grass, by which the produce of many farms on our salt water bays and rivers has been very much increased, is now generally believed to be the salt carried out with them. It has long been observed, that where a seine has been usually hung up to dry, the grass always grows with a luxuriance, that cannot be fairly ascribed to the mere drops of water, which fall off the seine; but is much more, probably, owing to the salt contained in those drops. A dressing of salt would undoubtedly produce the most effect on fresh land—that is, on land not immediately adjacent to a salt shore, or saline atmosphere. It is said that from 10 to 16 bushels to the acre, according to situation, is a good

dressing. It is also said that as high up the Chesapeake Bay as South River, or Poplar Island, there is a half bushel of Light blown salt contained in every 120 gallons of water. But every farmer on the salt water, by boiling down 15 or 30 gallons, an eighth, or a fourth of the first quantity, can easily discover the proportion of salt contained in the water he can command.

In your 22d No. vol. 5th, you have published a useful paper from Mr. Rowand on this subject. Having long been of opinion that our salt waters contain the cheapest manure, that can be applied to lands, on or near their margins, I had formed the plan of a cart for taking it out. Mr. Rowand does not state; but I presume the rolling hogshead must be loaded by hand with a bucket, and Mr. Smith's cart is loaded by a pump. Under the impression that a cheap cart can be made to load with vastly more facility, and to distribute its contents at least equally well with either of the others, I will endeavour to explain the construction. The width and size may be varied to suit any one. For my purpose a pair of wheels five feet diameter with strong felloes, and no tire. (A pair of well made wheels constructed strong, and purposely to be used without tire, will run for six or seven years; the best tire constantly used in salt water, will soon rust out; and two pair of wheels without tire, will cost less than one pair shod.) An axle as long as will permit the wheels to pass through a nine feet gateway, say six and a half feet between the hubs. A pair of strong shafts, to be made seven feet longer than is necessary for the horse. These shafts to be placed on top of the axle, in such a manner, that they may be the right width a part for the horse when three and a half feet of the after ends are behind the axle, and to be bolted through the axle in this position. As these shafts will not only have to bear the weight, but the framing to hold the body, the seven after feet of them ought to be stout. The body to be a box, water tight, except an opening of three or four inches on the forward part of the top—and to be six feet by four, and one foot deep in the clear, to be placed lengthwise under the axle—the middle of the box a little forward of the middle of the axle. Four pieces to be framed; two into the underside of each shaft, so wide a part, measuring along the shaft that they will take the box between—say one foot ten aft, and two feet two fore, and of the middle of the axle, in order to make the load bear a little on the back of the horse. Let two pieces be framed into each pair of these short pieces, parallel to the shafts, in such a manner that the box will rest safely on them under the axle, and between the short pieces—and the body and short framing on the sides may be so constructed, that should the joints open, they may be driven close, by wedges, or keys.

You now have a tight cart, that will hold about 120 gallons, placed snugly under the axle, and one foot clear of the ground. If this be not high enough—increase the diameter of the wheels—but one foot clear of the ground will do. Our fields lie generally in corn ridges, four and a half or five feet from ridge to ridge. In the back side of the box, near the bottom, five feet apart, and, of course, six inches from each end, insert two wooden faucets and spigots. Let the holes come straight through the faucets; and with a piece of slip wood weave a little bonnet, which you may lash on the end of each faucet to act like the spout of a watering pot, and distribute the water equally over the land. This is sufficient for me—but if you

would be still more particular—have a light box six feet long, six inches deep, and six inches wide, with two little cords; hang this over the spigots, the faucets in this case emitting the water below. Let the requisite number of holes be bored all along the bottom of this box. The water will then issue into this box from the two cocks, and be equally distributed over the whole surface. Make a snug, convenient seat for the driver on top of the shafts. But the loading?—Most farms on the salt water have one or more landings with a good firm bottom, where you can drive into three feet water. In the bottom of the box, or body, bore a two inch auger hole. Over this hole, on the inside, put a block of wood and a piece of leather, fit a valve, or what we call a pump clapper. Put in the horse, mount the boy, and drive right into the creek. As soon as the water is up against the bottom, up goes the valve and it rushes. If this does not load fast enough; as soon as water sufficient is admitted to keep the machine from floating, drive in till the water rushes over the top, and fills the cask in a moment. The boy has had nothing to do, but to sit still while the cart loads itself. The action of starting out closes the valve in the bottom, and away he goes with a dressing for the 20th or 30th part of an acre. When he gets to the place to commence his discharge, he comes aft, turns his spigots and starts. The emission of water should be gauged to run out only at half rate—that is, the load ought to be made to sprinkle double the surface you wish it to manure, and the spot where the load is exhausted should be marked, because from the starting of the water to the exhaustion of the load, it will flow out slower and slower, or in a constantly decreasing ratio. Therefore the second load should be brought to where the first load gave out. At this spot the sprinkling of the second load should commence, and the same ground wetted with the first load, should be again gone over in reversed order. In this way every inch of ground will receive the same quantity of water, and of course the same quantity of salt.

There are thousands of fields on the margin of our salt water courses, the centres of which are not more than half a mile from a landing, with a good hard sandy bottom.—In every such field a horse and water cart; and boy just big enough to drive a sober nag with nothing but the pleasant amusement of riding, would take out 30 loads, or manure one whole acre a day. In what other possible mode can you manure an acre so cheaply, and with so little trouble?—and by increasing the size of the cart, and doubling the team, salt might be carried out in this way, one, two or three miles with economy. One of your correspondents stated that he freed his wheat from insects and very much improved his crop, by strewing a very small portion of salt per acre on his wheat in the spring season.—Here then is the mode by which you may salt your wheat in the best manner, *ad libitum*.

Every manure yard should certainly be hollow, and have one or more vats—and one of the above carts always in place to take out and top dress any growing crop with their contents.—Would not this be the best construction for a cart to water your streets in the sultry season?—It would drive into Jones' Falls, load itself, and out again. The body box should be made of thick two inch white pine.—It is light, and if the key wedges did not drive it tight, it would always quickly swell tight.

Your humble servant,

SANDY POINT.

OXEN—THEIR USE IN AGRICULTURE.

We cannot be more fully persuaded of any fact than we are of the great saving that would be accomplished by the more general use of oxen, in place of horses, for agricultural purposes. A calculation made on a proper scale would shew, that by this reform alone there would be an annual saving of millions of dollars to the nation. This is the season of Cattle Shows, and Agricultural Exhibitions, and they have become so numerous that it would be impossible to give their proceedings, in detail, in the Farmer; but in the desire to illustrate what can be done by OXEN with the plough, we shall select the reports of committees on that subject at the Fairs in the eastern states. The common fear and excuse is that they cannot bear the heat of the South. This we doubt, provided the oxen are well trained and fed on dry food, but at all events we are perfectly convinced that the Tuscany breed of cattle imported by Commodore Bainbridge in the Columbus, and now in possession of Mr. Middleton of South Carolina, will give oxen that will bear the heat of that state as well as horses.

Edit. Am. Far.

The committee appointed to award the premiums offered by the Rhode Island Society for Ploughing (John H. Clarke, Esq. Chairman,) made the following report:

That they were happy to perceive an unusual competition, and excitement among the numerous candidates for premiums, arising confessedly from a conviction that good cattle and ploughs of improved structure, constitute the first security for good ploughing, within the least time; and that among the several yokes of oxen entered for ploughing many of them were fine animals equally remarkable for their strength and docility.

The first premium of ten dollars, for ploughing, and two dollars to the driver and ploughman, was awarded by the committee, to Mr. Harding Hudson, of Cranston; who ploughed one eighth of an acre of sward ground, in an excellent manner, in the unprecedented short time of 14 minutes and 5 seconds.

The second premium of eight dollars, with two dollars to the driver and ploughman, was awarded to Mr. Elisha Olney, Jr. of Smithfield, who ploughed an equal quantity of land, well, in 14 minutes and 25 seconds. His cattle were of fine form and broke in the best manner.

The third premium of six dollars, with two dollars to the driver and ploughman, was awarded to Mr. Abner Sprague, of Cranston; his cattle were of superior size, strength and beauty, and ploughed the same quantity of land, well, and very deep in 15 minutes and 6 seconds.

The fourth premium of four dollars, with two dollars to the driver and ploughman, was awarded to Mr. George Colvin, of Warwick, whose cattle, but of middling size, evinced uncommon nerve, and perfect subjection, and ploughed the same quantity of land in 15 minutes and 25 seconds.

Some other teams performed their work in less than 15 minutes, but the committee considered their ploughing as not so well done.

The excellence of the cattle of Jesse Foster, Esq. of Smithfield; of Mr. Martin Smith, of Scituate, and Mr. Halsey Ellis, of Cranston, excited the attention of the committee: they were animals of much beauty and great strength; and although, the committee have awarded to others the premiums, still so nice was the competition, and so nearly balanced were their claims, that your committee felt embarrassed in pronouncing their decision.

The committee feel it a further duty to no-

tice a voluntary ploughing match, which took place immediately after the ploughing for premiums was finished. A pair of oxen of superior strength and quickness, owned by Mr. Richard Fiske, of Cranston, and driven with great skill, by Mr. Joseph Sheldon, ploughed the same quantity of land, in the short space of eleven minutes. These cattle were excluded by the committee from entering for a premium, one of them having been a premium ox the last year.

The same cattle of Mr. Olney, to whom is adjudged the second premium, ploughed another piece of land of equal size, in 15 minutes and 45 seconds.

But in the last trial of excellence and speed nothing excited so much admiration, as a beautiful and well broken pair of three years old steers, owned and driven by Mr. Nicholas Waterman, of Johnston. These fine young cattle, ploughed one eighth of an acre of ground, well, in the short space of 15 minutes and 50 seconds. The committee consider Mr. Waterman entitled to great credit, for raising such animals, and for their extraordinary docility.

The committee cannot refrain from expressing their gratification at the very fine exhibition of draft oxen, particularly those owned by Mr. Foster, Mr. Ellis, Mr. Olney, and Mr. Colvin; and regret that they had not the power to award a premium to them. They beg leave to recommend, that in future a specific premium be awarded to draft cattle.

FROM THE NEW HAMPSHIRE PATRIOT.

HILLSBOROUGH CATTLE SHOW.

Report of the Committee on Working Cattle.

The committee appointed to examine the merits of Working Cattle, and to adjudge the awards, have attended to the duties of their office, and beg leave to report.

Agreeably to their instructions, they have taken into consideration not only the ploughing, but the goodness of the cattle, time, &c. What, or how much was intended by the &c. your committee were unable to determine; but they presumed that it embraced, or might embrace the discipline of cattle, and they have brought it into the estimate in making their decision. That cattle, destined for labour, should be well broken to the yoke, and submit to the authority of the teamster, is universally admitted, and generally practised. But it is of great importance that they be learned to exercise the plough without a driver. This is easily effected; and it is a great saving of expense in the cultivation of fields. Most of our ploughing can be done by one yoke of oxen; and with little attention they will perform as much labour on the plough without, as with a driver. Even two yoke may easily be taught to do the same. By using the most active and highest spirited pair for leaders, there will be little or no difficulty attending the practice. To save the expense of a man, or even a boy will be no small additions to the interest of a farmer. It is equally important to reduce the expense of cultivation, as it is to increase the quantity and value of crops.

While we make our observations upon cattle, we would not pass by the teamster with neglect. We cannot forbear to remark on the excessive use of the whip, though there is not so much cause of complaint as there was the last year. Oxen that are well disciplined, will do all they ought to do, and they will do all they can do without severe whipping. That the ox, that most useful animal, that most faithful servant of man, distinguished for his patience and indur-

pre-eminent among the herd of the stall, whose tongue was never defiled by an indecent, or profane word, whose breath was never polluted by the fumes of intoxication, and before whom the Egyptians bowed down in devout adoration, that the ox, I say, should be the object of the unmerciful scourge is an outrage upon that law, which has given to man dominion over the beasts of the field.

After trying the oxen presented, on the drag and on the plough, the committees have come to the following decision, and they make the following awards.

To Mark Morse, the committee award the first premium on Working Cattle. Taking into view the age, form, size, strength and activity of his cattle, they came to this result.

To Moses Greene is awarded the second premium. His cattle are five years old, measure 7 feet, 3 inches; they are remarkable for their strength; and they work with a good degree of activity. They are in a high state for beef, though they have done the necessary work on his farm, the past season.

To David Damforth is given the third premium. His cattle are five years old, of large size, good form and discipline, great activity, and promise to be very useful. These points led to the decision.

The fourth premium is awarded to John Johnston. His cattle are large, fleshy, strong, and performed his work very well.

Other cattle richly deserved premiums; and it was with some difficulty a selection was made. The committee, though past the meridian of life, decided as if they believed that advanced age was derogatory to character, or promising usefulness. Mr. B. Parker, and Mr. Joseph Kingsbury, presented no statements respecting their cattle, agreeably to the regulations prescribed.

The ploughing match demands a few remarks. It was cause of regret that a more suitable piece of ground could not have been selected for the purpose. The land was laid out into plats, of about one eighth of an acre each. There was a little difference in their size, a little difference in the quality of the work, a little difference in goodness and breadth of the ploughs, and a little difference in the time of performing the work. The average time was from 10 to 11 minutes, exceeding in shortness of time what has ever been done before in this society.

Fourteen yoke of cattle were entered for premiums, and thirteen entered the list for competition. They all excelled in some points; but as only four premiums were offered, the expectations of some must, of course, be disappointed. The general character of the working cattle was excellent; and though some of them could not draw a premium they could draw as much upon a drag, as the most highly favored oxen.

The progress, which is making in this department of stock is highly pleasing; and encourages the farmer to persevere in his exertions for improvement. It is hoped that all will give a hand to the work, in which they are all equally interested.

Respectfully submitted by your committee.

HUMPHREY MOOR,
in behalf of the committee.

Francestown, Sept. 25, 1823.

THE MARYLAND GAZETTE, printed at Annapolis, the seat of Government of Maryland, is now the oldest newspaper existing on this continent.—It was established in the year 1745, and has remained in the same family from its commencement to the present day.

It has always been remarkable for its typographical accuracy and neatness of arrangement; qualities essential to the professional character of every printer, as well as to the satisfaction of readers.—We heartily wish we could accomplish for the American Farmer better reputation in these respects.

For old acquaintance sake, and personal respect for a brother Editor, we give place to the following exposition of Mr. Green's views, in regard to some changes contemplated in the plan of the Maryland Gazette.—*Edit. Am. Far.*

To Mr. Monroe much praise must be accorded for that state of harmony, which has for some time past pervaded our country—so wise has been the course of policy that he has pursued, that he has satisfied all parties, and left us nothing to dispute about. So great then has been the change of circumstances which a few years have produced, not only in our own country, but in Europe also, that the Editor deems it no longer necessary to continue his paper as the advocate of any particular political party. *Its columns will henceforth be open to all who may choose to avail themselves of them*, without any other restrictions than requiring decency of language; the avoiding of personalities, and correctness of composition. But it will be the peculiar object of the Editor to render his paper subservient to the best interests of his own state.—He wishes to make it emphatically a *State Paper*. By this expression, he means a paper, whose province it will be to uphold and maintain the honor and dignity of the state—to promote her prosperity by diffusing such information with regard to her resources and her means of internal improvement, as he may be enabled to obtain. As an indication of the future character of his paper, he has given to it the new title of the *State Register*. It will in future become the repository of all state documents, and of such other information as may tend to elucidate the history of the state, or promote its improvement and prosperity.—It will also be the object of the Editor to present his patrons with the earliest intelligence, foreign and domestic; and he will be particularly careful to devote a due portion of his paper to the interests of Agriculture, Manufactures, and Domestic Economy.

With this statement of his objects and his views, the Editor submits his plan to the patronage of the public.—Should it be favored with their support, he will endeavor not to disappoint the expectation that may be excited.

If sufficient encouragement be afforded, the paper will be enlarged to an imperial size, and printed with a new type.

Purging Powder for Pigs.

Jalap, 1 dram. Should this be found insufficient, 10 or 12 grains of scammony may be added, or 10 grains of calomel; but it is better, perhaps, to try the jalap alone first. It is difficult to drench a pig, but if it can be done, a solution of Epsom salt may be given, with a little castor oil, or an infusion of senna; probably a solution of common salt would do, when there is nothing else, especially if a little oil be given with it.

Dog Mange.

This disorder is very common in dogs, and may generally be cured by rubbing in the following liniment, keeping them on a wholesome diet, chiefly of vegetable food, and giving them now and then a little opening medicine. The mange is known by the dog almost constantly scratching himself, and by the skin appearing moist, and sometimes scabby. The dog should be well scrubbed with soft soap and water, or tobacco

water, and well wiped with a dry cloth immediately after. When quite dry, apply the mange liniment, taking care to rub it well on every part.

There is an obstinate kind of mange, in which the skin appears of a bright red color, and sometimes scabby also. Here some internal remedies are required of the alterative kind, such as Ehipop's mineral, calomel, or even very small doses of sublimate, (from 1-8th to 1-4th of a grain.) Mange is sometimes extremely obstinate, and terminates in dropsy or consumption.

Mange Liniment.

Train Oil,	- - -	4 ounces
Oil of Turpentine,	- - -	½ ounce—mix

FROM THE NEW-YORK STATESMAN.

CULTIVATION OF THE VINE.

A friend has handed us proposals for publishing, by subscription, a work entitled the *Vineyard*; or, the art of cultivating the vine and of making wine; by *William Lee*, for several years Consul for the United States at Bordeaux. This work will be comprised in one volume, of 300 or 350 octavo pages, and contain the history of the vine from the earliest ages—the natural history, and the varieties most generally cultivated—the climate, soil, and exposure of the best vineyards in Europe—the choice of plants, manner of planting, and of cultivating the vine—diseases of the vine, accidents, and the manner of preventing both, and of renewing the plants—and the whole process of preserving the fruit, and making wine and vinegar. The whole will form a complete system for conducting a vineyard.

Within the last year, we have had an opportunity of tasting the most delicious wines, made in different parts of the United States; and in the course of the present season, we have seen in two gardens, one at Brooklyn, and the other at West-Point, the strongest proofs that in our climate the grape may be cultivated in the greatest profusion, of an excellent quality, and with very little labour and expense. There is a single stock growing at Brooklyn, which at this moment bears \$500 worth of grapes, while it has cost the proprietor scarcely as many cents for the cultivation, and at the same time furnished a most delightful arbor during the heat of summer. The vine is from North Carolina, and so far from degenerating, it appears to be improved by being transplanted to a more northern latitude.

The show of fruit at the agricultural dinner at *Brighton* was unusually fine this season.—Among the rarities, were some superb Lemons presented by the Rev. *Mr. Bigelow*, the products of his Green-house at Medford. The average weight of six of these was more than a pound each. One of them weighed no less than twenty two ounces, and measured fifteen and an half inches in the longer circumference, and thirteen inches round. The flavor of the lemons was perfect; although the rind, it was remarked, was somewhat thicker than in those imported. Other fruits were excellent in the kinds; particularly grapes from the gardens of Messrs. *Pomeroy*, *Perkins*, and *Cook*; several varieties of pears presented by the *Hon. John Welles*; wall-peaches from the garden of *Mr. Bigelow*; and last, not least, a basket of *Bon Cretiens*, the produce of a pear-tree planted in Salem by *Gov. Endicott*, about the year 1640. The last were presented by *E. H. Derby*.—*Ro*

MAMMOTH WHITE OAK.

The following were the dimensions of a tree cut down in Hardy county, for the purpose of a shaft, to be used at Union Forge in this county.

The stump measured 4 feet 10 inches across, and 14 feet 6 inches in circumference. When dressed to haul home, 3 feet 4 inches at butt, 3 feet 2 inches at top, and 25 feet long. It was ascertained to weigh 6 tons.

The tree was brought from Devil's Hole, 14 miles from the forge, over a mountain road, on a wagon with six wheels, drawn by twelve horses. The tree was the growth of Mr. Sager's land. *Virginia paper.*

Mr. Peter Boynton, of Shelburn, Vermont, has raised the past season, upon three acres and one tenth of an acre of land, *two hundred and fifteen bushels of winter wheat.* A considerable portion of this crop has been sold for seed at \$1.50 cents per bushel, averaging from sixty-one and a half to sixty-four pounds per bushel, which is pretty good evidence of its quality.

Rot in Sheep.—Dried Juniper Berries are the best antidote against this destructive epidemic. As soon as the slightest symptoms of it appear in a flock, a handful of these berries should be given for every two sheep per day, and to be continued until all apprehension is removed.

Bean Product.—Three beans planted in the garden of Mr. Barnum, of Stockbridge, the past season, produced, the 1st, 180 pods; 2d, 200, and 3d, 215, containing in all 2780 beans.

SPORTING INTELLIGENCE

The two mile heats, which were run yesterday over the Union Course, for the Jockey Club purse of \$200, afforded as great sport as ever was witnessed since the establishment of this course—the three heats having been so closely and beautifully contested, that each horse in his turn was the favorite; Sambo, to the astonishment of many, won, with apparent ease, the first heat, but not having sufficient strength and bottom to contend with the stock of Duroc, was forced to yield to his superior in Knickerbocker, who had to contest every inch of the two last heats with a young horse, full brother to Sir Walter, owned by Mr. Badger.

Knickerbocker,	2 1 1	} Time	m. s.
Sambo,	1 3 0		
Restless,	3 2 2		
Sr Rock,	bolted		
Hickory,	4 drawn		
Mohawk,	distanced		4 11

Sporting Intelligence.—Yesterday was the 3d and last day of the races, over the Union Course, Long Island. The heats were four miles, for a purse of \$500. Three horses started, viz. Mr. Laird's sorrel mare Fancy, Mr. Colden's bay mare Daffy, and Mr. Bate's horse Prince. Fancy took the lead, kept it the eight miles, and won the purse. The bay mare ran handsomely, and kept close behind Fancy for seven miles, but gave up in the course of the last mile. Prince was no match for the mares, and was withdrawn after the first heat.—*Daily Adv.*

LITERARY INTELLIGENCE.

M. CAREY respectfully informs the citizens of the United States, that he hopes to be able to publish, in the course of the ensuing year, a work for which he made considerable preparations a few years since, viz: "*Sketches of a*

History of Religious Persecutions, in two volumes, 8vo."

Any information, or communications calculated to facilitate the execution of this work, will be thankfully received. Books loaned for the purpose will be carefully preserved, and returned uninjured.

Such printers of newspapers as are favorable to this undertaking, are requested to insert the above once or twice.

JONATHAN'S ACCOUNT OF THE CATTLE SHOW.

Did y'ever to the Cattle Show go?
What kicking, and pushing and goring—
Cattle in pens—the pens in a row,
And tarnal great hogs, there, a snoring.

There's sheep too; ewes and weathers and lambs;
Some Bucks; (some are'n't in pens far 's I know)
There's sheep of the Dons—some Uncle Sam's;
Some natives—some "real Merino."

There's a tug too, or trial of strength,
With hawing and geeing and scolding,
Just to twitch a great stone a foot's length;
Haw! haw buck!—why don't ye!—gee golding!

Then for ploughing they give a reward,
And cute as a squirrel that burrows,
Off start the ploughs, cut through the green sward,
A turning the slickest of furrows.

And then, sir, in a room that they've got,
There's an "ocean of notions" display'd,
There's blankets, and stockings and—what not;
That the folks in their houses have made.

There's bonnets, both of straw and of grass,
And cloth too, of woollen and linen,
And there's yarn and there's thread, smooth as glass
That gals for themselves have been spinning.

There's hats, and there's shoes, and there's leather,
And there's—I can't tell half now, I fear—
Got a prize—gee ho! altogether!
And I'd go to the show twice a year.

New-Hampshire Patriot.

THE FARMER.

BALTIMORE, FRIDAY, OCTOBER 31, 1823.

THE WATER CART.—The remarks on this subject will be read with satisfaction, especially by those of our patrons who reside in the neighbourhood of the sea, bay, or salt water rivers, but the importance of contrivances, to facilitate the transportation and application of salt water, will be better understood and appreciated, when the value of salt itself, both as a manure, and as a wholesome condiment for the food of domestic animals, is more fully explained than it has hitherto been done in this journal. For this purpose we have commenced making some extracts from a pamphlet on THE USES OF SALT IN AGRICULTURE, republished at the instance of Judge Peters, who says of it in a letter to Messrs. M. Carey and Sons, the publishers:

"There is enough to satisfy the most incredulous; and to stimulate the friends to improve-

ments in agriculture, most sedulously to pursue agricultural trials of this substance, in every way. Its usefulness both to preserve health, and to cure or palliate diseases, in our domestic animals, has been long known in this country. But our knowledge in this regard, is yet imperfect. I have long believed that the absence of various diseases among our stock, is attributable to the general use of Salt, both in their food and in remedies or preventives.

"I think the republication of the pamphlet here, will be of public benefit; and that you will, of course, be remunerated for the expense. Consistently with the credit of the press, the cheaper you can afford it, the more widely its circulation will extend. I conceive that agricultural associations could not do a more important service to the object of their respective institutions, than that of encouraging your republication; by taking a number of copies for gratuitous distribution. But this should not prevent every farmer whose circumstances will afford it, (and there are few indeed of a contrary description) from buying the pamphlet for his own use, and to promote the interests of his art.

I am, Your very obedient Servant,

RICHARD PETERS.

MESSRS. M. CAREY AND SON."

RULES AND REGULATIONS

To be observed at the Cattle Show, Exhibition of Manufactures, Ploughing Match, and Public Sale of animals and manufactures on Wednesday the 5th and Thursday the 6th of November, 1823.

The members of the Maryland Agricultural Society, and all persons willing to become members, will meet at the Maryland Tavern, four miles from Baltimore on the Frederick Turnpike road, at 9 o'clock, A. M. to receive their badges from the Committee of Admission, at the entrance of the inclosure, on payment of the annual contribution of a sum not less than two dollars.

2. All stock entered for premium, or for sale, must be put into the pens, before 9 o'clock, A. M. of the first day under the direction of the marshals who will be distinguished by blue sashes.

3. Gentlemen who have fine animals, though not intended for premium will gratify the society by exhibiting them in the pens, appropriated for that purpose by the trustees.

4. The owners of stock are requested not to remove them from the pens, without previously conferring with the trustees.

5. All articles of domestic and household manufacture, must be exhibited on the first day of the show, between the hours of ten and twelve.

6. Machinery and articles coming under the head of "new inventions," will be exhibited on the lot adjoining the inclosure.

7. Butter and fermented liquors, will be delivered to the trustees, early on the first day, under a private mark or seal, as it is intended that the owners shall not be known, until the committees have formed their decision.

8. Competitors in the ploughing matches, are requested to announce themselves before twelve o'clock on the first day, to the committee having charge of that object.

9. Specimens of premium crops, must be delivered where practicable, on the first day of the exhibition, together with the necessary certificates and vouchers to the committee appointed in that case.

10. The owners of stock are requested to furnish placards, to be fixed on the pens, giving as far as practicable, the pedigrees of their animals, with the manner in which they have been reared

11. An auctioneer will be employed by the Society, to bid off the animals and articles on sale, free of charge to the owners; who are, however, expected to attend themselves to the delivery of the property and the collection of their own monies.

12. The Trustees not acting on Committees, will meet at their table, within the inclosure, at 9 o'clock A. M. on each day, to whom all persons having business with the society, will, in case of need, apply for information.

13. The various committees will be expected to withhold their decision, until they shall be formally conveyed in their Reports.

14. The Reports of the Committees will be made to the Society, and the premiums will be distributed by the President at the close of the ploughing matches, after which an election will be made of officers for the ensuing year. The Society will then dine together, and the proceedings will close with an Address, to be delivered by Gen. R. G. Harper, at the instance of the Trustees.

15. The inclosure is intended exclusively for the use of the committees, members of the Society, invited persons, and the owners of stock, and their attendants.—But the fields around the inclosure, commanding a perfect view of all things exhibited, will be free to all.

JAMES CARROLL, Jr. } Committee

J. S. SKINNER. }

THE CATTLE SHOW.

The races have passed, and with no occurrence to excite regret at the manner in which they were conducted. Those only can find fault, who object to the *thing itself*—about the use of such public exhibitions people may differ in opinion, but in this case, the managers have taken care that no argument shall be established on the abuse of this amusement against the legitimate use of it.

But the publick attention is now invited to an exhibition about the use and value of which, no doubt exists with any portion of the community—we mean the Cattle Show and Fair, for the exhibition and sale of domestic animals, household manufactures, &c. &c. on Wednesday next.—This association is connected with all the most substantial and best interests of Society, and has no tendency to generate a single bad passion or immoral habit.

When it is considered how far the labour and expense of originating these exhibitions in Maryland, devolved on a few individuals, it is but fair that now, when their practicability and usefulness have been demonstrated, they should be sustained by the countenance and support of the community at large—every class whereof is in some way or other benefitted by improvements in the processes, implements and productions of agriculture.

We are authorised to state that there will be for sale at the exhibition, a number of sheep of the Bakewell and Merino bloods, and young horses, together with young cattle of the North Devon and Improved Short Horn breeds, and fat cattle of superior qualities. Arrangements are also made for a fair test and display of Pope's Threshing Machine, by the kindness of Mr. Anderson, who gives the use of his barn for that purpose—and well contested ploughing matches with oxen and with horses on ground well adapted to the purpose, will give to the scene additional variety and attraction.

The public sale of live stock will commence at 3 o'clock on the first day of the exhibition. The ploughing match with oxen and with horses, will commence at ten o'clock on the second day.—

The trial of *Pope's Threshing Machine* will take place as soon on the first day, as the committee on machinery shall have been organised. The premiums will be delivered immediately after the ploughing match on the second day.

On that day the Society will dine together on the ground, and after dinner the exhibition will close with an address from Gen. R. G. Harper, prepared at the request of the Trustees, on the affairs of the Society, and the prospects and interests of American agriculture.

COMMODORE PORTER.

The trustees of the Maryland Agricultural Society, participating the common pleasure, experienced by their fellow citizens, on the safe arrival of Commodore Porter, after such severe sickness and exposure—and recollecting his efficient services at their last exhibition, have invited him to attend the exhibition on Wednesday next, and have requested his aid to decide on the claims of those who may compete for the premiums offered for agricultural machinery, and new and useful inventions. It is hoped that his appointment on the grand Union Canal Committee will not prevent his attendance here, as the Cattle Show closes on the 6th and the Canal Committee cannot well be organised before the 7th.

CANTON RACES.

THIRD DAY.—For the purse of one thousand dollars, produced on Friday last, the best running which has yet been witnessed. The racers which started were Col. Johnson's mare *Betsy Richards*, General Winn's sorrel horse *Sumpter*, and Mr. James Howard's brown horse *Jim Crack*. They set out at the hour appointed, *Betsy Richards* in front, and *Sumpter* and *Jim Crack* close behind. *Betsy Richards* preserved her lead and came out ahead at the end of the heat—but the interest was greatly increased by the handsome performance of *Jim Crack*, and the close match of his speed with *Sumpter*, each being at times before the other during the rounds. The time of running the first heat—(four miles) was eight minutes, five seconds.

In the start of the second heat, *Sumpter* was for a moment in front; but *Betsy Richards* soon shot ahead and retained her advantage with apparent ease throughout the heat.

WASHINGTON RACES.

FIRST DAY.—The purse of \$500, four mile heats, was won by Mr. Johnson's *Betsy Richards*, in two heats beating Mr. Winn's *Sumpter* with apparent ease, though the heats were well contested—the race being said to be a better one than that run between the same two horses at Baltimore.

SECOND DAY.—Mr. Winn's horse *Vanity* took the purse of \$200.

Mr. Wilson's *Experiment*, Mr. Ramsay's *Doubtful*, and Mr. Stonestreet's *Cornwallis*, were distanced the first heat.

In the second heat, Dr. Thornton's *Southern Eclipse* was distanced, and the heat was won with great ease by Mr. Winn's *Vanity*, beating Mr. C. Strother's *Atalanta*.

PRICES CURRENT—CORRECTED WEEKLY.

Flour, best white wheat, \$7 25—Howard street, from wagons, \$6 87½—fine do. \$6 37½—Wharf, do. \$6 25—White wheat, \$1 20 to 1 30—Red do. \$1 12 to \$1 15—Lawler, \$1 17 to \$1 22—Washington white, \$1 20 to \$1 35—Rye, 44 to 45 cts.—Corn, 41 cts.—wharf Oats, 33 cts.—wagon Oats, 35 cts.—Beef, 6 cts. per lb.—Live Cattle, \$5 to \$5 50, per cwt.—Bacon, hog round, \$12 50—Pork, \$7 50 per c. lb., 6 to 8 cts. per pound—Mutton, 4 to 5 cts. per lb.—Beans, retail, \$1 50, cargo price, 1 12½—

Peas, retail, 75 a 80 cts., cargo price 58 a 60 cts.—Red Clover Seed, \$6—Orchard Grass do. \$2 50—Herds' Grass do. \$2 50—Timothy do. \$4—Flax Seed, 75 to 80 cents—Whiskey, from the wagons, 33 cents per gallon including the barrel—Apple brandy, 30 to 32 cts.—Peach do. 65 to 70 cts.—Shad, No. 1, \$6 50, very dull, No. 2, do. \$5 to \$5 50, do.—Herrings, No. 1, \$2 50 per bbl., very dull No. 2, \$2 25 do.—Fine Salt, 75 cents per bush., coarse, do. 70—Butter, (firkin) 14 cts. per lb.—Eggs, 12½ cts. per doz.—New Hay, \$14 per ton, old do. \$16—Straw, \$9.

MARYLAND TOBACCO.—No Sales—Kentucky 4 to 6 cents, and scarce.

For Sale at Auction.

The following valuable animals of improved blood, will be sold by auction on the 5th day of November next, at the Maryland Tavern four miles from Baltimore, on the Frederick road, at 3 o'clock, P. M.

THE FULL BLOODED STUD HORSE, Top Gallant five years old, of great beauty, and very gentle.—The colts of this blood are as remarkable for their excellence under the saddle, as they are for the turf.

THE FULL BLOODED GELDING, Speedwell, two years old, by old Top Gallant, from a full blooded Virginia mare.

A FULL BLOODED ALDERNEY BULL, being calved 5 months after his mother—landed at Baltimore from Guernsey.

TWO FULL BLOODED BULLS, of the mixed breed of the Devon and the Alderney; both the sires and the dams were imported.

A FULL BLOODED HEIFER, from an Alderney cow and Devon bull.

A FULL BLOODED DEVON HEIFER, 2 years old, in calf by a Devon bull.

SIX HEIFERS, half bloods of the Alderney breed, in calf by an Alderney bull.

SIX HEIFERS, three quarter and half bloods of the Devon breed, in calf by a Devon bull.

THREE BULL & THREE HEIFER calves of three quarters blood, of the Devon breed.

Cash for all purchases under: \$100, will be required—three months credit for all above \$100, and under \$200—and six months for all above \$200—interest, with approved endorsers, payable at Baltimore.

For any other particulars, apply to J. S. Skinner, Editor of the American Farmer.

J. G. WALMSLEY, manager for R. Caton, at his farm at Brookland Wood.

Brookland Wood, October 29, 1823.

Improved Stock.

The following young stock will be offered on sale at the Exhibition of the Maryland Agricultural Society, to be held next week, viz:

Two fillies, from a celebrated Tom mare, one 4 years, and the other 2 years old.

One filly, from a full blood Virginia mare, 2 years old.

Two colts, from a handsome country mare, one 4 years, and the other three years old.

The sire of the above mentioned animals, was the beautiful imported Arabian horse, ARAB.

A colt from a full blood Virginia mare, sire the full blood horse Clifton; he is 15 months old and well grown.

A mare mule, from a fine large mare, by the imported Maltese jack, Sancho.

A very superior young bull, 8 months old, from an excellent cow, sire the "improved short horn" bull Champion.

Two half blooded Alderney heifers, 18 months old, from good cows, sire "Mark Anthony."

AGRICULTURE.

FROM THE NEW ENGLAND FARMER.

REPORTS

Of the Committees of the Massachusetts Agricultural Society, as to the premiums awarded at the Cattle Show and exhibition of Manufactures, held at Brighton, on Wednesday and Thursday, the 15th and 16th of October, 1823.

First Committee, on Fat Oxen, Bulls, and bull calves. The President, assisted by Hezekiah Gates, Esq. of Marlborough, and — Perry, Esq.

As chairman of the committee on certain descriptions of live stock, I am about to report the decisions of that committee, and to award the premiums to the successful competitors.

Before doing it, however, I hope I may be indulged with some prefatory remarks. They will be as short as I can make them, because I know the impatience of those who hope to find that they are among the *fortunate*, and I have not the vanity to believe, that I have the power either to instruct or entertain you—what I shall say, will be directed solely to the object of reconciling those who may be disappointed, not only in the awards of *this* committee, but in those of all my brethren, and their assistant judges.

It would not do to compare this exhibition to a lottery, for that would imply the absence of all skill, and judgment, and anxiety to do right; while in *this* case, every expedient has been adopted to secure competent skill, to exercise the soundest judgment, and with the deepest desire to give a just and impartial decision. We select the most experienced judges of animals—men, above temptation, or bias. They undertake this laborious and unthankful office, without the hope, or the wish, of any other reward, than the promotion of the public good. We choose the best farmers as judges of working cattle, and ploughing. We seek out the ablest and most skilful mechanics, (need I name such men as Mr. Moody, of Waltham, and Mr. Alger, of South Boston?) to judge of new inventions—we invite experienced importers or venders of manufactured goods, to examine the various and constantly increasing articles, which the ingenuity and taste of a country, preeminently distinguished for its inventive powers in objects of science and taste, the country of Fulton, and of a greater name, of Perkins, are constantly adding to the common stock.

It would seem, then, that we have done every thing in our power to secure intelligent and impartial awards—yet it must be seen and felt by every one, that in *one* respect, and in *one* respect only, a cattle show resembles a lottery—that point of resemblance is, that *as* in a lottery, *as* in these exhibitions, there are many blanks, and but few prizes—and would any fair man, and disinterested friend to agriculture and manufactures wish it to be otherwise? Would it be desirable, that all should draw prizes? There would be an end at once to all competition—there would be no reward to those, who by patient care, and cultivated ingenuity, had reared superior animals, or produced a fabric of superior beauty and durability. The very intent of these shows is to discriminate and reward superior exertions, and to encourage those who have come a little short of the prize this year, to make their utmost efforts to excel in another. It cannot be too often repeated, that the task of judging is as delicate, as it is laborious and unthankful. It is unthankful, because the disappointed much outnumber the successful candidates. It is also unthankful because the committees may occasional-

ly (though not often) differ from the public opinion—yet an intelligent and impartial public, and a fair and generous competitor will admit the serious difficulties in the case, and that it is scarcely possible, that all men will think alike as to the beauty of an animal, any more than they agree in the relative beauty of their wives and children,—neither will they be more likely to agree in the other qualities of the animals, their aptitude for labor, their disposition to fatten—and still less, can uniformity of opinion be expected in the varied and ever changing forms, so arbitrary as in fancy articles of manufacture.

Having made these general remarks, applicable to all my friends and associates,—I will add one or two peculiarly adapted to my own branch of inquiry and decision.

As to fat cattle, there can be little difference of opinion. The animal has then run through his course—has performed his destined, and faithful and invaluable labors, to man, and by a hard, but inevitable fate, he is to be submitted to the knife, and the sinews and muscles which turned the sod, are to be converted into the sustenance of man. He is, when so fatted, in his most perfect state, and skilful men (such as I have had the pleasure to be associated with,) can then decide, which animal is, on the whole, the best. They can do this with so much accuracy, that they can lay the ox (as the phrase is) within a score of pounds of his actual weight, and they can even decide in most cases the quantity of fat, or tallow, which will be found in parts concealed from the eye.

Not so as to the bull. In judging of a bull, many properties, or qualities, are to be taken into the estimate—his carriage, whether erect or grovelling—his temper, whether ferocious or tractable—his eye, whether full or sunken—his neck and head, whether thin and delicate, or thick and fleshy—his coat, whether coarse, like that of a buffalo, or fine like that of a full blooded racer—his limbs, whether stubbed and thick, like those of an elephant, or delicate denoting activity and power, like those of an antelope—his forehead and chest, whether deep and powerful, indicating that he will produce a progeny calculated to tear up the stiffest soil, and to remove the heaviest rocks—and a hind quarter, fitted with muscles, which when properly loaded with fat, will furnish an abundance of delicious food. There are many minor properties, such as the straitness, and breadth of the back, and the elevated insertion of the tail, known to good judges, which I forbear to notice.

But my enumeration will satisfy any reasonable mind, that it is not size alone which can determine the preference, and that it is no light or trifling task to decide upon the properties of that noble animal, the bull—the parent, and the most important parent, of our most valuable domestic animal. I would not be misunderstood, when I call him the most important parent, I mean it simply in *this* sense—while one cow can only transmit either her good or bad qualities to eight or ten individuals, a good or bad bull, may convey his good or bad properties, to some hundreds.

The remarks I have made as to bulls, are equally applicable to bull calves, with one exception, which I beg every intelligent farmer to weigh. Bull calves are imperfect animals in a state of growth, often preternatural growth—as in man, we find children, often disproportioned, when growing, and at mature age of the most perfect proportions; so bull calves of little promise, often become perfect specimens of their species, and the most perfect calves, when young, not unfrequently prove distorted, or coarse or ordinary, when arrived at maturity. I entreat

your patience for these details, which seemed to me, however, necessary.

- We award the first premium for a fat ox, to Asa Pond, of Petersham—weight 2597 pounds, \$30
- The second premium for a fat ox, to Samuel Bowen, of Adams, in Berkshire, 25
- The third premium for a fat ox, to Amos Davis, of Groton—weight 2200, 15
- The first premium for bulls, to Col. Jaques, of Charlestown, for his red bull, called Middlesex, out of Cœlebs, owned by him, 30
- The second premium to Samuel Keir, of Charlton, for his bull out of Holderness, owned by Gorham Parsons, Esq. of Brighton, and much approved in that part of Worcester, 20
- The third premium to Col. Jaques, of Charlestown, for his bull out of Cœlebs, called "Yankee," 10
- The first premium for bull calves, we award to Jacob Sawyer, of Westminster, for a native bull calf of a breed that has often gained our premiums, weighing at 7 months old, 725 pounds, 15
- The second premium for bull calves is awarded to John Brown, of Dudley, for a bull calf of the Holderness breed, 10
- The third premium for bull calves is awarded to Silas Stone, of Sherburne, Middlesex, for a calf out of Fill-pail's progeny, owned by Mr. Abner Wheeler—Note, Fill pail was presented to the Society by Col. Thorndike, and imported from the Netherlands. His progeny in the third degree inherit fully his qualities, 5

There were several other fine bull calves, among which I am requested by the committee to notice that of Nathan Nichols, of Malden, out of Cœlebs; that of William Dodge, and that of Daniel Stephens, of Marlborough.

Among many excellent bulls not included in the premiums, were a bull from Denton, by the Hon. Mr. Welles; Jupiter a white bull, of Col. Jaques—The bull of Henry Rice, Esq. of the same breed, and a native bull, exhibited by David Perham.

It will be seen by this enumeration, that even the second and third crosses, from the imported bulls, have carried the premiums, and yet it was not in any degree owing to any influence which I, as a trustee, exerted over two very respectable citizens from the interior—I am only the organ to communicate their opinion, carefully formed, and cautiously expressed. It will however, be seen, that some native bull calves, of a superior stock, carried the two first premiums—a proof that we need selection and care only, to make our own breed equal to any we could import. Yet we must rejoice at the opportunity we have had to cross our breed with the most improved of foreign countries. If no other effect should be produced, than that of exciting attention to the improvement of our native stock, all the care and expense hitherto bestowed would be only as the chaff is to the plump and healthy grain.

JOHN LOWELL, *Chairman*,

N. B. There was a cow exhibited, owned by Charles Vaughan, Esq. of Hallowell, which for several accounts, did not come within the list of our premiums.—Yet it would be improper not to notice her—she was from an imported breed, of great value; and she was without question one of the most perfect animals ever exhibited in Brighton.

A FINE COW.

In a note attached to the Report of the first committee on stock, exhibited at the late Brighton Cattle Show, of which Mr. Lowell was chairman, notice is taken of a cow exhibited, owned by Charles Vaughan, Esq. of Hallowel, "from an imported breed, of great value, and without question one of the most perfect animals ever exhibited at Brighton." This cow, we learn, has since been slaughtered, and her weight was as follows:

Hide	79 lbs.	
Tallow	98	
	175	} 2 hind quarters.
	168	
	190	} 2 fore quarters.
	198	

908 whole weight.

This fine animal, we are assured, has been at grass all the season, and had no provender till within a few weeks. This fact, considered in addition to her beautiful form, must place her high in the estimation of good judges of neat cattle. It proves her to have been one of those animals which possess a great aptitude to fatten, a quality held in high estimation by judicious and calculating graziers.—*Editor New England Farmer.*

REPORT No. II.

The committee on milch cows, heifers, sheep and swine, consisting of E. Hersh Derby, Esq. Willard Gay, Esq. of Dedham, and Abner Wheeler, Esq. of Framingham, report:

That there were three premiums offered for milch cows, for which there were twelve candidates, and after long deliberation they have awarded the premiums in the following manner—The 1st premium of \$30 to the Rev. John B. White of East Sudbury—2d do. \$20 to the Rev. Samuel Capen, of South Boston—3d do. \$15 to Henry Rice, of Boston, for the Duches of Marlboro'.

Mr. White who received the first premium, furnishes the following statement under oath.—His is a native cow, raised by Mr. Noah Smith of Sudbury, is nine years old, and came into his possession in the spring of 1821. She calved on the 28th of May, the calf was killed the 11th of July. She has furnished 156 lbs. 9 oz. of butter, besides furnishing the family with a supply of milk. Weight of one quart of her milk 2½ lbs. Weight of milk given in a day when the calf was a week old, besides what he would take, 55 lb. 8½ oz. Weight of milk when the calf was three weeks old 32 lbs. 13 oz. Weight of milk given on the day after the calf was killed 60 lbs. On the 27th of Sept. weight of milk given in one day, 38 lbs. 12 ozs. 15 qts. 1 pt. On the 11th of Oct. 36 lb. 14 qts. 31-5 gills.—From this it appears that the mean weight of milk given by the cow from the time when the calf was killed to the present is 48 lbs a day. It also appears that when the calf was killed she gave milk at the rate of a barrel of 32 gallons beer measure in 5-1-3 days, and that she now gives milk at the rate of a barrel in 8 days and 8-9 of a day.

Mr. Capen who received the second premium, stated under oath that his cow was raised by himself, is from a superior native cow and a bull of the Hon. John Welles's stock—is eight years old, calved the 2d May, since which she has furnished 202 lbs of butter; her greatest quantity of milk has been about 16 quarts per day, of very rich quality.

Mr. Rice stated that his cow by Denton was three years old last February, she calved July 27; she has given from the 9th of August, to the 13th Oct. 65 days, 2431 lbs. milk, averaging 38.5 lbs. per day.

The committee noticed with much pleasure two other very fine cows, one belonging to the Hon. John Welles, the other to Mr. Luke Fiske.

There were twenty-four heifers entered for premiums, and your committee had only three premiums to award. Among so many very fine animals, they found it extremely difficult to decide, and regretted that no distinction had been made in the premiums between those which had calved and those which had not. But taking into view every circumstance, they have been induced to award the first premium of \$15 to Mr. Samuel Jaques of Charlestown, for his full blooded short horned heifer of 16 months.

The 2d premium of \$10 to Major Benjamin Wheeler of Framingham, for his part blooded heifer of 14 months old.

The 3d premium of \$7 to Col. Joseph Valentine of Hopkinton, for his native heifer of 17 months old.

The committee were highly pleased with several other heifers, and regret that they could not award more premiums. They feel desirous of noticing in a particular manner the five heifers by Denton, owned by his Honor Levi Lincoln, of Worcester, also five heifers offered by the Hon. John Welles of Dorchester, 1 by John Pierce Esq. of Roxbury; 2 by Jacob Knapp Esq. of the same town; 1 by George L. Stearns, of Medford; 1 by Samuel Brooks of Brighton; 1 by the Rev. Lemuel Capen, of South Boston; 1 by Dr. Codman, of Dorchester, and two full blooded young heifers by Col. Samuel Jaques of Charlestown.

In deciding the premiums on Merino Sheep, they have been governed more by the fineness of the fleece on every part of the same, than by the size and appearance of the animal, and have therefore awarded

To Samuel Henshaw, of Boston, the first premium for the best Merino ram,	\$15
To Samuel Jaques, of Charlestown, the 2d do.	10
To Samuel Henshaw of Boston, the first premium for Merino Ewes,	20
To Samuel Jaques, of Charlestown, the 2d do.	10

There were several other lots of Merinoes, all of which the committee thought very highly of, several of which were very much superior in size and appearance to the ones to which they have awarded the premiums, but the quality of their wool was not of such exquisite fineness throughout. There were no Merino or native wethers offered for premiums.—They were much gratified by the appearance of four long woolled sheep from the Netherlands, imported by Col. Jaques, who has made great exertions to introduce fine breeds of sheep into the country, but as the Society have not offered a premium for sheep of that kind, they could not award any.

The committee award for the best boar, the 1st premium to Gorham Parsons, Esq. for his Cobbet an Wellington boar	\$12
For the 2d best to Silas Dudley, of Sutton	8
For the 3d, to Francis Moore, of Brighton	5
For the best Sow, to Silas Dudley, of Sutton	12
For the 2d best, to Gorham Parsons, Esq for his Leicester sow	8
For the 3d, to S. W. Pomeroy, Esq. of Brighton	5
For the best store pigs, to Josiah P. Kenny, of Roxbury, the 1st premium	10
For the 2d best, to Luke Fiske, of Waltham	5
For the best spayed sows, four in number, to T. P. Mariani, of Concord	20

[Your committee were much pleased with the appearance of these animals. Mr. M. furnished them with a description in writing of his mode of operation.]

Mr. Parsons desires the committee to state that he relinquishes the premiums awarded to him for his swine, having intended to enter them for exhibition only.

All which is respectfully submitted.

E. HERSY DERBY, *Chairman.*

REPORT No. III.

BRIGHTON, October 16, 1823.

The Committee on Agricultural Inventions, Report:

That among the articles presented of this description, Safford's straw cutter, is in their opinion entitled to the Society's premium, from its great simplicity as well as its effectual operation. The motion is communicated to the feeders directly by a double threaded iron screw, without bands or any complicated machinery. The knives are flat and oblong, and affixed to the radius of an iron wheel, and fixed and un-fixed, and regulated with the greatest ease.—The whole expense of the machine is fifteen dollars. It is said that it will cut a bushel of straw in a minute; and the testimonials in its favor are of the most decisive character, given by persons well acquainted with the use of such machines, who certify that "it exceeds any other they have ever seen, for cheapness, simplicity, despatch and durability." Your committee therefore award to Mr. Safford the Society's premium of \$20.

A machine, called Jaquith's threshing machine, was presented for premium by the inventor. It is chiefly characterized by its being the application of the same wheels to the action of flails, which are fed by geer, or bands. The operation of the machine is very simple and effectual, and in the opinion of your Committee is the best, which has yet been presented, for *mowed grain*. Its expense is thirty-five dollars, when prepared for the hand, and seventy-five dollars when prepared for the horse power. Your committee deem it entitled, and accordingly award a premium of \$20—the proprietor adducing certificates, to the satisfaction of the chairman, that the machine has been used and approved by some practical farmer.

Walter Janes presented for premium, a corn shelling machine, the principal component parts of which were a fluted cast iron cylinder hung under the segment of another fluted cast iron inverted cylinder. Without attempting further to particularize its conformation, your committee deem it sufficient to state that it performed its operations well, and is in their opinion an useful machine. Your committee do not however, deem it so decidedly, if at all superior to machines, for a similar purpose used in this vicinity, as to justify them in awarding any premium; although they deem it well adapted for its purpose.

A shearing machine, presented by John T. Cambridge, of Springfield, Vermont, the operation of which is chiefly characterized by the horizontal motion and sliding action of the knife, by which it differs from similar machines in common use in our manufactories. It is a machine extremely handsome in its structure, and performs its work well—but not coming under the head of agricultural implements, is not embraced within the sphere of the premiums, or the authority of the Society.

The same remark applies to a machine denominated "Jenck's Alleviator." This your Committee apprehend to be a very excellent invention, and is very powerfully recommended by Dr. Warren, of Boston, and others, for the raising of persons whose limbs are fractured, while in bed, with great ease and safety. While your Committee consider it a machine of great practical utility in hospitals and sick chambers,

they deem it not within the objects or power of this Society to award to it a premium.

Various agricultural machines were presented for exhibition only—among these your Committee particularly notice Mr. Pope's threshing machine, which on a former year obtained the Society's premium. It has been since improved, and now can thresh, as it is stated, with a hand power and the assistance of three men, from eight to ten bushels of grain per hour—and enlarged, to the application of a horse power, will thresh per hour, from ten to fifteen bushels of wheat, and from fifteen to twenty of rye or oats.

Messrs. Lincoln Fearing & Co. also presented for exhibition a variety of agricultural implements, consisting of forks, ploughs, Eastman's straw cutter, from Baltimore, and Curtis's churn, from Connecticut; all of them to be found in their excellent and extensive collection of agricultural implements in Boston, and all machines of different degrees of merit, the particulars of which your Committee did not deem themselves called upon to estimate. They cannot fail however, to express their gratification at the particular exertions of Messrs. Lincoln Fearing & Co. as well as at the general evidence of the increasing attention of the community to implements tending to improve and to lighten the labors of agriculture.

JOSIAH QUINCY,
CYRUS ALGER,
PAUL MOODY.

REPORT No. IV.

Wilmington, Oct 16, 1823.

The Committee on Manufactures award
To James Shepherd & Co. of Northampton, for the best specimen of Broadcloth, \$20
To Slater & Howard, of Oxford, for the next best, 15
To Thomas Dedman, of Templeton, for the best specimen of Woollen Cloth, of household manufacture, 12
To George M. Barrett, of Concord, for the next best, 8
To James Shepherd & Co. of Northampton, for the best specimen of Cassimere, 12
To the Wolcott Woollen Manufacturing Company, for the next best, 8
To Lincoln Burr, of Hingham, for a piece of Kersey, 2d premium, 8
To Messrs. Pomroy & Clapp, of Pittsfield, for the best specimen of Sattinet, 8
To Seth Bemis & Co. of Watertown, for the next best, 5
To Mrs. Stephen Fay, of New Braintree, for the best specimen of household Flannel, 10
To Jonathan Wilder, of Sterling, for the next best, 7
To Ephraim Coburn, of Dracut, for the best specimen of Linen Diaper, 5
To Gideon Delano, of New Braintree, for a piece of Linen Cloth, 8
To John Hunter, of Braintree, for the best specimen of Floor Carpeting, 15
To Joshua Melville, of Concord, for the next best, 7
To Benjamin Poor, of Newburyport, for the best piece of Stair Carpeting, 10
To Theodosia Converse, for a specimen of fine Blankets, 6
To Anna Buckman, of Tewksbury, for a specimen of Linen Diaper Table Cloths, Worsted Stockings, and Work Basket (as a gratuity) 3
Also to Polly Leland for a piece of Cotton Diaper, 5
To P. S. Ford and brother, of Medway, for a specimen of fine Cotton Thread, 5

To Elizabeth Cowan, of Boston, for a specimen of Thread Lace,
To Ann Heath, of Roxbury, for 13 pair of Cotton Stockings,
To Mary Ann Pimpton, of Medfield, for a Straw Bonnet,
To Olivia Stanley, of Dracut, for do.
To Eunice Danforth, of Norton, for two extra Fine Straw Bonnets,
To Martha Hapgood, of Shrewsbury, for a Bonnet,
To Lavina Sweet, of Foxborough, for a Bonnet made from the husks of corn,
To M. W. R. of Boston, for a Cotton Counterpane,
To Misses Baxters, of Quincy, for a Hearth Rug,
To Sarah Cushing, of Dorchester, for a Rug,
To Jane Coburn, of Dracut, for do.
To Betsey and Mary Munroe, of Lincoln, for two Hearth Rugs, each,
To Caroline Cutting, of E. Sudbury, for do.
To Mehitable Dean, of Mansfield, for do.
To Louisa Clark, of Boston, for do.
To Susannah Whiting, of Cambridge, for do.
To Anna Bemis, of Watertown, for do.
To Mary B. Converse, of New Braintree, for do.
To Mrs. Elijah Warren, of Leicester, for do.
To Catharine Pierson, for 3 pair of fine Worsted Hose,
To Hannah Hawks, of Sterling, for do.
To Frances, Nancy, Elizabeth, and Abiel Wheeler; of Worcester, for a specimen of Artificial Flowers, exhibited, as the work of young children each,
To John Thoreau & Co. for a specimen of Lead Pencils, manufactured from Plumbago, native of this country.
To Marian R. Haven, of Hopkinton, for 2 Straw Bonnets, and Calash of Straw
To Sarah Pollock, of Canton, for a grass Bonnet,
To Susan Whitney, of Dedham, for do.
To Abigail Goodale, of West Boylston, for wrought Buttons and Frogs,
To Nancy Wheeler, of Worcester, for Tip-pets of Turkey Down,
A bonnet from Plymouth, made of white paper, was considered by the Committee a curious and ingenious article, but they doubted whether it could be sufficiently serviceable to merit encouragement.
The number and amount of premiums on Factory Goods having been diminished since the last year, in favor of household fabrics, Factory Flannels were not a subject of premium the present year.
The best of the specimens sent for exhibition from the Amesbury Flannel Manufactory, were very fine and of excellent materials, and in all respects well finished. There were pieces of different qualities but all creditable to the Company.
The Committee can say no less of the six pieces exhibited by Mr. James Howorth from his Factory at Andover.
The four pieces from the Salisbury Woollen Manufactory were substantial goods, but not in a finished style.
Many of the Specimens of Household Industry, exhibiting a commendable taste, ingenuity and skill, are not rewarded by gratuities, not because they were undeserving this distinction, for inferiority in the qualities mentioned, but because it was necessary to put a limit somewhere

to this kind of reward—the committee have therefore conferred it on some of the most useful articles only. Much praise, however, is due to Miss Merrill, of Salisbury, for a parcel of fine linen thread—to Hannah Edson, of Hardwick, for worsted socks—to a lady, of Plymouth, for a paper bonnet—to T. P. Meriam, of Concord, for a specimen of stocking yarn and a pair of socks—to Mrs. Robinson, of Worcester, for stockings and socks, and to Mary Adams, for a specimen of good carpeting.

The pieces of calico from the Charleston Bleachery (a recent establishment) were thought by the committee to be excellent goods, and far preferable for durability to English calicoes of the same description.

A very fine beaver hat was exhibited by Messrs. Dike and Shepard, of Northampton. The committee could conceive of no improvement beyond it.

The case of hats, from the Boston Manufacturing Company, were of the first quality of gentleman's hats. This Company have in former years deserved and received the commendation of the committee on Manufactures, whose favorable judgment has been confirmed by the public. It is understood that the importation of men's hats, even of the best qualities, is now very small.

The two parcels of sail cloth, one by Mr. George B. Chase, of Salem, the other by Mr. George Johnston, of Cambridgeport, were pronounced by competent judges to be without fault, and these gentlemen have therefore secured to themselves a good prospect of the public patronage.

Four pieces of black Broadcloth, offered for exhibition only by the Wolcott Woollen Manufacturing Company, were very creditable to the makers, and with a little more skill in the finishing would have approached very nearly to those which obtained the first premium.

The best of the Broadcloths, Cassimeres, and Sattinets, were much superior, in all respects, to the same quality of goods exhibited at Brighton in any previous year.

RICHARD SULLIVAN, *Chairman*.
EDWARD TUCKERMAN,
JOHN LEMIST.

EXTRACTS

FROM MORE MODERN WRITERS ON THE USE OF SALT IN AGRICULTURE.—No. II.

From a Pamphlet entitled "Hints to Country Gentlemen and Farmers, on the importance of using Salt as a general Manure." By the late J. Hollinshead, Esq. of Chorley. Third edition, 1802.

"Salt" says Mr. Hollinshead, "will be found to be the cheapest, best, and most durable manure ever yet made use of: and for the realer distribution of this most excellent manure through the kingdom, the public and enterprising spirit of the nation has of late years provided very ample and cheap conveyances to almost any part of the country, which the gentleman farmer can wish, by means of the numerous navigable canals, which are either finished or projecting in almost every direction. Salt may be laid on the banks of the *Staffordshire* canal at fourteen shillings per ton; from whence, by means of the *Oxfordshire* Grand Junction, and other canals it will with the greatest ease, be conveyed to any part of the south of England, at a very trifling additional expense."

"Suppose a farmer to live twelve or fifteen miles distance from any canal, navigable river, or part of the sea coast (which in general, perhaps, will be found to be the greatest extent he can have to fetch it,) from whence he can im-

port Salt for the benefit of his lands; even at that distance, his team will fetch a load of Salt in one day, say at the expense of ten shillings; and with that team he will convey home one ton of salt; therefore, for fourteen shillings, the original price of the salt, five shillings (more or less) for the freight by the canal, river, &c. and ten shillings for the carriage home, he lays in his own field manure sufficient for two acres and a half of land, at the small expense of one pound nine shillings. What a vast superiority, in point of expense, this would have over all the manures now in use; for lime, dung, or marle, even where most plentiful, on account of their great bulk, cost more in the single article of cartage, without regard to the expense of buying or digging for them, than the whole charge of salt when laid upon the ground*. Besides, as so small a quantity of salt in weight will serve for manuring lands, this is no inconsiderable recommendation, because on that account it may with ease be conveyed to the most rough, steep, and mountainous parts of the country, to which the bulky and heavy manures now in use, could not be carried, but with infinite labor, and at an expense far exceeding all the advantages to be expected from it."

"That common salt is an excellent manure, experience, the most satisfactory of all evidences, clearly proves. It was used round Droitwich, in Cheshire, as a manure, so long as foul salt was permitted duty free, with very great success."

"Nothing in nature is so powerful as salt, to meliorate and drain strong and stiff soils, and also to give moisture to dry ground: it is also a certain destruction to weeds and insects. Besides its efficacy on corn and fallow grounds, its excellent qualities in giving luxuriance and salubrity to grass lands are peculiarly worthy the attention of the grazier and breeder of cattle."

"When a farmer intends to fallow a piece of ground, he ought first to sow it with such a quantity of salt as would be sufficient to destroy all vegetation, viz. forty bushels per acre†; which by cutting and dividing the viscous substances which are in the earth, would reduce it into a proper state to become food for plants. The farmer must take notice, that this salt is to be sown on the ground some time before he begins to work his fallows with the plough (the autumn will be the most proper season,) in order to give the salt sufficient time to destroy the grass and other roots upon it, before he begins to work it. The salt being thoroughly mixed and incorporated with the soil, during the spring and summer following, whilst the land is on the plough, will by the time the seed is sown upon it, be reduced to that strength which is the most proper for effectually and vigorously assisting and supporting vegetation while the seed is on the ground, and such lands will be found to produce a crop superior to those under any other mode of cultivation."

"What a striking and manifest superiority is here observable in favor of manuring with salt,

* This goes on the presumption of Waste-Salt being allowed the farmer duty free; but even with the present duty, a ton of Rock-salt, containing forty bushels, may be put on board a boat on the canal for five pounds ten shillings.

S. P.

† I think it necessary to remark upon these directions, that I believe the writer is here, and in the former extracts, speaking of foul Cheshire Salt, such as at that time was allowed to be used for land. Therefore in using Rock Salt, only half the quantities which he mentions ought to be employed.

which does, as it were, itself, in a good measure prepare the soil, before its nutritive operation takes effect; and thus having cleared the ground of all extraneous and pernicious weeds, gives room and full scope to the genuine plant."

"This method of sowing the intended fallows with salt will, therefore, serve much to lessen the labor of the husbandman in working his grounds; for the tough and adhesive clods and lumps which are generally so troublesome, especially upon clayey soils, will be so completely broken and dissolved by the operation of the salt, as to give much less obstruction to the harrow at the first working."

"In deep, loamy, dry earth, upon which wheat has grown, after the crop is got in, the land should be ploughed, and lie in that state until the spring, when it must be cross-ploughed and wrought fine with the harrow, and planted with potatoes; as soon as the potatoes are covered with earth, then sow or spread sixteen bushels of salt per statute acre upon them; and when they are dug up in the autumn, then sow a crop of wheat again, taking care to pick all the potatoes clean out, that they may not injure the wheat in the following spring by growing up amongst it. By this method of cultivation a crop of wheat, and another of potatoes, may be produced alternately on the same ground forever, instead of losing a whole year's produce, according to the old custom, whilst the land is fallowing."

"For other corn lands sown in the usual way, after a spring ploughing, the best method will be to sow sixteen bushels of salt per acre, immediately after the grain is covered in by the harrow; this, by meliorating the soil, destroying weeds and insects, and attracting moisture, will produce an abundant crop; and by sowing ten bushels per acre annually, these lands will ever after be exceedingly productive."

"There is still a further advantage, which is highly worthy the farmer's attention, which is, that by having constantly a plentiful supply of such a cheap manure, he can always keep his grounds in a condition fit to receive any kind of grain which he would wish to sow upon it, which at present is far from being the case: for instance, if he now wishes to sow a crop of wheat, he cannot do it without lime or marle; if he would plant potatoes, it cannot be done without a large quantity of dung, which if it is of his own producing, he will impoverish his other lands while he enriches this; if he buy it, it must be at an enormous expense, and also to the proportionate injury of the district from whence he procures it, where it ought to have been expended; and therefore, though it should enrich an individual, it will not be of the least advantage in a public point of view, which undoubtedly ought principally to be attended to in things of this nature. Also, when a person enters on a poor farm, unless he be possessed of a larger capital than usually falls to the lot of this most useful class of mankind, with all the industry and management of which he is master, his lease, nay even his life, may be expired before he has manured one-half of his estate, and generally speaking, the parts which he first tilled will be reduced to their former poverty, before one-fourth of the farm has received any benefit."

"But if he were permitted the use of salt, duty free, with a very moderate sum of money, he would have it in his power, in a few years, to bring his farm into the highest state of culture and fertilization; so that at all times he would be enabled to bring to market those articles, which his situation, or the particular necessity of his neighbors, pointed out as most beneficial to himself."

"Another considerable advantage would arise to the occupiers of small farms in particular, and especially those with large families, from manuring with salt, as they would be enabled to raise, not only a much greater quantity, but also a much greater variety, of the common necessities of life, from the same extent of ground. For example:—a man who rents a few closes of land gets, perhaps, nothing but milk and butter from his little farm, whilst he has the most substantial part of the sustenance for his family (bread) to buy, generally at a high price. But give him salt, duty free, and he may pitch upon one field which with the assistance of this manure, will produce him abundant crops of grain annually for ever, whilst his other fields will remain unmolested, and if also salted, covered with the most luxuriant and wholesome herbage for the use of his cattle. At present, if he ploughs at all it must be in rotation, or as the farmers term it, in shifts, and by that means he is constantly injuring his grass-lands."

"When salt is used upon pasture lands, it may either be sown upon them in its simple neat state, after the rate of sixteen bushels* the acre, or mixed with compost, mud, or loamy earth; sixteen bushels of salt to twenty loads of earth, and turned in the heap two or three times to incorporate it properly; this compost should be laid on and spread in the autumn."

"For meadow-lands, we would advise the farmer to sow six bushels of salt per acre, immediately after the hay is got in. This would be found peculiarly beneficial in hot and dry summers, and upon lime stone and sandy soils; which after they are mown, are often so much parched by the heat of the sun, that not only the eddish is destroyed, but also the crop of the ensuing year is very materially injured; but by sowing it with salt, moisture would be attracted and retained, sufficient to assist vegetation so powerfully, as in a short time again to cover the face of the ground with grass, and by that means effectually to screen the roots, which would otherwise be too much exposed to the direct rays of the sun."

"It may, indeed, be said that dung will answer the same purpose: in some degree it might, but dung cannot always be had, never in sufficient quantities: besides, if it could, this objection lies against it, that neat cattle will not eat the eddish after dung, consequently one valuable crop is lost to the farmer, which, if salt were used would be both productive and wholesome. Also, the hay, when put into the mow on stack, should be sprinkled with salt on every layer. When hay is housed soft, this should never be omitted, as it would prevent what the farmers call the mowburn, and make the hay far more pleasant and nutritious for the cattle in winter."

"Mr. Beck, gardener in Chorley, has constantly made use of salt in his garden for upwards of thirty years, principally upon his onions; and he has invariably found the salt to exceed every other kind of manure which he could have used for the like purpose; his method is to sow the salt immediately after the seed is covered in. But as he never had any thought of communicating his observations and experiments to the public, he took no care to ascertain the exact quantity necessary to be sown on an acre, and proportionably upon any smaller quantity of ground; yet he thinks, if he might hazard a conjecture, that he has not sown less, and probably more, than sixteen

* I think it necessary again to caution the farmer against using this quantity of pure salt upon grass-land, as it probably would burn up the grass. The writer speaks all along of foul waste salt, which was seldom more than one-third of its real salt.

S. P.

bushels per acre. One year, by way of trial, he sowed the usual quantity of salt upon a plot of onions, after they had begun to show themselves above ground, and the crop so far from being improved, was entirely spoiled; from this he infers, that the experimental gardener, who may be inclined to make use of salt, will do well to throw it on as soon as possible after the seed is sown."

(To be continued.)

NATURAL HISTORY. No. 3.

[Continued from page 250.]

Changes take place in the Color of the Clothing.—The distribution of color in the animal kingdom, appears to be connected with latitude as correlative with temperature. In the warmer districts of the earth, the colors of man, quadrupeds and birds, exhibit greater variety, and are deeper and brighter, than in the natives of colder countries.

Among the inhabitants of the temperate and cold regions, there are many species, which, in reference to the color of their dress, do not appear to be influenced by the vicissitudes of the seasons. In others, a very marked difference prevails between the color of their summer and winter garb. A few of the more obvious instances of these changes, in British species, may be here produced.

Among quadrupeds, the Alpine hare (*Lepus variabilis*) is a very remarkable example. It is found in this country, on the high mountains of the Grampian range. Its summer dress is of a tawney grey color; but about the month of September, its fur gradually changes to a snowy whiteness. It continues in this state during the winter, and resumes its plainer covering again in the month of April or May, according to the season. The *ermine* is another of our native quadrupeds, which exhibits in its dress similar changes of color according to the season. It frequents the outskirts of woods and thickets. During the summer months, its hair is of a pale reddish brown color; in harvest it becomes clouded with pale yellow; and in the month of November, with us, it is of a snow white color. Its winter dress furnishes the valuable fur called *ermine*. Early in spring, the white becomes freckled with brown, and in the month of May it completely resumes its summer garb.

Among the feathered tribes such changes of color in the plumage during winter are numerous. They greatly perplex the ornithologist, and have been the means of introducing into the system several spurious species. The white grouse or ptarmigan (*Tetrao lagopus*) may be produced as a familiar example of this kind of hibernation. This bird, like the Alpine hare, inhabits the higher Grampians, and is never found at a great distance from the limits of the snow. In summer its plumage is of an ash color, mottled with small dusky spots and bars. At the approach of winter the dark colors disappear, and its feathers are then found to be pure white. In remarkably mild winters the change is sometimes incomplete, a few dusky spots of the summer dress remaining. In spring, its winter garb becomes again mottled, and the bird loses much of its beauty. Even the young birds in their autumnal dress resemble their parents in the mottled plumage, which likewise becomes white at the approach of winter.

Among the aquatic birds, similar changes in the color of the plumage have been observed. The black guillemot (*Uria Grylle*), so common on our coasts, is of a sooty black color during the summer, with a white patch on the wings. During winter, however, the black color disappears, and its plumage is then clouded with ash-colored

spots on a white ground. In the winter dress it has been described by some as a distinct species, under the name of *spotted guillemot*. In the more northern regions, as in Greenland, for example, this bird, in winter, becomes of a pure white color.

These changes of color, which we have already mentioned, extend throughout the whole plumage of the bird; but, in some instances, the change takes place on a small part only of the plumage. Thus the little auk (*Alca alle*), during summer, has its cheeks and throat of a black color, but in winter these parts become of a dirty white. In this its winter garb, it is often shot on our coasts. Its summer dress induced *Pennant* to consider it as a variety, and as such to give a figure of it in his *British Zoology*. The black-headed gull (*Larus ridibundus*) has a black head during summer, as its English name intimates. During the winter, however, the black color on the head disappears; and, when in this dress, it has been regarded by many as a distinct species, under the name of the *Red-legged Gull*.

In many other birds there is a remarkable difference, in point of color, between the summer and the winter plumage, altho' not so striking as in those which we have already noticed. The colors of the summer feathers are rich and vivid; those of the winter obscure and dull. This is well illustrated in the dunlin (*Tringa Alpina*) whose summer plumage is much intermixed with black and rufous color, but whose winter plumage is dull and cinereous. In its winter dress it has been described as a distinct species, under the name of *T. cinclus*, or *Purre*. Similar instances might be produced in the wagtails, linnets, and plovers, and a great many other birds.

The circumstances under which these changes are observed to take place, indicate their dependence on temperature, as connected with the season. The deep colors of the summer dress are exchanged for the lighter or whiter colors of the winter, with a rapidity and extent proportional to the changes of the seasons. During a mild autumn, the shifting of the dark for the light colored dress proceeds at a very slow pace; and when the winter also continues mild, the white dress is never fully assumed. In some species, as the black guillemot, the white winter dress is never acquired in this climate, although its ash-colored plumage intimates a tendency to the change. In the climate of Greenland, on the other hand, the change is complete, and the plumage is of a snowy whiteness; as we had an opportunity of observing in the collection of the Dublin Society in 1816, in a specimen in its winter dress, brought from Greenland by an intelligent and enterprising naturalist, SIR CHARLES GIESECKE.

Having thus seen that the color of the clothing of many animals changes with the season, and that, however diversified the summer dress may be, the color during winter approaches to white, it may now be asked, What benefit is derived from this arrangement?

The rate at which bodies cool is greatly influenced by their color. The surface which reflects heat most readily, suffers it to escape but slowly by radiation. Reflection takes place most readily in objects of a white color, and from such, consequently, heat will radiate with difficulty. If we suppose two animals, the one of a black color, and the other white, placed in a higher temperature than that of their own body, the heat will enter the one that is black with the greatest rapidity, and elevate its temperature considerably above the other. These differences are observable in wearing black and light colored clothes during a hot day. When, on the other hand,

these animals are placed in a situation, the temperature of which is considerably lower than their own, the black animal will give out its heat by radiation to every surrounding object colder than itself, and speedily have its temperature reduced; while the white animal will part with its heat by radiation at a much slower rate. The change of color in the dress of animals is therefore suited to regulate their temperature by the radiation or absorption of caloric.

While it is requisite that the temperature of some species should be preserved as equally as possible, the cooling effects of winter are likewise resisted by an additional quantity of heat being generated by the system. An increase in the quantity of clothing takes place to prevent that heat being dissipated by communication with the cold objects around, and the dress changes to a white color, to prevent its loss by radiation. In summer, the pernicious increase of temperature is prevented by a diminished secretion of heat or the secretion of cold, increased perspiration, the casting of a portion of the winter covering and by a superior intensity of color in the remainder giving it a greater radiating power. This last character would, in the sunshine, by absorbing heat, prove a source of great inconvenience, were its effects not counterbalanced by other arrangements, and by the opportunity of frequenting the refreshing shade, or bathing in the stream.

In those cases, where particular parts only of the clothing change their color, there are probably local circumstances connected with the secretions, or the sexual system, which renders such arrangements necessary. Hair growing from a part which has been wounded, is always paler colored than that which is produced on the sounder parts, intimating the operation of local causes on the coloring secretions, or local purposes to be served by the change.

It is probably for the purpose of preventing a wasteful dissipation of the heat of the system, that the dress of many animals becomes lighter colored in old age, and that the human hair turns grey. Young animals seldom present the same dress and vivid colors, &c. which they assume upon arriving at maturity.

The change of color which takes place in the dress of some animals during winter, is supposed to serve other purposes than the regulation of their temperature. The white garb which they assume, assimilates them to the color of the snow, and in this way they are considered as better able to escape the observation of their foes.

All our conclusions concerning final causes, ought to be the result of very extended observations, lest we delineate arrangements which would be productive of pain and ruin to many species, where we intended to unfold the marks of wisdom and benevolence. If the white dress of the alpine hare and ptarmigan concealed them from their enemies, the eagle, the cat, and the fox, these last by being deprived of their ordinary food, would be in danger of starvation and death. But this variation of color is not confined to weak or defenceless animals. Beasts and birds of prey are likewise subject to the change. Hence, if it yielded protection to some, it would enable others to prey with greater certainty of success on their defenceless neighbors. Many of these rapacious animals, (as the *ermine* for example, which is at all times well qualified to provide for its wants by its determined boldness, extreme agility, and exquisite smell,) do not stand in need of such assistance. If this change extends to the rapacious as well as the defenceless, it may likewise be observed in aquatic as well as

in terrestrial animals. In reference to aquatic animals, we would ask, What protection is afforded to the black guillemot, during the winter, by its mottled plumage, or to the little auk, by its white chin, since the whiter their dress, so much the more unlike the dark colored water of the clouded season in which it is exhibited? The popular opinion on the subject must be relinquished as untenable; especially as the change of color from dark to white does not vary, however different the habits or even stations of the animals may be in which it takes place.

(To be continued.)

TO THE EDITOR OF THE AMERICAN FARMER.

POLITICAL ECONOMY.

ENCOURAGEMENT OF DOMESTIC MANUFACTURES.

DEAR SIR,

Should any apology to our agricultural brethren appear necessary, (which God forbid,) for addressing you on a topic of political economy, I hope to find it in the vital importance of the subject to the public weal; as well as in the peculiar interest that we agriculturists have in forming correct opinions on it, and causing them to be respected in our national councils.

To come at once to the point, my present purpose is to endeavour to call the serious attention of our friends and brethren to certain prevalent errors of a ruinous tendency both to our agriculture and commerce; which, unless something can be said or done to check such unnatural hallucinations, threaten to infect many of the very men who will suffer most from them, and whose professions (one would think) ought to protect them from such self destructive heresies. The particular circumstance which has prompted the undertaking at this time, is a very judicious, well written letter,—so far at least, as it regards the main subject,—sheep, lately published in your paper, and signed G. F. Featherstonhaugh. It contains the following remarks, which, I confess, took me nearly as much by surprise, as if I were to see a grave parson in the midst of his discourse, spring out of his pulpit, and fall to capering like a French dancing master, on his communion table:—so inapposite, out of place, and out of character for a farmer, did they appear.

"The time appears to be approaching, when this frugal and wise Government may be induced somewhat to change its policy. A constant surplus of revenue, will open a safe road to the gradual encouragement of manufactures in wool, and which the increasing wealth and skill of the country seems to call for. A moderate aid to manufactures would probably produce great effects. A prompt home market for wool would be created; a great impulse would be given to sheep husbandry, and to the inseparable improvements in agriculture. There would be a steady demand for the finest, as well as the coarsest wools, and the agriculturist would soon become independent and contented in every part of the state—wherein is comprehended every blessing that wise men desire."

Here, in less time than Mr. Featherstonhaugh could have given a crop, slit, or swallow-fork to one of his own Tups; and with full as little ceremony, three or four most important questions in constitutional and political law, are settled with a few strokes of the pen. In the first place, it is assumed as a point indisputable, that Congress

may do any thing they please for manufactures, and of course, for any other branch of industry, provided they will only call it *encouragement*! and *moderate aid*! Next, it is with equal facility asserted, in a kind of genealogical way, that this encouragement, applied to woollen fabrics, would beget a "prompt home-market for wool;" this market would beget "sheep husbandry,"—sheep husbandry would beget "inseparable improvements in agriculture," and lastly and most surprising of all, this would beget "*independence and content*" in every part of the state; which comprehends "every blessing that wise men desire." Verily, Mr. Editor, I have seen nothing in all my little reading, like this rapid, and reciprocating procreation, unless, indeed, it can be found (I mean no irreverence) in some of the chapters of Genesis. One word as to the desires of wise men—no holding myself among that favored class, I cannot so well tell, nor even imagine every blessing that a wise man *does* desire; but I know very well what a foolish one (if you please so to call him) does *not* desire, and that is, any congressional aid in regulating either his viands or apparel. But if all the momentous matters, so briefly glanced at by Mr. Featherstonhaugh, are to be adjusted by a process at once so plain and compendious, why do our legislators mock us poor clothoppers with the vain pretence of great caution, difficulty and delay being necessary in fixing the point of interference to which they may go, in making us eat, drink, and wear, see, smell, and hear, whatever they may fancy, both as to kind, quality and quantity? Why so much preaching before execution? It is surely an instance of wanton cruelty, little less barbarous than that of the cat, tantalizing with the mere show of liberty, the poor mouse which she designs to kill—and it is not by any thing in our constitution, but *special gratia*,—by the Royal favor of our sovereign, Congress, in tender commiseration of our meagre purses, we are permitted to regulate ourselves with a drink of cogniac grog, a mug of brown stout, or a glass of wine; to settle our stomachs with a bit of Cheshire, Double-Gloster, Stilton, or Parmesan cheese; or to indulge our bodies with shirts, coats, hats, or boots, at something between a quarter and a half, more than they need cost us, nay, so complete and uncontrollable must be this connoissance of our omnipotent masters, that even the shemises, gowns, frocks, caps, ribbands, and feathers, of our wives and daughters, are equally under their parental guardianship, and they, the said daughters and wives, might be compelled either to substitute for them, Mr. Featherstonhaugh's sheep-skins, or take Mother Eve's pla' for it.

Am I, for these opinions, an enemy to Domestic Manufactures? Heaven forbid. I am a friend to every honest kind of national industry; but let them all stand on their own bottom, and bargain with each other, or whom they please, *for* and *by* themselves. If, (as Mr. Featherstonhaugh truly says) "the wealth and skill of the country is increasing"—in God's name let them go on to do so, but let our statesmen forbear to intermeddle either with the mode or the measure any farther than to make men just and fair in their dealings. This is all that a free government—unless the term *free*, means *despotic*, has a right to do. But admit for a moment this right of interference to the full extent claimed—where is the present necessity, for its exercise?

If under existing duties, the manufacturer's profits increase, (which seems to be admitted on all hands) and the farmer's profits diminish, which is equally certain, what imaginable reason can there be, for believing that a farther augmentation of these taxes would operate differently? would it still raise the former, and depress the

latter? To maintain that it would be equally beneficial to the interest of the farmer, would be about as true in political economy, as it would be in Natural Philosophy to assert, that if a fellow trying to swim with fifty pounds tied to his heels, sinks only chin deep, fifty pounds more hung to them, would make him float breast high. But I should never come to an end, were I to enumerate all the monstrous absurdities involved in this doctrine of unlimited power in Congress, to encourage (as it is called,) any branch of domestic industry, that they chuse, at the expense of any, or of all the other branches.

Among these absurdities there can be none greater in my humble view, than the opinion that the best way to achieve independence and content, is to encourage domestic manufactures by law! By the term Independence, as Mr. Featherstonhaugh uses it, and indeed, as it is every where used in those everlasting essays on this subject, under which our news-paper editors, and all their readers have so long groaned, I understand that *state of the nation in which we shall come nearest to wanting nothing from any other nation*. Of course, if we could completely reach that point, it must be—according to the view of these gentlemen, the very consummation of all national felicity. To say nothing of the physical impossibility resulting from the nature of the planet we inhabit, which it would be necessary to overcome, before such a felicitous scheme could be accomplished—even by congressional supremacy; I would ask any man whose brain is not entirely addled by this eternal stang of national independence resulting from the national encouragement of home manufactures—which in plain English means prohibition of many foreign commodities and high taxation of all not prohibited;—I would ask him what would become of that foreign commerce which all the home market men swear by all their Gods, they have no wish nor design to destroy, if there was nothing in any country upon earth that we wanted? Nothing surely, *could there be*, if their project of making home-markets for every thing, can be realized by a congressional fiat, for which agriculture is to pay until these gentlemen cry—"enough" What too, would become of the very manufactures themselves, which they say *could*, and *would*, by their good wishes, be made for *exportation*? not to mention such small matters as the various products of Husbandry, such as cotton, corn, wheat, tobacco sugar, &c. which they would kindly allow us the privilege of exporting, after we had fed them at their own prices,—provided we had any left, as we probably should have, unless reduced to a state of barbarism? Would other nations want them? No, for we ought to presume that *they also*, would act upon the same cunning plan, of begetting home markets,—if it really be the perfection of political wisdom; and of course, *they* would want nothing from *us*! having acquired by the same wise contrivance, the power of supplying their own wants within themselves. The consequence of this delectable cure for the crying evil of "*an unfavorable balance of trade*;" of this millenium for all political economists of the Terrapin-Policy school, would manifestly be, that in a very short time, the commerce of the whole world would certainly and inevitably cease: for the wants of mankind considered as distinct nations, which are the sole cause of commerce, being all supplied at home—according to the independent plan; no possible motive could exist for their farther intercourse. But it may be said, that such a project could not be realized for the whole world, some nations being utterly incapacitated from supplying their own wants, and therefore that some commerce must still exist. Admit

* I was well—would be better—took phys. and—died.

† What, in God's name! would this gentleman call moderate, if he considers the present basis, nothing?

his to as great an extent as these gentlemen would venture to ask, without the most glaring contradiction of their own arguments, still, most of the pernicious consequences of their doctrine would soon follow its adoption. For they still maintain that there can be no national independence for us, but in proportion as the nation is compelled by our own government to apply our own wants within ourselves:—for this is the plain, unsophisticated meaning of all the flourish we have seen cut about such encouragement to domestic industry, as they claim for matter of right. And yet they profess themselves friendly to foreign commerce whose very existence is dependent upon the extent to which we do not supply our own wants within ourselves. Not that I am against it, to any extent in which it may be carried by natural means, unrestrained by prohibitions, bounties, duties, and all the other machinery of the hot-bed policy. To talk of exporting without importing,—or selling without buying, is a palpable absurdity in fact, as well as in terms. It is the childish selfishness of eating our cake, and having it too. To attain, therefore, the kind of independence which they are so continually eulogizing,—that is by excusing, as well as possessing the power created by taxation on all foreign commodities, of making every thing which we consume, would be to murder foreign commerce by the very means which they insist will not injure,—if they do not actually nurture it. No more, such an achievement would have a constant tendency to propel us back towards that primordial state in which every man was supposed to be his own house-builder, clothier, teacher, cook, and every thing else. For nothing can be affirmed in favour of nations being independent of each other, which would not equally apply to the individuals of the same nation pursuing the same plan; nor can any thing be said in praise of the division of labour as a motive of the happiness of a single nation considered apart from the rest of the world, that would not be just as true in regard to the whole family of mankind. *Live and let live* is a maxim of such universal application, that it has no other limitation but the habitable globe. In this reasoning be correct,—and for the life of me I cannot perceive wherein it is defective; foreign commerce must be not only highly beneficial, but absolutely necessary to the happiness of the whole human race, and, a fortiori, to each different community into which it is divided. And which seems needful for its maintenance in the fullest extent of which it is susceptible, is to have it to the influence of this natural necessity, resulting from the mutual wants of individuals and nations. Civilization itself—a blessing, (by the way) as far more estimable than what these same market gentlemen call *national independence*, as knowledge is better than ignorance, and the very child of its bosom; and no more able to exist without it, than man himself is, without the living principle which animates his body, and gives efficacy to his will. Indeed, the great variety of soils and climates which we find on the planet we inhabit, cannot, I think, be well explained but on the supposition that the God of all Wisdom, power, and goodness, benevolently designed that the respective wants of our fellow mortals resulting from this variety, should form the indissoluble ligament of the whole human race; because the only means of continually supplying these wants, is by continual and friendly intercourse. To attempt, therefore, to diminish this intercourse by human laws, is in fact, impiously to endeavour to counteract one of the most obvious laws of the divine legislator of the universe.

So far does this retrogressive contrivance appear to me from sound policy, that was there no middle course, I would infinitely prefer the other extreme. But thanks to our good fortune, we are not driven to any such necessity. Many of our wants we can supply on as good terms at home, as we can abroad, and some on better, without taxing either agriculture or commerce in any such way as these gentlemen are pleased to denominate *protection and encouragement to domestic industry!* So far let us go, but no further. Government, according to our principles and forms of it, has no more right to interfere in directing what we shall manufacture, and what we shall buy,—which they do in effect by means of duties upon foreign commodities, than they have to make us ride Mr. Featherstonhaugh's sheep, instead of horses, or commit any other enormous absurdity that could be named.

I am, Dear Sir,
Your friend and constant reader,
RURIS CONSULFUS.
TO THE EDITOR OF THE AMERICAN FARMER.

DISORDERS OF CATTLE.
October 26, 1823.

SIR,
In your paper of the 24th instant, a correspondent from Falbot, complains of a dreadful mauld among cattle on two different farms—query, if it is not occasioned by over feeding on turnip tops?—I have seen similar effects produced by it—the agony of mine appeared to be great—the skin and flesh much rubbed against trees, or any thing they could get at, on each side of the head—they did not live over twenty-four or thirty-six hours.

A SUBSCRIBER.

Good news for our agricultural friends.—On Wednesday last one of our merchants paid as high as 11s. per bushel for 1200 bushels of wheat, all raised by one man, and brought to this market in the canal boat Vermont, from Burlington. Thus, while the market price in the city of New-York for northern wheat is 10s. 6d. the first quality in this market. It is a fact, that the first quality of wheat does, and probably always will, command a higher price in this market, than in any other on the banks of the Hudson, for reasons which have already been mentioned in this paper, viz. the very extensive, flourishing business in which many of our capitalists are engaged.

Great price of Tobacco.—A single hogshead of tobacco, from the plantation of Mr. Johnson, of Frederick county, Md. was sold in Georgetown, at the enormous price of *fifty dollars per hundred weight!* So much for care and attention in the cultivation of the article. Five or six hogsheads of a quality somewhat less excellent sold at an average of about *thirty dollars per hundred weight.*—*Nat. Intel.*

Editorial Correspondence.

Duncansville, South Carolina, October 17, 1823.
"Our crops of corn and cotton in this district are fine, and if there had not been planted in our state this year much less cotton, and more corn than the last; there would have been a very fine crop of cotton for this year. In our lower districts we have had less rot this year than usual. But I am informed it is much worse than hitherto in some of the upper districts. Taking all things into consideration I must conclude that the cotton crop of this year will be less than the last year's crop. The

AGRICULTURE.

REPORTS

Of the Committee of the Massachusetts Agricultural Society, as to the premiums awarded at the Cattle Show and exhibition of Manufactures, held at Brighton, on Wednesday and Thursday, the 15th and 16th of October, 1823.

[Continued from No. 33, page 259.]

PLOUGHING WITH OXEN.—No. V.

The committee appointed to award premiums on the ploughing by single teams, or one yoke of oxen, have attended to the duty assigned them, and report as follows, viz:—That nine persons entered as competitors, and drew from the eleven lots laid out by the committee of arrangements, as follows:

No. 9. Joseph Dudley, of Sutton, himself ploughman, ———, driver. Work performed in 26 minutes; 12 furrows turned.

No. 10. Lincoln Fearing, of Boston, E. Cushing ploughman, Giles Woodman driver. Work performed in 29½ minutes; 10 furrows turned.

No. 11. Silas Dudley, of Sutton, himself ploughman, Isaac Hathaway driver. Work performed in 31 minutes; 13 furrows turned.

No. 12. Leonard Stone, of Watertown, Solomon Sargent ploughman, Jonas Smith driver. Work performed in 28½ minutes; 13 furrows turned.

No. 13. Isaac Cook, of Brookline, Isaac Cook, Jr. ploughman, Isaac Cook, Jr. driver. Work performed in 35 minutes; 13 furrows turned.

No. 14. Stephen Marsh, of Sutton, Simeon Phelps ploughman, Stephen Marsh driver. Work performed in 27 minutes; 12 furrows turned.

No. 15. Aaron Davis Williams, of Roxbury, Lewis Barker ploughman, Lewis Bliss driver. Work performed in 32½ minutes; 14 furrows turned.

No. 16. Joseph Miles, of Concord, Silas Lee ploughman, Joseph Miles driver. Work performed in 25 minutes; 11 furrows turned.

Your committee feel it a duty to report, that all the work was well performed, and did great credit to the performers; but having only three premiums to bestow, after due deliberation, having examined the work carefully, award as follows:

- To Isaac Cook, of Brookline, the first premium \$15
- Isaac Cook, Jr. as Ploughman, 8
- Isaac Cook, Jr. having no driver, 4
- To Aaron Davis Williams, of Roxbury, the second premium, \$27
- Lewis Barber, Ploughman, \$10
- Lewis Bliss, Driver, 5
- To Silas Dudley, of Sutton, the third premium, \$18
- Do. as Ploughman, \$6
- Isaac Hathaway, Driver, 3

The committee found some difficulty in awarding the premiums, and regretted that they had not at least one more to bestow, but have endeavored to award in the best manner the nature of the subject would permit. All which is respectfully submitted.

(Signed) GORHAM PARSONS, Chairman,
 ICHABOD NICHOLS,
 FRANCIS WINSHIP.

Brighton, October 16, 1823.

Vol. 5.—34.

REPORT, NO. VI.

The committee on the ploughing match of two pair of oxen to plough one quarter of an acre, consisting of John Prince as chairman, and Josiah Titcomb and Paul Upton, beg leave to report their opinion and award of premiums:

That four ploughs only were entered to contend for the three premiums, that the ploughmen drew for lots as follows:

No. 1. John Sherman, of Sutton, with plough and wheel on the end of the bean, made by J. Hall of Sutton—said Sherman himself ploughman, and Austin Sherman, driver.

No. 2. Stedman Williams, of Roxbury, plough made by Jesse Warren, of Dedham, with wheel on the bean—said Williams ploughman, and Samuel Prime, driver.

No. 3. Joseph Curtis, of Roxbury, plough made by Jesse Warren, of Dedham, with wheel and cutter—Amos Wyman ploughman, and Aaron Stone driver.

No. 4. Aaron Davis Williams, of Roxbury, plough made by Jesse Warren, of Dedham, with wheel and cutter—Thomas Howe ploughman, and David Howe, driver.

The rules and regulations were explicitly stated to the ploughman, particularly that *goodness of work, the state of the cattle when finished, and time* would be taken as criterions in deciding the premiums, and that the committee did not wish the cattle to be *hurried*, as good work could not be well done, when over driven. They have great satisfaction in stating that the work was all exceedingly well performed, and the cattle came out in good order, and could all of them with ease, have proceeded to do double the work if required. The only difficulty the committee experience is in deciding, and they trust from the pains they took, that the unsuccessful competitor will not feel dissatisfied, although he was the only one that could not obtain a premium, they much wish they had a fourth to give him.

No. 1 finished their task in 48 minutes 20 seconds, with 28 furrows in 24 feet width, making 10 1-3 inches per furrow—the cattle 3 and 4 years old.

No. 2 finished in 44 minutes 20 seconds, with 26 furrows in 24 feet, making 11 inches per furrow—cattle 3 and 8 years old.

No. 3 finished in 49 minutes 30 seconds, with 26 furrows in 24 feet making 11 inches per furrow—cattle 7 and 8 years old.

No. 4 finished in 49 minutes, with 28 furrows in 24 feet, making 10 1-3 inches per furrow—cattle 6 years old.

The chairman having stated his wish to the committee that they should agree on the premiums, if not he would be called to the unpleasant task of deciding—which he is happy to inform the Trustees he was not required to do—the committee agreeing in opinion to award as follows:

- The first premium to Stedman Williams—plough \$15
- Himself ploughman 8
- Samuel Prime, driver 4
- 2d prem.—John Sherman—plough \$10
- Himself ploughman 5
- Austin Sherman, driver 3
- 3d prem.—Aaron D. Williams—plough \$6
- Thomas Howe, ploughman 3
- David Howe, driver 2

They feel themselves in duty bound to state, that the goodness and well training of the 3 and 4 years old cattle of Mr. Sherman would have given him a fair claim for the first premium, had he not made two or three baulks in his work.— They would also state, that the work of Mr. Curtis's plough was very fine, but rather shallower than their rule, or any other plough.

The committee feel satisfied that all engaged exerted themselves to the utmost, in doing good work, and they only regret, that there had not been more competitors, that they should not have had the unpleasant feelings of leaving a solitary, faithful and deserving one.

(Signed)

JOHN PRINCE,
 JOSIAH TITCOMB,
 PAUL UPTON.

Brighton, Oct. 16, 1823.

ADVICE TO YOUNG FARMERS.

ON THE APPELLATIVES, QUALITIES, HABITS, AND DEFECTS OF HORSES.

Continued from No. 32, page 250.

I shall begin with generals, proceeding to particulars, as they present themselves to my recollection; but rather studying comprehension and use, than the graces of method and arrangement.

Time, which is continually changing all things has, in course, induced various alterations in the nomenclature of the stable. Horses, for the different purposes of the saddle; were in former days, termed *nags, amblers, pacers, stirrers, trotting horses, hobbies, great horses*, or horses for the *buff saddle* (for war) *hunting-horses, coursers, race-horses*.

The appellatives, whether synonymous or distinctive, in present equestrian use among us, are *road-horses, riding-horses, saddle-horses, nags, chafmens horses, hacks, hackneys, ladies horses, or pads, hunters, running horses, racers, race-horses, gallopers, welter-horses, managed horses, chargers, coach-horses, post-hacks, or post-horses, trotters, cantering hacks, or canterers, horses which carry double, cobs, galloways, ponies, and mountain-merlins*.

Chafmens horses, or common road-hacks, are of the strong and serviceable kind, having little or no racing blood, and calculated for those services, in which much speed is not required. *Hack* or *hackney*, is the general term for a road-horse, and by no means conveys any sense of inferiority, or refers exclusively to horses let out for hire. By trotters, we do not understand now, as formerly, horses which have been merely accustomed to that pace, but such as excel at it, in respect of speed; a similar observation holds, respecting canterers, but it usually refers to their powers of continuance. Gallopers mean race-horses.— Welter horses, are gallopers qualified by their strength for the Welter stakes, weight thirteen stone. The terms galloway and poney, refer solely to height. All under thirteen hands, are denominated ponies; from that height to thirteen three, they are called galloways; at fourteen hands they are deemed sized horses. Of foals, the male is called a colt-foal, the female a filly-foal, yearlings, two-year-old, &c. Cobs, cloddy, round-buttocked, fixed horses about, or not much above the galloway size. Of the Mountain Merlin, I have not heard of late years, nor could ever obtain any definition.

In the technical phraseology appropriated to this subject, a *bred* horse is understood to be one of the pure racing, or Oriental blood; the degrees of its commixture with the common blood, or breed, of this country, are signified by the terms, three-parts bred, half-bred, blood-horses, or having a shew of blood.

The characteristic signs of blood, are fineness of skin and hair, symmetry, and regularity of proportions; length, flatness, and depth, particularly in the shoulder and girthing-place; swell of the muscles, and sleek of substance in the fore-arms and thighs; leanness and symmetry of the head; large and bright eyes; pasterns somewhat longer, and more inclining than common, and deer-like hoofs. Of these a horse will generally partake, in proportion to his degree of blood.

Since we acquire symmetry, ease of motion, speed and continuance, in proportion to the racing blood our hacknies and hunters possess, it may be demanded, why not make use exclusively of full-bred horses? Osmer has spoken decidedly in their favour. I have heard it affirmed by a sportsman, that there is the same difference of motion between a racer and a common bred horse, as between a coach and a cart. It is moreover a fact, although it does not lie upon the surface, that no other horses are capable of carrying, with expedition, such heavy weights; and were a thirty stone plate to be given, and the distance made fifty miles, it would be everlastingly won by a thorough-bred horse. There is only one way in which a bred horse would be beat at high weights. It would be (to use a queer phrase) by making it a stand-still race; in that case, I would back a cart-horse, I think he would beat a racer by hours. Thorough-bred hacks are the most docile and quiet, and the least liable to shy of all others; they also sweat less on a journey.

He who possesses a thorough bred hack or hunter, sufficiently short-legged, lively, and active; which bends its knees, and goes well above the ground, and has sound tough feet; has perhaps obtained every qualification he can wish, for the road, except trotting; which he must never expect, in any extraordinary degree, in a bred horse. But horses of such a description are not common, because unfit for the turf; and nobody, as yet, has bred racers expressly for other purposes. The disadvantage of blood cattle, for the road or field, are too great delicacy, rendering them susceptible of harm, from wet and cold; tenderness of legs and feet; too great length of leg and thigh, and pliability of sinew, which gives a more extensive compass to their strokes, than is convenient to the common business of riding, or even of hunting; their stride also, natural sluggishness, and tender feet, occasion them to be unsafe goers.

Which then is the most proper species for the road? or rather (since it is agreed that blood is absolutely necessary) how much ought a hackney to have? I believe he ought either to be three parts bred, as much as to say, one got by a racer, out of a half bred mare, or *vice versa*, or one which is produced from good-shaped hackney stock on both sides, both sire and dam having some blood. I incline to the latter. In these mediums you may secure sufficient delicacy, symmetry, speed, and continuance, without any of the disadvantages attendant upon full blood.—The produce of three parts bred mares and race-horses, which might be called seven-eighths bred, if we wanted a new term, have too generally all the disadvantages of the latter, without the benefit of their peculiar qualifications.

The ancient prejudice of the superior fitness of the land of one English county above another, for the production of saddle-horses, and the supposed pre-eminence of Yorkshire, Northumberland and Durham, has been of late years fully and completely exposed. The Isle of Ely, Norfolk, and Suffolk, have for some years past, bred the best hacks, and the fastest trotters in England. It follows not however, from thence, that

equally good stock may not be bred in any of the other counties, provided they have as good stallions and mares, and pursue the business with as much industry. I was laughed at on all sides, some years ago, for referring the whole matter to custom, plenty of land, and convenience; and for asserting, that horse-breeding might be carried on elsewhere, with equal or even superior advantages to those experienced in Yorkshire.—The influence of custom over the human mind is truly wonderful, and beyond all doubt the real cause of the tardy progress of improvement.—An old farmer, was making bitter complaints of the high price of cart-horses, and the heavy tax it laid upon husbandry. I asked him why he did not breed his own horses, since they paid so well. "Aye, aye," said he "but you know this is not a breeding county." The good man rented fifteen hundred acres of land, full half of which was fit for little else but pasturing of cattle.

Even Mr. Marshall, before quoted, although he has made many very judicious observations, relative to horses, has not been, or rather was not, at the time of writing his rural economy of Yorkshire, able to steer clear of the contagious influence of established prejudice; doubtless because it related to a subject, upon which he had not bestowed a thorough examination. He observes; "In Norfolk, the breeding of saddle-horses has been repeatedly attempted without success. Yorkshire stallions have been, and still are, sent into Norfolk, in the covering season.—The foals may be handsome, but they lose their form as they grow up. On the contrary, in Yorkshire, let the foal which is dropped be ever so unpromising, it will, if any true blood circulate in its veins, acquire fashion, strength, and activity, with its growth." He seems to refer these advantages to "the influence of climature on the constitution;" and adds, that no man has yet been able to breed Arabian horses in England; English horses in France, or Germany; nor Yorkshire horses in any other district of England. Only the general principle of this reasoning appears to be just; the application is totally erroneous. There can exist no doubt of the favourable influence of genial climature, and rich pasturage. But it remains to be proved, that Yorkshire has ever excelled all other parts of England, either in those respects, or in the superior quality of their horses; the reverse, however, at this time, needs no proof. In the number of horses bred, there can be no doubt of the superiority of Yorkshire, but it appears to me, that the proportion of bad ones, has been full as large in that as in any other county. The Yorkshire bred horses have long and often been remarked, for their heavy heads, round, gummy legs, and general want of symmetry. These defects were ever visible enough, in many of the long, heavy, lumbering, half-bred stallions of that county. It is highly probable, that the ill success with which, according to Mr. Marshall's account, the early attempts of the Norfolk breeders was attended, may have been occasioned, among other disadvantages to which new undertakings are ever liable, by the very circumstance of their introducing Yorkshire stock.—Their own native stock was in all respects preferable; from which, assisted by the racing breed, they with their neighbour county Suffolk, have supplied the metropolis of late years with saddle-horses of superior form and estimation to those of Yorkshire.

The reasonings of this excellent author, owing merely to the cause already hinted, are not a whit more conclusive, on the subject of race-horses; of which more in its place.

St. Bel, also, asks very gravely for a solution of the difficulty, why Suffolk has a peculiar

breed of horses, and why they cannot be bred elsewhere? Experience teaches there is no difficulty at all in the case. Any other county having made choice of, and set off originally with that peculiar species (there lies the jet of the business, I believe) would have all along produced much such another breed, varying in a trifling degree, from local circumstances. I know of no county in England, in which I would not pledge myself to produce a race of Suffolk horses, so original in all respects, as to defy the penetration of the best jockies of that county.—But it must be effected by a more perfect method, than that which I have known practised by persons resident in some of those, which are said not to be breeding counties. They have been desirous of breeding the large black cart horses, but after repeated trials, have relinquished it, from an alleged impossibility of bringing them up to the required size; and yet their grass land has been equal, or superior in goodness, to that of the native soil of these famous cattle.—On enquiry, I always found, that they indeed sent their mare to a thorough-bred horse of the species in request, but that she herself was sure to be one of the common stock of their own county. I have known more than one person attempt to breed racers upon the same plan, and with equal success.

Major Jardine, in his entertaining and instructive letters from Barbary, Spain, &c. observes, very justly, that the world seems to be divided, for men, as well as cattle, into breeding and feeding countries; the determinations however, to either, I think usually depend upon accidental circumstances.

The natural superiority of one English county over another, as to the point in question, has always been over-rated. Some local distinctions, no doubt, must exist; for instance, the hardy mountaineers of Wales and Scotland excel in strength of constitution, ability to carry weight, and toughness of feet; but are deficient in size, figure, and speed.

I have observed, upon the little attention, merited by the colour of horses, with reference to their good or bad qualities. In some respects, it may interest nice and curious people, who are more solicitous about external appearance, than great and useful qualifications. Thus, greys and browns, spot and stain very much, with the dirt and sweat, and are made dry and clean with great difficulty; the stains remaining longer upon them, than on other colours. Light greys, nutmeg-coloured horses, and red roans, if well-bred, perhaps exhibit that symmetry to the best advantage, which is the concomitant of high-racing blood. The latter never fail to remind sportsmen of the old school, of the famous Sedbury, said to have been the justest proportioned horse ever bred in England; on this head an exception must be made, in respect to the legs and hoofs of horses, which constant experience has shewn to be best, when of a dark colour.

For their temperaments, both mental and corporeal, the strictest analogy may be found in the human species. We observe among horses, the hot, irritable, and weak; the cold, phlegmatic, slow, and durable; with all the various intermediate gradations. It can be only by way of refreshing the memory of his readers, when an author presumes to counsel them, to make choice of a medium.

Hot horses are generally speedy and safe goers, pleasant to ride, the best flying leapers, and their legs stand clean and dry, in the stable; but short and easy tasks, of all kinds, suit them best; they are unfit to carry heavy weights, and if they feed well when they play, they are sure to lose their appetite in work. It must be noted,

nevertheless, that there is a species of this genus, which may be styled, *resolute horses*; these, notwithstanding their heat and cholera, will endure to the very last, and in the hands of those who have skill and ability sufficient to manage them, will beat all other horses. Of this species, precisely, was the celebrated Eclipse.

It is only ringing the changes, to particularize the incidental qualities of the cold, phlegmatic, and dull; they are, among a variety of disorders, particularly liable to swelled legs, grease, and diseases of the eyes, besides being slow, and liable to fall. There is still a variety, partaking of the phlegm, and, in some degree, of the inconveniences of the last-mentioned, which have strong constitutions, feed well, and are fit for a long day, and constant work, whose want of speed is compensated by their powers of duration; in a word, stout horses. Of the extremes; the slow, and stout horse, is certainly of more value than the hot, uncertain and speedy one, in all situations, but upon the turf.

The tempers of horses, like those of their masters, are various, endowed with a greater or less proportion of intelligence, sagacity, and feeling; and it is but too often, the beast evinces the greater degree of rationality.— Their dispositions admit, conveniently enough, of the following classification; the docile and generous, the stupid and unnoticing, and the perverse and rebellious. In all these, the more they are treated with reason, temper, and compassion, the more they conduce to the ease, the profit, and contentment of man; and this, I am convinced by experience, will be acknowledged by none more readily than by those, who, having been accustomed to the contrary, will vouchsafe to make fair trial of such methods. As to the first, or the docile and generous, it is inconceivable to those who have not made the pleasing essay, to what a degree of perfection their faculties may be brought, by rational and conciliating usage. In a very short time, correction becomes perfectly useless, and the whip and spur, the mere harmless instruments of your direction.— The sound of his master's voice is at once loved, feared, and obeyed, by a generous, and well-managed horse. Instead of a reluctant and treacherous slave, you have obtained an humble, and faithful friend, a willing sharer in your toils, and in your pleasures; even an agreeable companion, who, although he cannot converse, understands you well; who takes every hint, every indication, from your hand or voice, in an instant; and plainly shews a pride and pleasure in obedience, whether it be to constrain himself for your ease, or to lay out the whole of his powers, even unto death, for your service. While such advantages are practicable, through the easy and pleasing means of humanity, who would take the pains to be a tyrant?

It is well known that some horses, although rather ill-natured to their own species, for which it is difficult to assign a reason, are exceedingly attached to the human, and will play with their keepers, with as much apparent delight, as spaniels; but horse-play is proverbially dangerous, and I have thence witnessed several fatal accidents.

The second class, or the stupid and unnoticing, it is obvious, can never be mended by harsh and cruel usage. It can only serve to increase the natural torpor of their disposition, and render their bodies insensible and callous; in fact, to lessen their use, and increase their owner's trouble. A post-boy would say to me, "Ah, master, your fine reasons would never bring my horses through their stage." These practical sayes are, however, not always right. It seems to me, at least plausible, that if they did not deaden their

horses feelings, by a premature, and too free use of the whip and spur, they would save their arms and legs much labour, and their masters a great deal of horse-flesh.

The perverse and rebellious, or vicious horses, are of two kinds, those which are so from natural predisposition, and such as are rendered restiff, or vicious, from insufficient breaking, or acquired habits. The first is ever a lost case, whatever the most skilful *domitor equorum* may pretend to the contrary; and in the second, the cure is but uncertain at best, which will be allowed by all those who have considered the mighty power of habit, even among us two-legged animals, who vaunt so highly of the strength of our reasoning faculties. The disciples of Locke will deny the existence of innate qualities, such as I have supposed. They should, I think, furnish some new hypothesis, on which to account for the following facts, the truth of which will be allowed by all who have had much experience in horses. Two colts, of like age, shall be broke at the same time, by persons of equal skill, or by the same person. They shall be treated precisely in the same manner, in all respects; and yet the one shall be tamed to obedience, with only the common difficulties, and remain perfectly quiet; whilst the other, even if rendered somewhat tame at first, shall always obey with reluctance, and continue self-willed and restiff all his life. Restiveness, and various other qualities, bad or good, are also known to be sometimes hereditary, and to run through many generations. Do not these natural tendencies, (granting their existence) either in man, or beast, arise from the accidental variation of specific quantity in the elements which compose the animal mass, or compound; from its peculiar structure, and organization?

It is impossible, by any mode of calculation, which includes the probable risks, to attach the value of a single penny to the living carcass of a determined restiff, or vicious horse; and it is the interest of every unfortunate proprietor of such an one, to knock him on the head, in preference to being obliged to keep and use him.— The conquest gained over his will, is always temporary and uncertain; in a single moment, more than the worth of his whole life of service is kicked down, and perhaps some melancholy accident induced. Many dashing young blades, I know, are fond of exhibiting their prowess, and their skill, upon these intractable animals; but I really think it a pity, that such as have any brains to lose, should risk a fracture, in so uninteresting and contemptible a business. In these cases, chance often throws them into situations, in which neither their strength, nor courage, can be of much use to them. The last accident of this sort, I particularly noticed, happened to a man, who had both his thighs broken, by his horse taking it into his head, to go down with him into the area of a house, near Leicester Fields.

(To be continued.)

NATURAL HISTORY. No. 4.

[Continued from page 262.]

An interesting inquiry yet remains to be made regarding the manner in which this change in the color of the dress is effected. The attention of naturalists has, of late years, been directed to this subject, and several important observations have been made, equally interesting to the physiological and systematical zoologist.

From the belief which is generally entertained, that in hair and feathers there is no circulation, neither secretion nor absorption, a conviction

arose in the minds of many naturalists, that the change of colour which takes place in the dress of some animals according to the season, was not the effect of any organical change in the hair or feathers, but accompanied a renewal of the whole. The late GEORGE MONTAGU, Esquire, who had long attended to the characters and habits of the feathered tribes, delivers his opinion on this subject in the following terms: "Some species of birds seem to change their winter and summer feathers, or at least in part; in some, this is performed by moulting twice a year, as in the ptarmigan, in others, only additional feathers are thrown out. But we have no conception of the feathers changing colour, although we have been informed of such happening in the course of one night." Staggered with the statements of such a frequent renewal of the dress of animals, accompanied by such a wasteful expenditure of vital energy, and guided by multiplied observations, we ventured to offer the following remarks on the subject in the Edinburgh Encyclopædia, under the article "Hybernation," vol. xi. p. 387, published in 1817.

"It has been supposed by some, that those quadrupeds which, like the alpine hare and ermine, become white in winter, cast their hair twice in the course of the year; at harvest when they part with their summer dress, and in spring when they throw off their winter fur. This opinion does not appear to be supported by any direct observations, nor is countenanced by any analogical reasonings. If we attend to the mode in which the hair on the human head becomes grey as we advance in years, it will not be difficult to perceive that the change is not produced by the growth of new hair of a white colour, but by a change in the colour of the old hair. Hence there will be found some hairs pale towards the middle, and white towards the extremity, while the base is of a dark colour. Now, in ordinary cases, the hair of the human head, unlike that of several of the inferior animals, is always dark at the base, and still continues so during the change to grey; hence we are disposed to conclude from analogy, that the change of colour, in those animals which become white in winter, is effected, not by a renewal of the hair, but by a change in the colour of the secretions of the rete mucosum, by which the hair is nourished, or perhaps by that secretion of the colouring matter being diminished, or totally suspended.

"But as analogy is a dangerous instrument of investigation in those departments of knowledge which ultimately rest on experiment or observation, so we are not disposed to lay much stress on the preceding argument which it has furnished. The appearances exhibited by a specimen of the ermine now before us are more satisfactory and convincing. It was shot on the 9th May, (1814,) in a garb intermediate between its winter and summer dress. In the belly, and all the under parts, the white colour had nearly disappeared, in exchange for the primrose-yellow, the ordinary tinge of these parts in summer.— The upper parts had not fully acquired their ordinary summer colour, which is a deep yellowish brown. There were still several white spots, and not a few with a tinge of yellow. Upon examining those white and yellow spots, not a trace of interspersed new short brown hair could be discerned. This would certainly not have been the case if the change of colour is effected by a change of fur. Besides, while some parts of the fur on the back had acquired their proper colour, even in those parts numerous hairs could be observed of a wax-yellow, and in all the intermediate stages from yellowish-brown, through yellow, to white.

"These observations leave little room to

doubt, that the change of colour takes place in the old hair, and that the change from white to brown passes through yellow. If this conclusion is not admitted, then we must suppose that this animal casts its hair at least seven times in the year. In spring, it must produce primrose-yellow hair; then hair of a wax-yellow; and, lastly, of a yellowish brown. The same process must be gone through in autumn, only reversed, and with the addition of a suit of white. The absurdity of this supposition is too apparent to be farther exposed.

"With respect to the opinion which we have advanced, it seems to be attended with few difficulties. We urge not in support of it, the accounts which have been published of the human hair changing its colour during the course of a single night; but we think the particular observations on the ermine warrant us in believing, that the change of colour in the alpine hair is effected by a similar process. But how is the change accomplished in birds?"

"The young ptarmigans are mottled in their first plumage similar to their parents. They become white in winter, and again mottled in spring. These young birds, provided the change of color is effected by moulting, must produce three different coverings of feathers in the course of ten months. This is a waste of vital energy, which we do not suppose any bird in its wild state capable of sustaining; as moulting is the most debilitating process which they undergo.—In other birds of full age, two moultings must be necessary. In these changes, the range of color is from blackish grey through grey to white, an arrangement so nearly resembling that which prevails in the ermine, that we are disposed to consider the change of colour to take place in the old feathers, and not by the growth of new plumage; this change of colour being independent of the ordinary annual moultings of the birds.

"Independent of the support from analogy which the ermine furnishes, we may observe, that the colours of other parts of a bird vary according to the season. This is frequently observable in the feet, legs, and bill. Now, since a change takes place in the colouring secretions of these organs, what prevents us from supposing that similar changes take place in the feathers? But even in the case of birds, we have before us an example as convincing as the ermine already mentioned. It is a specimen of the little auk (*Alca alle*), which was shot in Zetland in the end of February 1810. The chin is still in its winter dress of white, but the feathers on the lower part of the throat have assumed a dusky hue. Both the shafts and webs have become of a blackish grey colour at the base and in the centre, while the extremities of both still continue white. The change from black to white is here effected by passing through grey. If we suppose that in this bird the changes of the color of the plumage are accomplished by moulting, or a change of feathers, we must admit the existence of three such moultings in the course of the year—one by which the white winter dress is produced, another for the dusty spring dress, and a third for the black garb of summer. It is surely unnecessary to point out any other examples in support of our opinion on this subject. We have followed nature, and our conclusions appear to be justified by the appearances which we have described."

Since the preceding observations were communicated to the public, Professor JAMESON has obligingly pointed out to me the following passage in CARTWRIGHT'S Journal of Transactions on the Coast of Labrador (3 vols. 4to. Newark 1792.) vol. i. p. 278, as containing an expression of the same opinion which I had formed upon

the subject "28th September 1773.—This morning I took a walk upon the hills to the westward, and killed seven brace of grouse.—These birds are exactly the same with those of the same name in Europe, save only in the color of their feathers, which are speckled with white in summer, and perfectly white in winter, fourteen black ones in the tail excepted, which always remain the same. When I was in England, Mr. BANKS (now Sir JOSEPH BANKS,) Doctor SOLANDEK, and several other naturalists, having inquired of me respecting the manner of these birds changing colour, I took particular notice of those I killed, and can aver for a fact, that they get at this time of the year a very large addition of feathers, all of which are white; and that the coloured feathers at the same time change to white. In spring, most of the white feathers drop off, and are succeeded by coloured ones; or, I rather believe, all the white ones drop off, and that they get an entire new set. At the two seasons they change very differently; in the spring, beginning at the neck, and spreading from thence; now, they begin on the belly, and end at the neck. There are also ptarmigans in this country, which are in all respects the same as those I have killed on some high mountains in Scotland."

The total absence of every thing like demonstration of the truth of the assertion regarding the autumnal change of the colour of the plumage of the grouse, and the language of hesitation which he employed when speaking of the changes observed to take place in spring, probably induced those naturalists who had perused CARTWRIGHT'S work, to reject statements so opposite to the opinions generally entertained on the subject. The conjecture that all the white feathers drop off in spring, even those which were produced in the previous autumn, to be succeeded by coloured ones, has not been verified by any observations which we have been able to make on the subject.

The moulting of birds takes place in all cases gradually, and in those species whose plumage changes colour with the season, the different moultings take place at corresponding periods. In the autumn, we find that the black feathers on the head of the *Larus ridibundus* change to a white colour. But besides the altered feathers, others spring up, of a white colour, to increase the quantity of clothing. This gull has, therefore, during the winter, some of the feathers of the head old, and others young. Again, in spring the white feathers of the winter become black, and a few new feathers make their appearance, likewise of a black colour, to supply the place of the older ones which drop off in succession. Some of the feathers on the head of this gull are half a year older than others; and consequently, we may infer, will fall off sooner than those of more recent growth. From these, and similar facts, furnished by several species of British birds, we are disposed to conclude, that the feathers which are produced in autumn and the beginning of winter, and which correspond with the conditions of the season, change their colour in spring, and continue in this state until they are shed in autumn. The feathers which are produced in spring, continue of the same hue during the summer, change their colour in winter, and fall off again upon the approach of spring. In this manner, the quantity of the plumage fit for the different seasons of the year is easily regulated, and it is only necessary that the change of colour in each feather should take place but once in the course of its connexion with the bird. By these arrangements, the welfare of the individual is promoted by the simplest means.

Many animals, which are unable to provide against the vicissitudes of the seasons, by varying the quantity and the colour of their dress, are, nevertheless, protected by being able to shift their quarters, so as to live throughout the whole year in a temperature congenial to their constitution.

(To be continued.)

EXTRACTS

FROM MORE MODERN WRITERS ON THE USE OF SALT IN AGRICULTURE.—No. III.

From a Pamphlet entitled "*Hints to Country Gentlemen and Farmers, on the importance of using Salt as a general Manure.*" By the late J. Hollinshead, Esq. of Chorley. Third edition, 1802.

[Continued from page 261.]

"The only manure that can be procured in all places is dung (lime and marl being entirely local, and confined to certain districts,) and how insufficient it is to answer all the purposes of husbandry, need not here be insisted upon, since it must be plain to the most superficial observer. Let us turn our eyes for a moment to the generality of breeding and grazing farms, and see in what state they are. The dung that can be raised from the produce of the farm is all expended upon a few acres of meadow-land, whilst the pasture-grounds are destitute of every kind of improvement. This is no idle speculation; for which way soever we turn our observation, we shall find abundant proofs of the truth of the assertion—thousands and ten thousands of acres lying in the same state, with regard to any actual improvement that has been made in them in which they came out of the Creator's hands, and must inevitably remain so, unless some other manures are introduced into practice, besides those which are now in use."

"What a misfortune to the dairy must this neglect of the pasture grounds be! and this too is the ground upon which the occupier must principally rely; for it is well known, that during the summer months, whilst his cows are at grass, is the time in which he chiefly produces his butter and cheese; and yet this ground is entirely neglected. Whilst the demand for those articles is daily increasing, we are indifferent whether their productiveness be proportioned to that demand; by which inattention the price of those commodities has, in a few years, been doubled. And what shall bring them to their former price? *Manure these pastures with salt.* By this means we shall increase their produce two-fold, and consequently decrease the price of those necessaries of life nearly in an equal proportion. This would be an unspeakable advantage and comfort to the labouring poor, at the same time that it was enriching both the farmer and land-owner.

"I know some will say that there are many soils which cannot be improved. I deny the assertion. Let but the farmer be properly encouraged to make the trial, and I am convinced he will not find his labour lost. If our ancestors had always been indifferent to agricultural improvements, what must have been our situation at the present day? We might have lived upon the haws and berries of the field; for nature has not been so lavish in her gifts to this country as to some others: few of the necessaries of life will thrive and flourish without the most unremitting industry. *By nature our apples are crabs, and our plums sloes!* but art and nature have changed the scene; and health-giving exercise, properly directed, and duly encouraged, would bring the kingdom to an unexampled pitch of plenty and splendour.

"The proper cultivation of the soil is an object so peculiarly interesting to the community at large, that those who industriously attend to it are perhaps to be esteemed the most meritorious citizens of their country.

"Of such importance are the study and practice of agriculture in Scotland, that they have instituted a professorship in one of their universities; and it is much to be lamented, that a similar institution is not introduced into our universities, as it would essentially tend to the promotion of this most important department of knowledge, so highly beneficial to mankind."

"It is proved by the general returns of the number of inhabitants in *England and Wales*, that there has been an increase of two millions (or nearly one-fourth of the whole) during the last century. Then, as population and manufactures are rapidly increasing, is it not of the utmost consequence that we should have a proportionate increase in the productions of the earth?"

"With proper encouragement and management in agriculture, I have no hesitation in affirming that the generality of land, in most parts of England, might be made to produce double crops in a very little time; and with the addition of salt as a manure, instead of importing corn from abroad, to the great disadvantage of the nation, we might make our own produce, not only sufficient for home consumption, but also to supply the wants of our neighbours. I need not insist on the advantage to be derived from such an improvement, not only to the farmers, but to the public at large, for it is well known to every commercial man, of what importance it is that our merchants should always have it in their power to undersell their rivals in foreign markets: this, however, it will be impossible for them to do, even if there be no advance in the price of the raw material, unless by bringing down the price of provisions we proportionably keep down the price of labour. And no other mode can be adopted so likely to accomplish this most desirable end as the general use of salt for manure.

"We shall just mention one thing more in support of what has been advanced respecting the benefits of salt for manure, which falls within every farmer's notice, but which, probably, has not struck him in that light in which we are about to represent it. Cattle kept in a straw-yard, without any thing but straw for their sustenance, yield a poor light manure, little superior to natural soil; whilst cows or oxen feeding on good hay, assisted by corn, oil-cakes, or other invigorating food, produce manure of the best kind; thus the stronger the manures are impregnated with salts, of more value they are."

"We have at least seven millions of acres of uncultivated land in this kingdom. What a loss to the community must this be! Here is ground sufficient, if properly cultivated, to furnish all the inhabitants of the country with bread, lying entirely waste, whilst they are paying a double price for the necessaries of life! Let us not neglect the advantages which providence has so kindly put in our power: the means of relief are within our reach, if we are not wanting to ourselves. If half the money that was necessarily and humanely spent during the late scarcity, in bounties on the importation of grain, had been laid out in inclosing waste lands, and giving premiums to farmers, I am convinced that in any future unfavourable season we should not be obliged to rely upon a scanty and precarious supply of grain from other countries, but on our own granaries at home, which have been well stored in a time of plenty by the wholesome produce of our native soil.

"What a pleasing prospect would it be to every Briton to see even the barren hills throughout the united kingdom converted into rich pastures, and the low lands made capable of producing the most abundant and luxuriant crops of grain, or artificial grass!"

"If we turn our eyes to the empire of *China*, we shall there see the beneficial effects of a due attention to agriculture. The population, upon an average throughout that vast empire, amounts to the surprising number of three hundred inhabitants, to every square mile; that is, nearly three times the population of this country; and yet these people are maintained in plenty, without any assistance from other nations. How this is accomplished, Sir GEORGE STAUNTON, in his elegant and authentic account of Lord MACARTNEY'S embassy to *China*, informs us. 'The whole surface of the empire,' says he, 'is with trifling exceptions dedicated to the production of food for man alone. Few parks and pleasure-grounds are seen except those belonging to the Emperor. Little land is taken up with roads, the chief communication being by water. There are no commons or lands suffered to lie waste through neglect, or the caprice or for the sport of great proprietors. No arable land lies fallow. And whatever defects there are in the soil, it is supplied by mixture with other earths, by manure, by watering, and by careful and useful industry of every kind.' Let us copy after so useful an example.

"The present high price of salt, encumbered as it is with heavy duties, is such as to prevent all attempts of the farmer to ascertain its real utility by experiments. In order to do away this inconvenience, we sincerely hope the legislature will take this matter into its further consideration, and repeal the duty upon salt, as the only thing that can effectually promote the proper improvement of the country.

"The Salt Rock in Cheshire lies about thirty-six yards below the surface, in thickness from ten to forty yards; it extends twelve miles in length, and several miles in breadth; and throughout the whole district springs arise, which are made into salt. This rock, together with those which are in Worcestershire, &c. are sufficient to supply the whole kingdom forever, without any fear of their being exhausted; and if properly applied, are a treasure far greater than the gold mines of Mexico and Peru."

"The following account we had from Mr. Thomas Sutton, of Middlewich, in Cheshire. 'About twelve years since I dug up,' says he, 'a quantity of earth out of a field where a new building was going to be erected, in which there was some appearance of salt-springs, the water from which had oozed up through the soil, and left an incrustation composed of the particles of salt upon the surface of the ground. This soil, together with the salt contained in it, I mixed with horse-dung; after it had lain some time in the heap, I spread it upon a piece of meadow-ground, which has been mown ever since, without any other manure having been laid upon it; and the other part of the meadow has been manured in the usual way every second year, and yet is now in no better condition than that which was covered with the salt and dung twelve years ago.'

"A farmer at Glasson, near Lancaster, has for some time been in the habit of carting salt-water to put upon his dung whilst in the heap in the yard, before it was taken to be spread upon the ground, which he has found by experience very much enriches the dung, and makes it better manure. A great advantage might also be derived to the farmer from spreading sea-sand under and amongst the dung, whilst

it is in collecting, during the winter, and also in the cow-house, stable, and yard, not only on account of the particles of the salt contained in it, but likewise by its retaining and absorbing the urine of the cattle, which is itself a very excellent manure."

"A farmer in the county of Sussex, some years ago, had a field, one part of which was very wet and rushy, and the grass produced upon it was of so sour and unpleasant a kind, that the cattle would not graze upon it: he tried several methods to improve it, but to little purpose; at last, having heard of the benefits of salt as a manure, he determined to try that; for which purpose he procured a quantity of Rock salt, which in a random way, without any regard to the precise quantity, he threw upon this rushy ground, fencing it off from the other part of the field; the first effect of which was a total disappearance of every kind of vegetation. In a short time after, however, it produced the largest quantity of mushrooms ever seen upon an equal space of ground in that country. These in the spring following were succeeded by a most plentiful and luxuriant crop of grass, far exceeding the other part of the field in the richness of its verdure and the quickness of its growth: the cattle were remarkable fond of it; and though the salt was laid on it upwards of twenty years ago, this part is still far superior to the rest of the field." *Appendix to Mr. Hollinshead's pamphlet,—page 33—35.*

Mr. Wedge, in his agricultural survey of the county of Chester, says, "foul salt is a most excellent manure, either for pasture lands or fallows: and it is much to be regretted that so large a quantity as seven or eight hundred tons should annually, in Cheshire, alone, be lost to the community. The heavy duty laid upon refuse or dirtied salt prevents its use for manure.

"A difference of opinion," continues he, "having been entertained as to the utility of salt as a manure, we insert the following experiment which we have been favoured with by a gentleman of Norwich: In a meadow, where the after-grass being of a coarse, rank nature, which the cattle refused to eat, salt was laid upon a part of the meadow, and the cattle have ever since preferred the grass growing on that ground to every other part of the field, and eaten up every blade. He also states that the good effects of salt are particularly seen by mixing it even with the coarsest manure, and then laying it upon the land."

The late Thomas Butterworth Bayley, Esq. who was a Fellow of the Royal Society, and honorary member of the honorable Board of Agriculture in London, in his "Thoughts on Manures," after enumerating nineteen different substances which improve land, adds, "there is another source of improvement lost to the country, but not through the fault of the farmers, viz. refuse Rock-salt, and refuse liquor from the salt-works. I trust the very impolitic restriction which forbids the use of this valuable manure, and causes its total loss, will soon be removed by the exertions of this society, and those of the honorable Board of Agriculture." *From an address read to the Members of the Agricultural Society of Manchester, October 22, 1795.*

"Salt is the mother of all manures, as every kind of manure is higher or lower in value according to the salt it produces; and every kind of manure is portioned out to the land according to the quantity of salt or nitre it is thought to have in it. Formerly, salt was thought to be an impoverisher of land, but experience has taught us wisdom; it is now found to be otherwise, provided it is duly proportioned to the state the

land is in, and mixed to mollify it as follows: take ten bushels of salt, and six bushels of dry ashes, and mix all together; then spread them on the land, and harrow them in with the seed: this is a sufficient dressing for an English acre, as it is better to repeat the dressing than to lay too much on at once. By being thus mixed, one particle incorporates and mollifies the other. Salt itself is rather too severe and harsh in its nature, and if laid too thick on, might prove of bad consequence; but if conveyed into the earth by a soapy, smooth method, will prove the real enricher the earth wants to send forth vegetation; this dressing will last for three crops. Sea-weed, shells, fish, sea-water, sea-sand, have in them a proportion of salts or nitre, and, therefore, must be esteemed a manure."—From C. Varley, Esq. communicated to the *Chester Chronicle* by the Rev. B. Dacre of Moseley, near Manchester.

(To be continued.)

ANSWERS TO INQUIRIES UPON
MILLET, FARM BUILDINGS, AND THE
VALUE OF ORCHARD GRASS.

TO THE EDITOR OF THE AMERICAN FARMER.

DEAR SIR,

I am glad to answer your inquiries, on any matter, connected with the objects, you have, so zealously, brought into the view of the farmers in your county—and although I am not conscious that I merit the compliment you give to my judgment, I cannot resist the desire to embark with you, in the course which you have successfully pursued. To your inquiry—I answer, millet has not "the effect of binding the ground," nor is it an exhausting, crop when cut, in a green state. I do not cultivate it for its farinaceous product. I value it as fodder, more than any thing, I have seen. It requires a good soil, very fine tilth, very light harrowing, and rolling, at the time of sowing. I have no doubt, that "sheep would like it," if cut at an early stage, and from land, upon which the seeds had been sown thickly. If they be not thickly sown, the stalks become too large, and hard, for sheep—I should not recommend it for their use, unless it be cut at the time, when the heads have been just formed. I shall this year sow nearly thirty acres for hay. I shall cradle it when the seeds are half ripe, in order, that they may be thrashed, crushed in a mill, and after mixed with the fodder, when cut.

Millet is not "infallible," and although, I have been successful in its cultivation, some farmers have failed; oftener, from the fault of the seeds, the want of soaking, and care in harrowing, than any other cause. In recommending the cultivation of any new crop, some caution should be observed, until it be ascertained, what crops, it is fitted to follow. For if it should happen, that the experiment, be made upon a soil, which had been exhausted, by any crop, or system of crops, requiring the same particles, of matter for their nourishment, failure must ensue. Thus, the incaution of the Dilletanti, who in their zeal recommend for all situations, that which has succeeded but in a corner of a garden, or perhaps in their own heads alone, causes disgust, among practical men, for most that is new. I have tried orchard grass for ten years—it produces more pasturage, than any artificial grass, I have seen in America. There is some difficulty in "laying it down," at least two bushels per acre, should be sown, together with the usual quantities of clover seeds, in the latter part of September; it should be lightly harrowed and rolled. It ought not to be depastured the first year, as

animals pull it out by the roots in large quantities during the early stages, of its growth.

There is no "substitute for Indian corn." The best auxiliaries are millet, and mangel wurtzel. The beets, when assisted by small quantities of corn meal, have a surprising effect, in certain stages of the fattening process. They have really, I think, a large portion of the excellence, which we should derive from our richest meadows if they could be placed in their most luxuriant state, in the small compass of a bullock's manger from January to May. Millet in its farinaceous state, is certainly very nutritious—but I consider it and all other crops, which ripen with great rapidity, and of which the leaves are small, great exhausters; as they cannot derive much of their nourishment, from the atmosphere, they must take the more from the soil.

We have all made, in this state, a great mistake, in cultivating a species of Indian corn, which grows high, with large stalks, requiring wide intervals for cultivation.

In New England a smaller sort is grown, which produces much more in grain, and infinitely less of stalks—as it admits of being placed in rows not so far apart, the soil, is less exhausted by the exhalations of the sun in the early part of the season, and is not so much impoverished, as it bears less weight in stems and tops.

"The management of cattle" should depend upon the purposes, for which they are destined. If I intended, my son, or my calf to be a great heavy unwieldy tender animal, bloated with fat, I would cover his back with great care, and stuff him with the most nutritious aliment; but if I meant him, to encounter difficulty, to have vigor of constitution, and symmetry in shape, I would expose him after a certain age, to constant exercise, to every vicissitude of heat, and cold; guarding always, as much as possible, against his remaining in a state of rest, when wet. If any quadruped, be taken from a hot climate, to a colder one, nature, very soon supplies a thicker covering of hair; and it will be thus found, that all the brute creation, if gradually exposed to cold, whilst they are protected from currents, and dampness of air, have more thrift than if they be confined, in a close atmosphere, of higher temperature. The secretions of milk, are certainly, much diminished by cold; those of fat, I am satisfied, are in no wise lessened, by any degree of temperature, which is not very severe. Ample supplies of clean straw, and friction, without, tend almost as much, to the thrift of neat cattle, as the increase of food, beyond a certain point, can affect their "proof" within.

I am, dear sir,

Your's, &c.

CURWEN.

Philadelphia County.

Powelton, Philad. County, July 1, 1823.

DEAR SIR,

Your profitable management, much more, than the high state of cultivation, in which the officers of the society found your farm, leads me to desire, not merely a statement of the system, you pursue, in the preparation of your soil—the arrangement of your fields—the rotation of your crops—but the mode of securing your fodder—feeding your cattle—and the application of their manure. I was struck, by the appearance of your stock, and gratified, at finding, that our opinions, and practice perfectly coincide, in the preparation of hay, and distribution of it in hay houses, instead of huge mows.

I have thought, the parade of Pennsylvania barns, about as profitable as the decoration of our fine blue waggons, or the musical bells attached to our teams. The ingenious mode adopted to deprive our grasses, of their most valuable, and nutritious parts, is so absurd, that it long since would have been abandoned, I should hope, had not our prejudices in favour of old usages, which generally keep practical farmers right, in this instance put us all wrong.

In good weather, most crops of grasses, can be secured without being shaken from the swarth. My uniform practice for many years has been to allow my grass to remain nearly two days, untouched, to gather it by an horse rake, cock it in the hot part of the day, salt it, and place it in an hay house, which admits a free circulation of air. My clover like yours, retains much of the color of its blossoms, and leaves. The advantage of pitching hay, from the carriage into "a bank barn," does not counterbalance, the expense of labour in preparing, the loss of nutrition in drying, and the great danger of fire from heating, as well as from the escape of moisture, which so often in this climate, attracts lightning, to the utter destruction of the building, and all the hopes of the farm.

The convenience of feeding, has also been brought to aid the arguments, in favour of a great Pennsylvania barn. We owe much of our success, to the industry, care, and skill, of our excellent German population, but I think, it may be questioned, whether the expense they incur, in the arrangement of their farm buildings, is not very often mischievous, not merely useless, in making tender their cattle, and diseasing them by bad hay. It is scarcely possible in this state, where the changes of climate, are sudden and severe, to guard farm stock, from suffering when they are made warm throughout the night, and necessarily, left exposed to the pelting of storms, during part of the day. I am convinced, that milch cows, and very young calves, require protection from cold—all other cattle, if guarded from wet, and currents of wind, feed with more appetite, digest with more ease, work with more vigour, and encounter accidental exposure, with less danger of harm, than if they be confined within thick stone walls, inhaling an impure atmosphere, from which by the instinct of nature, if not thwarted by the ill judged contrivance of man, they would fly.

I would suggest, that the position for the farm yard be selected as usual at the foot of a small hill, of which the southern side, should be cut in such manner, as to admit the erection of a barn sufficiently large for all its usual purposes, except that of holding hay, and feeding cattle. Roofs pitching to the South, and sufficiently capacious to protect all the hay, straw, fodder, and stock of the farm should be extended at both gable ends. For the support of the fodder lofts, and roofs, pillars of brick, or stone, should be erected at proper intervals; for the security of the bank, and the road at its edge—a wall somewhat higher, than it, should be built—a space of two feet, should be left, between the northern side of the loft and the wall. Racks should be placed perpendicularly, with their outer edges, exactly corresponding, and parallel with the wall, and side of the loft. Thus a space, of two feet would remain between them and the wall, to be filled with hay. A long shutter, sufficiently wide, may be secured by hinges, attached to posts, on the outer side of the wall—in order that when the rack shall have been filled, by pitching from above, it may be closed, at a proper angle to exclude rain or cold air.

stalls for cattle, pens for sheep, and calves, should be at fit distances placed beneath the hay—pailings, and gates, might secure them on the southern, or outer side. The hay being exposed on two of its sides, would require infinitely less drying, than if pressed closely, in a great mass, within the thick walls of a barn. It is scarcely to be believed, by those, who have not seen the experiment, how little drying, grass requires, when it is to be salted, and thrown lightly, into an open hay house. By beginning at one end of a long loft, and discharging the loads, so as to not more than half fill it, until the hay be extended to the other, by the time, that the end at which the farmer began, shall be quite filled, his hay, in despite of the state, in which it had been hauled, will be sufficiently dry.

The advantages, I propose, are the saving of labour in making the hay, of money, in building the barn, of nutrition in not exhausting the grass by unnecessary exposure, to the rays of the sun; and to practical farmers, what to them, is of consequence, a return to their pockets, in profit, on cattle, which after being fed from January to July upon hay, and grass alone, may be exposed on Philadelphia shambles with credit to the feeder, as yours have been shown.

I am your's, &c.

JOHN HARE POWEL,
Corresponding Sec'y, Penn.,
Agricultural Society.

WINE—VARIOUS KINDS AND THEIR USES.

Le Vin est l'un des produits de la nature les plus difficiles à juger et à bien choisir: et les plus habiles gourmets sont souvent mis en défaut.—*Manuel du Sommelier*, Paris, 1817, p. 1.

WINE, especially Port, is generally twice spoiled—before it is considered fit to be drank!!! The wine-maker spoils it first, by overloading with brandy to make it keep.—

The wine drinker keeps it till time has not only dissipated the superabundant spirit,—but even until the acetous fermentation begins to be evident,—this, it is the taste now to call "flavour,"—and wine is not liked, till it has lost so much of its exhilarating power, that you may drink half a pint of it before receiving that degree of excitement,—which the wine-drinker requires to make him happy. We mean a legal pint containing 16 ounces.

The measure of a BOTTE OF WINE ought to be as definitive, as that of a POT OF PORTER:—is it not astonishing that the Legislature have not ordered a standard and stamped quart, for the wine-merchant—as they have a pot for the publican?

This would be equally as desirable to the respectable wine-merchant,—as to the public.

It would protect the former against the injurious competition of those who at present, by vending wine in bottles of inferior dimension, impose on the unwary purchaser under pretence of selling at a lower than the market price.

The purchaser of a dozen bottles of wine expects to receive three gallons of wine.

Proportions of the wine gallon, according to the last London Pharmacopœa:

Ozims.	Pints.	Floid Ounces	Drachms.	Minims or Drops.
1	8	128	1024	61,440

There are 32 ounces in a legal wine quart. Multiply by 12 quarts in three gallons.

384 ounces in ditto.

Measure the number of ounces your bottle holds—divide 384 by it, and the quotient will give you the number of such bottles required to contain three gallons of wine.

Some bottles do not contain more than 26 ounces.

26) 384 (14 bottles, 1 pint, and a quarter.	
26	
—	
124	
—	
104	
—	
20	OR,
Multiply	26, i. e. the number of ounces
By	12 your bottles will contain.
	—
	312 the number of ounces
	contained in your dozen
	bottles, which
Ought to hold	384 the number of ounces in
Subtract	312 three gallons.
	—
	72 (2 quarts and half a pint
Divide by the } number of oz. }	64 short of measure.
in a quart }	—
	8 ounces.

So, instead of THREE GALLONS—you have only two gallons; one quart, and a pint and a half. The quantity a bottle will contain, may easily be accurately ascertained, by LYNES'S graduated glass measure, which holds half a pint, and is divided into ounces, &c.—it is a convenient vessel to mix GROG in.

A PIPE OF PORT contains, on the average, 138 gallons, of which three must be allowed for lees, &c.—This is enough for waste, if the wine has been properly fined, and steadily bottled.

A BUTT OF SHERRY contains . . . 130 gallons.
MADEIRA, 110 ditto.

Hogsheads of CLARET, 55 ditto.
It is convenient for small families to have part of their wine in pint bottles.

That wine is much best when quite fresh opened, is a fact it is needless to observe,—half a pint of wine (i. e. 8 ounces, i. e. 4 ordinary wine-glasses) is as much as most people (who have not spoiled their stomachs by intemperance) require.

The rage for superannuated wine,—is one of the most ridiculous vulgar errors of modern epicurism,—“the bee's wing,” “thick crust* on the bottle,” “loss of strength &c.” which wine-fanciers consider the beauty of their tawny favourite, “fine old port,”—are forbidding manifestation of decomposition, and the departure of some of the best qualities of the wine.

The age† of maturity for exportation from Oporto, is said to be the second year after the vintage, (probably sometimes not quite so long.)

* A thick crust is not always the consequence of the wine having been very long time in the bottle—but is rather a sign that it was too little time in the cask, or has been kept in a very cold cellar.

† “Had the man that first filled the Heidelberg Tun been placed as sentinel to see that no other wine was put into it, I believe that he would have found it much better at 25 or 30 years old, than at 100 or 150, had he lived so long—retained his senses, and been permitted now and then to taste it—a privilege with which the natives are seldom indulged.

“To give a great price for wine, and keep it till it begins to ferish, is a great pity.” I cannot believe that very aged wine, when bordering on acid, is wholesome, though some wine-drinkers seem to prefer it in that state. “Respecting Port wine, there is a great fuss made

Our wine-merchants keep it in wood from two to six years longer, according to its original strength, &c.—surely this must be long enough to do all that can be done by keeping it—what crude wine it must be to require even this time to ameliorate it—the necessity for which, must arise either from some error in the original manufacture,—or a false taste, which does not relish it, till time has changed its original characteristics.

Ordinary Port is a very uncleaned, fretful wine, and experienced judges have assured us, that the best Port is rather impoverished, than improved by being kept in bottle longer than two* years, supposing it to have been previously from two to four years in the cask in this country,—observing, that all that the outrageous advocates for “vin fassé”—really know about it, is, that SHERRY is yellow,—and PORT is black,—and that if they drink enough of either of them,—it will make them drunk.

WHITE WINES, especially Sherry and Madeira, being more perfectly fermented, and thoroughly fined before they are bottled—if kept in a cellar of uniform temperature, are not so rapidly deteriorated by age.

The temperature of a good cellar is nearly the same throughout the year. Double doors help to preserve this. It must be dry, and be kept clean as possible.

The art of preserving wines, is to keep them from fretting, which is done by keeping them in the same degree of heat, and careful corking.† “If persons wish to preserve the fine flavour of their wines, they ought on no account to permit any bacon, cheese, onions, potatoes, or cider, in their wine-cellar. Or, if there be any disagreeable stench in the cellar, the wine will indubitably imbibe it; consequently, instead of being fragrant and charming to the nose and palate, it will be extremely disagreeable.”—CARNELL on wine making, 8vo. 1814, p. 124. See also *Manuel du Sommelier*, par A. Jullien, Paris, 1817.

That MADEIRA (if properly matured before) improves in quality by being carried to the East Indies and back, by which voyage it loses from 8 to 10 gallons,—or to the West, by which about 5 are wasted,‡—however these round

by some men about its age and the crust on the bottle, as if the age and crust on the bottle constituted the quality of the wine.” Such crusty gentlemen shall not select wine for me.”—YOUNG'S Epicure, 8vo. 1815, p. 23, 28, &c.

* “Wines bottled in good order, may be fit to drink in six months, (especially if bottled in October), but they are not in perfection before twelve. From that to two years they may continue so; but it would be improper to keep them longer.”—Edinburgh Encyclop. Britan. vol. xviii. p. 72, article Wine.

† “Cork the bottles very closely with good cork, and lay them on their sides, that the cork may not dry and facilitate the access of the air. For the greater safety, the cork may be covered with a coating of cement applied by means of a brush, or the neck of the bottle may be immersed in a mixture of melted wax, rosin, or pitch.” ACCUM on making wine, 1820, p. 40.

‡ A PUNcheon of BRANDY containing 130 gallons, after remaining in cask in a merchant's cellar for three years, lost two gallons in measure and ten gallons in strength. The stronger the spirit, the sooner it evaporates.

The London Dock Company are not answerable for any decrease of quantity in a PIPE OF WINE left under their care, provided it does not exceed one gallon for each year—which it is supposed to waste in that time.

about manœuvres may tickle the fancy of those folks who cannot relish any thing that is not far-fetched, dear bought, and hard to be had, and to whom rarity is the "sine qua non" of recommendation—it is one of those inconvenient prejudices, from which common sense preserve us!

The vulgar objection to new wine—(by which we mean wine that has been maturing in wood two years in Portugal—two in England—and in bottle more than twelve months,) is that its exhilarating qualities are too abundant, and intoxicating in too small a dose—those "Bons Vivants," to whom "the bottle, the Sun of the table," and who are not in the habit of crying to go home to bed while they can see it shining—require wines weaker than those which are usually imported from Spain and Portugal, —however PORT and SHERRY may be easily reduced to the standard desired by the long-sitter, —"paululum aceti acetosi," will give the Acid Gout,—"agua pura" will subdue their spirit "ad libitum,"—and produce an imitation of the flavour acquired by age, extempore—and you can thus very easily make fine fruity nutritious new wine,—as light,—and as old,—and as poor, as you please—and fit it exactly to your customer's palate, whether "Massa drinky for Drinky,—or drinky for Drunky Massa."

To ameliorate very new, or very old wine—mix a bottle of the one with a bottle of the other—or to a bottle of very old Port, add a glass or two of good new Claret—to very new, a glass of Sherry.

Of all our senses,—the taste, especially, for liquids, is the most sophisticated slave of habit—"De gustibus, non est disputandum."

The astringent matter, and Alcohol—which render PORT WINE the prop of an Englishman's heart—are intolerable to the palate of an Italian, or Frenchman.—But a stomach which has been accustomed to be wound up by the double stimulus of Astringents, and Alcohol also,—will not be content with the latter only,—especially if that be in less quantity—as it is in the Italian and French wines; which therefore, for the generality of Englishmen, are insufficiently excitant.

He who has been in the habit of drinking PORTER at dinner,—and PORT after—will feel uncomfortable with home-brewed Ale and Claret.

MR. ACCUM, the chemist, analyzed for the Editor some PORT and SHERRY of the finest quality—the PORT† yielded 20 per cent.—and the SHERRY 19.25 per cent. of ALCHOL of 825 specific gravity—i. e. the strongest spirit of wine that can be drawn, full double the strength

* CORNARO complains that old wine was very disagreeable to his stomach, and new wine very grateful; his dose was fourteen ounces, (i. e. seven wine-glasses) per day.

† Fermented liquors furnish very different proportions of Alcohol—and it has been sometimes supposed that it does not pre-exist to the amount in which it is obtained by distillation; but some experiments I made upon the subject in 1811 and 1813, and which are printed in the Phil. Trans. for these years, tend to show that it is a real educt, and not formed by the action of heat upon the elements existing in the fermented liquor. The following table exhibits the proportion of Alcohol by measure existing in one hundred parts of wine."—BRANDE'S Manual of Chemistry. 8vo. 1819, p. 400.

Table with 2 columns: Wine type and Alcohol percentage. Includes Hock, Claret, Sherry, Port, and Madeira.

of BRANDY, which seldom has 40 per cent. and common GIN* not more than 30—or 25.

Some people have a notion that if they go to the docks, they can purchase a pipe of wine for twenty pounds less, than they must pay to a regular wine merchant—and, moreover, have it neat as imported—as if all wines of the same name, were of the same quality.

PORT varies at Oporto in quality and price as much as PORTER does in London—it is needless to say how difficult it is to obtain the best beer at any price—it is quite as difficult to obtain the best port wine at Oporto, where the very superior wine is all bought up at a proportionately high price by the agents for the London wine merchants.

BRANDIES and WINES vary in quality quite as much as they do in price: not less than twenty pounds per pipe in the country where they are made.

The only way to obtain genuine wholesome liquor, is to apply to a respectable wine merchant—and beg of him to send you the best wine at the regular market price.

If you are particular about the quality of what you buy—the less you ask about the price of it the better—if you are not, bargain as hard as you please.

"There are three sorts of drinkers: one drinks to satisfy nature, and to support his body, and requires it as necessary to his being.

"Another drinks a degree beyond this, and takes a larger dose to exhilarate and cheer his mind, and help him to sleep—these two are lawful drinkers.

"A third drinks neither for the good of the body or the mind, but to stupify and drown both."—MAYNWARINGE on Health, &c. 12mo. 1683, p. 123.

"It would save many lives if gin, &c. was not allowed to be sold until reduced to one third the strength of proof spirit. People do not at first drink from any liking or desire, but being cold, or faint with hunger or fatigue, they find immediate comfort and refreshment from the use of spirits—and as they can purchase a dram with less money than they can cover their back, or fill their belly, so they gratify the strongest and least expensive appetite—and insensibly become drunkards."

"Ardent spirits are not only eminently destructive to the body, but are the most powerful incentives to vice of every kind; drunkenness engenders all other crimes. Does the robber pause in his trade? Does the murderer hesitate?—they are presently wound up at the gin shop. Has the seducer tried his arts in vain? The brothel is more indebted to this source, than to all the other lures to seduction." From Hint for the Preservation of Health.—CALLOW, 1813, 12mo. p. 2.

PUBLISHED IN THE AMERICAN FARMER, BY ORDER OF THE STATE.

A report of the tobacco inspected at and delivered from Williams & O'Donnell's Inspection Warehouse, during the quarter, commencing on the first Monday of October, eighteen hundred and twenty-three.

Table with 5 columns: Domestic growth, Growth not of this state, Re-inspected, Total, and Number delivered. Shows 714 domestic, 81 foreign, 24 re-inspected, 819 total, and 864 delivered.

JOSIAS STEVENSON, Inspector. TREASURY OFFICE, ANNAPOLIS, Oct. 11, 1823. True Copy, from the original report on file in this office. B. HARWOOD, Tr. W. S. Md.

THE FARMER.

BALTIMORE, FRIDAY, NOVEMBER 14, 1833.

The members of the Maryland Agricultural Society will meet at the office of the Editor of the American Farmer on Wednesday next—the 19th, at 10 A. M. for the choice of officers for the ensuing year.

The next number of this Journal will contain the report of proceedings at the late Cattle Show and Exhibition of the Maryland Agricultural Society.

The letter from Col. Powell on various topics of the first moment, to every farmer, will command the attention which is due to the suggestions of a gentleman who fortunately unites with great zeal, a sound practical judgment to discriminate between what is plausible in theory only, or practicable alone by extraordinary means; from that which is susceptible of being profitably put in operation by the generality of farmers under ordinary circumstances. It is when gentlemen of opulence and science thus make themselves familiar with the details of the field and the farm yard, and cheerfully instruct us, not only in the why, but the how things should be done and managed, that money and labour are applied to the greatest advantage, and the business of the farmer acquires that superior dignity and consequence in the public esteem, and safe and substantial profit in dollars and cents, which rightfully belongs to it—and who does not perceive that augmenting attractions and increasing respectability are filling this walk of life with young men of superior attainments, who hitherto sought distinction in other and much less independent and useful departments of society?

The news of the capitulation of Cadiz, has affected the prices of grain, flour, &c., as will be seen below.

BALTIMORE MARKET.

PRICES CURRENT—CORRECTED WEEKLY. Flour, best white wheat, \$7 25—Howard street, from wagons, \$6 62½—fine do. \$6 12½—Wharf, do. \$6—White wheat, \$1 15 to \$1 20—Red do. \$1 10 to 1 13—Lawler, \$1 12 to 1 15—Washington white, \$1 15 to \$1 30—Rye, 44 to 45 cts.—Corn, 42 cts.—wharf Oats, 33 cts.—wagon Oats, 37½ cts.—Beef, 6 cts. per lb.—Live Cattle, \$5 to \$5 50, per cwt.—Bacon, hog round, \$10—Pork, \$7 per c. lb. 6 to 8 cts. per pound—Mutton, 4 to 5 cts. per lb.—Beans, retail, \$1 25, cargo price, \$1—Peas, retail, 62½ cts., cargo price 48 to 50 cts.—Red Clover Seed, \$6—Orchard Grass do. \$2 50 Herds' Grass do. \$2 50—Timothy do. \$4—Flax Seed, 75 to 80 cents—Whiskey, from the wagons, 33 cents per gallon including the barrel—Apple brandy, 30 to 32 cts.—Peach do. 65 to 70 cts.—Shad, No. 1, \$6 50, very dull, No. 2, do. \$5 to \$5 50, do.—Herrings, No. 1, \$2 50 per bbl., very dull No. 2, \$2 25 do.—Fine Salt, 75 cents per bush., coarse, do. 70—Butter, (firkin) 14 cts. per lb.—Eggs, 12½ cts per doz.—New Hay, \$14 per ton, old do. \$16—Straw, \$7.

MARYLAND TOBACCO.—No Sales.

Printed every Friday at \$4 per annum, for JOHN S. SKINNER, Editor, by JOSEPH ROBINSON, on the North West corner of N. 1st and Belvidere streets, Baltimore: where every description of Book and Job Printing is executed with neatness and dispatch—Orders from a distance for PRINTING or BINDING, with proper directions promptly attended to, addressed to J. Robinson, Baltimore.

AGRICULTURE.

MARYLAND CATTLE SHOW AND FAIR,
No. 4.

The exhibition held by the Maryland Agricultural Society, on the 5th and 6th days of November, placed many very interesting objects under the observation of its members and their much respected visitors; and if, in some few instances, the number of animals was not so large as at former shows, this deficiency was abundantly supplied by the far greater extent of young, improved stock, that crowded our pens, and gave visible signs of those benefits which are now widely spreading, through these walks of husbandry—upon no former occasion, have we witnessed so many, or such valuable animals grouped together in Maryland. And when we remember, that this was but the third exhibition had on this Shore by our Society, we confess very candidly, that our most sanguine expectations have been surpassed by the display of so many creditable proofs of a well directed, and heartfelt emulation, which has been readily and extensively made to operate on the feelings and measures of hundreds, who so lately were unwilling to be drawn, even in connexion with the independent and creditable business of their lives, from the retired scenes of their every day occupations. But thanks to that spirit of improvement which characterises this age, we have now, through its happy influence, acceptable assurances of long continued and well concerted efforts to diffuse the knowledge and induce the adoption of every new mode of agricultural advancement; resources of profit will be disclosed, that have laid for years unexplored—economical means will be employed, that have been heretofore neglected or unknown—productions will be created and multiplied, in forms so various, and extent so wonderful as to surprise, delight and reward their ingenious and enterprising authors, whilst they shall be hailed as the discoverers of new enjoyments, and the benefactors of society.—In a cause, which seeks to augment, the blessings of every household, who will not engage? There are none to censure the means of our enterprise, the peaceful force of commendable ambition, the list of prizes, and awards of merit, that we fairly offer to those, who shall excel in designated matters. And since every one approves and applauds our undertaking, may we not hope that our members will augment with the progress of time, and that an institution which seeks exclusively to advance the general good, will ere long obtain the patronage of our public authorities? Boards of Agriculture and Societies formed in other states, have been patronized by their governments to the honor of rulers, and the advantage of the governed. And as we have been favoured with the presence and approbation of intelligent men, from every quarter of our state, and have given to them, on both Shores, the most conclusive demonstrations of the disposition and tendency of our association to be useful to the state at large, we fondly hope, that these facts will procure for our established society, enlarged means to exert its mild and salutary influence over the industry of the great mass of our population.

The display of machinery and implements, lately made to us, reflected great credit on our Mechanicians, who continue to vie harmoniously with each other, in their efforts to render their manufactures not only stronger and more convenient in form, but more powerful in principle—of course more operative and easy to employ, whilst unbounded competition fixes fair limits to the prices, and gives notoriety to the cheapness among the best.

The specimens of crops, and the statements of

their acreable extent, were truly gratifying, and in future, we hope to see them multiplied, and in all cases strictly ascertained, and fully certified—it is important to know how much may be produced per acre in our climate, of different crops, by definite tilth and manures, upon given soils—all things should be taken into the account and be fully set forth—no circumstance that has affected the results, should be left unknown: when we shall have ascertained what may be done in this way, we have the course and the goal fairly before us—the rest will depend on our respective means, judgment and perseverance. And if “the race is not always to the swift, nor the battle to the strong,” still the slow are generally the sure, and by recording the details of culture and management, which our rules ought to require and procure from all competitors, we shall fix lights on high, to guide the steps of all to yet greater improvement in every operation of husbandry.

The recent exhibition of household and domestic manufactures, was the first that has been made to us on this Shore, and therefore we presume it was, that it comprised a smaller number of specimens and articles, than the Society expected, or wished to see—but we entertain no doubt that the liberal amount of premiums bestowed for the encouragement of this truly creative branch of industry, will bring to future exhibitions a greater variety of manufactures—the production of which so well employs whole days and weeks that otherwise would pass listlessly away, nor leave a trace to show that they had not been lost forever. Who would not patronize these testimonials of untiring usefulness, and grant another and another tribute to those monuments of household worth, that shall go down from age to age, mementos of a mother's or a sister's merit, which claimed applause, and won it from competitors?

The field that was devoted to our ploughing matches became a most enlivening scene—the palpable desire of each competitor to merit approbation, presented a gratifying evidence of emulation on the part of our mechanicians, and their ploughmen; and, where all did so exceeding well it became difficult to prefer, and impossible to censure. The experience gained in this field will lead to more perfect arrangements, and these will insure more precise and definite information, than it was recently in the power of the Committee to acquire and impart. The introduction of oxen to this scene of labor, was an unexpected pleasure to the spectators, and as acceptable to all as it was unlooked for by most of them—the more agreeable, no doubt, from the perfect manner in which both teams had been trained to work, and especially from the great skill displayed by a young teamster, who ploughed a lot in the most masterly style, whilst he governed his oxen by his voice alone.

The offer at public sale of many choice young live stock on the last day of the Show, presented an opportunity to buy them at reasonable prices—and we regret that notice had not been given by the owners of those animals, of their intention to sell them thus, at moderate prices, long enough before the Show, to have permitted orders to arrive before the day of sale from farmers at a distance, who might have wished to purchase—besides, we were sorry that the weather was so inclement as to have caused many persons of this vicinity to think that a public sale of good stock would not be attempted—hereafter timely notice had best be given, and farmers may be assured that many and very choice animals, of most approved breeds, and of different species, will be offered at our Fairs on public sale.

The opinion that we ought to appropriate three entire days to our Exhibitions seems now very generally to prevail among the members of the Society. The Committees were all too much hurried through their duties, and with many spectators had too little time to observe the various objects which merited particular examination. The Society had also to neglect some important business: but these matters may be better arranged if the proposition to hold the Show and Fair, during three days shall finally prevail.

Some misapprehensions have existed that had best be corrected whilst the recollection of them is perfect. Many persons have supposed that it was necessary to become members in order to exhibit stock, &c. &c., or to enter into the ploughing matches, and that in these trials no individual could enter more than one plough for each premium; but these impressions are erroneous—the exhibition is free to every body who has any thing to show—there is no limit to the number of animals, articles, or implements that may be shown or tried by any person, but what may be imposed by the nature or extent of their own resources—and all the privileges of membership, are freely offered to the acceptance of every friend of agricultural improvement, who is willing to advance the objects of our association, by simply paying a small annual contribution, to create a premium fund.

It happened, unfortunately, that the grand meeting at Washington, friendly to the Chesapeake and Ohio canals occurred so nearly at the time of our Show as to deprive us of the company of many distinguished farmers of Maryland, and other states, who expected to be with us—and the society regretted that any cause should have deprived them of the presence of their especially invited friend, the gallant PORTER; the cause of whose reluctant absence has been better stated by himself, than we could express it, as will appear by his letter, ordered to be published.

The Society particularly regretted that they were denied the pleasure which they anticipated from an address that had been prepared for the occasion, by Robert G. Harper, Esq. but as they were only deprived of that satisfaction by the inclemency of the day, and his regretted frail state of health—they unanimously requested him to furnish a copy of his address for publication in our Journal, where we shall be happy to give it an early insertion.

Edit. Am. Far.

REPORT ON HORSES.

The horse has been the theme of admiration in all ages, and is of such great use in the affairs of Agriculture, Commerce, War and Sporting, that all laudable means, should be used to improve the breed of an animal, at once so noble, and extensively employed. We are happy to discover a spirit in our state favourable to this improvement, and no doubt, the institution of premiums by the Society, will have a most happy effect.

The committee to whom has been confided the important duty of deciding on the merits of horses, beg leave to report, that they have assigned to Mr. Henry Cost, of Frederick county, the first premium for his bay horse young Post Boy, possessed of size, strength and figure rarely to be met with in a blooded horse.

To Mr. T. R. S. Boyce, of Baltimore county, the second premium for his grey horse Fagdown, his fine action, power and docility, recommend him as a valuable animal to improve the stock of road horses.

To Mr. Thomas P. Stabler, of Montgomery county, the first premium for his bay mare, hav-

proved herself a fine brood mare,* from the exhibition of her colts, which are very promising animals.

To Mr. Samuel Owings, of Baltimore county, the second premium, for his fine full bred mare Primrose.

There were also exhibited several other horses, and the committee would have been gratified, if premiums had been placed at their disposal equal in number to those, which in their estimation merit them, and of this class they particularly designate Mr. Thomas Lewis' bay mare, also a full blood filly, belonging to Gen. Ridgely, and a filly the property of Mr. John Schwartz, 6 months old, of beautiful proportion, and in uncommonly fine condition; the two latter, however, do not come under the denomination of brood mares, to which class the committee were exclusively confined.

The committee have to lament, that the state of the weather was peculiarly unfavourable for the exhibition of horses, it being in most cases impracticable to view them *in action*—there were a number entered for premium, which from the above circumstance, were not submitted to their consideration.

HENRY THOMPSON,
Chairman.

REPORT ON ASSES AND MULES.

The committee appointed to adjudge the premiums for asses and mules take leave to report, that there was no jack nor jennet offered to the Society for premium, and that but two pair of mules competed for your premiums.

We adjudge unanimously the premium for the best mule, to Wm. Patterson, Esq. of the city of Baltimore, and

To the same gentleman, the premium for the second best mule.

The committee regret that there was not a fuller exhibition of this kind of stock, as they believe it to be highly valuable to the farmer.

All which is respectfully submitted.

THOMAS EMORY,
Chairman.

REPORT OF THE COMMITTEE ON CATTLE.

The Committee on Cattle report, that the animals presented for their inspection were generally very fine, and their improvement furnishes the strongest example of the good effects of that spirited system which annually produces a competition among the farmers of our state in relation to our valuable live-stock. As a further evidence of the fine quality of the cattle, the Committee declare, that they had much difficulty in deciding upon the respective merits of some of the classes, and were often divided in opinion.

Taking the cattle in order, as presented to them on the list, they award the first premium, for the best bull over two years old, to Mr. Caton, for his full bred Alderney bull, five years old, there being no other in competition, and they were bound by a rule, in such case, made and provided.

The premium of a silver can, for the best bull under two years, they award to the Honourable Edward Lloyd of Talbot, for his bull calf "Pilgrim," by Blaze, out of White Rose, eleven months old.

The premium of a silver can, for the second best bull under two years, they award to Mr. J. W. McCulloh, for his bull calf "Warrior," by Champion, eight months old.

* This mare was raised, and is owned by Richard Brook, of Montgomery county.

On this class of cattle, the Committee cannot refrain from making mention, in the highest terms of commendation, of several other fine and beautiful animals, among which are Mr. Carman's bull calf, seven months old, by a full bred Bakewell bull of Gen. Ridgely's breed, (between whom and "Warrior" there was some difficulty in deciding); the young Holder-ness bull, "Comus," exhibited by Mr. Joseph Gales, Jr. of Washington city. This animal, 14 months old, is by Columbia, a bull of the Holder-ness blood; being sired by Gorham Parson's bull Holderness, out of an Holderness cow, which took a prize at the Brighton Cattle Show; Col. Thomas Emory's bull calf, 16 months old, by Bergami—Mr. Henry Thompson's bull calf, "Clifton" 12 weeks old, out of an imported Devon cow, by Mr. William Patterson's Devon bull.—Mr. William Patterson's Devon bulls; Mr. William Lorman's brindle bull 15½ months old; and Mr. J. W. McCulloh's bull calf "Reuben" of the Tuscan breed, 8 months old, by Duke of Tuscany, imported by Commodore Bainbridge.

MILCH COWS.

The premium of a silver cream pot, for the best milch cow, is awarded to Mr. Christopher Carnan, for his black cow, mother of the 7 months bull calf of such high merit, before spoken of.

The premium of a silver tumbler for the second best milch cow, is awarded to Mr. David Williamson, of Baltimore county, for his large spotted cow of Doctor Fall's breed, with a calf by her side.

Among the other milch cows, there were several whose merits were very considerable; Mr. Whittimor's fine cow, Mr. John Mercer's Hereford cow, with her calves; together with Mr. Lloyd N. Rogers' two cows which were conspicuous for thriftiness and size.

HEIFERS.

The premium of a silver cream pot, for the best heifer, was awarded by one vote to the Honourable Edward Lloyd of Talbot, for his heifer "Flora," 17 months old, by Bergami, in competition with Mr. Lloyd N. Rogers' "Snow Ball."

The premium of a silver tumbler for the 2d best heifer, was unanimously awarded to Mr. Lloyd Rogers, of Baltimore county, for his heifer "Snow Ball," 18 months old, of the improved Short Horn breed, got by "Bishop," out of "Europa."

Of this class of cattle, there were many of great merit and beauty. The Committee particularise Mr. Henry Thompson's red and white heifer "Fanny," 16 months old, by Mr. William Patterson's full bred Devon bull, out of a cow bred by Gen. Ridgely of the Holland and English breed; Dr. Allen Thomas' half Devons, and a heifer of the Bergami breed; Mr. William Patterson's Devons, Mr. Morris's Devon.

The premium of six silver table spoons for the best yoke of oxen, is awarded to Mr. James Gettings, of Long Green, for a yoke of black oxen, not three years old.

The premium of a silver can for the 2d best yoke of oxen, is awarded to Mr. James Gettings, of Long Green, for a second yoke of black oxen.

But few yokes of oxen were presented for premium, and they were all good, indeed, fine; a yoke of Mr. David Williamson's, of Baltimore county, was admired, but excluded from competition, in consequence of one of them being bred out of the state.

The Committee will close their report with remarking, that although they feel conscious of having discharged the duty assigned them with their best judgment, yet such was the unfavourableness of the weather yesterday, and so great was their exposure and suffering from the rain, when called to view the cattle, that there may have been some animals of much merit, not particularly specified in this report, an inadvertence arising from such causes they hope will be pardoned, and they congratulate their brother farmers, from the specimens exhibited at the Cattle Show, upon the great improvement that is now so generally making in the breed of our stock of cattle.

ROBERT H. GOLDSBOROUGH,
PEREGRIN WETHERED,
AARON CLEMENT,
D. WILLIAMSON, Jr.
SAMUEL T. KENNARD.

REPORT ON HOGS.

The Committee to whom was referred the examination of the swine, offered for exhibition, beg leave to report, that they have attentively examined the same. Before entering upon the description of those offered for premium, they cannot forbear stating to the Society, their unfeigned regret that so few of that description of stock should have been brought for exhibition; but judging of the future from experience, they hope that as the usefulness of this institution increases in the public estimation, the exhibition of swine will be more ample.

The Committee award the premium of one soup ladle, value \$10, to the boar, offered by Theodore Anderson, of Baltimore county, of the Suffolk breed, 3 years old.

The Committee award a premium of one gravy spoon, value \$5, for the second best boar, of the Parkinson breed, 4 years old, to James Cunningham, of Frederick county.

The Committee award a premium of a soup ladle, value \$10, for the best brood sow, to Mr. J. W. Stone, of Baltimore county.

The Committee award a premium of a gravy spoon, value \$5, for the second best brood sow, to Mr. D. Williamson, Jr. of Baltimore county.

The Committee beg leave further to add, that there were exhibited 4 pigs, of rather upwards of 3 months old, of a mixed breed, very deserving of attention, by Mr. Barney, of Delaware; but inasmuch as these do not come within the rules of the Society, the committee can only remark on the superiority of the breed.

To these may be added 4 other pigs, belonging to Mr. John S. Skinner, forwarded to him by Mr. Johnston of Bridgeton, which the committee are sure will be found to be a valuable acquisition in the improvement of the breed of that valuable race of animals.

GRAFTON DUVALL,
SAMUEL OWINGS,
JOHN MARSH.

REPORT ON SHEEP.

The committee appointed to examine the sheep, have performed that duty, and beg leave to report, that they first proceeded to inspect those of the merino breed. In deciding upon the merits of this sort of sheep, which are principally valuable for their wool, the committee felt themselves bound to direct their attention chiefly to the quality of the fleece. Although several other rams of great merit were exhibited, yet the committee after a close inspection were unanimously of opinion, that the ram belonging to Gen. John Mason, of Annapolis Island, had the finest fleece, and therefore

award to him the premium of a pair of salts, value \$10.

Governed by the same principle, the committee after inspecting the merino ewes, decided in favour of the pair exhibited by Dr. Richard G. Bennett, of Anne Arundel county, and award him a pair of salts, value \$10.

In deciding upon the merits of other breeds, than the merino, the committee had a principal regard to the value of the carcase, and were of opinion, that the two rams of the Dishley breed, offered by Mr. Barney, of Delaware, for a premium, were the best exhibited, and award him a goblet, valued at \$10.

After an examination of the ewes of other breeds than the merino, the committee decided in favour of a pair exhibited by Dr. Allen Thomas, of Anne Arundel county, a cross of the Dishley, with the broad tailed Barbary sheep, and award him a premium of a goblet, valued at \$10.

In awarding the premium, offered for the five best fat wethers, the committee were governed by the same principle, and after some hesitation, between the merits of those exhibited by Edward Lloyd and Charles C. Brown, Esquires, of the Eastern Shore, although the fleeces of those belonging to the latter gentleman were superior, yet the carcase of those belonging to the former, were somewhat better, and the premium of a can was accordingly awarded to Mr. Lloyd, valued at \$10.

The committee cannot close their report, without expressing their satisfaction, on inspecting the fine sheep exhibited by several other gentlemen. They, in a particular manner, viewed with much pleasure a parcel of ewes, of the Dishley breed, shewn them by Mr. Barney of Delaware, also another parcel, with two rams of the same breed, exhibited by Mr. Clements of Pennsylvania, and the broad tailed Barbary ram, exhibited by Dr. Allen Thomas of Anne Arundel county.

J. SYKES,
J. S. WILLIAMS.

Committee.

REPORT ON MACHINERY AND IMPLEMENTS.

The Committee on Agricultural Machinery and Implements, Report—That they have with much pleasure viewed and examined a great number and variety of useful implements and machinery, brought together by our intelligent and enterprising mechanics, and which well deserve the continued patronage of the public; but feeling themselves confined by their instructions to the especial consideration of the merits of machines, or implements of new principles or construction, they have endeavoured to investigate more thoroughly those, which have appeared to them to come within this description.

They have long lamented the want of neatness in the preparation for market of our most valuable staple, wheat; and have considered a machine of simple contrivances, that could be constructed at a cost within the means of the small farmers for threshing wheat, as one of the real desiderata for the great body of our agricultural community. A machine for this purpose, invented by Mr. J. Pope has been submitted for their inspection. The principle is not entirely new, and it is so much the better on this account, as the committee can, from their knowledge of it, pronounce with more certainty upon its utility. They consider it in fact the Scotch machine, as constructed by several of our mechanics, and as reported by Mr. Dawson, reduced within the power of one horse; and with a trifling variation

in the application of the force, we believe a single ox might be used in it to advantage.

The wheat is well threshed out, but scattered too much, and not sufficiently separated from among the straw; tho' it is believed these objections might be easily obviated. On trial before us the wheat in the barn, and the straw to be put away also in the barn, with one horse, two men and two boys, this machine threshed straight wheat at the rate of 26 sheaves in 7 minutes, and its average work in practical operation is stated by the constructor, Mr. Merrick, of Philadelphia, to be 70 bushels per day.*

The price is \$125, and we deem it worthy of the first premium.

The next objects considered most worthy of the especial notice of the Committee were two ploughs for seeding wheat, one offered by Mr. Ramsey; the other invented by Virgil Maxcy, Esq. and made at the manufactory of Mr. Robt. Sinclair in Baltimore.

Mr. Ramsey's is composed of a right and left mould board forward, and a double mould board following between them, so as to make it cast four furrows, two each way, and was made for covering wheat between rows of Indian corn; but we think it would be a difficult implement to construct to run well, and unless the corn rows could be laid out of the same width, or with much more exactness than is found generally practicable, it would be too apt to leave that operation imperfectly performed. For working corn before the end of June, where so much nicety in breaking the whole space, and in laying up every furrow alike, would not be necessary, we should deem it a useful and real labour-saving implement;—but we prefer Mr. Maxcy's *Eschelon plough*. It has been well tested by two years' experience. As a double, or triple plough, it will be found useful in working corn, or seeding wheat among it, and in the preparation or seeding of naked fallow. They have been extended to the combination of five ploughs, casting five furrows, and with three horses and one ploughman executed the work of five single ploughs, and in a superior manner. They deem this one of the most useful implements that has been offered to the notice of the public since the establishment of our society, and with pleasure award to Mr. Maxcy the second premium.

A machine, new to us, for shelling corn, was offered to our inspection by Mr. Joseph Winman, price \$25. It is more complicated, and not so efficient as those made by Mr. R. Sinclair, which are very perfect and useful machines, but the price at which they are held we deem too high, and this probably is the only circumstance which prevents their coming into very general use.

A machine denominated a vertical spinner was offered to the notice of the Committee by Eastman and McCoy. It is a simple and very beautiful application of the machinery of the great Arkwright to spinning wool by hand. It can only, however, be used to spin rolls carded by machinery. The spinning requires very little skill. It runs 6 spindles, makes a uniform, even, and excellent yarn, and will accomplish with less labour from three to four times as much as one common wheel. It is about 6 feet high, and 3 feet square, price \$20, and the number of spindles can be increased at about \$1 a piece. We regret that we have not the power to confer a premium on this ingenious and simple machine.

* He also stated that it had threshed 131 bushels in a trial hour, and his belief that thro' a crop its practical operation would equal an average of 3 bushels per hour.

which we recommend to the notice of every family, who can have their wool properly cleaned.
SAML. McCULLOH, *Chairman*.

REPORT ON THE PLOUGHING MATCHES.

The Committee appointed to superintend the ploughing matches, have the pleasure to report, that they have been highly gratified in attending to the duties devolved upon them, as they were thus led to witness the universal and acknowledged satisfaction which the confidence and dexterity of many skilful competitors, and the performance of some excellent ploughs, afforded to a crowd of admiring spectators, who remained upon the field enjoying the animated scene, until they were forced to seek shelter by the heavy fall of rain, that finally interrupted our operations, before we could test the draught of the respective ploughs with instruments provided for that purpose—a circumstance that we particularly regret, as we had determined to subject them all to this examination, which could alone authorise us to give a settled opinion upon their *entire* merits.

The Committee, nevertheless, believe it to be their duty to report upon the *seeming* value of the different ploughs, and to award the premiums offered by the Society to those which have *appeared* to be the best, so far as they have been enabled to form an opinion—a task that has been rendered the more difficult by the interruption of an important test, as the ploughing was generally executed in the most masterly style, and with a rapidity so great and nearly equal, as to surprize and gratify all spectators—facts which permit us to assure the Society that the ingenuity and enterprize of our mechanics, and the zeal of our ploughmen continue to hold forth the most cheering prospect of valuable improvements in this department of our rural economy.

It was the wish of your Committee to have obtained the use of a piece of stiff sward, for the scene of their operations; and to have allotted one eighth part of an acre to each plough. We were obligingly accommodated, through the courtesy of John B. Morris, Esq. and the liberality of his tenant, Mr. Joseph W. Stone, at the nearest good spot—one that was in every respect suited to the purpose, except in its extent, which did not permit us to run the furrows more than ten rods long, nor to allow a greater breadth than one rod and a quarter to each competitor; so that in ploughing these twelve and a half square perches, an unusual loss of time was unavoidably occasioned by the great frequency of turning the ploughs. The soil on which they operated, although free from stones and other obstructions, is a compact, clayey loam—the surface was a tough sward, on which cattle had pastured for several years; yet, under these circumstances the competitors ploughed their several compartments, as will be fully detailed, at the rate of an acre, in less time than four hours, with horse teams; and at the same rate, in less time than five hours with ox teams, of one yoke; thus fairly rivaling, in Maryland, by this latter operation, the performances at Brighton, where "the working ox" has ever been a favorite, and of late is made their toasted champion—there a premium plough drawn by a yoke of oxen, governed by the ploughman, without a driver, required at the rate of nearly four and a half hours to turn an acre, in furrows sixteen rods long, which greater length of furrow saved but one third of the time that was lost in our experiment by frequent turnings.

But the most interesting fact that this display presented to the spectators, and fastened on the minds of your Committee, is the demonstration that it gave of the power of the ox, to compete on equal grounds with a more expensive animal. And who can estimate the saving that might be made, or, to speak more acceptably, the gain that might be realized to the agriculturists of Maryland, if they would substitute the hardy, cheap, and enduring ox, for the more delicate, costly, and perishable horse?

To your Committee, it has been repeatedly objected during these experiments, and by many observers, "that oxen cannot bear the heat of summer, nor travel well in winter," but we have in vain inquired, who has proved these axioms, and at the same time fed the ox, in hot weather, upon even one half of the suitable provender usually bestowed upon the horse? or, who has found them less efficient in winter, if so fed and shod in time to save their feet from injury? Too many there are, we fear, who deny to these invaluable animals what our climate renders absolutely necessary to their comfort and usefulness, whilst nearly all of us lavish, at least, twice as much upon our horses, as would enable oxen to perform equal services. Let the sceptical doubt even their own fears, until they shall have tested the truth of our opinions by fair and actual experiments. To us, this subject appears to affect the interests of Maryland so deeply, that we are unwilling to pass it over, as we must, in the cursory manner of a hasty report, which will scarcely permit us to call your attention to the most important considerations, before the usual notice of those scenes from which they spring, is expected at our hands by the successful candidates for your applause. But ere we proceed to these details suffer us to express the hope that many of you will make the most critical investigations into the comparative merit, of the ox and horse, in rural labors:—array the price, power, disposition, trappings, wants and end of each fairly against the other, and we have no doubt that you will arrive at a correct and eminently beneficial decision.

PLOUGHING, BY THREE HORSES.

Five ploughs, each drawn by three horses, were entered, and of these the plough made and exhibited by Mr. William Brown, of Brookville, Montgomery county, Md. is, in our opinion, best entitled to your patronage. It turned the sod completely under, and in fifteen and a half minutes, made sixteen furrows, each ten poles long, collectively one and a quarter pole wide, and nearly seven inches deep. We, therefore, award the premium to Mr. Brown, for the best three horse plough, and the silver medal to his expert ploughman, Mr. James Frame, as an evidence of particular approbation. The Committee were also much pleased with the performance of a plough made and exhibited by Mr. Chenowith, of Baltimore. We regret that an unexpected difficulty prevented its starting before the others had finished, and that an accident made it impossible to time his work. The extensive use made of his ploughs is, we believe, but the just consequence of substantial workmanship, upon a good model.

The plough made and exhibited by Mr. Robert Sinclair, of Baltimore, also executed its work in a very satisfactory manner, and the Committee consider it an excellent implement—it ploughed on an average, more than seven inches deep, turned the sod perfectly under, and in eighteen and a half minutes, made six-

teen furrows, that finished his allotted space. The Committee are also gratified in expressing the pleasure which they derived from the performance of an iron plough, made by Mr. Crawford, and politely exhibited by Lloyd N. Rogers, Esq. to the observation of the Society—it ploughed a division, in eighteen furrows, an average depth exceeding six inches, in seventeen and a half minutes. It appeared to be of light draught; and is in our opinion worthy of further examination.

Mr. Joseph T. Ford, of Baltimore, also exhibited a plough that was made at his extensive manufactory, it ploughed the allotted space in twenty minutes, an average depth of six inches at eighteen furrows.

PLOUGHING, BY TWO HORSES.

Five ploughs were started, each drawn by two horses, and the divisions in this match having been assigned as in the former case by lot—the Committee paid close attention to the work done by each implement, and they think that the plough exhibited by Mr. Jona. Eastman, guided by Mr. Whittimore, and made in Baltimore at the manufactory of Mr. Robert Sinclair, by that skillful mechanic, Mr. John Stewart, is entitled to the preference—we, therefore, award the premium for the best two horse plough to Mr. Jona. Eastman, and a silver medal to the ploughman, Mr. Whittimore. This plough appeared to perform its work with the least draught—it turned the sod perfectly down, and in sixteen and a half minutes, finished the allotted division, having made nineteen furrows, of an average depth exceeding five and a half inches.

Mr. Robert Sinclair's plough turned his land well, and finished in sixteen and three quarter minutes, having made eighteen furrows, at an average depth of five and a half inches.

Mr. Brown's turned seventeen furrows in fifteen minutes, an average depth of five and a half inches, but left nearly one slice unploughed in his division.

Both of these ploughs are excellent implements, and we recommend them as worthy of patronage.

Mr. Gideon Davis entered a plough of simple but strong construction, that worked very well—in seventeen and a half minutes it turned his space, at twenty furrows, four and a half inches deep. The irons of this plough are formed to anticipate the changes or impress that use would finally occasion, and pieces of leather are judiciously placed between the mould board and the share to soften those destructive shocks which unperceived obstructions frequently give to cast iron shares—and by the successive removal of these slips of leather, the original angle, or dip of the share may be preserved as long as this will last.

Mr. Joseph T. Ford entered a plough, which in twenty-one and a half minutes, turned his space at twenty furrows, each being four and a half inches deep. In this match as in the former, Mr. Chenowith was unprepared to run his plough with the others, and on account of its high reputation, we regret that it was not subsequently in our power to subject it to trial.

Your Committee would here most respectfully suggest the propriety of devoting an entire, and the second day of future exhibitions exclusively to the ploughing matches, and the trial of machinery—by this arrangement you would give time enough to the several Committees to discharge their duties without depriving them of reasonable opportunities to enjoy and improve occasions which bring together so many inter-

esting objects. We would also recommend that competitors in your ploughing matches, should be required to announce themselves hereafter, at least one week before the Show, because the selection and division of the ground renders some notice necessary, and one week will be found quite short enough.

This Committee having understood that your Trustees were anxious to get up ploughing matches, sustained by oxen; one of our number was persuaded, by the rest, to enter an ox team, and to invite an acquaintance to engage the rein also—both having agreed to our proposal, and performed the work; we will here close our report that the majority of the Committee may alone furnish the details of this match.

}
Comtee.

SUPPLEMENT—PLOUGHING BY OXEN.

Two ploughs, each drawn by one yoke of oxen, started at the same moment that the ploughing match by two horses began—and each of them had an equal quantity of similar surface to plough. One yoke entered by Mr. Thomas Stabler, of Montgomery county, himself ploughman, aided by a driver, ploughed the allotted space in eighteen and a half minutes, four and a half to five inches deep, making eighteen furrows. His oxen were exceedingly well trained to his command, but yet he used a driver in this operation—although it would not require much time to save him the expense of a driver, as a few lessons would teach his oxen to obey the voice; our farmers will do best who do not give even to these animals expensive habits. The other yoke was entered by Mr. John Marsh of Baltimore county, and was commanded entirely by the ploughman, master Henry Hunt. He completed a space in twenty three minutes, turning eighteen furrows, an average depth of more than six inches—nothing could surpass the performance of this yoke, controlled as it was, wholly by the voice of a youthful teamster, who turned the slice completely over, and drew his furrows most beautifully straight and equal, holding an excellent plough of wrought iron mouldboard that was made, as we understand, by Mr. Hinks, near to Ellicott's Mills. The spectators hovered about this team, charmed by the skill of the young ploughman and the powers of his obedient oxen. And the undersigned members of your Committee feel peculiar pleasure in awarding the first premium, which has been conferred in Maryland, upon "the working ox," to Mr. John Marsh of Baltimore county, and the silver medal to his ploughman, Henry Hunt—the Society having unanimously expressed its approbation of this use of oxen, by appropriating a premium and medal to this interesting match.

REPORT ON DOMESTIC MANUFACTURES.

The committee appointed to examine the Domestic Manufactures exhibited to this Society, have carefully inspected every article submitted to their notice, and they most respectfully report, that, although they have had occasion to regret in several instances, that there was but a single specimen exhibited, and that in other cases, none claimed the proffered patronage of the Society—still the excellent quality and use-

ful character of the manufactures shown to us for premiums, gave to the company and your committee very great satisfaction, and ample proofs that much benefit may be produced by encouraging these displays of household and domestic industry.

For the premium on KERSEY, an article extensively made in this state, there was not a single claimant; although the Society had solicited the exhibition of that article, and offered a liberal bounty to the manufacturer of the best piece, that might be shown to us.

For the premium on FLANNEL, there was but one claimant—her specimen was well made, and of excellent wool—your committee take pleasure in awarding to Mrs. Ann Kennard, of Talbot county, a silver ladle for exhibiting this evidence of her skill and industry.

Of CASSINET, there was only one piece submitted, this was manufactured by Messrs. John Sykes & Son, of Baltimore, at the FRANKLIN MILLS in this county—it is a well finished substantial piece of goods, which they sell at 137½ cents per yard, and fully entitles these deserving manufacturers to the premium offered on this article. We were also gratified by the opportunity which these gentlemen gave to the members of the Society, and our much respected visitors, of examining two beautiful pieces of seven-fourth's superfine BLUE CLOTH, sold at the low price of \$5½ per yard, and two pieces of equally good three-fourth's blue CASSIMERE, at \$2 per yard, together with a coarser, but excellent piece of five-fourth's GREY CLOTH, at the price of 175 cents per yard—all made at their prosperous manufactory.

Of CARPETING, two very good pieces were shown—one manufactured by Mrs. Mary Ann Murray, of Anne Arundle county; the other by Mrs. Mary Rickets, of Cecil county—both substantial and handsome carpets: Mrs. Murray's has the advantage in appearance, the colors being superior; but the committee have felt bound to award the premium to Mrs. Rickets, as they consider her carpet *really* the best fabric.

There were several HEARTH RUGS offered—one of splendid colours, beautiful figure, and very close texture, manufactured by Mrs. Mary Ann Denny, of Talbot county, to whom the committee unanimously award the premium: they, however, took great pleasure in repeatedly examining the handsome and excellent rugs that were exhibited as the manufactures of Miss Mitchell, and Mrs. Ann Reardon, of Easton, Md.

The premium is awarded to Mrs. T. H. Belt, of Baltimore county, for exhibiting a large and handsome COTTON COUNTERPANE, made by herself.

For your premium on SHIRTING, there was not any claimant.

Two specimens of TABLE LINEN, were submitted—one of very superior quality, and beautiful pattern, it had been used without any apparent injury, for many years, and was manufactured by Mrs. Ann Kennard, of Talbot county, to whom the premium is thankfully awarded.—But to Mrs. Henry Tilghman, of Chestertown, Kent county, the committee would also have given a premium most willingly, if two had been placed at their disposal for this article; because she also has made and exhibited a piece of very good table linen.

The premium for TOWELING remains unclaimed.

Several specimens of very fine knit WOOLEN STOCKINGS were shown to us, but the best, in the opinion of the committee, were made by Miss Mary Ann Norwood, of Baltimore coun-

ty, to whom the premium is awarded—we had nevertheless, to make a very strict examination between these stockings, and those which were knit by Mrs. Wm. Copper of Kent county.

The only knit COTTON STOCKINGS exhibited were made by Miss Mary Ann Norwood, of Baltimore county, but as they are very superior, she well deserves the premium.

The committee award the premium on knit THREAD STOCKINGS, to Mrs. Wm. Copper, of Kent county, who offered a pair of very good quality to their notice. These stockings were accompanied by a hank of beautiful white thread, spun by Miss Phoebe Gale, of the same county, and who we believe might have successfully competed for a stated premium.

Your committee regret that not a single grass or straw HAT or BONNET was exhibited; and especially, as they are satisfied that many ladies of this state, have converted materials which every where abound, and are comparatively of so little value, into these costly and ornamental objects.

A piece of cotton SAIL CLOTH, of very extraordinary quality was shown to us—it was made by Messrs. Charles Crook, Jr. & Brother, at their factory in Baltimore—the committee think it richly entitles them to a premium. We have been informed that Maj. M'Kim's new and elegant schooner Yellot, fitted with sails of similar canvass, left Baltimore and reached the Capes of the Chesapeake in the short period of sixteen hours—and the committee beg leave to conclude this report by most respectfully proposing that a discretionary premium of the value of \$10, be awarded by the Society to Messrs Charles Crook, Jr. & Brothers, for exhibiting this specimen of their manufactory.

EDWARD LLOYD,
WM. H. LANSDALE,
HENRY V. SOMERVILLE,
J. W. McCULLOH, } *Comtee.*

N. B. A piece of domestic carpeting manufactured by Mrs. Wm. Hall and daughters, of Anne Arundel county, was exhibited, but too late to compete for the premium. The spinning and dyeing were done in the family. The carpet was worked with the needle, and made in a quilting frame. Much time had evidently been devoted to it, but this beautiful and durable evidence, of hours well spent, will long remain to recompense its worthy manufacturers.

REPORT ON CROPS.

The committee appointed to judge of crops, regret that there has been so little competition; indeed they may say, that there has been none. The only crop, for which a premium has been asked by more than one person is wheat—and although the committee has the most perfect confidence in the statement of Mr. Nimrod Owings, which represents that he had made 50 bushels to the acre, yet as that statement was not accompanied by the necessary vouchers, they do not feel themselves at liberty to act upon it. They therefore award the premium for the wheat crop, to Mr. John Mercer, of Anne Arundel county, for a crop of 616 bushels exclusive of gleanings, (estimated at 20 bushels,) from 22 acres 75 perches of land.

For the corn crop, to Mr. N. Underwood of Baltimore county, for a crop of 60 bushels and 2 quarters per acre, on ten acres.

For the carrot crop, to Mr. John Mercer, of Anne Arundel county, for a half acre of carrots, producing 277½ bushels.

For an acre of mangle wurtzel, also to John Mercer, producing 1376 bushels of clean roots.

The committee have received a very satisfac-

tory account of a large crop of millet raised by D. Williamson Jr, Esq. of Baltimore county, on a small quantity of land—the produce was great, and although not so much as we have seen reported in other situations, still it was large enough to prove, that millet is a very productive and valuable crop: one that might be advantageously placed on our premium lists.

And in order to inform competitors as to the nature of the evidence, that your committee are permitted to receive, respecting the character and extent of crops per acre, we beg leave to submit the several statements that have been offered to us on this occasion—by which it will be seen, that the Society requires the testimony of disinterested persons—not because the members, or your committee would hesitate to believe the mere statements of competitors, but that they are convinced that it is best to accompany their awards with a higher degree of evidence, such as may claim, and will command universal confidence.

On behalf of the committee.

B. W. HALL,
Chairman.

Informal statement of a wheat crop—it being unaccompanied by disinterested testimony.

I hereby certify that I had a plat of ground of twenty acres, seeded in wheat, on the 4th and 5th of October, 1822, at the rate of three bushels to one acre, as nearly as my seedsman could sow it, (the residue of my crop being two bushels seed to one acre.) That I had the said wheat reaped in July, 1823, from which I got 2170 dozen sheafs. The wheat was of superior quality, and from 187½ dozen sheaves (or 2250 sheaves) thrashed, I cleared up 87 bushels superior seed wheat, leaving out of account tail ends, or such as I deemed unfit for seed—and that thrashed was in no respect different from the rest of the crop—it was the opinion of all farmers who saw it growing, and after it was reaped, that 50 bushels per acre would be realized. The above is a correct and true estimate which gives a fraction more than 1000 bushels superior wheat from the 26,040 sheaves, 2170 shocks, of 12 sheaves each. A sample of the wheat is herewith handed. I had other fields part, say 30 or 40 acres, of which I think was not much inferior to the above statement. I have not had this wheat weighed, but I think it will weigh 62 to 65 lbs. per bushel. The wheat is between the white and blue stem, not so fair as white wheat, though a brighter straw than the blue stem wheat. This is the eighth crop I have cultivated of this sort of wheat, preferring it to any other I have seen, the famous Lawler not excepted. The ground was tilled in corn in 1821, and ploughed in the fall; again in the spring, and then in September, prepared for a crop of timothy. The drought last summer deterred me from sowing grass seed, and I put it in wheat, sowed broad cast, and harrowed in by two harrowings cross ways—heavy two horse harrows, teeth six inches long. It may be remarked that the wheat I had seeded on the 3d, 4th and 5th day's (6th being Tuesday) of the month was decidedly better than that sown on the 1st, 2d 6h, 7th 8th, 9th, and 10th, when I finished. Although the weather was mild and seasonable, with moderate showers on the 9th and 10th, though not to prevent my seeding. I had one field of 50 acres of rye, which was seeded from the 3d to the 11th September, from which I reaped the heaviest crop that has been seen by the most experienced of our farmers. Mr. Joshua Dellaplane says, he never saw as good a field of rye; the yield was 1750 shocks, of 12 sheaves each. I have not thrashed any of

My crop of corn, though small, (60 acres) is very superior, and has been thought inferior to none in the state.

NIMROD OWINGS.

*Fountain Rock, Fred'k Co. Md }
November 3, 1823. }*

Estimate.—2170 shocks of 12 sheaves each, is 26,040 sheaves, on 20 acres. Thrashed 2250 sheaves—gave 87 bushels, is an aggregate of 1606 bushels and upwards.

Heat Crop, by Mr. John Mercer—Certificates of survey and produce.

I hereby certify that I surveyed a field of stubble for Mr. John Mercer, and found it to contain twenty-two acres and seventy five perches

JOHN IGLEHART.

Cedar Park, October 28, 1823.

I hereby certify that there were 616 bushels of clean wheat measured by me from the above field, exclusive of what I estimate at 20 bushels, gleaned with the horse rake, but which was not threshed or measured separately.

THOMAS LEETCH.

Corn Crop, by Mr. N. Underwood—certificate of survey and yield.

We do hereby certify, that we have examined a corn field of Mr. N. Underwood, at Orange Farm, Baltimore county—that having carefully measured the produce of one acre of said field, we have found that the said acre has this year produced 60 bushels and 2 quarts of very fine shelled corn, and that in our estimation, the produce per acre of the adjoining nine acres is as great as the produce of the said acre actually measured. This corn field is in drills 3½ feet apart, and the corn stalks two in a hill, are about 18 inches apart.

JOHN MURRAY,
JOHN STANDFORD.

Baltimore County, Nov. 4th, 1823.

Root Crops, by Mr. John Mercer—certificates of survey and produce.

I hereby certify, that I surveyed a piece of ground in mangel wurtzel, and another in carrots—the former of which contained one acre, and the latter one half of an acre.

JOHN IGLEHART.

Cedar Park, 28th October, 1823.

We hereby certify, that we attended the measuring of the above acre of mangel wurtzel for Mr. John Mercer, and found it to contain 1376 bushels of clean roots well heaped on the barrel, weighing 52,976 lbs. As the form of the ground was an exact parallelogram, and the growth as uniform as possible, we agreed to take every fifth row for 25 rows, to measure and weigh the whole quantity and take the average. Also the half acre of carrots, which we found to contain 277½ bushels.

ALEX. MURRAY,
MARTIN FENWICK,
JAMES CHESTON, Jr.

We, the subscribers, also selected 12 of the largest roots of the mangel wurtzel which weighed 127 lbs.

ALEX. J. MURRAY,
MARTIN FENWICK,
JAMES CHESTON, Jr.

Account of a crop of Millet raised by D. Williamson, Jr. Esq. of Baltimore County.

Having heard much of the value and produc-

tiveness of Millet, I was induced to make an accurate experiment to test its worth.

In the fall of 1822 I ploughed up a piece of ground that had been in grass for the last 44 years, turning the sod well under, the depth of 9 or 10 inches. In the spring, the ground was well manured on the surface, and harrowed in, after which it was lightly ploughed across, so as not to disturb the sod. On or about the 26th of May, one bushel of millet seed was sown, and harrowed in, which from the drought that succeeded, remained without any appearance of vegetation, till after the rains and damp growing weather late in June, when its growth was more rapid and astonishing than any thing I ever witnessed. It continued luxuriant, and grew, on an average, six feet high and as thick as it could stand on the ground; the heads measuring 9 a 12 inches in length. It was ripe on the 8th of August. But owing to the weather, and my other engagements, it was not cut till the 19th and 20th August, then tied into bundles. An accurate average, as to size, was taken of the bundles, and weighed, giving a product of 74 cwt. 1 qr. 7 lbs. from which there were threshed 48 bushels of good seed.

The yield would have been greater, had I been able to have cut it in proper time; it shattered and wasted much in the field. The ground on which this grew measures 24 perch. 5 feet, by 10 perch. 5 feet, which is a fraction more than one and a half acres. For the above statement, I refer you to the annexed certificate.

D. WILLIAMSON, Jr.

Lexington, Nov. 5, 1823.

I certify that the particulars as mentioned in the above statement are correct.

MARTIN THOMAS, *Manager.*

Nov. 5, 1823.

Baltimore county, 5th Nov. 1823.

I hereby certify that at the request of David Williamson, Jr., I measured, with a measurer's line, the piece of ground on which the crop of millet grew, as described by Mr. Williamson, in the annexed statement, and that it measured 24 perches 5 feet, by 10 perches 5 feet.

JAMES A. MCCREERY.

REPORT ON BUTTER.

The Committee appointed to award the premiums for the best Butter, approached that duty with a proper sense of its delicacy. The inherent difficulty of the task was augmented by the number of the competitors, and the almost equal merit of the samples of butter that were offered. It gives the Committee pleasure to say that, with the exception perhaps of one parcel, the whole was so excellent as to make it almost impracticable to discriminate between the different degrees of its merit. It was not therefore until after long deliberation that the Committee determined to award the premiums as follows:

The first premium to John Schwartz, of Baltimore county.

The second premium to James C. Gittings, of Long Green, Baltimore county.

It was a subject of regret to the Committee, that two samples of very fine butter were rejected from examination, because not coming within the description of the rule which requires the quantity exhibited to be "not less than five pounds." This was the more to be regretted, because this butter, which was afterwards understood to be the product of the farms of Messrs. Geo. and Jas. Howard, is said to have been sam-

ples of the quantity of thirty pounds, of like quality.

Some of the butter which failed to receive the preference, was rejected because somewhat too salt, and some of it because not sufficiently worked. The butter to which the second premium is awarded was in this respect of an excellent worthy of imitation.

These circumstances it is thought proper now to mention, as it may enable the candidates for this premium, at future exhibitions, to avoid the repetition of the error or inadvertence, which in all probability deprived at least one of them of the premium on this occasion.

By order of the Committee,

J. GALES, Jr.

REPORT ON FERMENTED LIQUORS.

The Committee on fermented liquors, report—that various samples consisting of bottles of currant wine and cider, were presented for their inspection. They award that the wine contained in the bottle marked D. D. is the best; the paper which was affixed to the bottle being lost, the Committee is uninformed as to the name of the maker—and we award the premium for the best cider to Dr. Samuel McCulloh, which we think of very superior quality.

WILLIAM GIBSON,
D. MURRAY,
JOS. KENT.

Nov. 5th, 1823.

Baltimore, Nov. 6th, 1823.

Dear Sir,

I very much regret that the state of the weather, connected with that of my health, renders it unsafe for me to attend the cattle show to-day, for the purpose of delivering the address which I have prepared, at the request of the Trustees.

Please to express to them my sense of the distinction conferred on me by this request, and my hope that circumstances may be more favourable at the next meeting.

Thinking highly as I do of the benefits to be expected from this institution, I have seen its progress with great pleasure, and shall always be very happy to assist in promoting its success, by every mean in my power.

With great respect,

I have the honour to be, Dear Sir,

Your most obedient servant,

ROBT. G. HARPER.

GEN. RIDGELY.

Meridian Hill, Nov. 2d, 1823.

MY DEAR SIR,

It is a subject of sincere regret, that I have it not in my power to attend the Agricultural Exhibition, near Baltimore, agreeably to the invitation I have been honoured with, by the Trustees of the Maryland Agricultural Society, as the early departure of my Squadron from the United States, requires my immediate presence in Norfolk, where I shall arrive on the day that the meeting takes place; and the same reason will prevent my attending the meeting of the Delegates at Washington, in relation to the grand Union Canal.

The two subjects are such as are regarded by me with the most lively solicitude, and heightens my regrets that I should be deprived both of the pleasure of a participation in the proceedings of their respective friends, and of the opportunity which occasions to accept

* It has since been ascertained that this was made by Mr. Hamilton.

would afford me of shaking by the hand many friends and acquaintances which they will bring together.

With sentiments of great respect

Your obedient servant,

D. PORTER.

J. S. SKINNER, Esq. Cor. Sec. Ad. }
Agricultural Society. }

The various premiums having been delivered to the president, according to the preceding report—the Society dined together in the utmost harmony and cheerfulness, and finally separated with increased dispositions to persevere in the promotion of the objects of their association.

JAMES HOWARD,

Secretary.

Selections.

Method of tanning leather by the decoction of bark, &c.

In 1804 a patent was granted for an improved method of tanning hides: viz. by immersing them in the liquor in which oak bark had been boiled. According to this improvement, the patentees filled a boiler of copper (or any other metal that does not stain or colour the liquor) half full, with ground bark, and poured water upon it, up to the brim. The whole is then boiled for three hours, till the tanning principle is completely extracted. The liquor is then suffered to run off by a cock into pits, where it stands to cool. The hides are now put into the liquor, and handled frequently, by taking them out and putting them in again, because the liquor is too powerful for them to remain long at a time, in the first stages of tanning. They are then to be removed to fresh liquors, from time to time, as the old is weakened, until the operation is complete. By this method a greater quantity of the tanning principle is collected into a small compass; less bark is consumed; and there is a great saving of labour.

If leather is required with a whiter colour or bloom, a small quantity of the dust of bark is mixed with the liquor. By this method, hides that have been shaved in the baits may be better tanned in two or three weeks, and skins in ten or twelve days, than in the one case in nine months; and in the other in six months by the usual process.

Observations. Here, the great advantage is that derived from extracting the tanning principle, by means of boiling; as business to any extent may be carried on with about one tenth part of the capital employed on the old plan.

Besides bark, the patentees make use of oak chips, and oak saw-dust, they have succeeded with the common heath or heather; and they find that the bark of most trees that produce hard wood has a tanning principle in them; but above all, they recommend the young shoots from the roots of oaks, and the superfluous twigs or branches that may be lopt off, so as not to injure the trees. These when cut in proper season, may be chopped and ground, and boiled with bark, and will produce a stronger tanning liquor than bark from the trunks of trees that have a thick rind, which cannot be separated from the bark.

By another patent in 1819, the art of tanning by decoction is still further improved. This patentee has proved that the trunk, roots, limbs, branches, and leaves of the oak, whether tree, pollard, coppice, or underwood, possess tanning properties in a sufficient quantity to be employed with advantage for tanning, by reducing them to chips or saw-dust, and then boiling and using them in the following way:

To tan calf, or other thin skins, put one hundred weight of the limbs or branches, chopped as above mentioned, into a copper containing about sixty gallons of water, and boil, till the water be reduced to from thirty five to forty gallons; draw off the decoction.

Now add to the same limbs or branches forty gallons of water, and again boil till the water be reduced to about twenty-five gallons. The liquor thus produced by the second boiling is used as a weak ooze, in the first process of immersing the calf-skins, after they come from the scouring beam. The decoction first produced, is then to be used in the same way.

To tan hides, take one hundred weight of the limbs or branches, three-quarters of a hundred weight of oak saw dust, (the sooner the latter is used after being made the better,) and one-quarter of a hundred weight of the root, boil in eighty gallons of water, till reduced to from fifty to sixty gallons. Draw off the decoction, and put it aside for use. To the materials left in the copper add sixty gallons of water, and again boil, till reduced to from thirty to thirty-five gallons. The liquor produced by this second boiling is to be employed in the first stage of tanning hides after they come from the beam; and afterwards the decoction first produced is to be employed. The skins and hides having undergone the before-mentioned processes, add as much oak-bark or tan liquor, or both, to the respective decoctions, as is necessary to complete the tanning. The quantity of each will vary according to the strength of such decoctions; which strength will depend on the age and size of the tree, and other circumstances.

Conversion of sheep skins into leather.

Sheep skins which are used for a variety of purposes, such as gloves, book-covers, &c. and which when dyed, are converted into mock-morocco leather, are dressed as follows:—They are first to be soaked in water and handled, to separate all impurities, which may be scraped off by a blunt knife on a beam. They are then to be hung up in a close warm room to putrefy. This putrefaction loosens the wool, and causes the exudation of an oily and slimy matter, all which are to be removed by the knife. The skins are now to be steeped in milk of lime, to harden and thicken; here they remain for a month or six weeks, according to circumstances, and when taken out, they are to be smoothed on the fleshy side by a sharp knife. They are now to be steeped in a bath of bran and water, where they undergo a partial fermentation, and become thinner in their substance.

The skins, which are now called *pelts* are to be immersed in a solution of alum and common salt in water; in the proportion of 120 skins to 3 pounds of alum and 5 pounds of salt. They are to be much agitated in this compound saline bath, in order to become firm and tough. From this bath they are to be removed to another, composed of bran and water, where they remain until quite pliant by a slight fermentation. To give their upper surfaces a gloss, they are to be trodden in a wooden tub, with a solution of yolks of eggs in water, previously well beaten up. When this solution has become transparent, it is a proof that the skins have absorbed the glazing matter. The pelt may now be said to be converted into leather, which is to be drained from moisture, hung upon hooks in a warm apartment to dry, and smoothed over with warm hand-irons.

Observations. To prepare sheep leather for various elegant purposes, by dyeing; the skins, after being taken from the lime-bath, are to be immersed in another, composed of dog and pigeon dung dissolved by agitation in water; here

they remain until the lime is separated, and until the skins have attained the state of *soft pliable pelt*. To dye this pelt red, the skins are to be washed and sewed into bags, and stuffed with clippings and shavings of leather, or any other convenient substance, and immersed with the grain side outwards in a bath of alum and cochineal of the temperature of 170° or 180° Fahr. where they are to be agitated until they are sufficiently dyed. Each bag is now to be transferred to a sumach bath, where they receive consistency and tenacity. From this bath it is customary to remove the skins, and to plunge them into a saffron one, to improve their colour.

To dye these skins black, the washed pelt is to be first immersed in the sumach bath, and then to be rubbed over on the grained side, by a stiff brush dipped in a solution of acetate, or pyrolignite of iron.

To give these skins the grain and polish of morocco leather, they are first oiled, and then rubbed on a firm board by a convex piece of solid glass, to which a handle is attached. The leather being now rendered more compact, is rubbed or pressed hard, by a sharply grooved box-wood instrument, shaped like the glass one just described.

Lamb and kid skins are dressed, tanned, and dyed in a similar manner.

Manufacture of real Morocco Leather.

Goat skins are to be cleansed, have their hair removed, and to be limed as in the before-mentioned processes. They are then to undergo a partial fermentation by a bath of bran and water, and afterwards to be immersed in another bath of white figs and water, where they are to remain for five or six days. It is now necessary to dip them in a solution of salt and water, to fit them for dyeing. To communicate a red color, the alum and cochineal bath is to be used as for sheep-skins; for black, sumach, and iron liquor as before; and for yellow, the bath is to be composed of alum and the pomegranate bark.

The tanning, dressing, and graining are the same as for sheep skins.

Statement of Miss Julia Harrison's Grass Bonnet, which received the first premium at the New York Fair, October 1823, and was bought by Mr. John Leonard, at auction, for \$100.

11 days in preparing and cutting the straw
48 days in braiding the same
34 days in sewing the same
120 yards of braid in the hat
288,000 times turned or handed in braiding
286,000 separate stitches in sewing, which is
2,400 stitches in each yard
65 rows around the front
7 inches in the front
92-7 braids to the inch
13 straws in the braid
2½ yards is a day's work at braiding
4 do do do sewing

Directions for curing the Grass.

The grass for the above hat, known by the name of "Spear Grass," was cut on the 18th of June, while in a green state, the blow just dropping off—put in scalding water for five minutes; laid in the sun one day; scalded again in the same manner; laid in the sun and dew till it becomes perfectly dry, time about one week, taking care that no rain falls on it; then trim it; for this instance only the top joint was used; scald it in pearl ash water and soap suds five minutes; then smoked in brimstone till nearly dry; taken out and laid in the sun till perfectly dry, when it is fit for use.

N. B. Miss Harrison resides in North East, Dutchess county, N. Y.—*Evening Post.*

HORSE OINTMENT.

Into a clean pipkin, that holds about a quart, put the bigness of a pullet's egg, of yellow rosin; when it is melted over a middling fire, add the same quantity of bees wax; when that is melted, put in half a pound of hog's lard; when it is dissolved, put in two ounces of honey; when that is dissolved, put in half a pound of common turpentine—keep it gently boiling, and stirring with a stick all the time—when the turpentine is dissolved, put in two ounces of verdigrise, finely powdered, but before you put in the verdigrise, you must take off the pipkin, (else it will rise into the fire in a moment,) set it on again, and give it two or three stirrings, then strain it through a coarse sieve into a clean vessel for use, throw away the dregs. This is an extraordinary ointment for wound or bruise in flesh, or hoof, broken knees, galled backs, bites, cracked heels, mallenders, or when you cut a horse, to heal and keep the flies away, nothing takes fire out of a burn or scald so soon.

HORSE MEDICINE.

½ oz. Crocus Metulorum

½ oz. Phenegreck Seed

½ oz. Salt Petre

½ oz. Sulphur.

One dose, and excellent for a horse in any situation.

INFALLIBLE CURE FOR THE TOOTH ACHE.

½ lb. best pale Peruvian bark finely powdered

1 pint old 4th proof French brandy

1 pint of rose water

1 pint pure water.

Mix, and after 24 hours it is fit for use.

For severe tooth ache, add ½ more brandy in proportion to any given quantity of the above, which hold in the mouth 5 minutes.

The above will preserve the teeth and gums from disease, and cure when already diseased.—It should be used every morning with a tooth brush.

INDIAN CORN.

It is remarked by our Farmers generally, since they began to "husk and lof" their corn, that there is a greater proportion of defective corn than usual; much greater, and all agree now that we can have too much rain, even in August, for Indian corn.—The crop, thank God! is a good one, but not extraordinary.—*Easton Gazette.*

Editorial Correspondence.

Extract of a letter to the Editor, dated Beattie's Ford, Lincoln County, N. C.

"Will you inform me Sir, whether I can make an arrangement with the patentees of different kinds of improved ploughs, and other implements of farming, so as to have them made for sale in this county? Also which are esteemed the best? We have several Iron works, and a number of excellent mechanics in this county—and I think, could make such implements well, and circulate them extensively."

Patentees of ploughs interested in the above enquiry, would do well to address themselves by letter, to J. F. Brevard, Secretary of the Lincoln County Agricultural Society, Beattie's Ford, N. Carolina.—*Edif. Am. Far.*

B. HARWOOD, Tr. W. S. M.

THE FARMER.

BALTIMORE, FRIDAY, NOVEMBER 14, 1823.

The proceedings of the Maryland Agricultural Society, have occupied in this number, much more space than we had anticipated—to the exclusion of many articles, which we could have wished to present to our readers this week. We have on hand, accounts of proceedings of the Agricultural Societies in Pennsylvania and Virginia—for the success of which, we feel on every account, the most friendly solicitude.—The first opportunity will be embraced to do justice to their zeal and usefulness.

The next meeting of the trustees of the Maryland Agricultural Society, is appointed for Wednesday the 17th day of December, at "The Mount," the residence of James Carroll, Jr. Esq. on the Washington road—there will be much business of importance to engage their attention, and it is desired that the members attend punctually at ten o'clock, A. M.

The young bull Pilgrim, now called Wye Comet, which gained the highest premium offered for a bull under two years old, was sold on the spot, by his liberal owner Col. Lloyd, for \$250, to Col. J. H. Powell of Pennsylvania.—This, under all circumstances may be considered a very low price, as an animal of the like good blood and fine points cannot now be obtained from England, for less than \$600—his sire was recently sold there by Mr. Champion, for 150 guineas.

AN AGRICULTURAL SOCIETY has been formed in Lincoln county, N. C. which promises to be of great public utility. The respectability and intelligence of its officers, as well as its objects, give assurance of such a result.—They consist of,

DANIEL M. FORNEY, *President*,
PETER HOYT, *1st Vice President*,
JOHN HOKE, *2d Vice President*,
JACOB FORNEY, *Treasurer*, and
J. F. BREVARD, *Secretary*.

Agency at Baltimore.

WILLIAM PORTER, No. 44, South-street, Baltimore, informs his friends, and the public generally, that he offers to transact business as agent to collect house and ground rents, annuities, open accounts, &c. also to settle and collect for deceased estates. He will attend promptly to any orders such persons may have, and generally in the performance of all duties or services wherein the aid of an agent may be convenient or useful. For a knowledge of the despatch and fidelity with which he has acted as agent, he confidently refers to all those for whom he has done business, and among them to Messrs. Gales and Seaton, of Washington City, Isaac Munroe, H. Niles, J. S. Skinner, (Postmaster) Esq's, of Baltimore, &c. &c.

N. B. All letters, by mail, post paid, will be attended to.

*Office of the National Intelligencer,
Washington, June 30, 1823.*

Mr. WM. PORTER has been our agent at Baltimore for three years, and has uniformly shewn himself vigilant of our interests, prompt, and faithful. We have pleasure in recommending him to our friends who have business to transact in Baltimore.

GALES & SEATON.

FOR SALE,

On the 29th of this month, at 2 o'clock, P. M. at the sign of the *Golden Horse*, kept by *William Frame*, the celebrated turf horse, YOUNG HICKORY; he is a dark bay, sixteen hands high, twelve years old, and of sufficient strength to carry the New York weight. He was sired by old Hickory, whose pedigree and performance is so well known that it is not necessary to mention much of it, with the exception that he beat Gen. Ridgley's horse Post Boy at the City of Washington, and was purchased by Bela Badger for \$2500; young Hickory's dam, Yellow Diomed, was got by Diomed, who was a descendant of the old Eclipse of England. When two years and an half old, he was trained with the Durock by Bela Badger, and could always lead him; but he was obliged to put a man on him that was too heavy, and he sprained his shoulder, but has got completely well.—A further description will be given at the time of sale.

N. B. Any gentleman that would wish to see his speed tried before purchasing, that will furnish a fast horse, and a good rider for Hickory, shall be gratified, by way of proof, but not for wager, as I am not in that line of business.

JOSEPH KERSEY.

Downingtown, 11 mo. 17th, 1823.

Printed every Friday at \$4 per annum, for JOHN S. SKINNER, Editor, by JOSEPH ROBINSON, on the North West corner of Market and Belvidere streets, Baltimore: where every description of Book and Job Printing is executed with neatness and despatch.—Orders from a distance for PRINTING or BINDING, with proper directions promptly attended to, addressed to J. Robinson, Baltimore.

Internal Improvements.

We have found in this paper sufficient space to make record of Mr. Calhoun's valuable Report which has been some months on our files, of a plan for the application of such means as are within the power of Congress for the purpose of opening and constructing such roads and canals, as may deserve and require the aid of government, with a view to military operations in time of war; the transportation of munitions of war; and also, a statement of the works of the nature abovementioned, which have been commenced, the progress which has been made, and the means and prospect of their completion; and, together with such information, as in the opinion of the Secretary, shall be material in relation to the objects of the resolution.

It will be seen that this great question for national consideration, loses none of its intrinsic importance in the hands of Mr. C. His reflections on the means of accomplishment, and the advantages to be secured, are clearly and eloquently exposed, and the public feeling in regard to internal improvements, is now in a condition to appreciate and take advantage of all the light that can be cast upon the subject.

To what extent the powers of the General Government are adequate to the execution of great public works of this character, with or without the consent of the states most immediately interested, is still a matter of doubt and disputation. We propose, as we can find room, to insert a few of the leading arguments on both sides of the question; because, independently of the fact that "Internal Improvements" have always constituted a distinct and avowed portion of the plan of this Journal, it must be seen that every measure which facilitates in any degree the means of intercourse and transportation, must have, in itself, a direct bearing on the interests of agriculture, and the value of real property.—*Edit. Am. Far.*

Report of the Secretary of War, relative to Roads and Canals, in pursuance of a Resolution of the House of Representatives, of the 4th April last.

Department of War, January, 7th, 1819.

Sir,

In compliance with a resolution of the House of Representatives of the 4th of April, 1818, instructing the Secretary of War, to report to that House at their next session "a plan for the application of such means, as are within the power of Congress, for the purpose of opening and constructing such roads and canals, as may deserve and require the aid of government, with a view to military operations in time of war; the transportation of munitions of war; and also, a statement of the works of the nature abovementioned, which have been commenced, the progress which has been made, and the means and prospect of their completion; and, together with such information, as in the opinion of the Secretary, shall be material in relation to the objects of the resolution;" I have the honor to make the following

REPORT:

A judicious system of roads and canals, constructed for the convenience of commerce, and the transportation of the mail only, without any reference to military operations, is itself, among the most efficient means for "the more complete defence of the United States." Without adverting to the fact, that the roads and canals, which such a system would require, are, with few exceptions, precisely those, which would be required for the operations of war; such a

system, by consolidating our Union, increasing our wealth and fiscal capacity, would add greatly to our resources in war. It is in a state of war, when a nation is compelled to put all of its resources in men, money, skill, and devotion to country into requisition, that its government realizes, in its security, the beneficial effects from a people made prosperous and happy by a wise direction of its resources in peace. But I forbear to pursue this subject, though so interesting, and which the farther it is pursued, will the more clearly establish the intimate connexion between the defence and safety of the country, and its improvement and prosperity, as I do not conceive that it constitutes the immediate object of this report.

There is no country to which a good system of military roads and canals is more indispensable, than to the United States. As great as our military capacity is, when compared with the number of our people, yet when considered in relation to the vast extent of our country, it is very small; and if so great an extent of territory renders it very difficult to conquer us, as has frequently been observed, it ought not to be forgotten, that it renders it no less difficult for the government to afford protection to every portion of the community. In the very nature of things, the difficulty of protecting every part, so long as our population bears so small a proportion to the extent of the country, cannot be entirely overcome, but it may be very greatly diminished, by a good system of military roads and canals. The necessity of such a system is still more apparent, if we take into consideration the character of our political maxims and institutions. "Opposed in principle to a large standing army, our main reliance for defence, must be on the militia, to be called out frequently from a great distance, and under the pressure of an actual invasion. The experience of the late war, amply proves in the present state of our internal improvements, the delay, the uncertainty, the anxiety, and exhausting effects of such calls. The facts are too recent to require details, and the impression too deep to be soon forgotten." As it is the part of wisdom to profit by experience, so it is of the utmost importance to prevent a recurrence of a similar state of things, by the application of a portion of our means, to the construction of such roads and canals, as are required "with a view to military operations, in time of war, the transportation of the munitions of war, and more complete defence of the United States."

In all questions of military preparations, three of our frontiers require special attention; the eastern or Atlantic frontier; the northern, or the Canadian frontier, and the southern, or the frontier of the Gulf of Mexico. On the west and northwest, we are secure, except against Indian hostilities; and the only military preparations required in that quarter, are such as are necessary to keep the Indian tribes in awe, and to protect the frontier from their ravages. All of our great military efforts, growing out of a war with an European power, must for the present be directed towards our eastern, northern, or southern frontiers; and the roads and canals, which will enable the government to concentrate its means for defence, promptly and cheaply, on the vulnerable points of either of those frontiers, are those, which, in a military point of view, require the aid of the government. I propose to consider each of those frontiers separately, beginning with the Atlantic which in many respects is the weakest and most exposed.

From the mouth of the St. Croix, to that of the St. Mary's, the two extremes of this frontier, is a distance along the line of the coast

and principal bays, without following their sinuosities, of about two thousand one hundred miles. On this line, including its navigable rivers and bays, are situated our most populous cities, the great depots of the wealth and commerce of the country. That portion of it, which extends to the south of the Chesapeake, has, with the exceptions of the cities and their immediate neighbourhood, a sparse population, with a low marshy country, extending back from 100 to 150 miles. To the north of the Chesapeake inclusive, it affords every where, deep and bold navigable bays and rivers, which readily admit vessels of any size. Against a line so long, so weak, so exposed, and presenting such strong motives for depredations, hostilities the most harassing and exhausting, may be carried on by a naval power, and should the subjugation of the country ever be attempted, it is probable that against this frontier facing Europe, the seat of the great powers of the world, the principal efforts would be turned. Thus circumstanced, it is the duty of the government to render it as secure as possible. "For much of this security, we ought to look to a navy, and a judicious and strong system of fortifications; but not to the neglect of such roads and canals, as will enable the government to concentrate promptly and cheaply, at any point, which may be menaced, the necessary force and means for defence."

To resist ordinary hostilities, having for their object the destruction of our towns, and the exhaustion of our means, the force ought to be drawn from the country lying between the coast and the sources of the principal rivers, which discharge through it into the ocean; but to resist greater efforts, aiming at conquest, should it ever be attempted, the force and resources of the whole community, must be brought into resistance. To concentrate then, a sufficient force on any point of this frontier, which may be invaded, troops must be marched, and munitions of war transported, either along the line of the coast, or from the interior of the Atlantic states, to the coast; or should the invading force be of such magnitude, as to require it, from the western states; and the roads and canals necessary for the defence of this frontier, are those which will render these operations prompt, certain, and economical.

From the coast to the Alleghany mountains and the high land separating the streams which enter into the St. Lawrence, from those of the Atlantic, in which the principal Atlantic rivers take their rise, the distance may be averaged at about 250 miles; and the whole extent from the St. Marys to the St. Croix, is intersected, at short intervals, by large navigable rivers, and the principal roads of this portion of our country, through which its great commercial operations are carried on. These, aided by the steam boats, now introduced on almost all of our great rivers, present great facilities to collect the militia from the interior; and to transport the necessary supplies and munitions of war.

Much undoubtedly remains to be done to perfect the roads and improve the navigation of the rivers, but this for the most part, may be safely left to the states, and the commercial cities particularly interested, as the appropriate objects of their care and exertions. The attention of both have recently been much turned towards these objects, and a few years will probably add much to facilitate the intercourse between the coast and the interior of the Atlantic states. Very different is the cause with the great and important line of communication extending along the coast, through the Atlantic states

No object of the kind is more important; and there is none to which state, or individual capacity, is more inadequate. It must be perfected by the general government, or not to be perfected at all, at least for many years. No one or two states have a sufficient interest. It is immediately beneficial to more than half of the states of the Union, and without the aid of the general government, would require their co operations. It is at all times, a most important object to the nation; and, in a war with a naval power, is almost indispensable to our military, commercial, and financial operations. It may, in a single view, be considered the great artery of the country; and when the coasting trade is suspended by war, the vast intercourse between the north and south, which annually requires five hundred thousand tons of shipping, and which is necessary to the commerce, the agriculture and manufacture of more than half of the union, seeks this channel of communication. If it were thoroughly opened by land and water; "if Louisiana were connected by a durable and well finished road with Maine; and Boston with Savannah, by a well established line of inland navigation, for which so many facilities are presented, more than half of the pressure of war would be removed." A country so vast in its means, and abounding in its various latitudes with almost all of the products of the globe, is a world of itself; and with that facility of intercourse, to perfect which, the disposable means of the country is adequate, would flourish and prosper under the pressure of war with any power. But dropping this more elevated view, and considering the subject only as it regards "military operations in time of war, and the transportation of the munitions of war," what could contribute so much as this communication to the effectual and cheap defence of our Atlantic frontier? Take the line of inland navigation along the coast, the whole of which it is estimated, could be completed for sea vessels by digging one hundred miles, and at the expense of \$3,000,000, the advantage which an enemy with a naval force now has, by rapidly moving along the coast, and harassing and exhausting the country, would be in a great measure lost to him. In fact, the capacity for rapid and prompt movements and concentration, would be to the full, as much in our power. We would have, in most of the points of attack, a shorter line to move over, in order to concentrate our means; and, aided by steam boats, would have the capacity to pass it in a shorter time, and with greater certainty, than what an enemy, even with a naval superiority, would have, to attack us. Suppose the fleet of such an enemy should appear off the capes of Delaware, before it could possibly approach and attack Philadelphia, information by telegraphic communication, might be given to Baltimore and New York, and the forces stationed there thrown in for its relief. The same might take place if Baltimore or New York should be invaded; and should an attack be made on any of our cities, the militia and regular forces at a great distance along the coast, could, in a short time, be thrown in for its relief. By this speedy communication, the regular forces, with the militia of the cities and their neighbourhood, would be sufficient to repel ordinary invasions, and would either prevent, or greatly diminish, the harassing calls upon the militia of the interior. If to these considerations we add the character of the climate of the southern position of the Atlantic frontier, so fatal to those whose constitutions are not inured to it, the value of this system of defence, by the regular troops and the militia accustomed to

the climate, will be greatly enhanced. Should this line of inland navigation be constructed, to enjoy its benefits fully, it will be necessary to cover it against the naval operations of an enemy. It is thought that this may be easily effected to the south of the Chesapeake, by land and steam batteries. That bay is itself one of the most important links in this line of communication, and its defence against a naval force ought, if practicable, to be rendered complete. It was carefully surveyed the last summer by skillful officers, for this purpose in part, and it is expected that their report will throw much light upon this important subject. Long Island Sound, another part of the line which is exposed, can be fully defended by a naval force only.

It remains in relation to the defence of the Atlantic frontier, to consider the means of communication between it and the western states, which require the aid of the government. Most of the observations made relative to the increased strength and capacity of the country, to bear up under the pressure of war, from the coastwise communication, are applicable in a high degree at present, and are daily becoming more so, to those with the western states; and should a war for conquest ever be waged against us, an event not probable, but to be laid entirely out of view, the roads and canals necessary to complete the communication with that portion of our country, would be of the utmost importance.

The interest of commerce and the spirit of rivalry between the great Atlantic cities, will do much to perfect the means of intercourse with the west. The most important lines of communication appear to be from Albany to the lakes, from Philadelphia, Baltimore, Washington, and Richmond, to the Ohio river, and from Charleston and Augusta, to the Tennessee, all of which are now commanding the attention, in a greater or less degree, of the sections of the country immediately interested. But in such great undertakings, so interesting in every point of view to the whole union, and which may ultimately become necessary to its defence, the expense ought not to fall wholly on the portions of the country more immediately interested. As the government has a deep stake in them, and as the system of defence will not be perfect without their completion, it ought at least to bear a proportional share of the expense of their construction.

I proceed next to consider the roads and canals connected with the defence of our northern frontier. That portion of it which extends to the east of lake Champlain, has not heretofore been the scene of extensive military operations, and I am not sufficiently acquainted with the nature of the country, to venture an opinion whether we may hereafter be called on to make considerable military efforts in that quarter. Without, then, designating any military improvements as connected with this portion of our northern frontier, I would suggest the propriety, should Congress approve of the plan, for a military survey of the country to be hereafter proposed to make a survey of it the duty of the engineers, who may be designated for that purpose.

For the defence of the other part of this line of frontier, the most important objects are, a canal or water communication between Albany and lake George, and lake Ontario, and between Pittsburg and lake Erie. The two former have been commenced by the state of New York, and will, when completed, connected with the great inland navigation along the coast, enable the government, at a moderate expense and in a short time, to transport munitions of war, and to concentrate its troops from any portion of the At-

lantic states, fresh and unexhausted by the fatigue of marching on the inland frontier of the state of New York. The road commenced by order of the executive from Plattsburg to Sackett's Harbor, is essentially connected with military operations on this portion of the northern frontier. A water communication from Pittsburg to lake Erie, would greatly increase our power on the upper lakes. The Alleghany river, by its main branch, is said to be navigable within seven miles of lake Erie, and by French Creek, within sixteen miles. Pittsburg is the great military depot of the country to the west of the Alleghany, and if it were connected by a canal with lake Erie, would furnish military supplies with facility, to the upper lakes, as well as to the country watered by the Mississippi. If to these communications, we add, a road from Detroit to Ohio, which has already been commenced, and a canal from the Illinois river to lake Michigan, which the growing population of the state of Illinois, renders very important, all of the facilities which would be essential "to carry on military operations in time of war, and the transportation of the munitions of war" for the defence of the western portion of our northern frontier would be afforded.

It only remains to consider the system of roads and canals connected with the defence of our southern frontier, or that on the Gulf of Mexico. For the defence of this portion of our country, though at present weak of itself, nature has done much. The bay of Mobile, and the entrance into the Mississippi through all of its channels, are highly capable of defence. A military survey has been made, and the necessary fortifications have been commenced and will be in a few years completed. But the real strength of this frontier is the Mississippi, which is no less the cause of its security, than that of its commerce and wealth. Its rapid stream, aided by the force of steam, can, in the hour of danger, concentrate at once, an irresistible force. Made strong by this noble river, little remains to be done by roads and canals, for the defence of our southern frontier. The continuation of the road along the Atlantic coast, from Milledgeville to New Orleans, and the completion of the road which has already been commenced from Tennessee river to the same place, with the inland navigation through the canal of Carondelet, lake Ponchartrain, and the islands along the coast to Mobile, covered against the operations of a naval force, every facility required for the transportation of munitions of war, and movements and concentration of troops, to protect this distant and important frontier, would be afforded.

Such are the roads and canals, which military operations in time of war, the transportation of the munitions of war, and the more complete defence of the United States, require.

Many of the roads and canals which have been suggested, are no doubt of the first importance to the commerce, the manufacture, the agriculture, and political prosperity of the country, but are not for that reason, less useful or necessary for military purposes. It is in fact, one of the great advantages of our country, enjoying so many others, that whether we regard its internal improvements in relation to military, civil, or political purposes, very nearly the same system, in all its parts, is required. The road or canal can scarcely be designated, which is highly useful for military operations, which is not equally required for the industry or political prosperity of the community. If those roads or canals had been pointed out, which are necessary for military purposes only, the list would have been small indeed. I have, therefore, presented all,

without regarding the fact, that they might be employed for other uses, which, in the event of war, would be necessary to give economy, certainty, and success, to our military operations; and which, if they had been completed before the late war, would, by their saving in that single contest, in men, money, and reputation, more than indemnified the country for the expense of their construction. I have not prepared an estimate of expenses, nor pointed out the particular routes for the roads or canals recommended, as I conceive that this can be ascertained with satisfaction only by able and skilful engineers, after a careful survey and examination.

I would, therefore, respectfully suggest, as the basis of the system, and the first measure in the plan for the application of such means as are in the power of Congress, that Congress should direct such a survey and estimate to be made, and the result to be laid before them as soon as practicable. The expense would be inconsiderable, for, as the army can furnish able military and topographical engineers, it would be principally confined to the employment of one or more skilful civil engineers to be associated with them. By their combined skill, an efficient system of military roads and canals would be presented in detail, accompanied with such estimates of expenses, as may be relied on.— Thus, full and satisfactory information would be had; and though some time might be lost in the commencement of the system, it would be more than compensated by its assured efficiency when completed.

For the construction of the roads and canals, which Congress may choose to direct, the army, to a certain extent, may be brought in aid of the monied resources of the country. The propriety of employing the army on works of public utility cannot be doubted. Labour adds to its usefulness and health. A mere garrison life, is equally hostile to its vigor and discipline. Both officers and men become the subjects of its deleterious effects. But when the vast extent of our country is compared with the extent of our military establishment, and taking into consideration the necessity of employing the soldiers on fortifications, barracks, and roads, connected with remote frontier posts, we ought not to be sanguine in the expectation of aid to be derived from the army in the construction of permanent military roads and canals, at a distance from the frontiers. When our military posts come to be extended up the Mississippi and Missouri, as far as is contemplated, the military frontier of the United States, not including sinuities, and the coasts of navigable bays and lakes opening into our country, as was stated in a former report, will present a line of more than 9,000 miles, including them, of more than 11,000. Thinly scattered along so extensive a frontier, it will be impossible, I fear, without leaving some points exposed to collect any considerable bodies in the interior of the country, to construct roads and canals.

As connected with this subject, I would respectfully suggest the propriety of making an adequate provision for the soldiers, while regularly and continually employed in constructing works of public utility. The present allowance is fifteen cents a day, which is considered sufficient in occasional fatigue duty, such as is now done at most of the posts; but if systematic employ, on permanent works, should be made the regular duty of the soldiers, who can be spared for that purpose, a compensation, taking into the estimate the obligation of the government to provide medical attendance and pensions to the diseased and disabled soldiers, not much short of the wages of daily labour ought to be

granted to them. Without such provision, which is dictated by justice, an increase of desertion and difficulty in obtaining recruits, ought to be expected. Among the leading inducements to enlist, is the exemption from labor; and if the life of a soldier should be equally subjected to it, as that of other citizens in the same grade, he will prefer, if the wages are much inferior, to labor for himself, to that of laboring for the public. The pay of a soldier is sixty dollars per annum; and if he were allowed, when employed permanently on fatigue, 25 cents a day, and suppose him to be employed 200 days in the year, his compensation, including his pay, would be \$110 per annum, a sum, it is thought, considerably short of the average wages of labor. If this sum should be allowed, the greater portion of it ought to be paid at the expiration of the term of enlistment. If fifteen cents a day were so reserved, and the soldier should be employed one thousand days in the five years for which he is enlisted, it would constitute a sum of one hundred and fifty dollars, to be paid at the expiration of his term, which ought, in the same manner as the bounty land, be made to depend on an honorable discharge. This would furnish an important hold on the fidelity of the soldier, and would be a powerful check to the great and growing crime of desertion. An honourable discharge is now worth but little to the soldier, and the consequence is, that desertions are more frequent with those enlisted since the war, than those who were then enlisted, and are entitled to the bounty in land on their honourable discharge. The latter patiently waits the expiration of his term of service, while the former frequently seizes the first favourable opportunity for desertion.

Should Congress think proper to commence a system of roads and canals for the "more complete defence of the United States," the disbursements of the sums appropriated for the purpose might be made by the Department of War, under direction of the President. Where incorporate companies are already formed, or the road or canal commenced under the superintendence of a state, it perhaps would be advisable to direct a subscription on the part of the United States, on such terms and conditions as might be thought proper. In other cases, and where the army cannot be made to execute it, the work ought to be done by contract under the superintendence and inspection of officers of the engineering corps to be detailed for that purpose. It is thus the government will be able, it is thought, to construct on terms at least as favorable as corporate companies. The system of constructing all public works, which admit of it, by contract, would be attended with important advantages.— It has recently been adopted in the construction of fortifications, and it is expected will be attended with beneficial effects. The principal works at Mobile and New Orleans have been contracted for on terms considerably under the estimates of the engineers. With such a system extended to military roads and canals, combined with a careful inspection and superintendence by skilful engineers, will enable the government to complete them with economy, durability, and despatch.

In the view which has been taken, I have thought it improper under the resolution of the House, to discuss the constitutional question, or how far the system of internal improvements which has been presented, may be carried into effect, on the principles of our government; and, therefore, the whole of the arguments which are used, and the measures proposed, must be considered as depending on the decision of that question.

The only military roads which have been commenced, are from Plattsburg to Sackett's Harbor, through the Chataugay country; from the southern boundary of the state of Tennessee, and crossing the Tennessee river, near the Muscle Shoals, to Madisonville, Louisiana; and from Detroit to fort Meigs, at the foot of the Rapids of the Miami of the Lakes. Documents marked A, B, C, show the progress which have been made. These roads have been commenced, and thus far completed, by the labor of the soldiers, who, while they are so employed, receive fifteen cents per day, with an extra allowance of a gill of whiskey. The labor of the troops is the only means within the reach of the Department of completing these roads; and as the troops are so employed, only when they are not engaged in active service, it is impossible to state, with accuracy, when the roads will be completed.

J. C. CALHOUN.

The Hon. HENRY CLAY,
Speaker of the House of Representatives.

AGRICULTURE.

EXTRACTS

FROM MORE MODERN WRITERS ON THE USE OF SALT IN AGRICULTURE.—No. IV.

A letter from a very considerable North American planter to the Editor of the Museum Rusticum, respecting the great benefit of salt to cattle, with the method of using it.

GENTLEMEN,

I do not find that the farmers in England know the great advantages which may be derived from the use of salt in the business of fattening cattle; whereas, in America, we think it in a manner absolutely necessary, and accordingly give it to almost every kind of cattle; and those with parted hoofs are particularly fond of it.

Horses are as fond of salt as black cattle; for with us, if they are ever so wild, they will be much sooner brought to a handful of salt than any kind of corn whatever. We also give salt to our sheep. To this practice of feeding with salt, it is generally ascribed, that the American cattle in general are so much more healthy than the same animals in England: certain it is, that they are there subject to much fewer diseases. There is one very advantageous practice we have, which I cannot enough recommend to the notice of the farmers here in England: it is mixing salt with our hay-ricks when we stack it, which we call *brining*.

Just before I left America, I had a crop of hay, which was in a manner spoiled by rain, being almost rotted in the fields; yet did this hay spend as well as if it had been got in ever so favourably. When my servants were making up the stack, I had it managed in the following manner: that is, as soon as a bed of hay was laid about six inches thick, I had the whole sprinkled over with salt; then another bed of hay was laid, which was again sprinkled in like manner; and this method was followed till all the hay was stacked.

When the season came for cutting this hay, and giving it to my cattle, I found that so far from refusing it, they ate it with surprising appetite, always preferring it before the sweetest hay, that had not in this manner been sprinkled with salt. I have, in North America, some very considerable plantations; but having been for some time in England, I dedicate all my leisure hours to the study of agriculture, and have regularly, since the first publication, taken in the numbers of the *Museum Rusticum*, with which I cannot but in justice declare myself perfectly well satisfied; and am of opinion

will be of great service, not in England only, but in America also.

I am, Gentlemen,
Your constant reader,
AMERICANUS.

London, May the 14th, 1764.
From the *Museum Rusticum et Commerciale*,
LONDON, 1764.

"After draining a piece of sour russy ground, about the middle of October, some refuse salt was spread upon a part of the land, after the rate of eight bushels to the acre, and in another part sixteen bushels. In a short time the vegetation disappeared totally; and during the month of April following, not a blade of grass was to be seen. In the latter end of the month of May, a most flourishing crop of rich grass made its appearance on that part where the eight bushels had been laid. In the month of July, the other portion produced a still stronger crop; the cattle were remarkably fond of it, and during the whole ensuing winter, (which is ten or twelve years since) and to this day, the land retained, and yet exhibits, a superior verdure to the neighbouring closes.

"A gentleman lately carried a small quantity of couch-grass roots and other rubbish harrowed off his land to the Salt Works, and laid it for some time upon the ground, where the foul salt, by the direction of the officer, is destroyed; he then carried it back, and mixed it with other manure. His barley and his hay-grass were strong from this composition, beyond his most sanguine expectations.

"Its effects on fallow-land are equally advantageous. By sowing it at the time of breaking up the lands for a fallow, its strong saline quality destroys vegetation and every noxious insect: but by being mixed sufficiently with the soil before the wheat is sown, it adds a strong nutriment, and ensures the best of crops." Dr. Holland's *Agricultural survey of the county of Cheshire*.

The following impressive expostulation is said to be from the pen of the Right Honorable Lord Erskine.

"The science of agriculture is by no means at its height; and in the almost miraculous advance of chemistry, new means may be found from the concentration of known composts, and the discovery of new, to lessen the cost of culture, and to increase its returns. But here again, your revenue stalks like a ghost across my path which ever way I turn; as otherwise you have a superior unbounded source of improvement trodden under your very feet, and cast as refuse into your rivers, beyond all that chemistry is ever likely to discover. You have SALT in endless abundance, but your necessity turns it into money, even to forty times its value, instead of spreading it abroad for various uses to rise up in property which no money could purchase.

"Do you know what salt alone would do for you? Can you be so ignorant as not to know, that by taking the tax upon it *directly as money*, you rob yourselves of fifty times its amount in the production of your soil, in your fisheries and manufactures, and in the universal prosperity of the country?

"Lime, which has caused to start into life the most inert and sterile parts of Great Britain, is just nothing as a manure when compared with SALT, which differs from it besides in two remarkable qualities decisive of its superior value.

"Lime, and I believe all other known composts, are powerful only according to the quantities in which they are used; whereas salt to be useful must be sparingly applied; it corrupts

vegetable substances when mixed with them in small quantities, but preserves them when it predominates in a mass. It is needless, therefore, to add, that, independently of its comparative lightness, the expense both of the article and its carriage must be very greatly diminished. Yet you rob the mother of your people of this food which indulgent nature has cast into her lap, sufficient, as you will see hereafter, to feed all her children, even if their numbers were doubled." *Armata*, part i. page 169.

"Salt answers best as a manure for green crops, especially for turnips and clover. It is not of much benefit to barley or wheat, if sown; but in compost it proves very advantageous; using thirty Cornish or forty-five Winchester bushels per Cornish acre, which is larger than the statute acre, nearly in the ratio of six to five. Prepare the ground for turnips, and sow the salt a fortnight before the seed, or longer, if a larger quantity of salt is used.

Mr. Seckler, at Herver, in the parish of Gwinear, has just applied salt in the above proportion to poor exhausted land; being clay, inimical to turnips: the effect has been a heavy, rich crop, which I have had an opportunity of seeing. It is such a one as a hundred tons of dung per acre would scarcely produce in the same land. The salt employed is that which is considered refuse, after having cured the fish, and been condemned by the excise. Over this they throw some dirt, and it is then sold to the farmers by the fish curers. If the duty were taken off salt, for every bushel now used, there would be at least a hundred bushels employed for this purpose. It has been said that the value of refuse salt, as manure, depends upon the soil and animal matter which adheres to it; but the farmer knows from experience, that salt is to be preferred which has cured only one bulk of fish; and they give a higher price for it than for that which has been twice employed, and which consequently contains more animal matter. Where an estate has been salted for two or three crops, the effects are visible for at least seven years. It has a particular tendency to convert poor and light soils into firm and adhesive ones, 'giving them body.' Among the farmers there is a general scramble for the refuse salt, to try who can get most of it by purchase.

The following curious anecdote may be related as serving to illustrate the effect of salt: Mr. Seckler made a little heap of earth in the midst of a field, on the top of which a cart load of refuse salt was thrown; the earth in the heap itself, and (after its removal) the earth under it, for upwards of two feet deep to the clay, was rendered so perfectly barren, that the most common weeds would not vegetate in it. This barren earth, however, furnished the richest dressing for the remainder of the field. Mr. Seckler found salt the best preservative against the mildew in wheat. When the wheat followed turnips with salt, it escaped the mildew which attacked other fields which were not salted; and this he finds to hold universally good, as far as his experience goes. The improvement of bad hay, by salt applied in the proportion of about one hundred weight* to three tons, and sprinkled between the layers, is very striking, preventing mildew, and rendering it more grateful and beneficial to cattle, especially if the hay is bad; and even in good hay it is very greatly ameliorated. A testimony in favour of the benefit of salt is furnished by the striking fertility of the land in the neigh-

* This is foul fishery salt; of pure salt, a third of the quantity might be sufficient.

bourhood of the sea-shore in Cornwall; more especially in those situations which are favourable to the general distribution of the saline spray, as is exemplified in the parish of Fenor." Sir Thomas Bernard's *case of the Salt Duties*, page 272, communicated by Dr. Paris, *late of Penzance*, but now of Dover Street, London.

"Notwithstanding the excessive duty, numerous experiments have been made, and almost invariably with uniform success. An interesting detail from the Rev. E. Cartwright will be found in the fourth volume of communications to the Board of Agriculture, which is conclusive, as to the application of salt as a manure for potatoes. It appears from this communication, that the experiment could not have been tried on a soil better adapted to give impartial results. Of ten different manures which were resorted to, most of them of known and acknowledged efficacy, one only excepted, salt was superior to them all. Its effects, when combined with soot, were extraordinary, yielding in a row two hundred and forty potatoes, whilst one hundred and fifty only were produced from the row manured with lime. It was observable also, where salt was applied, whether by itself or in combination, the roots were free from that scabiness which often infects potatoes, and from which none of the other beds (and there were in the field near forty more than made part of the experiments) were altogether exempt. And in Dr. Holland's *Agricultural Survey of the county of Chester* are clearly shown the good effects resulting from its use on grass lands, and as a manure for wheat and barley. In the twenty-seventh volume of the *Annals of Agriculture*, there is a communication from Davies Giddy, Esq. of some interesting experiments on the use of salt in the culture of turnips; by which it appears, that on a part of a field, which had been previously exhausted, half a crop of turnips was produced; but the crop totally failed in that part of the field where the ordinary manure was laid *without* salt. In another instance, three acres of land, which on the preceding year had borne a crop of wheat, not exceeding twelve bushels on an acre, were ploughed before Christmas, and brought into fine tilth by the midsummer following. On each acre were sown twenty bushels of salt, excepting that two ridges towards the middle of the field were purposely left without it; on these two ridges the turnips totally failed; but the remainder of the field produced a plentiful crop. It is farther instanced, that four acres of land, completely worn out by successive tillage, were ploughed before Christmas; three acres were sown with salt, at the rate of twenty-five bushels, and the remaining acre with eighteen bushels, without any other manure; the crop was in general a good one, but was visibly the best where the greatest quantity of salt had been used. Crops of turnips were subsequently raised with equal success; and in the severe winter of 1794-5, it was much less injured by the frost than others similarly treated and cultivated in the common way."—*Letter to the Right Hon. Nicholas Vansittart*, by William Horne, Esq.—page 7.

(To be continued.)

FOR THE AMERICAN FARMER.

MR. SKINNER,

Various lucubrations have occasionally appeared in your valuable paper, on the subject of a modification of the Tariff; in which it is unfortunately considered merely as a manufacturing question. It is impossible to conceive of a much

greater error. The languor and depression which pervade our country, almost universally owe their origin to this error: And until our statesmen regard it as a national question, as it truly is, and as it is regarded by all the wise statesmen of the old world, we shall never taste that high degree of prosperity, to which our immense natural, moral, and political advantages authorize us to aspire.

I send you three chapters of an unpublished work, in which the pernicious effects of our policy on the agriculture is discussed. Your insertion of them will oblige,
HAMILTON.

FARMING.

It was supposed, and very rationally, that the conversion of so large a portion of the armies of Europe, those *fruges consumere nati*, from the dreadful occupation of havoc and destruction, to the employment of civil life, in which husbandry must naturally partake largely, would create a superabundance of the fruits of the earth, immediately after the close of the war. The expectation was not realized.

England had at one time 400,000 men in pay—France, above 600,000—Russia, 600,000—Germany, and the rest of Europe, 800,000. Of these, not less than 800,000 were probably disbanded in 1815, or early in 1816. Notwithstanding the additions hereby made to agricultural labor, the crops so completely failed in Europe in the year 1816, that there was a full demand for all the surplus bread-stuffs we could spare; which therefore bore very high prices. The British ports were open for our flour till November 1817. This staple averaged, in the United States, according to the treasury returns, in 1815, nine dollars—in 1816, ten—in 1817, twelve—and in 1818, ten. Hence the farmers, during these years, in a great degree, escaped the effects of the destruction of so large a portion of the national industry. But times soon changed.

In 1819 the export of flour was 750,660 barrels, which were rated, in the treasury returns, at eight dollars, and produced 6,005,280 dollars. The export in 1820 increased to 1,177,036 barrels, of which the price fell to four dollars and fifty cents. The total value was only 5,296,662 dollars. Had the manufacturers, who were driven from their workshops, and obliged to occupy themselves with the plough and the harrow, and thus become rivals of the farmers, instead of customers, remained at their original occupations, the exportation of flour, in 1820, would not have exceeded that of the preceding year; and of course the reduction would probably have been prevented altogether, or in a great measure. This is a practical commentary on the policy of buying abroad, what can be had cheaper than at home, and thus stinting and starving manufacturers. A farmer possibly saved eight or ten dollars per annum by buying foreign goods instead of American; but, in return, lost half or three

* The difference of price, if it existed at all, would have been only temporary. The experience of our coarse cotton goods is abundant proof on the subject. They are protected by a duty that is almost prohibitory—and, contrary to all calculations hazarded on the subject, are furnished cheaper and incomparably better, than the goods for which they are a substitute. I invoke the aid of Alexander Hamilton's powerful pen on this important point:

Though it were true, that the immediate and certain effect of regulations controlling the competition of foreign with domestic fabrics was an increase of price, it is universally true, that the contrary is the ultimate effect with every successful manufacture. When a domestic ma-

quarters of a dollar per bushel on 500, 750, or 1000 bushels of wheat! Liberality, like honesty, is the best policy. This is a most important point, and demands the most serious consideration of our statesmen and agriculturists. Of the number of manufacturers divested of employment in 1816, 17, 18, and 19, it is impossible to form any completely accurate estimate. Calculations, predicated on data, collected with considerable care, respecting the decline of manufactures in Pittsburg, Philadelphia, Rhode Island, &c. have carried the number as high as 60,000, with families averaging three each. This would make the whole number 240,000. When it is stated that in thirty out of sixty branches in Philadelphia, the number was actually reduced three fourths, or 7400—that in Pittsburg, it was reduced two-thirds—that the reduction in Rhode Island and in other quarters was enormous—this does not appear an unreasonable estimate. But I shall only assume two-thirds, or forty thousand manufacturers with families as above, making in the whole 160,000—and suppose that one-half of these, or 20,000 heads of families, devoted themselves to agriculture. This was the conversion of 80,000 customers of the farming interest, into rivals.

Let us then see the result. Estimates of the grain consumed by an individual in a country where it constitutes a main article of food, have been carried as high as sixteen bushels per annum. I will assume only twelve. This would make 960,000 bushels, equal to 192,000 barrels of flour, for which the regular farmers lost a market. When to this is added the surpluses of the new made farmers, the whole will be found not to fall far short of the extra exportation of 1820, which produced the calamitous reduction of price of that year. Thus, to say nothing of the loss of the market for the great variety of other articles constituting human food, as meat, eggs, butter, cheese, garden stuffs, &c. and of wool, flax, skins, timber, and other raw materials, the farmers paid a heavy penalty for a policy which many of them have supported with ardor.

The subject deserves to be placed in every point of view of which it is susceptible. Excluded as our bread-stuffs are, from nearly the whole of Europe, and limited almost entirely to the West Indies and South America, I will suppose that these markets require 750,000 barrels of flour annually—and that a fair price, to remunerate the farmer, would be eight dollars, which, if the requisite quantity only were shipped, would be about the average price. Increase the quantity to 1,000,000 of barrels, and the article will generally be a drug, and the price will probably sink to six dollars—in some cases to five. Reduce the number to 600,000, and the price will probably rise to 10, 11, or 12 dollars—often 15 or 20. And the farmer ought never to forget, that the prices of the foreign markets regulate the prices of the domestic one. It is impossible for the farming interest to overrate the importance of this fact. A few calculations will render the position clear.

About one-fifth part of the population of the United States, are purchasers of grain from the other four-fifths. This fifth is about 1,950,000, according to the last census—at least 2,000,000 at

manufacture has attained to perfection, and has engaged in the prosecution of it a competent number of persons, it invariably becomes cheaper. The internal competition which takes place, soon does away every thing like monopoly; and by degrees reduces the price to the minimum of a reasonable profit on the capital employed. This accords with the reason of the thing, and with experience."

present. Assuming the consumption as before, it will be 24,000,000 bushels of wheat per annum, equal to 4,800,000 barrels of flour. A rise or fall of our flour in the foreign markets, raises or reduces the price not merely of what is shipped for those markets—but of what is consumed at home. Suppose a demand were to take place for Europe, of 500,000 barrels of flour, the price here would rise probably two dollars per barrel—but say only one; it makes in the year's consumption, a difference to the farmers of 4,800,000 dollars—if two, of 9,600,000.

Although our own experience sufficiently illustrates these positions, I think proper to corroborate them by the case of Great Britain in the years 1799 and 1800. The harvest was uncommonly unfavorable in the former year; but nevertheless, according to the most severe investigation by Arthur Young, produced crops amounting to two-thirds of the average crops of the country. The price, however, rose above one hundred per cent in less than a year, notwithstanding enormous importations, equal to above 11,000,000 bushels of wheat—and notwithstanding the free substitution of potatoes for flour—the prohibition of the use of flour to make starch—and also a prohibition to bakers to sell bread until one day old. From this strong case, it is fair to presume that a deficiency of one-third of an article of necessity, may raise the price 100, 150, or even 200 per cent. It can scarcely be doubted that the rise of grain and flour in England in 1800, would have been two or three hundred per cent. but for the energy, vigilance, and precautions of the government. Importations were invited from every quarter by considerable bounties, and every measure adopted, that could be devised, to prevent famine. The reduction, in consequence of an equal redundancy, will not probably be so great—but must often be ruinous to the parties interested.

(To be continued.)

GREAT AGRICULTURAL PRODUCE IN THE YEAR 1823.

At the late Agricultural Exhibition of Madison county, New York, Benjamin Bartlett "produced satisfactory proof," that he raised 174 bushels of Indian corn upon one acre of land; and also that he raised 305½ bushels of Potatoes upon one half acre of land, for which he received the first premiums.

Madison Co. Observer.

Mr. Peter Boynton of Shelburne, Chittenden Co. Vermont, raised the past season, upon three acres and one tenth of an acre of land, 215 bushels of wheat, averaging 61 to 64 lbs. per bushel.

The following persons obtained premiums at the exhibition of the Stafford Agricultural Society, New Hampshire, which was held on the 16th October.

- 1st. Ephraim Wiley, of Gilmantown, for 114 bushels of corn per acre.
- 2d. Jethro Locke, of Barrington, for 107 bushels 26 quarts.
- 3d. Joseph Edgerly, of Gilmanton, for 107 bushels 10 quarts.
- 4th. Joshua Otis raised 106 bushels.
- 5th. Ebenezer Eastman, 80½ bushels.
- 6th. Pearson Cogswell, 101½ bushels.
- 7th. Gideon Gray, 80 bushels.
- 8th. Nicholas Gilman, 85 bushels.

New Hampshire Patriot, Nov. 10, 1823.

Wayne County (Penn.) Agricultural Society, November 4th.

- Moses Harden, 95 bushels 10 lbs. corn, weighing 58 lbs. per bushel, on one acre.
Franklin Wheeler, 80 bushels 48 lbs. do.
Thomas Sillibridge, 77 bushels of oats, do.

Sheldon Norton, 183½ bushels barley on a quarter of an acre.

Do. do. 4 tons 2 hun. 21 lbs. hay on one acre.

David Wilder, 230 bushels of potatoes on half an acre.

ANIMALS.—A yearling, exhibited at the late Saratoga Show, weighed 1925 lbs. and a calf ten months old, weighed 872 lbs. both raised by Mr. Gilbert Waring.

At the fourth Annual Cattle Show Exhibition, of the Rhode Island Society for the encouragement of Domestic Industry, holden at Pawtuxent, on the 15th and 16th of October, 1823, Dr. Benjamin Dyer, of Providence, was clad in a complete suit of silk, of a superior quality, manufactured in his own family, even from the culture of the trees to the growing of the worms, producing the material.

Brighton, October, 1823.

Gideon Delano, of New Braintree, produced 2744 lbs. cheese, and 171 lbs. of butter, from ten cows, fed on grass, between the 15th of May, and 1st of October—that is, 274 cheese, and 17 of butter to each cow; nearly 2 lbs. of cheese daily.

The Rev. J. B. White, furnished the following statement under oath.—His cow was raised by Noah Smith, of Sudbury, is nine years old, and came into his possession in the spring of the year, 1821. She calved on the 28th May. The calf was killed the 11th of July, she has given 156 lbs. 9 oz. butter, besides supplying the family with milk. Weight of one quart of her milk, 2½ lbs.; weight of milk given in a day, when the calf was a week old, besides what he took 35 lbs. 8½ oz.; weight, when the calf was three weeks old, 32 lbs. 13 oz.

Weight of milk given on the day after the calf was killed, 60 lbs.

On the 27th September—weight of milk given in one day, 38 lbs. 12 oz.—15 quarts 1 pint.

On the 11th October, 36 lbs.—14 quarts 3 and one fifth gills.

From this it appears, that the mean weight of milk given by the cow from the time when the calf was killed to the present time, is 48 lbs. a day. It also appears that when the calf was killed she gave milk at the rate of a barrel of 32 gallons, beer measure, in 5 and one third days; and that she now gives milk at the rate of a barrel in eight days, and eight ninths of a day.

Mr. Capen stated under oath, that his cow was raised by himself; her sire was a bull of John Wells' stock, is eight years old; calved the 2d May. Since which she has furnished 202 lbs. butter; her greatest quantity of milk has been about 16 quarts per day, of very rich quality.

Mr. Rice, stated that his cow, by Denton, was three years old last February. She calved July 27th—has given from the 9th of August to the 13th October, 65 days, 2481 lbs. milk, averaging 38 and one fifth lbs. per day.

BUTTER.

Mr. Gilbert Van Emberg, at the late Brighton Agricultural Exhibition, in October, obtained a premium for butter. The following directions are given by him for making it.

The first object of the dairy woman, is to keep every article used in the manufacture sweet and clean. Tin is to be preferred for pails and pans.* These are to be scalded daily, and dried in the sun, or by the fire. In milking, great caution is to be observed, that no foreign ingredient gets into the pail. Take the milk from the cows overnight, after straining, keep it

cool, so that in the warmest weather it may not sour. On the morning following, add the morning's milk to that of the preceding night, without any additional heat. After standing some time, as soon as the milk begins to change, churn it. In summer this change generally takes place about ten o'clock; in colder weather it requires to be kept longer, for this purpose, say in spring and autumn, the milk of the first mass may be kept till the day following, and then it requires the addition of warm water to the milk to bring it to the proper temperature for churning. But in no case is the milk to be heated, except in the manner before described; where the cows cannot come daily to the salt water,* a quantity of blown or fine salt, is to be added to the milk before churning. The precise time for churning is to be carefully watched, and at the first indications of change, (or sourness) let it be immediately churned in the usual mode. The churn should be furnished with a plug at the bottom; and when the butter is fully come, the butter-milk is to be withdrawn by taking out the plug. Cold water of about half the original quantity of milk, is to be poured into the churn; and the churning resumed and continued until the butter is entirely separated from the milk, which may be easily learned from practice and observation. The butter is then to be taken out with a wooden ladle, and fine blown salt, worked into it with the ladle. Let it stand an hour, then work it over again in the same manner. This operation is to be repeated at the interval of an hour, two or three times, always with the use of the ladle, until the salt is thoroughly combined with the butter. It is then in a suitable state for moulding, or putting down in stone pots or kegs made of ash wood. The pots or kegs being well scalded, a strong pickle is then to be made of salt and salt petre; and being well strained, the sides of the pots or kegs are to be wet therewith, and as much fine salt sprinkled on as will adhere; the butter is then to be well packed down, and the pickle poured on the top.† The salt upon the sides of the vessel prevents the butter from adhering to it, and permits the pickle freely to pass to the bottom. The butter milk made by the foregoing process is of increased quantity and value from that made in the ordinary mode.

FOR THE AMERICAN FARMER.

SINGULAR PROPERTIES OF FOREST TREES.

In the Memoirs of John Evelyn, author of the *Sylva*, a work originally published in 1641, and lately republished, we find many curious properties, not generally known of forest trees. Whether the facts related by Evelyn, can be relied on, we know not; but the experiments are easily made:—

THE OAK.

1. The twigs of the oak, twisted together, dipt in wort, well dried, and then kept in barley straw, by being steeped in wort at any future time, will cause it to ferment and procure yeast.
2. The leaves of oaks, abundantly heaped on snow or ice, preserve it as well as an ice house.
3. Acorns, as well as oak leaves, and the masses of oaks, are sovereign remedies for many diseases.
4. Sleeping, or lying under the shade of an oak tree, is the best remedy for the paralysis.

* Salt will be necessary under any circumstance.

† It is supposed that about two or three inches deep would answer.

FOREST TREES IN GENERAL.

1. The loppings and leaves of the elm, dried in the sun, prove a great relief to cattle, when fodder is dear, and will be preferred to oats by the cattle. The Herefordshire people gather them in sacks for this purpose, and for swine.

2. Beech leaves gathered about the fall, and somewhat before they are much bitten, afford the best and easiest mattresses in the word, to lay under our quilts in place of straw. This he learnt in Dauphiny and Switzerland, where he had slept on them to his great refreshment. In another place, he tells us the French call these leafy beds, from the crackling noise they make when one turns upon them.

3. The keys of the ash, when young and tender, make delicate pickle; its bark is best for tanning nets, its wood for dryings, and for burning in a lady's chamber, being one of those which yield no smoke.

4. An excellent wine may be made from the sap of the walnut tree. Its green husk, dried and reduced to powder, makes excellent pepper. It is useful in corn fields, by keeping the ground warm, and its roots do not impede the plough.

5. The sap of the sycamore, and the sap of the birch, make also excellent wine, and may also be used in brewing, with such advantage, that one bushel of malt makes as good ale with sycamore, as four bushels with water.

6. The lombardy poplar ought to be used for farm houses, because mice and rats will not attack it, but will avoid such houses.

7. Ale, brewed with the ripe berries of the mountain ash, is preferred in Wales, to all other drink.

Occasional extracts such as these, of a practical character, connected with the objects of this paper, would be accepted with gratitude from our unknown correspondent.—*Edu. Am. Far.*

TO THE EDITOR OF THE AMERICAN FARMER.

OAK LEAVES FOR COVERING ICE—BETTER THAN STRAW.

Charlotte Court House, Virginia, }
November 6, 1823. }

SIR,—I see, in the American Farmer, Vol. 5, page 242, a writer on the subject of "building and filling ice houses." The season for filling is fast approaching, and I feel much obliged to the author of this communication; and why not all, who can add the least value to this scheme of preserving ice, do it in time? Cræsinus, your author, says one solid ounce of experience, is worth more than a whole ton of theory. This expression, immediately arrested my attention, and I read his piece with pleasure. It is well known to all who keep ice, that the mass, or bulk, should be large. The pit of my ice house is 20 feet square, and 18 feet deep; the floor, or bottom, is covered with split oak logs, and not well at the bottom; the square built up with round oak logs; at the top of this square, or perches of logs, a shingle roof is built on plates and joists on which a light floor is laid, except a place left to descend for the ice. It is needless for me to tell you, there should be a trap door made in the floor, which is only raised when putting away the ice. My only object at this time, is to convince you that straw is not a proper covering in any respect for ice, and should be avoided if possible. Oak leaves is the only thing that should be used as covering; and I was induced to try the oak leaves from reading a paper, a copy of which I send you enclosed. I recollect, when I was a boy, nothing delighted me so much as to see a snow—when off of the ice, I was balling and roll-

* Stone ware pans are certainly preferable.

up snow heaps—the larger the heap, the greater the fame. Many heaps, thus rolled, would last till nearly spring, and it was very remarkable, that whenever there were the most oak leaves with the snow, it lasted longest—and in recollecting this circumstance, I was convinced the oak leaves would do best as a covering for ice. Straw will heat and impart a bad flavour to any thing put about it. I have never known it put on, or about ice, but it would soon

get damp, and consequently, the ice must be much exposed. The oak leaves have an effect quite the reverse of all this; as repelling heat, and not absorbing the least degree of moisture—neither will they impart a disagreeable flavour. My neighbours, since I have made use of the leaves, adopt the same plan, and say they will not use straw again.

Your obedient servant,
MORTIMER.

FROM THE NEW YORK EVENING POST.

THE CRANK MILL.

The following representation of the Crank Mill recommended in England by Sir John Hippisley, member of Parliament, as a substitute for the Tread-Mill, has been engraved for the Evening Post from a similar one in the London Mirror. While crime renders it necessary that punishment should be inflicted on criminals, humanity enjoins that every species of severity bordering on cruelty, or calculated to injure the health of prisoners, should be avoided. As on almost every other subject, a variety of conflicting opin-

ions prevail in England respecting the tendency of the Tread Mill to enfeeble or mutilate the human body. From the declarations of several highly respectable physicians, who have made it their business to investigate the matter, we are inclined to think that it has that tendency, though perhaps, not to so great a degree as some have represented. Where, therefore, a machine can be substituted which produces the same effects, and answers the same purposes as the Tread Mill, without occasioning bodily injury, we apprehend no doubt can exist as to the propriety of giving it the preference.

in the first instance, of the Mirror we presented our readers with a correct view of the Tread-Mill at Brixton, which has since been adopted, in several gaols in England, and even in the United States of America. That it has had the good effect of inspiring some degree of terror in offenders we believe is acknowledged; but that it is the best means of employing or punishing prisoners, begins now to be very much doubted. Medical men have ascertained that it has a very injurious effect on the constitutions of prisoners, particularly females—a circumstance which certainly, if fully proved, ought to be decisive against Tread-mills; since, in punishing prisoners for misdemeanors, and keeping them in safe custody, it is against the spirit of our laws to render them enfeebled or mutilated, or to send them in a worse moral or physical condition from prison than when they entered it.

Without going so far as some of our philanthropists, who would refine away prison punishments so as to strip them of all their terrors, we may say that we think sufficient objections have been started to the Tread mill to make the subject worthy of further Parliamentary inquiry, which we doubt not will take place next session. In the mean time, Sir John Cox Hippisley has published a work which embodies all the evidence already taken before Parliament on the subject, with a very luminous letter from Dr.

Mason Good on the injurious effect of Tread-mills.

It would lead us too far to enter into an examination of what may be said in favor of or against tread mills, our purpose being at present to describe the Hand Crank-Mill in our engraving, and which is recommended by Sir John Hippisley as a substitute for the Tread-Mill.

In the machinery of the Crank-Mill, the principal objects are to apportion the degree of labor to the degree of punishment, and at the same time to throw every principal muscle of the body into healthful action. Our engraving shows the perspective appearance of a portion of this machinery, consisting of two cranks, in which two sets of men appear working at once. It is needless to observe, that any number of cranks may be placed, radiantly or otherwise, round the central shaft, so as to communicate the joint efforts of all the men to it at the same time, and that they may be so partitioned as to preserve the classification of the persons at work. The position of the men may be varied at pleasure: thus on the side of the sketch the men are shewn with their right hands only in action, and the right feet advanced; while on the other the left feet are advanced, and both hands in action. One man is likewise shewn with his face towards the others; and the whole may thus be disposed, alternately, by which the labor also may be occasionally in-

creased or diminished. The operation of the hand cranks is so simple, and must be so obvious on inspection of the figure, as to render a minute description unnecessary. The cranks should be covered with loose ferrils of plate iron as a protection of the hands—each ferril of a due length for the labor of a single man. Each crank carries a bevil cog wheel at its extreme end, and all these wheels take in common into the cogs of an horizontal bevil wheel, bearing upon the perpendicular shaft, which passes through the ceiling, and gives motion to mill-work for grinding corn, or any other purpose which may be desirable, and to which the workmen have no access. Any one or more of the cranks may, however, be thrown out of gear, at pleasure, by which the work will be rendered more severe upon those that remain. In addition to this means of varying the extent of labor, the crank on the right hand side of the sketch is made adjustable, by means of screw nuts, so that its throw, or the circle which it causes the hands to describe, may be varied in the speed of the machinery, or the cranks may be changed for others of more or less radius, at will. The room, which it would be desirable should be open to the air in which the men work, should contain a dial clock, for the regulation not only of such mill-speed, but to determine the length of time during which each set of men is to work.

The oval figure suspended to the left of the engraving, represents a counter or tell-tale, which by means of a dial-plate, shows the number of turns that have been given to the machinery in the absence of the inspector during any period of time. Sir John Cox Hippisley, recommends that females be exempted from the labor of the Hand Crank-Mill, as well as that of the Tread-mill altogether, it being evident it may be extended to a dangerous excess, without good vigilance on the part of the superintendants.

COURT OF KING'S BENCH.—MAY 28.

CULVERWELL V. EAMES.

This was an action brought by the above plaintiff, a master tailor, residing in London, against Messrs. Eames, the proprietors of the Portsmouth mail, for injuries which the plaintiff sustained, occasioned by the overturning of the mail, and of which he was an outside passenger.

From the evidence called on the part of the plaintiff, it appeared that when the mail was overturned, and the plaintiff's leg was broken, the proprietors ordered every care to be taken of the plaintiff, and even paid his bill for the surgeon's attendance, and also the expenses at the inn, amounting to upwards of £160.

On the part of the defendant several witnesses were called, and among them the guard and coachman of the mail; these proved that on the night of the accident, the mail came up with the Nelson coach from Portsmouth, that the guard blew his horn, when the Nelson started and went on, they, however, slackened their pace, and the mail again came up, when on the guard sounding his horn, the coachman of the Nelson broke the ground, allowing the mail to pass, and in so doing the coachman of the Nelson flogged his horses, whereby his lash caught the eye of one of the mail leaders, and starting forward run on a bank, when the mail was overturned. It was also proved that the mail allowed ten hours to perform the journey, and the Nelson thirteen.

Witnesses also proved that the plaintiff acknowledged the accident was occasioned by the coachman of the Nelson flogging his horses, and that no blame whatever was attributable to the coachman of the mail.

The SOLICITOR-GENERAL, on the part of the plaintiff, considered such acknowledgments might have been made at the time the plaintiff was suffering under great agony; and the Jury returned a verdict for the plaintiff—Damages £40.

CANINE RACES.

MID LOTHIAN COURSING CLUB.

The Mid Lothian Coursing Club, met at Dalkeith, on Tuesday and Wednesday, the 5th and 6th of November, when the following prizes and matches were run for, near the Roman camp, on the property of the Marquis of Lothian:—

First, a pair of silver couples, for dogs under twenty months:—

FIRST CLASS.

1st course—Mr. Dalrymple's b. d. Doubtful beat Mr. Anderson's yellow dog.

2d course—Mr. H. Dundas' w. b. Fly beat Mr. G. Wauchope's b. dog.

3d course—Mr. Wauchope of Edmonston's b. d. Nimrod beat Mr. Aitchison's b. and w. b. Menic.

4th course—Sir John Dalrymple's b. b. Needle beat Gen. Sharpe's y. d. The Stag.

SECOND CLASS.

1st course—Mr. Dalrymple's b. d. Doubtful beat Mr. H. Dundas' w. b. Fly.

2d course—Sir John Dalrymple's b. b. Needle beat Mr. Wauchope of Edmonston's b. d. Nimrod.

THIRD CLASS.

Sir John Dalrymple's Needle, Mr. Dalrymple's Doubtful—undecided.

Sir John Dalrymple's Needle beat Mr. Dalrymple's Doubtful, and won the couples.

Second, a cup for all ages:—

FIRST CLASS.

1st course—Colonel Wauchope's b. b. Needle beat General Maxwell's w. b. Nettle.

2d course—Lord Torphichen's b. b. Thisbe beat Mr. Aitchison's y. b. Mary.

3d course—Mr. Baron Clerk Rattray's y. b. Cremona beat Mr. G. Wauchope's b. d. Eclipse.

4th course—Mr. Clerk Rattray's b. d. Rapid beat Mr. Dundas of Arniston's b. d. York.

5th course—Mr. H. Dundas' b. and w. d. Dandy beat Sir G. Montgomery's b. and w. d. Champion.

6th course—Sir James Baird's y. d. Sultan beat Mr. Dalrymple's b. d. Darling.

7th course—Gen. Sharpe's b. d. Swift beat Mr. Dewar's Blue Beard.

8th course—Mr. Wauchope of Edmonston's b. d. Quiz beat Sir John Dalrymple's b. b. Romp

PUBLISHED IN THE AMERICAN FARMER, BY ORDER OF THE STATE.

A report of the Tobacco Inspected at, and delivered from Calhoun's Inspection Warehouse during the quarter, commencing on the 1st day of July, in the year eighteen hundred and twenty-three, and ending on the 1st day of October, 1823.

RICHARD MACKALL, Inspector.
TREASURY OFFICE, ANNAPOLIS, Nov. 10, 1823
True Copy, from the original report on file in this office.

B. HARWOOD, Tr. W. S. Md.

THE FARMER.

BALTIMORE, FRIDAY, NOVEMBER 28, 1823.

No perceptible change has occurred in the price of tobacco since our last quotations.

Good news for the agriculturists of New York.—Gen. S. Van Ransellaer, always studious of using his ample means to promote improvements in agriculture, has placed \$1000 in Liverpool, to be invested in neat cattle, of improved breeds.—To those who reflect how much time and money have been devoted in that country to attain the highest degree of perfection in all the qualities for which domestic animals are valued, it must be obvious that great benefit will now result from transplanting to our soil the matured fruit, produced by the skill and labour and close attention of more than half a century.

BALTIMORE MARKET.

PRICES CURRENT—CORRECTED WEEKLY.

Flour, best white wheat, \$7 25—Howard street, from wagons, \$6 50—fine do. \$6—Wharf, do. \$5 62½ to 5 75—White wheat, \$1 17 to \$1 18—Red do. \$1 6 to 1 8—Lawler, \$1 12 to 1 15—Washington white, \$1 15 to \$1 30—Rye, 42 to 44 cts.—New corn, 32 to 33 cents—Old do. 34 to 36 cents—Wharf Oats, 33 cts.—wagon Oats, 37½ cts.—Beef, 6 cts. per lb.—Live Cattle, \$5 to \$5 50, per cwt.—Bacon, hog round, \$10—Pork, \$7 per c. lb. 6 to 8 cts. per pound—Mutton, 4 to 5 cts. per lb.—Beans, retail, \$1 25, cargo price, \$1—Peas, retail, 62½ cts., cargo price 48 to 50 cts.—Red Clover Seed, \$6—Orchard Grass do. \$2 50—Herd's Grass do. \$2 50—Timothy do. \$4—Flax Seed, 75 to 80 cents—Whiskey, from the wagons, 35 cents per gallon including the barrel—Apple brandy, 30 to 32 cts.—Peach do. 65 to 70 cts.—Shad, No. 1, \$6 50, very dull, No. 2, do. \$5 to \$5 50, do.—Herrings, No. 1, \$2 50 per bbl., very dull No. 2, \$2 25 do.—Fine Salt, 75 cents per bush., coarse, do. 70—Butter, (firkin) 12 to 13 cts. per lb.—Eggs, 12½ cts. per doz.—New Hay, \$14 per ton, old do \$16—Straw, 7.

Durham Short Horn Stock FOR SALE.

Billy Austin, a large Bull of two years, from Prize, by the noted imported bull, Denton. Prize was by Denton, out of Bughorn—she took two prizes at Worcester County Cattle Show; one of forty dollars at the Philadelphia County Exhibition, and one of twenty-five at the Pennsylvania Exhibition—price \$200.

Jacob, a bull calf of 5 months from Prize, by Robroy, who was by Denton, out of Brindle, price \$75.

Leopold, a bull calf of 9 months from the imported thorough bred improved Durham Short Horn cow Moss Rose, by Robroy. He took a premium at the Pennsylvania Exhibition—price \$150—apply to

HENRY A. CARPENTER.

Paradise, Lancaster County, Pa. Nov. 24, 1823.

Robert Sinclair

Continues to manufacture and will constantly keep on hand for sale at his Factory in Baltimore, a complete assortment of agricultural implements and Machinery.—Among the first he would name the premium two Horse Plough, made for him by John Stewart, and exhibited this month to the Maryland Agricultural Society, as well as the three and two horse ploughs of his own pattern, that received the approbation

of the committee and intelligent observers.—He also keeps Maxcy's Eschelon premium three and five furrow seed ploughs, approved in like manner at our late show. Added to this, he will constantly have on hand Freeborn's, Wood's and Carey's ploughs of assorted sizes, with Extra Shares, and at very moderate prices; as low indeed as they can possibly be made, and yet be perfect in workmanship and materials.—He likewise makes most efficient Corn Shellers—they are small, durable, and admirable machines; and would save to any farmer, the whole cost of one in a season.

The much approved Daton, and the common straw cutters, together with very superior wheat fans, root cutters or turnip slicers, cultivators, hinge and common harrows, drill machines, garden tools—the Spring Steel, Hay and Manure forks—screen, safe, and window wove wire.—The well known Kinsey axes, and a very useful tool and implement that farmers ordinarily want, may be had at all times at his factory. Of garden seeds, he has on hand at present a very general assortment, and he has made arrangements to obtain fresh supplies from the Shakers of New England, and from one of the most reputable seedsmen in London: so that farmers and gardeners may depend upon the quality of the seeds which they obtain at his establishment, as being fresh, true, and of most approved varieties—none will be sold by him that are at all doubtful in any respect. He has raised many kinds with great care, and will continue thus to supply himself with many sorts. Added to garden seeds, he keeps at all times a full assortment of our field and grass seeds, viz:—Red and White Clover, Timothy, Lucern, Herds, Orchard, Millet, Rye, or Meadow Oat, and English grass seeds—all of which will be sold low for cash.

JACK FOR SALE.

BARBAROSSA, a jack bred by the subscriber from a large Spanish jennet, and sired by an imported Maltese jack of the pure Onagra stock is offered for sale.—He is two years and four months old, now measures fourteen, and will, undoubtedly, when full grown, exceed fifteen hands in height—uniting the bone and power of the large Spanish breed, with the spirit, activity, and vigor of the Maltese.

At the late exhibition at BRIGHTON, several gentlemen who have examined this species of stock in Spain—the islands in the Mediterranean—and in South America, pronounced him to be superior to any they ever saw.—Barbarossa is coal black, except a little white under the belly with a bay and mealy nose—perfectly kind and docile—was kept with a filly immediately after weaning, and has propensities seldom found in imported jacks; which must enhance his value in the estimation of those accustomed to breeding mules.—And the undersigned has no hesitation to assert, that he is equal to the celebrated jack Compound bred by General Washington being of similar grade, and that he is superior to any jack now in the United States, or that can be imported. The price is \$750 if speedily applied for, otherwise he will be shipped to the Island of Cuba. Letters free of postage will meet with prompt attention.

S. W. POMEROY.

Brighton, near Boston, }
November 20, 1823. }

Printed every Friday at \$4 per annum, for JOHN S. SKINNER, by JOSEPH ROBINSON, on the North West corner of Market and Belvidere streets, Baltimore; where every description of Job Printing is executed with neatness and dispatch, and from a distance for PRINTING or BINDING, will be most punctiliously attended to, addressed to J. Robinson, Baltimore.

[The readers of the American Farmer will unite with the Editor in thanks to Mr. BUEL, of Albany, for the following very interesting and valuable communication on the improvement of our meadow and pasture lands, and the various grasses applicable to these objects. The table compiled by Mr. B. is winnowed from a mass of calculations and objects, many of which are not adapted to the present condition of American Agriculture, and presents a *practical* aspect and character, calculated to impart information whereof every sensible cultivator may and ought to avail himself.

The brief, but comprehensive remarks of Mr. B. upon the habits and productiveness of the several kinds of grass mentioned in the table, are the more acceptable as coming from one, who, with extensive reading, unites diligent and judicious personal investigation by actual experiment on his own farm, and with his own hands. It would have been more satisfactory to have given the whole communication in our paper, but we are obliged often to forego our own judgment, for the sake of consulting the better taste of our readers, many of whom, as we have been lately admonished, have an aversion to what they call *long articles*; rather preferring, we sometimes fear, variety, to solidity of information—as the mass of an audience prefer laughing at the antics of MATTHEWS in the "Polly Packet" rather than view with breath-suspending admiration, the great workings of the human soul, as exhibited by KEAN in the most pathetic passages of Othello.—Our own taste is the other way, but *de gustibus non est disputandum*, and moreover the Farmer belongs to its patrons and not to its Editor.—The observations of Mr. B. on *Long-rooted clover, Sain Foin, Timothy, Fiorin, Upright bent grass, American Cock's foot, Flat stacked meadow grass, Reed meadow grass, Smooth stalked meadow grass, Floating fescue grass, Cultivated grasses, Meadow grasses, and Pasture grasses*, will appear in our next.—*Edit. Am. Far.*]

TABLE,

Exhibiting in one view, the comparative value of some of the best Grasses cultivated in the United States, and in Great Britain, their products, nutritive matter, time of flowering and seeding, &c.

† The produce was nearly three-fourths greater on a clayey, than on a sandy loam.

NOTE—Those marked with an *, are indigenous, or native plants of the United States.

TO THE EDITOR OF THE AMERICAN FARMER.

MR. SKINNER,

I have found in our publications on agriculture, very little information on the improvement of our meadow and pasture grounds. Indeed, the names of our native grasses are scarcely enumerated, much less are their habits described, or their relative merits, for hay and pasture, pointed out, in any American work

which has fallen under my notice. A considerable portion of our lands are unsuitable for the system of convertible husbandry, that is, an alternation of grain and grass crops. Of this description are our stiff clays, marshes and swamps, and all those lands in which tillage is rendered difficult, by reason of hardpan, stones or habitual wetness. These should be improved as permanent meadows and pastures; and it is of the first importance to the farmer to know the

grasses which will render them most conducive to profit: for that our grass lands are as susceptible of improvement as our tillage grounds, by a judicious selection of seeds, and suitable management, must be apparent to every reflecting mind. The improvement and productiveness of our cattle and sheep husbandry, which at this time deservedly engages much of the public attention, must depend materially on this branch of farming.

With a view to inform myself on this subject, I have been examining several British publications, which abound with information to the English farmer, and are not without their interest to the American cultivator. But this information is so diffuse, and so much of it inapplicable to our husbandry, that I have been induced, for my own gratification and benefit, to collect some of the most material facts in a condensed form, which, with some remarks of my own, I herewith communicate for publication, should you deem them worthy of a place in the American Farmer. I do it in the hope that its publication may induce experiments at home, and elicit useful information from gentlemen of science and practical knowledge, on the subject of grasses, particularly those which are indigenous to our country. The table is compiled from the appendix to Davy's agricultural chemistry. It is to be regretted that it embraces only nine species of American grasses. It, however, contains several approved foreign kinds, most of which have been more or less introduced among us already.

To those who do not possess Davy's work, it may not be amiss to say, that the results stated in the table may be implicitly relied on for correctness. The experiments were carefully made by George Sinclair, under the direction, and at the expense of the Duke of Bedford, at Woburn, in England.

Sweet scented Vernal grass.—This is a grass of diminutive growth, and it will be seen by the table, is not worth cultivating for hay. It is, nevertheless, considered valuable in pasture, on account of its affording very early feed, and growing quick after being cropped. We are advised by Muhlenburgh that it delights in moist soils; by the Bath papers that it does well in clayey loams, and by Dickson, that it grows in almost any soil, including bogs and sands. G. Sinclair, says it is eaten by oxen, horses and sheep, though not so freely as some other grasses are.

Meadow Fox-tail, possesses all the advantages of early growth with the preceding, and is much more abundant in product and nutriment. It generally constitutes one of five or six kinds which are sown together by the English farmers for pasture; and affords, withal, a tolerable crop of hay. It does best in moist soils, whether loams, clays, or reclaimed bogs. Sheep and horses have a better relish for it, says G. Sinclair, than oxen.

Rough Cock's foot.—Dr. Muhlenburgh and T. Cooper, concur in the opinion that this is the *orchard grass*, of the United States; though some that I have raised as orchard grass, does not seem to correspond with the figure of the *Dactylis Glomerata*, in the 2d vol. of Dickson's Farmer's Companion. In England cocks foot is taking the place of rye grass, with clovers. Arthur Young speaks in high commendation of it; though all writers concur in the opinion, that it should be frequently and closely cropped, either with the scythe or cattle, to reap the full benefit of its great merits. I should prefer it to almost every other grass; and cows are very fond of it. Cooper rates it above timothy, and says it is gradually taking the place of the latter, among the best farmers about Philadelphia. This is probably owing to the fact, that it is earlier than timothy, and of course more suitable to cut with clover for hay. Its growth is early, and rapid after it has been cropped. It does well on loams and sands, and grows well in shade.

If further facts are wanting in favor of this grass, for pasture, the reader will find it in the American Farmer of the 14th November, in an article signed Curwen, which, if I mis-

take not, means Col. Powell, of the neighborhood of Philadelphia, a gentleman who combines as much science with judicious practice, especially in cattle and grass husbandry, as any person in the union. He says, "I have tried orchard grass for ten years. It produces more pasturage than any artificial grass I have seen in America." Sow two bushels of seed on an acre.

Tall Oat grass. Both Arator, (Mr. Taylor,) and Dr. Muhlenburgh have placed this at the head of their lists of grasses, which they have recommended to the attention of the American Farmer. The latter says it is, of all others, the earliest and best grass for green fodder and hay. The Doctor was probably not advised of its deficiency in nutritive matter as indicated in the foregoing table. It possesses the advantage of early quick and late growth, for which the cock's foot is esteemed, tillers well, and is admirably calculated for a pasture grass. I measured some on the 20th June, when in blossom (when it should be cut for hay) and found it four and a half feet long. The latter math, it will be perceived is nearly equal in weight, and superior in nutritious matter, to the seed crop. Sinclair says it thrives best on a strong tenacious clay; and Muhlenburgh prefers for it a clover soil. Dickson speaks well of it; says it makes good hay, but is most beneficial when retained in a close state of feeding. I have sown it in autumn and spring, with clover, on a sandy loam, with good effect.

Tall Fescue, although a native grass, has not fallen under my personal observation. It stands highest, says Davy, according to the experiments of the Duke of Bedford, of any grass, properly so called, as to the quantity of nutritive matter afforded by the whole crop, when cut at the time of flowering; and meadow cat's tail (timothy) grass affords most food when cut at the time the seed is ripe. It grows naturally in wet grounds, in bog meadows, and on the sides of ditches, often to the height of four or five feet. Our ignorance of agricultural botany, and of the intrinsic value of this grass, can alone have prevented its being more generally known and cultivated. It must be very valuable for wet grounds, as from its rapid growth it is calculated to smother or keep down the coarser kinds which naturally abound in those situations.

Rye grass, is extensively cultivated in Scotland, and the north of England, and where cock's foot has not superseded it, is generally mixed with clover seeds. It is rather declining in the public estimation. It does well in pasture; and as it contains much nutriment, is considered valuable for cows and sheep. Dickson says it does best in rich moist meadows. Young does not speak well of it.

Red clover.—There are many species of the *trifolium*, and several varieties of red clover. Whether the kind we generally cultivate is the *pratense*, or not, I am unable to determine. The character of red clover, as an ameliorating and fertilizing crop, is too generally known to require illustration. It cannot be depended upon for permanent grass lands; though it yields to no grass in value for alternating with grain, in convertible husbandry. It formerly was as indispensable in a course of crops in Norfolk, England, (which has been considered pre-eminent for good tillage) as turnips; and the maxim then was, and still is, "no turnips no crops." But it appears from Young's survey of that county, that it cannot now be depended on oftener than once in from eight to twelve years. Trefoil, white clover, cock's foot, ray grass, &c. are therefore alternated with red clover in

the grass years. There is reason to believe that neither red clover, nor other grasses, will bear repeating for a course of years upon the generality of soils. They exhaust the ground of the peculiar nutriment required for their support. In Great Britain, white clover, trefoil, rye grass or cock's foot are generally sown with red clover seeds. From twenty to thirty pounds of seeds are sown to the acre. In the northern states, timothy is generally sown with clover; though it is evident from the table that the mixture is an improper one for hay; for the clover is fit for the scythe ten or fifteen days before the timothy has attained to maturity. If sown alone, from eight to sixteen pounds of clover seed should be put on an acre: more on old land than on new.

White, or Dutch clover, (*Trifolium repens*.) is considered, in England, of importance to husbandry, if we are to judge from the great quantity of its seed which is there sown annually. With us, many districts produce it spontaneously; but it is too seldom sown. It shrinks greatly in drying, and does not contain as much nutritive matter as red clover; yet its value, as a pasture grass, is universally admitted. Its increase is very much facilitated by a top dressing of gypsum, lime or ashes.

Lucern, although affording much more green food, contains less nutriment in a single crop, than red clover. It must, however, be borne in mind, that it grows much quicker than clover, and will bear cutting twice as often: In the soiling system, an acre of lucern will keep four cattle or horses from the 15th May to the first October. I cut a piece last summer about the 15th May, and again about the 20th June, to feed green, and then ploughed the ground, and cropped it with ruta бага, which yielded sixteen tons the acre of roots, as fine as I ever saw. Mr. Fowell (see Young's Norfolk, p. 345) derived a clear profit of £13 17s. 4d. per acre from his lucern, fed green to working horses. This is almost equal to \$60 the acre. An idea has prevailed, that it will not thrive in this latitude, (42—3); but the experiments of the late Chancellor Livingston, and of Le Ray de Chaumont, prove otherwise. I sowed seed in 1821, at the rate of 6lbs. the acre, with barley. It has stood the winters well, much better than clover; and has been in a state of progressive improvement. Drought has not afflicted it. The plants are very tender the first year; and require either a very clean tilth, or to be kept free from weeds and grass with a hoe the first year. It should have a deep loam, as it sends down tap roots five or six feet; and it is equally necessary that the ground should not be wet. It may be sown either in drills or broad cast, with or without grain. Fifteen pounds of seed are required for the acre if drilled, and 20 is not too much if sown broad cast. To the proprietor of a dairy, an acre or two of lucern would be valuable, to be fed to his cows, in addition to ordinary pasture.

(To be concluded.)

EXTRACTS

FROM MORE MODERN WRITERS ON THE USE OF SALT IN AGRICULTURE.—No. V.

A letter from a very considerable North American planter to the Editor of the Museum Rusticum, respecting the great benefit of salt to cattle, with the method of using it.

[Concluded.]

"Sea-Sand is very generally used in the country of Cornwall for manure, and the quantity which is every season carried away from different parts of the coast for the purpose of ma-

nure almost exceeds belief. From Bude, in the parish of Stratton, it has been ascertained that in one day as many as four thousand horse-loads have been taken; and from the harbour of Padstow, it has been computed, that fifty-four thousand cart-loads are annually carried. The expense of land-carriage for sand, used in the country, has been considered as amounting at least to thirty thousand pounds annually."

"That the beneficial operation of this sand depends upon the presence of calcareous matter there cannot be any doubt, but, at the same time, we are borne out by unequivocal facts, in believing that the sea-salt, with which it is impregnated, contributes materially to its fertilizing powers." Dr. Paris's *Memoir in the Transactions of the Royal Geological Society of Cornwall*, vol. i. 8vo. London, 1818, page 193.

"It has been said, that the benefit of salt as a manure has not been demonstrated: that neither the scale upon which it has been tried, nor the period for which it has been used, has been sufficient to remove all doubt upon the subject. The want of general use, however, and the paucity of experiments, are accounted for by the prohibitory duties, which the salt laws have imposed upon the use of it; and since that objection was urged on the part of the Excise, in April last, the production of Mr. Hollinshead's statement has added so much strength to the former proofs, as to carry them almost to moral demonstration. In other inquiries we balance the comparative weight of testimonies. The twenty-nine persons whom I have referred to, as having expressed their opinions in favour of the use of salt as a manure, are many of them men of the first rank in point of science; all of them respectable in character, and with the advantage of practical knowledge.

"I add the list of their names; Bishop Watson, Sir John Sinclair, Dr. Darwin, Sir Rose Price, Colonel Scobell, Mr. Hollinshead, Mr. Davies Gilbert, Dr. Paris, Sir Hugh Platt, Mr. Alderman Farley, Mr. Jay, Mr. Ford, Mr. Bayley of Hope, Mr. Elliott, Mr. Rigg, Mr. Le Grand, Mr. Kingston, Mr. Boaze of Penance, Major Taubman, Mr. Stephenson, Mr. Horne, Mr. Gilbert of Wycham, Mr. Hill, Mr. Wedge, Mr. Lee of Oldford, Mr. Beck, Mr. Sutton of Middlewich, Mr. Holt, and the Rev. Mr. Cartwright.* It is hardly to be conceived that they should all of them be misled, or to have united to mislead the world upon the subject. I presume not to offer either argument or opinion, but merely submit to the reader facts and authorities,—*quæ neque confirmare argumentis, neque refellere in animo est. Ex ingenio suo quisque demat vel addat fidem.*"—*Case of the Salt Duties*, by Sir Thomas Bernard, Bart. London, 1817, page 289.

Extract of a letter from I. C. Curwen, Esq. to the Editor of the Carlisle Journal.

"I avail myself of this opportunity to say a word or two on the subject of salt. I rejoice to find the trials of it are numerous. In addition to what I have formerly stated in favour of it, I am now enabled to add, that out of fifty shearing Devons, killed this winter at the Schoose,

* To this very respectable list the following names may be subjoined: Gervase Markham, Lord Bacon, Mr. John Evelin, Dr. Bury, Dr. Cox, Dr. Robert Plot, Dr. Brownrigg, Mr. Thomas Hitt, Mr. C. Varley, Dr. Holland, Lord Erskine, Mr. I. Christian Curwen, Dr. Rice, Lord Kenyon, Mr. Arthur Young, Mr. William Johnson, Mr. James Manley, and the late worthy Sir Thomas Bernard himself.—S. P.

the whole have been perfectly sound. Previous to the use of salt, it was rare to find a liver (of a sheep) that was not more or less tainted. The cattle and horses are continued in the free use of salt. Latterly, at the Schoose, I have given six ounces per day to work-horses—four with steamed potatoes, two with steamed chaff. I fully expect it will operate powerfully in preventing horses greasing. In the course of a few months I shall be able to speak more decidedly on the subject. I find the additional quantity of salt so far to agree perfectly well with the horses. The general use of salt will not only be found highly beneficial to the agriculturist, but will furnish so large an addition to the amount of the salt tax, as to justify and call for the reduction of the duty in favour of the public at large. About fifty thousand tons is all that pay duty in Great Britain. If salt were generally applied to the feeding of cattle, the consumption would reach six times that amount, and produce, at five pounds a ton, a sum equivalent to the present oppressive and unequal tax, in which a labourer pays a 26th part of his earnings, whilst the opulent do not pay more than from 500 to 1000th part on this indispensable necessary of life.—Copied from the *Farmer's Journal for the 4th of January, 1819.*

On a Remedy for the Black Scour in Sheep, extracted from a letter to the Editor of the Farmer's Journal.

Kilton, near Bridgewater, Somerset, Dec. 21, 1818.

SIR, Salt possessing septic and antiseptic properties, it is obvious that it should be used with caution; indeed, experience (the best test of wisdom) has so instructed me. I have for the last ten years, and more, given salt to sheep in the following proportions, in all cases of diarrhoea, with the best possible success: two drachms (apothecaries weight) of dry salt for a lamb of nine months old, and that quantity increased to three and a half drachms for a large and full-grown sheep; and in the same ratio for the intermediate ages. The mode I adopt is to introduce the specified quantity into the mouth of the sheep with a spoon, withdrawing the spoon and closing the mouth. In a few seconds the salt dissolves in the saliva, and the sheep readily swallows it. I consider water not only inconvenient, but improper, as a superabundance of it was, in my opinion, the original cause of the disease. I have seldom found a repetition of the above dose necessary; but if one should not prove effectual, there can be no objection to repeating it, every other day, till the desired effect is produced.

Desirous of communicating, as well as receiving, useful information, I am induced to submit the above observations, under the full impression that they will be found beneficial to those who may be induced to make trial.

Remaining, Sir, truly yours,
CHARLES ADDAMS,
From the *Farmer's Journal*, January the 4th, 1819.

Extracts from Papers published by the Right Honorable Sir John Sinclair, Baronet, on the uses of salt for agricultural purposes.

"Salt, if employed in large quantities, in its natural state, is hostile to vegetation, yet it operates advantageously, in various ways when judiciously applied to arable land. In large quantities it has a tendency, like every other excessive stimulant, to disorganise and destroy the vegetable substances with which it comes in contact; but in moderate quantities it promotes the growth of vegetables.

"It has been proved by Pringle, and Macbride, that though salt will, in large quantities, prevent putrefaction, owing to its antiseptic properties, yet that it has an evident tendency to promote the process, when used in small quantities. Hence the advantage of mixing it in moderate quantities with farm-yard dung, and other animal and vegetable substances.

"An experiment was tried in Cheshire, of mixing grass roots and other rubbish harrowed off the land, with foul salt; it was then incorporated with other manures; and the effects of this compost, on a crop of barley and grass seeds, is said greatly to have exceeded the most sanguine expectations that had been formed of it.

"A farmer mixed up a quantity of refuse salt with the earth taken out of water furrows, and another portion of the same earth with lime. Of the two, the vegetation of that part of the field which had the salt compost laid upon it was by far the healthiest and most vigorous.

Vermin. "Salt destroys vermin in the ground, by making them void the contents of their bodies, such evacuations being too powerful for them to withstand. It has this additional advantage, that the vermin thus become food for those very plants, which otherwise they would have destroyed.*

Turnips. "Equal quantities of salt, and of turnip seed, were tried on a small plot of a garden, by the author of this paper; and the produce was more abundant than from the same quantity of turnip seed sown without salt. The efficacy of salt, as a destroyer of the turnip fly, or beetle, ought to be ascertained.

Hay. "Lord Somerville is of opinion that salt cannot be conveyed into an animal in a more effectual manner than by sprinkling the salt through a sieve, at the rate of twenty-five pounds weight of salt to a ton of hay, when in the act of putting it together, for every particle is imbibed in the fermentation, without a possibility of waste. This salted hay is of great use to sheep, when put on turnips early in the season, for the tops being then rank and strong, many of the sheep die suddenly from pent-up wind, occasioned by excess of fermentation in the stomach. Salt, or salted hay, are then devoured by them with a greediness, which denotes their salutary effect. By the use of salted hay, Lord Somerville did not loose one sheep on turnips in the autumn of 1801, though the season was rainy and unfavourable.

Straw. "The ancients were accustomed to prepare their straw for feeding stock, by keeping it for a considerable time sprinkled with brine; it was then dried, rolled up in bundles, and given to oxen instead of hay.†

Horses. In Flanders, it has been found that a small quantity of pounded salt is very beneficial for horses, when new oats are given to them, if the oats are at all moist; and there can be no doubt that moist food in general might be rendered less injurious by the same means; for instance, when raw potatoes are first given to horses.

"Birkbeck, in his notes on a Journey in America, recently published, mentions, that the horses he saw in the interior of that country were of an excellent description, and are in high condition, even when travelling at the rate of forty-five miles per day, on long journeys. They are fed well, getting four to five gallons of oats

* Lord Dundonald on the Connexion of Husbandry with Chemistry. Page 138.

† Dickson's Husbandry of the Ancients. Vol. ii. page 408.

per day, besides hay, *with a good handful of salt about twice a week.*

"Salt given to horses cures the *botts*; and it is said might be given with great advantage to race horses, and would prevent the necessity of applying those severe purges to which they are at present subjected.

Bullocks. "In the East Indies they give salt to their bullocks, in general daily, to the amount of two or three ounces mixed with their feed of pulse; a due proportion of salt they consider to be essential for their health, and almost as necessary as food.

Hogs "Great quantities of salt are considered to be injurious to hogs; but, in America, salt is occasionally given to them, to render them tame, and to prevent their being lost in the woods. Mr. Curwen also mixes some salt with the steamed potatoes he gives his hogs, and he thinks with benefit.

"It is said that in Ireland, when fattening their hogs, they sprinkle a little salt with every meal, by means of which they are found to fatten in half the period they would otherwise require."—Observations by John Marshall, Esq. on the Medical as well as the Dietetic properties of common salt, in the *London Medical and Physical Journal*, vol. xxxix. fo 231.

Poultry. "Salt also may advantageously be given to poultry, and may prevent some of those disorders to which they are liable. The avidity with which pigeons consume salt is well known.

Hay. "In a recent communication from A. Bracebridge, Esq. of Walton on-Thames, he states, that some years ago, the clergyman of Holmes Chapel, who lived near the salt-works, gave a favorite old mare, who was much broken-winded, some spoiled hay *that had been salted* (at that time salt for agricultural purposes was free of duty.) The mare had nothing else to subsist on, but threw on that food so well, that she was fit to be put to work again next spring. This induced Mr. Bracebridge to drench some rotten sheep, night and morning, with strong brine; after which, he did not lose one; they became fat, and the meat was fine and good, as if the animals had never been affected."

FARMING.

[Concluded from page 285.]

When we consider the veneration, approaching to idolatry, entertained for Adam Smith, by so many of our statesmen, it is wonderful and inexplicable how they overlook and disregard the wisest maxim in his work, the want of attention to which is the cause of nearly all the evils with which this country has been or is afflicted. It is a maxim grounded on the eternal basis of truth and good sense—and it may be pronounced, without pretending to the spirit of prophecy, that we never shall enjoy our full share of prosperity till we square our conduct by it. The maxim is—

"Whatever tends to diminish in any country the number of artificers and manufacturers, tends to diminish the home market, the most important of all markets, for the rude produce of the land, and thereby still further to discourage agriculture."*

Were a convention held of all the wise statesmen of the earth, they could not have devised a sounder maxim than this, nor one more applicable to our situation. It unerringly points out the high road to "wealth, power, and resources."—"To the encouragement of the domestic market" for the "rude produce" not only of her own soil, but of every soil under the canopy of heaven,

* *Wealth of Nations*, Hartford 1818, II. 149.

Great Britain owes her power, and capacity to lay, as she does, nearly all the nations of the earth under contribution. From the commencement of our government to the present hour, our policy has been diametrically opposed to this maxim. It has undeviatingly tended to "diminish the number of manufacturers and artificers," by encouraging, for the sake of revenue, the introduction under low duties, of foreign manufactures, and thus "diminishing the market for the rude produce of the soil."

It is no objection to this maxim, that it is in hostility with nearly all the rest of the doctor's writings on political economy. This only proves that the doctor was not infallible, and ought to diminish the unbounded confidence of his disciples. When two dogmas are diametrically opposite to each other, it is for the good sense of mankind to judge between them—to reject the false and adopt the true. The doctor strongly urges the necessity and great advantage of free and unrestrained trade. This is the sum and substance of his celebrated work. But he admits that if high duties and prohibitions were all at once taken off, "*cheaper foreign goods, of the same kind, might be poured so fast into the home market, as to deprive all at once many thousands of our people of their ordinary employment and means of subsistence.*" This is not a problematical case. It would be some alleviation if the evil, if it were merely a "*might be.*" But the experience of the world shows that this is a slender reliance—and that the obvious and unfailling result is to "deprive numbers of their usual employment and means of subsistence." How then does the doctor provide a remedy for this most serious of all evils to a community, in a state of peace? He has two remedies. One, that those "*thousands of persons*" deprived "*all at once of their ordinary employment and means of subsistence*" might find "*collateral branches*" in which to provide "*means of subsistence.*" To this remedy there are two solid objections—one, there are no such "*collateral branches*" for nineteen out of twenty of all the trades and occupations on which human industry is employed—and the other, that if there were for every one, those "*collateral branches*" would be precisely in the same state of suffering, by the introduction of "*cheaper foreign goods.*" The second remedy is to send those "*thousands of persons*" to "*country labour.*" "*The greater part of such workmen,*" says the doctor, "*are employed in country labour.*" Here, then, the doctor, after deprecating the "diminution of the number of artificers and manufacturers" as pernicious to agriculture, by "diminishing the market for the rude produce of the soil," offers a system for general acceptance, in direct opposition to the practice of all the wise nations of the civilized world, the obvious effect of which is not only to "diminish the number" of those two classes, but to convert thousands of them into rivals of the agriculturists. This is not one of those trivial errors which may inadvertently escape in a great work through human fallibility, without materially interfering with its general scope and purpose.—No. It is a radical and vital error, and strikes at the very basis of his system, which it cuts up by the roots. If it be unsound policy, as it surely is, "*to diminish the home market, the most important of all markets, for the rude produce of the soil,*" and thus "discourage agriculture," Adam Smith's system of "unrestrained trade," which would, according to his own acknowledgment, not only produce that effect, but double the evil by unduly increasing the number of agriculturists, must be transcendently pernicious. I repeat, and it can never be too often repeated,

nearly all our evils result from not attending to his first maxim. We raise too much grain for exportation. Hence it is generally a drug abroad. We raise too much cotton. Hence, though an object of the utmost possible necessity, the price has been most ruinously reduced. We raise and export too much tobacco. Hence the price has fallen so low as not to remunerate the planter. Whence arises the superabundance of those three great articles, "the rude produce of the soil?" From "*diminishing the number of artificers and manufacturers,*" by an unreasonable jealousy—and converting into rivals those who would be lucrative customers. This simple truth, level to the simplest capacity, has been in vain preached for thirty or forty years to our politicians and statesmen. This topic is too important to be dismissed without further illustration. I will suppose the case of an immigrant, who arrives here with a capital of 20,000 dollars, and establishes whatever branch of business he has been accustomed to, suppose the woollen. He and his family became customers of the farming interest, and afford "*a home market, the best of all markets, for the rude produce of the soil.*" He hires a mill seat, purchases machinery, and raw materials, and engages workmen. His whole capital is thus invested—and he produces an excellent article, which, in order to remunerate himself properly, he ought to sell, we will suppose, at five dollars per yard. When he comes into market; he unfortunately finds it glutted with a foreign article, it may be a good one, or, perhaps, as frequently occurs, made up, like Peter Pindar's razors to sell, and sold at vendue for three, three and a half, or four dollars, which may be less than cost. He can scarcely find a market at all; but if he does, his price must be regulated by that of the imported article. He sells with difficulty, and must sell at a considerable loss. He is thus arrested in his useful career, sells his establishment at a great loss, and either returns home, venting maledictions on his folly for having quitted his native country, to which he brings dejected spirits and broken fortunes—or else he "*goes back*" to the westward, according to the advice held out by our statesmen for thirty years past, an asylum to manufacturers divested of employment, and suffering on the sea board. If he returns home, he only deprives the American farmer of a customer. If he "*goes back,*" he does the farming interest a double injury—by not only ceasing to purchase its productions, but by becoming a rival in the market. This is not "*a fancy sketch.*"—It is a picture drawn from real life, of which thousands of instances have occurred in the short period that has revolved since the date of our existence as a nation. It is not confined to immigrants. I have now before me a letter from an intelligent American citizen, who, about twelve months since, engaged in the manufacture of satinetts, and invested 16,600 dollars in the establishment, exclusive of raw materials and wages.

Mill, a building 38 feet by 45, cost	\$6000
Machinery	5000
Dye House, &c.	600
Water right	5000
	<hr/>
	\$16,600

He employed 15 weavers, 3 spinners, 2 carders, 3 finishers, 1 dyer and assistants, and 25 boys and girls—in all about 27 or 28 adults, and 25 children. His goods were as well manufactured as possible. Having reduced the wages to so low a rate as to afford a mere sustenance to his work people, his goods were offered cheap. But all would not do. He could not compete with

the great quantities of rival goods forced to sale at vendue. I will let him tell his plain story.—Such is the extent to which our markets are flooded with British woollens, that we cannot now get within five cents per yard of what ours cost; and this is not because they can make them in England, and sell them cheaper than we can; for the owners of English goods make heavy losses; but it is because they make our country the common sewer through which they vent all that remains on hand after they have supplied the home market, and their other customers; or perhaps they are determined to run an opposition coach against our woollen manufacturers, until they ruin us; which they can do without any thing like the loss to which we are subjected. Making a profit on their other sales, they can flood us with but little diminution to their gain." About three weeks since, the whole of the work people, about fifty four, were discharged, and the factory closed.—Some of them from want of employment probably became paupers, and a public burden.—Others betook themselves in all likelihood to field labour, increasing a branch already too numerous. And thus for the sake of revenue, and for the sorry consideration of buying goods cheap abroad, we devote our enterprising citizens to ruin, and our work people to idleness and all its concomitant evils. As if nothing were too ludicrous or extravagant to be pressed into service against manufactures and manufacturers, the tendency of the former to demoralize a nation, has been zealously insisted on. That is, in plain English, by employing the poorer classes of our people, we hazard the destruction of their morals! and we improve their morals by shutting up our establishments, and depriving them of employment! It is impossible to reflect on the consequence of a policy predicated on such fallacy, without melancholy sensations.

The farming interest, in the states of Pennsylvania, New York, New Jersey, Maryland, and in every quarter where grain formed its chief dependence, in consequence of the reduction of the price of flour, suffered the most intense distress at this period—a distress that could not be exceeded by the devastations of an infuriated army.

HAMILTON.

FROM THE NEW ENGLAND FARMER.

LESSONS FOR FARMERS.

Mr. Editor.—The following is founded on fact, and with a little variation is literally true.

Mr. A. and Mr. B. are two farmers living only eighty rods distant from each other.—Their farms each contain about one hundred and twenty acres of land, being of equal value.

Mr. A. manages his farm so as to summer and winter twenty head of cattle, and keep them well, and always has a ton or two of good hay left in the spring. He raises about two hundred bushels of corn in a year, and about the same quantity of English grain.

He and his two sons, the one twenty and the other fourteen years of age, perform all the work on the farm, as they hold it a fundamental principle not to hire any labor, unless something special and unforeseen should render it absolutely necessary. This work is always done in season, and much time is gained, which is spent in building stone walls and making other valuable improvements on the farm. He never makes any bluster about his business, but always keeps a steady course, beginning early in the morning, and finishing his work in season at night. He says that he chooses to do his own work rather

than hire it done, for if he does it himself it will be done as he wishes to have it, but if he hires it done he will have it to pay for; and there is the expense of boarding, which is something.

He says he is obliged to study economy that he may keep along and gain a little. He will not run in debt unless necessity compels him so to do, as he thinks it is better for him to do without things that would be convenient, but can be dispensed with, than to buy them on trust, and by and by be under the necessity of selling a yoke of oxen, or a piece of land to pay his debts. He and his sons drink no ardent spirit on any occasion whatever, for they have learned by experience that they can perform more work and be more robust and hearty without spirit than with it, and by abstaining from the use of it they save enough at least to pay their taxes, beside the hazard of consequences arising from the danger and force of habit. Thus by prudence and economy he is able to meet all his demands, contribute liberally to the various benevolent objects of the day, and add something to his permanent fund besides.

Mr. B. conducts his business in a very different manner. He has as much help of his own as Mr. A. yet his work is always driving him so that he is compelled to hire much extra labor, in order to keep business along.—He raises no more grain, nor cuts so much hay, nor gets done haying so soon, as Mr. A. He makes no essential improvements on his farm, for he says he can make more by working out with his team than he could to build stone wall and subdue his rough land. He is considered a temperate man, yet it costs him more for ardent spirit than it does to pay his taxes. He says he cannot work in hot weather, nor does he want his men to work without rum. He is in debt, and cannot bring both ends of the year together; yet he will not deprive himself or his family of the conveniences of life on this account. If himself or his family want any thing which they have not, he will buy it and pay for it when he can; so that instead of lessening his debts he is continually adding thereto, and according to the course of things he will sooner or later be obliged to sell a part of his farm to satisfy the demands of his creditors.

BOARD OF AGRICULTURE IN NORTH CAROLINA.

Agreeably to the act of last session, to promote Agriculture and Family Domestic Manufactures within this state, the following Presidents and Delegates of Agricultural Societies met at the Capitol on Monday evening last, viz:

Duncan Cameron, President of the Agricultural Society of Orange County;

Charles Fisher, President of the Agricultural Society of Rowan County;

Daniel M. Forney, President of the Agricultural Society of Lincoln County;

James W. Clark, President of the Agricultural Society of Edgecombe County;

Benjamin H. Covington, President of the Agricultural Society of Richmond County;

Jeremiah Pearsall, Delegate from the Agricultural Society of Duplin County;

Jacob Alford, Delegate from the Agricultural Society of Rebeson County; and

Tryam McFarland, Delegate from an Agricultural Society near Laurel Hill, in Richmond County.

On motion, Duncan Cameron, Esq. was unanimously chosen President of the Board, and J. Gales, Secretary.

Messrs. Fisher, Forney, and Clark, were appointed a Committee to report rules for the government of the Board.

The Board adjourned to Monday evening next at 7 o'clock, in the Conference Hall.

Internal Improvements.

CANAL FROM BALTIMORE TO CONEWAGO.

We have just read with great satisfaction the REPORT of THEODORICK BLAND, GEORGE WINCHESTER, and JOHN PATTERSON, Esqrs. Commissioners, appointed by the Executive of Maryland, to explore the route for a proposed canal between the points above mentioned.

The public mind, previous to the session of the last Legislature of Maryland, had become deeply impressed with the persuasion, that immense advantages were to be derived by opening a more easy communication with that vastly extensive and fertile portion of country, penetrated by the upper waters of the Susquehanna; but in attempting to calculate these advantages, and the possibility of realising them, it was at once perceived that the facts were wanting, upon which alone a satisfactory estimate could be made, and that these facts could only be gathered by mathematical surveys and personal observation: hence the appointment of three amongst our most intelligent and trust worthy citizens to make these investigations;—and the subject will now be made matter of legislative consideration with all the lights necessary to arrive at just and practical conclusions: for every one who reads this report, will agree with us in opinion, that the Commissioners have exerted the utmost industry and cautiousness in the collection of their materials, and exhibited them with such clearness, ability and precision that no mind, however sceptical or timid, can well doubt the results for which they contend. The Report is, indeed, so exclusively practical, every part of it is so indispensable to a correct development and understanding of the whole, and all superfluous considerations of the subject have been so rigidly rejected, that we find great difficulty in selecting any one part as being more pregnant than another. As, however, the portion of any one number of our Journal, which we can devote to one subject is necessarily very limited, we must be content with presenting a rough outline of the Report, wherein we shall endeavour to extract such parts as seem calculated to answer the enquiries that are supposed to be uppermost in the minds of those who take an interest in the subject, and desire to know what the commissioners have said and done.

On the abstract question, as to the advantages of canals in general, they have judiciously spoken very briefly, concluding that they are understood and admitted by all who have given themselves the trouble to enquire or think at all on the subject. The general view of these advantages, is thus happily set forth in a single page of their Report:—

"The great advantages of canal navigation are no longer a matter of speculation and theory; it has long since, and to a vast extent, and under every variety of circumstances, been reduced to practice; and unerring experience has every where furnished the same unequivocal evidence in its favour. These advantages are most important in many points of view; first, in cheapness; the expense of transportation on a canal amounts to no more than one cent a ton per mile; or one dollar for a ton for every hundred miles, the cost of transportation by land conveyance is thirty two dollars for the same distance, this difference is more than thirty to one in favour of the canal. Secondly, in speed; a loaded boat can be towed by one or two horses

at the rate of thirty miles a day. *Thirdly*, in certainty; a vessel on a canal is independent of winds, tides and currents, and is not exposed to the delays attending conveyances by land; and *lastly*, in point of the safety; the advantages are no less obvious and decided the injuries to which merchandise is exposed when transported by land, or by natural navigation are innumerable; but, in a canal boat they are little more exposed to damage than in a warehouse. A canal, in a commercial point of view, may be considered as a great labour-saving machine; and, politically considered, its influence and consequences are of the most incalculable importance, in binding us together as one great people, in harmonising the discordant sectional feelings, and reconciling the apparently clashing interests of the several states, and thus tending to perpetuate the happy constitution and frame of government under which we live."

As to the *practicability* of a canal on a *direct* route from Baltimore to the head of Conewago falls, the commissioners say—

"The resolution, which has assigned us our duties seems to have taken it for granted, that there was a choice of routes in which a canal might be conducted from the head of the Conewago falls to tide; the one, in a course over the country from the head of those falls to the city of Baltimore; and the other, from the same point to the tide of the Susquehanna. If this was the opinion of its authors, we now feel satisfied, that it was founded on a very erroneous notion of the shape, elevations, and general topography of the whole country between the tide waters of the Chesapeake and the head of the Conewago falls on the Susquehanna. But we are not at all surprised, that such an erroneous notion should have been indicated in the resolution, since we have found it to have been the prevailing opinion through the country, when we commenced our operations; and one, which seems to have taken so strong a hold on the minds of the great majority of the most intelligent inhabitants, in whose information we, for a long time, placed much confidence, that it was not until after a most laborious investigation we abandoned all hope of finding a route for a canal, over the country at any distance from the margin of the river."

"It is true, that some of the head springs of the Codorus, Deer creek, and Gunpowder are found within less than a quarter of a mile of each other; but in the summer season, it is believed, there would be a deficiency of water even at the mouth of Codorus, and in Gunpowder at Ridgely's furnace to supply a canal forty feet wide and four feet deep, which is likely to be as much used as the proposed canal. To look for, or expect, therefore, to find a sufficiency of water from those streams with which to pass over this vastly elevated summit, which, on an inspection of the profile of Mr. Poppleton's series of levels, that crossed it at right angles, it will be seen, is in breadth more than eighteen miles, and mounts to an elevation in some places of more than one thousand feet, and every where, in that width, more than four hundred feet above tide, must be admitted to be altogether out of the question; and has been pronounced to be so by Mr. Geddes, as will be seen in his communication hereto annexed; and, indeed, was a matter about which there was not the least shadow of doubt, or difference of opinion in the mind of any one engaged in the survey. But even suppose there might be a sufficiency of water, if those streams were wholly and exclusively applied to the canal, it will only be necessary to run the eye along them, and take a cursory view of the immense amount

of mills and manufactories upon them, every one of which must be bought out and suppressed, to be satisfied that it would be impossible from *pecuniary considerations alone*, so to monopolize and use them, even if it were in any way practicable to surmount the great physical difficulties."

"Upon the whole, therefore, we feel satisfied, that there can be found no other practicable route for a canal from the head of Conewago falls to tide, than that which we have surveyed along the right margin of the river."

To the same effect, Mr. Geddes the Engineer says—

"Contrary to the expectations of many, it is now ascertained, by the application of instruments, that a canal conducted on the level of the surface of the river, from the head of Conewago falls, will not leave the valley of the Susquehanna until it arrives at the valley of Deer creek, within less than two miles of the tide water.—The above level, beginning at the head of Conewago falls, will be designated the *Conewago level*. When led along the river valley, this line of level will run out into the several lateral valleys a short distance, and still be brought back again to the faces or brows of the hills between them. After entering Maryland, the Broad creek valley would allow said level to be carried many miles, out from the river, but the high land, separating Broad creek from Deer creek, would bring it again back to the stony steep hill, the base of which is the river shore, along the brow of which hill it must follow to the valley of Deer creek. The only method of conducting a canal, from York-haven, southward, must be by following the valley of the river, locking down occasionally, as has been done in the Mohawk valley, in the state of New York."

In reference to the *extension* of the Canal after bringing it down by the margin of the river to the head of tide water at Port Deposit, the commissioners state—

"But the resolution contemplates a canal from the head of the Conewago falls to the city of Baltimore, as well as to tide. The next inquiry, therefore, after we had completed our survey downward, as far as the tide at Port Deposit bridge, was, whether it were practicable in any way, and in what direction, to continue and extend the route from that point to the city of Baltimore. A straight line, from Port Deposit to Baltimore, would pass over the very crown of the high, dry elevations of Sater's ridge, where, according to the description we have already given of it, there could not be the least expectation of finding water enough for a canal of the very smallest capacity; and, on looking more northwardly, the lands were perceived to rise still higher. *There was, then, no hope of finding a practicable route for a canal in any other direction than over the river flats below all the projecting spurs of Sater's ridge.* This route has been accordingly explored, levelled, and surveyed, and has been found to be not only entirely practicable, but much shorter and better than we had at first any reason to expect."

Then as to the *length*, and the *expense* of constructing the whole line of the canal and of its several sections, the report sets forth—

"This whole route, from the head of the Conewago falls to the city of Baltimore, will require a canal of ninety-two miles and three quarters in length; which, for the more perspicuous consideration of the subject, we have divided into three sections; *first*, that extending from the head of the Conewago falls to the Pennsylvania line; *secondly*, that which is within this state, and passes along the margin of the river down to a point about a mile above Havre-de-grace,

where the route departs from the river, and takes a direction over the low lands toward Baltimore; and *lastly*, that which extends from the vicinity of Havre-de-grace to Baltimore. The first section, which is forty-one miles and fifty-one chains in length, is wholly within the state of Pennsylvania; and, in general, passes over a most uncommonly difficult, rocky, and uneven surface. In this section, if there are spaces where there will probably be found easy and cheap excavation; yet, there are others, where all the skill of an experienced and practical engineer must be called forth. For the whole of this section every allowance has been made in the estimates, for excavation, and the removal of all obstacles, that are in any manner apparent; and, that the aggregate amount of the estimate might be made as nearly accurate as possible, it has been divided into parts, according to the apparent character of each of them; and for every one of the several parts, a separate estimate made, taking into consideration the peculiar nature of each. Some portions of this section have been estimated as high as at the rate of eighty thousand dollars a mile; which it is believed, is as much as ever was allowed for any canal whatever passing over the surface, except the short distance where the great Erie canal of New York passes through solid limestone rock at Lockport. It is proposed, that in this section there should be a communication with the river by a lock at Wrightsville, immediately opposite to Columbia, so as to enable boats to pass through the canal to and from Columbia. The whole cost of this section has been estimated at one million, two hundred and twenty thousand, two hundred and sixty-five dollars.

"The second or middle section, is fourteen miles and twelve chains in length, and is altogether so entirely analogous in its nature to the first, that the same remarks will apply to it throughout. The cost of this section has been estimated at five hundred and sixty four thousand, four hundred and seventy-one dollars. The last and lower section passes over an alluvial soil, and is, therefore, expected to be every where very easy of excavation. In its whole length, of thirty-six miles and seventy-five chains and an half, it will pass, by aqueducts, at an elevation of twenty feet above the tide, over four rivers; that is, over a branch of Bush river, from the land of Doctor Davidge to that of Mr. Sewell; over another branch of the same river at Otter point; over Gunpowder, from the land of Mr. Caldwell to that of Mr. Oliver; and from General Stansbury's land over the principal branch of Back river. The cost, nature, and extent of these aqueducts have been carefully considered and estimated; they have all of them been deemed perfectly practicable; and the wooden frames, according to the experience on the Middlesex canal of Massachusetts, and the calculations on the canals of New York, may be accounted to last from fifteen to twenty years; when, if it shall be deemed advisable, the wooden structures may be replaced by iron, made after that manner which has been found, in Europe, to be comparatively cheap, safe, and practicable. It is proposed to open a communication, by locks, with this section and the tide near Havre-de-grace, for the purpose of admitting the arks, boats, and rafts, which may have descended the natural bed of the river, to enter and pursue their way in safety to Baltimore, without delay or transshipment; and also that the trade of Havre-de-grace, and the head of the Chesapeake bay, may have a ready access through the canal, either to the Susquehanna country above, or to the city of Baltimore. The whole cost of this lower section has been esti-

nated at eight hundred and forty-one thousand, two hundred and sixty-three dollars.—The three sections making together an aggregate amount of two millions, six hundred and twenty-six thousand dollars for the cost of the whole canal from the head of the Conewago falls, of ninety-two miles and three quarters in length, into the basin, at the city of Baltimore.

"For a more particular and detailed account of the nature of the obstructions; the manner of construction; the feeders and supply of water; the cost of each portion, and of the whole; and the incidental charges, we must beg leave to refer to the report, maps and drawings of our engineer Mr. James Geddes, which accompany this; and which, we feel satisfied, will make the whole subject perfectly clear and comprehensible to the understanding of every one. And, for further and more minute explanations of the sections of levels, that have been taken, and the surveys that have been made, we will also ask leave to refer to the books, plats, and drawings of Captain Bache, Mr. Poppleton, Mr. Bridges, and Mr. Bouldin, all of which accompany this."

(To be continued.)

Editorial Correspondence.

INTERESTING EXTRACTS from letters to the Editor of the American Farmer.

Rock Hall, Nov. 25th, 1823.

DEAR SIR,

I send you a sample of Carrots and mangel wurtzel, raised by me this last season. The mangel wurtzel is not so large as some few I raised two years past, but the aggregate of the crop is much larger: I gathered from 20 rows, 3 yards long, seven cart loads, closely packed and heaped up—and in many of the rows they were much scattered. I find the seed requires to be planted early in the spring, to ensure a crop, from the 1st to the middle of April, if the ground can be got in good order. I have failed in several crops by late planting—say 1st week in May. The seed will not vegetate when the earth becomes heated, and my land being low and wet, (which appears to be best adapted to their growth) it is but seldom I can get it sufficiently pulverized and dried early enough to ensure the seeds coming up.

The method of cultivation was precisely as Cobbet prescribes in the cultivation of ruta бага. That is, I first spread the ground thinly over with sea ore or grass, and turned it in, breaking the ground 7 to 8 inches deep. As my plough was the common size Cary, or Connecticut plough, I had to run twice in a furrow to break it that depth, then harrow and roll, then throw up a list or ridge, throwing up two furrows on each side the ridge, making the ridges about three feet apart. I then lay the manure, which consisted of green weeds gathered in July and August, the last summer, and laid in a heap; some little refuse lime thrown on them, and a small quantity plaster paris; then well covered over with mould—a hollow or basin formed on the top to collect the rain water, and left in that state until spring, when my ground was prepared as mentioned. The bank was then opened and well mixed together, and then laid in the trenches between the ridges; the ridges were then thrown back with the plough, over the manure, and a high ridge formed; I then run a light roller on the ridges, covering two ridges each time; I then dibble the holes twelve inches apart for planting the seed. This can be done with great expedition, by fixing five or

six pins, or pegs, one foot a part, in a piece of board three inches wide; then fix a forked or split stick in the board as a handle; the pegs to be about one and a half inches long, clear of the board; and when put on the ridge, a gentle press of the foot on the board, makes the holes very handsome and regular; the seed is then dropped and covered by hand. I find they grow more thrifty and larger from the seed than they do when transplanted. I have transplanted many, but have never had them of a tolerable size from that method. The ground the present crop grew on has not had any animal manure on it for the last three years, and only the vegetable manure made as before described, and I find that all vegetables that I have tried, grow much larger, and more thrifty with vegetable than with stable or cow yard manure. The carrots were raised with the same kind of manure: the method I adopted for them, was to make a narrow trench, forming an acute angle, 7 or 8 inches deep; the manure laid in about two inches, then covered with top mould, and raised one inch above the surface, to form a small ridge directly over the manure; this rise of the ground, or small ridge, makes it much more convenient to weed, while the plants are young. The seed of both the mangel wurtzel and carrot, I obtained from your friend Mr. Redding. I have grown carrots of the deep orange colour, in the same ground that produced the present crop, for a number of years past, and always applied animal manure, but never had them to grow to a third of the size of the present. We have gathered many much larger than those sent you.

Your very respectful,

Obedient servant,

THOMAS HARRIS.

The two carrots sent to the Editor, weighed 6½ lbs.; the mangel wurtzel, 13½ lbs.

Edisto Island, S. C. Nov. 9, 1823.

CRAB, OR CROP GRASS.

At the last meeting of our Agricultural Society, a specimen of crab (crop) grass was exhibited, which merits attention. It was seven feet high—grew on reclaimed marsh land, which last year had been planted in cotton, and was plucked from a field of twenty acres, the average height of which was upwards of five feet. After the cotton was harvested, the land was simply enclosed, and no care or labour subsequently bestowed. This fact sufficiently falsifies the assertion, that necessity obliges the planters of the South to become tributary to the Northern states, for fodder; and I am not surprised that this should have been so long the received opinion, when it is stated, that S. Carolina purchases from the state of New York alone, \$25,000 value of hay per annum. I would certainly be within the bounds of probability, were I to assert that 70 or 80,000 dollars are thus yearly lost to the agricultural interests of our state; for it is an incontestable fact, that our enclosed lands seldom fail in producing rich and abundant crops of crab grass, but from some inexplicable cause they are rarely ever cut. We thus appear to avert our eyes from one of the choicest gifts of nature, and seem disposed to bend our undivided efforts to the cultivation of a single plant, (cotton) in the confident but too often blasted expectation, that with its surplus proceeds, all the necessaries and even luxuries of life can be purchased. It is a matter of congratulation, however, to reflect that the laudable exertions of our Agricultural Societies will speedily effect a revolution in the minds of our planters, and teach them the admonitory lesson,

never to go abroad for that which can be procured, as it were, without labour, at home.

Very respectfully,

Your obedient servant,

W. B. SEABROOK

J. S. SKINNER, Esq.

Extract of a letter to the Editor dated WILMINGTON, N. C. November 8, 1823.

J. S. SKINNER, Esq.

Sir—The ruta бага you sent me were sowed about the middle of July, and have thriven admirably well—many of the roots now weigh from 5 to 6 lbs.

I received a short time since, the small parcel of "Hardy Rice Seed," which you forwarded—fearing from its appearance, and your doubts on the subject, that it would not vegetate, I made trial of one third the quantity sent me, and our fears realized; not one seed has sprouted.

I do not, however, think the seed would be valuable to plant on *tide swamps*, as far south as this. If it be peculiarly valuable at all, it must be because it thrives well in colder climates, or on *dry land*. The grain is inferior in size to the rice generally raised in this neighbourhood. It resembles in shape and appearance, (but is lighter) a species of rice, which was tried here some years since, called the "Patna rice."—The Patna rice, though heavier than the golden rice, now in general use, has been abandoned, because it does not bear beating so well, and shatters more in harvesting.

Very respectfully, your's,

WM. B. MEARES.

NILES'S WEEKLY REGISTER.

This work was commenced at Baltimore in September, 1811, and is still published there, at five dollars per annum, payable in advance. Of the character of the Register, which has been so long before the public, it is superfluous to speak. It was designed, at once, to be a faithful representative of political facts, and a watchful guardian of the rights of the people, without a prejudice or partiality to persons. How far it has succeeded is not for the editor to determine. He has only to say, that it shall continue to be published on its original principles, with fearless perseverance; and that it never shall be rendered subservient to the individual preferment or personal abuse of any man.

The ensuing session of congress will be one of more than ordinary interest. It is expected that some private business of the editor, totally unconnected with public men or political measures, will render it necessary for him to be much at Washington during this session, and he will, thereby, be enabled to present his readers with a nearer view of what shall be transacted than has heretofore been given in this work, that the people may the better know what their servants are doing or leaving undone. In representing facts, no consultation will be held with fear, or bargain made with expediency.

The subscription to the Register is one of the largest in the United States, but there is ample room for additions to it; and the editor respectfully requests his friends to increase his means of being useful, by extending the circulation of his work, for which purpose this paper is furnished.

As the current volume commenced on the first of September, ultimo, it is best that new subscribers should begin at that time, and that the back numbers will be furnished, that they may have a perfect work so long as they continue.—Complete sets in 24 vols. may be had. Including

the general index, and all the extra supplements, the price is seventy dollars, in sheets, folded and collected in volumes.

The safety of the mails, when money is enclosed to the editor, is guaranteed. Address
H. NILES, Baltimore.

FROM THE NEW ENGLAND FARMER.

On the necessity of destroying some animals and preserving others for the use of man.

Whate'er of earth is form'd to earth returns,
Or takes the shape of matter decompos'd
To pristine particles unorganis'd,
Which constitute the principles of things—
Plants, animals, and all the mighty mass
Which forms the Universe are shifting still
In ceaseless change. All but the soul of man,
That particle divine will be the same
Amid the crash of worlds and wreck of matter.
Hence, great the distance, which exists between
The brutes, which perish, and immortal man.
The lower order of created things
Were made for man, subservient to his will,
Plac'd under him by that ALMIGHTY POWER,
Whose word omnific gave creation birth.
The brute inhabitants of earth, sea, air,
Though subject all to Man's supreme control,
Still claim the rights contain'd in Mercy's code—
And he who gives them needless pain deserves
To feel the pain his cruelty inflicts.
But still the noxious and the useless tribes
Of animals are rightly doom'd to slaughter;
And some must bleed to pay the just demands
Of man who nourish'd them, without whose care
And toil incessant, they had never been.
Should he not kill (as erst Pythagoras
Taught his disciples, and as Indian Bramins
Vainly contend) the fierce and ravenous brutes
Would soon make earth a desert fill'd with nought
But beasts and birds of prey—should not his care
Improve his growing stock, their kinds would
fail:

Man then on roots and acorns must subsist,
And dwell in caves and hollow trees forlorn,
Quite destitute of every solace dear,
Connubial bliss, the ties of friendship—all
Which gives to life its polish and its zest.

THE FARMER.

BALTIMORE, FRIDAY, DECEMBER 5, 1823.

SEEDS, VEGETABLES, &c. &c. deposited at the office of the American Farmer, since last publication.

GUINEA GRASS—eight feet high, brought at Editor's request by CAPT. HODGSKINSON, direct from Jamaica. He says it is first planted thick in small lots—tillers very much—is then transplanted over a much greater surface in a manner to grow thus X, and is cut eight times a year.

A variety of seed of native flowers and plants of the Western country, by S. Garrison, Esq.—these were for presentation to the Horticultural Society of London, through D. Douglass, Esq. their botanical missionary. They will doubtless prove a very acceptable offering to that distinguished and publick spirited institution.

An ear of corn, by R. L. Colt, Esq. 15 inches long, such as is cultivated in the Eastern states.

MANGEL WURTZEL and CARROTS of immense size from the farm of CAPT. HARRIS, of Rock-hall. The mangel wurtzel, weighed upwards of thirteen, and the carrots nearly four pounds each.

HEADS OF EGYPTIAN MILLET, two feet six inches long, by Doctor J. S. SPENCE, member of Congress from Worcester, Md.

Proceedings of the Maryland Agricultural Society for the Western Shore.

A meeting was held at the office of the American Farmer agreeably to publick notice, for the election of officers for the ensuing year, and for the transaction of such other business as might be submitted for consideration:

The following officers were re-elected.

R. SMITH, Esq. *President*,
JAMES COX, Esq. *Treasurer*,
JAMES HOWARD, Esq. *Recording Sec'y*,
J. S. SKINNER, Esq. *Cor. Sec'y*, and
E. DE BUTTS, M. D. *Professor of Agricultural Chemistry*.

Dr. H. WILKINS, *Professor of Botany*.

W. F. REDDING, Esq. *Collector*.

BOARD OF TRUSTEES.

CHARLES RIDGELY, Esq. of H. *President*.

SAMUEL OWINGS,

CHRISTOPHER CARNAN, Jr.

JAMES M. BOSLEY,

JAMES GITTINGS,

H. V. SOMERVILLE,

JACOB HOLLINGSWORTH, Jr.

JAMES CARROLL, Jr.

B. W. HALL,

JOHN PATTISON, and

In lieu of Robert Gilmer, Esq. and Dr. Samuel M'Culloch, resigned, the Society elected

Gen. R. G. HARPER, and

DAVID WILLIAMSON, Jr. Esq.

On motion of J. S. Skinner, the following Resolutions were adopted—

Resolved, that the President of the Society be requested to prepare for signature and presentation to the Legislature of Maryland, a memorial praying for pecuniary aid, from the State to the Society, on the Western and Eastern Shores, to an amount not exceeding—dollars per annum for each, on condition that a like sum shall have been previously collected by the Society on each shore, respectively; and for an act of incorporation; and for such other enactments as may be deemed beneficial for the interest of agriculture in Maryland.

Resolved, that the Trustees of the Society have power to fill up, from time to time, such vacancies as may occur in the Board of Trustees on either shore.

Resolved, that it be the duty of the President, the Treasurer, the two Secretaries, the Collector, and each member of the Board of Trustees to use all convenient means to procure regular subscribers to the Maryland Agricultural Society, for the space of five years, and for a sum not less than five dollars each, and that each one of the said persons make return to the next meeting of Trustees, and each successive meeting, of the progress then made in procuring such subscribers.

The Society then adjourned, *sine die*.

The next meeting of the Trustees will take place at "THE MOUNT," the residence of James Carroll, Jr. Esq. near the first gate on the Washington turnpike, on Wednesday the 17th December, at 10 o'clock, A. M.

PROCEEDINGS OF THE MARYLAND AGRICULTURAL SOCIETY, AT EASTON.

The Maryland Agricultural Society met in Easton on Tuesday the 25th of November, 1823, agreeably to publick notice.—The Vice-President in the Chair.

The Constitution as amended being under consideration, the following resolution was unanimously adopted:

Resolved, That the Articles of Association, as amended at an adjourned Special meeting of the Maryland Agricultural Society, held at Balti-

more on the 23d June, 1823, be and they are hereby approved and adopted, as the Constitution of the Society.

The Society then proceeded to appoint twelve Trustees, when the following persons were unanimously elected, viz: Nicholas Hammond, Edward Lloyd, Samuel Stevens, Tench Tilghman, Perry Benson, Robert Moore, Robert H. Goldsborough, Daniel Martin, Thomas Hayward, Henry Holliday, Lambert Reardon, and Samuel T. Kennard.

Joseph Haskins, Esq. was unanimously re-elected Assistant Treasurer, and Dr. Thomas H. Dawson, Assistant Secretary in the place of Samuel T. Kennard who declined a re-election.

Resolved, that the above proceedings be published in the American Farmer, the Easton Gazette and Republican Star.

EDWARD LLOYD, *Vice President*.

SAMUEL T. KENNARD, *Ass't Sec'y*.

N. B. The Trustees are requested to meet at the "Easton Hotel," on Saturday next at 11 o'clock A. M.

BALTIMORE MARKET.

PRICES CURRENT—CORRECTED WEEKLY.

Flour, best white wheat, \$7 25—Howard street, from wagons, \$5 75—fine do. \$6—Wharf, do. \$5 50, cash—White wheat, \$1 12 to \$1 18—Red do. \$1 6 to 1 8—Lawler, \$1 10 to 1 12—Washington white, \$1 12 to \$1 20—Rye, 42 to 45 cts.—New corn, 33—Old do. 34—Wharf Oats, 33 cts.—wagon Oats, 37½ cts.—Beef, 6 cts. per lb.—Live Cattle, \$5 to 5 50, per cwt.—Bacon, hog round, \$10—Pork, \$5 50 to \$6 per c. lb. 6 to 8 cts. per lb.—Mutton, 4 to 5 cts. per lb.—Beans, retail, \$1 25, cargo price, \$1 —Peas, retail, 62½ cts., cargo price 48 to 50 cts.—Red Clover Seed, \$6—Orchard Grass do. \$2 50—Herds' Grass do. \$2 50—Timothy do. \$1—Flax Seed, 75 to 80 cents—Whiskey, from the wagons, 34 cents per gallon including the barrel—Apple brandy, 30 to 32 cts.—Peach do. 65 to 70 cts.—Shad, No. 1, \$6 very dull, No. 2, do. \$5 do.—Herrings, No. 1, \$2 25 per bbl., very dull No. 2, \$2 do.—Fine Salt, 75 cents per bush, coarse, do. 70—Butter, (firkin) 12 to 13 cts. per lb.—Eggs, 12½ cts. per doz.—New Hay, \$14 per ton, old do. \$16—Straw, 7.

Brown's Vertical Spinner.

The subscribers have obtained the patent right for this valuable machine for spinning wool for the states of Maryland and Virginia, and the counties of Adams and Franklin, Pennsylvania, and are willing to dispose of their privilege of vending them for all or any part of said territory, except that part convenient to this city. They will within a few days be prepared to supply those that are in immediate want of the machines, and are making arrangements to have them constantly for sale. It is thought that those spinners are much superior to any thing ever introduced for family use. For a description of them, see the report of the committee on Machinery, at the late Cattle Show, held near this city.

Letters addressed to either of the subscribers, (post paid) will receive the necessary attention.

D. G. M'COY,

Corner of Eutaw and Balt. Streets.

JONATHAN S. EASTMAN.

The price of the machine with six spindles is \$20.

Printed every Friday at \$4 per annum, for JOHN S. SKINNER, Editor, by JOSEPH ROBINSON, on the North West corner of Market and Belvidere streets, Baltimore; where every description of Book and Job Printing is executed with neatness, and despatch—Orders from a distance for PRINTING or BINDING, with proper directions promptly attended to, addressed to J. Robinson, Baltimore.

AGRICULTURE.

GRASSES.

(Continued from p. 292.)

Long-rooted clover, is a native of Hungary, and I do not think has ever found its way across the Atlantic. The root is biennial, and if sown in the fall, lasts only during the next season. It penetrates to a great depth in the ground, and consequently is but little affected by drought. It, therefore, requires a deep dry soil. The product of this grass, when compared to others that are allied to it in habit, and place of growth, proves greatly superior. It affords twice the weight of grass, and more than double the nutritive matter, that is given by the common clover. It gives abundance of seed; and, says G. Sinclair, "if the ground be kept clean of weeds, it sows itself, vegetates, and grows rapidly, without covering in, or any operation whatever. Four years it has propagated itself in this manner, on the space of ground which it now occupies, and from which this statement of its comparative value is made." This species would, no doubt, prove a valuable acquisition to our husbandry, whether we consider its value for green food, hay, or as a green crop to be turned in preparatory to grain.

Sain Foin is peculiarly adapted to a calcareous, or chalky soil. It is true it is cultivated in Norfolk, England, which is a soil of sand and loam, naturally destitute of calcareous matter. But it is common, there, to dress their lands with clay marle, which abounds with carbonate of lime; without which dressing, says Young, Norfolk soils will not grow Sain Foin. This writer considers it "one of the most valuable plants that were ever introduced into the agriculture of Great Britain." The well known Mr. Coke cultivates 400 acres of this grass; and sows it without other seeds. Several attempts have been made to cultivate sain foin in this country, but hitherto, I believe, without success.

Timothy. This grass is distinguished in Great Britain, by the name of *meadow cat-tail*; in New England by that of *herds-grass*. The table shows that it is one of the most valuable grasses that are cultivated,—and, what is worthy the notice of every farmer, that it affords more than double the nutriment when cut in the seed, to what it does when cut in the flower. Intenacious, strong and moist soils, it is entitled to a precedence, perhaps, to any single grass for hay; yet, for the reasons already stated, it does not seem to be suitable for mixing with clover seeds, when intended for meadow. Another consideration which renders it particularly worthy of attention is the seed which it affords, and which may be saved without materially diminishing the hay crop. From ten to thirty bushels of seed, may be taken from an acre of timothy, which at the price it now bears, is of itself, a handsome remuneration.

Forin,—has, of late years been brought into notice in Great Britain, by the experiments and recommendations of Dr. Richardson; who particularly recommended it for the cold, boggy soils of the mountainous districts, where ordinary grasses would not thrive. The peculiar value of the forin, and of other grasses of the *agrostis* family, arise from their fitness for *winter pasture*; as they lose very little of their bulk or nutriment by remaining on the soil after they have ceased to grow. Its name (*creeping bent*, or *couch grass*) implies a difficulty in mowing it, except on a surface perfectly smooth. We have seen it frequently recommended to the notice of American farmers; but from the very limited progress which seems to have been

made in its cultivation, we infer that it has fallen short of public expectation.

Upright bent grass. Dr. Muhlenburgh considers this the *herds-grass* of the southern, and the *foul meadow* of the eastern states, of which *white-top* and *red-top* are varieties. The small weight of hay, and of nutritive matter, afforded by the *agrostis stricta* in the table before us, shows that this grass is more congenial to our climate than to that of England; for, in both quantity and quality, our foul meadow and red-top seem to approach our favorite timothy. In my boggy soils, both varieties of this grass have come in spontaneously, as soon as the ground has been cleared and drained, have soon formed a compact sod, and afforded good hay and good pasture.

American Cocks foot, is wholly unknown to me; and I have not been able to learn much from enquiry as to its merits. M'Mahon calls it the *swamp cock's-foot*; and says it grows well in swamps and moist soils. As it is a native grass, and appears to afford an abundant crop, it is to be hoped that some one acquainted with it will bring it into further notice.

Flat stocked meadow grass. This, according to Muhlenburgh, is the *blue grass* which is considered a pest in many of our tillage grounds. The small crop which it gives, and the little nutritive matter which this affords, shows the little dependence which ought to be placed upon it for grazing or hay.

Reed meadow-grass, otherwise *water meadow-grass*, is not natural to our country. As it affords a great burthen of hay, and is, withal, rich in nutriment, it might be a valuable acquisition to our swamp grounds, which constitute its favorite soil.

Smooth stalked meadow grass, is a native plant, and is well adapted for permanent pastures. It grows quick after being cropped, and does well upon dry grasses.

Floating Fescue grows well in swamps and bog soils, where good kinds are most wanting.

I would suggest, with much deference, whether grasses may not be divided, for the *practical* benefit of farmers, into three kinds, to wit.—Cultivated grasses, meadow grasses, and pasture grasses;—and whether these may not be again subdivided to suit different soils and localities. I will illustrate my project, by attempting a classification, of the grasses enumerated in the preceding table, from the data which it affords, and the practice of judicious farmers:—and

1st. *Cultivated grasses*. All kinds, strictly speaking, which the soil does not produce spontaneously, are cultivated grasses: But the term, as generally used, and in the sense I here employ it, applies only to such as are sown to *alternate with grain, pulse and roots, in a systematic rotation of crops*. The grasses selected for this purpose, are generally the Red-clovers, Lucern, Sain Foin, Orchard, Tall oat, Timothy, or Rye grass. Clover is the primary dependence on all soils which will grow it, and particularly where gypsum can exercise its magic powers. As vegetables are said to exhaust the soil, in proportion to the smallness of their leaves (the larger their leaves, the more nutriment they draw from the atmosphere, and the less from the soil) clovers are entitled to the high commendation they have obtained among American farmers. But as these plants are liable to premature destruction by the frosts of winter, it is both prudent and wise to intermix with their seeds (those of some other grass more to be depended on. For this purpose,

On *sands, loams, and gravels*, and these constitute the soils usually employed in convertible husbandry, the orchard grass, or tall mea-

dow oat grass, appear to be best calculated to ensure profit. They grow early, delight in a clover soil, and are fit for the scythe when clover is in the bloom, the time it ought to be cut. The hay from this mixture may be made before harvest commences; and, if the soil is good, a second crop may be cut almost equal to the first. If intended for pasture the second year, either of these grasses will afford more abundant food than timothy.

In *clays*, the meadow fox-tail, an excellent grass, might be substituted, though, according to Sinclair, the tall oat grass will do well here also. In *wet soils*, where clovers do not grow well, timothy and meadow reed grass would be a good selection, sown either separate or together.

Lucern and sain foin require a deep dry soil, and are generally sown without other seeds. The first does not attain to perfection before the third year; and both, where successfully cultivated, are permitted to occupy the ground from six to eight years.

2d. *Meadow grasses*. In selecting these, the object is to obtain the greatest burthen of good hay, and to mix those kinds which may be profitably cut at the same time.

For *clayey and moist soils*, many valuable and nutritious kinds seem to be well adapted, that is to say, Meadow Fox-tail, Timothy, Tall oat, Meadow soft grass, floating Fescue, Rye grass, Reed meadow, Smooth stalked meadow, American Cock's-foot, upright bent or Herds-grass, and Tall Fescue. And the five last are peculiarly suited to swamp or bog soils. For *dry loams, sands and gravels*, which never ought to be kept long in grass, the cock's-foot, or orchard grass, and tall oat, are probably the best; and to these might be added red and white clover.

The great difficulty is to prevent the deterioration of meadows. This takes place from the better grasses running out, and giving place to coarser kinds, to moss and to useless or noxious plants; aided often by a neglect to keep them well drained. The finer and more nutritious kinds thrive best in *moist*, though they will not live long in *wet* soils. Hence it is of the first importance to keep the surface soil free from standing water, by good and sufficient ditches; and it often becomes necessary, and it is in most cases advisable on a flat surface, to lay the land in ridges, at right angles with the drains. Another precaution to be observed, is not to feed them with stock, when the soil is wet and poachy. Harrowing in the fall, has been found beneficial to meadows. It destroys mosses, and covers the seeds of grasses which have fallen, or may be sown, and thus produces a continued succession of young plants. In Europe, lime is used with good effect as a top dressing to grass lands, as are also ashes. With us, the annual application of a bushel of gypsum to the acre is found highly beneficial. It not only thickens the verdure with clover, but is of advantage to most other grasses. Stable manure should be applied only when it can be spared from the more profitable uses of tillage. When the means above enumerated fail to ensure a good crop of hay, it is time to resort to the plough and a course of crops.

3d. *Pasture grasses*. But few of the grasses most valued in Great Britain for pasture, are the natural growth of the United States; but it is believed, that if the seeds are once introduced upon our farms, we shall find little difficulty in naturalizing them. Neither the orchard nor vernal grass, which are said to be indigenous to our country, are recognised in the grass lands which have come within my observation:

yet they constitute, with fox-tail and tall oat grass, the earliest and most valuable varieties for perennial pastures. The meadow fox-tail, and orchard grass, together with our white clover and green meadow grass, *poa viridis*, (which seldom require to be sown) I think would form the best selection for all grounds which are moderately dry. The rye and oat grasses, or meadow soft grass, might be either substituted for the two first, or combined with them. These would afford spring, summer, and fall feed, abundant in quantity, and wholesome and nutritious in quality. On wet soils, (though pastures require to be drained as well as meadows, to ensure a rich herbage) the Tall Fescue, Smooth stalked Meadow, Upright bent or Herds-grass, may be introduced to advantage. Gypsum is applied to pastures with the same benefit that it is to meadows.

I will conclude this already tedious communication with a request, that you will confer on me a particular favor, by forwarding, if to be obtained in your city, a small parcel of seed of the Meadow Fox-tail, Tall Fescue, Hungary clover, and American Cock's foot, or either of them, care of Thorburn and Son, New York. I have the Tall oat, Rye grass, Orchard grass, and Lucern growing. Most of the other grasses that I esteem valuable are already among us.

J. BUEL.

NAMES OF DOMESTIC ANIMALS AT DIFFERENT AGES.

[In English works on Agriculture, domestic animals are spoken of, by different names, according to their ages, and sometimes to other circumstances, and in this country, butchers, graziers and other persons who deal in different species of these animals, designate them by particular names which are in some measure technical and not familiar to all. Young farmers are apt to think such things of trifling account, but we hold that they ought to be *up* to every thing of the kind, which is so immediately connected with their own business. It is their "vocation," and they ought to neglect no sort of information that may enable them to conduct their affairs or to understand with more facility whatever they read or hear in relation to any branch of their own pursuits. Under this persuasion, we have selected the following.]—*Edit. Am. Far.*

ACCOUNT OF THE NAMES OF DOMESTIC ANIMALS AT DIFFERENT AGES.

The general name by which the male sheep are known, is Ram or Tup. When lambs, they are called ram or tup-lambs as long as they suck. From weaning, or taking from the ewes, to the shearing or clipping for the first time, they are called hogs, hoggerels, or lamb-hogs. Then they take the name of shearing, shearling, shearhog, or dinmond tups or rams. After that, according to the years they are clipped or shorn, they are called two-shear, three-shear, and so on, which always takes place from the time of shearing.* But when gelt or castrated, they are called wether-lambs while sucking; then wether hogs, until shorn or clipped, when they take the name of shearings, &c.; until they are shorn a second time, when they are called young wethers, or two shear-wethers; then three or four shear-wethers, or more, according to the times they are clipped or shorn.

The general name by which the female sheep are known, is Ewe: while sucking, they are called ewe lambs, or gimmer-lambs; but when weaned, or taken from the dams, they are called ewe hogs or gimmer-hogs, until clipped or shorn for the first time, when they take the name of gimmers, which name continues only one year, until they lose their fleeces a second time, when they obtain the name of ewes, which they retain as long as they live; only, every time they are shorn, they add a year to their age, and are called two-shear, three-shear, or four-shear-ewes, according to the times they have been clipped or shorn: And this holds good of all other sheep: for, the age of sheep is not reckoned from the time they are lambed, but from the time of shearing: for, although a sheep is generally 15 or 16 months old when first shorn, yet they are not called shearings until once clipped, which is understood to be the same as one year old.

The general name of the male in Neat Cattle, is Bull. During the time he sucks, he is called a bull calf, until turned of a year old, when he is called a stirk or yearling bull; then a two, three, or four year old bull, until six, when he is aged: but when castrated or gelt, he is called an ox or stot-calf, until a year old, when he is called a stirk, stot or yearling; then a two year old steer, and in some places a twinter:—at three, he is called a three year old steer; and at four, he first takes the name of ox or bullock, though formerly I believe the castrated male was not called an ox or bullock until six years old,† when he is looked upon to be at the best, though some people think an ox improves until seven, eight, or even nine years old. The general name of the female of this kind is Cow: while sucking the dam, she is called a cow-calf, quey calf, or heifer-calf; then yearling quey or heifer; then a two year old quey or heifer, or twinter; the next year a three year old quey or heifer, and when four, she is first called a cow, which name is retained till the last. If castrated or spayed, she is called a spayed or cut heifer, or spayed or cut quey in the North parts of the island.

A Stone-horse or stallion is what we distinguish the male of the horse-kind by: while sucking, he is a foal or colt-foal, then a yearling colt,‡ afterwards a two and three year old colt, until four, when they are most commonly called horses, which name holds through.

The female of this breed is called a Mare: when sucking, a mare or filley-foal, then a yearling-filley, afterwards a two and three year old filley, and at four she becomes a mare.

Of the Pig-tribe the male is called a Boar or Brawn, the female a Sow, the castrated male a hog-pig, the cut or castrated female a gilt or gaut. Pigs or Swine are common names for the whole tribe.

† I apprehend the taking the name of ox or bullock at four instead of six years old, has taken place since the drawing or working of oxen has been so much disused.

‡ In some places a colt from one to two years old is called a stag.

From the Massachusetts Agricultural Repository and Journal, Vol. vii.

ON GELDING HEIFERS, SWINE, &c.

GENTLEMEN,
I have presented for premium five spayed sows perfectly healed and in good condition, and conformably to the rule prescribed to entitle an ap-

plicant to the premium, I beg leave to state the process in manner following, viz.:—The animal is laid on its side and held fast by one person unless over forty pounds weight; exceeding that weight two persons may be necessary. An incision is then made from three to six inches long, proportioned to the size of the subject, through the integuments and abdominal muscles to the peritoneum,* in a transverse direction from the spine toward the linea alba,† at the distance of about one inch from the last short rib of one side, (the opening nearly corresponding with the direction of the rib,) the peritoneum is then to be cautiously opened to prevent wounding the intestines. The intestines are next to be turned out with the hand, which exposes the ovaria (which are two oval bodies on each side of the uterus, about the size of a walnut in a pig of sixty or seventy pounds weight) consisting of a number of small vesicles called ova; these are removed by the knife, the intestines replaced, and the external wound sewed up, the pig may then be returned to the sty and fed sparingly for a few days. In addition to the pigs now exhibited, this operation has been performed on twenty sows of various sizes at Byfield, in the county of Essex, and at Brighton by direction of Mr. Parsons, who authorizes me to state to you, gentlemen, that he is perfectly satisfied with my ability to perform this operation successfully.

With great respect your obedient servant,
JOHN BAKER.

* Peritoneum, commonly called film of the belly.

† Linea alba, is a straight line drawn from the point of the breast bone, directly between the legs.

HORSES AND SHEEP.

A comparative view of the expenses and profits of raising horses and sheep.*

Expenses of raising one colt, viz.
Finding the mare one winter, including loss of use of her, and other unavoidable expenses, \$40 00
Finding the colt till four years old, at \$30 per year, 120 00

Amount, 160 00
Risk of the life of the mare and colt, during the raising, is worth the interest of the amount for one year, 9 60

\$169 60
Expenses of keeping 20 sheep for four years.
Feeding 20 sheep four years, at \$2 a year each, is \$40 a year, and four years is † \$160 00

* One of the most philanthropic and enlightened gentlemen of New England, has promised the Editor a paper on the natural history, capacities and qualities of the mule—and a comparison between that animal and the horse, for the various purposes to which each is applicable—we are bound to wait with patience, but were it only for the gratification we find personally, in perusing every thing from his pen, we could not repress the expression of a hope, that he may soon find leisure to fulfil his promise

Edit. Am. Farmer.

† This estimate is too low. To keep a sheep as he ought to be, summer and winter, will cost \$4 per year. But even at that rate, the superior profits of sheep is evident.—*Editor of Archives.*

* The age of sheep is also known or pretended to be known, by the changes on their fore-teeth; I say pretended, because I take upon me to say that it is a very uncertain way of judging, as I will endeavour to show afterwards.

They will probably raise in the time 80 lambs, at \$2 each, which ought to be deducted, 160 00

They will produce annually \$30 worth of wool, which will be a net gain of 120 00

By this calculation it will appear, that the horse when raised, must sell immediately on rising four years old, for the sum of 169 dollars 60 cents, to make the farmer whole for the expenses of raising him.—And of course, if he should remain one year on hand without profitable employment, the whole expense of keeping a full grown horse a year, say 60 dollars, must be added.

But the business of raising sheep, calculated to the same amount of expense, refunds the cost of feeding, and leaves to the farmer a net profit of 120 dollars. To which may be added the consideration of continual increase, by keeping them to any length of time. The advantage then in favor of raising sheep, rather than horses, is sufficiently proved by this estimate. And the immense and irreparable loss to individuals and the community, which attends the keeping of idle horses, should lead men to pursue a more rational course. It is unquestionably true from the premises, that the expenses of keeping one idle horse for an ordinary life time, say 20 years, would be 20 times 60, or 1200 dollars—a sum sufficient to buy your son a neat little farm, for ever lost. The same expense employed for the same term in raising sheep, would produce at least the same amount in absolute gain. The loss attendant on keeping an idle horse, should be added to the sum, which with the same money differently applied, might be gained—that is, 2400 dollars more. Then the fair conclusion, that the comparative advantage of raising sheep rather than keeping one surplus or unnecessary horse in 20 years, is 3,600.

Internal Improvements.

CANAL FROM BALTIMORE TO CONEWAGO.

[Continued from page 295.]

In regard to the geographical extent of country which must send its productions to market by the proposed canal, and be supplied by it in return with such commodities, as are wanting for its use and consumption, the commissioners present the following view, and they demonstrate its accuracy, by a well delineated map, accompanying their report—

“According to these principles, then, relative to the extent and influence of canal and river navigation, we will proceed to designate the boundaries of that tract of country, the commercial intercourse with which is now, in the descending line; and, when the proposed canal is complete, must be in the ascending line; and, in every way wholly and exclusively connected with the port of Baltimore. We will begin to trace this boundary from Mechanicsburg, near the line between Pennsylvania and this state; thence westwardly, including Shippensburg; thence to the Alleghany mountain, beyond Bedford and Frankstown; thence northwardly, including Clearfield and Potter counties in Pennsylvania; thence, including Steuben and Tompkins, through Courtland, Chenango, Otsego, and Delaware counties, in New York; thence, including Susquehanna and Luzerne, and through Schuylkill, Lebanon, and Lancaster counties, in Pennsylvania, to the Maryland boundary.—Within the line thus drawn round the navigable waters of the Susquehanna; and, which is evidently no more than barely of sufficient extent to embrace all the country from which produce is, at present, sent to market down the Susquehan-

na, and which must always be dependent on that great river for all its commercial intercourse with any sea port whatever, there is included more than half the territory of the state of Pennsylvania, and a great portion of that of the state of New York.

“It has been computed, that the whole state of Pennsylvania embraces an extent of twenty-four thousand, five hundred square miles, or twenty-seven millions, two hundred thousand acres of land. The half of which, on an inspection of the annexed map of the Sasquehanna country, and its practicable canal routes, on which we have laid down these boundaries just designated, it will be seen, is embraced within them; to which, it will also be seen, there must be added a portion of the state of New York, equal to six or seven counties of that state. Hence, it will appear, that according to a fair and impartial computation, the whole extent of the Susquehanna country cannot be estimated as containing less than about sixteen millions of acres; which is not far short of being three times greater than the whole state of Maryland together; which is computed at no more than six millions, nine hundred and twelve thousand acres. To those who have visited, or are well informed as to the general character of the Susquehanna country, it will be unnecessary to say any thing; and, to others, it will be sufficient to observe, in general, that this vast region, in point of fertility and excellence for all the purposes of agriculture, in fine climate, pure mountain air, and capacity to sustain a great and dense population, is equalled by few portions of this union, and surpassed by none. A very great portion of it is, as yet, but very thinly settled, owing no doubt, in part, to the vast tracts of vacant land in every direction, within our union, on which our people have been induced, by the various circumstances of advantage, fashion, or caprice, to plant themselves; but, as it has been justly observed, by a set of commissioners, appointed by the state of Pennsylvania, in their report of January 1790, “the great obstruction and bar to the wealth and population of this western country, has been the impassable falls in the river from Conewago to the tide.” This country is yet in a great degree to be filled with population; the extent and nature of its resources are yet to be explored; and the amount and value of its commercial intercourse with the sea-port, with which it is, by nature, so strongly connected, have been only begun to be developed within the last twenty years; and cannot, therefore, as yet, be fully appreciated. But some idea of the immense amount to which the value of that intercourse would be, almost immediately swelled, on the opening of the proposed canal, may be formed, by adverting to the very great amount of the commodities which has of late been annually committed to all the imminent dangers of the river, in its present condition, and submitted to be dashed down from Conewago to tide, a distance of about seventy miles, in less than seven hours, by one of the most furious, perilous, and ungovernable torrents in the world.

“By adverting to the last census of the United States, it will be seen, that there was, at that time, seated within this great range of the Susquehanna country, as extended through the state of Pennsylvania into the state of New York, a population of not less than five hundred and two thousand, six hundred souls; composed, almost altogether, of free whites, and principally of industrious agriculturists; and that the whole population of the state of Maryland, including all descriptions, according to the same census, amounted to no more than four hundred and seven thousand, three hundred and fifty. The

Susquehanna country being nearly one-fifth stronger, even in a numerical point of view, than the whole state of Maryland together. But the population, at present, seated within the Susquehanna country may be considered as among the most active, vigorous, and productive of any within our union; and, therefore, when we recollect the rapidity of the increase of population in every direction over the United States, where both soil and climate are friendly to human existence, it may be confidently predicted, that, at the end of twenty-five years from the date of the last census, there will be found within those limits, which we have designated as the Susquehanna country, a population of at least one million of souls; the great mass of whose exports and imports, to and from all foreign nations, can only be effected by means of the Susquehanna river, through that sea-port which shall be rendered most cheaply and easily accessible to its navigable waters; and, that access can only be effected, as we conceive, through the proposed canal from the port of Baltimore.

“It may startle the apprehension of some to find that we have approached, with the northern boundary of that which we designate as the Susquehanna country, so near to the grand Erie canal of New York, as to include the upper ends of the Seneca and Cayuga lakes, which have been generally considered by the citizens of New York as forming properly a part of their great work. And this, in some respects, is true. But it is a first principle in all commercial operations, that all commodities will always be sent to market along that route over which they can be transported soonest and cheapest. It is a fact then, that the transportation down the river is accessible so much sooner, and is so much cheaper, than down the lake and the grand Erie canal, that, from twelve and a half to twenty five cents more per bushel is given for wheat at the navigable points of Owego, Bath, &c. on the Susquehanna, to be sent down that river to Baltimore, than can be afforded for it any where on the lakes, to be sent to the tide. In consequence of which great quantities of wheat, and other commodities are annually sent across from those lakes, to the Susquehanna, and thence down to Baltimore.

“The costs and charges of navigating an ark of forty tons burthen, which is the average tonnage of those vessels from Owego to Conewago, a distance of two hundred and fifty miles, is about fifty dollars, and somewhat proportionally more or less, from any point higher up or lower down the river. But from Conewago, or Columbia, a distance, at farthest, of not more than sixty or seventy miles, by the river channel, to tide; the expense of navigating a similar ark down the torrent, (and with a burthen of more than fifty tons, no one will venture to descend,) is from fifty to seventy dollars. Thus constituting more than one half of the whole expense of navigating the river from any of its highest points; independent of the insurance, which to Conewago is nothing, or not more than one half per cent, but which from Conewago to tide is worth from seven to ten per cent on the value of the cargo; but on the proposed canal, from Conewago to Baltimore, the whole expense of transportation through, would not exceed half that amount. The proposed canal, then, would be the means of saving, in the descending navigation, one fourth in the expense of transportation from the most remote point, and all the premiums for insurance.”

To the following extracts, we would invite particular attention, of the many whom we know have, without sufficient knowledge of, or reflection on the subject, expressed surprise; that it should be thought desirable to continue the canal

on to Baltimore, after striking tide water at Port Deposit.—

"But, it has been asked with some degree of surprise, by many intelligent citizens; wherefore proceed farther with the canal after you have passed the great river obstruction, and reached such good tide navigation as that from Port Deposit and Havre-de-grace to Baltimore? This surprise seems to have been excited, and the inquiry to have been made from not advert- ing to the nature and object of canal navigation. The great object of all canals has been to open a communication by which bulky and heavy com- modities can be cheaply and readily water borne from the place of production to the market or place of sale. And, it is quite obvious, that in at- taining this object, every break in the continuity of the voyage of the canal vessel, every inter- ruption in the passage, and every trans-shipment of the commodity must be attended with delay and expense; and, consequently, produce an addition to the price of transportation. It is from these considerations, as will be seen, on an in- spection of the maps of the canal routes of all European countries, that all canals have been continued to a great market, sea-port, or place of sale and consumption. The same principles have governed in directing the route, and con- tinuation of all the canals, that have been made in our own country; or where they have been disregarded or overlooked, the evil has been loudly complained of when it was too late to remedy the defect, but at a very great expense. The Middlesex canal in Massachusetts, instead of stopping at the head of tide, where the naviga- tion is as good as could possibly be desired, of its kind, is carried along side of it four miles further into the harbour of Boston. The great Erie canal of New York is no where connected with the navigation of the river, by the side of which it passes, although it is in many places exceedingly good, and, for some distance above Albany, the canal passes just along side of the tide navigation. In speaking of the Potomac canal, Mr. Gallatin observes, that "the legisla- tive impartiality which has required the canal to enter the river at the very head of tide, in order that Virginia may have an equal chance of be- coming the depot of its commerce with Mary- land, has very much injured its utility to the country at large." And, speaking of the James river canal, he observes, that one of its princi- pal faults consisted in its not being continued down into the port itself, instead of being stop- ped at the upper end of the city of Richmond. The market for the produce brought down the Santee river is Charleston in South Carolina; and the river boats were obliged, at the mouth of the river, to enter the sea, and to reach that port by a navigation along the sea shore, for which they were not calculated. To remedy that inconvenience, and to insure a permanent navigation, a canal was opened, uniting the Santee with Cooper river, which empties into the har- bour of Charleston. Thus it appears, as well from general principles as from experience, in our own country and in others, that a canal, in order to produce all the benefits expected from such navigation, must be continued down actually into the market or sea-port.

But there never was a case, perhaps, in which the propriety of continuing the canal down into the very port could be sustained by more cogent and incontrovertible reasons and proofs, than that of the instance now under consideration.— It is perfectly obvious to every one, at all con- versant with the nature of tide navigation, that the arks and boats by which any of our interior streams are navigated, are utterly unfit to con- tend with the winds and waves on the exposed deep waters of the tide any where along the sea-

board; and, therefore, as we have seen, it has never been attempted where it could possibly be avoided. It is true, that for several years after the trade down the Susquehanna began to open, the bold enterprise of the boatmen of that river tempted them to put out upon the Chesapeake in their rude frail barks, with a determination, if practicable, to pursue their way to market; but the accidents, disappointments and losses, were soon found to be so very great, that all ideas of such perilous voyages were abandoned; and they are now never thought of or attempted. The cargoes of the Susquehanna river boats are now always trans-shipped, at Port Deposit, into bay craft, and sent thence, round by the Chesapeake to Baltimore. The proposed canal then, from the basin of Baltimore to a point opposite Port Deposit, may be considered as intended to con- tinue, expedite, and facilitate the transportation of any commodities from the Susquehanna coun- try, instead of stopping them at the head of tide, and sending them, thence, round by the Ches- apeake. A fair estimate, therefore, of the con- veniences and inconveniences of each, of the canal, and of the bay route, in some of the most important particulars, will place their compara- tive merits in the clearest point of view, and en- able every one, at once, understandingly to decide which of them deserves the preference.

"The average tonnage of the arks, that de- scend the Susquehanna is, as has already been ob- served, about forty tons each. We will take the case of such an ark, and suppose her cargo to consist of one or other of the three most impor- tant productions of the Susquehanna country; that is, of coal, of grain, or of flour. By the way of the proposed canal, her cargo would reach Baltimore in a distance of forty miles; but, by the way of the Chesapeake bay, it would have to travel seventy miles. Allowing for every pos- sible delay, any way incident to the mode of transportation, and the passage by the canal to Baltimore could be effected in two days; but at Port Deposit there would, on an average, be a delay of five days for getting a bay craft into which to trans-ship the cargo; and when that was done, the passage to Baltimore, on an aver- age, could not be made in less than three days more; the delay and passage by the way of the Chesapeake would, then be eight days. We will suppose the toll to be, as in New York, gradu- ated on the several commodities, passing on the canal, according to their respective natures, in bulk, weight, quantity, and value. Let us then set down the average of the three commodities of coal, grain, and flour, at one cent a ton, per mile; that will be forty cents a ton, or six- teen dollars for the whole cargo through to Bal- timore. The freight on a canal has never been reckoned at more than a cent a ton per mile; which would amount to just sixteen dollars more; but in this instance, such an allowance for freight would be entirely too much; because the only additional cost to the ark, when moving on the canal, instead of laying still until sold, would be the hire of the towing horses and attendants, which could not exceed five dollars. The toll and freight of either of those commodities would not, then, exceed twenty-one dollars by the way of the canal; but, by the way of the Chesapeake, the freight on coal is one dollar per ton; on grain, it is one dollar seventeen cents per ton, or three cents per bushel of fifty-eight pounds, or what is called running measure; on flour, it is eight cents a barrel, or eighty-two cents a ton, averaging the barrels at two hundred and eight- teen pounds each. To which must be added the cost of trans-shipping the cargo of an ark of forty tons, which is estimated at five dollars more; so that every forty tons of coal is charged with an expense, by the way of the Chesapeake, of

forty-five dollars, every forty tons of grain with an expense of fifty-two dollars, and every forty tons of flour with thirty-eight dollars. We say nothing of waste, and deterioration by trans- shipping, of perils, &c. which might make these differences still greater. This comparative view of the relative advantages of the two routes from Port Deposit to Baltimore, will stand thus:

<i>Canal.</i>	
Distance,	40 miles.
Delay and passage,	2 days.
Freight and toll on forty tons of coal, grain or flour.	21 dolls.
<i>The Chesapeake.</i>	
Distance,	70 miles.
Delay, trans-shipping and passage,	8 days.
Freight, &c. on forty tons coal,	45 dolls.
Freight, &c. on forty tons grain,	52 dolls.
Freight, &c. on forty tons flour,	38 dolls.

These advantages are perfectly obvious and decisive. And from this statement it is also clear, that with this continuation of the pro- posed canal from Port Deposit, no other market whatever can, with any thing like the same ad- vantages, come in competition with that of Bal- timore; because, to reach any other sea-port would require trans shipment at Port Deposit, additional tolls, exposures, delays, and the trav- elling a much greater distance by canal and natu- ral navigation. But, if the proposed canal were to end at Port Deposit, or to have no locks, or communication, near that, with the river, by which it could be entered, all commodities brought down to the tide, at that place, over the bed of the river, must necessarily be trans- shipped, and might be taken to other markets which they might reach as conveniently, as soon, and at as little expense as the city of Baltimore, by the way of the Chesapeake. It is believed that, taking advantage of the most favourable floods, for some time after the proposed canal may have been completed, a considerable por- tion of commodities will continue to be taken down the bed of the river to tide; to all such, the locks at Havre-de grace, and the canal thence to Baltimore, would open and afford a most inviting, convenient, and safe mode of being transported directly, and expeditiously, to the city of Baltimore; one from which it is con- fidently believed no river vessel would willingly turn away; and send the commodities with which she was freighted to any other market whatever.

"The price of the transportation of wheat on the river from Owego, Bath, or any other point on the Susquehanna, in the state of New York, is about twenty five cents a bushel, down, and round to Baltimore; or, at the average rate of about one hundred dollars for every forty tons of all articles down to tide only; more than half of which is paid for the transportation on the river from Conewago to tide; independent of the risk, which is estimated as equal to from seven to ten per cent. But on the canal, the commodity would be exposed to no risk, little delay, and comparatively a small expense. Let us now ex- tend the comparative view we have before exhi- bited, to the whole of the two routes from the head of the Conewago falls to Baltimore. Let us say, that each of the three articles of coal, of grain, and of flour, is charged with a toll through of one dollar a ton; and, that the freight of each ark would amount to ten dollars through; and, that the delay and passage would amount to four days on the canal. From Conewago to tide, by the river, the delay and passage may be set down at two days, and the freight and pilotage at fifty dollars for each ark of forty tons. The contrast between the expense of transportation on the two

routes from Conewago to Baltimore, (apart from insurance) will stand thus:

By the Canal.

Distance, 93 miles.
 Delay and passage, 4 days.
 Toll and freight through for an ark of forty tons, 50 dolls.

River and Bay Navigation.

Distance, 130 miles.
 Delay and passage, 10 days.
 Freight, &c. on coal, 95 dolls.
 Freight, &c. on grain, 102 dolls.
 Freight, &c. on flour, 88 dolls.

Thus the proposed canal, when completed, would be the means of saving full one half of the present price of transportation from Conewago to Baltimore, on every forty tons of commodities brought down the river, from any point beyond the head of the falls: and would, therefore, be, in effect, offering a bounty to that amount for all commodities exported from the Susquehanna country, as an encouragement for their increase.

(To be continued.)

EQUESTRIAN PERFORMANCES.

RAPID TRAVELLING AND PRINTING.

The President's Message was transported from the Office of the National Intelligencer, to the Printing Office in Baltimore, distance thirty-eight miles, and there printed and published, all in five hours. This reminds us of some of the following Equestrian Performances.

Edit. Am. Far.

One of the earliest in the order of time, in England occurred in the year 1604, in the reign of James I. when John Lepton, Esq. Kenwick, in Yorkshaire, who was one of his Majesty's grooms, undertook to ride five times between London and York, from Monday morning till Saturday night. He accordingly set out from St. Martin's-le-Grand, between two and three in the morning of the 26th of May, and arrived at York on the same day, between five and six in the afternoon; rested there that night and the next day returned to St. Martin's-le-Grand, about seven in the evening, where he staid till about three o'clock the next morning. He reached York, a second time, about seven at night, from whence he set off again for London about three in the morning, and reached London between seven and eight. He set off again for York between two and three in the morning following, and getting there between seven and eight at night, completed his undertaking in five days. On the Monday following he left York, and came to his Majesty's court at Greenwich, as fresh and as cheerful as when he first set out.

In 1701, Mr. Sinclair, a gentleman, of Kirby Lonsdale, in Cumberland, for a wager of five hundred guineas, rode a galloway of his, on the Swift, at Carlisle, a thousand miles in a thousand successive hours.

In 1745, Mr. Cooper Thornhill, master of the Bell Inn, at Stilton, in Huntingdonshire, made a match, for a considerable sum, to ride three times between Stilton and London. He was allowed as many horses as he pleased, and to perform it in fifteen hours. He accordingly started on Monday, April 29, 1745, and rode,

	<i>h. m. sec.</i>
From Stilton to Shoreditch church, London, (71 miles) in	3 52 59
From London to Stilton, in	3 50 57
From Stilton to London, in	3 49 56

Which was two hundred and thirteen miles in eleven hours, thirty-three minutes, and fifty-two

seconds; and three hours, twenty-six minutes, and eight seconds within the time allowed him.

On Wednesday, June 27, 1759, Jenison Shafto, Esq. performed a match against time, on Newmarket Heath; the conditions of which were, he was to ride fifty miles (having as many horses as he pleased) in two successive hours, which he accomplished with ten horses, in one hour, forty-nine minutes and seventeen seconds.

In 1761, a match was made between Jenison Shafto and Hugo Meynel, Esqrs. for two hundred guineas; Mr. Shafto to get a person to ride one hundred miles a day (on any one horse each day) for twenty-nine days together; to have any number of horses not exceeding twenty-nine. The person chose by Mr. Shafto was Mr. John Woodcock, who started on Newmarket Heath, the 4th of May, 1761, at one o'clock in the morning, and finished (having used only fourteen horses) on the first of June, about six in the evening

The last week in September, 1781, a great match of four hundred and twenty miles in one whole week, was rode over Lincoln two mile course, and won by Richard Hanstead, of Lincoln, and his famous grey horse, with great ease, having three hours and a half to spare.

December 29th, 1786, Mr. Hull's horse Quibler, ran a match for a thousand guineas, twenty-three miles in one hour, round the Flat at Newmarket, which he performed in fifty-seven minutes and ten seconds.

August 15th, 1792. To decide a wager of fifty pounds, between Mr. Cooper and Mr. Brewer of Stamford, the latter gentleman's horse, Labourer, ran twenty times round the race ground (exactly a mile) at Preston, in fifty-four minutes.

In October, 1791, at the Curragh meeting in Ireland, Mr. Wilde, a sporting gentleman, made bets to the amount of two thousand guineas, to ride against time, viz. one hundred and twenty-seven English miles in nine hours. On the 6th of October he started, in a valley near the Curragh course, where two miles were measured, in a circular direction: each time he encompassed the course it was regularly marked. During the interval of changing horses, he refreshed himself with a mouthful of brandy and water, and was no more than six hours and twenty one minutes, in completing the one hundred and twenty-seven miles; of course he had two hours and thirty-five minutes to spare.—Mr. Wilde had no more than ten horses, but they were all blood, and from the stud of — Daley, Esq.—Whilst on horseback, without allowing anything for changing of horses, he rode at the rate of twenty miles an hour, for six hours. He was so little fatigued with this extraordinary performance, that he was at the Turf Club House, in Kildare the same evening.

The expedition of the express, with the account of the drawing of the Irish lottery, for 1792, has never yet been equalled, as will appear from the following road bill of the third day's express, Nov. 15, 1792.

	<i>m. h. m.</i>
Holyhead to Birmingham	163½ in 11 45
Birmingham to Stratford upon Avon	23½ 2 4
Stratford upon Avon to London	105 7 45
	292 21 34

October the 14th, 1791, a trotting match took place on the Rumford road, between Mr. Bishop's brown mare 18 years old, and Mr. Green's chesnut gelding, six years old, 12 stone each, for 50 guineas a side, which was won with ease by Mr. Bishop's mare. They were to trot sixteen miles, which the mare performed in fifty-six minutes and some seconds.

[Sporting Anecdotes.]

PROGNOSTICATIONS OF THE WEATHER.

Mr. Kirwan has laid down the following plan, from observations that have been made in England, during a period of 112 years; namely, 1677 to 1789, vide "*Transactions of the Royal Irish Academy*," vol. v. 1. When no storm has either preceded or followed the vernal equinox, the succeeding summer is in general dry, or at least so, five times out of six. 2. If a storm happen from an easterly point, on the 19th, 20th, or 21st day of May, the ensuing summer, will four times in five, be also dry. The same event generally takes place if a storm arise on the 25th, 26th, or 27th days of March, in any point of the compass. 3. Should there be a storm, either at south-west or west-south-west, on the 19th, 20th, or the 19th, 20th, 21st, or 22d of March, the following summer is *wet* five times out of six. In England, if the winters and springs be dry, they are mostly cold; but if moist, they are generally *warm*; on the contrary, dry summers and autumns are usually *hot*; as moist summers are *cold*. Thus, if the humidity and dryness of a particular dry season be determined, a tolerably correct idea may be formed respecting its temperature. To these indications may be added the following maxims; which being the result of observations, made by accurate inquirers, may so far be depended upon as they will afford a criterion of the mildness or severity, and of the dryness or moisture of future seasons. 2. A moist autumn, succeeded by a mild winter, is generally followed by a dry and cold spring; in consequence of which, vegetation is generally retarded. 2d. Should the summer be uncommonly wet, the succeeding winter will be severe; because the heat or warmth of the earth will be carried off by such unusual evaporation. Farther, wet summers are mostly attended with an increased quantity of fruit on the white thorn, and dog rose; nay, the uncommon fruitfulness of these shrubs is considered as the presage of an intensely cold winter. 3. A severe winter is always indicated by the appearance of cranes and other birds of passage, at an early period in autumn—because they never migrate southward till the cold season has commenced in the northern regions. 4. If frequent showers fall in the month of September, it seldom rains in May, and the reverse. 5. On the other hand, when the wind often blows from the south west, during either summer or autumn, when the air is unusually cold for the season, both to our sensations and by the thermometer; at the same time the mercury being low in the barometer: under these conditions a profuse fall of rain may be expected. 6. Great storms, rains, or other violent commotions of the clouds, produce a kind of crisis in the atmosphere; so that they are attended with a regular succession either of fine or bad weather for some months. Lastly, an unproductive year mostly succeeds a rainy winter; as a rough and cold autumn prognosticates a severe winter.

PRESERVATION OF FOOD.

A sea voyage, though it generally produces a good appetite, does not as often furnish the means of gratifying it; and a ship, either for comfort or luxury, is not usually the place where those, who attach value to such matters, can be accommodated.

Still all pleasures are comparative, and the accommodations, personal and gastronomic, of those who from whatever cause are at this day induced to venture on board ship, are so much increased beyond any thing known to the older time, that, in that sense, they may be truly said to be both comfortable and luxurious.

Among the wants which are most sensibly felt

at sea, and which modern refinement and ingenuity have found the means of remedying, is that of fresh provisions. In this respect, Messrs. Kensett and Daggett, of this city, have accomplished so much that they can put up fish, poultry, game, nay custards, so as to preserve them in any climate, and almost for any time, without any perceptible alteration in their original taste or quality. This is chiefly effected, we believe, by having them enclosed in tin cases, hermetically sealed. We are pleased to learn that the use of these provisions is becoming general, and have much satisfaction in presenting to the public the subjoined testimonial of Commodore Porter as to their excellence:

Copy of a letter from Com. Porter in answer to Messrs. Daggett and Kensett, of this city, respecting his opinion of their preserved fresh provisions.

"WASHINGTON, Nov. 13th, 1823,
"Gentlemen—Your letter of the 30th ult. should have been answered, at an earlier period but for unavoidable absence and a great press of business.

"I have given to your preserved meats a fair trial, particularly the beef and poultry, both for the Hospital department and as rations, as well as at my own table—and I have taken every occasion to recommend them not only to the officers under my command, but to others going to sea. I have taken some pains to bring them into general use in the Navy, and you may calculate on a favorable disposition on my part toward your establishment so long as, by your care and attention in putting up the provisions, you may have a title to it.

"Some of the provisions, which I took from New York last winter, are now on hand, and as good as the day they were received.

Very respectfully,

Your obedient servant,

D. PORTER.

Messrs. DAGGETT and KENSETT, }
616 Water street, New York." }

FROM THE SCOTO GAZETTE.
THE STEUBENVILLE WOOLLEN
FACTORY.

This establishment, which has been in operation for several years, and has had to encounter the strong prejudices of the people in favor of every thing of foreign manufacture, seems, at length, to have obtained, in some degree, the high reputation to which it has always been justly entitled. The owners, deserve great credit, not only for their financial skill in collecting the resources requisite to carry into operation so expensive an establishment, but for their perseverance in keeping it up under many imposing and not a few real embarrassments, until, it may with propriety be said, it has fairly worn itself into public favor. Such men are an honor to the state and to the country, and are entitled to something more than the mere *good wishes* of the people for their success. By their enterprise, many thousand dollars are annually brought into the state, retained and kept in circulation, which otherwise would soon find their way into the coffers of some English manufacturer. And no small quantity of the produce in the neighborhood of this factory, finds a ready market, and is consumed in the vicinity of the place where it is raised. These are direct general advantages, resulting to no inconsiderable portion of the community.

Now we undertake to say that there is quite as great a difference in favor of our domestic cloths over those imported, as there is in favor of our domestic cottons over imported cottons. We speak with reference, more particularly, to the

cloths of the Steubenville Factory; but we have no doubt the truth of the observation holds good as to every woollen factory in the United States established on the same liberal scale. Our domestic cottons wore themselves into repute; and nothing but a fair trial of our domestic cloths is necessary, to produce a similar conviction as to their excellence and the economy of wearing them altogether, in preference to foreign cloths.

TO THE EDITOR OF THE AMERICAN FARMER.

IMPROVED BEE-HOUSE—Description of an elegant one on a large scale.

Laughlinstown, Oct. 17th, 1823.

DEAR SIR,

You ask a description of my bee-house, concerning which, I owe you an apology for my remissness, in not answering your letter sooner; but being myself "as busy as a bee" all summer, as well as being conscious of an inability to describe it with sufficient clearness and accuracy, was the cause of my delay.

The bee-house is built about eight perches from my dwelling house, where a small bank afforded a good site for a stone foundation. The foundation is circular five feet in diameter in the inside, and six and a half feet high, rising eighteen inches above the highest part of the ground, into this a door opens so as to admit access into the house below the lower tier of hives. On this stands the bee-house, which is ten-sided, and eight feet diameter from outside to outside of the weatherboarding. It is eleven and a half feet high from the stone work to the eaves, from whence the roof rises like a cone supporting a staff in the centre, that is crowned by a vane.

The body of the house is formed by framing together ten planks of eleven and a half feet long, eighteen inches broad, and two inches thick, set upright on their ends at the ten angles of the house, deviating as much from the radius of a circle as is necessary to bring their sides at a right-angle, with a corresponding front, or face of the building. This is done for the purpose of admitting one square hive, and a triangular one into each space between the planks; thus making places for twenty hives in each tier, or circle, of which there are four, being eighty hives in all. The upright planks are tenanted into circular frame work of other plank, above and below; and the places to support the different tiers of hives, are made by letting inch boards into these upright planks, by a dove-tail; the whole is weather-boarded and painted. The hives are in the inside, and stand on sliders which have a tongue that reaches through a notch in the weatherboarding, for a place for the bees to light on. The point of these tongues, and likewise a circle above the bee holes, are painted with the several primary colours, so diversified that no two of the eighty are alike. The object of such diversity is that the bees will readily know their own hives.

The inside of the house is provided with circular steps that wind round a shaft, and are wholly unconnected with the walls. The risers of each step are morticed through the shaft, and supports the steps. The shaft itself has a gudgeon in each end that works in beam above, and in the floor below. Thus fixed, the whole stairs can be turned round so as to bring a platform, or landing place that is level with each tier of hives, opposite any particular hive that may be necessary to work with.

The hives themselves are plain boxes made with inch boards, either an oblong square of twelve by eighteen inches, or a triangular box,

according to the place they are designed to occupy in the house. There are but two kinds of boxes in the bee house, which being all of one size and dimensions will fit in any part of it. They are six inches each in height, and two, three or four of them on each other, and covered by a lid, forms the hive. The main end and object of the whole is to take from the bees their surplus honey, without killing them, as is usual in the common method of managing that industrious and useful insect.

Very respectfully, your's,

JAMES CLARKE.

[In the valley of Ligonier, on the road to Pittsburg, we were struck with a neat and tasteful building, and being told it was a bee house, we ran to take a peep at the interior of it, while the horses were watering. The reader may form some idea of the quantity of honey which may be gathered in one of those valleys by the extent of preparations to accommodate that interesting insect, made by Mr. Clarke, and by him so kingly and minutely described below.]

Edit. Am. Far.

QUERY—FEEDING OF STOCK.

DEAR SIR,

The period is rapidly approaching, when farmers will have to feed their stock, and it behoves them to feed in a judicious manner, without running their provender too close. Now there is such contrariety of opinions on this subject, and which I have never seen in your valuable paper, that I now submit it to your numerous correspondents, who I hope will take it into consideration, as it is certainly of vast importance to the community at large. There is one method which I may say, most universally prevails, and that is, feeding in pens, and which cannot meet my approbation.

Your's truly,

A Friend to Agriculture.

J. S. SKINNER, Esq.

Editorial Correspondence.

Oaken Grove, Jefferson Co. Geo. Nov. 22d, 1823.

DEAR SIR,

I received your favour of the 2d September last, inclosing the parcel of wheat, and the sea kale seeds—accept my best thanks for the same. The seeds I have carefully sown, and will transmit the result of my experiments on the same, to you in proper time. The corn crops in this section of the state, have this year, been abundant; though our cotton crops are light, caused by the severe drought in the latter part of the summer; and the rot which has prevailed much in many places. The many theoretic sketches on this subject, recently published—if practical, appear not to succeed, probably arising from want of judicious application.

You will bring under obligation many citizens in this part of the state, by requesting from some of your experienced correspondents, a description of the glanders, a disease incident to horses, with its various symptoms, together with the best known cure—as a disease called the glanders, is very destructive among our horses.

Respectfully your's, &c.

ROBERT LOWRY.

J. S. SKINNER, Esq.

We will do it in our next—in mean time should be glad to hear from any correspondent on the subject.—*Edit. Am. Far.*

St. Mary's County, Nov. 20th, 1823.

MR. SKINNER,

Some time since, a neighbour told me he saw published in your valuable paper, that a farmer

New York, made from one acre of land, one hundred and seventy bushels of Indian corn—it would be gratifying to ascertain whether the corn was not shelled, as the quantity to farmers in this quarter, exceeds any thing they can make. We bought that sixteen barrels and better than a bushel of shelled corn, was doing pretty well upon high land; this quantity was made by John Simms, Esq.; and it was measured in the presence of respectable neighbours, upon whose statement the greatest reliance may be placed. Mr. Simms' farm lies upon the Patuxent river, in St. Mary's county—and he crops upon a large scale.

PHILO-AGRICOLAS.

The following letter from Mr. Middleton was not intended for publication, but as it contains some interesting information, we send it to the printer without fear of censure from the liberal writer.—*Edit. Am Far.*

Charleston, 13th Nov. 1823.

DEAR SIR,

You will receive herewith a paper parcel containing some Guinea grass seed; I do not know whether it will germinate, as it was imported the last year from the West Indies.—I will endeavor also, to procure you some of the seed grown the present year.

My Tuscan cattle are doing well; I have ten half bred calves, and twenty cows, that will have calves during the winter. Our crops the present year are generally abundant. I do not know whether they cultivate in your neighbourhood the Guinea corn. It is very good food for man, hulled and boiled as rice.—Chopped up ear and stalk, it is excellent for animals.—It is also used as food for poultry. A friend of mine made a hundred bushels to the acre; and if I mistake not, weighing 80 lbs. per bushel. Should you wish some of the seed I can supply you.

I am, Dear Sir,

With respect, your obt' serv't,

J. MIDDLETON.

TANNING.

We have always been under the impression that in England, hides remained in tan, from one to two years, and have heard the alleged superiority of English leather, attributed to the great length of time it is undergoing that process.—It appears, however, by the following extract from the London Farmer's Journal, of September 29th, that it only takes from four to six months to tan, curry, dress and prepare the hide for sale—this shortening of the time is the effect of modern science, applicable to the process of tanning, as will be seen in our next

[*Edit. Am. Farmer.*

To the Editor of the Farmer's Journal.

ON THE PRICE OF LEATHER.

Kent, September 26, 1823.

SIR—I had some conversation this morning with my collar maker. He complains of the high price of leather, and that within the last six months there had been a considerable advance upon it, which led to the following questions:—

Q. What is about the usual price given by the tanners for a hide?—A. About sixteen shillings.

Q. What is the price of it after it has undergone the process of tanning and currying?—A. About five pounds.

Q. How long does it require to dress, tan, curry and prepare the said hide?—A. From four to six months: formerly they gave it more time in the pits.

Now, Mr. Editor, through the medium of your Journal, I wish to elicit further information on this subject, as it appears to me (that now the duty is partly repealed upon leather,) there must be either enormous profits accruing to the tanner and currier, or they are at considerably more expense in carrying through this business than people are aware of. At all events, it is a question which interests the major part of the community.

I am, Sir, your's, &c.

INVESTIGATOR.

By the following it appears that one of our own most scientific citizens, has discovered an

IMPROVED METHOD OF TANNING.

The Gazette of last evening announces that Dr. H. H. HAYDEN of this city has discovered a very important improvement in the art of converting raw hides into leather, by means of a pyroligneous preparation, the use of which he has secured by letters patent, under the seal of the United States.

By this method, raw hides, of any description, after the usual process of *hairing* and *baiting*, are converted into excellent leather in less than *thirty six hours*.

Pyroligneous acid, or what may be termed *vinegar of wood*, is now to a considerable degree, and promises to be yet more extensively, applied to the preservation of meats. In a late English work, it is observed that "at the recent anniversary of the Whitehaven Philosophical society, two specimens of meat cured with the pyroligneous acid were exhibited by one of the members. They were prepared on the 7th of September 1819. One had been hung up at home and the other had been sent out by a vessel to the West Indies, to try the effect of climate upon it, and brought back on the return of the ship to that port. They were tasted by all present, and pronounced to be perfectly sweet, fresh, and fit for use, after a lapse of fifteen months."

On the subject of pyroligneous acid, its preparation and uses, as well as tanning in a practical view, we shall give some interesting extracts in early numbers, as these are topics of general concernment.—*Edit. Am. Far.*

THE PASTIME OF DESPOTS.

The King of Prussia, in his correspondence with Voltaire, relates an anecdote of the Czar Peter, which is worth extracting, as illustrative of Russian despots:—"I knew Printz, the great Marshal of the Court of Prussia, who had been ambassador to the Czar Peter in the reign of the late King. The commissions with which he was charged proving very acceptable, the Prince was desirous of giving him conspicuous marks of his satisfaction, and for this purpose a sumptuous banquet was prepared, and to which Printz was invited. They drank brandy, as customary with the Russians, and they drank it to a brutal excess. The Czar wishing to give a particular grace to the entertainment, sent for 20 of the Strelitz guards, who were confined in the prisons of Petersburg, and to every large bumper which they drank, this hideous monster struck off the head of one of these wretches. As a particular mark of respect, this unnatural Prince was desirous of procuring the Ambassador the pleasure, as he called it, of trying his skill upon these miserable creatures. The Czar was disposed to be angry at his refusal, and could not help betraying signs of his displeasure. This is not an invented tale: it is to be found in

the narratives of M. de Printz, which are preserved in the archives. I have also mentioned it to many persons who were at Petersburg at the time, and they all attested its truth."

PARLIAMENTARY PROVISION.

In the Memoirs of the late Mr. Edgeworth, it appears that on his being appointed executor to a friend's will, he had necessarily occasion to write to persons indebted to the estate, requesting the discharge of the debts, which applications were, without a single exception, resented as insults, and uniformly answered by a challenge. Indeed, we collect from various anecdotes, that no greater or more unpardonable affront can be offered to a gentleman in Ireland, than asking him to pay his debts; it is looked upon as a most impertinent proceeding, and the only discharge a creditor has to expect in consequence, is the discharge of a pistol. Possibly, in contemplation of this frequent source of quarrel, and with the intention of striking at the root of it, the legislature has providently enacted, under the insurrection act, that any person asking for money shall be convicted as idle and disorderly. The following is the clause:—"And be it enacted, that if any person shall, within any proclaimed district, or within any county, any part whereof shall be so proclaimed, print, write, post, publish, circulate, send, or deliver, or cause or procure to be printed, written, &c. &c. demanding any money, any person so offending shall be deemed and taken to be an idle and disorderly person." This provision must have most effectually put a stop to the ungentlemanly practice of asking for money in certain parts of the sister kingdom. The executor or tradesman who so far forgets the rules of good breeding as to require a settlement of his demand, is speedily awakened to a sense of decorum by the words of the statute, and declared idle and disorderly!

FROM THE NEW YORK ADVOCATE.

PICKLE FOR BEEF AND PORK.

The following receipt for making pickle for beef or pork, is strongly recommended to the adoption of those who pickle beef and pork for family use. Persons in the trade, who will adopt it, will find a ready sale for their beef and pork. It has been used by many families in this city, and always approved. I do not hesitate to assert that there is no pickle in use to be compared with it. It is familiarly known by the name of the "*Knickerbocker Pickle*." Could this receipt be generally adopted, our pickled beef and pork would have certain preference in the foreign markets.

RECIPT.

Six gallons water, 9 lbs. salt, coarse and fine mixed, 3 lbs. brown sugar, 3 ounces salt petre, 1 ounce pearl ash, 1 gallon molasses to every 6 gallons water.

In making a larger or smaller quantity of pickle, the above proportions are to be observed. Boil and skim these ingredients well, and when cold, put it over the beef or pork.

AN OLD HOUSEKEEPER.

The use of molasses is recommended by Dr. Mitchill, in fattening cattle and poultry, which it increases in size, and communicates a fine flavour to their meat. [If given with *pan cakes*, as boys get it on Shrove Tuesday, would it not be still better?]

TRUTH AND YOUNG ROMANCE.

A SONG.

Young Romance through roses straying,
Saw old Truth through lamely on;
One in pleasure's light was playing,
The other sigh'd for pleasures gone:
Cries Romance, "O rest a minute,
And discuss our views of Earth:—
Yours may have most prudence in it,
But in mine is all the mirth."

"Ah!" said Truth, "this world discloses
Nought but vain delusive wiles,
Thorns are under all your roses,
Sadness follows all your smiles:"
—Cries Romance, "Perhaps I often
Colour life with tints too warm;
Yet my warmth a shade may soften,
While your coldness chills a charm."

"What is Love?" the sage then asks him—
"Love—in summer-hours so sweet?
Winter weather soon unmasks him,
And your idol proves a cheat!"
"Love!" the youth replies, "O sever
Real love from vain deceits;
Constant Love brings hours that never
Lose their sunshine or their sweets."

"Friendship, too, you call a treasure,
But," says Truth, "it is a tie
Loosely worn 'mid scenes of pleasure,
And when fortune frowns—thrown by."
"Friendship," he replies, "possesses
Worth which no dark change destroys;
Seeking, soothing our distresses,
Sharing, doubling all our joys."

"Go," says Truth, "'tis plain we never
Can such hostile thoughts combine;
Folly is your guide for ever,
While dull sense must still be mine."
Cries the Boy—"Frown on, no matter,
Mortals love my merry glance;
E'en in Truth's own paths they scatter
Roses snatch'd from young Romance."

THE FARMER.

BALTIMORE, FRIDAY, DECEMBER 12, 1823.

The Editor has it in contemplation, after the completion of this volume, to publish along with each Farmer, one half sheet or four pages extra.—These extra pages will be appropriated to the insertion of advertisements relating exclusively to such objects as Farmers and Planters are particularly concerned in—such as the sale of live stock of all kinds—implements of husbandry—household articles—real estate—fruit trees—seeds—overseers wanted, or wanting places, together with a complete account of the drawings of all the Maryland state lotteries, and a summary of passing news of general interest.—This extra half sheet, containing matter of transient consequence, will not be *paged*, and therefore need not interfere with the *binding* of the regular volume. In the autumn of each year, it is proposed to send also to every subscriber an *Agricultural Almanack*—which besides containing what is found in ordinary almanacks, will furnish a number of valuable recipes and hints useful to the farmer, and especially to the housewife. In consideration of these additional offerings to our patrons, the subscription will be FIVE DOLLARS in all cases, and the Editor will guarantee the actual receipt of every number of the paper.

Great inconvenience has been found to result from the difficulty of procuring for remittance four dollars, and we are well assured, that a

large proportion of our subscribers were willing to pay five, for the paper as it is; but we have found it more agreeable to offer them a *full equivalent*, as we persuade ourselves we shall do by the proposed addition of four pages and an agricultural almanack.

We are sorry to think it necessary to make any apology to our subscribers, for occupying a page or two of our paper, occasionally on the subject of CANALS, at points where they may form great thorough fares for internal commerce; we say we are sorry, because it is obviously impossible that every article of a paper should be equally interesting in a local point of view to every reader—so it is obvious, that when we call the attention of farmers to a new, cheaper and more expeditious road to market, we thereby teach them, whereby they can save time and labour heretofore employed in *transportation*, to be now employed in *production*; in other words we point out how they can increase the fruits, and generally, of course, augment the income of their estate. Now, how more appropriately can we employ a *portion* of an agricultural journal, than by exposing to the view of farmers, where, and how, and for what cost, and with what benefit such canals or roads to market can be opened!—and then, if these expositions apply only to Pennsylvania, New York and Maryland, to day, will the enlightened patron of Massachusetts and the Carolinas say, you have too much about canals, what care I for the Susquehanna canal? no, he will reflect that what improves and multiplies the resources of a single state, adds strength and glory to the whole union—for we are emphatically *one people*. Suppose a citizen of Maine or of Georgia, in the best society of London or Paris, where the enterprise and powers and the enlightened application of the resources of nations, as displayed by their great public works, is the theme of discussion, would he not proudly point to the great works of New York, as the works of *his country*, the glory of *his nation*? and if we speak to day of the Susquehanna canal, which touches "the pocket nerve," of a large portion of New York, more than half of Pennsylvania, and all Maryland, let our friends in other states remember, that we are as ready to turn to them and their particular interests, whenever the materials are presented for doing so.

A JUDICIOUS APPOINTMENT—Never was there made a more appropriate selection, than that of GEN. S. VAN RANSELLAER, one of the best, and most unostentatious of men, and patriots—to preside on the *Committee of Agriculture*, in the House of Representatives.—It affords another proof of the knowledge of mankind, and the ready adaptation of talent and character to particular objects which characterises the official acts of the present able and discerning Speaker of that body. Agriculture, it will be admitted, is the most important concern which can attract the regard of the Representatives of a free and essentially agricultural community—one which ought to predominate, and control, if there must be subordination and subserviency of one class to another, in the order of human affairs; but her advocates and followers are so dispersed, and possess so little, either of the means or the disposition to confer, for the concentration of their opinions, and the preservation of their power, that it may almost be said that there exists no such spirit, as an *esprit du corps* amongst them. Hence, while other particular classes, that live, and move, and have their being by the fruits of the plough, readily confederate to extend

their influence, and to secure, by never ceasing importunities, both executive recommendation, and legislative protection to their peculiar concerns, Agriculture, alike unpretending and unobtrusive, either stands mute, or is heard as angels visit us, "rarely and far between." It follows that few measures are ever concocted, so to say, in the Agricultural Committee room, to engross much of the attention of Congress: indeed, were other interests to engage no more of their attention, in proportion to their relative importance, and the population concerned therein, the Sessions of Congress would be shortened by two thirds of their present duration. The existing Committee on Agriculture, will probably have little else to do, than to act on the defensive; to see that Congress in building up fences and providing special guards, to give artificial encouragement and protection, to other branches of industry, and to other institutions, does not trespass for their materials, on the rights and prosperity of the landed interest.

It must not be supposed that we are opposed to giving timely and suitable encouragement to domestic industry; on the contrary, let it be done promptly and efficiently, and to any extent, when it can be so done as to augment the aggregate sum of social comfort and happiness—the only true and legitimate object of legislation. On this great question our little bark shall sail in the wake of the illustrious Helmsman, who guides with so much skill and honour our national ship. I recommend, says he, a review of the tariff for the purpose of affording such additional protection to those articles, which we are prepared to manufacture, or which are more immediately connected with the defence and independence of the country.—What those articles are, and to what extent this *additional protection* should be carried, it is for the wisdom of Congress to say—all we mean to hint to our friends, the farmers, who are the consumers of imported commodities, and the true payers of the imposts is, that they should keep a bright look out. *Farmer bonds*, as far as we know, are cancelled only in one way, and that is by—paying them; and it is easy to see that in a war of legislative, and thrust, were one to ensue between town and country, the concentrated few, and the dispersed many, where so much depends on acuteness, union of forces, and perseverance,—the clodhopper would stand about the same chance falling uppermost, as would a street-corner dandy, in a rough and tumble fight, with half-horse-half-alligator Kentucky man.

BALTIMORE MARKET.

PRICES CURRENT—CORRECTED WEEKLY
Flour, white wheat, super., \$6 75—Howland street, from wagons, \$5 75—fine do. \$5 25—Wharf, do. \$5 50—White wheat, \$1 12 a 1 15—1 20—Red do. \$1 6 to 1 9—Lawler, \$1 10 to 1 12—Washington white, \$1 12 to \$1 20—Rye, 42 to 45 cts.—(Old corn, 34 to 35 cts.—New do. 32 to 33 cts.—Wharf Oats, 33 cts.—wagon Oats 37½ cts.—Beef, 6 cts. per lb.—Live Cattle \$5 to 5 50, per cwt.—Bacon, hog round, \$10—Pork \$5 50 to \$6 per c. lb. 5 to 8 cts. per lb.—Mutton, 4 to 5 cts. per lb.—Beans, retail, \$1 25, cargo price, \$1 15—Peas, retail, 62½ cts., cargo price 48 to 50 cts.—Red Clover Seed, \$6—Orchard Grass do. \$2 50—Herds' Grass do. \$2—Timothy do. \$4—Flax Seed, 75 to 80 cents—Whiskey, from the wagons, 34 cents per gallon including the barrel—Apple brandy, 30 to 32 cts.—Peach do. 65 to 70 cts.—Shad, No. 1, \$6 very dull, No. 2, \$5 do.—Herrings, No. 1, \$2 25 per bbl. No. 2, \$2 do.—Fine Salt, 75 cents per bushel coarse, do. 70—Ground allum do. 68—Butter (firkin) 12 to 13 cts. per lb.—Eggs, 12½ cts. per doz.—Hay, \$15 per ton—Straw, \$10.

Internal Improvements.

TUNNEL ACROSS THE RIVER THAMES.

To discover convenient and efficacious means for opening a spacious subterraneous communication between the shores of a great river, without occasioning any obstruction to the navigation, has long been a desideratum of considerable importance with the public, and in the estimation of scientific engineers. The difficulties which have opposed themselves to every attempt that has been hitherto made to execute a Tunnel under the bed of a river, have been so many and so formidable as to have prevented its successful termination in those instances where the attempts have been made.

To propose therefore the formation of a Tunnel after the abandonment of these several attempts, may appear somewhat presumptuous: on inquiring, however, into the causes of failure, it will be found that the chief difficulty to be overcome, lies in the inefficiency of the means hitherto employed for forming the excavation upon a large scale.

In the case of the drift-way made under the Thames at Rotherhithe in 1809, the water presented no obstacle for 930 feet; and when a great body of quicksand gave way and filled the drift, the miners soon overcame this obstruction, and were able to proceed until they were stopped by a second irruption, which in a few minutes filled it. Nothing comes more satisfactory in support of the system that is adopted here, than the result of the operations that were carried under that circumstance, to an extent of 1011 feet, and within 130 feet from the opposite shore.

It is to be remarked, that at the second irruption, on examining the bed of the river, a hole was discovered four feet diameter, nine feet deep, with the sides perpendicular;—a proof that the body of quicksand was not extensive; but what is most remarkable is, that this hole could be stopped merely by throwing from above, clay partly in bags and other materials; and after pumping the water out under a head of twenty-five feet of loose ground and thirty feet of water, the miners resumed the work, and proceeded a little further; but finding the hole at the first irruption increased, and the filling over the second very much sunk, the undertaking was abandoned.

The character of the plan before us consists in the mode of effecting the excavation, by removing no more earth than is to be replaced by the body of the Tunnel, retaining thereby the surrounding ground in its natural state of density and solidity.

In order so to effect an excavation thirty-four feet in breadth by eighteen feet six inches in height, the author of this plan proposes to have the body of the Tunnel preceded by a strong framing of corresponding dimensions, as represented in the accompanying drawings, and in the model proposed to be submitted for inspection. The object of this framing is to support the ground, not only in front of the Tunnel, but at the same time to protect the work of excavation in all directions. The body of the Tunnel, which is to be constructed in brick, is intended to be fitted close to the ground; and in proportion as the framing is moved forward, so the brick work is made to keep pace with it. But as this framing could not be forced forward all in one body, on account of the friction of its external sides against the surrounding earth, it is composed of eleven perpendicular frames which admit of being moved singly and independently of each other, in proportion as the ground is worked away in front. These several frames are provided with such mechanism as may be necessary to move them forward as well as to secure them against the brick-work, when they are stationary. It is to be observed, that six alternate frames are stationary, while the five intermediate ones are left free for the purpose of being moved forward, when required; these in their

turn, are made stationary for relieving the six alternate ones, and so on. Thus the progressive movement of the framing can be effected.

In order that a sufficient number of hands may be employed together, and with perfect security, each perpendicular frame is divided into three small chambers, which may properly be denominated cells. By this disposition, thirty-three men may be brought to operate together with mechanical uniformity, and quite independent of each other. These cells, which are open at the back, present in front against the ground a complete shield composed of small boards, which admit of being removed and replaced singly at pleasure.

It is in these cells that the work of excavation is carried on. There each individual is to operate on the surface opposed to him, as a workman would cut out a recess in a wall for the purpose of letting in a piece of framing, with this difference only, that instead of working upon the whole surface, he takes out one of the small boards at a time, cuts the ground to the depth of a few inches, and replaces the board before he proceeds to the next. When he has thus gained from three to six inches over the whole surface, (an operation which it is expected may be made in all the cells nearly in the same time,) the frames are moved forward, and so much of the brick-work added to the body of the Tunnel. Thus intrenched and secure, thirty-three men may be made to carry on an excavation which is 630 feet superficial area, in regular order and uniform quantities, with as much facility and safety as if one drift only of nineteen feet square was to be opened by one man.

The drift carried under the Thames in 1809, which was about the size of these cells, and was excavated likewise by only one man, proceeded at the rate of from four to ten feet per day. In the plan now proposed, it is not intended that the progress should exceed three feet per day, because the work should proceed with mechanical uniformity in all the points together.

With regard to the line of operation, if we examine the nature of the ground we have to go through, we observe under the third stratum, which has been found to resist infiltrations, that the substrata to the depth of eighty-six feet are of a nature that present no obstacle to the progress of a Tunnel; we are informed that no water was met there. It is therefore, through these substrata that it is proposed to penetrate, and to carry the line that is to cross the deep and navigable part of the river, leaving over the crown of the Tunnel a head of earth of from twelve to seventeen feet in thickness quite undisturbed.

Admitting that in descending to or in ascending from that line we should come to a body of quicksand, such as that which was found within about 200 feet from the shore, it is then we should find in the combinations of the framing, before described, the means that are necessary for effecting, upon a large scale, what is practised on a very small one, by miners when they meet with similar obstacles. Indeed, were it not for the means of security that are resorted to on many occasions, mines would inevitably be overwhelmed and lost.

Notwithstanding we may encounter obstacles that may retard the daily progress, it is with satisfaction we contemplate that every step we take tends to the performance and ultimate completion of the object; and if we consider that the body of the Tunnel must exceed the length of Waterloo Bridge, it must be admitted that, if, instead of two years, three were necessary to complete the undertaking, it would still prove to be the most economical plan practicable for opening a land communication across a navigable river.

No notice is here taken of the mode of constructing the descents or approaches into the Tunnel; because whatever form or direction it may be found

necessary to adopt, it is obvious that no difficulties oppose themselves to the accomplishment of that part of the work, the expense of which is however taken into account in the estimate.

Nature of the Ground under the bed of the River at the Rotherhithe, at a short distance below the place now proposed for opening a Roadway.

AGRICULTURE.

[We have read with satisfaction the address of Jonathan Roberts, Esq. President of the Pennsylvania Agricultural Society—and we believe that our readers will peruse with much pleasure the extracts from it, which we give below. The whole address is worthy of its author, who has been known to the publick as an able Senator, a genuine Republican, and withal, a *working practical Farmer*. Few persons illustrate in their mind, deportment, and habits, the theory and operation of our free government, more happily than the author of this address; because, in him we see how accessible are the highest seats in the halls of power, to the plainest citizen, relying on his inherent energies and personal merit—and how totally unessential and inoperative are the accidental advantages of birth, and the hollow pageantry of wealth in a free government, where every man is *compelled* to advance himself, by advancing the interests of his country. Mr. Roberts has, like the venerable Pickering, literally alternated the duties of national legislation, with the labours of the plough, and the fatigues of the harvest field; performing all in their place, with honor. A considerable portion of the address has been omitted, because, though eloquent and interesting, as the first delivered before the society and, as it were, introductory, we have wished to consult the interest of our readers in general, by copying only the most practical parts, or such as are of general application. His suggestions in regard to imported raw productions, especially that of wool, are deserving of particular notice, and may induce the Committee of Agriculture to cut out some work for Congress.]

Edit. Am. Far.

ADDRESS, &c.

It is in vain to talk of producing much beyond what the market demands; that for which there is no sale, will hardly be cultivated; many of our products are in little demand, and hardly bear the expense of culture; can this state of embarrassment be relieved? is a question, the solution of which claims the sober consideration of the wisest heads. Much has been done for commerce and manufactures—but when has the agriculture of the middle states shared

any benefit from national legislation?—Yet we have grown to be one of the most considerable agricultural nations in the world, and this portion is not behind in her productions.—This great national interest was well content to see commerce cherished as a pursuit that then needed it, and as a most valuable mean of prosperity; commerce then winged our products to every market. To us, then, every market was open.—In many markets, we are now forestalled, and this interest in her turn claims regard; it is time to harmonise and consolidate it; it will not seek the aid of bounties and premiums, but it has a right to the home market; it is in the power of the Congress to secure it without oppressing any other interest; the majority of the state and national representatives must ever be elected by those interested in the culture of the soil—their petitions must be secure of attention, and the legislative power, when it is proper, cannot be slow to interpose. Allow me to repeat that it is just, that those articles in which we abound, should be secured the home demand.—An accidental rise in the price at home, or depression abroad, cannot make the importation of such articles, a wise policy; we have, and must continue to have, a full supply of grain. Why then offer facilities for its importation. Countries which, perhaps, at no time grow sufficient for their own consumption, have found it necessary to protect the farmer against sudden depressions by importation. So far as consumption is concerned, absolute prohibition would seem the better policy. Wheat and potatoes of foreign growth have sold in our markets at good profits, when the products of our own soil would hardly repay the expense of cultivation. On nothing does prohibitory duties seem so strongly called for as the article of *wool*. By one of those changes in the affairs of nations, which rarely occur, the fine woolled sheep of Spain became transferred to our country;—we all remember at how much expense and some of us, perhaps, have to regret it. Practical men at length, became engaged in the growing of fine wool. This interest was at first checked by the large importation of woollen goods, immediately after the late peace with Great Britain. It had hardly begun to revive, when extensive importations of wool paralyzed the hopes of the farmer, and now seriously threatens the annihilation of this precious race of animals. For some time wool, the growth of the country, has not been exchangeable for money; the keeping of merino flocks under the best management is almost a total loss; I speak from actual experience. Prompt and effectual legislative interference is required for the preservation of this interest. No exertion ought to be omitted to secure so important an object; an encouraging bounty has long been secured to the growers of sugar, an article, which perhaps we have no means of cultivating to the extent of the home demand, while wool, an article we can produce to any extent, pays less duty on importation by one half than sugar. The best interest of the country loudly call for increased duties on foreign woollen fabrics, and onerous ones, at least, on the importation of the raw material. In the year 1816, our most successful manufacturers of cotton, despaired of producing goods at the India prices;—but in the short space of seven years, what astonishing facilities have been acquired in the cotton business, while the raw material is still at a good price. Our woollen manufacturers are fast following the success of our cottons, and the production of the raw material is little less important to the middle and eastern states, than the growing of cotton and sugar is to those of the south and west. It is not a high

price that is needed to encourage the growth of wool, but a market at which it may be exchanged for money.

Farmers are deeply interested in having the inspection laws so executed as not to give a preference to the products of other states in our own markets, as well as those abroad. Time has been, when our superfine flour was preferred to that of the neighboring states; lately, however, that of New York and Richmond, and perhaps Baltimore too, has been in better demand than that of Philadelphia inspection. This inconvenience has not arisen from the want of good laws, but from a mistaken policy in executing them. It is especially the concern of the producers to keep the standard of inspection as high as that of our neighbors. A bad inspection may easily disparage our products, but it will be always found a difficult task to restore their credit. The raising a degraded inspection will be felt oppressive, and in the natural order of cause and effect, credit once lost cannot be regained until it may have been some time deserved. Almost every man knows the value of credit, both as it relates to men and things, though it may be often less real than fanciful.

The freedom enjoyed by our citizens in the choice of their occupations, forbids us at an early time, to look for large investments in the cultivation of the soil, for the mere object of profit. Centuries are perhaps to pass before our farms will be so expensively wrought, or so minutely divided, as in the best populated countries. Necessity only can press man so closely on man, and that necessity cannot early occur in so extended a territory. An exemption from the inconveniences of a dense population forms not the least valuable item in our rich inheritance. Too much *land*, however, brings inconvenience, as well as too little. Speaking practically, the size of a farm is best regulated by the consideration of what a proprietor can conveniently superintend personally. That description of persons called managers, are rarely to be met with amongst us. Most of those qualified to take charge of other people's business, prefer having it of their own. This fact is a gratifying proof of the freedom and happiness of our people.

The true point of excellence in practical husbandry, is as far as possible to make the farm fertilize itself. Not that it is bad economy to buy manure, but that the production of it is the only resource for the country at large. The collections from stables, and the streets of cities, are to be had in comparatively few places. In years past, the demand for produce at good prices, and favorable seasons, gave to farmers a return for their capital and labor that cannot now be looked for. Unproductive seasons have been joined to dull markets for several years. Light crops make lean barn-yards, and impoverished fields follow as a consequence. There is, however, room for an improved economy in the production and collection of manure. Lately a beginning has been made to convert the whole corn plant into a nutritious fodder, or most valuable addition to the savings of the barn-yard. The advantages resulting from this method, it is to be feared, are too little appreciated. With less labor I have found it the best method of harvesting the crops; it is then cured with less liability to injury from autumnal rains. We may well doubt, whether we have learned the value of this magnificent plant; the crop is one of the most certain, and least exhausting to the soil, while it is one of the most productive, cheaply cultivated, and most useful;—by this crop our sward lands are best decomposed and mellowed. It forms an important item in the course

or crops, that must constitute our best husbandry. It may be doubted, if the root cultivation would be held in such high estimation in Great Britain, if this plant could be matured there; here the root culture has been little resorted to as a means for feeding stock; it is by no means certain, that the American farmer would find advantage in engaging deeply in this course of husbandry; crops of this kind can only be abundant on grounds heavily, and of course, expensively manured; they will generally require more labor than the corn crops; they are not easily secured from frosts in our severe winters, nor can they therefore be fed with perfect convenience. So far, however, as they can be used as food for cows giving milk, they form an excellent admixture with corn meal—but they fall much below the corn crops, in what they add to the savings of the barn-yard. The potato and the turnip are the only root crops I have had much experience in cultivating; I have found them both uncertain in their product, the former an expensive culture, and the latter of little value when abundant. Neither of them leave the soil in so good a state for a succeeding crop, as the corn plant.

In the course of twenty-five years experience, I have found summer fallowing a bad course of husbandry, even for a wheat crop, before the ravages of the insects made it so precarious a culture. By a course of corn, flax, oats or barley, wheat or rye, and clover, we have avoided fallows, and have been enabled to improve our soil.

Farmers can well recollect how beneficially gypsum was exhibited as a manure, and that in the course of eight or ten years after its general application, the clover afforded neither a wholesome summer pasture, nor winter fodder. Recourse was then had to the culture of the fibrous rooted grasses: an evident diminution of the ploughed crops followed. Of these grasses, timothy was found to be the most productive, but the most pernicious to the soil. It was recommended by its kindly commixing with clover, but with these qualities, it is in very little estimation at present among experienced farmers. The orchard, ray and herd grasses, appear to be entitled to no preference over the native grasses of our country; they do not afford so rich a sward for the plough.—The clover at present seems to have regained its original value. The cause of its deterioration or recovery, I pretend not to explain.

The use of gypsum for a while superseded the use of lime—during that period the soil became saddened and unproductive. A recurrence to its use promises the former results, an open and productive soil. The effect of lime on grass crops in this second trial, has been scarcely less visible and valuable than the effect of plaster when first applied. This precious mineral abounds throughout our country. It forms (limestone) an essential ingredient in restoring and improving the fertility of soils. Our farmers well understand this, and they now apply it to an extent and expense alike creditable to their enterprise and intelligence. But to realize its full benefit, it must be accompanied with moderate dressings from the barn-yard, at periods from seven to ten years. To keep grounds long in grass with plentiful top dressings will be found an unprofitable husbandry. I have experienced it to be advisable to plough the third or fourth year. The extent to be put under the plough, must be proportioned to the resources of the barn-yard and the manures obtainable. Ploughed crops will over exhaust the soil, and the farmer should be prepared to retain or improve its fertility. Dressings from the barn door are never doubtful in their effects. Disappointment never re-

sults from their application. Casualties may mar the crop immediately following; but benefit is sure at last to be realized.

Farms have been made singularly profitable by the cultivation of grass, and their fertility greatly increased. In this middle region, however, grass farms are less likely to multiply than in the interior and remote settlements. Frumentitious crops must remain a leading object with farmers here. A good system of husbandry comprehends a varied cultivation; and the keeping of several kinds of stock. The farm is thus made more productive, less liable to accidental discouragements from unfavorable seasons and other causes, and a succession of employment is kept up through the year, with fewer occasions of pressure or relaxation.

We have been slow to substitute the labor of oxen for that of horses; but the value of the ox as a laboring animal, is becoming every day better understood. With us the habit of keeping large stocks of horses has become inveterate. The horse it is true is a burden-bearing, as well as a draught animal, which the ox is not. In small farms they cannot both be kept, and the horse is justly preferred. This reason will not hold in larger ones. It is not easy for those who have not witnessed it to conceive how much more cheaply the ox can be kept than the horse. When the former becomes unfit for labor his value is but little diminished. It is not so with the latter; he becomes useless. It should be our care to breed only good horses, diminish their numbers, and substitute oxen for the draught drudgery of the farm. We are too little acquainted with the sagacity and docility of this animal, and how profitably he can be employed. Our prejudices are strong against him. He is considered the emblem of dulness and inactivity. But his degradation is a consequence of our ignorance, inattention and neglect. The ancient Egyptians chose him as an emblem of deity—what an homage to his usefulness! I inherit nothing from my father I value more than the preference he taught me to feel for the employment of the ox; nor can I hope to leave a better inheritance to my children. Experience has convinced me he will perform as much labor as the horse—in heavy plough draft he is greatly preferable. The exhibition of his performances here will give him that estimation he deserves. The driver and himself will not continue to be the object of the world's dread laugh. He will rank with the farmer as one of his most valuable animals.

In practical husbandry the expense of labour is a cardinal consideration. Since the year 1818, farmers have very sensibly felt that labour has been much dearer than produce. We cannot speedily look for their equalization: a mitigation of this effect may be sought in some degree by improved implements. Those who have used the drag-rake can attest its value in lessening the expense, and facilitating the gathering, of that important article, hay. The revolving rake of Pennock and Peirce, is a most valuable improvement of that useful machine. An ingenious application of animal labor in the cutting of grass, has been effected. Of its practical utility I cannot speak, not having seen the machine in operation. If it can be adapted to common farm purposes, it would rank the inventor deservedly among the benefactors of his country. Nothing is more wanted than the application of animal labor in the cutting of grain. It is the business on the farm which requires the most expedition, and it is always the most expensive labor. Such an invention can be no easy task, or the ingenuity of our fellow citizens would, ere this, have effected it. But we

have no right to despair, where there is not a physical impossibility. A liberal premium might well be employed to obtain such an object. Manual operations are greatly accelerated by properly constructed utensils. How much has been gained by substituting the steel hay fork, instead of those formerly used. The scythe is improving from year to year—not so with the sickle—thirty years ago it was better than it is now. Of all the utensils on the farm, the plough and the harrow are of primary importance. It is not very obvious that either of them are susceptible of much further improvement. It is desirable to ascertain, and bring into use, in the variety of existing models, those that will perform the requisite operations with the least possible force. This is within the range of our objects. The influence of habit is so strong, that it is difficult to get inventions into use, even when their utility had been demonstrated. How many years elapsed after steam power was applied to propel boats, before it could be brought into general use. He who succeeded in this will be better remembered than the discoverer. The rake drawn by animal power, is yet comparatively in little use. In no way can this society effect more good, than in accumulating and demonstrating, by actual operation, the utility of inventions calculated to facilitate the labors of husbandry and rural employments.

Household industry comprehends an essential interest in rural economy. It is the department in which the influence of that sex, to whom we are bound by the strongest ties of love and gratitude, is most conspicuous—it is the link which connects them with our exhibitions—it is the scene where the thrift, the ingenuity, the taste and intelligence of woman, has full latitude of operation. How many comforts, how many enjoyments are accumulated? how many endearments are secured, by raising her to her proper elevation? A community will be formed, refined, and happy, in proportion as woman is secure of respect. Employment is ever the shield of innocence, and the nurse of virtue. In a farmer's house it is the best maxim, *to make what you can*, even when foreign commodities are most depressed. Who would not prefer having their spinner, their dyer, their clothier, for their neighbors, rather than in a foreign land? Independently of all interested considerations, we must delight to cultivate an interchange of kindness and mutual good offices. How much must life languish where they are wanted? Our young people, who do not inherit farms, may in these pursuits commence life as heads of families, and end it as cultivators of the soil. But there are seasons in which the farmer needs their assistance in his business. They will be found ever ready to lend it. Agriculture must languish where it cannot, at intervals, bring tradesmen to aid in its labors. It is not in relation to the comforts of families only, that household manufactures deserve high regard and consideration: they are of essential importance to national prosperity. The community whose time is the most carefully and usefully employed, will be the most flourishing. Where there is no household manufactures, much time will be consumed to little purpose, and much expense must accrue, to purchase that which is not produced. The wealth sent abroad for foreign conveniences, as things now are, will slowly, perhaps not at all return. Thus the nation will become impoverished. National penury must militate against individual and domestic happiness. It is a point of sound policy, to nourish a taste for household manufactures—it is for the ladies to facilitate and effect their establishment. Teach them it is for their country's good, and they will do

their duty. They will not be slow to learn, when their fathers, their husbands, their lovers, become their teachers.

But, gentlemen, I am too long delaying the closing operation of the occasion. The distribution of premiums, though the last will not be the least pleasing part of our duty; the more especially as they will fall where well deserved. This exhibition, I am happy to believe, has been gratifying, in a high degree, to all who have witnessed it. Such perfection in the form and qualities of animals, to be believed, must be witnessed. Our farmers cannot, will not, continue to nourish the inferior races, when so much better are obtainable. I cannot but think it is for the Pennsylvania Agricultural Society, in the close of their first year's labor, to have good reason to hope for a long career of usefulness.

I cannot omit expressing the high gratification the Society feel, in the evidence they have now received of the approbation of their fellow citizens, of the undertaking they have embarked in; nor of offering the sincere thanks of the Society to Mr. Evans, for his public spirited exertions to accommodate the exhibition; and to the gentlemen of the neighborhood, who have so hospitably co-operated with him. To the committee of arrangement, for their untiring diligence and the perfect success with which they have executed their arduous and delicate duties, as well as to the various committees of examination, and the gentlemen who have kindly afforded their services to assist them, the thanks of the Society are justly due, and sincerely tendered.

REPLY TO MR. LOWRY'S ENQUIRY
About the symptoms &c. in cases of Glanders,
amongst horses, published in last Farmer.

GLANDERS.

A contagious disease, peculiar to the horse, the ass, and the mule. Glanders often attack horses that are in good condition, and so little is their general health sometimes affected by the disease, that I have often known glandered horses continue their work for four or five years without any interruption, except from lameness or other accidents. For more than ten years I have had the care of several teams of glandered horses, which were regularly worked from Exeter to Plymouth. Every precaution was of course observed to prevent mischief; detached stables were provided at every place where they halted; and the greatest care taken to prevent their having any kind of communication with other horses. The time a glandered horse continued fit for work varied considerably; in many instances, they have appeared strong, and worked regularly for four or five years; sometimes only a few months; most commonly, however, they lasted two or three years. They rarely died of the disease, for as soon as they became incapable of continuing their labour so as to earn the expense or value of their keep, they were destroyed.—The proprietor having a great number of horses working on other roads, whenever one of them became glandered, he was sent to the glandered teams, and by such recruits the strength of these teams was kept up for many years. It is worthy of remark, that when the superintendence of the horses, from which the glandered teams principally derived their reinforcements, devolved on a person who had been convinced by some decisive experiments that the disease was contagious, and who was scrupulously careful in separating a horse from others as soon as the slightest suspicion arose of his being infected, from that time

recruits became more and more scarce, and it was found necessary, as a glandered horse fell off, to replace him by one that was free from the disease: at length very few glandered horses remained, and at this time there is not one left.—During the time I attended these glandered teams, I was employed for about two years by another proprietor of wagons, who also kept a glandered team: here the stables and general management of the horses were but indifferent, the work too hard for their keep and condition, that is, they were not fed so well, or in any respect so well treated as the horses before noticed; the consequence was, they increased rather than diminished, and became unfit for work in a much shorter time; many of them became farcied as well as glandered. The above circumstances are stated merely for the purpose of showing, that the following observations on glanders are grounded on experience; and it may not be improper to add, that, previous to this, the disease particularly engaged my attention, during the seven years I had the honor to serve as veterinary surgeon in the Royal Dragoons.

There are two kinds of glanders; the mild and the virulent, or the chronic and acute.—The symptoms of mild glanders are, a discharge of matter from one or both nostrils, and a swelling of the glands or kernels under the jaw. When the discharge of matter is from one nostril only, which is often the case, the glands on the same side only of the under jaw-bone are affected.—The matter discharged from the nostril is not of a whitish colour and cream-like consistence, as it usually is from an abscess, or from strangles; it has rather a glairy appearance, and sticks about the upper lip and exterior part of the nostril. The discharge is seldom so considerable as in strangles or violent colds. There is no cough, and the general health does not appear in any degree affected: the horse feeds well, is lively, and continues in good condition. On inspecting the nostrils, ulceration is seldom observed, nor has the matter which is discharged any offensive smell; yet this has by many been considered as a distinguishing mark of glanders. The disease often continues in this stage a considerable time, particularly when the patient is of a hardy constitution, was in good condition at the time he was attacked, and is not over-worked and badly fed. But when it attacks horses that are pent up in hot close stables, employed in violent exertion, and when over heated exposed to rain and cold winds, and particularly if worked beyond their condition and strength, the progress of the disorder is usually more rapid, and the first symptoms are generally of a formidable appearance; hence it is, that stage-coach and post horses are often so violently attacked, and that in such horses, the virulent or acute glanders, sometimes accompanied by farcy, are most frequently met with. In virulent glanders there is generally a considerable discharge often from both nostrils, and the glands under the jaw are much enlarged. The inner parts of the nostrils are commonly ulcerated, and when the matter has an offensive smell, or is mixed with blood, though the ulcers cannot be seen, there can be no doubt of their existence in the higher parts of the nostrils.—When the disease has become thus virulent, there is generally a falling off in strength and flesh, respiration is often impeded by the matter and ulceration within the nostrils, abscesses form in the lungs, and the horse sinks under the complaint. The disease is sometimes preceded by langour, weakness, loss of flesh, a dry staring coat and tight skin, and want of appetite. In this declining state the horse may continue, two or three weeks; at length there is a copious discharge from the nostrils, the glands become en-

larged, and the progress of the disease in such cases is generally rapid.

Method of distinguishing glanders from some other diseases which may be mistaken for it.—In catarrh or cold there is often a discharge from both nostrils; but it is attended with cough, dullness of the eyes, and general indisposition, which is not the case in glanders. In strangles, there is frequently a discharge from the nostrils, and a swelling under the jaws. Here also the discharge proceeds from both nostrils, the matter is generally of a whitish colour like the matter of an abscess. The swelling under the jaw is more diffused than in glanders, it is also tender, becomes gradually larger, and at length suppurates and bursts; soon after this happens, the horse gets well. Strangles are also attended with general indisposition, dullness of the eyes, and cough; and not unfrequently before the swelling suppurates, there is considerable difficulty in swallowing. Chronic catarrh or mesenteric consumption is often mistaken for glanders.—From sudden changes of temperature, that is, by suffering a horse to stand in a cold wind or rain after being heated by exercise, the lungs may be affected with a chronic kind of inflammation, accompanied by a similar affection of the mucous membrane lining the nostrils and windpipe. In this case the horse generally falls off in flesh and strength, the coat becomes dry and rough, and the skin sticks close to the ribs. The horse has commonly a tolerable appetite. There is a discharge of matter from the nostrils, and a swelling of the glands under the jaw. As the disease proceeds, tubercles are formed in the lungs, and the mesenteric glands become enlarged. The tubercles gradually increase in size, at length are inflamed and suppurate, the lacteals are completely obstructed, and the animal dies. (see *Consumption*.) This is usually the progress and termination of the disease when the animal is neglected, or often exposed to the cause which originally produced the complaint. There is often considerable difficulty in distinguishing the earlier stages of this disorder from glanders. In one circumstance, however, there is a material difference. The former has never been known, I believe, to be communicated to other horses standing and feeding with the patient; whereas it is a well established fact that glanders are contagious, as will be presently shown. This circumstance led me in a former publication (see vol. iii. *Veterinary Medicine*, p. 40.) to propose a test for distinguishing glanders from other diseases. Since that time I have given it a further trial, and the result has fully confirmed what was there said of it. The best mode, perhaps, of explaining this subject will be to relate the last case in which it was employed. March 23, 1816, I was desired to examine a mare that was said to have the strangles coming on: there was a considerable enlargement of the gland on one side of the under jaw, and a small discharge of matter from the corresponding nostril. The proprietor was informed that it was very unlike strangles, as there was neither cough nor dullness of the eyes: in short the mare appeared to be in perfect health and in good condition. The swelling was blistered and some medicine given.—About a fortnight after this I found the mare precisely in the same state; but about a week before I found that a pony, which stood next the mare, had had a discharge from the nostril and a swelling under the jaw for some time; but here the gland was not much enlarged, the discharge was inconsiderable, and he was in perfect health and condition. I discovered also, that the proprietor of these horses had lost a horse from glanders about twelve months before, but the place where this occurred was at a considerable

ance from his present residence; and no kind of communication was known to have taken place between that horse and those now affected.— Another week elapsed, and no alteration was observed. The proprietor became anxious to ascertain whether it was glanders or not, as he was determined to destroy them if it proved to be that disease. As the mare was of considerable value, I proposed the *test*, which was assented to; and a healthy young ass about two years old was purchased for the purpose: a little of the matter, about the middle of the ass's neck, was cut from both sides, so as to leave a bare space about the size of a dollar. A small lancet was then introduced under the cuticle from above downward, but so as to cause a few drops of blood to appear; the same was done on the other side of the neck. Some matter was then taken from the mare's nose and introduced by means of a small slip of wood, about the size and form of the lancet, into the orifice on the right side of the neck. Some matter was then taken from the mare's nose, and inserted with a fresh slip of wood into the orifice on the left side. The ass had no communication with the suspected horses, but was kept in a different stable, and had a clean bucket to drink from. Two days after the operation the inoculated part on both sides was swollen and very tender; the next day the swelling was found to have increased considerably, and corded veins, (lymphatics, see *Farcy*.) as farriers term them, were seen proceeding from the inoculated parts, on both sides. The scabs being removed, the inoculated parts were found to have become large foul ulcers of a peculiar appearance; these gradually spread. Small tumours resembling farcy buds appeared on the corded lymphatics; these burst and became foul ulcers. About a week after the operation, a discharge was observed from the left nostril, and two or three days after the glands under the jaw on the same side were a little swollen. The discharge from the left nostril and the swelling of the glands gradually increased, and in little more than a fortnight the animal was decidedly glandered.— There was not the least discharge from the right nostril, nor were the glands on that side affected. The ass was now destroyed. The membrane lining the partition of the nostrils on the left side was much ulcerated; on the right side there were no ulcers, but the membrane appeared redder than usual. There was a small quantity of matter in the left frontal sinus, and the honey-comb process of the ethmoid bone was highly inflamed. On the right side these parts were healthy. On passing the hand over the surface of the lungs, small tubercles were felt. The ass fed and drank well to the last; but the ulcers had spread considerably. In this case the constitution was more speedily affected than we generally find it to be. In some instances a month has elapsed, and in one case it was two months nearly, before the horse was decidedly glandered. A young ass appears to be the best subject for the experiment, being more readily affected than a horse. That glanders are a contagious disease, is, I believe, universally admitted by those who have duly investigated the subject. But Mr. Coleman, and many eminent practitioners, are of opinion, that it is often produced by other causes than contagion; particularly by sudden changes of temperature, and confinement in close stables. It must be admitted that glanders have often occurred, when it cannot be ascertained that the horse has any time been exposed to contagion; but it should be recollected, that he may have been inadvertently so exposed, that is, he may have been fed in the same stall, and been watered from the same bucket, which had before been used for a glandered horse; and it is

an established fact, that a considerable time may elapse after the reception of the poison, before the glanderous symptoms make their appearance. When a sound horse was put into the glandered teams, I have several times noticed the length of time he remained free from the disease. The shortest time I recollect was between two and three weeks; more commonly it was from one month to two, and in some instances they have escaped it altogether. The last sound horse that was sent to the glandered team was about twenty years old, but of a hardy constitution. I have frequently examined him; and though he had, when I last saw him, been more than six months working and feeding with glandered horses, and drinking out of the same trough, he had not the slightest symptom of the disease. As to the manner in which glanders are communicated, there have been various opinions: I have proved, however, that it is not by any invisible vapours or effluvia that escape from the diseased horse, or by the glanderous matter being applied to the nostril, an opinion that very generally prevails. I have not, it is true, obtained any direct or positive proof from my experiments, that it is by swallowing glanderous matter the disease is communicated; yet there appears to be no other way in which it can be accounted for. According to Mr. St. Bel, the first professor of the veterinary college, "the virus (glanderous matter) mixed with a little flour, given to three horses for the space of a week, communicated the disease to the youngest in the space of a month; the two others did not sicken till some time after." I observed in the third volume of my *Treatise on Veterinary Medicine*, published nearly five years ago, "after having paid considerable attention to the subject, I have not been so fortunate as to discover a remedy for glanders; nor has it ever come to my knowledge, that any other practitioner has been more successful. Mr. Coleman has devoted much time and attention to the subject; I believe he has tried without success every method and medicine that he himself could devise, or that could be suggested by others. Many other practitioners have been no less industrious, and equally unsuccessful. With such authorities as these, I think no one will hesitate in admitting that the glanders have hitherto proved incurable." Since that time I have continued my attention to the subject, but have found no reason for altering my opinion. I have certainly heard of some *infallible remedies*, and have read a book, the professed object of which is to show, that glanders are not, as Mr. Coleman teaches, a disease "highly infectious," (Mr. Coleman says the disease is contagious, that is, propagated by contact,) "and to rescue from neglect and premature death a valuable animal, which in all probability under proper treatment might be preserved." This book contains eight prescriptions for glanders. The efficient medicines they contain have been repeatedly and unsuccessfully tried many years ago. In the first we have two or three drams of sulphat of copper (blue vitriol) in the second there is an addition of half a dram of calomel: in the third one dram of calomel and half a dram of opium; in the fourth one scruple or half a dram of sublimate and one dram of opium: in the fifth half a dram or a dram of Ethiop's mineral (the usual dose is about an ounce) and half a dram of opium: in the sixth one dram of white arsenic and half an ounce of assafetida: in the seventh two drams of arsenic, six drams of columbo root, and half a dram of opium: in the eighth two drams of sulphat of iron (salt of steel,) one ounce of bark, and half a dram of opium. *Qui vult, &c.* From what has been said on this subject it may be inferred, that

the most effectual mode of prevention consists in separating a suspected horse from others; and being particularly careful, that sound horses have no possible opportunity of swallowing glanderous matter, which may be dropped upon hay or corn, upon the litter, or in a trough of water, or upon the manger, or parts of the stable which horses sometimes are apt to lick. The most effectual method of purifying a glandered stable is to cleanse it thoroughly, and fumigate it. (See *Fumigation*.) A more particular account of glanders may be found in the third volume of *Veterinary Medicine*.

From the Massachusetts Agricultural Repository and Journal, Vol. vii.

RINGING THE BARK OF FRUIT TREES.

Observations on, and details of, some experiments in ringing the bark of fruit and other trees and plants. By Joseph Sabine, Esq. F. R. S. &c Secretary. Read March 21, 1820.

The publication of the papers, on *ringing the branches of fruit trees*, by Dr. Noehden, in the second volume of the transactions, has directed the attention of several Fellows of the Society, and other persons, to the subject. The results of these experiments, which have been communicated to me, appear to be of sufficient importance to be collected together; as they will serve as guides to those who may wish to make further trials, and will assist in ascertaining the causes, of the variety of effects, which appear to attend the operation on different plants.

The practice of ringing or circumcising the branches of fruit trees, in order to make them yield more produce, is not novel; it is not stated to be so, in the papers alluded to; but though occasionally used, it does not appear that much enquiry has been made, to discover the most advantageous method, or the proper seasons, for performing the operation, nor have any reasons been distinctly assigned why it should be so particularly successful in some instances, and so entirely devoid of benefit, in others. The production of a greater crop of fruit, is the most important of the advantages expected to ensue from ringing: this increase must, of course, arise from an additional number of blossoms, and in some cases, from blossoms, that would not have existed in the ordinary course of nature, without the intervention of ringing; the formation of flowers, is therefore, the point to be looked to, in considering the application of the practice.— In those trees where the blossom buds are produced on the wood of the preceding year, it is not to be expected that the operation will have any effect on the quantity of produce, in the year in which the rings are cut; and it is on trees of this character, that ringing has been chiefly practised. On the contrary, in those trees which produce the flowers on the present year's wood, (though not much has yet been learned from experiment, with respect to them) the effect of the ringing will be seen immediately.

The interruption of the passage of the descending sap, by the incision in the bark, causes, in some cases, an alteration in the quality and appearance of the fruit. In many instances, in the first produce after the operation; it is considerably increased in size, on the ringed branches; it is also ripened earlier in the season, and that circumstance is accompanied, with very extraordinary improvement, in those colours of the skin, which indicate full maturity. Taking therefore into consideration the expectation of a change both in the quantity and quality of the

fruit, it will be obvious that the spring is the most proper period to cut the rings; the bark is then very readily detached, and the work may therefore be done with greater ease at that season. With respect to the width of the incision it must be recollected that the separation of the communication of the bark, in every case, though in some more than others, materially affects the health and vigour of the branch. As long as the separation is kept up,* so long may the formation of additional blossom buds be expected: but the restoration of the communication, which will be the consequence of the union of the bark, from the opposite sides of the ring, puts an end to the whole of that unnatural process, which the interruption had occasioned. It is therefore requisite, that the bark should be separated, nearly the entire season, in which the ring is made, more especially in those trees, where an increase of the succeeding year's bloom, is intended to be produced; but it is not advisable, in any case, to keep the ring open for a long period; the deposit of albumum, at the upper edge of the ring, caused by the stoppage of the passage of the descending sap, increases the size and weight of the branch, in that place, so much, whilst the under part, remains of its original size, that it is very liable to be broken short off, at the ring, if the bark be suffered to remain long disunited.

Having taken this general view of the subject, I proceed to the consideration of the application of the practice to the different kinds of fruit trees, as far as my own observation, or the experiments of those with whom I have corresponded relative to it will enable me.

All apple trees form an abundance of additional flower buds, in consequence of ringing; but if the ring be wide, the ringed branches, especially young ones, speedily become sickly; it is therefore advisable, with them not to cut rings of greater width, than what will be closed up, at the end of the same season, or early in the following year; besides, it seems that the improvement in size and beauty, is obtained chiefly in the first year of the ringing, therefore the rings of apple trees certainly should not exceed a quarter of an inch in width, on strong branches, and they should be narrower on small and weak shoots. Fresh branches on the same tree, ought to be annually ringed, and thus a succession of produce be uninterruptedly kept up.

Mr. Twamley of Warwick, exhibited, to the Society, in the autumn of 1818, some specimens which fully illustrate the practice of ringing apple trees. In the spring of 1818, he ringed several espalier trees, some of which were the Minshull crab, the Court-pendu apple, and the French crab; the two former produced some of the most remarkable specimens of the kind, from the ringed branches, as to beauty, which perhaps were ever seen; the colours being most brilliant, whilst the apples from the unringed branches of the same trees, had their usual appearance; but the size of neither of these kinds was altered, whilst the French crabs from the ringed branches, were enlarged in an extraordinary degree, as well as improved in appearance. The same trees in 1818, had borne great crops on every branch, whether ringed or unringed;

* Since this paper was read to the Society, Mr. Williams, of Pitmaston, has mentioned to me, that a ligature on the branch, by a waxed string tied tightly round it, early in May, produces nearly the same effect of ringing. In this case, although the downward flow of sap, from the leaf is in some measure prevented, the albumum is not injured by exposure to the air, and there is less obstruction given to the ascending sap, so that the health of the branch is preserved.

but in 1819, they did not produce a single apple, except on a ringed branches, which then afforded a good crop, but the fruit, though very beautiful, were not so splendid in appearance as in the former year, and the French crabs were not larger than usual. Mr. Twamley has observed that the rings made in horizontally trained branches do not so readily close up as those on upright growing ones; and he found an advantage in protecting the exposed part of the wood at the ring with grafting clay. Mr. Hunt of Stratford-upon-Avon, having observed Mr. Twamley's success, tried the same experiments with trees in his own garden, in 1819, particularly upon the Ribston pippin, the nonpareil, and scarlet nonpareil. He made his rings a quarter of an inch wide, at the end of April and beginning of May, and in the winter covered the open rings with clay and cowdung. The Ribston pippin filled up its rings more rapidly than the other kinds; in consequence, as I suppose, of its being more vigorous in its general habit. The fruits of all in comparison with the produce from the unringed branches, were, exclusive of the additional quantity, either altered in size or in colour, but did not keep so well; and Mr. Hunt thought them inferior in flavour, which is the natural consequence of the increase in size. The Ribston pippins, from unringed branches, were of a pale greenish yellow, and averaged eight inches in circumference; those from ringed branches, were of a rich golden colour, with brilliant red streaks on the exposed side, and were ten inches in circumference. The nonpareil tree, (usually called the greer nonpareil) was trained to a wall, and its produce, consequently, was all large; but those from the ringed branches, were highly improved in colour, and measured twelve inches round. In the scarlet nonpareil there was no difference in colour,* but those from ringed branches, measured ten inches in circumference, while those from unringed branches, measured only eight.

Pear trees do not suffer so much from ringing, as apple trees; the ring, though kept open, does not appear to induce weakness, so speedily: the ringed branches do not make shoots in such numbers, nor in such vigour, but they retain their health, sufficient for all purposes of produce, many years. Indeed, so little injury is done to pear trees by ringing, that several branches can be kept cut at one time, without danger, and a continuance of crop, may be ensured, by occasionally taking out a branch which may have become decayed, and replacing it with new wood. In healthy and clean shoots, the bark of pear trees, soon restores itself over the ring, unless it is cut very wide. The effect of ringing them is a certain production of blossom buds, so much so, that even young trees may be brought into bearing, by this means. Mr. Twamley, in the spring of 1818, ringed a branch of a young and luxuriant Jargonelle pear tree, which had been planted only two years; the ring closed itself at the end of the summer; but the branch next year blossomed and brought to perfection four good pears, (shooting vigorously also) when no other part of the tree showed the least appearance of bloom, and even in the present spring it shows two branches of blossom, which are the only ones upon the tree. Mr. Kemple mentions that he had increased the size of pear trees by ringing: this is most probable, but an instance of it has not occurred to my observation.

* The scarlet nonpareils from ringed branches, in Mr. Twamley's garden, were, however, much more brilliant in colour, than the other apples on the same tree.

The branches of plum and cherry trees sustain injury and become cankered by ringing; but as they are always free blowers, an increase of blossom by artificial means is not wanted to make them produce fruit. The same observation is applicable to peach and nectarine trees; so that all the stoned fruits cultivated in this country must be excluded from the list of trees on which ringing may be usefully performed.

Vines are much benefited by ringing; their blossom is produced on the shoots of the same year, in sufficient plenty: for additional blossom, the use, therefore, of ringing, is not required, but increase of size, early ripening, and improvement of flavour in the grapes, all result from ringing. Mr. Williams, in a paper on the subject, in the first volume of the Transactions, has sufficiently described the mode of proceeding with the vines for this purpose.

In none of the experiments, the termination of which I have yet become acquainted with, has success attended the operation of ringing the Fig tree. The branches which have been circumscribed have put forth on the young wood, abundance of small Figs, such being in fact, the flower of the tree, which subsequently enlarges and becomes the fruit, when ripe. This production of fruit has even been effected, in trees which had not attained sufficient age to throw it out naturally in the regular course, but in such cases the crop has fallen off, without ripening. The branches of the Fig tree suffer by ringing; the incision should, therefore, when made, be very narrow, to admit of speedy closing, it not being necessary for the production of the blossom, (which is formed on the young wood,) to keep it so long opened, as is required in other fruit trees.

The preceding are all instances of the effect of ringing in the production of fruit: but as these incisions in the bark cause the formation of flower buds, when none, or only a few, would otherwise have appeared, the practice may be extensively and usefully applied to ornamental shrubs and plants, which do not readily blossom. I believe this use of ringing has not before occurred to the advocates of the practice, and as I am acquainted with some cases of perfect success, it will be worth while to enumerate them, in order to induce to further trials.

Mr. William Baxter, gardener to the Comte de Vandes, at Bayswater, has given me the particulars of three experiments, made in the spring of 1818, which fully answered his expectations. The first was with a Waratah Camellia, which he had never been able to make flower; he cut a ring round the stem; so close to the root, that he was able to cover the incision with the mould of the pot, in which the plant grew; the ring closed at the end of the year, and the plant remained in good health, but made rather short shoots, on which an abundance of flower buds were formed, and these blossomed perfectly in the following spring. The second experiment was on a plant of Aubletia Tibourbou, in the stove; the ringed branch speedily broke into flower; it was the first blossom which the plant had yielded, but its other branches did not blow; the ringed branch is still alive, and its bark nearly reunited. The third experiment was on branches of Pyrus spectabilis; those which were ringed produced last spring, abundance of splendid flowers, which were succeeded by ripe fruit; and they are now again full of blossom buds, the other branches showing little promise of bloom.

In addition to the above, I can state, that one branch of the Passiflora alata, in Messrs. Loddiges' stove, was ringed, in 1818; in two months after it produced flowers; it also did the same abundantly last year, whilst another branch which remained unringed, was entirely unproduc-

in both seasons. Mr. George Loddiges, in writing me this account, mentioned, that he had tried the same experiment, with other Passifloras, and with some stove plants, but that he had not succeeded. His failure may probably in some cases be attributed to his having made the slips too narrow; in the soft stemmed plants, which he ringed, the bark would reunite very rapidly, and if the separation is not kept open, sufficiently long, the desired effect will not be produced.

Excerpts from late numbers of the London Farmer's Journal, received at the office of the American Farmer.

ON CUTTING GRAIN.

In Cutting Grain earlier than usual, in a letter from Mr. D. Wark, of Old Hall, Dunlop, Ayrshire, to Sir John Sinclair, 21st July, 1823.

Sir—I have lately observed a proposal by you, to the Highland Society, to inquire into "The proper time of reaping Grain." I think it right, therefore, to send you an account of an experiment, which may throw some light upon that matter. It is the more necessary to attend to this subject, as people are often deceived by oats that had been hurt by the grub. In that case there are always suckers (as I call them) springing from the root, which often carry their heads above the ripe stalks, whose heads are heavy, and consequently fall down.

In 1822, I reaped a field of oats, in small lots, so much per acre, as the same shall measure (which is the custom in this quarter,) and offered a small premium to the first five who cleared the ground in a fit state for the barn or stack. As was to be expected, some took the benefit of my premium, while others mocked it. "They had more sense (they said) than to destroy the crop for the trifle offered." However, they in general agreed to let me know the produce of their respective lots: I also reserved one lot to myself, which I cut nearly a week before any of the other lots. The field was of very equal quality, and the following was the produce in meal of ten different lots, of which I got a particular account from the buyer of each, besides the lot I reserved to myself:—

Day of cutting in September.	Bolls of Meal.	Firlots.	Pecks.	Quantity of Meal in the lot first cut:—					
				B.	F.	P.			
3	8	3	3	8	3	3			
9	9	1	3	Average of the six lots cut early:—					
9	9	1	3						
10	9	1	3						
11	8	3	3						
11	9	1	1				B.	F.	P.
11	9	2	0				9	0	3½
13	8	0	1	Average of the four lots cut last:—					
15	8	0	0						
15	7	2	2				B.	F.	P.
14	7	3	0				7	3	1½

The lot cut on the 3d of September, the weather becoming very soft, was a little sprung, which lessened the produce.

The six following lots cut between the 9th and 11th of September were in fine condition, and very productive.

The four following lots were exposed to a heavy wind, and the loss thence sustained shows

the danger of leaving a crop of oats to the mercy of the elements, after they are in condition fit for cutting, the loss being nearly two bolls per acre.

ANTIQUITY OF TREES.

In "Major Rooke's Sketch of the Forest of Sherwood," are some very curious particulars concerning the manner of marking the age of the oak. In Clipstone Park, in Nottinghamshire is an oak called the Parliament oak, from a tradition of a Parliament having been held there by King Edward I. Near Blidworth, there is a large and ancient elm, called Langton Arbour, which even some centuries ago was sufficiently remarkable to give a name to one of the forest walks, and to have a keeper appointed to it.—Major Rooke tells us, that in cutting down some timber in Birkland and Bilhaugh, letters have been found cut or stamped in the body of the trees, denoting the King's reign in which they were thus marked. It seems that the bark was cut off and the letters cut in, after which the next year's wood grew over it, but without adhering where the bark had been cut. The cyphers are of James the First, of William and Mary, and one of King John! One of those, with James's cypher, was about one foot within the tree, and one foot from the centre: it was cut down in 1786. This tree must have been two feet in diameter, or two yards in circumference, when the mark was cut. A tree of this size is generally estimated at one hundred and twenty years growth, which number, subtracted from the middle year of James's reign, would make 1492 the date of planting the tree. The tree with William and Mary had the mark about nine inches within the tree, and three feet three inches from the centre: cut down also in 1786.—The mark of John was eighteen inches within the tree, and something more than a foot from the centre: it was cut down in 1791: but the middle year of John's reign was 1207, from which, if we subtract 120, the number of years requisite for a tree of two feet in diameter to arrive at that growth, it will make the date of its planting 1085, or about twenty years after the Conquest. The tree, therefore, when cut down in 1791, must have been 706 years old, a fact scarcely credible; for it appears from the trees whose marks are better authenticated, that these exactly of the same size when marked, had increased twelve inches in diameter in 173 years, whilst this tree had increased no more than eighteen inches in 584 years. Major Rooke says, that several trees with this mark had been cut down, so that deception or mistake is scarcely possible. This accurate delineator accounts for these phenomena, by supposing (as the increasing wood never adheres where the bark had been taken off) that the sap which rises from the roots through the capillary tubes of the wood, to the branches, returns in its circulation between the *blea* and the bark. "I have often (says he) examined many of the ancient hollow trees in Birkland and Bilhaugh, and always found that where the bark remained, even on their mutilated trunks, there they frequently put out small branches with leaves; but where that necessary covering of the returning sap was wanting, there was no appearance of vegetation."

The keeper of a tap-room in Trongate, known by the name of "Charlie's Stable," has a dog of the Irish bull-breed called *Princey*, which is possessed of uncommon sagacity. The animal was so well trained when young, that it obeys its master in almost every thing he orders it, and is as useful to him as a servant. It is nearly three years since it began to carry his breakfast regu-

larly every morning from the Townhead, by means of a tin can, the wire of which he holds suspended between his teeth. When the family dined to Taylor-street, and then to Rottenrow-lane, the animal shifted his route from the High-street, and now takes the nearest route, by High John street, to accomplish his errand. He has never yet gone wrong in any thing intrusted to him. It would be attended with the greatest danger were any person, even in diversion, to attempt to deprive him of his load, as he would probably sooner be killed than surrender. Nor will he accept the most favorite food when on business. He cautiously avoids any of his own species when he is on business; but if he cannot avoid it, he will disburden himself, give them battle, and then resume his load. Though what he carries be often of the most tempting description, the honest animal has never been known to make free with the smallest quantity, but faithfully delivers the articles untouched. He is frequently the bearer of letters between the family, and will carry any thing to the extent of half a stone. He brings every week from the market four or six pounds of beef, as occasion requires. When he returns home with his can, if the family are not in when he taps at the door, he returns back to his master, as he will enter no neighbor's house, nor intrust them with his can. When he is desired to go for his master's hat or shoes, he will immediately do it. He will take a snuff-box, or other article, to such of the neighbors as he knows, and are named to him. He will take a bank-note to the tap-room, and bring back change in silver. He understands Gaelic as well as English, his master speaking and giving his commands, in both languages. He will take a man's hat off his head on being told to do so. He is uncommonly docile and quiet, and will, at the command of the children, leap over a stick four feet high, or dance for their amusement on his hind legs. The people are highly amused to see him skipping along with his daily load, but he will not stop to accept of any favors while he is on business.

Glasgow Chronicle.

[ENGLISH COURT OF CHANCERY—Let us copy her with discrimination.]—Edit. Am. Far.

THE COURT OF CHANCERY.—At the Nottingham meeting "the health of Mr. WILLIAMS" was proposed and drunk with "a speedy reformation of the abuses of the Court of Chancery." In this sentiment we believe every Englishman of every party will cordially concur. It is, (we know not whether unfortunately or fortunately)—but it is not upon the opponents of Ministers only that that direful Court lays its heavy hands. We would not, therefore, have the efforts for its reformation or abolition mixed up exclusively with the proceedings of meetings held for political purposes. An evil so transcendent—an evil which is absorbing the proceeds of public charities, and reducing the most respectable and virtuous subjects to beggary in the pursuit of their clearest rights—should become the object of direct and special exertions for its removal or abatement. We say nothing here of the Judge of that Court—we have spoken of him before. He, no doubt, decides, when he does decide, justly; he can have no motive to the contrary; but we do say, that men of talents and zeal for the good of a munificent country, have in all ages distinguished themselves by ameliorating the institutions over which they have been called to preside. The English Chancellor has been enriched beyond all belief or conception by the practices of his Court, which practices have, meanwhile, carried more ruin into innocent fa-

miles, than all the gaming-houses and other haunts of vice throughout the kingdom put together.—*Times*.

The bet between Lord Kennedy and Mr. Coke is for 200 sovereigns a side, who kills and bags the greatest number of partridges in two days' sporting. Lord Kennedy to sport upon any manors he pleases in Scotland, and Mr. Coke to sport upon his uncle's manors in Norfolk. Both parties to shoot on the same days, the 26th Sept. and 4th Oct. 1823. Mr. Coke, on the 26th Sept. shot upon the Warham and Wighton Manors adjoining to Holkham Park. He killed and bagged 86½ brace of birds; and on Saturday last he shot upon the Holkham, Egmore, and Quarles Manors, and killed and bagged 88 brace of birds. He was accompanied in the field by his uncle Thos. Wm. Coke, Esq. P. M. for Norfolk, and by Colonel Dixon, his umpire; and Blunt, Esq. umpire for Lord Kennedy. He was attended by several gamekeepers, with one dog only to beat for and pick up the birds. There were a great number of spectators. This match, from its novelty, and the celebrity of the sportsmen engaged in it, has incited a considerable degree of interest, and bets to a large amount are depending on the issue. No certain accounts have been received of the result of Lord Kennedy's first day's shooting.

Origin of eating Goose on Michaelmas-Day—Queen Elizabeth, on her way to Tilbury-fort, on the 29th of September, 1589, dined at the ancient seat of Sir Neville Umfreville, near that place, and as *British Bess* had much rather dine off a high seasoned and substantial dish than a simple ragout or fricasee, the Knight thought proper to provide a pair of fine geese to suit the palate of his Royal guest. After the Queen had dined very heartily, she asked for a half-pint bumper of Burgundy, and drank "Destruction to the Spanish Armada." She had but that moment returned the glass to the Knight who had done the honors of the table, when the news came (as if the Queen had been possessed of the spirit of prophecy) that the Spanish fleet had been destroyed by a storm. She immediately took another bumper, in order to digest the *Goose* and *Good News*; and was so pleased with the event, that every year after, on that day, she had the above excellent dish served up. The court made it a custom, and the people the fashion, ever since.

At the time of the plague in London, a noted body-searcher lived whose name was *Snacks*. His business increased so fast, that finding he could not compass it, he offered to any person who should join him in his hardened practice half the profits: thus, those who joined him were said to go with *snacks*. Hence going *snacks*, or dividing the spoil.

Mail Twelve Miles an Hour.—It is said, that a Mr. Banglis, of Birmingham, is offering, by means of a self-acting machine, which he has lately constructed, to convey the Royal Mail through the kingdom at the rate of twelve miles per hour.—*Leeds Mercury*.

Early Maturity.—The fat two year old Steer, and the yearling Heifer, which were shewn by Mr. Thomas, at the Scarsdale and High Peak Agricultural Meeting, held at Chesterfield on the 4th ult. were slaughtered at that place on Thursday last, by Mr. Silcock, the purchaser of the Steer, and Mr. Bower, the purchaser of the Heifer. The following are the returns of their respective weights:—

The two year old Steer's carcass, of 8 lbs. per stone, 122 stone 5 lbs; inside fat, 12 stone 6 lbs. The yearling Heifer's carcass, 99 stone 3 lbs; inside fat, 7 stone.

A MOTHER'S LOVE.

BY MRS. HEMANS.

There is none,
In all this cold and hollow world, no fount
Of deep, strong, deathless love, save that within
A mother's heart—it is but pride, wherewith
To his fair son the father's eye doth turn,
Watching his growth. Aye, on the boy he looks
The bright glad creature springing in his path,
But as the heir of his great name, the young,
And stately tree, whose rising strength ere long
Shall bear his trophies well.—And this is love!
This is man's love!—What marvel! you ne'er
made
Your breast the pillow of his infancy,
While to the fullness of your heart's glad heav-
ings
His fair cheek rose and fell; and his bright hair
Waved softly to your breath—You ne'er kept
watch
Beside him, till the last pale star had set,
And morn all dazling, as in triumph, broke
On your dim weary eye; not your's the face
Which, early faded thro' fond care for him,
Hang'd o'er his sleep, and duly as Heaven's light,
Was there to greet his wakening! You ne'er
smooth'd
His couch, ne'er sang him to his rosy rest;
Caught his last whisper, when his voice from
your's
Had learned soft utterance; pressed your lip to
his,
When fever parched it; hushed his wayward
cries,
With patient, vigilant, never-wearied love!
No! these are woman's tasks!—In these her
youth
And bloom of cheek, and buoyancy of heart,
Steal from her, all unmark'd!

TO THE EDITOR OF THE AMERICAN FARMER.

TANNING.

Annapolis, December 11, 1823.

MR. SKINNER,

In No. 38, of this Vol. you state that it only takes from four to six months to tan, curry, dress and prepare the hide for sale, in England. If this be the fact, it is contrary to the statute regulations of that country, which, like the laws of other nations, are often violated. I have condensed the various statutes below, respecting tanning, which I request you to publish.

JAMES BOYLE.

No person shall tan leather, unless he has been an apprentice for seven years with a tanner, or he be the son of a tanner, &c. on the pain of forfeiting the leather tanned, or the value. 1. Jac. 1. ch. 22.

Tanners are prohibited from being curriers, and vice versa. Stat. 48, Geo. 3, ch. 60.

Tanners overliming hides, or using in tanning any thing but oak bark, ash bark, and culver dung, incur a forfeiture of the leather; and hastening the tanning of leather by unkind heats, are liable to a penalty of £10—and to stand in the pillory. *Hides for sole leather are to be in the noose twelve months, and upper leather nine months, or shall be forfeited.* 48. Geo. 3. ch. 60.

Shoemaker's making shoes of insufficient leather, are liable to 3s. 4d. penalty. 1. Jac. 1. ch. 22.

Red tanned leather, to be brought into open leather markets, and searched and sealed, before exposed to sale, and contracts for sale, otherwise to be void. 13. 14 Car. 2. ch. 7.

Many regulations are made to prevent the spoiling of hides and leather, by the flaying animals injudiciously. 39. 40. G. 3. ch. 66. 41. G. 3. ch. 55.

[We thank our friend for the above, and will give some interesting extracts, in regard to the theory and practice of tanning in our next.]

Edit. Am. Farmer.

THE FARMER.

BALTIMORE, FRIDAY, DECEMBER 19, 1823.

EASTERN SHORE CATTLE SHOW AND FAIR.

The Trustees of the Maryland Agricultural Society met in Easton on Saturday the 6th November, 1823—and adopted the following resolution:

Resolved, That a Cattle Show and Fair for the exhibition and sale of all kinds of Live Stock, Agricultural Implements and Household Manufactures, (with an award of Premiums) shall be held in Easton, in OCTOBER NEXT, under the direction and superintendance of the Trustees—of the particulars of which further notice will be given.

Resolved, That the above be published in the American Farmer, the Easton Gazette and Republican Star.

NICHOLAS HAMMOND, President.
S. T. KENNARD, Secretary.

BALTIMORE MARKET.

PRICES CURRENT—CORRECTED WEEKLY
Flour, white wheat, super., \$6 75—Howard street, from wagons, \$5 75—fine do. \$5 25—Wharf, do. \$5 37½—White wheat, \$1 12 a 1 15 to 1 20—Red do. \$1 6 to 1 9—Lawler, \$1 10—Washington white, \$1 12 to \$1 20—Rye, 42 to 45 cts.—Old corn, 35 to 36 cts.—New do. 31 to 32 cts.—Wharf Oats, 33 cents—wagon Oats, 37½ cts.—Beef, 6 cents per lb.—Live Cattle, \$5 to 5 50, per cwt.—Bacon, hog round, \$10—Pork, \$5 50 to \$6 per c. lb. to 8 cts. per lb.—Mutton, 4 to 5 cts. per lb.—Beans, retail, \$1 25, cargo price, \$1 50—Peas, retail, 62½ cts., cargo price 48 to 50 cts.—Red Clover Seed, \$6—Orchard Grass do. \$2 50—Herds' Grass do. \$2—Timothy do. \$2—Flax Seed, 75 to 80 cents—Whiskey, from the wagons, 34 cents per gallon including the barrel—Apple brandy, 30 to 32 cts.—Peach do. 65 to 70 cts.—Shad, No. 1, \$6 very dull, No. 2, do. \$5 do.—Herrings, No. 1, \$2 25 per bbl. very dull No. 2, \$2 do.—Fine Salt, 75 cents per bushel coarse, do. 70—Ground alum do. 68—Butter (firkin) 12 to 13 cts. per lb.—Eggs, 12½ cts. per doz.—Hay, \$13 per ton—Straw, \$8.

Employment Wanted.

The subscriber, a native of Scotland, and recently from Nova Scotia, wishes to procure a situation as Farmer. In this profession, he has testimonials to exhibit of his industry, and the experience of many years to recommend him. As he is a stranger in this part of the country, and out of employ, his expectations are moderate—a line addressed to JOHN ELLIS, care of the Editor, will meet with immediate attention.

Printed every Friday at \$4 per annum, for JOHN S. SKINNER, Editor, by JOSEPH ROBINSON, on the North West corner of Market and Belvidere streets, Baltimore; where every description of Printing and Job Printing is executed with neatness and dispatch. Orders from a distance for PRINTING or BINDING, with proper references promptly attended to, addressed to J. Robinson, Baltimore.

AGRICULTURE.

COMMUNICATED FOR PUBLICATION IN THE AMERICAN FARMER.

FIRST ANNUAL EXHIBITION AND CATTLE SHOW OF THE PENNSYLVANIA AGRICULTURAL SOCIETY.

The Directors in making public their proceedings, are glad to be enabled to state, that the result of their late meeting has equalled in every respect, their most sanguine expectations.

They had guarded against such irregularities as too often arise where incongruous multitudes are assembled, as it was their aim rather to prevent their occurrence by vigilance and precaution, than to repress them by the infliction of the penalties of law. They confidently believe, that nothing occurred to give dissatisfaction to the most correct and exemplary of the many respectable persons who were present. In the vast concourse of their fellow citizens who witnessed the scene, they had the most satisfactory, and decided evidence of public approbation, in support of their efforts.

The society earnestly desired, that the exhibition should be so conducted, as to attract the sanction of female countenance, for the important and interesting productions of household industry. In this wish they were gratified by the presence of many ladies, who heard the address from the President, and after assisted in the examination of some articles, upon which it was peculiarly their province to decide.

Various Agricultural Societies having been invited, the Presidents and Vice Presidents of the Societies of Brunswick and Bridgeton, of Buck's and Chester counties, the Secretary and other officers of the Philadelphia Society, as well as many distinguished strangers, from distant States, honoured the meeting by their presence.

The exhibition of stock comprised more than an hundred neat cattle, of the best and most costly foreign, and most useful native breeds;—an hundred and fifty sheep, with the various characteristics of English, Tunisian, Spanish and Irish origin, uniting in form and properties most that can be desired in excellence of flesh or fleece—thirty horses, varying from the graceful figure of the fleet and high mettled courser of Arabia, to the heavy frame of the patient, and powerful draught horse of Pennsylvania. The Arabians, Grand Sultan and Grand Bashaw, obtained from the stud of the Bashaw of Tripoli, through the spirited and liberal exertions of our late Consul, Judge Jones, attracted universal admiration.

The exhibition of some of the implements of husbandry, was interesting not merely to farmers, from their usefulness, but to mechanics from the ingenuity and skill displayed in their construction.

Pope's Thrashing Machine, adapted to the force of one horse, confirmed the impressions, which had long since led the Society to recommend it, for the purposes of Pennsylvania Farming.

Goodsell's simple and effective Flax Dresser, promises to be scarcely less useful, in rendering profitable the cultivation of hemp and flax in the middle states, than the famed machine of Whitney has been successful in aiding the production, of the great staple of those of the South.

Reading's Thrashing Machine excited attention from the ingenuity and simplicity of its construction; although, from its not having been properly adapted to horse power, it appeared to great disadvantage.

Mr. White's plough, in turning with great neatness, a furrow of stiff sward, six and a half

inches deep, and sixteen inches wide, required a draught of 616 pounds.

Mr. Stevens' plough, in turning a furrow six inches deep, and eleven inches wide, of the same sward, with equal neatness, required a draught of from 420 to 448 pounds.

Mr. Suplee's plough required a draught of 532 pounds, in turning, with great accuracy, a furrow, six inches deep, and thirteen inches wide, of the same land.

Bergen's "self-sharpening plough," made by Mr. Evans, in turning a furrow of the same sward, seven inches deep, and thirteen inches wide, required a draught of 728 pounds.

Mr. Nixon, of New York, exhibited his patent ploughs, harrows and cultivators, which do credit to his skill, and to his workmen. The ploughs appeared to be fitted rather for fallow, than sward land.

Mr. Hoopes, of Philadelphia, brought a plough which has for some time been used in this State.

Mr. M'Conaughy, exhibited his cultivator and his corn harrow; for the latter he took a premium.

Mr. Blight sent a Yorkshire root cutter, cheap, simple and effective.

Mr. Powell exhibited his cultivator and his Dibbling wheel, which were remarked, as fitted to save much labor in the cultivation of root crops, and also Beatson's improved Scarifier, well constructed for the production of fine tilth.

Mr. Pennock produced a revolving Horse-rake, and his Chaff Cutter, not unworthy of the ingenious inventor, who has contributed so largely to the improvement of farming implements.

Mr. Hoopes of Downingtown, showed a new modification of the Horse-rake, which has been much approved by the farmers of his neighbourhood.

Mr. John Beaver presented a Winnowing Mill, which is an improvement upon the wheat Fans in general use.

Mr. Williams's horse hoe, expanding harrow, and double mould board plough, although last in the list, were not the least worthy of notice.

The late organization of the society prevented the publication of their premiums, sufficiently early, to excite competition for the prizes offered for winter crops and household manufactures, so extensive as the good management, zeal and industry of the inhabitants of the fertile counties associated under the law, had led them to expect.

The decision upon claims for Indian corn, and root crops, has been necessarily deferred until their harvest shall have been completed.

Mr. Joseph M. Downing presented to the Society some bottles of gooseberry wine, showing that an excellent substitute for some of the wines of Europe is within the reach of most farmers, who have not the means of cultivating grapes.

The well contested trials of horses and oxen at the plough, contributed not a little to the interest of the scene; and it was a source of congratulation, that neither the emulation of the competitors, nor the anxiety excited among a vast concourse of spectators, interrupted in any shape the good order, good conduct, and good feeling which pervaded the whole.

NEAT CATTLE.

To the Directors of the Pennsylvania Agricultural Society.

The Committee on neat cattle, having given their most diligent attention to the duties assigned to them, submit their report, and recommend the award of—

The first premium for bulls, not more than six, nor less than two years old to Mr.

Alexander Reed, of Washington, Pennsylvania, for his short-horn bull, bred by Mr. Powell, from a native cow, by the imported Durham short horn bull Denton, \$50
The second premium to Mr. Joseph Kersey, for Oakes, by the imported Durham short-horn bull Cœlebs, 20

The third premium to Mr. Aaron Clement, for Roderick, bred by Mr. Powel, from an half bred Teeswater heifer, and Mr. Tomlinson's bull Major, 10

The first premium for bulls, not more than two years old, to Mr. Henry A. Carpenter, for his Durham short-horn bull Lothario, bred by Mr. Powel, from the imported cow Moss Rose, and the Durham short-horn bull George, 40
Relinquished for a medal.

The second premium to Mr. Henry A. Carpenter, for Leopold, from Moss Rose, by Mr. Powel's half bred Bull Rob Roy, 15
The third premium to Mr. George Sheaff, for Highlander, from Queen, by Mr. Powel's Rob Roy, 10

The first premium for Cows, not more than seven, nor less than three years old, to Mr. Benjamin Serrill, for his Kentucky cow Kate, derived from Mr. Parkinson's importation of short horns, and Gough's breed, 30

The second premium, to Mr. Henry A. Carpenter, for Prize by Denton, 25
The third premium, to Mr. John Serrill, for Meadow Maid, from Mr. Benjamin Serrill's cow, by Mr. Powel's George, of Teeswater blood, 19

The first premium for heifers, not more than three, nor less than one year old, to Mr. Smith, for Lucy, from a fine native cow by Mr. Tomlinson's bull Major, 20
The second premium, to Mr. Serrill, for Red Beauty, from his cow, derived from Mr. Ketland's heifer of Durham short horn blood, 10

The third premium, to Mr. Benjamin Serrill, for Violet, from Kate, by Mr. Powel's bull George, of Teeswater blood, 5

The first premium for heifers, not more than twelve months old, to Mr. Smith, for Sophia, by Mr. Powel's Rob Roy, from a Kentucky cow, derived from Mr. Parkinson's importation of short horns and Gough's breed, 20

The second premium to Mr. George Sheaff, for Diana, from Steamboat, by Mr. Powel's half bred bull Rob Roy, 10
The third premium to Mr. Joseph Kersey, for Fill Pail, from a native cow by Oakes, 5

The premium for the best ox, not more than nine, nor less than three years old, to Mr. Benjamin Serrill, for his brindled Ox, bred by himself, 15

The premium for the best steer, not more than three nor less than one year old, to Mr. Henry Serrill, for his steer Durham, bred by himself, from a cow descended from Mr. Ketland's Durham short horn heifer, 10

The following stock was exhibited, all possessing great claims to notice.

The committee very much regret that they cannot reward the owners of more of these fine animals by premiums.

Your committee are not directed to give their opinion upon such animals as have not been offered for premiums, yet they cannot forbear noticing the neat cattle which Mr. Powel has exhibited, although he has declined contending for a prize. His "Improved Durham short horn"

Cow Flora, of 5 years, and her remarkable calf Hebe, of 8 months by Rob Roy, particularly attracted their attention, and proved the justice of the award, which, at a former exhibition near Philadelphia, had given to the dam the first premium. His white heifer Fairy, of three years by the thorough bred "Improved Durham short horn" bull Denton, from Prize, a half blood heifer, was marked by the strong points of the improved Durham stock.

His imported short horn heifer Cora has many of the best characteristics of her race.

Yorkshire, of 3 months, from Cora, by the Durham short horn bull, Lothario, has the fine shape and good points of his sire.

Europa, from the imported cow Assurance, begotten by Mr. Curwen's bull General, has some very good points which show her claims to the high pedigree of the dam and sire, traced in the Herd Book to the year 1777, yet she exposes the effects of very bad keep and to early breeding before she was brought into this state.

Julia, of 3 years, has good form, with the marks of high breeding, but betrays the defect of Devon blood.

Laura, an imported heifer, of 2 years, has all the characteristics of deep-milking, and carries proof upon her carcase of tendency towards fat.

Flirt, of 3 year, from Julia by Denton, has good size, fine head, neck and bone.

Sussex, of 12 months, from Laura, was begotten in England, has long frame, small bone, head, horns and neck, and very strong points of high breeding.

Your Committee decidedly think, that in blood, points, and all the characteristics of fine neat cattle, Mr. Powel's breeding stock were generally superior to any on the ground, and had not Mr. Powel declined it, some of them would have been decidedly entitled to the first premiums.

Mr. John Tomlinson's seven heifers were marked by some of the good points of Holstein blood.

Mr. John M. Justis exhibited a large and well formed cow from Kentucky, also a one year old steer, with good frame and points.

Mr. Aaron Clement, two cows, two heifers and a three year old steer, of good shape and size.

Mr. Smith, two large cows from Kentucky; and a fine two year old heifer, by Mr. Tomlinson's Major.

Mr. Benjamin Serrill, two remarkably large and well shaped steers, of four years, and one of a year, bred by himself, as well as three Kentucky cows, with strong points.

Mr. Henry Serrill, one large four year old steer.

Mr. Smedly, a very good three year old steer. Mr. George Blight, an heifer of one year, bred by Mr. Powel, from Star, an half blood heifer by Denton, showing fine points.

Mr. James Hickman, two large fat oxen worthy of particular notice.

Mr. George Sheaff, four cows, large and fine, two heifers under one year, one of them from an inferior common cow, by Mr. Powel's Rob Roy, showing by her excellence the great advantage of crossing with the improved stock; also, the Bull Tom Jones, which took a premium at a former agricultural exhibition.

Mr. John Serrill, two very pretty twin heifers, one year old.

Mr. Robert Clement, a well formed and very fat calf, five months old, by Mr. Kersey's Bull Oakes from an inferior native cow.

Mr. Malachi Park, a large 3 year old cow, and a bull 16 months old.

Mr. Charles J. Davis, a bull and heifer of 18 months, worthy of notice.

THOMAS SMITH,
THOMAS SERRILL,
JOHN TOMLINSON,
MATTHEW ROBERTS.

SHEEP AND SWINE.

To the Board of Directors.

The committee appointed to examine Sheep and Swine recommend the following premiums to be awarded—

The first premium for Rams not more than two years old, to Mr. John Barney, for his Ram of Dishley blood, \$10

The second to Mr. Aaron Clement, for his Ram of Dishley blood, 5

The third to Mr. Joseph Kersey, for his Ram of Dishley blood, 5

The first premium for Ewes not more than two years old, to Mr. Joseph Kersey, for his Ewe of Dishley blood, 10

The second to Mr. Francis Hickman, for his Ewe of Bakewell and Irish blood, 5

The first premium for Rams not less than two years old, to Mr. Aaron Clement, for his Ram of Dishley blood, 10

The second to Mr. Aaron Clement, for his Ram of Dishley blood, 5

The first premium for Ewes not less than two years old, to Mr. Joseph Davis, Jr. for his Ewe of Dishley blood, 10

The second to Mr. Daniel Case, for his Ewe of Dishley blood, 5

The premium for the best Ram of Dishley breed not more than two years old, to Mr. Joseph Kersey, 10

The premium for the best Ewe of Dishley blood not more than two years old to Mr. John Barney, 10

The premium for the best Ram of Dishley blood not less than two years old to Mr. John Barney, 10

The premium for the best Ewe of Dishley blood not less than two years old to Mr. Aaron Clement, 10

The premium for the best Merino Ram not more than two years old to Mr. Thomas Serrill, 10

The premium for the best Merino Ewe not less than two years old to Mr. John Hare Powel, 10

The premium for the best Merino Ewe not less than two years old to Mr. John Hare Powel, 10

The premium for the best broad tail Ram of Tunisian blood not more than two years old to Mr. John Hare Powel, 10

The premium for the best broad tail Ewe of Tunisian blood not more than two years old to Mr. John Hare Powel, 10

The premium for the best broad tail Ram of Tunisian blood not less than two years old to Mr. John Hare Powel, 10

The premium for the best broad tail Ewe of Tunisian blood not less than two years old to Mr. John Hare Powel, 10

All the premiums awarded to Mr. Powel were relinquished for the benefit of the Society.

The premium for the best Boar not more than four nor less than one year old to Mr. G. W. Sargeant, for his Leicester Boar one year old, bred by Mr. Parsons of Brighton, 10

Relinquished by Mr. Sargeant for the benefit of the Society.

For the next best to Mr. Benjamin Hickman, 5

The premium for the best Sow not more than four nor less than one year old to Mr. Francis Hickman, \$10
The premium for the best Pigs not less than five in number, not more than nine, nor less than three months old, to Mr. Adley Brown for a litter of six Pigs, 10

SAMUEL WEST,
JOB ROBERTS,
WILLIAM EVANS,
REUBEN HAINES,

Committee on Sheep and Swine.

HORSES.

To the Board of Directors the Committee on Horses, respectfully report—

That among the seven blooded horses exhibited before them, they are of opinion, that the Arabian horse Grand Bashaw, owned by Mr. Joseph C. Morgan, is entitled to the premium of 50 dollars for the best thorough-bred stallion; but in preferring this horse, the committee take great pleasure in saying, that there were some others which possess a considerable share of merit.

That Planter Lyon, owned by Robert Long, is "the best stallion fit for draught," and is entitled to the premium of 50 dollars; but there were other horses shown, which are deserving of notice, particularly Stephen Webb's Chester county Lyon, Imlay J. Bennett's First Consul, and Joseph Kersey's Chester county bay.

That "for the best thorough-bred brood mare," the committee would recommend, a reservation of the premium: nevertheless, several mares of considerable merit were exhibited, particularly Kate, a white mare, with a very fine Bashaw colt, owned by Mr. John Elliott, and Gipsy owned by Mr. Reuben Haines; also Kate, a bay mare, owned by Mr. John Hill.

That "for the best mare fit for draught," the committee regret to say, that only two were exhibited, and that in their opinion neither of them is entitled to distinction by premium.

JAMES WORTH,
JOHN ELLIOTT,
JOHN G. WATMOUGH,
GEORGE BLIGHT,
AARON CLEMENT,
E. MORRIS,

Committee on Horses.

The premium for the best draught horses, "reference being had to their performances in the plough," was awarded to Col. Watmough.

The premium for the best yoke of oxen, "reference being had to their performance in the plough," was awarded to Mr. George Sheaff.

JONATHAN ROBERTS, President.

JOHN HARE POWEL, Cor. Sec.

Paoli, Chester County, October 25, 1823.

The committee on household manufactures, having examined the various articles exhibited for premium report:

LINENS.—For the best Linen Cloth, one yard wide and 29 yards long, to Charles Fish, of Philadelphia, \$15

CARPETING.—For the best Carpeting, two pieces, 50 yards, to Joshua Evans, of Chester county, 10

Second best, 27½ yards, to Hannah Cope, of Chester county, 5

Best Hearth Rug, to Mrs. Parker, of Chester county,

KNIT HOSE.—Best Woollen Knit Hose, two pair, to Elizabeth Kersey, of Chester county,

BLANKETS.—Best specimen of Blanketing, to Joshua Evans, of Chester county,

WOMEN'S HATS.—For the best Woman's Hat, made of straw, to the pupils of the Pennsylvania Institution for the Deaf and Dumb,

For the second best Woman's Hat, made of *shear grass*, in imitation of Leghorn, to the pupils of the Fellenborough School of Philadelphia,

BUTTER.—For the best preserved Butter, 180 pounds, three months old, to Mrs. Dr. Harris, of Chester county,

In addition to the articles for which premiums are designated, many other articles of manufacture were exhibited, some of which the committee deem worthy of notice.

A very fine child's gyp hat, and various articles of cotton and linen fabrics, by the pupils of the Pennsylvania Institution of the Deaf and Dumb.

A remarkably fine gentleman's Beaver Hat, manufactured by Mr. Shelmerdine.

A specimen of book-binding, executed by David Clark, of Philadelphia, highly creditable to his taste and workmanship.

The committee are compelled to express their regret, that the exhibition of household manufactures was not so extensive and multifarious as was to be expected from the great improvements exhibited in all the other branches connected with agriculture and rural economy. The late period at which the society was incorporated, and thereby enabled to give publicity to its list of premiums, may in some degree account for the scantiness of the exhibition of household manufactures, but it is confidently anticipated that at the next annual exhibition the display will afford abundant evidence of the household manufacturing skill and industry of our farmers.

The various articles manufactured by the pupils of the Pennsylvania Institution for the Deaf and Dumb, contributed much to the interest of the exhibition of household manufactures. This institution, reared by individual philanthropy and the bounty of the legislature, contains within its walls pupils from most of the counties in the state, and cannot therefore fail to excite a general feeling in behalf of its prosperity and welfare. The great and prominent design of the institution is to render the unfortunate mutes, intelligent beings, capable of exercising the faculties of the mind, and of receiving moral and religious instruction. In addition, however, to the successful accomplishment of this most important object, under the enlightened and watchful guardianship of the directors and teachers—the pupils are instructed in the various mechanical arts, and employed in occupations adapted to their peculiar situation, which will be to them, when separated from their associates, sources of innocent amusement and profitable labor.

Thus, by the happy union of individual benevolence and legislative munificence, the most unfortunate of the human family are rescued from the helplessness of their miserable condition, and elevated to the rank of intelligent creatures, and rendered useful members of society, contributing their share to its productive labour.

The committee notices, with equal pleasure, the bonnet manufactured from *shear grass*, in imitation of Leghorn, by the pupils of the Fellenborough school, in Philadelphia. The school is exclusively supported by the charitable contributions of some of the citizens of Philadelphia;

and was instituted for the purpose of instructing poor female children in the elements of education, and in the knowledge of manufacturing bonnets and hats from grass, straw and other vegetable materials.

The article exhibited as the workmanship of the pupils, and which took the second premium, was executed with great neatness, and evinced rapid improvement in this useful and important branch of manufacture, demonstrating the capability of our country, by proper encouragement, to render us independent of all foreign supply of an article in general use, and which constitutes an expensive item of consumption.

WILLIAM DARLINGTON,
JOHN ELLIOTT,

Committee.

Paoli, Chester County, Oct. 24, 1823.

CULLEY, ON LIVE STOCK.

Of the time the different Domestic Animals shed their teeth, and the rules for knowing their age.—By George Culley.

Neat cattle cast no teeth until turned two years old, when they get two new teeth; at three they get two more, and in every succeeding year get two, until five years old, when they are called full-mouthed, though they are not properly full-mouthed until six years old, because the two corner-teeth, which are the last in renewing, are not perfectly up until they are six.—It may also be worthy of notice, that the first wrinkle upon the horn does not take place until three years old, after which they get another circle or wrinkle every year as long as the horn stands on, though not always equally discernable in all horned cattle; and I am sorry to say, that it is too common for jobbers and cow-dealers to scrape, rasp, or file down these wrinkles in old cattle, to prevent the age being known, and by that means to deceive and impose upon the unwary, ignorant, and unsuspecting.

A horse does not cast or renew any of his teeth until between two and a half and three years old, when he casts two above and two below.* Between three and a half and four years, he casts four more, viz. two above and two below; and between four and a half and five years old, he casts the remaining four, which are called the corner teeth. It is remarkable that the eight first teeth which the horse renews, make all their growth in about 15 days, while the four last or corner teeth, take about a year and a half to make their full growth. The four first teeth he renews, are called *nippers* or *gatherers*, the next four are called *separaters*, and the four last, are the corner teeth, which also contain the black mark by which the dealers can so well distinguish the age of a horse. And some may think that I ought to say something of this matter here; but those that want to be acquainted with this doctrine, need only consult Bartlet, Brecken, or any of our books upon farriery, where they will find it fully explained. Horses have also four tusks, or tushes, (as the dealers call them) which stand between the fore-teeth and grinders, and usually make their appearance when a horse is about three and a half years old, but are not at their full growth until the horse be six years old.†

* Neat cattle and sheep have no teeth in the upper jaw before, but only in the under jaw, while the horse tribe has both above and below: indeed the former chew the cud, but the latter does not.

† The above is taken from the *Complete Horseman* or *perfect Farrier*.

Sheep in general renew their first two teeth from 14 to 16 months old, and afterwards every year about the same time, until they are turned three years old, or rather three shear, to speak technically, when they become full mouthed; for, though they have eight teeth in the under jaw before, I believe they only cast or renew the six inside ones. However, this matter is not perfectly clear, because I find the shepherds differ in opinion, some thinking they cast only six, others again all the eight fore-teeth.

Observations on the above.

It may be observed, that sheep renew their first teeth soon after they are past one year old, Neat Cattle not until they are past two, and horses not until they are near three years old. And this is perfectly consistent with the wisdom of the Great Creator in all his works:—because, the horse-tribe live the longest, and are evidently meant to bear the greatest hardships. The bull-tribe the next longest; and though very useful as a beast of draught, yet not at all equal to the horse in firmness and hardness: And the innocent sheep live the shortest time, and increase the fastest, not being intended as a beast of burden our draught, but to feed and clothe the lords of the creation.—I have heard of particular sheep living to near 20 years old,—those which the mountain-shepherds call guide sheep, viz. old wethers kept on purpose to guide and direct the bleating flocks upon those unfrequented wilds. I have also heard of particular bulls living more than 20 years; and I knew a horse live until 47 years. This horse had a ball lodged in his neck at the battle of Proud Preston in the Rebellion of the year 1715, and the ball was extracted when the horse died in 1758. This horse was supposed to be four years old in the year 1715, consequently would be 47 in the year 1758.

Now respecting the judging of the age of the above animals by the renewing of their teeth,—though perhaps the best rule we know of, yet I cannot think it is always to be depended on.—However, in sheep, I am certain we are liable to be misled by it; and I apprehend much depends upon being early or late lambed, well or ill fed, and so on. Particularly tups, I have frequently known to have what we call four broad or renewed teeth, when by the above rule they ought to have had only two. A friend of mine, and an eminent breeder, Mr. Charge, of Cleasby, a few years ago, shewed a shearing tup at Richmond in Yorkshire, for the premium given by the Agriculture Society there, which had six broad teeth; in consequence of which, the judges rejected Mr. Charge's tup (though confessedly the best sheep,) because they believed him to be more than a shearing. However, Mr. Charge afterwards proved, to the satisfaction of the Gentlemen, that his tup was no more than a shearing.

NATIVE FERTILITY OF WESTERN LANDS.

Extract of a letter to the Editor.

The mammoth turnips, and other extraordinary vegetable productions, of which we occasionally see accounts in the papers, are commonly vagaries of nature monsters that are rarely seen, and no indications of goodness of soil or skill in cultivation. Now I cannot offer you specimens equal to some exhibited by farmers far to the north of us, yet I can inform you of a crop of three acres of common field turnips, produced near the Forked Deer River in the Chickesaw purchase of Tennessee, that I suspect has never been exceeded for size of the

article. They were cultivated, (if a bare committal of the seed to virgin earth can be called cultivation) by a Mr. Butler, and weighed from eight to twelve pounds on the average. A cart load of these turnips passing through the town of Jackson, from one of Butler's quarters to another, several of the inhabitants had the curiosity to weigh *three*, and their weight was about *fifteen* pounds each. These particulars I have from Herndon Harrelson, and Robert Hughes, Esqrs. who were present at the weighing; and I have no doubt of their correctness. No agricultural society could be expected to reward the skill of the cultivation, for it consisted only in belting the trees, and harrowing the seed into the earth, without previous manuring, or after tillage. *Again*—Seeing at the table of a Mr. Morris, on the Obion waters, in the same purchase, some fine biscuit, it produced from him the information that his wheat crop was undesigned, and purely accidental; that he scattered some wheat thinly among his turnips, to save them from the fly, and from three acres he obtained thirty bushels of wheat. Rice there grows luxuriantly on the tops of high and dry ridges. *Once more*—I have seen Indian corn or maize, in the same country, planted on land, when the only preparation was belting the trees, and ploughing a single furrow with ill broke oxen, serving merely as a guide to plant the rows in; and the only tillage, once chopping round the corn with hoes, produced forty bushels to the acre. These are not monstrous mammoth productions, nor the effects of prepared land and tillage, but the fair specimen of what has been usually produced by the native strength of the soil in an extensive, healthful, and beautiful country, for the four years it has been the abode of civilized men: though well cleared and well cultivated land will produce twice the quantity of corn mentioned. These lands sell at from three to five dollars an acre, or for less than one fourth of the value of one year's productions, while in England, land sells at from fifteen to twenty year's purchase. We cannot, with a knowledge of all these facts, wonder at the powerful tide of emigration, that is setting to the west, which even the rapid improvements making in soil and tillage to the east, is not powerful enough to divert or restrain.

CALVIN JONES.

Wake Forest, Dec. 4.

TO THE EDITOR OF THE AMERICAN FARMER.

CULTIVATION OF THE FIORIN GRASS.

DEAR SIR,

I feel bound to atone for the little value which I attached to fiorin, (*agrostis stolonifera*) in my late communication on grasses, by sending to you some facts, which have subsequently come to my knowledge, and which have materially altered my opinion of its value.

Fiorin is indigenous in the north part of England, and in Ireland and Scotland. In its natural state, while growing promiscuously with other grasses, it excited but little notice, and was esteemed but of little value. The Rev. Dr. Richardson, of Ireland, first successfully undertook to cultivate it. His high commendation of its good qualities, led others to adopt his practice; and although many experiments proved unsatisfactory, from the want of judicious selections of soil, or proper care in preparing it, or nursing the young plants, its reputation has been increasing, particularly in Scotland, where it threatens to supersede most of the other grasses as a winter food for cattle. Nor can this predilection for fiorin excite surprise, if we give credit to the accounts which have been

published, (and I see no reason why we should not) of the advantages which have attended its cultivation, of its nutritious qualities, and of its astonishing product. But its peculiar fitness for peaty and mossy swamps, which abound in Scotland, enhance its value in that country.

Sir James Stewart speaks highly of fiorin. He cultivates it on what he terms a spongy moss, and obtains from five to six tons on an English acre. It is cut the last of September or beginning of October, put into small stacks, and left in the meadows till wanted. He feeds 11 lbs. to his saddle, and 16 lbs. to his carriage horses per day, with the usual allowance of oats—milch cows, 16 lbs. with no other food except straw—the form to his fattening oxen—22½ ounces to the pound. His cows, when fed with fiorin, gave 40 per cent. more butter than when fed with potatoes and straw.

James Baird, manager at Shotts iron works, Scotland, has cultivated fiorin with still better success. His product has been from five to seven tons per acre. He cultivates four acres, and is preparing to lay down 20 acres more, on a moss, which had hitherto not been worth sixpence an acre. The laying down of fiorin cost him from 12 to £14 an acre, (53 to 62 dollars) which he realised from the first year's crop.

Dr. Richardson has cut, on different pieces, his eleventh, twelfth and thirteenth crop, without any falling off in quantity.

Cultivation—The ground requires to be well drained, ploughed or spaded to a good depth, thrown into ridges, and ameliorated by potatoes or other crops; then pulverised, levelled, and cleaned by the harrow and rake. The stolones, or strings are then laid upon the surface, so as nearly to cover it, and a compost of earth and lime, or earth and ashes, is spread over, sufficient to fix them, and prevent their being blown away. After this it is necessary carefully to exterminate every other grass, and all weeds, so long as they continue to appear, which seldom requires much labor after the first season. A top-dressing, like that abovementioned, must be applied once in two or three years, to prevent deterioration. Sir James Stewart's compost consisted of one half of earth and one half ashes, fifteen cubic yards of each, to which he added six bushels shell lime, and applied this on an acre. The best soil, he says, for fiorin, is a well decomposed loamy peat soil. Though the fiorin is generally propagated by stolens, it produces seeds, and is produced spontaneously by means of draining and top-dressing only.

Albany, Dec. 11, 1823.

J. B.

N. B. The high value of this crop in Scotland, is evidenced by the fact, that the Highland Agricultural Society, in 1821, awarded two premiums of 20 and 10 guineas, for the greatest products of fiorin produced on an acre in certain counties.

FROM POULSON'S AMERICAN DAILY ADVERTISER.

ON THE USE OF CHARCOAL AS A CATHARTIC.

[In cases of obstinate costiveness.]

Dr. DANIELL has lately published some cases illustrative of the effects of CHARCOAL in cases of obstinate constipation. In the first case which occurred to him, after having employed the usual treatment of bleeding, warm bath, and mercurial purges, aided by jalap, castor oil, with other active medicines of this kind, without success, he conceived that a favourable opportunity had occurred for trying the efficacy of Charcoal.

'I give,' he has informed us, 'a table spoonful of it every half hour, and at the expiration of about seventeen hours, my patient's bowels were

freely evacuated. The discharges, which consisted chiefly of a thick mucus, were coloured by the Charcoal. This medicine was then discontinued, and castor oil substituted; the latter however evacuating but partially, I had recourse again to the Charcoal, which was continued until the patient recovered. My observations since have convinced me of the necessity of continuing the Charcoal until the discharges are no longer marked by the presence of slime or mucus, which I have found to abound in very considerable quantities, in all the cases of constipation which have fallen under my care. And I think the existence of this matter in the intestines, may explain the cause of failure, not only of powerful enemata, but of cathartics, to evacuate them. Lining, as it most probably does, the chief or whole extent of the bowels, it protects their surfaces from the influence of the medicines.

'The Charcoal probably exercises a chemical influence upon this matter. The evacuations produced by the Charcoal appear to be composed chiefly of this article, and the mucus or slime intimately blended.

'Since this case, I have used the Charcoal in fourteen or fifteen other instances, and always with complete success. In this disease, the sufferings of the patient are usually extremely great, and I have occasionally, since adopting the Charcoal, attempted to relieve them by other cathartics which operate more speedily, but I have invariably failed, and was afterwards compelled to have recourse to that remedy; sometimes however, not until the third and fourth days of the disease, and always with decided advantage. Further experience has convinced me, that the most speedy, as well as most certain relief, is to be obtained from the free use of Charcoal. If it does not wholly relieve, it always very much mitigates the pain in six or eight hours from the period of its first administration; and within my observation the patient has always been entirely composed before the operation of the medicine upon the bowels.

'To many, the tardy operation of this medicine may appear as a serious objection to its use. It was formerly so to me, but since I have been convinced of its certain efficacy, and that although it may not act upon the bowels in twenty-four hours, even after its first exhibition, yet that it will, in one third of the time, very much relieve, if not wholly remove, the pains, &c. This objection appears comparatively unimportant; for what avail a few hours in the cure of a disease, if we can control the sufferings of our patient, and afterwards certainly relieve him?

'In regard to the dose of this medicine, the rule which I have pursued is to give it as freely and as frequently as the stomach will allow. The quantity required is considerable. It has a happy influence in lulling the irritability of the stomach, when nothing else which I have used, would control the nausea and vomiting of the patient; thus fulfilling the double intention of alleviating a very distressing symptom, and then removing the disease itself. I usually give from one to three table spoonfuls of the Charcoal every half hour or hour; whenever the stomach becomes overcharged with the medicine, the excess is thrown off, and the stomach is again quiet. I give in lime-water, milk or water alone, the vehicle having appeared to me unimportant.'

London Medical Repository, No. 116.

Remarks on the above, by S. F. S. a Correspondent of the American Farmer.

It is very certain the complaint alluded to in that paper, viz: Obstinate Costiveness, attended with great pain and a constant rejection of cathartic medicines, is one of the most distressing to the

patient, and perplexing to the Physician that can occur in practice—an improvement in the treatment is worthy the attention of every member of the faculty—Cholic—Cramp Cholic—Iliac Passion, and the disease in question, are nearly one as regards the cure, and it is often dubious whether the stricture has produced the stoppage in the bowels, or whether the constipation has produced the irritation to the disease? Be that as it may, we must look to the action of some medicine that will clear out the bowels. Without this there will be no cure that can be trusted to, and with it little else will be required, but a repetition of suitable purgatives, in small doses, till the bowels recover their wanted action. A true idea of the disease, and a correct theory of the *modus operandi* of the medicines used are necessary to farther improvements in the case, and however happy Dr. Daniell may have been in his practice, his theory is quite inadmissible. The mucilage discharged into the bowels, which he believes to be of importance in the cause is surely the mere effects of a great push on the bowels, and is a salutary operation of nature, by which a higher grade of inflammation is prevented, it has nothing inimical in it, and requires no attention from the Physician, though its cessation will indicate an increase or a cure of the disease. In the former, a speedy mortification will ensue; in the latter, a sensible relief. To have a plain idea of the action of Charcoal, we must reflect on the quantity the Doctor has given, if his spoons were level full, he has given at least three pints, and if heaping full, at least five pints, besides the vehicle it is given in. This enormous mass of inert matter will distend the whole canal, and must act mechanically, and will be as a great piston in the bowels, making these its own syringe, and thus forcing the obstruction. It will also give a considerable friction by means of the peristaltic motion. Those therefore that use the Charcoal must not stop till they have given largely, or they will be disappointed; other articles have been formerly used, that acted mechanically, though not by a general distention, but rather as a perforator or lever, and it is a pity that quicksilver was ever laid aside—too much of a chemical rage was the cause of this. One of the most extensive and eminent practitioners in Maryland, informed the writer of this article that it never disappointed him; he often resorted to it in extreme cases. It is highly probable that many other articles, ponderous or light, might be used with advantage. Steel filings have been introduced very largely with impunity where worms were suspected—Say half to an ounce at a dose, and the Charcoal might be an admirable remedy for the tape, or other worms, actually pushing them out. There is however an article used by Dr. Daniell, that I would recommend more than the Charcoal; it is that grand article so useful in *morals* and *physic*, viz: *Patience*. The Doctor protracted this to seventeen hours, but with half of this extension of time and common remedies, nineteen in twenty cases admit of cure by very common remedies. The great error consists in giving full doses of medicine instead of very small. In several cases where the writer of this attended and all the medicines that promised success had been rejected, although rendered palatable and sedative by opiates, cinnamon, ether, &c. the following plan was successful: one to two grains of calomel, with one of aloes, was given every half hour; it was made into a pill as small as possible, with a little stiff basilicon, and no drinks allowed; ease was procured before the purgative operation—and in no case was more than twenty-five grains of calomel used before a free operation ensued. The bitter of the aloes is considered essential to strengthen and settle the stomach, and the basilicon hinders the pill from acting too quickly on the stomach,

It would be unpardonable to let the patient suffer till the pills operated. Bleeding to asphyxia is instantly to be performed, and a general warm bath administered. Blistering over the pained part after bleeding is not to be neglected, and a free use of enemata at all times. In several flatulent cholics there can be little doubt but that air might be extracted from the bowels with great advantage, by means of a syringe, with a long elastic pipe, with side openings, introduced with care, and the piston very gradually drawn, making at the same moment a turn in the syringe so as to prevent any of the guts being drawn into the apertures by suction. After bathing for half an hour, it is no uncommon thing for the medicine to act freely—it greatly facilitates the operation, as well as relieves the pain. A very large sponge is eminently useful where a large bathing vessel is not at hand. Such have been the means by which several cases of the most agonizing kind were relieved in November last, and what is a little remarkable, that they were within a hundred yards of each other in the country, and in different families—it was indeed somewhat epidemic. The same disposition in the climate at another season would have probably produced the dysentery.

TO THE EDITOR OF THE AMERICAN FARMER.

NATURAL HISTORY.

EMASCULATION OF SQUIRRELS.

Baltimore, Hanover-st. Dec. 16th, 1823.

DEAR SIR,

I regret very much that my time has not permitted me to give an earlier attention to the communication with which you have honored me, enclosing the remarks of your South Carolina and Kentucky correspondents, on the subject of the apparent emasculation of a great portion of the common male grey squirrel, (*sciurus cinn. Linn.*) a native of our forest. The Zoology of the United States, has been better described, being much less extensive than the other departments of our Natural History—but it would appear that the manners of this elegant and extensive species of *sciurus*, are not yet sufficiently well known to us. Every enquiry which tends to shed light upon the manners and habits of animals should be encouraged as a matter of general interest to man; and I hope the day is not far distant, when the vast and intelligent body of our agriculturists will give more of their time to the cultivation of natural history, and in particular, to the interesting and useful branch of comparative anatomy. It has been well observed by your Charleston correspondent, that it is contrary to the provision of nature, that the parent should mutilate its young, a fact which led him to doubt that the young squirrel was emasculated by the old one; and his acute observation has enabled him to arrive very nearly at a truth, which he could have established, had he been a comparative anatomist. In the mammiferous animals the testicles vary principally in their situation, according as a scrotum is developed, or not, for their reception. In the families of this extensive order of animals they are lodged naturally, after their formation, which in the foetal state is within the cavity of the abdomen, in three different situations.

1st. In the Quadrumanes, they are constantly suspended in a single bag, or purse—in the greater part of the carnivorous animals, as the Cats, the Bears, the Ichneumon, &c. they are situated in this purse, behind the pelvis, and below the anus;—in the pedimanes, and some of the diadelphes, as the kangaroos, this bag

is very long, and suspended in front of the pelvis, in which both testicles are connected together without any intermediate cellular substance. In most of the ruminating animals, and in the horse, this purse is divided into two distinct sacks.

2. In the Elephant, the Echidna, the Ornithorynchus, the Whales, and the amphibious animals generally, the testicles remain constantly in the abdomen, situated by the side of the kidneys, where they are enveloped, and retained in their proper position by a strong process of the peritoneum.

3d. In the Camel, the Otter, and some of the family of the Pachydermes; amongst some of the Carnivorous animals; in a great number of the family of Rodentia, or the gnawing animals, such as the Rats, the Agoutis, the Beavers, the Squirrels, &c. the testicles are bound down, either beneath the skin of the perineum, or groin; and they slide from the lower part of the belly into one or other of these places, particularly during the period of their loves.*

In the squirrels where these organs pass alternately from the abdomen under the skin of the belly, and vice versa, the communication is so large that the tunica vaginalis forms of the skin, as it were, but a *cul de sac*, which appears prolonged under the pelvis. Through the agency of the cremastu muscle, the testicles glide with great ease from the end of the sac into the abdomen, which sufficiently accounts for their absence, from beneath the skin of the belly, and the apparent emasculation. This sac is much more extended in the second or third, than in the first year of life, so that in the young male squirrel of six or eight months, the testicles can just be felt verging from beneath the skin of the belly—in after life, when in the sac, they are much more apparent. Here let me observe that in those inferior animals, in which the testicles remain constantly in the scrotum, the cavity of this bag communicates always by a straight canal with that of the abdomen; so much does the almost invariably horizontal position of most of the mammiferous animals diminish the danger of hernia. Not so in man; his position being erect, nature has used her utmost ingenuity to close this canal to prevent a misfortune under all circumstances of too frequent occurrence. During the season of copulation the combats which take place between the males in many classes of animals frequently end in their destruction, or mutilation. In the combat described by your Kentucky correspondent, the delicate spot where the wounds were inflicted on one of the knights, should be looked on as purely accidental. Nature appears to have been particular in her formation of these animals for propagation. They are in heat early in the spring, when it is often very diverting to observe the female, feigning an escape from the pursuit of two or three males, and to observe the proofs which they give of their agility, which is then exerted in full force.† The late professor Barton informed me that he had observed them, in the act of copulation, to fall from the summits of the highest trees, which ended in the destruction of one or both of the parties *dans le moment d'amour*. The gestation of the squirrel is not longer than six weeks, the female bringing forth from three to five young at a time, usually about the middle of May.

You ask, is it a fact that the male rabbit will destroy its defenceless young? Such a fact is not generally conceded by naturalists—but in my own opinion it rests on too many unequivocal

* Vide Cuvier *Leçons anat. comp. art. generation.*

† Shaw's *British Zoology.*

proofs to be doubted. It is by all admitted that the female at the parturient period, always separates and secretes herself from the male, and after bringing forth, continues thus secretly to nourish her offspring until they arrive at an age which places them beyond danger. M. Buffon observes, that on those occasions, the female digs herself a hole different from the ordinary one, by being more intricate; at the bottom of which she makes a more ample apartment.* This done, she pulls off from her belly a good quantity of hair, with which she makes a bed for her young. During the two first days she never leaves them; and does not stir out but to procure nourishment, which she takes with the utmost dispatch; in this manner suckling her young, for near six weeks, until they are strong, and able to go abroad themselves. During all this time the male never visits their separate apartment; but when they are grown up so as to come to the mouth of the hole, he then seems to acknowledge them as his offspring, takes them between his paws, smooths their skin, and licks their eyes. All of them, one after the other have an equal share in his caresses. Several gentlemen of Virginia and Maryland who possess extensive warrens, have informed me that they have always found it necessary to chain the males during the period of lactation, to prevent the young ones from being killed. It seems equally true, that on some occasions the male cat seeks and destroys the young of the female. Reflecting on this interesting fact in natural history, we are led to this conclusion, that these animals, unlike the crocodile of the Nile, who satisfies his voracious appetite by the destruction of thousands of his own offspring, are propelled to seek and destroy their young from the sole motive of enticing the female to receive the embraces of the male at an earlier period than she would do, if she continued to give them nourishment and protection.

I shall always be happy to contribute any information for the pages of your interesting and highly valuable paper, and I beg you to be assured of my high esteem and regard.

P. MACAULAY.

JOHN S. SKINNER, Esq.

Charleston, October 27th, 1823.

MR. J. S. SKINNER,

Sir—Three or four weeks ago, some of your correspondents made a few observations on the apparent emasculation of squirrels. As they did not doubt the fact, and no one, as far as I have seen, has solved the mystery, give me leave to attempt it.

That many squirrels have that appearance, cannot be disputed—the opinion is, therefore, prevalent, that they have been mutilated by their parents, when young. This opinion I always doubted, because, contrary to the provisions of nature; and while a youth, I observed, that those which were defective, were uniformly smaller than the male squirrels which were perfect. According to usage, with most other

*The Editor well recollects that when a boy, in the act of hunting, he found the bed of a common hare with four or five young ones, but though nothing could be better prepared for the warm and comfortable accommodation of infant existence, there was no intricacy in the construction of the apartment. It was a simple excavation, to the depth of, perhaps, eight inches on the southern aspect of a hill; first bedded with dry leaves, and then completely interlined with the fur of the dam.

animals, they would have been larger if mutilated—but this inference was not conclusive.

I next observed that this difference was discoverable only in the autumn and first of the winter, and cannot recollect that ever I saw one with this peculiarity after Christmas—certainly not in the spring. I, therefore, concluded that it was only the young male squirrel, which had this appearance, and that the parts in them were not matured. I was confirmed in this opinion by learning that in the human species, the male fœtus in utero has not the testes apparent any more than the young squirrel; but that they are matured within the body of the child, as is proved by dissection, and descend into their proper place, a little before birth—frequently during the labour of birth, and occasionally after the birth; in this case having sometimes been mistaken for a rupture.

I have, therefore, no doubt, that the organs of the male squirrel are not matured until four or five months after birth; and that they then descend from the body to their proper place. I have sometimes thought it might be better for the human race, if their males were a little more like the squirrels, and did not become matured for a length of time after birth, in proportion to their greater length of life. Might not several valuable consequences be the result, if our young men were not matured until they were about twenty years of age? But this is all speculation.

In confirmation of my opinion, respecting the young squirrels, I was lately told by a gentleman on whom the utmost reliance may be placed, that a young male squirrel was brought into his family as a pet—he was apparently a neuter, and was believed to have been “turned” like an Italian; but in a few months, he became as well formed as the most perfect of his species.

As this is the season of the year when young squirrels may be easily procured, I hope some of your friends will take the trouble to investigate the matter, both on the dead and living squirrel, and either confirm or disprove my suggestions.

SENEX.

Extract to the Editor, York, Pa.

A friend, to whom I read the communication between Governor Clinton and yourself, on the emasculation of the squirrel, told me that he has frequently heard old hunters say, that, in the battles between the males, they always attack that member, and, that the vanquished rarely escape without being thus mutilated. This may be only a reiteration of the fact, without any development of the cause, but the opportunities for observation of this class of men gives them claims to belief, so far as their information goes.

Extract to the Editor, from Mark Hardin, dated Shelbyville, Kentucky, 22d Oct. 1823.

Sir—I have noticed in one of your last numbers which has been received, a notice of the castration of a large portion of the male grey squirrel. I will remark to you on that subject, that an accidental occurrence took place when I was a boy, some thirty years since, on the road to school; myself and a younger brother saw many squirrels on a tree—the sows were then in heat, and the master male pursued the one nearest to him to some little distance on the tree from the female; in that period, another closely pursued her, the master returned, pursued up the tree, and immediately took hold of him—the nearest part, I presume, being the testicle—in the scuffle both fell entirely to the ground near us, and one of them we killed before it could get out of our reach; the bag con-

taining the testicles was considerably torn, and the chord by which the testicles are suspended was bitten through, which, I presume, would have caused them to rot off. In relation to the fact of none other of the animal kingdoms pursuing the same course, I should suppose, might and must be accounted for by their not being prepared with teeth, which at one exertion, could destroy the chord of the testicle. The rabbit and the rat with their species, are the only animals I have seen whose teeth could prove destructive.

Whilst on this subject, and as you appear to be a gunner, I will name to you, how you may kill all the males in the running season, which are after the female; that is, I can advise you how to discern the males from the female one (for if she is killed, they all scatter) which will give you an opportunity of killing many of them, the female in attempting to hide from her pursuers, leave many of the males some distance behind; they in attempting to find her run on the limbs and trees with their noses close to the limb or tree; this the female never does when in heat, and pursued.

Respectfully your's,

MARK HARDIN.

P. S. I have particularly noticed the curculis so destructive to our stone fruit; and had made some memorandums as to the enemies to the young peartree, which I intended for my late brother's benefit. On these two subjects, I shall make some communications at or before the season when they should be attended to.

[Many farmers emasculate their lambs by a ligature made on the spermatic chord, which soon occasions the testicles to rot off.—Edit.]

CULTIVATION OF STRAWBERRIES—SILK WORMS—FORM OF A GARDEN PLOUGH—CUTTINGS OF CHEROKEE ROSES WANTED.

TO THE EDITOR OF THE AMERICAN FARMER.

Annapolis, 20th Dec. 1823.

DEAR SIR,

As much is said, and many enquiries are made, about the best mode of cultivating the strawberry, I send you the enclosed account of the mode pursued by the late Col. Hawkins, at the Creek agency upon the Flint River, which you will see was attended with the greatest success. My practice is nearly similar, and I have never failed in having a great abundance of that delicious fruit. It is at your service to make what use of you think proper.

P. S. In one of your papers is an interesting piece, by a gentleman in or near Philadelphia, upon raising silk worms, and their great yield.—Where can the eggs be procured? I will thank you for the information through your very valuable paper—also where a few cuttings or plants of the Cherokee rose can be procured.

Whilst I have my pen in hand I will mention, that I have never seen any mention made in your paper, nor in use any where in this state, of that very useful and efficient instrument, the garden plough. With this light implement a boy of twelve or thirteen years of age can do more work in an hour than a grown man with a hoe in half a day, and stir the ground better and deeper. It is intended to stir between plants, either in rows or squares, which it does most effectually. A small shovel is fixed in a beam by its shank, and the beam has a small wheel in front and a pair of handles in the hinder part by which to guide it. Some of your numerous correspondents could give you a drawing, and description, particularly from the south, where I saw it in use.

The Editor trusts to the prompt and kind attention of his correspondents for the information sought.]

STRAWBERRIES.

The mode of cultivating the strawberry at the Creek Agency on stiff loam land, or what would be better understood in the southern states by oak and hickory land. Two squares of forty-five feet were covered with old manure spaded up, the roots taken up, raked even, laid off and planted 13 inches, plant from plant, in rows each way. The planting done in August, September and October as moist weather offered, watered after planting, and repeated for a night or two till the plants took root. The plants were from the runners of the year. The roots docked to one inch a half inch. The whole kept free from weeds by hoeing both ways, just under the surface of the earth. In November the squares were strewn over thinly with old manure. The first of January or early in February the squares were worked over, then strewn over thinly as before with well rotted manure. Afterwards kept clean from weeds by hoeing with small thin edged sharp hoes just under the surface and the runners taken off. Land moderately rich, requires no manure.

One square was planted with native strawberries from our woods, the other an oval cone-topped strawberry, sent to me by a Scotch gentleman as from Scotland. The native strawberry in the woods seldom produces more than ten on a single plant, from whence our plants were taken. A native bunch the last year under our culture produced, one hundred and eighty-three, one of which weighed seventy-seven grains, and they began to ripen the 12th April. Those from Europe fifteen days later. Some borders of the garden were edged with them one foot, plant from plant, and had a handsome appearance.

The Creek Agency is in lat. 32, 39. long. 84, 20. from Greenwich.

To the above account of the method of cultivating strawberries by Colonel Hawkins, the following note has been added by Doctor William Baldwin.

When I arrived at the Agency on the 21st February, I found the square containing the native strawberry [*Fragaria Virginica*] in full bloom; on the 31st of March two quarts of the ripe fruit was collected; and since that time not less than sixty-nine quarts have been collected from the same square, and they have not yet ceased to bear. From the root which last year produced one hundred and eighty-three berries, three hundred could be distinctly counted on the 27th of April, out of which one hundred were gathered perfectly ripe, weighing each from about two scruples to eighty-one grains. It has been customary to collect from thirty to upwards of seventy on a single root at a single gathering.

There was this year three weeks difference in the time of flowering between the native and foreign species, and about the same difference in the ripening of the fruit. The latter of which are now in the highest state of perfection, furnish berries of a large size, some of them weighing not less than one hundred grains, and they will no doubt continue to bear throughout the present month. Ninety-nine quarts of them have been collected, and one hundred and thirty-two pounds weight from the two squares preserved in loaf sugar.

The square which contains the native kind is only forty-five feet square, and the other forty-five by forty-seven, making in the whole 10 and 6-10ths of an acre. Hence it appears, that a single acre would produce the enormous quantity of eighty bushels, which would serve a large vil-

lage with this delicious fruit for at least two months. As the preceding account may be considered by some as bordering upon the marvellous, it is with great pleasure that I can add the names of Dr. Samuel Boyakin, of Milledgeville, and Mr. Thomas Ellis, who resides at the Agency, gentlemen of high respectability, who have been witnesses to all the material facts above stated.

The following is the account of the state of the weather for the months named.

January, range of temperature, from 5 3-4 to 70; mean temperature, 44 degrees.	
February, from 21 to 80 mean temperature	52
March	30 to 84 61
April	36 to 90 65

COMMUNICATED FOR PUBLICATION IN THE AMERICAN FARMER.

ESTIMATE OF THE DAILY LABOUR OF NEGROES.—Charleston.

Ditching.—In ditching, much depends upon the nature of the ground. In old rice fields, free from roots and stumps, the task for an able-bodied negro man is 600 cubic feet; but he cannot do as much in canals.

Ditching is much retarded by gravel and iron mould, as well as by roots and stumps. When these obstacles occur, no regular task can be assigned. If he excavates three or four hundred feet, he will do well. Where large cypress stumps are met with, the best plan is to select such negro men for cutting them out, as are most expert at the axe, and who will work without being closely watched. A very large cypress stump will take one or two day's work. In ditching, it is advisable to work in gangs of six or eight, in a given distance, consisting of men and women. A woman can do nearly as much as a man. While the negro man is handling the spade, or the axe, she can always find employment in hauling back the excavated earth upon the margin, and if necessity requires, she can make use of the spade to great advantage. All ditches ought to be dug with a great slant, making the upper diameter nearly double the width of the bottom.

Making Bank.—In making Bank, it will take one or two less in number than the same length in ditching. Where the soil is stiff clay, and the distance of the margin 20 feet, it will take the full complement, to have the bank well made, and trimmed properly. In making the bank, every chip and root ought to be picked out, and nothing but the solid earth put upon it; the clods chopped fine, will pulverize, consolidate, and cement much quicker, than if thrown on promiscuously. In old rice lands, free from roots and stumps, there is no necessity to make a centre ditch, as the basis for the bank turned up with a hoe, answers every purpose. In rooty land, a centre ditch should always be made.

Turning up land with a hoe.—A negro man, or woman, can, in light rice land of a deep mould, turn up one quarter of an acre, and do it well; but in a stiff, tenacious clay, it will require a third more labour.

Listing Ground.—In listing corn, cotton, or potato land, half an acre is the task for each hand; but in old pasture ground, which is always stiff, and bound with roots of grass, weeds, &c. a quarter of an acre is as much as he can do; and even then, it is hard work. The plough would much more effectually operate on such land; where it is of a light and sandy nature, half an acre can be accomplished in listing.

Bedding up.—The task in ridging or bedding up, is generally a quarter and an half, but as ex-

pressed above, in pasture land, where the texture is close, he will do well, if he does one quarter. In old pasture ground, matted with grass root, he cannot accomplish it, to do it properly.

In ridging potato beds, two negroes are always employed in one quarter of an acre.

Trenching Rice.—Each negro man can trench half an acre of rice land, containing 70 and 80 rows in one quarter, and each negro woman covers what the man trenches. In planting rice, the more compact your gang is, the better. A gang consisting of forty workers, may be divided into two parts, allotting to each two sowers, nine trenchers, and nine coverers, in which case each gang would plant five acres.

Hoing Corn, Cotton, and Potatoes.—In hoing corn, cotton, and potatoes, the usual task is half an acre; but if neglected in the first hoing, the negro will find it difficult to overcome the grass in the succeeding ones, particularly cotton and potatoes, which must be kept very clean—having once suffered, the plants never recover, to yield as much as they would, had they been kept clear of grass. On the appearance of the potato above ground, it is advisable to hand-pick the beds of grass, and continue doing so, until the plants are well advanced, and commenced running, when the hoe can with propriety be applied, and continue to be kept as clean as possible, until the beds are covered by the vines. So with cotton, early neglect will cripple the plant, and prevent its producing much.

Hoing Rice.—In hoing rice, in its early stage, much depends upon the judicious application of water, to destroy grass; improperly applied, it encourages it, and increases the labour of the negro; on the contrary, he can always get through half an acre with ease, during the season. In the first hoing on clay land, less than three negroes to the acre, cannot perform their work as it should be done, and great care taken to remove the clods from the young rice, which would otherwise be much injured. In the third and last hoing, every spear of grass ought to be pulled up by the roots, to allow the young shoots to come forth freely; at which time, the water ought to be applied, and kept on until the crop is harvested.

The *point flowing*, is so often injudiciously used, that it is a question whether more harm than good, does not result from it; but it is highly advantageous, when due care is observed.

Harvesting of Rice.—About a week or ten days before you begin to harvest rice, draw off the water from your fields. In order to judge when rice is fit to cut, examine the lower part of the ear: if there remain one or two grains of a greenish cast, the rice is then in a fit state to apply the sickle. Negro drivers, in general, allow it to remain until all the grains have turned yellow, in which case the crop ripens too fast, and you cannot keep pace with it in cutting; much is thereby lost by shelling. Avoid, if possible, stacking rice in the field; whole crops are sometimes lost by unforeseen accidents: have it brought home, and put in stacks of 8 feet diameter, and about 18 or 20 feet in length, 8 or 10 feet high. Be careful in stacking, to put away by itself all light or damaged rice.

Ricking Rice.—In ricking rice, great care ought to be observed to select all sheaves that are in the least injured by dampness, and put away in small stacks, with any light rice you may have. The propriety of the length of a rick depends upon the number of negroes you work; so that in threshing, the rick may not be too long exposed to the weather. In a gang of 25 or 30 workers, it is advisable to make them about 20 feet long, 12 feet wide, carried up

straight to about six feet, then slant off gradually, carrying it up to about 18 or 20 feet high; lay the sheaves all one way, and close. Such a rick, if solid good rice, will produce from 20 to 25 barrels of clean rice, of 600 wt. each barrel. Upon the top of each rick, have a heavy pole or rail, suspended on each side by a grape-vine, under which place a quantity of straw, to protect the rice from the weather. Rice should not be put into large ricks, until it has had about three weeks of the sun, otherwise it may be apt to mow-burn.

Threshing Rice.—Six hundred sheaves of rice, is the general task for a negro man, and five hundred for a negro woman, which can be done with ease; after which, the straw should be well shaken, and examined by the driver, before it is carried to the general heap.

Making Rice Barrels.—Three barrels a day is the task for a cooper, and in making half barrels four a day. The length of stave 3 feet 2 inches; and 2 feet across the head. Such a barrel will hold ten bushels of clean rice.

Hoop Poles.—Where hoop poles are plentiful, a negro can with ease cut one hundred, and bring them home, where the distance is not too great.

Splitting Staves.—In splitting staves, 4 hands are generally sent out, and employed thus: two to cut down and cross-cut the tree to the length of the staves wanted; one to bolt; and the fourth negro is employed in splitting. Five hundred is the task per day. The second day, another negro is sent to draw the staves split the day before; his task is 300. The staves being split, they are then put into piles of 4 and 5 hundred to season.

Splitting Barrel Heading.—The same number of hands are employed in splitting heads for barrels. The task for splitting, per day, is 250 pieces, of two pieces to each barrel head, and 150 in drawing and trimming, for one cooper per day. If more than two to the head, the task is 200.—They ought to be drawn, immediately as they are split, while the wood is green.

Splitting Puncheons.—250 broad puncheons, 4 and 5 feet in length, is the task for a negro to split per day; such as would answer for a barn or negro house.

Splitting Shingles.—In splitting shingles 22 inches long, 4 hands are sent out as above stated; two to cut down the tree, and cross-cut to the length; one to bolt, and the fourth to split one thousand. The next day, a negro will draw 500 per day, as his task. In splitting for negro houses, he will split 700 broad, heavy, cypress shingles, 2½ feet in length. In drawing, 400 is the day's work.

Squaring Timber.—A negro carpenter can cut down the tree, and square one hundred feet per day, with ease.

Making Worm Fences.—The rails being brought to the spot, and every thing ready, the bushes and weeds removed, a negro man and woman can put up, stake and rider, 100 pannels.

Post and Rail.—Four negroes can put up 35 or 40 pannels of post and rail fence per day; dig the holes between two and three feet deep, and put down the posts, properly rammed, at the distance of 9 feet from each other. The rails to be 10 feet long, to allow a good lap, or hold, in the mortice.

A negro carpenter can make 60 mortices per day, in the post and rail fence.

Splitting Rails.—One hundred rails of 12 feet long, and heavy, are the day's work of an able-bodied negro man.

Cutting Wood.—A negro man can cut for his task, one cord of oak wood, 4 feet long. The cord, when piled and well filled in, to be 8 feet long, 4 feet high.

Editorial Correspondence.

Charleston, December 4th, 1823.

I have saved a parcel of the magnolia seed; as soon as they are perfectly cured, and fit to pack up, I will send them to you by the Harvest, Capt. Emory. As it may not be uninteresting to you, I will inform you that I am just returned from a visit to Santee, where I saw the Duke and Dutchess of Tuscany, and a numerous family of their offspring. They were much improved, both in size and appearance, and very gente, so much so, that her ladyship ate from the hands of a negro. They were, I think, the handsomest couple of the quadruped kind, I ever saw; and will, no doubt, prove a valuable acquisition to the breed of cattle in the neighbourhood.

Extract of a letter from a correspondent dated GREENVILLE, Miss. Nov. 10.

"A lady requests me to forward you a few of the flowering bean, with a request that you will inform her why that vine and bean has been excluded from the esculent, and placed alone in the flower garden—the flower is ornamental, the vine strong, luxuriant and expansive, and the bean prolific. We think that a vegetable thus favored might be useful to other senses than that of sight, if well understood.

Very respectfully,
Your obedient servant,
COWLES MEADE."

Remarks by a gentleman of science and taste to whom the seed were given.

I take it for granted that your correspondent describes the *dolichos purpureus*, which is generally known by the title he gives it—the "flowering bean," though there are many other of the leguminous tribe under the same appellation. The seed, however, I think are of *D. purpureus*. The tribe is an extensive one, and excessively puzzling to the botanist—the greater part are annuals, and many are cultivated for their beans. It would seem that the purple has been generally excluded from the esculent garden, not, however, I apprehend from the fact of its not being as nutritious as some of the other varieties, but really because it is considered *superfluous*. Willdenow enumerates fifty-three species of dolichos—the pruriens affords us the celebrated vermifuge, cow-hage or cow-itch, and from the Soja, we get the liquid well known as the soy of our tables.

FROM THE PROVIDENCE JOURNAL.

JONATHAN'S VISIT TO THE STEAM-BOAT.

Did you ever go down to the steam-boat?

By jings! I'll knock under to that!

I can't hardly tell what to make on't,

It does beat creation all flat!

Why, that great copper kettle; my patience!

I'd tell what it holds if I could,

An' it beats all our Nancy's relations,

To see how they heave in the wood!

Then them wheels all a going and a jangling,

'Tis strange how they ever can sleep—

An' long iron rods, all a sprangling,

Lord sakes! what a threshing they keep.

The great wheels, too, that paw up the water,

An' send up a hogshead, a stroke!

Then that big iron *chimbley's* a snorter!

But cat owl! how it sends out the smoke!

I swagger! 'twould puzzle a fellow

To find out the head or the starn!

Why one o' the rooms in the cellar,

Is as long as the side of our barn!

THE FARMER.

BALTIMORE, FRIDAY, DECEMBER 26, 1823.

In this number, we have published the official details of the Agricultural Exhibition, held at Paoli, in Pennsylvania, on the 24th and 25th days of October last. Among the numerous associations to promote the cause and the practice of Agriculture which have been lately formed, none can more confidently challenge the public admiration and confidence, than the one whose proceedings we have here given—whether we judge by the energy of the few, by whose zeal and masterly judgment, it has been organized and put in motion—the maturity already given, by the best regulations to their whole system of action—the extent of their influence as evidenced by visible effects through a large portion of the state—the number and respectability of their members, and the amplex of their funds. We have been well assured by several gentlemen, who were present, that the awards of the judges appeared to give entire satisfaction; and when it is recollected that they were among their most respectable citizens, and best established farmers, no doubt of their judgment or fairness could possibly exist; and that the dignified department, and manly address of Mr. Roberts, the President of the Society, contributed not a little to give respectability to the scene, in which good order, good humour, and excellent regulations, prevailed throughout.

It was remarkable that all the bulls which took premiums, appeared, by the cards, to have been bred by Mr. Powell, and that all the calves which took premiums, had been begotten by his bulls.

ERRATA, In Mr. Buel's communication on Grasses—No. 37.—Caption, in 6th column figures for "acres," read *drachms*—*Holcus lanatus* instead of *lanatus*. Under cocksfoot, 13th line, for *I should prefer*, read *sheep prefer*, &c. next line any for *ever*—4th from bottom column for *facts are*, read *proof is*; again, for, *in favor of*, read *of the value of*. The last are probably errors in the MMS.

Vaccine Matter.

The subscriber respectfully informs the public that, being Agent for supplying Vaccine Matter to the United States' Army, he is compelled to keep constantly on hand a supply of RECENT GENUINE VACCINE MATTER.

He pledges himself to send to any part of the United States, by Mail, a supply of fresh Matter *put up in the crust*, with printed directions for its employment. Such arrangements have been made that none but choice crusts, procured from the most unquestionable Specimens of the disease will be sent.

The fee will be \$5 for each supply; but should it by any accident fail, on the subscriber being notified of this any time within one month after the first quantity is received, a fresh supply will be sent without any additional charge.

The subscriber will be under the necessity of not taking letters from the Post Office unless the postage be paid.

JOHN REVERE, M. D.

Agent for supplying Vaccine Matter

to the United States' Army.

Baltimore, North Charles-street, Dec. 26.

Printed every Friday at \$4 per annum, for JOHN S. SKINNELL, by JOSEPH ROBINSON, on the North West corner of Market and Belvidere streets, Baltimore; where every description of Book and Job Printing is executed with neatness and dispatch—from a distance for PRINTING or BINDING, with proper corrections promptly attended to, addressed to J. Robinson, Baltimore.

AGRICULTURE.

MR. INGERSOLL'S PIGGERY.

"Honor and shame from no condition rise,"
"Act well your part, there all the honor lies."

[We have the satisfaction to publish the following account of the most perfect system of breeding swine, that has fallen under our observation. We have visited the establishment which it describes, and there heard with pleasure the explanations of its intelligent owner, upon the different parts of his plan. And from our desire to profit by his experience, we subsequently requested him to give us a written description of his Piggery, and the management thereof, which he promptly furnished, in a letter that invited us to pursue our inquiries, and these procured for us the more ample details contained in his second letter. It was our wish to publish these communications soon after they were received, but we could not obtain his express permission to make that use of them; therefore, we have withheld his letters from the press until the present moment, when we are assured that the cause of his reluctance has ceased to exist; and that his plan may now be made public, without any prejudice to his interests, or violation of his wishes. This system challenges our admiration, and we cheerfully render it to his head and heart. How few of us take equal care of superior animals! And there are not many who carry equal method into their most important avocations—errors, which may justly be ascribed to defective education. It is easy to perceive in every part of Mr. Ingersoll's proceeding, that confidence which merchants feel in the employment of capital at some risk, and heavy charges, for the production of a probable and fair, although remote profit, through a definite channel. With such hopes and calculations education had made him familiar, whilst it gave him habits of critical investigation that must ever secure to their possessor eventual success in any occupation to which he may devote himself. As a farmer, we perceive that he has derived a handsome livelihood from the cultivation of a few acres of land, and the employment of a small capital, in connexion therewith; whilst there are many proprietors of princely estates, who can scarcely contrive to banish want from their domains. We have pointed to the chief cause of such painful deficiencies—it remains for parents to diminish their number in future times, by taking present and suitable means to qualify their children to pursue their respective occupations with benefit to their families, and advantage to society. And whilst we are zealously laboring to amass property for our offspring, let us not be unmindful of their intellectual treasures, but remember always, that the improvement of these can alone teach them how to enjoy and augment the wealth that we may give.]

Edit. Am. Far.

Brookline, Mass. Oct. 30th, 1821.

DEAR SIR,

I have, this evening, received your favor, dated 1st inst. inclosing some valuable seeds, and two numbers of your publication, for which I beg you to accept my acknowledgments. I should feel mortified that your interesting Journal should have been published near three years, without my availing myself of its information—the fact is, I have been a subscriber, through our mutual friends, Messrs. Wells and Lilley, from the beginning.

VOL. 5.—41.

I am happy to hear of the safe arrival of the pigs, and more gratified that you are pleased with them. It will give me great pleasure to send the boars you wish in the spring; and they shall, as you desire, be of different parentage from those you already have. I am fully satisfied, from repeated trials, that a fine race of animals cannot be kept up by breeding *in and in*; and I have, both in my sheep and swine, two distinct families, which are crossed with each other. And except to supply the number of each kind I want to breed from, the individuals of the same family are never allowed to come together. By attention and strict adherence to this plan of crossing, where both kinds are good, I have a fine healthy stock. The animals are improved, both in size and symmetry, and their disposition to get very fat, at an early age, has been increased. At twelve months old, the pigs you saw in my various pens, averaged 280 lbs.; and many of them exceeded 300 lbs. each. This weight, as they were fed almost entirely upon vegetables, was very satisfactory. A larger race has been often recommended to me by my neighbours. But a large race would not only require more food, but it must also be of much richer, and of more expensive quality. Boiled cabbages, turnips, and other vegetables, whose acreable produce is large, and which constitute the principal sustenance of my own breed, would make but poor returns when given to a larger framed animal.

My establishment consists of twelve breeding sows and two boars, that are kept as long as they bring fine litters of pigs—failing in this, they are fattened, and their places supplied by others of one year old, before they are put to the male. The sows are put with the boars the 1st of April, and the 1st of October, and farrow twice a year. Their inside pens are eight feet by five, and their outside pens are three by four feet. About the time they are expected to bring forth, the styes are littered with straw cut into chaff, very fine, that the little pigs may be dry and warm, without being entangled with long straw, and thus destroyed. The litters are always regulated, so as to leave not more than eight pigs to any one sow, either by changing their mother's, when necessary, soon after their birth, or by removing supernumeraries. I have always found a family of eight pigs at a month old worth more than one of twelve; their growth being so much greater. From each outside pen the pigs have access through a small hole, to a common yard, which is always kept well littered; in which they play—and when dry corn is placed in shallow troughs to induce them to eat as early as possible. Each party knows their mother, and they find their respective pens without difficulty. These pigs are *always* weaned the 1st of April and the 1st of October, at six or eight weeks old, that the sows may be again in the way of their duty, and my system progress. From these pigs I select seventy-two, and dispose of the rest. They are put into twelve pens, containing six each, and are fed with the best food my swill trough affords, six times per day for the first month, and three times per day afterwards. The inside pens are six feet square, and the outside four feet by six, both planked, with a quick descent, for the dirt, &c. to be carried off. *Much, indeed* every thing depends upon their sleeping dry and warm, and being well littered, and kept perfectly clean. In these pens they remain six months, or until October and April, when they are all transferred to the fattening pens, and their places supplied by the newly weaned pigs. The fattening pens are plank-

ed—there is a cellar under them, and each pig is allowed an area of about twelve square feet to live in; for these there are no outside pens. The fattening pens are cleaned out every morning, and fresh litter given. For three months the pigs in them are fed from the swill trough as store pigs; at the end of which time, say January and July their fattening commences, which consists in adding, for each of them, three quarts of cracked corn to their daily allowance of vegetables, for three months, when they are killed as near the 1st of October and the 1st of April as may be. Thus you will observe the 1st of October, and the 1st of April, are busy days in my Piggery, as the little pigs are then weaned, the sows again put to the boars, the fat hogs sold off, the store pigs removed to the fattening pens, and my system completed.

To feed this stock, consisting of

72 pigs from one to six months old, and
72 pigs from six to twelve months old, and
12 old sows, and
2 boars; in all

158 mouths—we boil a kettle of vegetables, containing six bushels, to which is added one bushel of cracked corn three times a day, and after putting this mass into the swill trough and mixing it intimately, we add as much water as will make 112 gallons, or of each bushel of vegetables and corn sixteen gallons. This swill is then distributed *sweet* and *warm* to the stock, morning, noon and night, with great regularity, in the following proportions, viz.

In October, November, and December—to each of 72 pigs, from one to three months old, one gallon; and to each of 72 pigs, from six to nine months old, three gallons.

In July, February and March—to each of 72 pigs, from three to six months old, two gallons; and to each of 72 pigs, from nine to twelve months old, two gallons, with 3 quarts of corn.

In April, May and June—to each of 72 pigs, from six to nine months old, three gallons; and to each of 72 pigs, from one to three months old, one gallon.

In July, August and September—to each of 72 pigs, from nine to twelve months old, two gallons; and to each of 72 pigs, from three to six months old, two gallons, with three quarts of corn.

8galls.

8galls.

And these eight gallons, divided by their terms, or four, shew that on an average, throughout the year, two gallons are required daily per head for the 144 pigs; or equal to 288 gallons; and to our twelve breeding sows, and two boars, we give per day, three gallons each, or equal to 42 gallons; making, altogether, an aggregate of 330 gallons; thus quite consuming our three messes of 112 gallons each. By the different ages of the pigs, as above combined, we have a constant and daily call for the same quantity of swill through the year, so that our business proceeds with perfect regularity.

Baltimore, Nov. 21st, 1821.

DEAR SIR,

Your detailed account of the management of your Piggery, has afforded me great pleasure and instruction. And your very obliging offer to send me a list of the vegetables raised for your monthly supply, tempts me, not only to ask for it, but for some other explanations which you likewise proffer. I am anxious to have a summary view of the total quantity of each and every kind of food used in your Piggery per annum—the cost of raising or purchasing

food—the extent of land on which it is, or might be raised—the labor of feeding and attendance at other times—the annual weight and value of the pork killed—the usual number and value of supernumerary pigs—the probable value on your farm, of the food consumed—and the quantity and quality of the manure saved or produced, as well as the cost of an equivalent in manure, if otherwise obtainable. I have, you see, some curiosity; but I persuade myself, that it cannot give one so systematic as yourself, any trouble to answer me on each of those points, and in a way to shew me by a glance of the eye, that it is better for you to convert your vegetables and corn into pork and manure, rather than buy manure and sell vegetables; whilst I shall, at the same time, be taught economy and method by your precept and example, which I will endeavour to observe, and imitate at my breeding establishment. I feel somewhat at a loss as to the manner of building my pens; and on the inclosed paper, you will see my doubts exemplified in rough diagrams; your correction on these would particularly oblige me. It is my desire to build them in a long narrow shed; on one side of my barn yard: and to have at one end, cooking and vegetable apartments.

At your request, I am induced to ask whether it would not be better, that is to say, cheaper, to steam than to boil your vegetables? I have seen it stated in the explanations of Scotch implements, published by their Board of Agriculture, in the year 1814, that one person by a simple apparatus, may steam in an hour, food enough, say of potatoes, to feed 50 horses a day, at 32 lbs. for each horse. And I had quite concluded to procure a boiler and steaming box from Scotland, on the strength of that statement.

I have been led to make some inquiries of you in this letter, from an attempt to push your proceedings to their results; as you will see by the enclosed estimates, which will best define the most of my inquiries.

Do you give the swill warm in summer as well as in winter? Do you spay your sow pigs, or put fattening sows to the boar, shortly previous to killing? Have you used the mangel wurtzel, and observed its comparative value or relish? I think highly of it, and wish that it may be fairly tried by every farmer in this country. In our climate it is more certain and productive than any other root. On this head I beg leave, however, to refer you, for my opinions, to No. 5, Vol. III. of the American Farmer, in the notes on Mr. Cooper's account of his several crops. And

I remain truly, Sir,
Your obliged and obedient servant,
JOHN S. SKINNER.

NATHANIEL INGERSOLL, ESQ.

Estimate of Food, Fuel, Labor, &c. employed at Mr. Ingersoll's Piggery, per annum.

6 bushels of vegetables, roots, &c. 3 times per day—18 bushels per diem; for 365 days—6570 bushels per annum, which at 25 cents per bushel,	\$1642 50
1 bushel of corn 3 times a day added to the above for 365 days, equals	1095 bu.
13½ bushels or 3 quarts per day, given to each of 144 fattening hogs, for 3 months or 90 days	1215
Corn per annum	2310 a 50 cts. 1155 00
Fuel 1½ cords per month, sawing &c. 18 cords,	100 00

Labor 1 man and 1 boy, wages and board	250 00
Yearly value bestowed on Piggery, Dr.	\$3147 50
<i>Cr. by Pork and Pigs sold.</i>	
142 hogs a 280 lbs. 39,760 lbs a 6 cts.	\$2385 60
24 pigs, one by each sow, at each farrow, over and above 8 suckled, \$1	24 00
	2409 60
	\$737 90

Shewing a difference lost by using the food in the piggery, instead of marketing it; provided the corn and vegetables are valued at a price at which they could be marketed free of expense, and also return manure enough to keep up the fertility of the soil, which I presume might be done near to this city, if not near Boston.

And if this is practicable near Boston would not the sale of vegetables and purchase of manure, be attended with less care than the piggery, and be more certain? At what price is the manure of stables to be had at Boston, say per load, of given cubic feet, when unrotted? And do your owners of market farms, who have been successful and long established, buy manure, and at what rate? An elucidation of my attempt to estimate your operations, will give me the marketable value of your vegetables at home and in Boston, as well as an idea of the expense of converting them into money by direct sale, all which will be very acceptable and useful to me personally, if you can find time conveniently to furnish it.

Estimate of Land and Labor, required for the Piggery, &c. &c.

For 2310 bushels corn for piggery, a 40 bushels per acre,	68 acres.
For 6600 bushels vegetables, 500 bushels per acre,	14 acres.
Acres for piggery,	72
For the farm purposes to support 2 horses, and 2 oxen, say grain and grass,	16 acres.
Pasturing, orchards, lots, &c.	12 acres.
Acres,	100

Labor required to cultivate 100 acres as above, say 2 hands, 12 months wages and board,	\$300 00
For additional labor, spring, summer and fall, supposed to be equal to the expense of 6 hands for 6 months, or 3 hands for a year,	450 00
Annual labour, say	\$750 00

A farm of 100 acres of first rate character, might be worth \$100 per acre, 10,000 00

And the increase of value, attributable to augmenting population, would be more than equivalent to the wear and tear of utensils and stock employed.

The interest might therefore be considered as rent,	\$600 00
Add for taxes,	25 00
And for labour as above	750 00
	1375 00

Then the farmer for his time may be considered as earning on a permanent scale, over and above interest, on his capital, by his piggery, for his own support, provided the ma-

nure keeps up the fertility of his soil, about	1034 60
	*\$2409 60

Brooklin, December 24, 1821.

DEAR SIR,
I received your favour of the 21st ulto, a long time after its date, and not until it was much worn and chaffed with its travels ere it reached me. I will endeavour to answer your enquiries in detail. The following is a "summary view of the total quantity of each kind of food used in my piggery per annum," and the months in which they are used; beginning with the 1st of July, which is about the time I begin to depend upon summer vegetables, viz:

<i>July and August</i> —Mangel wurtzel, roots and tops being the thinings from 2 squares each, containing 32 rods,	800
Summer squashes,	200
Early cabbages,	100
<i>September, October and November</i> —Winter squashes or pumpkins,	700
Large drum head ca'bbages,	800
Trimmings of mangel wurtzel, turnips, &c. &c.	150
<i>December, January, February, March, and April</i> —Mangel wurtzel, † (roots)	200
Carrots,	900
Ruta baga,	200
Cabbages,	1500
<i>May</i> —Parsnips which were left in the ground during the winter, and allowed to grow in the spring, until their tops are from 4 to 6 inches high, when they are daily dug as wanted, and all boiled,	500
<i>June</i> —Potatoes,	250
Early lettuce, peas, chopped up vines and pods when the peas are full grown, though still green,	250
Bushels,	6350

We always mix the vegetables by boiling some of either kind in each kettle.

My farming, or rather gardening, goes upon the principle of cultivating but little ground, and by great attention to get large crops, and in some instances two from the same land. The farm of one piece constantly in cultivation is an oblong, thus divided with an alley or walk 4 feet wide in the centre.

No. 1. Of the upper side was sowed this year, with mangel wurtzel, thinned out several times as described in a former letter, and finally cabbage plants set out two feet apart, (for a winter crop,) taken from square No. 3, of the lower side.

No. 2. Has now a crop of parsnips left to grow the next spring, to furnish food for the month of May. The frost, however severe, does not injure them, and they are very much liked by the hogs. The advantage of preserving without trouble through the winter makes them valuable.

No. 3. Upper side, produced parsnips that were dug in the month of May, and the 4th June was sowed with carrots. Produce 237 bushels of the short kind.

No. 1. Of the lower side was cropped with carrots this year; of the long orange kind.—Produce 248 bushels.

No. 2. Bore the crop of mangel wurtzel I described to you in a former letter.

No. 3. Cabbages.—The ground was laid out in 8 beds, 4 rods long, and one wide; the 12th June,

* See sales of Pork and Pigs.
† Cabbages and mangel wurtzel used first.

it was sowed with Pomfret cabbage seed, in rows 2 feet asunder. They were thinned out, as plants were wanted to set in other places, so as finally to stand 2 feet apart. Produce 500 bushels. This piece of land is constantly cropped in such routine, that the same vegetable occupies the same square once in three years. Each square is annually manured with well rotted hog dung, and always at the rate of 4 cart loads for 40 cubic feet. The cabbage square has in addition 20 bushels of unslacked wood ashes.

8 1/2 Rods wide.

24 Rods Long.

The aggregate produce this year of the whole 6 squares, or 1 1-5 acres was as follows, viz.

Upper Side.

No. 1. Mangel wurtzel tops and roots all boiled together, 510 bush.
Cabbages transplanted, 500 do. 1010 bush.

No. 2. Now filled with parsnips—no doubt, 500 do.
No. 3. Carrots, 237 do.

Lower Side.

No. 1. Carrots, 248 do.
No. 2. Mangel wurtzel, 533 do.
No. 3. Pomfret cabbages, 500 do.

Bushels, 3028

Upon the borders of this garden ground, which is one rod wide, I have a row of fruit trees.—Under them we have lettuce, early cabbages, ruta бага for transplanting, and such vegetables as our family require. But upon the plat above described nothing grows to shade the crops devoted to the piggery.

A second piece of garden ground, contains a square acre, and is divided into 4 equal parts and cropped in this manner, viz.

1/4 acre, early potatoes and peas for family use. Of the peas, those not wanted, are chopped up, vines and all, and boiled in June. This land is

cleared soon enough for a crop of transplanted swedish turnips, or ruta бага.

1/4 acre, summer squash. Produce 200 bushels.
1/4 acre, carrots. Produce this year, 310 bushels.
1/4 acre, cabbages, do. do. 560 bushels.

These two pieces of land are my sheet anchor—they are always highly cultivated and neatly dressed, without a weed allowed to seed upon them.

I annually cultivate besides, 3 acres of field land by breaking up 1 1/4 acres, and laying down the same quantity. These 3 acres are cropped as follows, viz.

1 acre Potatoes, 250 to 300 bushels
1 acre Winter squash or pumpkins, 700 to 900 bushels.
1/2 acre cabbages, 1000 bushels
1/4 acre mangel wurtzel, 250 { Roots, tops, &c. given to sheep and cows.
1/4 acre carrots, 250 bushels
2500 bushels

These crops are an average for the last 3 years. My whole farm, (if it deserves that name,) is only twenty one acres, within a ring fence. Of which one acre or more is occupied by buildings, yards, and approaches to them.

To carry on all my operations I keep two hired men through the year, one of whom however, does the duty of house servant at the same time; and I hire besides day labourers and cattle to plough, to amount of 150 dollars more. It occupies about the whole time of one man, to take care of my stock, consisting of 160 hogs, 60 sheep, 1 chaise horse, 1 cart horse, and one cow; though they are both engaged together, and when the animals are fed, are employed in the gardens in summer, and in winter getting out manure for the next season.

In answer to your question respecting the "probable marketable value of the vegetables on my farm," I would observe that the kinds and quantities of many which I raise, could not be sold at all; as for instance, the mangel wurtzel, ruta бага and all the tops and thinnings of others. Mr. Quincy tells me, he this year sells carrots in Boston, after carrying them 8 miles, at 9 dollars per ton, or 18 cents per bushel. Cabbages are sold by the load at 2 cents each, or about 8 or 10 cents per bushel. Parsnips and winter squashes must be retailed, and pumpkins in any quantity, would not sell for any thing.

To answer your question about market gardeners, I have endeavored to recollect, who among my neighbours have been successful and long established in that line, and I cannot select a single individual who has not driven his own cart to market, until he had sons old enough to take his place, and thus by attending to the minutiae of the business prevented that fraud and deception, that a gentlemen farmer cannot easily avoid. When I first bought my estate, I sat up a market cart, got a stout horse, and a man well recommended, but my daily receipts kept growing less and less; my man and horse were out late every evening, and after a vexatious and mortifying experiment, I was convinced, that I must either find a market for my vegetables upon the place, and under my own eye, or give it up as a losing concern—for I could not bring my mind to the constant and daily competition, for trifling sums, which a man habituated to it from infancy, rather takes pleasure in.

Manure bought in Boston, costs them two dollars per buck load, of 62 or 63 cubic feet, trod

hard and moderately heaped, in its unrotted state. The expense of carting put at the lowest rate, cannot cost the farmer less than \$1 50 per load, and when they bring it on hire, they charge \$2 50. My whole stock annually furnishes three hundred such loads, which after using all I want, finds a ready sale among the market gardeners in my neighbourhood at 3 dollars per load, they taking it away with their own teams.

This manure is without any mixture of pond mud, sods, &c. which, had I access to such materials, might be very profitably increased.

As it respects steaming, instead of boiling vegetables, the only expense saved is fuel, for the same labour is necessary in filling and discharging them. Our labouring people require to have their work simplified as much as possible, and their judgment not often called into exercise.—Were I to tell my man to steam 18 bushels of vegetables, and to give one-third of them 3 times a day to the stock, the consequence would be, that a much greater quantity would be given at one time, than another, and though the whole would be consumed in the course of the day, still the inequality of feeding would be hurtful. Besides in winter, particularly the swill, must be very warm, which could not be at night with vegetables steamed in the morning. Upon the whole therefore, I prefer to say to him, "fill the kettle with vegetables, and after they are boiled away sufficiently to make room, put in one bushel of cracked corn and oats, and give the whole for breakfast," thus marking out the exact line of duty, and leaving nothing to his discretion.

I give the swill warm in summer, and almost hot in winter, and always sweet and fresh. In conversation with Mr. Derby, he argued upon the propriety of feeding with sour food, and that cold. I have formerly tried it, and satisfied myself it was wrong. Pigs may be habituated to eat it, but place his cold sour stuff in a trough, and a good smoking hot breakfast of mine in another beside it, and I will venture to say, they will soon show a preference.

I never spay sows, because we have no one who knows the mode, which is to be regretted. They are sometimes admitted to the boar a few weeks before killing.

In yours received yesterday, through Wells and Lilley, you ask my opinion of the Byfield breed of hogs. As breeders they are the worst I know. The sows have small litters and destroy them oftentimes by laying down without any care. They are long coarse haired animals and very apt to be mangy, nevertheless to mix with almost any other breed, a Byfield boar is valuable, being a quiet race and disposed to get fat at an early age.

The Bedford is a hardier kind, and make good nurses. But for our uses have too much lean meat in proportion to their fat—their hams from that circumstance are excellent—a cross between a Byfield boar, and a Bedford sow furnishes a profitable and handsome stock.

Inclosed is a sketch of my piggery. I thought it might assist you in determining the mode of building yours—I find mine convenient, and know not, that I could alter it advantageously.

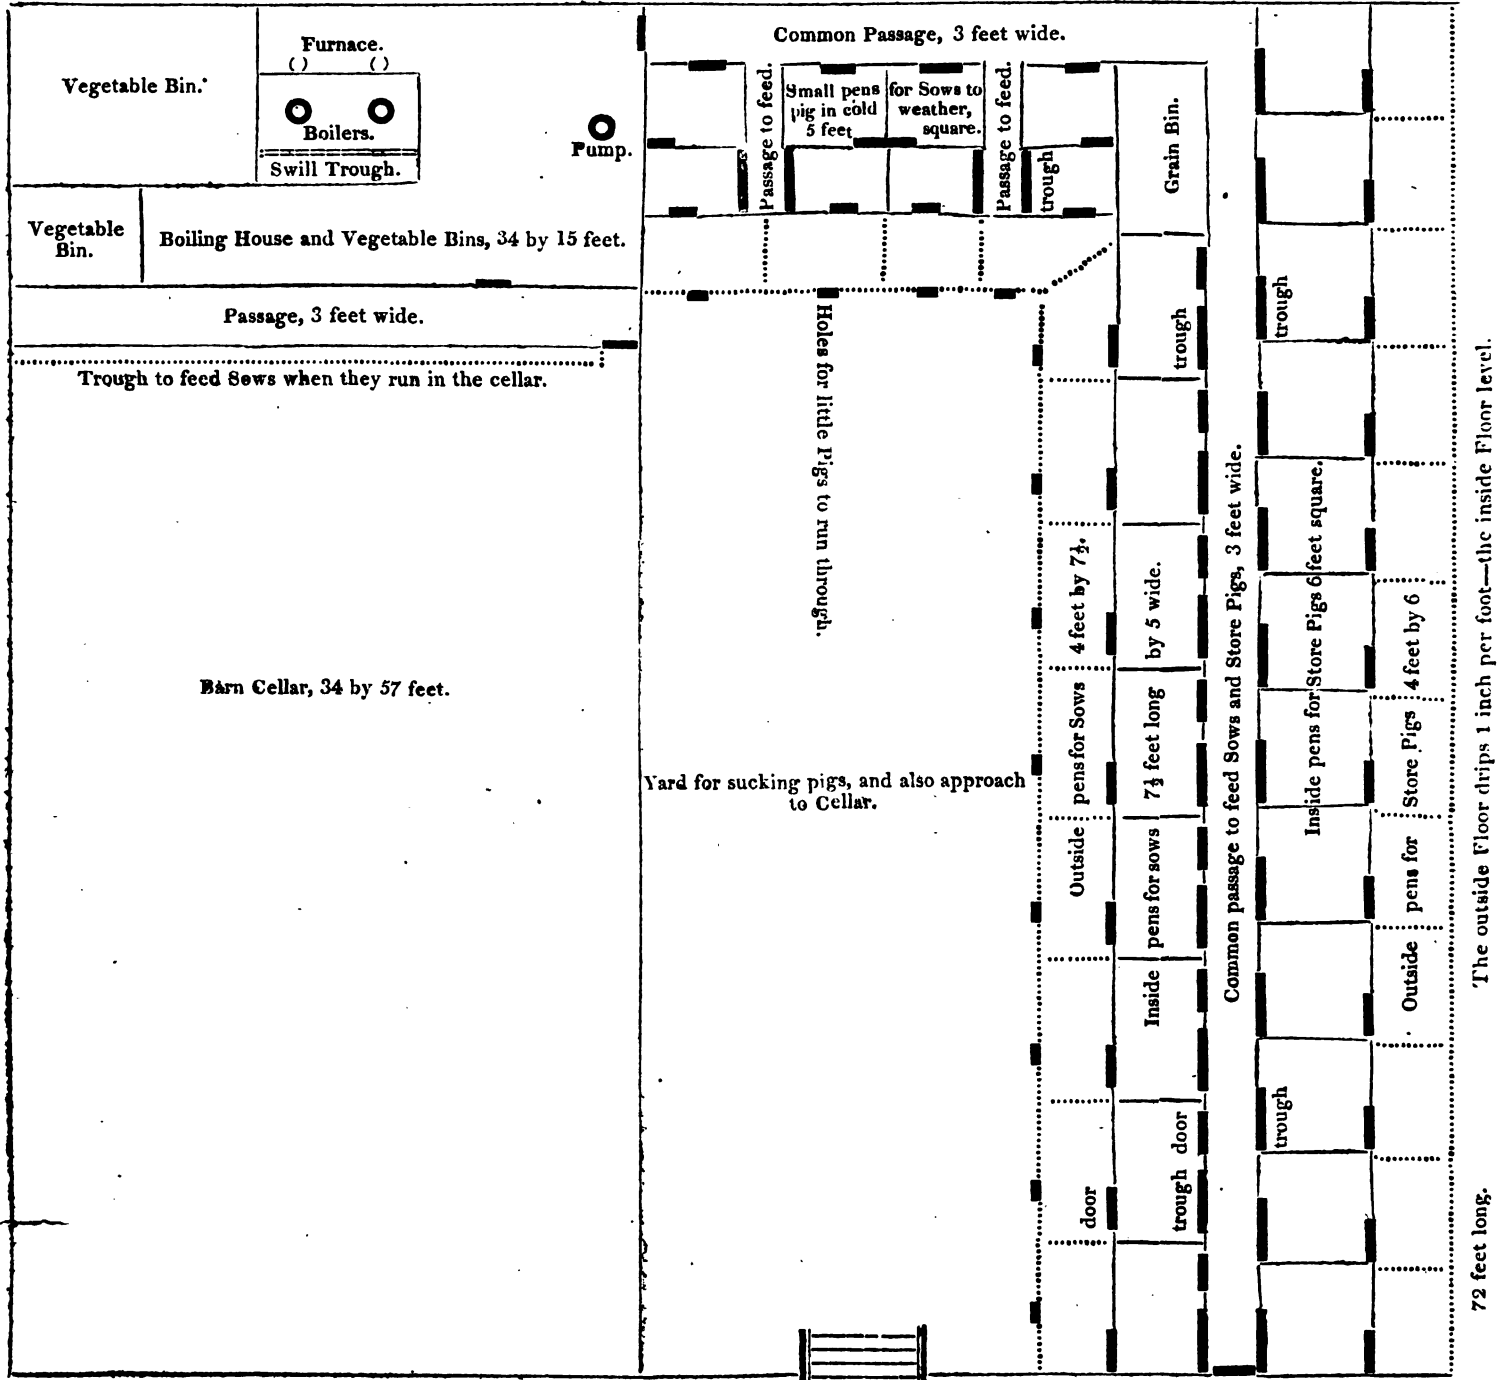

I have thus, my dear sir, attempted to give a comprehensive answer to your interrogatories: if there is yet any thing not perfectly clear to you I shall be happy to explain.

My letter has run on to a great length, but your politeness I trust will excuse it.

Your obedient humble servant,

NATHANIEL INGERSOLL.

J. S. SKINNER, Esq.

I have attempted to proportion the Building upon a Scale of 10 feet to an inch. [Gate.]

I have found it necessary to have communication with all the pens, from the principal inside

passage for the facility of moving the sows and if placed in shallow troughs. They have holes store pigs, because outside doors are apt to be sufficiently large for them to run out of. Since you were here, I have been obliged to new lay the floor of my piggery, and have now arranged the pens conformable to the above sketch. I have also dug a well in the boiling house, and have the nose of the pump placed high enough to carry water into the kettles.— Should my spring fail, I shall by spouts, conduct the water that falls in rain upon the building, into the well. My fattening hogs you will recollect are fed upon the barn floor, and cleaned into a cart, and the manure carried away, that the yard for sucking pigs, may always be clean— and where they will soon learn to eat whole corn,

72 feet long. The outside Floor drips 1 inch per foot—the inside Floor level.

ADDRESS of J. M. Garnett, Esq. President of the Fredericksburgh Agricultural Society—delivered at their Exhibition at Fredericksburgh, on the 12th and 13th of November last.

MR. GARNETT'S ADDRESS.

Once more, my fellow citizens, we are permitted to unite in witnessing and celebrating a spectacle which ought to be, and I trust is, in reality, highly gratifying to us all. The great accession of spectators beyond what we had last year; the much augmented number of competitors for premiums; together with the manifest improvement in the quality of the animals and articles exhibited—all afford unquestionable proof, that the spirit for agricultural improvement which we have so long labored to excite in this part of our state, has at last been effectually awakened. How long it may continue, depends upon yourselves; but now that you have had such satisfactory evidence of what it can effect, in the short period of twelve months, I must indulge the hope, at least in regard to all who are with us on the present occasion, that their efforts in the good cause will never be wanting. Few portions of our country have greater capacities for amendment of condition, or stronger motives to call them into active operation. For nothing appears to me wanting to ensure a great degree of prosperity, both to town and country, but a few very practicable improvements in your roads and navigation. Nor should it be made a question, where the interest is so obviously a common one, whether country or town would first begin to derive benefit from them. It is entirely immaterial at which end you begin; for the process may very aptly be compared to that of ditching ground that wants it, where a profitable increase of dimensions is the certain consequence of beginning at all. These are views which some, perhaps, may deem too sanguine. If there are any such, I would say to them, it is always best to anticipate good, rather than evil; and let what may happen, we should adopt as our constant motto, the heroic exclamation of our gallant countryman—"Dont give up the Ship." No, never "while there is a shot in the locker," let either sailors, or their brethren of the soil, yield to indolence, despondency, or fear, in their labours for their own, or the general welfare.

Such considerations are more necessary, I think, for us Agriculturists, than for men of any other profession; for none seem to have less power to bear up under actual adversity, or to meet, as they ought, the threatening approach of it. The cause of this I do not pretend to explain; but the fact I have had frequent occasion to remark and lament. Is it that we are worse economists than other people; that from keeping no regular accounts, we more frequently live beyond our incomes; or that the means of our subsistence, being more liable to great and sudden fluctuations in price, we often experience the trying vicissitudes of abundance and scarcity in our pecuniary resources, than the individuals of other professions? An empty purse is a marvellous dampener of the spirits, I believe, with all; but I know none upon whom it appears to have such an effect as on the planter and farmer. You may tell him, when in this woful predicament, by his care-stricken and dolful visage, as far as you can see him. If his temper happens to be of the acid kind, his countenance in a cheese-making dairy, might save all the expense of rennet in curdling the milk; but should his disposition be of the milk-and-water character, all hypochondriacs should carefully shun him, as nothing would sooner bring on their customary fits of the blue devils, than his looks. If I am right in the opinion, that the exertions of the agriculturist are more

easily checked by any discouragement than those of other men; it is easy to explain why we have been so hard to rouse from the torpor under which we have labored for some years past. Agricultural products have fallen in price far below what they once were; and although the obvious remedy for the inconvenience resulting from this very unpleasant state of things, was *economy*, yet few, or none, would adopt it, until they were forced. Abstemiousness in the use of money, is a virtue which most farmers find as much difficulty in practising, as abstemiousness in food or drink; yet both are acknowledged to be of sovereign efficacy. In vain does the dietetic physician prescribe the last, in diseases of the body, and Dr. Prudence recommend the first, for diseases of the purse; the irresolute, self-indulged, self-devoted patients turn a deaf ear to both, until Dr. Necessity lays his iron clutches on them; and then, alas! the abstinent course often comes too late. For instead of the manful, resolute, and persevering struggle, essential to the cure, which can be effected by nothing short of the timely and complete conquest of habits superinduced by pampered appetites for luxurious food, raiment, or other pageantries; the miserable victim of excessive indulgence becomes a querulous, moping, melancholy drone, incapable of almost any evidence of being alive, but sighs and groans. And what are the mighty causes that produce such apparent complication of wo? Why truly, in most cases, (for few are so desperate, as to be altogether remediless,) because the conviction has at last been forced upon the reluctant convert to the necessity of economy, that the long impending hour has at last arrived, when country brandy and whiskey must be substituted for imported spirit and wine; when extra super Saxon, and the finest Irish linen, must give place to homespun; when riding must be performed on horse-back, instead of being in the costly carriage or gig; and when fewer ribbands, feathers, and other frippery must be purchased, for those who probably attach much less importance to them than he does. But is there a man who deserves the name that ought not to be utterly ashamed of such childish weakness? Is there a woman, who has the slightest claim to the admirable character of a Virginia matron, that would not most cheerfully encounter any privation necessary for the good of her family; or who has ever neglected to inculcate similar principles on the minds of her daughters?—I fully believe that there is not; nay more, I am thoroughly persuaded, that where economical reforms become necessary—no matter from what cause, there are very few husbands who would set themselves earnestly about them, but would not be met more than half way by their wives. The chief reason why the latter are so often and so unjustly charged with the whole blame of wanting thrift, is, that the former too frequently prove insincere in their proposals to adopt the saving plan; and when this is the case, the wives very naturally think—if ruin *must* come, that they have a right to commit their full portion of the waste. If the husband guzzles away a part of his substance in places of idle resort; or spends it in gambling, or in any other selfish indulgence; he has no right to be surprised, should his wife squander away all she can lay *her* hands upon in whatever may appear to *her* a gratification. For although it will prove but a poor excuse in another world, for our culpable conduct in this, to say that we have done wrong because we saw others do so; yet, in that most important and sacred of all human copartnerships, called marriage, faults in one party will almost always provoke, if they do not extenuate them, in the other—for neither is it right to claim, that all the good examples necessary in both, should come solely from one

side. A very foolish and most destructive pride has frequently no small share in this business of mutual wastefulness—the individuals concerned, being more ashamed of reformation, than of perseverance in extravagance. But surely, true honor, true morality, and true religion—all tell us, that the nearest approach which human beings can make to perfection, is resolutely to correct our errors as soon as possible after we discover them.

It is undeniably true, that we agriculturists have, for some time past, had many difficulties, and not a few enemies to encounter—such as low prices for produce, bad seasons, and foes of the insect tribe, as formidable as either. But so far should these be, from either checking or extinguishing our efforts, that they ought to be considered only as increased demands on us for extra exertions. Economy will greatly alleviate the effects of the first; good and judicious tillage, with plentiful manuring, are a sure protection against the second—unless they are unpropitious to a very unusual degree; and as for the last, I am strongly inclined to believe, that we should subdue them effectually, if we would practice for their special use the maxim—"Fight the Devil with fire." Very many of these noxious pests are known to take up their winter habitations above the ground, in the different parts of the various plants which cover its surface; and especially in our arable fields. All insects thus located, would unquestionably be destroyed by burning off these plants, either as soon as they would burn, or late in the winter, before the warmth of spring had put their inhabitants in motion. And even on the supposition that the fire might, in some degree, injure the land, (which is by no means certain,) the experiment would surely be worth trying once or twice; for if successful, it would rid us of an enormous evil, with great despatch, and little or no expense. This process would also prove a powerful auxiliary in exterminating all those noxious weeds which are propagated from seed; and would thereby greatly facilitate the culture of artificial grasses, of which we are so much in need. I well remember when it was the constant practice to burn off every thing, (but especially broom-straw,) which threatened to be any great impediment to the plough; and in those days we had neither Hessian fly, chintz-bug, nor grass caterpillars. I mention this fact, because I think it well worth examination. All who are as old as myself, I am sure will recollect it; and although I will not assert that we owed our exemption to fire, such a coincidence appears very much like cause and effect. That this practice originated in sheer laziness, I have very little doubt; but that it may have had the beneficial operation which I suppose, seems to me highly probable. Should this conjecture be correct, it will furnish a strong reason, among many others which might be urged, to prove that it is not less wrong to discontinue, entirely, any agricultural practice, merely because it is old, than it is to adopt any, simply on account of its being new. We may commit gross errors both ways; and the sanguine credulity that would lead us, unhesitatingly, to follow every innovation upon established customs, is no more a proof of a liberal, enlightened mind, than the mulish obstinacy and disbelief which would shut both eyes and ears against every agricultural improvement whatever. In truth, the giddy, ever-changing projector, who greedily adopts every novelty in husbandry, be it what it may, is equally an object of pity or ridicule, with him who would fix it as a conclusive evidence of the superior excellency of any process in farming, that it was followed by Father Noah and his family, as soon as the waters of the Deluge had sufficiently subsided to admit of cul-

tivating the earth. Yet we have not a few who belong to each class of wrong-headed people; nor can agriculture ever arrive at that state of perfection of which it is susceptible, until both species of folly can be cured. The first, by their precipitate, ever-varying industry, are constantly in danger of discrediting every invention, however useful—every practice, however promising; while the last, with their good will, would prevent improvement of all kinds, by stamping with the indelible stigma of rashness and folly, every deviation from what they had been accustomed to see from their infancy. One party, provided they can have a hobby as often as they wish, care very little whether it is a boar or a ram, a bull or a cow, an agricultural machine, or a process in husbandry. The other treats with ineffable disdain and contempt all opinions different from their own; and would be as much ashamed to be caught at making what might be called “an experiment,” as they would of a really disgraceful action. Between the two, the true interests of agriculture suffer incalculable mischief. For what can be much worse for those interests, than for a numerous class of her sons to deem themselves far too wise to be instructed in regard to their profession by anything in writing or printing; while another class require no better reason for dashing at every thing, than to have seen it in a book. The truth is, that the middle course in this, as in many other matters, is the right course. We must learn to avail ourselves of the experience of other people, if we would ever grow wiser, either as farmers, or any thing else; and that experience, since printing has supplied the place of tradition, we *must* get from books, or not at all. It is a gross mistake, and the fruitful source of much of our ignorance in our profession, to consider most of the numerous volumes published on the various branches of husbandry, as merely theoretical. The fact is directly the reverse; for the greater part of them are the authentic records of actual practice, as much so indeed, as any law reports that have ever been published. From these last, none are so blind and stupid, as not to perceive that the lawyers derive infinite advantages; and why should not the farmers be equally benefitted by making themselves thoroughly acquainted with *their Reports*? Blended with these reports, indeed, we often find the conjectures of the writers in regard to the causes and effects of the phenomena which they record; and these conjectures, if they are as wild as they frequently prove to be, are the theories that bring discredit both on the science and practice of our profession. But surely the facts and experiments which a man publishes, are as distinct from the speculations that he may chuse to enter into about them, as he is from his coat; nor need we adopt any part of the last, in availing ourselves of the first. The latter alone, can, with any propriety, be called theory; for the former are nothing more than the materials upon which all theories are founded, and may be used equally well, according to the skill of the workman, to build a good one, or a bad one. The anti-theorists, in addition to the gross error of misunderstanding the true meaning of the term which they so much reprobate, commit another mistake still more fatal to their own improvement. They either cannot, or will not see the immense saving in point of time, which we make in acquiring a competent degree of skill in husbandry, by consulting books, as well as men, on the subject. For in this way we become acquainted with the practice of ages in a few weeks or months; and may learn more in a year, than we could in a whole life, if we relied

entirely upon our own solitary labours and observations.

One of the many advantages of such scenes as we now behold, is to dispel these most irrational and truly ridiculous prejudices against books on agriculture. For we here have many ocular demonstrations that the hints taken from them, can procure for those who judiciously use them, both emolument and distinction. We here learn another lesson, of at least equal, if not superior utility; and this is, to think somewhat more modestly of our own agricultural knowledge, than we are apt to do, when we confine ourselves continually at home; where we have neither rivals, nor friendly advisers of more skill than ourselves to apprise us of the progressive improvements daily taking place in the world; and to stimulate our endeavours to keep pace with them. We learn to contemplate our own pictures with less partial eyes, and to deem it not only very possible, but quite probable that nothing will sooner expose us, (and deservedly too) to be laughed at, than the self-admiration and inflation of men exceedingly wise in their own conceit, so apt to be contracted and displayed by all who long pursue, without question or contradiction any practice—no matter what, which they have dignified with the name of *System*, and formed a habit of calling *their own*. This foible, or mental disease, rarely afflicts men who mix much with the world; and if we agriculturists can either escape, or learn to controul it, by meeting together once or twice a year on so pleasant an occasion as the present, we surely have an additional motive of no small value, to encourage our Show and Fair. Another advantage which we gain by thus gathering together our brethren from distant parts of the country, is, that we learn to despise that pitiful selfishness often contracted in seclusion, which leads us to believe that we live only for ourselves; and must therefore lock up in our own bosoms all we may happen to learn of husbandry, on the principle that “the still sow sucks all the swill.” But although this may be a very good maxim for a pen of hogs, yet as a rule of conduct for men, nothing can well be more contemptible, base, and degrading. In fact, a readiness to communicate what we know, without vain boasting, or arrogant pretension, is not only a constant characteristic of an ingenious, liberal, and enlightened mind; but is one of the most useful and laudable dispositions a man can have. It is particularly becoming in the agriculturists who supply the staff of life to the whole race of civilized man: nor can there be any occasion better calculated to elicit, if not actually to create it, than one like the present. Here we have also, an excellent opportunity of comparing the results of our respective experience; here we see various demonstrations of what great things a little agricultural skill, industry and perseverance can effect; and here we can most conveniently fraternise together in regard to our mutual wants, hopes, and interests. The yeomanry of our land, above all people in it, should seek and *make* occasions to act in concert; and yet they rarely ever think of it. They are the primary support of all other classes in the community, by supplying most of the necessaries of life; they chiefly furnish, when needful, the sinews of war—men and money; they are the paymasters general, either directly or indirectly, for every purpose; and yet when their dearest rights are assailed; provided it only be in a *domestic way*, no people on earth are so entirely quiescent and passive under such injurious treatment. Meetings like the present, either do, or certainly might bring these matters more frequently to our minds; and if they had no other effect, this alone would

render them worthy of encouragement. We greatly deceive ourselves, and may do it most fatally, by continuing to believe, (as too many of us seem to do,) that because the agriculturists constitute a great majority of the nation, therefore the agricultural interest predominates in our public councils. The slightest enquiry into the composition of these councils will prove that such belief is very far from being true; for although most of the representatives of the different states may be *landholders*, yet agriculture is a very subordinate interest with the greater part of them. And this fact furnishes the solution of all the attempts made of late years—and which failed, the two last times, only from accident, to tax us enormously for the benefit of a particular and very inferior class—at least in point of numbers.—Having so frequently introduced this subject at our former agricultural meetings, I shall do nothing more at this time, than to avail myself of the present opportunity, publicly to warn all my agricultural brethren, as far as my voice can be heard, that this most unjust and pernicious project will in all probability be consummated at the next session of Congress, unless the yeomanry throughout the United States shall hold public meetings, and plainly say to their Representatives—“thus far, gentlemen, shall you go, but no farther. To *equal taxation* we will most cheerfully submit; and to *any amount* that the public good may require. But venture not, as you value your places, to tax us for the benefit of any local or minor interest whatever.” From all quarters our public Journals tell us of the flourishing condition of our manufactures, even with the present taxes in their favour. At the same time we hear of the depressed state of our agriculture; and we know and feel the effects of this depression in all our concerns; this none can deny. And yet, in flagrant violation of every principle both of justice and policy, the suffering class, being the majority too, is required to encounter still farther depression for the benefit of the prospering class. This is so great an absurdity in point of common sense, and so gross—so crying an outrage upon the plainest dictates of common equity, that no man in his senses could believe it ever would be attempted under a government founded on the representative principle, unless he saw it. But I have done with this topic—deeply and vitally as it affects us all. If the magnitude and near approach of the danger are insufficient to rouse those who are to suffer most from it, they would disregard the voice even of one who rose from the dead to incite them to self-defence.

And now, my fellow-citizens, permit me, before I conclude, to submit for your consideration, a few remarks relative to the Premiums, which are now ready for distribution, and to the views that we should all take of their design, as well as of the effects which we hope may result from them. Not that I will presume you to be ignorant on these interesting subjects; but the fact is, that the best informed among us, often require to be reminded of matters which, although they deeply concern us, are yet, not always present to our minds, when they should be. Let me then, beg you to recollect, that the sole object of such premiums as we have offered, is to apply additional excitements to that laudable spirit of generous emulation which should always exist between the sons of the soil—the brotherhood of agriculture; and which is as remote from every thing like envy or jealousy of our competitors, as it is from the niggardly passions of cupidity and avarice. Where this spirit prevails, as I trust it does in the present assembly, there cannot possibly be any just ground of complaint at the awards which may be made to promote its

farther extension. Permit me, therefore, once more to express the hope, that as all the candidates for premiums cannot be successful, those who fail will do us the justice to believe, that the merits of what they have offered, have been fully and impartially weighed; and if they cannot admit the correctness of our judgment, we confidently trust they will at least acquiesce in the equity of our decisions. To excel in any useful art or science is no small merit; and to have that merit publicly recognised, as it is on occasions similar to the present, is no inconsiderable praise. The immediate and ostensible benefit, accrues, it is true, chiefly to a few individuals; but a large portion of the honour is reflected on the society to which they belong; and there are none of us but may ultimately derive permanent advantages from these individual successes. Every improvement in husbandry, thus publicly elicited, is, in fact, the realization of so much agricultural wealth; and becomes a part of the general stock of agricultural knowledge which is to enrich the whole body of our yeomanry; to augment their importance and utility; and to adorn our country with every thing that can contribute to the comfort, independence, and happiness of our people.

These, my friends, are the sentiments which meetings like the present, appear to me, specially well calculated to call forth. They are as beneficial, animating, and honourable, as they are delightful. Nor can any thing better serve to cheer our progress in our various avocations; to invigorate our hopes; and to elevate our profession to that eminence in public estimation which it so justly deserves. Let us cherish this society then, and a similar yearly appropriation of the principal part of its funds, as the most efficient means to promote within the limits of our influence, the great, the vital object of agricultural improvement; and let us join our hearts and our hands in cordial pledges never to relax our efforts in maintaining our good cause against all the discouragements by which we may be assailed.

POPE'S THRASHING MACHINE.

[The following letter should have appeared soon after its date, but being placed on a file of letters, instead of our file of communications, it has been overlooked.]—*Edit. Am. Far.*

TO THE EDITOR OF THE AMERICAN FARMER.

Philadelphia, December 9th, 1823.

MY DEAR SIR,

I observed in the American Farmer, that in the report of the Committee on Machinery and Implements, at the late Maryland Cattle Show, they gave it as their opinion, that my father's Patent Thrashing Machine "was, in fact, a Scotch machine, as constructed by several of our mechanics, and as imported by Mr. Dawson, reduced within the power of one horse." If this is the fact, the idea is a new one, and has escaped the penetration of both the Pennsylvania and Brighton Agricultural Societies; at Brighton, a Scotch machine adapted to hand power, has been repeatedly exhibited. I should presume that the fact alone, of my father's machine, possessing capacity to thrash nearly, or the same quantity of grain as the Scotch machine, with the power of one horse only, and at one quarter of the expense of the latter, sufficiently demonstrative of its being a very different one, without further enquiry. But I deem it necessary to observe, that were the cog wheels of the Scotch, applied to the beater of my father's machine, the principle on which its action is grounded, would be destroyed, and the machine be rendered useless. (This is an important fact, and argues strongly in support of the originality of the invention.)

This is obvious, as the axes of the beater are not confined to their centres, (nor the feeders either,) they being at liberty, give the beater an opportunity to rise, that the straw may pass through with freedom. Thus the beater lifting during its momentum, and at the same time being upon the straw against an open circular rack flooring, constitute the thrashing principle; whereas, on the contrary, the axes of the beater in the Scotch machine, are confined to their centres, and whatever resistance the straw may make, is only overcome by augmented power. The only resemblance the machine has to the Scotch, so far as I can perceive, is in the beater only, setting aside its *different proportions*; but I think, my dear sir, it bears a much stronger resemblance to the cotton picker, for that too would thrash.

I remain, my dear sir,

With much respect, your's, &c.

JOSEPH POPE, Jr.

SHEEP—LARGE AND SMALL.

AGE OF TREES.

Dis't. Col. Dec. 21st, 1823.

DEAR SIR,

I was struck, sometime ago, with an address (I think it was) of Ransellaer, to an Agricultural Society, in which he is very long, and seems much convinced of the superiority of large sheep to the merino; and makes his calculations thereon. I wrote you on the subject, stating his errors, which were these, that the land that would maintain five hundred large sheep, would maintain one thousand merinos; and that five hundred merinos might be kept on land that would not keep one hundred large sheep: of this latter, I am well convinced, I was prevented by something from finishing my letter, and it was finally lost.

I now send you an account of the antiquity of trees. On my place there stood about sixty yards north of my house, three large oak trees, their bodies about from two to three feet diameter, and about fifteen feet long, standing by themselves; they had spread much, and grew like apple trees, and had a venerable appearance in 1790—the largest died in 1791—I cut it down, it was thirty inches across the stump of sound wood; indeed the whole tree was sound. I was building a stable and barn, and had it sawed into studs four inches through; when we came to the centre of the tree or stock, the sawyer found great difficulty in getting on, and their saws were much injured, but when we opened the stock, we found four or five spike nails, whose points had crossed each other, or passed each other, in the centre of the tree, which were cut in two by the saw, and spoiled four of the studs, and injured some of the adjoining ones. I think the heads of the nails must have been six inches from the centre of the tree; on recollection I found that, prior to the year 1740, and in that year my mother's first husband had kept store there, and that these nails had been driven in to hitch horses to; as the tree was thirty inches across, and allowing three inches to hitch the bridles on, the tree must have grown two feet, say one foot every way, from, say 1738, until 1790—fifty-two years. I have now a fine thriving white oak, two feet through, that in 1790 was only twelve inches in circumference.

[It is lamentable to reflect upon the neglect with which this invaluable animal—the merino sheep is treated in our country—only a few years since, and we seemed well aware of the treasure we had gained in having added this race of fine fleeces to our long woolled stock

but already they appear to be almost abandoned. When visited again, as we fear we shall soon be, by war and its inevitable calamity, a large national debt, those who have suffered their fine flocks to degenerate and die—will repent of their improvidence.

N. B. Have the people sufficiently attended to the remarkable suggestion of that enlightened statesman, Governor Clinton, that there is no instance of a large national debt ever having been paid off?—*Edit. Am. Far.*

NORTH CAROLINA GOLD.—We have seen several accounts in distant papers, of native gold having been found in Montgomery and Anson counties in this State, as well as in Cabarrus; but having received no satisfactory communication on the subject from any of our friends, we have never noticed these discoveries in the Register. But there is now, in the possession of Mr. Barker, travelling merchant in this city, a specimen of this gold, which we have seen. It is a lump of the pure ore as found in Anson, weighing about 13lb. worth about \$340; and we learn from a gentleman well informed on the subject, that larger pieces than this have been found in the two first mentioned counties, and that there is at present, in the Branch of the State Bank at Salisbury a bar of this gold, which, after being purified, is worth between 5 and \$600.

We have not heard that any person of science is engaged in the business. These large pieces of gold are met with occasionally, though what is collected by the persons who are engaged in the search, is mostly in small particles, which do not much more than compensate them for their labour. Were the business conducted with proper skill, it might prove a source of wealth to its proprietors, and be of great advantage to the State, in adding to its metallic medium.

[*Raleigh Register.*]

Extracts from late Numbers of The London Farmer's Journal, received at the Office of the American Farmer.

SAVINGS BANKS.—The following is a statement of Bank half-yearly dividend warrants (April 12, 1823,) as issued in October and January preceding:—

	£	No.
Not exceeding	5	90,755
Ditto	10	41,295
Ditto	50	99,582
Ditto	100	26,049
Ditto	200	15,459
Ditto	300	5,141
Ditto	500	3,243
Ditto	1000	1,372
Ditto	2000	487
Exceeding	2000	215

283,958

The amount of Savings Banks Deposits paid into the Bank (same date) was £7,323,179.

Upon this last amount some important observations arise. The sum, above *Seven Millions and a Quarter!* is immense; but its distribution leads to a curious result. The number of depositors in the Provident Bishopsgate Bank to 31st March, 1823, was 7320 persons, and the amount of its deposits £186,345, being £25 9s. 1d. each depositor on the average. Adopting this as the general average throughout the kingdom, if the sum of £7,323,179 be divided by £25 9s. 1d. it follows that 283,195 persons are interested therein! which gives 4237 persons more than the number of stockholders in the Government Funds! But as the proportion of £25 9s. 1d. is probably much higher than belongs to the country depositors in Savings Banks, the number will

be much greater; and this interesting confidence of the industrious classes in the stability of the country, is undoubtedly a great public benefit derived from the Savings Banks.

It may not be generally known, that a round thin plate of soft iron, fixed on a lathe spindle, and turned with great rapidity, is capable, in a very surprising manner, by the motion of its edge, of cutting hard steel; the groove in the steel acquiring an intense heat, without the same degree of heat penetrating the soft iron.

It is recorded, that when Spenser had finished the *Faery Queen*, he carried it to the Earl of Southampton, the great patron of the poets of those days. The manuscript being sent up to the Earl, he read a few pages, and then ordered his servant to give the writer twenty pounds. Reading further, he cried in a rapture, "Carry that man another twenty pounds!" Proceeding still, he said, "Give him twenty pounds more." But at length he lost all patience, and said, "Go turn that fellow out of the house; for if I read on, I shall be ruined."

We have heard of the fall of Lucifer, and the fall of Cromwell, and the fall of Wolsey; but one of the pleasantest tumblers upon record, was that of a Mr. John Fell, who, when he removed from one part of the metropolis to another, wrote over his door—"I Fell from Holborn Hill."

Mr. Orten, surgeon, 34th regiment, has explained the cause of fowls dying so often on ship-board. It is want of sharp cornered gravel to triturate corn in the gizzard. This he discovered by dissecting one of the dead fowls.—"The next step was to take advantage of the information thus gained; but the maxim that 'knowledge is power,' seemed likely to meet with an exception in this instance; for we were many hundred miles from land, and there appeared little chance of finding any substitute for proper gravel on board the ship. Inquiries were made for a stone, by which the experiment might be made with a few of the fowls; and it was soon found that abundance of a rock, resembling granite, had been taken on board as ballast at St. Helena. A quantity of this was immediately broken up into pieces, about the size of split peas, and given to the poultry. They swallowed it eagerly. The sick birds were collected, and a quantity of the specific placed before each; and though most of them were unable to stand, they devoured it with eagerness, several in quantities of a table-spoonful each. They all recovered except one. In short, the mortality from that time entirely ceased and the remaining poultry (by far the principal part,) instead of dying, became excessively fat. Fowls, when allowed to run about, are observed to be very nice in selecting the pieces of stone which they swallow. In many of those which I dissected, I found pieces of broken earthenware, chosen doubtless on account of their sharp edges. I would recommend hard stones to be laid in for fowls on board ship, and broken up, instead of natural gravel, which is commonly more or less rounded. River or sea sand, or gravel, is evidently useless."

(From the *Bombay Gazette*, May 14, 1823.)—The friends of Captain Gambier, R. N., will peruse with interest the following account of a most miraculous escape from immediate destruction;—"On a recent elephant shooting party at Ceylon, Captain Gambier and Mr. Hay, of the Royal Engineers, had separated from their

companions, and were following a large female elephant; when pretty close to her she suddenly and unexpectedly turned upon them; escape appearing impossible, they both fired, but with little effect; the animal immediately charged, knocked Captain G. down, and pursued Mr. Hay, who fell; Captain G. having recovered, and observing the imminent danger of Mr. Hay, gallantly ran with another gun to his assistance. The elephant, on perceiving Captain G.'s approach, turned round, seized him with her trunk, and raised him from the ground with as much ease as if he had been a straw; she then knelt down, and laid him on his back, still retaining her hold; she now began gradually to lower herself, and he already felt the pressure which appeared the forerunner of certain destruction, when, most unaccountably, the animal suddenly rose and retreated, leaving him without other injury than a severe bruise on one knee, which he probably received when she first knocked him down in pursuing Mr. Hay. So providential a rescue from apparent certain death may perhaps be accounted for by the elephant having been confused by the firing, or by her alarm at becoming so far detached from the rest of the herd."

THE FARMER.

BALTIMORE, FRIDAY, JANUARY 2, 1824.

At the last meeting of the BOARD OF TRUSTEES of the Maryland Agricultural Society, it was unanimously resolved, that J. S. SKINNER, Corresponding Secretary of said Society, be requested to attend in person, at Annapolis, to explain the views of the Society, in relation to certain legislative enactments, the benefit, whereof, the Society has determined to solicit from the General Assembly.

GEN. R. G. HARPER, DAVID WILLIAMSON, Jr. and J. S. SKINNER, were appointed a committee to prepare a scheme of premiums to be awarded at the next Agricultural exhibition, on the Western Shore—said scheme to be submitted for consideration to the Board of Trustees at their next meeting.

The next meeting of the Board of Trustees of the Maryland Agricultural Society is fixed for Wednesday, the 14th January, 1824—to be held at the residence of GENERAL R. G. HARPER, and to commence at 12 o'clock—as the scale of premiums is then to be adjusted and fixed, the punctual attendance of all the members is very desirable. There will be other business of importance submitted for consideration.

It will be recollected that it has been made the duty of the President of the Society, the Treasurer, the two Secretaries, and every member of the Board of Trustees, to obtain the signatures to subscription papers, of such persons as are willing to become members of the Society, and to contribute five dollars per annum for five years. These papers must be returned at the next meeting of the Board, as their application to the Legislature will have reference to, and be regulated in a great measure by the success of this effort to procure regular subscribers for a specified time.

It is needless to dwell on the importance of early and earnest attention to this duty, by such of those to whom it has been assigned, as really feel interest enough in the character

and success of our institution, to induce them to work a little, as well as talk, for its benefit.

The prospects of the Society for improved character, and extended usefulness were never so flattering as at present; but for these results it must obviously depend on its EXECUTIVE OFFICERS, and they will never accomplish any thing for its benefit—its reputation, or its perpetuity, by mutual endeavours to push the burthen of responsibility, and of active duty, from their own to other shoulders. Honors should be declined by those who imagine the duties associated with them, to be too humble or too onerous. In the case in question, if the President of the Society, the Treasurer, the Recording and the Corresponding Secretary, and the twelve Trustees, will exert themselves to procure each, only ten subscribers, which may be easily done; from that resource alone, we should derive a certain fund of \$800 per annum, for five years; and if such of those as are able, choose themselves, to make up in amount the deficiency in the number on their list—there is nothing in the constitution to prevent it.

A great variety of opinions exist, of course, on the subject of the proper objects, on which the Agricultural Society should bestow its premiums. It is, we well know, the wish of the Trustees to form such a scale as will judiciously promote the most desirable improvements, and the Editor solicits, and will feel himself much indebted for hints with which he may be favoured by gentlemen well wishers of the Society and of agriculture.

BALTIMORE MARKET.

PRICES CURRENT—CORRECTED WEEKLY.

Prices for some time have been nearly stationary, and the present state of the market devoid of interest:

First quality family flour, retail price, \$7—Wharf, do. \$5 12½ to 5 25—Howard street, \$5 75 to 5 87½—White wheat, \$1 10 to 1 20—Red do. \$1 5 to 1 10—Corn, 36 cts.—Rye, 43 cts.—Hogs, \$5 25 to \$6—Whiskey 34 cents—Pork prime, per bbl. \$11 50—do. mess, \$15—Lard, 8 to 10 cts.—Turks Island salt, 75 cts.—St. Uben, do. 62½ cts.—Ground allum do. 70 cts.—Fine do. 70 cts.—Sacks do. \$3 25—Molasses, 30 to 35 ct.—Green coffee, 23 to 25—St. Domingo do. 20 to 22 cts.—Timothy seed \$4—Orchard grass, \$5—Herd's do. \$3—Red clover, do. \$6—White do. \$10—Millet do. \$1—Mangel wurtzel per lb. \$1 50—Ruta baga do. 70 cts.—Mutton, 5 to 6 cts.—Beef, 8 to 10—Veal, 8 to 10—Turkeys, \$1 to 1 50—Geese, 50 cts.—Chickens, per doz. \$2 50—Ducks, canvas backs, \$2 to 2 50, per pair—Red heads, 75 cents to \$1 25, do.—Pheasants, 50 cts.—Butter, best fresh, 31 to 37½ cts.—Eggs, per doz. 20 to 25 cts.—Potatoes, 30 cts.—Turnips, 50 cts.—Onions, 50 cts.—Corn meal, per cwt. \$1 25—Buck wheat, do. \$3 25.

TOBACCO continues dull of sale, except fine yellow, and of that very little in market—sales of 3 hhds. from St. Mary's county, have been made the last week, one at \$11, and 2 do. at \$10—2 hhds. from Anne Arundel county near Friendship, new crop, raised by Mr. Francis Whittington, sold at \$15, and seconds at \$6.—Sales of good red, have been made at \$5 to \$8—do. dark, \$2 to \$4.

Printed every Friday at \$4 per annum, for JOHN S. SKINNER, Editor, by JOSEPH ROBINSON, on the North West corner of Market and Belvidere streets, Baltimore; where every description of Book and Job Printing is executed with neatness and dispatch—Orders from a distance for PRINTING or BINDING, with proper directions promptly attended to, addressed to J. Robinson, Baltimore.

AGRICULTURE.

TO THE EDITOR OF THE AMERICAN FARMER.

LETTER I.

DEAR SIR,

In all which you say in a late paper, relative to the appointment of Gen. S. Van Ransselaer to preside on the Committee of Agriculture, I entirely agree with you. I also concur most heartily in every remark which you make, in regard to the necessity which the agriculturists ought to feel of guarding, as far as they can, their rights and interests from injury. But I fear you have given up the whole argument in your comments upon that part of the President's Message, recommending legislative encouragement to domestic manufactures. With due submission, that worthy magistrate has therein run counter to some of the most important doctrines of the political school in which he was nurtured, and to which he has always professed himself strongly attached. The disciples of that school have never admitted, nor can admit, this to be a question of expediency—rather than it may incidentally become such. For it is, (if ever one was, or can be,) as much a question of right, as any that can occur under our constitution. And so I think, I shall hereafter prove, that even the sagacious Hamilton, (whose name has been so often and so much abused on this subject) ever considered it; but especially in his celebrated Report, which is continually quoted by certain men in support of the contrary doctrine. That the manufacturers, or any other class, would be materially benefitted if they could prevail on Congress to legislate into their pockets, the whole property of the agriculturists, or even a moiety of it, I shall not be the man to deny. But I would humbly ask, whence they derive any such power? That it can not be from the clause which authorises them "to regulate commerce," is too plain to need more than a single remark: for if they did get it there, then to regulate, and to destroy are convertible terms. This would be such an abuse of language, that nothing short of the Devil's own impudence could possibly contend for it. That it can not be deduced from the taxing power in the clause relating to imposts, seems equally clear. For unless this power is limited to the sole purpose of raising Revenue for general and national objects, the prohibitory clause, forbidding the taxation of exports would be worse than a dead letter: it would be insult and mockery to the whole agricultural people of the United States, who have vainly, and foolishly thought themselves secured by this plain sanction from all partial taxes imposed to benefit local interests. Yet this identical purpose can be just as effectually accomplished by taxing Imports as Exports: since the moment Congress shall go beyond the object of Revenue, there is no stopping place, but their own discretion; which, however great it may be, or has been, is not such a reliance as the good people of this country have ever yet discovered a willingness entirely to depend upon for any important and essential right. It is vain and preposterous to attempt to gloss the thing over by the imposing phrases of "encouraging manufactures," and "protecting national industry;" together with all the other humbug of the same coinage and stamp. The plain English, stripped of all disguise, is, that the agricultural class may, and must be taxed at libitum, for the sole benefit of the manufacturing class, in regard to all articles of consumption which the latter chuse to make, or to at-

tempt; and this too, by such a forced implication as has no parallel but in Swift's admirable satire called "A Tale of a Tub," wherein a power picked out "totidem literis"—(in so many letters) is pronounced full as good as one expressed with all the possible clearness that language could give. None would have the hardihood to assert that such a transfer of property could directly be made from one class to another; and yet if the same transfer can be effected by indirect means, what becomes of the security against the direct mode; or rather of what manner of use is it? Any tax upon imports, beyond what is required for national revenue, which enables the domestic manufacturer to make and to sell, what he could not before do, and to say to the agriculturist, "this, or nothing," is this indirect transfer to all intents and purposes: nor can all the sophists in the world make any thing else of it. The interminable arithmetical calculations, therefore, under which our news-papers have so long groaned,—proving how much money our manufacturers could make, if Congress would only pass as many laws in their favour, as they wish; serve no other purpose than to make a discovery which has about as much claim to novelty, as to justice; and is nothing more than a different version of the old game, "cross I win, and pile you lose." As to the other class of calculations going to show how many have been ruined by establishing certain manufactures dictated by their own fancies, what do they prove? Why simply, that the present state of things here, will not prevent providence, and want of skill from suffering what—since the creation of the world to the present day, they have always, and ever must unavoidably suffer in every country in the world. If this plea would authorise congressional interference, I could adduce thousands of instances, wherein men have purchased and set up farms as well as manufactures, without due consideration, and been ruined by it; yet not a word has ever been whispered, about Congress doing something to encourage them. What then would the additional duty gentlemen be at? Are all sorts of chimerical projects—provided only, that you call them "efforts of national industry," and "protection to domestic manufactures"—to be forced into successful operation by a legislative fiat, and at the expense of agriculture? Gentlemen will have the modesty, perhaps, to say no;—we only want a few of cotton, and wool, and hemp, and flax, and iron, and tallow! and God knows how many more,—for without the catalogue I have no chance to recollect them. And what then? Why we will most charitably and magnanimously, let you alone,—until some more projectors cry out;—"we have now a fine scheme, spic and span new, for making us all independent of foreign nations, which we have been hatching for some time; and all we now want is, that you routers and farmers, would not only act as men midwives for us, but pay us, instead of our paying you, for the accouchment."

I confess, Mr. Editor, that I lose all patience at such shallow pretexs for what looks to me like downright robbery, under the colour of law. Indeed, I would a thousand times prefer that a man should at once clap a pistol to my breast, and say;—"give up your money, or die," to this insulting my understanding, at the same time that he demands my consent to a legislative enactment by which I, and all my agricultural brethren are taxed for his benefit, as long as we live.

Suppose that too many of us have foolishly devoted ourselves to tilling the earth for a live-

hood; and that we do make "too much bread stuff,—too much cotton,—and too much tobacco," as one of your correspondents (who seems to know every man's business better than the man himself) tells us. Will it not suffice, that we suffer the usual consequences of such folly,—the only natural and legitimate cure for which is,—the suffering itself. Who appointed congress the guardians of our private concerns, or the judges of the occupations we should follow? And yet they must have a right to act in both capacities, or the discovery of your correspondent will avail very little towards a remedy for such self destructive stupidity, as he seems to think the making a superabundance of the necessities and luxuries of life. On this point, I believe myself lawyer enough to say positively, that the constitution is entirely silent. And unless silence in this case gives power, as well as it is said in some others, to give consent, our follies with all their consequences, great and small, must rest upon our own heads: for strange to say, the wise framers of that instrument have most thoughtlessly neglected to make any provision for limiting the quantity of products which the individuals of any trade, profession, or calling might make, by giving full scope to their industry and skill. Yet if this suggestion of your correspondent means any thing, it must mean that congress either has, or should have some such power; or our agricultural citizens will be eternally in danger of committing some such blunder in political economy. Alas! what a pity it is that after all his vilifying, tutoring, and coaxing, we agriculturists should still be such stupid and hardened hereticks as to be unable to see any thing in all which he has said, done, and written, but a very clumsy, and ill-disguised scheme, to make agriculture, through the instrumentality of congress; underwrite and bear harmless every manufacturing scheme—be it what it may, which either has been, or may be undertaken by any body, in any part of the United States.

Under our construction of the instrument which secures our rights, and guards our interests from all hostile attempts, either foreign or domestic, all men are free to pursue their own private concerns in their own way; nor can the ingenuity, nor incision of man, by any possible distortion of its provisions, that a person in his senses would make, prove that our legislators can interfere to disturb or take away this privilege. If all the various classes in the community are thus free, either to adopt or to abandon any particular means which they either collectively, or individually may deem best calculated to promote their own private interest, (and nothing appears to the contrary,) then is it as clear as the light of day, that Congress can have no manner of right, either express, or implied, to abridge or destroy this freedom of choice. It is a perfect waste of time and paper, therefore, to be overspreading the country, with pamphlet after pamphlet, and papers of all sizes, shapes, and kinds, proving that manufacturers could put more money into their pockets, if they could only get more taxes in their favour. No body has denied, or will deny it: all that we agriculturists ask, is, to see a demonstration of the right to impose such taxes. Until that is done, we do not consider ourselves bound even to listen to one word that is said, farther than to make our cheeks sound "buck,"* to it. Shall we be told, "that it is our best plan to make money too, to give higher prices for domestic, than for foreign manufac-

* See the 10th chapter of the history of John Bull, in which Nic Frog gives this reply to something which John said to him.

tures." or what amounts to the same thing; "that it is a very ruinous business to buy cheap, if we purchase from other nations." We think it a sufficient reply to all such officious dictation, that we believe we understand our own interest, at least as well as our would-be guardians; and whether we do or not, that we have a clear and undisputed right to determine for ourselves in all imaginable matters, relating to our private concerns and pursuits; provided, that in so doing, we interfere with no other mens equally free choice, in regard to similar objects.

This is the great, the all important point first to be decided between the petitioners for increased duties, and their opponents. We make one general reply to all their numberless arithmetical statements, which is, *that any increase of impost is whatever, other than for the increase of national revenue, is unjust, impolitic, and unconstitutional*—Unjust, because it injures some classes to benefit others; *impolitic*, because national comfort, wealth, and strength, are best promoted by free trade; and lastly and above all, *unconstitutional*, because it would evade, and render utterly nugatory, all our checks against partial taxation.

Your constant reader and friend,
RURIS CONSULTUS.

December 26, 1823.

TANNIN AND TANNING.

The following extracts are taken from "URE'S DICTIONARY OF CHEMISTRY."

TANNIN. This, which is one of the immediate principles of vegetables, was first distinguished by Seguin from the gallic acid, with which it had been confounded under the name of the *astringent principle*. He gave it the name of tannin, from its use in the tanning of leather; which it effects by its characteristic property, that of forming with gelatin a tough insoluble matter.

It may be obtained from vegetables by macerating them in cold water; and precipitated from this solution, which contains likewise gallic acid and extractive matter, by hyperoxygenized muriate of tin. From this precipitate, immediately diffused in a large quantity of water, the oxide of tin may be separated by sulphuretted hydrogen gas, leaving the tannin in solution.

Professor Proust has since recommended another method, the precipitation of a decoction of galls by powdered carbonate of potash, washing well the greenish-grey flakes that fall down with cold water, and drying them in a stove. - The precipitate grows brown in the air, becomes brittle and shining like a resin, and yet remains soluble in hot water. The tannin in this state, he says, is very pure.

Sir H. Davy, after making several experiments on different methods of ascertaining the quantity of tannin in astringent infusions, prefers for this purpose the common process of precipitating the tannin by gelatin; but he remarks, that the tannin of different vegetables requires different proportions of gelatin for its saturation; and that the quantity of precipitate obtained is influenced by the degree in which the solutions are concentrated.

M. Chenevix observed, that coffee berries acquired by roasting the property of precipitating gelatin; and Mr. Hatchett has made a number of experiments, which show that an artificial tannin, or substance having its chief property, may be formed, by treating with nitric acid matters containing charcoal. It is remarkable that this tannin, when prepared from vegetable substances, as dry charcoal of wood, yields, on combustion, products analogous to those of animal matters.—From his experiments it would seem, that tannin

is, in reality, carbonaceous matter combined with oxygen; and the difference in the proportion of oxygen may occasion the differences in the tannin procured from different substances, that from catechu appearing to contain most.

Bouillon Lagrange asserts, that tannin by absorbing oxygen is converted into gallic acid.

It is not an unfrequent practice, to administer medicines containing tannin in cases of debility, and at the same time to prescribe gelatinous food as nutritious. But this is evidently improper, as the tannin, from its chemical properties, must render the gelatin indigestible. For the chief use of tannin, see the following article.

According to Berzelius, tannin consists of hydrogen 4.186 + carbon 51.160 + oxygen 44.654. And the tannate of lead is composed of,

Tannin,	100	26.923
Oxide of lead,	52	14.

But there is much uncertainty concerning the definite neutrality of this compound.

TANNING. The several kinds of leather are prepared from the skins of animals macerated for a long time with lime and water, to promote the separation of the hair and wool, and of the fat and fleshy parts, in which recourse is also had to the assistance of mechanical pressure, scraping and the like. The skin, when thus deprived of its more putrescible part, and brought, considerably toward the state of mere fibre, is tanned by maceration with certain astringent substances, particularly the bark of the oak-tree.

The hide consists almost wholly of gelatin, and all that is necessary is, to divest it of the hair, epidermis, and any flesh or fat adhering to it.—This is commonly done, after they have been soaked in water some time, and handled or trodden to cleanse them from filth, by immersing them in milk of lime. Some, instead of lime, use an acescent infusion of barley or rye meal, or spent tan; and others recommend water acidulated with sulphuric acid. Similar acidulous waters are afterward employed for raising or swelling the hide, when this is necessary.

The skins, thus prepared, are finally to undergo what is properly called the tanning. This is usually done by throwing into a pit, or cistern made in the ground, a quantity of ground oak-bark, that has already been used, and on this the skins and fresh bark in alternate layers, covering the whole with half a foot of tan, and treading it well down. The tanning may be accelerated by adding a little water.

As it is a long time before the hide is thoroughly tanned in this mode, at least many months, during which the bark is renewed three or four times; M. Seguin steeps the skins in a strong infusion of tan, and assists its action by heat.—Chaptal observes, however, that this requires an extensive apparatus for preparing the liquor and the skins: the leather imbibes so much water, that it remains spongy a long time, and wrinkles in drying; and it is extremely difficult so to arrange the hides in a copper, as to keep them apart from each other, and free of the sides of the vessel.

The following account of M. Seguin's practice, was transmitted to England in the year 1796:—

To tan a skin is to take away its putrescent quality, preserving, however, a certain degree of pliability. This is effected by incorporating with the skin particles of a substance which destroys their tendency to putrefaction.

The operations relating to tanning are therefore of two kinds:—the first is merely depriving the skin of those parts which would oppose its preservation, or which adhere to it but little, such as hair and flesh; the other consists in in-

corporating with it a substance, which shall prevent its putrifying.

The operation of the first kind are technically termed, unhairing and fleshing; the operations of the second kind belong to tanning, properly so called.

Fleshing is an operation merely mechanical: unhairing is a mechanical operation if performed by shaving; or a chemical operation, if effected by dissolution or decomposition of the substance which connects the hair with the skin.

According to the ancient method, the dissolution of this substance was effected by means of lime; the decomposition either by the vinous fermentation of barley, by the acetous fermentation of oak-bark, or by the putrid fermentation produced by piling the hides one upon another.

Unhairing by means of lime would often take twelve or fifteen months; this operation with barley, or the acetous part of tan, could not be performed in less than two months.

The slowness of these operations, which the experiments of Seguin have shown, may be finished in a few days, and in a more advantageous manner, by means of the same substances, proves that the nature of those operations was not understood by those who performed them. Those of tanning, properly so called, were as little known, as the details we are about giving will prove, which we compare with the least improved routine now in practice.

Whatever the method of unhairing was, the mode of tanning was always the same, for skins unhairing with lime, or those prepared with barley or tan.

This mode of operating would take eighteen months or two years, often three years, when it was wished to tan the hides thoroughly.

Among the substances for tanning, gallnut, sumach, and the bark of oak, to which may be added catechu, appear the most proper, at least in the present state of our knowledge. In the middle departments of France, oak-bark is preferred, because it is the cheapest and most abundant substance. To use it, it is first ground to powder; then, according to the old mode, it is put into large holes dug in the ground, which are filled by alternate layers of ground bark and unhairing hides.

As the principle which effects the tanning cannot act in the interior of the skin, unless carried in by some liquid in which it is first dissolved, tanning is not produced by the immediate action of the powdered bark upon the skin, but only by the action of the dissolution of the tanning principle originally contained in the bark. The tan therefore has the tanning property only when wetted so much as not to absorb all the water thrown on it. But as tanners put in their vats only a small portion of water compared to what would be necessary to deprive the bark of all the tanning principle which it contains, the bark put into the vats preserves, when taken out, a portion of its tanning principle.

This waste is not the only disadvantage of the old modes of proceeding; they are, besides, liable never to produce in the skins a complete saturation with the tanning principle. For, as the property of attraction is common to all bodies, according to the different degree of saturation, the water containing in solution a certain quantity of the tanning principle, will not part, to a fixed weight of skins, with as much as the same quantity of water will, in which a greater quantity of the principle is dissolved.

As the water which, in the old manner of proceeding, is in the vats, can contain but a small portion of the tanning principle, owing to the nature of the operation, it can give but a small portion of it to the skin, and even this it parts with by slow degrees. Hence, the slowness in

the tanning of skins according to the old method, which required two whole years, and sometimes three, before a skin was well tanned to the centre. Hence also, the imperfection of skins tanned by that method; an imperfection resulting from the non-saturation of the tanning principle, even when it had penetrated the centre.

The important desideratum was, therefore, to get together, within a small compass, the tanning principle, to increase its action, and produce in the hide a complete saturation in a much shorter time than that necessary for the incomplete tanning produced in vats. But, first of all, it was necessary to analyze the skin, analyze the leather, and analyze the oak-bark. The principles of these three substances were to be insulated, and their action upon one another determined, the influence of their combination upon that action known, and the circumstances most productive of its greatest action found out.

Seguin, by following this method, has determined:

1. That the skin, deprived of flesh and hair, is a substance which can easily, by a proper process, be entirely converted into an animal jelly (glue.)

2. That a solution of this last mentioned substance, mixed with a solution of tan, forms immediately an imputrescible and indissoluble compound.

3. That the solution of tan is composed of two very distinct substances; one of which precipitates the solution of glue, and which is the true tanning substance; the other, which precipitates sulphate of iron, without precipitating the solution of glue, and which produces only the necessary disoxygenation of the skin, and of the substance which connects the hair to the skin.

4. That the operation of tanning is not a simple combination of the skin with the principle which precipitates the glue, but a combination of that principle with the skin disoxygenized by the substance, which in the dissolution of tan is found to precipitate the sulphate of iron; so that every substance proper for tanning should possess the properties of precipitating the solution of glue, and of precipitating the sulphate of iron.

5. That the operation of tanning consists in swelling the skins by means of an acidulous principle; to disoxygenize, by means of the principle which in the solution of bark precipitates the solution of sulphate of iron, that substance which connects the hair to the skin, and thus produce an easy unhairing; to disoxygenize the skin by means of the same principle, and to bring it by this disoxygenation to the middle state between glue and skin; and then to combine with it, after this disoxygenation, and while it is in this middle state, that particular substance in oak bark, as well as in many other vegetables, which is found to precipitate the solution of glue, and which is not, as has been hitherto conceived, an astringent substance.

Agreeably to these discoveries, there only remains, in order to tan speedily and completely, to condense the tanning principle so as to accelerate its action. Seguin, to effect this, follows a very simple process. He pours water upon the powdered tan, contained in an apparatus nearly similar to that made use of in saltpetre works.—This water, by going through the tan, takes from it a portion of its tanning principle, and by successive filtrations dissolves every time an additional quantity of it, till at last the bark rather tends to deprive it of some than to give up more. Seguin succeeds in bringing these solutions to such a degree of strength, that, he says, he can, by taking proper measure, tan calf-skin in 24 hours, and the strongest ox-hides in seven or

eight days. These solutions containing a great quantity of the tanning principle, impart to the skin as much of it as it can absorb, so that it can then easily attain a complete saturation of the principle, and produce leather of a quality much superior to that of most countries famous for their leather.

On the above I have only to remark, that every new art or considerable improvement must unavoidably be attended with many difficulties in the establishment of a manufactory in the large way. From private inquiry I find, that this also has its difficulties, which have hitherto prevented its being carried into full effect in this country. Of what nature these may be I am not decidedly informed, and mention them in this place only to prevent manufacturers from engaging in an undertaking of this kind, without cautious inquiry.

M. Desmond has recommended, to saturate water with tannin, by affusion on successive portions of oak-bark, or whatever may be used; and when the bark will give out no more tannin, to extract what gallic acid still remains in it, by pouring on fresh water. To the latter, or acidulous liquor, he adds one-thousandth part by measure of sulphuric acid; and in this steeps the hide, till the hair will come off easily by scraping. When raising is necessary, he steeps the hide ten or twelve hours in water acidulated with a five-hundredth part by measure of sulphuric acid; after which they are to be washed repeatedly, and scraped with the round knife. Lastly, the hides are to be steeped some hours in a weak solution of tannin, then a few days in a stronger, and this must be renewed as the tannin is exhausted, till the leather is fully tanned.

For the softer skins, as calves, goats, &c. he does not use the acid mixture, but milk of lime.

Of substances used for tanning Sir H. Davy observes, that 1 lb. of catechu is nearly equal to 2½ of galls, 3 of sumach, 7½ of the bark of the Leicester willow, 8½ of oak-bark, 11 of the bark of the Spanish chesnut, 18 of elm-bark, and 21 of common willow-bark, with respect to the tannin contained in them. He observes too, that leather slowly tanned in weak infusions of barks appears to be better in quality, being both softer and stronger than when tanned by strong infusions; and he ascribes this to the extractive matter they imbibe. This principle, therefore, affects the quality of the material employed in tanning; and galls, which contain a great deal of tannin, make a hard leather, and liable to crack, from their deficiency of extractive matter.—*Ann. de Chim. et de Phys.—Philos. Trans.—Philos. Mag.—Chaptal's Chem.*

FOR THE AMERICAN FARMER.

THE SESAMUM INDICUM, OR BENE PLANT.

MR. SKINNER,

Sir—The Bene plant, or *Sesamum Indicum* is a tender annual plant, that is easily injured by the frost, and requires a warm climate to bring its seed to maturity. The plants grow erect, stems from three to six feet high, with numerous branches, bearing their seed in small square capsules. The seed should be planted as early in the spring as it is usual to sow the seed of other tender annual plants.

One leaf of the Bene plant, immersed in a tumbler of pure water, changes the whole of it immediately, into a perfect mucilage; that is clear, tasteless, and inodorous. Sick children take this mucilage with the same avidity they would drink cold water—and as it is perfectly

innocent, they may be allowed to take as much of it as they like.

The Bene mucilage is useful in all cases, where other mild and mucilaginous remedies are proper to be recommended. It is particularly useful in the dysentery and summer complaints of children; and the leaves may be applied in cases of inflammation of the eyes, and as a dressing for burns, blisters, &c. There is no provident family, that knew the value of the Bene plant, I believe, who would ever neglect planting a few of these seed every spring, in some border of the garden, to have fresh leaves, always at hand in case of need, during the summer season. Although the seshamum requires a warm climate to bring its seed to maturity, it will grow well enough in any part of the United States to furnish its mucilage, during the whole of the season it is most generally wanted.

The greatest quantity of this mucilage is obtained from the youngest leaves; and it is best when made from them while green, just as they are pulled from the plants. These leaves, however, may be gathered at any time during the summer, and if carefully dried, they will serve to afford mucilage until green leaves may be had again.

The seshamum is one of the most invaluable plants I know. I do not mean to say, however, that such entire dependance ought to be placed on this or any other remedy, as to neglect such other means as have been heretofore found useful. In all cases of dysentery and colera infantum (both of which are diseases of great danger) the advice of a skilful physician should always be obtained when practicable. But I may safely assert, that if the virtues of the Bene leaves were known as generally as they should be, they would save the good people of the United States many thousand dollars annually, that are now spent to procure nauseous drugs of various kinds, that are not only useless, but often injurious to those who take them.

In August last, a boy six or eight years old, was severely afflicted with a bowel complaint, following the measles; and for two weeks he had tried various remedies, that had been prescribed for him, but with little advantage. For the last six hours, before I was called on to visit him he had sat almost constantly on the stool, passing small quantities of bloody and slimy matter; and crying with the pain and griping of his bowels. I made him a warm infusion of the Bene leaf, and let him drink as freely as he would. In less than half an hour his pain ceased, and he fell asleep, and was not disturbed for eight hours afterwards. On the next day, when I visited him, I found him complaining again, of a return of his pain, and frequent and ineffectual calls to the pot. I again administered the Bene mucilage, without any other medicine; and advised his persisting steadily in the use of it. He followed my directions, and was perfectly restored to his health by this remedy, in the course of a few days.

A child, aged about ten months, was seen by me in July last, having high fever, and great thirst, bowels griped, with passages slimy and mixed with blood. I put one of the green leaves of the Bene plant into a small tumbler full of spring water, and offered it to drink; but the infant turned from it with disgust, crying through fear of its being forced to swallow another dose of such physic as its mother had been giving to it. I removed the tumbler, therefore, immediately, out of its view, and took the leaf out of it. The clear Bene mucilage was then presented to the child, and it drank of it with

avidity, holding fast to the tumbler until its thirst was satisfied. This pleasant drink was repeated as often as the child would take it, and it was restored, thereby, to its perfect health in two or three days.

There was no resort to any medicine, in either of the above cases, after the Bene mucilage was given. Caster oil had been previously administered, and various other means had been used, but nothing that had been tried, seemed to be of any great use until this *new remedy* was resorted to. It is evident, therefore, that much good may be done with it; and I hope many persons will be prevailed on to sow the seed next spring; that a more full and fair trial may be given to this mucilage. On the first of September last, I was attacked myself, in the morning, with an inflammation in my right eye. During the whole day I was in constant pain, and as the evening approached the irritation increased to such a degree that I was obliged to retire from the light. I prepared some of the Bene mucilage with warm water; and applying it directly to my eye, I derived immediately, much greater relief from it than I had anticipated. I next took the leaves out of the warm water, and applied them to my eye. They were exceedingly soft, smooth, and comfortable; and procured me a good night's rest; and in the morning I found myself entirely free from any appearance of the inflammation that attacked me.

But independent of the uses of the Bene leaf, as above, the Bene seed, are invaluable on account of the oil they afford. Two gallons of the seed will yield, it is said, one gallon of oil, equal in every respect, if not superior to olive oil. Their seed are also good as food for man and beast. To obtain a crop for general purposes of this kind—the seed should be planted, I presume, like cotton, in rows, wide enough apart to admit of cultivation with the plough.

I fear, sir, my letter may have become as tedious as it is lengthy, I shall conclude it, therefore, immediately, observing only, that I have a plentiful supply of the true* Bene seed, just received from South Carolina; and it will afford me great pleasure to furnish them to any person who may want them. I intend to keep a regular supply of these seed for distribution annually, so that those of our good people who live in latitudes, where the Bene plant will not come to perfect maturity, may, notwithstanding, be provided with them always. The Bene seed are so very small, that half a thimble full of them will produce as many plants as any family will want for medicinal purposes. No charge will be made by me, at any time, for these seed; but as I am under the necessity of refusing all letters on which the postage is not paid, I must apprise your readers of this to prevent disappointments.

I am, very respectfully,
Your friend,
And ob't serv't,

JAMES SMITH.

Vaccine Institution, Baltimore, }

TO THE EDITOR OF THE AMERICAN FARMER.
CHEAT—AGAIN.

DEAR SIR,

A great deal has, of late, been written to very little purpose, on the subject of cheat. From actual experiment, I have found that wheat perfectly clear of cheat when sowed, will occasionally be filled with it at harvest; should the season have been unfavourable, the land badly prepared, or the wheat crippled by the operation of the fly. Could the point in dispute be decided at once, satisfactorily to every one, it would be of no advantage whatever, as we already know enough to enable us to avoid the deprecated evil, as far as is consistent with human means. Sow clean wheat, cultivate the land well, and ameliorate the soil, to the utmost practicable limit. If we are then pestered with cheat, no blame can be attached to us—we will have done our duty. But sow wheat mixed with cheat, cockle, and onions, and my word for it, you will be paid in kind. In one case the crop may possibly be infested with cheat; in the other the thing is absolutely certain—but worse than this, the wheat will continue to become much more foul every year. Much more heat and moisture are requisite for the germination of cheat and cockle, than wheat, they will, therefore, frequently remain in and on the ground perfectly sound, when wheat would have come up; consequently, the earth will, in the course of time, become filled with the germinating principles of these plants, exactly as it is with those of many other noxious weeds—with onions, thistles, docks, &c. The farmer, after sowing a crop in *first rate style*, is frequently much surprised to find at harvest many intruders, not reflecting at all upon the prolific cause of his disappointed hopes. Those persons who oppose the opinion that wheat produces cheat, do it upon this ground, that cheat in that event must be a mule plant, and could not, of course, reproduce itself, which it is well known, it does. This may be accounted for upon the supposition that wheat is a *species* of the genus, of which cheat stands at the head. In other words, that wheat is only improved cheat; to believe which, requires no greater stretch of fancy, than the acknowledgment of a fact, very generally known, that the finest apples we now have, are the improved progeny of the original crab.

Very respectfully,

R. B. BUCKNER.

Vint-Hill, July 28th, 1823.

ON THE CONSTRUCTION OF ICE HOUSES AND STOWING AWAY OF ICE.

TO THE EDITOR OF THE AMERICAN FARMER.

Sir—Having observed in a late number of the American Farmer, some remarks upon the convenience and utility of securing a plentiful supply of ice, for use through the summer season, I take the liberty to add a few observations upon the subject, which if you think useful, you are at liberty to insert in your valuable journal.

As it would neither be convenient to myself, nor beneficial to the object we have in view, to enter upon an extended discussion of this subject, I shall at once proceed to remark, that the common manner pursued, by almost every one in putting up ice, is to throw it promiscuously into the house, and then employ labourers, to break it into small pieces. In this manner of securing it, numberless interstices are formed by the angles of the pieces after they are broken, which being filled with air, operate of course through the season, to promote the decay of the ice, and greatly accelerate its dissolution.

The manner which I have pursued, and which I strongly recommend to the observance of your readers is, to cut the ice as nearly into squares as can conveniently be done, and when conveyed to the house, lay these down carefully, in regular layers, taking care to break them as little as possible. As soon as the first layer or stratum is completed, fill up with fine ice all the crevices, which the angles in the pieces may have occasioned, then sweep the surface clean, from all small fragments of ice, so as to leave a smooth clear floor or surface, to commence your succeeding stratum or layer upon; and thus proceed, until the house shall have been completely filled. In this manner, I have found that one-third more ice, can be stowed in a given space, than could be put into it by the ordinary mode of pounding; and as there will not be the smallest crevice throughout the whole mass, if the plan here recommended is properly executed, it is confidently asserted that the ice will last *double as long* as under the common mode of securing it.

Every ice house should be provided with a drain to carry off the drippings, throughout the warm season, unless the bottom be an open porous, sandy soil; as nothing is so fatal to ice as moisture. This drain should be so constructed as not to admit air, else a constant current of warm atmosphere will be drawn to the bottom of the ice, which will rapidly destroy it. The house which the writer of these remarks has erected, is of the most simple construction, and a similar one may be built by any farmer, for an expense not exceeding \$30. It has been filled in the manner here recommended, and has not been without ice since it was first stocked, and at this time, contains a considerable quantity, notwithstanding the most profuse use was made of it, by two families during the whole of last summer.

The following plan is recommended in the construction of ice houses. Dig a pit on the N. or N. W. side of a bank or hill, 18 feet square, and about 14 feet deep on the upper side, to which depth, the pit may be raised all round by the dirt, being thrown to the lower side; build in this pit a house of white oak logs, so as to leave a clear space between the outsides of the house, and the wall of the pit, of about 2 feet—if the bank is of hard clay, it will need no stay; if it be not of clay, or hard firm soil, it must be stayed by pieces of plank, propped against it from the outsides of the logs, so as to prevent its covering the space between the logs; and this bank should be filled all round with straw, and the insides of the logs boarded up, so as to present a smooth even surface, this will leave the inside of the house about 12 or 13 feet square, which will be sufficient for any family.

The drain from the bottom of the house should be placed on the lowest side, to which a sufficient fall ought to be secured from all parts of the foundation. The drain should be formed by stone, so laid, as to afford an opening, for the water readily to pass off, and then covered up with earth, taking care to allow to it a sufficient fall, and then its termination be covered slightly with earth, so that no air can pass up, whilst the moisture may gradually soak through. Lay at the bottom of the house sleepers, so as to raise the planks to be placed upon them, about one foot from the ground, and upon these planks lay your first strata of ice, as is here before directed.

After raising your house with logs, as here recommended, to the height of about 14 feet, build another house over it, with logs to be placed upon the surface of the ground at the outer edge of the pit, raise this house about three feet high, upon which place your roof, and from the inner logs, which inclose the ice to the outer ones, which support the roof, nail planks, and stow the whole

place under them with straw; you will thus have an ice house surrounded on all sides with a thickness of about two feet of straw. When the ice is put away, cover the whole with a suitable thickness of straw, which should be removed once or twice, in the course of the summer, as it becomes wet, and replace it with a fresh dry covering.—By pursuing these means, you need never be without a plentiful supply of ice at all seasons.

P. E. T.

TO THE EDITOR OF THE AMERICAN FARMER.

GLANDERS IN HORSES.

Downingtown, 12mo. 19th, 1823.

ESTEEMED FRIEND,

I have noticed in the last Farmer, a proposal to send thy subscribers one half sheet with advertisements, and an almanack in the fall; which I think I may be safe in saying, will be a gratuitous addition to all those who estimate the present value of thy paper properly.

I have also noticed a request made by Robert Lowry, in the last Farmer, for information respecting the glanders; to whom I feel willing to give my small experience, or do any thing in my power for the preservation of so useful an animal.

I have in all the cases that have come within my knowledge, uniformly traced them back to what is here termed the distemper; that is, the first stages of the disease, are in my opinion, what is called the distemper, and by some the strangles.

I consider the glanders to be a neglected or violent case of the distemper: from a repeated discharge from the nose, and constant inflammation, the glands become ulcerated, and finally the smaller bones of the nose become carious, and of course incurable, as they are not so situated, as to admit of an operation being performed on them; in this stage the horse has been inoculated, mercury has been tried, and both without success.

But take the distemper, or strangles, in time, cure it effectually and you prevent the glanders.

SYMPTOMS.

The first thing discovered is a rattling in the throat, with dulness of countenance, apparent drowsiness, and some fever, then a swelling in the throat and between the jaws, a discharge at the nose, and sometimes cough; if the horse does not die by the swelling at his throat, it becomes what is called glanders.

CURE.

Dissolve one pound of gaulther salts in warm water, set it in a bucket in his manger, and he will drink it; take half a gallon of blood from his neck vein; give a mash of two quarts of wheat bran scalded with sausafrass tea, after which offer him lukewarm water to drink, and do not suffer him to drink any other kind for that day, next morning take the same quantity of blood as before, give a mash as before, with the addition of half an ounce of salt petre dissolved in it, let his food be wet, and of a weak kind—a run at grass after the first two days would be of service.

If thee thinks this prevention better than a cure, thee may give it a place in thy paper.

Respectfully thine,

JOSEPH KERSEY.

MAGOTHY BAY BEAN, OR PARTRIDGE PEA.

Wake Fores, September 21, 1823.

DEAR SIR,

In an account of the Accomack pea, which I mentioned to you in a former letter, I will refer

you to page 273, vol. 6th, of the Medical Repository, published in the year 1803. On a perusal of the article, I attach great importance to it, and as it is well written, would recommend it to a place in the American Farmer. The account is in a letter from Mr. John Dennis, then a member of Congress from the eastern shore of Virginia, to Dr. Mitchell. Colonel Allen Rogers of this vicinity, was lately in Northampton, and yesterday assured me that the pea still maintained the reputation there, which it had when Mr. Dennis wrote, 20 years ago.

Very respectfully,

CALVIN JONES.

JOHN S. SKINNER, Esq.

From the 6th vol. of the New York Medical Repository.

An account of a plant called the Magothy bay bean, or Accomack pea, cultivated for fertilizing lands: In a letter to Doctor Mitchell, from the Hon. John Dennis, Representative in Congress from Maryland, dated Washington city, December 10, 1802:—

In conformity with your request, you will find herein a brief description of the Northampton bean, sometimes called the Accomack pea, alias the Magothy bay bean, with an imperfect sketch of some of its principal properties and uses.

The above mentioned bean or pea, is a plant of annual growth, varying from eighteen inches to three and a half feet in height, according to the fertility of the soil. It grows in almost every kind of soil, however poor by nature, or impoverished by an exhausting cultivation; though it succeeds best in a light, loose land, and does worst in hard binding clay. It has a small tap root, and a few inconsiderable lateral roots, with a wide spreading top, covered closely with a foliage, and bearing a pod, with peas or beans therein contained, strongly resembling the leaf, pod and pea of the locust tree. It has, therefore, been denominated, by some, a locust tree in miniature. This plant has the singular property of expanding its foliage in the day and contracting it in the night, thereby admitting the passage of the dews to the earth, and of excluding therefrom the rays of the sun. To this cause has been very much attributed, its supposed efficacy in the amelioration of the soil.

The modes of propagating and perpetuating it are various, but those generally in use, and most approved, are the two following, viz. to sow with oats, or other small grain, in the spring, from a pint to a quart of the pea or bean to the acre, or you may sow it on the ground newly ploughed by itself. If the land be of a light, loose quality, you may sow the above quantity on wheat, or on the land unploughed; but if the soil be stiff and binding, it is necessary to plough it. As it is sometimes injured by the autumnal frosts, and never sprouts until late in April or the first of May, it may be desirable in your northern latitudes, to sow it as early as possible; and where it is sown on wheat, or by itself, on account of the length of time for which it lies on the earth before it germinates, it may be scattered over the ground in February or March.—

The other method most approved, and that which is the most economical, with regard to seed, is to plant two or three of the peas or beans in the hill with Indian corn, common peas or beans, and suffer it to grow and ripen with the same, which it will do without any injury thereto; and, from the multiplicity of seed it contains, and the elastic tendency, which it possesses in the bursting of its pods, it will spontaneously seed the earth, with as much or more regularity than it can be effected by any other mode. The

shortness of your summers, and the liability of the pea to be injured by the frost, form the only objection to the latter mode in the state of New York, and therefore, perhaps, the other is to be preferred. When the earth is once replenished with the seed, it will perpetuate itself, provided that where the land be stiff, the ground be broken once every year, and where light, once in two years. I have usually planted the land in Indian corn, and seeded it in oats or other small grain, and cultivated it alternately in the one or other every year; and this is the most effectual and expeditious mode of introducing and of perpetuating it. The year the land is in corn, all the peas that sprout in the spring will be destroyed by cultivation; but there still remains in the earth a sufficient quantity to seed it, which will come up with wheat, oats, or other small grain, the succeeding spring, in great profusion; will grow and flourish with it; and will have attained a height, by the time of harvest, (which in Maryland, is in July,) that is sometimes, though not generally, in the way of the scythe.—As soon as the grain is removed, it progresses with great rapidity, and attains its growth some time in August—overshadows the land, suffocating and excluding all other weeds and grass. It now puts forth a yellow blossom, which (particularly in our large plantations,) causes the field to exhibit a most beautiful appearance for a few weeks, and ripens in the month of October, affording to the bees, in its bloom, delicious sustenance, and to the sportsman, in its maturity, delightful amusement, in the large number of quails which it attracts, and for which it furnishes a nutritious food, whilst it shelters them from the hawk. After the pea is ripe, we frequently open the enclosure to cattle and sheep, and other animals, and the cattle and hogs are fond of, and fatten on it; but carefully exclude cattle and sheep from it in its green state, since they speedily destroy it.

The principal use, however, to which it is applied, and for which it is the most prized, is its application as a manure, to which it contributes as well by its properties before-mentioned, of expansion and contraction, to which may be added that of attraction, as by the great quantity of litter which it leaves on the earth. The spring succeeding its growth, we find it a little in the way of the plough, and the labourers frequently complain of it on that account; but after two or three ploughings, it dissolves, and mingles with the earth, and, by the middle of summer, is scarcely perceptible. It opens a close binding land, and fertilizes and adds to the soil wherever it grows; but if it will only leave the land as it found it, under the severe but profitable system of exhausting cultivation, of Indian corn one year, and small grain the next year succeeding, for twenty years together, we apprehend it is a great point gained with us, in our wornout lands, where other sources of manure are yet unattainable in sufficient quantities. In the county of Northampton, in Virginia, where this plant was first discovered to be useful, they have cultivated their lands every year, for twenty years last past, in Indian corn or oats, and find the land, without the aid of any thing but the pea, considerably improved. The ardent and impatient, who expect from it all the effects of a dung heap, will, however, be disappointed; and the husbandman who is contented to grow rich, and flourish by a slow and progressive system, will alone appreciate its merits, and continue its cultivation.

I have communicated all that I deem important on the subject, but will, with pleasure.

answer any queries which you may think proper to suggest; and will refer you to the Hon. Mr. Stratton, who resides in the county in which this plant was first discovered, and where it is now in universal use, for a fuller account of its valuable properties.

FROM THE LONDON FARMERS' JOURNAL.

ON MERINO SHEEP.

(By C. C. WESTERN, Esq. M. P.)

Felix Hall, August 20, 1823.

SIR,

I am desirous, through the channel of your useful paper, to communicate to the public some remarks, the result of long experience and observation, upon the advantages to be expected from the encouragement of the Merino breed of sheep, and I trust you will give them a place when nothing more interesting happens to occur.

I have always declared my opinion to be, that the Merino sheep *want to be made*; as the Leicester and South-down have been. They required it, indeed, more than either, and I think *deserve* it better than either. If the same pains were bestowed upon them by men of the same superior intelligence as those who devoted themselves to the cultivation of the New Leicester, *the Merino would be the most valuable animal of the two*. It is impossible to open the fleece of a well bred and well fed Merino sheep, and not be struck with the extraordinary luxuriance, beauty, and value of the produce, and to avoid feeling at the same time, some degree of surprise and regret, that our most enlightened and intelligent breeders have hitherto neglected to bestow upon such an animal the full benefit of their science, skill, and attention. The experiments I have seen made upon them, have generally been rather of persecution, to try what hardships they could live under, (and which, by the by, they sustain in a manner I should have thought impossible, (or languid indifference of success, or even disinclination, lest they should attract for a time the favoritism attached to our established breeds. I do not myself wish they should supplant altogether an useful established breed, but I wish them to occupy a *full* share of our attention. I will go so far as to say, I think a *portion* of the Merino blood *may*, with advantage, be thrown into the flocks of all our *short*-woolled sheep, but it must be done with great judgment and care, in the selection of the male or female through which the blood is to be taken. The South-down flocks have for some years past reached the utmost point of perfection to which they can be brought without such aid, to improve *further* the quality of their wool. I am pretty sure the most enlightened South-down breeders will admit this position, and I am confident the Merino sheep may, in full purity of blood, be so improved as to give that cross without *much* detracting from the carcass. It may be done, through the *females*, which are much oftener (we all know) brought to perfect symmetry and shape than the males. I think I can shew many ewes as perfect in their frame as any South-down ewe that ever was seen; not so the rams: it is still very rare to find one that will satisfy the eye, of a Leicester or South-down breeder; but even there great advances have been made; the offspring of a Merino ewe by a South-down ram might thus be used in preference to taking the cross by a Merino ram. I only mention this, however, as one mode amongst many that may be adopted.

Now, as to the wool of the pure Anglo-Merino sheep, I am particularly desirous of draw-

ing the attention of your readers to the following observations upon some of the qualities which it possesses, of which they are, perhaps, in general uninformed, and which constitute a very important point for our consideration. I think it will be granted to me, by those who have turned their attention to the subject of wool, that the superiority of our long English wool arises in a great degree from the *superiority of our pastures*, and the *English practice of feeding*, which, whilst it produces fat mutton, produces *long and strong* wool. Attention to the breed, and judicious selection, are of course *indispensable*, but the same sheep transported to any other country of Europe, and *fed* as they are on the Continent, would soon degenerate; the wool would become *short and brittle*, and the animal would also deteriorate for the want of the same skill in the breeders: the same causes which thus make our long wool the best in Europe, will operate upon the growth of the Merino wool, and produce,—indeed, has produced—a *new species* of wool of *indescribable* value, and which, for the same reasons as are applicable to the long wool, will be rarely found out of England: this wool has *length and strength* sufficient for *combing*, and spinning to such a thread as will be applicable to an infinite variety of manufactures, to which *Merino wool never was before applied*, nor does the high feeding much detract from the *fineness* of the hair, and nothing from its softness: the *foreign* Merino wool is short and brittle, and cannot by possibility be used for this purpose. I shall deposit, for the inspection of your readers, a small quantity of the wool combed, and the yarn spun, in your hands. I by no means wish to found on this idea the hope of any practicable exaction of a very high price for Anglo Merino wool, or to encourage breeders with the expectation of immense profit. I fully admit, that a breeder embarking in a Merino speculation must possess no trifling share of experience and industry, to make it pay as well as the pursuit of the ordinary track, or even to escape loss; but, I think, if he has both, he may *now* make it answer a *little* better; the *manufacturer* must, however, make it answer a *little* better also; and if the breeder indulges in golden dreams for himself *alone*, he will overthrow the whole concern. I shall in the course of this letter endeavour to shew what is the *lowest* price for our wool that will carry us, breeders, through safely, instead of exhibiting prospects of advantage which can never be realised. If the manufacturers will bestow their skill upon our produce, and find a benefit in so doing, competition amongst themselves will sooner or later secure to us as good a price as the article will bear; infinite is the variety of manufactures to which this very fine combing wool has been already experimentally applied; and I think I am warranted in saying, that with such success as to insure us a *certain fair* market for our growth in future years, however much we may extend it.

It is extremely important for every sheep-farmer to estimate, *accurately*, the returns to be drawn from the wool *separately* from the carcass, in order to form a just comparison of the value of the different breeds; and I think this estimate is rarely made correctly; the calculation is formed upon each *individually*, instead of the aggregate flock, not considering that every flock-master, however he manages it, will have always more fleeces to sell than carcasses. Take the case of those who breed and feed their stock round:—I will suppose them to have 200 ewes, from which they rear 200 lambs, 100 ewes, and 100 males, and that they dispose of one hundred of each every year. Now, if the

wethers are sold at two-year-old, after the second clip, and 100 ewes in the autumn, there will be 500 fleeces to sell every year; that is to say, 200 ewe fleeces, 200 hoggets, and 100 wethers, their second fleece: any loss in carcass or gain in wool is then to be balanced. Suppose the comparison to be made between a South-down flock and a Merino, under the same mode of treatment, I will give here a calculation which I think a fair one; at all events, it will lead the way to a fair investigation. The growth of Merino wool I take from my own flock of this year's clip. It is to be observed, the wool is unwashed

		lbs.	Average.
		lbs. oz.	lbs. oz.
Ewe fleeces	333	2372	7 2
Hogget ditto	145	1392	9 9½
Wether ditto	142	1460	10 4
Rams	22	286	13 0
		642	5510
			Av. 8 2

On this data 500 fleeces will produce 4281 lbs. of wool, &c. which I will here suppose to be sold at 1s. 6d. per pound, being for the whole £321 1s. 6d. or for each fleece 12s. 11d. The weight of the South-down fleeces I average as follows, and having had for many years a South-down flock which I treated in the same manner, I think I can rely upon my statement being a fair one, viz.—ewes, 3 lbs.; wethers and hoggets, 4½ lbs. I know that some breeders carry the quantity higher, but I never did on the average of the whole flock, and I think many flocks do not equal it.—The account will stand thus:—

200 Ewes, at 3 lbs.	600 lbs.
300 Wethers and hoggets, at 4½ lbs.	1350 lbs.

Now, by a singular coincidence (for I can discern no reason for it), I have almost invariably sold my unwashed wool for the average price of the South-down washed wool, and have this year sold for 1s. 6d., which is about the price the South-down wool sells for. The account will be for the total of the wool £146 5s.; or per fleece averaging 3 lbs. 14 oz. say in money 6s., and the balance on the wool account in favour of the Merino flocks will be £174 16s. 6d.

Merino	£321 1 6
South-downs	146 5 0

Balance	£174 16 6
Or per head Merino	12s. 11d.
South-downs	6s. 0d.

Balance 6s. 11d. per fleece.

We see here how large a balance the South-down flock has to contend against in the article of wool; there being only two hundred carcasses to sell annually, 17s. 6d. more must be produced on each carcass to make up this difference. If the mutton will sell for the same price, and the market gives even 5s. per stone, it requires 3½ stone; and at the present time, as much more as the price is lower than 5s. But suppose the comparison was made individually, the second fleece being taken off the wethers, the South-down must exceed, in value of carcass, the Merino, to the amount of 13s. 10d. to balance the inferiority of wool, and the ewes must sell proportionally higher; and I think the South-down breed will not accomplish such an equivalent in either case: indeed, the depression in the price of wool might be carried further, if equally, on the South-down and Merino and the latter would still have the advantage. I have sold at 1s. 3d. in the grease, and by comparison with the South-down, under similar depression, I am now quite satisfied. I cannot doubt, especially as considering the circum-

ances stated in the former part of this letter, respecting the quantity and use of British Merino wool, that it did always bear a price as much higher than South-down as at present. As to quality, I affirm that I can find, on all occasions, as good a price for the Merino mutton as any other, but I will admit a loss of a stone or a half on the carcass in weight, and that they have not at present so full a muscle. The colour of the flesh is very bright and clear, and cooks remarkably well; they carry a large proportion of inside fat, but the carcass, altogether, weighs light in proportion to size: these are, however, defects to be remedied in time, by judicious selection. It cannot be done certainly as soon as if we had large numbers to draw from; but I have already made such an advance as affords *proof* of the practicability of accomplishing, eventually, as much improvement in this breed of sheep, in these particulars, as has been made in any other. I do not think it necessary to give any detailed estimate of flocks under a different system of management: if the others are sold when lambs, the proportionate number of fleeces and carcasses will be different; but the same mode of calculation being pursued, the *true* result will be found, instead of that which, being drawn from a comparison of individuals, is completely fallacious: neither will I attempt any comparative estimate of value with the long-woolled sheep of the *richest* pasture districts, because I do not think it desirable to stock such grounds with any other sort. I have seen some crosses between Merino and Leicester producing a most useful fleece and good carcass, and well calculated to graze the Midland districts. The wool of this cross is available for many articles of our manufacture, and which are in great demand. As to the treatment of the Merino sheep, generally, I have nothing to say because they appear to me to require nothing different from that which is due to others, except, indeed, that as they stand more in need of *improvement* than the South-down, for instance, they ought to be more attended to, and better fed, and less worked, if folding forms a part of the system. I think them as healthy as any other; quite as free from diseases to which sheep are liable, but I have no opportunity of knowing whether they could bear the mountainous districts of the North. As far as my experience goes, they seem not to regard the cold more than any other; they eat dry meat, and even straw, with great avidity: they do well upon turnips, and in my irrigated meadows thrive exceedingly.

Thus have I occupied in this statement more space than may be convenient for you to spare, but I have been unable to render it more concise. I am very fully convinced that the Merino sheep eminently deserve the attention of the British farmer, and that by extended cultivation of them the woollen manufactures of the kingdom may be infinitely improved and diversified, and that we may grow a species of wool, such as I have described, fine, long, and strong, which cannot be had elsewhere; and from which, consequently, various fine articles may be made, which cannot be produced in other countries. In any degree, I contribute to effect this object, shall so far promote the true interest of the country. My farm and flocks are always open to inspection, and my bailiff and shepherd will give every information in their power to those who are anxious to see and judge for themselves.

I am, sir,
Your obt' humble serv't,
CHAS. C. WESTERN.

Extracts from late Numbers of The London Farmer's Journal, received at the Office of the American Farmer.

ON POPULATION.—Supposing the earth to be peopled with one thousand millions of inhabitants, and allowing thirty-three years for a generation, the deaths of each year amount to 30,000,000—of each day, to 82,000—and of each hour, to 3,446. But as the number of deaths to the number of births is as 10 to 12, there are born yearly 36,000,000—daily, 98,650—and hourly, 4,109. Reckoning only three generations to a century, and supposing the world has existed 5700 years, there have been only 172 generations from the Creation, 125 since the Deluge, and 55 since the Christian Æra. Out of every 1000 there die annually 30; and the number of inhabitants of every city and country is renewed every thirty years. Of 200 children, one dies in the birth; but more than one-third of the births die within two years of age. The births are more numerous than the deaths in any given place; and the proportion of the births of male and female are not in a wide disproportion, not an uncertain accidental number, but nearly equal.

King Charles II. asked Stillingfleet how it came about that he always read his sermons before him, when he preached *extempore* elsewhere? He told the King that the awe he felt of so noble an audience made him afraid to trust himself, unless he put his discourse into writing. "But pray, says Stillingfleet, "may I be permitted to ask you a similar question?—Why does your Majesty read your speeches, who can feel no awe from the presence of superiors?" "Why, truly," replied the King, "the question is a fair one, and so shall be my answer. By reading my speech I keep my eye upon the paper; for I have asked supplies from the Commons so heavily, and they have granted them so often, that *we are ashamed to look each other in the face.*"

A singular circumstance occurred lately, at the church of St. Botolph, Aldersgate, London. Two persons, apparently of humble condition, were marrying at the altar, and the clergyman had arrived at that part of the ceremony where he says, "Wilt thou have this woman for thy wedded wife?" when the bridegroom making no reply to this question, the clerk said to him, "You must answer, 'I will.'" Instead of doing so, however, he fixed his eye intently on the clerk, and exclaiming, "I will—but I won't!" took up his hat, and left the church. He was followed out by a person, apparently to expostulate with him, but they were seen no more. The poor girl was quite overcome at the fellow's coarseness, and it was some time before she recovered sufficiently to leave the church with her friends.

Sir Everard Home has recently made some inquiries by way of comparison between the auricular organs of man and quadrupeds. The result of his researches seems to prove that shrill tones, or the upper notes of an instrument, have comparatively little effect in exciting the attention of animals, whilst the full lower tones stimulate them almost to fury. Sir Everard observes, "that the effect of the high notes of the piano-forte upon the great lion in Exeter Change, only called his attention, which was considerable, though he remained silent and motionless. But no sooner were the bass, or lower notes, sounded, than he sprang up, lashed his tail, and yelled violently, and endeavoured to break loose; and became altogether so furious, as to alarm the spectators present. This violent excitement ceased with the discontinuance of the music." The

deep tones of the French horn also produced a similar effect with the lower tones of the piano-forte, on the elephant, and other animals on which the experiment was made.

Editorial Correspondence.

Springdale, December 15th, 1823.

DEAR SIR,

In your paper of the 12th, a writer, under the signature of Philo Agricolas, asks "whether the corn was or was not shelled," which measured one hundred and seventy bushels from an acre in the state of New York.

The extraordinary crop of corn, to which I presume your correspondent alludes, was raised in the summer of 1821, by the Messrs. Pratts, of Madison County, New York,* the crop measured five hundred and two and a half bushels from three acres, making one hundred and sixty-seven and a half per acre, *shelled* corn, (not one hundred and seventy bushels, as Agricolas supposes). The proofs which I have in my possession I consider indisputable. The singular manner in which this crop of corn was planted, will account, in some measure, for the almost incredible yield.

Perhaps if your correspondent saw the inclosed extract of a letter from Earl Stimson to Governor Clinton, in relation to a crop of corn, raised by the former, in the year 1821, the doubts which he has indirectly expressed of one hundred and sixty-seven and a half bushels of *shelled* corn, being raised from one acre, would be removed.

If you will refer to the Winchester paper, (which I suppose you have in your office) you will find our society, gave a premium for a crop, amounting to one hundred and twenty-three bushels of *shelled* corn, from each of two acres.

Respectfully,
WILLIAM M. BARTON.

JOHN S. SKINNER, Esq

Extract from Governor Clinton's letter to Mr. Barton.

The inclosed communication from Mr. Stimson will inform you of his mode of raising corn, in addition to which, he says, I grew about fifty acres of corn in 1821, out of which it was judged that twenty or thirty acres might have been selected, which would produce from one hundred to one hundred and twenty-seven bushels per acre, when fit for the crib. The acre which was selected for premium, produced rising of one hundred and twenty-seven bushels."

Annapolis, Dec. 28th, 1823.

DEAR SIR,

I send you a copy of a receipt for a cheap white paint, which I have had for several years, but never tested it till this fall, and find it admirably calculated to add to the neatness of appearance of cottages, or for any building, when the owner wishes to avoid the expense of painting, as generally practised with oil, white lead &c.—viz. either for inside or outside work take sweet or new milk, two quarts—fresh slacked lime, half a pound—linseed oil, six ounces—burgundy pitch, two ounces and five pounds of Spanish whiting. The lime to be slacked in water, exposed to the air, mixed in about one fourth of the milk. The oil in which the Burgundy pitch is previously dissolved, to be added a little at a time, then the remainder of the milk, and afterwards the whiting. This quantity is enough for twenty or twenty-five square yards, two coats, and the expense trifling. Add lamp black, and ivory black,

* See Am. Far. Vol. 5, page 264.

to make a lead colour. It will be better if ground down with a mullar and slab.

One of the best and cheapest paints for the roof of a house, that I know of, is the gas oil, mixed with stone or shell lime—I usually put about five double handfull of lime into a bucket, containing about four gallons of the gas oil, and then lay it on with a painter's brush; two coats will give you a handsome glossy slate colour, and will be found to be very cheap and durable. Old brick houses nicely whitewashed, with such a roof as above described, have a very neat appearance. The smell of the gas oil is very offensive for a few days, but by choosing a favourable wind, and dry time when putting it on, it will be in a great measure avoided.

Your's respectfully,

R. J. JONES.

“Two of a trade seldom agree.”—The *Tallow Chandlers*, says the Boston Centinel, appear determined to extinguish the *light* which the *Whale-oilmen* have shed on Congress by their memorial for an augmentation of the duty on *tallow*. The former declare that the representations of the latter are over *strained*, and that with all their complainings they have waxed *fat* under existing regulations; while the latter aver, that the former live by a borrowed *light* at their expense, and do not *melt* at the sufferings of their neighbors.

THE FARMER.

BALTIMORE, FRIDAY, JANUARY 9, 1824.

CATTLE MEDICINE.

At the instance of a practical farmer of excellent judgment, the very spirited booksellers, Messrs. Carey & Lea, of Philadelphia, have published a small volume under the following title, which amply and justly indicates the contents of the work:

“A compendium of Cattle Medicine, or practical observations on the Disorders of Cattle and the other domestic animals, except the horse.—With a series of essays on the structure, economy and diseases of horned cattle and sheep, as communicated to the Bath and West of England Society. By JAMES WHITE, late Veterinary Surgeon of the first, or royal dragoons.”

Every farmer, who sets value upon *understanding*—and who does understand his own interest, and values properly the character of his children and family, should have for their amusement and instruction, an *appropriate library*, which should be *well selected*, rather than *voluminous*, and should have reference to the calling his children are destined to pursue, and the station they are destined to hold in society. The book in question, would necessarily make part of every *farmer's* library. At all events, there is on every farm, such frequent occasion to treat cattle, sheep and hogs for various diseases and accidents, which if not soon removed, are sure to destroy—that every one should have this volume within his reach, at a moment's warning.

It may be had in this city of E. J. Coale, Esq. price 87½ cents.

SEED SENT TO THE EDITOR OF THE AMERICAN FARMER FOR DISTRIBUTION—SINCE OUR LAST REPORT.

Fort Osage, (Mi.) Nov. 24, 1823.

SIR,

I send you two small parcels of buffalo or rabbit berries, recently brought from the Up-

per Missouri, near the Recara Towns, where they are found in great abundance.

The tree is of the size of a common plum tree, is described as being very pretty, and when loaded with ripe fruit, exceedingly rich and beautiful. The fruit is much like the red currant, though much larger, and is said to be very delicious and wholesome. If I am not misinformed, this fruit is quite equal to the cranberry and currant for jellies, sauces, tarts, &c. and will certainly be a very valuable addition to our cultivated fruits, if it can be raised from the seed; which I am pretty sure can be done. It is found growing most luxuriantly on the sand flats, near the Missouri, where there is a mixture of sand, and river slime and mud; but it also grows well on the uplands, and, indeed, seems to be thrifty in almost any situation on the river. There is some mention of this fruit in “the Journal of Lewis and Clark's expedition,” particularly in pages 51 and 114.—1st Vol.

Respectfully,

Your most ob't serv't,

G. C. SIBLY.

Extract of a letter from Dr. J. S. Bellinger, of Burnwell District, S. C.

SIR—“I send you a small parcel containing Guinea grass seed of this year's growth. I had this season, seed from what may be termed the volunteer seed, being produced from Guinea grass which had come up from the *shelling* of the seed the year before. I also send you a small parcel of the sword bean.”

In addition to the above the Editor acknowledges the receipt of a quantity of Guinea grass seed from Gen. Thomas Pinckney of South Carolina.

Since our last, no change has occurred in the prices of the articles usually reported in this paper—we have enquired for, but have not heard of any sales of tobacco. The last quotation was made after the most particular enquiry as to each item, and may be taken as a correct account of prices this week. The New York Gazette of the 6th inst. gives the following account of sales of southern and western produce:

“The editors of the Gazette have received from their New Orleans Correspondent the papers of that city to the 16th ult. Their stock of Cotton was fast increasing. Buyers were holding back, although it was supposed the crop would be short. Tobacco went off freely at 4½ for best. The Robert Fulton brought down from Natches nearly 1000 bales of cotton, the price of which is quoted at from 14 to 19 cents. The waters had not reached the desired height. There were in port 25 ships, 51 brigs, 11 schooners and 9 sloops and about 50 sail in the river, bound up—freights of course dull.”

IRELAND.—The Thermometer in Ireland in the months of June, July and August last, did not average sixty degrees, and an unusual quantity of rain fell: the consequence is that the potato crops are very scant, and the article itself of an inferior quality. The potato in Ireland has heretofore been planted altogether with the spade; recently, however, the seed potatoes have, in some instances, been put into the ground with the plough. The crops, last fall, of those put in with the plough would not pay the expense of getting in—and the potatoes were of a quality greatly inferior to those that had been planted with the spade. An eye-witness informs us that so late as the 27th of October

last, travelling from Belfast to Dublin, he saw many acres of *Oats* quite green from the want of sun to ripen them.—*Dem. Press.*

VACCINE INSTITUTION.

The late law of the United States to encourage Vaccination, having been repealed, many persons have been led to believe, that I had entirely abandoned this Institution; while others more unhappily have been induced to suppose that some terrible defect had been discovered in the Kine Pock itself. Both of these impressions are founded in error. Perfect Vaccination continues to be a perfect preventive of the Small Pox; and the genuine Vaccine Matter is still preserved, as heretofore, with the greatest care.

The general prevalence of the Small Pox, and varioloid diseases at this time, in the city of Philadelphia, should not be imputed to the inefficacy of the Kine Pock. These plagues may be justly attributed to the neglect of vaccination, and to the use, that is commonly made of imperfect and adulterated matter. Spurious vaccine matter (of which several distinct varieties are known to me) is always productive of an imperfect kind of vaccination, that unavoidably, leaves the persons concerned liable to be affected by the above mentioned diseases, at any time during life. But I have never yet known any one person to take either the Small Pox or varioloid disease, where genuine vaccine matter was used, and the pock was known to have terminated, in a perfect crust.

Regular supplies of Vaccine Matter from the stock I have preserved here, without any change for nearly twenty-three years, will be forwarded, as engaged, to all persons who have subscribed to this Institution, during the year past—and others who want this remedy from me, with my directions for using it, will be furnished with it regularly, on their paying in advance, or engaging to pay five dollars annually for the same.

All former subscribers to this Institution who have paid ten dollars or less, will please to recollect that the *term of five years*, for which I engaged to supply them with vaccine matter, expired on the first day of January, 1823—as heretofore notified. I will be gratified, nevertheless, to continue to supply them; if they will, at any time, signify to me their willingness to pay the same fees for it, as must necessarily be charged to all persons, who obtain this remedy from this Institution, previous to its permanent establishment, on the liberal plan I proposed: to effect which, no proper exertions on my part shall be wanting.

Should any annual subscriber to this Institution want the seed of medical, or any other rare and useful plants, that can be procured, either in the United States, or from abroad, I will be happy to make this Institution serve as the medium, through which any such seed may be procured, on the lowest terms, if not entirely free of expense. No charge will be made by me for any service I can render in this way. The postage on all letters to me must be paid, otherwise they cannot be received.

JAMES SMITH,

Late Agent of Vaccination }
for the United States. }

Baltimore, January 8th, 1824.

* One hundred and fifty souls are stated in the Bills of Mortality, to have perished by Small Pox in Philadelphia, since the 1st of November last.

AGRICULTURE.

CATTLE,

VARIOUS BREEDS—LARGE OXEN.

[Of neat cattle, there are various races, some best adapted to the yoke—some to a milk dairy—some to a butter dairy—some to the butcher's shambles, and some so ill formed, unthrifty and unprofitable, as to be fit only for hounds and buzzards.

It becomes all farmers, let their number be few or many, to keep such as are best adapted to their particular purposes; and this can only be done by making themselves acquainted with the peculiar properties and propensities of each race.

It is in England, that the most persevering and best directed efforts have been made, to perfect the various breeds, with a view to different purposes; and such has been their success, that it is now understood, that by successive and judicious selections and crossings, a breed of cattle, sheep, or hogs, may in a somewhat longer process of time, be *made up*, possessing any given colour, shape or quality, with almost as much certainty and precision, as the manufacturer can give to the productions of the loom, such stripes and texture as his fancy may suggest.

We shall endeavour to give our readers such information, as will enable them to understand the characteristic points of the breeds now most esteemed in that country, beginning with the "Improved short horns," which appear to be more in demand, and to sell for higher prices, than any other family of cattle at this time.—They were formerly found in greatest numbers and perfection in the county of Durham, on both sides of the river Tees, and hence the appellation of the Tees water breed. But this breed has of late years been greatly improved upon, and of this stock, so meliorated "THE IMPROVED SHORT HORN," is now the established and appropriate designation.

It is already known to the readers of the American Farmer, that we have this breed of cattle, in their greatest purity and perfection.—In Massachusetts, on the estates of Samuel Jacques, Esq. of Charlestown, owner of Cælebs, and Stephen Williams, Esq. of Northborough, owner of Denton—also a bull presented to the Massachusetts Agricultural Society, by Admiral Coffin of the British Navy, a native of Massachusetts. In Pennsylvania, the only full blood stock of this breed, male and female, that we know of, are in the hands of Col. J. H. Powel, and in Maryland at Wye farm, the elegant estate of Col. Lloyd, of the Senate of the U. S. may be seen the bull Champion, and heifers White Rose, and Shepherdess, imported in the spring of 1822, by the Editor of this paper, from Charles Champion, Esq. from whom Gen. Van Ranselaer, has ordered a bull and two heifers, to enrich and ornament his vast estates in the state of New York.

The following is the pedigree of Col. Lloyd's bull Champion, as given in his letter to J. S. Skinner, dated 6th of April, 1822.

"I had named him *Blythe Union*, in consequence of being bred both from Colling's and Coats' best blood, but I request you will give him any name you think most suitable; if you think he deserves it, I shall be proud for him to be named the *Champion*: he was got by Warrior, for whose dam I paid Mr. Robert Colling 200 guineas, his dam was by Blythe Comet, whose dam I bought at Mr. Charles Colling's sale, for 170 guineas. Blythe Comet was also the sire of the ox in my group of animals which you have, and he was bred in and in from Comet, who was sold for 1000 guineas, at Charles Colling's sale

in 1810:—his *gran-dam* was by Mr. George Coats' Palm Flower, who is own brother to my cow Crimson, for which I gave Mr. Coats 100 guineas when 13 years old, and Crimson is the dam of my bull Blaze, by Blythe Comet, which I am now using, and I hope your two heifers are in calf to him, as he is considered the most complete animal I ever bred, for symmetry and quality.—His *great gran-dam* by Patriot, the bull you named in one of your letters, and which Mr. Coats sold for 500 guineas, so that your bull partakes of Colling's and Coats' best blood."

This calf by Blaze, out of White Rose, came in November 1822, took the premium at our last Agricultural Exhibition in Maryland, under the name "Pilgrim," was sold to Col. Powel on the ground, and now bears at Powelton, near Philadelphia, the name "WYE COMET," of the origin and history of these cattle, we find the following in the "SURVEY OF DURHAM,"]

Edit. Am. Farmer.

THE TEES WATER BREED.

An attempt to improve them, (which I suspect was more with regard to size, than any other quality,) was made by Mr. Michael Dobinson, of the Isle, near Sedgfield, who brought a bull out of Holland, that is said to have improved the breed. A few years after, some other adventurers went over to Holland, and as *great bulk*, was then considered as the criterion of perfection, they brought home a complete lery animal, with immense buttocks, which did a great deal of mischief; but there were some intelligent breeders that steered clear of this evil; and from them the pure Tees water breed has descended to the present time, in which were united the properties of feeding to great weights, and being great milkers.

The visitants of Mr. Bakewell having seen what he had done with the long horns, by selection; and at how much earlier ages they got fattened, were induced to try what could be done by similar means, with the short horns; and several selections were made for this purpose with great success.

The first particular recorded instance of the Tees water breed, for fat and great weight, was an ox of Mr. Hill's, of Blackwell, which was killed at Darlington the 17th December, 1779, at seven years old; the particulars of his weight are as follows:

Two fore quarters	1057
Two hind ditto	1067
Carcase	2124
Tallow	154
Total	2278

* Of these, Mr. Milbank, of Barmingham, and Mr. Croft, of Barford, were the most eminent—and were considered as having the best and purest breed of the district at that period, (about 70 years since;) the colours of their cattle were red and white; and white with a little red about the neck, or roan.

This information was communicated by Mr. Thomas Corner, now near 90 years of age; and Mr. George Culley says, that he has repeatedly heard his father state the same particulars.

The colours of the above being similar to those of the present improved breed of short horns, makes it probable that they are descendants of the same race.

The next was a five years old ox, of Mr. Milbank, of Barmingham, killed at Barnardcastle in April, 1789: he weighed—

	lbs.
Two for quarters	1044½
Two hind ditto	1060
Carcase	2104½
Tallow	224
Total	2328½

This ox being at five years old only 19½ lbs. less than Mr. Hill's ox in weight of carcase, and having five stones more tallow, was certainly of a superior breed for fattening at an early age; and most probably was descended from the breed mentioned by Mr. Corner.

At that period it was thought that no ox could be made properly fat under five years old; and I remember going in the year 1786, to see as a curiosity, a steer 3½ years old, of Mr. Robinson's, of Hutton, that was supposed to weigh 1120 lbs, and had been sold for £20.* But to select a variety to fatten at a much earlier age than had ever yet been obtained, was left to the breeders of the present day to accomplish, who had the judgment to select, what accident threw in their way.

In the spring of the year, Mr. Bassett, of Darlington, purchased a cow, with a bull calf at her foot, and putting her into a good pasture, she got so fat, it induced him to dispose of her to a butcher in the August following, and the calf was sold to a farmer in the neighbourhood. At four years old he was purchased by Mr. Robert Colling, and Mr. Waistell, of Althill, who at that time did not keep a bull for any other purpose than serving their feeding cows; but Mr. Colling finding him have a great propensity to get fat, sold him to his brother Charles Colling, who was then beginning to breed, and anxious of selecting those with the best dispositions to fatten: for the same reasons, and with the same view, he soon after purchased of Mr. Maynard, of Ayreholm, a cow, and a heifer, her daughter.

This bull and cow, selected with so much judgment, are the original stock from which the celebrated Durham ox, and the justly acknowledged superior breeds in the possession of Mr. Charles Colling, Mr. Robert Colling, and Mr. Christopher Mason, are descended.

Messrs. Collings have frequently sold cows and heifers for £100, and bull calves at £100. Mr. Charles Colling has refused £500 for a cow; and in 1807, Mr. Mason refused 700 guineas for a cow.

These gentlemen let bulls out by the year; the prices from 50 to 100 guineas; and the public are so fully convinced of their merits, that these celebrated breeders cannot supply the demand from the PURE BLOOD, which they are as cautious of preserving, as the amateurs of the turf are the breeds of their race horses, and which the takers of bulls are become so well acquainted with, that the prices they give, are in proportion to the good qualities of the individuals, and merits of their progenitors—more regard being paid to their pedigree than to any thing else; for this purpose they have books containing the full pedigree of their stock, similar to the stud book of race horses, by which any person wanting to purchase any of their stock, or to hire bulls, may see how they are descended.

Of the surprisingly fat individuals of this variety, numerous instances might be produced:

* Four and one-fourth pence per pound, was a great price at that time.

I shall select one most deserving of notice, and well known in most parts of the kingdom by the name of

The Durham Ox;

Was bred by Mr. Charles Colling, of Ketton, in the year 1796: his form and nice handling, indicated every disposition to fatten at an early age and the expectations entertained of him by the best judges, were not disappointed: at five years old he was not only covered thick with fat upon all the principal points, but his whole carcase in a manner loaded with it, and was then thought so wonderful an animal, and so far exceeding whatever had been seen before, that he was purchased to be exhibited as a show, by Mr. Bulmer, of Harmby, near Bedale, in February, 1801, for £140: at this time he was thought to weigh 2352 lbs., his live weight being 3024 lbs.: this did not arise from his superior size, as will be seen on comparison in the following table containing

THE DIMENSIONS OF GREAT WEIGHTED OXEN.

Names of Oxen.	Age	Length from horns to rump.	Height at		Girths at		Breath at		Weights of		Carcase.	Tallow.	Hide.
			Crope.	Loin.	Crope.	Belly.	Loins.	Hips.	Shoulder.	Crope.			
	Ft.	In.	Ft.	In.	Ft.	In.	Ft.	In.	Ft.	In.	lbs.	lbs.	lbs.
Blackwell	6	9 5½	6 0	5 8	2 1	10 6	9 7	2 10	2 10	2 10	2124	154	126
Howick Red	7	9 4	6 0	5 10	1 11½	10 0	9 10	2 10	2 10	2 9	2137	231	128
Ditto Mottled	7	9 8	5 10	5 9½	1 7	9 8	10 10	2 11	2 7	2 7	2136	224	137
Barningham	5										2104	224	128
Mr. Charge's	7	8 2	6 2		1 8	10 7	10 10	2 9	3 0½	0½	2362	182	
Mr. Colling's	5	8 4	5 3		1 6	10 0	10 2	2 7	2 7		2352		
Ditto	10										3080		

Mr. Bulmer got a proper carriage made to convey him in, and after travelling with him five weeks, sold him and the carriage at Rotherham, Mr. John Day,

	£	s.	d.
On the 4th of May, 1801, for	250	0	0
On the 14th May, Mr. Day could have sold him for	525	0	0
On the 13th June, for	1000	0	0
On the 8th July, for	2000	0	0

Mr. Day preferred keeping him, persuaded that his merits were such, as would ensure him a greater return: but these prices are strong proofs of his very superior excellence, to whatever had been seen in those districts before.

Mr. Day travelled with him nearly six years, through the principal parts of England and Scotland, and arrived at Oxford, in February, 1807, where on the 19th, the ox by accident dislocated his hip bone, and continued in that state until the 15th April, when he was obliged to be killed; and notwithstanding he must have lost considerably in weight, during this eight weeks of illness, yet his carcase weighed

	lbs.
Four quarters	2522
Tallow	166
Hide	142*

This was his weight at 11 years old, under all the disadvantages of six years travelling in a jolting carriage, and eight weeks of painful illness; had he been kept quietly at Ketton, and properly fed until seven years old, there is little doubt but he would have weighed more than he did at ten years old, at which age Mr. Day states his live weight to be nearly 34 cwt. or

From which if there be taken for offal	3780 pounds	700
Leaves the weight of the carcase	3080 pounds.	

Mr. Charge's ox was of the same breed as the Durham ox, being descended from a bull of Mr. Charles Colling's: he had been unwell for some time before he was killed, which reduced his weight considerably, at least 112 or 140 pounds.

FROM THE NEW ENGLAND FARMER.

The following valuable communication will be highly and justly appreciated by the good sense of American Farmers. It will meet the more attention, and carry with it a greater weight of authority from the important circumstance that the writer has not given us the speculations of theory, but the results of practice. It is a plain unvarnished matter of fact relation of what a cultivator has done, the means, expenses, and profits attending a particular mode of husbandry, and certain rotations of crops in a light sandy loam.

We hope Mr. BUEL will pardon us for printing the following article with his name attached, notwithstanding some objections which he stated: An anonymous article will make less impression, and produce less benefit, other things equal, than one which has the signature of a well known, and respectable author: and we have taken it for granted that Mr. Buel has no insurmountable objection to lending his name to his disinterested and patriotic efforts to benefit the community.

Edit. N. E. Far.

* From Mr. Day's pamphlet, giving an account of this ox, the places he was shewn at, and distance travelled, during the time he was in his possession.

Estimate of the expense and profits of cultivating an acre of sand loam under two different courses of crops.

EXPENSE—FOUR YEARS COURSE.

First Year.

30 loads of long manure, 30 bushels each, at 75 cents	\$22 50
A man one day spreading the same	50
Ploughing \$1, rolling or harrowing 25 cents	1 25
2 days planting	1 00
2 do. harrowing and weeding \$1, boy and horse 25 cents	1 25
2 days ploughing and earthing or hilling	1 00
3 do. cutting and binding	1 50
2 men 1 day carting off and stooking	1 50
4 days husking and cribbing 80 bushels corn	2 00
1 day housing stalks	50
6 quarts seed 12 cents, 1 bushel gypsum 50 cents	62½

\$33 62½

Boy and team half a day harrowing stock ground	50
Ploughing, do.	1 00
Sowing wheat and harrowing in	62½
5 pecks seed, at \$1 25	1 56

Second Year.

2 days cutting and binding wheat	1 00
2 men half a day drawing in do. to barn	75
Threshing 25 bushels at 6 cents per bushel	1 56

\$6 99½

Ploughing and harrowing stubble	1 25
1 lb. turnip seed, and sowing, 88 cents, harrowing in do. 25 cts.	1 12½
10 loads manure and spreading same	7 66
4 days hoeing and thinning turnips	2 00
6 ditto pulling and topping	3 00

\$15 03½

Third Year.

1 day ploughing	1 00
1½ bushels seed barley	1 00
10 lbs. clover seed at 10 cents	1 00
Sowing barley and seeds, half a day	25
Harrowing both ways	50
Harvesting barley \$1, drawing in 75 cents	1 75
Threshing 30 bushels at 4 cents	1 20

\$6 70

Fourth Year.

2 day's cutting one acre clover	1 00
4 do. making hay and carting in	2 00
Rent at \$5 per annum	20 00

\$3 00

20 00

Total expense in 4 years \$85 35

3d Year, clover, do.	40 50
400 bushels ruta бага, at 12½ cents	50 00
	<hr/>
	\$90 50

4th Year, barley	23 75
5th Year, clover	40 50
	<hr/>

Produce in five years	\$248 00
Deduct expense and rent	93 85
	<hr/>

Profit \$154 15
or \$30 83 per annum

I have omitted to charge for threshing corn and pitting ruta бага, and to credit for turnip and ruta бага tops, which may offset against each other. Two bushels of gypsum should also be charged, which is sown upon the two clover crops in the five year course.

It may be well to remark, that potatoes are embraced with Indian corn, in the first year of each course, and that so far as the demand will warrant their culture, they are more profitable, and less exhausting, than corn.

The above estimates are predicated upon my own practice for the last five years, and are as accurate as my memorandums and memory will enable me to make them, except in regard to the price of labor, which is perhaps too low, though it corresponds with average prices.

The propriety of appropriating light loams and sands to convertible husbandry, that is, to a

succession of grain, grass and root crops, is apparent from several considerations. Such soils will seldom give more than two good crops of grass, or grain, in succession, without expensive manuring or top dressing. Hence they are not profitable for permanent grass or tillage. But under good management, and a judicious rotation of crops, they may be made to improve in quality, and to excel in profit: because they can be managed with half the expense in labor that is appropriated to stiff and adhesive soils under tillage. The history of Norfolk husbandry, affords a demonstration of these truths. Flanders exhibits a yet more striking evidence of their correctness. These two districts, which are mostly composed of sands and light loams, surpass all others in neat and profitable husbandry. In both, a rotation of crops is the basis of improvement. In both, summer fallows are nearly abolished; and only resorted to to cleanse a foul soil. In Norfolk, it is a general rule, never to take two white crops (such as wheat, rye, barley or oats) in succession,* while the Flemings are equally scrupulous in the observance of the maxim which enjoins that no field shall lay more than ten days without a crop.† A late traveller remarks, that he saw in a large field, in Flanders grain harvested, and the stubble ploughed and sown with turnips the same day.

I will subjoin a few observations on each of the crops embraced in my system of rotation.— And

1. *Indian Corn.* This not only gives more food to man, and to beast, than any other grain, but it gives more to the soil, in the form of manure, where the stalks are fed in a well constructed yard, as they ever should be. It is less exhausting than other grain; first, because of its broad and expansive system of leaves, which draw largely upon the atmosphere for food; and second, because, under my method of culture, it is cut before the leaves cease to perform this office, and consequently before the grain depends for its nutriment wholly upon the soil. It is peculiarly adapted to a loose, warm soil. Although a profitable crop, on such a soil, when well fed and cleaned, it returns little or no profit from one that is poor, wet or stiff, I make it the basis of my course. It answers all the purposes of a naked summer fallow, in cleaning the ground, and decomposing the soil. Although clay may require to be summer fallowed, for the further purpose of pulverizing a fallow crop, and that a hoed crop, I believe every reflecting man will admit, answers every beneficial purpose on light loams and sands. I spread my manure, and plough about the first of May. I prefer this time, because the clover has then acquired a good growth,—and, turned under with the manure, affords an excellent bed for the roots of the grain, with ample room to range, and abundance of food to nourish. I then, either with the roller or harrow, close the interstices between the furrows, to prevent the escape of the gasses, and to cover the manure from the exhausting influence of the sun and winds. The decay of the roots soon renders the ground permeable to heat, light, air and moisture, which all contribute to promote vegetation. The seed is then planted in hills, at the distance of 30 inches each way. I pass a harrow, at the first dressing, both ways, and with the hoe do little more than destroy the weeds and grass. At the second and last dressing, I plough shallow, and earth or hill slightly, taking care not to disturb the roots, or to bring the manure to the surface. As soon as the grain is glazed, which has been invariably the first week

in September with me, I cut the crop at the surface of the ground, with a hemp hook, laying four hills in a bundle, bind above the ears immediately, take it off the field on sleds, and stook it near my barn—and husk it when convenient. By this course I save labour, double the value of the fodder, and clear my ground in time for wheat. The stooks will not injure if put up wet, the ears keeping the stooks open to the air. The gypsum is sown before the ground is ploughed. All other things alike. I think the clover lay increases the crop from 25 to 30 per cent. and tends to counteract the effects of drought.

2. *Wheat.* The requisites for a wheat crop, are a clear, mellow and rich tilth. If either of these are wanting, or the soil be very porous or sandy, rye should be substituted. If long manure is applied directly to this crop, it introduces weeds and grass; and although the straw may be luxuriant, the grain is often light and shrivelled. If suffered to ferment in the yard, the manure loses nearly half its value in the process. But applied to corn and potatoes in the spring, it enriches these crops by its grosser and more volatile particles, loses its noxious seeds, undergoes fermentation, and becomes by the preparation for the wheat crop, intimately mixed and incorporated with the soil. I harrow down the crowns of the corn hills with a heavy harrow, plough, sow and harrow the seed by passing the harrow both ways.

I think you have remarked, that wheat will not grow in old soils which do not contain lime. I do not doubt but calcareous matter is essential in a good wheat soil. In Europe, it is applied to a great extent, in the form of lime, marl and chalk; and I trust we shall soon become familiar with the use of the two former. It cannot be too often mentioned that clay marls generally abound in sand districts, of no great depth, as if to incite the research and industry of man; and that they constitute the best dressing for the soils which cover them.

3. *Turnips.* These constitute an excellent preparatory crop to barley, as they leave the ground clean and mellow. But how is the crop to be consumed, it will be asked. If near a populous town or village, they will find a ready sale. If not, they may be fed on the ground during all October, November, and part of December, to sheep and cattle. And lastly, they may be buried in pits, like the Swedish turnip, and fed in the spring, when stock are much in want of succulent food. All I raise are taken to market from the field. The best crops which I have ever seen, were taken upon wheat and rye stubbles. Sandy loams are the best turnip soils.

4. *Barley* grows best on sand loams; and on those is more productive and profitable than oats or rye; and the demand for it is likely to increase with the multiplication of our breweries. It is recommended to roll the crop when three or four inches high. The operation induces the plants to throw up additional shoots, and facilitates the growth of the young grasses.

5. *Clover.* Upon this head I have nothing to say, except to reiterate your recommendation from Anderson, that when made into hay, clover should not be spread from the swath, and but slightly from the cock. It is worth 30 per cent. more, when dried in swath and small cocks, than when spread to an intense sun. If intended to stand more than one year, I sow orchard, tall oat, or timothy grass seed with clover. I prefer the two former on account of their early maturity for the scythe.

6. *Ruta Baga.* The value of this plant has lately been subjected to so full a discussion, that I will barely remark, that I have grown it five

* Young.
* Ratcliff's Flemish Husbandry.

years, and am confirmed in the utility of its culture.

Without investigating the physiology of plants, it is enough for the present to observe, that they are furnished with different systems of roots, through which the plants are principally supplied with nourishment; that some of these search for food near the surface, and that others penetrate for it deep in the soil; that some render the soil hard and compact—others loose and friable;—that some plants exhaust the soil, while others fertilize it; and that the object of a rotation is, to make such a selection from different classes, as shall produce the greatest profit to the cultivator, without impoverishing his soil. How far the course I have adopted is calculated to attain this end, I leave for the public to determine. J. BUEL.

TO THE EDITOR OF THE AMERICAN FARMER.

AGRICULTURAL EXHIBITION—AT WASHINGTON, PENNSYLVANIA.

DEAR SIR,

I was much disappointed on learning that in disposition had prevented you crossing the mountains in October last—I had understood from your friend, Judge W—, that he expected you in Pittsburg. He would have accompanied you to this place, to witness our agricultural exhibition. I anticipated no small degree of pleasure, by surprising you with an exhibition far beyond what you would be led to expect in our Backwoods.*

It cannot be expected that you should be able to publish the detailed account of all the exhibitions in our country. Should you, however, find room, we should be pleased, to see this sketch of ours in the Farmer.

The show of animals far surpassed the expectations of the most sanguine members of the association. Twenty-eight stallions, 26 brood mares, 10 colts, 9 bulls, 80 head of cows, heifers, and calves, 23 full blooded merino bucks, 182 full blooded ewes, and 50 lambs were entered, and on the ground. The show of hogs was but small. Several of the stallions were handsome—none of them first rate. Where we had high blood and fine figure, they wanted size. Many of the brood mares were fine; combining both size and form. Some of the colts very promising. The bulls did not come quite up to our expectations—with two or three exceptions, they were barely passable. The cows and calves excited universal admiration. An old English farmer who happened to be present, declared he had rarely ever seen a better collection of cattle. It is but justice to remark that almost every animal, of the cow kind, on the ground, could be traced back to some fine stock, brought into this country about fifteen years ago, by the late William Hoge, Esq. they were then known by the name of

* Nothing, truly, could have been more gratifying than the meeting of friends on such an occasion, in a country comparatively new, rich and flourishing. If our friends in the West, have not yet put in practice all the refinements, in practical husbandry, their exhibitions certainly excel in the display of things solid and useful—many which have been held in older settlements on this side the mountains. The foregoing sketch, condensed, but comprehensive as it is, gives a gratifying view of the extent of agricultural intelligence, and the rapid progress of improvements which invariably result from the association of industry, talent, and enterprise, for common benefit.

Edit. Am. Far.

the "O'Donnell breed." During the last summer, I was repeatedly an eye witness to sixteen quarts of my rich milk being taken from one of these cows at one milking. The sheep exhibited were only distinguishable for the fineness of their fleeces. They are mostly sprung from the flock of William R. Deckenson, Esq. of Stubenville. His flock at this time is believed not to be surpassed by any in the United States.

We had entered on our list no less than 121 separate articles of domestic manufacture. The leading ones were woollen cloths, carpeting, blankets, flannels, casinets, plaids, table linens, plain linens and drilling. Most of these articles were substantial, and some of them excellent. The linen would not have disgraced the looms of old Ireland. A spear grass bonnet made by a Miss McLelland, was much and justly admired. It bore comparison with a real Leghorn, No. 51. In our wheat crops we were rather disappointed—forty and a half bushels took the first premium. The applicants for corn had 108, 114, 118, 123, 127, and 132.

Enoch Wright, Esq. took the highest premium for the "best cultivated farm," twenty dollars. This I should consider more honourable to obtain than any granted by the society.

Although the weather was wet and unfavourable, the very numerous concourse of persons who attended on both days, evinces the lively interest that is felt by the great mass of our population in the success of our society. The astonishing improvement that has taken place since its organization has convinced the most credulous, of the solid and permanent advantages arising from these associations, when pursued with spirit and on liberal principles.

I forgot to notice in its proper place, that Mr. Moore produced satisfactory evidence, that his family had manufactured during the last year, 603 yards of cloth—linsey, flannel and linen, amounting in value, to four hundred and seventy-three dollars—for which he got a premium of ten dollars—(very deservedly.)

NATURAL HISTORY.—No. 5.

(Continued from page 268.)

3. *Periodical Migration.*—Quadrupeds in general, from their limited power of locomotion, cannot migrate from one country to another, with ease and safety, in order to avoid the variations of temperature which accompany the changes of the seasons. In the same country partial migrations may take place, as we witness in the stag and the roe, which leave the alpine regions at the approach of winter, and seek protection in the more sheltered plains. In America some species of the genus *Dipus* perform still more extensive migrations. Those quadrupeds, however, which have the faculty of flying, as the bats, or swimming, as the seals and whales, may overcome the obstacles which oppose a change of place, and execute safely periodical migrations. Individuals of these tribes are accordingly observed to avoid the extremes of heat and cold, by shifting their situations according to the seasons. The great bat (*Vesperugo noctula*), which inhabits England during the summer, is known to spend its winters in a torpid state in Italy. The Greenland seal forsakes the icy shores which it has frequented during summer, and migrates southwards, at the approach of winter, to Iceland.

The facts which have been ascertained in reference to the periodical migration of quadrupeds, are too few for enabling us to point out the laws by which they are regulated. The movements of birds, however, furnish more interesting results.

The migrations of the feathered tribes have

been the object of popular observation, since the days of the prophet Jeremiah: "For the stork in the heaven knoweth her appointed times; and the turtle, and the crane, and the swallow, observe the time of their coming." (ch. viii. ver. 7). The systematical naturalists have likewise collected many scattered observations, and the subject appears now to be capable of receiving a satisfactory illustration. It is not our intention to enter into any minuteness of detail, regarding the migrations of particular species, but to ascertain the laws of migration, and the circumstances under which it takes place.

Before entering farther upon the subject, it may be proper to state, that the same species which is migratory in one country, is in some cases stationary in another; as the linnet, which is migratory in Greenland, but stationary in Britain. In Britain, both male and female chaffinches are stationary, while in Sweden, the latter are migratory. Some species of the same natural genus are migratory, while others are stationary. Thus the fieldfare is migratory, while the blackbird is permanently resident.

Migrating birds may be divided into two classes, from the different seasons of the year in which they arrive or depart. To the first class will belong those birds which arrive in this country in the spring, and depart from it in autumn, and are termed *Summer Birds of Passage*. The second will include those which arrive in autumn, and depart in spring, and are called *Winter Birds of Passage*.

THE SUMMER BIRDS OF PASSAGE are not confined to any particular order or tribe; nor are they distinguished by similarity of habits. Some of them belong to the division of *Water Fowls*, as the terns and gulls; while others are *Land Birds*, as the swallow and corn-crake. They differ also remarkably with regard to their food. Thus, the hobby is carnivorous; the gulls and terns, piscivorous; the swallow, insectivorous; and the turtle dove and the quail, granivorous. They, however, present one point of resemblance. All of them, during the residence in this country, perform the important offices of pairing, incubation, and rearing their young; and hence may, with propriety, be termed the natives of the country. We hail their arrival as the harbingers of spring, and feel the blank which they leave on their departure, although it is in some measure supplied by another colony of the feathered race, who come to spend with us the dreary months of winter.

THE WINTER BIRDS OF PASSAGE have more points of resemblance among themselves than those of the former division. They chiefly belong to the tribe of water-fowls. None of them are insectivorous, and very few are granivorous. They chiefly frequent the creeks and sheltered bays of the sea, and the inland lakes, or they obtain their food in marshy grounds, or at the margins of springs. When the rigours of the season are over, and when other birds which are stationary are preparing for incubation, these take their departure, to be again succeeded by our summer visitants.

We have stated generally, that our summer and winter birds of passage visit us at stated seasons of the year; that the summer visitants arrive in spring and depart in autumn; and that the winter visitants arrive in autumn and depart in spring. But the different species do not all observe the same periods of arrival and departure. Thus, among the summer birds of passage, the wheat-ear always precedes the swallow, while the swallow arrives before the martin, and the martin before the corn-crake. Among the winter birds of passage, simi-

the differences in the time of arrival are observable. Thus the woodcock precedes the fieldfare and the fieldfare the redwing. The periods of departure have not been observed with such attention, as the subjects have then lost their novelty, so that we do not readily perceive their absence. It is probable, however, that in their departure, as well as their arrival, each species has its particular period.

The periods of arrival and departure, even in the same species, do not always take place at exactly the same day, or even month of the year. In different years these vary several weeks or even months, and evidently depend on very obvious circumstances. The meanest rustic, in regard to the summer birds of passage, is aware, that cold weather prevents the arrival of these messengers of spring; and that the early arrival of our winter birds of passage indicates a proportionally early winter. The same circumstances of temperature which retard our summer visitants also check the progress of vegetation. Hence, in all probability, we might be able to prognosticate the arrival of these birds, by attending to the time of the leafing or flowering of particular trees or plants. As the state of vegetation depends on the temperature of the season, and the life of insects on the state of vegetation, we may safely conclude, that the movements of the phytivorous and insectivorous birds must be dependent on the condition of plants.

LINNÆUS bestowed some attention on these connected circumstances, in his Calendar of Flora for Sweden; and STILLINGFLEET in that of England. LINNÆUS observed, that the swallow returned to Sweden when the bird-cherry came into leaf, and when the wood-anemone flowered. He also found the arrival of the nightingale accompanied with the leafing of the elm. STILLINGFLEET says, that the swallow returns to Norfolk with the leafing of the hazel, and the nightingale with the leafing of the sycamore. It has also been observed, that the cuckoo sings when the marsh marigold blows. It would tend greatly to increase our knowledge of this subject, were observations of this sort multiplied. We earnestly recommend the subject to the attention of the practical naturalist.

Having thus offered a few observations on the periods of arrival and departure of migrating birds, let us now enquire after the places from whence they come, and to which they return. In doing this, it will be proper to bestow some attention on the migration of those birds which merely shift from one part of the island to another. The movements of such birds, though confined within narrow bounds, are probably regulated by the same laws, which, in the other species, produce more extensive migrations, and have the obvious advantage of being easily investigated.

In the inland districts of Scotland, the lapwings make their appearance about the end of February or the beginning of March, and, after fulfilling the purposes of incubation, hasten to the sea-shore, there to spend the winter, and to support themselves by picking up the small crustacea from among the rejectamenta of the sea. These birds seldom, however, remain all winter on the Scottish shores, though they are always to be found at that season on the southern English shores. In that part of the island they do not perform such extensive migrations, but may with propriety be considered as resident birds. The curlew arrives at the inland districts along with the lapwing, and departs in company about the beginning of August. The curlew, however, remains, on the Scottish shores during the winter. The oyster-catcher, though

it breeds in Scotland, retires to the English shores during the winter, and joins those which have remained there during the breeding season. The black headed gull breeds both in England and Scotland; but it retires from the last mentioned country, while it continues resident in the former.

From the examples quoted, it appears that some birds, which are stationary in one district, are migratory in another. But that which chiefly merits our consideration is the circumstance of those birds, whose annual migrations are confined to our own shores, forsaking the high grounds on the decline of summer, and seeking for protection at a lower level, and in a warmer situation. When these migrations become more extensive, the bleak moors and shores of Scotland are exchanged for the warmer and more genial climate of England. Hence it happens, that some of our Scottish summer visitants come from England, while some of the English winter visitants come from Scotland; the summer birds of passage coming from the south, and the winter passengers from the north. Do those birds that perform more extensive migrations obey the same laws?

As the summer birds of passage are more interesting to us, since they perform the great work of incubation in our country, than the winter birds of passage, which are the harbingers of storms and cold, and only wait the return of spring to take their leave of us, we shall endeavour to find out the winter residence of the former, before we attempt to discover the summer haunts of the latter. Natural history, it is true, is still in too imperfect a state, to enable us to point out with certainty the retreats of all those birds which visit us during summer. But enough appears to be known to enable us to ascertain the laws by which these migrations are regulated in a number of birds; and as the points of resemblance in the movements of the whole are numerous, we can reason from analogy on safer grounds with regard to the remainder.

(To be continued.)

ADVICE TO YOUNG FARMERS.

ON THE APPELLATIVES, QUALITIES, HABITS AND DEFECTS OF HORSES.

(Continued from No. 34, page 267, Vol. 5.)

As for the size of horses, perhaps sixteen hands ought to be the extreme, for whatever purpose, either of saddle or draught. I believe, on the strength of my own experience, and what I more respect, the opinions of men who have had the longest and greatest practice, that all possible advantages may be concentrated within that compass, and numberless disadvantages resulting from over-size, avoided. It has been said, that "a great, good horse, will beat a little one;" and there is no doubt, but where the goodness, in all points, is equal, the largest must be the best; but we generally find, in all animals, that as they advance beyond the usual standard, they lose in symmetry and proportion as they gain in bulk. It is rare to see a man, of six feet high, well shaped. Among horses, perhaps, the smallest size, or ponies, are upon the average, of the truest make. The Latins say, *Inest sua gratia parva*—what is little, is pretty.

A hunter, or charger, should be between fifteen hands, and fifteen three. It is obvious, that in the field, low horses can never clear their leaps so well, or carry a man so gallantly over the country, as those of a commanding size.—The most advantageous height of a hack, is between fourteen and fifteen hands one inch. A lady's horse, either for road or field, should

never exceed fifteen. The convenience of ponies and galloways, for the summer season, and their inconvenience, in deep roads and dirty weather, are in the way of every body's observation.

It is a truth, like numberless others, much better known than practised, that horses should never be put to severe labour whilst young. Our doing so much violence to their strength, in this country, whilst their sinews are yet too flexible and tender, and have not acquired due substance and tensity, is the occasion of their growing old so soon, and becoming at such a premature period of their lives, totally unfit for any, but the lowest drudgery. We have had some instances of horses reaching forty years of age, but thirty seems to be, in general their latest period; and it may be compared to the human date of three-score and ten. As man is in the flower of his strength, from thirty-five to forty years of age; by a parity of reasoning, our horses would be in the highest state of perfection, for strength, toughness, vigour, and expertness at their business, from ten to fifteen, were we honest and humane enough, to allow them the fair chances of existence. That such theory will not treacherously abandon us in practice, as is too often the case, I have reason to be convinced, from some pleasing experiments of my own, and from the observation of those of other people. What a happy plan, where we can make humanity and interest coincide—but they do not always coincide! What a saving to individuals, and the country at large, to double almost the period of service in that vast number of our horses, which are now prematurely torn to pieces, and destroyed. I shall embrace every opportunity which presents, in the course of this work, to point out the means most conducive to this desirable end.

Horses for slow-draft (the least injurious of all their labour) may be put to gentle work, in careful hands, even at two years old, without sustaining any injury; and it is the custom of the country: but great care ought to be taken, never to put them upon long and heavy jobs, or subject them to heats and colds, and piercing winds; and, in particular, not to strain them at dead pulls; for amongst an infinity of accidents, to which, in that green age, they are liable, hurts in the loins are to be apprehended, from which they never after recover. Every body will tell you that road-horses and hunters should not be worked until five years old; and it is most true: the latter, indeed, ought not to endure many severe runs, the first season. But it is not enough, that young horses are not worked hard; that is to say, ridden fast, or long journeys; for whatever bone they may have, no high weight ought to come upon their backs, until they have attained, at least, five years' growth. From the improvident custom of over-weighting them too early, even if they are ridden slow, arise wind-galls, splents, spavins, weakness of the joints, and that common tribe of defects, which are the consequence of over-stretched ligaments.

The English have been ridiculed by foreigners, for "making curtains," both upon their kings and their horses. As to those made upon the latter, I think there can be no doubt of the utility. Long tails, for which some people are such warm advocates, setting aside the incommodity to the rider, of being fanned by them, dirty or clean, do not in their appearance convey that idea of expedition upon which our affections are so bent in this country; buckled up, they to be sure have the air *militaire*, but do not look sportsman like, which is our mark. A horse will carry even a better tui tail (a long one I mean) for having been docked; and it is an old opinion, which carries a shew of reason with it, that by abridging the tails, you strengthen the loins of

horses. As what I have to say upon the tails of horses, is of a general nature, I may as well say it in this place, and have done with it. It has ever been my favourite study, when leisure was permitted me, to endeavour by all feasible means, to lessen the miseries of animals, and it is true, this principle has often forced me to turn executioner. I had heard of many accidents, some of them fatal, from horses being docked at too late a period, and by bungling blacksmiths; and indeed I had seen several operations of the kind, which made me sick. It occurred to me, that colts ought to be docked early, whilst the tail is tender and grisley; which operation I ever afterwards performed, upon my own, myself, with a good sharp kitchen knife, with all possible success, and which I wish to recommend as a general custom. The two last I docked, were, one about three months, the other about three weeks old; the one got by a cart, the other by a bred horse. These colts were perfectly tame and handy, a state in which I always chuse to have them, and whilst eating a few carrots, they suffered me to tie their hair up *secundum artem*, and to make the stroke, which curtailed them in an instant; and with so little pain, that they scarcely left their carrots. The usual quantity taken off, agrees in length with the width of a man's hand; but perhaps it ought to be rather more from the consideration of its being done so early. The bred colt was so indifferent about the matter, that he suffered me, about half an hour afterwards, to lay hold of his tail again, and make a ligature to stop the blood. If a flux of blood be not desired, a ligature may be made, previously to the operation: but in case of plethora, dulness, or heaviness about the head and eyes, it may be presumed that bleeding will benefit the colt, and the wound may be entirely neglected. If any application be thought necessary, nothing is so proper as French brandy. No twitching, trammelling, searing with hot irons, nor any of the barbarous Vulcanian apparatus, is here required; and what will weigh more than all the rest, with certain of my readers—no farrier's bill. (To be continued.)

TO THE EDITOR OF THE AMERICAN FARMER.

HORSE POWER—WHAT DOES IT MEAN?

DEAR SIR,

There is a vast advantage in clear and definite ideas. Indeed nothing useful is to be accomplished without them. We hear every day of steam boats—of machines—of engines—of so many horses power. We meet with a steam engine in this place of so much power—with one in another place, of 50 per cent. more power—of another in a third place, of double the power of the first—and all called a twenty horse power. This leads to, and keeps up great confusion in all the talkers on this subject—but what is much worse, it engenders disputes, and bad feelings, and animosities between purchasers and makers of engines.

Is there any real and fixed standard in this matter? Do have the goodness to request some one of your intelligent correspondents to state clearly the facts. How do you try the power of a horse? How many pounds weight, and in what position; and under what precise circumstances, is any force considered equal to the average power of the horse? A. B.

ANSWER TO THE ABOVE FROM ONE OF OUR MUCH ESTEEMED CORRESPONDENTS.

SIR,

The term "Horse Power," is much more generally used than understood. The consequences is, that impositions are frequently prac-

tised, by designing men, who puff off their machines, as possessing energy far beyond their actual power.

When any animal moves at its greatest speed, it overcomes no resistance, except what results from its own weight; and consequently, in that case, produces no useful effect. If it be resisted by a force equal to its strength, no motion will ensue; and of course, no useful effect be produced. It is then at what is vulgarly called, "a dead pull." Between these extremes, an endless variety of cases may be assumed, in which the animal will overcome any assigned resistance less than its whole strength, and move with a determinate velocity; but which will be diminished in proportion as the resistance is augmented. The question then, is, from having given the greatest velocity of an animal, when moving without resistance, and also the greatest resistance it can counteract, without moving, to determine the velocity with which it should move, and the resistance it should overcome, so that the useful effect may be the greatest possible: or, which amounts to the same, that the velocity with which the animal moves, multiplied into the quantity of resistance overcome, shall be the greatest possible?

Mathematicians demonstrate, and experience proves that when the animal moves with one third of its greatest velocity, without resistance, and overcomes a resistance which is four-ninths of the greatest it can sustain at a dead pull, the useful effect will be the greatest possible. For if either the resistance or velocity be increased beyond those quantities, the other must be diminished in a greater proportion, or else the animal will not be able to continue the action, during the usual hours of daily labour. But examples explain things best.

If a man can just counteract the force of 60 lbs. suspended vertically, by means of a rope, passing over a pulley, and drawn horizontally, at the height of his breast; and if he can walk at the rate of six feet per second, when unresisted; then will the third of six, or two feet per second, (that is one and five-elevenths of a mile per hour,) be the velocity with which he must move, and four-ninths of 60, or 27 lbs. nearly, the resistance he will overcome, when he produces the greatest useful effect—and if we multiply the velocity (2) by the resistance (27) overcome, the result, 54, will be the numerical measure of such a man's power, when exerted in drawing horizontally.

Again, suppose 420 lbs. to be the weight which a stout draught horse can just counteract, when suspended as above, and connected to his collar in the usual way; and that twelve feet per second is his greatest rate of walking when unimpeded; then, according to the above rule, four feet per second, (or two and ten-eleventh miles per hour) will be his rate of moving, and four-ninths of 420, or 187 lbs. nearly, his draught, when the useful effect is the greatest: and consequently, 4 times 187, or 748 will be the measure of one horse power. But we have just seen that 54 is the measure of one man's power, in like circumstances; and 54 being contained nearly 14 times in 748, indicates, that one horse drawing horizontally, is equal to 14 men. Here we may observe, that at a dead pull, seven men would be equivalent to one horse; (for 7 times 60 is 420) but as we suppose the speed of the horse to be double that of the man, it will require double the number, to produce the same useful effect.

Since the number 748 expresses the power of one horse for one second of time; 60 times the same, or 44,880 will express his power for one minute. But on account of friction and other obstacles, let us, with Mr. Watt, take the round

number 44,000, for the measure; and this multiplied by 600, the minutes in 10 hours, will give 26,400,000, for the measure of one horse power during a working day. Let us now compare our horse power with that of a steam engine.

We are told that a hundred weight of coal burned in a steam engine, will raise 20,000 cubic feet of water, 24 feet high. Now, a cubic foot of water weighs 62 1-2 lbs.; and, therefore, 20,000, must weigh 1,250,000 lbs.—This multiplied by 24, the height to which it is raised gives 30,000,000, for the measure of the effect produced; which being divided by 264,000,000, gives eleven and four-elevenths. Hence it appears that 112 lbs. of coals, would, in such an engine, be equivalent to more than eleven days labour of one horse.

Thus it appears, that if the weight in pounds which any agent can raise in one second, be multiplied into the height, in feet, through which it is raised, and the product divided by 734; or if the weight raised in one minute, be multiplied into the height, and divided by 44,000, the quotient, in either case, will express the number of horse power, to which that agent is equivalent. And if the whole weight raised be multiplied into the height, and divided by 26,400,000, the quotient will express the number of days labour of a draught horse, capable of producing the same effect.

Your's &c.

J. D. C.

TO THE EDITOR OF THE AMERICAN FARMER.

December, 27, 1825.

THRASHING MACHINE.

DEAR SIR,

Useful machinery is increasing among us—and that adapted to agricultural purposes, it is believed, notwithstanding the wonders in the world of steam, must continue to depend chiefly on the impetus received from the animal fibre—from bone, muscle and sinew.—There are various ways of applying a horse to a machine; and, no doubt, with different degrees of advantage. The most common is to hook the singletree to the end of a sweep, or lever, passing through the shaft of the main wheel. You often see a horse with his withers between a fork, or a gothick arch, descending from the end of a lever, or the rim of a wheel. Sometimes you see him mounted high upon the top of a verticle wheel, his forehead moving down hill, or on a level, and his hinder feet climbing up hill. Sometimes he is placed upon a platform, framed to the main wheel, either horizontal, or at various angles of inclination.—Thus making him step, as the platform turns under him, either horizontally, or constantly up hill. I have once seen a poor devil fixed inside of a verticle wheel, and one, not of large diameter either, continually loosing the power of his hinder feet, from pushing against a curve, receding upwards, and constantly clawing up his with his fore feet. Every muscle, and sinew, and nerve of the poor devil was on the strain—even to look at him, put me in agony, and I thought the person, who forced him to work thus, deserved the rack.

It is of much, and real consequence to farmers, particularly, sir, to have a clear and intelligible statement, and if practicable, demonstrations, of the mode of applying the power of a horse, with the greatest efficiency to a machine. I once heard a gentleman say he had a machine, which had long been smart labour for six mules, attached in the first described mode—that he had so altered his fixes, as to place three animals on an inclined plane, how, or at what angle of inclination I know not, but that the three kept his machine in full operation, with much less exertion.

and fatigue, than the six had suffered in the mode, here is a secret certainly worth know-

Will you have the goodness to endeavour to get the experience of practical men on this subject. The statement to be really useful, should be full and precise, that any good carpenter will work by its directions. The information required is, the mode of applying the power of one or more horses to machinery with the greatest efficiency.

A SUBSCRIBER.

is being exempted from liability for debt, and favour improvements—lessen ruinous speculations—check nefarious speculations, and promote the moral and monied interests of the community.

A pamphlet, on various subjects of state policy, addressed to the Hon. Alfred Moore, Speaker of the House of Commons of North Carolina, of which the following is an extract, attributed to the pen of Judge Murphy, the author of the extensive plans of internal improvement, now progressing in that state. The plan, that exempting lands from sale for debt, would increase the general wealth of the country, and the happiness of the community, is new to me; but when presented to me, I was instantly impressed with the justice and the importance of it. As intimately connected with agricultural improvements, this brief extract from the concluding part of the pamphlet is offered to the American Farmer.

A. B.]

The laws respecting creditor and debtor must be changed, otherwise the poor are destined never to remain the slaves of the rich, the imprudent to be sacrificed by the cunning, and property to be the sport of nefarious speculation. We must abolish imprisonment for debt; we must exempt the soil of North-Carolina from liability for debt. Let not this change affect existing debts; let society pressure for the change; let the General Assembly fix a distant day, after which if debts be contracted, the creditor shall not look to the person of the debtor, nor to his lands, for satisfaction. And I would go further, and exempt the furniture of his house, a reasonable number of milch cows, of horses to cultivate his farm, his farming utensils, and provision for the support of his family for at least six months. What would be the consequences?

1. The poor would enjoy that equality in society, which the frame of our government promises to them, but which they have never yet enjoyed.

2. The poor class of the community would improve in their social and moral character; they would acquire a sentiment of independence, and cherish, love, and defend their country and its laws.

3. That vile speculation which fattens upon human misery would be in great part suppressed.

4. An effectual check would be given to that extensive system of credit, which is often as injurious to him who gives, as it is to him who receives it.

5. Men would be trusted for their honesty, and not for their property; and in this way, sound morality would be encouraged.

6. The agriculture of the state would improve rapidly; it will derive more encouragement from this change in our laws, than from all the bounties and premiums which the wealth of the state can give. A man will have some heart to build a good house, and to make a

good plantation, when he knows, that let him be unfortunate or imprudent, his house and plantation will remain his own.

7. Emigration would be checked. The poor would become endeared to their native state, and not change their certain condition here; for an uncertain one elsewhere.

8. People from other states would emigrate to North-Carolina.

9. The value of our lands would greatly increase. This may be seen on the Virginia line; where a space of twenty feet makes a difference of one-half in the price of lands.

I love North-Carolina; she gave me birth! her soil covers the bones of my family; and I hope will cover mine. Let us honour her soil. let us render it sacred. Let it neither be taken in execution, nor charged with mortgages nor deeds of trust. Let us impose no restraint on its alienation, but declare it shall remain free from the pollution of debt. Blessed will be the day, when this shall be done! On that day shall the poor man hold up his head and none shall make him afraid; on that day shall the mother wipe the tears from her eyes, and gladness shall be in her heart; on that day will honesty and industry receive a new impulse, and love, respect and reverence for North-Carolina and her laws, be cherished by her people. May you and I, my dear sir, live to see that day! It will be a day of thanksgiving and rejoicing.

Your's,
A Citizen of Orange.

FROM POULSON'S AMERICAN DAILY ADVERTISER.

ECONOMY.

The following is the result of an experiment, actually made in order to ascertain the comparative expense of oil, and candles. An ordinary Glass Lamp, with a flat wick half an inch in breadth, was placed beside a Mould Candle, of the size called sixes, and both allowed to burn 16½ hours without being moved. In that period of time 2 candles and 3-5 were consumed, and a fraction less than one third of a pint of oil. (A pint weighed 15½ ounces, and the quantity consumed was 5 ounces.)

From the experiment, it appears that one gallon of oil will burn 402 hours and 3-5, and that it requires 10 and 3-5 pounds candles, to burn the same time, so that supposing oil to be 75 cents per gallon, it will be equal in expense to Mould Candles, at 7 cents per pound.

As oil may be purchased for less than 75 cents, and in the ordinary use of candles there is a considerable waste from their being moved, it is evident that the advantages on the side of oil are very great.

A HOUSEKEEPER.

TOOTH ACHE.

In consequence of having read an advertisement in the Federal Gazette a few evenings ago, respecting the discovery of a cure for the tooth ache, when produced by its decay, I was induced to obtain a small vial of the Elixir of Acacia and on applying a portion of it, through the medium of a small piece of cotton saturated and placed in the hollow of the tooth, an instantaneous relief was obtained. I can only attribute this wonderful and certain remedy for a most intensely distressing pain to the powerful antiscorbutic and antiseptic qualities of the Elixir, and as such I earnestly recommend it to the attention of the suffering, being convinced from experience that the cure is certain and effectual.

ONE OF THE RELIEVED.

VEVAY WINE.

The present season has been unusually favorable to the culture of the grape, in the neighborhood of this place. About 5,500 gallons of wine have been made by six dressers.

Two situations appear to be particularly favorable for the culture and growth of the vine; one upon the margin of large rivers, and the other upon high elevated places. No part of the globe is better adapted to the culture of the vine, to produce the most exquisite wines, than the rich ground on the margin of the large western rivers—we are pleased to see the exertions made use of to increase the quality and quantity of wine in this neighborhood.—Indiana Register.

The Messrs. Schuyler's, of Troy, have in their possession a pig, of the grass breed, three years old, which weighs *twelve hundred and thirty-two pounds!* He measures nine feet in length, two feet five inches across the back, and round the girth seven feet two inches. If not sold this winter, this pig will be sent to New York in the spring.

THE FARMER.

BALTIMORE, FRIDAY, JANUARY 16, 1824.

MARYLAND AGRICULTURAL SOCIETY.

The monthly meeting of the Board of Trustees, held at the residence of GEN. R. G. HARPER, on Wednesday last, was well attended; and the affairs of the Society, with reference especially to future efforts and exhibitions were canvassed with an earnestness, and in a temper highly promising to the laudable objects of the institution. The memorial to the Legislature of the state, prepared by the President, at the instance of the Society, praying for an act of incorporation, and for pecuniary aid, was submitted, approved, and signed by the members present. The Committee appointed at a former meeting, to prepare a scheme of premiums to be awarded at the next exhibition, begged to be indulged until the next meeting of the Board, as it was found impracticable to come to a satisfactory decision in regard to various subjects; from the uncertainty of the amount of funds which may be at the disposal of the Trustees; depending, as that amount necessarily must do, on the disposition of individual contributors, and the liberality of the Legislature. In the mean time, that uncertainty will have been removed, as each member of the Board, as well as the President of the Society, the Treasurer, and the Recording and Corresponding Secretary will then make a final report of the amount of subscriptions, which each may have collected; and the disposition of the Legislature to grant something in aid of individual exertions for the most important branch of human industry, will have been ascertained by the fate of the proposed appeal to their munificence and good judgments.

In the mean time it is thought to be sufficient to state for present purposes, that besides the objects upon which premiums have been hitherto usually bestowed, the lists will be so extended as to embrace a much greater number and variety of articles than heretofore, particularly under the heads of—

CROPS of all the principal GRAINS and GRASSES—FRUITS, VEGETABLES, and FAMILY DOMESTIC MANUFACTURES, in all their useful varieties—with reference both to quantity, and to quality, as may suit the case.

Besides the premiums to be awarded by the Society, should the desired aid be procured from the Legislature, we are particularly gratified in having it in our power to state, that many gentlemen have concluded to offer *volunteer premiums* of useful pieces of plate, for certain objects to be designated by themselves.

The objects, as far as they have yet been indicated, which will thus attract the reward of private munificence, are

The best sketch of the Natural History of THE MULE, with a comparative estimate of the capacity, expense of keep, power of endurance, and length of life of that animal and

THE HORSE, in reference to the general purposes and labours of a Maryland Farm.

For the BEST CULTIVATED FARM—with a view to clear profit on all the capital employed.

To the farmer who hauls out the GREATEST QUANTITY OF BARN YARD MANURE, in proportion to the force employed, and the number of stock advantageously kept.

To the WIFE of the Farmer, in whose family the GREATEST QUANTITY OF USEFUL FAMILY MANUFACTURES is fabricated in proportion to the number of females and children employed.

To the MANAGER of the farm, on which the GREATEST NUMBER OF DOMESTIC ANIMALS ARE REARED IN THE BEST CONDITION, and in proportion to the number of the breeding stock.

To the Farmer or Manager, who shears the GREATEST QUANTITY OF WOOL, in proportion to the number of the flock, that being not less than twenty.

To the HOUSEWIFE under whose management there shall have been raised, to marketable size, the GREATEST NUMBER OF POULTRY, in proportion to the number of breeding fowls, that being not less than thirty of all sorts.

For a description of the cheapest and best method of REARING STOCK CALVES.

For an acre of the BEST FLAX.

The premiums given in these instances, will consist of silver pitchers, spoons, cans, &c. valued at from 10 to 20 and 30 dollars, in each case. We are not yet at liberty to mention the names of the gentlemen, by whom they will be offered and the object of this general sketch is, to advise other gentlemen, who will doubtless unite in setting to the community, and to other agricultural societies, an example so praiseworthy and patriotic, of the particular subjects already selected for distinction, by the offer of volunteer premiums.

Those inclined to draw attention to, and to promote improvement in any branch of industry, or item of rural or domestic economy, by preferring a special reward in any amount, will please signify their willingness to do so, to J. S. SKINNER, Corresponding Secretary of the society, before the next meeting of the Board.

At 3 o'clock, the Trustees having finished the consideration of the specific business before them were invited to follow their Host to the dining room, where agriculture in all its branches, with the lights shed upon it by modern science, and the savings of time and labour, accomplished by modern improvements in the implements, and the practice of the art, continued to be the favorite, and the animating theme of conversation.

The Trustees finally adjourned to hold their next monthly meeting at the residence of RICHARD CATON, Esq, at 11 o'clock, A. M. on Wednesday the 11th of February—a punctual attendance at that hour, of all the Trustees is particularly requested, as the scheme of premiums will then be submitted; and each particular discussed; and, as finally approved, will be forthwith published for the information of the public.

☞ A letter from Dr. S. McCulloh to Joseph Pope, Jr. in relation to Pope's Threshing Machine, will appear in our next.

BALTIMORE MARKET.

PRICES CURRENT—CORRECTED WEEKLY.

The state of the market enables us to vary our quotations a little this week, and we give the wholesale prices of the following articles:—Wharf Flour, \$5 37½ to \$5 50—Western country

do, from the wagons, \$5 62½—Fine do. \$5 12½—Whiskey, including the barrel 28 cts.—Wheat white, \$1 10 to \$1 20—Red do. \$1 05 to \$1 10—Corn, 34 to 35 cts.—Rye, 43 cts.—Hides, dried, 16 to 20 cts.—Iron, pig, per ton, \$35 to \$40—Country bar, \$90 to \$95—Sheet, \$160 to \$180—Lime, bushel, 30 to 33 cts.—Leather, soal, best 24 to 27 cts.—do. Eastern tan, 18 to 20 cts.—Coal, Virginia, 20 to 25 cts. per bushel—Susquehannah do. per ton, \$20 to \$25—Feathers—35 cts.—Herrings, Susquehannah, \$2 75—Gunpowder, 25 lbs. \$5 to \$5 50—Baltimore manufacture, do. \$5—Shot, all sizes, per cwt. \$8 50—Beef, northern mess, \$10—Cargo, No. 1, \$8 to \$8 50—No. 2, \$6—Baltimore prime, do. 10—Cotton, Louisiana, 16 to 17 cts.—Georgia "pland," 14 to 16 cts.—Alabama, do. 12 to 13 cts.—Cotton yarn, No. 8, 30 cts., with an advance of 1 cent each No. to No. 18—Candles, mould, 12 to 13 cts.—Dipped do. 10 to 11 cts.—Spermaciti, do. 25 cts.—Hops, fresh, 35 to 40 cts.—Tar, barrel, \$1 75—Pitch, \$2—Turpentine soft, \$2 50—Rosin, soft, \$1 50—Beeswax, 30 cts.—Wool, cleaned and assorted, 15 to 20 cts. advance—Merino, full blood, 35 to 40 cts.—Crossed, 28 to 30 cts.—Common country, 20 to 28 cts.

TOBACCO.—A few unimportant sales the last week, and our quotations remain the same as last report.

FOR SALE,

The whole of a Dairy Stock of Cattle, consisting of an Alderney Bull, full bred, and several half bloods, of the Alderney and Devon blood. As the gentleman who offers these cattle, is breaking up the establishment, he will sell them very low, viz.

The full bred Alderney Bull, calved in Baltimore county, five months after the landing of the mother, \$100.

Eight three years, two years, and one year old cows and heifers—each \$30.

These cattle, if offered for sale in England, would probably fetch double the price asked for them here; and the Bull is offered at one half the price the Alderney Bulls sold for when imported.

I offer also for sale, two Bulls, half Devon and half Alderney, three and four years old—the price is sixty dollars each.

I can accommodate any gentleman with three quarter blooded Bulls and Heifers, of the Devon breed, at thirty dollars for each female, and twenty dollars for each male calf, at two months old; or fifty dollars for each female, and forty for each male yearling.

I have for sale the full blooded Stud Horse, *Top Gallant*, five years old.

Enquire of the Editor of the American Farmer, Baltimore, January 10th, 1824.

PIGS FOR SALE.

Farmers who are desirous of improving their breed of Hogs, may purchase from a litter of pigs, obtained this season, from the brood Sow, which took the first premium at the last Maryland Cattle Show. There can be had, five Boars and five Sows, on application to Mr. J. W. Stone, proprietor of the Stone Tavern, at the two mile stone, on the Frederick Turnpike road.

Printed every Friday at \$4 per annum, for JOHN S. SKINNER, Editor, by JOSEPH ROBINSON, on the North West corner of Market and Belvidere streets, Baltimore: where every description of Book and Job Printing is executed with neatness and dispatch—Orders from a distance for PRINTING or BINDING, with proper directions promptly attended to, addressed to J. Robinson, Baltimore.

AGRICULTURE.

ADVICE TO YOUNG FARMERS.

ON THE APPELLETIVES, QUALITIES, HABITS AND DEFECTS OF HORSES.

(Continued from No. 43, page 342, Vol. 5.)

For many years past, the people of this country, have wisely adhered to the natural paces of the horse, which are *walk, trot, canter* and *gallop*. The *canter* is a natural pace, although many horses require to be taught, as is obvious, from colts of a few weeks old performing it in a handsome manner. In former days, when factitious principles of all kinds were in vogue, and were held so indispensable; and when the studies of men seemed to be directed to an inversion of the order of nature, in so many respects; they did not forget to supplant her in the motions of their horses, by forcing them into artificial paces.—Thus Markham, and the old writers, describe *pacing* and *racking*, which they took the pains to teach their horses by cruel and dangerous methods. These motions were a kind of mixture, or confusion of the natural paces, as may be conceived from the mode in which they were taught, namely, by forcing the horses to go with their legs tied. Racking, it seems, was that irregular run, between a trot and a gallop, which we often, at this time, observe a horse to fall into, when badly ridden, and of which many horses acquire the habit. Pacing was not entirely out of vogue in Bracken's days, and I have known one pacing-horse, within my own memory; they called him a natural padder, but his padding seemed to me to proceed either from some defect, or from bad riding.

In Normandy, Mr. Green informed us, a few years since, there are natural padders, which pace six miles per hour, so easily, that a man may ride seventy miles in a day without fatigue. It ought not I think, be St. Thomas's day. To excel he adds, they must be true bred padders, both from the horse and mare.

I shall defer awhile speaking farther of the paces, and proceed to the proper shape and qualifications of saddle-horses. And first, with respect to beauty in horses; strictly speaking, it is the necessary result of symmetry, and exact proportions; but nevertheless, many thorough-shaped horses are not accounted handsome; and more, which have a beautiful and gallant appearance, are far enough from being thoroughly well made. This requires no explanation. In this country, where speed is the first object, provided a horse be well made in the cardinal points, if I may be permitted that expression, or those parts most immediately contributory to action, beauty is taken for granted, by the knowing ones. Has he a large head? Well, he carries it himself; the question is, does he carry it fast, and in a good place? Is he a ragged hipped one? Never mind, he is well filleted.—Goose-rumped? What o'that, he rises well before, and is deep in the girt. There is, however, a very erroneous notion, which has been long current, but most assuredly, is not sterling. It is said, that "horses of all shapes and makes may be goers." This verisimilitude has taken its rise, from horses of rough and displeasing appearances, but in reality, possessing considerable extent in the most material parts, being often endowed with great powers of action. I have heard it was the saying of old Frampton, or old Bracken, or some other great judge, that "horses always go with their shoulders." In truth, no horse with a small, feet, upright shoulder, was ever a goer. Goodness depends so far upon shape, that whenever you have obtained hack, hunter, or racer, right in the material points, you are sure of some

qualification above the common run; you have got either extraordinary speed, or great powers of continuance; which will, again, materially depend upon animal temperament. The material points are, a deep and oblique shoulder, length, width in the quarters, and free course for the wind.

Flatness, and depth, are the basis, or principle of speed; but to produce strength, goodness, and beauty, substance is necessary. So to speak, rotundity, swelling over a deep and flat ground, forms the true shape of a nag; that is most apparent in the counter shoulder, and deep oval quarter.

A hack, or hunter, ought to be shaped, in all points, exactly like a race-horse, bating somewhat of his length; the abatement for the hunter, it is obvious, need not be so considerable.

As to the defects of horses, and parts most liable to defect, here follows a catalogue of the principal; which a man ought to have in his mind's eye, whilst about to make a purchase, more particularly, if unattended with warranty: viz.

Head ill set on, or too long, eyes, age, wolves teeth, bladders in the mouth, gigs, glanders, jogged under the jaw, hide-bound, broken wind, crib-biter or ticker, run-a-way, restiff, vicious, neck-reversed, or cock-throppelled, ewe or deer-necked, shoulder straight and heavy, chest narrow or wide, high on the leg, broken knees, round legs, grease, windgalls, sinews down, splent, oslet, speedy, cut, nock, mallenders, hurt in the joints, toes turned out or in, feet soft or hard, large, small, or deep, quitter, false quarter, ringbone, sand-crack, groggy, founder, thrushes, corns, high goer, daisy-cutter, forelow, shallow girth, hollow-backed, beam-backed, long backed, broken-backed or megrim, light carcass, bursten, ragged hipped, droop-arsed, dutch or round buttocks, hipshot, stifled, lame in whirlbone, shavings bone and bog, curb, thoroughpin, cupped hocks or houghbone, sullenders, sickle-hammed, cut behind, hammer and pinchers or over-reach, wrong-end first, string-halt.

A horse may be good with a large head, provided it shew symmetry, is joined to the neck with a curve, or is wide enough in the upper part of the jaw-bones, to admit of being pulled in, without impeding respiration; otherwise, a heavy, fat head, forebodes dulness and distemper, particularly of the eyes. A long head occasions the horse to bear heavy upon the hand, however good his mouth may be, as soon as his flow of spirits is over. A head too short, as St. Bel observes, detracts from the equipoise of the body; it certainly detracts from the idea of proportion, as well as a too long one; and without alleging any particular inconveniences belonging to it, I think we seldom see a capital horse with a very short head.

The eye should be viewed in a good light, or rather in the sun shine, the examiner standing in the shade. It ought to be bright and transparent, as it were, to the bottom, and free from haze, dulness, or cloud. The dull, or coal-black eye, or that encircled with a blue cloud are precarious. As to external conformation, the eye should be somewhat prominent, without being too full and large; the large glassy eye is always suspicious; as is also the small pig-eye. Thick, moist eye-lids denote a flux of humours. It is easy to distinguish external accidents, of the probable danger of which, it appertains to experience to determine.

It is said, Roman-nosed horses are generally stout and hardy. The term *stout*, in equestrian language, applies invariably to the courage, not the substance of the horse.

The *mouth*, to be perfect, ought to contain the

bit handsomely, and well; and to be of such just temper, as to be able to bear considerable pressure with the snaffle, and yet be sensible of the least directing motion of the rider's hand; also, to be free of wolves teeth, namely, irregular ones, which may cut the tongue, gums, or inside of the lips, in mastication; of gigs and bladders, which get between the teeth; and the teeth themselves, untouched by art. I once purchased a mare, in very low condition, which did not amend, although she did, or indeed was able to do, scarcely any work. She ate little, particularly of hay, which she was observed to take into her mouth, and drop out again, without being able to chew it. On a nearer inspection, it appeared, all her teeth had been filed down; and there is no doubt, but the miserable creature soon sunk under her work, for want of due sustenance. It was with regret, but I was obliged to part with her.

A discharge from the nostrils, even if it be somewhat thick, may be nothing more than a cold; but if it be attended with a swelling of the glands, under the throat, it indicates a disease of some standing, of which the consequence may be both trouble and danger. As to the Glanders, granting the discharge to have been suppressed by art, the disease is indicated by an over quantity of foam in the mouth, by swelling of the glands, and by the deadness of the hair, which will come off with the slightest pull of the fingers.

Broken Wind is discovered by the quick and irregular heaving of the flanks, and a more than ordinary dilatation of the nostrils; sometimes also, by a consumptive appearance of the body. But the usual method of trying the soundness of a horse's wind, is, to cough him; which is performed by pressing the upper part of the wind-pipe, with the finger and thumb. The strong, clear, and full tone of the cough, prove his wind to be sound; if, on the contrary, the note be short, whistling, and husky, the horse is asthmatic, and unsound.—Horses labouring under the worst stage of this disease, are styled, in the language of the repository, Roarers, from the noise they make in work, of very little of which they are capable. Broken-winded mares are generally barren, although I have heard of one, which bred a whole team of horses, after she became asthmatic. Some persuasive and thick-winded horses are, of all others, the strongest, and most thorough-winded. They catch their wind with difficulty at first; but it comes more free and clear, as their action increases.

(To be continued.)

“AGRICULTURAL SOCIETY OF THE VALLEY,” OF SHENANDOAH, VIRGINIA.

From the *Winch. Republican*, of Nov. 15, 1823.

The first cattle show and fair of the Agricultural Society of the Valley was held in this town on Wednesday and Thursday last. It would be difficult to say whether the event exceeded or fell short of public expectation. The exhibition was certainly a respectable one; and when it is recollected that the weather had been extremely adverse for several days previous—that the state of the roads rendered the transportation of animals from the neighbourhood difficult, and from a distance next to impossible—that an unusual and lamentable sickness had deranged the purposes of almost every farmer in this and the neighbouring counties, and that indisposition still confined many members to their homes; add to this that the occasion was a novel and untried one, in which it was doubtful whether success or disappointment, pride or mortification would be its attendants—contingencies which of themselves would intimidate the bold and deter the

timid; add these considerations together, and it may safely be said that the result is a matter of felicitation.

We regret that it has not been in the power of the secretary to furnish us with his minutes of the proceedings of the fair. Knowing the anxiety of our readers on the subject; we also regret that we can only present to them the following imperfect list of the premiums awarded, gathered from an unofficial source:

To Mr. Richard K. Mead, for the best farm,	\$30 00
To Mr. Wm. M. Barton, for the next best	20 00
To Mr. Amos Lupton, for the best two acres of corn,	10 00
To Mr. John W. Page, for the next best	5 00
To Mr. T. F. Nelson, for the best bull,	10 00
To Messrs. John Mackey and Wm. B. Barton, for the two next best, each 5 dollars,	10 00
To Mr. Edward M'Guire, for the best milch cow,	10 00
To Mr. David Ridgeway, for the next best,	5 00
To Mr. Nathan Perkins, for the best boar,	8 00
To Mr. Thomas Cramer, for the best yoke of oxen,	10 00
To Mr. Aaron Hackney, for the next best,	5 00
To Mr. R. D. Glass, for the best brood mare and colt,	10 00
To Mr. Martin Cartmell, for the best barrel of flour,	2 50
To Mr. John Heiskell, for the best plough (Davis's)	5 00
To Mr. John W. Baylis, for the best piece of woollen cloth (less than the measure,)	3 00
To Mr. Amos Lupton, for the next best (full measure,)	4 00
To Messrs. Holmes & Ward, for the best blanketing,	6 00
To Mrs. John W. Baylis, for the best flannel,	6 00
To Mrs. Thomas B. Campbell, for the best carpeting,	6 00
To Mrs. Martin Cartmell, for the best butter,	5 00

Discretionary Premiums.

To Mr. John Heiskell, for corn,	5 00
To Mr. John Macky, for his specimen of stock,	5 00
To Mr. Isaac Christman, for his specimen of stock,	2 50
To Mrs. Judge Holmes, for a reticule made by herself of straw,	1 00
To Miss Brown, of Georgetown, D. C. for do, made by herself of cantelope seed,	1 00
To Mrs. Martha Barton, for a counterpane,	3 00
To Miss Hines, for a counterpane,	3 00
To Miss Newman for a pair of stockings,	1 00
To Mr. Lysle Robinson, for a hearth rug,	2 50
To do, for blanketing,	2 00

[The premiums awarded in plate.]

[In the same paper we have read with much pleasure, a beautiful address from Wm. M. Barton, Esq. Vice President of the society, from which, not having room for the whole, we extract the following practical facts and suggestions, persuaded, that they will be found worthy the particular attention of our readers.]

Edit. Am. Farmer.

When I look around me, and discover many who have grown gray in the cultivation of the soil, and some too, who are known as practical and successful tillers; I can but with diffidence recommend many alterations in our system of farming. Though willing to admit that the

young are too fond of novelty, yet I believe it is equally true that the old are too averse to innovation; they are either too tenacious of ancient customs, or look with too much suspicion and jealousy on the efforts of the rising generation. One grand and prominent error in the agricultural system of Virginia—one which unfortunately bears the sanction of time and the authority of general adoption—is the practice of cultivating extensive farms. I am perfectly satisfied that if correct accounts of profit and loss were kept, it would be found that the proprietors of those unwieldy and unmanageable farms live less comfortably and realize infinitely less than those who concentrate the same labor and attention in one fourth the quantity of ground. You who are candid and who have kept regular accounts of your profits on farms of five or six hundred acres, will acknowledge that your clear gain rarely exceeds five hundred dollars per annum. Now, if you have in grass three fourths of such a sized farm, and from the remaining fourth make annually one thousand dollars, which I am sure ought to be done, is it not the best argument that can be offered in favor of such a curtailment? If you doubt the practicability of realizing so much from so small a quantity, I can only ask of you to suspend your opinions until proofs the most satisfactory can be produced of much larger sums being realized from a smaller quantity of ground. In Saratoga county, New York, there lives a Mr. Stimson, who made in the summer of 1821, two thousand bushels of merchantable corn from twenty acres of land, being an average of one hundred bushels per acre. Among many memoranda which were taken during an excursion to the north, (with the hope that this society could have gleaned from them some information worthy of notice), but two were preserved—the one noticing the extraordinary crop of corn raised by the Messrs. Pratt's, of New York, which is already in possession of the Secretary, and the other an imperfect sketch of the farm of Judge Buel, near the city of Albany. From the one last mentioned, I collect the facts now detailed. The farm of Mr. Buel contains eighty acres: the soil is principally silicious, nearly resembling the poor lands bordering our tide waters; the timber, a stunted pine, with thick undergrowth; the flat land, a wet cold soil in the hands of nature, barren and unproductive. For the last five years the average crop of corn on this farm has been fifteen barrels per acre; the average of wheat, twenty five bushels; of potatoes, four hundred bushels; of ruta bage, or Swedish turnip, five hundred bushels; of mangle wurtzle, upwards of six hundred bushels; and of common American turnips, two hundred bushels. Mr. Buel sold the produce of forty acres of this poor land, in the summer of 1821, for fifteen hundred dollars. Although we must acknowledge that Mr. Stimson and Mr. Buel are among the best practical and most zealous and successful farmers of New York; yet when we are informed that the last mentioned gentleman cultivates land not superior in its natural condition to the poor pine hills of Frederick, from which he produces crops infinitely superior to those on our best lands; we are compelled to draw an inference most unfavorable to our system of farming and general management.

From some rough calculations which I have made, I suppose that on a large portion of the lands forming our eastern states, there are comfortably supported on each square mile, or six hundred and forty acres of land, from twelve to fifteen families. How frequently do we find that a single family subsists on the same quantity of land in Virginia with much difficulty. We can

ascribe this difference to nothing more rationally than to superior skill in agriculture.

Although, gentlemen, of the society, I have already trespassed on your patience much longer than I intended, I cannot refrain from employing the present opportunity to recommend to you, in the strongest terms, the application of green crops as an enricher of your lands. The cost of applying a crop of oats in this way, will rarely exceed, under the most unfavorable circumstances, fifty cents per acre. It is impossible, without the fullest experiments, to say, what the gain may be; but in all human probability it will exceed ten times the cost. No one can for a moment apprehend the least injury to the soil from such an application. I trust, then, that none will, for the sake of saving a trifling expenditure, remain longer in doubt on so important a subject.

Let me also recommend the substitution, in some measure at least, of roots for corn, particularly as a food for milch cows, sheep and hogs.—There is no crop which we cultivate in this country so injurious to our lands; there is none which requires a more constant and uninterrupted attention; and, in fine, there is none which returns so small a profit to the farmer, as the corn crop. By a little superior cultivation, the produce in roots of one acre will go as far as the corn gathered from ten. In the vicinity of Boston resides a Mr. Ingersoll, who has devoted his attention almost exclusively to a piggery, which he has established on a farm containing in all but eighteen acres; on one-third of this, which is the most he ever has in cultivation at one time, he cultivates roots of various kinds, the mangle wurtzle, however, being his favorite. From the produce of this six acres he raises and kills annually one hundred and sixty hogs, which have never averaged him less two hundred and fifty weight each, making the enormous quantity of forty thousand pounds of pork annually. This pork is hardened with corn previous to killing, which he always obtains by the sale of his surplus manure. Then is Mr. Ingersoll realizing more by prudent management from eighteen acres of land, than is made by, with a few exceptions, any farmer in the county of Frederick.

Permit me once more, fellow-citizens, to invite and entreat you to join with us and aid in accomplishing what we have so auspiciously commenced. Rest assured, that, whatever your occupation may be, the surest guarantee to your success is the prosperity of the husbandman. Although in your various careers of honor and usefulness, you may prefer to tread the labyrinth of state—and you to hold converse with other worlds and to expatiate among the wonders of creation—and you to minister relief to bodily diseases—and you to cleanse the corruption of the heart, and shed the light of immortality o'er the gloom of the grave—and you to hold the scales of justice, or to wrest from destruction the violated law;—in all these diversified employments, your chief dependance is on the products of agricultural enterprise. Come, then, and walk into the fields with me, and contemplate nature robed in her own loveliness; abandon for a time the haunts of idleness and dissipation; relinquish the vain and unsatisfying enjoyments of crowded life; come into the country, inhale the pure atmosphere of rural peace and quiet, and taste the genuine sweets of rural philosophy.

American Flannels.—Considerable quantities of flannel will be made this year within 40 miles of Boston.—The New York Mercantile Advertiser says 30,000 pieces:—their authority, they tell us, is good.

FROM THE NEW ENGLAND FARMER.

HORTICULTURE.

The following articles are from a gentleman, who has added experimental to theoretical knowledge, in Horticulture, and has put in practice what he inculcates. We hope that those who cultivate small tracts of ground in the vicinity of large markets will give a particular attention to the subjects here discussed, and derive such advantages from the information contained in these Essays as we are sure will best meet the views of the writer.

Edit. N. E. Far.

1. I apprehend that too little is thought of successive crops the same year, perhaps little known of the practicability of raising them. Through almost the whole of a garden two crops may be raised, in considerable parts of them three, without either crop receiving any considerable injury by it, while the most will be essentially benefitted. And this may be effected with little if any additional expense of manure, especially if the land be dry and sandy. The reason why little if any more manure is required than for one crop, is that the ground is thereby covered, or shaded so much of the time that much less of the richness of the soil, and volatile parts of the manure are carried off by evaporation, or destroyed by chemical changes. I will mention a few successions as specimens for those who have not much ground to till; successions which have been virtually followed for several years with the most encouraging success. Between the hills of corn may be sowed, spinage, lettuce, cabbages, and things of a similar nature, all of which will be out of the way before the corn is sufficiently large to require the space they occupy. Then about mid summer, set out, or plant, in or between the hills of the same corn, French turnips, Ruta Baga, or English turnips, which after the corn is removed will have time to arrive to good perfection.

Between the hills of cucumbers, melons, &c. plant rows or hills of low peas, which will ripen before the vines run much. And as the vines decay set out cabbages or sow English turnips. When peas are sowed, which run upon sticks, raddishes may be raised; and as I mentioned in a former communication, parsnips, which will, in this way make the third crop.* Various other successions might be mentioned; these will serve as introductory, to those who are disposed to make the experiment. It may be proper to observe, that all this may be done on land not under the highest state of cultivation; but which is only in what may be called a good state. And by the way, I will observe that if persons wish to have their vegetables to possess a fine relish, and to be nourishing and healthy, they must never manure them to excess.†

2. Hot houses and hot beds in their proper and appropriate use are good things—away from this they are not to be tolerated. Their legitimate use is to secure the growth and perfection of those things, which in any particular

* See New England Farmer, Vol. i. page 151.

† This observation is doubtless well founded. Sir John Sinclair, says, "when a large portion of dung is used, the vegetable is forced so rapidly, that it is deficient in flavour. A moderate quantity of dung produces a better quality; but vegetables grown luxuriantly in a fresh maiden earth, are the sweetest. In such soil the leaves of the bransica or cabbage tribe are sometimes so superior in quality as to be nearly transparent.—Edit. N. E. Far.

climate could not be otherwise enjoyed. But when they are used to secure particular produce out of season, they diminish instead of increasing the means of good living. A person, for instance, who will take a little pains, may have his cellar filled, and his table ornamented with a great variety of fine fruit, and tasteful vegetables, and all in season in the month of January, at an expense not essentially differing from what it costs to secure a half dozen hot bed cucumbers, which nobody really wants at that season, and which nobody of uncorrupted taste would ever eat, were it not for the most ridiculous of all reasons, that they are out of season. The worst evil, however, is, that having them out of season, little pleasure is derived from them when in season, and when, prejudice to the contrary notwithstanding, they are a most pleasant and healthy refreshment. Every thing is beautiful and good in its season. Expense and labor should be directed to increase the number and enlarge the variety of such things as are good for food, and pleasant to the eye, but not in procuring out of season what God in his great goodness enables us by the warm inference of his own sun to have in great perfection. The sun and kindly influences of the heavens should be permitted to do what they are able to do. And with respect to what can be raised, our exertions should be directed to increasing the number and multiplying the variety, and bettering the quality of vegetable products, not in forcing them upon ourselves, when they are not really wanted, and when from their meagre appearance, had they sense, they would be ashamed to exhibit themselves on our tables.

WEEDS.

3. Were you not, Mr. Editor, acquainted with my little lot, I should not incline to write, what I am about to send you. But, you know my garden is not like the field of the sluggard, all grown over with weeds, though you know I view them in a light somewhat different from the generality of those, who delight in rural employment. That instead of considering them as evils only to be dreaded, I regard them as a kind provision of a wise and good Providence, designed not only as a wholesome food for many of his creatures, but also as a covering for the earth to secure it from the great heat of the Father of Day, when without any interruption he is permitted to pour his rays on its naked and mellow surface. Not to counteract the wisdom of the *Best*, my way is, after preparing the ground and putting in the seed to let the weeds spring up and grow, taking care only to keep them out of the rows and hills, and removing them as they interfere with the growth of vegetables. By this means the earth is early shaded, and a quantity of food raised for swine or cattle surpassing what any person would at first imagine. And what, perhaps, will not till trial is made be readily assented to is, notwithstanding, true. If the experience of four years is sufficient to satisfy me in judging, a garden is kept in such a state as to have the vegetables grow well with less labor than it can by destroying the weeds as soon as they spring out of the ground. But while I would encourage the growth of weeds to protect the ground, and thus help the crops, nothing can be further from my intention than to countenance the idleness and neglect of those who suffer the weeds to choke or shade the plants. All I maintain, is, that weeds are good servants, but like fire, they are bad masters, they must be kept under, but not exterminated. They must be made to hold their proper place and do their proper work, and subserve their proper end. If they are entirely destroyed they can do neither. And who will believe that so

large a portion of the works of God were made in vain. If a person has a regard to the profit of his horticultural labors, and his circumstances will allow of his doing things at the most proper time, he will permit the earth to clothe itself with these light garments, which nature has provided in anticipation of those which she intends for her more staple and substantial dress.

Another advantage from this practice is, the weeds afford a food for the innumerable insects and worms with which the air and earth are at that season filled. And if they do not entirely protect the rising plant from the ravages of these insects, and worms, they in a considerable degree relieve them from the injury they are liable to receive from these destroyers of vegetation.

One considerable objection to this mode of cultivation will present itself to the mind in the appearance a field or garden will exhibit. This, however, in part arises from the influence of imagination. A garden overrun with weeds, is to be sure a disagreeable sight. But this is the case, not because the weeds themselves are destitute of beauty, for many that go under this name are among the handsomest of the vegetable world; but because, from association they carry the mind to the bed of the slothful, who prefers a little more folding of the hands to sleep, to the labor to which the appointment of Providence calls him. When it is perceived that these are drawn into the service and subjected to the control of man, and are made to subserve his interest, to hold their proper place and do their proper work, they immediately appear to become what they really are, a part of that creation, which God pronounced, and all wise men have found to be good. They become indeed the more pleasant, because they are as it were, redeemed from what has generally been considered the wild and unprofitable part of creation, and offer one more proof that where God works, nothing is made in vain.

REMARKS BY THE EDITOR. It will be allowed that the ideas suggested in the above are not only novel but contradictory to the general current of agricultural authority. Writers on husbandry direct the farmer and gardener to wage ceaseless war with weeds, and destroy them if possible while yet in the seed, before they have begun to vegetate. And we believe for common practice, and farming on a pretty extensive scale it is best for the cultivator to destroy weeds when he can most easily effect their destruction. If they are made protectors of the ground against the rays of the sun, they are apt to monopolise the soil to the exclusion of more valuable vegetation. Still we agree with the writer that the soil should never in the summer season, be destitute of a vegetable covering. The action of the sun on the surface of the soil in warm weather disengages and dissipates the volatile and gaseous products which constitute its fertility. This is in a great measure prevented by keeping the ground constantly covered during summer with a vegetable carpet. It is better that this carpet should be composed of vegetables of little value than to suffer the earth to remain without covering of any kind. But at all events, weeds should all be cut down or dug up before their seeds have become ripe, and if their races should become extinct, it will be easy to find substitutes to shade the soil—such as spinage, lettuce, cabbage plants, &c. the seeds of which cost but little, and their produce is more valuable either in shading the soil, or furnishing food for man or beast.

FROM THE CONCORD GAZETTE.

The Trustees of the Society of Middlesex Husbandmen and Manufacturers, report for the information of the Society, that at their annual meeting at Concord, December 31, 1823, they awarded to Col. Joseph Valentine of Hopkinton, the premium of \$10 for having raised the greatest quantity of Indian corn on one acre of land, being 127 bushels and three pecks.

Col. Valentine gives the following account of the mode of cultivation adopted by him, viz :

The quality of the soil is a deep yellow loam, situated on a western declivity and naturally moist. The land has been improved for mowing six years last past, and until the last year it has yielded very heavy crops. In July, 1822, the crop of hay falling below the produce of former years, I thought it expedient to stir the ground. In August following the ground was broken up, and in November it was harrowed and cross ploughed. In the spring of 1823, it was again ploughed and harrowed, and twenty loads of green barn manure, spread equally over it and ploughed in. It was then furrowed in rows about three feet and a half a part, with a large horse plough, the plough going twice in each row to make a deep channel for the compost manure, and also to leave the seed when planted lower than the general surface of the ground. The rows thus prepared, were filled with twenty loads of barn, hog-yard, and night manure, well mixed and pulverised with Smithfield lime: the manure was then levelled, and the kernels of seed placed about ten inches apart width-wise, and four inches lengthwise in the rows and lightly covered with fine mould. The seed was the yellow twelve rowed corn, which was soaked in a strong salt-petre brine, twenty-four hours, and then spread, sprinkled with quick lime and raked over until completely coated with lime. It was ploughed twice and hoed three times. At the last hoeing, the first of July, the suckers were pulled out, and in the fore part of August, the suckers were again pulled away and the false stalks cut up. In hoeing the corn I was particularly careful to loosen the soil and remove the weeds without raising the earth about the stalks as I had usually done. The stalks would average from nine to ten feet high, and were cut the first week in September. The first week in October, the corn was harvested, and carefully measured in baskets by two men who had assisted in cultivating the crop. I directed the same men to take each of them a basket and fill it with ears in the same manner, as when they measured the whole, and to shell and measure the quantity of shelled corn obtained from each basket of ears; the amount of shelled corn from each basket of ears was the same, viz. nineteen quarts, and when turned together and measured, the result was one bushel six quarts and a fraction over, from the two baskets.—By computing the produce of the whole acre from the quantity of ears as measured in the basket, and the amount of shelled contained in a basket of ears, the result is one hundred and twenty seven-bushels and twenty-one quarts of shelled corn. The field in which the above acre was measured contains three acres, one half of which was planted with seed prepared as above described; the other half was planted with seed in its natural state. The corn in every part of the field came up well, and as all the ground was cultivated and manured alike, there could be no difference in the quality of the soil to invite or repel insects and vermin. But that part which was planted with seed in

its natural state, at least one sixth part of the blades were eaten off and destroyed by worms; while in the part planted with seed soaked in brine and coated with lime, not a blade was discovered that had been attacked by them. This is the first experiment I ever made to prove the utility of securing corn against the ravages of worms; by any process applied to the seed. Perhaps the mode above described and pursued by me will not always be attended with the like success. It may, however, be the means of exciting the attention of others who have more leisure and ability than myself to discover and apply a certain remedy for so great a nuisance to the farmer.

EXPENSES OF CULTIVATION.

Four Ploughings,	\$ 5 00
Harrowing,	1 00
Manure, 40 loads,	30 00
Furrowing,	75
Seed,	50
Planting,	4 00
Ploughing and hoeing,	7 50
Cutting stalks,	3 00
Harvesting,	4 00
	<hr/>
	\$55 75

The value of the stalks and fodder I consider equal to a ton and a half of English hay.

NATURAL HISTORY.—No. 6.

(Continued from page 342.)

Periodical Migration.—The swallow, about whose migrations so many idle stories have been propagated and believed, departs from Scotland about the end of September, and from England about the middle of October. In the latter month M. ADANSON observed them on the shores of Africa after their migrations from Europe.—He informs us, however, that they do not build their nests in that country, but only come to spend the winter. M. PRELONG has not only confirmed the observations of ADANSON, in reference to swallows, but has stated, at the same time, that the yellow and grey wagtails visit Senegal at the beginning of winter. The former (*Motacilla flava*) is well known as one of our summer visitants. The nightingale departs from England about the beginning of October, and from the other parts of Europe about the same period. During the winter season it is found in abundance in Lower Egypt, among the thickest coverts, in different parts of the Delta. These birds do not breed in that country, and to the inhabitants are merely winter birds of passage. They arrive in autumn and depart in spring, and at the time of migration are plentiful in the islands of the Archipelago. The quail is another of our summer guests, which has been traced to Africa. A few, indeed, brave the winters of England, and in Portugal they appear to be stationary. But in general they leave this country in autumn, and return in spring. They migrate about the same time from the eastern parts of the Continent of Europe, and visit and revisit in their migrations the shores of the Mediterranean, Sicily, and the islands of the Archipelago.

While these birds perform those extensive migrations which we have here mentioned, others are contented with shorter journeys. Thus, the razor-billed auk (*Alca torda*), and the puffin (*Alca artica*), frequent the coast of Andalusia during the winter season, and return to us in the spring.

These facts, and many others of a similar nature, which might have been stated, enable us to draw the conclusion, that our summer birds of

passage come to us from southern countries, and, after remaining during the warm season, return again to milder regions. A few of our summer visitants may winter in Spain or Portugal; but it appears that in general they migrate to Africa, that unexplored country possessing every variety of surface, and consequently great diversity of climate. It is true that we are unacquainted with the winter retreats of many of our summer birds of passage, particularly of small birds; but as these arrive and depart under similar circumstances with those whose migrations are ascertained, and as the operations which they perform during their residence with us are also similar, we have a right to conclude that they are subject to the same laws, and execute the same movements. What gives weight to this opinion, is the absence of all proof of a summer bird of passage retiring to the north during the winter season.

In proof of the accuracy of the preceding conclusion, we may observe, that it is a fact generally acknowledged, that the summer birds of passage visit the southern parts of the country a few days, or even weeks, before they make their appearance in the northern districts. Thus, the common swallow (*Hirundo rustica*) appears in Sussex about the beginning of the third week of April; while in the neighbourhood of Edinburgh it is seldom seen before the first of May. The cuckoo appears in the same district about the last week of April; in Edinburgh seldom before the second week of May. The reverse of this holds true with these summer visitants at their departure. Thus, dotterels (*Charadrius morinellus*) forsake the Grampians about the beginning of August, and Scotland by the end of that month; while they return to England in September, and remain there even until November. A difference of nearly a month takes place between the departure of the goatsucker (*Caprimulgus Europæus*) from Scotland and from the south of England.

Having thus ascertained the winter haunts of our summer birds of passage, let us now endeavour to find out the summer retreat of our winter visitants. The conclusions which we have already established dispose us to look for these birds in countries situated to the northward.—And as we are much better acquainted with the ornithology of those countries than of Africa, it will be in our power to prosecute our researches with greater certainty of success.

The snow-bunting (*Emberiza nivalis*), which is among the smallest of our winter guests, retires to the hoary mountains of Spitzbergen, Greenland, and Lapland, and there executes the purposes of incubation, making its nest in the fissures of the rocks. In these countries it is therefore a summer visitant, as it retires southward in autumn, to spend the winter in more temperate regions. To the sea-coasts of the same countries, the little auk (*Alca alle*), and the black-billed auk (*Alca pica*), repair for similar purposes as the snow-flake. The woodcock winters with us, but retires in the spring to Sweden, Norway, and Lapland.

The fieldfare and the redwing resemble the woodcock in their migrations, depart at the same season, and retire for similar purposes to the same countries.

These instances may suffice to support the conclusion, that all our winter birds of passage come from northern countries, and that the winter visitants of the south of Europe become the summer visitants of its northern regions. This is evidently an arrangement depending on the same law by which the African winter visitants become the summer birds of passage in Europe.

support of this conclusion it may be mentioned, that, in their progress southward, the winter visitants appear first in the northern and eastern parts of the island, and gradually proceed to the southward and westward. Thus the snow-bunting arrives in the Orkney islands about the end of August, and often proves destructive to the corn fields. It then passes into the mainland of Scotland, and is seldom seen in the Lothians, even in the high grounds, before November. In like manner, the woodcock, which crosses the German Ocean, is first observed on the eastern side of the island, and then by degrees disperses towards the west and south.

That these periodical movements take place, in order to guard against the vicissitudes of the seasons, must appear obvious to all, from the consideration of the facts which have been stated. An early winter brings the migrating birds from the north to this country before their usual time, and an early spring hastens the arrival of our summer visitants. In the beginning of winter the snow-bunting is found only in the high grounds and it descends to a lower level with the increasing severity of the season.

During the autumn, we thus observe a latitudinal movement of many species of birds towards the equator, in search of the temperature congenial to their constitutions, and which the winter of the district of their summer residence could not afford. The autumnal shifting of the feathered tribes, may therefore, with propriety, be termed the *Equatorial Migration*; all those species in which it is observed, returning from the pole towards the equator, each according to limits peculiar to itself.

The vernal shifting takes place with the increasing temperature of the high latitudes, and may be termed the *Polar Migration*, as all the species in which it is observed recede from the equator and approach towards the pole.

The extent of degrees of latitude traversed in these migrations, differs, as we have seen, according to the species, and even in the same species in different parallels of longitude. Thus, the nightingale, in its polar migrations, does not reach the 55° of north latitude in Britain, while in Sweden it reaches to the 60°. Anomalies of this kind cease to excite our surprise, when it is considered, that the *isothermal lines* (or the latitudinal lines under which the mean annual temperature is the same,) are not parallel with the sun's course, or do not observe a regular increase or diminution with the difference of latitude.—Even the *isothermal lines*, (under which the mean heat of summer is the same,) and the *isothermal lines*, (under which the mean heat of winter is the same,) are neither parallel to one another, nor to the isothermal lines. These differences, which HUMBOLDT has investigated with so much success, exercise a powerful influence on the distribution of plants and animals, and regulate the limits of those periodical migrations we have now been considering.

The preceding remarks relate to the equatorial and north polar migrations. Movements depending on the same circumstances, in all probability, take place on the other side of the equator towards the south pole. The Cape swallow (*Hirundo Capensis*), according to the observations of Captain CARMICHAEL, arrives at the southern extremity of Africa in the month of September, the commencement of the summer of that district, and departs again in March or April, on the approach of winter. Reasoning from the analogies of the north polar migrations, we may conclude, that this species of swallow resides the remaining part of the year near the equator,

and that its south polar migrations extend to the Cape of Good Hope.

It appears from these movements of birds, that in the cold season, the polar regions are deserted by some species, and that there is an accumulation of life towards the equator. At another season, the equatorial regions are, in some measure, deserted by their temporary inhabitants, and the polar districts become peopled by the change.

Having now ascertained the period and the direction of these migrations, let us next attend to the act of migration itself, and the circumstances attending the flight.

(To be continued.)

HYDROPHOBIA—SINGULAR EFFECT OF.

Extract of a letter from a farmer of great worth and respectability, in Jefferson County, Virginia, to W. M. Barton, Esq. Vice President of the Agricultural Society of the Valley, dated Nov. 27th, 1823.

"The facts which I related to you, in a late conversation at Washington, in relation to a case of hydrophobia, occurred here several years since, in the instance of a cow, which had received the infection from the bite of a dog, labouring under that dreadful malady:—they passed under my own observation, and although of a most singular and astonishing character, were regarded at the time rather as anomalous, than as symptomatic, or indicative of the hydrophobial disease; and I thought little of the matter until it was recalled to my recollection by your communication to the Editor of the American Farmer, in Vol. 5. No. 1. of his valuable Journal, detailing the effect of the disease, as exhibited in a flock of sheep, in remarkable co-incidence with what I had noticed in the instance of the cow above alluded to. A few weeks after the animal was bitten, (the precise time not recollected) I observed her in the pasture, remote from the herd, accompanied only by the bull—the first circumstance that attracted my attention was her "bold countenance, staring and glassy eyes," with a fixed gaze; but betraying no evidence of ferocity, or a disposition to make battle. In a little time I discovered all those libidinous actions, and veneral inclinations as described by you to have been displayed by the sheep, and her amorous asiduties were unremitting as long as I remained near enough to notice her, which, however, (the scene being a disgusting one) was for a very short space of time. I saw nothing more of the animal for two or three days after the above described scene, when I found her dead *very near the margin of a stream*. Upon inquiry afterwards I was informed by the dairy maid that she continued to milk this cow from the time she was bitten, until the symptoms of hydrophobia became apparent."

[We have conversed with several physicians who have read and seen much of hydrophobia, but have no where witnessed an exhibition of accompanying symptoms, such as are described above—and in number one of this volume. They corroborate each other so strongly, that we deemed it proper to record the cases, as by a comparison and combination of these, and similar ones, scientific and professional men may draw inferences, and establish theories that may prove useful in the medical department. It is with the same view of aiding researches in the natural sciences that we register the following remarks of our correspondent on the subject of superfetation, and the influence of the mother's imagination on the offspring.]—*Edit. Am. Far.*

TO THE EDITOR OF THE AMERICAN FARMER.

PLEASE BEFORE THE HON. CHIEF JUSTICE RATIONAL, IN THE VALE OF KENTUCKY.

Nature, alias } vs. { Superfetation, alias the } upon a }
The Mare and } Quagga & the } writ of }
the Sow. } Wild Boar. } error.

This is a cause which originated with Earl Morton and Doctor Wollaston; was reported to the Royal Society, and was communicated by John Farey, Esq. to the London Farmer's Journal, from which it was copied in the American Farmer, vol. 3, page 308; and no decision having been reported to the Back Woods, it was determined to try the question before we receive extravagant BULLS.

To understand this cause perfectly, the publication referred was read, and although it appeared that two separate actions were originally maintained, the first, the quagga against a sorrel mare, for secretly, fraudulently, and beyond a reasonable period, retaining properties belonging to the said quagga. The second cause was of a chesnut coloured boar of the wild breed, against a black and white sow for the like fraud.

The trial of this cause was objected to on the grounds that none of the parties were within our jurisdiction, but this objection was overruled when NATURE claimed to be heard in every country, and that Chief Justice RATIONAL ought to preside in every clime, and offered to substitute her name in the place of the mare and the sow, and to blend the two actions.

In the opening of this cause on its merits, dame nature urged that the idea of superfetation when not limited to that portion of creation, whose embryo is brought forth in the shell, was such an outrage upon her principles, that she did not know how to meet the question until she heard the arguments of the gentlemen in opposition, that it was her universal and known law, that whatever was conceived was timely brought forth, that an imperfect deposit was (if she might use the expression) converted into all that it would make, and that no portion of it was ever *cabaged*. With this statement she would, for the present, give way, not only to such as were employed on the other side, but to those who might wish to volunteer.

Mr. Surface remarked that he could not say he was, strictly speaking, a volunteer in this cause; that he was requested by his friend Worsted, to establish the doctrine now advanced. That although this cause is not in hearing before a regular court of the realm; yet if the doctrine could be established, he expected to be employed by his friend, in the regular courts of the country. That by the statutes of this state, if my neighbour has a beast which breaks over my lawful fence, I may either kill the beast or bring an action against its owner for damages.

That Mr. Worsted is the breeder of sheep upon a large scale, that one of his neighbors owns a ram of bad fame, who some years since, broke into his close, knocked down his shepherd, beat both of his merino bucks, and took possession of his flock, that his sheep now yield wool of different qualities in the same fleece; that he had no doubt but this bad wool was the breed of this ram of ill fame. That it appears in evidence in the record before us, that the second and third foal of the sorrel mare, were in form perfect horses, and that they only partook in colour and mane of the quagga; that it does seem, that the first foal must have slipped from its warm bed and left a coat

of its hair behind, which adhered to the two subsequent foals. Now if this could have happened in the present case, I shall contend that the same thing may have taken place with Mr. Worsted's lambs.

Mr. Carcase observed that he might truly say he was in a situation similar to Mr. Surface, but that his friend was Squire Broadhorns, who had procured a bull of superior form and blood; yet his calves were not remarkable, except for the size of their horns and tails, resembling in form and color his neighbor's breakfence bull; and that he should, for his friend, bring suit immediately against the owner of the said bull, for the damages sustained in his cattle by previous impregnation; that the doctrine was sufficiently plausible to be adopted without further enquiry, and the facts too strong to be resisted. It is true Mr. Surface's ideas do not go quite deep enough to answer Squire Broadhorns' case, yet adopt any portion of the doctrine, and we must go the whole. It is a trite saying that beauty is but skin deep, yet I have heard it said that ugly goes to the bone, and I am sure there is nothing in this doctrine so beautiful as to prevent its penetrating even to the marrow.

Mr. Wag hoped it would be no intrusion to say a few words, although he was wholly a volunteer in the cause. He was the neighbour of both Mr. Worsted and Squire Broadhorns, but was neither the owner of the ram of bad fame, nor of the breakfence bull, he would, however, inform the court that in his opinion it was not the blood alone of improved breeds which was to make such a revolution in our stock, we must give those improved breeds more attention than our common cattle, or they will not even equal them. Mr. Worsted lets his merinos, half starved, run through the briars, (which he says is good food for them) and pull out nearly half the fleece; here then his fleece is of different growths. Squire Broadhorns lets his quality calves become skeletons about the time the cuckold burrs are ripe, they totter through them, and pull their tails nearly off by the load of burrs which are dragging at their heels, and having to push the stiff iron weeds before them, to get through his pastures, their horns become enlarged, and now by this new doctrine, both of my neighbors expect to shield themselves from that portion of amadversion which always awaits slovenly farmers.

Could I hope to escape being thought censorious, I would further add that this new doctrine must have originated with those who have the improved stock for sale, and expect by awakening the fears of us clodpates, to induce us to send for a greater portion of their breeders. The doctrine I consider, however, about upon a par, with our sassafras nutmegs; and I hope its advocates may derive as much advantage from our invention, as we shall from their discovery.

Dame Nature again urged, that as nothing had been said which seemed to add to the facts already before the court; she would in conclusion, bring to view some facts which must have their weight in proving that superfætation, as presented here, could not take place.

It is well known to all who know any thing about births, that whether a single or plurality of embryos are conceived, that each has its separate secundæ; that this secundæ can never afterwards be penetrated, and that it must soon follow the birth, or death ensues to the mother. If this doctrine be true (and it cannot be controverted) it would seem that nothing was left on which the new theory could rest. But "to make assurance doubly sure,"

we will endeavour to account (and we hope satisfactorily) for the colours of the young, without tracing it to the blood of their most remote ancestors on either side. We must admit that the mare and the sow have imaginations, or at least recollections. Their first offspring was from animals, of which their second and third young partook in colour. Will it seem strange to any reflecting mind, that when the mare again become in season, her recollection dwelt upon the quagga, the only object of her dalliance, that at the second and even third impregnation that she should recollect that her similar; her previous, exquisite sensibilities were first called into action by the quagga?

If this assumption be true the experience, the every day's experience of all observing breeders, is that the young most frequently partake of the colour of animals present at conception, the quagga then being present to the imagination of the mare, his colour was imprinted on the foal.

The same may be said of the sow and her young, and as strong corroborating evidence of this, the third litter was more slightly tinged than the second, owing to the lapse of time having weakened her recollection. Witness also the pious fraud (if I may so speak) which JACOB practised upon LABON, by placing the ring streaked speckled rods before the flocks at the time of their conception. With these views before the court we submit the cause.

The Chief Justice decided that the charge of fraud in this action is without foundation, the colourable pretence, notwithstanding. And this cause is hereby remanded to the society where it came, with instructions to enter up a final decision, not inconsistent with the doctrines which dame Nature, in her discussion, advanced.

A Copy attested—
A BACKWOODSMAN, Clk.

FROM ANOTHER CORRESPONDENT.

"The late Doctor Smith related the following tale of a setter; and from which he maintained that a bitch and a dog may fall passionately in love with each other.

As the Doctor was travelling in Hampshire, the dogs, as usual in country places, ran out barking as he was passing through a village; and amongst them he observed a little ugly cur that was particularly eager to ingratiate himself with a setter bitch that accompanied the Doctor; whilst stopping to water his horse he remarked how amorous the cur continued, and how courteous the setter seemed to her admirer. Provoked to see a creature of *Dido's* high blood so obsequious to such mean addresses, the Doctor drew one of his pistols and shot the cur; he then had the bitch carried on horseback for several miles; from that day, however, she lost her appetite, eat little or nothing—had no inclination to go abroad with her master, or attend to his call, but seemed to pine like a creature in love, and express sensible concern for the loss of her gallant.

Some time after she was coupled to a setter of great excellence, which had been procured with great pains and difficulty—and the Doctor had the greatest caution, that the whelps might be pure and unmixed; yet not a puppy did *dido* bring forth but what was the picture and colour of the Cur that he had so many months before destroyed—and what is still more remarkable, *Dido* never produced a whelp afterwards in her subsequent litters which was not exactly similar to the unfortunate cur, who was her first and murdered lover."

Daniel's Rural Sports, III. 340.

The above is the fact I alluded to in our conversation on this subject—and would be deemed by me conclusive, if the veracity of the Doctor was perfectly established. I have heard many persons of consideration in the world, as well as Doctors, tell things, which if out of the common experience of their auditors were very properly considered—as mistakes—such may, or may not be the case with Dr. Smith. M.

FROM THE NEW YORK GAZETTE.

REMEDY FOR HYDROPHOBIA.

The following interesting notice of the discovery of means to prevent that dreadful disease so frequently consequent upon the bite of a mad dog, is a translation from a German paper of the 2d of November last:—

"All caustic alkalies have, in consequence of the numerous and repeated experiments of Messrs. Von Redi, Fontani, Mederer Von Wuthwehr, and others, been found to possess the property of rendering altogether harmless the poison of the bite of a mad dog. The wound must be well washed, as soon as it can be procured, with *ley*, which, however, must not be stronger than can be borne in the mouth. If it be stronger than this, it has the effect of drawing the edges of the wound together, and preventing the *ley* from being applied to the bottom of the wound, where it might meet with and neutralise the poison."

"It is astonishing," adds the abovementioned paper, "that this, so simple a remedy, should not have been before discovered; and were it published in all the schools and academies of medicine, it would have the effect of saving many valuable lives."

HYDROPHOBIA.

The following mode of curing hydrophobia is certainly novel, and may supercede *scutellaria*.—"An extraordinary surgical operation was performed a few days ago in one of the great hospitals of Paris, upon a man labouring under the dreadful *malady, hydrophobia*. He had for some time manifested the utmost horror for liquids, and showed a disposition to bite whatever came in his way.—The surgeons of the hospital determined to try upon him an experiment which had been found successful when applied to animals. The operation consisted in the introduction of water into the veins, by means of an incision above the wrist. The experiment fully succeeded, as the patient now takes liquids without aversion, betrays no inclination to bite, and is free from fever.

APPARENT EMASCULATION OF SQUIRRELS.

TO THE EDITOR OF THE AMERICAN FARMER,
Charleston, January 9, 1825.

SIR—In your farmer of the 26th Decemr last, I was much pleased with the learned and liberal communication, signed "P. Macaulay" and solicit for your readers some further productions of his pen, which I feel assured will continue to afford them, as it has me, both instruction and amusement. I candidly confess my limited knowledge of comparative anatomy, and admit the facts and positions of your friend; but will excuse me in differing from him in the conclusion drawn from these premises.

Although the adult male squirrel may have the power of occasionally redrawing the testes, and their descent from his abdomen, into their external position; I cannot admit that their apparent emasculation is often, if ever, occasioned by their voluntary agency. The Scrotum

receptacle for the testes, formed by their descent, when eight or nine months old, is so prominent and conspicuous, that it could not contract, or be absorbed, and be totally invisible, under many months after it had been so drawn up by the animal. Now I appeal to the observation of sportsmen, and all who have noticed this peculiarity in the squirrel, whether the part where this apparent defect is discovered, is not as smooth and as uniformly covered with hair, as any other part of the perineum, even in the female squirrel. I appeal to the candour of your correspondent, whether this could possibly be the case, if the scrotum had been voluntarily deprived of its contents, by their being occasionally withdrawn by the squirrel? Even if so drawn up by the muscular power in life, would not that cease to act on the death of the animal; and the relaxation, and prostration that ensues, admit of the immediate return of the testes to their proper position.

Your friend has been pleased to say of my first communication "his acute observation has enabled him to arrive very nearly at a truth, which he could have established, had he been a comparative anatomist," he has been good enough to supply this defect in evidence. From this evidence and from "the case in point" stated in my last, I conclude, that the apparent emasculation of squirrels is a mistake, that this mistake arises from the age of the animal, as these organs are not matured until he is eight or nine months old, the season for his first sexual intercourse. That they then descend to their proper place, and are ever after visible; that although the squirrel may have the power of drawing his testes back again into his body, yet his doing so, is seldom, if ever the cause of his supposed emasculation.

Your's,
SENEX.

TO THE EDITOR OF THE AMERICAN FARMER.

GRAFTING AND BUDDING—SEEDS OF A NATIVE GRASS, &c.

Edgefield, S. C. Pottersville, Jan. 5th, 1823.

DEAR SIR,

I made some experiments, the preceding year, on summer grafting, useful and new to me, at least. At that time I had never read, or heard of this operation being performed in the summer, except with twigs cut the preceding winter. About the first of July, when the growth of some trees had become stationary, I cut a twig of the pear tree, and inserted it on a nursery stock, which readily grew off. I next tried almost every variety of orchard fruits, which succeeded perfectly well. I was induced to make this experiment from the rationality of the theory, it having occurred, upon the slightest reflection, that failures in spring grafting might originate from the dissipation of moisture, by the drying winds peculiar to that season, before the sap of the stock acquires sufficient motion to furnish the graft with due nourishment; but from the rapid motion of the sap in some stocks, with the general moisture of the air during midsummer, the operation would seldom fail; and the result fully proved this conclusion well founded. It next occurred to me that the walnut, fig, and persimmon, which will not succeed in the spring except by mere chance, might now answer upon the same principle of reasoning: I accordingly made the experiment, and succeeded.

To make the success of summer grafting certain, take the twigs to be inserted, from a

tree in which the sap is, as near as possible, stationary; and select a stock, in which the sap has the greatest possible motion. July is the proper time for summer grafting, and indeed the most suitable month of the twelve for that operation. However, the operation may be performed with tolerable success, during the remainder of the summer and the fall months. The information I have suggested in this hasty communication, is of considerable importance to the orchardist; as it will enable him to propagate fruits at any season of the year, whether in bloom, bearing, or casting their leaves. In May and June budding will succeed well, while grafting can be performed successfully, at any time during the remaining part of the year. Such trees should be preferred for summer and fall grafting, unless otherwise objectionable, which continue their growth late in the season. A plum, whose leaf resembles that of the cherry, and is called the cherry plum, brought to this district by Col. C. Brightop, I believe, from N. York, is on this account, well calculated for a stock for plums, peaches, nectarines, and apricots. The wild crab should be generally preferred for the apple.

The foregoing observations may not be new to all your readers, they will doubtless, not only be productive of novelty, but profit to many of them; and as often as any thing of utility occurs, in the course of my practice, I will cheerfully submit it to your disposal.

I have sent you some more of the swamp grass seed, which are calculated to render clayey bogs, and wet land generally, of much value. Last spring I sowed the seed of a grass, from Barnwell district, called the Missouri grass, and esteem it very highly. It is the tenderest grass I have tried; and perhaps the sweetest. The whole summer's growth, not only remaining green till winter, but has continued to throw out fresh shoots from the old joints. At the close of the ensuing season, I hope to be able to give you a better account of its properties, with a few of the seeds.

The theory I suggested to you, in a former letter, for preventing the washing of hilly lands, by horizontal rows of winter grass; practice is daily confirming, you shall be duly apprised of the final result; which, if successful, will prove of incalculable benefit to proprietors of broken land possessed of fertility.

Very desirous of witnessing the successful prosecution of your undertaking,

I remain, your's, &c.

POPE'S THRESHING MACHINE.

Rockland, January 11, 1824.

MR. JOSEPH POPE, JR.

Sir—Your letter of the 5th inst. did not reach me until yesterday, by which, as well as by your letter addressed to Mr. Skinner, published in a late number of the American Farmer, I regret to find that you think you have cause to complain of the opinion, given by the committee on agricultural machinery and implements, relative to the Threshing Machine, exhibited at the late Maryland Cattle Show, as the invention of Mr. Joseph Pope, of Boston; and I should still more regret, if that opinion should have the effect either to lessen the confidence of the public, in the utility of the machine in question, or in any degree to paralyze your efforts to bring it into more general use.

The language used by the committee, under circumstances certainly not the most favourable, to critical accuracy, was intended as descriptive of its leading principle of action, which they considered of Scotch invention, first introduced by Mr. Andrew Mickle, about the year 1772—I allude to the Threshing Drum, or Cylinder, placed in a horizontal position, upon the circumference of which beaters were attached in such a manner, as to endure the necessary motion.—Various have been the contrivances since that period, to apply this principle to the greatest advantage, and the committee certainly considered the machine presented to their examination, as possessing a more happy and successful combination of power connected with this principle, than any heretofore offered. With such claims to the public patronage, they considered it entitled to the premium awarded.

I, therefore, cannot but think, the prejudicial effect apprehended by you, from the clause objected to, will be found to be more hypothetical than real. It is assuredly my wish, that it may prove so, and I believe every member of the committee would concur with me in the sentiment.

Very respectfully,
Your obedient servant,
SAML. McCULLOH.

POPE'S PATENT THRESHING MACHINE, Adapted to Hand or Horse.

The reputation of this machine being established for usefulness, among all those practical and intelligent agriculturists who have witnessed its performance—it is offered for sale.

The Machine is simple in its construction, not liable to get out of order, cheap, powerful, and efficient in its operation; and its thrashing principle will stand the test of the most critical investigation relative to its mechanical combinations for originality in economising power. With the ordinary draught or power of one horse, and with one man to feed the machi-

and another to remove the straw, the inventor guarantees it shall possess capacity to thrash with easy labour, eight bushels of wheat per hour—other grain and seed, such as oats, rye, millet and rice, it will thrash with the same facility. Although the inventor does not wish, from motives of prudence only, to guarantee the performance of the machine, beyond the quantity stated above, it has been proved by the various agricultural societies, who have witnessed its operation, and awarded it their highest premiums, that its capacity is much more extensive.

A single machine adapted to the power of one horse, well made, durable and efficient, can be furnished at \$125.

And a machine is, in every respect, like the above, without the horse gear, to be worked by hand, at \$75.

Privileges of the patent right for making and using this machine in state or county, will be sold on moderate terms, as an inducement to mechanics particularly, to become purchasers; and it will appear obvious, upon examination of this valuable and important invention, that its simple contrivances are immediately understood, and its construction within the reach of any of them.

Notice will be given by agents in the respective states where to apply.

THE FARMER.

BALTIMORE, FRIDAY, JANUARY 23, 1824.

In compliance with the wish of the Trustees of the Maryland Agricultural Society, the Editor went down to Annapolis to explain personally the views of the Board, in relation to their prayer, for an act of incorporation, and for pecuniary aid—but circumstances made it impossible to remain long enough to seek the honour of a personal interview with many of the members; and he was forced to have recourse to the medium of letter communication. The one below was addressed to an honourable member from — county, and as the suggestions it contains, may with equal propriety, be addressed to all, and is altogether confined to a topic of public and general interest, he has concluded to send it to the printer for insertion in the American Farmer.

DEAR SIR,

I much regreted that circumstances did not allow me, personally, during my short stay in Annapolis, last week, to invite your attention, and bespeak your support, to the views of "the MARYLAND AGRICULTURAL SOCIETY," as exhibited in the sketch of a bill, now in the hands of Mr. Chesley. Under a firm persuasion of the substantial benefits that would arise from a wider distribution of premiums, for improvements in agriculture and the various branches of domestic economy; the society pray from the legislature, a small sum, say one thousand dollars, between the two shores, in aid of individual contributions, for the space of five years. The effect of the donation, will then have been fully developed and seen, and the legislature, acting in correspondence with the public sentiment, can renew or withdraw it accordingly.

Should local jealousy, that political *Incubus* which suffocates all who attempt to raise their voice in behalf of internal improvements in Maryland, here again suggest, "my county being more distant, may not derive from this donation,

its full share of benefit," that objection will be readily obviated by the fact, which you are authorised to aver, that the whole sum given by the state will be applied to objects, for which every farmer, and farmer's wife, may compete on equal terms, without regard to locality. For example, take the case of excellence in CROPS, of every kind—grain, grass, fruits, tobacco, culinary vegetables, &c. &c. Claims for these, will be supported by *documentary evidence*, and by judges drawn from every county in the state; so that whether the claimants reside in St. Mary's, in Anne Arundel, or Allegany, in Worcester, in Caroline, or Cæcil, their pretensions will be subjected to the same test, and their merits impartially weighed. The remainder of the donation from the treasury, will be bestowed in rewarding the taste and industry of the fairer and better part of creation, the farmers' wives and daughters, and all the fruits of their emulation, being of small bulk, and of easy and safe transportation, may be exhibited, with comparatively no inconvenience. They will consist chiefly of family domestic fabrics, of every description, in regard to which, as well as to every thing else, coming from near or more distant points; it ought to be considered, that the place and the occasion, constitute for them the most eligible market. It is only in the case of domestic animals, that vicinity to the place of exhibition will confer any advantage, and that is often over balanced by the greater convenience of water transportation from more distant situations. For the premiums in these cases, we shall be indebted, *exclusively*, to individual contributions, nine-tenths of which, be it remembered, are collected in the immediate neighbourhood of the show, and invested in premiums which are freely offered to competitors, from all parts of the state. The project of the law submitted to the agricultural committee, enjoins, that a stipulated sum shall, each year, have been previously collected, by voluntary contribution, and that a detailed report be made by the society on each shore, of the distribution of the funds.

I need not advert to the certainty, with which a laudable feeling of emulation would be excited throughout the country, by the distribution of honorary distinctions in the permanent form of silver vases, goblets, cups, &c. to be transmitted from mother to daughter, and from sir to son, as heir-looms, and bloodless trophies of taste and industry, acquiring veneration with increasing years. In short, sir, it cannot be apprehended, that the legislators of a state, essentially agricultural, will refuse the means to honour and to "speed the plough," that most prolific source of human sustenance, to which even deserts, in all the magnificence of wealth, and pride of power, have seen fit to pay annual and reverential homage.

Allow me to add, that in the great state of New York, the pioneer in all public spirited enterprises, ten thousand dollars have been given for ten successive years, at the instance of that enlightened administrator of her internal resources, Governor Clinton. Should the supporting arm of the state be withdrawn from our infant institution, at the expiration of five years, we may confidently indulge the hope that the conviction of the benefits resulting from the labours of the Maryland Agricultural Society, will have been so widely diffused and so well confirmed, that it may, thereafter, safely rely on the spontaneous offerings of individual patriotism, and on that true discernment which dictated the philanthropic declaration, that

"He who causes two blades of grass to grow, where only one grew before, is entitled to

"more honour and gratitude than the most renowned warrior."

Very truly and respectfully,
Your obedient servant.

CATTLE.—We have been compelled to postpone, for want of room, some additional observations and facts relative to the Improved Short Horn breed of cattle, in continuation of an article on that subject, in our last paper.—It will be followed up in subsequent numbers; and the subject of domestic animals will not be dismissed, until we shall have explained the peculiarities of the various breeds of cattle, horses, and sheep most esteemed, under various circumstances.

ERRATA, in the publication signed "Ruris Consultus." In the 2d column, and 15th line from the bottom read "Planters," instead of "Routers"

In the 3d and last column, and 27th line from the bottom, read "incivism," instead of "incision."

BALTIMORE MARKET.

Burton, Esq.—Horticulture—Method pursued in making a crop of 127 bushels of Indian corn to the acre—Natural History, No. 6, on the migration of birds—Hydrophobia, confirmation of its effect upon the sexual passions—Superfostation, the influence of maternal imagination on the offspring—Apparent emasculation of squirrels—Summer grating, easy and practicable—Reports of tobacco inspections—Pope's Threshing Machine—prices of country produce, &c. &c.

Printed every Friday, at \$4 per annum, for JOHN S. SKINNER, Editor, by JOSEPH ROBINSON, on the North West corner of New and Biddle's streets, Baltimore; where every description of Book and Job Printing is executed with neatness and dispatch—Orders from a distance for PRINTING or BINDING, with particular directions promptly attended to, addressed to J. Robinson, Baltimore.

AGRICULTURE.

CATTLE.

VARIOUS BREEDS—IMPROVED SHORT HORNS.

(Continued from No. 43, Vol. 5, page 338.)

As a specimen of a female of this family, I shall select a near relation of the ox, [mentioned in No. 43.]

A COW OF MR. MASON'S, OF CHILTON.

In point of fat, not less remarkable than the ox. When I saw her in 1808, the depth of fat from her rumps to her hips, in a perpendicular position, was not less than 12 inches; upon her loins and crop, not less than 10 inches; and the shoulder score at least 9 inches thick.

Mr. Robert Colling has a white heifer four years old, a perfect counter part of his brother Charles's ox; being, like him, completely covered over her whole carcass with fat: she is estimated to weigh 1820 lbs.

Of the aptitude to fatten at an early age, I shall select a few instances.

Mr. Robert Colling sold in Darlington market, the 18th of April, 1808, a two years old ox for £22, supposed to weigh 832 lbs.; the price of fat stock at that time being 6d. per lb.

A few days before this, I saw at Mr. Nesham's, of Houghton-le-Spring, an ox two years old in March, 1808, (bred from Mr. Mason's stock,) completely covered with fat over his whole carcass, and supposed to be the fattest ox of his age ever seen: butchers estimated him to weigh 1050 lbs. Neither of these animals were of large size, and would not have weighed above 560 lbs. had they been no fatter than are usually killed for the markets.

Mr. Wetherill, of Field House, sold at the fair in Darlington, the first Monday in March, 1810, two oxen under three years old, for £47 10s. each. The price of fat cattle at this fair was about 8½d. per pound.

Mr. Arrowsmith, of Ferryhill, has for seven years back fed his two-year olds, and sold them to the butchers as follows:—In

	£	s.	d.	
1801, sold 4	for 25	0	0	each. 2 stots* and 2 heif.
1802,	£ for 17	10	0	each. 3 stots and 3 heif.
1803,	4 for 17	0	0	each.
1804,	6 for 18	10	0	each.
1805,	6 for 17	10	0	each. 2 stots and 4 heif.
1806,	4 for 16	0	0	each.
1807,	8 for 18	0	0	each.
1808,	8 for 19	0	0	each.

The time of selling, from the beginning to the latter end of May.

Their management is as follows: In the first winter they get straw in a fold yard, with nearly as many turnips as they can eat; in May they are turned to grass; in November put to turnips through the winter; and turned out to grass the first week in May.

In 1807, and 1808, on account of turnips being scarce and dear, they had four cwts. each of oil cake, from about Candlemas: the price of four cwts. of cake about £3.

A twin heifer calved the last week in April, being kept the first year the same as the common stock, was entered for a sweepstakes to be shewn in June, when two years old, and was then put to grass with other stock of the same age in the usual pasture; in November she was estimated to weigh 392 lbs. when she was put to ruta baga, and hay, and oil cake, of which she eat four cwts. and two bushels of bean meal, and one bushel of barley: went to grass the first of May, and had no oil cake afterwards. On the 3d of July, when she was shewn, it was the unanimous opinion of the best judges, that she weighed 812 or 840 lbs. having gained two pounds per day, for 30 weeks.

In April, 1808, I saw eight yearlings, intended for the same course of feeding: they were then *very lean*, not more than 210 lbs. each; and had they been offered for sale in a fair, no person unacquainted with the breed, would have given more for them than £4 10s. or £5 per head.

Mr. Walton, of Middleton, in Teesdale, has for the last six years sold his oxen about mid-summer, 2½ years old, for £ 0 to £21 each; their weight from 700 to 756 lbs. nett.

Their keeping is as follows: the cows seldom calve sooner than April; the calves get new milk for the first three weeks, after that a moderate quantity of scalded skimmed milk, mixt with oil cake boiled in water, about two quarts of each, along with good hay, for about six weeks; after which they do very well in the pastures without any kind of hand feeding, until the latter end of November, when they are tied up, and fed with straw and turnips until the beginning of April, from which time they get hay till the pastures are ready. The mode of proceeding is exactly the same through the next year, to the time of selling; they never get oil cake or corn.

Mr. Walton has great merit in improving the stock of this district, which was uncommonly bad before he began to hire bulls of Mr. Mason, and to purchase cows of the improved breed.

He sometimes buys in calves of the unimproved or old breed of the country, and finds that his own, at two years old, get fatter and fitter for the butcher than the others do at three, though kept and fed exactly alike.

It is a common practice among the breeders of the improved short horns, and which I first observed at Mr. Wetherill's, of Field House, near Darlington, to put the year old heifers to the bull the beginning of July, so as to calve not later than the middle of May: the calves run

* *Stot is a provincial term applied to a young steer or bullock.*

with, and suck their dams, until August; the cows are then put upon fog, fed through the winter with turnips, and sold to the butchers in May and June following, for £25, on an average, which, with the value of the calf, cannot be reckoned at less than £30 for a three years old heifer.

It has been already stated, that the short horned cattle were great milkers: this cannot be said of the variety which has such an aptitude to fatten, for though they give a great quantity for some time after calving, they decline considerably afterwards; but the variety of great milkers is yet to be found, wherever the dairy is the chief object, and this variety is as carefully preserved and pursued, as the graziers do that of the fatting tribe. It is very common for cows of this breed in the beginning of summer to give thirty quarts a day, and there are particular instances of more. Where the object is selling milk, they are probably superior to any breed in the kingdom; but in respect to butter and cheese, there are some doubts whether they are entitled to claim a superiority or not, as the quantity of those articles does not depend on the quantity of milk.

I was informed by Mr. Walton, of Stanhope, that Mrs. Watson, near that place, got two ounces of butter from a quart of kyloe milk, which is nearly double the quantity that she obtained from a quart of milk of the short horned breed. Mr. Thomas Bates, of Halton, made similar experiments, and got two ounces from a quart of kyloe milk, and one ounce from the same measure of short horned milk.

The above induced Mr. Walton to make similar experiments on a quart of milk of each of six cows, which produced as follows:

No.	ozs.	drs.
1.	3	0
2.	1	6
3.	1	12
4.	1	10
5.	1	14
6.	1	6

The quantity from No. 1 being so great, he had it tried a second time, with the same result.—No. 1 is six years old, and the others only two years old, which he thinks in some measure accounts for the difference in quantity; as he is told that the produce of butter increases with their age to a certain period; and it is very probable the above two years old cows would when three and four years old, give upwards of two ounces of butter per quart, or more than the kyloe milk. The difference between this experiment and those of Mrs. Watson's and Mr. Bates's, may be owing to the breed, Mr. Walton's being of the improved short horns, and the others of the great milking tribe. This is a subject well worthy of further and more accurate investigation.

Crosses.

Mr. Robert Collin has frequently crossed with the improved short horned bulls, and the best kyloe cows he could procure: the produce made very fat, and much earlier than the pure kyloe; but he has now given it up, finding that the pure improved short horns are more profitable.

(To be continued.)

Dead weight of the Durham steer, at 2 years 11 months old.

The fore quarters weighed	692 lbs.
The hind quarters	732
Nett weight of carcass,	1424 lbs.

Loose fat or tallow,	199 lbs.
Hide and horns,	91
Head,	36
Feet,	28
Blood,	34
Tongue and heart,	17
Liver, &c.	26
Entrails, &c. empty,	34
Call, melt, &c.	6
	—
	471
Carcase as above,	1424
	—
Total dead weight,	1895

The above is the weight of the Blythe Comet ox, at less than 3 years old, bred by Mr. Champion, the breeder of Col. Lloyd's cattle.

NATURAL HISTORY.—No 6.

(Continued from page 348.)

Migration.—Migrating birds, before they take their departure, in general collect together in flocks. This is very obviously the case with the swallow, and is even still better known with woodcocks, terns, puffins, and shearwaters. Woodcocks arrive in this country in great flocks about the same time; and should adverse winds occur at the period of their departure, they accumulate in such numbers on the eastern shores, as to furnish the fowler with excellent sport. Geese too, dotterels, and many others, during their migratory flights, always keep in company.

But there are many migrating birds which have never been observed to congregate previous to their departure. Thus the cuckoo, seldom seen in company with his mate even during the breeding season, is, to all appearance, equally solitary at the period of migration. These birds are supposed by naturalists to go off in succession.

It is certainly a very curious, and perhaps unexpected occurrence, that the males of many species of migrating birds appear to perform their migrations a few days before the females. This is remarkably the case with the night-gale. The bird-catchers in the neighbourhood of London, procure males only on the first arrival of this bird. The females do not make their appearance for a week or ten days after. Similar observations have been made with respect to the wheat-ear.

Those birds which feed during the night may be expected to perform their migrations during the same interval, it being the season of their activity; while those birds which feed during the day, may be expected to migrate with the help of light. The migrations of the woodcock and quail confirm this conjecture. The woodcocks arrive in this country during the night, and hence they are sometimes found in the morning after their arrival, in a neighbouring ditch, in too weak a state to enable them to proceed. Poachers are aware that they migrate during the night, and sometimes kindle fires on the coast, to which the woodcocks, attracted by the light, bend their course, and in this manner great numbers are annually destroyed. Quails, on the other hand, perform their migrations during the day, so that the sportsman in the islands of the Mediterranean can use his dog and gun.

It has often excited surprise in the minds of some, how migrating birds could support themselves so long on wing, as to accomplish their journeys, and at the same time live without food during their voyage. These circumstances have

induced many to deny the existence of migration, and have excited others to form the most extravagant theories on the subject; to account for the preservation of these birds during the winter months. But the difficulties which have been stated, are only in appearance, and vanish altogether if we attend to the rapidity of the flight of birds.

The rapidity with which a hawk and many other birds occasionally fly, is probably not less than at the rate of 150 miles in an hour. Major CARTWRIGHT, on the coast of Labrador, found, by repeated observations, that the flight of an eider duck (*Anas molissima*) was at the rate of 90 miles an hour. Sir GEORGE CALEY computes the rate of flight, even of the common crow, at nearly 25 miles an hour; and SPALLANZANI found that of the swallow completed about 92 miles, while he conjectures that the rapidity of the swift is nearly three times greater. A falcon which belonged to HENRY the Fourth of France, escaped from Fountainbleau, and in twenty-four hours afterwards was found at Malta, a distance computed to be no less than 1350 miles; a velocity nearly equal to 57 miles an hour, supposing the falcon to have been on wing the whole time. But as such birds never fly by night, and allowing the day to be at the longest, his flight was perhaps equal to 75 miles an hour. It is probable, however, says MONTAGU, that he neither had so many hours of light in the twenty four, to perform his journey, nor that he was retaken the moment of his arrival. But if we even restrict the migratory flight of birds to the rate of 50 miles an hour, how easily can they perform their most extensive migrations! And we know, in the case of woodcocks, and perhaps all other migrating birds, that they in general take advantage of a fair wind with which to perform their flights. This breeze perhaps aids them at the rate of 30 or 40 miles an hour: nay, with three times greater rapidity, even in a moderate breeze, if we are to give credit to the statement of aerial navigators, who seem to consider the rate of the motion of winds as in general stated too low.

It has been already observed, that many species do not perform their migrations at once, but reach the end of their journey by short and easy stages. There is little exertion required from such; while those who execute their movements at one flight, (if there be any that do so), may in a very short time, perhaps a day, by the help of a favourable breeze, reach the utmost limits of their journey. Many birds, we know, can subsist a long time without food; but there appears to be no necessity for supposing any such abstinence, since, as CATESBY remarked, every day affords an increase of warmth, and a supply of food. Hence we need not perplex ourselves in accounting for the continuance of their flight, or their sustenance in the course of it. Such journeys would be long indeed for any quadruped, while they are soon performed by the feathered tribes.

It is often stated as a matter of surprise, how these birds know the precise time of the year at which to execute their movements, or the direction in which to migrate. But this is merely expressing a surprise, that a kind and watchful Providence should bestow on the feathered creation powers and instincts suited to their wants, and calculated to supply them. How, we ask, does the curlew, when perched upon a neighbouring muir during the flowing of the tide, know to return at the first of the ebb, to pick up the accidental bounty of the waves? How are the sea-fowl, in hazy weather, guided to the sea-girt isles they inhabit, with food to their

young, which they have procured at the distance of many miles? "The inhabitants of St. Kilda," says MARTIN, "take their measures from the flight of these fowls, when the heavens are not clear, as from a sure compass; experience shewing, that every tribe of fowls bend their course to their respective quarters, though out of sight of the isle. This appeared clearly in our gradual advances; and their motion being compared did exactly quadrate with our compass."

In the course of these annual migrations, birds are sometimes overtaken by storms of contrary wind, and carried far from their usual course. In such cases, they stray to unknown countries, or sometimes are found at sea in a very exhausted state, clinging to the rigging of ships. Such accidents, however, seldom happen, as these birds, year after year, arrive in the same country, and even return to the same spot. The summer birds of passage return not, it is true, in such numbers as when they left us; but amidst all the dangers of their voyage, the race is preserved.

We thus see, that animals possess various resources, to enable them to accommodate themselves to the variations of temperature corresponding with the seasons. But these appear in some species to be inadequate for their protection, and another is provided for their safety.

4. **Torpidity.**—This is one of the most curious subjects in zoology, and has long occupied the attention of the natural historian and the physiologist. All animals we know require stated intervals of repose to recruit exhausted nature, and prepare for farther exertion,—a condition which is termed Sleep. But there are a few animals, which, besides this daily repose, appear to require annually some months of continued inactivity, to enable them to undergo the common fatigues of life during the remaining part of the year. These animals exhibit, therefore, two kinds of sleep,—that which they enjoy daily during the season of their activity, and that which they experience during their brumal retirement. This last kind of sleep is generally denominated *torpidity*, and is also known by the term *hibernation*, as it is evidently designed to afford protection against the cold of winter.

As the phenomena which torpid animals exhibit are somewhat different, according to the classes to which they belong, it will be more convenient for us to treat of the animals of each class separately, beginning with QUADRUPEDS.

The quadrupeds which are known to become torpid, belong exclusively to the unguiculated division. Some species are found among the *feræ*, as the different kinds of bats; the hedgehog and the tanic; while among the *gliræ* the torpid species are numerous, and their habits have been studied with the greatest attention, as the marmot, the hamster, and the dormouse.

The food of these animals is very different, according to the orders or genera to which they belong. The bats support themselves by catching insects, and those chiefly of the lepidopterous kinds; the hedgehog lives on worms and snails; while others, as the marmot and hamster, feed on roots, seeds, and herbs. They are nearly all nocturnal, or crepuscular feeders.

It is usually supposed that torpid animals are confined to the cold regions of the earth. That they abound in such regions must be admitted; but their range of latitude does not appear to be so limited as to prevent their occurrence in warm countries. Thus the *Dipus sagitta*, is equally torpid during the winter months in Egypt as in Siberia. In the former country it is more easily revived by a very slight increase

temperature, its lethargy not being so profound. The tannic (*Centenes caudatus*), which is an inhabitant of India and Madagascar, becomes torpid even in those countries, and continues so during nearly six months of the year.

The precise period of the year in which these animals retire to their winter quarters and become torpid, has not been ascertained with any degree of precision. The jumping mouse of Canada (*Gerbillus Canadensis*) is said to enter its torpid state in September, and to be again restored to activity in the month of May. The torpid animals of this country usually retire in October, and reappear in April. It appears probable, however, that the different species do not all retire at the same time, but, like the migrating birds, perform their movements at separate periods. It is also probable, that the time of retirement of each species varies according to the mildness or severity of the season. In general, however, they retire from active life when their food has become difficult to obtain, when the insects have fled to their hiding places, and the cold has frozen in the ground the roots and the seeds on which they consist. At the period of their reviviscence, the insects are again sporting in the air, and the powers of vegetable life are exerted in the various processes of germination and vegetation.

Previous to their entrance into this state of lethargy, these animals select a proper place, in general assume a particular position, and even in some cases provide a small stock of food.

(To be continued.)

ADVICE TO YOUNG FARMERS.

ON THE APPELLETIVES, QUALITIES, HABITS AND DEFECTS OF HORSES.

(Continued from No. 44, page 345, Vol. 5.)

Ewe or *deer* necked horses, have frequently fine shoulders, and are fast goers; and when the neck does not belly out too much, and the head is well set on, and the jaw-bones wide, they may be made to ride light in hand, and handsomely; but if they are much cock thropled, and the head is at the same time set on abruptly, they must always bear heavy on the hand. In this case, art affords no remedy; and it is only tormenting the horse fruitlessly, to attempt it: when you bear, with great force, upon the martingale, you choke him. Let it be observed, that the need of a martingale detracts considerably from the worth of a horse. I should conceive, at least, five pounds in twenty. There is a defective form, which I have often seen, but cannot well describe, called by the French, a *talse*, or *hatchet neck*; it is thin, and straight along the throat, having a cavity between the top of the shoulder and the withers. Thin, loose, and swivel-necked horses, carry their heads up in the air, particularly if short headed, or tender-mouthed. When a martingale is used to palliate a natural defect, the bits, and curb, ought ever to be of the mildest. Long rainbow necks are more for beauty and ornament, than real service. They seldom belong to capital goers. It is easy to conceive, that a long and bulky neck must encumber, and retard progression, by destroying the equipoise of the machine; also, that with a shorter neck, the horse has a less distance to tetch his wind.

The form and size of the *shoulder* is obviously a point of the first importance. St. Bel, speaking of the mechanical causes, of the power of progressive motion, in every animated machine, says, "The bones and muscles are simply an apparatus of columns, levers, pulleys, cords, wedges, &c. the combined operations of which occasion greater or less speed;"—and, "on the good or bad construction of the shoulder, pro-

gression materially depends, as its motion determines that of the inferior parts. A long and oblique shoulder is the indication of speed, because, in proportion to the length and obliquity of that part, the farther the arms of the lever will be extended, and the greater will be the portion of the circle which it will describe." In order to capital action, and that the horse may extend his legs very far forward the shoulder must fall backward from a deep breast in an oblique direction (the sternum, or keel, somewhat projecting) and lessening by degrees, go fairly up to the top of the withers. Mr. Culley, whose observations have always weight, is partial to horses wide a-top, upon the withers; and supposing the shoulders to be, at the same time, very obliquely placed, there can be no doubt but such horses will carry greater weight, in proportion, and with equal speed. They are also, in general, easy goers. The famous Mother Neesom, according to Bracken's account, was so shaped; and I have known some such, with capital action: but this is rare, such forms being, in general, straight shouldered, and wide chested, and by no means distinguished for speed.

The extreme obliquity, or slant of the shoulder, it must be observed, is requisite only for the running horse, and even amongst them, it is rare; extent of shoulder, providing it be flat and deep, or considerable, (always conferring proportional powers of progression. The straight heavy-shouldered horse is, evidently, unfit for any purpose, but slow draft; both the weight, simply considered, and its mal-position, impeding progression. This accounts for well shaped horses being more capable of high weights, than others with much greater shew of substance.

A high and well placed shoulder is accompanied with all sorts of advantages, of which it is a very eminent one, that a proper place is thereby secured for the saddle, without the use of a crupper, the need of which, as well as of a martingale, decreases the value of a horse. I have said that the shoulder blades ought to reach up to the top of the withers, diminishing gradually, that the withers be not too thick and wide. But this indeed is a rare perfection. Many, which are esteemed good shoulders, have a cavity between their upper extremity and the withers, admitting the saddle too forward, and bringing the weight too far before the centre.

The least experienced eye will readily determine, whether a horse be *leggy*, or too high upon the leg. It is very apparent, when the legs form the most conspicuous part, and appear too long for the carcass. The horse is weak in proportion, but it detracts more from strength and continuance than speed. The legs being very short, is also a defect, and of a contrary tendency. But legs are never too long, when the horse is sufficiently deep in the carcass.

The *knees* must be wide and strong, but lean, and free from puffiness; the hair bear no vestige of derangement. A nice eye will instantly detect any accident which may have happened to the kness from a fall, even if years have since intervened; there will be either an inequality of the surface, a few staring hairs, or those which have grown after a cut, will be of a different colour, or will be too long, and so not lie level with the rest. The back part, or bend of the knee, is the situation of *mallenders*, or *chops*; the inner side somewhat below it, of the *speedy cut*, which is occasioned by strokes of the hoof in going. If the wounds have been healed, an excrescence will be distinguished by the finger, or the hair will appear to stare. Trembling knees denote injury, from excess of labour,

which is generally without remedy. *Osetts* are long excrescences situated under the knee, on the inside, and sometimes contract the joint. Splents are of the same nature; their place is upon the shank; they are sufficiently palpable, either to sight or feeling, but of no detriment, when they do not interfere with the sinews. They seldom increase in size, after six years old. When they are so placed as to contract the sinews, it is much the cheapest and safest way to deem them incurable.

If the legs be round and fleshy, and no preternatural heat, or extraordinary pulsation is to be discovered in them, by handling, it may be their natural shape. They will be subject to grease and scratches, and belong to a horse of inferior kind. A good flat leg may have become round, hot, and swelled, either by over-work, or the want of it, and from standing week after week, tied up in a hot stable. The horse may shift and change his feet, from the pain in his legs, and yet the main sinew may not have sustained any material injury; for when that has really happened, he will be sure to inform you of it, by putting his leg and foot forward, in a loose, faint, and faltering way. If he stand thrusting out his fore-leg boldly, as if from wantonness, and resting on his heels, he is groggy; that is to say, his sinews are contracted, or his feet battered. To try how far the horse has been injured, let him be walked about for half an hour, when the swelling of his legs will, in all probability, subside. If you then observe the *tendo achillis*; or main sinew, distinct from the shank; if on pressing it with the finger towards the bone, you find it firm, and tense; if you discover by the feel, no soft, spongy sinews between the shank and the tendon, no extraordinary pulsation, but that all is well braced and wiry, you may conclude the swellings not dangerous. A person of experience, with a nice and discriminating finger, will scarcely ever fail to detect lameness in the back sinews; but I must declare, that I have never yet in my life met with such persons among common grooms, and farriers, who never attend to any other symptoms in these cases, than heat and tension; whereas those symptoms may have prevailed, in a very slight degree, or may be past, and the sinews remain in a very lax and unsound state. I met with a remarkable example of this very lately. Two men were returning from the house of a veterinary practitioner of some note, with a fine young coach horse, which went lame. Upon enquiry, he had been lame sometime, and neither themselves, their master, nor the doctor, could possibly discover the seat of his lameness, but they had blistered his pastern joints, and taken several other steps at a hazard. I examined him out of curiosity. He had scarcely stood still a minute before he set his near fore-leg out. I found the foot and joint perfectly cool, and apparently without complaint. I had him walked upon soft ground, and observed, he *threw his fore-arms freely, and far enough forward*, by which I was convinced of the soundness of his shoulders. On pressing the back sinew of the near fore-leg, the horse winched, and on farther examination, I found the sinews soft and flabby, with some little heat and beating. It was in vain that I communicated this discovery to the men, or that I demanded of them, whether, independent of other ailments, which they supposed the horse might have, that which I had found was not sufficient to make him halt? No. One said he was lame behind, the other, that the lameness was in his shoulder, and that he knew a farrier who could remove it at a certainty.

There seems a strange disposition in the stable people, to attribute effects to occult and imaginary causes, when the real ones are so obvious, that one would wonder how common sense could possibly avoid stumbling upon them. Horses, which plainly tell of themselves, that they are lame from hard and hot feet, and overstrained back-sinews, are usually contradicted by their keepers or doctors, who rather choose they should be lame in the shoulders. Should the chest be of a peculiar thin make, and have a cavity in front, the business is done at once and the case declared a chest-founder. That disease is then perhaps hereditary, as I have more than once seen foals, of only a few days old, with the said cavity, and all the appearances of a wasted chest. To be serious, I have also seen a case of a recent and sudden foot founder, with the chest remarkably shrunk, and a violent palpitation in the cavity, for which Osmer accounts very rationally. The shoulders seldom receive any other damage from labour, than concussions, which occasion stiffness and cramp. It is very plain that the articulations of the lower joints and the hoofs, enduring the severest service from being obliged to support the whole natural and imposed weight, must be most exposed to accidents.

When the horse wounds his pastern joints, in going, it is called *knocking*. If the places be healed, an escar will be discovered by the finger, or the fresh-grown hair will be long and uneven. The speedy cut, and knock are capital defects in horses, the former natural, and past all remedy, the latter so likewise, except it be the consequence of weakness and low condition. The width of a horse's chest is no security against knocking, nor is it occasioned by the narrowness of the chest, the stroke being given by the toe or heel; of course those horses are liable to it, which turn the toe either out or in. In the latter case, they are styled *nigeon-toed*. In a natural defect of this kind, it is ever productive of disappointment and mischief to listen to the proposed remedies of grooms and smiths from shoeing; since your horse would knock, or cut in the speed, with his hoofs, if ridden without shoes. The only remedy is never to ride him without those round leather guards, which have of late years been adopted. To be properly formed for action, a horse ought to go with his feet as near together before, as possible, with out brushing the hair, and proportionally wide behind. When they proceed in the contrary form, a case by much too frequent, they are said to go with the wrong end first.

(To be continued.)

FROM THE NEW ENGLAND FARMER.

I am induced to hand you the enclosed extract for publication, from an impression that some of the remarks are so *apposite* to the present juncture, that they ought to be in possession of the public. And this motive I trust, will secure a pardon from my friend for the liberty thus taken. It may be thought, sir, that the time has arrived for the FARMERS and PLANTERS of the Union, to begin to ask the Government for a share of protection so strenuously demanded by a portion of their fellow citizens engaged in other pursuits.

Should your publication of the letter, meet the eye of the estimable gentleman at the head of the Agricultural Committee of the House of Representatives in Congress, he will recognise the writer as one of the most systematic and efficient farmers, upon a very extensive scale, in the United States. Your's truly,

S. W. POMEROY.

Brighton, Jan. 8, 1824.

"Geneee, Livingston Co. N. Y. 8th Dec. 1823.
"DEAR SIR,—I received a few days since, a "New England Farmer." Judging from one number, I should think it a well selected and judicious paper.

"I doubt whether I should agree with the Editor in recommending the cultivation of roots for cattle. You know my axiom is, that the process of farming (I wish I had a better word at command) must be regulated by the price of produce. The same paper which recommends the culture of mangel wurtzel, quotes the price of the best pieces of beef at eight cents: reducing the average probably to four cents. I am deceived if it is possible to feed cattle with roots and sell the beef at four or five cents, without a loss;—if so, I believe *Say* would pronounce the root culture an unproductive operation. I am not insensible to the fascinating appearance of any section of our country, cultivated nearly in the style of horticulture; but its counterpart I am afraid ever must be pauperism in most of its painful forms. Farmers pursue their interest—not always—but more generally than you, gentlemen farmers imagine. The nett income of our farmers is miserably small—they cannot afford ornamental husbandry. Labor, says Washington in his letters to Young, is every thing with us, and land nothing. I do not say but you can feed your cows near Boston, cheaper on roots than with hay: I doubt it however:—But I can raise cattle in Ohio and sell them at such prices as will ruin a root-feeder, twenty miles distant from Boston.

"Our manufacturers are earning double the amount of farmers of equal capital. Government is paying them a bounty of 30 per cent. on their products—while the good natured farmer jogs on, quite contented with an occasional treat of splendid declamation in praise of rural life.

"I am doubtful as to the expediency of small premiums on cattle; I think the raising of these animals may be left to self interest. Suppose you take a hint from Napoleon, and offer very liberal rewards for great improvements in agricultural implements. The cast-iron ploughs even now cause a saving to the U. S. of at least \$60,000 a year—(here is a million saved for other objects.) Our Blacksmiths have lost about one third of their customers' work which was expended in laying and sharpening plough irons, &c.—We have a threshing mill in this village now in use, which operates perfectly well and saves one half the expenses of manual threshing. It may be transported in a wagon—costs about \$60.—We wonder why the Romans did not think of stirrups; and it is a little wonderful that the cast iron plough in its present form has not before been introduced. There ought to be national premiums for great objects that would excite attention through the U. S.—\$10,000 for a flax dressing machine, if it brought one to light, would save half a million a year. Agricultural labor is not up to the lights of the age—while mechanical labor since Arkwright began to spin cotton, has been increased many hundred fold. There are many processes in farming which invite the aid of mechanical inventions; for instance, mowing, threshing, cradling, flax-dressing, &c. Mr Whitney, of New Haven, made a present to the cotton growing sections of the southern States of a machine, equal in value to the yearly labor of one fourth of the black population. I mention it to show what remains to be done, to abridge the rural labor of the northern and middle States.

"Samuel W. Pomeroy, Esq."

PENNSYLVANIA AGRICULTURAL SOCIETY.

At a meeting held on Saturday, the 10th of January, in conformity with the act of Incorporation, the officers for the ensuing year were elected, viz.

President—Jonathan Roberts.

Vice Presidents.

William Harris,	George Sheaff,
James Worth,	Thomas Serrill.
Stephen Duncan,	

Corresponding Secretary—John Hare Powel.

Treasurer—George Blight.

Counsellor—Levi Pawling.

Directors.

William Darlington,	Job Roberts,
Manuel Eyre,	Algernon Logan,
Elijah Lewis,	Jesse Kersey,
William Evans,	Samuel West,
Joseph George,	Samuel Davis,
Matthew Roberts,	John G. Watmough,
Richard B. Jones,	John Elliott, of Mont-
Thomas Smith, of De-	gomery County.
laware County.	Reuben Haines,
John Wilcox,	Henry L. Waddell,
George W. Holstein,	Euos Morris.

Recording Secretary—Joseph Kersey.

Assistant Recording Secretaries.

John P. Milnor,	Henry Serrill.
-----------------	----------------

A communication was made by John Hare Powel, accompanied by affidavits and certificates from a surveyor and various persons, showing that he had raised in the last autumn on one hundred and seventy-four perches of his farm land, sixteen hundred and thirty-four bushels of Mangel Wurtzel Roots, free from dirt and closely cut beneath the crowns, equal to fifteen hundred and two bushels, weighing 32 tons, 3 cwt. 2 qrs. 23 lbs. per acre.

Communications were presented by the Corresponding Secretary, and ordered to be printed, viz:

On wheat crops and Hessian fly, on fences, on peach trees, on the effects of Lightning—by *James Worth*, of Buck's County.

On Alderney cattle, on peach trees—by *Reuben Haines*, of Philadelphia County.

Letter from G. W. Featherstonhaugh, Esq. Corresponding Secretary of the New York Agricultural Board, to John Hare Powel, on cattle and their management

John Hare Powel's reply.

On the effects of lightning—by *Matthew Roberts*, of Montgomery County.

On manures, on hay houses and securing hay, on various breeds of cattle, on millet, on the cultivation and uses of mangel wurtzel, on the advantages of deep ploughing—by *John Hare Powel*, of Philadelphia County.

On the properties of improved short horn cattle as deep milkers—by *Henry A. Carpenter*, of Lancaster County.

On the management of Indian corn crops—by *Joseph Kersey*, of Chester County.

On the extraordinary effect of mangel wurtzel upon the quality of butter—by *James G. Thompson*, of Philadelphia county.

The Society determined to award premiums at their next Annual Exhibition, for neat cattle, sheep, horses, swine, crops, butter, cheese, maple sugar, potash, domestic wine, cider, implements of husbandry, ploughmen, and animals at the plough, and household manufactures, under certain stipulations.

From the Minutes.

JOHN P. MILNOR,
Assistant Recording Secretary.

OBSERVATIONS

ON A REMARKABLE DISEASE AMONG CATTLE, AND ITS PROPAGATION TO THE HUMAN SPECIES.

By J. Kercheval, M. D. of Bardstown, Kentucky.

I have lately witnessed some cases of an anomalous and extraordinary disease, which appeared to proceed from an infection communicated by the bodies of cattle that had died of a singular and fatal disease that raged among them.

This disease first made its appearance among the cattle of this neighbourhood during the summer of 1819, and its fatality was so great that horses, cows and sheep, were alike the victims of its fury. Cattle brought to the fold in the morning apparently in good health died before noon; and many that had taken their accustomed food in the evening were found dead in the morning; nay, those grazing in the fields, but half an hour before, were seen writhing under the pangs of death, and dying in a few minutes.—Death in such cases was often attended with violent agitations, and manifestations of the most agonising distress.

The external signs of disease, were an intumescence, sometimes originating in the throat, but generally commencing at the breast and extending along the sides to the flanks, and uniting across the lumber regions. These swellings were soft and elastic, resembling inflations, and upon post mortem examination, were found to contain extravasations of grumous blood, and effusions of coagulable lymph, and were of a dark and gangrenous appearance. The blood in some instances was so dissolved that it transuded through the pores of the skin.

Such were the prominent features of this most deadly distemper. Alike novel in its character and unique in fatality, it is viewed here, as a new disease; nor is my knowledge of veterinary pathology sufficient to enable me to assign its appropriate rank among the many maladies of our domestic animals.

In the human subject this disease, or at least one which was derived from it, commenced in a small and circumscribed vesicle, containing a dark and turbid fluid, exhibiting an appearance not unlike that which is sometimes excited by the first effects of spurious vaccine matter.—This cuticular elevation extending itself equally in every direction, formed a circular and progressive margin to the ulcer, and as it receded the centre became livid, black, and finally sphacelated. This gangrenous spot become encompassed in the course of its progress with a hard swelling of very great extent, attended with a peculiar torpidity and loss of sensorial power in the part.

Almost simultaneous with the appearance of local affection, the entire system become more or less deranged. The constitutional affection commenced by chills and rigors, these were soon succeeded by febrile excitement, attended with dull aching pains in the joints and extremities, headach, and a distressing sensation of pains along the course of the spine. In one instance petechiæ appeared upon the skin. All these symptoms were accompanied by much prostration of the vital powers, and the disease exhibited a train of phenomena, altogether novel and perplexing.

In the treatment of this malady, after a few general remedies adapted to the state of the system, my attention was more immediately directed to the local affections. With a view, therefore, of bringing the remedial articles to bear more immediately upon the subjacent parts, I removed, by excision, the superincumbent dead parts. Although in several instances this was

effected in considerable masses, yet such was the insensibility of the parts, that the scalpel gave little or no pain, nor did the most potent stimuli and antiseptics excite, for some days, the slightest sensation.

The carbonate of potash in substance and a saturated solution of the muriate of ammonia in vinegar appeared to be beneficial as applications to the diseased parts. I also derived advantage I thought, from dressings dipped in the compound tincture of myrrh and aloes, covering at the same time the contiguous surface with stupes out of cold aqueous solutions of acet. plumb.

Although the ulcers were extremely malignant and inveterate, yet by rigidly persisting in this treatment, at the end of five or six days, a circumscribed margin of red and healthy granulations announced, in every case, the arrest of the gangrene and restoration of the healthy action of the parts surrounding the slough. During the process of sloughing, I applied the submuriate of mercury to the part, and exhibited pulv. cinchon with evident good effect.

With regard to the origin and character of this disease, it may be observed, that no one was affected with it, who had not been previously engaged in flaying or otherwise handling and touching the carcase of an animal that had died of the distemper described. In three out of four persons, in whom the disease occurred, it made its first appearance upon the fore arms. In the fourth the gangrenous pustules appeared on the cheek. All persons, however, who were thus employed upon the carcasses of animals, were not affected with this disease. Nor did I hear of any person of colour having received the disease. This may have been owing to the morbid virus not coming in contact with sensible or absorbent parts, for want, in those instances, of a scratch, or abrasion of the skin.

TO THE EDITOR OF THE AMERICAN FARMER.

SCORCHING OFF THE HAIR OF HOGS, BETTER THAN SCALDING, FOR BACON.

Mr. Skinner,

In the 4th vol. of the American Farmer, page 223, there is an account of the English mode of cleaning hogs by singing, which states that the quality of the bacon cleaned in this manner, was in much higher estimation, than that prepared in the ordinary way by scalding. My informant was Mr. James Scareley, a butcher, a few years since from England, now a resident at "Fells Point." In the Edinburgh review of February, 1823, in an essay reviewing "Cobbett's Cottage Economy," page 115, there is a portion of Cobbett's works extracted, which details the English (or more properly the Hampshire) mode of cleaning by singing. As to my taste, no one is perfectly competent to give Cobbett's meaning in as satisfactory way as this singular man himself. I will extract so much of the "extract," as gives an account of cleaning hogs by singing, hoping that Cobbett's manner of relating may attract attention, and cause some one to make an experiment, and give us through the medium of your paper, the result of their experiments. Cobbett's words are, "there are two ways of going to work to make bacon; in the one you take off the hair by scalding, this is the practice in most parts of England, and all over America. But the Hampshire way, and the best way is to burn the hair off there is a great deal of difference in the consequences. The first method slackens the skin, opens all the pores of it, makes it loose and flabby by drawing out the roots of the hair. The second

tightens the skin in every part, contracts all the sinews and the veins in the skin, makes the flitch a solidier thing, and the skin a better protection to the meat. The taste of the meat is very different from that of a scalded hog—and to this chiefly, it was, that Hampshire bacon owed its reputation for excellence. As the hair is burnt off, it must be dry, and care must be taken that the hog be kept on dry litter of some sort, the day previous to killing. When killed he is laid upon a narrow bed of straw not wider than his carcase, and only two or three inches thick. He is then covered all over thinly with straw, to which, according as the wind may be, the fire is put at one end. As the straw burns it burns the hair. It requires two or three coverings and burnings, and care is taken that the skin be not in any part burnt or parched. When the hair is all burnt off close, the hog is scraped clean, but never touched with water. The upper side being finished, the hog is turned over, and the other side is treated in like manner. This work should always be done before day light—for in the daylight, you cannot so nicely discover whether the hair be burnt off. The light of the fire is weakened by that of the day. Besides it makes the boys get up very early for once at any rate—and that is something—for boys always like a bonfire."

Thus far Cobbett—for the sequel of his remarks contained in the extract, your readers are referred to the work as quoted. Let me observe that in my communication published as stated in the 4th vol. of the Farmer—that there is a typographical error, which I will beg leave to correct—towards the close, read "Maryland lady," instead of "me ry landlady."

Your's, &c.

RUS-IN-URBE.

Baltimore, July 10th, 1824.

TO THE EDITOR OF THE AMERICAN FARMER.

MAN-POWER.

SIR,

In a late communication, I pointed out the simplest mode that occurred to me, for comparing the power of any mechanical agent with that of a man or horse, when drawing horizontally to the greatest advantage. I will now proceed to state, and compare, the different degrees of force which an active labouring man can exert, under different circumstances. For this purpose it will be requisite to have some fixed standard of comparison. Now it has been fully ascertained that an active labouring man, working to the greatest advantages, and without impediment, can, on a moderate estimation, raise 10 lbs. avoirdupois, through 10 feet, in a second, for 10 hours per day;—or 100 lbs. which is the weight of 12 gallons of water, through 1 foot; or through 36,000 feet in one working day of ten hours. If, therefore, the weight raised, be multiplied into the height through which it is raised; that is, 100 lbs. into 36,000 feet, the product 3,600,000, will express the daily labour of a man when acting under the most favourable circumstances: and its one-thousandth part, 360, will answer the same purpose, and be much more convenient.

It has long since been ascertained that a man of ordinary strength, can turn a winch through 3½ feet per second, and overcome a resistance of 30 lbs. and continue the exertion for ten hours in the day without injury. His daily labour therefore, reduced to the above standard would be 378; or 1-20 more than the standard; again, it is known that two men at a winch, with handles at right angles to each other, can raise

lbs. with greater ease than one can raise 30. This reduced to our standard of 360 will be 439 1-5.

A man can raise by means of a good common pump, a hogshead of water 10 feet high, in a minute, and work 10 hours per day. Now, since 12 gallons weighs 100 lbs. 63 must weigh 525; he will therefore in ten hours or 600 minutes, raise 600 hds. weighing 315,000 lbs. to the height of 10 feet, which gives 315, for the measure of his daily labour at pumping.

A feeble old man in St. Petersburg, raised 7 cubic feet, (437½ lbs.) of water 11½ feet high, in one minute, for 9 hours per day, by walking backward and forward on a lever, to whose extremities pump-rods were connected. This gives 271, for the measure of his day's labour; which if continued 10 hours would be 301.

A young man weighing 135 lbs. and carrying 30 lbs. raised 9½ cubic feet to the same height every minute, for ten hours in the day, without fatigue: the measure of his day's labour will be found to be 391.

If the force which a man can exert when turning a winch be expressed by 100; then his force in pumping will be 61; ringing a bell 136; and in rowing a boat 145. The last of these appears to be the greatest that the human body can exert.

When a man ascends a flight of stairs without any load, his velocity and action is the greatest; but he produces no useful effect. If he be loaded with twice his own weight, he is unable to ascend. Between these extremes, as in hauling horizontally, there is a mean load with which he can ascend, and in a given time, produce the greatest *useful effect*. This load, for a stout, active labouring man, will be about three-fourths of his weight; and the same will be the most advantageous load when he travels horizontally; but if he return unloaded to carry away another load, he will produce the most useful effect, when the load is nine-tenths of his own weight.

When a man ascends stairs without a load, the quantity of mechanical action; that is, the weight (of his body) raised, multiplied into the velocity with which he ascends, exceeds that when he carries three-fourths of his weight, in the proportion of nearly four to one. Consequently three-fourths of his labour is lost in this application of his strength: and it will cost four times as much as that of a man who will ascend the stairs without any load, and then raise a weight by allowing himself to descend, by the force of gravitation, through the height to which he had ascended.

The act of turning a *tread mill* is precisely similar to that of ascending stairs, and consequently a man's labour will be four times more beneficially expended on it, when he sustains no weight but that of his own body, than if he carried in addition a weight, equal to three-fourths of his own.

The expenditure of muscular action, and consequently, the fatigue, in ascending stairs, even without any load is very great. It is demonstrable, that to ascend 13½ feet, requires as much exertion, as to walk 230 feet on a level road. Indeed this application of man's strength, even when producing the greatest useful effect, is very unprofitable, the measure of his daily labour being no more than 148, which is less than one-half the effect of the "feeble old man," walking on the lever.

Thus it appears, that the quantity of useful labour, which a man's strength will afford, is very different, according to the mode in which is applied. His peculiar conformation, assisted by his ingenuity, enables him to exert his

physical powers in an endless variety of ways. The case is very different with other animals; but of this on some future occasion.

Your's respectfully,
J. D. C.

ON STORING MANGEL WURTZEL.

North Creek, Burnham, Norfolk, }
August 23, 1823. }

SIR—Lest your correspondent's letter in this week's Journal on mangel wurtzel should mislead the growers of that root, by stating that it will stand the frost, I would beg leave to caution them against trying the experiment, lest they should meet with a serious loss. If they are a good crop and well covered with tops, I believe they will stand the frost as well as our common

white turnips. Some gentlemen in this part of Norfolk about seven or eight years since, grew a fine crop; they were valued by a surveyor at £12 per acre, and the turnips on the same farms at three or four pounds. They were advised to take them up and store them for spring feed; their mode of doing it was, all the tops were taken off, the roots were then taken from the ground, and left in small heaps to be carted home when a convenient opportunity offered; a sharp frost caught them in that situation in the end of November, and destroyed their whole crop to the amount of several acres; this made them so angry that I believe not one of them have grown any since. Many acres have since that time been grown near them and much approved of. I have some roots now by me very sound and good, that were planted in July 1822, after my hay was taken off: the rows, three feet apart, were covered up by the plough in autumn, and remained there all winter. I had also some that were not moulded up, but had a heavy crop of tops that stood till the spring, although the winter was very severe, but these were eaten off by my cows as soon as the frost broke up, or I believe they would have rotted very soon. If our common white turnips were topped and taken from the ground, a slight frost would destroy them as soon as it would the mangel wurtzel; for that part of the roots that grow in the ground is very tender and susceptible to the frost. I store the greater part of mine. We take no more tops off than we cart roots to the heap in the day, commencing as early in November as we can. Two carts, three horses, six or eight women or youths to load, and a man to drive them to the heap, will remove a great many in a day. The driver shoots them out of the end of the cart, or tumbrel, in a promiscuous way, on as high a heap as he can, about two loads deep, on the level ground in some sheltered situation; he continues to add to that heap in the same way he began, till he has got as long a ridge as he wants; the scattered ones are then thrown upon the top of the heap to as sharp a point as they can conveniently be laid; as much straw must then be scattered over them as will prevent the mould from mixing with them. The ground round the heap, with the carts and treading of the horses, is pressed so close as to be difficult to dig. I plough as many deep furrows round the heap as I want mould to cover it, about six or seven inches; it is then harrowed and rolled till fine, then ploughed a second time, beginning each time next the heap; by this means the mould is brought to it, and in its fine state is easily cast over them with a shovel, for the lighter and finer the mould is, the better it will resist the frost. I prefer this method to putting them into a hole, as the practice is with some, because the waters are carried from the heap into the trench; in the latter case they fall into the trench amongst the roots: I have preserved them good till after Midsummer, and have found them useful for stock in a dry season, when the grasses fail. The ground cleared at this time is ready for sowing wheat, or to be ploughed, and remain the winter for a spring crop. I have seen heavy crops of barley where the tops have been ploughed in, but I prefer giving them to the stock, as they eat them with avidity. My people are now reaping wheat that was sown after the mangel wurtzels were taken off last November; it is laid at twelve coombs per acre. Your *Surry Correspondent*, in a recent letter in your Journal, is very much mistaken respecting the fattening qualities of the mangel wurtzel. I heard a respectable grazier state, in a public market, that he made a quantity of beasts fat this last spring, with these roots in the shortest time he ever

saw any fattened before with any thing. I have some friends who have regularly fattened beasts for the London market several years, who all concur in the same opinion. I feed my cows, horses, and pigs with them, and find them very nutritious. I am, Sir, your's respectfully,
THOS. HEROD.

History of a German Bed.—"Imagine a young Frenchwoman accustomed to sleep between two sheets, and finding for her bed in her German bed chamber a large feather mattress, under which was concealed a very small sheet. I called up my hostess, but was a long time labouring to make her understand my complaint. Her custom had been to sleep under the mattress. I made signs to her to fetch me a quilt; she did so, but with the most inconceivable obstinacy persisted in placing it under the mattress in question. This scene at length became so ridiculous, that I could no longer conceal my laughter, but I was obliged to make my bed over again, and the surprise of my hostess was not a little at seeing me place the sheets upon the feather-bed, and the quilt over the sheets. We parted in mutual admiration."

Editorial Correspondence.

Extract of a letter from Dr. J. S. Spence, to the Editor, dated Washington, January 17, 1824

"While on this subject, it may not be out of place to state, that there is perhaps no grain, which is sought for more eagerly, by domestic fowls, and mice, than the millet. I am certain that either family, would leave corn or wheat, to feed upon it"

"I feel interested in the other subject of your note. These destroyers of our fish, whilst entangled in the net, are enemies of recent appearance in our waters.* But although, the entomologist, may assign to them their name, and lineage, little actual benefit will result to the fisherman. Like other tiny pests, they are too powerful in the aggregate, to be eluded, or destroyed. I will write very soon, to a neighbour who was first to detect, and complain of their unkindness, to *drown* some of them in spirit, and imprison others, giving them the sole comfort of their own salt water. It is almost certain, that you will have a view of them, in a state so active, and with eyes so clear, as to convince you, that they can be mischievous."

"I enclose some seed, from grapes which grew on the side of a swamp, entirely open to, and a little more than a mile distant from the Atlantic. I could say something of the beauty of the vine, branching within a foot of the ground, and covering the tops of three oaks, of moderate height; but, my object is, to put you in possession of the seeds of a grape, which certainly contain more saccharine matter, than any of the natives which I have ever seen. I was aware that I should not be at home, for cuttings.

Your's truly,
JOHN S. SPENCE.

JOHN S. SKINNER, ESQ."

* The Editor had been informed by Major Prideaux of the Maryland Executive, that within a few years past a singular species of insects, or vermin, had appeared in the waters on the sea board of Worcester county; which, entering by the mouth, in great numbers, thoroughly devoured the fish, which they find entangled by the gills in the gill nets; but what is remarkable, they do not break the skin; so that though not a particle of the interior remains, except the bone, the skin being filled with water, has the appearance of being a plump fine fish, until taken up, it is found

to be nothing but skin and bone. Is it not probable, that this piscivorous depredator upon the hopes of the fisherman, is the *sea louse*, spoken of in Capt Parry's last expedition to the North pole; to which recourse was had, to make skeletons of such birds, or animals as they desired to preserve, by placing them under the ice, in the way of these ravenous devourers of fish and flesh?

The grape seed, being few in number, have already been divided amongst John Lowell, Esq. of Massachusetts Col. George Gibbs, New York, Major Adlum, Georgetown, D. C., and N. Hervemont, Esq. of South Carolina.

Edit. Am. Farmer.

Extract of a letter from a correspondent near Washington, Georgia.

"The corn crops in the state, from Augusta, westward, are very abundant, almost without a parallel in production. The cotton crops are not so extensive (as to acres,) as formerly, say as three to five, but the production per acre is unusually large, and the cotton I think, is of a fairer quality, as to staple and appearance, than is common."

DISEASES OF HORSES AND CATTLE.

Paris, Bed. Co. Ky. Dec. 22, 1823.

Do not think, my dear sir, because I almost invariably address you on the subject of horses' diseases, that I am, therefore, a professed horse jockey;—believe me the conclusion would be erroneous.

I am feelingly alive to all the distresses of animated creation; but more especially to that noble animal a horse. It is to his subjection, and labour, our farmers owe their rich and luxuriant crops, the pleasure of being whirled about in their carriages, the graces of horsemanship, and the high entertainment of well matched races.

From all these considerations I naturally infer that relieving such an useful creature, would result in benefitting man, and would impart pleasure to him in the exercise of that tenderness and humanity, God has for wise purposes, implanted in his nature.

On travelling through one quarter of Kentucky, I was informed by a respectable and wealthy farmer, the "*Founder*," was cured by rubbing the hoofs, and pasterns of the afflicted creature with spirits of turpentine, and also, rubbing it over his nose, at the same time.

I saw lately a paragraph in the National Intelligencer, describing a disease in cattle, in Montgomery County, Md. or else where, and describing its mode of attack.

Some fine horned cattle have been afflicted in the same manner in this neighbourhood, and every remedy tried, has failed of curing them of the visitation and violence with which they are seized, and death only had power to quiet them.

After investigating every obvious cause, it has been found out to a certainty (I am creditably informed) that feeding cattle with cut up corn, with *hops* in the same pen, or pasture, communicates the disease. I will give you no philosophical reasons on the subject; you can examine the pro's and con's at your leisure. I hasten to let you know the fact; perhaps the hints I have given, may in some way be serviceable.

"Procrastination" is a great evil, and from some reason I cannot now explain, perhaps diffidence, or some other feeling had a part in it; but however, or whatever it may be, I have delayed longer than I ought, sending this communication. Your friend, respectfully,
S. B. D.

N. B. The description of the "*bee chest*," with any thing else connected with that interesting insect, will be acceptable.—*Edit. Am. Far.*

MR. SKINNER,

I believe it is now more than six months since I saw in your paper, a respectful call on Dr. S. Black, for a statement of the effects of his system of improvement, for the four years which have passed since his essay on the intrinsic value of land was published. Being one of those who had read that essay with pleasure, I was anxious to know the present impression of its ingenious author—and confidently expected a reply to the question of your unknown correspondent; but the time which has elapsed, shews that the expectation was vain. This silence of the author, amounts to confessing his doctrine to be false; and by allowing this impression on the public mind, he does injustice to his essay, which (notwithstanding his silence) I still think well of.

Every writer on agriculture is apt to deceive himself, and consequently to deceive his readers. No one should be blamed for this fault, when he commits it, in attempting to disseminate true and useful knowledge. But whenever he discovers that he was mistaken, it is his duty to undeceive his former readers by a frank and voluntary avowal of his mistake. Such a course would command our approbation; and even the most distinguished writers on agriculture would be raised instead of being lessened in our esteem, by their giving such proofs of their love of truth, and freedom from prejudice. By adopting the opposite course, they become guilty of intentional fraud on the public. R.

Lost hours.—One person rises in the morning at half past nine, another at six. If each live to be fifty years old, the one will have enjoyed sixty-three thousand eight hundred and seventy-five hours, or two thousand six hundred and sixty-one days more than the other. Let us suppose, that there are throughout Great Britain, one million five hundred thousand persons who rise at a quarter past nine, or later. Of these, perhaps, nine hundred and fifty thousand would, if they rose at six, be usefully employed. At this rate, fifty-six thousand three hundred and forty-six millions, eight hundred and seventy-five thousand hours, or six millions four hundred and thirty-two thousand two hundred and ninety-two years of individual improvement are lost to society every half century.—This is supposing, that these nine hundred and fifty thousand get up at a quarter past nine, whereas thousands do not leave their beds till eleven or twelve.

All this time is uninterrupted day, and composed of hours in which the intellect is far clearer and more fit for study, than the rest of the day.

It must be remembered, too, that nothing conduces more to health, and consequently to longevity, than early rising.

Suppose, out of the above number of persons, five hundred thousand should live four years longer than they otherwise would have done, viz. fifty-four years instead of fifty; according to the ratio above, here are two millions more years of actual existence utterly wasted.

By a letter from a respectable citizen of New Jersey, dated the 23d December, we learn, that a manufactory for converting iron into steel, has recently been commenced in that city, which produces as good, as firm and as beautiful steel as any imported from England or Germany, and that too from Morris county iron. The best of Russia, Swedes and Morris have all been tried and all are good, but the latter is found superior to any other, from the trials which have been made of it in sundry edged tools. I am persuaded no cast steel, ever imported from Great Britain, excels it for the firmest and finest instruments. We regard this manufacture as one of incalculable value to the United States. All our edge tools, hammers, cutlery, &c. &c. depend upon good steel. We do not yet manufacture iron, as it ought to be manufactured, but we trust we soon shall. For the hundredth time we repeat—upon COAL and IRON we must found the greatness of Pennsylvania.

Pedestrianism.—The match against time, for which Capt. Parker, of Hothersall Hall, in this neighbourhood, has been a short time in training, was, on Tuesday se'night, decided near Buxton. Captain R. (as our readers will recollect) undertook for a considerable wager; to walk seven miles in one hour. The almost seeming impossibility that he would be able to accomplish so long a distance in so short a time, made the odds run high against him. Confident, however, in his capability to perform the task, he took the odds to a considerable amount, and on Tuesday se'night he commenced the match at the second mile-stone from Buxton, on the Manchester road, walking seven miles (which had previously been measured by an eminent surveyor) right a head, and completed the distance one minute 26 seconds within the time—the greatest feat on record.—The following is the time each mile was walked in by Capt. Parker:

1st mile in 7 minutes 52 seconds.

FROM THE PROVIDENCE JOURNAL.

JONATHAN'S VISIT TO THE COTTON FACTORIES.

Did you ever go down to Pawtucket?

Good Lord! what a buzzing it makes!

Like fifty live crabs in a bucket!

What a darn'd sight o' cotton it takes!

What a whirling and splashing! I never

Did see such a racket afore!

An' then, that 'are up and down river,

My stars! how the water does roar!

By George! what a nation o' spindles,

An' millwheels all whirling around,

Some on 'em in garrets o' houses,

An' some on 'em down under ground.

One fact'ry, I vow, 'tis a smasher!

'Tis pretty near flat on the top,

You might put our house here right on it.

An' Uncle Sam's saw-mill an' shop!

I walk'd round awhile, and went in it,

Then, whew! what a terrible buzz!

I swagger! 'twas more than a minute!

Before I could tell where I was!

Confound it. You never could hear there,

A body might stand still and bawl!

I believe that you might stay a year there

An' find something new after all!

I snore! why it does beat all nater!

Such oceans o' pickers and reels!

My conscience! how can they contrive it!

To tend all them spindles and wheels?

An' then, such great piles o' spun cotton!

As big as a common sized mow!

By jings! if my eyes had'nt seen it,

I would'nt believe it, I swow.

THE FARMER.

BALTIMORE, FRIDAY, JANUARY 30, 1824.

Very little business transacting at this season, and consequently we have no alterations to make in our quotations of last week.—We publish a statement of the latest prices of cotton in the Liverpool market:

LIVERPOOL, Dec. 2.

Cotton—39,216 bags have been imported in November 1823, viz. from Charleston 3187—same month 1822, 3919; Savannah 930, do 749; other ports in America 10,913, do. 2691; New Orleans 1636, do. 1156.

Import the first eleven months, 1823, viz. from Charleston 93,351—in 1822, 76,992; Savannah 91,235, do. 76,194; other ports of America 103,536, do. 71,987; New Orleans 102,892, do. 56,626.

The total supply of Cotton to this port exceeds that of the first eleven months of 1822, by 87,588 bags; the increase from America is 109,215, and from the East Indies 5764, whilst there is a decrease from the Brazils and Portugal of 20,708, and from Demerara and the West Indies of 6683 bags.

December 6.

The total sales in the course of the week have been 8000 bags of which 6300 are American cottons. Our import amounts to 7800 bags of which 4700 are from the United States.

Our public sale at auction yesterday, was composed of about 1300 Orleans, 600 Sea Islands, 800 Uplands, 500 Alabamas, and 100 Bahamas. There was a good attendance of dealers and spinners, and every description of American cotton offered was sold.

The Upland, Orleans and Alabamas, at $\frac{1}{2}$ d. to $\frac{3}{4}$ d. lower than last week, especially middle and lower qualities.

The Sea Islands of common quality, and stained, went at a reduction of $\frac{1}{2}$ d. to 1d. and good to fine 1 $\frac{1}{2}$ d. and in many brands considerably more from the former nominal rates; for the cottons have been so much neglected of late that we have scarcely a guide to go by. The prices of these have been of late gradually lowering to those of common qualities, which it is generally understood arises from the great improvement in machinery, enabling spinners to make common cotton serve where good were formerly required.

Manchester Dec. 2.—"Referring to my lines of 24th November. I have only to say you must not ship any Uplands but at the lowest prices of last season, nor any good clean sound Sea Islands that shall exceed 11d. per lb. laid down in Liverpool."

CATTLE, Improved short horn breed, continued—NATURAL HISTORY, migration and torpidity of birds and animals—HORSES, on the appellatives, qualities, habits, and defects of—ROOT CULTURE for cattle, too expensive—MANUFACTURERS earning more than farmers of equal capital—PREMIUMS, what kind ought to be offered—PENNSYLVANIA AGRICULTURAL SOCIETY, list of officers and communications made to—DISEASES OF CATTLE, remarkable one described, and its propagation to the human species—HOGS—scorching off the hair preferable to scalding for bacon—MAN POWER, what it means, and how most advantageously exercised—SMITH-FIELD MARKET, cattle and sheep sold in since the year 1789—WHEAT, average price of since 1789—MANGEL WURTZEL, how to cultivate and store it—EDITOR'S CORRESPONDENCE, on millet, a destroyer of fish in the gill nets—valuable native grape, corn and cotton crops—diseases of horses and cattle—Dr. Black's system of improvement—TOBACCO, reports of inspection—Lost hours—Pedestrianism—Iron converted to steel—Poetry, Prices Current, &c. &c.

Printed every Friday at \$4 per annum, for JOHN S. SKINNER, Editor, at No. 15, B-lvidere street, Baltimore; where every description of Book and Job Printing is executed with neatness and dispatch—orders from a distance for PRINTING or BINDING, with proper directions promptly attended to, addressed to J. Robinson, Baltimore.

AGRICULTURE.

AN ADDRESS

TO THE HAMPSHIRE, FRANKLIN AND HAMPTON AGRICULTURAL SOCIETY, NORTHAMPTON, MASS. OCT. 23, 1823, BY I. C. BATES, ESQ.

At a meeting of the Hampshire, Franklin and Hampton Agricultural Society held at Northampton, October 23, 1823.

On motion, resolved, That the PRESIDENT, and the Hon JOSEPH STRONG be a committee to return the thanks of this Society to ISAAC C. BATES, Esq. for his excellent discourse this day delivered, and to request of him a copy for the press.

Attest,
DANIEL STEBINS, Secretary.

ISAAC C. BATES, Esq.

SIR—On behalf of the Hampshire, Franklin and Hampton Agricultural Society, we beg leave to present to you their thanks for your learned and excellent Address delivered before the Society on the 23d inst. and we are instructed respectfully to solicit the favour of a copy for publication.

We are, with respect and esteem,

Your friends and humble servants,
JOSEPH LYMAN,
JOSEPH STRONG.

Northampton, October 24, 1823.

Northampton, October 24, 1823.

GENTLEMEN,

The address, a copy of which you do me the honor to ask for publication, is submitted, without apology, to your disposal.

I am, very respectfully,

Your obedient servant,

I. C. BATES.

HON. JOSEPH LYMAN,

HON. JOSEPH STRONG.

The encouragement of household manufactures is a primary object of the Hampshire, Franklin and Hampton Agricultural Society. Hence the female competitors for premiums and ladies generally, attend the public exercises on the second day. Without the knowledge of this fact, some of the allusions in the address, and some of the topics of remark, would be deemed inapplicable.

ADDRESS.

GENTLEMEN,

We have again assembled under circumstances which are favorable to the views of our society. Since the last meeting, the Legislature have continued the annual grant for the encouragement of Agriculture and Manufactures, for the further term of five years. And it is worthy of remark, that in doing it, they have only executed the trust committed to them by the framers and founders of our constitution and government. It shall be the duty of the Legislature, say they, to encourage private societies and public institutions, rewards and immunities, for the promotion, among other things, of AGRICULTURE and MANUFACTURES.

It is too late, I apprehend, to arraign the policy or question the propriety of our agricultural associations. If there be any thing worthy of patronage, it is the art upon which all other arts depend; the occupation without which all other occupations are useless. The Dublin society, established in 1731, as it was the first in order of time, so it was for a series of years supported by the voluntary contributions of its members, until at length, its effects be-

coming apparent, other societies were formed; and now they are established throughout Great Britain, France and Germany, and indeed throughout Europe. All that is granted by this Commonwealth, and the several states combined, for the encouragement of agriculture, is absolutely nothing compared with what is done by France for a single national establishment, and that too in a land of vines and olives. Experience therefore, has settled this question; experience in different countries; under great diversity of forms. It is not too much to say, we have the judgment of mankind in our favour; not upon a subject remote from observation and difficult of research, but full in the public eye, opened by its effects and known by its fruits.—What then ought the conjectural scruple of the prospective calculator to avail, against this mass of practical evidence, which near a century has accumulated? If the only effect of our act of incorporation were to bring together once a year, the gentlemen whom I now have the honor to address; awakening their attention to what has been done and what is doing; leading them to an interchange of views and feelings; animating them to enterprise and emulation; I should think the society rested upon an unquestionable basis of utility.

Let it not be imagined, gentlemen, there is nothing more to be learned in the arts of life.—No obstacle to the march of mind, is more in surmountable than the conceit, that we are wise enough. It closes the eye of enquiry and shuts out the light of knowledge. True, according to the received chronology, this world is about six thousand years old. Yet it was more than four thousand years before you learned how to make a good plough. Cincinnatus talked with as much complacency as we do, of "the good old way," when he was following his land with the limb of a tree for his plough beam and a knot to it for his colter and shear; and the patriarchs, when they were grinding corn with pestles. How long since you learned the art of printing—and a thousand other arts? How long since you found out the value of the potato?—Since you naturalized Dutch clover? Since you discovered that your plain lands were not made in vain? Depend upon it, gentlemen, there is a better way than that now in use, in every act of field husbandry, and in every operation of mechanics. Think you, that in this immense repository in which we live, you have explored the whole of its contents—or any part of them? The recent discoveries and improvements in the arts and sciences shew, that even now, in this age of late and fancied maturity, knowledge is in its pupilage. I would excite you, therefore, to a *thinking* cultivation of your lands; to attentive and nice observation. Push your inquiries to the extent of your capacity, and your experiments as far as a prudent economy will permit; and make no other use of "the good old way," which is often circuitous and often bad, than to keep along in it, until you can find a better. I hazard the conjecture, that there is now about each of your establishments at home, some defect, or misarrangement over which your eye has wandered a thousand times without discovering it. Extend the remark to your farms, fences, tillage and stock; you will find enough to fix your attention, and put in requisition all your powers, be they what they may.

Having thus spoken of our society and attempted to remove an obstacle to its success, I should be glad to present you with something worthy of it. The diversified subject of practical husbandry, you better understand than I do; and I have neither skill nor disposition to enter upon the details of stock. But the best fruits, which my in-

dustry has collected for the occasion, are at your service.

We find ourselves here, gentlemen, dependent upon four elements. What the industry of man cannot accomplish for him, the benignity of Providence has furnished ready fitted for use. The air, fire and water, essential as they are to our existence, are without price, and never, except in connexion with something else, become the subject of price. Of universal use, they are of universal enjoyment.

But the earth, from which we derive our subsistence, or by the agency of which we make the other elements subservient to the same purpose, is the subject of property; we call it ours and attach to it different degrees of value according to its quality, situation and condition. When lands were first taken up, they were of no value; and were they as abundant as the air, yielding sustenance as spontaneously, they would be of no value now; that is, not the subject of price. But for the support of the human family, they must be cultivated. The supplies they furnish, are, therefore, limited. And hence, although when our ancestors first established themselves upon this river, lands were of little value; yet as population increased and the lands first taken into cultivation became insufficient to satisfy the demand for their products, it became necessary to take into cultivation more land. Those under tillage then rose in value, and as each successive tract, under the influence of a growing population and an increasing demand, was taken into cultivation, the price of those already under improvement, continued to rise. Hence it was *demand* for the produce of land, that originally gave value to it, and that still regulates the price of it. A farm, that yields the interest of one thousand dollars, agency and expenses being paid, is worth a thousand dollars. If but the interest of half the sum, it is worth but half the money, and precisely for the same reason the bank stock, which yields six per cent. is worth its par value. Now, it is obvious that the interest which a farm will pay, taking for granted it is cultivated to the best advantage, depends upon the price obtained for its produce; and that the price depends upon the demand for it. *Demand*, therefore, for the produce, regulates the *price*, of land. We shall have occasion to make use of this principle hereafter.

We not only find ourselves thus located and dependent upon our own industry for subsistence; but we find ourselves distributed into classes; and it will be sufficient for my purpose to say, into LABORERS, FARMERS, MECHANICS, TRADERS and PROFESSIONAL MEN. And I must ask your attention for a moment, to the principles by which their income is governed, with a view to deduce the means by which their condition is to be improved.

The class of Laborers I intend, comprises those of *ordinary* skill, health and strength, who have a family to maintain. In relation to this class, it is an established law, that the rate of wages cannot rise much above what is requisite for their support, according to the custom of the place in which they live; nor fall much below it.

It cannot fall below, because, you perceive at once, the race would become extinct; or at least that population would be checked and discouraged, and the number of laborers reduced by death, or emigration, so as to bring the rate of wages up to the point assumed.

It cannot rise much above in any given place or country, because laborers from other places, or from abroad, would come in. The rate of wages would allure them. The supply thus becoming more abundant, the price would gradually fall to the point stated.

If there should not be sufficient competition to reduce the rate of wages, and it should continue to rise in spite of this obstacle, there is another, which has all along been resisting, that will effectually check it. It is to be found in the adverse interest of the employer. When wages become as high as he can afford to pay, they can rise no higher. This point is the extreme of their elevation. And thus the rate of wages ranges between these two extremes. And the extremes themselves are not infrequently nearly in contact. They approach and recede as business is productive. Probably at this moment, no farmer can afford to pay more than the minimum rate of wages. Indeed, from the mere effect of competition, it seldom rises higher.

It is mainly upon this principle you account for the difference between the ordinary wages of a man and a woman.

You perceive I limit the application of my remarks to laborers with families, because they are the nurseries of population, and must therefore be sustained; to those of ordinary skill, health and strength, because they constitute the mass of laborers. It is obvious, therefore, that to improve his condition, such a laborer must reduce his expenses below the ordinary standard or improve his skill and ability so as to command more than ordinary wages.

And hence it is further obvious, that laborers without families, and laborers with, who have more than ordinary skill, or from any cause, are more than ordinarily useful, may accumulate property; and it not unfrequently happens that they emerge from the condition of their early life and become men of great wealth and respectability.

In addition to the income of the laborer, the Farmer has an income from his farm and stock, which constitute his capital, equivalent to the current rate of interest upon the cash value of it for the time being. Should land produce more or even this rate of interest, taxes, agencies and repairs deducted, capital would be invested in it, and land, in consequence of the demand for it, would rise in value, until the rate of interest should be reduced as much below the current interest, as the security of real estate rises above personal security. And although the capitalist, who might not be able to superintend his lands, could not make the investment so advantageously as the husbandman, yet there is a wide field for competition among farmers themselves; and, if lands will produce more than the current interest, they either have, or can readily command capital to buy them. So that the income of the farmer is very little, if any thing more, than the income of the laborer, added to the interest of his capital, and seldom falls below it; for the number and business of farmers would decrease until the demand for their produce should raise the profit of their business to the common standard.

The income of the Mechanic is that of the laborer, and as much more, in the whole, as his time and expenses in acquiring his trade and the tools with which he prosecutes it, are worth.—It will neither permanently exceed, nor fall short of this, for the reasons already assigned.

At present the wages of a mechanic exceed this ratio. Take seventy-five cents, as the average of a laborer's days work, and one dollar and twenty five cents, that of a mechanic, it gives to the mechanic a fraction more than the interest of twenty six hundred dollars, above what the laborer receives. Nor do I know whether there is much difference between the certainty and regularity of their employment.—It is plain that the knowledge of his trade and the tools of his occupation, cannot cost this sum,

But it is to be remembered, that he is entitled to more than the interest of his disbursements, for this species of capital will be extinguished by his death. Yet this allowance being made, the income of the mechanic is still disproportionate to that of the laborer; but, in the number of apprentices, there is a cause in operation, that will equalize their profit.

The Trader is subject to the control of the same general principles. He, like the mechanic, must make a profit that shall pay him for his apprenticeship and the incident expenses; for his time and services in superintending and prosecuting his business; for the interest of his capital, and as much more as will cover the ordinary risk of losses. If he cannot do this, no wise man will embark in trade; and if he can do more, enough will, to reduce his profit.

The same general law regulates the professions. A Lawyer, for instance, must derive an income from his profession, that shall refund to him the expenses of his education; of his library; that shall pay him for his services, and enable him to live as custom and general propriety require. And his income must rise and will rise in proportion to the perplexity, or any other undesirable circumstance attending the business of his particular pursuit. Otherwise, no man, who valued his own comfort, or consulted his own interest, would engage in it. Permit me, as connected with the subject under consideration, to suggest one among many reasons, why the salaries of clergymen are comparatively so low. It is the certainty of support. Should the time ever arrive, therefore, when the basis of this contract is to be changed, and the security of a support for life lessened, salaries will and must rise to cover the risk.

Thus it is manifest, that the subject of income, which seems to be arbitrary and to operate capriciously and unequally, is governed by established principles; that the income of a man of ordinary talent, health and strength, let him belong to which of the classes in society he may, is limited, by a law of general efficacy, to the standards I have named; and that competition is the repressing, and the sustentation of life the reacting, power.

You perceive that the further a business is removed from competition, the greater will be the chance of profit. This might be illustrated in a variety of interesting particulars. The mechanic is further removed than the laborer. Most men can work, but few comparatively can make a watch. The trader is still further removed. He must not only have skill, but capital. Professional men, still further. Nothing short of a life of a laborious application, aided by good natural talents, can insure them success. Hence it is, that here and there an individual, possessing great powers and rare attainments, outstrips all competition, moves in his own sphere, and prescribes his own laws. Suppose every man could write the Waverly novels? The copy-right would not be worth more than that of Tom Thumb. So in all the mechanic arts, he who is skillful beyond others, dictates his own terms and profits by his own genius. This principle runs through all the orders and grades in life, from the youngest domestic of our families, to him who directs the industry of a farm, shop, or nation.

The conclusion then is, which I wish to impress distinctly upon your minds, that without extraordinary talent, extraordinary industry, or extraordinary economy, no man, with a family, can reasonably expect any thing more than a bare living. Those whose estates are already sufficient to meet the demands of old age, or

premature infirmity, are of course excepted. If you have favoured me with your attention, you will have perceived that this is but a corollary from the principles established.

Now, a competency—neither poverty nor riches—is essential to our happiness; so essential, that he who is married without the possession or prospect of it is a mad-man; and waving all courtesy, the girl that would marry him is a fool; and that as well whether he be in the possession of it with habits likely to dissipate it, as when he is without either the possession or prospect of it. There is no weighing, nor measuring, nor counting the calamities incident to a destitute and embarrassed condition. They press upon the breast of a man like an incubus; they obstruct the pulsation of his heart; they deaden the current of his life; they wither all the beauties, with which nature would cheer him by day and fancy beguile him by night; they are the ever present messenger of fresh and evil tidings. And nothing but the reduction of a father to something less than human, or the elevation of him to something more, can render such a state supportable. It is, therefore, one of the highest duties and ought to be inculcated from the cradle up, as well upon those who are born to a competency, to maintain, as upon those who are not, to acquire it; for it is favourable to the growth of all the virtues and essential to domestic comfort. It is the little vase of earth in which your flowers and shrubs, that are to ornament and embalm your fire sides and sweeten and cheer the intercourse and sympathies of husband, wife and children, are to grow and flourish. Is it not then worth a little self-denial, the doffing of an extra ribbon, and another and another effort to accomplish it? Tell me, ye who can recollect enough of the trifles you have thrown away as of nameless importance and for which you were not a whit the better, to wrap your children warm in flannel, to light up a cheerful fire in your own neat and comfortable dwellings, to spread your table with abundance of wholesome food, and to cheer you, if sick, with the prospect that these blessings will continue and brighten upon you, without the aid, or at least without the reproof, of charity,—tell me, is it not worth an effort?

You recollect, that without extraordinary talent, industry, or economy we have nothing more to expect than a living. While, therefore, I have only time to urge you to IMPROVEMENT, without dwelling upon the means; and to redouble your DILIGENCE, without noticing wherein we are remiss; I will detain you for a moment, if you please, upon the subject of ECONOMY—economy within your houses; economy in building them; and economy in one other particular.

Economy is to industry, what the memory is to the mind—it retains for use. The great secret of making estates, lies in this. You have only to apply your arithmetic to the operation of compound interest, during a moderately long life, to be satisfied of this fact. A dollar expended at twenty-one, does not accurately denote the extent of your loss. You not only lose the dollar, but you lose many more, which without subjecting you to any trouble, it would have earned you. You grub up the measure of wheat which is well sown, and in a good soil, and which would yield you, not merely one, but an annual, and a perpetually increasing crop. Extend the application of this remark to your expenses for dress, furniture and equipage, and indeed to your business and methods of conducting it, you will find various particulars in which savings may be made, trifling in them-

lives I admit, but in their results, wealth. Throw in a few ten dollar hats, ye who have your estates to make and who would vault the stars without wing or trumpet; throw in a few pair of five dollar boots; a few watches—a most abundant article—to say nothing of their appendages, or indications, which have involved in such uncertainty, the business of metallic research—throw in a few other superfluous commodities, if the gallery will permit, and if not, throw them in. You will have a collection directly, which, without any other magic than that of a little patience, will make you an estate.

However, it is more to my purpose to suggest, that negligence, in the department of a house-wife, will either make, or keep, her husband poor. No providence nor exertions of a man can sustain his family and improve their condition, against this silent and ceaseless corrosion at the heart. It is the perpetual dropping, that will wear the marble and exhaust a sea. If a man, therefore, has a slatternly wife, it is all over with him. The weird sisters may wind up his destiny as soon as they please.

Entering upon life, a young man, with some thing before hand, builds a large house. It is then to be furnished. By this time, all he is worth and his wife too and perhaps something more, is invested in it. Fences and out-buildings must correspond. Repairs must be made at occasion may require. Taxes must be paid. Furniture replenished as fashion varies. And, with such a fine establishment, there would be no resisting the temptation to shew it frequently to one's friends. Now I affirm, that at the age of fifty, if instead of building, he had hired, or limited his accommodations strictly to his wants, the capital he would have saved and the profit upon that capital, would have amounted to a handsome estate. But suppose he has been able to maintain and educate his family. When he makes his will, he gives his homestead to his favorite son, and, to make his children equal, charges him with the payment of legacies to the others. Thus the son begins life, with an accumulation of debt upon him, and, in the issue, sinks under it. Go where you will, the eye meets with a succession of large houses, in every stage of dilapidation from broken windows, to falling sheds, and prostrate walls. And, what is singularly characteristic, we build for the summer; so that in order to keep cool, one third of the year, we have full employment, the other two thirds, to keep warm. A different practice would have put a new face upon New England. But who would live in a little hutch of a place! is the general objection, and away goes all a man's philosophy on the subject.

The other particular, upon which I promised a remark, although too important to be passed in silence, yet, as it has been the subject of comment by my predecessors, I shall be excused if I only notice; for, if the certain consequence of ruin to health, to character, to fortune, to family, and, if you choose to look beyond, the career of ruin onward; if to a man who admits the truth of these realities, and feels them too, and with a sensibility that madens to mental torture, and deepens to anticipated hell, these living images appeal in vain, what think you words can do! Oh, there is not in nature, an object more to be commiserated, than an intemperate man, thus bound down, and chained to his destiny by this tyrant habit. He is in the condition of Laocoon, in the folds of two enormous serpents; and what heightens the horror of the conception and finishes the analogy, the same complicated wreathes of the strong and poisonous and re-

sistless monsters that wring the father to death—embrace his children also. Is it not an object worthy of this society, of the combined effort of this society, to see if something cannot be done to stay the progress of this appalling evil? If you cannot extinguish the fire, may you not countermines and counteract it, so that when the materials upon which it feeds are consumed, it shall go out? But, at present, it is bursting every barrier and kindling along the whole line of life.

Upon this subject of economy, a wide field is open for remark. The facility with which money was made, during the war in Europe, has entailed upon the country generally, habits both of thinking and acting, that leave it still questionable, whether, in the end, we shall gain, or lose by it. And the rage of speculation in lands, seems to have connected itself, in its influence, like an evil star, with the generation then coming into being. But feel, think and act as we may, the time has come when the airy castles of other days must crumble, and estates must be made, if at all, by long continued, well directed industry, and universal, rigid economy. I however dismiss the topic, for it is in vain to expect a general improvement, against the influence of your poor laws. They are a direct bounty upon indolence and extravagance. If provision were to be made, for the very purpose of encouraging these positive evils, I know not how it could be done more effectually than it has been done. You take from men the motive to exertion, when you provide for their support without it. If either the indolent, or the extravagant, had to depend upon their own exertions for subsistence, and not upon their more industrious and prudent fellow citizens; if there was neither bed nor board spread for them by public law; they would have at least enough of the instinct of animals about them to make some provision for themselves. Those, who are in want from misfortune, or infirmity, have an interest in the sympathies of the heart of every man, upon which they can draw, at pleasure, to the extent of their need, and confer a favor, while they receive an obligation. But at present, they are like debtors in the company of felons.

I have said, that the income of the common laborer does not ordinarily exceed the expenses of his family; nor that of the farmer the interest upon the *current cash value* of his capital, added to the income of the laborer. But when demand for labor is abundant and the supply limited, wages will rise to the highest price the employer can afford to pay. And when the demand for the produce of land is steady and increasing, lands will rise in value and to an indefinite extent. These points have been established. The same remark will apply generally; for improvement, in any one branch of productive industry, affects beneficially the whole community.

The question then is, and a question worthy of your consideration, addressing itself to a vital interest of New England, how are we to *increase the value of our lands?* or, which is the same thing in other words, how are we to *improve our market?*

You have looked at home and abroad for a succession of years. Your merchants have explored every sea and port; and you have no reason to expect an improvement in your external commerce, for it rests upon the basis of general reciprocity. We know not what new channels of commerce may be opened, nor what mines of wealth explored. These are among the contingencies of the future, upon which no calculation can be made, nor reliance placed.

The important, practical inquiry, therefore, returns upon us; can any thing be done to improve our market?

If we all become farmers, the effect will be, an *increase* of supply, and a *diminution* of demand.

I know of but one answer to the inquiry, and of but one expedient that promises to be effective.—We must manufacture, so far as we are able, the products that come to us, in millions sterling, from other countries. I am aware that the public journals, with but few exceptions; the periodical works of the day; and the notes of American editors and publishers, appended to every work upon political economy that passes through their hands; to say nothing of the prejudices and feelings of the people on the subject; all maintain, that this is not for the interest of the farmer. Their position is, *that he ought to buy his coat, where he can get it cheapest.* The position contains a truth; but in its *application*, it is false, and in this lies a deception which has not been without its effect.

I admit, that as between two American manufacturers, other things being equal, you ought to buy of him who sells the cheapest. This is the *truth*. But, as between an American, and a foreign manufacturer, you ought not to buy of the foreigner, even if he sell the cheapest. This is the *falsehood*; and this position I am to sustain.

Let us suppose that we were to manufacture the article of broadcloth, to the extent of our wants.—Capital and industry must, of course, embark in the new business. That capital must have the means by which to operate—mill seats, buildings, machinery, raw materials, laborers. That industry must have the means of subsistence. The *effect* then will be, to create an additional demand for the capital and industry that remain, and, consequently and necessarily, to give a larger profit. As the produce of land rises, land itself will rise, and every thing, upon which the increased demand bears, will rise. Although the farmer now makes, for illustration say, double the money he did before, twelve per cent. instead of six, yet the capital and industry thus embarked, cannot return to be invested in lands, because lands are worth double the money they were before. The capital, therefore, will continue, and the profit of the new business will be gradually reduced by corivalry to the common standard, or, as commonly happens at first, to something below it; but at that point it settles. This is the *way*, in which the new capital and industry will affect you. Look for a moment to the *extent*.

An hundred thousand laborers, converted into soldiers, not only create a demand to the extent of their own wants, but of two or three hundred thousand more, whom their labor supplied. The manufacture of broadcloth merely, would give new employment to a multitude of men, women and children. It would call into being a variety of new crops, such as woad, rape-seed, teasles, &c. It would introduce into your pastures another variety of stock—the fine wool sheep; and when you collect that about two million pounds of wool, costing little less than two million dollars, were imported during the last year, you will form some conception of the value of this article. It would create engineers and machinists, and furnish extensively new employment to smiths, joiners, carpenters, and mechanics of all kinds.

But instead of broadcloth merely, suppose we were to manufacture the endless variety of products, for which we are now dependent upon the workshops of Europe. Would it not give a new impulse to industry! Would it not create a new demand for produce! And it would be cont-

dicting a law of nature to say, that lands would not rise in consequence.

We are, however, not left to speculation upon this subject. We have the demonstration of experience, as well as the conclusions of reason. Go to Waltham, to Providence, to Munson, to Southwick—go into the vicinity of any manufacturing establishment.—Col. Shepherd's of this town, for example—a prominent case to illustrate and establish, not only the truth of the position assumed, but to shew what individual enterprise, skill and perseverance, are able to accomplish,—and open your eyes, and the proof will enter.

If we continue to buy the manufactures of other countries, we must continue to sell at present, or more reduced, prices. But, if we manufacture ourselves and pay more for what we consume, we shall be indemnified in the advance of produce, rise of land, and general improvement of the market. Ask a gentleman from Springfield, whether he had better pay ten dollars for his musket, with the resulting benefit of the armory, taking into the account, not only its influence upon his shop, but upon his produce and lands,—or eight, for one from the tower of London, without it? And yet the position would be as tenable in relation to him as it is in relation to the farmer. It would be as much for his interest to buy his gun, where he can get it cheapest, as for the farmer, to buy his coat.

I have presented you with but one view of this subject; but in relation to the farming interest, it is in my apprehension decisive. How then is the object to be accomplished?

Manufacturers, at present, having large capital and able to hold their goods, continue their business. But there are no new establishments, unless it may be in the manufacture of cotton. There can be none. Capital will not be embarked, unless sales are regular. There can be no regularity, nor certainty of sale, while the market is left to fluctuate under the unequal importation of British goods, which are more or less, according to many causes alike beyond our apprehension, or control. Who could have anticipated, that, in imitation of the satinett into which our coarse wool is wrought, such quantities of goods would have been thrown into market and sold at less than sterling cost, as nearly to annihilate, at least for a time, this valuable branch of our domestic industry and reduce the growth of the raw material to a losing business? You might as well expect a man, not a Knight of Malta, but a sergeant of the guard here, to list himself for conflict with one or twenty, as might *happen*, he unarmed and they in steel, as that an individual, or company of individuals, should attempt, under existing circumstances, to rival Great Britain in the business of manufacturing. Sales are fair and prompt to-day; to-morrow, a ware-house of London is emptied in the streets of Boston. The manufacturer will hold his goods, if he can; if not, he must sacrifice them; and in either event, sustain loss.

Let the government, therefore, give birth and protection to manufactures, by increasing the duties on importations, cautiously and prudently, but to the needful extent. Practice will soon perfect skill; competition, reduce prices; and the advance of the consumer return to him, in another form, with rich commissions.

But the commercial theory is, "let manufactures alone,—if profitable, they need no protection; if otherwise, they do not deserve it."

I have already replied to this assumption. I have no disposition to retort it. The mine is rich. It is ours. If we permit other nations

to work it, it is our own folly, or something worse.

But I answer further. It is admitted, and by those who resist an increase of duties, that the existing factories are profitable to the country. Yet, but for the *exclusion* of British goods, by the declaration of war, there would not have been a spindle in operation to this day.

I answer further. The arguments against an increase of duties, go, with a concentration of all their force, to shew, that there should be no duties at all.

I answer still further, and my appeal is to this society. You patronise household manufactures and encourage them by your rewards. You do right. But upon what principle is it, that the labor of a girl, that turns a single spindle, can be productive, and the labor of another, that turns one hundred, the reverse? There is the expense of the machinery! True, and there is the saving of the wages and board of ninety-nine persons. And not only so; while the labor of one hundred persons is thus despatched by one, the ninety-nine are all at liberty, and each of them can do as much work, in the same way, as the individual spinster. If the one deserves patronage, therefore, I leave it for you to determine, whether the other is not entitled to protection? But the master of a family, if he cannot sell, can consume; the manufacturer, however, must sell, or his business must cease. And, therefore, a wise government will enable him to do it—not for his own sake merely, but for the good of the great fraternity; or, if you please, of the family.

The balance of trade, as it respects England, is against us; but the conclusion, that therefore it is a losing trade, is denied. Without stopping to trace the arguments in their windings, or contending that the custom-house returns indicate the exact truth on this subject, or controverting the position, that it does not follow, *of course*, that it is a losing trade; yet it is quite apparent that an individual may purchase and consume more than he can pay for. A nation may do the same. And an individual does it, when the amount of his purchases and consumption, for a given time, exceeds the spare product of his industry and capital, supposed to constitute his means, for the same time. A nation does it, under like circumstances. When an individual mortgages his estate, or parts with vested and productive property, to the trader, his condition is obvious. What means then, permit me to inquire, the almost unlimited transmission of stock, both bank and national, to England? When the day of reckoning and payment comes, let the guardians of the public credit look to it, that its pillars do not tremble.

It is not two hundred years since Great Britain imported her broadcloths from Belgium, and not one hundred since she derived her cotton goods from Germany. Had she acted upon the principles which we oppose, she would not have sold a yard of either, even in her own market, to this time, while now she supplies half the world with both. But, instead of leaving manufactures to originate and protect themselves, she originated them, by prohibitory and protecting duties. In the time of Elizabeth, we find the great Bacon, vehement, in protesting against the importation of foreign products, on account of the national dependence and poverty which it involved. To this day the ports of Great Britain are closed against the introduction of a single manufactured article, which British industry and British capital can make. No sooner did our straw-braid find its way into London, than a petition went to Parliament for an act of exclu-

Suppose the tables reversed and that we could undersell Great Britain, in her own market.—Would she permit it? She would sacrifice her manufacturing capital, it will be said. I say more. She would not only sacrifice that, but her agricultural capital with it.

It may be for the interest of the merchant, that importation should be free, and consumption to the extent of our ability to pay. The more he sells, the greater his profit. But it is not for the interest of the farmer, nor of the country. It will pave your commercial cities with gold, but it will fill your towns with beggars. I say this, "not that I love Cæsar less, but that I love Rome more." The agricultural interest, in connexion with *commerce merely*, never did become rich, and never will, and never can. Its capital is too limited; its products too bulky; its market too remote. What makes an acre of cabbages in the vicinity of Boston, worth ten acres of corn in the country? Or an acre of land, for *mercantile*, worth an hundred dollars there, that would not be worth ten here? The demand must be brought home to you. The country must be filled with activity and industry, not of the plough and spade merely; but of the spindle and loom; the forge and hammer, and all the busy machinery of the manufacturing process. It is this, and this only, that can make you rich.—The principles, that govern your income, shew that it cannot be otherwise. And your innumerable mill-seats and the abundance of your water power, are an indication of nature, and a pledge too, that you may become rich in this way.

BUT THE PRICE OF LABOR!—Sell your wheat for two shillings and six pence by the bushel, and you may hire labor for a shilling. Nominal values are of no importance. *Relative value* is the only thing material.

BUT THE REVENUE—THE SUPPORT OF GOVERNMENT!—I am aware that when you buy a coat, you pay a tax. One part of the price goes for the support of government; the other to pay for the cloth. But I answer—pay directly, what you now pay indirectly, and what you pay, with a triple profit, as well upon that part of the cost of your coat which is tax, as that which is cloth; one to the importer, one to the retailer, and a third to the intermediate merchant.

The government that appeals to the understanding and consults the interests of the people, will never lack resources while any remain.

I would venture to inquire then, whether, since British ships have contrived to find employment, and British merchants to make fortunes, and British subjects to accumulate a fund in the hands of government, to the unexampled amount of their national debt, notwithstanding an absolute *exclusion* of foreign manufactures, our commercial and mercantile interests—distinguished as our merchants are for enterprise—may not, possibly, *survive* a more limited importation of them?

Increase of population and consequent demand for produce, originally gave, and still give, value to land. How injurious, therefore, to New England has been the emigration to the westward! The magic that has reared the towns and villages in that part of the country, has been your citizens and your capital, under the double influence of increased exertion and increased economy, the prevalent virtues of a new settlement. I know that, politically, some advantages may accrue from a New England population there, and I by no means wish ill to those of our friends who are interested in the lands there, but, to the same extent as emigration prevails, the value of property is reduced here, to say nothing of the loss of capital and of men—the most valuable of all capital. It is this, among

her causes, that has left farms upon the hills without tenants, without purchasers, and without price. Bleeding at every vein, for a succession of years, will reduce any subject to depletion. The way to restore health and soundness, in such a case, is to cut the ligatures and stanch the blood.

The bounties of Providence are distributed with more impartiality than we imagine. Wherever privilege is given, or hardship imposed, an equivalent is exacted, or conferred. Our hills are rough; but the business of grazing affords pasture to farmers, for the very purpose of enabling them to subdue the rebellious character of the soil. Our river lands are productive; but the price of them is comparatively high, and, without yielding the proprietor a better return than the hills for the interest of his money, they exact of him more labor. With industry and economy, the necessity of which is a blessing, we can all live, and in the Arcadia of the western world, they are not exempt from the common lot. At certain points of remove, deformities disappear in the indistinctness, or blend in the light, of the landscape. For more reasons than I have time to assign NEW ENGLAND is the place in which to live and to die.

The classification of men in society is not arbitrary, but grows out of the nature of things.—You may as well, therefore, attempt to change the immutable principles upon which society is founded, as to change the organization of it in any particular. You cannot do the one, without the other. Each department of industry, whether intellectual or corporeal, is filled, because there is something in it to be done, by which subsistence, or distinction, or both may be gained. This diversity of occupation forms classes, all governed by the same motive, and posting, with what ability they have, to the same results.—Were you to take the fabric of the social state to pieces, therefore, it would make itself up again in the same general form. As in every character so in very class, there are blemishes and defects; but much of the unhappiness of men results from magnifying the one and the other.—And it will usually be found, that he who is most in fault, is most censorious; and that the same spirit, which kindles at the renown or elevation of another, would plant itself upon the crown of the arch of both, either by mounting to its height, or by levelling it to its capacity. There are lawyers who are the ornaments of their profession; others who are the disgrace of it. There are men of power and authority, who are the benefactors of their country; others who are its scourge. There are men of fortune, whose riches give means to charity and influence to virtue, that are the golden spires that glitter upon the capitol of society—objects upon which the sun loves to shine and from which to reflect his own beams of magnificent glory. There are others, on whom Providence seems to have smiled and around whom to have scattered a profusion of temporal blessedness and all the radiance of temporal honors, who are nevertheless an iron bound coast, from which a fellow creature, however he may have been shipwrecked in the storms of life, however much an object of pity and compassion and charity, had better keep off and trust himself to the mercy of the elements—a coast upon which there is no life boat, and along which the passing mariner, whatever tempests may beat upon him and with whatever blackness or darkness cover him, never ventures the signal of distress a second time. I might run through all the classes in the circle of society and apply the same general remarks to individuals of each. You meet with farmers and mechanics who are conspicuously worthy, who adorn the station they

occupy and would have adorned any other. You meet with others, the circle of whose being is narrowed to self alone, and whose imagination, in its most playful and discursive flights, never ventures beyond it.

But as we are all embarked in the same vessel, the conclusion is, we have storms enough to encounter and calamities to endure in this voyage of life, without mingling bitterness in each others cups, or infusing poison into each others comforts. We mar the incomparable beauty of our inheritance, by petty disputes and rivalries among ourselves. Run over the map of the world; you cannot select a spot more privileged than that which you occupy. We wish the patriots of South America, of Spain, of Greece, success; because we look forward to the time, when they may enjoy what you now possess without limitation and may possess without end. But, after they shall have gone through the struggle of right against wrong, of the people against power, they will hardly have improved their condition, until, by education and moral culture, they shall have formed the mass of population into a race of men, capable of understanding their rights, as well as able to assert them. True, the convulsions of the revolution break up the old foundations of despotism; lay open the unexplored recesses and dormitories and cells of superstition; and send the light and air of truth and liberty through the dark domain of many centuries of mysterious and terrific power; and prepare the way, by thus rolling their scourge fiercely over the earth, for another and a better state of things; yet the time is far distant, when your sun will shine in their firmament; when the dews of your parochial, religious and civil institutions, will descend upon their mountains, and awaken, into life, the countless blessings and beauties of your free and happy land. Here you have perfect security for life, liberty and property. Here, you have equal rights and equal honors. He who will, may run the race and take the garland, or scale the heights and deck himself with the plumes of glory. I would inspire you, therefore, with the deepest emotions of filial and grateful affection for your pilgrim fathers;—these are the fruits of their toil; this is the land of their sepulture; here all your hopes are anchored;—and I would elevate you in adoration to HIM who has manifested HIMSELF more distinctively, theirs and yours, than to any other people on the earth.—O! it is a subject upon which I would dwell, and grow immortal as the theme. But I am admonished that I have passed the limits of the hour assigned me. There is a time,—when friends must part.

ADVICE TO YOUNG FARMERS.

ON THE APPELLATIVES, QUALITIES, HABITS AND DEFECTS OF HORSES.

(Continued from No. 45, page 356, Vol. 5.)

Windgalls, improperly so called, are encysted tumours, or bags filled with a gelatinous fluid or jelly, which being pressed from the tendous by over weight or exertion, stagnates between the joints, and forms for it self those cysts or bags.—Their situation upon the pastern joints is well known. Some horses are very little subject to them, even if hard-worked; others will have them before they have done any work at all. If not too large, and they feel elastic and disappear on rest, they do not render the horse unsound; but if large, and soft to the touch, they become exceedingly painful, and the horse soon grows lame. The only radical cure is excision, which I have experienced, and shall describe in its place.

The *ring bone* is a hard, or bony excrescence, upon the coronet, which sometimes almost surrounds the top of the hoof, occasioned perhaps, by the iron lock, which has fastened a clog or fetter; it also may proceed from no visible cause, and is then supposed to be hereditary.—However, I have never yet known it effectually cured; the horses supposed to be cured, never standing sound in work.

A *quittor* or *horny quittor*, or whitlow, is also situated on the coronet, or between hair and hoof. Those which I have seen, were immediately above the inside quarter; when deeply seated, they are no otherwise curable, than with the loss of part of the hoof, whence a seam or apparent partition, up above the heel, called a *false quarter*. In this latter case, the soundness of the horse can scarcely ever be depended on and he is liable to drop down suddenly on his way, as I have more than once experienced to my cost.

The *sand-crack* is a small cleft on the external surface of the hoof. No horse ought to work a single day with one, because if neglected, or aggravated by work, the crack may enlarge, and end in a *quittor*, and *false quarter*.

Of the *founder* in feet, chest or body, the symptoms are so well known, as to need no description. Progression seems universally impeded. The horse bears upon his heels, and inclines backward. Few recover, even if the disease be sudden and acute.

Running-thrushes are a foetid discharge from the frog, the aperture of which, in consequence, appears moist, the horn perhaps decayed. It indicates a strong, full habit, and hard feeding, and has been well compared by Bartlet, to the copious excretion of sweat from human feet, which it would be dangerous to repel. To talk of curing running thrushes, is merely to amuse. Horses much liable to them, will always have tender heels, and should be ridden with bar-shoes.

Corns, upon horses, bear no analogy with those upon the human feet; indeed the term is a misnomer. There are still callous, horny excrescences about horses feet, similar enough, in all respects, to human corns, but they are not so distinguished. We are to suppose the feet of Cæsar's horse had proper corns. The ailment, in question, is called by the French *bleime*, and is, properly, a bruised spot or speck upon the sole of the heel, wearing either a red and blood-shot, or black appearance, according as it is recent or otherwise, as we observe of the same accident in the human nail. Its most common origin is from bad shoeing, and is curable by the contrary. I have cured, perfectly, very bad corns of two years standing, which never afterwards appeared, in the course of years, the hack dying in my possession.

The *feet*, in general, may be divided into the extremes of hard and soft, both of which are too frequently met with. I have had two hacks with feet of each kind; one of which I rode constantly nine, the other, occasionally, three or four years. For too hard feet I know of no remedy, except their constantly running abroad, and then a fortnight's work upon the road, will render them so feverish and painful, that your horse will be crippled; in short, will have the appearance of an incipient founder. Overstrong and hard hoofs are said to occasion lameness, by compressing the internal structure of the foot. Their appearance is usually high and deep, sometimes like ass-hoofs, very hollow, with scarcely any frog; sometimes much contracted atop by the coronary rings; at others, deep, thick, and clubbed, and the horse, though sound, goes in a fumbling way. I have, now ar-

then, seen Welch horses with this last description of feet, which soon become lame in the stable. Soft feet, and low tender heels, may do great service throughout, with bar shoes, and constant attention. Bred hacks are apt to have the feet too small; and often you will find horses, with feet of the right black flint colour, and to all appearance unexceptionable, and yet they will stand no service on the road.

Aliquando bonus dormitat Homerus, and I think Dr. Bracken's wits must have been at any rate sleepy, when he corrected Sir William Hope, for the assertion, that tender footed horses bear heavy upon the hand; a fact, of which I have had long and troublesome conviction.—We do not often catch the good Doctor napping; but I can mention another instance. To oblige his friend, Sir William Parsons, as it should seem, Bracken disgraced his excellent work, by inserting a cruel and ridiculous pretended remedy for cutting behind; which was, to fasten a knotted whipcord between the horse's thighs; as if the infliction of tortures could possibly change mal-conformation, or strengthen weakness. How like to the cruel sophistries of ignorant and cold hearted political quacks, who punish misfortune *in terrorem*.

Heavy shouldered horses, and high, hammering goers, beat and founder their feet. The ill consequences of being *forelow*, in a saddle horse, are sufficiently obvious; but to a pack horse, it is an advantage. The old prejudice, in favour of short backs, round barrels, and carcasses ribbed home up to the huggen bones, seems to have given way to the reasonings of Bracken; and the idea of an equal and proper distribution of length, is in general adopted by our sporting people. Indeed, to view the back of a horse, merely as a bearing fixed upon upright columns, the intent of which is solely to stand under a given weight, a short bearing would have the preference; but as the back of a horse is destined to move, as well as sustain weight, it must be considered how far a defect of its longitude, and an irregularity in the general disposition of length, retards action. Our Jockies say, "A racer," they might have said a goer, "must have length somewhere." That is perfectly just; but in consequence, it always happens, that a horse which wants length in his back, will be sure to have it in some improper place, the legs for instance. Short-backed stallions are very apt to get leggy, spider-shaped stock. A horse which stands over a great deal of ground, may be a goer, merely by virtue of his general length, if his shoulder be not too unfavourably made.

The spine, being too short, is not sufficiently pliable, and the want of room between the ribs, and hip bones, occasions the entrails to be so pressed towards the lungs in action, as in a considerable degree to impede inspiration. Length of back will always be found advantageous, when there is sufficient general substance, and particularly, width and swell of the muscles in the loins and fillets; but short backs are infinitely to be preferred to long thin shapes, with hollow flanks, and narrow weak lines.

Hollow backs are apparently weak, and the curvature of the spine must in degree hinder action, as well as all other irregularities of form. Horses of this form have sometimes a very elevated crest, look handsomely mounted, give an easy, convenient seat, and are pleasant goers.—High, or *bream-backed* horses, throw the saddle forward, and are liable to be galled by it, and are often hard stumping goers. But a horse, unless a capital one be the object, must never be rejected, merely on account of being either hollow, or *swine-backed*.

I am uncertain, whether a mare, so much hurt in her loins, as to be called *broken-backed*, would breed; but thoroughly convinced, that every horse of that description should be knocked on the head. They are sometimes styled *Megrim Horses*. They will feed, and even get fat. The defect is discovered by trotting them briskly about two hundred yards, when they will infallibly sink down upon their buttocks; this they will do upon being put to any labour; it is totally incurable. I have seen but two of this kind, one of which I was unlucky enough to purchase; and, to amend the matter, he handled his forefeet with all the dexterity of a pugilist; a vice, no doubt, acquired from the abuse the poor animal had suffered, in consequence of his deplorable misfortune.

A sinking is sometimes observed at the extremity of the back, as if it were parted from the rump by a cross-line, instead of the fillets being oval and elevated; it detracts from strength.—The hip-bones being sharp and not handsomely turned, the horse is said to be *ragged-hipped*; a defect, in point of beauty, according to the rule laid down in Hogarth's Analysis.

The large *carcassed* horse is generally robust and durable, eats much, requires much water, and digests well. One with a light greyhound belly is speedy, most probably hot; if loose, and weak-loined, he is seldom worth his keep.—These are such as give their jockies the slip, by running through the girths. But a light carcassed horse, deep in the girth, and well filleted may be among the most excellent, both for speed and duration. Such are often found to be good and sufficient feeders, and of rare temperament.

The *goose-rump* is, as well as the ragged hip, another angular infringement of Hogarth's curve of beauty. If the rump be too high, the hinder will press too much upon the fore-quarters in action. When the quarters droop, they are, in course, too short, and the tail is set on too low. Round, full buttocks shew the common or cart-breed.

To be *hipped* or *hipshot*, is to have one hip lower than the other, and the flesh wasted on that side. It may arise from a blow or strain.

A horse lame in the *whirl-bone*, or hipjoint, drags his hind leg after him, and drops backward when he trots. This lameness, and that of the stifle, if taken in time, and the subject be young, are always curable.

The bay gelding, which I sold to the late Mr. Beaufoy, member for Yarmouth, and which he rode, I believe, nearly seven years, I purchased lame in the whirl-bone, at five years old. In 1797, at nearly twenty years old he carried seventeen or eighteen stone, in the Hants Yeoman Cavalry.

(To be continued.)

TO THE EDITOR OF THE AMERICAN FARMER.

HORSE-POWER.

SIR,

Having stated and compared the useful effect of man's labour, in a variety of the most important modes, in which it is generally applied; let us now turn our attention to that of horses, and other draught animals.

The strength of an able bodied draught horse, is estimated, as might be expected, very differently, by different writers on the subject: some fixing it at that of five men; others at six, and some as high as seven; which last is perhaps nearest the truth. We are told by one author that two horses yoked to a plough, exert a force of 150 lbs. each; another

informs us that he can draw with a force of 200 lbs. and travel $2\frac{1}{2}$ miles per hour, for 8 hours in the day; or 240 lbs. for six hours. Another informs us that he can raise by means of pumps, 250 hds. of water 10 feet high in an hour. This would require but four men for the same time. A third tells us, that on a level road, one horse can draw 25 cwt. on a cart weighing 10 cwt. with wheels 6 feet diameter: that in a common cart 2 horses can, with ease, draw 30 cwt.; in a common wagon 6 can draw 80, and in three carts they would draw 90, with more ease; and in six, 150 cwt. No doubt, the practical farmer is the best judge on these subjects. It is very desirable, however, to have an instrument capable of determining the absolute strength of horses, as well as of men and other animals. The best yet invented for this purpose is Regnier's *Dynamometer*. It consists of an elliptical ring, of spring tempered steel; to which is attached a brass plate with a graduated edge and moveable index, so contrived, as to point out the quantity of the force by which the sides of the ring are compressed. It could be easily procured, in either London or Paris; would cost but a trifle; is very portable, its whole weight being less than three pounds; and would not only afford a measure for the absolute strength of animals; but also the quantity of force, required to draw all kinds of agricultural implements: and thereby enable the farmer to apportion the physical strength, to the resistance to be overcome. It would also afford a fine field for competition at fairs and cattle shows.

Let the absolute strength of animals be what it may, the question of greatest moment is, how to apply that strength to the greatest advantage? Coulomb whose researches on these subjects, far exceed those of all others, both in extent and accuracy, has shewn that the mechanical action which a man can exert, when travelling on a level road, exceeds that which he can endure, when ascending a flight of stairs, in the proportion of 3,500 to 205; or of 17 to 1 nearly: and surely no person could for a moment suppose, that a horse, mule, or ox, could travel up stairs with less fatigue, or to more advantage than a man. Now, turning a vertical wheel, by walking thereon, either inside or outside, requires an exertion, precisely similar to that of going up stairs; and consequently the application of animal power in the latter case, is not more unprofitable than in the former: and there, as just stated, it is diminished from 17 to one. The truth is, that all projects, and patentee pretensions on this and similar subjects, are founded on erroneous principles. Like the infatuated herds, that run after perpetual motions, and other impossibilities, they imagine that certain combinations and applications of mechanical powers, can create force. But it is an immutable law of nature, that action and reaction, are always equal to each other, and take place in opposite directions. Hence it follows, that no combination, or arrangement of machinery, can exert more force than is communicated to it: and that the agent, or moving power, may communicate the greatest force, in a given portion of time, it is evident that it ought to act under the most favourable circumstances; but we have seen that the most favourable circumstances under which either man or beast can travel is that of walking on a level or horizontal path.

When a horse, mule, or ox, is placed over a vertical wheel, with his fore-feet on an immovable platform, he turns the wheel by the action of his hinder limbs; and the same quantity of action, would impel his whole body forward

is a horizontal circle, of equal diameter with the wheel, with as great a velocity as he impels the wheel, and with far less labour. If he be placed on a moveable inclined plane; the exertion he has to make, is precisely the same, as would be requisite, to travel up stairs, having the same inclination, and at the rate with which the circumference of the moveable plane is driven. If then the useful effect of a man's force, in such an application of it, be but one-seventeenth of what it would be on a level surface; it is not to be supposed that the force of any quadruped would be more advantageously applied. Besides, the awkward situation in which the animal is placed, and the unnatural muscular exertions it has to make, fret its temper, and strain its body, so as to render it, in a little time, entirely useless. It is, therefore, to be hoped, that humanity, as well as economy will intercede in favour of those invaluable animals which were, evidently, never labor of the intended for any such purpose, and restrict the stepping mill, exclusively, to the abandoned portion of the human species.

When rotatory machinery is to be driven by horse power, let the animal move in a horizontal circular path, not less than 30 feet in diameter. But the usual mode of attaching him to a revolving lever, by means of a single-tree and traces, causes, in consequence of the oblique direction of the draft, a loss of about ten per cent. of his force. To avoid this, the revolving beam or lever, should be fixed into the vertical axis, at such a height, that the animal could be placed under it. Two upright posts, are to be firmly morticed into this beam, at a proper distance, for the animal to stand, and walk between them. To the lower ends of these, the traces are to be connected, and of such a length, that, when the animal is in motion, the revolving beam may be right over the middle of his body; and the direction of the traces, or line of draught, should descend from his shoulders, about six or eight degrees; or 1 inch in 9, below the level. He will then exert his force to the greatest advantage; and consequently, produce the most useful effect.

J. D. C.

Editorial Correspondence.

THE TUSCANY CATTLE,

IMPORTED BY COM. BAINBRIDGE, AND PURSER HAMILTON, AND NOW IN SOUTH CAROLINA.

Charleston, January 20th, 1824.

DEAR SIR,

Your favour of the 20th November, I received on my return to town a few days since. The first calf of the Tuscan cow was a female, the second a male, and are doing well. The half blooded calves are strongly marked in figure and colour; I believe that one could select them out of the stock. I shall have about thirty of the half bloods by the spring; I intend keeping all the females, and about six of the males; the remainder I shall dispose of at a moderate price, to such as may wish to purchase. Since I last wrote, I have seen the gentleman who grew the crop of Guinea corn I was correct as to the quantity per acre, but his manager was mistaken, as to the weight; its weight is from 63 to 64 lbs. per bushel. I shall send you some of the grain by the Harvest, Capt Emory, by whom I sent the Guinea grass seed, which I hope you have received. I intend planting ten acres the present season; I shall put it in small beds, five feet apart, and from two to two and a half feet apart on the bed; a few seeds in each hole will be sufficient. Attend it in the same man-

ner as you would corn; plant about the 1st of May. In rich land the product is great, and on a poor soil it produces, I am informed, more than any other grain. It is not injured by water, that is to say, it will grow well in such land as may be partially covered in wet seasons. It has a discouraging appearance, until the heats of summer, when it grows rapidly, and will continue to put out heads until checked by the autumnal dews.

Your obedient serv't.

J. MIDDLETON.

REMARKABLE MANGEL WURTZEL.

Nottoway Court House, Jan. 12th, 1824.

DEAR SIR,

At a stated fall meeting of the Agricultural Society of Nottoway County, Virginia, Doctor Archibald A. Campbell, exhibited twelve mangel wurtzels, grown in his garden; the size of them were so far beyond any thing of the kind I have ever seen before, I was induced to weigh them; they weighed 152 lbs. averaging 16 3-4 each; the largest of them weighed 16 2-3; one of them measured 30 inches in length; they are of the mottled kind, and grow more out of the ground than any I have ever seen: from the well known properties of the mangel wurtzel, I am induced to believe they are far preferable to the common turnip or the ruta бага, whether as a food for cows or hogs; they are eaten with avidity by both.

I am, sir, with respect,

Your's &c.

N. WARD.

THATCHING HOUSES WITH STRAW—HOW IS IT BEST DONE?

I wish some of your intelligent correspondents would favour your readers with the best mode of thatching houses with straw. I have had two houses thatched by men professing to be well acquainted with the business, neither of which have been capable of resisting the late winds.

The great scarcity of timber in many parts of our country, has rendered this mode of covering houses, cattle, and other shelters indispensable, and I know of no object more deserving the attention of our agricultural societies

With great respect,

A SUBSCRIBER.

Pyroligneous Acid.—Knowing the strong prepossessions of the people as to the use of all new articles, it was not supposed that the Pyroligneous acid for the curing of hams, and other species of animal flesh, would go into general use the first year; but notwithstanding all prejudices, several barrels were retailed to the citizens of Utica and its vicinity the last year; the result of which experiment was demonstrated beyond contradiction, that the smoking of hams and other kinds of meat in this way is altogether to be preferred.—Some of the most respectable gentlemen in this town have given it their decided approbation in several particulars. First, the hams are not exposed to any change or decomposition near the bone, as they many times suffer when the heat is carried too high while hanging in the smoke house; secondly, the hams may continue in pickle through the warm season without any particular attention, from which they may be cooked at any time, containing all those excellent qualities peculiar to that dish. The idea of drying hams has unquestionably arisen from necessity and not from any supposed improvement. Thirdly, no trouble is necessary, except to put one quart of acid to two hundred pounds of hams after they are sufficiently penetrated by the salt.—*Utica paper.*

It is stated in the counties of Worcester, Middlesex, Norfolk and Bristol, Mass. there have been manufactured about 300,000 bonnets in a year, on an average price of \$2 75 per bonnet, amounting to \$125,000—employing 25,000 persons, most of whom are females, from the age of four to twenty years. Those employed in plating the straw have been enabled to support themselves, and in many instances to assist those of their immediate friends in destitute circumstances. The business now is at a stand. The bonnets that three years ago, would command \$2 75, will now not sell for more than \$1 25.

From *Brewer's Pseudo-phical Journal.*

REMARKS ON THE PHENOMENA OF THE
FALL OF THE LEAF.

The phenomena of the fall of the leaf in autumn has been variously accounted for. The learned and eloquent President of the Linnean Society has presumed it dependent on the maturation and expansion or swell of the bud, and this opinion has been adopted by others. M. Vaucher ingeniously compromises the question by considering the leaf soldered or cemented to the twig. This latter hypothesis is soon discussed. The most careless observer can discover the continuity of the vessels. The experiment is a very simple one. Let a leaf be torn from the twig, and a portion of bark and wood follows. When the leaf assumes the autumnal tint, then indeed, as with the ash, &c. it may be insulated, but the leaf is now dead, the vessels of supply no longer minister their living juices,—its veins are exhausted, and it hangs a withered appendage, and prey to the first autumnal breeze.

These are, in like manner, circumstances which do not harmonize with the first opinion: but to mention the fall of the early blossom in an analogous relation, the sudden denudation of the mulberry tree, without any change of colour, by early frost, shews us that the cause may act suddenly and prematurely, and must be something distinct from the dimensional increase of the bud.

The sap has its periodical revolution, and as it moves in its channel, acted on and influenced by the vicissitudes of an atmosphere ever varying its density, and the thermometric, hygrometric and electrical relations of which are always fluctuating, it must change its pulse conformably; and the flux of its stream must correspond with the circumstance on which it hinges, and by which it is accelerated or retarded, regulated or checked.

The spring gives an animating stimulus to the *punctum saliens* of vegetation, which is thus aroused from its *hibernaculum*, and the tree then assumes its beautiful and refreshing mantle of green. This is succeeded, as the season advances, by the blossom and the fruit.

Now, the sap must not only be much varied in its periodic times of revolution, but be obedient to the external agents enumerated, and thus will the character of its deposits be essentially changed. The sap, at first rapid, becomes, as the sun advances toward the tropic of Capricorn, more languid in its course. The tints of autumnal foliage are the external insignia which announce the changes that take place. The gradual disunion and final fall of the leaf is connected with the gradual contraction and close of the anastomosing vessels, and this constriction is the consequence of a loss of caloric, by reason of radiation to the unclouded sky, or in the absence of the illumining sunbeam, dark weather. All circumstances being the same, the amount of denudation will have a faithful correspondence with the phenomena which favor radiation; and I am persuaded, from repeated observation, that the leaves which strew the brooks are more numerous in the evening, and at night, than during day, when the calorific impressions of the sunbeam play on the leafy surface.

There is a phenomenon which I do not remember to have seen any where estimated, though it seems to me to add force to the opinion presumed. In the *beech* and *oak*, &c. particularly in the former, the leaves begin to fall from the tips of the twigs or branches, and are shed gradually downward: now this is in exact conformity with what should happen in consequence of radiation; the lower foliage is protected from its effects by that above it, the last, being lowered in tempera-

ture, falls, and exposes that leafage which before was comparatively concealed and sheltered; it falls in turn, and is succeeded by the next, &c.—We cannot suppose this phenomenon connected with the gradual retirement of the sap from the extremities of the branches. The twig can never be wholly exhausted of sap;—the circulation is comparatively languid, and its action torpid; but were it to evacuate the branch entirely, it must cease to live. In torpid animals the circulation continue, though reduced to its lowest ebb. Experiment has determined this, and the analogy holds good.

In Spring, the temperature acquired by absorption more than counterbalances the loss sustained by radiation, while in autumn this last is a maximum. In very early spring, the premature blossom is often cut off by the sudden contraction of the vessels which supply it.

By watering the early bloom before sunrise, the fatal consequence referred to is perhaps prevented; because the effects of radiation are modified by a film of aqueous vapour; or the previously contracted vessels are softened.

Mr. Cooper, in his Dictionary of Surgery, gives the following recipe as infallible for the cure of corns. Take two ounces of gum ammoniac, two ounces of yellow wax, six drachms of verdigris, melt them together, and spread the composition on a piece of soft leather or linen; cut away as much of the corn as you can with a knife, before you apply the plaster, which must be renewed in a fortnight, if the corn is not by that time gone.

THE FARMER.

BALTIMORE, FRIDAY, FEBRUARY 6, 1824

We shall be blamed, at the first glance of it, for publishing an article in one paper, so long as Mr. Bates' address. All we have to ask in extenuation or justification is, that we be not condemned, until the address is read. The views of political economy it exhibits are profound, and yet clearly and simply expressed, a great excellence in writing on that subject—but they are not so clearly conveyed as not to require it to be read with attention. The subject does not admit of that—studies of this nature are as necessary to young Farmers, who would understand their interests and their rights, as experience is to a practical workman. We would recommend that such papers be read at the family fireside—and aloud by the farmer's son. Thus will amusement be mixed with utility, and the ideas and truths they convey will in this way be imparted at the same time to several minds instead of one. As to the application of Mr. Bates' premises, that is another matter—about which our readers can form their own judgment. The reasoning may be clear and good, which leads us to perceive and understand important truths in political economy; and yet those truths may be used in attempting to establish ulterior positions and hypotheses, which are not tenable. The benefit which agriculture is to receive from an increase of duties on imported articles consumed by the farmer, and paid for with his products, will be better understood when we come to publish some additional papers on the score of its expediency—in the mean time, those who would deny or affirm the constitutional power of Congress to enact such an increase, with an exclusive view to the encouragement of particular branches of domestic industry, are respectfully referred to the able essay under the signature

of RURI CONSULTUS, in number 42 of this volume.

For the very interesting and eloquent address of Mr. Bates, we are indebted to the kindness of the Dickinson Library Company.

SKINNER, Editor, by JOSEPH ROBINSON, on the North West corner of Market and Bulwider streets, Baltimore, where every description of Printing and Job Printing is executed with neatness and dispatch, and from a distance for PRINTING or BINDING, with particular attention promptly attended to, addressed to J. Robinson, Baltimore.

Political Economy.

TO THE EDITOR OF THE AMERICAN FARMER.

LETTER II.

DEAR SIR,

Although I utterly disclaim the mere authority of great names, either for, or against any particular doctrine, the truth or error of which can be tested by reason; yet I have always deemed it fair to hurl such missiles at any man's head, who first throws them at yours. It was upon this principle that I promised in my first letter, to attempt to prove that the justly praised Hamilton—not *Matthew*, but *Alexander*, never did maintain any such heresies in political economy, as have so often, and so triumphantly been ascribed to him. On the contrary, I shall proceed to show,—and by the very report too, from which these heresies have been so strangely extorted, that the aforesaid *Alexander* Hamilton took special care every where to speak of the encouragement of manufactures by duties upon imports, as incidental to the raising of revenue; and as a measure which should never be attempted by any rate of duty that was likely to injure either agriculture or commerce.

In doing this I shall begin with his first report made in pursuance of a call from Congress for some project to support public credit. This report was dated 9th of Jan 1790, from which it will be needless to make more than the following extracts. In speaking of the advantages of a well established public credit, with a small public debt, he observes that among the various and obvious benefits resulting from, it may be reckoned—

First—"Trade is extended by it; because there is a larger capital to carry it on, and the merchant can at the same time afford to trade on smaller profits; and his stock, which when unemployed, brings him in an interest from the government, serves him also as money, when he has a call for it in his commercial speculations."

Second—"Agriculture and Manufactures are also promoted by it; for the like reason, that more capital can be commanded to be employed in both; and because the merchant whose enterprise in foreign trade gives to them activity and extension, has greater means of enterprise."

Again, in the same report, in recommending a provision for the public debt, after showing that a larger sum would be wanted for that object, than would accrue from the existing rates of duty, he goes on to say;—"This sum may be obtained from the present duties on imports and tonnage, with the additions which, without any possible disadvantage either to trade, or agriculture, may be made on wines, spirits, including those distilled within the United States, teas and coffee."

"The Secretary conceives, that it will be sound policy, to carry duties upon articles of this kind, as high as will be consistent with the practicability of a safe collection. This will lessen the necessity, both of having recourse to direct taxation, and of accumulating duties where they would be more inconvenient to trade, and upon objects which are more to be regarded as necessaries of life."

Without saying how far these opinions accord with my own, it is sufficient for my present purpose to remark that these extracts demonstrate, as clearly as the light of day, that Mr. Hamilton had then no idea that protection to manufactures should be carried so far, as to interfere either with agriculture, or commerce; still less to put them in jeopardy, as the proposed enormous augmentation must inevitably do, or to produce a necessity for direct taxes, or to raise the prices of articles which may be regarded as the necessaries of life." On the contrary, it is most manifest that he considered any measures which furnished the

merchants particularly, with the means of greater enterprise, as calculated to give activity and extension both to manufactures and agriculture.

The report on public credit was sent to Congress early in January, 1790; and on the 15th of the same month a resolution passed, referring to the Secretary the subject of manufactures. This produced his celebrated report so often quoted of late years, as unanswerable, by men who would not then have taken his opinion for any thing; nor even have treated his character with common christian charity.

In this important state paper, although Mr. Hamilton goes so far as to recommend even bounties and premiums in addition to protecting duties, it is perfectly clear from the whole tenor of his opinions and reasoning, that he never considered manufactures entitled to any permanently exclusive privileges; or that they should be favoured at the risk of injuring any of the great interests of the country: in particular he never contemplated such high duties on foreign commodities, as now exist; or that even the moderate advance which he recommended, should be of long duration. To prove this point the more clearly and satisfactorily, I shall give a fair specimen of his reasoning, both against and for us. First, in allusion to the common arguments for preferring agricultural industry to that employed in manufactures, he says;—"This mode of reasoning is founded upon facts and principles, which have certainly respectable pretensions. If it had governed the conduct of nations more generally than it has done, there is room to suppose, that it might have carried them faster to prosperity, and greatness, than they have obtained by the pursuit of maxims too widely opposite. Most general theories however, admit of numerous exceptions; and there are few, if any, of the political kind, which do not blend a considerable portion of error, with the truths they indicate.

"In order to an accurate judgment, how far that which has been just stated, ought to be deemed liable to a similar imputation, it is necessary to advert carefully to the considerations which plead in favour of manufactures, and which appear to recommend the special and positive encouragement of them in certain cases, and under certain reasonable limitations."

Who would not imagine after such an emphatic recommendation to do something "special and positive" for manufactures, that the next suggestion would be a set of rates of duty nearly, if not quite equal to the present. But when we come to notice the application, (as we presently shall,) of the foregoing general reasoning, how much surprised will those be who never read his report, to find that some articles then subject to duty, he proposed to exempt entirely; on others he advised that the existing duties should remain as they were; and on none of the important articles of cotton, wool, iron, brass, books, leather, linen, &c. did he recommend a higher duty than 7½ per cent. What then, shall we say of the attempt made by the manufacturers of the present day, and their friends, to found the wild and extravagant pretensions which they now set up, on this celebrated paper of the much abused Mr. Hamilton. In this it is every where clearly seen, that whatever encouragement or protection he recommended for manufactures either by duties, bounties, or pensions, was never designed to interfere with other branches of national industry: as a farther confirmation of which, the whole tenor of the report, as well as all the particular parts thereof specially applicable to the subject, develop this opinion; that these duties and bounties should be highest at the commencement of the manufactures intended to be promoted by them; and that if they did not succeed within a

reasonable time, the government ought to abandon them. The very reverse of this, is the policy which our manufacturers are continually and most importunately demanding; for what else do they claim but such constant augmentation every 3, 4 or 5 years, as will at last enable them to realise any air-castle which they choose to build; the only subject of enquiry and solicitude with them, being to exclude foreign competition, no matter who pays for it, so they do not.

In speaking of bounties, which Mr. Hamilton considered of the same nature with high duties, he says;—"The continuance of bounties on manufactures long established, must almost always be questionable policy; because a presumption would arise in every such case, that there were natural and inherent impediments to success."

How widely different is this remark from the doctrines so pertinaciously ascribed to him in all the numerous publications which we have seen, purporting to be only a new version of his opinions. And how much at war with it, are the repeated demands for additional duties to protect certain manufactures which their friends cry out have not yet got enough, although from the time of the first tariff to the present moment they have been continually receiving more and more of this sort of encouragement.

Keeping these introductory extracts and observations in view, let us now see what protection the Secretary actually did recommend, and also the particular articles selected by him to be favoured by duties.

The material which he deemed of far superior importance to all the rest, was iron; and what did he propose to do for that? Why, simply to raise the duty of 75 cents per cwt. on steel, to 100 cents; the duty of 1 cent per lb. on nails and spikes, to 2 cents; on fire arms and other military weapons to 15 per cent; and on all other manufactures of iron or of which it was the material of chief value, 10 per cent.—iron in pigs and bars he advised to exempt from all duty.

Brass and copper wares he proposed, should be rated at 7½ per cent.—the 1st having been 5, and the last 7½. He merely suggests for consideration! whether they might not bear 10 per cent: the raw materials of both, he advised to admit free of duty.

On lead he thought the existing duty sufficient; the 7½ per cent on pewter wares, he believed might bear a little increase, but this was not pressed.

On fossil coal he proposed no duty. In regard to skins, after speaking of their manufacture as highly important to the country, he advises that the existing duty of 7½ per cent. should remain as it was; that on glue he was for raising to 15 per cent.

I will here give a single remark of Mr. H. in relation to this article, (and it is applicable to all the rest,) as worthy of particular attention; because it explains as clearly as a whole volume would do, the leading principles of his report, and the striking difference of his views, from the views of those who are so fond of quoting him.—Speaking of the manufacture of leather he says, "There may also be this argument in favour of an increase of duty. The object is of importance enough to claim decisive encouragement, and the progress which has been made, leaves no room to apprehend any inconvenience on the score of supply, from such an increase." Now what does this amount to, but in other words, to say that no augmentation of duty on any article which we are in the habit of importing, should ever be made so high, as to subject us to the hazard of a scanty supply, or to the manifest privation and trouble which would accrue from our having to wait for it, until we could get it of home make.

Yet the men who claim Mr. Hamilton's opinions as their own, would not only subject us to all this risk and inconvenience, but compel us to pay for their schooling, while learning to fabricate the very articles of which we are to be deprived, by the political self-murder, now proffered for our acceptance.

But to proceed with the Secretary's tariff. On ardent spirits, he recommended a duty of no more than 2 cents per gallon, of the first class of proof, and a proportionate increase on those of higher proof—on malt liquors, 8 cents a gallon generally.

The duty on starch, hair powder, and wafers he advised to be raised to 15 per cent.

Sailcloth he proposed to class among articles rated at 10 per cent.—and as to drillings, tickenlenberg, dowlass, canvass, brown rolls, bagging, and all low priced linens, he merely suggests—without urging it, that the duty should be raised to 7½ per cent.

As to cotton, he actually recommended a repeal of the existing duty of 3 cents per lb.; and advises that the 7½ per cent. on certain kinds of cotton goods, should not be extended to all kinds of which cotton was the principal material.

The only protection which he proposed for manufactured wool, was a small bounty, for improving the breed of sheep instead of a duty!! to be derived from the addition of 2 per cent. on carpets and carpeting.

The raw material silk, he recommended to exempt from all duty, leaving the existing rate of 5 per cent. on manufactured silk to stand as it was.

The existing duty of 12½ per cent. on glass, and 10 per cent. on gun powder, he deemed quite sufficient. That on paper he also thought as high as it need be; and on printed books, the duty of 5 per cent. he proposed to raise to 10 per cent.

In regard to refined sugars and chocolate, he recommended that a drawback of the duty on the raw material should be allowed on the exportation; and that 2 cents per lb. should be laid on imported chocolate, instead of the existing duty of 5 per cent. ad valorem.

Nothing was done by Congress with this report, but a year after, at their next session, upon finding more revenue necessary, they again called upon the Secretary by a resolution dated 8th March, 1792, to say what would be the most eligible mode of raising the supplies. On the 16th of the same month he reported, and named the three following modes, viz. selling United States' stock—loan, and additional taxes and duties—the last of which he preferred.

After remarking that the interests of commerce are always greatly injured by frequent and unexpected alterations in the rates of duty on the objects of trade, and regretting that so early a resort to new demands, on the mercantile class, should be the made—he concludes the subject of the additional duties which he recommends, by the following paragraph.

"The addition of 2½ per cent. to the duty on the mass of articles now rated at 5 per cent." (among which were cotton and woollen goods, manufactures of iron, brass, copper, linens, books, &c.) "will constitute an important, though not an extensive augmentation. Nevertheless it is proposed, that it shall be but temporary, and there is reasonable ground for expectation, that the cause for having recourse to it, will not be of very long continuance!"

It is needless to add farther quotations to prove the position with which I commenced. They speak a language which a child may understand; and if any man in his sober senses will read them deliberately, and afterwards assert that there is the slightest grounds for imputing to Mr. Hamil-

on any opinions in regard to the encouragement of manufactures, at all resembling such as are continually hawked about the country for his, I can only say that such man has at least 50 per cent. more of that very efficient commodity called impudence, than would suffice to effect any purpose, towards the achievement of which the said article was the material of chief value.

Yours very truly,

RURIS CONSULTUS.

P. S. One more letter Mr. Editor, and I shall be done; for I confess to you, that I am sick at heart, from the prospect of the enormous oppression with which both agriculture and commerce are threatened, by this new tariff bill.

AGRICULTURE.

VIRGINIA AGRICULTURAL SHOW.

Report of the committee appointed to prepare for publication an account of the second Fredericksburg Agricultural Show and Fair.

The committee congratulate the Society, and their fellow citizens at large, upon the proud result of the second Show of the Fredericksburg Agricultural Society. The pleasing anticipations indulged in, after the Show of last year, have been more than realized on the recent occasion.

Notwithstanding the badness of the weather during the greater part of the two previous days, must have prevented the attendance of many who lived at a distance, yet the concourse of spectators was much greater than had been witnessed on any occasion in this town for many years. Great gratification was expressed on all hands, at the spirit which manifested itself among this very unusual assemblage of amateur agriculturists. The Society gained an accession of 74 members—many of them men of established reputation in their profession. Indeed, the benefit both to town and country, has now become so obvious to all, that it is hoped and believed, that very few who are within reach of it, will hereafter withhold their aid from an institution which has been languishing for several years under all those discouragements resulting from the lukewarmness and apathy of the very class for whose chief advantage it was originally organized.—But we are happy to add, that these obstacles appear, at last, to be nearly overcome by the irresistible evidence of such facts as speak both to the hearts and understandings of all who have paid the least attention to them. There is scarcely a farmer of any standing, within a convenient distance from Fredericksburg, but has become a member; and many of those whose means are most limited, are among the most zealous contributors to the continuance and prosperity of the society. Several patriotic individuals of other professions have also united in support of the good cause; and to crown the whole, all the beauty and fashion, and good housewifery of the town and adjacent country, have not only manifested their cordial good wishes for our success, but have made such a display of their taste, their industry, and their skill, in the number, kind and quality of the articles of household manufacture exhibited by them on the late occasion, as reflects lasting honor, both on themselves and on the country of which they are the brightest and mostly highly valued ornaments. With such support, and such encouragement, the sons of agriculture need fear nothing. Let them only do their part towards the promotion of good husbandry, and they may feel the most perfect reliance on the perseverance and fidelity with which their wives, and daughters, and sisters, will perform theirs, in the same truly honorable cause.

The Show took place on the 12th and 13th November, on the ground that was occupied for the same purpose last year, in the lots of Mr. John S. Thornton, on the Western side of the town.

The first day was devoted to the exhibition of Stock, and was closed with an address from James M. Garnett, President of the Society.

The second day was occupied with the examination of Agricultural Implements, trial of Ploughs, and an exhibition of Domestic Manufactures. This latter display was originally intended to have been on the ground where the other exhibitions were made, but on the eve of the occasion it was determined, with a view to the better accommodation of the ladies, whose presence was earnestly desired, that it should take place in the Town Hall. This unfortunate step deprived the exhibition of much of its splendor. Owing to the insufficient size of the room, and the total absence of counters on which to expose the goods, many of them could not be shown to advantage; and so great was the crowd who anxiously pressed in, that hundreds were compelled to retire without being able to gratify their laudable curiosity. The committee indulge the hope, that on a future occasion, their brethren will profit by the experience of this, and adopt better regulations. This day was closed with the distribution of Premiums on the ground—and the show, notwithstanding some little drawbacks, the natural consequence of inexperience in those things, terminated in a manner highly gratifying to all who witnessed it.

The following condensed statement of the manner in which the Premiums were awarded, is taken from the reports of the several Committees.

Horses, Mares and Colts.

A *Silver Pitcher*, with an emblematic device and inscription, value \$30, was awarded to Mr. John Graves, of Louisa, for his horse Florizel, 11 years old, got by old Florizel, out of a Spread Eagle mare, as the best Stallion. But, the Committee remark that had Judge Stewart, of Staunton, been a member of the Society, his horse Eagle, which was shewn by Mr. James Coleman, of Orange, would have had the unanimous vote of the committee.

A *Silver Pitcher*, value \$25, with inscription and device, was also awarded to Mr. Graves, for his Mare 4th of July, four years old, a full sister to Florizel, as the best brood mare.

A *Silver Pitcher*, value \$25, with device and inscription, was awarded to Mr. Lawrence Ashton of King George, for the best saddle horse, a Bay Gelding.

A *Silver Goblet*, value \$17, was awarded to Mr. Jeremiah Wilson, of Spotsylvania, for his Colt *Premium*, two years old—got by Friendship, out of a Hyatoga mare, as the best colt exhibited.

N. B. There were shown 7 Stallions—10 saddle Horses and Mares—7 Brood Mares, and 9 Colts. There were several other fine animals brought upon the ground, and intended to be exhibited, but were excluded by the rules of the Society, for not being entered in time. It is hoped, that gentlemen intending to exhibit Stock on a future occasion, will be more attentive to their own interest, and comply in time with the rules of the Society.

Horned Cattle.

A *Silver Pitcher*, value \$25, was awarded to Col. George Love, of Fauquier, for his Bull, Comet, the only one exhibited.

A beautiful *Silver Cream Cup*, value \$20, was awarded to Mr. Thomas B. Barton, of Fredericksburg, for the best Milch Cow.

A *Silver Cream Cup*, value \$15, was awarded to Mr. William Bernard, of Mansfield, for the second best Milch Cow.

A *Silver Cream Cup*, value \$17, was also awarded to Mr. William Bernard, for the best heifer.

A Cup, value \$20, was awarded to Mr. Alexander Sorrell, of Fredericksburg, for the best Beef.—This beef was raised in Culpepper, by captain John Turner, and sold by him, with a drove, to Mr. Sorrell.

Sheep.

Two Cups of the value of \$15 each, were awarded to Mr. John Gray, of Travellers' Rest, for a Ram and Ewe. They were the only two exhibited.

A Cup, value \$15, was awarded to Capt. Wm. Jackson, Jr. of Spotsylvania, for the best Mutton.

Hogs.

A Cup, value \$15, was awarded to Mr. Wm. Smalley, for his Boar, being the only one shown.

A Cup, value \$15, was awarded to Mr. Horace Haislip, for his Sow, being the only one shown.

Agricultural Implements.

A Cup, with device and inscription, value \$15, was awarded to Mr. Jacob Gore, of Fredericksburg, for an improved Wheat Fan, the only one shown. The superior excellence of this Wheat Fan principally consists in the ease with which motion is communicated to the sifter. The committee respectfully recommend Mr. Gore to their brother agriculturists, as an ingenious and deserving mechanic.

A discretionary premium of \$10, was awarded to Capt. Wm. Jackson, Jr. for a very cheap and excellent Machine for sowing and rolling at the same time, small grass seed. The whole cost of this machine will probably not exceed \$6 or \$7, and may be made by any common carpenter.

A discretionary Premium of \$5 was awarded to Mr. — Minor, of Hanover, for a Drill Plough, for planting Corn—being the same, a model of which was shown last year.

Although the Ploughs exhibited by Messrs. McCormick & Stewart were excellent, the Committee awarded no Premium—as they considered Mr. McCormick's almost identically a similar Plough to the one for which he obtained a Premium last year—and Mr. Stewart's three Ploughs nothing more than good imitations of McCormick's.

The model of a very ingenious Machine for reaping and saving Wheat from the scythe, was exhibited by Mr. Geo. Banks, of Stafford; but being a model only, the committee did not deem themselves authorised to award a Premium for it; although, as far as they could judge, without an actual trial, they were disposed to think very favourably of its utility.

An improved Machine for getting out Wheat, Barley, Rye, and Oats, and for grinding grain, made by Mr. William Boadler, of Culpepper, unfortunately arrived too late in the evening of the second day to be examined; but those who have actually tried it, speak highly of its power to do so, that the improvement promises for it.

As some surprise may be felt at our committees having awarded Premiums where there was no competition—viz: in the cases of the Bull, Ram, Ewe, Boar, Sow, and Wheat Fan—we beg leave to assign their reasons. It is simply the hope (a fearful one, we fear,) that by this means they may at last stimulate the proprietors of fine Stock—at least those who live at no great distance, to send some of them to our Exhibitions.

Their most unaccountable neglect in this particular, will scarcely be credited by our Brother Farmers to the North, whose fine displays of every kind of Stock, at all their Agricultural Shows and Fairs, have deservedly acquired for them such well merited praise and distinction.

Domestic Manufactures.

Carpets.—There were 7 specimens exhibited, all excellent. A silver Cup, value \$15, was awarded to Mrs. Frances Hawes, of Culpepper, for the best.

Table Cloths.—There were 7 specimens exhibited. A pair of Sugar Tongs, value \$5, were awarded to Mrs. F. Hawes, of Culpepper, for the best—a beautiful Linen Damask, wrought from Flax, raised by Dr. Aylett Hawes.

Bed-Ticks.—Five specimens were exhibited. The Premium of 1 doz. Tea Spoons, value \$10, was awarded to Mrs F. Hawes, of Culpepper, for the best.

Counterpanes, wool and cotton mixed.—Fifteen specimens were exhibited. A Silver Soup Spoon, of the value of \$12 50, was awarded to Mrs. — McCormick, of Fauquier, for the best.

Counterpanes of Cotton.—Four specimens were shown. A Silver Soup Spoon, value \$11 80 was awarded to Mrs. Geo. Buckner, of Carolina, for the best.

Hearth Rugs.—Five specimens were exhibited. The Premium of a pair of Sugar Tongs, value \$5, was awarded to Miss Mary Cady, of Fredericksburg, for the best—wrought entirely of domestic materials.

Butter.—Fifteen specimens were exhibited; ten of which were so excellent that the Committee, although they made repeated and pleasing trials, could not conscientiously decide which was the best. They therefore declined awarding any premium for Butter.—They respectfully suggest to the respectable Housewives who have shown so much skill in the preparation of this delicious article, to send a portion of the products of their Dairy to the Fredericksburg market, where the supply is by no means abundant or regular, and where a good quality always commands a good price.

Cheese.—Three specimens only were exhibited. A Premium of Six Tea Spoons, value \$5, was awarded to Mr. Wm. Benton for the best. It was made on the Farm of President Monroe, in Loudon. The manufacture of Cheese is yet in its infancy in this State; but from the specimens shown, and from the spirit of emulation already awakened, we look forward to an early day, when our Tables will be independent of a foreign supply for this article. The specimen shown by Mr. Waller Holladay, promised to be very fine when it shall attain more age.

Discretionary Premiums.

The rich variety and superior excellence of the articles for which premiums were offered, so far surpassed the expectation of the committee; and our meritorious housewives displayed so laudable an emulation in sending forward for exhibition a great number of beautiful articles for which no premiums were offered, that the committee gladly avail themselves of the power given them by the rules of the society, in awarding the following discretionary premiums, as an expression of their high sense of the value of our household manufactures and the great merit of those ladies who have thus set so laudable an example to our country—Viz

To Mr. Robert H. Rose, of Fauquier, for the 2d best Carpet, \$5.

To Mrs. Byrd, of Stafford, for the 2d best Hearth Rug, \$4.

To Col. Geo. Love, of Fauquier, for a pair of black Worsted Stockings, wrought by his daughter, \$2 50.

To Mr. John S. Slaughter, of Culpepper, for pair of 10-4 Blankets, \$5.

To Mr. Wm Slaughter, of Culpepper, one pair do. \$3.

To Miss Dorcas Horn, of Spotsylvania, for a fine wove Valen, \$2 50.

To Miss Sarah M. Horn, of Do. for Do. \$2 50.

To Miss — Noel, of Spotsylvania, for a Bed Canopy of singular fineness and beauty, \$2 50.

To Mr. Hezekiah Ellis, of Spotsylvania, for a piece of linen drilling, \$2 50.

To Miss — Dermitt, for a Valen, \$2 50.

To Mrs. John B. Woodford, of Caroline, for a Toilet Cover, \$2 50.

To Miss Ann Seddon, of Fredericksburg, ditto, \$2 50.

To Miss — Andrews, for a piece of domestic Plaid, \$2 50.

To Miss Dorcas Bryant, for do. do. \$5.

To Mrs. Martha Fitzhugh, of Fauquier, for a piece of Swansdown Vesting, two pieces of Plaid and one piece of Satteen, \$5.

To Miss Susan Parrott, of Fredericksburg, for a pair of richly wrought Crickets, \$2.

There were also exhibited a variety of other articles, not named, which excited general attention—particularly two specimens of thread Lace of singular fineness, wrought by Miss Nancy Seddon of Stafford, and a piece of blue Cassinett, exhibited by Mrs. Hawes, the successful competitor for the three first articles on the above list, which the committee deemed the finest specimen of domestic cloth they had ever seen.

OFFICIAL ACCOUNT

Of the Proceedings of the Fredericksburg Agricultural Society at their late meeting; and of their Agricultural Show.

The Society met, according to notice, at the Indian Queen Tavern, at 9 o'clock, on the morning of the 12th November, and continued its session by adjournments, until the evening of the 13th.

The following Gentlemen were elected officers for the ensuing year:

James M. Garnett, President; John Taliaferro, (of Hagley,) Vice President; William F. Gray, Secretary; John T. Ford, Assistant Secretary; R. S. Chew, Treasurer.

Corresponding Committee.

John Taliaferro, Robert Lewis, Garrit Minor, Enoch Mason, William F. Gray.

The following Committees for awarding Premiums were appointed by the president, viz: :

On Horses, Mares and Colts.

Francis W. Taliaferro, James Smock, Wm. C. Willis, Geo. N. Grymes, Wm. Bernard.

On Beef, Bulls, Milch Cows and Heifers.

John Taliaferro, Geo. Hamilton, Geo. Banks, Geo. Buckner, Enoch Mason.

On Mutton, Sheep and Hogs.

Robert Lewis, Geo. Love, John T. Ford, John Dade, Wm Richardson.

On Domestic Manufactures.

Geo. Hamilton, Horace Marshall, John S. Wellford, Alex. F. Rose, John Graves.

On Agricultural Implements, and trial of Ploughs.

Wm. Bernard, F. W. Taliaferro, Thos. Brown, Walter Holladay, John G. Stuart.

Marshalls.

Wm. Jackson, Jr. Henry Thompson, Robert Ellis.

Ordered, That H. Marshall and J. T. Ford, be appointed a committee for settling any accounts, that may be brought against the Society, for expenses incurred in the arrangements for the Exhibition.

Ordered, That the Treasurer pay the amount of the discretionary premiums, awarded by the several Committees, either to the successful candidates, or other persons authorised to receive them.

On motion of Major J. Richards,

Ordered, That the Treasurer pay the sum of \$2 to the Ploughman, (John, the slave of Mr. H. Thompson,) who assisted in the trial of Ploughs.

The President having retired—Capt. R. Lewis in the chair.

On motion of Col. Geo. Love, seconded by Major J. Richards—it was

Resolved, That the thanks of this Society be voted to their President, Secretary and Treasurer, for their laborious services to the Society;—and that a cup, with appropriate devices be presented to each of them: that for the President to be of the value of \$20, and those for the Secretary and Treasurer of the value of \$10 each—and that the Treasurer be authorised to procure them out of the funds of the Society.

Extracts from the Minutes.

W. F. GRAY, Sec.

From the Philadel. American Daily Advertiser.

FATTING SWINE.

BELMONT, Dec. 10, 1823.

Mr. Poulson—Several of my neighbors have recently suffered heavy losses, by diseases fatal to *fattening swine*; when preventive precautions had not been taken. With the view to avert such misfortunes, when I farmed, on an extensive scale previously to and since the revolutionary war, I tried many experiments in precautionary measures, as well as in cures. I most frequently failed in the latter; but at length I adverted to my having been informed of a simple *preventive*; which I can confidently declare, has, with me always succeeded. That I might be certain of this point, I have fortified my recollection by inquiry of an old farming laborer, who is yet in my employ, and who had the charge of fattening my hogs, in pens, during a great portion of the time since the close of that war. He recollects the loss of one hog only; and that by improper feeding. I deem it incumbent on me to re-publish; under a hope that the subject of it may be as beneficial to others as it has been to me; part of a note to a communication I made to *The Philadelphia Society for Promoting Agriculture*, March 8th, 1808; see vol. 1st. *Memoirs of the Society*—page 229.

“But sour food is the most grateful and alimentary to swine. One gallon of sour wash, goes further than two of sweet.” I mean the wash *acidulated* to the degree required for distillation—not *acetous*.

“*DRY ROTTEN WOOD* should be constantly in the pens, that the hogs when confined for fattening, may eat it at pleasure. Nature points out this absorbent, (or whatever it may be,) as a remedy, or preventive. They will leave their food to *devour* the rotten wood, when they require it. I have not lost a fattening hog for more than 30 years, when I used it, but have suffered by neglecting it. Some of my neighbors met with frequent losses of fattening hogs till I informed them of my practice; of which I was told by a woman from East Jersey, before our Revolutionary war. She said it was then known and practised there.”

I add my experience since the foregoing was published; which has been uniformly similar.

In the 2d volume, page 32, near the close of a very valuable communication from Mr. *De Gruchy*, of Northumberland, in our state; who fattens great numbers of Swine, prepared at first with wash from a large distillery, and finally fatted with Indian corn; the following important information will be found. The whole communication is worthy the perusal of every farmer.

“*Dry Rotten Wood* is a good thing; but I will take the liberty to mention what I think a better; we have three blacksmiths in this town; and my hogs eat up all the *ashes* or *cinders* they make; we haul it into the pens by cart loads, and the hogs will, you observe by the *Rotten Wood*—*devour* this at times with more avidity than their ordinary food.”

The *carbonated cinders* contain some of the ingredients of *rotten wood*; and perhaps in greater proportions. Be this as it may, every farmer can readily obtain the latter; and many can procure the former. It is anxiously desirable that a preventive so efficacious as either has been found to be, may not be unwisely and fatally overlooked and neglected. Nothing in human art is invariably infallible; but the experiment is so easy and cheap that the most incredulous should be induced to give it fair trial. Clean elevated sties or pens, dry litter and a small enclosure, adjacent to the pens, for air and exercise, and a moderate, but constant supply of *salt*, no doubt add to the efficacy of the preventive.—

The diseases I have seldom known to be cured. The most formidable of them are sudden, violent, and rapidly fatal, never allowing time for remedies. Their victims are unexpectedly (for gradual approaches are unperceived,) attacked with the last paroxysms, before their danger is decisively known.

Pigs and sheep are subject to sudden and incurable maladies.

Preventives are, therefore, of the first importance. Professed cures are, too often, mere quackeries in relation to both these estimable parts of our stock.

RICHARD PETERS.

ADVICE TO YOUNG FARMERS.

ON THE APPELLATIVES, QUALITIES, HABITS AND DEFECTS OF HORSES.

(Concluded from No. 46, page 365, Vol. 5.)

Stifled, or lame in the *stifle*. The stifle is the knee-pan of the thigh; the ligaments, by which it is articulated to the great bone of the hock, are sometimes overstretched, and the stifle-bone may be moved, in all directions, by the hand. The horse will go lame, and only touch the ground with his toe.

Bone spavins are, in the hind, what splents are in the fore-legs, but always of much worse consequence, because usually nearer the joint. They are to be felt on the inside of the hough, or hock. They are said to be hereditary, as well as acquired by strains, the signification of which perhaps, is, that a horse may be predisposed to them, by a natural moistness of constitution and laxity of the tendons. They occasion lameness, either perpetual, or at intervals; and as, nine times out of ten, this is the case, after a pretended cure, it is safest to hold them incurable. Spavins, by the pain they occasion, generally prevent a horse from getting flesh.

Bog spavins, termed by the French, *veffigons*, and improperly called blood-spavins by our farriers, are swellings like wind-galls, situate in the hollow or inside of the hock, and may also

be seen and felt, on each side, without. When these prevail to any great degree, or the inside of the hock feels puffed or flabby, instead of close, dry and elastic, it is the certain indication of hard service; and although it is often neglected, even by dealers, it is of the utmost consequence to examine the hocks minutely. We have the authority of Bracken, for their being safely curable, by excision, as well as windgalls, of which I entertain no doubt, although I have never experienced it. When they are large, they occasion lameness, particularly at intervals. I have seen heavy, overgrown, three year olds, although they had never been worked, troubled with bog-spavins.

A *cubb* is a spavin situated along the back part of the hock, just below the elbow, or extremity. It runs tapering downwards. After the curb has been extirpated by fire, I have usually seen the horse go lame.

Thorough pin. A tumour or wind-gall, between the bones of the hock behind, which may be pressed by the finger to either side.

Capped-hocks, formerly named by Blunder-ville, *hough-bony*. This is a swelling on the point of the hocks become callous. It is the general case of *kickers*, which wound their hocks, by striking against hard bodies.

Jardons are hard tumours upon the bending of the ham, on the outside. They arise, in managed horses, from their having been kept too much upon their haunches, and occasion lameness.

Sickle-hams, or sickle-houghs, in horses, may be compared to knock, or nap-knees in men. The legs bend, the hocks approach each other, and the feet are thrown out. It is an indication of weakness, as is every other breach of proportion. Such horses, when young, are often lame in the hocks, and will cut themselves, notwithstanding they appear to go wide. They are reckoned speedy.

Sallenders are, behind, the same as malleanders before. *Rat-tails*, *scratches*, *crown-scab*, *grease*, &c. are all visible enough, or to be felt upon the shank, coronet, and pasterns.

What has been said of knocking before, applies exactly to *cutting* behind. Good shape and condition are a security against this. A saddle-horse ought to be frigate-built, sharp in the keel, and spreading behind, in the quarters; of course, he ought to go wide behind. When a wide-going horse cuts, it indicates weakness in the loins.

To go *hammer* and *finchers*, is to overreach and strike the hinder toe upon the fore heel; the wound thus occasioned was formerly called an attain. A horse which throws his haunches well forward in action, may occasionally strike the heel of the fore shoes, and such frequently do it; but those which do it at every stroke, and discover it by the noise their shoes make, are very dangerous to ride; in fact, fit for nothing but draught. When the thigh is too long, and the angle formed by the hock too extensive, the horse is subject to spavins, from the too great weight thrown upon the hocks, also to over-reach.

The *string halt*, called by the old farriers, the *mary-nincho*, every one knows to be a sudden and preternatural catching up one, or both the hinder legs in action. The cause, obviously proceeding from over contraction, no writer, that I know of, has attempted precisely to ascertain. All receipts for its cure are good waste paper. In horses which have it not in a very high degree, it is sometimes scarcely perceptible, but visible enough after a hard day's work. They should stand in a loose stable, and be as much abroad as possible. They are not

deemed unsound. I have heard the late Mr. Cartersall say, he scarcely ever knew a string-baited horse which was not a good one. As much is generally averred in favour of rattailed ones. Perhaps their whole tendinous system is tough, firm, and dry.

The *crib biter*, formerly called a *ticker*, is sometimes distinguished by his dead coat, and thin appearance. These horses will stand biting at the rack, or manger, or even at a post, throwing themselves backward, and sucking in the air with greediness. It is a habit acquired when they are young, and which never forsakes them; as I have known grown children, of thirty years of age, suck their tongues. Crib biters are apt to ruin their teeth. I know not why, but I think bred cattle most subject to it.

A variety of rules have been laid down to determine the seat of lameness in horses, few of which, I believe, to be infallible. Very little else is to be discovered by the old method of turning a horse, which is lame before, short sound, than that you have increased his pain. Osmer says, if a horse drags his toe upon the ground, the ligaments of the shoulder are certainly strained, or perhaps even the scapula, or blade-bone dislocated, backward or forward. But strains of less consequence may happen to the shoulder, which are very difficult to distinguish from those seated in the lower extremities. In such case, I know of no other rule by which to judge of the soundness of the shoulders, than that which I have already noted in *Italica*, a few pages back. Both the hand and the eye should be sedulously employed, in the endeavour to form a correct judgment; the former much more than is usually the case. The pastern joint should be turned by the hand, in order to discover any lurking uneasiness. The patient himself, although unable to speak, will give very plain indications, in particular, by constantly attempting to favour the injured part. In strains of the *cubiti joint*, or bone of the foot, the horse will stand with the toe only touching the ground. In a hot or *surbated* foot, he will be alternately changing, or lifting up his feet. If a foot be pricked, or gravelled, or if the shoe set hard upon the sole or heel, or in short, if the horse have any complaint against the smith, he will frequently shew it, by setting the injured foot upon the other. Going short, and catching up the feet, as if the horse was treading upon hot iron, also denotes uneasy shoes, or tender feet. Horses with cramped or contracted sinews, or hurt in the knee joints, as post hacks frequently are, will fall down suddenly in their walk. If a horse trot sideways, sometimes with one, sometimes with the other foot first, or if he perpetually tend to one side of the road, it shews universal stiffness from hard labour, and the want of a long run at grass. Hurts in the loins are known by a rolling or wavering motion of the hind-quarters. In a sudden jerk or strain of the loins, the horse will seem to go, as it were, whole, and fixed behind, and upon his heels, as if foot-fouled. Horses are not so often lamed in the back sinews, behind, as before; but I have known several cases of the tendon of the hind-leg being suddenly let down, and in the course of two or three weeks, by the help of bandage and astringents, braced again and placed in *statu quo*. The symptoms were, lameness, and dropping suddenly at intervals; inflammation and tension; after these had subsided, a palpable laxity, and softness of the tendon.

The flying lameness, as they are styled, in the shoulders, and lower joints of young, or unseasoned horses, it is the custom of farriers to attribute to peccant humours. I must boldly

avow my scepticism on this head, although Gibson and Bartlet be of the opposite party. They might just as well, in general, I conceive, lay these griefs to the charge of the lunar influence. They are often nothing more than the consequence of sudden and unusual exertion upon young and tender fibres, or those unaccustomed to stress and action. I know that copious bleeding and purging, much to the credit and emolument of the groom or farrier, are usually prescribed, and with success; but I have also repeatedly seen a loose stable, or a fortnight's run abroad, succeed full as well. So much for *humours which fly about a horse*; they much oftener fly about the brain of his keeper. Horses are, in truth, sometimes subject to rheumatic pains, and the *sciatica*, or hip gout.

It is the opinion of many, that there is no necessity for great substance in the shank and pastern, provided the sinew be large and distinct, and the loin wide and good; in which, it is insisted, the chief strength of the horse resides. Baret and Osmer are of this opinion; but I think it scarcely correct, since an equal distribution of substance is obviously as necessary, as of length. Osmer, no doubt, intended to speak comparatively between the different species, and it is certain, that the southern bred horse, with his small hard shank, and large, dry, and tough sinew, is able to move with a much larger proportional weight, than the thick gross horse of these northern countries. Nevertheless, to be able to carry weight, a large sinew should be attached to a shank, and joints proportionally large; and the whole supported by a foot of compass sufficient to form a steady foundation. It is the result of my constant observation, that hacks, with large bone under the knee, will always endure most rattling over the hard road.

Horses formed too bulky upwards, for their lower extremities, are liable to various accidental lameness and defects, merely from the unequal pressure of their own weight. Hence windgalls, splents, spavins, and particularly crookedness of the joints. These, and all early-grown cattle, should be put to work very late, in which case they will improve; otherwise will seldom stand sound long. It is a mathematical truth, that a crooked joint cannot be so strong as a straight one, as a column is strong, in proportion as it is perpendicular.

There is a certain reason why St. Bel did wrong in not quoting Osmer by name. In one case, he has very properly corrected him. Osmer, though an excellent writer, was a little too positive. He offers a method of shoeing, or paring one side of the foot of a colt, which is infallibly to prevent his ever turning out his toes. But he erred in supposing the defect to be the mere consequence of early habit, since it is no doubt almost ever the result of natural conformation, and his proposed remedy might be attended with dangerous consequences. He, perhaps, received the opinion of the Stagyrite too literally, "that Nature never errs," which if predicted of her original determinations, is unquestionable; but if of spontaneous and fortuitous action, is contradicted by every day's experience.

It is a very just observation, that a horse "can scarcely go too wide behind," and, that he ought to be very wide across the knee, forearm, thigh, and hock. But I have, as well as Bracken, seen now and then one which excelled in those particulars, and which were inapt for action in consequence, but robust and hard feeders. A horse must obviously lose strength, if the hinder legs be too far extended, and I have thence seen that wavering of the group,

noted by St. Bel, in both saddle and draft horses. Two extensive quarters press too much upon the fore-parts, and occasion the horse to overreach. I know not whether it has been hitherto remarked, that a horse going wide behind, appears to an unskilled observer, to be lame of that hind-leg, upon which his eye is fixed, notwithstanding it be perfectly sound; but so it certainly is.

The health and condition of animals is ascertained by the gloss, sleekness, and evenness of the coat. If the horse's hair stare, or stick out, and look dead, he is diseased, or ill-fed. If nits appear upon the extremity of the hairs, he has been lately at grass.

The signs of vice and ill nature in horses, must be sought in the eyes and countenance. A vicious horse, when he lays his ears and looks back, exposes the whites of his eyes, and his malicious intentions are very visibly painted in his countenance. He stands commonly with his neck fixed, as if prepared for offence. Care should be taken to discriminate. The best natured horses will, on the approach of man, lay their ears, smile, for they are most truly risible animals, and move their necks to and fro, in a wanton and playful manner. There is an expression of nobleness and generosity beaming from the eye of a good, and well tempered horse; and it is grievous, often to see the friendly advances of this excellent, this next to human creature, treated with surly indifference, or cruel stripes.

Jockies say, "a horse should carry his head in a proper place, when mounted;" how is that? So that his chin, or under jaw, recline somewhat under his windpipe, and his neck and head form a portion of a circle. But this relates only to a slow pace.

In the purchase of a horse, with the usual warrant, we will suppose, the buyer ought to attend first of all to the most important considerations, in which being satisfied, it is vain to hesitate, since as the case stands, he may not meet that satisfaction every day. These, I think, are—age, ability to carry his weight, safe going and good feet; freedom from knocking, cutting, or overreaching; that there be no need of martingale, or crupper; speed.

What has been already said of form and blood, the reader will find as strictly applicable, in general, to the hunter as the hackney; but the former not being required to trot, or to go much over hard roads, are additional arguments in favour of thorough blood. Nor can it be doubted, that a bred horse, if not too high upon the leg, from the cleanness of his make and the strength of his sinews, is the fittest to carry twenty stone, over the deepest and most inclosed country.

I have observed, that the Irish hunters are the highest leapers in the world, from their being early trained thereto. Would it not be advantageous, to bring all our colts of size and figure to the bar? Good standing-leapers are, I think, generally scarce; and some, which are good in that respect, will hesitate and boggle at their flying leaps. Perhaps an early attention might remedy those defects.

FROM THE NEW ENGLAND FARMER.

SIR,—In this age of improvement, as it is justly called, I wonder no person has invented a suitable press for extracting the juice of currants. It has become very fashionable to make currant wine; and it is an *excellent*, and *cheap* substitute for any imported wines, but the want of a press is much felt. It appears to me that the man who shall invent a cheap press, will find a great demand for the article. A FARMER.

SYLVA FLORIFERA.

ACACIA.—ROBINIA PSEUDACACIA.

Natural order, Papilionaceæ, or Leguminosæ.
A genus of the Diadelphica Decandria class.

"Light-leaved acacias, and the shady plain,
And spreading cedars, grace the woodland reign."
BARBAULD.

Although we are far from being amongst the number,

"Whose proud disgust and scorn
Detest those treasures which at home are born;
Who feel no joy, though spreading to the air
His pompous trees their verdant branches rear,
Unless from Afric's soil their rise they boast,
From India's deserts, or Columbia's coast.

* * * * *
But if some foreign tree, of noble size,
With boughs majestic should adorn the skies,
Our forest natives with attention meet,
And hospitable care the stranger greet;
Pleas'd 'mongst themselves his future dwelling
make,

Not for his scarceness, but his beauty's sake:
If haply profit too should join with grace,
To civic honours they admit his race."

DELILLE.

Of all the exotic trees with which we have adorned our native groves, this North American stands first. We have no tree that displays more elegant foliage than is formed by its pinnated leaves, which appear so judiciously scattered over the branches that not one obscures its fellow, and their feathery lightness is only surpassed by the pleasing emerald tints with which they are coloured; nor are its bunches of pendant papilionaceous blossoms less acceptable for succeeding the more gaudy laburnum, and thus lengthening the charms of spring. The sweet perfume with which they scent the surrounding air only makes us regret their short duration; but to these succeed pods of so rich an amber brown, that autumn seems to peep through the veil of spring, and repay us for the loss of its orange-flower odour; whilst the nightingale loves to confide her nest to this new inhabitant of our climate, whose long and strong thorns seem to insure her family a protection, and she descends to the lower branches to ravish our ears with her sweet melody.

"Nor rural sights alone, but rural sounds
Exhilarate the spirits, and restore
The tone of languid nature."

COWPER.

We cannot with indifference behold this tree which the uncivilized natives of America have consecrated to the genius of chaste love. These proud children of the desert are not less susceptible of the pangs which cupid occasions, than the more polished inhabitants of Europe; nor are they less delicate in expressing their sentiments, which, instead of flattering words, are told by a branch of acacia in blossom. It is natural to suppose that this seducing language is as well understood by the young savage of the forest as by the tutored coquette of the city.

The introduction of American plants into Europe made a change in the system of botany absolutely necessary; for that which had been arranged by Tournefort and others, was found impossible to be applied to the plants of the new world. This tree, when first introduced, was supposed to be a species of the acacia known in the ancient world, because its thorny branches and winged leaves bore resemblance to the Egyptian thorn, or binding bean-tree, which

the Greeks called *Λακκία*, of *αναζω*, to sharpen, from whence the Latin *acacia*. But by the system of Linnæus we discover that it cannot be ranged in the same class or order as the true acacia.

It is therefore commonly called the false acacia, while, in America, it is named the locust-tree.* We have now collected thirteen different species of this tree, all of which bear the generic name of *Robinia*.

Europe owes this vegetable beauty to Monsieur Jean Robin, nurseryman to the king of France, and author of a "History of Plants," who first brought the seeds from Canada; and, in gratitude for the gift, botanists have given it the name of *Robinia*.† Soon after its introduction into France, the English gardeners received seeds from Virginia, from which many trees were raised. Parkinson observes in his Theatre of Plants, which was published in 1640, that "it was grown of an exceeding height, by Mr. Tradescant;" and Evelyn recommends it to the nation in his Sylva, which was presented to the Royal Society in 1662. In this work, he says, "The acacia deserves a place among our avenue trees, adorning our walks with their exotic leaves and sweet flowers; very hardy against the pinching winter; but not so proof against its blustering winds." This great man, who so eminently displayed his desire to embellish and enrich his native country, by plantations, adds, "I would encourage all imaginable industry in such as travel foreign countries, and especially gentlemen who have concerns in our American plantations, to promote the culture of such plants and trees, especially timber, as may yet add to those we find already agreeable to our climate."

These observations appear to have met with little attention, as the tree seems to have been rare in 1720, when Bradley notices it as growing in the court before Russel House, Bloomsbury, and in the Old Palace-yard, Westminster. In both of these situations their roots have given place to flag-stones, brick and mortar; their trunks to lamp-posts, and their waving branches to clouds of coal smoke. Mortimer says, "a great number of them were formerly planted in St. James's Park, and that in consequence of some of their branches being broken by the wind, they were all cut down."

This graceful tree is to be found in every well planted shrubbery, yet it meets the eye less frequently than could be wished by the admirers of beautiful scenery, while in France it not only ornaments the gardens, and shades the public promenades, but its winged leaves shine through their woods and forests, so as to give an idea of its being a native of the soil. There it adds utility to luxury, and profit to beauty, for the turner finds the wood both hard and firm, while the joiner uses it for durability, and the cabinet-maker for the beauty of its yellow and brown veins; nor must we forget a singular quality in this tree, which is, that it burns well even on the day that it is felled; a property of no small importance to a country where wood continues to be the only fuel. This tree grows from fifty to seventy feet in height, and so rapidly when young, that it is not uncommon to see shoots of this tree six or eight feet long in one summer. In New England, we are told of a *Robinia* tree, of forty

* A name which most probably was given to it by some of the early missionaries, who would wish to create a belief that it was the same tree the fruit of which supported St. John when in the wilderness.

† Gerard received the nasturtium seed from M. J. Robin.

years old, that was in 1782 sixty feet high at four feet ten inches in girth, at three feet from the ground. This timber has been employed with success in Virginia for ship-building, and found to be far superior to American oak, elm, or ash, for that purpose; it is even said to be as durable as the best white oak, and esteemed preferable for axletrees of carriages, trenails for ships, &c. Most of the houses which were built at Boston in New England, on the first settling of the English, were constructed of this timber. The native Americans make the bows of this wood, and point their arrows with one of its thorns. Its tap-root, when cleared of the bark, has an agreeable perfume.

We are told, in Martin's edition of Miller, that Sir George Saville had, in 1807, planted many thousands of these trees at Rufford; and we feel confident that they will ultimately benefit his estate, notwithstanding the character given them by most English writers, that their branches are subject to be broken by the wind in summer. We have seen them so shattered in situations injudiciously chosen, while on the banks of the Thames, and in other sheltered spots, we have remarked them of more considerable age and magnitude than even in France.

The *Acacia Robinia* seems particularly adapted to ornament the modern villa; its light and loose foliage, that pleasingly admits the light, seems to harmonise better with the trellis work of the viranda than any other flowering tree, while the grace of its bend, and the gaiety of its head, correspond with the nicety and cheerfulness of this style of building, which has of late years so greatly embellished our country. Nothing, perhaps, displays more conspicuously than this the liberty of the people, and the equity of the laws that protect the lone cottager more securely, than any ramparts or moats could have protected our forefathers, who found no security but in their castles, or the walled towns, where their reliance was on their numbers. These towns were called *Villa*,* and from whence we have derived the name of villa for detached country dwellings; and as long as our liberties and laws remain unimpaired, so long will the acacia wave its banners in security over our peaceable villas.

In placing this tree in the shrubbery or plantation, a sheltered situation should be chosen. It is a beautiful tree, either to look through, or to look down upon, and it is equally ornamental when its feathers to the ground, or carries its plumage above evergreen shrubs, which its shade injures less than that of other trees, and it is certainly less hurtful by its drip than any tree we know of. This may be accounted for from a singularity in the nature of its pinnated leaves: they fold over and join their upper surfaces in bad weather, leaving the tree, as it were, stripped of half its foliage, while the rain is conducted by the branches to the trunk, and from the trunk conveyed to the root. These winged leaves expand themselves again in fine weather to exhale oxygen gas, but at the approach of night they again close their leaves, as if to sleep, and are thought to give out carbonic acid from their under surface. An infant, who had observed this natural phenomenon from its nursery window, observed, "it

* The Latin word *Civitas*, properly, is referred to the people and inhabitants who live under one, not only one law, but also under one and the selfsame magistrate and government. *Urbs*, *Villa*, and *Oppidum*, signify the place wherein those citizens live and assemble themselves. Tale on the Antiquity, &c. of Cities, Boroughs, and Towns, 1598.

out bedtime, for the acacia tree had not given its prayers;"

"Thus every object of creation,
Can furnish hints to contemplation;
And from the most minute and mean,
A virtuous mind can morals glean."

GAY.

The Robinia, or, false acacia, is not delicate soil, for it will grow in earth of every kind, and prospers best in such as is light and sandy. The finest trees are those raised from seed, which should be sown in light earth, about the end of March, and in about six weeks the young plants will appear; they may be transplanted the following year, for all trees that have a tap root it is advisable to transplant young. This tree is also propagated by suckers and cuttings; but these seldom prove so handsome as those raised from seed.

We do not learn that this tree has in any shape added to the catalogue of medicines. The *Stacia* of the shops was formerly made of the unripe pods of the true acacia tree; but of later years, the *Acacia*, *Germanica*, which is made from unripe sloes, is preferred as an astringent medicine to the true acacia.

—D—

TO THE EDITOR OF THE AMERICAN FARMER.

HYDROPHOBIA—SEVERAL INSTANCES OF, WITH ACCOMPANYING SYMPTOMS.

Brandywine, January 25, 1824.

MY ESTEEMED FRIEND,

Seeing an account of a singular instance of hydrophobia in the last number of the American Farmer, noted by a Virginian of Jefferson county, Va. stating several circumstances, which may appear novel in that disease, to many that have not been eye witnesses to facts. But from my frequent opportunities of seeing cases immediately under my notice, can attest the same disposition in a cow of mine, that is related by him.

I had a cow bitten by a small sized dog, that was suspected from his behaviour, to be infected with hydrophobia, but after his biting the cow and several other of my domestic animals, I thought best to secure him to ascertain the fact by keeping him confined, until time should reveal the truth of the case.

One of my neighbors had called on me to know if such a dog had been seen, describing him; I found he had bitten several animals, before he arrived at my house; he had been about with my boys who had caressed him for his activity, and business to attack any thing that came in his way; the attack of my young bull dog, was one of his first acts of valour, about twice the size of himself; my hogs, and even a horse he took by the nose; all those circumstances happened in the early part of the day, when I was absent; as soon as my neighbor informed me of his behavior, before he came to my place, I took the alarm, and was very desirous to secure him for proof of his infection.

I ordered an open hogshead to be got ready while I went in search of him, I found him lying in the entry of my stable, where he had been with the boys that had been feeding the horses some time before, and coiled up as if asleep—I opened the door and spoke, he looked up without rising—the moment I saw his eyes with that green *glistening* appearance, I was confirmed in the belief, of the certainty of his case of infection, and remarked to my neighbour, who was with me, that he was surely mad. I took a small cord and a club, and cautiously approached him, speaking to him in a soothing tone till I fastened

my cord about his neck, and led him out; the hogshead not being yet ready, he began to snap the rope that I held him by, until his sharp teeth cut it off; ran toward the house and took shelter under an oven where I could not so readily come at him; I procured a piece of meat, showed it to him; called him and threw it on the ground, he readily came out, and began to eat what I gave him; I caught him by the back of the neck so effectually, as to ensure safety, and carried him to the hogshead, and covered it with heavy plank, with such weight as to ensure his safe keeping.—From that moment, he seemed distracted with all the symptoms of dreadful hydrophobia, gnawing frequently at the bunghole of the hogshead violently—and by putting a stick in at the hole, he would snap it, with all the symptoms that accompany that disease—he was dead next morning in his confinement.

The cow that was bitten, (although I could not discover any wound,) was milked as usual, not used in the family, but fed to a calf then raising, until the subject had become less alarming, and the milk of that cow was put with others for family use—about two months had elapsed when she was milked in the morning as usual, for family use, and went for that purpose.

But while the cattle were yet in the yard she was discovered to ride on some of the others, as if wanting a bull; she was driven immediately to the next neighbor, who kept one, but in a few hours he sent in haste a messenger to have the cow taken away, as she was "mad;" I hastened to relieve him of his anxiety, for the safety of his large stock. She was so agitated and in such a paroxysm of rage, as to run into thickets and precipices, as no animal in their common senses and habits would attempt, and induced us to put an end to her misery on sight.* My young bull dog was timely put out of harm's way, my hogs were suffered to remain, and about nine or ten days after being bitten, they took the infection and died, my horse was bitten in the side of his upper lip, a soft fleshy part. I thought of an experiment several days after it happened—he had been at work, when he came home, one evening I took a penknife and by careful amputation removed all the wounded part, and he never was infected.

I have been the more tedious in giving a relation to shew the little incidents that often lead to discoveries of importance; there is one other, that may shew us the errors that we establish as facts without a sufficient ground, that is, the dread of water, in all cases—it was not the case with this dog—my boys were in a boat on the milldam, when they first saw him as it hunting along shore, they called him, and although strangers to him, he jumped into the water, and swam perhaps fifty yards to them, and they helped him into the boat.

I happened to pass that way on shore, and saw the dog, enquired how he came there, they informed me; he was then standing with his forefeet on the gunwale looking at me, and as they afterwards said had been gnawing the side of the boat at intervals, while in that position.

I knew another instance of a dog passing my mill after night, who bit a female of his own kind as he passed, that was standing at the door; hearing her cry out, as if bitten by a dog, struck me with an idea of his madness, because if free from that disorder, no such violence would take place from the male to a female.

We examined in the morning, (as it was night when it happened,) and found a track of large size had entered the fording of the creek, below the mill, and gone over through the water;

* I have lost several cattle by hydrophobia.

strict search was made, and a wound was found on the head of the slut, which was fatal to her in about 9 or 10 days—she was kept confined to witness the event—the dog had crossed the water 80 or 100 yards wide.

Those two instances shews a voluntary entering the water, although it may not be generally the disposition of all infected with that malady.

A "mad dog" and an angry dog are very different, the former will fly from you if pursued, and seems timid and suspicious of danger, the latter I need not describe. I am ready to conclude, that cutting the infected part away, any time within eight days, is the surest cure that can be made use of.

I never knew an instance of earlier infection; but from that period to seven months, I have known frequent instances of the effects being fatal to the subject. We find it confined to the place where the virus is deposited at least eight or nine days, and as I have been ready to believe as much longer, as no symptoms of hydrophobia appear—therefore, the skilful application of the knife to flesh wounds, might be looked upon a sure remedy. But many instances would require the best skill of practical surgeon, when the wound is made amongst the more vital parts of the system.

C. KIRK.

—D—

TO THE EDITOR OF THE AMERICAN FARMER.

TURNIPS.

Pittsfield, (Mass.) January, 20th, 1824.

SIR,

Some months ago, I was induced to write you a communication on the subject of turnips, in consequence of an article of one of your correspondents, tending to discourage the cultivation of them—and as I then promised to give you the result of this year's crop, I avail myself of a little leisure, to redeem my pledge.

According to the weather, I have for six years practised sowing turnips, from the 15th to the 25th June. But this year, a severe drought through the whole of June, and until the fore part of July, obliged me to delay it until the 10th—(too late by 15 days, at least, to warrant the hope of a crop of *ruta бага*.) The land (gravel) had been previously manured, at the rate of 20 ox cart loads to the acre. Immediately after sowing and rolling, gave the drills a top dressing of 12 bushels of slacked ashes per acre. They were ploughed, and hoed out, twice. On the 10th of November, began to harvest them—and had at least 450 bushels to the acre, estimating an ox cart at 30 bushels.

The expense of cultivation, and harvesting, does not exceed that of corn—of which the average crops of the country may be stated at 25 bushels. The corn I raised this year, was manured in the same manner as the turnips, and we had about 50 bushels to the acre. In my estimation, six bushels *ruta бага*, are equal to a bushel of corn, for any kind of live stock.

It is objected by some, that it is a troublesome crop to secure through our long, and severe winters;—It is not more so, however, than potatoes, and the value of them for stock, especially sheep, at the close of winter, and until grass will afford a good bite, (which is not generally until the 10th of May) can only be duly appreciated by experience.

It is doubtful in my mind, if the cultivation of turnips will answer to any extent, so far south as Maryland; but for the eastern and western states, it must, methinks, as we progress in agricultural improvements, become an important item in the rotation system of every good farmer, who combines arable and grass farming.

I have long been of opinion, that we might cultivate *rape* to advantage, in this section of our state, (at least for sheep,) being ignorant of the best mode of cultivating it, its proper soil, and the manner of curing and securing it, if raised for the seed. I beg leave to ask of you to appropriate a place in your valuable paper, to an article on the subject, in the belief that it would be interesting to this vicinity.

AGRICOLA.

AMERICAN IRON.

Baltimore County, Feb. 1st, 1824.

MR. SKINNER,

Sir—In your last number, you give an account of a manufactory in the city of New Jersey, for converting iron into steel, which is found to be of excellent quality, and you say, "we do not yet manufacture iron as it ought to be manufactured, but we trust we soon shall."*

My present object is to ask wherein we are defective in making iron; for if this is pointed out, perhaps a remedy may be applied, at least, an attempt shall be made by one that is interested.

SOHO.

* The remark was not made by the Editor of the Farmer—if this should meet the eye of its author, he will probably answer the enquiry.

THE FARMER.

BALTIMORE, FRIDAY, FEBRUARY 13, 1824.

The first meeting of the Trustees of the Maryland Agricultural Society for the Eastern Shore was held at St. Aubins, the seat of Nicholas Hammond, Esq. on Thursday last the 29th Jan. Owing to several members of the Board being absent, upon public business, and to the circumstance of others being unfortunately detained by the indisposition of their families, a single member was wanting to constitute a majority, which by the rules of the association is necessary to transact the business. The company however spent a most agreeable and useful day, engaging themselves in conversations on agricultural matters, and in the interchange of opinions, intelligence and suggestions upon husbandry and its kindred concerns.

The attention of the company was drawn to Mr. Hammond's fine stock of different kinds, which were very beautiful, and did great credit

to the management and care bestowed upon them—to his enclosures, which are neat and durable—and to his grounds which are in an admirable state of culture, and exemplify this important maxim in agriculture, that a small piece of ground well manured and cultivated, will yield three or four times the quantity of product, with half the expense and labour, that double the quantity of land now gives under the common mode of cultivation. The farm yard and buildings at St. Aubins are particularly worthy of the attention of agricultural gentlemen, as they constitute an establishment far superior to any thing of the kind that any of the company ever witnessed in Maryland.

After the most hospitable entertainment, the Board adjourned to meet at Mr. Samuel T. Kennard's, in the next month.—*Easton Gazette.*

BALTIMORE MARKET.

No. 2, \$6—Baltimore prime, \$10—Bacon and hams, 10 to 11 cts.—Cotton, W. I. Island, 18 to 20 cts.—Louisiana, &c. 16 to 17 cts.—Georgia upland, 14 to 16 cts.—Alabama, 12 to 13 cts.—Candles, mould, 12 to 13 cts.—Dipt, 10 to 11 cts.—Spermaciti, 25—Feathers, live, 30 to 35 cts.—Fish, herrings, Susquehanna, \$2 75—Fall mackarel, No. 1, to 3, \$4 50 to \$7—Shad, trimmed, \$6 to 6 50—Flax seed, rough, per bushel, 70 to 75 cts.—cleaned, cask, \$8—Flax, per lb. 10 to 11 cts.—Hemp, Russia, \$1 75 ton.—Country dew rot, 7 cts. per lb.—do. water rot, 9 cts.—Hops, fresh, 35 cts. per lb.—Hides, dried, 15 to 19 cts. per lb.—Hog's lard, 12 cts. per lb.—Lime, per bushel, 30 to 33 cts.—Leather, soal, best, 24 to 27 cts. per lb.—do. Eastern tan, 18 to 20 cts.—Lumber, board measurement, cargo prices:—Of the following articles we give the yard prices.—Oak timber and scant. \$1 to 1 25—Boards all sizes, \$1 50 to 2—Pine scantling, do. \$1 to 1 25—Boards 4-4, \$1 to 1 25—White do. 5-4, \$1 75 to 2 50—do. co. 4-4, \$1 15 to 1 30—do. cl. 4-4, \$1 80—Shingles, cyp. 18 in.—\$3 to 3 50—Shingles, junip. 24 do. \$7 50 to 7 75—jun. com. \$3 50 to 5—Staves, W. O. pipe, \$40 to 45—do. hhd. \$25—do. bbl. \$15 to 17—R. O. bbl. \$15—do. hhd. \$17—Wool, fleece, merino full blood, 35 to 40 cts. per lb.—Cropped, 28 to 30 cts.—Common country, 20 to 30 cts.—Skinner, 35 to 40 cts.—When assorted and cleaned, any of the above will obtain an advance of 15 to 20 cts.

Retail prices of provision market—Beef, prime pieces, 10 cts.—Veal, 8 cts.—Mutton, 6 to 7 cts.—Turkeys, 75 cts. to 1 25—Geese, 50 to 75 cts.—Ducks, Canvasbacks, \$1 25 to 2—Red heads, 75 cts. to \$1—Chickens per pair, 50 to 6 1/2 cts.—Eggs, 15 to 18 cts.—Butter, 1st quality, 25 to 37 1/2 cts.—T. rumps, per bushel, 50 cts.—Potatoes, do. 50 cts.—Parsnips, do. 6 1/2 cts.—Celery, 8 to 10 cts.—Carrots, 4 to 6 cts.—Cabbages, 2 cts. &c. &c.

Prices of Robert Sinclair's, Hood's and Carey Ploughs.—No. 3. Woods' or Freeborns' \$11—No. 2, do. do. \$10—No. 1 1/2, do. do. \$8—No. 1A, do. do. \$6 50—Corn, do. do. \$6—No. 21, do. do. for seeding, \$5, (Extra shares always on hand, at 5 1/2 to 50 cts.) No. 3, Carey or Dagen, \$6—No. 2, do. do. \$5 50—No. 1, do. do. \$5.

Premium and other barshare ploughs, is 10 per cent. lower than last year.

Liverpool Market, December 16.

Tobacco.—There has been a good demand for leaf, partly on speculation, and partly for the Irish market, viz. 180 hds. Kentucky, on the former account, and 100 Virginia for the latter, chiefly at previous rates. The sales of steamed tobacco to the trade do not exceed 60 hds. at the quotations.

Naval Stores.—Rough Turpentine experienced a very steady demand from the trade, and prices remain quite stationary. About 3000 bls. were brought forward by auction last week, none of which was of fine quality, and some ordinary, which operated against the sales; in consequence only 1340 bls. were disposed of at 12s 6d to 13s 9d per cwt. the best not exceeding 2-3ds soft.—The transactions in Tar consist of 580 bbls. of Carolina from the Quay at 13s 3d to 13s 6d per barrel.

ROBERT SINCLAIR,

Ellicott-street, Pratt-street wharf, head of the Basin, Baltimore.

Has for sale, a good supply of red and white clover, orchard grass, herds, timothy and lucern seeds, northern naked barley, spring rye, Albany peas, seed oats, 300 bushels early white potatoes from his farm, 200 bushels millet seed, 50 bushels of hominy bush beans, or true Cockstone, 120 lbs. mangel wurtzel, of the growth of last year.

GARDEN SEEDS—he has now on hand a very general assortment of the growth of 1823, and has made arrangements to keep up fresh supplies from the Shakers in New England, and from one of the most respectable seedsmen in London, from whom he has, and expects supplies—so that farmers and gardeners may depend on the quality of the seed they may get from this establishment as being fresh, true, and of the most approved kinds—none will be sold by him that is at all doubtful in any respect—he has raised many kinds with great care, and will thus continue to supply himself with many sorts.

In store, a general assortment of farming and gardening tools; and as usual, an excellent assortment of implements of various sorts, among which are, 300 of the premium and other barshare ploughs.—Also Woods' pattern, with extra shares to repair them, of No. 21, corn, No. 1 A, 1 1/2, 2, 3. Also, the Carey ploughs assorted sizes, from No. 1 to No. 5, about 200 of the last two kinds, with cultivators, wheat fans, corn shellers, scives, straw cutters and cultivators, &c. &c. all at reduced prices.

CONTENTS OF THIS NUMBER.

POLITICAL ECONOMY, letter 2—VIRGINIA AGRICULTURAL SHOW, Report of the committee appointed to prepare for publication an account of the second Fredericksburg Agricultural Show and Fair—FATTING SWINE—ADVICE TO YOUNG FARMERS, on the appellatives, qualities, habits and defects of horses—PRESS for extracting the juice of currants—SYLVA FLORIFERA. *Acacia Robinia pseudoacacia.* Natural order, Papilionaceæ, or Leguminosæ. A genus of the Diadelphia Decandria class.—HYDROPHOBIA, several instances of, with accompanying symptoms—TURNIPS—American iron—Tobacco report—A meeting of the Trustees of the Maryland Agricultural Society at Easton—Prices current, Advertisement, &c. &c.

Printed every Friday at \$4 per annum, for JOHN S. SKINNER Editor, by JOSEPH ROBINSON, on the North West corner of Market and Belvidere streets, Baltimore: where every description of Letter and Job Printing is executed with neatness and dispatch—Orders from a distance for PRINTING or BINDING, and proper corrections promptly attended to, addressed to J. Robinson, Baltimore.

Political Economy.

TO THE EDITOR OF THE AMERICAN FARMER.

LETTER III—AND LAST.

DEAR SIR,

Having demonstrated, as I fully believe, that the man set up by the manufacturers of the present day, as the great apostle of their peculiar doctrines, never uttered a sentence in any of those writings, upon which they chiefly rely, that could bear, if fairly interpreted, any such construction as they are pleased to give them, I will recur once more to the common sense reasoning upon this subject.

And here I beseech all those who are most concerned, to keep constantly in view, the very wide difference which has always been discernable from the very commencement of every government, however free, that ever existed, between the real objects of those who made, and those who carried into practice, the constitutions thereof. The first, ever aim to limit and restrain, while the last, (call them whigs, Tories, Federalists, republicans, or what else you please,) are continually buying their inventions, to enlarge and to extend beyond their legitimate bounds, the powers which are to be exercised.—This results inevitably from the very nature of man himself; nor can it be otherwise, unless some effectual means could be devised, either to eradicate from the human heart, all pride, arrogance, avarice, and ambition; or so to control them, that like weeds in a garden, they could be cut up, as fast as they appeared. The history of every year's legislation, since our government was organised, will most clearly show this fact; for it is confidently believed, that not one can be named, let the administration have been what it may, wherein several attempts to usurp power, (some of them successful too,) may not be pointed out, of soggling a character, that neither party spirit, nor the most charitable interpretation of motive, can explain them away. The only possible way in which this usurpation can be made, under a constitution like ours, is by exercising, what are called *incidental and implied powers*, rather than those which are direct and positive. This has constantly been done by all parties, wherever it suited their purpose, if the powers of the latter description appeared to forbid what they wished to do. What they were unable to do, "totidem verbis," they have spelt out "totidem literis;" disregarding entirely, the obvious and incontrovertible truth, that no deduction nor implication can be legitimate, which contradicts the plain and positive provisions of the instrument, from which it purports to be drawn. Even on the supposition, that our constitution-makers had been too niggardly or destitute of foresight, to bestow a quantum sufficient power, for all necessary and useful purposes, a forced construction, and application of what they really have given, is not the remedy for their failure. But the fact, I believe, is, that these wise and cautious men, being fully aware of the constant hankering after unlawful things, which beset a great majority of mankind, have been too strict for modern appetites, in guarding against all those abuses of power, to which they know, that all public functionaries are so incurably prone. Not that ours are worse than other men. But how, in the name of common sense, can we see any possible reason for their being so much better, as to be exempt from a universal inferiority. If the unvarying history of the whole human race, exhibits but one uniform scene of contention between the governors, and the governed, to extort on the one hand, or to

extend; and on the other, to withhold or to restrain power; what imaginable right have we to believe that *the men of our day*, will differ in this respect, from those who have preceded them?

I have made these general remarks, with a view to apply them to the particular case of the proposed tariff. When our constitution was first formed, it was known to all, that there were many and great conflicting interests to reconcile. These principally resulted from the circumstance, that some of the states were, and ever would be essentially agricultural; while others were, and must forever remain, essentially manufacturing. From this state of things it was manifest, that should either obtain the ascendancy in the great councils of the nation, there would be great danger of the others being oppressed; unless effectual means were taken to guard against it. Among the most obvious of these means, was the positive, unconditional prohibition of taxes upon exports; as any such tax, must necessarily have operated, for many years at least, exclusively against the agricultural states. Could it have entered into the imaginations of the members of the general convention, that precisely the same injustice might be perpetrated by taxes upon imports, if extended beyond the object of public revenue; can it possibly be believed, that they would have failed to impose such positive restrictions on this last power also, as to prevent the practicability of its being so exercised, as entirely to defeat the positive prohibition of the first? I may safely answer, that such belief is impossible, to any man not actually mad, or so far devoured by self interest, as to be incapable of seeing any side of a question but his own.

The reason why any tax upon exports was forbid, was so entirely plain, that it surely would have been surplusage in the extreme, not only to have enumerated every object of legitimate taxation; but also to have added, that none of them should be so taxed, as to draw from one portion of the union, a greater sum in proportion to its wealth and population, than from another. If this remark be correct, it follows most conclusively, that when our legislators are about to impose any tax whatever, even where the abstract right is unquestionable, it may become both inexpedient and unconstitutional, if it contravene the reason which produced the prohibition of taxes upon exports. If it is to operate with very unnecessary, and easily avoidable inequality, on the different parts of the United States, then are they bound by every principle of common sense, common justice, and duty to consider it as much forbidden, as if the constitution had said, "*this thing thou shalt not do, under pain of political damnation.*"

Shall I be required at this time of day to prove, that such a tax upon imports, as the new tariff bill proposes, will have the same unequal operation with a tax upon exports, confined to particular states, and particular articles, made alone in those States? Take a single case, (for one is as good as a thousand,) to demonstrate the fact to the understanding even of a child.

Suppose that I am under the necessity, or believe myself so, (which amounts to the same thing,) of buying a yard of coarse woollen, which I can get for 50 cents. Some man goes to Congress and says, I wish to manufacture the same article, but cannot do it, unless you require, that all purchasers shall give 75 cents for such an article, instead of 50. His request is granted; his manufacture either entirely excludes what I had formerly bought, or so nearly does it, that I am obliged to purchase of him, and to give 25 cents more than I formerly gave, or go without. It

will hardly be necessary, I presume, to add, that unless he was to pocket this additional sum, he would not ask Congress to impose it, as it would be wantonly to injure me without benefitting himself. Nor need I take the trouble to prove, that although he may consume some of the same article himself, it does not cost him so much by all the profit of his labour, as well as by the additional duty of 25 cents, as it costs me, who do not make it. Now if this is not unequal, partial, and unjust taxation, I know not what is. But this is not all, nor half the outrageous grievance. The man from whom I bought before, lived in some other country, no matter where. But I avoid naming any particular one, because there are many men among us, so exceedingly nervous and sensitive as to be utterly incapable of viewing in the abstract, this subject of duties, upon foreign commodities, when particular countries are named. For instance, if you even mark in juxta position, the letters E, N, G, L, A, N, D, all the hallucinations and madness of party, immediately seize their brains; they fall to ranting and roaring about "colonial governments," want of patriotism, and God knows what besides; and like frantic horses that have run away with their riders, after taking the bits between their teeth, they scamper away over the illimitable fields of party contention, as regardless of what first started them, as if they have neither seen, nor heard it. But to resume my case—this man, who lives in some other country, used to buy a part of my produce, or take it in exchange for what I bought of him; but as he is not at liberty to sell his yard of cloth to me at the same price as at first, having to pay the government 25 cents more than he did, for the privilege of selling, he cannot allow me the same price for my grain, tobacco, cotton or sugar. Our barter then, must either cease entirely, or be greatly curtailed.—But there is another, and another, and another man in some other countries, who also sold to me the same, or other manufactures; and who is subjected to the same disabilities. The same cessation or curtailment, of necessity ensues in our commercial intercourse. Now unless we can stretch our credulity to the point of believing that one northern, or eastern man, provided he be a manufacturer, can eat as much of the surplus productions of American agriculture, as a thousand Europeans; and that the northern and eastern manufacturing establishments, can fabricate as many consumable articles as all the work shops of the commercial world, put together, we must unavoidably be drawn to the conclusion, that the inevitable effect of the new tariff must be, to compel us to buy dearer, and at the same time to sell cheaper than we now do, by diminishing both the number of the purchasers of our products, and the quantity of those articles—not of our own make, which we consume either from necessity or choice; and all this too, for the exclusive benefit of the domestic manufacturer. A loss of revenue, and the consequent necessity for direct taxes must certainly follow. The purse of Agriculture, like a candle burning at both ends, is exhausted by a double operation, as wasteful, as it is unnecessary.—The means of supplying it are first to be destroyed, and then, is to be "taken from it, even that which it hath not." It is to be gutted for the public treasury, when a complete evisceration has already been made for the private citizen-artificer. But the worst is yet to come.—The profits of agriculture and commerce, being thus greatly diminished; if not utterly destroyed, many of those who heretofore have cultivated the soil, and ploughed the ocean, from that freedom of choice, which nature's God has given them, will be as effectually compelled to abandon

their occupation, as if Congress had said in so many words; "go to the spinning jenny, the loom, the anvil, or some other mechanic calling; for no longer shalt thou plough, sow, nor reap; no longer shalt thou spread thy canvass on the deep, unless you are resolved to starve, rather than obey us. Elect for yourselves—some must still delve in the earth, and coast along our shores; but we who have the right, (*the divine right*, for we derive it from no human source,) to judge and choose for you, tell you, that too many of you are engaged in these pursuits, and some must quit them. Be gone, and let us see you no more, but in the character of a manufacturer of some sort or other. We, the Congress of these United States, are irrevocably determined to be independent of the whole human race; and *home made*, we are resolved that every thing shall be, in despite of soil, climate, natural productions, prudence, policy, common sense, and common justice."

This, or something like it, Mr. Editor, appears to me to be nothing more than a fair specimen, of what should be the preamble of the new Tariff Bill; and I sincerely hope, if it *must* pass, that something of the kind may be moved. If we agricultural people, and our brethren of the ocean are to be crushed in this way, it would be some small consolation to us, to see that the authors of such outrageous oppression, had boldness enough to proclaim to the world, both the reasons for their conduct, and the power by which their object has been accomplished. Let future ages see that at a time when the light of science was fast dispelling from the whole face of the civilized, globe the pernicious heresies which heretofore had impeded the progress of political economy, it remained for an American congress to say;—"we,—we alone will resist this light with might and main. Nay, we will do more,—we will take up your cast off errors, and hug ourselves, and chuckle in our ignorance; as who should say,—Sir Solomons all, none but ourselves can be our parallels."

Mr. Editor, I will trespass on your time and patience, but a few minutes longer. Should this new Tariff Bill become the law of the land, my labours as a cultivator, and yours too, my good sir, as a teacher of cultivation, may as well be discontinued. For where will be the use of the American Farmer's preaching to us about the various matters of husbandry, when scarcely any farm in America will be worth cultivating, except those few which are immediately contiguous to manufacturing establishments; or those which supply them from a distance with the raw materials to work up,—the number of which can bear no comparison with the whole that would be cultivated, were the agriculturists of our country left at liberty to use foreign, as well as domestic markets. Their limbs, it is true, will not be restrained either by chains, or prisons; but if all the profits of foreign commerce are destroyed by the burthens imposed on it, the liberty of pursuing it is just as effectually annihilated, as by the incarceration of our bodies; because profit is the chief, or only object of the pursuit.

If this bill is passed, the principle assumed, is equivalent to a declaration that the various occupations of our citizens are completely under the controul of our government; who may cause them to be changed or discontinued when, and how they please. For the framers of the law will to no purpose disclaim the right to say to the agriculturist and the sailor, you shall turn spinner or weaver; so long as they assert any power, by the application of which they can so far diminish the profits both of agriculture and commerce as to leave no alternative to those

who follow them, but starvation, or the abandonment of their professions. Nor will it be of the least use or advantage to us for these gentlemen to deny that they have any abstract constitutional sanction to tax one class of citizens for the benefit of another, so long as they *practically* take money from one, in the form of a tax upon foreign commodities, to put into the pockets of another. It is impossible not to see that they do this, when any duty upon imports is so high, as either to exclude foreign commodities altogether, or greatly to diminish their consumption. For it is most manifest that the duty in every such case will always be added to the price of the domestic manufacture, and will go into the pocket of the maker of the article for his *exclusive benefit*; whereas in all those cases where the duty was sufficiently low to admit of the sale of foreign commodities, *it being levied upon them, went into the public treasury*, there to contribute in the form of *public revenue*, to the *public good*.

To conclude;—there seems to me, Mr. Editor, but one remedy for this impending, and most enormous injustice. It is acknowledged to be a desperate one; but so will be the disease for the cure of which it appears to be the only legitimate means left to us. Reason and argument, dissuasion, petition, remonstrance,—all have been tried, but I fear, in vain. This remedy is neither more nor less, than a non-consumption agreement solemnly entered into among ourselves; and inviolably observed, as was done in the Boston tea affair, which the new Tariff Bill strictly resembles in principle, as it does in all its chief bearings. For will it not be a tax contrary to the wishes,—against the consent,—and in violation of the interests of those who are to pay it? Will it not be a tax imposed by a legislative body wherein there is no adequate representation of agriculture or commerce; and *where there are many individuals—probably not less than twenty or thirty, who are themselves to receive a large part of this tax from being directly engaged either as principals or partners in manufacturing establishments?* And lastly,—will it not be a tax as much in contravention to the spirit of that federative, and compromising compact uniting under one government, those states originally entirely independent of each other; as the tea tax was a violation of those principles by which these same states constituted a part of the British Empire? I most conscientiously believe, sir, that it will; and that no other rightful way of opposing it, will be left. But I will stake my life upon the complete efficacy of this, if the intended victims of such ruinous policy will only resolutely determine on such a mode of counteraction, and patiently persevere in it, under all the temporary privations which it may bring upon them. But a short time would elapse before all matters would be put to rights.

In the name of the whole agricultural people of this union, I believe myself warranted in avowing that they all feel a preference for domestic manufactures, provided the price and quality be the same with similar articles of foreign fabric. But in their name also, I claim the liberty of choice, as matter of *right*, not of *favour*. Nor will we tamely, like sheep, submit to be shorn of this right. If we must be eternally stunned with the cry of "let us be independent of the whole world;"—in the name of all the powers of infatuation and folly, let us have this insulated blessedness in perfection. Let us carry this principle of "*living within ourselves*" to the last point to which it can go; and after annihilating our intercourse with nation after nation, and people after people, nothing

will remain to be done, but for every man to become his own clothier, victualler, artificer, and every thing else; for to *this consideration* does the policy which I am deprecating, inevitably tend; and *in this*, or something not very different, must it necessarily terminate.

If there are any rights, immunities, and privileges enjoyed by agriculture and commerce of an exclusive character—away with them all; and let manufactures enjoy with them, every benefit of protection which government can legitimately afford; *but no more*: to award any thing beyond this, to manufacturers, as it is now proposed to do, will be unjust, oppressive, and tyrannical. That the Tariff should be revised, and permanently fixed, is highly desirable for all parties;—frequent changes in the rates of imposts being far more pernicious, than even high duties, to every interest liable to be affected by them. But in my humble judgment the sole design of such revision should be to reduce,—not to augment the existing duties. For if the only rightful object of them be revenue, and nothing appears to me more clear; I challenge any man to produce a single instance from the history of the impost-laws of any country upon earth,—deriving revenue from such a source, wherein the reduction of a duty, already high, has not produced an augmentation of revenue.

As a striking illustration of this fact I will finish what I have to say, with some very remarkable instances taken from the history of British taxation, by which it will appear as manifest as the light of day, that *decrease of revenue as invariably follows increase of duty*; and vice versa, *increase of revenue, the decrease of duty*, as day follows night.

Previous to 1745 the excise duty of four shillings a pound upon tea, yielded on an average about £150,000 a year. In that year this duty was reduced to one shilling, and 25 per cent. ad valorem; and in 1746 this reduction augmented the revenue to £243,000!—in 1747 to £257,937! and in 1748, to £303,545!!

In 1748 the duties were again increased, and fluctuated from 64 to 119 per cent. ad valorem; which gave rise to such excessive smuggling, and consequent loss of revenue from this source, that the parliament having dearly bought some experience, once more (in 1784) reduced the duty from 119 to 12½ per cent. Even a greater increase of revenue followed than before; for the East India companies' sales were nearly tripled in the two subsequent years,—having risen from £5,857,883 (the sales of 1783) to £16,307,433—being the amount of sales for 1785.

In 1787 the duty upon wine and spirits was reduced 50 per cent. and the revenue was greatly increased. In 1805 the duty on coffee was raised 1-3, and that year the product of this duty diminished 1-8, instead of increasing 1-3. At last this duty was lowered from two shillings to seven pence per cwt. Previous to 1808 when this reduction took place, the average annual revenue for the three preceding years, was £166,000, whereas the average annual produce of the reduced duty, for the next three years, was £195,000.

From 1803 to 1806 the duties upon sugar were augmented about 50 per cent. The product of the old duties for the 3 previous years, had been £2,778,000, that of 1784 after these duties had been raised 20 per cent was only £2,537,000, being £241,000 less than the low duties yielded.

The duties on leather, after being stationary for nearly a century, were doubled in 1813, and have scarcely ever since, (say to 1822) exceeded half a million, having frequently fallen

short of that sum; although in 1812 the low duty produced £394,000

The duties on foreign wines have been nearly tripled since 1792. The last increase in 1815 imposed £30 a ton on French, and £20 a ton on Portuguese wine. The consequence has been, that the annual diminution of their consumption for the five years subsequent to 1815, compared with that of the five preceding years, has been seven thousand four hundred and sixty four tons!! and a similar comparison of the average annual duties of the same periods, show an annual decrease of revenue, by this augmented duty, amounting to £126,841!!

But it is surely unnecessary to cite more examples to demonstrate my position, that high duties diminish, and low ones increase revenue; and consequently that the new Tariff bill can not for a moment be sustained on the plea of aiding the treasury. The only possible ground left then, upon which even a plausible pretext can be founded to support it, is, that it may aid manufactures. It now remains for an enlightened public to decide, whether this expected benefit will in any degree compensate for the certain and monstrous oppression which it will most assuredly inflict on all other classes of our citizens; and even upon all that portion of the manufacturers themselves, immediately connected with, and dependent upon agriculture and commerce.

Your friend,
And fellow sufferer,
RURIS CONSULTUS.

AGRICULTURE.

DRY CULTURE.

IN COUNCIL, 27th August, 1823.

The committee of dry culture submitted to Council a letter from Dr. Screven, on the subject of dry culture in the south of Europe.—They stated it was received in consequence of an application to him by the committee, that he would communicate the result of his observations whilst in Europe upon that subject. That it embraced a more comprehensive view, than any hitherto presented to the public, and that it appeared eminently calculated to set the question of the utility of the dry culture system permanently at rest, it doubts still existed.

WM. C. DANIELL,
M. HERBERT,
F. S. FELL.

On Motion—Resolved, That the communication of Dr. Screven on the subject of dry culture be published for the information of the citizens.

Extract from the minutes of Council.
M. MYERS, c. c.

TO WILLIAM, C. DANIELL,

Chairman of the Committee of Dry Culture.

Sir—Although a silent, I was an early advocate for the system whose operations your committee has been appointed to inspect. I witnessed with pleasure the enthusiasm with which all classes of the community contributed to the trial of the grand experiment which has for its object the amelioration of our autumnal diseases. The sacrifices made by the planters, the debt incurred by the public treasury, the exertions of the council and of private individuals to put the system in operation, and the generous devotion of the Physicians, who by their reasoning, and by their experience illustrated its utility, deserve the admiration of the world and will come and that of succeeding generations. Consuls, Emperors, Kings and Dukes have improved the health of countries and cities, by draining marshes; by making canals and other internal improvements, by prohibiting the cultivation of vege-

tables noxious in their influence upon the human body, and by removing other causes productive of disease. But where in the annals of history do we read of a whole people reflecting upon the causes of their epidemics, and endeavouring to remove them at an immense sacrifice of public as well as private property? We search in vain for a parallel to an event so conspicuous in the history of Savannah, as the voluntary substitution by the people of dry for wet culture. If we look abroad, we cannot find a precedent among even the most civilized nations. It is only in America, where the people have been accustomed to think and act for themselves, to find out and remove the causes of disease whether of a physical or a moral nature, that we can expect great and glorious events to arise out of the sole agency of communities of men without the occurrence of revolutions and civil wars. The culture of rice, as we will presently show, has been forbidden altogether in some countries, limited to certain districts in others, and in all, where it is tolerated, it is subject to certain rules of public Hygiene; but these prohibitory and restrictive laws emanated in each instance from arbitrary power, and not from the will of the people.

The injurious influence of rice-fields, marshes, collections of stagnant water, &c. has been triumphantly proved. The citizens of Savannah have acknowledged it, and with the liberality and the enterprise characteristic of them, have endeavoured to remove the causes giving rise to that influence. But there are persons who doubt, some who absolutely deny the fact, and others who through various motives which it is unnecessary to enumerate, are determined enemies to a system ennobled by its origin, by the sacrifices made to support it, and by its happy influence upon the public health. It is therefore incumbent upon all who take an interest in the system to adduce facts in its favour, in order to confirm the faith of those who believe and remove the doubts of the incredulous. Under that impression, I have been induced to put together a few facts in illustration of the dry culture system. They were furnished by the best works which treat on the subject, and by observations made during a visit to two of the countries to which they relate.

1st. Attempts were made in the 18th century to introduce into France the culture of rice. During the reign of Louis XV. and under the ministry of Cardinal Fleury, it was cultivated in the province of Auvergne and succeeded very well, but its farther cultivation was prohibited by order of government, because it infected the air, and produced epidemics in the places where it was cultivated.—See. Dict. univ. d'agriculture par l'Abbe Rozier. In the same work is the following observation—"It is notorious that in the countries of Europe where rice is cultivated, tertian fevers are almost constant, and prove very destructive to the inhabitants." It is added that fevers were multiplied in the province of Languedoc and the territory of Fore's when its culture was there introduced.

2d. Spain is one of the countries of Europe in which rice has been pretty extensively cultivated. It is there forbidden by order of government to make rice plantations within three miles of the cities. In the early part of this century, there appeared a very interesting publication by Don Antonio Joseph Cavinilles on the agriculture of Valencia, in which he treats the subject of rice culture and its influence upon health; "he gives a table of births and deaths from the year 1750 to 1787, in the different places in which the cultivation of rice has been practised. The result is, that during the space

of 38 years, there have been born 42,022 children in the places where rice was not cultivated, and only 36,248, where the cultivation of rice was carried on; on the other hand, during the same period of 38 years 39,595 persons have died in the places where rice was grown, and only 29,630 in the places where it was not cultivated." See N. Y. Med. Rep. The same author examines the question whether the cultivation of rice should not be altogether proscribed in Spain. The above mentioned result of his investigations evinces what was his opinion upon this subject.

3. Denina, in his revolutions of Italy, says that the cultivation of rice commenced in Italy between the 15th and 17th centuries, at a time when the inhabitants and cultivators were few, and the deserted and uncultivated lands had become wet and marshy. It was introduced into Tuscany about the year 1600, by Francis I. whose object in introducing it was to enrich the public treasury which was kept empty and poor by the want of a sufficient population. Denina eloquently opposes such a policy in the following words—"Now this expedient of increasing the riches of a country, is in truth the means of perpetuating its misery: because, as is well known to all, rice fields, by rendering the country unhealthy, not only destroy its population and prevent its increase, but extinguish industry, activity and enterprise." He again says elsewhere, that "the cultivation of rice in Italy has been in the first place an effect and afterwards a cause of depopulation and of real misery in many places." With a few exceptions, there is perhaps no part of the world better adapted for the culture of rice than the vast plain of Lombardy. The alluvial nature of its soil, the numerous streams which, having their origin in the eternal fountains of the Alps, Appenines and in the Lakes, traverse it in every direction: the number of canals intersecting it; the mildness of the climate, and the protection from winds, afforded by two high barriers of mountains—all these advantages combine to render it extremely well suited for wet culture. An active, industrious and intelligent population has not lost sight of such advantages. Rice has been cultivated to a considerable extent in Piedmont and Milan, and still continues to form one of the prominent articles of their agriculture, notwithstanding its acknowledged bad effects upon the health of the inhabitants. The traveller sees numerous rice fields on the public roads leading from Turin and Pavia to Milan; as he approaches the latter, he suddenly loses sight of them within five miles of the city, and very naturally begs to be informed why lands so well adapted to the culture of rice are not used for that purpose: he is told that this grain was formerly cultivated in the vicinity of Milan, but that in consequence of its having been found detrimental to the health of the inhabitants, its cultivation was prohibited within five miles of the city. It is curious to observe the difference in the aspect of the people inhabiting the rice countries of Lombardy, and of those living in the same plain where rice is not cultivated. In that of the former, is to be seen the *sallow* complexion so characteristic of unhealthy regions, and on the contrary in that of the latter, the rosy hue of health, Chateauvieux in his lettres ecrites d'Italie, gives an animated, though perhaps an exaggerated description of those engaged in the cultivation of rice—he says "as you pass along the dykes of the rice fields, you see the unhappy labourers wandering like so many ghosts through the reeds and stopping at the sluices which they have hardly strength to open and shut. They are not the only victims—the reapers sel-

dom finish the harvest without being seized with shiverings, and carrying with them an ague, from which their return to the high grounds does not always enable them to recover. The countries therefore under the cultivation of rice are thinly inhabited, and the few inhabitants are in a sickly and diseased state." Melchiorre Maggiore, an Italian statistical writer has compared the fatality among the inhabitants of ten departments of Lombardy under rice culture with that of the same departments under dry culture. The following is his table.

Rice Culture.		Dry Culture.	
	Deaths.		Deaths.
Adige	1 in 26	Adige	1 in 28
Agogna	1 " 25	Agogna	1 " 29
Alto Po	1 " 28	Alto Po	1 " 30
Bracchilogne	1 " 26	Bracchilogne	1 " 30
Brenta	1 " 27	Brenta	1 " 25
Passo Po	1 " 25	Passo Po	1 " 27
Mella	1 " 26	Mella	1 " 32

Olon	1 " 28	Olon	1 " 26
Sirio	1 " 26	Sirio	1 " 31

See Lyman's Polit. State of Italy.

The same author gives more births and marriages to rice countries. His calculation may be correct as it regards the departments upon which he made his observations, but that it will not apply to all countries is evident from the statement above cited of Cavinilles who gives an excess of births to countries of Spain not cultivated in rice of 5,774. The government of Milan well aware of the tendency which rice cultivation has to keep down and degrade the population of the country, has forbidden the extension of rice fields beyond their present limits.

4th. The culture of rice is very limited in the states of the church. The only part of them where it has been cultivated at all, is the country situated to the east of Bologna. Its culture was there introduced about 20 years ago, but is since almost abandoned in consequence of its observed bad effect upon the health of the inhabitants. Dr. Clark in a late work on the climate and diseases of France and Italy, makes the following observations—"There were a few intermittent but no continued fevers in the hospital of Bologna, when I was there. The former had become more frequent since the cultivation of rice had been introduced into the country around Bologna, about 20 years ago." In 1816, a report was made by a board of Commissioners appointed by the Roman government, to examine into the influence upon public health, of the rice plantations situated in that portion of the states of the church. The result of their investigations is to the following effect—

1st. "That it is due to public health to abolish all rice fields in districts enjoying a good air, and that are suitable for a more wholesome cultivation, or where the villages and houses are not situated at a sufficient distance for safety. 2nd. That rice fields should be maintained only in those low, damp places suitable for no other cultivation, at proper distances from human habitations and in natural valleys—the creating of artificial valleys for the purpose of collecting water being forbidden."

See Lyman's Polit. state of Italy.

(To be concluded in our next.)

REMARKS ON SOILS.

Notwithstanding the different appearances which the surface of the earth exhibits, it is, in reality, compounded, in all its varieties of wet

and dry, of warm and cold, of light and heavy; of barren and fruitful, only of four simple and primitive earths—clay, sand, lime, and magnesia.

I. Clay, called indifferently in agricultural publications, alumine, or argillaceous earth, is a substance so easily distinguished from all others, and so familiarly known, that it needs no particular description. When pure, it is white; but in general it is found discoloured by the mineral waters, which are perpetually escaping from their beds, and running on the surface. It is tinged with blue, brown, gray, and red shades, for it has a strong affinity to all colouring matter, but these tints affect it not materially in an agricultural point of view, and are, therefore, of little consequence. As an ingredient of soil, it has the four following properties, by which it exerts a powerful effect on vegetation:

1st. It absorbs water like a sponge, and is so close in the texture, as to prevent it from filtrating through its pores.

2d. When thoroughly soaked, and afterwards dried, it hardens and cakes into a solid mass.

3d. It shrinks considerably in bulk, when exposed to heat, and the contraction of its parts is in proportion to the intensity of that heat.

4th. It powerfully retards putrefaction, by enclosing as in a case, animal and vegetable remains, and thus shutting out the dissolvent action of the external air.

If we now call to our recollection the purposes served by the soil, and detailed in my last letter, we shall be enabled to judge how far clay, in its original and unsubdued state, is favourable to vegetation. The roots, which are the collectors of the nutriment, and are withal of a tender and delicate texture, cannot easily stretch themselves in a substance of such stiffness and tenacity; and which, besides, so readily consolidates after rain into a compact body. Its closeness opposes material resistance to their extension, and accordingly, in its unmelled state, the fibres are hampered, and cannot ramble forth to pasture. Besides, admitting that they overcome in part this obstacle in the soil, they must, whenever it hardens in the sun and gapes into chinks, be violently torn asunder, and separated from the stem. The stronger fibres may escape unhurt; but, generally speaking, the finer and more slender filaments must suffer considerably. If clay be so hurtful on the surface, it is almost equally pernicious in the subsoil, from the capacity it has of interrupting the passage of water downwards, and keeping the roots perpetually drenched—an evil no less destructive to the health and vigour of the crop, than the opposite extreme. From its antiseptic power, putrefaction goes on slowly, and the vegetables growing on it are ill supplied with that generous and nutritious food, essential to their perfection and maturity. All its qualities, therefore, are unfriendly to vegetation, except its capacity of absorbing and retaining moisture, and this is of such immense importance as, in some measure, to make atonement for its other defects. When existing by itself, this virtue which it possesses, in so eminent a degree, is useless and unavailing; but when mixed with other materials of a loose and friable nature, it gives tenacity and firmness to the whole, and is highly retentive of the dews and rains which fall to fertilize the soil.

II. Sand or gravel, called sometimes silex, silica, silicious matter, or earth of flints, is distinguished by properties of a totally opposite character, which require to be enumerated that their influence may be distinctly and visibly displayed.

1st. Sand is incapable of retaining water when poured on it, and far less of attracting moisture from the atmosphere.

2d. It powerfully promotes putrefaction, but allows the gases set at liberty to escape.

3d. It has little or no cohesion among its parts, and never binds by the alternations of wet and dry into a compact body.

It will appear from this account of the properties of sand, that it is provided as a corrector of alumine, and that in their effects, the two are destined to counterwork each other. This sort of contrivance in nature is no uncommon occurrence; and while we trace such remote tendencies and bearings, we are struck with the wisdom that fabricated and reared this noble edifice.—Inconveniences are obviated by correspondent checks, and this system of balancing all things displays more conspicuously the indications of design, than if there had been no difficulties to overcome, and no evils to remedy. Let us contrast sand and clay in their qualities, that this singular and important truth may be more strongly impressed. Sand suffers water to filter easily; clay is highly retentive; sand promotes putrefaction; clay delays it, but absorbs the gases, which are formed in the decomposition: sand opens an unobstructed path for the extension of the roots; clay gives them firmness in their course, and supplies the moisture which sustains them; in fine, the two may be classed among the contending elements of matter, which, by a union, heighten their common virtues, while their defects are rectified and subdued.

III. Lime, commonly called calcareous earth, enters into the composition of soils. This is never found naturally in a pure state, but in combination with carbonic acid, for which it has so strong an affinity that it attracts it from the atmosphere. The burning of limestone is undertaken for no other purpose than to expel by heat the carbonic acid, and reduce it to a caustic powder, for the purpose either of building or agriculture, and in this process it loses about the half of its weight. But no sooner is quick lime applied to use, and exposed to the atmosphere, than it greedily absorbs, first moisture, and then carbonic acid, and thus either in the ground, or in the new formed wall, it quickly hardens and returns to its original state.

1st. Lime is closer than sand, but much less adhesive than clay. It occupies, therefore, a middle region between the two, free from their imperfections, and blending their common qualities.

2d. It is a powerful promoter of putrefaction, and helps to decompose the animal and vegetable matter, lying in the soil. To this circumstance is owing, in a great measure, its efficacy as a manure.

3d. It has the power of fixing and retaining a very great quantity of carbonic acid, and although it combines chemically with a certain portion, which can only be expelled by red heat; yet the excess can be easily disengaged in a low temperature, and thus tends to nourish the growing crops.

It is not necessary to dilate farther upon the properties of calcareous earth, as, at the first glance, it must be recognised as a highly valuable ingredient; and accordingly, wherever agriculture is carried on with spirit, it is eagerly sought after, though at a high price. This earth exists in immense abundance among the solid strata of our globe, mostly without any foreign mixture, except the acids with which it combines; but occasionally is blended also with the other primitive masses. With carbonic acid, which in a

previous letter I particularly described, it forms the most frequent compounds—denominated carbonates of lime—and assumes a variety of names and appearances, and even possesses distinct properties. Spar, marble, stalactites, limestone and chalk are all varieties of this combination.—With the sulphuric acid (which is composed of sulphur and oxygen) it forms plaster of paris—a rock well known, as it is profusely scattered by the hand of nature throughout this Province. Lime is, also, found mixed with clay, and sometimes with sand, and then receives the appellation of marl, and which is valuable precisely in proportion to the quantity of this earth. Sea shells too derive their fertilizing qualities from the lime of which they are composed; and, without descending to farther particulars, it may be safely affirmed, that so necessary is calcareous earth in the composition of soils, that wherever nature has not blended it in their original formation, the agriculturist should, though at great expense and much trouble, supply the deficiency.

IV. The last earth which has been found in soils, and that too in a much smaller proportion than the other three, is magnesia—a substance, with which every farmer must be acquainted, since it is commonly used as a medicine of the shops. Its properties are nearly analogous to those of lime, and were long supposed to operate in the same way. It has also a strong, though less affinity for carbonic acid, and often forms a constituent principle in limestone rock; but at present agriculturists are divided about its usefulness as a manure; some of them holding it up as a poison to plants, and others supporting it by an appeal to experiments. It is not worth while to introduce my readers to this dispute; as I am uncertain whether our limestone contains any portion of magnesia; although its presence in the old country, upon accurate investigation, is found to be a very common occurrence. At all events, it is only pernicious when applied in an excessive dose; and this holds equally true with respect to lime, for these two earths should, in all cases, be used sparingly by the skilful cultivator.

By analyzing the various soils and subsoils, they have been found to resolve themselves into one or all of these primitive earths; and their barrenness and fertility have, in no small degree depended on the mixing and assorting of these ingredients. Loam is by no means a distinct body, possessing in itself appropriate and marked character, as many of our farmers, with whom I have conversed, ignorantly suppose; but is a combination of clay, sand or calcareous matter; and as we advance in science, and men among us arise, versed in conducting such investigations, the component parts of our rich intervals and uplands will be ascertained and given to the public. The very diversity, which exists among what are accounted loams, is a decisive proof of what I advance. Some of them we denominate clayey, from the excess of argillaceous matter, others open and light, from the preponderance of sand. In fact, these two original ingredients seem capable of being compounded in such an infinite variety of ways, as to give occasion to that diversified texture of soils met with in all countries and situations, and are contrived to counteract each other's qualities, that by their union, they might furnish the basis of that beautiful and splendid creation of flowers and plants, of shrubs and trees, which decorate the face of nature, and charm us by a sweet assemblage of all that is gay and soft in colouring, with all that is elegant and attractive in design.

Besides these four primitive earths, which con-

stitute equally the soil and subsoil, the upper of these, or the mould as it is sometimes called, contains the putrid relics of organized substances, that have grown and decayed upon it, or have been conveyed thither in the progress of cultivation. The decomposition of these is the proximate cause of fertility; and the richness of soils bears reference to the relative quantities. The residual earth remaining after the process of dissolution, is extremely light in weight, and always of a blackish colour. It is owing to this, that a garden, which has been under long continued culture, approaches to a black tinge, progressively deepening according to the abundance of this matter.

In addition, all soils lying in the territories of an old country, are found to contain various chemical compounds, mineral salts, and metallic oxids; some of which are beneficial, others harmless, and a few injurious to vegetation; and which either pre-existed in the strata, from which the surface has been formed, or have been carried to it by subterraneous springs, or by foreign causes operating in the course of past ages. These chemical bodies are so few in number, so small in quantity, and generally of such unimportant efficacy in vegetation, that it would be preposterous, considering the present state of knowledge, to dilate upon them in these elementary letters. The most frequent are, epsom and common salt, combinations of potash, lime, and magnesia, with the acids, and the oxid of iron—which is just the rust produced by exposing this metal to the action of the air. It is this oxid, which gives the brown and reddish colour, as well as the intermediate shades, to sand and clays.

It seems plain, that considerable advantages must be derived to the practical farmer from analyzing the different kinds of soils, from comparing the proportion of the earths in the productive, with those found in the barren, from studying the separate effects of these ingredients and from all these results, deducing the most skilful plan of procedure in effectuating permanent improvements. Chemists of great fame have embarked in this line of research, and vast progress has been made by their elucidations.—They have laid down rules to assist and guide the agriculturist in this department of the arts; they have exemplified the different processes to be performed, and even described the instruments necessary for an elaborate, and accurate analysis.

There is, however, a less laborious and less intricate analysis of soils, defective as our knowledge of chemistry may be, which is placed within our reach, and which may in time lay the foundation of more perfect and accurate methods.

In the field to be examined, take earth a little below the surface, from four separate places, about 1-4 lb. avoidupois from each. Expose it to the sun, or before the fire, till it is completely dry, and turn it over frequently that it may be well mixed together. From the heap take exactly four ounces, and pass this through a fine sieve, which will allow all the particles of sand and gravel to escape, but hold back stones, small fibrous roots, and decayed wood. Weigh the two parts separately, and take a note of each.—The stones and other bulky materials are then to be examined apart from the roots and wood.—If they are hard and rough to the touch, and scratch glass easily, they are siliceous or flinty; if they are, without much difficulty, broken to pieces by the fingers, and can be scraped by a knife to powder, they are aluminous or clayey; or if, when put in a wine glass, and common vinegar poured upon them, small air bubbles as-

send to the top of the liquid, they are calcareous. The finely divided matter, which ran through the sieve, must next undergo the test of experiment. After being weighed, agitate the whole in water, till the earth be taken up from the bottom and mechanically suspended, adding water till this effect be produced. Allow the mass then to settle for two or three minutes, and in that time the sandy particles shall have all sunk to the bottom. Pour off the water, which will then contain the clay in suspension with the insoluble earth arising from animal and vegetable decomposition. The sand should first be attended to; and if from inspection it be thought either siliceous or calcareous in its nature, the requisite tests may be instantly applied. By this time the mixture will have deposited at the bottom of the vessel the clay, and other earths, with the insoluble animal and vegetable matter. After pouring off the water, dry the sediment, and apply a strong fire by placing it on the bottom of a pot heated to redness, and the animal and vegetable matter will burn and fly off in aeriform products. The remainder lying in the bottom will be found to consist of clay,—magnesia or lime. To obtain accuracy, another 1-4 lb. of earth should be taken from the same heap, and the whole process gone over, a second, a third or even a fourth time, that the operator may rectify any blunders he had previously committed, and be satisfied as to the results of his experiment. He should provide himself with a pair of fine scales and a set of weights, divided at least into ounces and drachms. Although vinegar will detect lime by effervescence, it does not dissolve it so effectually as the nitric or muriatic acids; small quantities of which may be procured from the druggists at no great expense.

[Acadian Recorder.]

GARLIC—HOW TO EXTIRPATE IT—

From a practical and judicious farmer, and one of our most enlightened correspondents.

TO THE EDITOR OF THE AMERICAN FARMER.

Dear Sir,

When I state the fact to you, that for some years after I commenced farming, my fields were full of garlic, and my wheat had so much in it, that we never thought of sending it to mill for our own use without hand picking, after all had been done with the fan, that could be done—and as my wheat now goes to market nearly free from this pest, you may be inclined to place some confidence in my method of it of freeing my wheat.

My mode is to attack this pest in its strong hold, and I have destroyed its bulbs by millions and tens of millions in the soil. My instruments were simply the *plough-share*, the *roller*, and the *harrow*. My method of using them as follows—into the field intended to be laid down in wheat the following autumn, I put my ploughs, in December, January, or the first half of February, according to weather and convenience. The flushing, or turning up was done, so as to disturb and turn topsyturvy all the bulbs of garlic, and to expose them as much as possible. To be sure of this, the ploughing was done a fraction deeper (but not more) than the ground had been usually ploughed before.

In April the field was cross ploughed the same depth, rolled, and well harrowed. It has been during this harrowing, that I have particularly observed the effects of my method. I have followed the harrow and examined bunch after bunch of garlic. The main bulbs appeared very much worsted, and in a very unthriving condition. The offset bulbs in every stage of

evient decay. Many not only dead, but easily reducible to powder by the rubbing pressure of the thumb and finger. The field was again cross ploughed, and harrowed in June. At this cultivation a great majority of the offset bulbs, which had existed, could not be found, and most of the others were lifeless. Many of the main bulbs were alive, but did not recover so as to produce seed tops in the crop of wheat. The field was again ploughed and harrowed in August and September, and in October was seeded in wheat, and the wheat ploughed in. The spring after this crop of wheat was harvested, the field was again broke up and put into Indian corn, and of course was well cultivated through this season. In October wheat was seeded among the corn.

The above work was done in order to prepare the ground in the best manner for wheat, and in prosecution of what has been called in Maryland the five field system, two of which are annually in wheat and one in corn. Each field was first subjected to the process first described (called naked fallow) for the purpose of cleaning it of filth generally, noxious weeds, blue grass, &c. and of putting it into the best tilth.

It has been said that different crops would kill garlic. Among them the oat crop has had a decided preference. A part of one of my fields, which had been broken in January and February for wheat, was put down in oats in March. The remainder had the April and June cultivations of my system. In August and September the oat stubble was ploughed and harrowed with the rest of the field. The next spring there was certainly much less garlic in the wheat on the oat ground, than there had been in the previous crops of wheat from that field; but still there was more garlic in it than I wished to see, and with large seed heads. Among the wheat on the parts of the field not encumbered with the oat crop; but which had had the benefit of the April and June cultivations, there was scarcely a head of garlic to be found. From the above I concluded that the oats had run off with a credit entirely belonging and due to the plough and the harrow. I know of no crop, that deserves the name of a cleaning crop, except precisely in the ratio of the labour and frequency of the cultivations, which it requires to prepare for it, or to make it. And only one which I would think of admitting where the prime object was to get rid of garlic; to wit—tobacco—and I would rather be without that. I pronounce the plough, the roller, and the harrow, all sufficient, and best, if judiciously and actively employed. I know very well this system will be objected to, because it involves a great deal of labour. I shall be told I work almost a year for nothing; nay for worse than nothing, for I shall kill my land by exposing it naked to the sun.

I have seen and heard a hundred such assertions written and oral; but the real fact of a piece of land having been killed by exposure to the sun by cultivation I have never yet found. That this mode of keeping a field naked, will produce less profit than by taking from it a summer crop is a point not now under consideration. To kill garlic is the object; the injury of the land by exposure to sun the question. And this injury I say has been a thousand times asserted; but I have never seen it proved. I pursued this course from 1810 to 1817; during which time all my fields were subjected to it once, some twice. In 1810, I subjected a particular field to it, without manure—in 1811 I cut upwards of twenty bushels of wheat per acre from it—in 1812 it went into Indian corn—in 1813 I cut wheat from it after corn, about half the quantity

per acre, of the preceding naked fallow crop. between December, 1814, and February, 1815, it was again well turned up, and particularly well cultivated in April, June, August and September; kept light and open, and exposed naked to the sun, except twelve acres (which I considered the best twelve acres in the field). These were seeded in oats; and the last of June a thick oat crop just well in head, was with a chain plough completely turned under. The after harvest cultivations of the whole field were alike. The field was seeded in wheat in October. The seeding of the oat dressed piece was the last, and was done on the 25th and 26th of October. Carry along with you that from first to last, I put no manure on this field, except the green oats, if that may be so called. My ground showed no failure from its second sunning. My wheat grew kindly, except on the oat ground, and was perfectly free from garlic and all other filth—and 68 acres of the field yielded me by actual measurement 24 bushels of wheat per acre. The oat ground gave me very little over twelve.

Recollect, sir, I am not lauding a system; I am merely recording facts.

After this period I was driven from the system, because I could not produce corn enough from one fifth of my ground, to feed my family and stock. But I pursued the system a sufficient length of time to clear my fields of filth, to show me that it was by far the most certain and best mode of making a crop of wheat; that I could make from 50 to 100 per cent. more by this mode, than I could after corn or oats; and that I could not then, nor have I yet been able to discover any injury which I inflicted on my ground, by exposing it naked to the full power of the sun. Any one would rationally expect, that the effort of an acre, by which it produced 24 bushels would exhaust it double as much, as the effort to produce twelve bushels; but I did not find the exhaustion at all in this ratio.

If I mistake not some of the gentlemen, who have preserved the five field system with clover; and have turned in their clover in August, can bear testimony to my garlic system. All of them, who had any garlic in their lands, can most grievously testify that August fallows and clover lays have increased their garlic a million fold; and some of them, who have winter broke the stubbles of these clover lay wheat fields, and put them in corn the following spring, can also testify, that the wheat seeded among this corn on the field, that had been winter broke, (notwithstanding the previous crop of clover lay wheat had been full of garlic) was comparatively free from garlic.

It is useless to pretend to farm, if you are afraid of labour. I have never produced a useful agricultural result without adequate force; and very generally my success has been exactly in the ratio of the labour and pains bestowed. I consider the winter breaking, and the April and June cultivations as the garlic destroying operations. The work done after that time had no reference to the garlic, but was merely a continuation of the preparation for wheat. The above system reduced the garlic to a trifle, and cleaned my ground of all other filth, except one or two small plots of snow-drop. And I believe five successive winter ploughings, and spring cultivations, would effect the destruction even of this pest; the ground might be manured after every one cultivation, and planted in a crop of Tobacco, or Irish potatoes to repay the expenses of cultivation. Were I now to undertake to destroy the garlic in a piece of ground, to perfect the system, in addition to what I did, I would also winter break

the field for the Indian corn, that was to succeed the fallow wheat.

Very respectfully,
Your obt' serv't,
CRÆSINUS.

GARLIC.

CONTRIVANCES FOR SEPARATING GARLIC FROM SMALL GRAIN.

[A letter was addressed some weeks since by a gentleman in the South to his friend at Washington, to know what contrivances were in use in Maryland for separating garlic from small grain—and how far the presence or absence of garlic affected the price of grain in our market, &c. The letter was handed over to the Editor of this paper as being more in his way, and by him again passed to a correspondent to whom he was sure the best machinery and the most effectual practises for this object were familiar. His answer was in the shape and spirit of one private letter to another, but the subject is one which concerns so many that we have ventured to insert it in the Farmer, suppressing all names. There it will equally well answer the purpose of the enquirer, and prove useful to many others.]

Edit. Am. Far.]

"The only contrivance that has ever been much used in this section of our country, is what is called a garlic riddle, fitted to the common wheat fan, and used in the stead of the common fine riddle. The holes in the net of a common riddle are square, and of a size a fraction over the length of a large grain of wheat—so that the grain will pass through, whether it fall on the net crossways or lengthways. The common screen riddle of a fan is a wire net of the same square construction, but with the meshes so small as not to permit a grain of wheat of any value to pass through it. Garlic being a rounder grain than wheat, and varying more in size, the garlic riddle is made with the holes, or meshes, parallelograms—through these parallelograms, the largest grains of wheat will pass lengthways; but all the grains of garlic larger, or of a fraction greater diameter than a large grain of wheat, will not pass, but must shake over among the tailends and larger filth. The grains of garlic smaller than the wheat, find their way through the screen riddle. Thus, by a few fannings, all the grains of garlic larger than wheat, and many of those smaller than wheat, are separated—but all the grains of garlic of the average diameter of good wheat, and this is generally the full half, will accompany and remain with the wheat. I have seen fans with a great variety of riddles, but none that would effect more than above mentioned.

"I recollect to have seen an account of a contrivance some years ago, and I think in the Farmer, of a gentleman in Calvert county, of this state—and the impression I have left of it is this—the wheat is supposed on the floor of the third story; in the second story there was a hopper filled, with one side several inches lower than the others.—to this lower side was attached an inclined plane, contracting like a funnel into a pipe. A pump was so placed, as to throw a constant stream of water into the hopper. The wheat also descended through a spout into the hopper. The wheat and water were made to fall into the hopper together—the wheat just as fast as the aperture in the bottom of the hopper would deliver it; the water so much faster, that the hopper was kept full of water, and a portion constantly running over its lower side. The idea was, that as soon as the wheat, and garlic, and water mingled in the hop-

er, the wheat would sink and be delivered with a portion of the water through the bottom; and that the garlic would instantly float, and all pass over the lower side of the hopper with the surplus water through a pipe out of the house. The wheat was to be immediately separated from the water by passing over a very fine inclined screen, and was to descend in a scattering shower into a stove room on the lower floor, heated to so high a temperature as to dry it as it descended.

This contrivance was to do business upon a large scale, and was calculated for the use of large flouring mills. I have heard nothing of it for some years.

I have known garlic to injure the sale of wheat from 5 to 40 per cent. according to the quantity of it. A gentleman whose lands are very much infested with it, mentioned to me in the last autumn, that it gave him infinite trouble; that he had been driven to separate it by opening the sheaves and taking it out by hand. His wheat thus cleansed brought him 125 cents, while that gotten out without this tedious and most troublesome precautionary work, was dull sale at 75 cents the bushel.

A simple, effectual, and cheap contrivance would certainly be extremely useful in Maryland. But it must be very cheap, or it would never get into general use. The garlic is generally most troublesome on the poorest farms. After the wheat has been kept till the fall, and the garlic has become dried a little, and evidently lighter than the wheat, the best and simplest method I ever tried is to take the shaking riddle entirely out. Let the wheat descend from the hopper in a broad thin stream directly on the screen board, and of course exposed to the full effect of the wings—let the screen board be well pushed down; the fan being turned very briskly, while the superior weight of the wheat causes it to fall on the screen board, the garlic is blown over by the force of the wind.

I have heard of a light rake head, long enough, say eight or ten feet, to reach from furrow to furrow of a wheat land, with small teeth four or five inches long, and placed so close as just to let heads of wheat pass between the teeth, but to catch and take off the round heads of the garlic. This is carried by two men, each walking in a furrow, who carry it the proper height to catch and pull off the heads of garlic. But this is a dreadful method—while it cleans the wheat, it fills the ground and multiplies the evil."

TO THE EDITOR OF THE AMERICAN FARMER.

BUDDING.

Salem, (Ind.) Jan. 14, 1824.

DEAR SIR,

I have practised a mode of budding fruit trees, for some years past, which I do not recollect to have seen described in print; it has succeeded so far, very well with me, and may prove new and useful, to some of your readers. It is, budding from cuttings, taken from bearing trees in February, and preserved in boxes of sand in a cellar, until wanted, in the same manner as if intended for grafting. They will keep, in this manner, sound, until the middle of June, and perhaps longer, and which may thus be transported to any distance; while cuttings in July, (and buds are seldom mature enough for budding, before that time,) can with difficulty be preserved a few days. As soon as the sap rises freely in the spring, (say the middle of April,) you may commence budding with these winter cuttings, with as much success as at any other time of the year,

which may be continued until June or July.— Budding is a neater and pleasanter operation than grafting, and this mode places them upon an equal footing with grafts in March; I continue the wrapping of coarse yarn on, seven or eight days, then head them down, and by the winter, the buds will have grown, (if the season proves favourable) two or three feet in length. I find it an injury to prune the bodies of standards too closely below the buds; the first season, the new bud cannot, (until it has attained same size,) imbibe and assimilate to itself all the sap that rises, which must, if all the conducting limbs are pruned off, stagnate and disorder both body and roots; will sometimes destroy the stock altogether, or make the body eventually, less than the top or budded part; merely shortening or cutting out too luxuriant shoots, I conceive best, the first summer. In my nursery, I prefer budding on the leading top shoot at the height of four or five feet, as soon as it is three eighths of an inch in diameter; at that height, the juncture of the two growths being more complete in such, than in those of larger growth. One man may bud three hundred in a day, and with an assistant to tie after him, twice that number; in this manner, of those which I bud myself, I do not lose five in the hundred.

Your obedient servant,

C. HARRISON.

N. B. I have only attempted budding apples and pears in this way, but have no doubt, it will succeed equally well, with stoned fruit.

FROM THE NEW ENGLAND FARMER.

Boston, Jan. 29, 1824.

SIR,—I am induced to request the publication of the following letter from T. A. Knight, Esq. President of the London Horticultural Society, as a just tribute to him for this repeated proof of his regard for this country, and his desire to communicate to us, some of the finest fruits, recently introduced into Europe. I had barely hinted to him, that I was apprehensive that some of those which he sent to us last spring would fail, and it will be seen that he has promptly offered to send out duplicates of them all the ensuing spring. The least we can do, in such a case, is to make known his liberality. I have distributed, in the course of the last summer, more than two hundred buds of those which he sent; and I have promised many scions the ensuing spring. Should the new parcel arrive safely, I hope to be able to give them a circulation as wide as the liberality of the donor could desire.

That part of his letter which speaks of an ear of sweet corn sent by me to him, has reference to a question lately discussed in Horticultural transactions, relative to the effect of the farina or pollen, of one variety of plants upon another of the same species; some of the writers contending, that a change is effected in the fruit in the same year by the interchange of the farina, while others maintain that the effect is only visible in the fruit raised from the seed in subsequent years. Mr. Knight has invariably maintained the latter opinion, in which I fully coincide. I sent him, however, an ear of our sweet corn, which I thought might be an exception.—The kernels of that corn, it is well known, are white and shrivelled; but on the ears which I sent, there were several kernels of plump, yellow corn. This explanation will enable the reader to understand this part of Mr. Knight's letter. It will be seen that he does not consider this an exception to the general rule, for the reasons that he states.

I am, Sir, respectfully, your humble servant,
JOHN LOWELL.

Downton, near Salop, Wales, Oct. 23, 1823.

MY DEAR SIR,—I am sorry to hear that the fruit trees I addressed to you, arrived in so ill a state. The value of them to me was very trifling, and I shall have much pleasure in sending other trees in the next spring, and till you are in possession of the different varieties, which I am satisfied you will find a great acquisition to your gardens and orchards. I should have written sooner to express my wishes to send you another box in the spring, but I have waited to receive a letter, which you proposed to send me, to say what varieties had succeeded, and what had failed. I still hope to receive such letter before the spring, that I may not send any thing, which you already possess. We have recently introduced a variety of apple from the north of Italy into the garden of the Horticultural Society, of which the Belgic as well as Italian gardeners speak in rapturous terms; and Galesio, the author of a splendid publication of delineations of the Italian Fruits has placed this apple first, at the head of the list of Italian fruits.—And a Belgic gardener states its flesh to be as rich and melting as that of the finest pear. I have only obtained a few buds of it for insertion in the last season, but I propose sending a budded stock to you.

I thank you for the ear of Indian sweet corn which you were so kind as to send me. The facts you state are very interesting; but they do not present to my mind any thing anomalous.—The color of the seed coats in the blue and yellow grains is not changed. It is the matter which composes the cotyledons only, which acquires a tinge from the operation of the pollen.

An English gentleman, by the name of Goss, has pointed out, in the Horticultural transactions of the present year, a similar change in the color of the Prussian blue pea; a variety cultivated in our gardens, of which the color of the cotyledons is a dull blue, which is seen through a white skin. Mr. Goss conceived erroneously, that he had changed the color of the seed coat; but I have, in a subsequent communication shown that he has drawn an erroneous inference; and that the seed coat of the pea, or of Indian sweet corn retains the same color, which it would have presented if its natural pollen, that of the plant itself, which afforded the seed, had alone been present. I planted a few of the white shrivelled seeds, taken from the ear you sent me, soon after it arrived, and I have kept each plant wholly separate from any other; and all the seeds (which have been some time perfectly ripe,) are white and shrivelled. You will probably think that I have been very expeditious in obtaining ripe seeds. But we do almost every thing here by machinery; and I have a couple of dry stoves, which are always kept at a very high temperature; and into those I introduced several plants in succession, as their periods of shewing blossoms approached, suffering one only to bear its male flowers at a time. I have of the plants, growing under glass, in a lower temperature: But those have not yet ripened their seeds. The sweet corn, in its immature state, must be, I conceive, a most admirable vegetable. I beg to assure you that I did not make the foregoing experiments under any doubts of your accuracy. On the contrary, I have given you full credit for perfect accuracy; and I think the habit of hearing from many correspondents, some of them certainly not accurate has given me a facility of distinguishing truth from falsehood in the statements and opinions of such correspondents. I have, in the present year, seen a great number of new seedling nectarines, obtained from experiments, purposely and scientifically made; and I have got one or

two varieties of, I believe, unprecedented excellence. But our climate is, I believe, too hot for the melting varieties of the nectarine.

I remain, my dear Sir, sincerely yours,
T. A. KNIGHT.

THE FARMER.

BALTIMORE, FRIDAY, FEBRUARY 20, 1824.

TO CORRESPONDENTS.

It appears that Dr. Cooper, now residing in South Carolina, has written a pamphlet against the policy of those who would augment the duties on a great variety of imported commodities, so high, as to ensure a profitable business to American capitalists, who might set up establishments for the manufacture of similar commodities in this country.—This pamphlet, or tract of Dr. Cooper's, has escaped our notice, and we have no reason to believe that it has appeared in any of the news papers, except the Richmond Enquirer—several numbers under the signature of Hamilton, written expressly in reply to Dr. Cooper, have been published in most of the leading papers of the United States—few if any of which, besides the Enquirer, ever published the doctors original essay, and although we have never read, much less published it, we have been requested to insert the answers to it, as a reply to the numbers of RURI CONSULTUS; whose numbers appear as original in this paper.

Now we have made the foregoing statement, as a prelude to the following positions and remarks, whereby we desire, once again and for all to be understood to say—That,

1st. We are ready and glad to publish original essays, on the general principles, which should guide the country in prosecuting schemes of internal improvement—and on the question of giving legislative aid to particular branches of domestic industry—not because such essays will teach the farmer how best to harness his working cattle, or what crop he can most profitably cultivate—we publish such essays, because they tend to enlighten the minds of young farmers, and to teach them how to understand, and to estimate their political rights, and the powers of the government on subjects which directly concern and bear upon the prosperity and the profits of their own vocation. We suppose ourselves to be something like our patrons, and we would not have one of our own sons, to know merely how to make the most corn, or the most hay, at the least expense. It is true that to do that, requires experience and skill, which are not to be despised; but a farmer may possess these, and yet have little else that belongs to the dignity of a man. The history of the world admonishes us that men and governments, will always be found ready to filch the hard earnings of men, who are ignorant of their rights, or without the requisite spirit to sustain and defend them. Hence it is we say, that we feel it to be within the proper sphere of this journal, which be it remembered, aims to improve the moral power, as well as the practical habits of its patrons,—to publish occasionally, original essays on the politics of agriculture. But we cannot afford, this being only a weekly paper, to copy numerous essays, which have already gone the rounds of daily papers, and that too, in reply to other articles, that we never saw or published, and this brings us to say,

2dly. That in publishing such original essays, we are always ready to let both sides be heard—we despise that prostitution of the press, committed by those who, while they profess to enlighten, speak only on one side, and practise fair dealing, by suppressing all that is not agreeable to their own views.

If therefore, the correspondent, who requested the insertion of Hamilton, in reply to Ruri Consultus, (although published in reply to a different writer, and before Ruri Consultus appeared,) will send an original answer, it shall be promptly inserted—"give us but light" say we, no matter what objects it may reveal, or to what conclusions it may lead.

Finally, we must repeat the wish, that this being only a weekly paper, and chiefly practical, abstract essays may be as much as possible compressed.

Amongst other articles on file, and which will appear in our next, are several interesting communications, one—

On the "rubbing disorder" of cattle, as it is denominated in Tennessee, supposed to be the same, as that which destroyed some valuable cattle on the Eastern Shore of Maryland, last fall.

On the garden hoe, with an engraving.

On bread making.

Proceedings and constitution of an agricultural association at Jonesboro in Tennessee.

On Sulphate Quinine, &c. &c.

The document on "DRY CULTURE" of rice is expected to prove entertaining to the general reader, and especially interesting to our numerous patrons in the south—it may also, says the valued correspondent, from whom we received it, be "made to subserve the benefit of a vast portion of the middle and western states."

BALTIMORE MARKET.

PRICES CURRENT—CORRECTED WEEKLY.

Wharf flour, \$5 37½—Howard-street, do. \$5 62½—Best family do. retail, \$7—Wheat, red, \$1 10—Corn, 35 cts.—Rye, 40 cts.—Oats, 28 to 30 cts.—Whiskey, 23 to 26—Butter, inspected, 10 to 15 cts.—Coal, Liverpool, bushel 40 to 45 cts.—Virginia, 28 cts.—Susquehanna, per ton \$6 50 to \$7—Rice, per cwt. \$3 75 to \$4—Beef, northern mess, per barrel \$10—Cargo, No. 1, \$8 to 8 50—do. No. 2, \$6—Baltimore prime, \$10—Bacon and hams, 10 to 11 cts.—Cotton, W. I. Island, 18 to 20 cts.—Louisiana, &c. 16 to 17 cts.—Georgia upland, 14 to 16 cts.—Alabama, 12 to 13 cts.—Candles, mould, 12 to 13 cts.—Dipt, 10 to 11 cts.—Spermaceti, 25—Feathers, live, 30 to 35 cts.—Fish, herrings, Susquehanna, \$2 75—Fall mackerel, No. 1, to 3, \$4 50 to \$7—Shad, trimmed, \$6 to 6 50—Flax seed, rough, per bushel, 70 to 75 cts.—cleaned, cask, \$8—Flax, per lb. 10 to 11 cts.—Hemp, Russia, \$1 75 ton.—Country dew rot, 7 cts. per lb.—do water rot, 9 cts.—Hops, fresh, 35 cts. per lb.—Hides, dried, 15 to 19 cts. per lb.—Hog's lard, 12 cts. per lb.—Lime, per bushel, 30 to 33 cts.—Leather, soal, best, 24 to 27 cts. per lb.—do. Eastern tan, 18 to 20 cts.—Lumber, board measurement, cargo prices:—Of the following articles we give the yard prices.—Oak timber and scant. \$1 to 1 25—Boards all sizes, \$1 50 to 2—Pine scantling, do. \$1 to 1 25—Boards 4-4, \$1 to 1 25—White do. 5-4, \$1 75 to 2 50—do. 4-4, 1 15 to 1 30—do. cl. 4-4, \$1 80—Shingles, cyp. 18 in.—\$3 to 3 50—Shingles, junip. 24 do. \$7 50 to 7 75—jun. com. \$3 50 to 5—Staves, W. O pipe, \$4 to 4 50—do. hhd. \$25—do bbl. \$15 to 17—R. O. bbl. \$15—do. hhd. \$17—Wool, Reece, merino full blood, 35 to 40 cts. per lb.—Cropped, 28 to 30 cts.—Common country, 20 to 30 cts.—Skinner, 35 to 40 cts.—When assayed and cleaned, any of the above will obtain an advance of 15 to 20 cts.

Retail prices of provision market—Beef, prime pieces, 10 cts.—Veal, 8 cts.—Mutton, 6 to 7 cts.—Turkeys, 75 cts. to \$1 25—Geese, 50 to 75 cts.

—Ducks, Canvasbacks, \$1 25 to 2—Red heads, 75 cts. to \$1—Chickens per pair, 50 to 62½ cts.—Eggs, 15 to 18 cts.—Butter, 1st quality, 25 to 37½ cts.—Turnips, per bushel, 50 cts.—Potatoes, do. 50 cts.—Parsnips, do. 62½ cts.—Celery, 8 to 10 cts.—Carrots, 4 to 6 cts.—Cabbages, 2 cts. &c. &c.

Prices of Robert Sinclair's, Hood's and Carry Ploughs.—No. 3. Woods' or Freeborns' \$11—No. 2, do. do. \$10—No. 1½, do. do. \$8—No. 1A, do. do. \$6 50—Corn, do. do. \$6—No. 21, do. do. for seeding, \$5, (Extra shares always on hand, at 37½ to 50 cts.) No. 3, Carey or Dagen, \$6—No. 2, do. do. \$5 50—No. 1, do. do. \$5.

Premium and other barshare ploughs, is 10 per cent. lower than last year.

Liverpool Markets, January 6.

Cotton.—Comparatively little business has been done during the last week, the disposition for speculation having wholly subsided, and the demand from the trade having been very limited, so that the total sales have not exceeded 5400 bags. American descriptions barely maintained their currency, in which the transactions have been usually light. The following are the particulars; 600 Howeds at 7½d to 9½d; 300 Orleans, 9d to 10½d; 820 Alabamas 7½d to 8½d; 70 Sea Islands, 13½d to 17d; 130 stained do. 9½d to 11½d; 700 Pernams 11½d to 11½d; 520 Bahias, 10½d to 10½d; 280 Maranhams 10 d to 11d; 150 Mina Novas, 10½d; 30 Demarara 10½d to 12d; 200 Egyptian 11d to 11½d; 70 Carthagens 7 3 8d to 7½d; and 90 Surats at 5 2-3d to 6½d per lb.

Tobacco.—The quality continues very limited, and we can only comprise in our weekly report the sale of 120 hhds.

Naval Stores.—The sales of raw turpentine since our last report, (in which we omitted 2000 bbls. of fine at 13s. 3d. per cwt.) have been very trivial, nearly the whole in the importers' hands having been bought up, there remaining only about 200 bbls. the principal stock, say about 11,000 bbls. being in the possession of the trade. The import last year was very abundant, amounting to 69,430 bbls. The supply of tars has fallen off 23,400 bbls. and as the increase in the stock since the preceding year is only 3,700 bbls. a considerable diminution in the consumption is exhibited.

London Markets—Tuesday, Jan. 6.

We continued to have a good demand last week for cotton, but less was done, through a difficulty of making purchases in India cotton on a par with the prices of the preceding week. The sales were about 1900 bales.

250 hhds. of ordinary Virginia tobacco, attempted at 3 1-8d. and about 100 hhds. ordinary leaf tobacco at 2 5 8d per lb. are the reported sales of last week.

CONTENTS OF THIS NUMBER.

POLITICAL ECONOMY, letter 3, and last—DRY CULTURE—REMARKS ON SOILS—GARLIC, HOW TO EXTIRPATE IT, from a practical and judicious farmer, and one of our most enlightened correspondents—GARLIC, contrivances for separating garlic from small grain—BUDDING—A letter from T. A. Knight, Esq. President of the London Horticultural Society, to John Lowell—Editor's notes to correspondents—Prices Current, &c. &c.

Printed every Friday at \$4 per annum, for JOHN S. SKINNER, Editor, by JOSEPH ROBINSON, on the North West corner of Market and B. widere streets, Baltimore; where every description of Job Printing is executed with neatness and dispatch—Orders from a distance for PRINTING or BINDING, with proper directions promptly attended to, addressed to J. Robinson, Baltimore.

AGRICULTURE.

DRY CULTURE.

Concluded from our last number.

While on the subject of the Pontifical States, it may not be uninteresting to make a few observations upon the Campagna di Roma and the Pontine marshes.

The Campagna di Roma is not, as one would be induced to suppose, a perfect plain. It is diversified with hills and vallies, plains and marshes, lakes and rivers. The most elevated points are Mont Albano, Monte Rosi, Mont Oreste and Monte Mario, all of which are situated from one to twenty miles from Rome. Besides these, there are many other elevations of inferior altitude. Between these elevations are situated vallies where the hills are much approximated and plains where they are more remote. The surface of the Campagna is particularly irregular to the east where it joins the chain of the Appennines—Its western portion where it borders upon the Mediterranean is less irregular, and for the most part composed of a low marshy soil, in which are situated considerable bodies of water called stagni, that communicate with the sea and are supplied by it. Numerous streams having their origin in the Mountains traverse the Campagna and empty themselves either directly into the Mediterranean or into the Tiber. They are generally sluggish in their course and their waters invariably coloured with the soil through which they pass. The venerable Tiber cannot be excepted from the remark.

Non con onde liete e chiare
Corre al mare,
Passa torbido ed oscuro.—*Guidi.*

Its course is through a lime stone region from which it derives its yellow colour. The ancient poets, so accurate in their description of natural objects, call it the *Yellow Tiber*. There is perhaps no part of the globe that contains in the same space a greater number of lakes than the Campagna. They have no natural outlets for the discharge of their waters. The deep cavities in which they are situated are according to geologists craters of extinct volcanoes. Four of them are upon Mont Albano. The largest derives its name from that Mountain. A canal was made three hundred and ninety-three years before Christ, to drain off its water, which from its constant accumulation threatened an inundation of the surrounding country. This subterranean canal perforates the mountain and is more than a mile in length. It still serves the purpose for which it was originally intended. For this great work Rome is indebted to the oracle of Apollo at Delphi, which declared to the Romans the impossibility of conquering the Veii unless they drained this lake. Another of the lakes upon the same mountain, has a similar artificial outlet—the history of which has not been handed down. Besides these, there are seven or eight lakes in what is properly called the Campagna, independently of other similar small collections of water. Several of them have been drained, but the draining of the remainder is next to impracticable, except upon the plan of the ancients, and they still continue to exhale pestilential miasmata. The Solfatara, a lake whose sulphureous exhalations are perceived long before the traveller arrives at its shores, was drained in modern times, by the cardinal Hippolite d'Este. It is now much smaller than it was, and it is supposed that it will soon close up by reason of the depositions which are constantly forming on its banks. The Campagna is nearly destitute of trees, cultivated fields and houses. It presents

on every side little else than waste and desolation. Scattered spots of cultivation, a few wretched houses which serve as taverns, ruined aqueducts, the remains of ancient towns, villas, temples and funeral monuments, are the only objects by which the eye can measure the wide expanse. Innkeepers, shepherds and their flocks, are now the only occupants of a once thickly inhabited country where Mæcenas, Cicero, and Adrian were proud to build their villas.

Tal nonfosti gia tu, quando vedesti
I consoli aratori in campadoglio,
E tra ruvidi fasci in umil soglio
Seder mirasti dittatori agresti.—*Testi.*

To what are we to attribute the present degenerate state of the Campagna? Denina, and after him Chateauvieux, have attributed it to the destruction of property, and of the empire by the Northern Barbarians and the abolition of slavery by the introduction of christianity. In the time of the republic and the empire, the country was divided among a large number of owners, and slaves were the only husbandmen. At present the Campagna is in the possession of a few individuals, and the small quantity of land under cultivation is tilled by men who go there for that purpose from the Adriatic coast of Italy, and the Abruzzo—and who fall victims to the exhalations given out by the lakes, marshes, and the neglected soil. Pestilential air which was the effect of the ruin, is now by its reaction one of the causes of the present state of the Campagna. From the imperfect description which has been given of the environs of Rome, it cannot but be perceived that its situation is unhealthy. On every side of it, are vallies which serve as receptacles for water in the rainy seasons, muddy streams and lakes which exhale mephitical and sulphureous gasses—to the west are the marshes and stagni about the mouth of the Tiber, and to the south the Pontine marshes from which long continued southerly winds have conveyed pestilential exhalations even to Rome, as would appear from the following lines of Pliny, "Ob Putridas exhalatione, harum paludum, Ventum Syrophaenicum Romae summopere noxium voluit nonnulli." The ancient Romans guarded against the evils arising from the natural situation of their city by declaring the forests sacred, by cultivating the soil with slaves, by building country houses, and decorating them with gardens, by making numerous aqueducts, canals and roads, and by draining the lakes and marshes. Religion, agriculture, the fine arts, and the sciences, at the same time that they embellished the country, purified the air and rendered it salubrious. The health of Rome, commanded the attention of her greatest, her best, nay even of her worst governors. The enterprising Appius, the magnificent Augustus, the cruel Tiberius, the virtuous Titus, and the benevolent Trajan, contributed alike to the promotion of public health, by the various internal improvements of which they were the authors; and Suetonius informs us that the untimely death of Julius Cæsar prevented the execution of the grand project which he entertained, of turning the course of the Tiber through the Pontine marshes in order to drain them more effectually. Before we leave this subject, a few observations upon the malaria fevers may not be misplaced. Malaria signifies literally bad air, and is the noxious principle which exhales from the low grounds, lakes, marshes and uncultivated soil of the Campagna; and causes the fevers of Rome and its vicinity.—These fevers vary from the mildest intermittents to the severest remittents. The prevailing type

is the tertian. They are similar to the fevers of the lower country of Carolina and Georgia.—Those most obnoxious to them are strangers who consist chiefly of the inhabitants of the Adriatic coast of Italy, and who visit Rome and its environs in the summer and autumn for the purpose of harvesting the few crops of grain made upon the Campagna. Rainy seasons are most favourable to their production, particularly when the rains are followed by a long continued hot sun. Subjoined are the bills of mortality caused by the malaria fevers in the largest hospital (Santo Spirito) of Rome—during the autumnal seasons of 1818 and 1819—

1818 Received 8137, Died 363.
1819 " 6134, " 258.

The Pontine marshes commence a few miles south of Cisterna and extend for twenty-four miles to Terracina. They are from 6 to 12 miles broad. History informs us that the principal persons who have been conspicuous in their attempts to drain them were Appius Claudius Cæcus, in the time of the republic, Augustus and Trajan during the empire, Theodoric after the fall of the Empire, and the Popes Boniface VIII Martin V. Sixtus V. and Pius VI. in modern times; most of these attempts were successful in restoring the soil to agriculture and in purifying the air; but the immediate successors of those great men neglected the improvements which they had made and allowed the marshes to relapse into their original state. For their present improved condition, Italy is indebted to the late Pope Pius VI, and his engineer Rapini. A fine road 24 miles long and bordered with elm trees divides the marshes into nearly two equal parts. To the west of the road and close along side of it, is a navigable canal which receives the water of all the other canals which have been made to drain the marshes. This road occupies the site of the Apian way, some of the remains of which still exist; and the canal is the same as that upon which Horace embarked in his famous journey to Brundisium. Notwithstanding the vast efforts made by the late Pope to restore these marshes to agriculture, and to render the air salubrious, he did not fully succeed in either of his objects. That part of them situated to the east of the road is better drained than the other half, and contains a few fields of grain, but it is chiefly used as pasture land for immense droves of Buffaloes. To the west of the road are a few cultivated spots, but the greater part of it is still fenny, and in some places, particularly in the vicinity of the sea, the land is covered with stagnant water. The air of the marshes has been a good deal improved by their partial desiccation but their whole extent is still considered insalubrious, and so much so that the inhabitants living upon them are wretched looking objects, and those who labour in the fields and upon the canals retire at night to the neighbouring mountains and villages. The present Pope with the benevolence characteristic of him, is engaged in draining still further, by means of a canal, their eastern section. His paternal care aided by his liberal and enlightened minister, the cardinal Gonsalvi, will, I have no doubt, very much ameliorate the condition of this part of the Pontifical states. Notwithstanding that it is so imperfectly drained, it is already in part cultivated, and inhabited, and its air is become more salubrious. What then may we not anticipate as the result of the complete desiccation which the works now in progress and the plan, (if is adopted) of a French engineer, which consists of making parallels of canals and secondary ones at an angle of 45 degrees, are calculated to effectuate? With such assistance, a few active and enterpr

sing farmers would soon change the face of this plain and restore it to that state, when according to Pliny, twenty-three cities and numerous villas were situated upon it and in its vicinity, and when in the year 352 of Rome, as Livy informs us, it was divided among the people for cultivation—"Quinqueveros Pomptino agro dividendo creaverunt." It must once therefore have been more salubrious than it is at present. Why may it not become so again? Let it be well drained, which is not physically impossible, for there is a declivity of seven feet, and the ancients must have had it dry in order to cultivate it and to people it with twenty-three cities. Let the land be divided among farmers and they will cultivate a soil naturally fertile. Restrict them to dry culture and they will make dams and ditches to keep the land dry. Canals upon the plan of the French, clean dams and free ditches, the surface of the soil covered with vegetation, fields bordered with trees as in Lombardy, well built houses, cattle to keep down the weeds of meadows, and other agricultural improvements, would purify the air and restore to this country the salubrity which it enjoyed in former ages.

5th. Rice was formerly much more extensively cultivated in the kingdom of Naples, than it is at present. Its cultivation is now pretty much restricted to Calabria and Sicily. While Naples was in the possession of the French, its cultivation was prohibited in certain places, and in others it was regulated by the following conditions. 1st. The rice fields shall be watered by running water—2d. The petition requesting permission to open a rice field, must contain mention of the precise spot where the field is situated, the extent of the field, the body and the quantity of water that the cultivator proposes to employ—this petition must be posted up three weeks in the chief places of the canton, and an engineer appointed by the prefect shall repair and report as to the soil and situation at the expense of the petitioner. It is necessary to obtain permission as aforesaid, that the engineer reports that the spot can be appropriated to no other cultivation, that the inclination of the soil is sufficient to cause a constant and free circulation of water—that it is capable of being surrounded with a canal fit to receive all the water irrigation and to conduct it to a neighbouring stream—that the water shall be sufficient to keep the whole land constantly covered—that the rice field shall be situated at least 1500 feet from the nearest habitation—3000 feet from the nearest highway, and 12000 feet from the nearest village.

See Lyman's Pol. state of Italy.

On the southern side of the Gulf of Salerno is an extensive plain in which the most remarkable objects are the ruins of the city of Pæstum.—This plain is low, fertile, and being well watered by the river Sele, is perfectly adapted to rice, which was formerly cultivated upon it, but owing to its bad effects upon the health of not only the inhabitants of the plain, but of those of the neighbouring towns—its cultivation was abandoned. The exhalations extended to the city of Salerno, which according to the information received from its inhabitants, has since become more healthy, though its air is still considered insalubrious. The plain is now almost wholly uncultivated and uninhabited, and supports large herds of Buffaloes. Pæstum is inhabited by a few miserable families who act as Cicero's, and live upon the charity of the curious who visit the ruins. I was informed by them (indeed their appearance was a sufficient evidence of the truth of what they asserted,) that the air of that place is pestilential during the summer and autumn, that they were forced to take refuge in the

neighbouring mountains so long as the warm weather lasts.

6th. It is a remarkable fact that pestilential diseases are neither so frequent nor so extensive or fatal in Europe as they were formerly. To what are we to attribute this amelioration of disease? To agriculture and other arts, and to civilization—or as Fodere has more eloquently expressed the same idea—"A la main bienfaite ante de la philosophie qui a desseché les marais, construit des chemins, bride des rivieres, enrichi la culture et multiplie les moyens de subsistance qui a porte le gout de la propriété et meme une certaine aisance parmi toutes les classes." Philosophers thus account for the difference of the former, and the present state of Europe as regards the health of its inhabitants. Governors would attribute it to the magical influence of quarantine laws, and "Cordons Sanitaires."—The same happy result will in time be the consequence of the progress and perfection of agriculture, the increase of population, and the extension of civilization in America. Need we promise ourselves an amelioration of disease in Savannah? Has it not already taken place to a certain extent, through the happy influence of the Dry Culture system? All who observe well, testify to the fact. Already have we gained an important advantage over our invisible enemy, marsh miasma. Let us then occupy with firmness the ground we have won from its dominion. Let us pursue the system to its fullest extent, and not rest satisfied till we finally destroy, in imitation of Hercules, all of whose labours were for the benefit of mankind, the nine headed Hydra which infests the neighbourhood of our city. Much of the public treasure has been expended, let us not permit posterity to say that it was squandered. Much more must yet be done to complete the system, let us not stop short in a career so auspiciously commenced. A great reward is before us, let us spare no expense, no exertions to obtain it.

Let us reflect, that we are now to set an example, by which countries whose topography is similar to our own, may profit—that we are now establishing a precedent by which future generations of men are to be guided.

Philanthropy calls upon us to be firm and industrious in this our *good work*: self interest dictates to us that the course we are pursuing, is the one best calculated to promote our prosperity and happiness. We are now justly the subject of admiration to all foreigners who are acquainted with the history of the Dry Culture system adopted by our city—a dereliction of our duty at this time would call forth their contempt, and cannot certainly raise us in our own estimation—

May you, Mr. Chairman, and your honorable committee, continue to pursue the system with all the zeal and firmness which become guardians of the public health. In the faithful execution of your duty you will be seconded by the council, by the best wishes and support of the citizens of Savannah, and by no individual with more fervour, than by, Sir, Your very humble servant,
JAMES P. SCREVEN.

Communicated for the American Farmer.

"WASHINGTON AGRICULTURAL SOCIETY" OF EAST TENNESSEE.

Pursuant to public notice given, a numerous collection of the subscribers to articles of association for forming, an agricultural society for Washington and Carter counties, met in Jonesborough on Friday 16th January, 1824.

Thomas Emmerson, Esq. was called to the chair, and Nathaniel Kelsey, Esq. appointed secretary. The meeting being thus organized, the following constitution for the government of the society was proposed, and unanimously adopted.

Constitution of the Washington Agricultural Society.

Art. 1st. The Society shall be styled the Washington Agricultural Society.

Art. 2d. The Society shall consist of every upright individual friendly to its objects, who may have originally subscribed to the article of association, or may hereafter be elected by a majority of the members present at any meeting.

Art. 3d. The Society shall elect a President, a first and second Vice President, Corresponding and Recording Secretary, a Treasurer, a Committee of correspondence, consisting of nine members, any three of whom shall constitute a quorum for doing business—whose acts shall be registered, and communicated to the Society at any meeting by the Corresponding Secretary—a Committee of accounts, consisting of three members, whose duty it shall be to inspect and report annually upon the treasurer's accounts, and the state of the funds of the Society—to receive and adjust all claims against the Society for its contingent expenses, and to see that the Treasurer shall collect all dues to the Society from members and others.

Art. 4th. The Society shall meet regularly in the town of Jonesborough, on the first day of each county court, held in the months of April and October.

Art. 5th. Nine members at the least shall be required to constitute a quorum for the transaction of business, but any three members shall be sufficient to adjourn from day to day, until a quorum shall be formed at any time during the sessions of said court.

Art. 6th. All the officers of the Society shall be elected annually, on the first day of every autumnal stated meeting that a quorum shall be formed, and in the event of any vacancy, any meeting may elect, by a majority, a successor.

Art. 7. It shall be the duty of the president to preside at the meetings of the Society, and cause order to be observed, and continued attention to the business of the Society; during any session, in his absence, the first Vice President, and in his, the second shall preside and fulfill the duties of the president, and in the event of the absence of all these, a president pro tempore shall be called to the chair by the members present.

Art. 8th. The Treasurer, Secretary, &c. shall fulfill the duties assigned to them according to the directions of the Society, and the import of their titles.

Art. 9th. The members of the Society shall be distinguished into honorary and ordinary members—all shall be ordinary members who have subscribed the articles of association for the formation of the Society, or may hereafter subscribe to them under permission of a majority of members present at any stated meetings. Honorary members shall be such distinguished citizens of this or any other state, as may be elected for their known patronage of agriculture or the other arts more immediately connected with its prosperity—and strangers who desire to be present may be introduced upon the recommendation of members during the proceedings of the Society—provided that no more shall be introduced than may conveniently be accommodated with room without incommoding the members.

Art. 10th. Every ordinary member shall pay one dollar annually into the Treasury of the Society.

Art. 11th. Any member of this Society may withdraw at any time by notice given to the Secretary, in writing, provided he shall first have paid all arrearages due to the Society.

Art. 12th. The funds of the Society shall be appropriated by a majority of the members present at any stated meeting, to purposes only for promoting the interests and improvement of agriculture, and the benefit of the members.

Art. 13th. Donations may be received by the treasurer from any member of the Society, or any other individual; and shall be accounted for with the other funds of the Society.

Art. 14th. The proceedings of the Society for the purpose of order, shall be regulated by the rules for that purpose, which are observed by the General Assembly of this state.

Art. 15th. At any stated meeting any article in this constitution may be altered by two-thirds of the members present, or any new article added—provided that a majority present at the next stated meeting thereafter, shall approve the same.

Art. 16th. It shall be the duty of the Society to provide a system of by-laws for the government of the members and officers, not incompatible with this constitution.

Art. 17th. It shall be the duty of the committee of correspondence (selected for their distinguished talents and experience) to collect useful information in whatever relates to the promotion of the interests of agriculture, from every practicable source, and to disseminate information from the Society to the community generally, to determine upon what is useful to be published for the benefit of the Society and other and to propose to the Society the considerations of any improvement in this constitution that their experience and observation may determine to be necessary; and the Corresponding Secretary, as the organ of this committee, shall record and report their proceedings, and be the immediate agent of their communication with the other societies, and individuals, as instructed—a quorum of the committee, which may be named, and act at any time or place during the recess or session of the Society.

According to the provisions of the constitution, the meeting proceeded to the election of officers for the ensuing year, which resulted as follows:

Thomas Watkins, *President.*

Alfred Carter, 1st. *Vice President.*

John Kenny, 2d *Vice President.*

Committee of Correspondence.

Thos. Emme, Esq.

William B. Carter,

John G. Easo

Montgomery Stuart,

Jacob Howard

Robert Reeve,

James Sevier,

James McAlister.

James P. Tay,

O. B. Ross, *Irresponsible Secretary.*

David A. Dierick, *Recording Secretary.*

Committee of Accounts.

Samuel G. Cheir,

Samuel Hunt.

William Mitch,

Samuel Crowl, *Treasurer.*

Resolved, that this meeting do recommend the general attendance of the members, at the first constitutionally stated meeting in April next.

Resolved, that the Corresponding Secretary, transmit the proceedings of this meeting, together with a copy of the constitution, for publication in the American Farmer, and American Economist.

TO THE EDITOR OF THE AMERICAN FARMER.

MARLE.

MR. NNER,

I find it is becoming to be a subject of great inquiry and is very generally growing upon the attention of the agricultural world. There is no log which merits attention more, for in every stance where it has been ap-

plied it has been considered the most successful of all manures. There was a writer in your paper (Mr. Ruffin) who gave us one of the most correct accounts of the operation of marle on lands that I have ever seen, and further views from the same pen would still lay the agricultural interest under greater obligations to him. What Mr. Ruffin there asserts of marle correcting the acid quality in lands has been found to be true by all who have used it; and besides, he might add, that it is a great cleanser of lands, which manures are generally not—it certainly destroys all the noxious growth which puts up in acid lands, oftentimes to the great injury of the crop; and to the sheep sorrel it is certain destruction.

All the marle I have seen in Maryland is shell marle, which lies in large beds or strata, and has been generally found near the margin of the banks of rivers or creeks—this, I presume, is because it has cost less labour to find it there than elsewhere; but I have no doubt that the same strata can be found in the interior, if it was diligently searched for. They are generally from three to six feet under the surface, and present considerable variety in appearance. Some are composed of common oyster shells alone, which are very different from what are called shell banks—others are composed of what are commonly called clam shells—others of clam shells, muscle shells, and a great variety of scollop shells—others of shells so decomposed that it is difficult to class them, and these last are often intermixed and discoloured with a sort of ferruginous substance—others again present you shells completely broken down to lime, intermixed with sand, which of itself makes a pretty strong cement; and indeed the varieties are not only numerous and singular, but often very beautiful. The comparative effects of these different kinds of marle have not been ascertained, as they are generally different on different farms, but all agree who have used them, that the first year's product in wheat is increased to more than half as much more, but that the second crop, from one marling, is oftener more than double than less than double—this is easily accounted for upon the supposition that the marle does not become so well incorporated with the earth upon the first as upon the second tillage—but if the marle was strewed on fallow land, and two extra harrowings were given it after strewing, there can be little doubt but the incorporation would take place, and the product be improved. I find my marle acts better upon wheat succeeding my corn, than upon naked fallow, where the marle was spread on both the same year; and I account for this result, so different from what is experienced from all other manures, from the frequent harrowings I give my corn during its cultivation; for I cultivate corn principally with the harrow, as being the cheapest, most expeditious, and best implement, and my lands are stiff soil.

None but those who have been eye witnesses to the effects of marle can believe them—they are truly wonderful—old worn out clay soils, that were literally good for nothing, have been regenerated by marle alone, and present the appearance of our best and natively rich lands—and there seems to be no end to the improvement—under one marling the product increases at each cultivation, and a second marling is followed by results proportionable to the first. Such is the conviction here as to the effects of marle, and the conviction arises from practical experience, that the discovery of a marle bank is supposed to double the value of the farm.

My principal object in making you this com-

munication, is to endeavour to elicit Mr. Ruffin out upon this subject, whose experience, observation, and reasoning are far more satisfactory and useful than any thing I have ever met with.

TO THE EDITOR OF THE AMERICAN FARMER.

SULPHATE OF QUININE.

Fashion has always had a power over the world from the earliest history of civilized life—in some things it seems almost reasonable, because it relieves society from a deadening uniformity, and gives life to new things—stirs up genius, and leads to improvement. But amid all the captives of whim, we should scarcely expect to see the Medical Faculty in the number; nevertheless they are found bowing to the all powerful goddess of fashion.

In proof of this I bring forth the article in question as their present hobby, viz: Sulphate of quinine, so much talked of, so much used, and so little known. I should have passed it over, and let it die in its own vials and pots, had it been confined to them, but alas! my cook has been cured of a chill or a sweat by it, and the fellow having attended three or four popular lectures on chemistry, is incessantly plaguing me to let him make an essential salt of beef, he says it will be the true pabulum of life, and will make blood in half an hour after being swallowed, and flesh the first night; nay, he thinks that a pill of five grains taken three times a day will support the most robust constitution, and that we shall never hear more of dyspepsia, emaciation and a thousand other diseases, so that it will in a great measure reduce the doctor's bill in a family to a mere *line*! I have reasoned with him, and I fear in vain, my arguments I trust were not bad, they were as follows:—That beef would not bear condensing, and be *beef still*, further than by making good soups; that by bringing it down to an essential salt, we should confound beef with mutton, and fish with veal; the essential salts of each could be the same: nay, that great impositions would be practised upon us, and whilst we were flattering ourselves that we were eating stall fed beef, we might be eating the essential salt of a starved horse. That France would soon ship us the essential salt of frogs for the best Italian beef; and the Dutch, who are born chemists, would soon make a salt from sour kroust, to imitate the appearance of best beef pills; I told him also of the portable soup of the last generation, but all in vain; this last article he called a gross one, and said he would take it to begin his pabulum vitæ with—moreover he has completely upset some of my arguments by telling me that every person knows enough of crystallography to distinguish salt petre from salt, and these from epsom and glauber salts, and that a very short period will do the same to these nice articles of cookery. I must, therefore yield for the present, fearing that he will go mad, if opposed, for he is very absent at times, and silent, except now and then, when entirely alone, he exclaims wo to the doctors; wo to the tavern keepers; and then flies into a passion with George the III, the Barbers, and P. Pindar. To keep the poor fellow from actually losing his senses, I propose to eat my own dinners privately, and furnish him with three of his beef pills per diem, till he recovers. But passing over this striking parallel, let me seriously ask the worthy doctors of the fashion, if they recollect such a thing as the essential salt of bark, which had its run about thirty or for-

* He calls it a "Holoraciate of Boine."

ty years ago, and whether they suppose the addition of a little vitriolic acid at 12½ cts. per lb could make such a tremendous difference in either price or quality, and if we are to be led away by every variation that can be made through all the long list of acids; if so, we, and especially the apothecaries, shall have more pleasure in prospect than a belle who expects to receive a whole year of London and Paris Fashions in one letter; indeed ours would last for a century; and lest I should not live to see the run of the whole race, I beg they would indulge me speedily with a pyrolignite of quinine; this I think would take the lead of the whole acidification; a man could not then putrify dead or alive—nay more; when we had used what we wanted, the residuum sticking to the paper would cure our beef and pork, or make leather. But I would beg to ask the learned doctors whether this sulphate of quinine cures by a quinine principle, or by what is common to all bitters? the latter is my humble opinion, and I see no good reason why we country doctors may not have a sulphate of cornine, (dogwood); a nitrate of lyriodendrine, (poplar); a muriate of salixine (willow); or a pyrolignite of amygdaline, (peach kernels); this last I verily believe would outdo the quinine, and as the bitter principle is of a poisonous nature when concentrated, if it should prove sluggish, we might help it with a few drops of Fowler's solution of arsenic, or with a mite of prussic acid.

"A COUNTRY DOCTOR."

NATURAL HISTORY.

(Continued from No. 46.)

Torpidity of Animals.—All the torpid animals retire to a place of safety, where, at a distance from their enemies, and protected as much as possible from the vicissitudes of temperature, they may sleep out, undisturbed, the destined period of their slumbers. The bat retires to the roof of gloomy caves, or to the old chimneys of uninhabited castles. The hedge-hog wraps itself up in those leaves of which it composes its nest, and remains at the bottom of the hedge, or under the covert of the furze, which screened it, during summer, from the scorching sun or the passing storm. The marmot and the hamster retire to their subterranean retreats, and when they feel the first approach of the torpid state, shut the passages to their habitations in such a manner, that it is more easy to dig up the earth any where else, than in such parts which they have thus fortified. The jumping mouse of Canada seems to prepare itself for its winter torpidity in a very curious manner, according to the communications of Major-General DAVIES, on the authority of a labourer. A specimen which was found in digging the foundation for a summer-house in a gentleman's garden about two miles from Quebec, in the latter end of May, 1787, was "enclosed in a ball of clay, about the size of a cricket ball, nearly an inch in thickness, perfectly smooth within, and about twenty inches under ground. The man who first discovered it, not knowing what it was, struck the ball with his spade, by which means it was broken to pieces, or the ball also would have been presented to me."

Much stress has been laid upon the position which these animals assume, previous to their becoming torpid, on the supposition that it contributes materially to produce the lethargy. In describing this position, Mr. CARLISLE observes, "that this tribe of quadrupeds have the habit of rolling up their bodies into the form of a ball during ordinary sleep, and they invariably assume the same attitude when in the torpid

state: the limbs are all folded into the hollow made by the bending of the body; the clavicles, or first ribs, and the sternum are pressed against the fore part of the neck, so as to interrupt the flow of blood which supplies the head, and to compress the trachea: the abdominal viscera and the hinder limbs are pushed against the diaphragm, so as to interrupt its motions, and to impede the flow of blood, through the large vessels which penetrate it, and the longitudinal extension of the cavity of the thorax is entirely obstructed. Thus a confined circulation is carried on through the heart, probably adapted to the last weak actions of life, and to its gradual commencement." But as none of these effects are supposed to be produced by the same position during ordinary sleep, their existence cannot be admitted in the case of torpidity. Professor MANGILI of Pavia, with greater simplicity of language, says, that the marmot rolls itself up like a ball, having the nose applied contrary to the anus, with the teeth and eyes closed. He also informs us, that the hedgehog, when in a torpid state, in general reposes on the right side. The bat, however, during the period of its slumbers, prefers a very different posture. It suspends itself from the ceiling of the cave to which it retires, by means of its claws, and in this attitude outlives the winter. This is the natural position of the bat when at rest, or asleep. In short, little more can be said of the positions of all these torpid animals, than their correspondence with those which they assume during the periods of their ordinary repose.

It is also observable, that those animals which are of solitary habits during the summer season, as the hedgehog, and dormouse, are also solitary during the period of their winter torpidity; while the congregating social animals, as the marmot, the hamster, and the bat, spend the period of their torpidity, as well as the ordinary terms of repose, collected together in families or groups.

It is generally observed, that animals, previous to their torpidity, have their bodies charged with fat. In the marmot and some others, there are two peritoneal processes, which may be considered as lateral omenta, and which, as well as the great omentum, are filled with fat. In the dormouse, however, and others, these lateral processes do not exist, the fat being more generally distributed. This store of nourishment enables the animals to support that gradual waste which takes place during the period of their slumbers. By some it has ever been regarded as the cause of their lethargy. SPALLANZANI, however, found, among the dormice procured for his experiments, a considerable difference among the individuals in regard to fatness, yet all were equally disposed to become torpid on the application of cold.

Many of those animals, particularly such as belong to the great natural family of gnawers, make provision in their retreats, during the harvest months. The marmot, it is true, lays up no stock of food; but the hamsters fill their storehouses with all sort of grain, on which they are supposed to feed, until the cold becomes sufficiently intense to induce torpidity. The *Gricetus glis*, or migratory hamster of PALLAS, also lays up a stock of provision. And it is probable that this animal partakes of its store of food, not only previous to torpidity, but also during the short intervals of reviviscence, which it enjoys during the season of lethargy. The same remark is equally applicable to the dormouse.

Having thus made choice of situations where they are protected from sudden alterations of temperature, and having assumed a position si-

imilar to that of their ordinary repose, these hibernating animals fall into that state of insensibility to external objects, which we are now to examine more minutely. In this torpid state they suffer a diminution of temperature; their respiration and circulation become languid; their irritability decreases in energy; and they suffer loss of weight.

(To be continued.)

FROM THE RALEIGH STAR.

Letter from John F. Smith, Esq. of Newbern, to the Editors of the Star, dated June 26th, 1811.

"In compliance with the request contained in your letter, received by Mr. Allen, I now transmit such information as I possess relative to the subjects of your enquiry.

The year before last I sowed a small patch in benni, which did not produce to my expectations, owing, I presume, to my then ignorance of the proper methods of cultivating the plant and saving the seed. Four bushels of this seed I ground in a mill with iron cylinders, and expressed without any application of heat, which yielded six quarts of oil to the bushel. The appearance of the oil is very fine, and although I have used it in diet, give it a decided preference to olive oil, among whom are Judge Taylor and Mr. Gaston, whom you will see at the Supreme court; and to them I refer you for further information of its merits. The cake, after the oil is expressed, mixed with other meal or flour makes a palatable nutritious and wholesome bread. I have discontinued the cultivation of the benni, because the oil is yet too little known to be in much demand and the castor oil affords a certainty of profit: but I have no doubt the cultivation of benni and the manufacture of the oil might be made profitable, and think it will, in time, supersede the use of sweet oil in this country, and become even an article of considerable export. Of the Chinese old raddish, I have no experience.—The apparent difficulty of cleaning the seed prevented any attempt being made to extract the oil.

There are five species of the *alma christi* known here—two only of which are profitable; the others being difficult to clean. It should be planted early in March, in the same manner as corn, and requires much the same tillage. The seed should be wet and planted in hills, and not in holes, the plant having a long tap root: a good soil will produce fifteen bushels to the acre. The trusses, as they mature, must be cut and exposed to the action of the sun a few days, in which time the seed will disengage themselves from their outer covering. One gallon and three-fourths of cold pressed oil may be obtained from a bushel, and by the application of heat afterwards, the cake will produce more of an inferior quality. I have sent considerable quantities to New York, where it is greatly preferred to the West India oil. Its superiority over the latter consists in its requiring much less for a dose, being more pleasant to the taste, not nauseating and being less liable to produce pain. I have a letter from Dr. Osorn to this effect. Mr. Joseph Tagert of Philadelphia has lately sent an order for some for his own particular use, and a gentleman of Fayetteville, who had some of it last year is so much pleased with it that he has now ordered a hundred bottles.

Should you or any of your friends collect any Benni or Chinese raddish seed, in quantity not less than a bushel, I will, if it is desired, have the oil extracted from it.

THE EDITOR OF THE AMERICAN FARMER.

ON THE "RUBBING DISORDER" IN CATTLE.

Franklin, Missouri, Dec. 19th, 1823.

SIR,—I have seen, in a late number of the National Intelligencer, some account of a disease which had made its appearance among the cattle in Maryland, for the first time, last fall. From the symptoms which you have enumerated, as accompanying and evidencing this, which as far as I have known it, incurable disease, it is very similar, if not the same, which I have occasionally witnessed the ravages of, amongst the cattle of Tennessee, some eight or ten years past. About four years last past, I have lived in the State of Missouri, where this disease has never appeared to my knowledge.

In the State of Tennessee, it was usually denominated the rubbing distemper, because the cattle when attacked, would rub their heads and necks against the trees and other firm objects, until their horns would sometimes drop off, or their eyes be rubbed out of their heads—sometimes the cattle would die, before they were carried to such heights by the itching of their skins.

Causes—as far as my observations have led to any conclusion: *Scant* pasturage in the latter part of the summer, and suddenly overloading their stomachs in the fall by being turned into fresh cornstalk fields. This phrase will perhaps be unintelligible to you, but it is generally used in the western countries, to convey the idea of fields from which Indian corn has been lately taken, when a great portion of the stalks abound with saccharine juices, and particularly in the joints near the ground.

When cattle that have lived upon but scant forage for some time, are turned upon pastures of the above description, they fill themselves so full of this rich food, that they are incapable of digesting it. I hence conclude, that as the secretions are clogged and incapable of action, the excretory ones convey all or most of the humors of the system to the skin; this produces the itching, &c. I am not sufficiently acquainted with physiology, to say how any organ of the system of animals should act so as to entitle it to the appellation of a healthful or morbid action, but I here express myself in such a manner as I presume will convey to you my meaning.

This distemper is not contagious, as I believe, though I have known eight or ten die of it on one plantation, and all nearly about the same time, and always in the fall of the year.

I have never examined one of the victims of this distemper after its death, but have been told by those who have suffered considerably by this malady, that upon dissection, the contents of the paunch are found to be as dry as ashes.

I am of opinion that this distemper is most apt to appear in those seasons, in which the frost falls earliest. If so, this fact will farther corroborate my supposition of its cause.—For the juices of vegetables are concentrated more, and prevented from evaporation longer, by frost, than they would be without it. My practice is to keep my cattle out of my fields until the ground becomes frozen, not for the purpose of preventing this disease alone, but for the double purpose of keeping my grounds loose, and preventing the disease, if it should depend upon the causes thus guessed at. The result has been equal to my anticipations.

It would be worth the trouble to enquire of your neighbours, whether the facts which have fallen under their observation correspond with my opinions or not. It will at least lead the way to the discovery of the true cause in time.

Your's respectfully,

JOHN HARDEMAN.

TO THE EDITOR OF THE AMERICAN FARMER.

GARDEN PLOUGH.

Bee Hive, Feb. 3, 1824.

DEAR SIR,

In No 40, of the present volume, you request some instructions about the garden plough—always desirous of aiding you with my mite of information, I now enclose you a sketch of one, rough, it is true, as I have neither a plough by me, or my protracting instruments to scale with; but plain enough, I hope, to enable your ingenious mechanics to make by. The idea was taken from Knight's turnip drill, and it is a useful little instrument in light soils.

Fig. 1. a, A piece of plank, 2 inches thick, 8 wide, and about 32 long.

b. A wheel usually of plank, 1½ inch. thick, 12 to 15 in. diameter.

c. A pair of light handles, nailed to the beam, at f, and braced behind by a couple of light stanchions d, and pins between them in the usual way.

e. A thin light shovel plough, about 3 in. wide, fastened to the beam above, by a key passing through two staples, in it, and one of the eyes in the shank g, which are at different distances to regulate the depth.

Fig. 2. A front view of the shovel.

Should you not be fortunate in getting a better sketch, and description, I hope this may prove acceptable to you.

I remain, Sir, respectfully,

Your obedient servant,

W. S. GIBBS.

ON BREAD MAKING.

MR. SKINNER,

In perusing Simond's Switzerland, I met with the following plan for kneading and raising bread, which being simple in its construction may be tried with little expense should it answer, it will certainly be a useful article to the housewife.

Your's, &c. W.

"A deal box two feet long, one foot high, and one wide, turning by means of a crank on its axle, secured at the two ends not passing through the box;) one side opens on hinges; the inside is

divided by means of one or two moveable partitions for different sorts of bread at one time. The lump of dough is thrown in, and the crank turned in the manner of a coffee roaster. No bars, or any thing inside. A hissing noise occasioned by the carbonic gas escaping, indicates the working of the dough: and in about a half hour, (less in warm weather) it is fit for the oven. The fault, if any, is, that the bread is too much raised."

FROM THE CONNECTICUT JOURNAL.

TO FARMERS.

The season promises a very great crop of grass with more than usual proportion of white clover, which flowers abundantly. It is very desirable that the farmers in New England should use the opportunity which is near at hand, of securing a good supply of the seed of this very valuable grass, which for many purposes excels all the other grasses.

Pasture grounds well stocked with white clover yield more nutriment for cattle and sheep per acre, than any other, and cows fed on white clover give milk of a superior quality. Besides affording the best pasturage in the world, the white clover may be cultivated to advantage for hay. White clover and herds' grass sown on rich land, make a thick bottom, and the crop of hay will be more valuable than the crop from the same land sown with red clover and herds' grass.

Besides the advantages above mentioned to be derived from the culture of white clover, it has another excellence of no small importance to the farmer. The sward of turf formed by white clover is always tender and easily ploughed or broken up, and all kinds of grain and corn flourishes wonderfully well after this grass.

As white clover is what some would call natural to this country, that is, as it will after a few years get into land used for pasturing, the farmers have generally suffered it to grow, but have not saved the seed. This is a very great error. When land is laid down for pasturing and sowed with other grass, it generally happens that the grass seed does not spring well, and the weeds spring up and occupy the ground a year or two before it is covered with white clover, whereas if the seed is sown, it will produce twice the quantity of feed. The best time for sowing white clover is in the fall with winter grain, but it will do well sown in the spring, and if by reason of drought it does not spring the first season, it will the next, as the seed is of a very imperishable nature.

The seed is collected by an instrument in form of a rake with long sharp teeth set so near together as to let the flower stalks of the clover slip in between them, but not to allow the heads to pass. These will be broken off and collected on the upper side of the rake, and may be removed from time to time, as the rake gets full. When the heads are collected these should be put into a dry place, and when thoroughly dried, they may be threshed on a clean dry floor, and the chaff winnowed out.

The seed when clean is worth half a dollar a quart, or \$16 a bushel. The instrument for collecting will cost but little, and children can do the work, which may be done to very great profit.

FASCINATING POWER OF SNAKES.

The idea that snakes possess the power of charming birds, has been, we know, exploded by many, as one of those idle tales, which are

ever found where the light of science has not penetrated. But we confess ourselves to belong to that school of philosophy, which is controlled by facts and which sacrifices any theory at their command. We have had access to facts on this subject, by which we are constrained to believe, that some kinds of serpents do possess the power of affecting not only birds, but men, in a powerful manner, apparently, by looking at them merely; certainly without touching them. The following statement, from the Salem Register, has occasioned the preceding remarks.

"A very singular fact occurred at Manchester a few days since. As Mr. Samuel Cheever was at work in the field, his attention was arrested at the sight of a number of dung hill fowls with heads erect and wings extended, standing in a circular manner. On going near to ascertain the cause, he saw a large black snake of 5 feet in length, within the circle, and his squamish head elevated 8 or 9 inches above the surface of the earth, while his other parts remained in a spiral form. And so complete was the fascination that Mr. C. was under the necessity of getting a pole to disperse the fowls, in order to kill the snake, in which he happily succeeded."

Among the facts to which we have had access, as mentioned above, are the following, which were communicated to us in such a manner, and upon such authority, that we would believe them, though the whole tribe of naturalists should laugh at us "till doomsday." A very near connexion of ours, a man who could not easily be deluded or imposed upon, was at labor with others, in a field. A few yards ahead of him, he discovered at the foot of a hill of corn, what to his eyes appeared the most fascinating object he had ever beheld. The colours seemed to combine every thing rich and beautiful. He walked forward to grasp the prize, but was seized by the arm by a friend, at the very moment he was about to clasp in his hands a large copper head, coiled up in the position for striking its victim!

The other fact was this: A man in New Haven county, now no more, but who was known to us, discovered a large rattle snake. He had heard stories of the fascinating power of snakes, and being a sceptic resolved upon an experiment. For this purpose, and to guard against danger, he provided himself with a goodly sized club, and stopped to gaze upon the poisonous reptile.—Presently the object of his aversion and even dread, appeared transformed to something too beautiful for description. Admiring its ever-varying and gaudy hues, resembling the rays of the sun glancing upon emeralds, and liquid gold, he unconsciously drew nigh it, until his reason admonished him of his danger. He could not, even then, raise his arm to strike the lovely object, which had, as it were, enchanted him.—But not altogether unconscious of his danger, he was compelled to shut his eye to strike; when a single blow dissolved the spell cast over his senses by the venomous charmer, and he was no longer reluctant to "bruise the serpent's head."

[N. Y. Com. Adv.]

Extract from the Memoirs of the Wernerian Natural History Society, vol 4.

The following narrative is taken from the Calcutta Journal, Nov. 1, 1821.—Case of William Kingston, born without arms or hands. I went to Ditcher, and got him to breakfast with me at Mr. Goodfellow's. He highly entertained us by putting his naked feet upon the table as he sat, and carrying his tea and toast between his great and second toe to his mouth with as much facility as if his foot had been a hand, and his toes fin-

gers. I put half a sheet of paper upon the floor, with a pen and inkhorn. He threw off his shoes as he sat, took the inkhorn in the toes of his left foot, and held the pen in those of the right.—He then wrote three lines, as well as most ordinary writers, and as swiftly. He writes all his own bills and other accounts. He then showed us how he shaved himself with his razor in his toes; and he can curl his own hair. He can dress and undress himself, except buttoning his clothes. He feeds himself, and can bring both his meat and broth to his mouth by holding the fork or spoon in his toes. He cleans his own shoes and can clean the knives, light the fire and do almost any other domestic business, well as any other man. He can make hen coops. He is a farmer by occupation. He can milk his cows with his toes; and cuts his own hay, binds it up in bundles, and carries it about the field for his cattle, and last week he had eight heifers constantly to fodder. This last summer he made all his own hay ricks. He can do all his business of the hayfield (except mowing) as fast and as well with his feet as others can do with rakes and forks. He goes to the field and catches his horse; he saddles and bridles him with his teeth and toes. If he has a sheep among his flock that ails any thing, he can separate it from the rest and drive it into a corner, where no body else can; he then examines it, and applies a remedy to it. He is so strong in his teeth that he can lift ten pecks of beans with them. He can throw a great sledge hammer as far with his feet as other men can do with their hands. In a word, he can nearly do as much without, as others can with their arms.—He began the world with a hen and chickens; with the profit on them he purchased an ewe; the sale of these procured a ragged colt (as he termed it) and a sheep; and he now occupies a small farm.

There is at present (December 1822,) in Belfast, an ingenious young man named Roger Branaugh, who was born without arms, and is of course devoid of hands, which may be justly classed amongst the most useful members of the human frame. His feet, however, serve him in their place, and enable him to perform various operations, for which, at first view, he would appear wholly incapacitated. He has been seen opening out, with his toes, a closed penknife, with which he trimmed a quill, and made an excellent pen, in a very short space of time.—He can write rapidly and distinctly, his small letters being well formed, and his capitals cut with taste and ease. It is surprising with what expedition he can thread needles, and even tie a knot at the end of the thread with nearly as much facility as the most practised sempstress. He can darn his own stockings, and twist the thread or worsted line which he uses for that purpose to the proper degree of thickness. Branaugh can row in a boat with singular energy, though it must be confessed his attitudes are more unique than graceful. On such occasions, he leans his back against the stern, and one foot on one of the seats, so as to keep the oar, which he propels with the other, in due position. With boys he can play at marbles, and clear the ring with remarkable skill, his big toe bulking, as the phrase is, his jaw to the mark with the precision of an air gun. He can convey his food to his mouth with his toes, and is by no means deficient as a carver. Neither is he a timid equestrian, but can even drive a cart or a carriage.—The reins on such occasions are placed round his body, and by moving to and fro, to the right or to the left, he so varies their position as to affect the horse's mouth and direct his motions. This ingenious poor man makes his livelihood by running errands.

NEW TARIFF.

A writer, in the New York Gazette, gives the following illustration, of the deceptive features of the Tariff bill, and of its oppressive character, in the duties on low woollens, to the labouring class of the community, who will be the principal consumers of these articles.

[Salem Observer.]

"A piece of flannel, original cost, 27s. sterling, 46 yards long, 26 inches wide, would contain 39 square yards at the price established by the Tariff; 46 cents per yard, is \$13 20, at 30 per cent. ad valorem, is \$3 96 duty, which is 66 per cent. duty on the original cost.

"A piece of baize, 30 yards long, 42 inches wide, original cost, 15d. per yard, is £1 17s. 6d. or \$8 33—contains 35 square yards, at 40 cents is \$14—at 30 per cent. ad valorem, is duty \$4 20 or 50 per cent. duty.

"A piece of tow cloth, 30 yards long, 44 inches wide, original cost 2s. 6d. per yard, is £3 2s. 6d. or \$13 88—contains 30½ square yards, at 80 cents per yard, is \$24 40, at 30 per cent. ad valorem, is duty \$7 32, or 53 per cent. ad valorem duty.

"A piece of plains, (which is almost altogether the clothing of sailors) 30 yards long, 26 inches wide, original cost at 10d. per yard, is £1 5s. or \$5 55—contains 21½ yards square, at 80 cents per yard, is \$17 20, at 30 per cent. ad valorem, is duty \$5 16, or 93 per cent. duty."

At a special meeting of the CHAMBER OF COMMERCE, New York, on Monday evening, 26th January, to take into consideration the proposed Tariff now before Congress, the following resolutions were adopted and ordered to be published.

Resolved, As the sense of this Chamber, that the true and legitimate object of taxation is revenue, and that the power to lay and collect taxes and establish imposts, which is given to Congress by the Constitution of the United States, was not granted with the intention, nor will it bear the construction, that it may be so exercised as to cherish and elevate one class at the expense of all the other classes of our citizens.

Resolved, That the bill now before the House of Representatives of the United States, for altering the Tariff of duties, will, if it should become a law, be attended with the most pernicious consequences to the commerce, navigation, and agriculture of the United States; that the increased duties which it proposes will operate as prohibitions and restrictions on trade—will promote exclusive interest at the National expense—will impair the revenue, and will, in direct repugnance to the equal and benign principles of our political institutions, impose heavy burdens on the great body of our citizens, and give to a small number the advantages of an oppressive monopoly.

Resolved, That the duty proposed on the raw materials, iron, hemp and wool, is so great as to be almost prohibitory—that it is calculated to delude the agricultural interest to support a measure which will enhance the price of winter clothing to every laboring man in the community—to increase the expense of almost every implement for farming, and every machine for manufacturing; and the cost of every ship of vessel in our extended inland, coasting and foreign commerce.

Improved mode of carrying out anchors in ships' boats.

An elegant model of a boat, on a peculiar construction, to effect this purpose with much more ease and safety than has hitherto been ac-

ished by larger boats by the ordinary method, has been some time in our possession; and account of its properties shall be laid before the public next week, while the highly finished vessel, with anchor, cable, &c. will be placed at the office for the inspection of merchants and commanders or vessels. The plan has been highly approved of, and adopted by several of His Majesty's finest vessels; and testimonials of its excellence, from the commanders, addressed to the ingenious and able inventor, a highly marine architect of Woolwich, are in our possession. [Liverpool Mercury.]

Medical qualities of Oysters in Fevers and Consumptions.

Oysters are a mild, balsamic and cooling article of food, and are of the utmost benefit to those who are troubled with warm flushings of the face, and other feverish symptoms, usually felt in declines, and in nervous and irritable constitutions. It is quite possible, indeed, by making them a principal part of a meal, to prevent, in a great measure, the irritation and heat which produces the hacking and distressful cough in the more advanced stage of consumption. Oysters, indeed, and other mild nourishing food, often altogether prevent consumption in those who are disposed to it from hereditary causes.

A young lady, of very narrow chest, and slender consumptive make, whose mother and two sisters died of declines—by avoiding beef, mutton, pork, and all sorts of red meat, and confining herself wholly to a diet of oysters, and other shell fish, while they were in season, and to broiled chickens and other white meats, with biscuits instead of bread, and rice instead of vegetables, soon became healthy and active, and escaped for many years the dangerous decline which threatened her. It is to be remarked, however, that oysters, when too copiously eaten, are too cold for very weak stomachs, unless accompanied with good pepper, or cayenne.—Vinegar ought never to be used by those who eat oysters "to enrich their blood," or to prevent consumptions. Instead of vinegar a very little white wine may be added; but not when there is a fever or cough. When too many oysters have been incautiously eaten, and are lying cold and heavy on the stomach, we have an infallible and immediate remedy in hot milk, of which half a pint may be drank, and it will quickly dissolve the oysters into a bland, creamy jelly. Weak and consumptive persons should always take this after their meal of oysters.

METHOD OF PRESERVING FRUIT WITHOUT SUGAR.

By T. Saddington.—Trans. Soc. of Arts, vol. 26. The expense of sugar is frequently urged as a reason for not preserving fruits, and to this may be added the uncertainty of success from the strong fermentable qualities of many fruits. They may be preserved for a length of time without sugar, by baking or boiling, and then closely stopping them up; but if the cork become dry, the atmospheric air exchanges place with what is impregnated by the fruit, which then soon becomes mouldy: but fruits may be preserved in good condition by the following process, for two years, or for a longer time, even in hot climates; as some that were done in 1806, have been exposed in an upper room to the sun during the whole of the summer, without injury.

The fruit being clean picked, and not too ripe, is to be put into wine or porter bottles, as they are

cheaper than gooseberry bottles, and more easily obtained. The bottles must be filled as full as they can be packed, and corks being stuck lightly into them, they are to be placed upright in a Kettle of water, and heated gradually to about 160° or 170° of Fahrenheit; that is to say, until the water feels very hot to the finger, but does not scald. This degree of heat is to be kept up for half an hour, and then the bottles being taken out one by one, they are to be filled up to within an inch of the cork with boiling water, the cork fitted very close and tight, and the bottle laid on its side, that the cork be kept moist. To prevent fermentation and mould, the bottles are to be turned once or twice a week, for the first week or two, and once or twice a month afterwards.

When applied to use, some of the liquor first poured off serves to put into pies, &c. instead of water, and the remainder being boiled up with a little sugar, will make a rich and agreeable syrup.

The fruit ought not to be cracked by the heat. They may be picked out of the bottles with a bent wire or iron skewer.

APPLE JELLY.

Peel and quarter a half bushel of white pippin apples, and throw them into cold water to prevent their becoming dark coloured. When all are done, put them into boiling water, and let them remain in it, until they are entirely stewed. Then pass the water and apples through a sieve, or flannel; then proceed in making the jelly in the same manner as with currants. The juice of a lemon must be put into the syrup. The peelings of the lemon must be cooked separately, with loaf sugar, and put into the jelly when finished.

TOMATOE, OR LOVE-APPLE CATSUP.

Slice the apples thin, and over every layer sprinkle a little salt; cover them, and let them lie twenty-four hours; then beat them well, and simmer them half an hour in a bell-metal kettle; add mace and allspice, strain through a sieve, and simmer again. When cold, add two cloves of shallots cut small, and half a gill of brandy to each bottle, which must be corked tight, and kept in a cool place.

MUTTON HAMS.

Mix two ounces of brown sugar with an ounce of fine bay salt, and half a table spoonful of salt petre; rub the ham therewith, and lay it in a deep dish; baste and turn it twice a day for three days; throw away the pickle which in this time will have drained from the ham, and wipe it dry. Rub it again with the same mixture of sugar, &c. one day, and baste it the next, for ten days, turning it every day. Smoke for ten days, (with green hickory, if possible.) The hams are best eaten cold.

GINGER WINE.

To sixteen quarts of water, add one pound of ginger bruised, (not powdered,) infuse it in boiling water, put it into a large jar, and let it stand 48 hours by the side of the fire; strain off into a cask, and add to it eight pounds of loaf sugar, seven quarts of brandy, the juice of twelve lemons, and of twelve bitter oranges; peel the skins of them very thin, which put into the spirits, the night before, and pour the spirits off the skins, when you put it into the cask. Cork up the cask for three or four weeks till the liquor is fine, and shake the cask for the first week to dissolve the sugar: a very small quantity of isinglass helps to fine it.

CURRANT WINE.

Fifty-five pounds of currants, produced four and a half gallons of juice; this was put into a ten gallon keg, and 20 lbs. of sugar added, and then filled with water: as the liquor decreased by fermenting, and running over the bung, the deficiency was supplied by water: three pints of brandy were added. Well distilled apple brandy answers perfectly well. Light coloured brown sugar, or clean Havana sugar, should be used.

To make strong or bookbinders paste.—Mix wheaten flour first in cold water, then boil it till it be of a glutinous consistence; this makes common paste. When you wish it to be of a stronger nature, mix a fourth, fifth or sixth of the weight of the flour, of powdered allum; and where it is wanted of a still more tenacious quality, add a little powdered resin.

IRON CARRIAGE WHEELS.

C. Hoxie, of the city of Hudson, has been engaged a number of years in making an improvement in carriage wheels; which consists in the rims and spokes being made of wrought iron, and the hub of cast iron. These wheels are so put together, that it is impossible for a spoke to get loose; of course they are strong and very durable, the weight about the same as those made of wood, and all the centre part of 50 of those wheels may be completed in 15 minutes.

The inventor being desirous of having them generally introduced, invites the attention of furnace companies, manufacturers of iron, and such as may feel disposed to purchase a privilege for making those wheels. There can be no doubt but such an establishment would be lucrative to the owners, and beneficial to the public, as also an article of extensive exportation. It is believed that but a few years will roll away, before wooden wheels, for carriages of every description, will be rolled out of existence. All stages ought to be furnished with iron wheels, having the rims plated with steel, especially in the winter, on account of the safety of passengers.—*Northern Whig.*

REFINEMENT.

It is amusing to observe how little cleanliness and comfort the Romans enjoyed, with all their wealth and power, and ingenious luxury. Many things with which our Alms Houses are supplied, were wanting in the imperial palace of Rome. To give one instance for many; forks were utterly unknown to them; nor were they used in Europe until Henry IV. of France, somewhere in the sixteenth century, discovered that they were for certain purposes, quite as convenient as fingers. The first fork used in Christendom, a great steel thing, one prong of which would make ten forks of these degenerate days, is now or was lately in the Castle of Pau.

TEA.

This shrub is propagated by seeds, which are sown in holes three or four inches deep. Nothing is used but the leaves. It bears great plenty at three years of age, but fewer at seven. It is then cut down to the stem and shoots out sprigs, every one of which bears nearly as many leaves as a whole shrub. It is cultivated in most provinces of China; but is not equally good every where, though they are always careful to place it in a southern aspect, and in valleys. That which grows in stony ground is far preferable to what grows in a light soil; but the worst sort is that which is produced in a clayish ground; but its different degree of perfection is more owing to the season in which it is gathered, than to the difference of soil. The first crop is gathered in March, when the leaves are small and delicate, and this is called *imperial tea*, because it is chiefly reserved for the use of the court, and people of fashion. The second crop is gathered in April, and the last and coarsest in May. That however which is imported is adulterated by mixtures of other leaves, so that tea in its purity and excellence is only to be enjoyed by the natives themselves.

FROM THE PORTLAND GAZETTE.

THE RETORT COURTEOUS.

Two neighb'ring lawyers, clever fellows,
One lack'd a book, and one a bellows.
Their names perhaps you'd like to know:
Elias one—the other Joe.
Joe sent a message to Elias,
For *Eshannasee's Nisi Prius*:

This answer back Elias sent;
His *office books* he never lent,
But Joe might call if that would do,
And in his office read it through.
It chanc'd, Elias on the morrow,
To Joe, his *bellows* sent to borrow,
My *bellows* tell my worthy friend,
Says Joe, is what I never lend,
But he may call, if he's inclin'd to,
And *blow* all day, if he's a mind to.

PHILADELPHIA SOCIETY FOR PROMOTING AGRICULTURE.

At the annual meeting of the Philadelphia Society for Promoting Agriculture, held on Tuesday, the 20th of January last, the following gentlemen were elected officers for the ensuing year.

President—Richard Peters.

Vice Presidents.

William Tilghman, Robert Coleman, of
James Mease, M. D. Lancaster.

Nicholas Biddle,

Treasurer—William M. Walmsley.

Secretary—William H. Keating.

Assistant Secretary—William S. Warder.

Curators.

Israel Cope,

Joshua Longstreth,

Reuben Haines,

Joseph Cloud,

Adam Eckfeldt.

Committee of Correspondence.

Richard Peters,

William Tilghman,

Zacchens Collins,

James Mease,

John Vaughan.

Librarian—William S. Warder.

Editorial Correspondence.

Extract of a letter to the Editor, from a friend in Albany, dated 20th February.

"Our agricultural prospects are at present very inauspicious:—Grain did not attain half its ordinary growth before the winter closed upon it, owing to the cold and dry autumn. The month of January has afforded the novel spectacle of successive rains and frosts. The mean temperature for the month, I presume, has been fifteen degrees higher than usual. Apprehensions are of course, entertained that the wheat and clover are seriously injured, if not nearly destroyed."

THE FARMER.

BALTIMORE, FRIDAY, FEBRUARY 27, 1824.

BALTIMORE MARKET.

PRICES CURRENT—CORRECTED WEEKLY.

Wharf flour, \$5 37½—Howard-street, do. \$5 62½—Best family do. retail, \$7—Wheat, red, \$1 10—Corn, 35 cts.—Rye, 40 cts.—Oats, 28 to 30 cts.—Whiskey, 23 to 26—Butter, inspected, 10 to 15 cts.—Coal, Liverpool, bushel 40 to 45 cts.—Virginia, 28 cts.—Susquehanna, per ton \$6 50 to \$7—Rice, per cwt. \$3 75 to \$4—Beef, northern mess, per barrel \$10—Cargo, No. 1, \$8 to 8 50—do. No. 2, \$6—Baltimore prime, \$10—Bacon and hams, 10 to 11 cts.—Cotton, W. I. Island, 18 to 20 cts.—Louisiana, &c. 16 to 17 cts.—Georgia upland, 14 to 16 cts.—Alabama, 12 to 13 cts.—Candles, mould, 12 to 13 cts.—Dipt, 10 to 11 cts.—Spermaciti, 25—Feathers, live, 30 to 35 cts.—Fish, herrings, Susquehanna, \$2 75—Fall mackarel, No. 1, to 3, \$4 50 to \$7—Shad, trimmed, \$6 to 6 50—Flax seed, rough, per

bushel, 70 to 75 cts.—cleaned, cask, \$8—Flax, per lb. 10 to 11 cts.—Hemp, Russia, \$1 75 ton.—Country dew rot, 7 cts. per lb.—do. water rot, 9 cts.—Hops, fresh, 35 cts. per lb.—Hides, dressed, 15 to 19 cts. per lb.—Hog's lard, 12 cts. per lb.—Lime, per bushel, 30 to 33 cts.—Lard, ther, soal, best, 24 to 27 cts. per lb.—do. Eastern tan, 18 to 20 cts.—Lumber, board measurement, cargo prices:—Of the following articles we give the yard prices.—Oak timber at scant \$1 to 1 25—Boards all sizes, \$1 50 to 2—Pine scantling, do. \$1 to 1 25—Boards 4 to \$1 to 1 25—White do. 5-4, \$1 75 to 2 50—do. 4-4, 1 15 to 1 30—do. cl. 4-4, \$1 80—Shingles, cyp. 18 in.—\$3 to 3 50—Shingles, junip. do. \$7 50 to 7 75—jun. com. \$3 50 to 5—Stave W. O pipe, \$40 to 45—do. hhd. \$25—do. hhd. \$15 to 17—R. O. bbl. \$15—do. hhd. \$17—Wool, fleece, merino full blood, 35 to 40 cts. per lb.—Cropped, 28 to 30 cts.—Common country, 20 to 30 cts.—Skinner, 35 to 40 cts.—Wool, assorted and cleaned, any of the above will obtain an advance of 15 to 20 cts.

Retail prices of provision market—Beef, prime pieces, 10 cts.—Veal, 10 cts.—Mutton, 5 to 6 cts.—Turkeys, 75 cts. to 1—Geese, 50 to 56 cts.—Ducks, Canvasbacks, \$1 25 to 2—Red heads, 50 to 75 cts.—Chickens per pair, 50 to 62½ cts.—Eggs, 12½ cents—Butter, first quality, 20 to 31 cts.—Turnips, per bushel, 50 cts.—Potatoes, do. 50 cts.—Parsnips, do. 62½ cts.—Celery, 5 to 10 cts.—Carrots, 4 to 6 cts.—Cabbages, 2 cts. &c. &c.

Alderney Breed of Cattle FOR SALE.

One half blood Alderney Cow of large size, small neck, head, and horns, of brindle colour, five years old this spring, out of a handsome country cow, and got by James Creighton's imported Alderney bull.

One 3-4 Alderney heifer calf of 6 weeks old, large size, of a beautiful dark red, out of the above cow, and got by George Howard's imported Alderney bull.

One half blood three years old Alderney heifer, now with calf by a full blood Devon bull, will calve in July next.—This heifer is of fine size, out of one of General Ridgley's Bakewell cows.

Apply to me at my Agricultural Repository,
ROBERT SINCLAIR.

SKINNER, Editor, by JOSEPH ROBINSON, on the North West corner of Market and Belvidere streets, Baltimore; where orders for the Book and Job Printing is executed with neatness and dispatch—Orders from a distance for PRINTING or BINDING, with proper directions promptly attended to, addressed to J. Robinson, Baltimore.

Political Economy.

THE EDITOR OF THE AMERICAN FARMER.

“THE HOUSE DIVIDED AGAINST ITSELF MUST FALL.”

If there can be such a thing as degrees in truth, I would say, that in the whole catalogue of propositions there never was, nor will be, one more true, than the foregoing; and that there never was, nor probably will be a more forcible exemplification of it, than the late address of I. C. Bates, Esq. delivered before an agricultural society at Northampton in Massachusetts. When such men as he appears to be, come out in opposition to the best interests of the particular class to which, I must presume he is a member, the influence which he is likely to exercise over the minds less informed than his own, is much to be regarded. For his eloquence excites our admiration; his uncommon persecuity delights our understandings; and his great display of good feelings, so warms our hearts, that we are thrown almost entirely off our guard, against the false argument with which, (I verily believe, unconsciously to himself,) his address abounds. This erroneous reasoning, it shall be my humble endeavour to attempt to detect; as it threatens more mischief to our cause—from being the sounds of an apparent, and I dare say real friend, than an hundred wagon loads of such stuff, as we usually see written on this subject.

This excellent address, contains a very clear enunciation of the most important principles of political economy; but when he comes to apply them to the great interests of the community, it is truly surprising, that he should fall into some of the most striking errors of those writers, on the same subject, who have nothing in common with him, but these erroneous opinions. Another peculiarity in his address is, that he furnishes stronger arguments in self refutation, than most men probably could bring against him; but they are so separated from the positions which he has to establish, that their connexion and convincing tendency require to be pointed out.

He first assumes as a fact, that agriculture is overstocked with labour; from which he infers that the excess should be employed in something else; as the best means of creating a demand for these agricultural products now so abundant, as to sell for little or nothing. So far, so good, if true; provided he leaves the sons of agriculture to find out this blunder for themselves; and to retain, as they have always heretofore possessed the liberty of choosing, whether they would change their profession, or persevere in a long business. Mr. Bates having previously set it down as a first principle, that no losing business will long be followed, where men are free to determine; and that all men have an indisputable right to change, or to continue their lawful callings, as may best suit their inclinations; where does he get the right, for government to interfere in such matters; and to prescribe, not only that a change *shall be made*, but to point out the time and manner, as they must do, if they take his advice, where he says: “Let the government, therefore, give birth and protection to manufactures, by increasing the duties on importations, cautiously and prudently at first, but to the needful extent.” This is carrying the matter up to the hub at once; for if his “birth and protection,” are to be given at every hazard “to the needful extent,”—that is, until they are established in despite of all obstacles; the caution and prudence which he also recommends in doing it, would certainly be a great aggravation of the evil, instead of an alleviation; for who would not prefer being shot, or hanged instantaneously, to being put to death by slow and con-

tinual torture? But the best of it is, that Mr. Bates himself has saved us, (as I conceive,) from the apprehension of such mischief, should the government, instead of acting upon the above advice, without farther examination, proceed to the following passage of his address, wherein he has gone, I think to the full extent of denying the right to do, that which he has recommended. “The classification, (says he,) of men in society is not arbitrary, but grows out of the nature of things. You may as well therefore attempt to change the immutable principles upon which society is founded, as to change the organization of it in this particular. You cannot do the one without the other. Each department of industry, whether intellectual or corporeal, is filled, because there is something in it to be done, by which subsistence, or distinction, or both may be gained. This diversity of occupation forms classes, all governed by the same motive, and posing with what ability they have, to the same results. Were you to take the fabric of the social state to pieces, therefore, it would make itself up again, in the same general form.” And yet, only a few paragraphs before, he has advised government to undertake this very job, the inutilty, and unlawfulness of which he has so clearly and happily illustrated. Now, if his last quoted position be true—and I pronounce it undeniably so, at least by any man having the smallest pretensions to common sense; where in the name of that common sense, would be either the use, or the justice of such compulsory, “taking to pieces,” this grand social fabric, the classification of which is very properly said to result from the nature of things, as would ensue, were the national legislature to attempt, either by high duties or any other means, to change the relative numbers of the different classes into which society naturally divides itself. Ought not the obvious inefficacy of the attempt to alter, direct, and controul this right of self division, inherent in every community, so perspicuously pointed out by Mr. Bates, to satisfy even the most sceptical, that government cannot possibly possess any such power. Again, Mr. B. says; “here you have perfect security for life, liberty, and property. Here you have equal rights, and equal honors.” But how can this possibly be true, if the mode by which I sustain life, the liberty of choosing this mode, and the property acquired in exercising it, are all so far subject to the will of government, that they may alter the first by taking away the second; and may transfer to others any portion of the last, which they please, “to the needful extent of giving birth and protection to manufactures?” How can this possibly be true, if our government can enhance the price of all the articles we consume, not for general purposes, as in the case of a tax producing public revenue, (which they have a right to impose,) but for the private benefit of a minority of its citizens? If this be equality of right, in God’s name let us no longer make any boast of it, as a peculiar privilege of inestimable value; for the most despotic governments of the world have identically the same.

What Mr. B. says on the subject of competition amounts to this—“Let us give up the certainty of that greater competition which now exists between all the manufacturers of foreign countries, and such as we now have at home, securing lowness of price, and excellence of quality in all our purchases; for that partial and contingent competition which it is supposed will follow among our manufacturers alone, should the duties be raised high enough to exclude or greatly lessen the importation of foreign commodities; the inevitable effect of which, would be to leave the whole class of consumers dependent for an indefinite time, upon this contingency for

a supply of all their wants, at greatly increased prices too, with greatly diminished means of procurement.

In regard to his most paradoxical assertion, that we ought to give more for an article of domestic, than of foreign manufacture; I must say, that he evidently takes for granted, what he ought first to have proved—to wit, that an increase of manufacturing establishments must occasion an increased consumption of agricultural products. This cannot be true, at least as to the two great staples, bread stuffs and meats, unless the population of the whole country is also augmented. For if the same number of citizens are only classified differently, so as merely to change the relative numbers of cultivators and manufacturers, it is most manifest that the same quantity of food will be consumed, as before. Our citizens being numerically what they were, can neither eat nor drink more than they did. The only alteration will be, that the producers of this food, being diminished by some of them being obliged to turn manufacturers, those who still continue to provide it, must of course get a higher price; but how this is to benefit the country at large, can be much more readily asserted, than believed. If this higher price is the consequence only of diminished supply, (as it evidently is,) the whole value of this supply—estimated in any way you please, cannot exceed, if indeed, it would equal the whole value of the much larger supply at a lower price. Our surplus products have not yet perished on our hands, and until they do—until they sell for so little, as not to leave some profit, after paying for the labour bestowed on them; they will continue to be produced, unless government should force a portion of our agriculturists by means of high duties to abandon their avocation. Yet it is upon the supposition of a considerable part of these products, being altogether unsaleable; as well as upon the assumption, that a mere change in the relative proportions of our classes, while their aggregate number remains the same, can increase the demand for agricultural productions, that Mr. Bates erects his fine air castle for augmenting the national wealth, by taxing agriculture and commerce, to “give birth and protection to manufactures.”

Before it possibly could be advantageous in a national point of view, to give more for domestic, than for foreign manufactures, Mr. Bates, or some body else for him, must prove, that the whole amount of sales made by our domestic producers,—I do not mean at Waltham, Providence, Munson, and Southwick alone, but throughout the whole United States, would exceed in value, what they do at present, by more than the difference of the whole additional sum which they will have to pay in consequence of the increased price, of the whole of their purchasers. Can it be necessary to add, that unless such excess of value would result from the exercise of such excess of legislative authority, the nation at large could not possibly gain any benefit by this most delectable scheme, for a new and coerced classification of the good people of our Union. I call it new, because its advocates in enumerating the various blessings to be thereby dispensed, assert that it will diminish the number of agriculturists, which they have discovered, is too great; and will augment the number of manufacturers, which they affirm to be too small; although most strange to say, these few are unable—according to their own declarations, to live by trades which already divide from 15 to 18 per cent on the capital invested. That this is true of Waltham, and several other establishments, I have the most unquestionable authority for believing; while it is equally true, that poor agriculture, the ill-fated subject of so

much praise, so many prayers, so much parental solicitude on the part of our legislators, but at the same time of so much oppression, can scarcely divide 3 per cent. for her labours; and is yet called upon for a still farther reduction. She already pays, either directly or indirectly almost every cent of every tax imposed either for state or national purposes; but she is still deemed, (as it would appear,) too plethoric, and must therefore be subjected to yet greater depletion. Far better would it be to make a finish of her at once; and let it be hereafter, fully understood, that she is to work for others, and to any extent they please, whenever called upon; and that too, without the least murmur or complaint. I have denominated the proposed measure, a coerced classification of the good people of our Union, because law is called upon to effect that which the free citizens of our country are not expected to do voluntarily. This brings me back to the old enquiry, which cannot be too often repeated—whence comes the right of such violent interference, as that which is required of government? Cui bono—for whose benefit is it asked? Certainly not for that of the Nation.—Either it is not true, as we are told on all hands, that we are free to choose whatever lawful calling we please; or government cannot possibly have the power to render this freedom of choice utterly nugatory, by making the adopted calling too unprofitable to live by it. If however, in the exercise of this liberty to choose, I take up a profession which proves to be a bad one, (that of a manufacturer, for example,) this is my own affair, one of the results of this free agency; and ought of course, to be at my own risk. No other man is bound, still less a majority of the nation, by any principle either of reason or justice, to pay for my errors of calculation in regard to my own private interests: consequently both justice and reason are violated by that government which undertakes to coerce this payment from others, to compensate me for my blunders. But, says Mr. Bates, “the arguments against an increase of duties, go, with a concentration of all their force, to show, that there should be no duties at all.” And so they most assuredly would, but for a small proviso, which he seems entirely to have overlooked; and that is, *if there was any better way of raising the funds necessary to support government*: this being the *ne plus ultra*, according to our doctrine, of the constitutional power to impose duties.

There was one view of the subject of foreign competition, which I designed to present, but omitted in its proper place.—As it is calculated to show more clearly than any thing, which I have yet said; the difficulty, as well as the enormous cost of any attempt to counteract it in the way proposed, I must beg leave (as the huntsmen say,) “to cast back.” We have been told, and, I believe truly, for it is English testimony against England,—printed in their books, and proclaimed to the world in their Parliaments, that the manufacturers of that country labour upon an average, sixteen or seventeen hours in the twenty-four:—that in general they rarely ever see, much less taste meat:—that many of their occupations are nearly as destructive to human life as the plague; notwithstanding which, the lust of money and the high price of comfortable subsistence in so dense a population, supplies more sacrifices, as fast as their predecessors are cut off:—that they are necessarily brought up in total ignorance of every thing, but the various manipulations of their art:—that lingering disease, famine, pauperism, and death, no where find so many victims, as in the manufactories: and that the consequence of all this is, a most deplorable and ap-

alling depravity of morals, as shocking to humanity, as it is poisonous to every genuine source of national happiness: And it is with a host amounting to some millions of people, *thus* organised, and *thus* managed, that we are required to compete, in order to undersell them!

Most of the advocates of this competition, being fully aware of the conclusions to be drawn from such facts, endeavour, (I except Mr. Bates,) to represent human nature as quite a different affair on the western side of the Atlantic:—What they have said, may be translated into intelligible language by some such paraphrase as the following:—We will not work our people near as hard—say not more than nine or ten hours in four-and-twenty—we will feed them well with meat and bread:—we will give our little boys and girls plenty of time to run about and kick up their heels to keep them healthy, provided they have any spirits left to do it, after ten hours confinement in the atmosphere of a crowded factory:—we will take special care of their morals—aye, *their morals*, by sending them to school a considerable part of their time; and when they get to an age to be taking improper liberties with each other,—why they shall be most studiously kept apart:—moreover, we will make them attend prayers night and morning, and go to church every Sunday, supplying them constantly with Bibles and Testaments: we will never turn them adrift to become parish nuisances, (as those hard hearted English do,) when worn out by noxious occupations in our service; oh no! we can never be so cruel and wicked,—we will keep them as the apples of our eyes. All this and a great deal more will we do, provided Congress will only be so *regardful of the public weal*, in plain English, so kind to us-ward, as to make all who cultivate the soil, and all who navigate the ocean; every mother's son of them, pay us for the extra expense of a procedure, so different from the mode in which they manage such matters across the water.

RURIS CONSULTUS.

Virginia, Feb. 17th, 1824.

AGRICULTURE.

TO THE EDITOR OF THE AMERICAN FARMER.

IMPROVED DURHAM SHORT HORNS.

DEAR SIR,

I have less hesitation in sending to you, the pedigree of my improved short horn stock, as you have in 43d number of the Farmer, noticed the purchase I had made, of a calf begotten in England, by Mr. Champion's celebrated bull BLAIZE, and produced at Wye, by White Rose. You will perceive, that I could have no motive, to seek better blood, although I was glad, to avail myself, of the liberal intention, of my friend at Wye, to exhibit in Pennsylvania, a very beautiful calf, begotten by the bull, which Mr. Champion says, in his letter to you, of the 6th April, 1822, “*is considered the most complete animal I ever bred for symmetry and quality*,” on a heifer, which he also says, excels for correctness of frame, neatness of bone, and uncommon appearance for milk.

I always considered White Rose, a fine animal; and you may recollect, I proposed to purchase her *alone*, at the time you offered to me, the bull Champion, and the other heifer at cost. I confess, I have had a strong predilection, in favour of Wetherill's stock, not only as he was one of the purchasers of Comet, and of some of the finest cows at Colling's sale, but as Mr. Williams' extraordinary bull Denton, was bred by him, and as all the heifers of his stock, which I have seen, are good milkers. At your sugges-

tion, I applied to Mr. Champion, and offered a price, much higher, than that which, he had received for the bull, you imported, or than he had asked, for such an one, as he supposed would satisfy me. He answered, “I regret it, not in my power to send you a bull, possessing the many qualifications you expect, the description you have given of Denton, it is impossible for me to equal.” I proposed to pay to Mr. Champion more than he had demanded, as I did not suppose, that he would send to America, his finest bulls, at *sixty guineas*, at the moment he was selling Brigade Major, at Blaize, at *one hundred, and one hundred and fifty*, upon his farm. I have no doubt from the points, and shape of Wye Comet, and the pedigrees, of some of his stock that he possesses fine cattle, as any man in England, although I confess, I was of a very different impression, until I had seen this calf by BLAIZE. If you have any doubt, of the valuable properties, of the “*Improved Short Horns*,” as milkers, quick feeders, and small consumers—I should be glad to convince you on my farm, that in early maturity, and all these essential items, their excellence is determined, by the degree of affinity, to the pure blood. I am, dear sir,

Most truly your's,

JOHN HARE POWELL

Powelton, Philadelphia County, }

FOR THE AMERICAN FARMER.

SEEDS.

Albany, February 21, 1824.

Appreciating the importance of good seeds, both to the farmer and gardener, I send you, Mr. Skinner, some hints on this subject, suggested by experience and reading, which may be of interest to some of your readers.

1. *To raise good seeds*, care must be taken, not only to select from the choicest plants, but also, that bad or different kinds of the same family, be not suffered to blossom in their vicinity, as the fecundating farina of the poorer sorts, which is carried by winds and by insects, will deteriorate the seed of the good. Hence, no two kinds of cabbage, turnips, beets, &c. should be suffered to seed within ten or twenty rods of each other, and it will be better, if they are put into different enclosures. And hence, if we would preserve from a fine variety of melons, it is necessary to plant them at a distance from other varieties. The brassica, (cabbage,) family not only mix among themselves, but are said to be affected by the pollen of the cauliflower, kale, and turnip.

2. *Seeds should be gathered as soon as they are ripe*, both to prevent waste and damage.

3. *They should be preserved* in a dry and temperate place, accessible to air; and, where it is convenient, kept in their pods or husks till wanted for sowing. This may be done, with most kinds of annuals cultivated in the garden. It prevents injury from heat or moisture, and preserves them in a healthy condition. Miller made this experiment. He divided parcels of lettuce, parsley, onion, and other seeds, one portion of which he put into vials which he hermetically sealed; the other portion into bags, and kept the whole one year—when planted, not one of the seeds grew, which had been kept in the vials, while all of those which had been kept in the bags grew well. An experienced gardener tells me, that the seeds of many annuals will, if preserved in the pods, &c. retain their vegetative power for two or three years, whereas, if taken out, they will seldom grow after the first

My experience, and observation of the results of plants, confirm this remark.

When should seeds be sown? Repeated sowing in the seeds of perennials and biennials, to vegetate, when sown in the spring, led me to consult the economy of nature, and to adopt her as my guide. I found that the maple, birch, ash, and other forest trees—several shrubs, most of the bulbous flower roots, and a large portion of the biennial and perennial flowers, shed their seed upon the ground in autumn, and that the seed thus sown, if slightly covered, vegetated either immediately or in the following spring, and that if these seeds are thoroughly dried, as they must be by being wintered in the house, they either will not grow at all, or lay dormant in the earth for a year or more.

5. The pods of melons, cucumbers and pumpkins, improve by being kept till they are three or four years old. At that age they produce earlier, and more fruit, and run less to vines. The benefit of age may be partially obtained, by washing the seeds well, when taken from the pod, to cleanse them from mucilage, or by carrying them loose in the pocket, some days or weeks before they are planted.

6. Wheat is said to be improved, as seed, by being kept a year; and, what is an important benefit, will then produce a crop without smut; nay, more—I am induced to believe, that the crop will escape the injuries of the fly also. For I am almost a proselyte to the opinion, that the smut is deposited in the down of the kernel, before the grain is harvested, and that the same warmth which causes the seed to vegetate in the earth, hatches the insect there also. I am inclined to favour the hypothesis, and not without evidence, that the seed of both the smut and the fly lose their reproductive power during the course of a twelvemonth. I will not venture to say, that liming seed is as efficacious against the smut, as it is against smut; but thus much I can say, that I always lime my seed wheat, and never have it injured by smut or fly, while many fields in my neighbourhood are annually devastated by the one, or materially injured by the other.

7. Seeds may be preserved in a healthy state according to the nature of their essential oil and the nature of the shell or covering, which encloses the embryo plant. Miller says, "the seeds of cucumbers, melons and gourds, which have thick horny coverings, and the oil of this seed being of a cold nature, continue good eight or ten years; and raddish, turnip, rape, &c. with their oily seeds, (whose coats, though they are not so hard and close, as the others, yet) abounding with oil, which is of a warmer nature, the seeds will keep good three or four years; whereas, the seeds of parsley, carrots, parsnips, and most other umbelliferous plants, whose seeds are, for the most part, of a warm nature, and have little oil in them, do lose their growing faculty often in one year, but seldom remain good longer than two years."

8. **Steeps.** The experiments of Duhamel and others, show that steeping seeds in any liquor, or mixture, with a view of *invigorating the gum*, is always without benefit, and often attended with injury—the seed containing the best nutriment, and all that is requisite, to extend the root, and unfold the feminal leaves. Steeps may be beneficially used to accelerate germination, to preserve the seed from grubs and other insects, and to destroy the seeds of insects, and parasitic plants, which may adhere to it. Corn soaked in a strong decoction of the roots of black hellebore (sometimes called itch weed,) and strongly saturated with nitre, has, with me, resisted the attacks of insects, birds and squirrels. A steep of water, will also protect seed in the ground.

Lime and alkalis are most efficacious in destroying the eggs of insects, &c. The best method I know of to facilitate early vegetables, is to sprout the seeds, before planting, between two sods of earth, placed in the kitchen corner, and occasionally wet with warm water. The larger kinds may be laid in loose, the smaller wrapped in papers. They will sprout in from 24 to 48 hours.

J. B.

TO THE EDITOR OF THE AMERICAN FARMER.

ON THE CULTURE OF RAPE.

Newport, (Del.) Feb. 24, 1824.

DEAR SIR,

Your Correspondent Agricola, in your paper of the 13th inst. having requested some information on the method of cultivating Rape, I beg leave through the medium of the "American Farmer" to supply it.

To raise Rape for Sheep feed, the best is usually obtained upon good rich bottom land, but it may be raised upon any land not naturally barren; the land should be properly cleaned, and if it needs it, well manured; the proper season for sowing, is from the middle of May to the latter end of June, and should be eaten off in time to sow wheat in the fall, for which it is an excellent preparation; it may be sown broadcast on land just turned over by the plough; about two quarts of seed is sufficient for an acre, and kept until it is a foot high before the sheep are put upon it.—It is very rich feed, and if your correspondent puts his breeding ewes upon Rape about twelve or fourteen days before he puts the ram to them, (and to remain,) he will find his account in so doing at the lambing season.

To raise Rape seed, there is no danger of the land being too rich; the richer the better; and a naked summer fallow, except upon rich, clean bottom land, is, with good manuring, the way to obtain a crop. It may be sown as the season may suit, from the middle to the end of August, or the first week in September, in the manner above described; only that four quarts of seed per acre is the proper quantity, as it seeds better when sown thick; but thin sowing is proper for a crop to be eaten, as it grows more feed. It must be closely watched, so as it does not get too ripe before it is cut, in which case the loss of the best part of the seed would be the result. In order to avoid this, the cutting should commence as soon the seeds begin to have a light brown tinge on one side of the seed, which is ascertained by picking the forwardest pods and opening them daily; a great part of the crop will of course be quite green, but the evening dews will be sufficient to perfectly ripen the seed notwithstanding. I have found it the least trouble to sheaf it like wheat, making the band of the rape, which when green, answers very well; and it should be laid in regular rows towards the middle of the lands when shorn, so as to leave sufficient room for the carts to come between without touching it, as it is so very apt to shed when it has got dry.—After three or four days if the weather is dry, it will be ready for the stack, the bottom of which should be made of hay; but perhaps the barn may be at liberty, which is better.—The cart or carts employed in hauling the crop home, should be covered over to the outside of the shelvings with canvass, so that all the seed which shakes out in loading and hauling may be secured, otherwise one third, or, perhaps one half of the crop may be lost. It may be well to let it remain three or four weeks in the straw before the seed is thrashed out, as it will in that time be cured.—It requires a steady hand to fork the sheaves to the

cart, as a great loss will arise from employing a clumsy bungling hand, by the seed shaking out; and if it was taken home before the morning dew was gone, it would prevent much waste.

As soon as the field is cleared of the crop it should be ploughed lightly and harrowed, and after taking all the care in securing the crop which I have recommended, there will perhaps, be ten times as much seed grow as is proper to sow for a crop. After the land is become green, the harrow should be used lengthwise, and across the field; and if the season is favourable, there will be excellent eatage for sheep or calves, and the land may be sown with wheat in the fall, with a much better chance of success than after a naked fallow.

I should be glad to be informed if there are any mills where Rape Oil is manufactured.—The consumption of this article among the woollen manufacturers in Britain is enormous, and if it is wanted here, it can be supplied to any amount.

It was my intention to have made some remarks upon the advantages of live fences, but want of time prevents my adding more at present, than, that

I am Sir,

Your's respectfully,

WILLIAM PARKIN.

If your correspondent or correspondents, are in want of Rapeseed, my brother, John Parkin, has a few bushels of the growth of last season, price \$3 per bushel.

I would beg to suggest as an improvement to your very excellent paper, the occasional insertion, say once in a month, of the London Corn Market litter, with the averages of grain to shew the indication of the ports being open for grain and flour.

TO THE EDITOR OF THE AMERICAN FARMER.

ON THE MANAGEMENT OF FRUIT TREES.

DEAR SIR,

Having seen, in your valuable paper, many useful remarks on the treatment of orchards, and as the season is at hand, when it is usual to trim them, wash, &c. I beg leave to give in my mite to the general stock, and to protest against that too common practice of white washing the trees, as it is, in my opinion, attended with the worst consequences. It is done under the impression that the caustic quality of the lime will destroy the insect—were it to end there, I would cordially approve of the application.—It will not only destroy the insects, but trees also, by stopping up the pores of the bark, thereby preventing the absorption of those gases that are as essential to preserve, and promote vegetation; as it is necessary, in the human system, to keep open the pores of the body, to preserve health and vigor, how long would a man continue healthful, were his body to be incrustated with a thick paste? I have for many years, given considerable attention to the management of fruit trees, and am satisfied, cleanliness is as important to them, as it is to the human family. This is to be produced by scraping off the moss and old bark, and a good washing with soft soap and water in which tobacco has been steeped, during a moist spell of weather, in the months of February, or March. The taking off the moss and bark serves to expose the insects and their eggs to the sharp frosts, that are usual at that period of the year.—The soap suds soften the bark, open its pores, assist in destroying the insects, and act also as a stimulant. I have used all kinds of mixtures as a dressing to the trees, and have never found any to equal tobacco. It not only is active in its ope-

ration, but will effectually banish all insects and mice from the roots—other manures attract them.

I am unwilling to occupy your time by giving a detail of my experiments—I will, however, mention to you one fact, in confirmation of my opinion of the utility of keeping open the pores of the bark.

Contiguous to my garden, I have a small orchard, and have had for several years past, the scrapings of the walls and the weeds from the garden thrown into a heap, between a row of apple trees, which served, when rotted, as a top-dressing for the small seeds sown in the garden.—The trees nearest the heap far outstripped the others, and those limbs immediately over it, were of a much more luxuriant growth; and, as if anxious to inhale every exhalation from the weeds, inclined towards and bent over them, instinctively impelled to seek for nourishment, which was received through every pore, and which could not have been imbibed, had the trees been covered with a thick crust of lime, by white washing.

A friend to Pomona,

D. W. Jr.

REMARKS

ON THE CULTIVATION OF THE LOCUST TREE,
Written in 1817, by Dr. S. Ackerly.

The cultivation of the locust tree, on Long Island and in other parts of the state of New York, has been attended to with considerable profit to the agricultural interest, but not with that earnestness which the importance of the subject demands. This may have arisen from the difficulty of propagating it by transplanting, or not understanding how to raise it from the seed.

The locust is a tree of quick growth, the wood of which is hard, durable, and principally used in ship-building. To a country situated like the United States, with an extensive line of sea coast, penetrated by numerous bays, and giving rise to many great rivers, whose banks are covered with forests of extraordinary growth, whose soil is fertile, rich and variegated, and whose climate is agreeably diversified by a gradation of temperature; to such a country, inhabited by an industrious and enterprising people, commerce, both foreign and domestic, must constitute one of the principal employments. As long as the country possesses the necessary timber for ship-building, and the other advantages which our situation affords, the government will continue to be formidable to all other powers. We have within ourselves four materials necessary for the completion of strong and durable naval structures. These are the *live-oak*, *locust*, *cedar* and *pine*, which can be abundantly supplied. The former is best for the lower timbers of a ship, while the locust and cedar form the upper works of the frame. The pine supplies the timber for decks, masts, and spars. A vessel built of live-oak, locust, and cedar, will last longer than if constructed of any other wood. Naval architecture has arrived in this place and other parts of the United States, to as great perfection, perhaps as in any other country on the globe. Our "fir-built frigates" have been compared with the British oak, and stood the test; and in sailing, nothing has equalled the fleetness of some of our sharp vessels. The preservation and cultivation of these necessary articles in ship-building, is a matter of serious consideration. It might not be amiss to suggest to the Congress of the United States to prohibit the exportation of them. The pine forests appear almost inexhaustible, and they will be so in all probability for many generations to come; but the stately cedars of Mo-

bile, and the lofty forests of Georgia, where the live-oak is of a sturdy growth, begin to disappear before the axe of the woodsman. The locust, a native of Virginia and Maryland, is in such demand for foreign and domestic consumption, that it is called for before it can attain its full growth. It has been cultivated as far eastward as Rhode Island, but begins to depreciate in quality in that state. Insects attack it there which are not so plentifully found in this state, or its native situations. These give the timber a worm-eaten appearance, and render it less useful. The locust has been extensively raised in the southern parts of the state of New York, but the call for it has been so great, that few trees have attained any size before they were wanted for use. Hence they are in great demand, and of ready sale, and no ground can be appropriated for any kind of timber with so much advantage as locust. Besides its application to ship-building, it is extensively used for fencing; and for posts, no timber will last longer, in or out of the ground. On Long Island, where wood is scarce, and fencing timber in great demand, the locust becomes of much local importance from this circumstance alone, independent of its great consumption in this city, among the ship-builders. In naval structures it is not exclusively applied to the interior or frame. In many places where strength is wanting, locust timber will bear a strain which would break oak of the same size. Thus an oak tiller has been known to break near the head of the rudder in a gale of wind, which has never happened with a locust one. Tillers for large sea vessels, are now uniformly made of locust in New York. It is the best timber also for pins or tree-nails, (commonly called trunnels) and preferable to the best of oak. The tree generally grows straight with few or no large limbs, and the fibres of the wood are straight and parallel, which makes it split well for making tree-nails, with little or no loss of substance. These are made in considerable quantities for exportation.

The locust tree does not bear transplanting well in this part of our country, but this in all probability arises from the custom of cutting off the roots, when taken up for that purpose. Most of the roots of the locust are long, cylindrical, and run horizontally not far under the surface. In transplanting, so few of the roots are left, to the body of the tree removed, that little or no support is given to the top, and it consequently dies. If care was taken not to destroy so much of the roots, a much larger proportion of those transplanted would live and thrive. So great has been the difficulty in raising the locust in this way, that another method of propagating it, has been generally resorted to. Whenever a large tree was cut down for use, the ground for some distance around was ploughed, by which operation the roots near the surface were broken and forced up. From these roots suckers would shoot up, and the ground soon become covered with a grove of young trees. These, if protected from cattle, by being fenced in, would grow most rapidly, and the roots continuing to extend, new shoots would arise, and in the course of a few years a thrifty young forest of locust trees be produced. The leaves of the locust are so agreeable to horses and cattle, that the young trees must be protected from their approach. When growing in groves they shoot up straight and slender, as if striving to out top each other, to receive the most benefit from the rays of a genial sun.

Another difficulty has arisen in propagating the locust, from inability to raise it from the seed. The seed does not always come to perfection in this part of the state of New York, and if it does, it will not sprout, unless prepared before

planting. The method best adapted to this purpose, was proposed by Dr. Samuel Bard; but it is not generally known, or if known, is not usually attended to. When this shall be well understood and practised, the locust will be easily propagated, and then instead of raising groves of them, the waste ground along fences and places where the Lombardy poplar encumbers the earth, will be selected to transplant them, as by having them separated and single, there will be an economy in using the soil, the trees will grow much better, and the timber be stronger.

Doctor Bard's method of preparing the seed, was to pour boiling water on them, and let it stand and cool. The hard outer coat would thus be softened, and if the seed swelled by this operation, it might be planted, and would soon come up. This has been followed with success on Long Island; and on a late visit to North Hempstead, (in 1817) I was led to admire Judge Mitchell's nursery of young locust trees, planted the spring.

The judge took a quantity of seed collected on this island, and put it in an earthen pitcher, and poured upon it water near to boiling. This he let stand for twenty-four hours, and then decanted it, and selected all the seeds that were always swelled by this application of heat and moisture. To the remainder he made a second libation of hot water, and let it remain also twenty-four hours, and then made a second selection of the swelled seeds. This was repeated a third time on the unswelled ones, when nearly all were swelled, and then he prepared the ground and planted them. He planted the seeds in drills about four feet apart, and in eight or ten days they were all above ground, and came up as regular as beans, or any other seeds that are cultivated in gardens. When I saw them, the middle of July, they were about a foot high, all thrifty and of a good color and condition.

It is the Judge's intention, to leave them in their present situation about three years, and then transplant; and provided he does not mutilate the roots in removing them, they will bear transplanting, live, and thrive, and be the most productive forest tree that a farm can have. This method of preparing the seeds and planting the locust, cannot be too warmly recommended to the farming interest. On Long Island, where fencing timber is growing scarce, the cultivation of the locust tree is of great moment. In the centre of the island, on and about Hempstead plains, where there is no timber at all, it must be a most valuable acquisition; and from the trials made in raising it from the seed, all difficulty must be removed to its extensive cultivation.

P. S. (1823.) Judge Mitchell transplanted the above-mentioned young trees, on a side hill of waste ground, which has been for many years uncultivated, and his farm has been improved by the addition of a large grove of locust trees, which are now in a thriving condition.

FOR THE AMERICAN FARMER.

PEDIGREE OF MR. POWEL'S STOCK, VIRGINIA.

Was begotten in England, on Rosemary, by Mr. Curwen's General.
Rosemary, was by Flash; from Ked Rose.
Red Rose, by Petrarch, d. by Alexander, g. d. by Traveller, gr. g. d. by son of Bolingbroke.
Petrarch, (bred by Charles Colling) by Comet, d. Venus by Ben—g. d. Phoenix by Foljambe—gr. g. d. Favorite, by Alcock's bull.
Alexander, (bred by Charles Colling) by the bull Favorite.
Traveller, by Bolingbroke, d. old Blossom.
Comet, sold to Wetherill & Co. for 1000 guineas.

Ben, bred by R. Colling, by Punch, d. by Foljambe, g. d. by Hubback.

Flash, (bred by Mr. Seymour) got by C. Collings' Sir Dimple, d. Carnation, (bred by Mr. Seymour) by Cripple, g. d. Moss Rose by Henry—gr. g. d. Rosebud, by Misfortune—gr. gr. g. d. Red Rose, by Favorite, gr. gr. g. d. by Bolingbroke.

General, the sire of Virginia, got by Young Star. *Young Star*, by C. Colling's North Star, d. Mary, (bred by C. C.) by Favorite, g. d. Venus, by Ben.

Queen, the grandam of Virginia, by Bruce. d. Empress, by Western Comet, g. d. Bright Eyes, by Marquis, gr. g. d. by Simon, gr. gr. g. d. by Traveller, gr. gr. g. d. by Colling's Lambull.

Bruce, by Jupiter, d. Rola.

Western Comet, by C. Colling's Major, d. Gentle Kitty, by Charges' Grey, g. d. by Favorite.

Marquis, d. by Daisy Bull, g. d. by Favorite, gr. g. d. by Hubback.

Simon, got by Favorite, d. by Punch, g. d. by Bolingbroke.

Bolingbroke, bred by C. Colling, got by Foljambe, d. Young Strawberry, by Dalton Duke, g. d. Favorite, by Alcock's bull, gr. g. d. by Smith's bull, gr. gr. g. d. by Jolly's bull.

MR. POWEL'S BISHOP

Was bred by Mr. Curwen in England, got by Wellington, d. Arbutus, (bred by Mr. Gibson,) by Harlequin, g. d. by Yarborough, gr. g. d. by Duke, gr. gr. g. d. by Jobling's Traveller, gr. gr. g. d. by Bolingbroke.

Wellington, got by Comet, d. Peeress, by Favorite, g. d. Cherry, by Favorite, gr. g. d. Old Cherry by C. Colling's Samebull, gr. gr. g. d. by Hubback.

Harlequin, bred by Mr. Gibson, got by Alexander, d. Liberty, (bred by C. Colling) by Washington, g. d. Young Houghton by Punch, gr. g. d. Old Houghton, bred by Alexander Hall, by Hubback.

Washington, (bred by Mr. C. Colling,) got by Favorite, d. Lady by Grandson of Bolingbroke, g. d. Phoenix, by Foljambe, gr. g. d. Favorite, by R. Alcock's bull.

Punch, (bred by R. Colling,) d. by Broken Horn, gr. d. bred by Mr. Best.

Hubback, calved in 1777, (bred by John Hunter, by Snowden's bull: (dam from Sir James Pennyman's stock, which were from Sir William, St. Quintin's stock.) Snowden's bull by Robson's bull, (bred by Mr. Wastell near Darlington,) d. Wastell's Roan Cow, Robson's bull by Masterman's bull, Masterman's bull by the Studley bull.

Mr. Powel's Matchless, bred in England, by Mr. Wetherhill, and of pedigree equal to Virginias: also fourteen others.

Mr. Powel's Wyecomet, begotten in England, by Blaize, d. White Rose, by Warrior, g. d. by Charles (which was let at 450 guineas to Col Mellish and Mr. Champion, for two years,) gr. g. d. by Prince.

IMPROVED DURHAM SHORT HORNS.

Extract from a report to the Workington Agricultural Society, by Mr. Curwen, the distinguished member of Parliament, for Cumberland; and a successful farmer, on an immense estate, in the north of England.

"In the last year, the valuable stock of my late friend, Lieutenant General Simpson, was disposed of; with the merits of which I was well acquainted, knowing it to be descended from some of the very best specimens, in

"the possession of Mr. C. Colling. At the time Mr. Colling sold North Star, the own brother of Comet was let to General Simpson, a son of his—Young Star, was the most perfect animal I ever saw—all General Simpson's young stock were from him, or his immediate descendants. Had not the distance, and the difficulty of removing, without great risk, precluded the attempt, I should certainly have tried hard to have become the purchaser of Young Star; he fell into the hands of Mr. Gray, and is since dead.

"General, the bull I bought, was out of Queen, Stars mother, and got by North Star. This I esteemed to be the next desirable animal, and I fortunately became the proprietor of him, with six cows and three heifers, and I have now to regret, that I did not farther extend my purchases.

"The cattle were in miserable condition; their subsequent improvement has been the surprise of many: in size, they are diminutive in symmetry and predisposition to fatten, producing at the same time, flesh of excellent quality, they cannot be surpassed. These, in the first instance, have been crossed by a son of Duke, the property of Mr. Smith, of Grindon. I shall continue to breed from the cross, and from the full blood also; it is likewise my intention to keep distinct, the blood of Mr. Donkin's cows, which, in uniting the two essential qualities, of milking and fattening, are highly valuable. Those which have hitherto been bred at the Schoose, have been much approved. Two heifers and a bull, were this spring, forwarded to Thomas Law, Esq. at Washington. From friendship and connexion, as well as a desire to support the credit of my farming, the very best specimens were selected; and I have reason to believe, that on their landing in America, even, after so long a voyage, they were greatly admired!

"The food on which those which have been sold, as well as those which remain, have been reared, is milk whilst calves; and green food, with turnips, chaff, and straw only, steamed, afterwards. The young cattle are reared under sheds, in small yards. New milk is given to the calves until they are six months old, sparingly the first month, but afterwards, from two to three gallons a day. The steers which have been bred and slaughtered, have been equal, in quality of beef, to any thing I could have expected or desired. Had these been slaughtered, when two years and a half old, weighing as they did at that time, from eighty to eighty five stones, of fourteen pounds each, (equal to 1120 or 1190 pounds,) they would have been found as heavy as at three years old.—Hence has arisen a doubt whether, without some very material change in the food of the animal, its fattening can be progressively increased beyond a certain weight. The stock has been not less remarkably than uniformly healthy."

ON DIET.

Diet, in animal economy, is a regimen or course of living, adapted both to the preservation of health and its recovery, especially from chronic diseases.

The dietetic treatment ought to be conformable to the different constitutions of individuals. Those whose solids are relaxed and weak, should avoid all tough or viscid food, and such as is difficult to be digested. Their nutriment, however, ought to be substantial; and they should take frequent exercise in the open air. The plethoric, or those who abound with blood, cannot

more effectually consult their health, than by a sparing use of whatever is in a high degree nourishing, as fat meat, rich wines, strong ale, &c. Their aliment should consist chiefly of bread, or other vegetables, and their drink of water, whey or small beer.

Persons of a lean habit ought to follow a course directly opposite to that before suggested.—Those who are troubled with acidity, should live chiefly on solid meat; and those afflicted with hot alkaline eructations should principally use acid vegetables. Invalids subject to the gout, to low spirits, to hypochondriac, or hysteric disorders, should avoid all flatulent food, as also all salted, or smoke dried provisions, and whatever is difficult of digestion, or apt to turn sour and rancid on the stomach. Their food should be light, spare, cool, and of an opening nature.

Another important object to be considered, is the manner of life and age, together with the season and constitution. Those whose inclination, business, or profession lead them to a sedentary life, ought to be more sparing as to the quantity, and more attentive to the quality of their aliment, than others whose pursuits are widely different, or who are accustomed to take much exercise: the former ought particularly to avoid the use of every thing that is sour, flatulent, rancid, and oppressive to the digestive organs.

Persons liable to particular diseases, should be cautious in eating whatever tends to aggravate them. The gouty, for instance, should avoid drinking rich wines, strong soups, or acids.—Those who are subject to the gravel, ought to shun all austere and astringent aliments: nor should the scorbutic indulge in animal food.

The aliment in early life ought to be light, nourishing, and taken frequently, but in moderation; that of adults should be solid, and sufficiently tenacious; the diet proper for those advanced in life should resemble that of infancy.—At every period of life, gluttony ought to be sedulously avoided; for, not unlike too great abstinence, it destroys the powers of digestion; but the moderate repetitions of aliment is necessary for restoring the continual waste of the body.

Diet ought also to be regulated according to the different seasons of the year; because variations in the atmosphere produce corresponding changes in animal bodies. In consequence of the increased elasticity of the air, in the winter, the fibres are stronger, and better qualified for performing their various functions, and for digesting the stronger kinds of food. If there be no particular reason for the contrary, generous wines, and wholesome ale, together with warm broths and infusions, may be then taken, to promote the insensible perspiration, which is in some degree checked; as the cold air remarkably contracts the cutaneous pores. Some attention should also be paid to this circumstance, that the perspiration bear a due proportion to the liquid and solid nutriment consumed.

In the spring, the quantity of food ought to be somewhat diminished, and an additional allowance of the liquor usually drunk might be granted. In autumn, similar regulations are to be observed as in the spring; because the moisture and density of the air are nearly the same, and the weather is equally variable; so that perspiration is easily obstructed. During the summer, health may be most effectually preserved by vegetables and diluent liquors. Considerable care should be taken to abstain from provisions that are heavy and difficult to be digested, but especially from wine and brandy.

The feeble and convalescent ought to eat frequently, and but little at a time: the number of meals should be proportioned to the weakness of

their frame:—for it is far less hurtful to a debilitated person to eat a few mouthfuls every hour, than to make two or three hearty meals in one day: an exception, however, ought to be made with respect to those who are naturally of a delicate and irritable constitution.

ON CHILBLAINS.

Chilblain is a small tumour, or ulcer, in the hands, feet, heels, &c. It is occasioned either by exposing warm parts too suddenly to a cold temperature; or by holding the hands, or feet, when extremely cold, too precipitately to a considerable degree of heat. Such affections always have a great tendency to mortification, in which they frequently terminate.

Children of sanguine habits, and delicate constitutions, are most liable to chilblains: which may be prevented by such remedies as invigorate the system: by wearing flannel socks from the beginning of September to the latter part of spring, and occasionally taking gentle laxatives when they are disposed to become costive. All these precautions, however, will be attended with no benefit, if young people are suffered to repair to the fire immediately after coming from the most severe external cold.

In the commencement of this painful complaint, the cure is easy: immerse the part affected, several times a day, for a few minutes, into cold water, and guard against sudden vicissitudes of heat and cold, as either are equally hurtful. But, if simple water procure no speedy relief, dissolve an ounce of salt-petre in half a pint of vinegar and an equal quantity of water, and foment with it the part affected every night. When the tumours will not yield to these applications, and still remain in a swelled and painful state, without producing ulceration, a few drops of the pure tincture of benzoin may be rubbed occasionally on them; and the parts should be defended against the external air, by soft linen cloths; from this simple treatment, the best effects have been experienced.

THE TIGER AND ALLIGATOR.

An interesting Anecdote, related by the Captain of a Davenport Guineaman.

The bosom of the ocean was extremely tranquil, and the heat which was intolerable, had made us so languid, that almost a general wish overcome us, on the approach of the evening, to bathe in the waters of Congo—however, myself and Johnson were deterred from it, from the apprehension of sharks, many of which we had observed in the progress of our voyage, and these enormously large. At length, Campbell alone, who had been making too free with his liquor case, was obstinately bent on going overboard—and although we used every means in our power to persuade him to the contrary, dashed into the watery element, and had swam some distance from the vessel, when we on the deck, discovered an alligator making towards him from behind a rock that stood a short distance from the shore. His escape I now considered impossible, his destruction inevitable, and I applied to Johnson how we should act, who, like myself, affirmed the impossibility to save him, and instantly seized upon a loaded carbine, to shoot the poor fellow before he fell into the jaws of the monster. I did not, however, consent to this, but waited with horror, the tragedy we anticipated—yet, willing to do all in my power, I ordered the boat to be hoisted, and we fired two shot at the approaching alligator, but without effect, for they glided over his scaly covering like hailstones on a tiled penthouse, and the progress of the creature was by no means

impeded. The report of the piece and the noise of the blacks from the sloop soon made Campbell acquainted with his danger—he saw the creature making for him, and with all the strength and skill he was master of, made for the shore. And now the moment arrived in which a scene was exhibited beyond the power of my humble pen perfectly to describe. On approaching within a very short distance of some canes and shrubs that covered the bank, while closely pursued by the alligator, a fierce and ferocious tiger sprung towards him, at the instant the jaws of his first enemy were extended to devour him. At this awful moment, Campbell was preserved. The eager tiger by overleaping him, encountered the gripe of the amphibious monster.

A conflict then ensued—the water was covered with the blood of the tiger, whose efforts to tear the scaly covering of the alligator were unavailing, while the latter had also the advantage of keeping his adversary under water, by which the victory was presently obtained, for the tiger's death was now effected. They both sunk to the bottom, and we saw no more of the alligator. Campbell was recovered, and instantly conveyed on board; he spoke not while in the boat, though his danger had completely sobered him; but the moment he leaped on deck, fell on his knees and returned thanks to the Providence who had so protected him, and what is most singular, from that moment to the time I am writing, has never been seen the least intoxicated, nor has been heard to utter a single oath. If ever there was a perfectly reformed being in the universe, Campbell is the man.

Calligraphy.—M. Le Roi, of Paris, has contrived a new and very simple method for teaching the art of writing. A thin and perfectly transparent plate of horn, of the usual size of a leaf of paper, has the polish removed from one of its sides.—When laid upon the copy the hand of a child easily traces the letters upon the unpolished side, which neither absorbs the ink nor allows it to spread. When the whole plate is written over, the ink is washed off with water, and is ready for a new exercise. Thus the same horn, which is not liable to break, may serve indefinitely, and by this means produce a great economy of paper—a consideration not to be neglected. Several analogous methods have been adopted both in England and France. Oiled paper, glass, a machine for guiding the pupil's hand, &c. have been used, but it is evident that the method of M. Le Roi has none of their imperfections. The minister of the interior, who has witnessed the success obtained by this invention, has rewarded the author; and the societies of encouragement, and of elementary instruction, as well as the writing academy, have expressed their approbation of this new process. Mothers may teach their children to write in the absence of the master, or even dispense with his attendance, by the adoption of the horn.

PITTSBURG, Jan. 20.

Longevity of the Horse.—There is now employed at the Point Brewery in this city a horse whose age is at least thirty-one years. For the last fourteen years he has been in the possession of his present owner; and he is now as active and sprightly as most horses of seven years old. He has hauled within the last fourteen years, upwards of 49,980 barrels of beer and porter.

BLACKBERRY WINE.

Squeeze fifty pounds of blackberries, strain them, and add 25 lbs. of New Orleans, or clean white Havana sugar; put all into a ten gallon

keg, and fill it with water. As it works add water, keeping the cask full. Add three pints of good brandy. The keg, if new, must be soaked with well distilled apple whiskey, or French brandy.

YEAST.

To one gallon of water, add three pints of malt, and one quart of hops, boil to two quarts, and strain the liquor boiling hot, over as much wheat flour, as will make it of the consistence of thickened milk; and when almost cool, add half a pint of good yeast, when done working put it into a jug or stone pot, with about two quarts of cold water over it, and every time you use it pour off the water, and return fresh, when what yeast is wanted has been taken. It will keep good for two weeks.

The working will be done in two days, and the yeast is then fit for use, and may be put into a jug until wanted.

Sulphur a preservative against Measles.—During the winter of 1817, the measles prevailed epidemically at Munster. Children affected with the itch, who were using sulphur externally and internally, were exempt. In 1822, measles occurred again, preceded for many days by a convulsive cough. For this symptom, I prescribed flowers of sulphur and white sugar, half a teaspoonful. Many trials were made on children of different families and ages, and all who took it in time escaped the disease.—M. Tourtual.

Horace A. Hayden, Esq. of Baltimore, has discovered that the empyreumatic oil which comes over in the distillation of pyro ligneous acid is peculiarly valuable for preserving anatomical preparations. "Imbued with this oil, the animal textures seem entirely defended from all the changes of time." The acid is sold by the manufacturers for 25 cts. per gallon.

To make Opodeldoc.—This well known liniment is prepared by digesting three parts of soap in sixteen parts of the Spirits of Rosemary, till the former be dissolved, when one part of the Camphor should be incorporated with the whole.—This unguent is of great service in bruises, rheumatic affections and similar painful complaints; but being very volatile, it ought to be kept in bottles closely stopped, to prevent the access of air.

To clear Iron from rust.

Pound some glass to fine powder, and having nailed some strong linen or woollen cloth upon a board, lay upon it a strong coat of gum water, and sift thereon some of your powdered glass, and let it dry; repeat this operation three times, and when the last covering of powdered glass is dry, you may easily rub off the rust from iron utensils, with the cloth thus prepared.

To take Mildew out of Linen.

Take soap, and rub it well; then scrape some fine chalk, and rub that also in the linen; lay it on the grass; as it dries wet it a little, and it will come out at twice doing.

Proper Method of making Toast and Water, and the Advantages resulting therefrom.

Take a slice of fine and stale loaf bread, cut very thin, (as thin as toast is ever cut) and let it be carefully toasted on both sides, until it be completely browned all over, but no wise blackened or burned in any way. Put this into a common deep stone or china jug, and pour over it, from the tea kettle, as much clean boiling water as you wish to make into drink. Much depends

in the water being actually in a boiling state.—Cover the jug with a saucer or plate, and let the drink cool until it be quite cold; it is then fit to be used: the fresher it is made the better, and of course the more agreeable. The above will be found a pleasant, light, and highly diuretic drink. It is peculiarly grateful to the stomach, and excellent for carrying off the effects of any excess in drinking. It is also a most excellent drink at meals, and may be used in the summer time, if more agreeable to the drinker.

Method of preserving Fruit fresh all the year.

Take of salt petre one pound, of bole armenic two pounds, of common sand, well freed from its earthy parts, four pounds, and mix all together. After this, let the fruit be gathered with the hand before it be thorough ripe, each fruit being handled only by the stalk; lay them regularly, and in order, in a large wide mouthed glass vessel; then cover the top of the glass with an oiled paper, and carrying it into a dry place, set it in a box filled all round, to about four inches thickness, with the aforesaid preparations, so that no part of the glass vessel shall appear, being in a manner buried in the prepared nitre; and at the end of a year such fruits may be taken out, as beautiful as when they were first put in.

To the Honorable the Senate and House of Representatives of the United States in Congress assembled.

**THE MEMORIAL OF THE SUBSCRIBERS,
FARMERS OF THE STATE OF PENNSYLVANIA,
Respectfully sheweth,**

That your Memorialists, wholly cultivators of the soil, and no otherwise concerned in Manufactures, than in their own families, are firmly persuaded that the solid interests of the nation require, that an efficient protection be afforded to the manufacturing portion of our fellow citizens, who, with few exceptions, have been greatly depressed ever since the return of peace.

The depression of Manufactures has had the effect to injure agriculture, in a two-fold point of view:—

1st. From the close of the late war it has driven thousands of manufacturers and artizans, natives as well as emigrants, to agriculture, thus depriving the farmers of a considerable portion of the domestic market for the necessaries of life, which those classes afford: and moreover converting customers into rivals, by the surplus produce, beyond their own consumption, created by those persons thus deprived of employment at their usual occupations, and compelled to resort for support to the cultivation of the soil—thereby perniciously increasing that glut in foreign markets, to which may be fairly traced nearly the whole of the complicated distresses experienced by the farming interest in the middle states, in past years, particularly in 1820 and 1821.

2dly. The want of sufficient protection of Manufactures, greatly impairs the market for raw materials, hemp, flax, iron, hides, skins, &c. for which, at present, the demand is languid, and in many cases the price hardly adequate to the remuneration of the producer.

The idea, which, in common with the majority of our agricultural brethren, we long entertained of the advantages resulting from purchasing goods abroad, because they can be had cheaper than at home, has been proved by experience, to be ruinously fallacious. The saving, supposing a saving really to be made, of a few dollars, in the expense of clothing and other manufactured articles, is but a poor compensation for the great diminution of the domestic market for raw ma-

terials—and for the loss of a quarter or half a dollar in the price of a bushel of wheat, and in that proportion in other agricultural productions.—which diminution and loss are necessary results of that policy which so essentially and inevitably impairs the domestic market for those productions. But experience, which is an incomparably safer guide than theory, abundantly proves, that even the poor saving, which has been so speciously held out to induce the agriculturists to oppose any further protection of manufactures, has no existence. Of this position the event of the high duties imposed on coarse cotton goods, removes all possibility of doubt—as the American markets have been steadily supplied for years with those articles very far superior to the imported, and at a much lower rate than we formerly had to pay for the worthless foreign article for which they are a substitute. It therefore clearly appears that high duties in this instance, so far from proving injurious to the agricultural interest, have conferred on it a solid and substantial benefit; thus proving the utter fallacy of dogmas hitherto received by the mass of our citizens with the most implicit confidence. And there is every reason to believe, that the same results would follow the adoption of a similar course of proceeding in the case of woollen, iron, and other manufactures. If it were necessary to adduce foreign facts and experience to prove this effect of domestic competition, both would be amply found in the case of Great Britain, which excludes, by duties nearly tantamount to prohibitions, almost all foreign manufactures, and is yet enabled to undersell in manufactured goods in their own markets those nations which do not protect the industry of their people by adequate duties.

Whatever plausible arguments might be found for the refusal to afford adequate protection to manufactures, during the wars of the French Revolution, when we had abundant markets for all our agricultural productions, are totally inapplicable to our present situation, in consequence of the exclusion of our bread-stuffs, from nearly all the ports in Europe, unless when the failure of crops produces a danger of famine. Thus those nations from which we receive such immense amounts of manufactured articles, refuse to receive the chief, indeed almost the only important productions with which nature enables the inhabitants of the middle states to pay for them. We might therefore, as we have done in the case of our tonnage, without impropriety, reciprocate prohibition by prohibition. But this is not called for. Such an increase of duty, as would prevent our manufacturers from being overwhelmed in our own markets by their foreign rivals, would be sufficient for the purpose.

The pernicious effect of the above exclusion is palpable from the reduction in the amount and value of the flour exported from the United States lately, as follows:—

	Quantity.	Amount.
	Barrels.	Dollars.
Aver. of 1811, 12, 13	1,383,149	13,980,000
1816, 17, 18	1,121,982	12,346,774
1821, 22, 23	879,743	4,819,506

Thus it incontestibly appears, that the fortunes and prosperity of those of our fellow citizens engaged in the first and most important of all human pursuits, the raising of grain and other necessaries of life, are held by the precarious tenure of the seasons in Europe. If they are adverse, farming may be prosperous in the United States; but if otherwise, our hopes of a fair re-

muneration for our labours are blighted and withered. This servile dependence on the state of the European markets—is, we respectfully submit—unworthy of an enlightened age, and an independent nation, blest with such transcendent advantages as heaven has lavished on the United States.—Such a state of things is destructive of the vital interests of above two-fifths of the white population of the Union, depending chiefly on farming; and on every principle of justice calls loudly on the national representatives for a prompt and decisive remedy.

The protection of that important portion of industry employed in manufactures, at all times a sound and necessary policy, and supported by the opinions of the wisest statesmen, and the example of the most prosperous nations, has become at present an imperious duty—the foreign demand for our staples having, as above stated, considerably decreased; the quantity about one-third; and the amount nearly two-thirds; since 1811, notwithstanding the increase of our population in the intervening period.—Whereas our demands for manufactured goods must increase with our increasing population. We in consequence buy more from, than we sell to, foreign nations; and this, with nations, is as unerringly the road to ruin, as it is with respect to individuals.

Were there any doubt on the important subject thus respectfully presented to your view, it would be removed by a comparison of any two tracts of our country, in one of which manufactures are carried on extensively—and in the other agricultural pursuits chiefly or wholly, particularly when remote from the advantages of sea-port towns, as is the case with one-half of our territories. In the one, agriculture and horticulture, certain of steady and increasing markets, are carried on with life and spirit—lands are rising in price—every thing flourishes—and, what is of incalculable importance to the farmers, their females and children find valuable employment in and from the factories, for fragments of time which would otherwise be wholly lost. Habits of industry are thus acquired and rewarded—and public and private prosperity promoted. Whereas, in parts of the country destitute of manufacturing establishments, circulation is either arrested, or moves with a sluggish pace—money is rare and difficult to be procured—there are no markets for horticultural articles—lands are of little comparative value—in a word, every thing languishes. To exemplify this position, and to place it beyond the power of contradiction, it is sufficient to refer to the neighbourhood of Providence and Wilmington, on the one hand, and numerous districts in the interior of Pennsylvania and in the fertile districts of Kentucky and Tennessee on the other. The difference of soil, and some other natural advantages, is greatly in favor of the latter. But the contrast in prosperity is immensely in favor of the former—and the inference in support of the system we advocate irresistible.

We therefore respectfully request you will adopt such a modification of the existing tariff, as may afford complete protection to the manufactures of our common country.

December 15, 1823.

CASHMERE GOATS.

These valuable animals will doubtless soon be introduced into our own country. The Massachusetts Agricultural Society some time since, offered "the sum of one hundred dollars to the person who should introduce into Massachusetts from Europe, a male and female goat of the pure Cashmere breed." From a letter published in

th. Massachusetts Agricultural Repository for January 1824, from John Wells, Esq. in Paris, it appears that these animals have been successfully introduced into France; that the price of them are from \$15 to \$75 a piece, and that the duty on their exportation is only about four cents. The original stock from which France is now supplied was procured with much labour and expense, by Messrs. Ternaux and Jaubert, from the foot of Mount Caucasus, in Asia: out of 1,229 goats with which they set out, only 460 reached home alive. It is from the *down or wool* of these animals, that those expensive articles, called *Cashmere shawls*, are made. The down is procured from them in the month of April by combing them with fine combs.

THE LAKE COUNTRY.

The following is an extract of a letter from a citizen of Crawford County to his friend in Harrisburg; and shows that the direction of trade has been turned from New Orleans to New York; that, in consequence of the forward state of the New York Canal, wheat has rose near 100 per cent in value there, and at Erie, more than 100 per cent.

Extract, dated February 1, 1824.

"In this county we begin to feel the effects of the New York Canal. Wheat is just passing the door that is to go to that canal:—they pay 75 cents a bushel for it—and I understand there are merchants on from Buffalo at Erie, purchasing all they can get, and giving one dollar per bushel. This augurs well for us. Our lands will rise in value and settlements on vacant lands will become more rapid."

THE FARMER.

BALTIMORE, FRIDAY, MARCH 5, 1824.

MEETING OF THE TRUSTEES OF THE MARYLAND AGRICULTURAL SOCIETY.

The last meeting of the trustees was at the residence of Richard Caton, Esq.—The members were nearly all present, hearty and zealous in the good cause. Good temper gave zest to good cheer. The list of premiums was not fully decided on, because it was not then anticipated, that the legislature of the state, would, in their wisdom, for it is said, that "in a multitude of counsel there is wisdom," deem our institution unworthy of pecuniary patronage. They have, however, given us a naked act of incorporation, and as to a donation, we must hope for better things in bet-

ter times; we are not to wonder at the result in this case, when some of the delegates from the very country, in which our exhibitions have been held, and who ought to be sensible of the utility of our institution, if it possess any, voted against us!—The delegates from Talbot county, in which the Eastern Shore exhibitions are held, seem to have taken a different view of their duty; they saw on the ground, at their first and only exhibition yet held, more than three hundred travelling vehicles of different kinds, and probably concluded, that an institution, which brings together, for friendly intercourse, and mutual interchange of opinion and experience, such a concourse of intelligent agriculturists, could not fail to be useful in many important respects to that neglected class of citizens, and even as worthy of legislative encouragement, as Penitentiaries, Medical Colleges, &c. and many other establishments, which have attracted the favour of the state—for the present, however, we must lay this question on the shelf, but we shall take it down again.

The next meeting of the trustees will be held on Wednesday next, at the residence of B. W. Hall, Esq. at 12 o'clock, when arrangements will be made for the next exhibition—a punctual attendance of all the members, at the hour, is earnestly expected. At the meeting at Mr. Caton's, a resolution was passed, which made it the duty of the corresponding secretary, to request each one of the trustees, to make return on Wednesday next, of the amount of his subscriptions, and to express to each, the hope of the Board, that they would come, with not less than ten names on their list.

We are apprehensive, that some gentlemen, whose good wishes for the society cannot be doubted, may not have taken the necessary pains to accomplish, in this important concern, what cannot be done, without a little activity and earnestness. Why is it that one shall get twenty subscribers, and another with equal means, get none at all? The fact is, that in the various concerns of this life we are too apt to postpone our duties, "time enough," is the bane of useful enterprises. Let us remember, that "one to-day, is worth two to-morrows," as poor Richard says, give me your *doers of the work*, "the cat in gloves catches no mice."

We could wish that other gentlemen who own domestic animals of improved and valuable blood, would comply, as Col. Powel has done, with our request to be furnished with the Pedigrees of their Stock, to be recorded in the Farmer.

There is as much difference in the various races of neat cattle, as of horses—and, who can sell a blooded horse, let his performance be what it may, unless he can trace his pedigree?—Pedigrees will not be kept, where no attention is paid to the stock itself, and where continued attention is not paid, permanently fine qualities cannot be established.

The bull Bishop, and one of the heifers by General, were purchased by Mr. Powel, upon whose farm, animals from this stock, as well as from his various cows, may be had at prices from \$100 to \$300.

There is in this number, more of the *politics of Agriculture* than we could have wished; but the moment is critical, and invites discussion.—The Tariff Bill pending in Congress, is of more vital importance to the whole agricultural community, than they seem to be aware of.—They are dispersed, with imperfect means of concert, slow to apprehend, and yet slower to move.

PRICES CURRENT—CORRECTED WEEKLY

Wheat flour, \$5 37½—Howard-street, do. \$4 62½—Best family do retail, \$7—Wheat, red, \$1 10—Corn, 35 cts.—Rye, 40 cts.—Oats, 28 to 30 cts.—Whiskey, 23 to 26—Butter, inspected, 10 to 15 cts.—Coal, Liverpool, bushel 40 to 45 cts.—Virginia, 28 cts.—Susquehanna, per ton \$6 50 to \$7—Rice, per cwt. \$3 75 to \$4—Beef, northern mess, per barrel \$10—Cargo, No. 1, \$8 to 8 50—do. No. 2, \$6—Baltimore prime, \$10—Bacon and hams, 10 to 11 cts.—Cotton, W. I. Island, 18 to 20 cts.—Louisiana, &c. 16 to 17 cts.—Georgia upland, 14 to 16 cts.—Alabama, 12 to 13 cts.—Candles, mould, 12 to 13 cts.—Dipt, 10 to 11 cts.—Spermaciti, 25—Feathers, live, 30 to 35 cts.—Fish, herrings, Susquehanna, \$2 75—Fall mackerel, No. 1, to 3, \$4 50 to \$7—Shad, trimmed, \$6 to 6 50—Flax seed, rough, per bushel, 70 to 75 cts.—cleaned, cask, \$8—Flax, per lb. 10 to 11 cts.—Hemp, Russia, \$1 75 ton.—Country dew rot, 7 cts. per lb.—do. water rot, 9 cts.—Hops, fresh, 35 cts. per lb.—Hides, dried, 15 to 19 cts. per lb.—Hog's lard, 12 cts. per lb.—Lime, per bushel, 30 to 33 cts.—Leather, soal, best, 24 to 27 cts. per lb.—do. Eastern tan, 18 to 20 cts.—Lumber, board measurement, cargo prices:—Of the following articles we give the yard prices.—Oak timber and scant \$1 to 1 25—Boards all sizes, \$1 50 to 2—Pine scantling, do. \$1 to 1 25—Boards 4-4, \$1 to 1 25—White do. 5-4, \$1 75 to 2 50—do. 4-4, \$1 15 to 1 30—do. cl. 4-4, \$1 80—Shingles, cyp 18 in.—\$3 to 3 50—Shingles, junip. 24 do. \$7 50 to 7 75—jun. com. \$3 50 to 5—Staves, W. O. pipe, \$40 to 45—do. hhd. \$25—do. bbl. \$15 to 17—R. O. bbl. \$15—do. hhd. \$17—Wool, fleece, merino full blood, 35 to 40 cts. per lb.—Cropped, 28 to 30 cts.—Common country, 20 to 30 cts.—Skinner, 35 to 40 cts.—Wheat assorted and cleaned, any of the above will obtain an advance of 15 to 20 cts.

Prices of Seed.—Orchard Grass per bushel, \$2 50—Lucerne, do. do. 50 cents—St. Foin, do. do. \$7—Red Clover, do. do. \$5 50—Timothy, do. do. \$4—Herds Grass, do. do. \$2—Millet, do. do. \$1—Mangel Wurtzel, do. do. \$1 50—Ruta Baga, do. do. \$1.

Retail prices of provision market—Beef, prime pieces, 10 cts.—Veal, 10 cts.—Mutton, 5 to 7 cts.—Turkeys, 75 cts. to 1—Geese, 50 to 56 cts.—Ducks, Canvasbacks, \$1 25 to 2—Red heads, 50 to 75 cts.—Chickens per pair, 50 to 62½ cts.—Eggs, 12½ cents—Butter, first quality, 20 to 31 cts.—Turnips, per bushel, 50 cts.—Potatoes, do. 50 cts.

SKINNER Editor, by JOSEPH ROBINSON, on the North West corner of Market and Bolvidere streets, Baltimore: where every description of Job and Printing is executed with neatness and despatch, and from a distance for PRINTING or BINDING, with proper directions promptly attended to, addressed to J. Robinson, Baltimore.

AGRICULTURE.

SINGULAR DISEASE OF CATTLE IN OHIO.

The following description of intensely painful and very singular disorders of cattle in Ohio, would be more valuable to our readers, if it were accompanied with a *prescription* for their cure—by making publick the symptoms, however, it may be, that remedies may be discovered.]—*Edit. Am. Far.*

TO THE EDITOR OF THE AMERICAN FARMER.

Marietta, Ohio, Feb. 12, 1824.

DEAR SIR,

Observing in a late number of your paper, some notices of a new and singular disease amongst neat cattle in Maryland and Kentucky, I am induced to transcribe from my note book, in account of what appears to me to have been a similar disease, which appeared amongst the cattle in this county, in the year 1813.

Should you think them of any value, you are at liberty to make them publick.

Very respectfully,

Your obedient servant,

S. P. HILDRETH.

About the 10th of September, A. D. 1813, Col. Joseph Barker, an intelligent and observing farmer, living near the big Muskingum river, seven miles from Marietta, noticed in one of his cows, an unusual propensity for rubbing her nose, and side of the head against every hard substance that came within her reach. He also noticed some slight twitchings in the muscles of her neck, which would draw her head a little to one side; she appeared to eat well, to drink, and was in other respects seemingly in health. In a few hours the inclination to scratch and rub the side of her face, and the angle of the lower jaw, increased to an alarming degree—the more she rubbed, the more the desire of rubbing appeared to increase. He also noticed a slight swelling along the course of the salivary duct, from the parotid gland, to where it passes into the mouth. This gland on the opposite side was also swelled, and the swelling spread along the neck, and over the side of the head. The hair and scarf skin, was in a few hours entirely rubbed off from the side of her neck and head; she appeared to be in the greatest agony, and in the course of 12 or 13 hours from the time he first noticed her illness she expired. For several hours previous to her death, she was unable to stand, but the desire of rubbing herself continued to the last, and the earth was all torn up in a circle, round where she lay, by her continual efforts in rubbing. The following day, another of his cows was attacked in a similar manner. He first noticed it by her sticking her nostrils with unusual eagerness; this was continued until the blood would follow each stroke of the tongue. The subsequent symptoms were similar to those in the first attacked, and she died in about the same time. After this one or two fine large steers were attacked, and several more cows, who all died in the same manner.

On the 17th September, I was at his house; a cow had been attacked but an hour or two before my arrival. She was licking her nostrils with great violence, and every 6 or 8 minutes had sudden twitches in the muscles of the neck; the side of her face had begun to swell, and particularly along the course of the principal salivary duct. His mode of treatment had been bleeding very copiously, in some of the cases, to the amount of two gallons, or thirty-two pounds—

cutting off the end of the tail, &c. By my advice burning with a red hot iron, just back of the horns, immediately over the spina medulla, or spinal marrow, as it leaves the head, was tried on this cow. The operation appeared to give the cow ease; and she would follow the burning iron with her head, with great eagerness. No sensible benefit appearing to arise from this operation, and the disease continuing to increase, the operation of trepaning was next tried, with the expectation that insects or worms, similar to those often found in the frontal sinuses of the heads of sheep, might be the cause of the disease, and in this way removed. Accordingly an incision was made in the skin, about midway between the eyes and horns, and two portions of the bone removed. The lower opening communicated with the frontal sinuses, and as no signs of worms could be discovered, another opening was made higher up, communicating with the brain. The dura mater, or membrane of the brain, appeared turgid, and on puncturing it, discharged a considerable quantity of bloody serum or water. The cow did not resist the operation, nor make much struggling at the incision in the skin. It did not, while I was by, appear to afford any relief. The blood drawn from them all has been unusually dark coloured. The flesh of this cow, was to my feeling, colder than when in health; the eyes dull and glassy, and the lids widely extended under the operation of rubbing or licking; which last operation is carried to such excess, as to produce the utmost distress, and make them bellow aloud.

The bowels of the diseased are in good order, and the viscera of the abdomen and chest, appear healthy, on examination after death. The weather previously to the appearance of the disease had been very sultry and dry; but the cattle diseased had fed in a pasture, well shaded with forest trees, and lying immediately on the bank of the Muskingum river, to which they had access at all times. One of the steers, after he was attacked went into the water and continued there until a short time before his death, being the greater part of a day. The disorder was not confined to this farm, but attacked several other cattle in the neighbourhood. In one instance, the itching commenced on one of the hind legs, near the hoof; and in another it began on her udder.

Amongst other remedies tried, were strong decoctions of jamestown weed, or stramonium; tobacco; and saltpetre, in doses of three or four ounces, with strong purges. But all without benefit—so far as I have heard, the disease has in every instance proved fatal. The following year, a few cases appeared in a distant part of the county; but since then, I have no knowledge of its existence in this part of the state. The disease appears to have been in some measure contagious, as there is one instance of a dog being attacked, who was known to have eaten of a cow recently dead with the complaint. In a few hours after he gave notice of his illness by his howling, and continually rubbing the top of his head. His master, a curious observing man, took a live coal from the fire, and placed immediately on the affected part—so far from complaining, he immediately ceased howling, and as long as it continued to burn, was apparently easy. However, in a few hours the dog died. From this circumstance, some idea may be formed of the intense suffering of the poor brutes, who were subjects of this very curious and singular disease.

I have often thought it was a fortunate thing for the illnatured and ugly old women, any where in the neighbourhood of this disease, that the belief in witchcraft has been banished from our

land, or I fear, that many a harmless old soul would have had this sin laid to her charge.

AGRICULTURAL SOCIETY OF BARNWELL DISTRICT, N C.

(INSERTED BY REQUEST OF THE SOCIETY.)

The *Farmer's Society* of Barnwell District, this day awarded the following *Premiums*, of twenty dollars, or a silver cup of that value.:

1st. To Orsamus D. Allen, for his Gallatin Mare, 3 years old.

2d. To William B. Bull, for his two year old bull—*Coeke*.

3d. To George O. Dom, Senr. for his year old bull.—*Lafayette*.

Also, *Premiums* of 15 dollars, or cups, of that value.

1st. To Wm. R. Bull, for the greatest quantity of Potatoes, from one acre, being 352 bushels and a half. Dr. Bellinger made from his acre 263 bushels and a half.

2d. To Wm. R. Bull, for his crop of Rice, from one acre, being 65 bushels and four quarts. This was an acre of pond land.

3d. To James D. Erwin, for the greatest quantity of Corn, from one acre of high land, being 86 bushels and 12 quarts. The first crop, was 69 bushels and one peck. The 2d crop planted the 20th of June, and measured in October, was 17 bushels and half a peck. Dr. Bellinger made from one acre of Gourd Seed Corn, 67 bushels, 3 pecks, and two quarts, of sound merchantable Corn, and one bushel and 15 quarts of unripe and rotten corn. The first crop was 57 bushels and 2 quarts of sound and merchantable corn, and 7 quarts of rotten corn. The 2d crop planted in June, and measured the 11th of December, was 10 bushels and 3 pecks of sound and dry corn, and 1 bushel and 1 peck of unripe and rotten corn. Dr. Bellinger also made from one acre of Flint corn, 63 bushels and 5 quarts of sound corn, and 2 bushels and 5 quarts of unripe and rotten corn. The first crop was 51 bushels, 3 pecks, and 3 quarts of sound corn, and 5 quarts of rotten corn. The 2d crop planted in June, and measured the 11th of December, made 11 bushels and 10 quarts of sound, dry and merchantable corn, and 2 bushels of unripe and rotten corn.

Samuel Ashley, made from one acre of high land, 24 bushels of wheat, 22 bushels of corn, and 6 bushels of pease, being 52 bushels of grain from the acre.

Also *Premiums* of Ten Dollars, or Cups of that value.

1st. To John Nimmons, for his two year old hog, "Don Quixotte," weighing 453 lbs.

2d. To Dr. Bellinger, for his year old female hog, "Bessie Bell," weighing 225 lbs. B. H. Brown's boar, do. 198 lbs. Do. do. young sow, do. 192 do.

To Wm. R. Bull for the greatest crop of pease, reported to the society, from one acre, being six bushels, and one peck of sound dry and merchantable pease.

4th. To Wm. R. Bull, for his 3rd blooded Merino ram, "Col. Humphreys."

A *Premium* of Five Dollars, was awarded to Samuel Ashley, for his specimen of Homespun, of Cotton Warp, and Wool Filling; Mrs. Thurston was presented with Three Dollars, for a piece of Homespun of Cotton Warp, and Wool Filling, which she submitted to the inspection of the Society, F. J. Hay, reported to the Society, having obtained the last season, from three quarters of

an acre of high land, planted with Alabama Cotton Seed, 1234 lbs. of Seed Cotton.

JENNINGS O'BANNON, *Secretary.*
Of the Farmer's Society, of Barnwell District.
Barnwell Court-House, 19th of Jan. 1824.

A list of Premiums to be distributed at the next Exhibition, will be inserted in our next.

Edit. Am. Far.

ON ORCHARD GRASS.

TO THE EDITOR OF THE AMERICAN FARMER.

Brookville, Montgomery Co. Md.

DEAR SIR,

As I conceive I have received valuable information, very frequently, from perusing your excellent work, without ever offering for the consideration of its numerous readers, a single hint, suggested by my own observation, I was led to consider, that I could not have benefitted in this way so much, had others done as I have. Now this reflection has been an inducement to me, to state for information, that I have been in the practice of sowing orchard grass seed liberally, for about six years, during which time my observations have led to the following conclusions, to wit—that it will afford more pasture upon ground, in a moderate state of improvement, than any other grass I am acquainted with, which perhaps, is in part owing to the blades continuing to grow on, after being bitten off, without having to shoot out again from the root, as other upland grasses do. That it is not liable to be thrown out by the frost, but continues to thicken from year to year, so as to form an excellent sward. That a farmer who will save his own seed, can supply his farm with it, at a less expense, or with less labour, than with any other I have ever known.

That upon good land, it will give a good crop of hay, (and I don't know of any grass that will upon poor land,) and that during the three last summers, I have had, I think, a fair opportunity of observing the most conclusive evidence of its being much less liable to cause the slavering distemper in either horses, kine, or hogs, having at the season, when that prevails, repeatedly turned my stock, from grounds affording a good supply of clover, timothy, and the natural grasses of the country, and where they were falling off daily, into a field of orchard grass, and in a few hours, the disease would be arrested, and very soon a manifest improvement take place in their condition. And this to the no small surprise of a neighbour, who at such times, particularly during the late summer and autumn, had no other resort, but to feed his horses on grain, every day, even when idle.

Without any other interest than that, which every friend to agricultural pursuits must feel, I have been induced to offer the above remarks, on this most valuable grass, founded on actual experience; and thus, to throw my mite of information, into the public stock.

AMOR PATRIÆ.

From Radcliff's Agriculture of Flanders.
FORCE OF WORK HORSES AND MAN-
NER OF FEEDING.

Eight horses perform the entire work of the 200 acres, and are in the highest possible condition. They are of the most compact kind of Flemish horse, and do not exceed 15½ hands in height; chiefly roan and chesnut in color. As the banks of the river supply good hay, in this district they are indulged with that species of

food, which is not the case in other parts of Flanders; but they are also fed upon straw, chiefly of rye, and upon oats with chopped straw in every feed, and after every feed, a bucket of water, richly whitened with rye, or oatmeal. A vessel of this composition is in every stable; nor are the horses suffered to have any other drink. The quantum of food in the 24 hours for each horse, in winter, is 15 lb. of hay, 10 lb. of sweet straw, and 8 lb. of oats; in summer, clover is substituted for hay; the other feeding remains the same; and the white water is never omitted: on this they place a chief reliance. The allowance of oats is but moderate, and yet the horses are in superior condition: the chopped straw contributes much to this, in converting by the mastication necessary, every grain of corn to nutriment. The use of it is so universally approved throughout Flanders, that in every town it is sold by retail, and if generally adopted with us, it could not fail to improve the condition of the working horses, and lessen the expense of their provender.

In Flanders, a farmer will work fifty acres with two horses; and by the regularity of his care and keep, will preserve their condition. In Ireland, the great wheat farmer of Fingal, upon a similar extent, will keep four times the number, fed more expensively, but not so judiciously, always over-worked and always poor. Some of these farmers, upon 100 acres, keep sixteen horses in their employ, and there have been instances of three-fourths of that number being lost within the year by hardship and disease. By these means the profits of a farm are consumed without benefit to the farmer; and what would reasonably support and enrich him, is squandered upon supernumerary horses. This special circumstance not the high rent, keeps the tenant in indigence and difficulty. If landlords interfered to procure for their tenantry a good description of working horse, and encourage them to use him properly, and feed him well, it would tend more to their advantage than any abatement they can give. Upon the farm of Vollandre, the management was in all points, to be approved: economy prevailed in every respect, except in the application of manure; the occupier was in comfort and affluence, and yet his rent was near 40s. by the plantation acre, and his taxes triple those of the Irish farmer. The difference is to be found in established system, skilful management, and unceasing industry.

Upon the farm of which we have been speaking, all the crops yield a great return—too much so to be stated as the average of a district; the succession, however, is pretty generally the same.

The answers of Mr. Van de Poes, President of the Commission of Agriculture in South Holland, to questions of the Right Honourable Sir John Sinclair, Bart. Respecting the Dairy of Mr. Van de Poes.

Q. 1st. The number of cows?

A. Sixty-four of all ages.

Q. 2d, How is the milk disposed of? in making butter? or cheese? or feeding veal?

A. The total produce of the milk is sold wholesale, and being carried to the Hague in copper vessels, immediately after the cows are milked, is retailed there by the purchasers.

Q. 3d. What is the most profitable management?

A. For those within reach of great towns, the most profitable mode is to sell the milk;—but for those at a distance, the making of butter and cheese is more productive.

Q. 4th, What quantity of milk is given by one

cow, by the day, the week, the month, the year, upon an average of twenty cows?

A. Forty cows well fed, and well taken care of, may give from 200 to 250 pints of milk* by the day, during the entire year.

According to the calculation of the Commission of Agriculture of the Province of South Holland, one good cow produces 78 lbs. of butter, and 180 lbs. of cheese, in the six summer months.

Q. 5th. How are the cows fed in summer and in winter?

A. In summer they feed in the pastures day and night: in winter, they are fed with hay, turnips, carrots, grains from the breweries, cakes of linseed, bean-meal, &c. &c.

Q. 6th. What is the best age for a bull, and why?

A. A bull well kept, well fed from a calf, and of good blood, is fit to serve cows generally at one and a half, or two years old; and this is considered the best age, as those more advanced are heavy and wicked. The cow served by an aged bull is more likely to miss being in calf; and if impregnated, is more liable to suffer inconvenience with respect to the fetus.

Q. 7th. At what age are the bulls sold or dismissed?

A. At the age of two, or two and a half years, they are replaced by younger bulls.

Q. 8th. Is it an advantage that the tails of cows should be tied by a chord, and raised high up, and why?

A. Cleanliness requires that their tails should be fixed in this manner, otherwise they acquire dirt, and communicate it to the milkers.

Q. 9th. How is the butter made? with the entire milk, or only with the cream?—Is it sometimes saved with sugar and saltpetre?—Is it washed?—How is the butter-milk consumed?

A. In the greatest part of Holland, they make butter of the cream only: they wash it very much, and save it with salt. There is a great demand for butter-milk—what is not sold, serves to fatten pigs, and to feed calves.

Of the skimmed-milk, they make cheese with a material called *Komyde Kaas*. In some parts of Holland, where less butter is made, they make a rich cheese with the entire milk.

Here terminate the answers of Mr. Van de Poes, which relate to the dairy. In the Island of Cadsand, a gentleman very willing to communicate, but not versed in that kind of information, mentioned generally, his having remarked, that in the dairying districts, the best kept cow-stables, were strictly attended to in point of cleanliness and temperature. He spoke of having drank coffee with the cow-keeper in the general stable, in winter without the annoyance of cold, of dirt, or any offensive smell.

In Flanders, they preserve in their cow-stables the temperature of the month of May.

In Mr. Roper's well-conducted establishment, in Ireland, consisting of nearly two hundred cows, the thermometer is kept at sixty degrees, and it is considered, that any variation from that temperature tends to reduce the quantity of milk.

The Reporter regrets extremely, that he had not the opportunity of detailing from personal inspection, the practice of the chief dairies in Holland.

* This, on an average of the Flemish pints, of different districts, would be 121 quarts English per day, which, from forty cows, would be but about three quarts from each cow. This, even for the year round, seems but a trifling produce. The reporter is not aware whether there is any difference between the pint of Flanders and that of the Hague.

ON THE PLANTING AND CULTIVATION OF ORCHARDS.

From that valuable work, COXE on Fruit Trees.

The first thing to be determined upon in the planting of an orchard, is the proper distance of the trees: if a mere fruit plantation be the object, the distance may be small—if the cultivation of grain and grass be in view, the space between the trees must be wider: at thirty feet apart, an acre will contain forty-eight trees; at thirty-five feet, thirty-five trees; at forty feet, twenty-seven trees; and at fifty feet, about eighteen to the acre—these are the usual distances. In my own plantations, I have adopted the various distances according to the depth and character of the soil; about two thirds of the ground, comprising about one hundred acres, are planted at 50 feet; on the remaining fifty acres, I have tried 30, 35, and 40 feet; and as far as could be conveniently done, I have planted the trees of smallest growth on the lightest soil: taking every circumstance into consideration, it will probably be found, that forty feet is the most eligible distance for a farm orchard.—It will admit sufficient sun and air, in our dry and warm climate; and until the trees shall be fully grown, will allow of a profitable application of the ground to the cultivation of grain and grass.

Much trouble will be saved, and much accuracy in planting will be ensured, by marking the sites of trees by stakes, previous to digging holes. In shallow soils, I would recommend making the holes of the depth of two spits of earth, scattering the lower spit at some distance; and supplying its place by an equal quantity of the neighboring surface earth—the depth of the hole must depend upon that of the sub-soil.

An eligible mode, which I have practised with success in a large portion of my orchards, on the lighter soils, is to supply the place of the stratum of poor earth, by one or two loads of meadow mud, ditch banks, or good surface soil, laid round each tree after planting; ploughing the ground for a fallow crop the next spring, when the mud has become completely pulverised by the frost: the size of the hole should be sufficiently large to admit a spade handle, when laid horizontally in the bottom; affording ample space for the expansion of the roots in loose rich earth. Well digested compost is useful round newly planted trees, in stiff or cold soils—both lime and fresh stable manure, I have found prejudicial in the dry and hot weather of summer; the latter substance is also frequently a cover for moles and field mice, which are extremely injurious in winter, to trees of even six or eight years old in light soils. I have found great benefit from the application of every kind of manure on the surface, and mixing it gradually by cultivation with the soil, as the best security against drought in summer, and vermin in winter.

The proper season for planting, will be found to depend on a variety of circumstances—in light soils, the winter settles the earth round the roots, and best secures them against the drought of the following season—it is a time of leisure to the farmer, and affords an early selection of trees from the nursery. In stiff or wet soils, I should give a preference to spring planting, other circumstances being equal—I have planted at both seasons, and have generally found that care and attention ensured a correspondent success in the growth of my trees. In whatever season an orchard may be planted, too much attention cannot be given to extend the roots in every direction; to cut off all wounded parts, and more especially, not to plant too deep; this I believe is the common error of inexperienced planters: as a general rule, I would recommend that the tree be placed in the orchard with about three inches

of earth over the upper tier of roots, which will make it about two inches deeper than it stood in the nursery; that the tree, after being partially covered, should be well shaken, to admit the finer particles of the earth among the fibrous roots, and that it be well settled by treading the earth around it—with these precautions, I have never found the necessity of stakes. The tops of young trees should never be shortened, lest it should produce a growth of suckers: I would recommend in preference, that they be thinned, if found too heavy: if the trees have been long out of the ground, and the roots have become shrivelled at the time of planting, the labor of pouring a pail full of water round each tree, will be amply repaid in the success it will ensure in their growth.

The looser the ground is kept for the first, and indeed for several succeeding years, the more certain and more vigorous will be the growth of the orchard—in the luxuriance and color of the foliage of contiguous plantations, I have found every stage of cultivation strongly marked: those orchards which have been two years under cultivation, exhibit a striking superiority over those which have been but one year under the plough; while these, in their turn, surpass the fields in clover or in grain, both in the quantity and size of the fruit: when clover is sown in young orchards, I have been in the habit of digging the earth for about three feet, at the root of each tree: A man will dig round one hundred trees in a day; the trifling loss of grass and labor, will be fully remunerated by the improved vigor of the tree. When the ground can be spared from cropping, four or five furrows on each side of a row, will be found a most eligible mode of promoting the growth of a young orchard.

All fallow crops are most favorable to the growth of orchards, at every early stage of their cultivation—indian corn, potatoes and vines, are preferable to oats or barley; and these again are more favorable than winter grain: Buckwheat is among the most beneficial crops for the promotion of the autumnal growth of trees—Clover is by many farmers believed to be injurious to young trees; its tendency to check the growth of trees will be found, I believe, to be in proportion to the air and moisture which its greater or less vigorous growth may keep from the roots; light and heat, appear as necessary to the roots, as to the branches of trees—clover, while it occupies the ground, must prevent cultivation; so far I apprehend it will be found pernicious, but probably not in a greater degree than any other luxuriant and deeply rooted species of grass, absorbing the moisture, and exhausting the strength of the soil which covers the roots of small trees. In the arrangement of an orchard, both convenience and beauty will result from planting each kind in distinct contiguous rows. Some cultivators pay particular attention to continue in the orchard the aspect the tree maintained in the nursery: I have sometimes adopted the practice, without much confidence in its efficacy; nor can I think it probable, that trees growing in close rows, not much exposed, in the nursery, can by any habit so limited in its duration, be affected by any permanent contraction or rigidity of the bark, or sap vessels, which are the only effects I have ever heard ascribed to the influence of aspect, on the stems of young trees.

The prevalent winds of our climate, are from the north-west: in light soils, their violence will sometimes give an inclination to newly planted trees to the south-east: this may easily be remedied by setting up the trees while young; and when they have attained a large growth, it may be overcome in a great degree, by cutting off the

leaning branches, and by freely pruning the leeward side of the tree.

Moss is a plant produced by poverty and neglect; it is very prejudicial to trees, and should be carefully removed: this can be readily done, by rubbing the trees in damp weather with a bone, or the back of a knife; good cultivation will generally prevent the growth of moss—white-washing* the stem, not only cleanses the tree of moss, but destroys many kinds of lice very injurious to fruit trees; it is followed by a cleanliness in the bark after it has been dissolved by rain, and promotes the health and vigor of the tree whenever applied.

* For reasons against this, and in favour of soap-washing, see American Farmer, No. 50.

Edit. Am. Far.

FROM THE EDINBURGH FARMER'S MAGAZINE.

Experiments in Reaping Barley at different Stages in its progress towards Ripeness.

Some observations lately circulated by Sir John Sinclair, regarding the stage at which it is proper to apply the sickle to corn crops, led to an experiment, of which the following is a detail. As it was conducted on a minute scale, it may not be regarded as very conclusive; but considerable pains were taken in endeavouring to equalise the criteria; and such an experiment, perhaps, affords facilities for this which an extensive one might not command, as a slight difference either in the quality of soil, in the preparation of land, or in other obvious circumstances in an experiment on a large scale, might occasion error greater in the one case than what is likely to attend the other.

A particular spot in a field of barley having been selected for the trial, 24 stalks of grain, all as nearly as possible of the same size and state of advancement, were cut close by the ground at different periods; and each parcel, being tied up and labelled, was suspended in a room. The following are the dates of reaping, and the appearances of the plants when cut.

August 11th.—1st, 24 stalks.—The ear pretty well filled, but soft and quite green. The stem and hose also green, and the leaves very partially decayed.

August 18th.—2d, 24 Stalks.—The ear full and plump, but still green, and the grain soft and pulpy, so that it separated from the husk on a slight pressure between the finger and thumb. The stem quite green. The hose withered on the lower joint, but green on the upper. The leaves almost withered.

August 25th.—3d, 24 Stalks.—The ear firm, and with its awns beginning to assume a yellowish hue. The grain doughy, and no longer to be separated from the husk by pressure of the fingers. The lower part of the stems turning to straw color; the upper part still green, or very little changed. The upper part of the hose, on the side towards the sun, changed to straw color. The leaves quite withered.

September 1st.—4th, 24 Stalks.—Awns quite withered. Ear straw color, with a remaining tinge of green. The hose faded, except on the upper joint, where it is still somewhat green. The stem quick, but yellowish at the foot, and, immediately below the ear, nearly changed to straw color. The grain still soft and doughy.

September 6th.—5th, 24 Stalks.—A slight tinge of green remaining on the ear. Part of the hose still quick. The stem also quick, but immediately below the ear, entirely changed to straw color. The grain still soft, and easily crushed between the finger and thumb.

September 11th.—6th, 24 Stalks.—Awns, ear, stem and hose, completely straw color. Grain still soft; but the field, on the whole, in the state of ripeness commonly esteemed sufficient; and accordingly it was this day begun to be reaped.

On the 10th of October, by which time the parcels were properly dried, the grain was carefully rubbed out, and subjected to an operation equivalent to a complete winnowing, each parcel being still kept separate from the others.

The produce of No. 1. was found shrivelled and imperfect, and that of No. 2. little, if at all, superior to what is usually dressed from good grain by the fanner. With regard to these two parcels, it is obvious they were cut when, with a view to weight of grain, reaping would be improper. It is presumable, from their appearance, that they would both vegetate; and it may be desirable to ascertain whether barley, reaped in the state of either of these parcels, might safely be used as seed; because, if so, an evident advantage would arise from the additional value, which the consequent preservation of its juices would give to the straw, while perhaps, as seed, the grain might go as far as when perfectly ripened.

The produce of No. 3. was also defective, being what is termed hungry, and containing a large proportion of light grain; but it was not, upon the whole, of a quality, which would be considered unmarketable.

Nos. 4. and 5. had the appearance of maturity, but contained more light grain than No. 6.; from which it may be inferred, that a crop reaped in the state in which they were, would not, *ceteris paribus*, prove as productive as one reaped in the state of No. 6., although it may deserve to be considered, whether, in a late and precarious season, the benefit is equal to the risk of delay in reaping, after the crop has arrived at the state of No. 5.

The six parcels were subjected to various tests, by measure and weight, with a view of determining their comparative value; and the results appeared to warrant the following statement of their relative proportions.

No. 1. being as 40
No. 2. was as 59
No. 3. — as 77
No. 4. — as 81
No. 5. — as 89
No. 6. — as 95

A greater difference, it will be observed, is noted between No. 5. and 6., than occurs, in a similar space of time, between No. 4 and No. 5; and this may be attributed, partly to an improvement in the weather, which had become more favorable for a week before No. 6. was reaped, than it had been previously, and partly to the accelerated progress towards maturity which it is supposed crops acquire in the latter stage of ripening. It appeared, also, that although No. 6. was proportionally heavier, upon the whole, than No. 5., yet this parcel contained a considerable portion of grains equal to the best in No. 6.; so that the superiority of the latter seemed to have proceeded entirely from the improvement of the lighter grains in the period between the 6th and the 11th of the month. If, in that period, high winds, or weather otherwise unfavorable, had ensued, the consequence might have been, to turn the scale in favor of No. 5., and to afford an instance of the danger of delay in reaping, after the more valuable part of the crop has attained maturity.

Stonehaven, October, 1823.

PHILOSOPHY OF ZOOLOGY.

FOOD OF ANIMALS.

Although temperature appears to exercise a very powerful controul over the geographical distribution of animals, yet is likewise indispensably necessary that they be provided with an abundant supply of suitable food. When this supply is deficient in quantity, both the size and shape of the animals are altered. The frame becomes diminished in stature, its symmetry is marred, and its feebleness indicates the scantiness of its nourishment.

The dependence of the geographical distribution of animals on the supply of nourishment, is most conspicuously displayed in those species which are destined to feed on particular kinds of food. Thus many species of insects are restricted in their eating to one kind of plants, or are parasitical on one species of animal. The distribution of such animals is thus dependent on their food.

The same remark is generally applicable to carnivorous and phytivorous* animals. But, in many species, though the restriction is absolute as to the nature of the food, it admits of a considerable range with regard to the variety or kind. Thus, though the lion is restricted to flesh, his cravings are equally satisfied with the carcase of a horse, a cow, or even of man. The hog in general feeds on roots, but it is not confined to those of one kind of plants; hence it can subsist wherever the earth is clothed with verdure.

The seasons exercise a powerful influence on animals, directly, in reference to their temperature, and, indirectly, with regard to the production of their food. Thus, the insect that feeds on the leaves of a particular tree, can only enjoy its repast during that part of the season when this tree is in leaf. How, then, is life preserved during the remaining portion of the year? The resources are numerous. It either exists in the form of an unhatched egg, an inactive pupa, in the imago state, requiring little food, or actually becoming torpid.

The birds which feed on insects in summer, in this climate, are, from the absence of this kind of sustenance in winter, obliged to have recourse to various kinds of vegetable food during that season. Should this change of diet be unsuitable, migration to other districts, where a proper supply can be obtained, becomes indispensably requisite.

In compliance with these regulations, we observe numerous mammalia, birds, and fishes, accompany the shoals of herrings in their journeys; and the grampus and seal enter the mouths of rivers in pursuit of the salmon. The bats, which feed on insects in summer, could not, in this country, obtain a suitable supply of food. Yet the race is preserved, since the same fall of temperature, which is destructive to insect-life, brings on their winter-torpor.

With many quadrupeds, however, and even insects, especially the bee, where migration to more fertile districts is impracticable, and where torpidity is not congenial to the constitution, there is an instinctive disposition to be provident of futurity,—to subject themselves to much labor, during the autumn, when the bounties of nature are scattered so profusely, in heaping up a treasure for supplying the deficiencies of a winter, of whose accompanying privations, the young at least are ignorant. The quadrupeds which possess this storing inclination are all phytivorous, and belong to the natural tribe of gnawers.

Of all those animals, whose industry in collecting and wisdom in preserving a winter-store, have attracted the notice of mankind, the bea-

* Eaters of grass and vegetables.

ver stands pre eminently conspicuous. The number of individuals which unite, in cutting down timber to supply their storehouse, and the regularity with which they dispose of it, in order to make it serve the double purpose of food and shelter, are equally calculated to excite astonishment. But as we rather wish to confine our remarks to British animals, wherever the subject will permit, we select as an example of this kind of storing propensity, the common squirrel, (*Sciurus vulgaris*.) This active little animal prepares its winter-habitation among the large branches of an old tree. After making choice of the place where the timber is beginning to decay, and where a hollow may be easily formed, it scoops out with its teeth a suitable magazine. Into this storehouse, acorns, nuts, and other fruits, are industriously conveyed, and carefully concealed. This granary is held sacred until the inclemency of the weather has limited the range of its excursions, and consequently diminished its opportunities of procuring food. It then begins to enjoy the fruits of its industry, and to live contentedly in its elevated dwelling.

MAGNOLIA.—MAGNOLIA.

Natural order, *Coadunatae*. *Magnolia*, Juss.
A genus of the *Polyandria Polygynia* class.

[We have received for distribution, another supply of magnolia seed, from Mr. Rowand of Carolina. Our friends are to understand, that these are not seed of the common magnolia, to be found in swampy grounds in Maryland, that is the swamp magnolia, *glauca*, sometimes called swamp laurel, or swamp sassafras, a comparatively diminutive shrub, which seldom grows to the height of more than 15 or 20 feet; the magnolia *grandiflora*, is the one described below by Phillips, an English author, who has added so much to the stock of elegant literature, and botanical knowledge, by giving us, in the most entertaining form, the natural history of forest trees, culinary vegetables, shrubs, &c.]

Edit. Am. Far

— "Columbus shew'd
The western world to man."

If we except the general deluge and the origin of Christianity, the discovery of America may be considered the most important event that has been recorded since the creation of the world.—It has discovered to us an immense territory of land; a people whose habits and minds were new to us; it exhibited unknown animals, and afforded us vegetables no less novel than numerous. It has had the effect of a new creation; new wants have arisen, and new inventions have sprung up to gratify them.

"Then commerce brought into the public walk
The busy merchant; the big warehouse built;
Raised the strong crane; choaked up the loaded street
With foreign plenty; and thy stream O Thames
Large, gentle, deep, majestic, king of floods!
Chose for his grand resort."

Thomson.

The shrubs of the new world have been transplanted into our gardens, and the forest trees of America rear their heads in our woods; whilst, in return, we have planted colonies on the newly discovered shores, who have reared their national constitution and laws with such care, that it may probably be found thriving there in its purity when time and corruption shall have destroyed the parent trunk.

The magnolia grandiflora, or laurel leaved magnolia, is a native of that part of America which has been named Florida, from the beautiful plants with which it abounds; and when growing in its native soil, the magnolia is esteemed the most beautiful tree known; it reaches from 90 to 100 feet in height, and is clothed with an evergreen leaf of the most lucid colour on the upper surface, and of a russet tint beneath. The shape is nearly that of the common laurel leaf, but much larger; and being agreeably waved on the edge, it has not the heavy and stiff appearance of the laurel leaf, although the consistency is the same. It is sessile, and branched without order on every side of the branches. The flowers appear from June to September, during which time they perfume the air for a considerable distance round with the most agreeable odour, which at one moment reminds us of the jasmine or lily of the valley, and the next of the violet mixed with the apricot.

During the last summer we saw a fine tree of this description in the exotic gardens of M Bourseaue, Rue Mont Blanc, in Paris, which scented the whole of that elegant plantation.

We have also seen a most noble magnolia in the grounds of the Priory, near Ryde, in the Isle of Wight; and which, we were then told, often wafted its delightful fragrance to more than half a mile in distance. The flowers are produced at the ends of the branches, and are so large as to measure from seven to eight inches in diameter, and are composed of eight or ten petals, narrow at their base, but broad, rounded, and a little waved. They spread open like a tulip, and have the appearance of white kid leather more than of a vegetable substance. In its native country this tree begins to flower in May, and gives out a succession during the whole summer, so that the woods are constantly perfumed with its odour. The pencil can give but a faint idea of the splendour of this beautiful tree, which defies the pen altogether to describe its charms; its leaves are more glossy than those of the laurel and from nine to ten inches in length, and about three inches in breadth, with a softness on the underside, that gives great variety to the foliage. The young branches are of a fine purplish brown, and whence each spray, for a hundred feet in height, is holding up its petaled vase, as if to offer incense to the sun that nourishes its fruit, a mass of beauty is composed, that rivals the proudest work of man.

The fruit of the magnolia is seated in the flower in a manner similar to the strawberry, which afterwards becomes a strobile or cone, composed of many capsules, each of which, when perfect, contains two scarlet seeds. We are not aware that the fruit has ever matured its seed in this country, though we have seen some old plants that have formed strobiles of considerable size.

This splendid plant received the title of magnolia from Plumier, who so named it in honor of Pierre Magnol, prefect of the botanic garden at Montpellier, and author of several works on plants.

Sir John Colliton is thought to have reared the first plant of this kind in England, at Exmouth, in Devonshire, some time prior to 1737. It was unknown to Mr. Miller, in 1724, when he published the first edition of his Gardener's and Florist's Dictionary; but in a later edition, he mentions that there were a great many plants in England before the year 1739, but the severe winter of that year destroyed most of the young ones. He also tells us, that he had a pretty large plant which was apparently killed by the severe winter of 1739 40, but that he cut it down after Midsummer, and that it shot up again the

year following. We notice this circumstance more particularly, because in case of similar accidents, gardeners may not be too hasty in grubbing up the roots. The magnolia is generally injured most by the early frost, as the extremities of the young shoots are then tender.

His Grace the Duke of Richmond has two of the finest standard magnolia grandiflora trees in this country, at his seat at Goodwood in Sussex, one of which at six inches from the ground, girths three feet one inch, and at four feet from the ground, two feet five inches; at about five feet from the earth it divides into branches, forming a very beautiful head about twenty-three feet in height. The other is thirty-five feet in height, and measures four feet in circumference at fourteen inches from the ground: these trees flower abundantly every year. The time of their having been planted cannot be now correctly ascertained.

The magnolia should occupy a situation sheltered from the north and north-east winds, but fully exposed to the south or south west sun. It seems to thrive in the sea-air, when the situation is not exposed; and the soil congenial to this tree is a deep rich loam, rather dry than moist.

From the great rarity and extreme beauty of this tree, we think it deserving of more care than is generally bestowed on it, so as to secure it from the frost, and which might easily be done by placing blocks of wood in the earth, with mortices in them, into which poles might be fixed, and a frame or wire-work thrown over, to lay mats or other covering on during the inclement nights. Tall evergreens, of the darkest foliage, form the most proper back ground for this tree.

Our nurserymen raise these trees from seeds, which are sown in pots, and plunged into old hot beds of tanners' bark.

We have now eighteen species of this plant, nine of which are natives of North America, and nine belong to India, China, or Japan; and should we be able to naturalize them so as to endure our winters in the open air, as the common tulip tree has been made to do, they cannot fail of being regarded as one of the greatest ornaments of the shrubbery.

MISCELLANEOUS EXTRACTS

From late numbers of the London Farmers' Journal, received at the office of the American Farmer.

ANSWER TO X. Y.'s QUERY.

Castle Hay Park, Nov. 5, 1823.

SIR—Having perused your letter in *The Farmers' Journal* of the 3d ult. I beg leave to acquaint you, that any description of cut straw will be a good substitute for hay, provided you mix oil cake along with it. Or cut oats in the straw, and turnips will be excellent feed for fattening beasts, without any thing else.

I remain, Sir,

Your obedient humble servant,
JOHN BROWN.

P. S. Being short of hay in general myself, I speak from experience. Let the cattle have what cut straw, &c. they will eat, three times a day, and drink plenty of water.

METHOD OF CURING THE FOOT-HALT, &c.

Near Banbury, Nov. 7, 1823.

SIR—Your having treated so largely on the foot-halt in sheep, I shall not trouble you with any remarks of mine, only my mode of cure, which is short. I once had a flock of aged down ewes feeding on pasture, and was quite in Pastor's

case, having a score bad together, and tried almost all the nostrums you have enumerated; but of no service. I remember, made matters worse; some had lost their claws; at last a person dressed them: in the first place, with a sharp penknife, cut the unsound part from the sound, till the blood starts, then take a small pot or oyster shell, put a small quantity of sweet oil, add a few drops of oil of vitriol, more drops or less of vitriol, according to the badness of the foot; stir up the oil and the vitriol together with a flat stick, directly spreading it over the part affected; the mixture is best made fresh for every foot; after dressing turn them upon dry pasture; if not at hand in a dry hovel, &c. for an hour or two; after a week or ten days, look them over again; those that are not quite well, dress as above directed, and you will find them cured.

As several of your correspondents complain of a distemper amongst their pigs, I have annexed a receipt of an uncle of mine, who was in the farming line upwards of fifty years:—"For the garjet in hogs—madder 1 oz.; diapente ½ oz.; turmeric ½ oz.; brimstone ½ oz." This is sufficient for a large hog; little pigs, three, four, or five.

If you think these worthy of insertion in your valuable Journal, they are quite at your service.

I remain your constant reader.

A FARMER.

To start the blood can be of no service.—Our correspondent may observe that his oils differ but little from the composition we proposed. Train oil is recommended for cheapness; for from the decomposition which takes place with the vitriol, the mixture becomes precisely the same.—*Edit. Lon. Far Jour.*

RECEIPT FOR POISONING RATS AND MICE

Haigh Hall, near Wakefield, Nov. 7, 1823.

SIR—In consequence of many enquiries lately made as to the best mode of preserving corn stalks from vermin, I beg you will insert in your Journal the following receipt for poisoning rats and mice, which was purchased of the renowned Mawson, of Eckup, near Leeds, for £10, and is now used with great success by several persons who get a good livelihood by it, in the neighborhood of Leeds, Wakefield, Pontefract, &c.

For enticing rats and mice—take ten table spoonful of oatmeal and one table spoonful of common raw sugar, which must be well rubbed together with a piece of wood, and laid three nights on the decline of the moon on bits of slate, where these vermin frequent. On the fourth night the poison must be laid, which is as follows:—Take ten table spoonful of oatmeal and one of raw sugar as before, and rub it well together; then add two table spoonful of white mercury in powder, which must be very well pounded together a second time; then put a table spoonful of clean water into a bottle, and drop it regularly over the whole, and mix it again, a third time, very well together; the water is merely to take off the dustiness of the mercury, which gets into the nostrils of the animals and prevents their eating it.

It is advisable to confine dogs and other animals the night the poison is laid, and to take it away the next morning, to prevent accidents. The poison should be kept in a bladder

I remain, Sir, your's truly,

JOHN WOOLLIN.

Polar Expedition.—We understand it is in the contemplation of the Admiralty to commission the Discovery Ships for another voyage to the Polar Seas, with this difference, that their route is now to be by Behring's Straits, whence they

will sail eastward. The distance which must be traversed before they can well be said to commence proceeding to the object of their mission, and the consequent difficulty of reserving the necessary supplies, has hitherto been the obstacle to the attempt by this passage. This latter impediment it is now proposed to obviate, by sending a supernumerary vessel, laden with necessaries, which will probably accompany them, to the neighbourhood of the Kamschatkan coast. Captain Parry is again to take the command.

Etiquette.—Barrow states, that the visiting ticket sent by the Governor of Pe-tche-lee to the British Ambassador, was crimson paper, and of such dimensions, that a room of moderate size might have been papered with it!

God and my Country.—The common question asked a criminal, viz. How he will be tried? is improperly answered, says Barrington, in his work on the statutes, *By God and my Country.* It originally must have been *By God or my Country*—that is, either by ordeal or by jury; for the question asked supposes an option in the prisoner, and the answer is meant to assert his innocence, by declining neither sort of trial.

ON A WONDERFUL VEGETABLE.

Somersetshire, Nov. 15, 1823.

SIR—A constant reader of your valuable Journal copies from the *Bath Journal* the following account of Cæsarian kale:

"This valuable and most excellent vegetable will soon rank high in cultivation and esteem, there being no species of vegetables in this country resembling this prolific plant during the winter, particularly in severe frosts and deep snows.—When other green fodder for cattle cannot be had, this plant, from its elevation, growing to four or five feet, and its natural hardness, yields abundant and successive supplies, which is an important desideratum. The mode of using it for cattle is, by cutting off the large leaves as wanted, when a regular succession takes place continually through the winter. Very early in spring, previously to most other vegetables, it produces vast numbers of large delicious sprouts for the table, equal in sweetness to asparagus, so that it may be said to produce two crops. Cows fed on this plant give a greater quantity of milk, and the butter is richer than when fed on any other vegetable: a matter also of great utility is, that of its comforting and cheering qualities in feeding of ewes in winter, whilst suckling house lambs. Culture—sown in spring or beginning of summer, broadcast, and transplanted at the distance of about two feet. When sown with turnips, it answers an admirable purpose, as few crops are more subject to fail than that of turnips; whereas, Cæsarian kale may be depended on; it is so prolific and hardy that it will vegetate in almost any soil or climate, and prosper even in the shade of fruit or other trees."

If we can rely on the above account, it deserves attention; but I, as one of your numerous readers, who believe nothing authentic on such subjects but what comes from you, beg your account of it and its best mode of culture.

I am, Sir, a well wisher to your useful Journal,
B. M.

QUERY ON FEEDING BULLS.

Somersetshire, Nov. 12, 1823.

SIR—Several of my acquaintance who have procured high bred bulls, of different breeds, having had cause to complain of their want of issue, have learned, that it is from the bulls being highly fed on *Corn* and *Turnips* (as they mostly are when made up for sale.) I shall be

glad to be informed if the same disappointment will happen from bulls highly fed on *oil cake*, particularly yearlings?

C.

ANSWER TO THE QUERY ON FEEDING BULLS, SIGNED C.

London, Nov. 21, 1823.

SIR—It is not the quality of food that is given to bulls, which prevents their having issue, but an unfortunate obstinate perseverance in the *in-and-in* system of breeding, which has been carried to the most fatal extent, particularly in what are called "*improved short horns*." all sprung, male and female, from Mr. Charles Collings' bull *Favourite*, and continued through his descendants from the year 1794 to the present time. (See Coates's herd book of short horned cattle.) The weakness of constitution, and consequent great mortality of calves, at this time, may, as assuredly, be attributed to this cause.

I am, Sir, your humble servant,

JOHN HALL,

Of Little Marshall, near Exeter, a Breeder of Sockburn short horns.

Oil Gas.—At a meeting of the new Gas Company at Edinburgh, on Thursday se'night, Sir Walter Scott said, that he had now had three months' experience of oil-gas light in his house at Abbotsford, and he could assure the meeting that nothing could be more pleasant, more useful, safe, and economical. He was sure the expense was not the twentieth part of what it had formerly cost him for oil and candles. The light itself was greatly superior, was extremely cleanly, saved much trouble to servants, and did not produce the least smell, or the least injury. Not only could it be used in kitchens and dining-rooms, but it was extremely useful in bed-rooms, where a flame could be kept up during the whole night so minute as to be scarcely perceptible, which could be enlarged to a powerful light in an instant at any hour when wanted. It was also very safe, at least was much safer than common lights, it was not carried from place to place as common lights were; and unless combustibles were brought to it, no danger could arise. The light was indeed, so convenient, cheap, and delightful, that were it once introduced, he was convinced it would be used within two years, in every private house in Edinburgh.

FACTS RELATIVE TO FELLING TIMBER.

TO THE EDITOR OF THE AMERICAN FARMER.

Brookville, 3d month, 5th, 1824.

DEAR SIR,

In the latter end of the 8th mo. (August,) 1820, I cut two gum poles, say about two inches in diameter at the but end, for the purpose of sighting, in laying off furrows in my rye field, to sow grass seeds and plaster by. When the work was done, the poles were left where last used, and one of them at least fell, on a rich spot of land, where I suppose, during the growth of grass and weeds around it the following summer, it was placed under circumstances as well calculated to rot, as could well be.

Nearly twelve months after, that is in the early part of the 8th month (August,) 1821, I was passing by the spot, and took it up, when to my astonishment, I found no appearance of decay about it, not even in the bark. I then laid it on the fence, and immediately set to work, and cut about fifty poles, of which there was an equal proportion of gum, white oak, black oak, and

spanish oak, and hickory; these poles would average about seven or eight inches in thickness at the but end, and perhaps, about thirty five feet in length, and were laid on what we call a trunnel fence, as riders.

I continued to examine the small pole, first spoken of, frequently cutting it with my knife, and trying to break it by holding one end of it in my hand, putting the other on the ground, and placing my foot in the middle. But it remained perfectly sound, until sometime during the last summer. I brought it to the house, for the purpose of showing it to some of my neighbors, to whom I had spoken of the circumstance, and where it was ere long, transferred from the place where I had lodged it, to the kitchen fire, or the oven, which circumstance I very much regretted, as I cannot so soon know how long a gum pole will last, when cut at that season of the year.—It is now time to say, that the large poles cut in the 8th month, (August,) 1821, all appear to be perfectly sound, even the bark seems to have suffered little or no decay, and is in many instances leaving the wood so hard, that it is a curiosity. The bark on some of the poles gives them a singular appearance, detaching itself at one point, and curling round, forming something like small hoops. The hickory has suffered a little by the worm, but none of the rest. If these remarks are considered worthy of notice, so far as to be worth publishing, and should in that event, induce others to make further experiments on this, (as I conceive,) important subject, I have no doubt, but discoveries will be made, which will prove valuable to many of us.

AMOR PATRIÆ.

[The whole case is confirmatory of the facts and opinion advanced by Col. Pickering, as to the best time of felling timber, with a view to its durability. Yet the general impression is, that timber, cut when the sap is up, will speedily decay—and the practice accordingly is, in most cases, to cut timber in mid winter—in the "dark of the moon in February," where durability is an object. Our surprise is, in this case that decay was not greater, in consequence of leaving the bark on. But why has not the writer, who is an observing farmer, and not afraid of the labour, taken the pains to cut other poles of the same wood, and of the same size, at different seasons, and subjected them to the same temperature, and the same exposure? that would at once lead to the establishment of certain facts from which useful and practical results might be drawn.]

Edit. Am. Far.

TO THE EDITOR OF THE AMERICAN FARMER.

MANUFACTURES.

SIR—With respect to manufactures, and your correspondent *Ruris Consultus*, or some such unfarmer like name, I must let you know, that I am a practical farmer of a thousand acres, and was a manufacturer of some thousand yards per annum, of homespun, till the effect of the financial tariff of 1816, cutting the nation, (farmers, merchants, and all,) over the backs of the poor manufacturers, cut me out of \$20,000, in a few years afterwards—put my building and machinery,* in "dry dock," to rot—and sent my 300 head of merinos to bleed and die, for the good of the treasury! And though my motto has been that of the brave and persevering Lawrence, using the French pronunciation, "dout give up the sheep," yet I have scarcely crooked horns

* The windmill, that goes by water.—Hon. J. Randolph.

ough left, should the new tariff set me "a wool gathering" again, to begin a flock with.—I was fool enough to think, that

Genius and talents, often fail,
But perseverance will prevail.

And had I not *tacked ship*, and left John Bull victorious, I should have gone to "Davy Jones' locker," like poor Lawrence himself. Indeed, it almost broke my heart, any how, to see that though we could maul him on the ocean, our helmsmen (rather landsmen) would let him murder us in our workshops, and nearly starve us on our farms.

You published a few weeks back a wee extract from "the Crisis," addressed to president Monroe. If your correspondent will read that pamphlet, it may save him much ink-shed, for he appears to me, to write more to convince himself, than others. If he has read it, and will still write on, I am sure, it would be useless for me to attempt to stop him.

I hope, Mr. Editor, you will publish this, because it is *original*, though I fear you may consider the style as *too original* for the gravity of your useful and instructive columns.

PHILO-HAMILTON.

Frederick County, Md. Feb. 22, 1824.

"*Wild Geese*.—When wild geese are tamed, they will join with a flock of domestic geese, but at the usual time of migration, are very apt to join any flock which approaches near them in their passage."—*Williamson's Hist. Vt. p. 136.*

A number of years since, a farmer in Massachusetts shot at a flock of wild geese that was passing over to the south, and broke the wing of one of them. He kept and domesticated the goose, until it was apparently as tame as any one from our common flocks. The ensuing spring he neglected to clip her wings, and she flew away in a flock that was passing to the north, and he conceived her lost. The next autumn, however, when a very large flock was returning to the south, eleven detached themselves and alighted in the farmer's yard. They proved to be one old and ten young ones. The old was the same that left him in the spring.—*Hartford Mercury.*

Vegetable Milk.—In addition to the vegetable bread, vegetable butter, and cabbage tree, which have been brought to light by recent travellers, we now learn by the *Gazette de Santa* of the 25th July last, that M. de Humboldt has discovered in that region a tree which abundantly affords a milky juice, similar in its properties to the milk of animals, and employed for the same purposes. This liquid, which was drank by Humboldt, is stated to be derived from the *palo de leche*, or *da vaca*, a tree which grows, abundantly in the mountains above Periquitto to the north-east of Maracay, a village to the west of Caraccas. The milk possesses the same physical qualities as that of the cow, with this only difference, that it is a little viscous; it has the same taste also as cows' milk.—*Ev. Post.*

Fire proof and Water proof Cement.—To half a pint of milk put an equal quantity of vinegar in order to curdle it, then separate the curd from the whey and mix the whey with the whites of four or five eggs, beating the whole well together; when it is well mixed, add a little quick lime through a sieve, until it has acquired the consistence of a thick paste, with this cement broken vessels, and cracks of all kinds may be mended. It unes quickly and resists the action of fire and water.

Blankets.—Took their name from Thomas Blanket, who established the first manufactory for this comfortable article at Bristol, about the year 1340.

Vinegar.—The vinegar manufactured by all the great establishments in London is made from malt. Most of the vinegar consumed in Paris and indeed throughout France is extracted either from wood or potatoes.

In the tenth century, Gregory V. excommunicated Robert, king of France, and such power had the Pope in those days that the king was forsaken by all his courtiers, and even by his confidential domestics, there only staid with him two servants, who threw into the fire what he left at his meals, from the horror they felt at what had been touched by an excommunicated person.

Catnip poultice, good for obstinate ulcers.—The way to make a poultice of it, is to put it on in vinegar, and boil it until it becomes soft, then thicken it with bran, spread a little butter, that has no salt in it, over it, to prevent its sticking.

For a common cold.—Take two or three swallows of molasses, four or five times a day, at bed time drink as much of it as your stomach will bear. This I know from experience, to be an excellent remedy.

Mammoth Hog.—Mr. John Mail, near Cohocksing, in the Northern Liberties, has fattened and killed a hog weighing 914 lbs. Length from nose to tail 9½ feet, girth 7½ feet.

Mammoth Egg.—A gentleman of this town, whose acute observation has more than once penetrated into the *arcana* of nature, and discovered latent wonders, that might otherwise have remained hidden from the vision of man for ages to come, one day last week, brought into our office a *Hen's Egg*, which weighed 5½ ounces, and measured 9½ inches in circumference. It was as large as a goose egg; and we stoutly contended it was such, until the gentleman broke it, with the hope thereby, of convincing us of our error; he did convince us; for on opening the egg, a smaller one, of the size of a common hen's egg, was found within the larger shell. The interstice between the inner surface of the large shell and the outer surface of the small egg, contained a yolk, and the white viscous substance found in common eggs. Whether nature, in her freaks, ever produced the like before, we know not.—*Western Carolinian.*

A wonderful Grain of Wheat.—One grain the first year produced a stem containing 11 ears, each ear averaging 87 grains; the second year produced half a bushel; the third year 20 bushels; the fourth year, 768 bushels, or 96 quarters! This *morceau* is making, with great industry, the circuit of the papers.—A Mr. Labor, of Essex, the grower of the corn, and a Mr. Smith, of Mark-Lane, the voucher of the fact.

A letter from New Orleans, to a gentleman in this city, dated January 21, says, "our cotton and sugar crops have fallen short, and the port is crowded with vessels that are without employments. Cotton is very high, and rules from 13 to 20 cents. Sugar is selling from 6½ to 6¾. Exchange on New York, from 2½ to 3 per cent. discount."

THE LITTLE PET PLANT.

A Florist a sweet little blossom espied,
Which bloom'd like its ancestors by the road side;
Its sweetness was simple, its colors were few,
Yet the blossom look'd fair in the spot where it grew;
The florist beheld't, and cried, "I'll enchant
The botanical world with this sweet little plant;
Its leaves shall be sheltered and carefully nurs'd,
It shall charm all the world, tho' I met with it first!

Under a hedge!"

He carried it home to his hot-house with care,
And he said, "Tho' the rarest exotics are there,
My little Pet Plant, when I've nourish'd its stem,
In tint and in fragrance shall imitate them,
Tho' none shall suspect from the road-side it came,
Roadum Sidum I'll call it, a beautiful name;
While botanists look thro' their glasses and view
Its beauties, they'll ne'er suspect that it grew
Under a hedge!"

The little Pet Plant, when it shook off the dirt
Of its own native ditch, soon began to be pert,
And toss'd its small head; for, perceiving that none
But exotics were round it, it thought *itself* one,
As a wild flower, all would have own'd it was fair,
And prais'd it, though gaudier blossoms were there;
But when it assumes hot-house airs, we see thro'
The forc'd tint of its leaves, and suspect that it grew

Under a hedge!"

MORAL.

In the by-ways of life, oh! how many there are,
Who, being born under some fortunate star,
Assisted by beauty, or talent, grow rich,
And bloom in a hot-house instead of a ditch!
And whilst they disdain not their own simple stem,
The honours they grasp may gain honours for them;
But when (like the Pet Plant) such people grow pert,
We soon trace them to their original dirt
Under a hedge!"

THE FARMER.

BALTIMORE, FRIDAY, MARCH 12, 1824.

The next number will close the fifth volume of the American Farmer, and all those who intend to continue their subscriptions, will be indebted for the sixth volume, according to the expressed terms of subscription, which require the payment in advance. To those who have hitherto complied with these terms, and there are few exceptions, we cheerfully submit, whether we have not faithfully performed our part of the contract. We have kept our eye and heart, steadily on our original design, to amuse and enlighten our readers on the most important of all human avocations and interests—agriculture, domestic economy and internal improvements—studiously avoiding politicks, whether state or national, and other subjects, to which journals, numerous and able, were already devoted, while American agriculture, whether as a science or a practical calling, had not a single advocate.

It is for those who take a pride in their profession, and wish their sons to be, not only successful, but *enlightened* farmers, to say, whether they will uphold a journal, which serves at once, as the repository and disseminator of whatever can give embellishment to the mind, and profit to the labours of those, whose lives are to be employed in the noble occupation of tilling the earth; and thereby increasing the means of human subsistence, multiplying the sources of comfort, augmenting the means of charity, and diversifying the elegancies of life.

But we do not mean in this number, to put forth what might be called an address to our subscribers. The chief object in taking our pen, was to announce, that we have relinquished the design of raising the terms of the Farmer to "five dollars in all cases," as heretofore intimated. The price will continue as heretofore—that is, to those who take the risk of all casualties, \$4 per annum, payable in advance—but those who prefer, as we hope most of them will, to pay \$5 in advance, will be entitled to have each paper supplied, which may happen, from any cause, not to reach them in good order, and an agricultural almanack, in the bargain. The almanack, besides the contents of common almanacks, will have recipes, short essays, &c. connected with the farmer's and the *housewife's* duties and business. Those who prefer the payment of four dollars, are assured that the Farmer is regularly put up and sent off in at least as good condition, and with as much security for its safe arrival, as any paper in the United States, excepting always that invaluable work, Niles' Weekly Register. We are still of opinion that our plan of simplifying the terms by demanding \$5 in every case would be justifiable and eligible, but we are aware that *times are hard with farmers, and may be worse before this session of Congress is over.*

As some subscribers always withdraw at the end of a volume, we must, and do confidently rely on our old and steadfast friends, to say in its behalf to their neighbours what they may think it merits, and thus enable us at least to "hold our own" until times get more propitious.

In No. 49 of the Farmer, were given several very useful receipts in domestic economy, without stating the source whence they were derived, except of the first. Upon referring, however, to the "Archives of useful knowledge," the Editor finds that all but the first and last, originally appeared in the 2d volume of that work, and that

the first was also copied from it, into the miscellany, from which we took it. This article is an abridgment of one, in the transactions of the society of arts of London. This statement is made by the Editor, from a sense of justice, and because he also thinks it useful to know the sources of our knowledge. The "Archives," have been common property with the compilers of miscellanies, in the United States, who have generally and improperly omitted to give credit to the authors, who contributed to fill their pages with useful matter.

ERRATA.—IN THIRD LETTER OF "RURIS CONSULTUS."—In the second paragraph, 1st column, 11th line, instead of "buying," read *buying*.

Four lines from the bottom of the same column instead of "inferiority," read *infirmity*.

In the 3d line from the top of the 3d column, (2d page,) for "consideration," read *consummation*.

ERRATA.—In No. 50—On the management of fruit trees, page 395, last column, 3d line from the bottom, for "mixtures," read *manures*.

Page 396, first column, 9th line from the top, for "walls," read *walks*.

PRICES CURRENT—CORRECTED WEEKLY.

Wharf flour, \$5 62½—Howard-street, do. \$5 75—Best family do. retail, \$7—Wheat, red, \$1 15 to \$1 17—Corn, 35 cts.—Rye, 40 cts.—Oats, 28 to 30 cts.—Whiskey, 25 to 27—Butter, inspected, 10 to 15 cts.—Coal, Liverpool, bushel 40 to 45 cts.—Virginia, 28 cts.—Susquehanna, per ton \$6 50 to \$7—Rice, per cwt. \$3 75 to \$4—Beef, northern mess, per barrel \$10—Cargo, No. 1, \$8 to 8 50—do. No. 2, \$6—Baltimore prime, \$10—Bacon and hams, 10 to 11 cts.—Cotton, W. I. Island, 18 to 20 cts.—Louisiana, &c. 16 to 17 cts.—Georgia upland, 14 to 16 cts.—Alabama, 12 to 13 cts.—Candles, mould, 12 to 13 cts.—Dipt, 10 to 11 cts.—Spermaceti, 25—Feathers, live, 30 to 35 cts.—Fish, herrings, Susquehanna, \$2 75—Fall mackerel, No. 1, to 3, \$4 50 to \$7—Shad, trimmed, \$6 to 6 50—Flax seed, rough, per bushel, 70 to 75 cts.—cleaned, cask, \$8—Flax, per lb. 10 to 11 cts.—Hemp, Russia, \$1 75 ton.—Country dew rot, 7 cts. per lb.—do water rot, 9 cts.—Hops, fresh, 35 cts. per lb.—Hides, dried, 15 to 19 cts. per lb.—Hog's lard, 12 cts. per lb.—Lime, per bushel, 30 to 33 cts.—Leather, soal, best, 24 to 27 cts. per lb.—do. Eastern tan, 18 to 20 cts.—Lumber, board measurment, cargo prices:—Of the following articles we give the yard prices.—Oak timber and scant, \$1 to 1 25—Boards all sizes, \$1 50 to 2—Pine scantling, do. \$1 to 1 25—Boards 4-4, \$1 to 1 25—White do. 5-4, \$1 75 to 2 50—do. co. 4-4, \$1 15 to 1 30—do. cl. 4-4, \$1 80—Shingles, cyp 18 in., \$3 to 3 50—Shingles, junip. 24 do. \$7 50 to 7 75—jun. com. \$3 50 to 5—Staves, W. O. pipe, \$40 to 45—do. hhd. \$25—do. bbl. \$15 to 17—R. O. bbl. \$15—do. hhd. \$17—Wool, fleece, merino full blood, 35 to 40 cts. per lb.—Cropped, 28 to 30 cts.—Common country, 20 to 30 cts.—Skinner, 35 to 40 cts.—When assorted and cleaned, any of the above will obtain an advance of 15 to 20 cts.

Prices of Seed.—Or-hard Grass per bushel, \$2 50—Lucerne, do. do. 50 cents—St. Foin, do. do. \$7—Red Clover, do. do. \$5 50—Timothy, do. do. \$4—Herds Grass, do. do. \$2—Millet, do. do. \$1—Mangel Wurtzel, do. do. \$1 50—Ruta Baga, do. do. \$1.

Retail prices of provision market.—Beef, prime pieces, 10 cts.—Veal, 10 cts.—Mutton, 5 to 7 cts.—Turkeys, 75 cts. to 1—Geese, 50 to 56 cts.—Ducks, Canvasbacks, \$1 25 to 2—Red heads, 50 to 75 cts.—Chickens per pair, 50 to 62½ cts.

—Eggs, 12½ cents—Butter, first quality, 20 to 21 cts.—Turnips, per bushel, 50 cts.—Potatoes, do. 50 cts.

Agricultural Implements.

Charles B. Palmer respectfully informs the public, that he has opened a warehouse on Elliott and Light-street, seven doors from Pratt-street, where he has on hand and offers for sale, the following articles, principally of his own manufacture:

150 Ploughs of different kinds. Pennsylvania Bar share ploughs, all wrought iron except the mould-board, and easily repaired by any country smith.

No. 1 or Seed Plough, and 2, 3, and 4 Horse Ploughs with wings, bar of share, and coulter layed with steel—a two horse left hand plough, made in the same manner.

Dagon, or Connecticut plough.—Wm. Hinkse's wrought iron mould board ploughs.

Mr. Wood's Cast Iron ploughs. Double mould board ploughs, for hilling corn and to'acco.

Shovel ploughs—Sub-soil ploughs—hill side ploughs—Cultivators of several kinds—Beast-man's Scarifier.

Mr Eastman's Cylindrical straw cutters—common hand straw cutters with or without treddles—Fans, Sieves, Screens, Wove Wire, &c., Smith's Bellows, Spades, Shovels, Hoes, and all kinds of agricultural implements to suit the seasons—Edged tools of all kinds, made by George Gillingham.

Iron or wood of any implement furnished separately, if required.—Ploughs and implements of all kinds repaired at the shortest notice and of the best materials; and implements not answering on trial, may be returned uninjured, and exchanged or the money refunded.—A considerable deduction made to those who purchase a large quantity.

Charles B. Palmer hopes by his personal attention and labour to business, to receive a portion of public patronage.

Persons making ploughs in the country, can be furnished with iron at the lowest prices.

CHARLES B. PALMER.

For Sale.

A very fine stallion colt, two years old this Spring. He was got by the Cleveland Bay Horse imported by Mr. Robert Patterson from England, and out of a very fine half blooded mare.

For terms apply to the Editor of this paper. February 24, 1824.

AGRICULTURE.

Communicated for publication in the American Farmer.

JONATHAN ROBERTS, ESQ. PRESIDENT OF THE PENNSYLVANIA AGRICULTURAL SOCIETY.
Powelton, November 28, 1823.
Philadelphia County.

DEAR SIR,

I enclose certificates showing that sixteen hundred and thirty-four bushels of Mangel Wurtzel, weighing seventy-eight thousand four hundred, and forty-eight pounds, were produced at Powelton, upon one acre and fourteen perches of farm land, accurately measured by a regular surveyor.

I selected a parallelogram, containing thirteen contiguous rows, which were drawn, and measured in my presence, to ascertain the largest quantity, which had grown upon the richest part of the field. One hundred and forty-three baskets, equal to one hundred and seventy-four bushels, were produced upon thirteen and an half perches, at the rate of two thousand and sixty-five bushels per acre, weighing 44 tons, 5 cwt. 0 qrs. 27 lbs.

I am satisfied that the account of my farmer is correct, and as the roots had been drawn ten days, had been closely cut beneath the crowns, were dry, and entirely free from dirt, both the measurement by the basket, and the estimate by weight, must be fair. If a barrel had been used, or any other large vessel, of similar shape, the crop would appear greater, as the measure would not have been so often filled, and consequently not so often heaped.

Mr. Milnor, the Recording Secretary, was good enough, to superintend the measurement of the basket, and saw the manner in which it was filled.

I submit to you, the shingles containing the original scores, and refer you to him, for corroboration of the facts. It may be well to state, that however great this crop may appear, in England a larger product has been obtained.

My soil was not naturally strong; it has been gradually so much deepened, as to enable me, with Wood's plough, No. 2. drawn by four oxen, to plough fourteen inches deep. Fresh barnyard manure, was equally spread upon the surface, and ploughed under in the early part of April, in quantities not larger, than are usually applied, to potato crops in this county. Early in May the land was twice stirred with Beaton's scarifier—harrowed—rolled—after stirred—harrowed and rolled again in the opposite direction. The holes for the seeds, were made by a wheel containing pegs in its circumference, which penetrated the ground, about an inch, leaving intervals of four inches—the rows were made two feet asunder—two capsules were dropped into each hole—the wheel of a common barrow was passed over them, thus compressing the earth, and leaving a slight rut, for the retention of moisture.

A small cultivator which I had contrived for the purpose, was drawn between the rows soon after the weeds appeared; a three inch triangular hoe, removed the alternate plants, leaving the others at distances, varying from eight to twelve inches asunder. The cultivator was twice used before the 20th of July. The heavy rains of August made another hoeing necessary, and surcharged the ground so much, with moisture, that roots increased much less in that month, than they had grown during the same time, in the two last years.

In order to convey an idea of a Mangel Wurtzel crop, to some of the members, who are not acquainted with its usual product, it may not be improper to state, that three fourths of the root

extend above the ground—that I last year obtained one which at Mr. Landreth's shop weighed some days after it was drawn, 17 lb. 10 oz.

I this year desired smaller roots which might grow so closely, as by their leaves, to protect the soil, as much as possible from the exhalations of the sun. My cultivator, by its peculiar form, enabled me to cut off the weeds, when the plants were so young, that if I had applied the plough, their crowns must have been covered in many instances, by earth which occasionally falls from its land side. The failure, which attends the cultivation of most root crops in drills, proceeds from the neglect of weeds in their early stages. Four or five days of delay, frequently make the difference of fifteen days in the labour of making clean an acre of ground. The same weeds which a boy with a sharp shingle, could remove at the commencement of one week, may, before the end of the next, require the application of an implement drawn by an horse.

I ascribe my success, in great measure to the use of Wood's extraordinary plough, which enters the soil more deeply, and pulverizes it more perfectly than any other I have ever seen with equal force in any country—to the habitual use of cultivators, which complete the production of fine tilth—to the destruction of the weeds on their first appearance—to leaving the smallest space upon which a horse can walk between the rows, and above all to planting the seeds of a prother kind upon a surface which is kept perfectly flat.

In proof of the advantages of this invaluable root, I exhibit cream obtained from one of my cows, which has been fed for several weeks, exclusively upon Mangel Wurtzel and Millet fodder. You will find that its color and flavor, are perfectly good—the butter which it affords, is more like that produced in June, than any I have used, excepting such as had been derived from cows fed on carrots, and corn meal.

Notwithstanding the large product, I am confirmed in the opinions, which I have repeatedly expressed, that in this country, nothing can supplant the king of vegetables, Indian Corn. I would recommend Mangel Wurtzel, in preference to all other roots, for dairy and breeding farms: and to a limited extent, where labour and manure, are not too dear, in comparison with the value of land, it should be cultivated upon all farms.

The expense of preparation for a mangel wurtzel crop, is not so great as might be supposed. The labor of four oxen, a ploughman and driver in ploughing one acre, fourteen inches deep,* costs \$3 00
3 stirrings with Beaton's improved scarifier, which two oxen managed by one man, can readily pass over five acres in good condition, in one day, \$1 25
2 harrowings and 2 rollings, 1 25
Dibbling with a wheel, 1 00
Dropping seeds, (if performed by men,) 5 00
Pressing them under by a wheel, 1 00
Hoeing and thinning, 15 00
Cleaning with Blockley cultivator, drawn by one horse, 3 00

\$30 50

JOHN HARE POWEL.

* The great depth of ploughing, was noticed by Dr. Buck, the Secretary of the Agricultural Society, at Bridgton, New Jersey, in an early number of the present volume; and we are authorized to assure our much valued correspondent of Talbot, that a Pennsylvania farmer, although no Hercules, can plough fourteen inches, and obtain good crops, without the Augean filth of a great city.—*Edit. Am. Far.*

JOHN S. SKINNER, ESQ.

Sir,

At a meeting of the Pennsylvania Agricultural Society, held in November, Mr. Powell exhibited a bottle of cream, produced by a cow, which he stated, had been fed solely on Mangel Wurtzel roots, and millet hay. It was pronounced by all who examined it, to be equal, in richness and flavour, to any they had ever seen.

His Durham short horn heifers, fed upon these roots, yield very large quantities of milk, affording the richest cream I ever tasted.

Respectfully yours,

JOHN P. MILNOR,

Assistant Recording Secretary

Penn. Ag. Soc.

Philadelphia County, March 3, 1824.

We have counted the scores, examined William Powell the farmer, and are satisfied, that the piece of land at Powelton, measured by Mr. Henry Serrill, produced thirteen hundred and forty-one baskets of mangel wurtzel, and that the part thereof containing thirteen and an half perches, produced one hundred and forty-three baskets, all the roots having been closely cut below the crowns.

JOHN P. MILNOR,

HENRY SERRILL.

Powelton, Nov. 19, 1823.

I have carefully measured the basket used by William Powell, and referred to in the foregoing certificate, and find, that it contains, precisely one bushel and seven quarts. A basket of this size, wide at top, and of sufficient height, was selected, in order that the beets might be fairly measured, by being placed singly, nearly perpendiculary, their necks extending above the sides, upon which others were afterwards laid horizontally, until the usual heaped measure was given; thus leaving as few interstices as possible.

JOHN P. MILNOR.

November 19.

Having measured the above piece of ground, I certify it contains one acre and fourteen square perches. A part of which, containing thirteen and an half square perches, had been staked out in order to ascertain the exact quantity of mangel wurtzel thereon.

HENRY SERRILL.

November 19th, 1823.

I have measured the mangel wurtzel, taken from farm land at Powelton, surveyed by Mr. Serrill, and am convinced from the careful manner in which I scored upon shingles with a knife every basket as it passed, from my hand, and as I was checked in my account by the person who assisted me, it is not possible any mistake could arise. Upon one acre and fourteen square perches, thirteen hundred and forty-one baskets were produced. From the piece which had been staked out, in order to ascertain the exact quantity of mangel wurtzel thereon, I took one hundred and forty-three baskets. The strip included thirteen adjoining rows, which were measured from the edge towards the centre of the field without any break.

WILLIAM POWELL.

Farmer at Powelton.

Philadelphia County, ss.

Personally appeared before me, the subscriber, one of the justices of the peace, in and for the county aforesaid, the above named William Powell, who being sworn according to law, saith, that

the foregoing statement, is true, to the best of his knowledge and belief.

Sworn and subscribed, this twenty-eighth day of November, A. D. 1823.

GEORGE HOWARTH,
Justice of the peace.

A farm basket, properly filled with mangel wurtzel, was brought to my store, by Mr. Powell and his farmer. The roots alone, weighed rather more than fifty-eight and an half pounds.

DAVID HOOPES.

West Philadelphia, Nov. 28, 1823.

THE AGRICULTURE OF FLANDERS.

[Attracted by the rumours of excellence, in the practices and the great products of Flemish husbandry, and especially by an interesting outline of it by Sir John Sinclair, the Directors of the Farming Society in Ireland resolved to procure a more minute detail of it, and accordingly deputed the Rev. THOMAS RADCLIFF, to make a tour of Flanders, and from personal and particular inspection, to draw up a report on the subject. The duty was, we think very judiciously executed and resulted in a valuable work, published in 1819, from which in our last number, we extracted two articles—one on the forces and manner of feeding work horses in that country—the other, answer to queries, propounded by Sir John Sinclair, respecting a celebrated dairy establishment, of Mr. Van de Poes, President of the commission of agriculture in South Holland.

The report abounds with curious and valuable hints and details, and we shall occasionally extract from it, such as seem most appropriate and useful to the readers of this journal. They will, we think, be gratified with the accounts which follow, of the "MANNER OF FEEDING HORSES AND COWS IN DIFFERENT DISTRICTS."

The "FORMS OF LEASES IN FLANDERS," and a description of the "NEW METHOD OF STEEPING FLAX," will be given in the first number of our next volume. The last mentioned article, will be, at this time, no doubt acceptable, and at all times valuable.]—*Edit. Am. Far.*

From Radcliff's Agriculture of Flanders.

MANNER OF FEEDING HORSES IN DIFFERENT DISTRICTS.

This subject has been touched on in different parts of this Report, and it has been stated, that in some places where hay is scarce, the withholding of that species of provender does not affect the condition of the animal. In the following districts, however, hay is made a part of the forage, and the proportions are as follow:

In the district of *Bruges*—Winter feed, per diem, for each horse, seven litres, being six and one-third quarts of oats; sixteen kylogrammes, thirty-five and one-third pounds avoirdupois of hay. In lieu of fifteen pounds of the hay, thirty-three kylogrammes, (being seventy-three pounds) of carrots. Summer feed per diem, seven litres, being six and one-third quarts of oats; clover in the manger, eighty pounds; four litres of bruised beans are frequently substituted, instead of the seven litres of oats. The drink is water, in which some oil cake has been dissolved, and whitened with rye meal, oat meal, or the flour of buckwheat.

In the district of *Courtray*—Winter feed per diem, fifteen pounds of hay; ten pounds of straw; seven pounds of oats. In summer, clover, in place of hay, and straw; quantity of oats the same. Drink, whitened with rye meal.

In the district of *Termonde*—Summer feed, five months, six sacks, being 927 lb. of oats; one ar-

pent, being nearly one-ninth English acre, clover. Winter feed for seven months, fourteen sacks, being 2163 lb. avoirdupois, oats; 600 bundles, six three-fourth lb. avoirdupois each, of hay; chopped straw and chaff; quantities vary.

In the district of the *Pays de Waes*—Summer feed for five months, the produce of half an arpent of clover; ten hectolitres, being twenty-eight two-fifths Winchester bushels of oats; ten hectolitres, ditto ditto chopped straw. Winter feed for seven months, twenty-one hectolitres, being fifty-nine three-fifths Winchester bushels of oats; twenty-one hectolitres, ditto ditto chopped straw; 4200 lb. of Ghent, being one four-fifths tons English, of hay.

In the different districts a variation takes place in point of regimen; but the object of all, is to keep up the uniform good condition of their working-horses, in which they are universally successful; the operations of the farm never meet with interruption or delay, from the fatigue or debility of the horses allotted for its cultivation.

MANNER OF FEEDING COWS, &c. IN DIFFERENT DISTRICTS.

In the district of *Bruges*, the mode of keeping cows is as follows:

In *summer*, where pasturage is to be had, they are left at liberty; where this is not the case, each cow is led by a rope, and permitted to feed round the grassy borders of the corn fields, which are left about ten feet wide for this purpose.

In *winter*, the kinds and quantity of food for one cow within twenty-four hours, are, straw, eighteen pound; turnips, sixty pound. Some farmers boil the turnips for them; others give them raw, chopping them with the spade: one or other operation is necessary, to obviate the risk of the animal being choaked, where the turnips, which is usually the case in Flanders, are of too small a size.

In lieu of turnips; potatoes, carrots, and grains, are occasionally given; bean-straw likewise, and uniformly a white drink, prepared in the same manner as for the horses.

In the district of *Courtray*, very little variation takes place, except in giving about one-sixth less straw.

In that of *Termonde*—The *summer* keep for each cow is nearly an English acre of clover, as soiling.

For *winter*, nearly an English acre of turnips, and one of carrots, with a very little hay and straw; perhaps five pound of hay, and ten pound of straw per diem.

The white drink, as for the horses, is regularly given.

In the district of the *Pays de Waes*—The *summer* keep for each cow is about half an English acre of clover, cut and carried to the stall.

For *winter*, nearly an English acre of turnips, one and a half of carrots, six sacks of chaff; and white water, or *soupe*, as it is termed, prepared in the same manner every where, and as is described in the former section, upon the keep of horses.

The precise quantity and kinds of provender given to each animal per day, have been mentioned, as to particular instances, in a former part of this report. The present section states the general practice of the different districts, from the best authorities. From these statements may be deduced the inferiority of the turnip crop of Flanders to that of our countries; they furnish, however, an excellent example of the value and feasibility of the soiling system by the means of clover. In Ireland a prejudice operates against it, from the supposed danger of the fixed air generated in the stomach of the

animal thus fed. This, in the worst cases, may be remedied by the flexible tube or the trochar,* but may better be prevented, as in Flanders, by giving the clover in small quantities at a time, and always from that which has been cut at least four-and-twenty hours, that the fixed air contained in the stalk of the clover, may have time to evaporate.

If this excellent Flemish practice of soiling upon clover, with that of saving their own clover seed, could be established in Ireland, the benefit to the farmer of every class, would be incalculable.

The manner of feeding *sheep*, in Flanders, is the same throughout, and has been already detailed. That of feeding *swine*, has also been particularized.

With respect to *calves*, those to be reared for a succession, have very little new milk, and for a very short time, averaging, perhaps, two quarts a day for a month; they are then reduced to buttermilk and water, and have the refuse of the cows' diet, with a portion of their drink, and a little hay.

Those intended for the butcher, as veal, are uniformly kept upon their legs in narrow boarded stalls; they are bled, as is usual with us; are kept particularly clean, and fed abundantly with sweet milk fresh from the cow.

In the *Pays de Waes*, a peculiar attention is given to this branch of rural economy; and, besides the usual routine, they give them once in the day a mixture of new milk, eggs, and white bread, carefully beaten up and blended. The veal is uncommonly fine and white, and is ready for market after six or eight weeks feeding.

It may be expected that something should be said upon the subject of dairies, but it has been already remarked, that they do not prevail in Flanders on any considerable scale: the chief points respecting them, as to the management of the cows, and produce of milk and butter, have been already mentioned.

Had time and circumstances permitted, the author of this report would have gladly extended his tour to Holland for the purpose of this inquiry. He endeavoured to obtain useful information through a friend, who had connexions there, but did not succeed. The proprietors of dairies in that country, have for the most part an insurmountable objection to communicate the detail of a business in which they have attained a character for superiority, which they wish to preserve: little can be done, except by residence, and personal inspection.

Mr. Charles d'Ufford, Secretary of the Commission of Agriculture in South Holland, interested himself most politely, in endeavouring to procure some information upon the subject, and transmitted from the president of the commission, some answers to queries put by Sir John Sinclair, who visited the dairy of that gentleman. As Sir John has not noticed them, in his interesting publication, it may be well to let such of them appear here, as relate to the transactions of the dairy.

* *The flexible tube forces back the leafy matter against the generation of the fixed air has pressed against the orifice of the stomach, and lets the air escape, which would otherwise expand, to the destruction of the animal. The trochar, a surgical instrument, inserted between the hip and short rib, produces the same effect.*

From Willich's Domestic Encyclopedia.

PRESERVATION OF FLESH MEAT.

Meat can be preserved fresh in hot weather.—1. By covering it with fresh charcoal powder in

a cool cellar. 2. By covering it with molasses. 3. By keeping it in a vessel wherein carbonic acid gas has excluded the common air. 4. By folding it in a cloth dipt in vinegar wherein pepper has been infused. 5. By wiping it dry, and enveloping it in melted suet.

Under the article BEEF, in the first vol. ample directions were given for salting beef. The following additional account of the result of a successful trial to preserve beef, killed in very hot weather, in August, will be found useful.

The animal fasted a night and day before being killed. About nine o'clock in the evening he was killed, and cut up immediately. At 4 A. M. every piece was quickly wiped, rubbed with finely pounded salt, and instantly put into a barrel in a cool cellar. The next night the pieces were taken out, drained for half a minute, put into another barrel, and the following pickle was poured on them boiling hot :

To every two gallons of water were added 40 oz. of salt, and 3 oz. of salt petre. This was poured on boiling hot, 1st. to kill the egg of any fly-blows: 2dly, to corrugate the external fibres of the meat where it is first apt to taint.

N. B. The meat was deprived of all the large bones.

In about a week the meat was taken out of pickle; the pickle boiled and scummed, and again poured on hot. The meat kept perfectly well.

The pickle of meat should be often examined, and once a fortnight boiled and scummed.

The above proportions of 20 oz. of salt and 1½ oz. of salt petre to the gallon of water, is the best proportion for pickling meat for family use.

FLOUR.

The proportion of flour, which a bushel of grain affords, greatly varies. A bushel of Essex wheat, Winchester measure, weighs upon an average about 60 lbs. which when ground, will yield (exclusive of the loss incurred by the grinding and drying,) 45½ lbs. of the flour called seconds, which alone is used for baking throughout the greater part of England, and which affords the most wholesome, though not the whitest bread. Beside the seconds, such a bushel of wheat yields 13 lbs. of pollard and bran: the total loss in grinding seldom exceeds one pound and a half.

A correspondent of the Editors of the *Encyclopædia Britannica* (Article BREAD,) states, that he weighed two bushels, Winchester measure, of white and red wheat, the whole of which amounted to 122 lbs. This wheat was ground under his own inspection, and yielded 121½ lbs. of meal, so that the waste or loss in grinding the two bushels, amounted only to half a pound.—The meal was also dressed in his presence, and produced 93½ lbs. of seconds, and 25½ lbs. of pollard and bran, so that the whole loss in the two bushels, both by grinding and dressing, did not exceed two pounds and a half. The bran and pollard were also dressed in a bolting mill, and produced,

	lbs. oz.
Sharps,	6 0
Fine Pollard,	5 8
Coarse ditto	7 8
Broad Bran,	5 3
— — — — —	— —
24 8	

One pound only was thus lost in the bolting, and if the sharps had been sifted, they would have afforded three pounds of good flour. We are inclined to think, from these and similar data if the price of wheat were given, that of flour might be easily ascertained, and those frauds which are now practised with impunity, could be effectually prevented.

LIFE.—DURATION OF.

LIFE, in a peculiar sense, denotes the animated state of living creatures, or that space of time during which the soul is united to the body.

Longevity has always been highly estimated by man; hence the art of preserving life has become an important study, and ought to form part of the education of every individual. There is, however, a period at which mankind cease to grow; and beyond which our existence continues for a limited time. Thus, if a person attain his full growth at the age of fifteen, he generally dies at that of sixty; provided that no accidents intervene, by which the vital principle be affected, and prematurely extinguished. According to the calculations of others, every animal body is by Nature destined to live eight times the length of its growth.

From the most accurate political accounts, made by comparing the bills of mortality published in different countries and climates, we shall insert the following result:—Of one thousand persons living in large cities, no less than thirty-five or thirty-six die annually: while, in country places, or small towns, only from twenty-eight to thirty deaths happen in a similar period. Among 1000 children, five die during parturition; and scarcely half that number in childbed; but about three hundred are computed to fall victims to a perverse mode of education, though suckled by their mothers; and not less than five hundred, or one half of all that are born, if reared by wet nurses. The mortality of infants, indeed, has increased to a most alarming degree in this luxurious age; as the plurality of them is carried off by convulsions, and difficult teething. Among one hundred and fifteen dead persons, there is only one woman deceased in childbed; and, of four hundred mothers, only one by previous pains. A greater proportion of boys than of girls die of the natural small pox.—There are always to be found more aged persons in hilly or mountainous countries, than in low situations; and it is proved by the most authentic computation, that of 3,125, only one individual survives the hundredth year. From the same source, the following is the most probable chance which persons may have for the duration of their lives, after a certain fixed period; namely,

	Years.	Months.
A new born infant will probably live,	34	6
A person of 1 year old,	41	9
of 3	45	7
5	46	4
10	44	9
15	41	6
20	38	3
25	35	3
30	32	3
35	29	8
40	26	6
45	23	0
50	20	11
55	17	0
60	14	2
65	11	5
70	8	11
75	6	8
80	4	10
85	3	3
90	2	0

The proportion of the female sex to that of males, with respect to the number of deceased, is as 100 to 108. Previously to the 60th year, the chance of survivorship is in favour of women; but after that age, men generally survive them. Married women, on the whole, live longer than those in a state of celibacy. From observations made for the space of fifty years, it is

evident that most persons die in the months of March, August, and September; but the fewest in November, December, and February. In populous cities, however, such as London and Paris, death makes the greatest havoc during the winter.

One half of the human race is doomed to dissolution, before they have completed the 17th year of their age; but, after this critical period, the survivors' chance of life becomes more valuable with every year: hence, for instance, a person thirty years old, according to the preceding calculation, will probably live thirty-two years longer: so that he may attain the age of sixty-two; whereas a youth of fifteen, though he have a chance of living forty-one and a half years longer, will nevertheless arrive only at the 56th or 57th year of his age.

According to BOERHAAVE, the most healthy children are born in the months of January, February, and March; and indeed, the greatest number of births takes place during the two months last mentioned. The proportion of boys, annually born, is to that of girls, as 104 to 100; but, on the other hand, a greater number of the former die during infancy than of the latter; so that, about the age of puberty, both sexes are nearly equal. Among 65 or 70 infants, there is generally but one instance of twins. The number of marriages, compared to that of the whole population of a country, is as 175 to 1000. Four children are generally computed to arise from each married couple; but, in towns, only thirty-five children from ten families. Lastly, it is proved from the records of the most experienced physicians, that, among 160 persons living in cities, throughout the year, only twenty are indisposed, or confined to their beds for one month; or twenty-four for the space of a fortnight.

We have already pointed out the most proper treatment of persons in a feeble state, under the article DEBILITY; and, at the same time, stated the necessary rules and directions for the preservation of health, and consequently the prolongation of life. There is, however, so much justice in the observations of the late illustrious HALLER, on this subject, that we are induced to insert the following brief statement. He remarks, that some of the causes which contribute to protract life, beyond its usual period, are external. Such, for instance, is climate: hence, the more northern latitudes, or about 50 degrees, are the most proper for youth; because, in such a region, the circulation is less rapid, and acute diseases seldom occur. But in a more advanced age, when the pulsations of the heart are faint or slow, and its irritability is diminished, a warmer region is more salutary; and he recommends aged persons to migrate 30 or 40 degrees, or even nearer to the equator, where they may enjoy, at pleasure, the genial warmth of the sun, or the cooling shade.

Among the internal causes of longevity, the rudiments of a sound body, descended from parents uncontaminated by hereditary disease, are to be considered as the principal: thus dropsy, gout, apoplexy, consumption, and the long train of disorders that are too frequently transmitted from one generation to another, will in a great measure be prevented. With respect to the mode of living, HALLER recommends abstemiousness during youth; the drink should be water, which Nature has provided for our common use; and he justly considers wine as a species of medicine. Animal food should be sparingly eaten, together with a large proportion of vegetables, and but a small addition of saline, or aromatic substances. Temperance is, in every respect, an essential point; so that the quantity eaten may be well digested, and perfectly assimilated;

that the blood may circulate regularly, and free from all corruption or infection, similar to that of an infant. Aged persons, however, may somewhat more freely indulge in the use of animal food; on the other hand, tranquillity, both of body and mind, is of the greatest consequence; as nothing is more detrimental, than an irritable or irascible disposition. Hence, a due mixture of a lively and placid temperament, is a very desirable condition, so as to be neither insensible of pleasure, nor too much addicted to the gratification of sensual desires. Moderation is, therefore, here likewise a beneficial attribute; but, with regard to sleep, old and decrepid people may be more indulgent. Those readers, who are anxious to become acquainted with more minute rules and directions for prolonging human life, both in a state of health and disease, will derive considerable information from Professor HUFELAND'S "*Art of prolonging Life*," and from Dr. STRUVE'S "*Asthenology; or, The Art of preserving feeble Life*," in which the subject is amply and philosophically discussed.

From the Compendious Dictionary of the Veterinary Art.

THE DISEASES OF DOMESTIC ANIMALS AND THEIR CURE.

Falling down of the Calf Bed. Inversion of the womb. This accident occurs sometimes immediately after the extraction of the calf, particularly in difficult labours, or when much force has been used in the delivery of the animal. It may also happen from the cleansing remaining in the womb after delivery, which generally causes the cow to lie down and strain. This accident is more likely to happen when the floor of the cow house is lower behind than before; when this is the case, the animal should be removed to another place, or the floor so raised, that the cow's hind parts may be rather higher than the fore parts. If any dust or bits of straw are observed about the womb, they should be carefully removed; and if the placenta or cleansing still adheres, it must be gently separated, before any attempt is made to put back the womb. A linen cloth is to be put under the womb, which, being held by two assistants, the cow should be made to rise, that being the most favourable position. The operator is then to grasp the mouth of the womb with both hands, which will enable him by gently pushing forward, to force that part into the body of the cow; when so returned, one hand is to be immediately withdrawn, while the other remains to prevent the part from falling down again. The hand at liberty is then to grasp another portion of the womb, which is to be forced into the body like the former, and retained with one hand: this is to be repeated until the whole of the calf bed is put back. In grasping these different portions of the womb, it is to be particularly observed, that it must be done by its upper surface, or that lying next the back of the cow: for, if grasped at the under part, it would be impossible to return it, and there would be danger of wounding some large blood-vessel. During the operation, the assistants must be careful to support the womb, and on no account suffer it to hang down. If the cow cannot be made to stand during the operation, the hind parts should be raised by placing some trusses of straw under them. When the operation is finished, the hand is to be thrust gently up to the bottom of the womb, and kept there until the parts have regained their natural situation, which will be known by moving about the hand. When the womb has been properly returned, it seldom falls down again. Some farriers, however, put two or three stitches in the shape as a preventive. Mr. Clater recommends

for this purpose, the passing a piece of wire through the "lips of the womb." In old cows, whose parts have been much weakened or relaxed, and where the accident has occurred several times, some expedient of this kind may perhaps be necessary. It would be proper, however, to try first if it could be effected by means of a pessary. After the operation, Mr. Clater, *very considerably*, for he is a druggist, directs an expensive drench to be given, which, in my opinion, is much more likely to do harm than good: *sed utilis est sibi*. Sometimes the vagina falls or becomes inverted, but it is easily replaced: and farriers usually put two or three stitches in the shape to prevent its returning: in this also if the cow is in a stall, she should be made to stand higher before than behind. The only medicine that can be necessary in either of these cases is some laxative medicine, if the bowels are not sufficiently open; and when the straining is so considerable as to render it impossible to replace the womb, an anodyne or opiate clyster should be thrown up, and if this fail, from half an ounce to an ounce of tincture of opium may be given as a drench.

Farcy. This was formerly considered as a disease of the superficial veins, which, in the language of farriers, became knotted and corded. It has been ascertained, however, by Mr. Coleman, that it is an affection of the lymphatic or absorbent vessels. Its most usual form is that of small tumours, or buds, as they are termed, about the legs, inside of the thigh, neck, face, and other parts: the buds are at first hard, but gradually become softer, and at length suppurate and burst, and become a foul ulcer. Between the ulcers or buds there is generally a line of communication, or what farriers term a corded vein is seen, which is, in fact, an inflamed lymphatic or absorbent vessel. When the farcy bud has burst or has been opened, it sometimes spreads under the skin, forming what are termed sinuses or pipes; these should always be laid open with the knife through their whole extent, except when they occur about the joints or tendons, in which case they generally occasion lameness, and are difficult to cure. Sometimes the farcy comes on in a more violent and malignant form: there is a prodigious swelling of the legs or other parts; foul, spreading ulcers appear; the nose swells and discharges stinking matter; there is also considerable fever, and the horse soon falls a victim to the disorder. This malignant form of farcy, however, is not very common. When no remedies are applied, the farcy ulcers usually spread; but by dressing them with caustics, and laying open any sinuses there may be, they gradually heal, and the horse often appears to be cured. This apparent cure may continue from two or three weeks to several months, but it is generally followed by glanders. In some instances farcy is merely a local disease; and in such cases, if proper remedies are seasonably applied, it may be radically cured without being followed by glanders. The farcy sometimes attacks horses that are in good condition, and without any previous illness; at others it is preceded by various symptoms of constitutional derangement. In some cases the horse gradually loses flesh and strength, the coat becomes dry, the skin sticks close to the ribs, and the legs swell. These symptoms are followed by the appearance of farcy buds, and soon after by glanders. When farcy attacks a horse that is in good condition, there is a probability of its being cured by a proper mode of treatment, particularly if the buds are not numerous and confined to the fore legs, without affecting the joints or tendons. Topical applications alone ought never to be depended on, but the following ball should be given morning and

evening, provided it does not occasion sickness or uneasiness of the bowels.

Ball for Farcy.

Sulphate of copper (blue vitriol) from one to two or three drachms;
White arsenic and sublimate, of each, from ten grains to a scruple;
Powdered] cascarilla-bark, from one dram to two;
Oil of caraway seeds, twenty drops;
Linseed-meal, half an ounce;
Venice-turpentine, enough to form a ball.

When the buds become soft and appear to contain matter, they should be opened and dressed with some caustic preparation; as solution of sublimate in muriatic acid, with the addition of spirit of wine and water, in the following proportions:

Corrosive sublimate, one drachm;
Muriatic acid, three drachms;
Spirit of wine, one ounce;
Water, half an ounce.

First mix the sublimate and the acid, then add the water, and lastly the spirit. This is a strong preparation, and need be applied only once or twice, provided the bud has been completely laid open, so that every part of the diseased surface may be exposed to its action. After this, the sore generally heals of itself. Some practitioners use lunar caustic, powdered blue vitriol, with red precipitate and burnt alum; in fact any caustic preparation will answer the purpose. Blistering the corded lymphatics has also been recommended. The horse's diet should be nutritious, but rather of an opening nature, as bran-mashes, with oats or malt, carrots, vetches, or lucerne: his water should be at the summer temperature, or have the chill taken off. Regular exercise is necessary; taking care to avoid rain and cold winds, and clothing according to the season during the time of exercise. By adopting this mode of treatment at an early period, a cure may often be effected, provided the horse is in good condition, and not previously diseased; but the use of proper remedies is too often delayed until the poisonous matter has been absorbed; and then, though the farcy may be completely healed, and the horse apparently cured, I have generally found that he has eventually become glandered. In some instances, there has been an interval of several months between the supposed cure of farcy and the appearance of glanders. As to the cause of farcy, we only know that it may be produced by inoculating a sound horse, in any part of the body, either with matter taken from the nose of a glandered horse, or from a farcy bud, when first opened, or to which no caustics or other dressings have been applied. It may also be produced by rubbing glanderos or farcy matter upon a common sore on the body of a sound horse; but in this case the disease does not so readily take place; and though the sore generally assumes a different appearance after the poisonous matter has been rubbed on it, appearing at first indisposed to heal, or even to spread, yet, after a short time, it often heals spontaneously, and is not followed by glanders. Farcy sometimes appears in a horse that has for some time been glandered; and if a sound horse be suffered to feed or drink with one that is glandered, the first symptoms of his being infected by such communication will sometimes, but not often, be the farcy. The farcy, however, frequently takes place where there has been no known communication, either with a glandered or a farced horse; in such cases, the disease is, perhaps, produced by some cause with which we are unacquainted. Dropsical swellings sometimes occur in the limbs, or other parts of horses, which farriers name Water Farcy; but is a very different disease.

From Adams' Medical and Agricultural Register.

A COMPARISON

Between the advantages and disadvantages of Agriculture in Britain and in America. By ROBERT R. LIVINGSTON, Esq.

The first advantage England possesses, consists in her early spring; this enables the farmer to commence his work sooner than he can in this country: to this cause it is owing, that such crops as require early sowing on a well prepared fallow, succeed better in Britain than here. Barley, for instance, requires four good spring ploughings, and yet should be put in by the first of May; this cannot be done here, except upon very light lands, our clays being hardly fit to plough before May; but light land will not produce good barley without manure. In England it may be raised to advantage on strong loams, and even on clay. It is for this reason that barley is nearly as cheap in England as here, though every other grain is nearly sixty per cent. dearer than in America. The same reasoning applies to beans, which are unproductive in England, unless sown in February and March, which is hardly possible here on strong clays, the soil these require. Turnips cannot be raised in our climate to advantage, as a food for cattle; the season in which they are sown being usually very dry, and the plants liable to be destroyed by the fly.

Great Britain has also some advantage over us in the shortness of the winter, but much less than is generally imagined. Their autumn is cold and wet; and though there is some apparent verdure, yet the vegetation is so slow, as to render it usual for good farmers to house their cattle by the first of November, rather than suffer them to poach their fields, in gleaning a scanty subsistence from them; nor do they turn them to pasture till late in April.

These, I believe, are all the advantages that the British farmers fairly claim over us. Let us now examine those we exclusively possess. The noblest of these is the *maize*, or Indian corn, [which does not grow in England.] Neither the beans* or turnips* of Britain can be compared with this plant. First, it need not be planted till the last of May; so that the farmer is never hurried by it with his spring work. Secondly, it is cultivated with a plough or horse hoe; and as the plants are large, and placed at five feet distance, there is ample room for this; and though it is also usual to hand hoe, yet, as this is done after the ground is loosened by the plough and when the plant is a foot high, and then only just about the stem, it is easier to hoe ten acres of this than one of the turnips or beans. Thirdly, it defies the drought, and never fails to make ample returns to the husbandman that cultivates it with diligence; forty bushels an acre being a common yield when well tended, and from sixty to seventy in a good soil and in the best state of cultivation. The grain furnishes a palatable and nutritious food for man, and is greatly superior to any other species for farm stock. And while bean-haulm is of little value, the tops and blades of maize are not inferior, if gathered in season, to the best hay; and as this crop is easily and necessarily kept clean, it is the best of all fallow crops.

The want of turnips in this country, may be amply compensated by carrots, which may be raised at less expense here than in Britain, because we have much fewer weeds, which are the greatest enemies to that root; by cabbages and

potatoes, which grow well here; and by pumpkins, which are raised in very considerable quantities in our Indian corn fields, without any other expense than that of dropping a few seeds in the hills and carting the crop. Nor can I help recommending them as a rich and nutritious food, that will save two month's hay, if used in the beginning of winter, and afford milk and butter equal in quantity and quality to the finest pasture.

These legumines would not be so much neglected here as they generally are, were it not that hay is made in this country at half the expense that it requires in the moist climates of Britain. Vegetation there is extremely slow; their spring is nearly one month earlier than ours; yet, though their wheat begins to grow in March, it is not reaped till late in August; ours is cut six weeks earlier, though it does not begin to vegetate till late in April; so that it takes five and one half months in Britain, to perfect a crop which is performed here in little better than three. The same causes influence the growth of grass. In soils, therefore, of equal quality, much less will grow in a given time in Britain than in America, as I infer from the general average of their clover and natural grass in not exceeding ours, though they are longer in a growing state. It is true, that the moisture of the climate, and mild winters, give a great verdure to their fields at some seasons; but this is only an apparent advantage, which deceives superficial observers, while it is attended with real inconveniences; first, the grass itself is by that circumstance rendered less nutritious, as is well known by every farmer; secondly, while the hay is lighter, it is got in at more expense than ours, which is made at the driest season of the year.—In our crops of grain we enjoy similar advantages; their harvests are frequently wet, while nine years in ten ours is got in without the least obstruction from rain. The produce would also, I am well satisfied, be greater here than in England, on highly cultivated soils, since it is well known that the strength of the straw depends upon the dryness of the season. In a moist climate, therefore, without sufficient sun to harden the straw, heavy crops must be very often injured by lodging, especially if we take into consideration, that high winds are much more usual in Great Britain than here. Blight and mildew are effects of a moist climate. These are seldom and partially known in this country, prevailing only in particular districts, in extraordinary seasons. In Britain it often happens, that wet weather, when the wheat is in blossom, affects all the wheat in the kingdom, many parts of which, on this account, do not pretend to raise it.

If vegetation is slower in Britain than here, and if the grass is also less nutritious, it must follow, that with the same attention to stock, our pastures with the best grass, and to keep the cattle out of them at improper seasons, a larger stock may be maintained on the same quantity of ground in this country than in England; and thus the difference in the length of our winter be amply compensated. This observation leads me to a circumstance in British husbandry, which might be advantageously practised by us. Many of their farmers sow rye, for the use of their sheep and lambs, in the spring. In order to do this, they must be at the expense of a fallow; and as their rye grows two fifths slower than ours, it must follow, that they can only keep three sheep where we may have five. If, therefore, this practice is advantageous in England, it would be much more so in America, to sow our corn fields with rye, to feed off with sheep in the spring, not only because of the additional numbers we can keep, but because we are more pinch-

ed for sheep food in the spring; besides that the rye that costs the British farmer a complete fallow, costs us nothing but the seed, if sown among the corn when it is topped. As five sheep will leave more manure than three, the rye field so fed down, will be left in better order here than it would be in England.

In the healthfulness of our stock, we have great advantages over Britain. Among our black cattle I have been told that some disorders prevail, though they are so extremely rare, that in twenty years since I commenced farming, I do not recollect to have lost one creature, unless it were by some accidental hurt; nor have I known any others to die among my neighbours, except from the same cause, or bad keeping in the spring; and while the rot sweeps away whole flocks of sheep in Britain, it is a disorder entirely unknown in this country.

All these natural advantages being in favour of the American farmer, I shall be asked how it happens that the lands in Britain are more productive? The answer is, more labor is expended upon less land there; and the product is always in proportion to the labor, the soil, and the climate.

MISCELLANEOUS EXTRACTS

From late numbers of the *London Farmers' Journal*, received at the office of the *American Farmer*.

Some Account of the Origin of Cards.—Cards were invented by Jacquemin Gringonneur, a painter at Paris, in the reign of Charles the Fifth, King of France. They were first made use of for the purpose of diverting or diminishing a deep melancholy under which that unfortunate monarch laboured for many years; and he is said to have experienced temporary relief and considerable amusement from Piquet, the first game ever played at with cards, if we may rely on the respectable authority of a French writer, who has composed "A dissertation, symbolical, allegorical, political and historical, on these pictures of human life."

It seems from his account, they were meant to represent, in the rude efforts of those days, particular persons, and sometimes the productions of nature and art.

"The ace," says this author, "is, in fact, only the Latin word *as*, which signifies literally, only a piece of money, but in a general sense, wealth. Aces accordingly have precedence before Kings, and all other cards; for as riches are the sinews of war, the most powerful monarchs submit to their controul, and the great question of peace or war must, in a great measure, depend on the finances and resources of a country."

"*Piques et carreaux*, spades and diamonds, mean arms, the heavy arrows formerly shot from cross-bows, being shaped like diamonds on cards; the inference to be drawn is sufficiently clear, that without arms and courage (under the appropriate typ. of hearts) to make use of them, neither life nor property can be secure."

"The kings of the four suites, originally were portraits of David, the son of Jesse, Alexander the great, Julius Cæsar, and Charlemagne, each of whom had his ecuyer, modified into the modern word esquire, and called in the middle ages, valet or knave—titles, in those days, considered as honourable. The names of two distinguished individuals of this rank, the companions of knights and of kings are preserved, Ogier and La Hire, famous intrepid French captains, who would not have suffered any one to have applied the term knave to them in its present signification with impunity."

* Both these (beans and turnips) are important crops in England, for the feeding of horses, cattle, and sheep.

"Argine, the queen of Clubs, is an anagram formed of regina, and was a representation of Mary of Anjou, wife of Charles the Seventh. The queen of Diamonds, under the name of Rachel, was meant for the beautiful but frail Agnes Sorrel; and the queen of spades, under the semblance of the chaste and warlike Minerva, was the heroic Maid of Orleans; while Judith, the queen of hearts, was designed as a picture of the enchanting Isabeau de Barriere.

"Clubs trefle or trefoil, a herb that grows in the meadows, implies that a general should never encamp without good opportunities for forage."

The figured cards, as king, queen, and knave, were at one time called coat, and not court cards, as at present. The knave probably was intended at first to represent the Prince, or son of the King and Queen, as Chausser twice applies the term knave-child to the son of a Sovereign Prince. Cards, as well as other games had their origin in times of chivalry. The kings, queens, knaves, all carry marks of that period. The present absurd figures stamped on cards seem to be faithful and accurate representations of elegant original ornaments of the reign of Henry VIII.

Herefords and Short Horns.—The following statement has been sent for insertion:—

The Steer bred and fed by the Marquis of Exeter, 2 years 11 months, by a son of Blyth Comet, was sold for £45; the seven steers bred and fed by Mr. Charles Fibbits, Esq. under three years old, were sold for £31 each; and £48 was refused by Mr. Champion for his Steer, (3 years and 3 months old, by Warrior,) from a butcher, to slaughter him at Deptford. The above animals, it will be recollected, were exhibited at the late Smithfield Show. The weight of Mr. White's yearling Hereford Heifer, shewn at Tredegar, was 12 cwt. 3 qrs. This heifer, being 22 months old, at 12 cwt. 3 qrs., averages not quite 65 lbs. per month; and Mr. Champion's Short-horn, weighing 11 cwt. 10½ lbs., averages near 78 lbs. per month, she being 16 months old at the time of exhibition.

Match for 100 Sovereigns.—An interesting race took place on Wednesday morning, made on the preceding evening over some mellow port, at the Turf Coffee house, between Mr. Hewston, late of the Guards, and Gilbert Stanhope, Esq. It was to go on foot twenty miles; and Mr. Hewston backed himself to do his work within two hours and a half, in several bye bets. The match was run on a mile piece of ground leading from Hanwell towards Harrow, and betting was even. Mr. Stanhope cut out the work, and did his first mile in six minutes and ten seconds. It was a very fine race, Mr. Hewston keeping close with his opponent. Both were together at the tenth mile, which was performed in one hour and ten minutes. The travelling pace was a mile in about seven minutes and ten seconds; but in the sixteenth mile Mr. Stanhope fell off his speed, and resigned in the eighteenth. Mr. Hewston kept at work to win his bye bets, and he did so, by accomplishing the ground in two hours and twenty-five minutes, with apparent ease.

Extraordinary Kidney.—A small four-year-old heifer was last week slaughtered by Mr. Mullins, butcher, of Maidstone. Upon opening the animal, one of the kidneys was found to be of an amazing size, the solid suet being computed to weigh at least ten stone, and measures in circumference full four feet. The exact weight cannot at present be ascertained, as the kidney is not yet removed from the side to which it grew. The other kidney was of an ordinary size. The heifer

was purchased at Smithfield, last Monday week, and slaughtered on Wednesday. The animal had nothing particular in its appearance previous to being killed.

Advice.—Would a man wish to offend his friends? let him give them advice. Would a lover know the surest method by which to lose his mistress? let him give her advice. Would a courtier terminate his sovereign's partiality? let him offer advice. In short, are we desirous to be universally hated, avoided and despised, the means are always in our power; we have but to advise, and the consequences are infallible. Two young ladies, whose friendship, though apparently founded on the lock of eternal attachment, terminated in the following manner:

My dearest girl, I do not think your figure well suited for dancing, and, as a sincere friend of your's, I advise you to refrain from it in future." The other delighted, as you may well suppose, with such a mark of friendship, replied, "I feel very much obliged to my sweet friend for her advice; and as this fresh proof of her friendship demands some return, I would recommend her to relinquish her singing, as some of her upper notes resemble the melodious squeakings of the feline race." The advice of neither was followed; the one still continued to sing and the other to dance, and they never met but as bitter and implacable enemies.—*Gazette of Fashion.*

To kill Cockroaches.—An infallible means to destroy them will be found in giving them the root of the Veratum Vinex, commonly called black hellebore, which grows wild in our country marshy grounds, and may be got of our market people. Strew these roots about the floor at night, and next morning you will find all the family of the cockroaches dead or dying, from having eaten it, which they will do with much avidity. They will never fail to eat it while they can get it, and will assuredly die. It causes them to foam at the mouth, and to split in the back occasionally.

WHAT REVOLUTIONS IN THE MORAL WORLD!!
[When the reader reflects on the numberless associations which have of late years been formed, for the translation into all languages, printing and gratuitous distribution of the Bible—that men of the highest rank and power, not excepting *peace loving* KINGS and EMPERORS, have vied with each other in this pious work; until Bibles have become as cheap as almanacs—he will be, as we were, the more forcibly struck with the following anecdote mentioned by himself, in the life of that greatest of philosophers and philanthropists, BENJAMIN FRANKLIN.]—*Edit. Am. Far.*

Our humble family early embraced the reformed religion. Our forefathers continued Protestants through the reign of Mary, when they were sometimes in danger of persecution, on account of their zeal against popery. They had an English bible, and to conceal it, and place it in safety, it was fastened open with tapes under and within the cover of a joint stool. When my great grandfather wished to read it to his family, he placed the joint stool on his knees, and then turned over the leaves under the tapes. One of the children stood at the door to give notice if he saw the apparitor coming, who was an officer of the spiritual court. In that case the stool was turned down again upon its feet, when the bible remained concealed under it as before. This anecdote I had from uncle Benjamin:

PUBLISHED AT THE REQUEST OF THE SOCIETY.

AGRICULTURAL PREMIUMS.

The Farmer's Society of Barnwell District, will award the following premiums of Fifteen Dollars, or a silver cup of that value:

1st. For the best bull, steer, or cow, not more than 3 years old.

2d. For the best bull, steer, or heifer, not more than 2 years old.

3d. For the best male or female calf, not more than 1 year old.

4th. For the greatest quantity of corn, from one acre of high land.

5th. For the greatest quantity of corn, from one acre of either swamp or pond land.

6th. For the greatest crop of root, or slip potatoes, from one acre of either high or low land.

7th. For the greatest crop of rice, from one acre of either high or low land.

Also, premiums of Ten Dollars, or cups of that value.

1st. For the best stud horse, not more than 7 years old.

2d. For the best mare, not more than 7 years old.

3d. For the best hog, not more than two years old.

4th. For the best male or female hog, not more than 1 year old.

Also premiums of five dollars:

1st. For the best ram, not more than 1 year old.

2d. For the best specimen of cotton homespun, not less than 10 yards.

3d. For the best specimen of homespun of a cotton warp and wool filling, not less than 10 yards.

The animals, if not raised by the competitors, must have been owned by them, at least 6 months previous to the regular meeting in January 1825, on which day they must be exhibited to the Society at Barnwell Court House, when the premiums will be awarded.

The acre to be square, and not more than 2½ feet square. The crops to be harvested, and measured in a sound and merchantable state.

Whenever practicable, the Society expects some of the members to be invited to attend to the gathering and measuring of the crops. It not, disinterested farmers must attest as to the quality and quantity of the crops, and also state precisely the mode adopted to ascertain the amount of each crop. The corn crop must consist of only one crop, which must not be harvested previous to the 15th day of October next, and the quantity made to be ascertained the day gathered from the acre.

JOHN S. BELLINGER, *President.*

JENNINGS O'BANNON, *Secretary.*

Barnwell Court-House, }
January 19th, 1824. }

FROM THE DEMOCRATIC PRESS.

AGRICULTURAL REMARKS,

On the state of Pennsylvania, Anno 1823.

We have reason to be thankful for the munificence of nature this year. The farmer's cup of joy would indeed have been full to overflowing, had not disease checked his industry, and clouded the brightness of his rural prospects.

The spring was pleasant and seasonable, and the heat of the summer moderate, accompanied by plentiful showers.

Within 20 miles of Philadelphia, the average of Farenheit's Thermometer was in June 70 and 72°.

The prevailing winds were, S. W. N. W. N.

There were 9 rains—10 clear and 14 cloudy days.
—No thunder and lightnings.

In July, average thermometer 73 2-3 degrees, prevailing winds, S. W., N. W., N. E.—8 falls of rain—20 clear days, and 11 overcast. This month was remarkably cool. The thermometer stood on the morning of the 1st. at 58°. We had several gales of wind, but little thunder and lightning—it occurred twice only, and a total eclipse of the moon on the night of the 22d.

In August, average thermometer 78 1-3 degrees, prevailing winds S. W., S. E., N. E.—10 rainy days, 18 clear, and 13 cloudy and overcast,—very little thunder and lightning. The weather was unusually cold.

In September, average thermometer 70 degrees, prevailing winds N. E., N. W., S. E.—10 rainy days,—15 clear, and 15 cloudy. This month was cold. There was frost on the 22d and ice on the 30th. No thunder and lightning.

The productions of the year, may be estimated as follows.

Corn was abundant. The repeated showers followed by a warm sun, caused it to grow with great vigor. It was the best corn season for many years.

Wheat generally, not good. Perhaps to be attributed to the deficiency of snow last winter.

The crops of Rye, and Oats, and Hay were plentiful.

Pasture rich and very good during the summer and fall. Refreshing and nourishing showers preserved the grass green and vigorous.

Peaches, scarce and of an inferior quality.

Apples, not so good and abundant as last year, but no deficiency. They were not in much demand for exportation. The consequence was, an unusual quantity of cider was made. The Crab Cider was of superior flavour and quality.

All other fruits generally good, and of sufficient quantities.

Green Peas, plenty.

Potatoes in great abundance. Our markets overflowing. Not I believe from any increase in their culture, but the productiveness of the season.

Turnips, uncommonly large and abundant.

Our winter vegetables, celery, cabbage, rutabaga, beets, radishes, &c. very fine.

The summer of 1823, was in many respects peculiar. It was the coldest since 1816, and the most prolific in showers. I have paid some attention to the seasons for many years, and I do not recollect one where there was so little thunder and lightning. This observation applies with almost equal force to the summers of 1821—22. The summer and fall were very sickly. Might not this be owing to the deficiency of electric fluid in the air? If epidemic diseases are generated by animalculæ, may not these be destroyed by electricity?

These hints and reflections would soon lead me out of my depth. I shall therefore leave them to the investigation of natural philosophers and physicians.

AGRICOLA.

DIRECTIONS FOR BOILING POTATOES.

We copy the following from the Irish Farmer's Journal, a very good authority on such a subject.

How to boil potatoes nicely, without waste.—Seldom do we see potatoes well cooked, and still seldomer do we see them cooked without waste. By the following directions, both ends will be attained. Choose your potatoes of equal size, and put them into a saucepan or pot without a lid, with no more water than is sufficient to cover them; more would only spoil them, as the potatoes themselves, on being boiled, yield a considerable portion of water. By being boiled in a vessel without a lid, they do not crack, and all

waste is prevented. After the water is come nearly to boil, pour it off, and replace the hot by cold water, into which throw a good portion of salt. The cold water sends the heat from the surface to the heart of the potato, and makes it mealy. Like all other vegetables, they are improved by being boiled with salt, which ought not, therefore, to be spared. The only proper test of their being done enough, is trying them with a fork. When they are boiled with a lid, cracking is usually considered as the test of their being done enough; but they will often crack when they are quite raw in the heart. After straining off the water, they should be allowed to stand ten or fifteen minutes on the fire to dry.

The following recipe to cure a cold, is said to be so efficacious, that we republish it at the request of a correspondent who has tested its virtues.

Take a large tea-spoonful of flaxseed, with two penny worth of stick licorice, and a quarter of a pound of sun raisins. Put them into two quarts of soft water; and let it simmer over a slow fire, till it is reduced to one; then add to it a quarter of a pound of brown sugar candy, pounded, a table-spoonful of white wine vinegar; or lemon juice.

Note. The vinegar is best to be added only to that quantity you are going immediately to take; for if it be put into the whole, it is liable, in a little time to grow flat.

Drink half a pint at going to bed; and take a little when the cough is troublesome.

This recipe generally cures the worst of colds in two or three days; and if taken in time, may be said to be almost an infallible remedy. It is a sovereign balsamic cordial for the lungs, without the opening qualities, which endanger fresh colds on going out. It has been known to cure colds, that have almost been settled into consumptions, in less than three weeks.

HUSWIFERY ADMONITIONS.

Written Three Centuries back.

Learn you that will thee,
This lesson of me.

1. No breakfast of custom, provide for to save,
Not only for such as deserveth to have.

2. No shewing of servant, what victuals in store,
Shew servant his labour, and shew him no more.

Of havock beware,
Cat nothing will spare.

3. Where all thing is common, what needeth a hutch?
Where wanteth a saver, there havock is much.

4. Where window is open, cat maketh a fray,
Yet wild cat with two legs, is worse, by my fay.

Look well unto thine;
Slut slothful must whine.

5. An eye in a corner who useth to have,
Revealeth a drab, and preventeth a knave.

6. Make maid to be cleanly, or make her cry
creak;
And teach her to stir, when her mistress doth
speak.

Let holly wand threat,
Let Fizgig be beat.

7. A wand in thy hand, though ye fight not at all,
Makes youth to their business, better to fall.

8. For fear of fool had I wist, cause thee to wail
Let Fizgig be taught, to shut door after tail.

Too easy the wicket,
Will still appease clicket.

9. With her that will clicket, make danger to
cope,
Lest quickly her wicket seem easy to ope.

10. As rod, little mendeth, where manners be
spilt,
So naught will be naught, say and do what
thou wilt.

Fight seldom ye shall,
But use not to brawl.

11. Much brawling with servant, what man can
abide?
Pay home when thou fightest, but love not to
chide.

12. As order is heavenly, where quiet is had,
So error is hell, or a mischief as bad.

What better a law,
Than subjects in awe?

13. Such awe as a warning will cause to beware,
Doth make the whole household the better to
fare.

14. The less of thy counsel thy servants do know,
Their duty the better, such servants shall
shew.

Good music regard,
Good servants reward.

15. Such servants are oftenest painfull and good,
That sing in their labour, as birds in the wood.

16. Good servants hope justly, some friendship
to feel,
And look to have favour, what time they do
well.

By once or twice,
'Tis time to be wise.

17. Take Runagate Robin, to pity his need,
And look to be filched, as sure as thy creed.

18. Take warning by once, that a worse do not
hap,
Foresight is the stopper of many a gap.

Some change for a shift:
Oft change, small thrift.

19. Make few of thy counsel, to change for the
best,
Lest one that is trudging, infecteth the rest.

20. The stone that is rolling, can gather no moss,
For master and servant, oft changing is loss.

Both liberall sticketh,
Some provender pricketh.

21. One dog for a hog, and one cat for a mouse;
One ready to give is enough for a house.

22. One gift ill accepted, keep next in thy purse,
Whom provender pricketh, are often the
worse.

ON A SCULL.

[The following lines by Lord Byron are hardly inferior to Hamlet's meditations in the grave yard.]

Look on its broken arch, its ruin'd wall,
Its chambers desolate and portals foul,
Yes, this was once ambition's airy hall,
The seat of thought, the palace of the soul.
Behold through each lack-lustre eye-less hole
The gay recess of wisdom, and of wit
Can all that saint, sage, sophist ever writ
People this lonely tower—its tenement refit?

THE FARMER.

BALTIMORE, FRIDAY, MARCH 19, 1824.

NOTICE TO SUBSCRIBERS.—Those who continue their subscription to the Farmer, are respectfully reminded that the *best proof* they can give of their approbation of our labours, will be a prompt compliance with the stipulated terms of subscription, which will remain, as heretofore, to wit:

To those who take the risk of all casualties, \$4 per annum, payable *in advance*—but those who prefer, as we hope most of them will, to pay \$5 in advance, will be entitled to have each paper supplied, which may happen, from any cause, *not to reach them in good order*, and an agricultural almanack, in the bargain. The almanack, besides the contents of common almanacks, will have recipes, short essays, &c. connected with the farmer's and the *housewife's* duties and business. Those who prefer the payment of four dollars, are assured that the Farmer is *regularly put up* and sent off in *at least a good condition*, and with as much security for its safe arrival, as any paper in the United States, excepting always that invaluable work, Niles' Weekly Register.

The money whether four or five dollars, to be remitted, in all cases, directly BY MAIL, to the Editor's risk—he, requiring only the word of the subscriber that the money was deposited in the neighbouring post office. The difficulty arising from the impracticability of getting \$4 notes, in many places, may be obviated in this way.—Let the subscriber send a \$5 note, with a request that the odd dollar be passed to his credit for three months of the succeeding year, and it will be done: but where \$5 are received, without any such *wish expressed* by the subscriber, it will be taken for granted, that his desire is to be considered as a *guaranteed* subscriber, and entitled to an Agricultural Almanack, and he will be so entered on the books. Lastly, the Editor assures his friends, that from the variety and value of materials on hand, the regularity of his supply from abroad, of such publications as afford matter adapted to this journal, and above all, from the number, zeal, intelligence and generous publick spirit of his correspondents in all the states of our own blessed country, with her infinitely diversified soil and climate, and unexplored resources of Agriculture and Natural History, he can promise, *without fear of failure*, that the Farmer will continue to be at least as *well worth* of their patronage as heretofore; to say nothing of *improvements* in the plan and substance of the work, which ought to be expected from greater experience and facilities, and undiminished fondness for the subject.

The most inattentive observer, must have perceived the progress of publick opinion, within the last few years, in attaching more respectability, and a higher moral consideration to the business and character of the Farmer, embellished as it now is, with researches in Natural History, Botany, and other liberal studies, and guided by the results of modern discoveries, in physiology, chemistry, &c. No longer is the practice of agriculture, associated with the idea of mere *brute force*, and all its results, considered as ending solely in calculations of profit and loss. Its votaries are expected to combine the polish and the pleasures of reading, with *better judgment*, in directing the labours of the field—and hence it is, that we witness the just pride, which is now felt, in selecting the cultivation of the soil, in all its alluring varieties, as their regular profession, by young men of the first consideration and talents, and

how much more useful and honorable are the resolutions, which thus lead them, to renounce the unmanly and enervating pleasures, and pursuits of the town, of which, if ever, it may now be truly said

“Where news and politicks divide mankind,
“And schemes of state involve th' uneasy mind,
“Faction embroils the world; and every tongue
“Is mov'd by flattery, or with scandal hung:
“Each rival Machiavel with envy burns,
“And honesty forsakes them all by turns;
“While calumny upon each party's thrown,
“Which both promote, and both alike disown.”

To seek, where “all the grateful country breathes delight,” the invigorating toils of the field, and the never tiring studies of nature.

It is from reflections like these, and not from the vanity, which is the growth of overweening partiality, for our own offspring, that we anticipate the time, when every tiller of the soil, will patronise the “AMERICAN FARMER.” To the intelligence and the liberality of our correspondents, we owe unspeakable gratitude, for enabling us to say with confidence to *every farmer*, that in its pages, his wife may find the most valuable recipes, and instructions in every branch of household industry—that his children may find in them, amusement and edification, and that to himself, they will furnish the results of experiments and practical directions, applicable to the whole circle of agricultural operations—finally, we ask the favour of all those, who think its usefulness not overrated, not only to consider themselves as agents to receive subscriptions, but that the Editor will feel himself under particular obligations to all those, who by sending him a *single* subscriber, so far enable him to continue, the *first American Journal*, devoted exclusively to the instruction and benefit of the agriculturists of America. To promote their interests, to defend their rights, to deserve *their* esteem, and to exalt and embellish their vocation, in the estimation of themselves, and of mankind, is the greatest pride, and the highest ambition of their humble servant,

THE EDITOR.

The Editor has occasion to beg pardon of many, amongst his most esteemed correspondents, for inattention to letters, which civility, as well as duty and feeling require to be answered. But for some weeks he has been confined to his room, by protracted indisposition, until the file of unanswered letters, has become unusually voluminous—in postponing the demands of correspondents, it often happens, that the greatest license is taken with friends, nearest to our heart, of whom we are apt to think—“He knows the sincerity of my regard, another day will do for him.” We shall, however, take the first moment, to wipe off these old scores, and the commencement of the Editorial, like the beginning of every year, brings with it the mental resolution—at least, to turn over a new leaf, and do better for the time to come.

A few complete sets of this Journal may be had on application to the Editor, or may be forwarded to any part of the Union.

The Index for the fifth, will not be delayed, beyond the appearance of the second number of the sixth volume.

ERRATA, in the article on Seeds, in Farmer No. 50.—2d paragraph, 4th line, for *their* read *the same vicinity*—14th line, for *brassica* read *brassica*—5th paragraph, 1st line, for *bulbs* read *seeds*—8th paragraph, 3d line, for *gum* read *germ*—7th line, for *feminal* read *seminal*—17th line, for *alkites* read *alkalies*.
